²Nicolaus Copernicus University in Torun - Ludwik Rydygier's Collegium Medicum, Chair of Clinical Neuropsychology, Bydgoszcz, Poland

Introduction/Background

Aim: The assessment and the comparison of influence of four-week therapy with the use of PBU on: pain intensity, life quality, SLS, DLS and number of recurrence of health ailments among patients with non-specific pain of lower spine among people aged between 18 and 35 in 4-week and 6-month follow-up.

Material and Method

Research was conducted among group of 161 people, 100 of them suffered from non-specific lower back pain and 61 did not suffer from non-specific lower back pain, everyone was aged between 18 and 35.

Results

Statistically significant differences (p<0.01) were presented between SLS and DLS in the group of people with non-specific back pain in its lumbar and spinal part and in the group of people without pain aged between 18 and 35. Both forms of therapy had positive and essential impact on statistically significant differences (p<0.01) and on pain intensity in the NRS scale after a four-week therapy and in a six-month observation. Statistically significant differences (p<0.01) in NRS in all groups were presented only 6 months after the treatment had been completed.

Conclusion

1. Both forms of treatment, first, with the use of Pressure Bio-Feedback Stabilizer and second, with the use of general exercises, had positive impact on pain intensity (NRS) and on life quality (SF.36v.2 and RMDQ) considering people with non-specific lower back pain in a 4-week and 6-month follow-up. The therapy with the use of Pressure Bio-Feedback Stabilizer was statistically more successful in a 6-month observation.

2. After 6 months that the 4-week treatment with the use of Pressure Bio-Feedback Stabilizer had been completed people in this group had statistically significant lower number of average pain ailments recurrence in the lumbar and spinal part of the back in comparison to the group of people treated with the use of general exercises.

THE EFFECTS OF CERVICAL KINESIO TAPING ON PAIN, RANGE OF MOTION, AND DISABILITY IN PATIENTS FOLLOWING THYROIDECTOMY: A RANDOMIZED CLINICAL TRIAL, PRELIMINARY RESULTS

A. Genç¹, V. Genç², S.U. Celik², D. Gokmen³, B.S. Tur¹

¹Ankara University Faculty of Medicine, Physical Medicine And Rehabilitation, Ankara, Turkey
²Ankara University Faculty of Medicine, General Surgery, Ankara, Turkey
³Ankara University Faculty of Medicine, Biostatistics, Ankara, Turkey

**Introduction/Background**

Thyroidectomy is a frequently performed surgical procedure and the head and neck extension during this operation facilitates surgery. Patients may experience postoperative neck pain and range of motion (ROM) limitation due to the surgical position following thyroidectomy. We aimed to investigate the short-term effects of Kinesio Taping (KT), applied to the cervical spine, on neck pain, cervical ROM, and disability in patients following thyroidectomy.

**Material and Method**

This was a prospective, double blind randomized controlled trial. A total of 80 patients were randomly assigned to applied either KT (Group 1, n=40) or sham taping (Group 2, n=40) using sequence of random numbers. Six patients from each group dropped out. Patients were only allowed to use paracetamol after surgery and the daily dose was recorded. Neck pain, cervical ROM, and neck disability were evaluated with VAS, inclinometer, and Neck Disability Index (NDI) questionnaire, respectively. While VAS was recorded preoperatively and 30 min, 4 hr, 12 hr, 24 hr, and 7 days after surgery, ROM and NDI was recorded preoperatively and 24 hr after surgery.

**Results**

The mean ages of the Group 1 and Group 2 were 51.6 and 49.2 years, respectively. There was no significant differences with respect to age, gender and educational background and body mass index. The demographic data of the two groups are presented in Table-1. The improvement in VAS values was more significant in favor of Group 1 (p=0.032) (Figure 1). There was no significant differences with respect to improvement of ROM values and NDI values between groups during study (Table-2). Patients in Group 1 needed less paracetamol during study than patients in Group 2 (p=0.011).
Figure 1. The change of VAS in groups during study
Conclusion

Our results revealed that cervical KT reduced postoperative neck pain and pain medication consumption. KT can be used as an alternative treatment for neck pain relieving after thyroidectomy.

A RANDOMISED CLINICAL INVESTIGATION INTO PLACING PAIN SPOT EXTERNALLY TO CROSSING AREA OF THE TWO CURRENTS OF INTERFERENTIAL THERAPY ON PAIN

A. Beatti¹, E. Al Zahrani², T. Al Qahtani³, H. Al Saif³, A. Khamis⁴
¹Alhada armdforce hospital, Rehabilitation Centre, Taif, Saudi Arabia
²Prince Sultan Military College of Health Sciences-, Admin, Dharan, Saudi Arabia
³King Fahd Military Medical Complex, Physiotherapy, Dharan, Saudi Arabia
⁴Mohammed Bin Rashid University of Medicine and Health Sciences, Research, dubai, United Arab Emirates

Introduction/Background

Interferential therapy (IFT) has been applied in a quadrupolar way so that the two currents intersect in the painful area. Clinically, no clear reduction effect of pain has been confirmed with this application method of IFT. Experimentally, the highest voltage of IFT is being induced outside the intersection area of the two used currents. Thus, it is probably true that placing the painful area outside the intersection spot of the two currents would reveal a significant pain reduction.

Material and Method

A Double-Blind Placebo-Controlled Clinical Investigation. Setting: A public hospital physiotherapy department. Participants: 168 subjects with subacute low back pain. Interventions: Participants were randomly assigned to: 1- external IFT (painful spot was at 2 cm outside of the outer borders of the electrodes) 2- placebo external IFT 3- traditional IFT (painful spot was at the crossing area of the two currents) 4- placebo traditional IFT. Groups 1 and 3 received 20 min of IFT at 100 Hz and comfortable stimulation intensity. Groups 2 and 4 received sham IFT for 20 min. Main outcome measures: Before and immediately after IFT session, pain severity, pressure threshold (PPT) and distribution were assessed using visual analogue scale (VAS), algometer, and distance from pain source, respectively. Distance from the tip of middle finger to the ground during forward trunk flexion determined range of motion (ROM)

Results

Only VAS and ROM improved with all groups, P<0.03 with no statistical differences between them, P>0.1. Active IFTs changed all outcomes to same extent. There was a trend of better VAS reduction with active IFTs compared to placebos.

Conclusion
No therapeutic difference between external and traditional applications. The effect IFT in pain and ROM is not more than placebo. However, a trend of better pain reduction with active IFTs compared to placebos was noticed.

Interests and Limits of Electromyography in the Diagnosis of Lower Limbs Radiculopathies

J.P. Camdessanche¹, J.C. Antoine¹, E. Henri Martin¹
¹CHU Nord Saint-Etienne, Service de Neurologie, Saint-Chamond, France

Introduction/Background

Radiculopathies are a frequent cause of consultation leading to neurophysiologic exploration, namely electromyography (EMG), with a prevalence of 1.2% to 43% Konstantinou et Dunn, 2008.

The main objective of our study is to analyze the indications and limits of neurophysiologic explorations in the diagnosis of root neuropathy. We analyzed the results of EMG for the diagnosis of radiculopathies in comparison to anamnestic features and clinical findings.

Material and Method

We retrospectively studied the consecutive characteristics of 67 EMG studies realized from 2010 to 2015 in the laboratory of neurophysiology of Saint-Etienne University Hospital. We especially looked for root neuropathy of the lower limb involving L3, L4, L5 and/or S1.

A concordance between the proposed diagnosis and the electromyographic diagnosis was studied in a statistical study including non-parametric tests. Two levels of statistical significance were retained: p < 0.05 and p < 0.01.

Results

The EMG examination was abnormal in 73.2% of patients tested, with characteristics features of root neuropathy in 61.2%. Correlation with clinical findings was positive in 49.3% of cases. Statistical significance was reached between root neuropathy on EMG findings and clinical assessment (p < 0.01).

EMG sensitivity is limited for the diagnosis of root neuropathy. The clinical findings consistent with a radiculopathy does not preclude an EMG confirmation of a root neuropathy. This lack of sensitivity in our study is compatible with the findings of others. Dillingham et al draw similar conclusions in their study.

Conclusion

Our study, compatible with the findings of others and the medical literature shows that EMG is a specific tool in the diagnosis of root neuropathy but has a low sensitivity. Proper clinical
examination is the best way to draw appropriate conclusions from the EMG analysis. This was shown in studies by Camdessanché et al (2006) and Inal EE et al (2013) in upper limbs pain investigation.

Introduction/Background

The effect of the combination of the physiotherapy (low-frequent variable magnetic field, electrical stimulation) and of the acupuncture on the patients having acute discogenic pain low back pain was investigated.

Material and Method

110 patients aged from 20 to 50 (49 females and 61 males) having acute low back pain (osteocondrosis, osteoarthritis, spondyloarthritis) for 1 – 14 days were observed. The pain was examined and measured according to the visual analogue scale. The patients were divided into two groups. The first group (72 patients) received in addition acupuncture (individual points) and physiotherapeutic complex with low-frequent variable magnetic field and electrical stimulation treatment on the projection of pain. Every procedure exposure was 12 – 15 min. The complete course was 10 – 12 procedures. The second group (control, 38 patients), received only the basic medication (non-steroid anti-inflammations and anticonvulsants).

Results

The pain intensity of the patients in the first group was reduced after 10 – 12 days of treatment (65.3% patients) compared to the control group, where pain reduction after 20 – 26 days of treatment (31.6% patients); p<0.01.

Conclusion

The addition of the non-medication therapy (combination of acupuncture, low-frequent variable magnetic field and electrical stimulation) to the treatment of acute discogenic pain resulted in earlier remission.

OBSERVATIONAL STUDY TO EVALUATE HIGH PRESSURE INJECTION AS A POSSIBLE CAUSE OF VASCULAR PROBLEMS DOCUMENTED WITH SPINAL INJECTIONS
A. Bhargava

Introduction/Background

Particulate steroids have for some years considered to be cause of vascular injury during spinal injections. There are various theories pertaining to the cause of injury. Objective was to observe the effect of injecting particulate steroid under high pressure on a blood vessel.

Material and Method

IRB exemption was obtained. Blood vessels from 2 chicken thighs were dissected. The external surface of blood vessels was injected with lidocaine and methyl prednisolone 40mg/ml with pressure. The injection procedure was recorded.

Results

The outer layer of the blood vessels was visibly damaged where particulate steroid was injected. There was no damage to the site where only lidocaine was injected.

Conclusion

This study shows gross visible damage to a vessel when particulate steroids were injected under high pressure. Future research will be targeted at smaller vessels and obtaining histology sections.

RETROSPECTIVE STUDY TO DETERMINE THE EFFECTIVENESS OF COMBINING PRE-PROCEDURE CLINICAL EVALUATION WITH FLUOROSCOPY BEFORE DIAGNOSTIC FACET JOINT INJECTION FOR EVALUATING THE SOURCE OF NECK PAIN
A. Bhargava

Advanced Interventional Pain & Sports Medicine Center, Spine & Sports Medicine, Owings Mills, USA

Introduction/Background

Use of minimally invasive procedures has increased over the years. Use of fluoroscopy for diagnostic purpose before a procedure has not been well defined to increase the accuracy of the injections. Objective was to retrospectively evaluate the effectiveness of combining pre procedure clinical evaluation with fluoroscopic evaluation with diagnostic cervical facet joint injection.

Material and Method

Retrospective observational study of 15 neck pain patients of cervical facet joint injection after pre procedure clinical evaluation and fluoroscopic evaluation. Assessment was: percentage pain relief. Successful pain relief was defined as ≥50% reduction in pain.

Results

The mean age of the entire group was 50.3 (43-58) years. The mean BMI was 29.34 (24.69-37.66). There were total of 18 injections performed on 15 patients (two were bilateral and one was 2 level). 16 of the 18 tender areas were at the facet joint under fluoroscopy evaluation and 2 were posterior to the facet joint. The cervical facet joints which were injected were C2-3 (5-including one two levels and one bilateral), C3-4 (6-including two levels), C4-5 (6-including one bilateral) and C5-6 (1). The percentages of patients experiencing successful pain relief were 82.3 % (14/17 injections-one patient had two level injection) including 5 who had 100% relief after the diagnostic injection.

Conclusion

This small trial demonstrates the overall clinical success of diagnostic cervical facet joint injection when combined with pre procedure clinical evaluation and fluoroscopy evaluation. Further research with a larger trial is needed to evaluate the efficacy of this procedure.

COMPARISON OF MONO AND COMBINED THERAPY OF TOPICAL ETOFENAMATE, AESSIN + DIETHYLMAMINE SALICYLATE IN ACUTE MUSCULOSKELETAL DISORDERS
H. Koyuncu¹, B. Sezer Kiral¹, S.S. Karamehmetoğlu²
¹Cerrahpasa Faculty of Medicine- Istanbul University- Istanbul, Department of Physical Medicine and Rehabilitation, Istanbul, Turkey
²Emsey Hospital- Istanbul- Turkey, Department of Physical Medicine and Rehabilitation, Istanbul, Turkey

Introduction/Background
Musculoskeletal disorders are common diseases of which the cause is usually mechanical. Anti-inflammatory agents are often used in treatment systemically and topically. Topical products do not have gastrointestinal side-effects. There are studies on soft tissue diseases which are superior to one another in some aspects regarding the placebo. We investigated the efficacy and safety of separate and combined use of etofenamate cream, Aessin + Diethylamine Salicylate gel in this study.

Material and Method
This is an open, randomised and comparative observation study. From the three groups, the first was administered etofenamate, the second was administered aessin + diethylamine salicylate, and the third group was administered the combination of these two. The pains, swellings, sensitivities and dysfunctionalities of the patients were classified according to Likert. The findings were assessed prior to and one week into the study. All three groups received the topical administration 3 times. The dosage was 1cm every time.

Results
The groups were homogenous in terms of age, gender and number of patients (p > 0.05). Each group contained 30 patients. Spinal involvement was prominent in the range of diseases. While the assessment parameters improved significantly throughout the group, the group receiving combined administration was superior to the others. There was no difference in terms of paracetamol usage. In terms of local side-effects, while 5 patients from the first group experienced rashes, 2 patients experienced side effects in the second and third groups. They did not cause the patient to withdraw from the treatment. Doctor and patient assessment showed that the number of good and very good patients in the third group was 20 and 19, and that it was significantly high (p< 0.05).

Conclusion
Non-systemic topical nonsteroids may be safely used for pains and inflammations in patients with acute musculoskeletal disorders. Combined usage of two different products may increase the efficacy and reduce the side-effects.

LAVAGE OF LUMBAR FACET JOINT FOR LUMBAR FACET JOINT CYST PRESENTING WITH RADICULAR SYMPTOMS A CASE REPORT.
A. Bhargava

Introduction/Background

Lumbar facet joint cyst are usually degenerative in nature originating from lower lumbar facet joints which may compress nerves and cause radicular symptoms. There are various options of treatment including medication, physical therapy, injections, aspiration, bursting of the cyst, and surgery. A case study describing approaching the lateral extension of the lumbar facet joint cyst, bursting and lavage of lumbar facet joints cyst compressing on a nerve.

Material and Method

IRB exemption was obtained. A 70-year-old male presented with complaints of right gluteal pain radiating to lateral aspect of the leg to the ankle for 3 weeks. He was referred for physical therapy. MRI revealed spondylosis and 4 mm cyst in the right lateral recess at L5-S1 adjacent to or compressing the right S1 nerve root. NCS/EMG revealed acute right S1 radiculopathy, chronic right L5 radiculopathy, chronic left L4/L5 radiculopathy, bilateral sensory peripheral polyneuropathy. Patient had short-term pain relief after initial right S1 transforaminal injection and attempted bursting the cyst and injection of right L5-S1 facet joint injection. Two weeks later, right L5 transforaminal injection was performed and a second needle was inserted into the right L5-S1 facet joint. On injecting the facet joint, fluid was noted to exit from the needle in the L5 foramen. After injecting lidocaine, steroids were injected into the facet joint.

Results

At last conversation about ten months after the injection, the patient did not have pain. The MRI of lumbar spine was again reviewed and on T2 axial images fluid like structure was noted lateral to the facet joint in addition to the facet joint cyst, which was confirmed by radiologist to be lateral extension of facet joint cyst.

Conclusion

This case study illustrates that one may look for lateral extension of a cyst which may be used to rupture and lavage.

THE NEEDS OF ACUTE PAIN CONTROL IN LARGE EARTHQUAKES

H. Hu

West China Hospital of Sichuan University, Emergency Department, Chengdu, China

Introduction/Background

After a large earthquake, medical resources were less. Many trauma patients can not get regular medical resources. Among them, post-traumatic pain patients, which is with temporary non-life-threatening, such as limb fracture, cannot get the timely medical treatment of pain control. The Object of our study is to explore the post-traumatic pain and without non-life-threatening patients' needs in earthquake.

Material and Method

The West China earthquake victims' database was used for retrospective analysis. We enrolled more than 1800 records. And the general characters, the duration between the injury and first aid, diagnosis and the pre-hospital treatment were collected in our study.

Results

The median duration of pre-hospital pain control of the middle age and young people was 6 hours. And that of children was 2h, and that of elderly was 2h. It was significant difference between the groups (p<0.05). The median duration of pre-hospital pain control of the upper limb fracture patients was longer than others (p<0.05).

Conclusion

The duration of pre-hospital pain control of the middle age and young people was longer than the rest of the population; most of them were limb fracture victims. The duration of fracture fixation is also longer than other groups. In the case of a shortage of medical resources, it is recommended to widely popularize early traumatic first-aid knowledge. For fracture patients, it is recommended to be handled early by volunteers.

FACTORS ASSOCIATED WITH PSYCHO-COGNITIVE FUNCTIONS IN PATIENTS WITH PERSISTENT PAIN AFTER SURGERY FOR FEMORAL NECK FRACTURE
A. Kiatayama¹, M. Hida²
¹Iwaki Meisei University, Faculty of Allied Health Sciences, Iwaki-City, Japan
²Osaka Kawasaki Rehabilitation University, Department of Rehabilitation, Kaizuka-City, Japan

Introduction/Background
To solve problems arising from fracture of the femoral neck in elderly people, the proportion of which continues to increase in the population of Japan, we need to examine factors in patients with fractured femur necks to develop and ways to assist affected patients.

Material and Method
In this study, we examined the relationships among sex, age, fracture site, operative procedure, physique, lifestyle, psycho-cognitive functions, and types of pain in 142 patients, performed multiple regression analysis using the Mini-Mental State Examination (MMSE) and the Montgomery–Asberg Depression Rating Scale (MADRS) scores as dependent variables, and created MMSE and MADRS models.

Results
The results of analysis of the MMSE and MADRS models identified night pain and the number of family members as factors that affected mental function in a population with persistent pain for 1 week after surgery for fractured femoral neck. In addition, the number of family members was identified in multiple regression analysis models as a factor associated with psycho-cognitive functions. Pain, night pain in particular, affects psycho-cognitive functions. We speculated that emotional ups and downs were associated with the number of family members. The results showed that the patients living with family members maintained psycho-cognitive functions better than did those living alone, even when they experienced pain in their daily lives.

Conclusion
We speculated that emotional changes were associated with number of family members. Patients living with family members maintained psycho-cognitive functions better than did those living alone, even when they experienced pain in their daily lives.

PHYSICAL MEDICINE AND REHABILITATION CHALLENGES OF ALLEVIATING SYMPTOMS OF TRIGEMINAL NEURALGIA. CASE REPORT.
A. Pažėrienė¹, A. Petrauskaitė¹
¹Hospital of Lithuanian University of Health Science, Rehabilitation clinic, Kaunas, Lithuania

Introduction/Background

Trigeminal neuralgia is characterized by short episodes of unilateral acute unbearable pain, sudden in onset and termination, in the zone of the fifth cranial nerve branches. According to the latest data, there are surgical, pharmacological and nonpharmacological methods applied to treat trigeminal neuralgia. Rehabilitation methods, which are being applied to relieve symptoms, are: TENS, laser therapy, acupuncture, Botulinum toxin injection, ultrasound therapy.

The purpose of this trigeminal neuralgia case is to review all available rehabilitation methods in reducing the pain, to analyze our case and to offer treatment according best available evidence.

Material and Method

The patient of our case report, 39 year woman, is suffering from acute pain episodes (VAS 10 scores) and constant pain (VAS 3-4 scores), located in the two lower branches of trigeminal nerve. This case is unique because our patient is suffering not only from acute face pain, but also she gained left leg disability ant gait dysfunction that was not approved by any neurological or radiological diagnostic tests. Her gait improves after pain is relieved. During acute episodes, the only effective treatment is blockage of nerve rout by Pethidine and intramuscular injection of Ketoprofen. For persistent pain between acute episodes only peroral Carbamazepine is effective, however pain persists to 3-4 VAS scores. The patient was directed to Physical medicine and Rehabilitation Physician and an individual rehabilitation plan for pain reduction was made: TENS N10, polarised light and ultrasound N10.

Results

After applying these physical agents, the pain was reduced to 1-2 VAS scores for a short time.

Conclusion

Physiotherapy procedures reduce the pain, improve the patient's well-being, yet they have a short-term positive effect and the pain regresses. Further analysing of the effect of Physiotherapy procedures is necessary.

THE PAIN RELIEVING EFFECT OF KINESIOTAPING ON DENTAL PAIN: A PLACEBO-CONTROLLED TRIAL

H. Mubarak1, N. Mayasari2, H. Thahir3, M. Ruslin4

1Faculty of Medicine- Hasanuddin University, Physical Medicine and Rehabilitation Department, Makassar, Indonesia
2Wahidin Sudirohusodo Hospital, Physical Medicine and Rehabilitation, Makassar, Indonesia
3Faculty of Dentistry- Hasanuddin University, Periodontology Department, Makassar, Indonesia
4Faculty of Dentistry- Hasanuddin University, Oral and Maxillofacial Surgery Department, Makassar, Indonesia

Introduction/Background

Kinesiotaping is currently appreciated as a practical and low cost management for relieving pain, with relatively minimal adverse event. It has been proven in edema control, tissue support, and relieving heat produced from active inflammation. Dental pain arises from various pathology in oral cavity, mostly from tooth impaction and pulpitis. Dental pain limiting patient to daily activity involving oral cavity, like chewing, swallowing, and facial mimicking. Clinical application of kinesiotaping in patient with dental pain are rarely reported desiptes its potential to ameliorate pain and improve function.

Material and Method

A randomized, placebo-controlled clinical trial was perform to asses the effect of kinesiotaping on reducing dental pain. The primary outcome were VAS (Visual analog scale), milligrams of analgesics taken, and numbers of mastication strokes eliciting pain (masticatory pain tolerance). These datas were recorded before treatment, during treatment, and 1 day after tapes are released. Independent and paired t-tests were used for analysis.

Results

Sixteen patients randomly allocated to two groups; First group to receive kinesiotaping application (Group I) and another to receive placebo cohesive tapes (Group II). KinesioTex™ and the placebo tape with skin color were used. Both group received acetaminophen as analgesics. Significant VAS decrease observed during and after treatment in Group I (ΔVAS1 = 9.63; P=0.001 and ΔVAS2 = 4.88; P = 0.03) and during treatment in Group II (ΔVAS1 = 4.63; P=0.02). No significant VAS decrease in Group II after treatment (ΔVAS2 = 0.38; P = 0.42). Group I also showed significant improvement in masticatory pain tolerance (ΔNMAS1 = 5.88; P=0 and ΔNMAS2 = 3.88; P = 0.004) and acetaminophen taken for both measurement.

Conclusion
This study suggests Kinesiotaping decrease VAS significantly during treatment and one day after treatment. Improve in masticatory pain tolerance would benefit patient in digestion. Kinesiotaping could be adjuvant therapy in management of dental pain.

NON-TRAUMATIC HIP PAIN DURING PREGNANCY
D. Pozo Crespo¹, C. De Miguel Benadiba¹, G. De Bernardo¹, P. Sánchez Tarifa¹, M.J. Buzzetta Devis¹, J.C. Estupiñán Guzmán¹
¹Ramón y Cajal Hospital, Physical medicine and rehabilitation, Madrid Spain, Spain

Introduction/Background
The non-traumatic hip pain is a common symptom during the third trimester of pregnancy and it's usually under-diagnosed when there is an underlying disease. Thus, these women must have a correct differential diagnosis of the hip pain between two different pathologies. On the one hand, transient osteoporosis (TO), unusual and unknown etiology that appears on the third trimester of pregnancy or the puerperium, it has a good prognosis towards healing, being its biggest complication a hip fracture. On the other hand, the avascular osteonecrosis (AON), is rare (40 cases), being necessary the separation with the previous diseases for having a worse prognosis than the other cases as it is resolved with an arthroplasty, since the cases of spontaneous healing are exceptional for AON.

Material and Method

Case 1: Woman. 29 years old. Bilateral atraumatic hip pain and limited motion during the third trimester of pregnancy. During birth, she notices a clicking and subsequent functional limitation in both hips. Imaging tests showed subcapital fracture on left hip and TO on right hip.

Case 2: Woman. 42 years old. Relates atraumatic pain on the left hip after giving birth a month ago, she refers functional limitation as well. On MRI, AON is showed on the left hip with a subchondral fracture.

Results

Case 1: underwent surgery with cannulated screw fixation and muscle strengthening rehabilitation resulting on a great recovery.
Case 2: therapy based on muscular strengthening exercises in discharge. On MRI, four months after, there are no signs of any injury, with healing ad integrum.

Conclusion

Our contribution as Physiatrists is to suspect a possible pathology when non-traumatic hip pain appears associated with pregnancy, being the MRI the best test to diagnose it, and later, the treatment will be conservative with physical therapy, bed rest, analgesic and prevention of weight-bearing in order to avoid future associated fractures.

Introduction/Background

A considerable proportion of work absence is attributed to low back pain (LBP), with high lost productive time and health spending, especially after a work-related injury.

The French Health Insurance try to improve the return-to-work for these patients with an early care in rehabilitation centers.

The objective of this study is to determine if early care three months after a work stoppage after a work-related injury improves the return to work three months after, and to determine factors that influence the return-to-work.

Material and Method

Five centers in France took part in this protocol, in an open prospective study. 147 LBP patients (handler) were included in 2016, three months after the work-related injury. The intervention was a multidisciplinary functional restoration program for 67 patients. The others were followed up about the return-to-work.

The outcome was the return-to-work rate three months after the intervention.

Results

In the 52 remaining patients, 26 (50%) were at work at 3 months: 16 in full time at the same job. 9 patients were in occupational retraining. For the other 80 patients, 70 (87.5%) were at work at three months.

Active physiotherapy, TAMPA, FABQ, DALLAS, Visual Analog Scale (VAS) after the program were found to have relationships with the outcome.

LBP background and being sportif before or after the program, were not found to have relationship with the outcome.

Conclusion

Unfortunately, we found an adverse effect of the multidisciplinary functional restoration program from patients with low back pain in work stoppage after a work-related injury in our study.
Maybe the overmedication, or the drama caused by this program in hospitalization, must influence the situation of workers.

Surprisingly, sports practice did not show any influence on the results. Active physiotherapy should be offered to any patient in this situation to promote the return to work.

Piriformis muscle syndrome (PMS) is caused due to the excessive contraction of the piriformis muscle with sciatica-like symptoms. PMS is associated with paresthesias and pain in the hips, buttocks and lower part of body and its diagnosis is based on clinical grounds mostly. Common methods to treat this condition are fluoroscopic, electromyographic, magnetic resonance imaging guidance or computed tomographic while ultrasound-guided piriformis injections has several advantages compared to these prevalent and common approaches, such as well-set shape, availability, direct imaging of neurovascular structures and lack of exposing to ionizing radiation.

Material and Method

First the injection of Methyl Prednisone was applied under guidance of a Micromaxx ultrasound machine and using a 5–10MHz, 38-mm broadband linear probe. For piriformis injection under ultrasonographic guidance, a linear ultrasound probe is positioned with its lateral side medial to the greater trochanter and its medial side lateral to the ischial tuberosity. In this position, the sciatic nerve is identified as an oval honeycombed structure with mixed echogenicity. The sciatic nerve is then followed cephalad until it courses beneath the piriformis. Ultrasound probe is directed parallel to piriformis. Needle is inserted in lateral third of piriformis. The therapeutic effect was assessed before and a month after injection via Visual Analogue Scale (VAS) as three groups: improvement, partial improvement, or failure depending on the degree of symptom.

Results

According to the results, 7 patients (46.6%) showed improvement, 4 (26.6%) showed partial improvement and 4 (26.6%) failed to respond to the initial treatment.

Conclusion

Ultrasound-guided piriformis injection may be a suitable treatment strategy to reduce the symptoms in patients with Piriformis muscle syndrome.

ISPR8-2085
EVALUATION OF THE THERAPEUTIC EFFECT OF BOTULINUM TOXIN A ON HALLUX VALGUS DEFORMITY AND PAIN
A. Moghtaderi

1Physical medicine and rehabilitation, Isfahan University of Medical Sciences, ISFAHAN, Iran

Introduction/Background

Hallux Valgus is a kind of Toes aberration where the Metatarsophalangeal joint that connects the big toe to the foot, leading to the inner side and a protrusion on the inner surface of toe arise. This study aimed to determine the effect of botulinum toxin A injection to reduce pain and deviation angle of the thumb in Hallux Valgus and to increase outcomes of treatment as an adjuvant therapy.

Material and Method

Randomized clinical study was performed on 18 patients at the Clinic of Physical Medicine and Rehabilitation, Isfahan University of Medical Sciences. In this study the Halgvs valgus angle (HVA) between the metatarsals (IMA) and cartilage distal metatarsal angle (DMAA) and pain was assessed before and after injection

Results

Average of Hallux Valgus angle before and after Botox injections were 28/89 ± 10/21 and 21/56 ± 8/22 degrees and the angle deviation in the 6 months after treatment was significantly improved (p <0.001).

Conclusion

Injection of botulinum toxin Ais a suitable and acceptable method to reform the skeleton deformities and also to reduce the pain in patients with Hallux valgus

ISPR8-2208
EFFECTIVENESS OF BOTULINUM TOXIN TYPE A FOR PAIN CONTROL IN CHILDREN WITH SPASTIC CEREBRAL PALSY
D. Valencia¹, L.E. Jerez²
¹Universidad Nacional de Colombia- Universidad El Bosque, Departamento de Medicina Física y Rehabilitación, Bogotá, Colombia
²Universidad El Bosque, Departamento de Medicina Física y Rehabilitación, Bogotá, Colombia

Introduction/Background

A before and after prospective longitudinal study was made in 12 pediatric students with ages between two and 18 years with diagnosis of cerebral palsy, evaluating the presence of pain by using the FLACC scale; the participants had indication to receive Botulinum Toxin type A for the control of their spasticity. Another evaluation of pain was made a week and a month after the application.

Material and Method

Before and after prospective longitudinal non-experimental analytical study for related samples from a cohort of children with a diagnosis of spastic cerebral palsy and the presence of pain reported by the parents, to whom the FLACC scale was applied prior to the application of botulinum toxin and after her the first week and the first month.

Results

The present study of children and adolescents diagnosed with Spastic Cerebral Palsy was performed at the Hospital de la Misericordia Foundation in the city of Bogotá, meeting 15 patients, one of whom was excluded for presenting a value of 0 on the FLACC scale and other 2 patients did not continue with the study because they did not went to the controls.

The normality test was carried out, for being a sample of less than 30 participants the Shapiro Wilk test was used, a significance for the age of 0.219 was obtained, higher than 0.05 which shows that this variable had a normal distribution.

Conclusion

Botulinum toxin type A has a significantly positive effect for pain management identified with the FLACC scale in children with spastic cerebral palsy.

A 45 YEAR FEMALE PRESENTING WITH UNILATERAL PAINFUL KNEE WITH CALCIFICATION WITHIN THE LATERAL COLLATERAL LIGAMENT : A RARE CASE REPORT

A. Ranga¹, M. Joshi², O. Choudhary²
¹S. M. S. Medical College and attached group of Hospitals, Physical and Rehabilitation Medicine, Jaipur, India
²S. M. S. Medical College and attached group of Hospitals, Physical and Rehabilitation Medicine PRM, Jaipur, India

Introduction/Background

Acute calcific periarthritis (ACP) is an acute periarticular inflammation associated with juxtaarticular calcification. ACP is normally mono-articular, presenting with pain and swelling, with sometimes restricted movement. Here we report a rare case of ACP in a middle aged female.

Material and Method

A 45 year old woman presented to the Physical and Rehabilitation Medicine (PRM) OPD with acute onset of severe pain of the lateral aspect of the right knee along with swelling since 2 weeks. Her symptoms were sudden in onset, gradually worsened over next 48 hours and aggravated with weight bearing/walking and her gait was antalgic.

Her right knee joint had mild diffuse swelling and was slightly warm along with marked tenderness. Knee flexion and extension was associated with extreme pain and there was restriction in end range of motion.

All routine blood investigations were normal except slight raise in ESR and CRP. Ultrasonography of right knee joint showed hypoechoic free fluid along with calcification and 1 ml of chalky white, milky fluid was aspirated. Von kossa staining demonstrated calcium deposits. X-ray and MRI scan showed calcification on the lateral aspect of knee joint.

Results

On the basis of patient’s history, laboratory, radiological and histo-pathological investigations we reached the final diagnosis as ACP. Initially the patient was managed with rest, NSAID, ice and heat and the patient’s symptoms started to subside within 48 hours. After two weeks of treatment, during her last follow up visit, calcification had gradually absorbed and she was symptom free.

Conclusion
ACP is a rare, but self-limiting condition that normally resolves with minimal treatment within a few weeks. Radiologically, ACP demonstrates juxta-articular calcification. Therefore it can be mistaken for other conditions including gout, pseudo-gout, or systemic conditions such as hyperparathyroidism and renal failure. Since this disease is self-limiting, correct diagnosis is important to avoid unnecessary investigation and proper management.

TRAUMA IN FOOTBALL, CARE AND PREVENTION OF 136 CASES.
J.M. Angoué¹, M. Anicet², E.O. Thimothee³
¹Hopital d’Instruction des Armées Omar Bongo Ondimba, Médecine Physique et Réadaptation, Libreville, Gabon
²Hopital d’Instruction des Armées Omar Bongo Ondimba, service de chirurgie orthopedie, Libreville, Gabon
³Hopital d’Instruction des Armées Omar Bongo Ondimba, Service d' Imagerie Médicale, Libreville, Gabon

Introduction/Background

Introduction: The practice of football is generating various pathologies. Any incident deserves a quick diagnosis to avoid any serious sequelae.

Material and Method

Objective: To evaluate these traumas, their consequences on the health and the career of the athletes. Evoke therapeutic and preventive strategies to restore the function, allow the player to resume his sporting activity as soon as possible.

Results

Results: Included 136 injuries of the male champions of the professional championship of first division and those of the national team of Gabon. Average age 25 years. Midfielders: more affected by 37%, attackers: 25%; defenders: 24%, goalies: 14%. Stroke right 51%, left 31%, bilateral 18%. The most affected joints: knees 23cas, ankles 17 cases, shoulders 6cas. The affected muscles: adductors: 11cas, quadriiceps: 11cas, hamstrings: 9cas, triceps sural 7cas. Diagnosis: typical clinical presentation 44%, clinical and para-clinical confrontation 29%, standard radiography 3%, scanner 1%, ultrasound 16%, magnetic resonance imaging 6% and arthroscopy 1%. Conservative treatment 93% and surgery 7%. Evolution: total recovery 77%, partial recovery 18%, stopping the sport 3%, death by trauma 2%.

Conclusion

Conclusion: The prognosis of football trauma depends on the quality of the initial intervention, the diagnostic and therapeutic approach. Respect of the deadlines of unavailability. Some footballers, have never been able to regain their level before the injury from where, the return to the competition remains the nightmare of the medical staff.

MANAGEMENT OF PLANTAR FASCIITIS FOR 80 CASES

E.O. Thimothée, J.M. Angoue, M. Anicet
1 Hopital d'Instruction des Armées Omar Bongo Ondimba, Service d'Imagerie Médicale, Libreville, Gabon
2 Hopital d'Instruction des Armées Omar Bongo Ondimba, Médecine Physique et Réadaptation, Libreville, Gabon
3 Hopital d'Instruction des Armées Omar Bongo Ondimba, Service de Chirurgie Orthopédie, Libreville, Gabon

Introduction/Background

Introduction: Plantar fasciitis is the inflammation of the fascia, a fibrous blade of the plantar region extending from the heel to the base of the toes.

Material and Method

Objective: To evaluate the long-term effectiveness of the management of this pathology by a retrospective study of patients followed for three years

Results

Results: We recorded 80 cases of plantar fasciitis, with a male predominance of 65%, unilateral 77.5% and bilateral 22.5%. Compared with the body mass index, the majority of patients affected was overweight 80% and the average value of the body mass index was 28.02 so: overweight 52.5%, moderate obesity 25%, severe obesity 2.5%, patient of normal body size 20% of impairment. The diagnosis establishes before a characteristic clinical picture 17,5%; standard radiography 15%; ultrasound 52.5%; magnetic resonance imaging 15%. The evolution was marked after 24 months of management by: total disappearance of the pain 45%, notable reduction of the pain at the analogical visual scale to 4 out of 10 in 40%, persistence of the pain greater than 6 out of 10 at 15%

Conclusion

Conclusion: The management of plantar fasciitis is intended to relieve pain and restore function. It requires the simultaneous use of conventional therapeutics. The tendency to chronicity of this pathological process disappoints the patients but also the doctors. These results illustrate the complexity of this treatment and the uncertainty of their future.

MANAGEMENT OF SUPRASPINATUS TENDON INJURIES IN 82 CASES.
M. Anicet¹, J.M. Angouë², E.O. Thimothée³
¹Hopital d'Instruction des Armées Omar Bongo Ondimba, Service de Chirurgie Orthopedie, Libreville, Gabon
²Hopital d'Instruction des Armées Omar Bongo Ondimba, Médecine Physique et Réadaptation, Libreville, Gabon
³Hopital d'Instruction des Armées Omar Bongo Ondimba, Service d'Imagerie Médicale, Libreville, Gabon

Introduction/Background

Introduction: The supraspinous muscle helps the abduction of the arm, belongs to the "rotator cuff" which stabilizes the humeral head inside the joint capsule. This muscle passes between the acromion and the humeral head. The subacromial bursa reduces friction between the tendon and the acromion.

Material and Method

Method: Retrospective study of 82 cases of supra-thorny supraspinatus lesion in adult patients of both sexes. The variables studied: age, sex, activity, pain and medical imaging.

Results

Results: Included 44 men for 38 women. Average age: 50 years. Non-traumatic injuries 68.29%. Injury after 31.71% shoulder trauma. Right lesion 60.97%, Left lesion 39.03%. Professional activity: Physical work 42.69%; office work 23.17%; sports injury 13.41%. No specific activity 20.73%. Injury on the same side as the right-handed dominant arm 58.54%, left-handed 24.39%. Injury on the same side as the right-handed dominant arm 58.54%, left-handed 24.39%. 24.39% Clinical Positive Diagnosis, 31.71% Standard Radiography, 29.27% Ultrasound, 14.63% Magnetic Resonance Imaging. Isolated involvement of the supraspinatus tendon 73.17%. Achievement of supraspinatus associated with another lesion 26.83%. Evolution: total disappearance of pain 51%, pain reduction to less than 4 out of 10 on the visual analog scale 36%, persistence of pain to more than 6 out of 10 on the 13% visual analogue scale.

Conclusion

Conclusion: Supraspinous tendon lesions are common. Despite the satisfactory results of their management, it is important that this pain is the subject of greater attention in a functional rehabilitation environment.

PAIN MEASUREMENT BY THE SKIN IMPEDANCE IN CASE OF STROKE PATIENTS

K. Kagechika\(^1\), M. Tsubokawa\(^1\), Y. Yamauchi\(^1\), N. Tanabe\(^1\), Y. Takagi\(^2\), A. Nakanami\(^2\)

\(^1\)Kanazawa Medical University, Rehabilitation Medicine, Uchinada, Japan
\(^2\)Municipal Tonami General Hospital, Rehabilitation, Tonami, Japan

Introduction/Background

To examine whether it is possible to evaluate of the pain by the measurement of the change in the skin impedance in patients with stroke.

Material and Method

The skin impedance obtained from the electrode applied to the hand was measured, and it made comparative study of the value before and after the pain treatment. The patients with omalgia and the low back pain in paralyzed side were done the hyperthermia of hot pack and the xylocaine intramuscular injection, and visual analogue scale was compared additionally before and after treatment as sight scale.

Results

For the patients with omalgia and the low back pain, the difference was admitted in the individual value that was able to be put in the resting state, and the change was seen in response to the state of their posture.

Impedance decreased with the exacerbation of the pain, and it has increased with the improvement of the pain sensation.

The larger the improvement of the pain sensation was, the smaller increases of impedance when the low back pain was improved by the effect of the hyperthermia.

Conclusion

The pain is a subjective phenomenon, and it is changeable. The objective evaluation is difficult because there are extremely a lot of troubles that cause the pain. The improvement of the pain and the change in the skin impedance were in the correlation. It was suggested that a quantitative evaluation of the pain sensation was possible though it was thought the change of the pain took place through the autonomic nerve system.

THE EFFECTS OF MYOFASCIAL CUPPING THERAPY AND CALLIET NECK EXERCISE IN MPS-SYMPTOMATIC PATIENTS

L. Adorable\textsuperscript{1}, J. Alicabo\textsuperscript{1}
\textsuperscript{1}Southwestern University, College of Rehabilitative Sciences, Cebu City, Philippines

Introduction/Background

This research study intends to use Instrument-Assisted Soft Tissue Mobilization Technique (IASTM) on individuals who are suffering from Myofascial Pain Syndrome and limited range of motion (ROM) on the neck. This discusses the implication of cupping therapy and Calliet exercise in long term effects in treating Myofascial Pain Syndrome.

Material and Method

A true experimental design was used in the study that includes an experimental group which are treated using Myofascial Cupping Therapy and Calliet exercise and a control group which are treated with Calliet exercise only. Participants in the study includes male and female with age ranging from 20-55 years old who experienced neck and shoulder pain and limited ROM. A goniometer was used to gather data for ROM. Massage oil was used as a medium together with the silicone cups for the Myofascial Cupping treatment. Twenty-four (n=24) individuals who had experienced neck and shoulder pain were assessed for the presence of MPS and limited ROM. Twelve (n=12) participants (age=32.3±10.5) served as an experimental group which received a cupping treatment and Calliet exercises and another twelve (n=12) participants (age=28.3±8.9) served as a control group which received Calliet exercises only. Both groups were evaluated and were given a therapeutic intervention once a week for 4 weeks. Measurements includes ROM and pain using Numeric Pain Rating Scale (NPS) and a one-way ANOVA was used to calculate all the gathered data.

Results

Both groups were statistically significant showing a great improvement in ROM and a decrease in pain severity. However the experimental group showed better results compared to the control group based on the gathered data and upon evaluation of the respective mean values.

Conclusion

Myofascial Cupping Therapy can be used as treatment for individuals with neck and shoulder pain and decreased ROM.

³Centro de Investigaciones Médico Quirúrgicas, Physiotherapy, Habana, Cuba
⁴Ministerio de Salud Pública, Rehabilitation, Habana, Cuba
⁵Centro de Investigaciones Médico Quirúrgicas, Physiotherapy, Habana, Cuba

Introduction/Background

Objective: To evaluate the evolution of patients with acute mechanical lumbago pain with deep oscillations in relation with others treated with interferential current and cryotherapy.

Material and Method

Methods: An experimental explanatory study was completed in the period from January 2015 to July 2017 of the patients that were assisted at the Physical Medicine and Rehabilitation Office of the Clinical Research Center with the diagnosis of acute mechanical Lumbago pain, the Analogical Visual Scale, the Likert Test, and the Foral Waddel Test were applied at the beginning and at the end of the treatment. The sample was divided in 2 groups; in the study, one group received deep oscillations therapy and the other interferential current and cryotherapy, to both groups the postural hygienic measures were suggested. The data were evaluated and the significant fixed level was p≤ 0, 05.

Results

Results: Prevalence existed in the masculine sex, with 45, 15 years old media, normal weight; the factors that developed pain were intense physical work, followed by the maintained static postures. More than 90% of they didn't have knowledge of the norms of postural hygiene. The pain level at the beginning of the treatment behaved equally in both groups, being highly significant the results when concluding the treatment in the Analogical Visual Scale and the Test of Likert. The Test of Waddell was significantly modified in both groups. Conclusions: The treatment with deep oscillations went superior to those with interferential current and cryotherapy with a beginning of the analgesia before in the study group.

Conclusion

Conclusions: The treatment with deep oscillations went superior to those with interferential current and cryotherapy with a beginning of the analgesia before in the study group.

³Sapienza University of Rome, Unit of Physical Medicine and Rehabilitation, Rome, Italy
⁴Sapienza University of Rome- S.Andrea Hospital, Unit of rheumatology, Rome, Italy

Introduction/Background

FM is a prototypical form of central sensitization syndrome that affects the dysregulation of mechanisms that normally govern pain sensation and should have to be treated in a multidisciplinary approach, which entails physical exercise, multimodal cognitive behavioral therapy, and pharmacological therapy. The aim of this research is to investigate whether a neurocognitive rehabilitative approach based on the use of motor imagery (MI) could be efficacy in reducing chronic pain in FM. Furthermore, as a secondary outcome, we assess the efficacy of MI on the improvement in the recognition and awareness respect pain by EEG.

Material and Method

Ten females (mean age 51 ±6,1 years) with FM were recruited and performed ten rehabilitation sessions, twice a week lasting one hour, using the motor imagery. The following evaluation scales were used at the baseline (T0), after treatment (T1) and after two months of follow-up (T2): The Fibromyalgia Impact Questionnaire (FIQ), The Visual analogue scale (VAS), The Fibromyalgia Assessment Status (FAS) and the Health Assessment Questionnaire (HAQ), the SF-12 was administered to assess the quality of life. The EEG was used to record cortical activation with respect to recognize pictures divided into "algic" and "non-algic", versus a control group of healthy women.

Results

By Mann-Whitney test, at baseline, by EEG there is a statistically significant difference in the recognition of "algic" images compared to "non-algic" ones between the FM group and the healthy group (P<0,05): this difference is not found after the rehabilitative treatment. In the FM group there is a statistically significant improvement for FIQ, FAS, VAS (P<0,05) and SF-12. Follow-up date are still ongoing.

Conclusion
A neurocognitive rehabilitation approach with motor imagery improves the recognition and perception of pain in the FM patient and is efficacy in reducing pain and improving related symptoms.

PREVALENCE OF CENTRAL POST-STROKE PAIN AND ITS IMPACT ON QUALITY OF LIFE
S. ösken
1Eskisehir State Hospital, physical therapy and rehabilitation, eskisehir, Turkey

Introduction/Background

OBJECTIVE: This study aims to determine the prevalence of central post-stroke pain (CPSP) in a patient population with stroke as well as investigating the relationship between CPSP and patients' clinical/demographic characteristics, pain intensity, functional status and quality of life.

Material and Method

MATERIAL AND METHOD: The study included 150 patients, who had a stroke and aged 18 years and above. Demographic data of the patients, stroke duration, and etiology, localization of the cerebral lesion, affected side, ambulation status, and Brunnstrom stages were recorded. Douleur neuropathique 4 questions (DN4) were used to assess the presence of CPSP. Visual Analog Scale (VAS) was used for pain intensity, functional ambulation scale (FAS) was used for ambulation status, Barthel Index (BI) was used for functional status, and the stroke impact scale (SIS) was used for quality of life.

Results

RESULTS: The mean age of the patients was 67±11.5 years, 54.7% was male, and 45.3% was female. CPSP was evaluated in 15.3% of patients. There was no significant difference between the affected side of the body and age, gender, duration of stroke, Barthel Index scores, and ambulation status of patients according to their CPSP status (p>0.05). There was no statistically significant difference between SIS sub-parameter scores and presence of CPSP (p>0.05).

Conclusion

CONCLUSION: Poor functional status, post-stroke pain intensity, advanced age, and the presence of right hemiplegia has a negative impact on the quality of life.

MUSCLE MASSAGE EXERCISE IN PATIENTS WITH MYOFACIAL PAIN DYSFUNCTION SYNDROME

S. Yura¹, N. Aki²
¹Tonami General Hospital, Oral and Maxillofacial Surgery, Tonami, Japan
²Tonami General Hospital, Rehabilitation, Tonami, Japan

Introduction/Background

The purpose of this study is to investigate the effectiveness of muscle massage exercise in patients with masticatory muscle tenderness and factors related to the effectiveness of the therapy.

Material and Method

In 54 patients with masticatory muscle tenderness, improvement of muscle pain and trismus were examined to determine the effectiveness of the therapy. With respect to conditions of the patients, we examined gender, age, duration of symptoms, range of maximum mouth opening, difference and site of the muscle. These factors were statistically analyzed by using logistic regression analysis.

Results

Two months after the therapy, the incidence of successful resolution was 92 % (50/54). A factor related to the effectiveness of the therapy was duration of symptoms.

Conclusion

The result indicates that muscle massage exercise is an easy and highly efficient procedure in masticatory muscle tenderness cases whose duration of symptoms is in particular short.

CHRONIC PAIN IN PERSONS WITH MULTIPLE SCLEROSIS
B. Amatya¹, J. Young¹, M. Galea¹, F. Khan¹
¹Royal Melbourne Hospital, Department of Rehabilitation Medicine, Parkville, Australia

Introduction/Background

Pain can be a significant long-term problem for a substantial proportion of persons with multiple sclerosis (pwMS). The aim of this study was to examine the course and impact of chronic pain over a span of 10-years.

Material and Method

A longitudinal, cross-sectional study assessed pwMS residing in the community at seven and ten years using validated measures: Visual Analogue Scale; Numerical Rating Scale; Chronic Pain Grade (CPG); Assessment of Quality of Life and the Carer Strain Index (CSI).

Results

Mean age of the participants (n=70) was 59.8±9 years (range: 39-74 years) and majority (70%) were female. The findings show that over 10-year period, majority report bilateral lower limb dysesthesia (40%), mixed pain (35.2%) and widespread pain (17.1%). There was a significant deterioration in quality of life (QoL) in those with more severe CPG. Almost half of the participants (44%) required care either from a private carer/family or institution. The carers (n=13) reported higher carer strain (mean CSI=5.2), with over half reporting sleep disturbance, inconvenience, physical strains, family and personal constraints. Although fear of taking medications and side effects were common barriers to treatment for pain, there was an increase in the use of pharmacological treatment and healthcare services, mainly neurologists and general practitioners over time.

Conclusion

This study demonstrates that persistent chronic pain is a significant issue over time in pwMS, with clinical and health implications, poorer QoL, and increased healthcare utilisation. Greater awareness of chronic pain in pwMS and interdisciplinary approach is required to improve long-term patient outcomes and well-being.

NON-PHARMACOLOGICAL INTERVENTIONS FOR CHRONIC PAIN IN MULTIPLE SCLEROSIS: A. COCHRANE SYSTEMATIC REVIEW
B. Amatya¹, J. Young¹, F. Khan¹
¹Royal Melbourne Hospital, Department of Rehabilitation Medicine, Parkville, Australia

Introduction/Background

Chronic pain is common and significantly impacts on the lives of persons with multiple sclerosis (MS). Various types of non-pharmacological interventions are used to improve pain control in persons with MS (pwMS), however the effectiveness and safety of many modalities is still unknown. This review evaluated the effectiveness of currently used non-pharmacological interventions for chronic pain in pwMS.

Material and Method

A literature search was performed using the Cochrane MS Group Trials Register which contains Cochrane CENTRAL, Medline, EMBASE, CINAHL, LILACUS, Clinical trials.gov and World Health Organisation International Clinical Trials Registry Platform in April 2017. Manual searching in the relevant journals and screening of reference lists of studies was done. Randomised controlled trials (RCTs), cross-over studies and clinical controlled trials were included. All authors independently selected studies, extracted data and assessed the methodological quality. Pooling data for meta-analysis was not possible due to methodological/statistical heterogeneity of included studies.

Results

Overall, 12 RCTs (610 participants) which investigated different non-pharmacological interventions for the management of chronic pain in MS fulfilled the review inclusion criteria. The non-pharmacological interventions evaluated included: transcutaneous Electrical Nerve Stimulation (TENS), psychotherapy (telephone self-management, hypnosis and electroencephalogram biofeedback), transcranial random noise stimulation (tRNS), transcranial direct stimulation (tDCS), hydrotherapy (Ai Chi) and reflexology.

The findings suggest that there is 'low level' or limited evidence for the use of evaluated non-pharmacological management for chronic pain in MS. Though, there is improved changes in pain scores and secondary outcomes, these were not clinically or statistically significant for TENS for lower back pain and tRNS, hydrotherapy exercises, tDCS, reflexology and psychotherapy for overall pain. The evidence was limited for other interventions.

Conclusion
Despite the use of wide range of non-pharmacological interventions for the treatment of chronic pain in pwMS, the evidence for these interventions is still limited and/or insufficient. More robust studies are needed to justify the beneficial effect of these interventions.

ACUTE PAIN IN THE FIBROMYALGIC PATIENT: WHAT HAPPENS IF WE USE PHYSIOTHERAPY?

G. Deinite¹, O.L.F. Ragusa²
¹Médecin MPR, Centre de soins de suite et de réadaptation Orcet - Mangini, Hauteville Lompnes, France
²Asl To 3, Medicina Fisica e Riabilitazione, Venaria Reale, Italy

Introduction/Background

The aims of the present study are to evaluate the results of the association of the most common treatments of the acute phase with rehabilitation, in order to reduce the dependence on drugs of these patients and perhaps propose a treatment model to be used also in the disease stabilization phase.

Material and Method

Between 2016 and 2017, were drafted 12 patients with fibromyalgia syndrome in the phase of algic relapse and in standard treatment with muscle relaxants and serotoninergics. All patients underwent VAS assessment, functional objective examination and screening with Euroqol and intensive treatment with Tecarterapia for 40 minutes and TENS for 20 minutes combined with relaxation and stretching exercises for 30 minutes with physical therapy, for 10 consecutive days.

Results

All patients showed a reduction in algic symptoms between the fifth and seventh session with VAS values at the end of treatment around 3.5 of average (min 2 max 4) and recovery at the Euroqol up to about 78 (max 85 min 65). During treatment, drug dosages were progressively reduced, 2 sessions suspended before the end of treatment, included in the less responsive patients.

Conclusion

The treatment with physical therapy and rehabilitation has contributed significantly in our opinion to improve the pain crisis of FM patients. The data collected confirm what is highlighted in other observations, suggesting that a specific rehabilitative treatment can be favorable in the acute acute patient with FM.

ISPR8-0559
STUDY OF THE LOW BACK PARAVERTEBRAL ALLODYNA SURFACE OF CHRONIC LOW BACK PAIN PATIENTS BEFORE AND AFTER PAIN NEUROSCIENCE EDUCATION
O. Raymaekers¹, R. Keunebroek¹
¹CHU Lille, prm, Lille, France

Introduction/Background

Thanks to advances in neuroscience, we know that pain neuroscience education (PNE) helps to reduce central sensitisation. We adapted PNE to chronic low back pain patients.

Measuring the alldynia surface is indicative of central sensitisation. We applied this method on low back pain to assess the effect of PNE.

Material and Method

Controlled and non-randomised single-blind study involving 31 adults having an average age of 43.74 years, recruited from the Regional University Hospital of Lille.

A control group (CG) followed a multidisciplinary protocol during 4 weeks. An experimental group (EG) benefitted, in addition to the protocol, of one hour of PNE. They must then fulfil a questionnaire in order to prepare an individual interview of twenty minutes during the 4th week. Allodynographies were performed during the 1st and 4th week and after 3 months.

Results

The surfaces are very significantly decreased in the EG at 4 weeks while the CG shows no significant difference. After 3 months, the evolution of the surfaces is very significantly improved in both groups. On the other hand, between the allodynography performed at 4 weeks and at 3 months, the CG shows a very significant decrease of the surfaces, where the surface increases very slightly for the GE.

Conclusion

We have successfully adapted to chronic low back pain patients an allodynography technique that had already been tested in other studies.

Compared with the CG patients, the PNE provided to EG patients significantly decreased low back paravertebral alldynia surface after 4 weeks but no further improvement was observed after 3 months. Further studies are needed to understand the reasons.

SPINAL FLUID TAPS PROVIDE TEMPORARY RELIEF IN PATIENTS WITH UNEXPLAINED WIDESPREAD PAIN AND FIBROMYALGIA

M. Hulens

KULeuven, rehabilitation Sciences, Sint-Joris-Weert, Belgium

Introduction/Background

Chronic unexplained widespread pain (WSP) and fibromyalgia (FM) are generally assumed centralized pain disorders. However, FM shows characteristics of neurological disorder. Moreover there are similarities between FM, WSP and cerebrospinal pressure dysregulation syndromes such as Idiopathic Intracranial Hypertension and Idiopathic Normal Pressure Hydrocephalus.

When intracranial pressure increases, drainage of excess CSF through the cranial and the spinal nerves increases. Increased CSF pressure inside the nerves irritates the nerve fibers and consequently causes widespread radicular pain.

We hypothesized that the neurological symptoms may be caused by CSP dysregulation and that withdrawal of spinal fluid might relieve the pain in patients suffering from FM and unexplained WSP.

Material and Method

Retrospectively, CSP measurements followed by spinal fluid taps in an attempt to relieve the pain were reviewed in 30 patients (12 males and 18 females, mean age 42.0y + 11.2y) suffering from debilitating WSP and FM.

Within the first week postpuncture, patients were asked to observe to list the most striking changes of their symptoms.

Results

The opening pressure ranged from 12 to 32 cm H20 (mean 19.7 + 4.8 cm H20, median 20.0 cm H20).

In 21 patients (70%) spinal fluid withdrawal had a favorable effect on the pain from a few hours to 8 weeks.

Other improvements were: relief of low back pain, leg pain and/or coccygodynia; disappearance of headache; improved concentration; improved mood; improved sleep; more clear in the head;
being able to sit longer without pain; being able to walk better; no more urinary frequency; more easy to empty the bowel and/or the bladder; less pain in the jaw.

Conclusion

Exploring the issues on raised CSP may open perspectives for the diagnosis and treatment of unexplained WSP and fibromyalgia.

In patients with chronic pain, when performing a lumbar puncture for diagnostic reasons, opening pressure should be measured.

Keywords

fibromyalgia; lumbar puncture

Introduction/Background

Background:

Chronic pain is defined by a continuous or recurrent pain that lasts at least 12 weeks, or a pain that persists through the normal expectation of time.

Among the most commonly used drugs are opioids, of which Tapentadol is one of the most innovative, which demands from professionals a thorough review of its efficacy, benefits and adverse effects.

Aims of systematic review:

- Evaluate the benefits of applying Tapentadol in patients with chronic pain
- Compare the therapeutic effect and the adverse effects of Tapentadol with respect to other analgesics
- Intuit degree of pain reduction after the implantation of said drug

Material and Method

A search was carried out through the main medical databases, specifically Pubmed, Cochrane and Medline.

We obtained around 120 results, which were subjected to the following inclusion criteria:

- Publication in the last 4 years.
- Experimental or observational studies
- Inclusion of at least 3 key words in the title of the text.
- Do not be duplicated.
Once these criteria were applied, 7 articles were obtained and analyzed.

**Results**

- Tapentadol is a very useful drug for chronic nociceptive and neuropathic pain, in addition to reducing side effects of classic opioids, with better tolerability, good satisfaction and an easy progressive decrease.

- Is an ideal candidate for patients with chronic pain who have developed neuroplasticity.

- In patients with chronic moderate-severe cervical pain, is effective and well tolerated, decreasing pain and neuropathic symptoms and improving motor function of the neck.

- After 12 weeks of treatment with tapentadol in patients with chronic musculoskeletal pain, analgesic efficacy was obtained. With positive influence on the quality of life and on chronicity.

**Conclusion**

- Currently, chronic pain is one of the most frequent causes of consultation in rehabilitation.

- Tapentadol seems to be a good alternative for chronic pain management.

- In my opinion, there should be greater efforts in the creation and research of analgesic drugs to fight against pain.

STRAIN COUNTER-STRAIN TECHNIQUE VERSUS KINESIO TAPE IN TREATING PATIENTS WITH MYOFASCIAL NECK PAIN SYNDROME
A. Abdelfattah¹, O. Kattabe², S. Nasef²
¹Faculty of Physical Therapy - Cairo University, Department of Basic Science, Giza, Egypt
²Faculty of Physical Therapy - Cairo University, Department of Basic Science, Cairo, Egypt

Introduction/Background

Myofascial pain syndrome is one of the most common complaints in clinical practice. Strain Counter Strain technique is non-invasive therapeutic modality for treatment of soft tissue disorders. Kinesio tape is now widely used in management of musculoskeletal injuries.

Material and Method

Forty five patients with myofascial neck pain syndrome assigned randomly into: strain counter-strain technique group (n=15), kinesio tape group (n=15) and control group (n=15). The strain counter-strain technique was applied for two weeks (3 sessions/week-20 minutes per session). Kinesio tape was applied for upper Trapezius muscle for two weeks (3 days on and one day off). Pressure algometry, Visual analogue scale (VAS) and Neck disability index (NDI) were used to evaluate participants before and after the corresponding interventions. Analysis of variance test (ANOVA) was used to determine differences between groups for all measured parameters. Paired t-test was used to compare between the pre- and post-treatment values within groups.

Results

For the 45 study participants (33 women and 12 men; mean age=44.1±7 years) statistical analysis revealed that subjects in strain counter-strain technique and kinesio tape groups experienced significant increase in pressure pain threshold, decrease in neck disability scale and pain level than those in the control group in favour of strain counter-strain technique group (p>0.05)

Conclusion

The results suggest that treatment with strain counter-strain technique and kinesio tape were effective however strain counter strain technique was more effective for management of myofascial neck pain syndrome.

EFFECT OF KINESIO TAPE IN MYOFASCIAL PAIN SYNDROME RANDOMIZED CONTROL TRIAL
A. Abdelfattah¹, O. Kattabé², S. Nasef²
¹Faculty of Physical Therapy - Cairo University, Department of Basic Science, Giza, Egypt
²Faculty of Physical Therapy - Cairo University, Department of Basic Science, Cairo, Egypt

Introduction/Background
Myofascial pain syndrome is one of the most common complaints in clinical practice. Kinesio tape is now widely used in management of musculoskeletal injuries

Material and Method
Thirty subjects with myofascial pain syndrome (14 males and 16 females), with age ranged from 20 to 50 years old participated in this study. They were assigned into two equal groups each one has 15 subjects: group A kinesio tape for 3 days. Group B (control group) did not receive any physical therapy modality, Patients were randomly assigned into 2 groups using the simple randomization in selection. An almost infinite number of methods can be used to generate a simple randomization sequence based on a random number from the table of numbers of patients and the take odd and even number for equal allocation. Pressure algometry, Neck disability index and Visual analogue scale were used to evaluate participants before and after application kinesio tape technique, and for patients in the control group before and after 3 days

Results
Statistical analysis revealed that there was a significant increase in pressure pain threshold, decrease in pain level and function between before and after treatment with kinesio tape group with percentages of 46%, 40%, and 52%. while there was no significant difference in the same measuring variables in the control group. Comparison between groups revealed that there was a significant difference between groups and between each groups in pressure pain threshold (PPT) and visual analogue scale (VAS) and neck disability index (NDI), P: probability< 0.05.

Conclusion
Kinesio tape technique is effective method of treatment of neck myofascial pain syndrome

ULTRASOUND-GUIDED GENICULAR NERVE BLOCK IN CHRONIC KNEE PAIN
N. Albuquerque¹, J. Pinto², M.D.C. Loureiro², T. Félix¹, I. Peixoto¹
¹Centro Hospitalar Tondela Viseu, Physical Medicine and Rehabilitation, Viseu, Portugal
²Centro Hospitalar Tondela Viseu, Anesthesiology Department - Chronic Pain Unit, Viseu, Portugal

Introduction/Background

Chronic knee pain is the most common site of osteoarthritis. Pain associated with it is multifactorial and its management is multimodal, including minimally invasive procedures such as nerve block of geniculates. The objective of this study is to evaluate the immediate and short-term symptomatic improvement of patients with chronic knee pain after an ultrasound-guided block of genicular nerves.

Material and Method

Twenty ultrasound-guided blocks of geniculate nerves (Ropicavaine + Methylprednisolone) were performed in patients with chronic knee pain. The efficacy of the block was evaluated through the Numerical Analgesic Scale, immediately after the procedure, after 48 hours and 1 month later. Safety was also evaluated through monitoring of side effects and the level of patient satisfaction. Statistical analysis was performed using IBM-SPSS Software version 24.0.

Results

A total of 20 patients were included (85% female) with an average age of 75 years. The median pain before the procedure was 9, immediately after it was 2, two days later it was 3 and one month later 6 (37% pain relief at the end of one month). Regarding the overall Patient Global Improvement Change Scale (PGIC) 90% reported improvement 48 hours after the procedure. 100% of patients reported being willing to repeat the procedure. No adverse effects were reported after one month.

There was a tendentially significant positive correlation ($p<0.10$) between pain before the procedure and pain one month after the procedure and a statistically significant positive correlation ($p<0.05$) between pain with the procedure and pain one month later. Conclusion

Corticoanesthetic ultrasound-guided blocks of geniculate nerves contributed to the symptomatic relief of these patients in the short term. The most ab initio complainants and those who complained of the greatest pain with the procedure, were the patients with lowest symptomatic relief at the end of one month.

⁵Shohada-e-Tajrish Hospital, Physical Medicine and Rehabilitation Department- Shahid Beheshti University of Medical Sciences, Tehran, Iran

**Introduction/Background**

Myofascial pain syndrome (MPS) is a common musculoskeletal disorder among young adults. There are many therapeutic options including oral medications, physical agent modalities and some alternative treatments like dry needling (DN) without any drugs, ozone (OI) or lidocaine injection (LI). Our aim is to compare these last three methods in a randomized clinical trial.

**Material and Method**

In this single-blinded study among patients who presented at our musculoskeletal clinic, a total of 72 eligible participants were enrolled. Patients were randomly divided into three groups: first group (DN group) underwent dry needling, while the second and third groups received wet needling with ozone and lidocaine injection, respectively. All injections were repeated in three weekly sessions. Visual analog scale (VAS) for pain, neck range of motion (ROM), pain pressure threshold (PPT) and neck disability index (NDI) were the main outcome measures, applied two times: once before intervention and another at 4 weeks after the last injection.

**Results**

One month after injections in comparison to baseline, significant improvement was seen in pain and function for all three groups. Cervical ROM, except for dry needling group, was significantly improved in ozone and lidocaine groups (p value= 0.025 and 0.009, respectively). In comparison to DN group, both ozone and lidocaine had significantly better efficacy in PPT and NDI improvement (p value= 0.05 and 0.01, respectively); however there was no significant
difference regarding to VAS changes between three groups (p value=0.21).

TREATMENT WITH LIDOCAINE PATCHES VERSUS LIDOCAINE INJECTIONS IN MYOFASCIAL PAIN SYNDROME IN THE SHOULDER GIRDLE MUSCLES

N. Lara¹, C. Rangel Gomez², L. Rodriguez¹

¹Universidad Nacional de Colombia, Physical Medicine And Rehabilitation, Bogota, Colombia
²Universidad Nacional de Colombia, Osteopathy, Bogota, Colombia

Introduction/Background

The myofascial pain syndrome (MPS) in the shoulder girdle muscles is a very common musculoskeletal disorder, which is chronic and recurring, with components of mixed pain (nociceptive and neuropathic). Lidocaine patches and injections are two treatments that have been used in these patients. The aim of this study is compare the use of lidocaine patches versus lidocaine injections for MPS in the shoulder girdle muscles.

Material and Method

A comparative, prospective cross-sectional study with two parallel groups in a secondary hospital in the Bogotá city. Sample was 20 patients with MPS in the shoulder girdle muscles for more than 4 weeks and pain greater than 50mm in visual analog scale, and was evaluated at baseline and 1 month after treatment. Two groups were assigned: The patch of lidocaine (daily use for 1 week) and the injection group (single application). It was performed a statistical analysis with GraphPad software © 2016 and was used the Student t test for equal variances given the Gaussian distribution of the data.

Results

It was found a P 0.0001 when comparing the data of the EVA at the beginning and end of treatment in each of the groups individually. However when comparing the two groups against each other at the end of treatment the P value was 0.3955 as shown in the table.

Conclusion

Our study shows that both treatments separately, were effective in the treatment of MPS, and no significant difference when comparing the two treatments with each other. Patches being less invasive and therefore less complications lidocaine injections.

**THE RELATION BETWEEN PERSONAL RESOURCES AND QUALITY OF LIFE IN PATIENTS WITH FIBROMYALGIA**

A. Winkelmann¹, B. Oettl¹, M. Weigl¹

¹University Hospital- LMU Munich, Department of Orthopaedics- Physical Medicine and Rehabilitation-, Munich, Germany

**Introduction/Background**

Patients with fibromyalgia (FM) suffer from chronic widespread pain, nonrestorative sleep and varying more complaints like depressive symptoms or anxiety. We hypothesized that analogously to patients in psychotherapy FM patients have low levels of personal resources. We aimed to evaluate the reliability of the Essen Resources-Inventory (ERI), to compare resources of FM patients to other groups and to assess the association of resources to health-related quality of life.

**Material and Method**

In this cross-sectional study with 169 FM patients we applied the ERI scales for personal resources, the quality of life questionnaire Short-Form 36 (SF-36) and the Patient Health Questionnaire (PHQ-4). Reliability (internal consistency) of the ERI scales was assessed by Cronbach’s alpha. Scores of ERI scales were compared to historic control groups. Associations between ERI scales and the SF-36 Physical Component Summary (PCS) and Mental Component Summary (MCS) were analyzed by Pearson correlation coefficients or Spearman correlation coefficients according to the scale distributions.

**Results**

The mean age was 50.9 (SD 10.5), 94.1% were female. FM patients compared to healthy controls showed worth scores for PHQ depression (3.05 vs. 0.95), anxiety (2.98 vs. 0.90), PCS (31.9 vs. 49.9) and MCS (39.6 vs. 47.5). Internal consistency of the Eri scales was moderate to high (Cronbach’s alpha = 0.67 to 0.95). The comparison of resources of FM patients to controls is presented in table 1. All Eri scales showed significant correlations to the MCS (p < 0.01), but not to the PCS (p > 0.05). Correlation coefficients above 0.3 were found for the total ERI personal scale (r=0.38), openness (r=0.39), meaningfulness (r=0.35) and social competence
(r=0.32).

THE EFFECT OF COMPREHENSIVE NURSING INTERVENTION ON THE NEGATIVE EMOTIONS OF PATIENTS WITH NEURALGIA AFTER SPINAL CORD INJURY

Z. Haina1, X. Guangmeng2, Z. Jun1, G. Shuang1

1The Second Hospital of JiLin University, the Rehabilitation Department, Chang Chun, China
2The Second Hospital of JiLin University, the General Surgery Department, Chang Chun, China

Introduction/Background

To explore the effect of comprehensive nursing intervention on the negative emotions of patients with neuralgia after spinal cord injury.

Material and Method

Using Self-rating Depression Scale (SDS) and Self-rating Anxiety Scale (SAS), questionnaire and statistical analysis were conducted for patients with neuralgia after spinal cord injury. 60 patients with anxiety and depression were randomly divided into observation group and control group, each group consisting of 30 patients. The control group received routine care in pain department, while the observation group was given comprehensive nursing intervention on the basis.

Results

SDS and SAS scores in the observation group after 4 weeks were significantly lower than those in the control group ($P<0.05$).

Conclusion

Comprehensive nursing intervention can effectively improve the mental state of patients with neuralgia after spinal cord injury and relieve their anxiety and depression. It is worth popularizing and applying.

REHABILITATION PROGRAM IMPROVES QUALITY OF LIFE IN FIBROMYALGIA PATIENTS UP TO ONE YEAR: PRELIMINARY RESULTS
H. Jacobs¹, B. Grillet², D. De Bacquer³
¹Maria Middelares Ghent, Physical Medicine and Rehabilitation, Assenede, Belgium
²Reumazorg Zuid West Nederland, Rheumatology, Terneuzen, The Netherlands
³Ghent University, Departement of Public Health, Ghent, Belgium

Introduction/Background
Cognitive Behaviour Therapy (CBT) and Graded Activity (GA) have a beneficial effect on the Quality of life (QoL) of patients with fibromyalgia. However the question remains how long this effect will last.

Material and Method
Patients with fibromyalgia meeting the 1990 ACR classification criteria are well informed about the problem of fibromyalgia and checked on motivation before starting the program.

They were evaluated by the SF36v2 questionnaire at the beginning (T0) of an 8 week multidisciplinary (psychologist, occupational therapist and physical therapist) rehabilitation program, at the end of the 8 week program (T1), at 6 months (T2) and 1 year (T3).

Results
So far, of the 88 patients that were included, 71 were evaluated after 8 weeks, 55 after 6 months and 30 had a final evaluation after 1 year. Dropout at 1 year is 5/35 (14%).

At 8 weeks, a substantial improvement compared to baseline was noticed in all subscales of the SF-36v2. At 6 months, the effect was slightly reduced, but both Physical Component Summary score and Mental Component Summary score were still significantly improved when compared to baseline (p<0.001). At 1 year, a persistent improvement (p<0.001) in Role Limitation (physical), General Health Perception, Energy and Vitality scores was observed.

Conclusion
One year after starting the rehabilitation program with CBT and GA, QoL has consistently improved. The effect was most explicit in the domain of Role Limitations (physical), General Health, Energy and Vitality and weakest in the domain of Physical Functioning.

MUSIC INTERVENTIONS ASSOCIATED WITH PERSONAL HYGIENE CARE BASED ON THE GOOD PRACTICES OF NURSING AIDES IN LONG-TERM CARE FACILITIES : A CONTROLLED, RANDOMISED STUDY

A. Loko¹, S. Guétin², E. Coudeyre³, J. Belmin¹
¹Université Pierre & Marie-Curie Paris 6 Sorbonne, Neurology, Paris, France
²University Paris 5 - René Descartes - France, Clinical Psychology and Psychopathology Laboratory EA4056, Paris, France
³Clermont-Ferrand University Hospital- France, Physical Medicine and Rehabilitation Service, Clermont-Ferrand, France

Introduction/Background

Objective: to compare changes to pain levels experienced during personal hygiene care in long-term care facilities associated with:

- a validated MUSIC CARE® music intervention using the "U" sequence;
- a period of listening to the radio,
- “music-free” conditions.

The secondary objectives concerned its impact on refusal, aggressiveness, satisfaction and the duration of hygiene care.

Material and Method

This was a controlled, “cross-over” randomised study that included institutionalised patients who did not present with any auditory deficiency and agreed to sign a consent form. The principal endpoint was a Visual Analogue Scale (VAS) completed by the patient after each session of hygiene care. Secondary endpoints concerned refusal, aggressiveness and the duration of care, which were recorded by the care team. Paired tests on the sessions were compared between the use of "MUSIC CARE®" and other interventions: “radio” and “music-free”.

Results

Our sample comprised 21 patients with a mean age of 86.6 years. The pathologies diagnosed included dementia (mild to moderate) in 57% of cases and Parkinson’s disease in 19% of patients. Significant differences in the reduction of pain, refusal, aggressiveness and the duration of care were observed between the three interventions, in favour of the MUSIC CARE® intervention (p<0.01). A significant difference was also observed with respect to patient satisfaction.
Conclusion

Within the limitations of this study, MUSIC CARE® mainly enabled a significant reduction in the pain related to hygiene care when compared with “music-free” or “radio” care conditions. It also caused a reduction in refusals of care, violence and aggressiveness. Furthermore, a significant difference was observed concerning the duration of care, reducing the time required by 30% thanks to the use of MUSIC CARE® versus listening to the radio. MUSIC CARE® is perfectly adapted to the principal activities of nursing aides.

AN INNOVATIVE DIGITAL MUSIC THERAPY APPLICATION (MUSIC CARE APP) USED IN THE MANAGEMENT OF CHRONIC PAIN

S. Guétin¹, E. Coudeyre², J. Touchon³

¹University Paris 5 - René Descartes - France, Clinical Psychology and Psychopathology Laboratory EA4056, Paris, France
²Clermont-Ferrand University Hospital - France, Clermont-Ferrand, France
³CHU Montpellier, Neurology, Montpellier, France

Introduction/Background

The principal objective of this paper is to report on research work that has enabled the standardisation and evaluation of a new music therapy technique ("U" sequence) used by the Physical Medicine and Rehabilitation Service (1).

Material and Method

Following a complete review of the literature on the subject, a series of controlled and randomised studies were carried out in Physical Medicine and Rehabilitation, Neurology, Geriatric Medicine, Rheumatology and Anaesthesia-Intensive Care departments and in the Chronic Pain Treatment Centre.

Results

The effect of listening to music ("U" sequence) was evaluated in the context of different types of acute and chronic disorders of different origins: mechanical, inflammatory, fibromyalgic and neurological. Actions of a psychological and physiological nature (on haemodynamic and respiratory parameters, etc.) were thus demonstrated in favour of a “listening” relationship between caregivers and patients. These actions resulted in lower levels of pain, anxiety and depression, which enabled a significant reduction in the consumption of anxiolytics and antidepressants.

Conclusion

A review of the international literature and initial controlled and randomised studies testified to the value of using musical interventions for therapeutic purposes ("U" sequence) when managing pain that was chronic or related to care procedures (2).

THE EFFECTS OF TRANSCRANIAL DIRECT CURRENT STIMULATION COMBINED WITH AEROBIC EXERCISE ON PRESSURE PAIN THRESHOLDS AND ELECTROENCEPHALOGRAPHY IN HEALTHY CONTROL: PILOT STUDY

G. Sato 1,2, M. Osumi 1, S. Nobusako 1, S. Morioka 1

1Kio University, Neuro Rehabilitation Research Center, Kitakatsuragi-gun, Japan
2Nara Prefecture General Rehabilitation Center, Department of Rehabilitation, Shiki-gun, Japan

Introduction/Background

Transcranial direct current stimulation (tDCS) has an analgesic effect and increases the peak alpha frequency (PAF) on electroencephalography. The analgesic effect of tDCS also appears to be greater when combined with another intervention (e.g. motor imagery), compared to tDCS alone. Aerobic exercise (AE) itself was reportedly effective for decreasing pain sensitivity. Therefore, we hypothesize that tDCS/AE would exert a larger analgesic effect than tDCS alone, or sham tDCS/AE.

Material and Method

Ten healthy adults participated in this study under three conditions: tDCS, tDCS/AE, or sham tDCS/AE. All conditions were performed over a single session. For tDCS, the anode was placed just above the left primary motor cortex and the stimulation intensity was 2 mA for 20 min. AE was carried out using an ergometer at an intensity of 50%~60% for 20 min. We used a measure of pressure pain threshold (PPT) on the right middle finger to investigate the effects of interventions. PPT was measured at pre-intervention and at every 5 min and post-15 min. We recorded resting-state electroencephalography for 3 min, both before and after the intervention. PAF was defined as the frequency with the highest mean power within the alpha band. Statistical analyses included the Friedman and Wilcoxon signed rank tests, Bonferroni correction, and the level of statistical significance was set at 5%. This study was approved by our institution’s ethics committee.

Results

Significant differences were found in PPT among the three conditions at all time points. On post-hoc testing, PPT increases during tDCS/AE were earlier and higher magnitude than other two conditions. No significant differences were found in PAF.

Conclusion

The combined intervention of tDCS/AE exerted analgesic effects that manifested earlier, and at a higher magnitude, than those produced during the other two conditions. However, PAF did not significantly vary among the three conditions.

DEVELOPMENT AND EVALUATION OF A COMMUNICATION SKILLS TRAINING FOR NURSES IN INPATIENT REHABILITATION
S. Dibbelt¹, E. Wulfert², B. Greitemann³
¹Institute for Rehabilitation Research Norderney, Bad Rothenfelde, Bad Rothenfelde, Germany
²Institute for Rehabilitation Research Norderney, Clinical Center of Rehabilitation- Klinik Muensterland, Bad Rothenfelde, Germany
³Institute for Rehabilitation Research Norderney, Clinical Center of Rehabilitation- Klinik Muensterland, Bad Rothenfelde, Germany

Introduction/Background

The goal of this study was to develop a communication skills training for nurses that meets the specific needs in inpatient rehabilitation. Additionally, we evaluated the effect of the training on the quality of interaction.

Material and Method

During a two day in-house training nurses were trained in basic conversational skills as well as in dealing with challenging situations. In six participating rehabilitation centers 44 nurses and patients rated the quality of their admission interviews before and after training with the Conversation Rating Questionnaire (CRQ; Dibbelt et al., 2014). Scores of positively worded items were aggregated to an index of communication promotors and negatively worded items to an index of communication disturbers. Wilcoxon tests for dependent samples were performed to compare the means of indexes in the baseline (before training) and in the intervention group (after training). N=637 cases were included in the baseline and N=428 cases in the intervention group.

Results

The nurses’ ratings of the communication promotors in their admission interviews tend to be higher after training, whereas the ratings of communication disturbers tend to decrease. However, none of these differences were statistically significant, neither for the entire sample nor for single rehab centers.

Conclusion

Ceiling effects might be the reason why increased ratings in the intervention group did not reach statistical significance (nurses). The nurses and patients knew that their interaction would be rated afterwards. This probably improved communication behavior in the baseline. Methods to control this “checklist-effect” will be discussed.

THE QUALITY OF NURSE-PATIENT-INTERACTION AND REHABILITATION OUTCOMES: DO THEY RELATE?

S. Dibbelt1, E. Wulfert2, B. Greitemann2

1Institute for Rehabilitation Research Norderney, Bad Rothenfelde, Bad Rothenfelde, Germany
2Institute for Rehabilitation Research, Clinical Center of Rehabilitation- Klinik Muensterland, Bad Rothenfelde, Germany

Introduction/Background

Many tasks of nurses in inpatient rehabilitation are communicative in nature. This study examined the relationship between patient-nurse communication quality and rehabilitation outcomes.

Material and Method

637 patients rated the quality of their admission interviews with nurses with the Conversation Rating Questionnaire (CRQ; Dibbelt et al., 2014). Additionally, patients rated their health status before rehabilitation and 6 months after discharge. Among others they rated (1) current pain frequency and pain intensity, (2) perceived ability to cope with disease, (3) mobility and (4) general health status. The means of positively worded items in the CRQ were aggregated to an index of communication promoters, the negatively worded items to an index of communication disturbers. The patient sample was split into 2 groups by the median of the promoter index: high-raters index were above the median and low-raters median below the median. As measure of effect size (improvements mediated by rehabilitation) the mean score differences before rehab and 6 months after discharge were calculated for (1) Pain frequency and pain intensity, (2) Coping with disease, (3) Mobility and (4) General health rating. Effect sizes were compared by Mann-Whitney-U-Tests for the both groups of high and low raters.

Results

These results indicate that nurses' interaction quality has an impact on long term rehabilitation results. The role of mediators such as patient characteristics (education, health literacy) will be discussed.

Conclusion

These results indicate that nurses' interaction quality has an impact on long term rehabilitation results. The role of patient characteristics (e.g. education, health literacy) will be discussed.

ISPR8-1556
MICROCURRENT ELECTRICAL NEUROMUSCULAR STIMULATION TO IMPROVE MYOFASCIAL NECK PAIN AND STIFFNESS
J.W. Park¹, J. Kwak¹, S. Lee¹, S. Lee¹
¹Soonchunhyang University Hospital, Physical Medicine & Rehabilitation, Seoul, Republic of Korea

Introduction/Background

Myofascial pain syndrome can cause not only the pain, but also the muscle stiffness by the densification of excessive hyaluronic acid in muscle and fascia. The first aim of this study was to evaluate the therapeutic effects of microcurrent electrical neuromuscular stimulation on chronic myofascial pain syndrome of upper trapezius muscles and the second aim was to evaluate the viscoelastic change of myofascial trigger points and neighboring tissues with ultrasonoelastography using acoustic radiation force impulse (ARFI) imaging.

Material and Method

This study was designed as a prospective, randomized, double-blinded, placebo-controlled trial. The patients with chronic neck pain who visited the outpatient clinic voluntarily were included in this study. Total 40 minutes’ microcurrent electrical therapy using a Granthe Advance (8Hz, 25 μA, Cosmic Co., Seoul, Korea) or sham stimulation was applied on both upper trapezius muscles daily for 2 weeks, total 14 times. All MENS and control groups took the standard care including postural education, and self-exercise. All participants visited total 3 times; baseline, 2 weeks and 4 weeks follow-up. At every visit, we evaluated the usage of analgesics, existence of trigger points of upper trapezius, visual analogue scale (VAS), pressure pain threshold, neck range of motion (ROM), and viscoelasticity by shear wave velocity using ultrasonoelastography.

Results

There was no significant difference in baseline characteristics. MENS significantly improved pressure pain threshold on upper trapezius muscles ($p=0.001$). Also, MENS significantly reduced shear wave velocity ($p=0.001$) on upper trapezius muscles and patients rated pain
intensity ($p=0.024$). The detailed values were summarized in Table 1.

$P$ values were calculated by Friedman's test. MENS = microcurrent electrical neuromuscular stimulation, VAS = visual analogue scale, ROM = range of motion.

Conclusion

Our findings demonstrate that the microcurrent electrical neuromuscular stimulation improved pressure pain threshold, pain intensity and shear wave velocity in chronic myofascial pain syndrome on upper trapezius muscles. Therefore, MENS can be a useful treatment tool for the myofascial pain syndrome.

FNIRS A NEW TOOL FOR ASSESSMENT OF CENTRAL SENSITIZATION IN FIBROMYALGIA

Introduction/Background

Fibromyalgia (FM) is a multi-symptomatic disorder with a varying degree of widespread pain in the body. With emerging evidences pathophysiological concept shifted from peripheral damage or inflammation to central neural mechanism. Fibromyalgia is characterised by dysfunction in central pain processing, “central sensitivity”. In this cross sectional study central sensitization was recorded in patients with fibromyalgia by observing cortical oxygenation in prefrontal cortex using Functional Near Infrared Spectroscopy (fNIRS).

Material and Method

fNIRS 300B (BIOPAC), a wearable continuous fNIRS system with 4 optode and 16 detectors was used to assess changes in oxy-haemoglobin concentration (μM) from Brodmann areas 9, 10, 45 and 46. Number of activation (max and 60% max signals) was compared in time series of Oxygenated Haemoglobin level with Rt foot immersed in ice cold water. For comparison of categorical variable, sex Chi-square test was used. For non-parametric data ie age and fNIRS data Mann-Whitney U test was used. Both of the test was done in SPSS Statistics 23 by IBM, Chicago, IL with a confidence interval of 95% and a significance level lower than 5%.

Results

Fifty FM patients diagnosed according to ACR 2010 fibromyalgia criteria and equal number of age and sex matched controls were enrolled in the study. There was increased oxygenation in FM compared to control in prefrontal cortex.

Conclusion

This increased oxygenation in prefrontal cortex in FM group objectively demonstrates alteration in central activity in FM group. Changes in central activity along with pain hypersensitivity in FM points towards central sensitisation. Lack of 3D digitiser restrict us to comment on localisation of activation. fNIRS can be used as tool to evaluate central sensitization.

NEUROPATHIC PAIN IN SPINAL CORD INJURY POPULATION IN CALI, COLOMBIA

W.A. Reyes Campo¹, S.G. Pacichana Quinayáz², F.J. Bonilla Escobar¹,³, M.A. tovar sánchez⁴
¹Universidad del Valle, Medicina Fisica y Rehabilitación, Cali, Colombia
²Universidad del Valle, Escuela de Salud Pública, Cali, Colombia
³University of Pittsburgh, Clinical Research and Translational Science, Pittsburgh, USA

Introduction/Background

Neuropathic Pain (NP) following traumatic Spinal Cord Injury (SCI) is the complication that has the worst negative impact on the quality of life of people with SCI. The prevalence of NP in high-income countries is 53% and predictive factors related to its presentation have been described, such as mechanisms of SCI and others like clinical complications associated. The characteristics of NP in this population are unknown in Cali and Colombia.

Aim: To determinate differences between patients with NP following traumatic SCI and patients without NP but with traumatic SCI, in Cali, Colombia.

Material and Method

A Cross-sectional study based on clinical histories records of people suffering SCI, who attended a trauma center during 2016. Adjusted risk analyses of NP were performed using multiple logistic regressions. Risk was expressed with Odds Ratio (OR).

Results

190 patients of SCI were included, 91 (47.89%) of them had NP, age mean of 35.35±13.31 years old, mostly men (95.60%). 81.32% of the injuries were traumatic in the context of violent aggressions; follow by 14.29% car accident. The most frequent injury level was thoracic (65.93%) and ASIA (American Spinal Injury Association) classification mainly A and B (64.84%; 12.09% respectively). Clinical complications like spasticity and neurogenic bladder/bowel were presented in 49.45% and 93.41% of patients with NP. Higher probabilities of developing NP (p<0.05) were found when injury mechanism was car accident (OR=8.96; IC95%=1.51-53.40), and when there were clinical complications like neurogenic bladder/bowel (OR=6.09; IC95%=1.97-18.90). This probability decreased when injury chronicity was higher than 10 years ago (OR=0.23; IC95%=0.074-0.71).

Conclusion

Prevention and treatment strategies aimed to reduce clinical complications should be prioritized. It is necessary to continue exploring factors associated to NP in this population and complications such as bladder or neurogenic bowel, besides the injury stabilization through the time.

**Introduction/Background**

Indonesia is one of the countries with high prevalence of leprosy in the world. WHO (2013) places Indonesia on the third rank in the world after India and Brazil. Researchers found more than 50% of patients with leprosy had neuropathic pain (Ramos et al). When left unchecked, neuropathic pain can cause physical and psychological disability due to disruption of daily activities and social participation of the patient. Currently the treatment of neuropathic pain is limited to the medicamentous such antidepressant drugs (Arco 2016). The prognosis is good, but some adverse effects remain existed for long-term use. WBV is one of the therapeutic modalities which are safe, relatively cheap and effective in use, but further exploration has yet to be done (Hong, et al., 2015). A study in diabetes mellitus type II patients with peripheral neuropathy in 2011 shows the use of WBV in reducing neuropathic pain and improve walking ability.

**Material and Method**

A randomized pretest-posttest control group design study was conducted in "leprosy village Jongaya" Makassar on October to November 2017. The measurement of neuropathic pain intensity was performed before and after therapy using Neuropathic Pain Scale (NPS) and VAS. Participants (n = 16) with neuropathic pain were divided into 2 groups: Group 1; who received WBV therapy three times a week for four weeks with different frequency every week and Group 2; who received WBV therapy once a week for four weeks with the same frequency every week.

**Results**

The result shows there was a significant decrease in neuropathic pain after WBV therapy is given in both groups (p = 0.018) and 7 patients (75%) reportedly healed after had 4 weeks of therapy. Besides, there was no significant difference (p>0.05) found among two treatment groups in decreasing neuropathic pain.

**Conclusion**

Whole Body Vibration is effective for reducing neuropathic pain in leprosy patients.

A POLE OF COMPETENCE FOR EHLERS-DANLOS SYNDROMES

M. Enjalbert
Centre Bouffard-Vercelli, MPR, CERBERE, France

Introduction/Background

The Ehlers-Danlos syndromes (EDS) are a heterogeneous group of heritable connective tissue disorders characterized by joints hypermobility, skin hyperextensibility and tissue fragility. The international EDS Consortium proposes a revised EDS classification (1) and a set of clinical criteria that are suggestive for the diagnosis. In France, poles of competences were created in 2017, one of which in Perpignan Hospital. We report one year’s activity of this.

Material and Method

We use the EDS Consortium classification and clinical criteria for diagnosis, possibly supplemented by a geneticist for questionable diagnosis. The confirmed diagnosis entered into treatment protocols including rehabilitation, pain treatment, psychological and socio-professional handlings.

Results

The population includes 36 subjects (29 female, 7 male) with a median age of 36.7 years (6-73) with EDS diagnosis. 19 of them (52.8 %) were confirmed, 6 (16.6 %) refuted and 11 (30.6 %) questionable, justifying a geneticist view. Among these, 6 were confirmed, 5 refuted. Finally, 25 subjects (69.4 %) were confirmed and enter into treatment protocols, including sphincters disorders for 9 (25.0 %), 11 (30.6 %) were refuted, arising from differential diagnosis.

Conclusion

EDS have underestimated for a long time. Currently, the risk is the opposite, relating to the banality of some symptoms that can carry a diagnosis by excess, hence the importance of specific criteria (1). As to the treatment protocols, they can make use of validated drugs and technics. A work in this area (evidence based medicine) is ongoing to define these with French Health Insurance and National Authority for Health.

No conflict of interest
Introduction/Background

To assess sex-related characteristics in patients with fibromyalgia, specifically in terms of patient demographics (age, body mass index, marital status, and educational level), tender point count, symptoms (cognition, sleep disorder, fatigue, anxiety, and depression), and quality-of-life measurements.

Material and Method

We studied 668 consecutive patients (606 women) who participated in the Fibromyalgia Treatment Program at Mayo Clinic (Rochester, Minnesota) from May 2012 through November 2013. All patients completed a series of questionnaires at the initial consult, including the Patient Health Questionnaire-9 (PHQ-9), the Generalized Anxiety Disorder-7 (GAD-7), the Medical Outcomes Study Sleep Scale (MOS-Sleep Scale), the Revised Fibromyalgia Impact Questionnaire (FIQ-R), the Multidimensional Fatigue Inventory (MFI-20), the Multiple Ability Self-Report Questionnaire (MASQ), and the 36-item Short Form Health Survey (SF-36). Nonparametric Wilcoxon rank test and the χ² test for continuous variables and categorical variables were used to detect differences between sexes.

Results

We observed no significant sex-based differences in demographics, including age, marital status, and educational level. Likewise, no significant sex differences were seen in body mass index, mood, sleep, cognition, symptom impact, or fatigue. However, women had a significantly higher tender point count than men (P=.001).

Conclusion

The only sex-related difference observed in our cohort was the tender point count; the assumption of other sex-based differences in the clinical presentation of fibromyalgia was not supported in our study.

Symptom Clusters in Fibromyalgia: Correlation with Dysautonomia

Introduction/Background

Fibromyalgia (FM) is a disorder with varied symptoms characterized by chronic widespread pain. The pathophysiology of FM is enigmatic and dysautonomia, an imbalance between sympathetic and parasympathetic drive has been implicated in some studies. In this cross-sectional study, symptom cluster analysis of patients with FM and correlation with autonomic tone was studied.

Material and Method

Patients diagnosed with FM as per ACR 2010 criteria were included in the study. Visual Analogue Scale (VAS) and Depression Anxiety Stress Scale 21 (DASS 21) were observed. Dysautonomia can be observed by Heart Rate Variability (HRV). In this study, HRV was observed at rest, sympathetic stress (cold) and deep breathing using BioNomadix MP 150 (BIOPAC). Matlab R2016a was used for "k means" symptom cluster analysis of patients with FM. SPSS Statistics 23 (IBM, Chicago, IL) was used for statistical analysis. Mann-Whitney U test was done for comparing non-parametric HRV data in time domain and frequency domain. p value less than 5% was considered significant.

Results

Fifty patients with FM, 8 males and 42 females with mean age of 38.9 ± 10.5 years, participated in the study. Two sub-groups (16;34) were observed by symptom cluster analysis. No significant difference in symptoms was observed between the two sub-groups, though the difference in mean of depression, anxiety and stress was more between the two sub-groups in comparison to WPI, SSS and VAS. In FM patients, there is a variable degree of sympathetic hyperactivity with a blunted response to stress. No significant difference in HRV was observed between the two sub-groups.

Conclusion

Two symptom clusters of FM patients were identified. There was no statistically significant difference in autonomic tone between the two groups.

THE PREVALENCE OF CARPAL TUNNEL SYNDROME AMONG LONG-TERM MANUAL WHEELCHAIR USERS WITH SPINAL CORD INJURY: A CROSS-SECTIONAL STUDY

M. Asheghan¹

¹Baqiyatallah Hospital, Physical Medicine and Rehabilitation, Tehran, Iran

Introduction/Background

Use of a handrim wheelchair could force the wrist into extreme excursions and encroachment of the median nerve.

Material and Method

A cross-sectional study was conducted for one year in an outpatient clinic of spinal cord injury.

Participants: Patients had traumatic injury at the first thoracic level and below, with time since injury of at least 5 years.

The prevalence of carpal tunnel syndrome by history taking, clinical examinations and motor and sensory nerve conduction studies of median nerve performed for both hands.

Results

Participants (N = 297) were all male. Mean (SD) age and duration since injury were 48 (8.5) and 23 (6.6) years, respectively. A significant difference in median duration of injury based on the severity of the syndrome (P < 0.001), and a significant trend in time since injury for the severity (P (one tailed) < 0.001) were seen. There was a significant difference in the median age among the groups (P = 0.009), and the median increased with the severity (P (one tailed) = 0.001).

Conclusion

Carpal tunnel syndrome is a common side effect of the long time use of wheelchair, and its severity is associated with duration of wheelchair use and age. Alternative methods for wheelchair propulsion should be developed to diminish the likelihood of the syndrome.

**DRY NEEDLING UNDER ULTRASOUND GUIDANCE DECREASE NEUROPATHIC COMPONENT AND INCREASE LEVEL OF MOTION IN PATIENT WITH LOW BACK PAIN**

R. Bubnov¹, L. Kalika²

¹Clinical Hospital “Feofaniya”, Ultrasound, Kyiv, Ukraine

**Introduction/Background**

Dry needling (DN) of myofascial trigger points (MTrP) under ultrasound (US) guidance is an effective method for treatment myofascial pain, and restoring postural imbalance. Crosslinks among TrPs, movement patterns in spine, pelvis and extremity and neuropathic pain in low back pain patients have not been studied. **The aim** was to evaluate efficacy of dry needling under US guidance for neuropathic pain treatment; and resoring joints motility and muscle function in spine, pelvis and lower extremity.

**Material and Method**

We included 23 patients, 10 males and 13 females, (aged 18-55 years) with clinically diagnosed low back pain over 3 month with neuropathic component and reduced motility in spine, pelvis and lower extremity. We conducted precise physical tests and neuromuscular ultrasound using M-mode and evaluated nerves and motion in intervertebral spaces, pelvis, intrinsic foot and leg muscles. Patients received DN of MTrP under US guidance according to approach by Bubnov [PMID:23088743]. VAS (0-10) and Leeds Assessment of Neuropathic Symptoms and Signs (LANSS) scores were measured before, immediately after, 24 hours, and 7 days after intervention.

**Results**

After 7 days, VAS scores showed pain improvement from 7.6 to 2.3; LANSS scores improved from 15 to 4. US demonstrated improvement nerve structure, increasing motility, contractility (muscle contracted / rested thickness) on M-mode during functional tests and walking in all levels.

**Conclusion**

Our preliminary data demonstrated that DN under US guidance effectively reduce myofascial pain, ameliorate symptoms of neuropathy and local hypomotility. Further research needed for development US patterns and study causation in chain spasticity-contractility-motio-neuropathic pain.

Osteoporosis is a serious health problem. Disease characterized by high morbidity, mortality and socio-economic costs. It is a disease characterized by a reduction in bone density. Bones become porous, crutches therefore, they are subject to fractures, which occur spontaneously or with a force less than needed to break the healthy bone.

Material and Method

The data from the healthy cartons and protocols for the physical medicine and rehabilitation of the Health Center Nis were analyzed after the screening of the examination of patients of both sexes and different years for four weeks (28 days), in October 2017, on the Sonost 3000 Desintometer.

Results

A total of 212 patients were examined (between 50 and 70 years old), 114 of them (53,77%) are women and 98 of them(46,23%) are men. The normal finding of T-score 0-1 had 110 (51.89%) patients, 51 of them are women and 59 are men. Osteopenia and T-score -1-2.5 had a total of 64 (30.19%), of which 33 are women and 31 are men. Osteoporosis T-score > -2.5 was diagnosed in 38 (17,92%) individuals, in 30 of the female population and 8 of the male population.

Conclusion

To prevent the occurrence of osteoporosis and to slow down its osteoporosis, proper nutrition is needed. This provides a recommended daily intake of calcium and vitamin D and adequate physical activity according to age and healthcare possibilities of patients. Certainly, for younger patients sport activity is recommended and for older generations long walks in the nature. It is necessary to remove harmful habits (consumption of cigarettes and alcohol) and timely measurement of bone density of people at risk. Ultrasound osteodesintometry is a fast, economical method without radiation. Measurement is done on the heel bone and this measurement can be used as a screening method in the prevention of osteoporosis.

NERVE STIMULATION WITH A MINIATURE, WIRELESS STIMULATOR IN CHRONIC PERIPHERAL NEUROPATHIC PAIN
N. Khakpour¹
¹Physical medicine and rehabilitation, Isfahan University of Medical Sciences, Esfahan, Iran

Introduction/Background

Peripheral nerve stimulation (PNS) belongs to the least invasive neuromodulative procedures approved for the treatment of neuropathic pain. PNS requires surgical exposure of the target nerve or percutaneous implantation of a cylindrical electrode in the vicinity of the stimulated nerve. Stimulation of peripheral nerves produces paresthesia in the area innervated by this nerve and induces analgesic effect in several mechanisms: peripheral, spinal segmental and central. The aim of this review was to assess the effectiveness Peripheral nerve stimulation in Greater occipital nerve block in chronic migraine, Popliteal Nerve Block. Percutaneous Tibial Nerve Stimulation for the Treatment of Overactive Bladder

Material and Method

Neuromodulation is the process by which nervous activity is regulated by way of controlling the physiological levels of several classes of neurotransmitters. Neurostimulation devices involve the application of electrodes to the brain, the spinal cord or peripheral nerves.

Results

This has been proven a safe and effective therapeutic approach for managing chronic pain of the arms and legs, neck and back often after spine surgery, or for other neuropathic conditions. (PNS) Clears Stimwave Peripheral Nerve Stimulator (PNS) System for the relief of severe intractable chronic pain of peripheral origin

Conclusion

Occipital nerve stimulation (ONS) is a form of neuromodulation therapy neurostimulation for headache includes occipital nerve stimulation, supraorbital nerve stimulation, and infraorbital nerve stimulation. One prevalent theory is the involvement of the trigeminocervical system, which is the anatomic overlap of the trigeminal and occipital afferent systems at the level of C2 in the spinal cord. Trigeminal afferent pathways, and thus primary headache disorders, can be modulated at the C2 level by occipitally mediated afferents. The theory of neurologic stimulation therapy is that stimulation of the nerves can stimulate pelvic muscle contractions or detrusor contractions. It is thought to interrupt abnormal reflex arcs that may affect bladder dysfunction

ASSESSING THE IMPACT OF PATIENT UNDERSTANDING ON PAIN PERCEPTION SCORING IN A COHORT OF PATIENTS ATTENDING A CHRONIC PAIN CLINIC

S. Javaid1
1ABM University Local Health Board, Rehabilitation Medicine, Port Talbot, United Kingdom

Introduction/Background

Nearly 1 in 5 people report periods of moderate to severe chronic pain. The physical, psychological, social and economic impacts on the individual and society are enormous. Given these facts, it is a pressing issue which requires investment, research and attention.

As part of the Swansea University Medical School’s curriculum, students decided to develop a resource that would convey some of the complexities of neuroscience and nociception and the current medical and surgical therapies.

Material and Method

In October 2015, questionnaires were handed out to all patients who attended the clinic over a period of two months. The aim of the questionnaire was to obtain from the patient cohort an understanding of:

- Beliefs surrounding pain, specifically: where pain originates from, how mood affects pain and the difference between acute and chronic pain
- Whether a resource that gave them more information about pain and its perception would be useful
- What treatment modalities they wanted more information on

Results

100 questionnaires were distributed, with 25 returned completed by December 2015. Of these, 72% said they wanted to know more about how pain is produced by the body. 56% selected a booklet, which informed the choice of format for the patient resource. Accompanying the booklet was a questionnaire asking for feedback on the resource. Patients could return this by post to the clinic, or they were given the option of an online version of the feedback form to encourage participation in the process.

Conclusion

This resource has now been distributed to patients and we are awaiting feedback.

\textsuperscript{3}University Hospital “Maggiore della Carità”, Physical Medicine and Rehabilitation Unit, Novara, Italy

Introduction/Background

Pain is a harmful symptom, strongly influencing HRQoL and rehabilitative treatment and often refractory to pharmacological and non-pharmacological therapeutic strategies. In recent years, Percutaneous Electrical Nerve Stimulation (PENS) has been proved to be an effective procedure in the management of refractory neuropathic pain and some conditions of refractory mixed pain like low back pain. However, up to date, evidences in literature about the effectiveness of PENS in terms of pain reduction and HRQoL improvement in the rehabilitation field are scarce. Therefore, aim of our study was to evaluate safety and effectiveness of PENS on short-term pain reduction in patients suffering from neuropathic or mixed pain, non-responders to conventional therapies in a rehabilitative setting.

Material and Method

This retrospective study was performed on a cohort of 75 adults (25 men and 50 women), mean aged 70.05±14.16 years, suffering from neuropathic or mixed pain non responsive for more than 3 months to both pharmacological and non-pharmacological therapies. From 2014 to 2017, patients were treated by subcutaneous needle-electrode insertion in the sore area and return-on-skin electrode placement, both connected to a generator (AS SUPER 4 digital by TÜV Rheinland) for a 40-minute session at alternate frequencies of 2 and 100 Hz. Pain was assessed by Numerical Rating Scale (NRS) before and immediately after the treatment.

Results

Five patients experienced self-limiting and short-term pain mainly due to subcutaneous needle placement. No complication affected the continuation of the procedure. There was a significant reduction in NRS (defined as >50%) after treatment in 70% of patients.

Conclusion

PENS has been proven to be a safe and effective procedure in the treatment of neuropathic and mixed pain in patients non-responders to both pharmacological and non-pharmacological
treatments. Its use in Physical and Rehabilitative Medicine should be encouraged and supported by other studies.

STATE ANXIETY IS INDEPENDENTLY ASSOCIATED WITH VISUAL ANALOG SCALE PAIN RATING IN WOMEN WITH FIBROMYALGIA

H. Rogers¹, S. Cardosa², S. Olivera Plaza³, A. Córdoba Patiño³, M. Peña Altamar⁴

¹BioCruces Health Research Institute, Psychology and Health, Barkaldo, Spain
²University of Oporto, Psychology, Oporto, Portugal
³Surcolombian University, Psychology, Neiva, Colombia
⁴Saludcoop Clinic, Rheumatology, Neiva, Colombia

Introduction/Background

The relationship between psychosocial factors and pain may not be the same across social-cultural contexts. The aim of this study was to examine associations among psychosocial factors and pain perception in women with Fibromyalgia (FM) from Colombia.

Material and Method

96 women with FM were recruited from an ambulatory clinic in Neiva, Colombia. They had an average age of 54 and 87.5% were from the lowest socio-economic strata (SES) in the country. Visual Analog Scale (VAS) pain rating was administered, with the State-Trait Anxiety Inventory (STAI) to measure transient anxiety; Symptom Checklist 90 Revised (SCL-90R) to measure psychopathology; and the Brief COPE to measure coping with stress.

Results

Spearman correlations indicated that increased VAS pain scores were positively associated with years of diagnosis (rho=0.21, p=0.040), STAI-S (rho=0.21, p=0.043), SCL-90R global severity index (rho=0.21, p=0.037), SCL-90R positive symptom distress index (rho=0.26, p=0.012), SCL-90R somatization (rho=0.28, p=0.006), and SCL-90R depression (rho=0.26, p=0.009). Higher VAS scores were associated with more active coping (rho=0.23, p=0.024), positive reframing (rho=0.21, p=0.040), self-distraction (rho=0.21, p=0.040), acceptance (rho=0.25, p=0.014), and religiosity (rho=0.27, p=0.008). The multi-variable linear regression model showed that STAI-S was the only independent factor associated with VAS rating (Beta=0.31, p=0.012).

Conclusion

Transient emotions are more highly associated with pain perception in women with FM than more stable psychosocial factors. It is possible that those women with more state anxiety experienced more pain, or that the experience of more pain caused more anxiety. Further research is warranted, especially with under-studied populations like those with low SES.

Introduction/Background

Chronic postoperative inguinal pain (CPIP) is one of the major complications in patients with inguinal hernia repair. The quality of life in the patients with CPIP is very low due to inguinal pain. We report the treatment of CPIP after inguinal hernia repair using combined ultrasound and nerve stimulator technique for injection of genitofemoral nerve (GFN).

Material and Method

A 59-year-old man was diagnosed with left inguinal hernia and perfumed Laparoscopic hernia repair - Totally extraperitoneal on February 20, 2017. The patient developed pain from the left inguinal area to the scrotum form the beginning of March, and then underwent conservative treatment (3 cycles of ilioinguinal nerve and 1 time of GFN block with ultrasound and medication) was performed but the pain persisted. But he suffered a sustained inguinal pain. Therefore, we used nerve stimulator to increase the accuracy of the neural approach. When stimulated with nerve stimulator, scrotum contraction and stimulus of the GFN distribution were confirmed by nerve stimulator after the approach of GFN with ultrasound.

Results

This procedure yielded symptom relief. In a follow-up of five-month, he was very satisfied with the treatment because he didn’t have any pain and medication. Ultrasound nerve blocks are commonly performed, but the results may not be satisfactory.

Conclusion

Nerve stimulator allows for selective nerve block and greatly enhances the technical ability to perform precise localization and injection. The use of combined ultrasound and nerve stimulator injection technique are an effective and non-invasive approach to treat CPIP.

CHRONIC NECK PAIN AND ITS RELATIONSHIP WITH STRESS SYMPTOMS: REGULAR PHYSICAL EXERCISE COULD BE A PROTECTIVE FACTOR?

G. Camacho¹, T. Nakazato¹
¹Cedomuh, Lima, Lima, Peru

Introduction/Background

Mental stress is usually associated with neck pain. Physical exercise is typically recommended to deal with stress and therefore, to relieve neck pain. We studied the relationship of these common variables.

Material and Method

A national cross-sectional interview survey was carried out to the adult Peruvian population with a probabilistic sample on November 2016, through the market research institute GfK. Chronic neck pain was considered for those who referred pain in the neck, the nape and/or the upper shoulders at least once a week on average for the last 6 months. Mental stress was determined asking for eight common symptoms (headache/migraine, stomachache/heartburn, feeling tired, difficulty to sleep, irritability, nervousness, dizziness, and hands tremor – all without any reason or disease), and considered positive for those with 5 or more. Regular physical exercise was determined for those who responded making any sports activity two or more days a week on average, and the lack of it for those making it once a week or none. Odds ratio was calculated using multivariate simple logistic regression with IBM SPSS 20.

Results

A total of 1244 responded the survey. The OR between mental stress and chronic neck pain was 7.096, p>0.000, adjusted for age, sex, socioeconomic status. The OR between the lack of regular physical exercise and neck pain was 0.978, p>0.377. See Table.

</table>
Conclusion

The study confirms the usual belief about the strong association between chronic neck pain and mental stress but does not with the lack of regular physical exercise. We ought to consider the management of mental stress in the treatment of cervicalgia, but we should not recommend any sports activity to relieve it. Future studies may determine if specific exercises, such as aerobics or stretching, would be a protective factor.

LOOKING AT THE SMARTPHONE SCREEN FOR A PROLONGED TIME IS ASSOCIATED WITH CHRONIC NECK PAIN, SPECIALLY IN YOUNG ADULTS

G. Camacho 1, T. Nakazato 1
1Cedomuh, Lima, Lima, Peru

Introduction/Background

Never has a technology been so universally accepted as the smartphone. Of concern is the potential consequences of its prolonged use. Studies have conflicive results to find an association between them and musculoskeletal disorders. Looking at the small screen of these devices would be a crucial factor for bad neck posture, and therefore we studied if that would be related to chronic neck pain.

Material and Method

A national cross-sectional interview survey was carried out to the adult Peruvian population with a probabilistic sample on February 2017, through the market research institute GfK. Chronic neck pain was considered for those who referred pain in the neck, the nape and/or the upper shoulders at least once a week on average for the last 6 months. Prolonged look at the smartphone’s screen was defined for those who responded reading e-mails and news, watching photos or videos, or interacting with social networks for two or more hours a day on average. Odds ratios were calculated using multivariate simple logistic regression with IBM SPSS 20.

Results

A total of 1246 responded to the survey. The OR between chronic neck pain and prolonged look at the smartphone screen was 1.604, p>0.01, and in the 18-24 yrs-old group was 3.078, p>0.002. These results were adjusted for gender, socioeconomic status, mental stress and prolonged use of other computer devices (PC, laptop, tablet). See Table.
**Conclusion**

We found an association between prolonged looking at the smartphone screen and chronic neck pain in the general population, being three times higher in young adults. The use of smartphones is not harmful per se, but it seems that the bad posture using them would be the critical factor. We recommend preventive health campaigns about proper posture when using these devices.

A LITERATURE REVIEW OF COMPLEMENTARY THERAPIES OF PHANTOM LIMB PAIN

J. Cui
Shanghai University of Traditional Chinese Medicine, School of Rehabilitation Science, Shanghai, China

Introduction/Background

Phantom Limb Pain (PLP) is a painful or unpleasant sensation in the distribution of the lost body part. The incidence of PLP after amputation is about 60-70%. This review is to summarize the main findings from research on the complimentary therapies of PLP.

Material and Method

Articles on PLP published in English between 1983 to 2016 were identified through a PUBMED search. Relevant clinical studies and review articles were found using the keyword-search strategy of (Phantom Limb Pain OR PLP OR Phantom Pain OR Phantom Limb) AND Complimentary Therapy. The reference lists of identified articles were checked for any additional studies that might have been missed in the original PUBMED search.

Results

The complimentary therapies of PLP has been well documented in the forms of case study, case series, Randomized Controlled Trials (RCT), and reviews. The types of complimentary therapies found from the articles include Mirror Therapy, Acupuncture, Mind-body Intervention, modalities, and others such as reflexology treatment and combination exercises, could be effective to reduce PLP in different levels and courses.

Conclusion

PLP is a complicated disease which is difficult to treat since its cause and mechanism are not so clear presently. Complimentary therapies are generally easy, less cost, effective in reducing pain and almost no adverse effects; however, the long-term effect after treatment still needs to be followed up. Thus, well-designed, long-term, controlled clinical trials evaluating the comparative efficacy of complimentary therapies for PLP are need in the future study.

INTEREST OF BOTULINUM TOXIN IN THE MANAGEMENT OF THE SPASTIC UPPER LIMB
OF CHILDREN WITH CEREBRAL PALSY (CP): ABOUT 24 CASES
Z. Talem¹
¹Faculte D Oran, De Medecine Oran, Oran, Algeria

Introduction/Background

Evaluate the efficacy of botulinum toxin in the treatment of spastic upper limbs in paralyzed cerebral patients with residual motor skills for hand use

Material and Method

Patients were followed between May 2015 and May 2017 before and after injection of botulinum toxin for upper extremity hypertonia secondary to a central neurological lesion. All had motor activity on the extensor muscles of the wrist and fingers.

Deficiencies (range of motion, spasticity), pain, prehension and satisfaction of parents of patients were analyzed. Two to three custom goals were predefined. Injections were performed after spotting

by a neurostimulator for the purpose of functional improvement

Results

24 patients were included. The pain decreased by 3.4 points on an analog scale. Spasticity was reduced by one point on the Ashworth score. The grip was improved and the improvement focused on bimanual functions

Seventy-five percent of the functional objectives were achieved. Optimal efficacy required repeated injections with modified targets and doses

Conclusion

Effective on deficiencies, botulinum toxin also improves pain and grip, even if the injured hand remains an extra hand. The importance of antagonistic motricity is critical to functional outcomes, and assessment should include two-hand tasks. It is essential to inject the intrinsic muscles in addition to the extrinsic muscles and to use a neurostimulator for the muscles of the forearm. Comparative studies with surgery are needed to clarify the place of this treatment

ULTRASOUND-GUIDED CERVICAL MEDIAL BRANCH BLOCK
N. Khakpour¹, A. Moghtaderi²
¹Postdoctoral researcher Of Medical Biotechnology, Medical Sciences Isfahan Iran, Esfahan, Iran
²Md. Fellowship Of Interventional Pain Management- Physical Medicine And Rehabilitation Specialist, University Of Medical Isfahan, Isfahan, Iran

Introduction/Background

Cervical medial branch blocks (CMBBs) and third occipital nerve blocks (TONBs) are commonly used in the diagnosis and treatment of chronic neck pain and headaches.

Material and Method

Patients are placed in the lateral decubitus position with the head supported in a neutral position. An L14-5 MHz linear array probe and a 2.5 inch, 22- or 25-gauge block needle are commonly employed.

TON, C3, C4 medial branch. The neck is first scanned in the coronal plane along the posterior edge of the AP in order to identify the drop-off at the C2-C3 level. Further confirmation is sought by imaging the vertebral artery (cephalad and anterior). The probe is then rotated to a transverse plane, and the C2-C3 zygopophyseal joint identified, for the third occipital nerve block. From this point,

C5, C6 medial branch. C5, C6 medial branch. The base of the neck is scanned in the transverse plane and the TP of T1 identified. As the probe is moved cephalad from this point, the TP of C7 is localized, followed by the targets on the AP of C6 and C5

Needle placement after target level has been identified. Once the target has been identified in the transverse plane, pressure on the probe is reduced and the color doppler mode engaged to detect potential blood vessels in the needle path A posterolateral in-plane approach is used.

Results

The diagnostic cervical branch block for neck pain due to cervical facet joint pain has been traditionally done under fluoroscopic guidance. Its diagnostic value and technique have been well established.

Conclusion
A medial branch block is an effective form of pain management that reduces pain by disrupting damaged nerves in facet joints from transmitting signals to the brain.

THE CURING PROBLEM OF THE ISCHEMIA OF THE LOWER EXTREMITIES IN THE INOPERABLE PATIENTS THE IMPORTANCE OF THE PHYSICAL THERAPY IN CURING OF PREISCHEMIC STATES

D. Rondovic

Introduction/Background

The appearance of ulceronecrotic changes presents the final progression stage of the artery obstruction process and of the development of the tissue ischemia.

Material and Method

131 patients with PAOD were cured and evaluated from 01.01.2017 till 31.12.2017. (56 patients with IIa stage, 43 with IIb stage, 15 with III stage and 17 with IV stage of artery insufficiency).

Balneophysical therapy complex was being applied during the treatment: thermomineral water of the indifferent temperature in IIa and IIb stages, vacusac, vasculator, electro and kinetic therapy (except in extensive ulcerations), magnet and laser therapy.

The patients with III and IV stages of ischemia were treated with HBOT

Evaluation of the results was supervised by duplex scanning, by Doppler sonographically and by claudicational interval.

Results

By applying balneophysical treatment in the period of 21 days and by the repeated treatment, by result objectivization Doppler sonographically and by CI, in patients with IIa stage, CI was extended for more than 50% in 85% of patients, and Doppler indexes were increased for more than 0,15 in 37% of patients.

In patients with IIb stage, CI was extended for more than 50% in 60% of patients, and Doppler indexes were increased for more than 0,15 in 25% of patients.

In patients with III stage of ischemia after applying HBOT, CI was extended for more than 50% in 35% of the patients. There wasn't significant change of Doppler index.
In patients with IV stage after applying HBOT, in 5 patients with minor ulcerations healing up of ulcerous changes was achieved, in 6 patients demarcation line was created, and 6 patients were addressed to amputation.

**Conclusion**

The quality of collateral flow and its well-timed development in preischemic stages has the significant influence on improving of artery perfusion, on enabling of the adequate cellular oxygenation and on preventing from artery insufficiency progression

CRPS AND EATING DISORDERS - IS THERE A JOINT ETIOLOGY OR IS IT A UNIQUE CASE REPORT?
A. Book¹, O. Barzel¹
¹Sheba Medical Center, Orthopedic Rehabilitation Ward, Ramat-Gan, Israel

Introduction/Background

Eating disorders (ED) risk factors include psychological factors, but when addressing Chronic Regional Pain Syndrome (CRPS) the psychological risk factors are only marginal. Even though psychological factors might not be as important in the initial development of CRPS as neurogenic inflammation or sympathetic nervous system function, it seems that they have a role in the maintenance and aggravation of both diagnoses.

Material and Method

In this case report, we review the case of a woman who was diagnosed with CRPS type II and ED. As far as the literature review we conducted, we didn’t find any documentation to comorbidity of CRPS and ED.

Results

Ms. R., a 43 year old woman, married, and mother of two grown girls, was diagnosed with CRPS type II and AN. Ms. R.’s initial injury occurred when a plate fell on her leg. The injury was at the lateral aspect of her foot. She described her pain at this initial phase as very severe and started limping. She was referred to neuroectomy surgery of her sural nerve. By the time her stitches were removed she started reporting severe pain and started walking with crutches. Not long after this, she was diagnosed with CRPS type II. From the intake at the Orthopedic Rehabilitation Clinic we learned that she also has an ED approximately the same amount of time.

Conclusion

Even though we didn’t find any documentation of comorbidity of CRPS and ED, both diagnoses share alexithymia as a characteristic. Alexithymia is a set if characteristics that include difficulties identifying feelings, differentiating between them, and differentiating between them and bodily sensations, difficulties communicating feelings, lack of fantasy, and a cognitive style focused on the external environment. Understanding those two diagnoses in the context of alexithymia may throw light on the treatment of those diagnoses as separate as well as conjoint.

ISPR8-0326
COULD THE COMPLEX REGIONAL PAIN SYNDROME (SUDECK ATROPHY), EMERGED AS A DISTAL RADIUS AT THE TYPICAL SITE FRACTURE COMPLICATION, BE PREVENTED BY PHYSICAL THERAPY?

D. Petrovic¹, M. Zlatkovic-Svenda², B. Lazovic³
¹Physical medicine and rehabilitation specialist, The Belgrade City Institute of Gerontology/ rehabilitation, Belgrade, Serbia
²Institute of Rheumatology, University of Belgrade School of Medicine, Belgrade, Serbia
³University Clinical Hospital Center "Zemun", University of Belgrade School of Medicine, Belgrade, Serbia

Introduction/Background

the complex regional pain syndrome (CRPS)-Sudeck disease is a frequent complication of a distal radius at the typical site fracture (DRF). Aim of the study was to evaluate the conventional physical agents application alone and combined with light therapy for treatment of distal radius at the typical site fracture and to follow-up patients for the CRPS occurrence in a six months period.

Material and Method

Study comprised 52 female patients with DRF, involved after removing of the plaster and divided into two age-matched groups. Besides identical drug therapy, Group1 was treated with cryotherapy, exercises and Group2 with cryotherapy, exercises and the bioptron (polarized, polychromatic, non-coherent low energy radiation) light on the wrist and dorsal side of the hand. Patients were evaluated at 0, 7 and 15 days for pain (visual numerical rating scale-VAS), range of the wrist motion-supination and pronation, and the hand fist forming capacity and followed up for 6 months. Results were analysed by computer statistic programme SPSS 20.0.

Results

Pain was significantly decreased in Group2 at 15th day of therapy. Significant improvement in supination was shown for Group2 on 7th (p=0.019) and 15th day of treatment (p=0.001) (Table 1). Both groups have shown significant improvement in VAS, supination and pronation on 15th day of therapy, as compared to baseline (p=0.000). The complete hand fist forming capacity was achieved in 16 (61.5%) patients in Group1 and 19 (73.1%) in Group2. In a 6 months period of follow-up, CRPS was developed in 4 patients (15.4%) from Group1.

Conclusion

bioptron light therapy combined with conventional therapy has shown good pain control, significant degree of pain reduction and improvement of the wrist motion range, with no CRPS development within the 6 months period of follow-up. Further studies would be beneficial.

INTERSTITIAL CYSTITIS AND DORSO-LUMBAR SYNDROME: A CASE REPORT
F. Brunet1, F. Grandjean1, M. Le Ralle1, C. powels1, Y. coulomb1, S. Fardjad1, N. Bayle1
1Hopitaux universitaires Henri Mondor, fédération de rééducation neurolocomotrice, creteil, France

Introduction/Background
The clinical symptoms of a woman’s cystitis without bacteriuria are a common motive for visits to physicians. A negative clinical exam and urological work up may point to a syndrome of the thoracolumbar junction, with pseudo-visceral projected pain, characterized by quick and easy treatment.

A syndrome of the thoracolumbar junction may indeed be revealed by projected pseudo-visceral pain, in particular urogenital, potentially misleading the diagnostic process.

Material and Method
A 40 year-old woman, came to the clinic 11 days after the onset of pollakiuria, both night (every 2 hours) and day (every hour) with urgencies and urinary burns associated with left lumbar pain. The uro-gynecological examination was normal. The bacterial urinary examination was negative, and abdominopelvic ultrasonography was normal.

Results
Considering the combination on the left side of both a posterior lumbar mechanical pain and an anterior inguinal pain, a thoracolumbar spine examination was performed. Spine lexibility was normal, palpation of the posterior inter-apophyseal joint D12-L1 on the left was painless. The pinch-roll maneuver was negative. The diagnosis of a minor intervertebral disturbance of the thoracolumbar junction was considered. A spinal manipulation was performed the same day. Complete disappearance of urological symptomatology occured within 3 days.

Conclusion
The existence of a pseudo-visceral pain projected from a dorso-lumbar syndrom (minor intervertebral disturbance) is a diagnosis to keep in mind when confronted with a urogenital pain syndrome in the absence of obvious local organic disorder. These pains are attributed to an irritation of the nerves arising from the dorsolumbar junction (sensory branches of the lumbosacral, iliopubic and lateral gluteal skin territories). Simple treatment (manipulation of the dorso-lumbar hinge) may clear symptoms quickly.

Keywords
thoracolumbar junction; cystitis; minor intervertebral disturbance

PERIPHERAL NERVE BLOCK (BNP) IN REHABILITATION OF COMPLEX REGIONAL PAIN SYNDROME (CRPS): ABOUT 116 CASES

Nerve block or peripheral catheterization is a technique of choice in the treatment of intense pain, with an undeniable benefit in terms of the quality of analgesia and patient comfort. It is a technique recommended by the experts of the SFETD (Société Française d’Evaluation et de Traitement de la Douleur) and SFAR (Société Française d’Anesthésie et Réanimation), for the treatment of Complex Regional Pain Syndromes, for facilitate functional rehabilitation in case of resistance to well-managed systemic treatments. This type of therapy can be a source of complications, during the application, related to the use for several days or to the products used. It is therefore necessary to rely on a human organization, trained in this technique. From a maximum of 10 days at the beginning of our experience at St Helier Pole (PSH, RENNES) in 2007, this duration now averages one month.

Material and Method

Here we present the results of a retrospective study of 116 patients managed at St Helier Pole in 10 years.

Results

We noted in 75% of the cases, an improvement in terms of joint mobility and functional gain. More than one third of patients returned to work after a long period of absence.

Conclusion

Well-conducted prospective studies are needed to properly position BNP in the CRPS therapeutic strategy.

Keywords

No conflict of interest
Introduction/Background

Plantar fasciitis is the main cause of foot pain in adults. The pain is worst when taking first steps after a period of rest. The aim of this study is to evaluate the changes of heel pain during and after high intensity laser therapy (HILT) for plantar fasciitis.

Material and Method

Patients who were diagnosed with unilateral plantar fasciitis were included. Patients were asked to evaluate heel pain using numerical pain rating scale (NPRS) before every procedure and one month after treatment course. Pressure algometry was performed on both affected and healthy feet before treatment, right after it and one month later. The patients underwent the BTL-6000 High Intensity Laser (mode=continuous, power=7W, dose=120J/cm2, total time=7min. 8sec.) procedures 3 times per week (total of 8 procedures).

Results

There were 57 subjects (mean age 54.07±10.83 years) who participated in this study. 36 of the subjects were reevaluated after one month. The treatment was started on average 5.053±0.52 months after the pain started. According to NPRS, the pain of the first step in the morning decreased from 7.28±0.34 before treatment to 3.04±0.32 before the last procedure and kept decreasing to 1.45±0.25 after 1 month (p<0.005). According to NPRS, the pain of the first step after prolonged sitting decreased from 6.67±0.3 before treatment to 3.00±0.28 before the last procedure and kept decreasing to 1.9±0.3 after 1 month (p<0.005). The pain of the first step in the morning decreased by 1.58±0.39 (p=0.005) and the pain of the first step after prolonged sitting decreased by 1.23±0.33 (p=0.01) before 4th procedure. Mean pressure algometry value (kg) difference between feet were 3.63±3.38 before, 2.42±2.23 after and 1.15±2.19 one month after treatment (p<0.035).

Conclusion

HILT effectively reduces plantar heel pain. Clinically important and statistically significant pain reduction (NPRS improved >15% or 1 point) was achieved before 4th procedure.

THE POSSIBILITY OF USING BIOFEEDBACK TRAINING OF ELECTROMYOGRAM IN THE REHABILITATION OF PATIENTS WITH HEADACHE

M. Mozheiko¹, I. Maryenko¹, S. Likhachev¹
¹Republican Research and Practical Centre of Neurology and Neurosurgery, Neurological, Minsk, Belarus

Introduction/Background

The most common types of headaches (HA): migraine headache (MH); tension-type headache (TH); headache associated with increased arterial tension. It was established that (TH) and (MH) are often accompanied by voltage of pericranial muscles and shoulder girdle. The aim is to estimate the effectiveness of a course of rehabilitation using biofeedback training (BFT) with electromyogram (EMG) to reduce intensity of pain, to decrease the stress, the excessive muscle activity of patients with (MH) and (TH).

Material and Method

The course of rehabilitation included 8 trainings with using the hardware and software complex "REHACOR" (Russia, Taganrog) in 12 patients (mean age - 49.5 ± 7.4 years), including 8 patients with (TH), 4 patients with (MH) and complaints of headache at the start of the rehabilitation course. The training methodology includes: the patient arbitrarily relaxes the muscles of shoulder girdle, and in the computer screen under influence of relaxation the visuals and sound effects are changing with simultaneous registration envelope of electromyograms (EEMG) of symmetrical zones of trapezius muscle. When patient is strained, the sound and noise was heightened, when patient is relaxed the noise disappears. To assess the intensity of the HA before and after the course of rehabilitation there was used the "Visual Analog scale (VAS)".

Results

The intensity of the HA of «Visual Analog scale» before the course of rehabilitation amounted 7.4 % ± 0.6%, after course it decreased reliably and amounted 3.6% ± 0.8%,p < 0.05. In results of EMG the convergence coefficient of values (right) and (left) in the first training was 1.9%, to the 8-m training was 1.1%.

Conclusion

Using the (BFT) with (EMG) in rehabilitation of patients with HA improves the nervous regulation of functions and allows to develop the skill to relax the muscle of shoulder girdle and to reduce arbitrarily the intensity of the HA.

COMPLEX REGIONAL PAIN SYNDROME TYPE II FOLLOWING SCIATIC NERVE INJURY TREATED BY DEXTROSE NERVE HYDRODISSECTION: A CASE REPORT

C.T. Huang¹, W.C. Lin²
¹Chi Mei Medical Center, Physical Medicine and Rehabilitation, Tainan, Taiwan R.O.C.
²Chiali Chi Mei Hospital, Physical Medicine and Rehabilitation, Tainan, Taiwan R.O.C.

Introduction/Background

Complex regional pain syndrome (CRPS) is a well-known clinical entity, first described in the 1800s, consisting of pain, hyperalgesia, edema, and sudomotor changes either without (Type I) or with (Type II) a definable nerve injury. Here, we describe a case of CRPS Type II after sciatic nerve injury caused by a femur fracture in which the pain was treated successfully by ultrasound-guided dextrose nerve hydrodissection.

Material and Method

A 75-year-old female was referred to our rehabilitation clinic for post-operational rehabilitation program of her femoral shaft fracture. Two months earlier, she had undergone open reduction and internal fixation of the left femur mid-shaft comminuted fracture from a traffic accident. She presented with drop foot after the accident and electrophysiology exam revealed a concomitant sciatic nerve injury. Erythematous change of her skin with progressive allodynia and pain gradually developed after the accident. She did not respond to conventional treatments including medications or physical modalities. After ultrasound evaluation, swollen sciatic nerve, common peroneal nerve, superficial and deep common peroneal nerve was revealed. We then chose to do a ultrasound guided dextrose nerve hydrodissection of those nerves to relieve her symptoms.
Results

After serials of injection, improving of skin temperature, edema, trophic changes, and skin color changes were found in physical examination. Her pain and active motion of her toes and ankle significantly improved.

Conclusion

CPRS type 2 is a disabling entity causing pain and severe motor-sensory dysfunction. US-guided dextrose nerve hydrodissection may be an effective and durable treatment modality for the management of refractory pain in CRPS Type II.

CURRENT SITUATION AND UNMET NEEDS FOR REHABILITATION IN COMPLEX REGIONAL PAIN SYNDROME IN KOREA : A PILOT SURVEY

J.Y. Lim¹, I.S. Kim², S.E. Hyun², E.P. Ju¹, J. Park¹

¹Seoul National University Bundang Hospital, Rehabilitation Medicine, Seongnam, Republic of Korea
²Seoul National University Hospital, Department of Rehabilitation Medicine, Seoul, Republic of Korea

Introduction/Background

Complex regional pain syndrome (CRPS) is a debilitating, painful condition in a limb, associated with sensory, motor, autonomic, skin and bone abnormalities. In CRPS, rehabilitation is important with pain treatment. However, in Korea, CRPS patients do not receive appropriate rehabilitation properly and consistently. The purpose of this study was to evaluate the degree of pain, degree of depression and quality of life in patients with complex localized pain syndrome in Korea and to evaluate the subjective rehabilitation treatment need and unmet need of patients.

Material and Method

The subjects (n=19) were recruited based on the medical records of single-center. They were assessed through structured questionnaires (BPI, WHODAS-K, EQ-5D-5L, rehabilitation need).

Results

The average BPI and WHODAS-II were 7.95 ± 0.52 and 68.39 ± 10.21% (Table 2). In the Pain, Ache, Anxiety, and Gait disturbance domains, patients were provided the desired treatment, but the satisfaction was poor. In the Fatigue, Body weight, and Memory domains, patients stated that they did not receive appropriate treatment consistently or continuously. (Table 3)

Conclusion

In Korea, patients with CRPS may not get adequate rehabilitation treatment. Proper management of rehabilitation and the provision of care guidelines are needed.

Introduction/Background

Patients with complex regional pain syndrome type I (CRPS I) often have body schema perception disturbances which has significant impact on patients quality of life. Mirror therapy requires minimum equipment, is relatively simple to perform and effective in various pathological conditions but its efficacy in CRPS I patients rehabilitation has not been definitely established. Study objective: to investigate the influence of mirror therapy (as an addition to the standard complex rehabilitation program) on body schema perception in CRPS I patients.

Material and Method

The study is based on the analysis of the of 6 weeks treatment results of 50 patients with CRPS I, developed as a result of the distal radius fractures (duration no longer than 3 years); all patients were enrolled in standard rehabilitation program (physical therapy, exercises, medications); in addition to standard care 30 patients consented to practice mirror therapy (study group), 20 received only standard rehabilitation program (control group). All patients underwent complex evaluation, including assessment by Bath CRPS Body Perception Disturbance Scale, before the treatment, after three days and after 6 weeks.

Results

After 6 weeks of treatment the majority (83.33 %) of patients in study group and 35% in control group demonstrated improvement in body schema perception (p<0.05). The positive effect was statistically significant for the first five points of the Bath scale after 6 weeks of treatment compared to the control group.

Conclusion

Mirror therapy, included into standard rehabilitation program is effective for the body schema perception disturbances treatment in patients with CRPS I developed after fractures of the distal radius less than 3 years duration.

DRY NEEDLING TRIGGER POINTS IN RECTUS AND OBLIQUUS CAPITIS INFERIOR MUSCLES UNDER ULTRASOUND GUIDANCE IS EFFECTIVE FOR CHRONIC HEADACHE
R. Bubnov¹, L. Kalika²
¹Clinical Hospital “Feofaniya”, Ultrasound, Kyiv, Ukraine

Introduction/Background

Myofascial pain is widespread, can be reliable cause of large number of headaches. Suboccipital triangle has high complexity of vasularity and innervation network with sympathetic signalling. Recently we proposed a new approach of trigger point therapy, performing precise muscle dry needling under ultrasound (US) guidance.

The aim was to evaluate efficacy of deep dry needling of myofascial trigger points (MTrPs) in suboccipital muscles (rectus and obliquus capitis inferior muscles) treat chronic headaches.

Material and Method

This study included 24 patients (15 females, avarage age was 38±6 years old). All patients suffered from intensive chronic persistent or recurrent one- or two-sided pain in temporal and/or occipital areas; sometimes radiation to neck, arm. The treatment approach by Bubnov [PMID:23088743] was applied that included ultrasound identification of MTrPs with following dry needling under US guidance using steel 28G needles to elicit the local twitch response (LTR). Visual analogue scale data (VAS0-10) were measured before, immediately after and 24 hours after the intervention. A decrease in pain as measured by a VAS of 50% or more one week after treatment was considered as success.

Results

Main active MTrPs were diagnosed in rectus and obliquus capitis inferior muscles, the additional (latent) MTrPs were defined and effectively needled in muscles of the ipsilateral shoulder rotator cuff. In one session 1-3 needles were inserted, 1-2 sessions applied to each patient. Retention of needles depended of muscle LTR duration. Seventeen patients showed decrease in pain as measured by a VAS of 90%, the difference was significant in this group (p<0.01) and pain relief outcome after one month observation; seven patient received another session after 2-3 weeks after first procedure.

Conclusion
Dry needling trigger points in suboccipital muscles under ultrasound guidance is effective to treat headaches, evoked by myofascial disorders. Further profound studies needed to establish unified Dx and Tx protocol.

MANAGEMENT OF LONG-TERM COMPLEX REGIONAL PAIN SYNDROME WITH ALLODYNIA: A CASE REPORT

I. Quintal¹,²,³, L. Poiré-Hamel⁵, D. Bourbonnais¹,³, J.O. Dyer¹
¹Université de Montréal, School of rehabilitation, Montreal, Canada
²Centre Professionnel d'Ergothérapie, Occupational Therapy, Montreal, Canada
³Center for Interdisciplinary Research in Rehabilitation of greater Montreal, Rehabilitation, Montreal, Canada

Introduction/Background

Complex Regional Pain Syndrome (CRPS) is characterized by sensory, motor, sudomotor, vasomotor edema and/or trophic signs (Harden et al., 2010). Abnormal painful sensations (e.g. hyperalgesia, allodynia), and skin sensibility disorders are often the leading cause of complaints and decreased function in CRPS (Savas et al., 2009). This case report describes a successful innovative tailored rehabilitation program that was used in a patient having upper-limb CRPS with static mechanical allodynia (SMA), who initially did not respond to conventional rehabilitation alone.

Material and Method

The tailored rehabilitation program initially consisted of occupational therapy including the somatosensory rehabilitation method (SRM) and graded motor imagery (GMI). Conventional treatments (pain management, active mobilizations, strengthening and task simulation) were then added successively.

Results

Over a period of 22 months of tailored rehabilitation, this patient showed: decreased pain (Numeric pain scale; McGill pain questionnaire), resolution of SMA, reduced tactile hypoaesthesia, increased range of motion and strength, and improved functional independence (DASH; interviews).

Conclusion

A tailored rehabilitation program that takes into account the patient’s symptoms, causes of these symptoms and patient’s personal priorities seems promising for treating patients with upper-limb CRPS with SMA. Further studies are needed to explore how SRM and GMI should be combined to optimize their beneficial effects and to identify which patients would benefit the most.

THE RESULTS OF SOMATOSENSORY TESTING AND REHABILITATION IN NEUROPATHIC PAIN

D. Sharan¹, J.S. Rajkumar²

¹RECOUP, Orthopaedics and Rehabilitation, Bangalore, India
²RECOUP, Physiotherapy, Bangalore, India

Introduction/Background

Nervous system sensitization can be accompanied by both positive and negative sensory signs. The aim of this study was to explore the spectrum of sensory abnormalities in clinically diagnosed adults with neuropathic pain (NP) using a well-defined assessment protocol using quantitative somatosensory testing methods followed by Somatosensory Rehabilitation Protocol (SRP) developed by Claude Spicher.

Material and Method

A comprehensive assessment protocol of 60 subjects with NP associated with varying sensory abnormalities was conducted. The protocol involved Somato-Sensory Testing (SST) procedures and was performed by a Physiotherapist specially trained in SST methods. The subjects were assessed and diagnosed using a mix of subjective and objective measures as follows: Somatosensory Qualifiers, McGill Pain Questionnaire, DN4 Questionnaire, VAS and other specific tests for mapping the prognosis and were characterized under 4 different Neuropathic Dysfunctional Categories (NDC) followed by Somatosensory Rehabilitation Program (SRP) based on the type of NDC. Tests were repeated 1 month post rehabilitation for determining the reduction of symptoms and follow up after 3 months.

Results

Among 60 patients, 70% of the participants were male and in the age group of 30-40 years. 68% reported pain as the major symptom, 35% burning sensation, 20% tingling sensation, 15% pulling, electric shock like, parenthesis and hypersensitivity. 88% of the patients had involvement of lower extremity (LE). Posterior antibrachial cutaneous nerve was the most commonly affected nerve in the upper extremity and medial cutaneous nerve was most commonly affected in the LE. The most commonly affected regions were foot, heel and sole with burning, tingling and numbness as major symptom and elbow and ankle least affected. 45 subjects recovered completely post rehabilitation and maintained the progress during the follow-up, while 15 recovered partially.

Conclusion

SST is an effective diagnostic protocol for individuals with NP and plays a key role in the effective rehabilitation of NP.

Introduction/Background

CRPS implies sympathetic, inflammatory, neurogenic, vascular, peripheral and central mechanisms. The pathophysiology of type 1 CRPS is complex and yet poorly understood. The relative part of each mechanism in CRPS type 1 development and resistance is not established, as their respective contribution varies amongst patients during the course of clinical evolution. A growing consensus has developed for a central participation to this pathology, even if the very nature of spatial and body representation alterations is still discussed. It has been clinically observed and repeatedly argued that CRPS implies pathological motor neglect.

Material and Method

We reviewed the available literature about central pathophysiology and new therapeutic approaches and will illustrate new perspectives with our own clinical and research practice.

Results

Even if spatial cognition explorations has given rise to a variety of inconsistent results, it is now admitted that central participation, manifested as a spatial reference frame alteration plays a central role in CRPS. This new view blazed the trail to new therapeutic strategies targeting spatial reference frame alterations: mirror therapy, prism adaptation, rTMS.

Conclusion

Central participation to CRPS’ pathophysiology is nowadays admitted. Amongst the new therapeutic strategies rising from this recent comprehension, the most promising seems to be prismatic adaptation.

TYPE 1 UPPER LIMB COMPLEX REGIONAL PAIN SYNDROME (CRPS) IN STROKE PATIENTS: COMPARISON OF TWO PROTOCOLS OF MIRROR THERAPY WITH A MULTIPLE BASELINE DESIGN.

C. Vidal¹, A. Krasny-Pacini¹, E. Bagot¹, M.E. Isner-Horobeti²

¹University Institute of Rehabilitation Clemenceau, Physical Medicine and Rehabilitation, Strasbourg, France
²Translational Medicine of Strasbourg Federation, EA 3072 “Mitochondrie- stress oxydant et protection musculaire”, Strasbourg, France

Introduction/Background

CRPS is a frequent disabling condition after stroke. Among non-pharmacological interventions, mirror therapy (MT) has shown to be effective. However it remains unclear, how mirror therapy should be applied, especially regarding the type of movement to be performed during MT. The aim of this study was to determine if MT should be applied using distal or proximal movements of the upper limb in the treatment of post-stroke type 1 CRPS.

Material and Method

Inclusion criteria: patients with a stroke in the past 6 months, diagnosed with type 1 CRPS according to the clinical criteria of the IASP Budapest, confirmed by scintigraphy.

Design: Single Case Experimental Design using a three phases, multiple baseline design across three subjects, with repeated measures of pain and function in baseline (without intervention), proximal movement MT, and distal movement MT, applied in a randomized order.

Repeated measures: pain measured on a Visual Analogic Scale, function measured on the Frenchay Arm Test and the Abilhand scale. Intervention: precisely described MT applied for two times fifteen minutes a day, five days a week, during four weeks, using either distal or proximal joints movements.

Results

MT decreased pain in all patients, regardless of the type of MT used. Using distal movement MT following a four-weeks period of proximal movement MT did not bring additional gain. Using proximal movement MT following a four-weeks period of distal movement MT seemed to slow down pain improvement. Function improved on all patients.

Conclusion

Using MT with distal movements only, and no mobilisation of the shoulder joint, seems the best option to alleviate pain in post-stroke type 1 CRPS as it is easier to use and no less effective than the more cumbersome proximal movement MT. Better description of interventions, as done in this study, is needed for clinicians to be able to replicate finding of effective interventions.

CERVICAL MYOFASCIAL PAIN SYNDROME - IS THE ULTRASOUND-GUIDED NEEDLING APPROACH A THERAPEUTIC OPTION?

P. Araujo¹, S. Serrano¹, A. Canelas¹
¹Centro Hospitalar de Leiria, Medicina Física e de Reabilitação, Leiria, Portugal

Introduction/Background

Myofascial Pain Syndrome (MPS) is a frequent entity in clinical practice and is characterized by the presence of trigger points, limitation of joint mobility and neurological symptoms. The main purpose of this work was to evaluate the results obtained by perform an ultrasound-guided needling of the trapezius and levator scapulae muscles with simultaneous injection of steroids and local anesthetics, in the pain intensity and interference in daily life and the subjective benefits in patients with cervical MPS.

Material and Method

Prospective longitudinal study, including patients with clinical diagnosis of unilateral or bilateral cervical MPS refractory to the conventional rehabilitation program, submitted to treatment during the year 2017. The technique included to pepper the trigger point with a fanlike manner under ultrasound guidance, using a 22G needle with simultaneous injection of 2% lidocaine and methylprednisolone acetate 40mg/ml. A sociodemographic questionnaire, the pain numerical rating scale (NRS) and the brief pain inventory (BPI) were applied prior and 1 month after the procedure. In this last evaluation, a Likert scale was also applied to evaluate the subjective benefits.

Results

Eighteen patients were included, 82% female, with a mean of 54 years (SD = 8.2). No adverse effects were recorded. There was a statistically significant and clinically relevant reduction in the score obtained in the NRS (2.9, P < 0.001) and in all components of the BPI, including intensity (2.6, p < 0.001), pain interference in general activity (1.9, p < 0.001) and in the affective subdimension (1.7, p < 0.001). 54% of the patients reported a very significant improvement with the procedure, but only 33% presented a ≤ 4 value in the NRS at 1 month reassessment.

Conclusion

The results presented in this study show the importance of ultrasound-guided needling procedures in the treatment of myofascial pain and, at least, it short-term efficacy on relieving pain, particularly in refractory cervical MPS.

COMPLEX REGIONAL PAIN SYNDROME: NEUROSTIMULATION AND REHABILITATION IN A PORTUGUESE HOSPITAL

J. Vilaça Costa1, R. Prado Costa2, F. Vilabril3, I. Ferro1, P. Caetano4, I. Simas4, I. Lucas1
1Centro de Medicina de Reabilitação da Região Centro – Rovisco Pais, General Rehabilitation, Tocha, Portugal
2Centro Hospitalar de São João, Physical and Medical Rehabilitation, Porto, Portugal
3Centro Hospitalar de Trás-os-Montes e Alto Douro, Physical and Medical Rehabilitation, Vila Real, Portugal
4Hospital Divino Espírito Santo, Anesthesiology, Ponta Delgada, Portugal

Introduction/Background

Complex Regional Pain Syndrome (CRPS) is a clinical and exclusion diagnosis characterized by disproportionate pain caused by a limb injury. Budapest criteria includes sensory, vasomotor, sudomotor and/or motor/trophic symptoms. Prevalence is 5,5-26/100000, higher among women and the upper limb (UL). Treatment is poorly defined, however it should be multidisciplinary, including physical, pharmacological, psychological and invasive techniques, like nerve blocks. Spinal cord stimulation (SCS) has been shown beneficial.

The aim of this paper is to describe a population of a CRPS who underwent SCS.

Material and Method

Retrospective longitudinal study of 21 patients followed by a Pain physician from Centro Hospitalar São João, diagnosed with CRPS between 2001-2015, who underwent SCS. Statistical data was accessed using IBM SPSS 22.0.

Results

The mean age of the 21 patients (100%) was 46,3(±2,5) years-old, with a 2:3 M:F ratio. UL was affected in 57,1% of them. The predominant event associated was fracture(33,3%), followed by minor trauma(28,6%), other post-surgery(23,8%) and other non-post-surgery(14,3%). This cohort took a median of 24months to attend Pain consultation and 42months to implant SCS; 42,8% of these patients enrolled on a PMR consultation - mostly the younger (40,8±7,8 vs. 50,5±12,0 years-old; p=0,049) – and the majority of them underwent surgery (77,8%). Overall, 53,8% patients with CRPS who went through surgical therapy were in PMR. PMR patients took less time (48,9±11,4 months) to implant SCS (vs. 79,6±25,1 months).

Conclusion

CRPS epidemiological data is variable, probably due to lack of standard criteria for the diagnosis. On this cohort, as described in the literature, most of the patients were female, the UL was more affected, and the main etiology was traumatic. Those in PMR implanted SCS in a
shorter period, possibly due to a more severe illness. Patient referral to PMR was predominant in the post-surgery population and on younger, perhaps as they have more active years ahead.

57 years old gentleman presented in pain clinic with Shoulder Dystonia secondary to his right shoulder replacement surgery. He presented with severe pain due to recurrent dislocations of his right shoulder and painful spasms. This affected his ability to use his right arm with subsequent reduction in range of movements. This also had an impact on his psychological well being as he was very fearful of dislocations that he had several times a day at times. The concept of Peripheral lesions to neural structures resulting in dystonia is a controversial subject. But is becoming more acceptable recently. There have been case studies of patients developing dystonia following spinal surgery. We report this rare case that we have managed successfully with botulinum neurotoxin.

Material and Method

Patient reported sequence of events post shoulder replacement, review of orthopaedic notes, clinical examination in pain clinic with previous oral medications tried for this condition. Consent regarding non licenced use of Botulinum Neurotoxin for shoulder dystonia patient’s feedback after receiving botulinum Neurotoxin injections has been used to report this case study.

Results

Patient reported good benefit from Botulinum Neurotoxin injections (Botox) compared with oral Medications i.e. Baclofen, Diazepam, Tramadol and Gabapentin. Patient reported reduction in intensity of his pain and frequency of his shoulder dislocations. He has been having treatment with multiple Botulinum Neurotoxin injections in muscles around his shoulder girdle for several years. Each treatment lasts for 3-4 months.

Conclusion

Botulinum Neurotoxin is safe and effective first line treatment to prevent recurrent dislocations and painful spasms of post surgical peripheral Dystonia.

TRANSCUTANEOUS ELECTRICAL NERVE STIMULATION AND PLACEBO ANALGESIA: ARE YOUNG AND OLDER ADULTS THE SAME?

I. Daguet¹,²,³, K. Bergeron-Vézina¹,², M.P. Harvey¹,², M. Martel¹,², G. Léonard¹,²
¹Research Center on Aging, University Institute of Geriatrics of Sherbrooke, Sherbrooke, Canada
²Université de Sherbrooke, Faculté de médecine et des sciences de la santé, Sherbrooke, Canada
³Institut Celle Souche et Cerveau, Département de Chronobiologie, Lyon, France

Introduction/Background

Placebo analgesia refers to a perceived reduction in pain following the administration of a simulated or otherwise medically ineffective treatment. Previous studies have shown that many factors can influence placebo analgesia. However, few investigations have examined the effect of age on placebo analgesia, and none have done it in the context of rehabilitation interventions. The objective of this study was to compare the placebo response induced by sham transcutaneous electrical nerve stimulation (TENS) between young and older individuals, using an experimental heat-pain paradigm.

Material and Method

Twenty-two young (21-39 years) and 22 older (58-76 years) healthy adults participated in this comparative study. Experimental heat pain was evoked with a thermode (2-min stimulation at a constant, individually adjusted temperature) applied on the lumbar region. Participants were asked to evaluate the intensity of their pain using a computerized visual analog scale. Experimental pain was induced before and after an unconditioned placebo intervention (sham TENS).

Results

In young individuals, no significant pain reductions were noted, whereas in older individuals, a statistically significant pain reduction was observed after the placebo stimulation ($P<0.01$). Between-group analysis revealed that placebo analgesia was greater in older individuals (40% pain reduction) compared to young individuals (15% reduction; $P<0.05$).

Conclusion

Our results indicate that placebo analgesia is influenced by age, with older individuals showing higher placebo analgesia than young adults. Although these results should be confirmed in clinical pain populations, the current observations bear important consequences for the design of future placebo-controlled trials in rehabilitation and for healthcare professionals.

THE IMPACT OF BENZODIAZEPINE ON ANALGESIC COSTS TO TREAT SPINAL CORD INJURY PATIENTS IN TAIWAN: A POPULATION-BASED RETROSPECTIVE COHORT STUDY

W.C. Lien1

1National Cheng Kung University Hospital, Physical Medicine and Rehabilitation, Tainan, Taiwan R.O.C.

Introduction/Background

The aim of this study was to evaluate the impact of benzodiazepine (BZD) on analgesic costs to treat spinal cord injury (SCI) patients in Taiwan.

Material and Method

The retrospective cohort study used a subset of the Taiwan National Health Insurance Research Database (NHIRD) comprising information on two million beneficiaries randomly sampled from the entire population of Taiwan. A total of 3170 patients aged 16 and above with newly diagnosed SCI were identified during a period from 2001-2010.

Results

The multivariate linear regression using average daily costs of prescription of nociceptive pain, including non-steroidal anti-inflammatory drugs (NSAIDs) and opioid analgesics for 1 year and 4 years after SCI showed increased costs in benzodiazepine (BZD) user, especially in high-dose BZD users (cumulative defined daily dose [cDDD] > 0.3) (parameter estimate = 3.79 and 1.37 respectively. P value < 0.05). The multivariate linear regression using average daily costs of prescription of neuropathic pain, including antidepressants and anti-epileptic drugs for the treatment of neuropathic pain for 1 year and 4 years after SCI showed increased costs in BZD user, especially in high-dose BZD users (parameter estimate = 5.95 and 3.85 respectively. P value < 0.05).

Conclusion

This study showed that the baseline BZD exposure may significantly increase the analgesic costs in SCI patients.

EFFECTS OF LONG TERM OPIATE USE AMONGST MINE AND MILL WORKERS IN RURAL NORTHERN ONTARIO: A CROSS SECTIONAL STUDY FROM AUGUST 2015 TO MARCH 2017
A. Bruno-petrina¹, G. Whyne²
¹Mics Group Of Health Services, Family Medicine, Iroquois Falls, Canada
²Northern Ontario School Of Medicine, Family Medicine, North Bay, Canada

Introduction/Background

Opioids are prescribed with the goal of returning function to patients to allow them to perform daily tasks and work. However many of those patients prescribed opioids are found to continue to be disabled and never return to work.

Research Question: Does the use of opioids in patients with low back pain increase the risk of being on long term disability?

Material and Method

This was a cross sectional study. Through use of a chart audit from the Iroquois Falls family health team patient list from 2009 to 2017, we gathered charts of mine and mill worker patients treated for low back pain through known diagnostic codes. Exclusionary criteria including female gender, sedentary jobs (managers, supervisors) was implemented. Comparison of patients relating to their disability status, opioid use and worker status and opioid performed by statistical analysis. Further analysis of the mechanism of injury and type of medication used was also gathered.

Results

Results: From the 58 charts that met criteria it was found that 30 were on disability and 28 were not. Of those disabled 22 were currently on opioids and those that were not had 5. A P value of 0.002 was found for this correlation. Of those disabled 7 required surgery, 16 had mechanical back pain and 18 had radicular pain. There was a positive correlation between high opiate use and disability.

Conclusion

Although there was a positive correlation between opioid use and disability, this was a small study and more research is needed.

ASSESSMENT OF HEALTH RELATED QUALITY OF LIFE OF OUTDOOR PATIENTS AT PMR DEPARTMENT OF A TERTIARY CARE HOSPITAL IN BANGLADESH

J. NESSA
SHAHEED SUHRAWARDY MEDICAL COLLEGE, PHYSICAL MEDICINE AND REHABILITATION, DHAKA, Bangladesh

Introduction/Background

In a middle low socioeconomic status country like Bangladesh a good number of people attend the government hospital outdoors to get services at low cost. In PMR department various types of patients are treated who have different types of disability. Quality of life assessment is important in these patients to improve and planning the service delivery. This type of assessment is easier using RAND SF-36 Health survey method.

Material and Method

By using SF-36 Health Survey tool, a hospital based cross sectional study was done on the outdoor patients attending the PMR department of a tertiary hospital of Dhaka city of Bangladesh. Total numbers of patients were 190.

Aim :

The aim of this study was to detect the trends of disease among outdoor patients and to assess their quality of life.

Results

Among the study population most of the patients were of different types of musculoskeletal pain (70 percent), 20 percent were of neurological diseases, 10 percent were in miscellaneous group- including postoperative orthopedic and neurosurgical conditions, cardiac and pulmonary patients, post burn and cancer patients after surgery; head, neck and breast cancer with lymphoedema, cerebral palsy and other pediatric conditions.

Physical and mental quality of life was assessed by PCS (Physical component summary) and MCS (Mental component summary) by working out the mean average of all the physically relevant questions and emotionally relevant items. The age range of patients was 26-70 years. Acute cases were 64 percent; sub acute cases 8 percent, chronic were 28 percent. Male: female was 1.9: 1. The PCS range found was 22.49 -61.26. The MCS range was 29- 74.36.
Conclusion

S F-36 Health Survey tool is relatively easy to be administered. In low resource country like Bangladesh with population overload, there is scope to use this tool for large number of patients.

STUDY OF CARPAL TUNNEL SYNDROME IN PERIPHERAL NEUROPATHY WITH COMPARISON OF TWO METHODS: INCHING METHOD AND SECOND LUMBRICAL-INTEROSSEI TEST
M. Emad¹, L. Abolfathi Momtaz¹
¹Shiraz University of Medical Sciences, Physical Medicine and Rehabilitation, Shiraz, Iran

Introduction/Background

Diabetes mellitus is the most common metabolic disease. The carpal tunnel syndrome (CTS) occurs frequently in this disease. In diabetes mellitus due to effects of generalized neuropathy on peripheral nerves, the diagnosis of CTS with conventional EDX criteria (onset latency of median SNAP or distal latency of median CMAP) is challenged, so another methods such as 2nd lumbrical-interossei test is used. On the other hand, inching method is a technique in which used for diagnosis and determining the site of compression in carpal tunnel. The purpose of the present study is to evaluate diagnostic value of the inching method and 2nd lumbrical-interossei test in patients with diabetic peripheral neuropathy and signs or symptoms of carpal tunnel syndrome.

Material and Method

Thirty hands with history of diabetes mellitus and signs and symptoms of CTS that confirmed diagnosis of peripheral neuropathy with conventional electrodiagnosis were evaluated. Then for diagnosis of CTS, sensory and motor median distal latencies were measured by nerve conduction study. In the next step, inching method and second lumbrical interossei test was performed for all hands and sensitivity and specificity of two tests was calculated.

Results

Mean age of participants was 53.87 ± 11.53 years (range 26 to 70 years). 10 participants were female and 6 participants were male. The sensitivity and specificity of inching method in this study were 95.65 and 85.71 respectively and the results for second lumbrical-interossei test 73.91 and 71.42 were calculated.

Conclusion

In this study, we showed the inching method is more sensitive and specific than second lumbrical-interossei test in diagnosis of CTS in diabetic peripheral neuropathy with sensitivity and specificity 95.65 and 85.71 respectively and also the sensitivity of inching method was greater than specificity.

ISPR8-0321
REGISTRY FOR PAIN IN HOSPICE
Y. Dionyssiotis\textsuperscript{1,2}, M. Kokolaki\textsuperscript{2}, S. Kotsalidou\textsuperscript{2}, A. Danopoulou\textsuperscript{2}, A. Vadalouka\textsuperscript{3}
\textsuperscript{1}European Interbalkan Medical Center, Physical Medicine and Rehabilitation, Thessaloniki, Greece
\textsuperscript{2}Hospice for Neurodisability, Medical Department, Athens, Greece
\textsuperscript{3}Hellenic Society of Pain Management and Palliative Care, Medical Department, Athens, Greece

Introduction/Background

Hospice for the disabled is treating patients from all over Greece and hosts people whose condition is incurable. Patients remain by the end of their life which implies increased medical, nursing and pharmaceutical care. For their care 110 people are employed (doctors, physiotherapists, nurses, occupational therapists, administrative staff, technicians, etc.), providing 24 hour support. The purpose of this study was to investigate the percentage of pain and pain categories.

Material and Method

One hundred seventy five subjects (men and women) are hosted in the hospital suffering from paraplegia, quadriplegia, encephalopathies, multiple sclerosis and diseases of the central nervous system, etc. 80% of patients are bedridden. Pain categories included musculoskeletal, neuropathic, mixed type pain and pain of malignancy. All received pharmacotherapy against pain including analgetics, opioids drugs, non-steroidal anti-inflammatory drugs, anticonvulsants, tricyclic antidepressants, serotonin–norepinephrine reuptake inhibitors (SNRIs). Subjects were evaluated with visual analogue scale (VAS). Physical therapy sessions were offered to all patients and a multi-disciplinary approach was initiated after cooperation and counseling from our colleagues in Hellenic Society of Pain Management and Palliative Care (PARH.SY.A.)

Results

Fifty eight subjects are suffering from pain (33%). Pain was categorized as follows: musculoskeletal 1% and 25%, neuropathic 12.6% and 38%, mixed type 12% and 36%, pain of malignancy 0.6% and 1.72%, of total and suffering patients, respectively. VAS was significantly decreased after treatment (p<0.05) after adjustment for physical therapy.

Conclusion

We found a positive response to the pharmacotherapy which suggests the importance of this intervention as a part of the multi-disciplinary approach.

PHANTOM PAIN IN CONGENITAL AMPUTEES: MYTH OR REALITY?
D. Garcia¹, E. Flores¹, P. Nahuelhual², F. Solis²
¹Instituto Teleton Santiago, Physical Medicine and Rehabilitation, Santiago, Chile
²Instituto Teleton Santiago, Investigation Department, Santiago, Chile

Introduction/Background

Until not long ago, pain was underdiagnose in children (1). Its similar in congenital amputees (CA) and the presence of phantom pain (PP). Even do PP is common in adult amputees, its existence in CA is denied by many clinicians. But articles have corroborate that pediatric CA can develop PP (2-4). The aim is to study the presence of PP in CA who assist to our center and study its characteristics.

Material and Method

Descriptive study. Population: 10 years and older patients with diagnosis of CA or deficiency who attended our center. Instruments: Previously validated telephone survey to determinate the presence and characteristics of PP (5). Variables: PP and sensation, ISPO classification, prosthesis use. Analysis: Lapsic prevalence, data was analyzed using STATA 14.

Results

77 patients were contact, 57 of them consented to answer the telephone survey. Main age was 18.6 years (12-25), 43.9% male. 60% had longitudinal deficiency, 38% had a transversal and 2% had both. The most commonly affected extremity was the left arm. 33% reported to use prosthesis. Regarding our survey, 24.6% had phantom sensation and 7% had PP, with a lapsic prevalence of 5.3%. Analyzing the patients with pain, all of them had an upper extremity deficiency, none used a prosthesis and 1/2 had phantom sensation.

Conclusion

This is a small study, but its an important contribution to consolidated that PP can be present in CA. Nowadays there is much more conscience on the importance to suspect, diagnose and treat pain in children, so phantom pain should not be an exception.

PAIN AND FUNCTIONAL DISABILITY IN PATIENTS WITH POST-POLIO SYNDROME. ALGERIAN OBSERVATIONAL STUDY FROM 2010 TO 2017

B. Zouhir\(^1\), A. Bouamra\(^1\), A.C. Nouar\(^1\)

\(^1\)University Saad Dahlad Blida, Medicine, Blida, Algeria

**Introduction/Background**

Pain in polio, associated with new muscle weakness, fatigue, causes a suspicion of post-polio syndrome. Our goal is to describe this pain, and to appreciate the handicap and his impact on everyday life.

**Material and Method**

A historical cohort study of 119 former polios, ranging from 2010 to 2017. Judgment criteria: biometrics settings' measurements, pain EVA, DN4 questionnaire, measure of functional independence "MIF", scale and measurement of walking distance, Borg scale.

Statistical study: SPSS.20.0.

**Results**

The average age of polios 42.29 ± 9.90; sex ratio 1.16, average BMI 25.8 ± 4.6; The pain is 79%, its time of onset: 3.5 years; the pain is mixed in 22%; neuropathic pain in 16%; spinal localization is 40.6%; 44% of patients have joint pain and 15% have at least two articular and / or muscle locations. The pain is correlated with gender (p <0.05), an PPS is present in 59.4%. The functional degradation before and during the onset of PPS is 4.2 points on the MIF. Obesity among older polio patients and the existence of a history of polio caught beyond 4 years old at childhood are each a risk factor for developing PPS.

**Conclusion**

Pain in polio is almost present, consistent with American and European studies. The correlation of gender to pain corresponds to the results of the Danish study by Marita Widar. The pain among the old polios is a sign of PPS. It has a considerable impact on everyday life. Prevention requires a healthy lifestyle and an energy saving.

OSTEOARTHRITIS AND LIPODERMATOSCLEROSIS: EFFICIENCY OF NON-PHARMACOLOGIC TREATMENTS

O. Egorova¹, M. Sukhareva¹, B. Belov¹
¹V. A. Nasonova Research Institute of Rheumatology, Rheumatology, Moscow, Russia

Introduction/Background

Lobular panniculitis lipodermatosclerosis with osteoarthritis is becoming more frequent in medical practice. LDS is lobular panniculitis which manifests in degenerative-dystrophic changes of subcutaneous fat. It is common among middle-age women with chronic venous insufficiency.

Purpose: to examine efficiency of mesotherapy and ultrasound in case of LDS with OA.

Material and Method

Among 539 patients duration of disease 11.8±6.4 months was verified for 8.5% (44 women, 2 men), age 18-82 with, extra weight (32 patients). Patients were randomized into two groups 23 patients each: Group 1 received MT treatment (10 sessions) with homeopathic drugs with antioxidant, anti-inflammatory, lymph-drainage and lipolytic action and US treatment of the induration area. Group 2 was daily treated with MT with 9% Natrii Chloridum solution in comparable dose with Group 1. Control methods included general clinic examination and ultrasound elastography of indurations. Main stages of control: initial (T0), 14 days (T1), 1 month (T2) and 3 months (T3).

Results

All patients of Group 1 had positive dynamics in VAS intensity (T0 50±18 mm; T1 35±11 mm), reduction in diameter (T0 6±2.2 mm; T1 4.5±1.7 mm) and color intensity of indurations (p<0.002), thickening of SCF and reduction of ESR and CRP. In 44% of cases the effect from treatment increased by T2 (p<0.05). After 3 months 15 patients needed a second course of physiotherapy. In Group 2 a positive clinical effect was evident in 14 patients (60.8%) by T2 and in 19 patients (83%) by T3 (p<0.05). Over the whole period of observation LDS recurred in 19 patients (41%) of Group 1. Recurrence was associated with aggregation of nodes. MT and US were tolerated well, side effects were not recorded.

Conclusion

Use of MTC with 9% Natrii Chloridum made it possible to achieve positive dynamics in patients suffering LDS with OA, Assessing the significance of said methods needs further investigation.

**REHABILITATION OF OROFACIAL PAIN FACES PROGRESS: OVERVIEW OF CURRENT ADVANCES IN OROFACIAL REHABILITATION**

H. Mubarak¹, N. Mayasari², H. Thahir³, S. Anshory⁴

¹Medical Faculty Hasanuddin University, Department of Physical Medicine and Rehabilitation, Makassar, Indonesia
²Wahidin Sudirohusodo Hospital, Department of Physical Medicine and Rehabilitation, Makassar, Indonesia
³Faculty of Dentistry, Department of Periodontology, Makassar, Indonesia
⁴Hasanuddin University Hospital, Department of Physical Medicine and Rehabilitation, Makassar, Indonesia

**Introduction/Background**

Orofacial pain is a symptom marked by unpleasant sensation in face or/and oral cavity, it occurs unilaterally or bilaterally and related to various pathologies. Orofacial pain is frustrating for most of its patient and the recovery is relatively unsatisfying. It interferes with daily activities since its exacerbation closely associated with increase of activity intensity.¹ Corticosteroids, NSAIDs, carbamazepines, and acetaminophens regularly becomes the first line therapy for this symptom. The use of medication usually sustained for long period since ceasing medication might exacerbates the pain. This makes patient even more traumatic to taper the medication off. Adverse events that regularly reported after long use of these medications are dyspepsia and gastric ulcers².

**Material and Method**

Non-pharmacological approaches offer safer option for pain alleviation but large randomized control trial of these methods, to the best of our knowledge, is not yet available.³ The objective is to increase the pain threshold and to develop coping strategy in anticipating episodes of pain exacerbation.

**Results**

The therapeutic exercises focus in exercising the muscles in daily task pattern like chewing, swallowing, and grinning.⁴ Transcutaneous electrical stimulations (TENS) mask pain stimulation thus increase pain threshold.⁵ Recent studies have support the effectiveness of low-level laser therapy (LLLT) in treating musculoskeletal conditions, it has been proven to enhance cellular healing.⁶ Myobiofeedback exercise also has been proven in trials to be effective in treating muscular chronic pain by reeducating contraction and relaxation phase of facial muscle.⁷ Kinésiotaping is relatively simple method to relieve the pain temporarily despite its evidence based medicine is insufficient.

**Conclusion**
Various rehabilitation methods are available for management of Orofacial yet lack of strong evidence suggesting research on this field is still highly on demand. Collaboration with other health professionals like dentists or plastic surgeon would assist orofacial rehabilitation to emerge in clinical implementation.

LOW-DOSE TRANSDERMAL BUPRENORPHINE PATCHES FOR BENIGN CHRONIC PAIN: A NOVEL EXPERIENCE. INDISA CLINIC, SANTIAGO, CHILE

P. Ritter¹, L. Gambini², L. Berna³

¹Physiatrist, Clínica Indisa, Santiago, Chile
²Physiatrist- head of physical medicine and rehabilitation service, Clínica Indisa, Santiago, Chile
³Physiatrist, Teletón Institute, Valparaiso, Chile

Introduction/Background

Objective: To describe both demographic and clinical adults patients profiles who received low-dose transdermal buprenorphine patch prescription by a Physiatrist.

Material and Method

Observational, descriptive study. Retrospective data from medical records of adults who were admitted as outpatients from December 2016 to March 2017. An Excel spreadsheet was made, and statistic (central tendency, frequency) was measured. Inclusion criteria were Presence of any painful benign locomotor system disease VAS 7 or more (Visual Analogue Scale); absence of renal and/or hepatic failure; nociceptive pain; treatment started before any rehabilitation therapy prescribed; naïve to strong opioids and patients who used to forget oral analgesic intake.

Results

Eighteen adults patients were analysed, 77% female. Mean age 67 (range 33-85 year-old). Buprenorphine average time use: 82.3 days. 50% received 5 mcg weekly, 27% 10 mcg/weekly and 23%, 20 mcg/weekly. Two cases had adverse event (localized and painful allergic rash), needing medication withdraw. Twelve patients reported pain relief more or equal to 50%, and 4 less or equal to 40%, considered clinically significant.

Conclusion

There were patients with severe benign chronic pain who would be benefit with low-dose transdermal buprenorphine patches, prior to rehabilitation therapy onset, to control nociceptive pain.

Watsu as a Coadjuvant Therapeutic Method in Benign Chronic Pain

A.M. Jacob¹, P. Ritter², L. Gambini³, L. Berna⁴

¹Physiotherapist, Clínica Indisa, Santiago, Chile
²Physiatrist, Clínica Indisa, Santiago, Chile
³Physiatrist- head of physical medicine and rehabilitation service, Clínica Indisa, Santiago, Chile
⁴Physiatrist, Teletón Institute, Valparaíso, Chile

Introduction/Background

Watsu is an aquatic therapy which combines the use of heated pool with passive mobilization plus therapeutic massage Shiatsu-like, performed by the therapist and where the patient has a “no-action” state. In Chile was introduced in 2002 and performed at Indisa Clinic since 2008. Objective: To describe diagnosis profile and Watsu outcomes, applied it to adult patients with benign painful locomotor disease.

Material and Method

Observational descriptive study. Retrospective revision of patient’s clinical records, from patients who complete Watsu program, between May 2016, to Juny 2017. Excel spreadsheet confection and frequency measure. A numeric analogue scale for pain relief, 0 to 10. Data with pain relief, therapy satisfaction (dichotomy question) and presence of any nocturnal sleep effect were collected.

Results

A total of 29 adult patients were admitted, who had locomotor diseases as follows: Fibromyalgia 34.4%, Spine disease 31%, miscellaneous 34.4%. 93% of total declared been satisfied with therapy, el 100% had pain reduction more or equal than 70%, measured with numeric scale; however, duration of effect is unknown. A 69% of patients got better nocturnal sleep.

Conclusion

Watsu constitutes a therapeutic tool that could be useful at a Physical and Rehabilitation Medicine Service, to achieve a deep relaxation and sleep quality improvement, which it could be associate as coadjuvant in pain relief with other therapeutic modalities.

PREVALENCE OF MUSCULOSKELETAL SYMPTOMS AMONG FEMALE READYMADE GARMENT WORKERS IN DHAKA CITY

E. Ehsanul Haque Khan¹
¹Shaheed Suhrawardi Medical College, physical medicine and rehabilitation, Dhaka, Bangladesh

Introduction/Background

The Prime objectives of this cross-sectional descriptive study were to identify the prevalence of musculoskeletal symptoms and associated factors among female readymade garment workers in Dhaka.

Material and Method

This cross-sectional descriptive study used multistage sampling techniques to select 400 workers from four garment factories among 100 medium-size factories. Data were collected from the female workers by direct interviews and rapid upper limb assessment scale (RULA) were also used during collection of data.

Results

The response rate was 100% and all the respondents were female. Ninety-two percent (95% CI=90.0–94.0) of the workers reported musculoskeletal symptoms in at least one body region in the previous 12 weeks. The neck, shoulder and lower back were the most affected body regions. In addition, the RULA data showed that 81.2% of the workers’ postures were rated as action level 3, indicating that investigation and change were required soon, and that 7.5% their postures were rated as action level 4, indicating that investigation and change were required immediately.

Conclusion

Female garment workers of Dhaka, Bangladesh reported a high prevalence of musculoskeletal symptoms in upper body regions, and their workplaces were rated as high risk ergonomically.
USE OF NON-PHARMACOLOGICAL MEASURES FOR PAIN RELIEF DURING LABOUR
AND ITS RELATIONSHIP WITH LACERATIONS

A. Báez Suárez¹, E. Martín Castillo¹, J. García Andújar¹, J.Á. García Hernández¹, Q.M. María P. ¹, J.F. Loro Ferrer¹
¹University of Las Palmas de Gran Canaria, Medical and Surgical Sciences, Las Palmas de Gran Canaria, Spain

Introduction/Background

Epidural analgesia is the most efficient method for pain relief in labour and it has become very popular in modern obstetric practice. Investigators suggested that epidural analgesia increases the risk of midpelvic procedures and leads to a higher rate of operative vaginal deliveries, which contribute to increase the risk of neonatal and maternal postpartum morbidity. Furthermore, women undergoing epidural analgesia demonstrated a prolonged second stage of labour, a higher rate of episiotomy and an increased use of oxytocin.

There are several non-pharmacological analgesic methods to relieve pain during labour, that is among the transcutaneous electrical nerve stimulation (TENS). TENS is a low frequency electrotherapy technique, analgesic type, generally used in musculoskeletal pathology, but it has also come to be used as an alternative treatment during labour.

The aim of this study was to determine if TENS could increase the risk of obstetric lacerations during spontaneous vaginal delivery.

Material and Method

We conducted a randomized, double-blind, placebo-controlled trial. Participants were randomly assigned to three groups: active TENS 1, active TENS 2 and placebo TENS.

We enrolled 63 women Department of Gynaecology Service of CHUIMI of Las Palmas de Gran Canaria, Spain. The data of a visual analogue scale and a satisfaction questionnaire were also collected.

Results

A total of 63 women (21 per group) participated in the study. We obtained an improvement with clinically significant pain relief results at several stages was active TENS groups. We found an 87% of superficial vaginal tears, which would be solved by nurses and 12.7% of lacerations grade II-III. There were not differences between the groups with or without active TENS. There were no side effects.
Conclusion

Transcutaneous electrical nerve stimulation is a safe, cheap and useful treatment for pain relief during labour and it does not increase the risk of obstetric lacerations during spontaneous vaginal delivery.

STUDY OVER PHONOPHORESIS WITH CAPSAICIN IN HIP OSTEOARTHRITIS.

B. Simona

University of Oradea, Faculty of medicine, oradea, Romania

Introduction/Background

There are numerous methods of administering drugs to the body, both passive and active.

A recent review of the literature on phonophoresis reports that 75% of the studies reviewed reported positive effects,

ultrasound energy with drugs like gel or cream can travel through body tissue.

Capsaicin was the active ingredient in hot chilli peppers has selection actions on unmyelinated C fibres and thinly

myelinated A primary sensory neurones.

Material and Method

We underwent an observational prospective study, to porpose measurement of phonoporesis with capsaicin

on pain of the hip, in comparison with phonoporesis with ketoprofen applications.

The study included 60 patients aged 45 years and over with clinical and radiological osteoarthritis of hip in

according to ACR criterias. All the patients were included in the standard therapy program (drugs and rehabilitation)

over a period of 10 days.

Group A – 30 patients was taken phonoporesis with capsaicin and Group B – 30 patients was taken phonoporesis with

ketoprofen, both intensity was 0.6 W/cm² on the knee, 6 minutes every day.

Results
In group A patients presented a significant improvement of pain according VAS scale, on the other group B who present an insignificant improvement of pain for the short time.

**Conclusion**

We can consider phonoporesis with capsaicin a significant method of therapy in hip osteoarthritis with an important benefit towards long term pain relief for the patient.

THE INHERENT ROLE OF THE MULTIDISCIPLINARY PALLIATIVE CARE TEAM ON PAIN MANAGEMENT: A CRITICAL REVIEW

I. Amorim¹, S. Rego², G. Pires¹, S. Proeça¹, F. Correia¹

¹CMRA, Serviço de Reabilitação de Adultos, Lisboa, Portugal
²Centro Hospitalar Universitário do Algarve, Serviço de Medicina Física e de Reabilitação, Faro, Portugal

Introduction/Background

Cancer pain and palliative care (PC) are recognized as significant international health issues. Treatment of pain and rehabilitation programs in PC are challenging. Rehabilitation is the process that helps a person to reach physical, psychologic, social and educational potential with physiologic, anatomic impairment, desires and life ambitions. Rehabilitation improves patients physical function, independence and pain management to improve quality of life and patients’ dignity.

Material and Method

Update on the role of rehabilitation in PC by detailed view of rehabilitation treatment methods and their evidence for application into PC conditions. Databases of Cochrane Library, Google Scholar and Pubmed were search from January 2005-December 2016.

Results

There is few evidence that rehabilitation can impact function and pain management in PC. However, experience suggests that physical modalities should be applied early to minimize the generalized deconditioning and aid in the pain management, decreasing the need for pain medications. Physical modalities can be applied by health care providers. Passive, active, and active-assisted motion exercises and gentle strengthening exercises can aid in the maintenance of strength and joint range of motion. The prescription of assistive devices, and the teaching of compensatory techniques for mobility can aid in ambulation. There is also evidence that immune function may be improved by moderate exercise.

Conclusion

A rehabilitation team has the ability to integrate physical aspects of treatment in a biopsychosocial model of pain into a comprehensive rehabilitation program for cancer patients. More research should focus on the role of rehabilitation and defining appropriate interventions.

THE EFFECT OF CHINESE NEEDLE ELECTRO ACUPUNCTURE IN CHRONIC LOW BACK PAIN
A. Raza¹, T. Khalil²
¹CMH Malir, Rehabilitation Medicine Department, karachi, Pakistan
²National University of Medical Sciences .NUMS Rawapindi Pakistan,
Medicine & Allied Department, Rawalpindi, Pakistan

Introduction/Background

Chinese needle electro acupuncture (EA) is complement alternative medicine pain relieving procedure for ages in chronic low back pain (CLBP). It is a fairly safe procedure. Evidence based medicine needs to add it as treatment modality in modern medicine. Various studies are recommending use of needle EA in CLBP. It is widely used these days in japan, Korea, Asian countries, Europe and Australia as a pain intervention in CLBP. This study aims to see relief of CLBP in 24 hours and at 4 weeks of intervention.

Material and Method

This is a quasi experimental study. Patients with nonspecific CLBP of more than 3 months’ duration, both genders all ages were recruited at outpatient rehabilitation department of Rehabilitation Department of Karachi Institute of Medical Sciences Malir Karachi Pakistan. 20 patients had series of needle placements using Chinese huanqiu brand needles with 0.3x 25 mm dimensions and using WQ 6 F electronic acupunctoscope for stimulating Chinese Acupoints in back and legs using varying intensity of electric current. Numeric Rating scale(NRS) of pain was used to measure pain relief in 24 hours and at 4 weeks follow up. Statistical analysis is done using statistical package for social sciences version 25.

Results

Total no of patients (n=20) including 14 males & 6 females. Mean age is 27.8+ 1.8 years. Mean duration of pain is 2.9+ 0.5 years. The difference between pre-intervention mean NRS score (7.45) and post intervention mean NRS score immediately post intervention (3.30), at 24hrs (3.80) and at 4 weeks (3.85) is statistically significant (p-value <0.001). No side effects of the procedure were noticed in 24 hours and after 4 weeks.

Conclusion

Needle EA showed significant pain relief in CLBP patients in 24 hours and after 4 weeks.

AN EXPERIMENTAL STUDY TO ASSESS THE EFFECTIVENESS OF TRANSDERMAL ANESTHETIC CREAM ON PAIN RESPONSE IN CHILDREN DURING VENIPUNCTURE IN CHILD HEALTH CARE AREAS
A. Alphonsa¹, M. Cheeda²
¹Christian Medical College, Physical Medicine and Rehabilitation+, Ludhiana, India
²Christian Medical College, Nursing, Ludhiana, India

Introduction/Background

Pain is a difficult concept for a child to communicate. Venipuncture is commonly seen as one of the most painful and frequent performed invasive procedures by nurses and is a major source of concern for children and their caretakers.

Objectives of the study - to assess the pain response in control group during venipuncture; to assess the effectiveness of transdermal anesthetic cream upon pain response during venipuncture in experimental group; to compare the pain response during venipuncture between experimental group and control group; to ascertain the relationship of effectiveness of transdermal anesthetic cream with the selected variables such as age, gender, size of cannula, allergic reaction to cream and previous experience to Eutectic mixture of local anesthetic (EMLA) Cream.

Material and Method

An experimental research approach with posttest only design was used to achieve the objectives of study. The sample size of 60 children were selected using consecutive sampling technique. FLACC Scale, standardized tool was selected after extensive review of literature and expert’s opinion. Pilot study was conducted on 1/10 of the sample from 3 to 8 years of age. The final study was conducted in pediatric Medicine and Surgical Ward, Pediatrics Medicine and Surgical OPD of Christian Medical College and Hospital, Ludhiana, Punjab.

Results

The data analysis was done using descriptive and inferential statistics. The findings of the study revealed that maximum Children in control group had obtained highest mean pain score (8.8) followed by those in experimental group (3.7). Difference in mean pain was analyzed with 't' test.

Conclusion

The findings of the study indicate that transdermal anesthetic cream is effective in pain reduction in children undergoing venipuncture. It was found that children in the experimental group experiences less pain than children in the control group. Now it is a protocol in Christian Medical College and Hospital, Ludhiana.

“WHITE FLAGS” IN CHRONIC BACK AND NECK PAIN – THE SOCIO-CULTURAL ASPECT
T.U. Schreiber¹, C. Winkelmann²
¹Reha Rheinfelden, Curativa - Das ambulante Zentrum, Rheinfelden, Switzerland
²Duale Hochschule Baden-Württemberg Heidenheim,
Studienzentrum Gesundheit - Interprofessionelle Gesundheitsversorgung, Heidenheim,
Germany

Introduction/Background

Persistent chronic pain, especially back and neck pain, represent a major medical and health economic problem. In the assessment of the individual pain situation, the classification of various factors (flags) has become established and clinically proven.

Material and Method

Structural biomechanical factors are classified as “red flags”, indicating potential serious diseases which require immediate intervention. Psychological or behavioral factors are summarized as „yellow flags“. Recently it was proposed to classify psychiatric and mental illness as “orange flags”. Both conditions are important for planning adequate therapies or rehabilitation, as well as for decisions to prognoses and tailored reintegration programs. An extension of the flag model was achieved by naming personal factors at workplace as “blue flags”, and “black flags“, if there additionally, system obstacles exist, that restrict return to work.

Results

All these groups do not take into account some other important reasons for unsuccessful rehabilitation or failed reintegration. In these refractory cases, patients sometimes show a special subjective understanding of illness that cannot be treated by either psychological interventions or behavioral therapy. These include convictions that arise, for example, from cultural socialization, religious education or spiritual experience and rarely correspond to the views of “Western Medicine”. Since these individual illness conceptions are ideologically based, they should be classified in an additional group called "white flags". The advantages of categorizing socio-cultural aspects separately from the other flags are: avoidance of unnecessary treatments including surgery and prevention of iatrogenisation or litigation.

Conclusion

For medical professions it is important to recognize, that only health inabilities are taken into account for insurance compensation and not individual socio-cultural circumstances or health beliefs. In the future, the classification of “white flags” could help to assess persistent pain conditions correctly and eliminate reservations and misunderstandings with an intercultural approach.

Introduction/Background

The carpal tunnel syndrome (CTS) is the compressive neuropathy most common of the upper limb and with neurophysiological studies it is calculated between 15 to 20%. It is produced by compression of medium nerve in the carpal tunnel. This compression can occur due to well-identified causes, although most cases are idiopathic.

Material and Method

The main purpose of this study is to describe our technique that we used to treat patients with CTS, using a nerve block technique with ultrasound guidance. Patients were treated with perineural injection of 1 mL of Triamcinolone and 2 mL of Bupivacaine. The patients were reviewed at one and two months after procedure.

An ultrasound was used with a linear transducer with high frequency of 10-15Mhz to identify the nerve in the proximal palmar fold, placing the focus at 1 cm with a depth of 2-3 cm. The medium nerve is the first elliptical tubular structure well differentiated under the flexor retinaculum. The median nerve passes just below and lateral to the tendon of palmaris longus and the best form to identify the nerve is to localize it in the forearm, between the superficial flexor and deep flexor digitorum and follow it distal to the wrist. Then ask the patient to flex the third finger to differentiate the flexor tendons from the medium nerve. The place of infiltration is performed on the ulnar side to dissect the nerve.

Results

Three months after procedure the patients presented total reduction of pain and loss of paresthesia. None patient felt pain during the needle injection and no one required a second infiltration.

Conclusion
The procedure with corticoid (neuritis) decrease the inflammation, the compressive phenomena of the nerve and the anesthetic block of the nerve conduction with the improve the symptoms. We are making an action protocol to establish the optimal treatment.

**Keywords**

carpal tunnel syndrome; medium nerve block; infiltration

Introduction/Background

The evaluation of pain in chronic musculoskeletal conditions is challenging. The relationships between patient self-reports and various operator determined (OD) measurements are still not fully understood. This study explores the relationship between commonly employed self-
reported and OD pain measures with clinical musculoskeletal findings in patients presenting with chronic myofascial pain.

**Material and Method**

Thirty-one participants (19 women) who met criteria for chronic myofascial pain affecting the neck region were recruited. All underwent a standard clinical history and physical examination to identify myofascial trigger points (MTrPs). Pain measures included: Brief Pain Inventory (BPI), Widespread Pain Index (WPI), Pain Pressure Threshold (PPT), and Quantitative Sensory Testing using standardized weighted pinpricks to determine Windup Ratio (WUR). Each participant was also examined for hypermobility using a combined Beighton-Brighton score. Scores ≥8 indicate a high or severe level of hypermobility syndrome. Widespread pain (WSP) was assigned if the WPI ≥ 6.

**Results**

Clinical descriptive variables are presented in Table 1. Other results are summarized in Table 2. A total of 8 patients (26%) presented with WSP. Compared to those with only regional neck pain, those with WSP had higher average pain scores (BPI) (4.81±1.81/10 vs. 3.28±1.58/10; p<0.03), had lower minimum PPT (4.35±2.93lb/in² vs. 7.46±3.40lb/in²; p<0.03), were slightly more likely to have windup (75% vs. 56%), were more likely to have 2+ active MTrPs (62.5% vs. 17%), and had a higher combined score for severity of hypermobility syndrome (8.29±3.3/19 vs. 4.62±2.89/19; p<0.01).

**Conclusion**

People with WSP have a higher level of average pain, worst pain, and lower PPTs. They are also more likely to be classified as hypermobile and have a high level of hypermobility. Our study results may be influenced by the small sample size.

KINESIOTAPING IMPROVES FUNCTION, PAIN AND MODULATES SOMATOSENSORY PROCESSING IN A SERIES OF SUBJECTS SUFFERING FROM CERVICAL DYSTONIA.

E. Andrenelli¹, M. Capecci¹, M.G. Ceravolo¹, P. Girlandà², F. Morgante³

¹Università Politecnica Marche, Department of Experimental and Clinical Medicine, Ancona, Italy
²Università di Messina, Dipartimento di Medicina Clinica e Sperimentale, Messina, Italy
³Università di Messina- St George’s University of London, Dipartimento di Medicina Clinica e Sperimentale- Neurosciences Research Centre- Molecular and Clinical Sciences Research Institute, Messina /London, Italy

Introduction/Background

Pain is a prominent and disabling symptom of cervical dystonia (CD). First-line treatment is botulinum toxin (BoNT) that ensures an overall duration of benefit of about 12 weeks; yet, individual response is variable with some patients experiencing an earlier wearing off of BoNT benefit with pain relapse. Ancillary treatments to prolong the effect of BoNT are an unmet need. The study is aimed at investigating the effects of KinesioTaping (KT) on pain and abnormal posture in CD patients with wearing-off of BoNT effects.

Material and Method

We enrolled 10 patients with idiopathic CD and pain and applied KT at least 3 months after BoNT injection. KT was applied according to inhibition technique over the hyper-contracted muscles (mono-or bilaterally) and kept for 5 days. Clinical evaluation included Toronto Western Spasmodic Torticollis Rating Scales (TWTSRS) (severity, disability and pain scales) and patient’s Clinical Global Impression (PCGI). Somatosensory processing was evaluated by tactile temporal discrimination threshold (TDT). Each subject was assessed before and at 5 days of KT.

Results

At 5 days of KT, there was a significant improvement of TWSTRS severity scale (p=0.008) and pain scores (severity: p=0.028, duration: p=0.043). Moreover, TDT significantly decreased in the most affected side (p=0.012), as patients improved their ability to process tactile somatosensory stimuli. CD patients with tremor had more severe dystonia and showed a greater improvement after KT in term of severity (TWTSRS total score p=0.03), global disability (p=0.03) and pain disability (p=0.025).

Conclusion
This pilot study demonstrates that KT can reduce pain and disability in patients with CD, especially if presenting with tremor, through enhancing the effect of BoNT toxin in the interval between consecutive injections.

EFFECT OF POWER TRAINING ON WALKING ABILITIES IN CHILDREN WITH CP WITH POOR GROSS MOTOR FUNCTION

*ISPR8-1632*

**EFFECT OF POWER TRAINING ON WALKING ABILITIES IN CHILDREN WITH CP WITH POOR GROSS MOTOR FUNCTION**

_S. Smati*1,2, M. Chevalier*2, M. Lemay1,2,3, L. Ballaz1,2,3

1UQAM, Departement of Physical Activity Sciences, Montreal, Canada
2Sainte-Justine UHC, research center, Montreal, Canada
3Groupe de recherche en activité physique adaptée GRAPA, Physical activity Sciences, Montreal, Canada

**Introduction/Background**

Power training (PT) has recently been raised as a promising training modality to improve functional abilities in children with cerebral palsy (CP). Nevertheless, its effect on walking ability in CP children with poor gross motor function has never been investigated. The present study aimed to evaluate the feasibility to implement PT in an adapted school and its effect on walking abilities.

**Material and Method**

Eleven children with CP (6-11 years old, Gross Motor Function Classification System (GMFCS) level I-V, including 9 children with GMFCS level III-V) were included. They were trained three times a week during 12 weeks. The training session took place during the 50-minute physical activity courses and included 20 minutes of high intensity exercise (i.e. running, fast walking with appropriated technical aids, including weight bearing walker), as well as a warm up and cool down period. Heart rate was monitored during three training sessions for each participant. A kinesiologist, a physical therapist, and the sport teacher, supervised the training sessions. Self-selected comfortable and fast walking speed, gait efficiency, as evaluated with the energy expenditure index (EEI), as well as running speed were assessed before and after the training period.

**Results**

Ten children completed the whole training period. Participants spent 19±7min and 6±7 min at an intensity superior to 40% and 60% of the heart rate reserve, respectively. The EEI was reduced after training (p= 0.01), resulting in a more efficient gait. Comfortable and fast walking speed also increased after training (p<0.05). Greater improvements were observed in children with higher GMFCS level.

**Conclusion**

PT is feasible in adapted school environment with children with CP with GMFCS level III-V. These data suggested that PT increases walking capacities. More studies are needed to assess the impact of PT in children with poor walking abilities.

IMPORTANCE OF SLEEP QUALITY IN CHRONIC PAIN
M. Parada Marcilla¹
¹FLENI, Neurology, Buenos Aires, Argentina

Introduction/Background

Poor sleep is a risk factor of a range of several adverse outcomes including disabling pain conditions.

The aim of this study is to analyze the Interdisciplinary Outpatient Pain Rehabilitation Program (IOPRP) treatment outcomes of chronic back and neck pain (spinal pain) with comorbidity sleep disorders.

Material and Method

We included 513 patients, between 1/8/14 and 28/2/16, in our IOPRP. A battery of self-reported questionnaires was completed at the beginning and end of a 16-session program; follow up visits were scheduled three months and one year after discharge. The presence of chronic spinal pain and sleep disturbances were recorded. All subjects were separated into two groups, chronic spinal pain with sleep disturbances group 11.30% (n=58), and chronic spinal pain without sleep disturbances group 88.7% (n=455). Visual analogue Scale (VAS) was used to evaluate pain, Insomnia Severity Index (ISI) to evaluate sleep quality, those with ISI > 8 underwent polysomniography to confirm sleep disturbances, and Short Form Survey (SF-36) to evaluate the quality of life. Both groups were treated with the IOPRP, working under international standards (Carf accreditation). Treatment included pain medication, physical and occupational therapy, cognitive and behavioral techniques for pain, sleep and stress management.

Results
Mean age was 55.76±0.44 years; 68.9% were females; IOPRP at baseline showed: Visual Analogue Scale (VAS) 5.66±0.07, poor quality of life (SF36) 41.9(Â±0.54), subclinical insomnia Insomnia Severity Index (ISI) 11.31Â±0.26. At the end of the program, statistically significant improvement (p<0.05) was observed on VAS, SF-36 (8 domains), and ISI.

**Conclusion**

The IOPRP, working under international standards, shows improvement in sleep associated with better physical functioning and pain reduction.

Interventions in the interaction between pain and sleep could potentially reduce pain and increase quality of life for patients suffering chronic pain. More studies are needed for a better understanding of this relation, pain-sleep disorders.

MULTILEVEL EVALUATION OF MOTION AND POSTURE PATTERNS IN LOWER EXTREMITY AND SPINE USING DYNAMIC ULTRASOUND

R. Bubnov¹, L. Kalika²

¹Clinical Hospital “Feofaniya”, Ultrasound, Kyiv, Ukraine

Introduction/Background

Evaluation of intrinsic/extrinsic muscles posture is a crucial task for physical therapy and pain treatment. Integrative assessment of pain case in order restoring postural imbalance has not been developed. The aim was to evaluate feasibility of motion posture analysis using M-mode ultrasound in foot, ankle, gluteus region, pelvis and spine.

Material and Method

We included 33 patients (both sexes, aged 17-52 y.o.) with clinically diagnosed leg, back pain with reduced motility in spine, pelvis and lower extremity levels. Another 20 patients (aged 18-53 y.o.) without pain and related complains on MSK disorders were controls. We conducted precise physical tests, extensive neuromuscular ultrasound using M-mode to evaluate muscle thickness, CSA and motion in intervertebral spaces, pelvis, intrinsic/extrinsic muscles in pelvis, gluteus region, foot and ankle.

Results

We obtained sufficient quality panoramic scans on leg using convex 5-8 MHz probe in 2 approaches to evaluate structure and motion of extrinsic/intrinsic muscles during one session. Thickness measurements of peroneal portion, plantar intrinsic foot muscles on the plantar surface in two transverse positions and one longitudinal using linear probe; contractility using M-mode tested in walking were most representative data. We evaluated different patterns of decreasing motility, contractility (muscle contracted/rested thickness) on M-mode during functional tests and walking at all levels in group 1 (p<0.05). We preliminary observed correlation of changes (muscle hypertrophy) in contralateral extrinsics/intrinsics muscles at same levels, due to biomechanical instability; trigger points detection corresponded to areas of hypomobility in 95% cases.

Conclusion

Extensive evaluation of motion posture in foot, ankle, and gluteus region, pelvis and spine is feasible and informative protocol. Further research needed for development US patterns, conducting comparative RCT using US, CAREN, static & dynamic balance tests, pressure analysis, etc.; and to develop educational programs).

TREATMENT OF HAND PAIN AND CARPAL TUNNEL SYNDROME USING PRECISE DRY NEEDLING UNDER ULTRASOUND GUIDANCE - RELEVANCE OF SUPINATOR SYNDROME

R. Bubnov¹, L. Kalika²

¹Clinical Hospital “Feofaniya”, Ultrasound, Kyiv, Ukraine

Introduction/Background

Myofascial pain is a widespread problem, considered as reliable cause of hand pain and carpal tunnel syndrome. Precise dry needling of muscle trigger points under ultrasound (US) guidance is proved and effective method for treatment pain in many anatomical sites.

Material and Method

We included 46 patients (32 females), avarage age was 37±6 years old, with symptoms of carpal tunnel syndrome (CTS) and pain in hand. The treatment approach by Bubnov [PMID:23088743] was applied that included ultrasound identification of myofascial trigger points, precise neuromuscular ultrasound; with following dry needling under US guidance using steel fine needles (28 gage) to elicit the local twitch response (LTR) effect verified on M-mode ultrasound. Visual analogue scale data (0 to 10) were measured before, immediately after and 24 hours after the intervention. A decrease in pain as measured by a VAS of 50% or more one week after treatment was considered as success.

Results

Active active trigger points were diagnosed in deep forearm muscles, mostly in supinator muscle, potnetially compressing radial nerve branches (posterior interosseous nerve, PIN entrapment near arcade of Frohse). Additional needling was conducted in thenar area (flexor pollicis brevis) and small muscles in hand and forearm when neccessary. In one session 1-3 needles were inserted. Retention of needles in muscles depended of accuracy of needle position in spastic area and LTR detection. All patients demonstrated decreasing pain as measured by a VAS of 90 %, the difference was significant in this group (p<0.01) and pain relief outcome after month observation.

Conclusion

Dry needling trigger points under ultrasound guidance is effective for treatment carpal tunnel syndrome and myofascial hand pain.

Background and Goals
Botulinum toxin was used as a local antispastic treatment in patients with stroke sequelae, trauma to the skull, spinal cord injury and corticobasal degeneration, among other pathologies. The botulinum toxin acts locally by blocking the release of acetylcholine, which results in temporary muscle paralysis. The end effect is temporary chemodenervation at the neuromuscular junction without causing any physical damage to the nerve structures. This work aims to show the secondary benefit obtained after local treatment of patients with different causes and degrees of spasticity. The objective is to show patients and the medical community in general, that botulinum toxin can be an alternative treatment of pain in patients with spasticity.

Material and Method
Method
Retrospective study of case reports (reality cohort). Data collection of 46 patients treated between 2012 and 2017 inclusive. Modified Ashworth Scale were used to measure the degree of spasticity, modified O’Brien Scale for subjective assessment of global improvement and Visual Analogical Scale for pain assessment (VAS). Post-application controls were performed at fifteen days, at the first month and at three months, using those scales at each medical visit.

Results
Results
Patients showed decreased spasm in at least 75% of cases, as expected. The most interesting at the time of the corresponding controls, were the secondary benefits to the decrease in tone, such as the decrease of pain, which in the cases of omalgia, pain in hand and foot, allowed a better quality of life: decrease of analgesic taking and improvement of nocturnal sleep, and to a lesser extent improved independence in activities of daily living.

Conclusion
Conclusions
The local antispastic treatment is beneficial in decreasing the tone of the infiltrated muscles and
in a secondary way it was observed that it generates symptomatic relief of pain and improves quality of life, aspects objectivable by VAS and O'Brien scale.

INTRODUCTION/BACKGROUND

Postoperative pain is often a major problem for functional recovery after elective orthopaedic surgery. There is evidence that following patient discharge, moderate to severe pain is commonly reported early on and later in the postoperative period. The aim of the study was to analyze analgesic prescription habits after discharging patients who went through surgery on an orthopaedic department in a low-resource setting. The second aim was to determine if there are any disparities in the prescribed analgesics, depending on whether the operation was elective or traumatic.

MATERIAL AND METHOD

We performed a retrospective study including all patients that underwent surgery at the Clinic for orthopaedic surgery and traumatology at the Clinical Center of Serbia, over a 6 month period. The study included 371 patients. We recorded demographic data, discharge diagnoses, types of surgery and pain medications prescribed for use at home.

RESULTS

87.9% patients received no analgesic prescriptions at all at hospital discharge. In the group of patients who have been recommended analgesics, there were optionally prescribed analgesics for 3.5%, whilst NSAIDs were prescribed for 8.6% patients. No patients received paracetamol or opioid analgesics. There were no statistically significant differences in prescribed analgesics depending on whether the operation was elective or posttraumatic.

CONCLUSION

The results of this study emphasize the need for further research, education and guidelines aimed at improvement of pain management in our setting. Better access to potent analgesic drugs, organization of acute pain teams and chronic pain clinics in order to provide effective pain relief is necessary. Ensuring such combined actions could improve pain management in a low-resource setting and make certain that patients do not suffer unnecessarily from unrelieved pain.

IMPORTANCE OF ACUTE EXAMINATION IN PARKINSON’S DISEASE EARLY DIAGNOSIS.

M. Pérez Bonilla, F. Luna Cabrera, D. Carretero Dios, F.J. Mayordomo Riera

Hospital Universitario Reina Sofía, Rehabilitation y Medicina Física, Córdoba, Spain

Introduction/Background

Parkinson’s disease (PD) is a long-term disorder of the central nervous system that mainly affects the motor system. Often presents with back pain, among other osteoarticular limitations, and may delay diagnosis. Our goal is to highlight the importance of early diagnosis for the treatment of the disease through the accurate examination of the patient.

Material and Method

This is an observational descriptive study that was carried out with two patients (65 and 68 aged women), who were referred to the Rehabilitation Unit from Primary Care for analgesic-resistant back pain, between September 2016 and October 2017. Patients were diagnosed by spondyloarthrosis and were treated with non-steroidal anti-inflammatory analgesics without any betterment. Both of them showed intense fatigue, inexpressive face, rigidity (at upper limbs level), movement disorders and walking difficulties. After filling a brief questionnaire about pain Numerical Visual Scale (NVS), depression and anxiety which included the standardized tests Beck’s Depression Inventory (BDI) and Fatigue Severity Scale (FSS), they started a rehabilitation program, together with neurologist visits for a farmacologic treatment.

Results

Both patients experienced a considerable amelioration after parallel treatments with neurological drugs and inclusion in rehabilitation exercises programs, followed by the daily exercise practice (for 6 months), with the subsequent improvement levels in BDI, FSS and a healthier lifestyle. NVS decrease from 5-7 to 2-4 pain score, BDI varied from 25-31 to 20-25 depression score, and FFS ranged from 56-61 to 20-25 fatigue score after the treatment.

Conclusion

The importance of an accurate clinical history as well as a properly examination is pointed out herein. Early sings cannot be ignored or mislead including factors such as age and several early symptoms. The rehabilitation exercises programs seems to slow down the progress of the disease, as we could observe in less rigidity and fatigue, with the consequent delay of orthesic material use.

WHAT IS THE EFFECT OF CLINICAL PILATES EXERCISES PLUS CONNECTIVE TISSUE MASSAGE ON DISEASE ACTIVITY, ANXIETY AND QUALITY OF LIFE IN INDIVIDUALS WITH FIBROMYALGIA?

E. Gur Kabul¹, B. Basakçı Calık², U. Karasu³

¹Pamukkale University, School of Physical Therapy and Rehabilitation, Kınıklı-Denizli, Turkey
²Pamukkale University, School of Physical Therapy and Rehabilitation, Denizli, Turkey
³Pamukkale University, School of Medicine- Department of Internal Medicine- Division of Rheumatology, Denizli, Turkey

Introduction/Background

Fibromyalgia treatment is difficult. The effects of combined interventions are being investigated in recent years in order to reduce fibromyalgia symptoms and improve functioning. This study aimed to compare the effectiveness of a clinical pilates exercises (CPE) with and without connective tissue massage (CTM) on disease activity, anxiety and quality of life in individuals with fibromyalgia.

Material and Method

Fourteen individuals (13 females, 1 males; mean age=53.64±8.57 years) with fibromyalgia were included in this study. Disease activity, anxiety and quality of life were assessed using Fibromyalgia Impact Questionnaire (FIQ), Beck Anxiety Inventory (BAI) and Short Form-36 (physical and mental subscales) respectively. Participants were randomly assigned to Group I (CPE+CTM; n=7) and Group II (CPE; n=7). All interventions were applied 3 days per week for 6 weeks by the same experienced physical therapist. CPE, in which individuals activated core muscles and maintain neutral spine, were lasting 60 minutes. CTM was started from lumbosacral region and continued lower thoracic, scapular, interscapular, and cervical regions, respectively. Wilcoxon and Mann Whitney U tests were used to analyze the data.

Results

After the interventions, the difference in FIQ and physical scores of SF-36 was significant in both groups, mental scores of SF-36 showed improvement only in group II (p<0.05) and there was no significant difference in BAI (p>0.05). When the groups were compared, there was no significant difference (p>0.05).

Conclusion

This study showed that CPE and CTM might be used to provide improvements in individuals with fibromyalgia. CPE showed more advantages than CTM and so we recommended physiotherapists to use CPE in the clinics to reduce the symptoms of fibromyalgia.

THE COMPARISON OF STRENGTHENING EXERCISE EFFICACY BETWEEN TENSION HEADACHE PLUS NECK PAIN AND CERVICOGENIC HEADACHE

M. Azimi¹, M. Abolhasani², S. Razeghi Jahromi³, M. Togha⁴

¹Sports Medicine Research center- Neuroscience Institute- Tehran University of Medical Sciences- Tehran- Iran, Sports and Exercise Medicine, Tehran, Iran
²Sport Medicine Research Center- Neuroscience Institute- Sina Hospital- Tehran University of Medical Sciences- Tehran- Iran, Sports and Exercise Medicine Department, Tehran, Iran
³Department of Clinical Nutrition and Dietetics- Faculty of Nutrition and Food Technology- Shahid Beheshti University of Medical Sciences- Tehran- Iran, Department of Clinical Nutrition and Dietetics, Tehran, Iran
⁴Headache department- Iranian Center of Neurological Research- Neuroscience Institute- Tehran University of Medical Sciences- Tehran- Iran, Headache department, Tehran, Iran

Introduction/Background

Tension type headache (TTH) is the most prevalent form of adult benign headache. TTH contribute to a large burden of disability. Cervicogenic headache (CH) is a recently validated type of headache. The aim of this study is the comparison of Strengthening Exercise efficacy between tension headache and cervicogenic headache.

Material and Method

In this study we enrolled 70 untrained patients in two groups. One group (n=35) had Tension headache plus Cervicogenic headache and other group had only Cervicogenic headache. Both groups received a training program consist of Isometric Strengthening exercise of neck muscles, strengthening of deep flexors of neck and shoulder girdle muscles, 3 times per week during 8 weeks. The intensity of headache was measured at the baseline and after intervention with VAS (Visual Analog Scale).

Results

Both groups had reduction of pain intensity at the end of study but As a result, exercise program reduced significantly the intensity of pain in tension headache plus cervicogenic headache group (2.5±1.3) as comparison with cervicogenic headache significantly. (0.86±1.3). (p=0.00)

Conclusion

Exercise may be an option for the treatment of tension and cervicogenic headache. According to this study isometric Strengthening exercises of neck muscles, strengthening of deep flexors and shoulder girdle muscles exercise can reduce intensity of pain in tension headache plus cervicogenic headache superior than cervicogenic headache alone. Further high quality
research is required to determine the effectiveness of different types of exercise in different types of headache.

Introduction/Background

Parkinson’s disease (PD) is a long-term disorder of the central nervous system that mainly affects the motor system. Often presents with back pain, among other osteoarticular limitations, and may delay diagnosis. Our goal is to establish the bases for a prospective study on the prevalence of back pain as a starting symptom in Parkinson’s Disease.

Material and Method

This is an preliminary study that was carried out with two patients (65 and 68 aged women), who were referred to the Rehabilitation Unit from Primary Care for analgesic-resistant back pain, between September 2016 and October 2017. Patients were diagnosed by spondyloarthrosis and were treated with non-steroidal anti-inflammatory analgesics without any betterment. Both of them showed intense fatigue, inexpressive face, rigidity (at upper limbs level), movement disorders and walking difficulties. After filling a brief questionnaire about pain Numerical Visual Scale (NVS), depression and anxiety which included the standardized tests Beck’s Depression Inventory (BDI) and Fatigue Severity Scale (FSS), they started a rehabilitation program, together with neurologist visits for a farmacoligic treatment.

Results

Both patients were diagnosed through a correct anamnesis and clinical exploration, improving at the level of fatigue and pain after 6 months of treatment with group rehabilitation exercises, presented: NVS decrease from 5-7 to 2-4 pain score, BDI varied from 25-31 to 20-25 depression score, and FFSS ranged from 56-61 to 20-25 fatigue score after the treatment.

Conclusion

It is essential to make a correct clinical history and exploration, not letting ourselves be carried away by first diagnostic impressions in view of age and initial symptomatology, we must always bear in mind the possible differential diagnoses. The group exercise program can help with maintenance and seems to slow down the progression of both stiffness and fatigue in these patients, also delaying the need for orthotic material, as the revised literature.

Background:

Technological advances in the domain of wearable rehabilitation medical technology holds promise to optimize delivery and efficiency of healthcare.

In no area of PRM is this more evident than in acute pain management. The combination of wearable technology with a “Digital Ingestion Tracking Program” (DITP) embedded within a pain pill may allow patients, caregivers as well as healthcare providers to track ingestion of pills through the web or a smartphone app. Monitoring of pill consumption compliance and adherence may be optimized.

Method:

This study will explore the DITP system and assess its clinical utility and applicability to rehabilitation medicine. A systematic review of the literature will be presented along with the illuminating case history of a PMR patient who's functional outcome was significantly impacted by the technology. Photos of DITP technology will be shared for didactic purposes.

Results:

While there are many advantages of DITP including fostering enhanced compliance, improved adherence, empowerment of patients; several disadvantages exist such as cost and potential privacy concerns.

Conclusions:

DITP can aide physiatrists in the daily management of pain patients by electronic verification of whether the patient has taken their prescribed pill and at what time. For patients on opioid medication, this is immensely important as compliance is a cornerstone of proper pain management. Enforcement and support of statutory safeguards can prevent improper diversion and abuse of pills. In an age of international concern over opioid abuse, DITP may offer an innovative strategy for enforcing proper use of pain medication in PRM.

RESEARCH ON THE SENSORY PREFERENCE STRATEGY OF BALANCE MAINTAINED  
D. Linru¹, Z. Jiejiao¹, X. Guohui¹  
¹HuaDong Hospital Affiliated to Fudan University, Shanghai 200040, China

Objective:
Explore the influence of cognitive-dual task on balance function and analyze the sensory strategy of balancemaintained.

Methods:
35 young people without dysfunction were selected and randomly divided into two groups: the control group and the cognitive task group. Assessed with the Modified CTSIB balance function on Neurocom balance manager, two weeks later, Testing control group again, while to dual-task group, on the basis of the Modified CTSIB and mental arithmetic cognitive task. To ensure balance function, The mean center of gravity (COG)sway velocity in both eyes open and eyes closed condition was measured and analyzed statistically.

Results:
There were significant differences between the EC condition when standing on form support and the comprehensive condition in the center of gravity sway velocity in the control group before and after experiment; EO condition when standing on form support and the comprehensive condition in the center of gravity sway velocity in the dual-task group before and after experiment and the same result compared to control group after experiment, while EC conditions showed no significant difference.

Conclusion:
1)After increasing cognitive tasks, youth balance function decline.2)Various trainings on Neurocom balance manager can improve the balance function.3)Calculation tasks eased the disequilibrium state when standing on form support with eyes closed.4)Two or more tasks when keeping balance, sensory preference strategy is used.

Keywords

With the rapid development of aging in China, most of the elderly suffer from falling. The balance ability deficit is the main reason for falling while there are many other factors, which include, muscle strength reduction, neuromuscular control deficit, proprioception and cognitive attention deficit. Falls cause serious adverse consequences and increases social and family burdens. Experts from China and abroad have developed guidelines for preventing falls in the elderly, they recommend fall intervention in sports training, medicine, vision, vitamin D, environment, education and other aspects, but the role of cognitive function is ignored. The innovative theory suggests that the cognitive factors can cause the abnormal posture and balance of the human body, supplemented by the evidence of cognitive prevention at home and abroad. The research team developed cognitive-balance dual-task training technology, targeted muscle training technology, and spatial location technology, then developed the standardized rehabilitation intervention strategies for the prevention of falls.

INVESTIGATION ON THE STATUS OF COMMUNITY-BASED REHABILITATION MEDICAL RESOURCES IN SHANGHAI

D. Jianwei¹, Z. Jiejiao¹, Y. Yin¹, L. Yong¹
¹Huadong Hospital Affiliated to Fudan University, Shanghai 200040, China

Abstract

Objective
To investigate the present status of the Shanghai community-based rehabilitation and figure out developmental strategies to elevate the abilities of community-based rehabilitation.

Methods
238 communities of health care were investigated through questionnaire survey.

Results
None-independent departments of rehabilitation medicine account for 55.88% of all communities. And 8.82% of communities have none rehabilitation services or have very limited rehabilitation capacities. 96.14% of communities was configured with several sets of physical therapy, exercise therapy and traditional therapy equipments. There are 677 doctors and 596 therapists served in rehabilitation departments in all communities. Only 1.77% of 677 doctors has the specialty education background of rehabilitation medicine.

Conclusion
The quality and level of rehabilitation services in communities of Shanghai has been significantly improved. However lackage of rehabilitation staff still is the key factor restricting the development of community-based rehabilitation in Shanghai.

Objective:

The purpose of this study is to investigate the acute effects of hamstring static stretching on kinematics and kinetics and surface EMG in female athletes during cutting, then discuss its influence on the factors associated with ACL injury.

Methods:

Twelve female athletes from Shanghai University of sport completed cutting task both before no stretching and hamstrings static stretching in two days. The 3D motion data, ground reaction forces and surface EMG date were recorded and analyzed during the cutting process. Paired T-test was applied to compare the statistical difference between no stretching and hamstring static stretching.

Results & Discussion:

(1) Compared with the no stretching, there were significant increases in the range of motion of hip in sagittal plane after hamstrings static stretching (p=0.041). Also, there were significant increases in the range of motion of knee in frontal plane (p=0.049). After stretching, the initial-contact knee angle significantly decreased (p=0.046) and the peak value of ankle varus significantly decreased (p=0.037) comparing with no stretching. These results indicates a negative affection on motion performance.

(2) Compared with no stretching, there was a significant differences in the timing of stance-phase peak vertical ground reaction force (p=0.032), peak vertical ground reaction force occurred later after being stretched. Besides, the exterior tibia shear force (ETSF) significantly decreased after being stretched (p=0.036). All this reveals that hamstring static stretching may potentially decrease the risk of ACL injury during cutting.

(3) Our results determined that the aEMG of biceps femoris during the initial stage of cutting significantly decreased after hamstring static stretching (p=0.033), that subjects were more dependent on hip muscles during initial stage of cutting.

Conclusions:
Hamstrings stretching not only affects the motion performance of cutting, but also potentially reduces the risk of ACL injury.

ATYPICAL PAINFUL MYOTONIA VARIENT OF MYOTONIA CONGENITA IN HISPANIC
MALE AND HIS FAMILY: A CASE REPORT

F. Tan\textsuperscript{1}, S. Biliciler\textsuperscript{2}
\textsuperscript{1}Baylor College of Medicine, Physical Medicine and Rehabilitation, Houston, USA
\textsuperscript{2}University Texas Health Science Center, Neurology- Section of Neuromuscular Medicine,
Houston, USA

Introduction/Background

A 29 year old Hispanic male complained of weakness, diffuse painful muscle cramps precipitated by cold temperatures since age 15. He is unable to sleep in air-conditioning because he awakens entirely paralyzed with exception of eye movement. Although he avoids exercise, he is very muscular. His symptoms are not brought on with stress. He previously lived in a small community in Central America where there was no air-conditioning before immigrating to the United States. His father, 6 male siblings, 2 male half siblings, one aunt and her child all have similar symptoms, but two sisters do not.

Material and Method

PHYSICAL EXAM: Sensation is intact to light touch. Motor strength is 5/5 in all limbs. There is muscle hypertrophy throughout the body including paraspinal musculature. He has the appearance of "Hercules". There is positive percussion myotonia. The patient cannot open his hand or eyes after squeezing tightly for 30 seconds. Reflexes are 1+ symmetric throughout.

TESTING: Laboratory chemistries were normal including K+, Na+, TSH. Motor and sensory NCS of upper and lower limbs were normal. EMG showed diffuse myotonic discharges in bilateral APB, gastrocnemius and orbicularis oris muscles. (EMG/NCS tables and waveforms from an AANEM accredited lab will be included in poster). The patient was referred to Neuromuscular Neurology Clinic.

Results

Neuromuscular Neurology Clinic diagnosed the patient with Myotonia Congenita. The patient was started on carbamazepine XR 200 mg per day then increased to twice per day. The patient had improvement and relief from cramping. Further testing of the family is being pursued.

Conclusion

This case reports the very rare "atypical painful myotonia" variant of myotonia congenita. Myotonia congenita has been reported in European, French Canadian, Japanese, and Arabic populations, but not in Hispanic patients. The differential diagnosis, inheritance, and rehabilitation strategies in this unusual case are presented.

WHAT ARE THE GENERAL LIFE HABITS OF FIRST-GRADE STUDENTS WHO HAVE JUST STARTED A HEALTH UNIVERSITY?

H. Yucel

Bezmialem Vakif University, Physiotherapy and Rehabilitation, Istanbul, Turkey

Introduction/Background

It is aimed to emphasize researches which increase awareness of students who study especially at health-related departments, revealing their general life habits.

Material and Method

All first-grade students studying at Health Faculties were included (n = 682). General life habits of them about health were questioned with a questionnaire. SPSS 16.v was used.

Results

The mean age of students was 21.07±1.28 (17-26) and as their average body mass index was 22.02±11.08, 76.5% were at healthy limits (Table).

The average cigarettes of smokers were 8 ± 0.9 per day and they had these habits for 2 ± 0.7 years. 298 (43.69%) of students did not play any sports, 23.5% of them had less than 1 hour a week, 28.2% had 1-3 hours and 20.0% had more than 4 hours of sports. The most frequently played sports was fitness (79, 11.58%), (Figure 1).

The average daily walking distance of students was 1 ± 0.3 km. The mean of television watching hours was 3±0.81 a day. The mean of computer using hours was 5 ±0.52 a day. Students were choosing sitting position the most when they study at home (516, 75.65%), Figure 2. Female students most frequently chose wearing sneakers (243, 45.25%).

Conclusion

This study is important because students could primarily raise their awareness first as being in health-related departments. The rate of not playing sports of students was high. This is because the number of hours of lessons are a lot and sports alternatives at university are not sufficient. Students could be informed about the importance of sports. The majority of students were not smoking; may be once they prefer health-related departments. They may be taught in school education programs to improve negative parameters above. When they arrive in the last class, this study could be repeated to see if there has been a change in their awareness.

CORRELATION OF DIAPHRAGMATIC ULTRASONOGRAPHY WITH VITAL LUNG CAPACITY

N. Nusdwinuringtyas1, F. Anestherita1, M.W. Sahruni1
1Cipto Mangunkusumo General Hospital, Physical Medicine and Rehabilitation, DKI Jakarta, Indonesia

Introduction/Background

Evaluation of diaphragm function as the important muscle for respiratory system is very crucial, more over in rehabilitation medicine field. Evaluating the diaphragmatic work usually needed expensive tools such as computed tomography, dynamic magnetic resonance imaging, and fluoroscopy. Evaluating diaphragm using ultrasonography had been proof easier to perform and less expensive, for large range of subject from healthy to critically ill patients in intensive care unit. In this study we want to evaluate if the thickness of diaphragm will correlate with the vital lung capacity.

Material and Method

This is a cross sectional study analytic. We performed evaluation of diaphragm using ultrasound in healthy adult subjects using high frequencies probe, in right anterior axillar line between intercostal 7-9. We measure the thicness of diaphragm during relax breathing and maximum inspiration in lying position. Subjects also done the spirometry evaluation. We analyzed data using spss with correlation test.

Results

We evaluate 26 healthy adult subjects, age range between 22-34 years old with mean age 28.38. Thickness of diaphragm was measure in milimeters, with the mean of thickness during maximum inspiration was 36.54mm, and the mean thickness during relax breathing was 16.12mm. Correlation between maximum inspiration thickness and vital capacity measured with pearson correlation was significant with p = 0.014

Conclusion

Ultra sonography of diaphragmatic work during respiration can be a usefull evaluation that easier to perform and less expensive than other methods to evaluate respiratory function. Further study is need to evaluate the use of sonography imaging of diaphragm in different cases and trough all range of ages.

Keywords

The impacts of various factors on bone mineral density (BMD) differ across diverse population. The aim of this study was to determine the relationship between BMD in the femoral neck (FN) and lumbar spine (LS) with some common clinical, demographic, and biochemical parameters in postmenopausal women.

**Material and Method**

In this cross-sectional case-control study, all postmenopausal women of the Amirkola Health and Ageing Project (AHAP) who performed bone densitometry were included. BMD at FN and LS was measured by DXA method. Data regarding clinical, demographic, and biochemical characteristics were provided. OP was diagnosed by the International Society for Clinical Densitometry criteria. Pearson correlation and multivariate regression analyses with simultaneous adjustment were performed to determine relationship.

**Results**

Five hundred thirty-seven women with mean age of 67.9±6.7 years and mean menopause duration (MD) of 15.8±5.1 years were studied. MD correlated negatively with FNBMD and LS-BMD g/cm² ($r=-0.405$, $p=0.001$ and $r=-0.217$, $p=0.001$). Body mass index (BMI) correlated positively with FN and LS-BMD g/cm² ($r=0.397$, $p=0.001$ and $r=0.311$, $p=0.001$). The association of MD with risk of FNOP was stronger than LS-OP. Obesity and metabolic syndrome (MS) and higher serum ferritin reduced the risk of OP at both LS and FN similarly, whereas the impacts of parity, prior fracture, high level of education, and physical activity were significantly different across BMD measurement sites.

**Conclusion**

The results of this study indicated a significant association between OP and MD, obesity, parity, MS, history of fracture, serum ferritin, level of education, and physical activity. However, the direction and the strength of association varied across BMD measurement sites.

MINIMUM TECHNICAL STANDARDS AND RECOMMENDATIONS FOR TRAUMATIC BRAIN INJURY SPECIALIST REHABILITATION TEAMS IN SUDDEN-ONSET DISASTERS (FOR DISASTER REHABILITATION COMMITTEE SPECIAL SESSION)
V. Vasudevan¹, B. Amatya¹, S. Chopra¹, N. Zhang¹, I. Astrakhantseva¹, F. Khan¹
¹Royal Melbourne Hospital, Rehabilitation Medicine, Melbourne, Australia

Introduction/Background

Sudden-onset disasters (SODs) result in increased number of survivors with complex and long-term disabling injuries, including traumatic brain injury (TBI) that warrants comprehensive specialist rehabilitation. This presentation highlights the minimum technical standards required for specialised TBI rehabilitation teams and their integration into WHO Emergency Medical Teams (EMTs) to facilitate comprehensive management of TBI survivors in disaster settings.

Material and Method

A team of medical rehabilitation physicians from the Royal Melbourne Hospital conducted a comprehensive review of literature for TBI management, based on the WHO core-guidelines for 'Minimum technical standards and recommendations for rehabilitation for EMTs'. These were endorsed by a specialist TBI expert panel in the Asia-Pacific region.

Results

Comprehensive rehabilitation programs improve functional outcomes and quality of life of TBI survivors. It is recommended that specialised TBI care teams need to be embedded into EMTs for disaster response and management for early diagnosis, management and social reintegration. This guidance documents the minimum standards for deployment of TBI specialist rehabilitation teams in the context of SODs, including: skill requirements, team configuration and profile, professional competencies for management of TBI and complications, list of required equipment and consumables, information management/dissemination.

Conclusion
TBI rehabilitation should commence from the early response phase in SODs by accredited rehabilitation professionals to minimise complications and disability. Integration of specialised TBI rehabilitation professionals into EMTs for disaster response will improve functional outcomes of survivors.

DEVELOPMENT AND PRELIMINARY PSYCHOMETRICS OF THE EXERCISE THERAPY BURDEN QUESTIONNAIRE FOR PATIENTS WITH CHRONIC CONDITIONS

W. Martin¹, S. Poireaud², C. Palazzo¹
¹Cochin Hospital, Physical Medicine and Rehabilitation department, Paris, France

Objective

Chronic diseases are the leading cause of mortality and disability worldwide. Exercise therapy has been found effective for mortality, disability and well-being in many chronic conditions. Burden of treatment may reduce patient compliance and treatment efficacy. We aimed to develop and validate a self-reporting questionnaire assessing the burden of exercise therapy for patients with chronic conditions.

Material and Method

We conducted semi-structured interviews with patients to develop items of the questionnaire. The dimensional structure of the questionnaire was assessed by principal component analysis. Construct validity of the instrument was assessed by exploring convergent validity with the Treatment Burden Questionnaire (TBQ) and divergent validity with pain, self-efficacy, treatment satisfaction and health state. Reliability was assessed with the Cronbach alpha coefficient, a test–retest method using the intraclass correlation coefficient (ICC) and Bland-Altman plotting.

Results

A preliminary list of items was developed from semi-structured interviews with 28 patients and reviewed by two expert physicians. Items obtained were reduced. Then, a sample of 163 patients was used to measure the psychometrics of the Exercise Therapy Burden Questionnaire (ETBQ), consisting of 10 items. Principal component analysis extracted one dimension. The Cronbach alpha was 0.86 [0.82-0.89]. Test–retest reliability (n=24 patients) was good, with ICC 0.93 [0.85-0.97], and Bland-Altman analysis did not reveal a systematic trend. The ETBQ showed expected convergent validity with the TBQ ($r_s=0.52$) and expected divergent validity with pain ($r_s=0.37$), self-efficacy ($r_s=-0.34$), treatment satisfaction ($r_s=-0.49$) and perceived health state ($r_s=-0.28$).

Conclusion
The ETBQ is the first questionnaire assessing exercise therapy burden in patients with chronic conditions. Its psychometric properties are promising.

ISPR8-0518
CAN SPINAL SCOLIOSIS BE A PREDICTOR OF REFRACTORY BENIGN PAROXYSMAL POSITIONAL VERTIGO (BPPV) IN CLINICAL PRACTICE? DIAGNOSIS AND MANAGEMENT: A CASE STUDY
J. Berke¹, I. Kedzierska¹
¹NYU Langone Health, RUSK Rehabilitation, New York, USA

Introduction/Background

BPPV is a common cause of dizziness, usually successfully treated with canalith repositioning treatments (CRT). Refractory and intractable BPPV can present secondary to morphological abnormalities, including stenosis and obturation of canals. MRI studies have showed morphological abnormalities in the inner ear of patients with intractable BPPV. Adolescents with idiopathic scoliosis showed 1) Left horizontal semicircular canal (SCC) and left posterior SCC were significantly further from midline, 2) displacement of the horizontal SCC from the midline resulted in more vertical alignment.

Material and Method

Case Description: 67-year-old male referred to physical therapy with diagnosis of central vertigo, history of scoliosis, and intermittent vertigo with generalized dizziness. Symptoms were provoked with bed mobility, computer use, and playing tennis. Vestibular examination was unremarkable except for atypical BPPV presentation. Right dix-hallpike produced right torsional up beating nystagmus (RTUBN), more pronounced in 30 degrees of cervical flexion. Roll testing produced RTUBN in right roll, which reversed into left torsional down beating nystagmus (LTDBN) during left roll, all reproducing symptoms. Differential diagnosis included posterior versus horizontal canal involvement due to observed nystagmus and symptom provocation. Functional gait assessment (FGA) indicated impaired dynamic balance: 24/30. Dizziness handicap inventory (DHI) showed mild self-reported disability: 16/100.

Intervention: Traditional CRTs were unsuccessful. Modified CRTs for R posterior canalithiasis with patient head in 30 degrees flexion resolved BPPV.

Results

Patient was asymptomatic during BPPV testing. There was only a faint RTUBN noted in the right roll test. FGA improved to 30/30 and DHI improved to 4/100. Patient reported no symptoms with all daily activities.

Conclusion

Studies have demonstrated associated anatomical anomalies in patients with scoliosis, which may contribute to refractory/intractable BPPV. Patients with intractable/refractory BPPV may
benefit from scoliosis screening and modification of head position during treatment, as successfully noted in this case. Further studies are suggested to determine if intractable BPPV is common in patients with scoliosis.

THE EFFECTS OF MESH ULTRAVIOLET RADIATION IN THE TREATMENT ON CERVICAL SPONDYLOSIS OF NERVE ROOT TYPE

Z. Haina¹, X. Guangmeng², Z. Jun¹
¹The Second Hospital of JiLin University, the Rehabilitation Department, Chang Chun, China
²The Second Hospital of JiLin University, General Surgery Department, Chang Chun, China

Introduction/Background

To observe the effects of mesh ultraviolet radiation in the treatment on cervical spondylosis of nerve root type.

Material and Method

60 patients with radicular cervical spondylosis were randomly divided into 2 groups, each group was treated with medium frequency pulse electric stimulation, ultra-short wave and McKenzie for 2 weeks. The observation group was treated with mesh ultraviolet radiation additionally. Before and after treatment, visual analogue scoring (VAS), Japanese Orthopaedic Association Scores (JOA) and clinical assessment scale for cervical spondylosis (CASCs) were used to evaluate the effects.

Results

After 2 weeks’ treatments, the VAS score decreased, the JOA and CASCs scores increased, and the observation group was better than the control group.

Conclusion

The mesh ultraviolet radiation has a good clinical effect on the treatment of radicular cervical spondylosis.

ISPR8-0570
REFORM AND PRACTICE OF TEACHING ASSESSMENT METHODS IN REHABILITATION MEDICINE
Z. Haina¹, X. Guangmeng², Z. Jun¹
¹The Second Hospital of JiLin University, the Rehabilitation Department, Chang Chun, China
²The Second Hospital of JiLin University, the General Surgery Department, Chang Chun, China

Introduction/Background

With medical development, teaching of rehabilitation medicine in China has advanced by leaps and bounds. But some traditional assessment methods are out of style which seriously hinder the development of students' innovation ability. Closed-book examination mode can't meet the needs of talent cultivation. Therefore reform of the methods of assessment is of great significance.

Material and Method

1. Reform the content of teaching and strengthen appraisal target: Classroom teaching is diversified. Case teaching method, activity teaching method, discussion teaching method and game teaching method are introduced into the teaching. In the practice students are divided into three groups: physical therapy group, occupational therapy group and ward group. interest-oriented teaching is also adopted. Wards and rehabilitation halls are opened on weekends or holidays. Students are encouraged to participate in clinical practice activities and in the study of teachers' research groups.

2. Reform assessment content and strengthen guidance of teaching: In practice through classroom assessment, inter-class homework assessment, course report, interclass internship, final examination etc, teachers innovate the assessment content boldly. The teaching orientation is enhance.

3. Reform assessment methods and enhance time effectiveness: Daily performance is strengthened and test scores are weakened to build a reasonable grade: attendance accounts for 10%, internship accounts for 10%, homework accounts for 5%, class answer accounts for 5%, course report accounts for 10%, final exam accounts for 60%. Assessment pressure is divide into daily learning.

Results

Diversified assessment methods can effectively improve students' awareness and skills of rehabilitation medicine and cultivate the students' ability to analyze and solve problems.

Conclusion
In order to cultivate high-quality medical talents that meet the requirements of modern medical development, we should attach importance to the construction of assessment system and infiltrate knowledge assessment into all aspects of teaching.

Introduction/Background

Objective. To access the utility of the responses of chronically ill patients to ad hoc legacy clinician-generated medical and social questionnaires used by many institutions in assessing mood, function, symptoms, and social support.

Material and Method

Design. The study population included 8,561 unique patients who generated a total of 12,659 hospital admissions over the period of the study. Items administered from 2004 to 2014 to outpatients in a large US Midwestern medical center who were hospitalized during the study period were identified. Exploratory factor analysis yielded item-to-factor loadings that were in turn used to identify meaningful clusters. Content-matter experts independently described the attributes of the clusters and rated the relevance, coverage, and clarity of the involved items. Factor scores were established with a confirmatory factor model. Validity based on inter-factor relationships and to assigned diagnostic codes was assessed.

Results

Results. Six factors addressing depression, pulmonary symptoms, musculoskeletal pain, living situation, mobility, and activities of daily living had reliabilities of >0.64 and were retained for further analysis. Content-matter experts rated the clarity each item and their relevance to their assigned domains. Factor inter-correlations provided evidence of convergent and discriminant validity, as did weak to moderate relationships (-.13 to .32) with the related diagnostic code assignments.

Conclusion

Conclusions: A legacy PRO instrument similar to those of many healthcare systems can be utilized to aggregate and characterize the validity of items that can be used to assess the mood, function, symptoms, and social support of chronically ill patients. However, the relationships are likely to be only weak to moderate.

INTERDISCIPLINARY COLLABORATION: 30 YEARS OF EXPERIENCE IN A NEURO-ORTHOPEDIC CONSULTATION AT RAYMOND POINCARÉ HOSPITAL

M. Salga¹, L. Gatin², A. Geffrier², F. Calé², A. Schnitzler³, F. Genêt³, P. Denormandie²

¹Raymond Poincaré Hospital, Physical Medicine and Rehabilitation, Garches, France
²Hôpital Raymond Poincaré- APHP- CIC-IT 1429, Department of Orthopedic Surgery, Garches, France
³Hôpital Raymond Poincaré- APHP- CIC-IT 1429, Department of Physical Medicine and Rehabilitation, Garches, France

Introduction/Background

Raymond Poincaré hospital is a national rehabilitation center for disabled patients with orthopedic issues. Physical Medicine and Rehabilitator physicians and orthopedic surgeons have developed interdisciplinary neuro-orthopedic approach for treatment of patients, with over 30 years of experience. The framework of diagnosis and therapeutic treatment outcome decision making considers patient concerns and expectation. An initial selection consultation is performed to identify complex cases requiring interdisciplinary expertise, as approximately 60% of new patient referrals (1000 patients annually) present with a surgical indication; otherwise patients are reoriented to different departments.

Material and Method

Patients are stratified into one of four consultation services, dedicated to conditions associated with: upper limb and geriatric /lower limb /cerebral palsy /heterotopic ossification, Charcot-Marie-Tooth, and poliomyelitis.

Results

Consultations are split into 4 phases. The primary phase is performed by a single physician and is dedicated to understand what the complaint is depending on the patients’ medical history. Phase 2 involves the entire interdisciplinary team, where there is time dedicated to clinical exam and an interactive discussion between doctors and patient and the best therapeutic options are debated. In the 3rd phase of consultation, the therapeutic options are presented to the patient with clear goals being established in a formal “agreement” with the patient. The 4th part of the consultation is done by one single doctor who stay with the patient to summarize, answer questions and precise the procedure. Discussion with patients is essential for identifying the unique pathological features of individual cases. The interdisciplinary team is comprised of experts in OS and PMR seniors and interns; who participate equally in the process.

Conclusion
The interaction between medico-surgical experts in this framework of consultation has developed a cooperative network of experts in PMR that spans French territory. Thus, diagnosis and consultation using this novel framework delivers ideal treatment strategies for the rehabilitation of patients.

DISASTER PREPAREDNESS IN REHABILITATION IN AN AREA AT HIGH RISK OF MEGA-EARTHQUAKES IN JAPAN

S. Katoh¹, N. Sato¹, M. Kurihara²
¹Tokushima University Hospital, Department of Rehabilitation Medicine, Tokushima, Japan
²Nagasaki Rehabilitation Hospital, Japan Disaster Rehabilitation Assistant Team, Nagasaki, Japan

Introduction/Background

At the Great East Japan Earthquake, more than 15,000 people perished, and another 3000 people were died of the disaster-related conditions.

Material and Method

Japan Disaster Rehabilitation Assistant Team (JRAT) was established after the earthquake by physiatrist and the allied professionals' organizations, and JRAT has been playing a pivotal role of the preparedness to decrease preventable deaths.

The main foci of the preparedness of JRAT are sustaining rehabilitation in hospitals and community, and prevention of inactivity or disuse of the suffered inhabitants. The principles of JRAT are officially authorized and not volunteer-basis.

Results

At the Kumamoto earthquakes in 2016, the JRAT started working on the next day of the first attack. A total of 2039 rehabilitation professionals worked in the area and another 895 worked for logistics in the next 10 weeks, and he manual of the disaster rehabilitation is revised.

Risk of the mega-earthquake of south-east Japan has been estimated as 70% in the next 30 years. Worst scenario in Tokushima with 777,000 inhabitants close to the epicenter, is expecting 46% of the inhabitants being in the shelters, and many disaster-related deaths. The local government appointed physiatrists and allied professionals as the coordinators, and they are reviewing condition of planned refugees’ shelters, and seeking collaboration with other health professionals.

Conclusion

The society which does not have comprehensive information of the disabled and rehabilitation would need to prepare for the massive natural disasters.

This is a part of ISPRM-ISCoS collaborative session: Supporting global disaster planning and response for sci in low resource settings

RELEVANCE OF URINE CYTO-BACTERIOLOGICAL EXAM IN A PRM WARD

P. Ribinik\textsuperscript{1}, A. Carrèr-Causeret\textsuperscript{2}, F. Charoenwong\textsuperscript{1}, R. Nouar\textsuperscript{1}, M. Salib\textsuperscript{1}, M.M. Hmida\textsuperscript{1}, M. Terki\textsuperscript{3}

\textsuperscript{1}centre hospitalier Emmanuel Rain, physical and rehabilitation medicine, Gonesse, France

\textsuperscript{2}centre hospitalier Emmanuel Rain, bacteriological ward, Gonesse, France

\textsuperscript{3}centre hospitalier Emmanuel Rain, bacteriological ward, Gonesse, France

Introduction/Background

to assess the indication of urine cyto-bacteriological exam (UCB) and to improve UCB prescription's relevance in a PRM ward.

Material and Method

229 patients entered the ward from 02/01/2017 to 11/30/2017. 80 UCB were performed. A retrospective analysis of performed UCB was achieved.

Results

43 urine specimen were sterile, 31 specimen have shown positive bacteriuria and leukocyturia, 6 specimen have bacteriuria without leukocyturia. Among the 80 urine samples, 66 analysis were justified as followed. 26 samples were prescribed for suspicion of clinical UTI and/ or pyelonephritis of which 17 were biologically confirmed and 14 patients were treated (1 is infected with multiresistant germ). 4 samples were prescribed for post treatment control and 12 samples for invasive exploration of the urinary tract (urodynamic, cystoscopy). 2 samples were taken before immunosuppressive therapy, 7 for increasing spasticity and 15 for infectious assessment after lower limb surgery, 10 urine analysis were clinically irrelevant and 4 were not registered in the patient record. 17 UTI are reported in 14 patients (6%). Of these, one was detected at the entrance in the ward and 16 were nosocomial.

Conclusion

UCB is indicated according to the following recommendations for clinical practice: clinical suspicion of urinary tract infection, invasive exploration of the urinary tract, control when no clinical improvement under treatment. The recommendations concerning patients at risk: introducing immunosuppressive treatment, fever after lower limb arthroplasty are not consensual. Although our indications are mostly in agreement with the recommendations, 17% of urine samples still remain unjustified. However, they were not followed by antibiotic prescription. Unjustified UCB increases care’s burden and has a cost for both wards (PRM and laboratory). Next assessment will be conducted six months after making aware of the PRM team.

THE USE OF IONTOPHORESIS IN LOCALIZED HYPERHIDROSIS: A CASE REPORT
A. Cordeiro¹, J. Martins¹, J. Silveira¹
¹Centro Hospitalar e Universitário de Coimbra,
Physical and Rehabilitation Medicine Department, Coimbra, Portugal

Introduction/Background

Hyperhidrosis is a medical condition characterized by abnormally increased sweating, which can deteriorate quality of life from a psychological, emotional, and social perspective. Hyperhidrosis can either be generalized, or localized to specific parts of the body.

It may be idiopathic or secondary to other diseases such as Blue Rubber Bleb Nevus syndrome, dermatologic manifestations of Glomus tumor, POEMS syndrome, or Goplan’s syndrome. It is also important to exclude secondary causes for hyperhidrosis, such as disorders of the thyroid or pituitary glands, diabetes mellitus, gout, menopause, drug abuse, and others. Clinical presentation with symmetry of excessive sweating in hyperhidrosis are most consistent with primary hyperhidrosis, caused maybe by overactivity of the sympathetic nervous system.

Material and Method

Results

We report a case of a female with 39 years old that presented bilateral plantopalmar hyperhidrosis for more than 3 years. She was followed in dermatology consultations and it was prescribed topical treatments that didn’t have any effect in the sweating complaints. After 3 years, she was also directed by her family physician to our consultation. She, then, started iontophoresis up to a maximum of 10 mA with tap water during 20 minutes, after which the polarity was inverted for more 20 minutes. Initially the treatment was repeated 3 times a week, but this was reduced according to the patients complaints. She is now doing maintenance treatments, once a month.

Conclusion

It is important to keep in mind that hyperhidrosis can manifest itself in more than one location, with different intensities in each of the patients, and that the response to treatments is also different from patient to patient. There is a wide range of nonsurgical and surgical treatments available for patients with focal hyperhidrosis. This case shows that tap water iontophoresis can be used as an effective and safe treatment for plantopalmar hyperhidrosis.

HEALTH - RELATED QUALITY OF LIFE IN MOTOR DISABILITY AFFECTING GREEK POPULATION

M. Micha1, K. Grigoriadis2, I. Efstathiou2, P. Zikos2
1University General Hospital "Attikon", Physical Medicine & Rehabilitation, Athens, Greece
2University General Hospital "Attikon", Physical Therapy, Athens, Greece

Introduction/Background

OBJECTIVE: The evaluation of health-related quality of life (HRQoL) in patients suffering from motor disability and the identification of associated factors.

Material and Method

MATERIALS AND METHODS: 142 patients with motor disability due to underlying neurological diseases (60.9% men) were examined in the outpatient department of Physical Medicine and Rehabilitation, University General Hospital "Attikon", Athens from 2015 till 2017. HRQoL was measured using SF-36 questionnaire, while for the evaluation of activities of daily living (ADL) Barthel index was used. Demographics and clinical characteristics of the patients were also recorded. Data was modeled using multiple linear regression analysis.

Results

RESULTS: The mean age of the patients was 54.7 ± 18.1 years with mean duration of disease 11.8 ± 14.1 years. 39.1% of them had suffered a stroke, 18.5% multiple sclerosis, 29.4% spinal cord injury and 13% peripheral neuropathies. The mean scores on SF-36 dimensions ranged from 23.4 (physical functioning) to 53 (role emotional). Multiple analysis revealed that more than two coexistent somatic diseases were independently associated with physical functioning (β=-11.8, SE=4.31), bodily pain (β=-28.5, SE=7.7) and general health dimensions (β=-32.4, SE=7.9). Furthermore, psychiatric disorders were associated with lower scores on physical functioning (β=-8.9, SE=2.2) and mental health (β=-12.3, SE=5.3). In addition, advanced age was associated with lower scores on social functioning dimension. Lower scores on bodily pain were found for patients with neuropathic pain and heterotopic ossifications. Being bedridden or wheelchair user were also independent predictors for most of the SF-36 dimensions. Patients with peripheral neuropathies had lower levels of HRQoL. Barthel index was negatively correlated with all SF-36 dimensions (p<0.001).

Conclusion
CONCLUSION: HRQoL was found substantially lower compared to Greek and foreign general population. The results are similar when compared to disease-specific populations of other countries. QoL was related to potentially modifiable factors that, if addressed by rehabilitation team specialists, may lead to QoL improvement.

STUDY OF DIAGNOSTIC VALUE OF ULTRASONOGRAPHY IN COMPARISON WITH ELECTRODIAGNOSIS IN RHEUMATOID ARTHRITIS PATIENTS SUFFERING CARPAL TUNNEL SYNDROME
M. Bayat¹, Z. Bagheri¹, S.A. Raeissadat¹, S.M. rayegani¹, A. ahmadzade¹, S. bagheri¹
¹Shahid Beheshti university of medical sciences, physical medicine and rehabilitation, Tehran, Iran

Introduction/Background

Increased cross-sectional area of the median nerve has been shown with Ultrasonography (US) in patients with carpal tunnel syndrome (CTS). The diagnostic value of cross sectional areas (CSA) of the median nerve in patients with rheumatoid arthritis (the group who suffers from Carpal Tunnel Syndrome and the group who do not) and a healthy group, was evaluated and compared in this study.

Material and Method

38 patients with RA were evaluated, which 17 cases had CTS clinically. 20 healthy patients compared as control group (in total 58 cases included in study). The CSA of median nerve at the entrance of the carpal tunnel was measured with ultrasonography. The result compared to Nerve Conduction Study (NCS).

Results

The mean cross-sectional area of median nerve in healthy people was 9.45±1.36 mm², in RA with CTS group:11.65±1.8 mm² and non CTS RA group:10.15± 1.6 mm². Area Under the Curve (AUC) for cross-sectional area of median nerve for right hand was 0.772, with the cutoff point of 10.46mm² and sensitivity of 78.5%, specificity of 67%, positive predictive value of 44% and negative predictive value of 90.62%. These findings for left hand were: AUC: 0.783, cutoff point: 10.7mm², sensitivity: 72.2%, specificity: 69.5%, PPV:36.3% and NPV: 91.4%. The results of cross-sectional area of median nerve and NCS were significantly correlated. (Pvalue<0.013).

Conclusion

Ultrasonographic measurement of cross-sectional area of median nerve is a sensitive test for detecting CTS and can be noticed more as a possible alternative way of CTS screening. The CSA of median nerve in patients with RA and CTS was significantly higher in comparison with patients with RA and no CTS. The CSA of median nerve in RA patients without CTS, was similar to healthy individuals.

HEMOPHILIC ARTHROPATHY IMPACT AND MEDICAL CARE IN A PMR SERVICE, BLIDA, A 6 YEAR RECOVERY

Z. Boukara¹, S. Benzaoui¹, C. Louazani¹, L. Charef¹, S. Arbaoui¹, L. Maouche¹, A.C. Nouar¹
¹University Saad Dahlad Blida, Medicine, Blida, Algeria

Introduction/Background

Untreated haemophilic haemarthrosis is the cause of joint destruction and a major educational and functional handicap. The therapeutic strategy is based on the prevention and well-managed treatment of haemarthroses.

Material and Method

Prospective observational study of 44 hemophiliacs, from 2011-2017. The evaluation is done before and after the treatment of haemarthrosis by: EVA pain, Gilbert and Petterson clinical score; radiological classification of Harnold Hildgarthner; hemophilia handicap score. The medical care is done after the supplementation in hemophilic factors, by the chemical synoviorthèse (hexatrione), and a training with the self-reeducation.

Results

Mean age 22.43 years, Standard deviation 13.42, 38 have hemophilia A and 6 have hemophilia B, 43% have or had an average level of schooling, 75% of whom have dropped out of school. 30% have a similar case in the family; 3 have HBS+ serology; 20% have a school handicap score of 3; 39% have a mobility handicap score of 3; EVA-Pain is 80 to 100 mm at the time of hemarthrosis, 46% have a Gilbert score, any joint between 16-18 and 25% have a Harnold score of 3. 17 are on prophylaxis; 20 received synoviorthesis, of which 60% received it at the knee. The improvement is significant in terms of pain, clinical and disability hemophilia after synoviorthesis at 3 weeks.

Conclusion

Haemophilic arthropathy in our series, remains relatively in late management, from which the need for an early management. The means of prophylaxis by synoviorthesis, remains the most effective.

Preventing hemophilic hemorrhagic accidents has become an evidence, synoviorthesis remains an effective preventive measure.

ISPR8-1646
PATIENT PERSPECTIVES ON IMPROVING PERSON-CENTRED REHABILITATION: IMPLEMENTATION AND EVALUATION OF A REHABILITATION SPECIFIC PATIENT EXPERIENCE SURVEY; FACILITATORS AND BARRIERS
A. Elmalik¹, I. Windle¹, F. Khan¹, B. Amatya¹
¹Royal Melbourne Hospital, Rehabilitation Medicine, Melbourne, Australia

Introduction/Background

Routinely patients receive surveys sent by the hospital on the care that they experienced and any comments they would like to make; however these comments may be very broad. This project is patient-centred rehabilitation study, which study the implementation and evaluation of a rehabilitation specific patient experience survey using the Modified Client-Centred Rehabilitation Questionnaire (CCRQ). Furthermore; a further follow up single phone call to the participants to ask them to name the most important four (4) facilitators and four (4) barriers from their for person-centred rehabilitation.

The aim of this study is to better characterise and determine barriers and facilitators to patient-centred experiences in inpatient rehabilitation, from a patient’s perspective

Material and Method

Study design: Cross-sectional telephone survey
Settings: Inpatient rehabilitation unit, Royal Melbourne Hospital
Participants: 100 consecutive admitted patients over six months.
Procedure: After an informed consent was obtained, participants will be provided with the background of the survey at the start of the phone call, once the background has been provided, and then they were required to answer two questions on how we could improve their person-centred experience.

Results

Participants were predominantly female (52%), mean age 68 ± 13 years. Almost one-half (43%) had neurological conditions and 41% musculoskeletal problems. Elderly patients were generally grateful and reluctant to provide negative comments, however younger were more particular about their dislikes forthcoming with their comments. Elder patients keen on interaction and socialising more; however younger group do treasure their privacy.

A few patients were disappointed by the lack of culturally appropriate dietary preparation, and room temperature control units.

The availability of free wireless internet was big bonus for younger patients

Conclusion
This short specific Questions and Answers survey has identified facilitators and barriers, which would essentially assist the rehabilitation multidisciplinary staff in delivering better and most needed patient-centred care

Introduction/Background

More than eight million Canadian caregivers provide 75% of the assistance needed for individuals of all ages with varying disabilities to remain living in the community. Being a caregiver can have psychological, health, professional, and financial consequences. Finding ways to reduce caregiver burden is critical. The objectives of this study are to identify: (1) aspects of caregiving that caregivers find most challenging and the areas in which they provide care, and (2) caregivers’ preferences and priorities for the development of innovative solutions within these areas of care.

Material and Method

Present or past caregivers of older adults were recruited across Canada. As part of a larger study using a mixed-method design, the Caregiver Assistive Technology Outcomes Measure (CATOM) was administered to measure the perceived impact of assistive technology on caregivers’ burden. Semi-structured interviews followed to explore caregivers’ challenges and needs.

Results
Sixty caregivers between the ages of 30 and 82 years old (63 ± 9 years) have been recruited. Results show that caregivers provide more assistance with instrumental activities of daily living but the most challenging are basic activities of daily living and mobility activities, namely toileting, washing and transfers. Assistive technologies are frequently used. Three categories of innovative solutions have been identified: devices (e.g., smart cane), programs (e.g., better accessed respite programs), and revised policies (e.g., changes to building codes).

Conclusion

Preliminary findings emphasize the need to support caregivers with the provision of assistance with basic activities of daily living. Potential innovative technological solutions, programs, and policies have been identified and are currently being presented to caregivers to validate them before further development.

ISPR8-1916
EFFECTIVENESS OF ABDOMINAL EXERCISE FOR NARROWING DIASTASIS RECTUS ABDOMINIS IN WOMEN: SYSTEMATIC REVIEW AND META-ANALYSIS
Y. Yokoi¹, K. Morishita¹, A. Morii²
¹Josai International University, Physical Therapy, Togane, Japan
²Hyogo University of Health Sciences, Physical Therapy, Kobe, Japan

Introduction/Background

Diastasis rectus abdominis (DRA) is defined as abnormal separation of the rectus abdominis muscles (Venes et al., 2005), causing dysfunction in the linea alba by increasing the width and losing the integrity. Although it could be treated by abdominoplasty, this review aimed to clarify whether non-surgical treatment is effective in reducing the inter-recti distance (IRD) in women with DRA.

Material and Method

MEDLINE, EMBASE, the Cochrane Library, PEDro, CINAHL, and Web of Science were systematically searched by two independent reviewers for studies published from earliest till 31st January 2018 with search terms relating to the condition (DRA) and intervention (conservative treatment). The same reviewers also independently assessed the methodological quality by using the Down and Black checklist for both randomized and non-randomized studies. Meta-analysis using either a fixed effects model or a random effects model was conducted to calculate mean difference (MD) and 95% confidence intervals (CI) where appropriate.

Results

Of eight methodologically fine to good studies that were eligible for inclusion, three reported the effect of certain period of exercise, mainly targeted abdominal strengthening during the perinatal period, on reducing the IRD, and five reported the immediate effect of curl-up and isolated transverse abdominis (Tr.A) activation on the IRD. The results of meta-analysis showed that both regular abdominal exercise and a single curl-up significantly narrowed the IRD (MD=-8.97; 95%CI=-14.59, -3.34; I²=91% and MD=3.68; 95%CI=2.67, 4.69; I²=0%, respectively), while a single isolated activation of Tr.A slightly increased the IRD.

Conclusion

This review indicated that the IRD in women with DRA is narrowed by exercising the superficial abdominal muscles. However, since the function of linea alba, such as transferring the force through the trunk, might be improved by stretching or tensing it up rather than only reducing the width (Lee et al., 2016), the results of this review need to be treated with consideration.

DYSPHAGIA LIMIT AS DETECTION TEST OF SWALLOWING DISORDER
S. Castellar\textsuperscript{1}, R. Valenzuela\textsuperscript{1}, J. Diaz\textsuperscript{1}, F. Ortiz\textsuperscript{1}, E. Ruiz\textsuperscript{1}, C. Mendoza\textsuperscript{1}, N. Muñoz\textsuperscript{1}, C. Hoyos\textsuperscript{1}
\textsuperscript{1}Universidad Nacional de Colombia, Medicina Fisica y Rehabilitacion, Bogota DC, Colombia

Introduction/Background

In the context of ICF, swallowing is defined as the function of passing food and beverages through oral cavity, pharinx, esophagus and stomach at a proper timing and rate. Dysphagia makes reference to a swallowing disorder.

Swallowing function’s evaluation includes quick screening tools to detect dysphagia, a focused physical examination and instrumental tests where necessary.

Objective: To establish the usefulness of dysphagia limit EMG test in a cohort with swallowing disorders

Material and Method

32 healthy individuals and 32 patients with some degree of swallowing disorder detected by EAT 10 self administered questionnaire using colombian spanish validated and translated versión.

As quantitative and non invasive method a dysphagia limit test was used in order to evaluate swallowing function through Surface EMG with electrodes located in submental muscles complex and cricothyroid space.

Progressively increasing water volumes were administered at 5, 10, 15, 20 y 25 ml respectively. All subjects were instructed to drink the total volume in a single swallow. The number of swallows and swallowing burst required to drink the total amount of water administered were established.

Dysphagia limit test results were compared between groups. Correlation between EAT 10 and dysphagia limit test was established. Diagnostic accuracy of dysphagia limit test was calculated.

Results

We found dysphagia limit test has a good diagnostic accuracy to detect swallowing disorder (table 1). Significant correlation between EAT 10 score and dysphagia limit test EMG was established (p<0.0001, r=0.8).

Conclusion
Dysphagia limit test is a tool with good diagnostic performance in order to detect swallowing disorder.

Introduction/Background

Ingrowing toenails are frequent disorders which both decrease patients' quality of life and influence on their biomechanical factors like posture and gait. There are some methods of treatment, however in many cases they are not completely effective because of the shortage of appropriate preparation prior to the treatment and the rehabilitation process after it.

Material and Method

Patients undergo treatment by non-invasive Arkada’s Method which consists in the reconstruction of damaged nail plate. Usually the Method is effective, however some patients require more complex treatment in combination with Arkada’s Method: this is the excision of nail sulcus. All the patients are properly prepared e.g. using special preparation to make nail plate and nail folds flexible. Subsequently to the treatment, all the patients are recommended to follow the rehabilitation process e.g. regular medical and podological follow-up, the posture and gait analysis performed by medical professionals (physicians, physiotherapists, podologists) and connected with insole examination, self-sufficient dressing.

Results

Patients who treated in this way achieve the good effects: they stop suffering from pain, start walking right and come back to their professional duties.

Conclusion

The treatment of ingrowing toenails should always be comprehensive and must not finish when the procedure exclusively is done: the rehabilitation process subsequently to the procedure is as important as all former stages, enabling the patients to come to normal daily activities.

LOOKING AT HOSPITALIZED PERSONS THROUGHOUT THE PRISM OF THE HANDICAP

M. GIRAL¹, B. Boussat², F. Lombard², S. Stempfle², P. Francois³, D. Perennou²
¹general hospital metropole-Savoie, Savoie, chambery, France
²CHU, Isere, Grenoble, France
³CHU, Isère, Grenoble, France

Introduction/Background

To describe the disability status of non-selected hospitalized persons.

Material and Method

We conducted a cross-sectional survey to assess activity limitations of every persons older than 18 years old hospitalized in a regional university hospital covering all medical fields. Evaluators rated on a scale from 0 to 4), 22 selected items of the International Classification of Functioning, covering the 6 following domains: learning and applying knowledge, general tasks and demands, communication, mobility, self-care, interpersonal interactions and relationships. Univariate and multivariate analyses were performed to analyze the prevalence, severity and profile of the handicap in terms of socio-demographic characteristics and care pathways.

Results

Among 1572 eligible persons, 1267 (81%) were surveyed (mean age 62.7 ± 20.4 years; 655 male [51.7%]). Overall, 82% showed at least one activity limitation. For 52%, disability was severe or total for at least one ICF item. Prevalence of disabilities was higher for mobility (75%) and self-care domains (63%). Disability was strongly related to age: age older than 80 years versus 18 to 44 years (OR=12.8; p<0.01). Disability was associated with hospitalization in rehabilitation units (96%; OR=4.3; p<0.01). Severe disability was associated with hospitalization in critical care units (OR=6.7; p<0.001) and psychiatry units (OR=5.3; p<0.001).

Conclusion

Handicap was common in hospitalized persons, involving all 6 tested ICF activity domains, particularly mobility and self-care. This study alerts care givers, hospital administrators, and in general people influencing health policies about the need to plan actions to reduce activity limitations of hospitalized persons, whatever the cause of the hospitalization.

**CLINICAL EVOLUTION OF CERVICARTHROSIS PATIENTS TREATED BY CALIBRATED CERVICAL TRACTION. ABOUT 35 CASES FOLLOWED AT UNIVERSITY CLINICS OF KINSHASA (UCK)**

G. MEYA KIALAGEORGES¹, J.M. Mbuyi Muamba², H. Nkakudulu Bikuku²

¹University Hospital of Kinshasa, Physical Medicine and Reaabilitation, Kinshasa, Democratic Republic of the Congo
²University of Kinshasa, Internal medicine, Kinshasa, Democratic Republic of the Congo

**Introduction/Background**

To evaluate the efficiency of calibrated cervical traction devices and to develop a management protocol and a referential table determining the play loads during cervical traction in cervicarthrosis in developing countries where electronic traction devices are lacking.

**Material and Method**

A case study conducted at university clinics of Kinshasa, during the period from January 2011 to October 2016. 35 patients, male and female, were treated by calibrated cervical traction devices, the force varying between 10 and 18 kg, proportionally to the body weight, during 2 to 15 minutes following the tolerance of patients.

**Results**

For 35 patients, including (34.3%) men and (65.7%) women, a sex ratio of 1.9 predominantly female. The age ranges from 30 to 80 years and the highest frequency of cervicarthrosis is between 61 and 65 years, or (20%). The clinic was dominated by cervical pain (80%), irradiated pain (37%). Other signs (blurred vision, headache, vertigo) were poorly represented. For radiographic signs, cervical lordosis was reduced in (91%) of cases, followed by intervertebral nip (68%), canal stenosis (62%) and osteophytosis (20%) of cases. Osteoarthritis myelopathy: (2%). At the end of treatment with calibrated cervical traction, (97%) of patients had no felt neck pain, (67%) had no upper limb irradiation pain and (97.3%) no stiffness of the neck. According to the body weight, a useful traction load varying between 6 and 18 kg was applied during cervical traction, for a number of sessions, between 1 and 15 sessions and duration of 1 to 15 minutes.

**Conclusion**

Calibrated cervical traction has been shown to be effective in the management of common cervical arthritis. This result allowed to develop a protocol for the management of common cervicalgia, as well as a referential table of payloads adapted to the weight of the patients for a safe and effective cervical traction.

ASSOCIATION BETWEEN FLOATING TOE AND TOE GRIP STRENGTH IN TANZANIA
Y. Nishida¹, M. Tatsumi¹, Y. Suzuki¹, Y. Kajiwara¹, H. Zeidan¹, K. Shimoura¹, K. Nakai¹, T. Bito¹, S. Yoshimi¹, T. Aoyama¹
¹Kyoto university, the graduate school of medicine, Kyoto, Japan

Introduction/Background

In Japan there are many foot injuries (e.g. Hallux valgus, flat foot or hammer toe), and now floating toe is received attention as a possible cause of toe dysfunction. It is reported that the floating toe is related to the falling. Person with a floating toe is weaker in toe grip strength than one with normal feet in Japan. Toe grip strength has also attracted attention as an important clinical indicator, because it is related to foot structure and toe deformities. It is not clear whether floating toe that is being investigated in Japan is similar overseas, especially in Africa. The aim of this study is to investigate the association between floating toe and toe grip strength in Tanzania.

Material and Method

A total of 64 Tanzanian people participated in this study. Floating toe was evaluated by footprint and toe grip strength was measured by a toe grip dynamometer. All 128 feet were classified into a floating toe group or a normal toe group according to visual evaluation of the footprint images. Intergroup difference in toe grip strength were analyzed using unpaired t-test and logistic regression analysis adjusted for age, gender, and BMI. We got approval from the National Institute for Medical Research.

Results

There were 91 feet (71.1%) in the floating toe group. Mean toe grip strength of the feet with floating toe was significantly lower than that of normal feet (p=0.023, normal toe group : 16.74±7.09kg, floating toe group : 13.87±6.04kg) In addition, lower toe grip strength was associated with floating toe on logistic regression analysis after adjustment (odds ratio : 1.11, 95% confidence interval : 1.01-1.25)

Conclusion

This study revealed that lower toe grip strength was significantly associated with floating toe not only in Japan but also in Tanzania.

PREDICTORS OF DISABILITY OUTCOME AFTER MAJOR TRAUMA
P. Kersten¹, K. Czuba², D. Anstiss², R. Maheswaran³, G. Smith², N. Kayes², G. Terry², R. Siegert⁴
¹University of Brighton, School of Health Sciences, Brighton, United Kingdom
²AUT University, School of Clinical Sciences- Centre for Person Centered Research, Auckland, New Zealand
³AUT University, Biostatistics and Epidemiology, Auckland, New Zealand
⁴AUT University, Department of Psychology, Auckland, New Zealand

Introduction/Background

Many people survive major trauma, often with complex consequences of their injuries. However, data on outcomes is lacking. This paper aims to evaluate disability and functional outcomes after major trauma at 12-months post-injury.

Material and Method

A one-year prospective cohort study of major trauma survivors, recruited from two major trauma centres in New Zealand. In- and exclusion criteria are in table 1. Baseline variables included demographics, Injury Severity Score, diagnosis, cause of injury, length of hospital stay (LOS), 12-months post-injury participants completed the Extended Glasgow Outcomes Scale (GOS-E), the Short Form 12 (SF12), the EQ5D, Pain Numeric Rating Scale (NRS), World Health Organization Disability Assessment Schedule 2.0 (WHODAS), questions regarding productivity status. Ordinal step-wise regression was performed to investigate the impact of baseline variables on GOS-E outcome. Ethical approval was received from the Health and Disability Ethics Committee of New Zealand.
Table 1 Inclusion and exclusion criteria

<table>
<thead>

</tbody>
</table>

Results

121 people took part (response rate 58%), the majority having received injuries through road traffic accidents (33%) or falls (24%); 58% sustained neurological injuries. 69% were in paid employment pre-injury, 41% at 12 months.

36% reported experiencing moderate to severe pain within the last 24 hours at 12-months post-injury. Ongoing disability was significant as measured with the GOSE (15% severe and 32% moderate disability) and WHODAS (23%). Many had ongoing problems with mobility (33%), usual activities (39%), pain (52%) and anxiety (34%) (EQ5D).
Ethnicity (p=0.003), LOS (p=0.002), education (p=0.056) and comorbidity (p=0.051) were significant predictors of GOS-E outcome (table 2).

Disclosure statement:
The study received funding from the Accident Compensation Corporation of New Zealand. The views and opinions expressed in this article are those of the authors and do not necessarily reflect the official policy or position of the funder.
Both neurological and rheumatic diseases constitute significant causes of disability. Participation (defined as involvement in a life situation) and health-related quality of life (HrQoL) are considered important outcomes in physical and rehabilitation medicine. Documentation of participation and HrQoL in various disabling conditions would guide rehabilitation professionals while planning their treatment interventions. The aim of this study is to determine and compare the participation and HrQoL of people with neurological versus rheumatic diseases.

Material and Method

90 patients with neurological disorders (44% stroke, 23% spinal cord injury, 20% Parkinson’s) and 89 patients with rheumatic diseases (49% osteoarthritis, 33% rheumatoid arthritis, 18% ankylosing spondylitis) who were in the follow-up at the Department of Physical Medicine & Rehabilitation of a university hospital were included. Participation was assessed by Impact on Participation and Autonomy Questionnaire (IPAQ), HrQoL by Nottingham Health Profile (NHP) and activities of daily living by Modified Barthel Index (MBI).

Results

Mean age was 58.1 in neurological patients (61% male) and 61.5 in rheumatic patients (19% male). Mean disease duration was 40.3 months in neurological group while it was 170.6 in the rheumatic group.

MBI score was significantly lower in neurological group (p=0.0001) showing more dependence in activities of daily living. Comparison of IPAQ revealed that neurologic patients experienced more participation restriction than rheumatic patients regarding autonomy indoors (p<0.0001), family role (p=0.023), autonomy outdoors (p=0.001), and work and education (p=0.05) while social life was similar. Rheumatic group reported more distress in pain (p<0.0001) and sleep (p=0.009) domains of NHP, whereas neurologic group was worse in physical mobility (p=0.012). Fatigue, social isolation and emotional reactions domains did not differ.

Conclusion
Although neurological diseases had great impact on physical activities and participation of patients, their social and emotional aspects of health status were similar with patients having rheumatic diseases. Furthermore, rheumatic diseases led to more pain and sleep problems.

Introduction/Background

Rheumatoid arthritis (RA) is the most common form of inflammatory arthritis in adults and is characterized by synovial inflammation and hyperplasia, autoantibody production: rheumatoid factor (RF) and anti–citrullinated protein antibody (ACPA), cartilage and bone destruction, and systemic features, including cardiovascular, pulmonary, psychological, and skeletal disorders. FRAX (Fracture Risk Assessment Tool) is a computer-based algorithm developed by the World Health Organization (WHO) Collaborating Centre for metabolic bone diseases and first released in 2008. The outputs of FRAX are the 10-year probability of a major osteoporotic fracture (hip, spine, humerus or wrist fracture) and the 10-year probability of hip fracture.

Material and Method

The study included 25 premenopausal RA patients and 20 healthy subjects. The serum ACPA level was assessed by ELISA technique, RF using Rose waaler test in IU/ml was measured as well. BMD in (g/cm²) has been measured for all subjects enrolled in the study by a Lunar Prodigy Advanced DEXA scanner system and were carried out by the same technician. FRAX index was calculated for all members in both groups by using online FRAX calculator. Femoral neck BMD was added to enhance fracture risk prediction.

Results

The range of ACPA in the patients group ranged between 11.40 – 525.0 U/ml. 80 % of our patients were ACPA positive. While RF range was from 8.30 to 648.0 IU/ml. Strong statistically significant difference between both groups was found where FRAX index was significantly higher in patients group compared to control group as regards major osteoporotic and hip fractures (p <0.001). Serum ACPA and RF level showed insignificant correlation with FRAX index in premenopausal RA patients.

Conclusion

FRAX index was found to be high in RA patients but it was not correlated to ACPA nor RF serum level.

A2.01 Musculoskeletal Conditions - Inflammatory Joint Diseases (e.g. Rheumatoid Arthritis, Ankylosing Spondylitis)

ISPR8-0185
EFFECTIVENESS OF COMBINED USE OF CRYOTHERAPY AND NEUROMUSCULAR ELECTROSTIMULATION IN RHEUMATOID ARTHRITIS
M. Sukhareva, A. Karateev, A. Lila
V.A. Nasonova Research Institute of Rheumatology, Department of Physical Therapy and Rehabilitation, Moscow, Russia

Introduction/Background

Non-pharmacological methods have an important role in the complex treatment of rheumatoid arthritis. The combination of cryotherapy and neuromuscular electrostimulation (NMES) is one of the new non-pharmacological methodic that reduces pain and local inflammation.

Material and Method

The study group comprised 69 RA patients, 52.4 ±17.6 years, 88.4% women with moderate activity (DAS28 3.48 ±1.17) who received standard therapy: methotrexate or leflunamide, glucocorticoids <10 mg prednisolone (43.5%), NSAIDs. The criterion for inclusion was the presence of pain and a decrease in muscle strength in the hand. Three groups were randomly assigned to 23 patients who received 10 daily procedures: group 1 NMES on the posterior surface of the forearm muscles, with cooling (t -10 ° C), group 2 NMES on the posterior surface of the forearm muscles, with false cooling t + 10 ° C), group 3 only cryotherapy with cooling (t -10 ° C), NMES was switched off. Evaluation of the results was conducted after 28 days.

Results

In group 1, there was a greater improvement in comparison with groups 2 and 3. DAS28 decreased from 3.51 ±1.31 to 3.11 ±1.07, from 3.44 ± 1.24 to 3.34 ±1.12 and from 3.45 ± 1.24 to 3.31 ±1.24 (p <0.05). Severity of pain (100 mm VAS) decreased by 15.01 ±5.21, 6.4 ±5.45 and 8.12 ±5.01 mm (p <0.05). The increase of compression force of the most affected hand > 50% was noted in 53.0%, 18.2% and 25.6% of patients (p <0.05). In 5 patients from group 1 who had symptoms of the carpal canal, a significant decrease in numbness of the fingers was noted. Serious side effects were not noted.

Conclusion

Cryotherapy and NMES can reduce pain and improve function in RA. The combined use of cryotherapy with NMES provides more pronounced effect and is well tolerated.

SECONDARY FUNCTIONAL BENEFITS OF ANTI-IL-6 THERAPY IN RHEUMATOID ARTHRITIS: OUR EXPERIENCE IN A PMR SERVICE

Z. Boukara, S. Benzaoui, A. Sélim, A. Lahreche, K. Henni, A. Bouamra, L. Boudjella, A.C. Nouar

1University Saad Dahlad Blida, Medicine, Blida, Algeria

Introduction/Background

The articular deformities in the RA are at the origin of a real motor handicap. Often we receive patients with irreversible deformities. The objective is to prevent these deformations by a global and early therapeutic strategy associating: biotherapy, apparatus, education and rehabilitation.

Material and Method

Prospective observational study of 23 patients with active RA, treated with Anti IL6 over a period of 4 years (2012-2016). The recruitment is done according to EULAR recommendations, in multidisciplinary. The evaluation of the treatment is on D0 and S192 according to: MOS SF36; HAQ; measuring the grip force on the dynamometer; 6mn test and 10m walk test; DAS28-CRP; patient satisfaction, response to treatment according to EULAR criteria; Observance (equipment, self-rehabilitation) and synovial echo-doppler.

Results

The average age is 50.3 ± 11.09 years; 3 men and 20 women. BMI: 27.1. The average seniority of the PR is at 12.1 years. 5 patients required prior antituberculous prophylaxis (QTF +).

The average gains observed were significant: on the morning rustling; on the strength of the right hand: on the test of 6mn: on the test of 10 meters: on the quality of life in%; patient satisfaction; on the HAQ; on the SF36 MOS scale. According to the EULAR response we got the following results: 12 good and 9 average and 2 bad. Conclusion

Anti-IL 6 in RA, associated with PMR therapy, leads to good results in the prevention of deformities and disability avoidance.

The management of RA, associated with Anti-IL6 in PMR has proved its superiority in preserving function and quality of life.

Early intra-articular corticosteroid injection (IACI) is commonly used for adhesive capsulitis, but not enough studies exist on the optimal timing of the injection.

**Material and Method**

The object of the study is to determine whether IACI has better outcomes in patients with earlier stage than later stage. Visual analog scale, Shoulder Pain and Disability Index, and passive range of motion (flexion, abduction, external rotation, and internal rotation and extension) were evaluated at pretreatment, month 1 and 12 after the first injection.

**Results**

Medical records of 661 patients were reviewed. 246 had pain that improved after conservative treatment. IACI was recommended to the rest of the patients (415) with pain of VAS ≥6; 40 refused and 375 accepted the recommendation. Of the 375 who accepted, 36 were not included in the 12-month follow-up; 17 did not attend the follow-up, 8 were treated at other clinics, and 11 could not be reached. Finally, 339 patients completed the follow-up at month 1 (short-term effects) and 12 (long-term) after injection. The result of the multiple regressions, which considered the main and the interaction effect of confounding variables, showed that the differences of all outcomes in both short-term effect at month 1 and long-term effect at month 12 are greater when the duration of pain prior to injection is shorter. Among the confounders, the injection number in the difference of internal rotation and extension between month 0 and 12 (IRE Δ(0-12)) was statistically significant. IRE Δ(0-12) was also greater when the pain duration was shorter, though the decrease in IRE Δ(0-12) differed depending on the number of injections.

**Conclusion**

This 1-year follow-up retrospective study reveals that an early IACI shows greater improvement in pain and function than late IACI. If pain persists despite non-invasive and conservative treatments, an early injection may be considered to shorten its natural history.

Introduction/Background

The aim of this study was to evaluate the demographic and clinical features of the patients with Ankylosing Spondylitis (AS) using biological agents and to investigate the relationship between the disease activity and these features.

Material and Method

A hundred patients were included in this study. Demographic characteristics of participants were recorded. Severity of pain (rest and activity) by Visual Analogue Scale (VAS), disease activity by Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), functional status by Bath Ankylosing Spondylitis Functional Index (BASFI), quality of life by Ankylosing Spondylitis Quality of Life questionnaire (ASQoL), and satisfaction with the respondent's life by Satisfaction With Life Scale (SWLS) were evaluated in patients with AS. Chest expansion and lumbar mobility measurements were performed.

Results

Patients were aged between 19 and 69 years, with a mean age of 42.00±11.00 years. The mean duration of disease was 7.33±6.23 (1-30) years, the duration of use of biologic agents was 44.96±34.43 (3-144) months. Of the patients, 59% were male, 82% were married, and 41% had high disease activity (BASDAI ≥4). Because of inadequate response, % 21 of patients had switch from first biological agent to other. BASDAI was positive correlated with pain VAS, BASFI, and ASQoL scores (p<0.001), whereas BASDAI was negative correlated with chest expansion and lumbar mobility measurements, and SWLS scores (p<0.05). There were no statistically significant correlations between BASDAI scores and age, duration of disease and, duration of use of biological agents (p>0.05).

Conclusion

In this study, female to male ratio was 0.6. About half of the patients had high disease activity. Strong relationships were found between the disease activity and severity of pain, functional status, quality of life, and satisfaction with life. However, no significant relations were detected between the disease activity and duration of disease, duration of use of biological agents, and age.

TRENDS IN MUSCULOSKELETAL SURGERY AND POSTOPERATIVE REHABILITATION IN PATIENTS WITH RHEUMATOID ARTHRITIS

S. Maniwa1, N. Maeki2, H. Ishihara1, T. Tadenuma1, Y. Sakai1
1Shimane University, Rehabilitation Medicine, Izumo, Japan
2Shimane University, Rehabilitation Medicine, Izumo, Japan

Introduction/Background

Trend in the use of methotrexate (MTX) and biological disease-modifying anti-rheumatic drugs (DMARDs) has led to decrease the number of musculoskeletal surgery in patients with rheumatoid arthritis (RA). We investigated the changes in incidence of surgery and prescription of postoperative rehabilitation.

Material and Method

Retrospective study was performed using medical records in Shimane University Hospital from 2002 to 2016. The number of surgery, prescription of postoperative rehabilitation, duration of hospital stay, and status of pharmacological treatment were studied in 152 patients. Linear regression analysis and Bonferroni / Dunn test were used for statistical analysis for the time trends in the incidence of surgeries.

Results

There was a decreasing trend in the incidence of surgery, especially in the surgery of lower extremities (p=0.08). On the other hand, there was an increasing trend in the incidence of spinal surgery and operations in upper extremities. Hospitalization days became shorter (p<0.01) and the incidence of postoperative rehabilitation decreased, especially for occupational therapy (OT). The proportion of patients receiving MTX and DMARDs significantly increased from 33.3% and 0% in 2002 to 63.2% and 52.6% in 2016, respectively.

Conclusion

The incidence of surgery of lower extremities decreased, however, the number of surgery in upper extremities increased among the patients with improved ADL and QOL owing to the use of effective drugs. Decreasing prescription of OT might bring a negative influence to individualized joint protection education in patients with RA.

FROZEN SHOULDER AND HYDRODILATION, THE BEST EARLY CHOICE TREATMENT
J. Bautista Troncoso¹, G. Beardo Rodríguez², L.E. Alarcon Mora³, M. Linares Gago³, A. León Valenzuela¹, R. Del Pino Algarrada³
¹Hospital Puerta Del Mar, Medicina Fisica Y Rehabilitacion, Cadiz, Spain
²Hospital Puerta Del Mar, Medicina Fisica Y Rehabilitacion, Cadiz, Spain
³Hospital Puerto Real, Medicina Fisica Y Rehabilitacion, Cadiz, Spain

Introduction/Background
To show the effectiveness of glenohumeral hydrodilatation as an initial treatment in frozen shoulder.

Material and Method
We present you a pre-post study, in patients with frozen shoulder treated by ultrasound-guided suprascapular block and glenohumeral hydrodilatation from May to November 2017.

After identifying the clinical diagnosis and signing the informed consent, ultrasound-guided suprascapular block and hydrodilatation was performed with 30 mL of saline, followed by home exercises or supervised in the physiotherapy room according to the gain in degrees of joint range in flexion and abduction after the technique.

We compared pain intensity using the EVA scale, and functional status by the Quick-Dash scale before and after treatment (4 months after the intervention).

With a statistical analysis using the SPSS 23 we identified pre-post differences through the Wilcoxon signed rank test for qualitative variables, and the Student's T test in quantitative variables, establishing the 95% confidence interval.

Results
28 patients were treated, 12 men and 16 women, with an average age of 54.8 years +/- 7. There were no adverse effects or incidents after performing the interventionism.

We immediately appreciate a mean gain in flexion and abduction of 40.7º +/- 12.2. The average reduction of pain in the EVA scale was 5.8 (+/- 1.3) points, however the most important improvement in the functional situation with an average mean decrease of 50.8 (+/- 9.9) points in the Quick-Dash scale at 4 months, both results being statistically significant (p <0.001).

Conclusion
Given the early and fast results, efficacy and low cost, hydrodylation could be considered as one of the main options of initial conservative treatment in patients with frozen shoulder.

THE STUDY ON USERS’ HEALTH REHABILITATION TRAINING RECOGNITION BASED ON INTELLIGENT SENSING TECHNOLOGY

L. Zhang¹, X. Wang², F. Yang³, D. Wu³, Y. He³
¹Renmin University of China, Sports Department, Beijing, China
²Shaanxi University of Science and Technology, College of Electrical and Information Engineering, Shaanxi, China
³Shaanxi University of Science and Technology, College of Electrical and Information Engineering, Shaanxi, China

Introduction/Background

In recent years, a variety of smart mobile devices and related sensors are applied to individual sports activities and provide personalized rehabilitation training and guidance, which will become a useful complement to modern medical means. Researchers mainly focus on motion sensor-based recognition technologies. However, in fact, when measuring human motion, the existence of measurement error is undoubtedly the main reason leading to unsatisfactory results of the analysis, inadequate feedbacks of guidance, and poor rehabilitation effects.

Material and Method

In view of the problems existing in the process of sports rehabilitation training and guidance, this paper first summarizes various mobile devices and sensors that are widely used in current academic research results, compares their applicability, advantages and disadvantages respectively, proposes a new method of recognition and analysis which combines laser vision sensor and pressure sensors to establish individual motor function.

Results

Experimental analysis shows that this scheme not only provides more accurate and scientific data collection than existing schemes but also can provide diversified and personalized user requirements like privacy protection so as to effectively implement the diversified privacy protection rehabilitation training program under the network environment.

Conclusion

Besides, the scheme can achieve the goal of effectively removing pains and restoring physical functions, which provides scientific guidance and basis for the development of the rehabilitation medical industry and the modern sports industry.

EXPLORING THE RELATIONSHIP BETWEEN DISEASE ACTIVITY AND DISABILITY IN PATIENTS WITH RHEUMATOID ARTHRITIS
E. Gur Kabul¹, U. Bas Aslan¹, B. Basakci Calik¹, M. Tasci², V. Cobankara²
¹Pamukkale University, School of Physical Therapy and Rehabilitation, Denizli, Turkey
²Pamukkale University, School of Medical Science - Department of Internal Medicine - Division of Rheumatology, Denizli, Turkey

Introduction/Background

Rheumatoid Arthritis (RA) may lead to limitations of physical activities and restrictions in participation. These limitations are considered as disability. In previous studies, there is no clear consensus on the relationship between disease activity and disability in the patients with RA.

The aim of the study is to analyze the relationship between disease activity and disability in patients with RA.

Material and Method

A hundred patients (86 women, 14 men, mean age=49.93±11.38 years) were included in this study who had RA diagnosis. Average duration of disease was 8.29±7.30 year. Disease activity of patients was evaluated by use of DAS28. Disability was assessed by Disabilities of the Arm, Shoulder And Hand (DASH), Michigan Hand Outcomes Questionnaire (MHQS), Duruöz Hand Index (DEI) and Arthritis Impact Measurement Scales 2 (AIMS2). The presence of relationship between disease activity and these scales was evaluated by Pearson’s correlation analysis.

Results

There was low to moderate correlation between DAS28 scores with all outcome measures (DASH; r=0.643, DEI; r=0.575, MHQS total score and subscales; r= -0.399 to r= -0.696, AIMS2 subscales; r= 0.220 to r= 0.638).

Conclusion

The findings indicate that disease activity in patients with RA lead to disability. Disease activity is a consistent determinant of disability.

⁴Pamukkale University, School of Medicine- Department of Internal Medicine- Division of Rheumatology, Denizli, Turkey

Introduction/Background
The majority of patients with rheumatoid arthritis (RA) experience upper limb impairment which causes considerable disability. This study was carried out to investigate the effect of RA on mobility of the upper extremity during jar opening function by 3-D motion analysis and to compare with healthy subjects.

Material and Method
Twelve patients who had been diagnosed as RA according to the American College of Rheumatology criteria (age 45.17±10.1 years) and 12 healthy (age 22.50±1.98 years) right dominant females were included in the study. A motion analysis system using surface markers has been used to digitize the 3D kinematics of the upper extremity joints in the function to open the jar on the table. The jar opening function is divided into 2 phases; Phase 1. The time between the start command and the start of opening the jar lid, Phase 2. The time between opening the jar lid and opening the lid. The differences in the measures between the RA and control groups were examined with independent sample t test.

Results
The total duration of phase 2 and phase was significantly greater in the patient group than in the healthy group (p<0.05). In all phases, shoulder-to-table distance was less in the patient group (p<0.05). In addition, the elbow angle at the start of opening the jar lid was significantly lower in the patient group (p<0.05). Throughout the entire function; Upper arm abduction-adduction angle, elbow ulnar and radial deviation angle in the frontal plane; flexion-extension angle in the sagittal plane of the hand, and vertical angular rotation angles in the upper arm, forearm and hand anatomic axis systems were significantly lower (p<0.05).

Conclusion
The study demonstrated that RA restricts the motion of the upper extremity joints during the function to open the jar and prolongs the completion time of the function.

QUALITY OF LIFE IN TUNISIAN PATIENTS WITH RHEUMATOID ARTHRITIS

H. Migaou, S. Boudokhane, T. Elhersi, S. Hammami, A. Jellad, Z. Bensalah

1University Hospital of Monastir, Physical Medicine and Rehabilitation, Monastir, Tunisia

Introduction/Background

The objective of this study was to evaluate quality of life in patients with rheumatoid arthritis (RA) and study its associated factors.

Material and Method

Patients, with a confirmed diagnosis of Rheumatoid Arthritis followed at the Rheumatology department and the Physical Medicine and Rehabilitation department, were included in a cross-sectional descriptive study.

Epidemiological, clinical, laboratory and functional characteristics were taken. Quality of life was assessed using the Rheumatoid arthritis quality of life (RAQol), sleep quality (Pittsburgh Sleep Quality Index PSQI), fatigue with the Visual Analogic Scale of Fatigue (VAS-F) and the multidimensional fatigue inventory (MFI-20), functional capacity (Health Assessment Questionnaire HAQ), anxiety and depression (Hospital anxiety and depression scale HAD), and sexual function (Female Sexual Function Index (FSFI) and Sexual Health Inventory for Men (SHIM)).

Results

One hundred patients were included, predominately female, with an average age of 55.88 ± 10.5 years. The disease was moderately active in 55% of cases (3.2< DAS28<5.1).

The mean RAQol total score was 19.78 ± 8.25. More than 53% of our patients had a RAQol score > 20.

Quality of life was positively correlated with joint deformities, the activity index of RA, higher sedimentation rate, the presence of radiological signs of joint destruction, functional capacity, fatigue, anxious and depressive disorders and some items of the PSQI questionnaire: subjective sleep quality, sleep latency, habitual sleep efficiency and sleep disturbances. There was also a positive association between RAQol and both unemployed patients and inefficient therapeutic education.

The RAQol was negatively correlated with all items of the FSFI questionnaire except for pain.

However, there was no correlation between the RAQol and male sexual dysfunction.
**Conclusion**

This study shows that RA may disturb the patient’s quality of life. More needs to be done and achieving better results will depend on measuring the impact of the disease in routine practice.

SLEEP QUALITY IN TUNISIAN RHEUMATOID ARTHRITIS PATIENTS
H. Migaou¹, S. Boudokhane¹, T. Elhersi¹, S. Hammami¹, A. Jellad¹, Z. Bensalah¹
¹University Hospital of Monastir, Physical Medicine and Rehabilitation, Monastir, Tunisia

Introduction/Background

The aim of this study was to assess sleep quality in patients with rheumatoid arthritis (RA) and study its associated factors.

Material and Method

A cross-sectional descriptive study was conducted on patients, with a confirmed diagnosis of Rheumatoid Arthritis followed at the Rheumatology department and the Physical Medicine and Rehabilitation department of the University Hospital of Monastir.

The variables analyzed were Sociodemographic, clinical, laboratory and functional characteristics with sleep quality assessment by the use of the Pittsburgh Sleep Quality Index (PSQI), functional capacities by the Health Assessment Questionnaire (HAQ), anxiety and depression by the Hospital anxiety and depression scale (HAD).

Results

Our population consisted on one hundred patients with a mean age of 55.88 ± 10.5 years (25 to 84 years). The majority was female (85 F/15 M). The disease was moderately active in 55% of cases (3.2< DAS28<5.1).

PSQI global scores were higher than 5 in 65% of our patients. The most common abnormalities reported were sleep efficiency lower than 85% in 75% cases, and insomnia in 65% cases. Daytime dysfunction was reported in 2% of our patients.

There was a significant positive correlation between the items of the PSQI and the activity index of this disease, higher sedimentation rate, functional capacities and anxious and depressive disorders.

However there was no correlation between sleep quality and Sociodemographic and radiological parameters.

Conclusion
A high prevalence of abnormal sleep quality in RA patient populations was observed. Its associated factors are multiple. A review of sleep hygiene and optimization of rheumatologic disease control may prove beneficial in terms of sleep health.

Fibromyalgia is characterized by deep pain, tenderness and stiffness of muscles, areas around tendon insertions and adjacent soft tissues. It is a frequent and complicated disorder affecting as much as about 2% of the population. The real cause of fibromyalgia is still not sufficiently known – the illness is often not recognized early enough. In diagnosis it is important to exclude all other comorbidities and overlapping symptoms of other diseases.

Klinikum Bad Gastein is an orthopedics and rheumatology rehabilitation centre, which uses thermal water rich in radon (\(^{222}\text{Rn} – \text{radioactive gaseous element}) for treating patients. Generally, it has been shown that such water – among other benefits – has a very beneficial and healing effect on muscles, tendons and joints.

At Klinikum Bad Gastein each patient receives individual care by interdisciplinary teams of specialists, thus applying multidisciplinary treatment. In parallel the following treatments are used: physiotherapy (ergotherapy, hydrotherapy in pools, fangotherapy and a paraffin treatments), bathing in radon-rich thermal water, psychotherapy and also dietary support and education are provided, including a serious of short lectures on pain treatment, improving health habits, proper nutrition and the choice of recreational activities.

For a small sample of 7 female patients with diagnosed fibromyalgia, for which bathing in thermal waters was the main therapy, the treatment results were analyzed and statistically processed. Pain relief after the treatment was identified in the range of 33% to 50%, and in patients who, apart from fibromyalgia, also suffer from depression, the pain was relieved for about 20%.

In spite of a small number of the patients in our modest research, multidisciplinary treatment of Fibromyalgia combined with thermal radon-rich water shows satisfying results.

¹Fattouma Bourguiba Hospital, Rheumatology department, Monastir, Tunisia
²Taher Sfar Hospital, Rheumatology department, Mahdia, Tunisia
³Taher Sfar Hospital, Physical medicine and rehabilitation department, Mahdia, Tunisia

Introduction/Background

Despite recent therapeutic advances (improved patient selection, new drugs, « treat to target » concept), rheumatoid arthritis (RA) continues to induce significant disabilities and mortality. Our objective is evaluating the functional status and its determinants in RA patients.

Material and Method

This is a monocentric, cross-sectional study of 90 RA patients according to the ACR 1987 and/or EULAR 2010 conducted at the Rheumatology Department, in Tunisia, between November 2016 and April 2017. The functional evaluation was based on Steinbrocker functional score and Tunisian Health Assessment Questionnaire (HAQ).

Results

The mean age of patients was 52 years±10 [27-78]. Females accounted for 89%. The mean disease duration was 121 months ± 86 months [1-333]. In 60% of patients, the globular sedimentation rate and/or C reactive protein were elevated. The mean DAS28 was 4.57±1.44 [0.97-7.26]. In more than half of the patients, RA was moderately active. RA remission was noted in 10% of cases.

The mean HAQ was 1.22±0.73 [0-2.88]. Thirty per cent of the patients had low handicap, 41% moderate handicap and 29% severe handicap. There was no disability in 11% of cases. The most important scores (most difficult tasks) were found for items 3 (eating) and 5 (holding) with means at 2.40 and 2.35 respectively. Mean Steinbrocker score was 2.14 ± 0.75. Low handicap was noted in 20% of cases, moderate handicap in 47% and severe handicap in 34% of cases.

HAQ was statistically associated to DAS28 (p<0.041), advanced age (p<0.025), hand deformity (p<0.003), RA duration over 5 years (p<0.031). Logistic regression noted that HAQ determinants were RA disease activity and duration over 10 years.

Conclusion
Nowadays, RA still results in moderate functional handicap in almost half of the cases. Those tasks requiring precise hand movements (eating / holding) are most affected. This could impair patients’ professional and social activity.

COMPARAISON OF RHEUMATOID ARTHRITIS CLINICAL ASPECTS OVER 15 YEARS INTERVAL
S. Zroui1, H. Mouanaa1, H. Hachfi2, W. Langar3, M. Jguirim1, I. Bèjia1, M. Touzi1, M. younes2, N. Bergaoui1
1Fattouma Bourguiba Hospital, Rheumatology department, monastir, Tunisia
2Taher Sfar Hospital, Rheumatology department, Mahdia, Tunisia
3Taher Sfar Hospital, Physical medicine and rehabilitation department, Mahdia, Tunisia

Introduction/Background

Recent advances in pathogenesis, early diagnosis and management of rheumatoid arthritis (RA) suggest that its clinical aspects have changed over the last two decades. Our goal is to compare the clinical parameters in two groups of RA patients at an interval of 15 years.

Material and Method

This is a monocentric comparative cross-sectional study conducted at the Rheumatology Department, on two different groups of patients with RA according to EULAR 2010. Group 1 (G1) is composed of 45 consecutive patients followed in 2001-2002, and group 2 (G2) is made up of 90 consecutive patients, followed in 2016 - 2017.

Results

Groups comparison, between G1 and G2 respectively, revealed no statistical differences in age (mean age 51 years ± 14 [27-89] versus 52 years±10 [27-78] for G2), gender (sex ratio 0.15 versus 0.10), RA disease duration (103 months ± 93[3-324] versus 121 months ± 86 [1-333]), age at diagnosis (41 years ±18 [12-72] vs 42 years±12 [11-71]). However, diagnosis delay decreased significantly (74 months ± 84 [2-300] vs 42months±40 [1-230], (p<0.037)). For disease activity symptoms, there was no statistical difference between the two groups, notably in morning stiffness duration (100 ±70 minutes [0-300] vs 84min ±71 [0-240]) and sleep disturbance (night awakening) (69% vs 63%). Extra-articular manifestations were noted in 62% of G1 and 86% in G2, especially the sicca syndrome. Streinbrocker functional score was 2.78±2.3 for G1 and 2.14±0.75 for G2 (p<0.128). The rheumatoid factors were positive in 67% of cases for G1 and 72% for G2. Methotrexate was prescribed in 42% of cases in G1 and 100% in G2 and biologics in only 15% of cases in G2.

Conclusion
At present RA diagnosis is early but diagnosis delay remains long. The functional status is better and extra-articular manifestations are more known and better evaluated. The treatment has been improved, based essentially on methotrexate.

INTERFASCIAL PECTORAL SYNDROME AS A CAUSE OF SHOULDER PAIN

J. Bautista Troncoso¹, B.R. Gema¹, A.M. Luis Eduardo², C.G. Juan¹, G.A. Laura¹, D.P.A. Rogelio²

¹Hospital Puerta del Mar, Medicina Física y Rehabilitación, Cádiz, Spain
²Hospital Puerto Real, Medicina Física y Rehabilitación, Cádiz, Spain

Introduction/Background

Shoulder pain is one of the most frequent reasons for consultation among the middle-aged and elderly population. It is the most mobile joint of the body but also the most unstable, in close relationship with the neck, scapular waist and thorax, structures that sometimes make a correct diagnosis difficult.

Material and Method

We present the case of a 45-year-old male patient, in the bakery profession, who presented right shoulder pain of 3 years of evolution, previously assessed by his orthopedic surgeon, being infiltrated 3 times at supraspinatus level without clinical improvement. As a complementary test, an ultrasound report is provided: subscapular tendon calcification, this being the reason for consultation.

However, on examination, selective pain on palpation in the pectoralis major and on ultrasonography a discrete pectoral interfascial inflammation (in a region more medially anatomically than the aforementioned calcification) attracts attention.

Given that the calcification did not generate conflict with the coracoacromial ligament in dynamic maneuvers to mobilization, it was decided to treat the pectoral by interfascial infiltration with depot corticosteroid and local anesthetic, as well as home kinesitherapeutic enhancement of the area.

Results

After 2 months the patient is asymptomatic except for occasional discomfort that is related to overexertion due to his profession.

Conclusion

From this case it is clear that it is as important as having a diagnostic image to attend to the clinic, a good anamnesis and physical examination. Repetitive acts at work led to a chronic pectoralis major contracture with consequent selective pain in this area.
Increasingly we find ourselves treating images, with which we lose the principle of good medical practice, a basic exercise that should be that of a good specialist.

CORRELATIONS AMONG DISEASE ACTIVITY, FUNCTIONAL STATUS, QUALITY OF LIFE AND CLINICAL AND ULTRASONOGRAPHIC ENTHESITIS ASSESSMENT IN PATIENTS WITH SPONDYLOARTHRITIS

G. Er
T Abant Izzet Baysal University, Izzet Baysal Physical Medicine and Rehabilitation Hospital, Bolu, Turkey

Introduction/Background

Enthesitis is regarded as the primary lesion in all spondyloarthritis (SpA) subtypes. The aim of the study is to determine the relationship between disease activity, functionality, quality of life and enthesitis assessment in patients with SpA.

Material and Method

90 patients with diagnosis of SpA according to 2009 ASAS criteria were recruited to the study. In the clinical evaluation, BASDAI, ASDAS, BASFI, ASQoL, SF-12 scales were applied. Enthesitis assessments were done clinically by MASES and SPARCC. Bilaterally distal triceps tendon was evaluated clinically. Ultrasonographic enthesis was evaluated by a 10 years-experienced, blinded sonographer according to MASEI.

Results

The mean age was 37.5 and 57 of cases were male. The median scores of BASDAI, ASDAS-CRP, ASDAS-ESR, BASFI, ASQoL, MCS and PCS were 3.9, 3.5, 2.6, 2.5, 7, 44.1 and 41.7, respectively. The median scores of both MASES and SPARCC were 2. The median score of MASEI was 16. Clinical enthesitis scores correlated with disease activity scores, functional status and quality of life measure. No correlation was found between the MASEI and clinical enthesitis score, BASDAI, quality of life measure. There was also correlation between MASEI and ASDAS-CRP, BASFI.

Conclusion

Although clinical enthesitis scores correlated with clinical parameters, but not with biochemical markers and sonographic score. Sonographic score was not correlated with disease activity measure except ASDAS-CRP. The result attributed to clinical scales that were less sensitive. Due to the requirement of scales that depend on more objective methods in evaluation of disease activity, ASDAS-CRP could be preferred compared to other present scales. US confirms its validity and reliability in the assessment of enthesal involvement in patients with SpA. This study propose also that sonographic detection of enthesopathy should be incorporated into the clinical protocol for evaluating patients with SpA in routine clinical practice.

**DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS: ROLE OF PSYCHOLOGICAL FACTORS AND COPING IN A COLOMBIAN SAMPLE**

*H. Rogers¹, S. Trapp², S. Olivera Plaza³, A. Córdoba Patiño³, M. Peña Altamar⁴*

¹BioCruces Health Research Institute, Psychology and Health, Barkaldo, Spain  
²University of Utah, Physical Medicine and Rehabilitation, Salt Lake City, USA  
³Surcolombian University, Psychology, Neiva, Colombia  
⁴Saludcoop Clinic, Rheumatology, Neiva, Colombia

**Introduction/Background**

The relationship between psychosocial factors and Rheumatoid Arthritis (RA) disease activity may not be the same across social-cultural contexts. The aim of this study was to examine these relationships in a Colombian sample.

**Material and Method**

103 RA patients were recruited from outpatient centers in Neiva, Colombia. They were 85.5% women with an average age of 54 years and 85.0% in the bottommost socio-economic strata (SES) in country. The Zung Self-rating Depression Scale, Brief COPE, Short Form-36 [SF-36; Health-Related Quality of Life (HRQOL) measure], and Quality of Life-RA (QOL-RA) were administered. Disease Activity Scale 28 (DAS28) total scores were obtained and then dichotomized into severe (DAS28>5.1) vs. moderate or less disease activity.

**Results**

47 patients (45.5%) comprised the severe DAS group. Socio-demographic characteristics were not associated with DAS scores. The severe group was more likely to use disease modifying anti-rheumatic drugs (DMARDS) (p<0.01), had higher Zung scores (p<0.05), and had lower scores on six SF-36 sub-scales (p's<0.05) and the QOL-RA (p<0.01). They were less likely to use venting and acceptance as coping strategies (p's<0.05). Venting was associated with a 74% reduction in odds of being in the severe DAS28 group [OR=0.26(0.07-0.97), p<0.05], controlling for use of DMARDS, depressive symptoms, acceptance coping, and HRQOL.

**Conclusion**

Increased depressive symptoms, less acceptance coping, and lower HRQOL were associated with increased RA disease severity. Venting was found to be protective in this Colombian sample and the only factor independently associated with disease activity. These findings are biologically plausible and deserve further study.

Ankylosing Spondylitis (AS) is a degenerative inflammatory disease that may affect the ligaments and joints of the entire spine, including the sacroiliac joints. This study was planned to investigate the relationship between demographic and characteristic features and disease activity in individuals with AS.

Material and Method

The study included 63 individuals (38 women, 25 men; mean age of 39.11±10.89 years) who were diagnosed with AS according to Modified New York Criteria. Demographic (gender, body mass index (BMI)) and characteristics (exercise habit, smoking, morning stiffness, enthesitis, root joint involvement, ocular involvement) of individuals were recorded. Disease activity was calculated using BASDAI. After calculation, participants were divided into 2 groups, active and remission periods. Pearson chi-square test was used to analyze the data.

Results

When the data were analyzed, it was found that there was a significant relationship between disease activity with female gender(p=0.000), morning stiffness(p=0.002), enthesitis(p=0.001), root joint involvement (p=0.000) and ocular involvement(p=0.042); but the relation between disease activity with BMI(p=0.309), exercise habit(p=0.530) and smoking(p=0.755) was not significant. In terms of demographic and disease-related characteristics of the difference, it was seen that in active period, morning stiffness was 8.92 times, ocular involvement was 0.30 times, enthesitis was 0.15 times, female gender was 0.12 times and root joint involvement was 0.11 times more risky respectively. The intercostal muscle attachments, achilles and plantar fasia were determined to be the most affected areas and percentages for enthesitis were 36.5%, 33.3% and 30.2% respectively.

Conclusion
During active period of AS, morning stiffness, enthesitis and ocular involvement were found to be at high risk. The activity of the disease is an important criterion in terms of evaluation and treatment. Therefore, factors such as morning stiffness, enthesitis and ocular involvement can be taken into consideration.

PREDICTIVE FACTORS OF MUSCULOSKELETAL DISORDERS AT A GROUP OF CASHIERS IN LEBANON: ABOUT 100 EMPLOYEES
K. Ghoussoub¹, S. Kalakech¹, M. Sayegh Ghoussoub², G. Sleilati³
¹CHU hotel Dieu de France, PMR, Beirut, Lebanon
²Lebanese university, orthodontics, Beirut, Lebanon
³CHU hotel Dieu de France, Chirurgie cardiaque, Beirut, Lebanon

Introduction/Background

Our study aims to evaluate the risk factors for the occurrence of musculoskeletal disorders (MSDs) in a group of cashiers in Lebanon, to establish a correlation between these MSDs and factors related to the professional practice and personal data of cashiers.

Material and Method

Descriptive prospective study. Target population: cashiers in 7 different supermarkets in various neighborhoods of Beirut. Data collection is done using a grid with demographic data, logistics data, data concerning the cashier profession and data on MSDs. Statistical study: Analysis of data on SPSS software v 10. Descriptive and univariate study using the Chi² test. A p <0.05 is considered significant.

Results

Descriptive study. 100 cashiers. Female predominance 52%. Mean age: 26 ± 6.5 [18-50]. Weight gain in the last 12 months 62%. Smokers 57%. Sports and leisure activities 55%. Full time work 43%. Seniority at work 4 years [1 - 8]. Number of hours of work per day 7 hours [5-10]. Number of days of work per week 6 days [5-7]. Stress at work 90%.

MSDs last month: tingling 78%; pain 74% (shoulders 73.5%, neck 61% and lumbar spine 51%).

Stop work: 61%

MSDs during the last 12 months: 90%; Work stoppage 47%, Medical consultation 25%, Physiotherapy 7%

Univariate analysis (Risk factors of MSDs): Our results showed a significant correlation with age (p = 0.0191), length of time at work (p = 0.0018), length of sitting (p = 0.002), pauses (p = 0.0016), tingling (p = 0.00053) and full-time work (p = 0.003).

Conclusion

Musculoskeletal pathologies are common among cashiers in Lebanon, in relation to the vicious postures at work, the repetition of movements, the material of poorly adapted work. It will be interesting to introduce the notion of ergonomics in companies.

ITEMS COMPARISON OF QUESTIONNAIRES, SCALES AND CLINICAL OUTCOMES USED IN ANKYLOSING SPONDYLITIS BASED ON THE INTERNATIONAL CLASSIFICATION OF FUNCTIONING, DISABILITY AND HEALTH: A SYSTEMATIC REVIEW

P. WANG

1Shanghai Jiaotong University School of Medicine, Ruijin Hospital, Shanghai, China

Introduction/Background

To identify questionnaires and scales used measuring Ankylosing Spondylitis (AS) patients’ functions, disability and health as well as determining whether these instruments can be matched to the International Classification of Functioning, Disability and Health (ICF) framework. Therefore comparing the results with available ICF Core Set for AS.

Material and Method

We searched PubMed in English from January 2001 to December 2016 using the search term: Ankylosing Spondylitis. Among all searched literatures, AS specific questionnaires and scales were identified and classified. Based on the ICF framework, each item of all included instruments was extracted and interpreted into ICF categories.

Results

A total of 15 questionnaires, involving reviewed 295 articles, were identified. A total of 112 items were analyzed and a total of 148 concepts covered these rest 99 items, left 13 items not being linked to ICF concepts. 69 linked to body function, 21 to body structure, 50 to activities and participation and 8 to environment factors. In the body function component, most questionnaires covered sensation of pain, mobility of joint functions and muscle stiffness as well as movement. In the activities and participation component, most questionnaires covered body position changing and maintaining, lifting and carrying objects as well as carrying out daily routine. We recommend the Assessments in Ankylosing Spondylitis Working Group 5/6 improvement criteria (ASAS5/6) and Ankylosing Spondylitis Quality of Life Questionnaire (ASQoL) for well-balanced and comprehensive distribution of four ICF contribution.

Conclusion

The research may help choose the proper questionnaire in clinical and research setting on the framework of ICF with comprehensive functioning assessment.

RELATIONSHIP BETWEEN SPONDYLOLISTHESIS AND EARLY PREGNANCY: A CROSS SECTIONAL STUDY IN IRANIAN WOMEN
S. Kazemi¹, M. Azadvari¹, Z. Emami Razavi¹, F. Rezayee Moghadam²
¹TUMS, physical medicine & rehabilitation, tehran, Iran
²Army University, physical medicine, Tehran, Iran

Introduction/Background
Spondylolisthesis is a common skeletal disorder which is rather prevalent among human beings occurring at various areas of spinal coulmen with higher prevalence particularly in lumbar area. There are several risk factors contributing to occurrence of spondylolisthesis especially in the lumbar area including multiple pregnancies, early age pregnancy, etc. The objective of the present study is investigating the pregnancy history of women afflicted with spondylolisthesis and probing the relationship of these factors with spondylolisthesis.

Material and Method
Women with low back pain, afflicted with spondylolisthesis diagnosed based on the medical scanning were included in the study. The exclusion criteria comprised affliction with acute diseases, rheumatologic diseases such as rheumatoidarthritis, and history of direct trauma to their backs. The patients were then examined and the related questionnaires were filled for them. The results were analyzed using SPSS 20.0.

Results
113 women with mean age of 53.79 (SD: 10.79) were investigated. 74.3 % of the patients had a history of pregnancy prior to 20 years of age. The spondylolisthesis most commonly occurred in L4-L5 intervertebral area (49.6 %). With regard to the grade frequency, the most frequent grade is grade1 (82.3%).

Conclusion
Early age and multiple pregnancies are considered important risk factors increasing the likelihood of developing spondylolisthesis. Provision of appropriate education about time for first pregnancy and number of pregnancy, training and raising public awareness can help reduce this risk factor.

The purpose of this study was to compare the changes and resumption of sports and physical activities (SPA) between older and younger patients after opening wedge high tibial osteotomy (OWHTO).

Material and Method

One hundred and one patients (120 knees) with medial compartment knee osteoarthritis were investigated. The 53 patients aged >65 years were defined as the O group and the 48 patients aged <64 years were defined as the Y group. The ratios of SPA cases, time points at which SPA was started after surgery, frequencies of SPA, and Lysholm scores were compared between the two groups. The level of significance was set at p<0.05.

Results

The preoperative and postoperative ratios of SPA cases were 28.3% and 26.4% in the O group, respectively (p=0.82). The corresponding ratios were 20.8% and 41.6% in the Y group, respectively (p=0.027). The mean time points for starting SPA after surgery were 12.3±7.5 months in the O group and 11.2±11.0 months in the Y group (p=0.18). The mean frequencies of SPA after surgery were 4.04±2.15 days/week in the O group and 2.7±1.99 days/week in the Y group (p=0.021). The mean postoperative Lysholm scores were 89.5±5.4 in the O group and 88.8±4.9 in the Y group (p=0.61).

Conclusion

The postoperative ratio of SPA cases showed a significant increase compared with the preoperative ratio in the Y group only. However, older patients performed SPA more often than younger patients postoperatively. Both older and younger patients required a relatively long time to resume or start SPA.

CONSERVATIVE TREATMENT OF HIP OSTEOARTHRITIS WITH BOTULINUM TOXIN TYPE A

1Deutsches Rheuma-Forschungszentrum DRFZ, Pitzer Lab Osteoarthritis Research, Berlin, Germany
2Instituto de Seguridad y Servicios Sociales de los Trabajadores del Estado ISSSTE, Hospital General Tacuba. Medicina Física y Rehabilitación Physical Medicine and Rehabilitation, México City, Mexico
3Escuela Médico Naval Naval Medical School, Ciencias Clínicas Clínicas Sciences, Mexico City, Mexico
4Instituto de Seguridad y Servicios Sociales de los Trabajadores del Estado ISSSTE, Hospital General Tacuba. Department of Orthopaedics and Traumatology, México City, Mexico

Introduction/Background

Osteoarthritis (OA) is a multi-causal articular disease characterized by destruction of the articular cartilage, subchondral bone and inflammation of the synovium caused by mechanical stress and local low-grade inflammation. Intramuscular Botulinum Neurotoxin Type-A (BoNT-A) produces temporal, well-delimited and reversible flaccid muscular palsy that can be strategically applied to decrease mechanical stress between the femoral head and acetabulum. The aim of this study was to evaluate the effect on pain, function and stiffness perceived by patients and measure changes in flexion, internal and external rotation after the application of intramuscular BoNT-A.

Material and Method

In this clinical, experimental and longitudinal trial a total of 35 patients (45 hips) were included. All patients had hip OA grade II-IV according to Kellgren and Lawrence radiographic classification. The therapeutic approach consisted in abobotulinum toxin type A (500U) diluted in 1 mL of saline solution. Application of the treatment was performed using 27 G x 1 ½" needles following the scheme: 350 U in iliac muscle, 175 U in adductor brevis and 175 U in adductor longus muscles. Clinical symptoms were evaluated using Western Ontario and McMaster Universities OA Index (WOMAC) and Visual Analog Scale (VAS). Joint motility was evaluated with goniometry before therapy and 90 days after treatment. All patients signed informed consent. Wilcoxon signed-rank test was used to compare change in clinical scores between days 0 and 90.

Results

A significant decrease in referred pain (p<0.0001) and stiffness (p<0.002) was observed. Additionally, increase in perceived function was found after treatment (p<0.001). Goniometry showed improvement in joint flexion, internal and external rotation (p<0.0001). No Side effects
were reported during this study.

**Conclusion**

In this study, we found that BoNT-A therapy provides a safe conservative option to treat symptoms and physical constrain caused by hip OA.

Knee replacement surgery is to replace the native joint. Its main indication is osteoarthritis. This procedure will restore joint mobility and ensure a painless support to resume physical activity in the best conditions. The rehabilitation has an important place in the management of these replacements. This work aims to determine the clinical and epidemiological characteristics of patients treated in Physical Medicine and Rehabilitation Department following a total knee replacement.

Material and Method

This is a retrospective study conducted in the Department of Physical and Rehabilitation Medicine in Sahloul Hospital TUNISIA among patients hospitalized for total knee replacement over a period of 4 years. Data were collected from medical folders.

Results

32 patients (4% of patients hospitalized during this period) with an average age of 68.3 years, were included in the study. The majority was female (81.3%). All patients were exclusively addressed by the orthopedic department after an hospitalization average of 5 days. 61.5% of patients moved with walker on admission in rehabilitation with an average Functional Independence Measure (FIM) of 102, visual analogue scale (VAS) pain was 6/10, an average flexion of 60° and an extension deficit of 10° were found. Patellar shock was present in 93% of cases. The quadriceps strength was rated at 3 in 75% of cases. The average hospital stay in our unit was 13.5 days with at the output an average flexion of 90° and an extension deficit of 5°. At the end of hospitalization, 34.8% of patients walked with two canes, 21.7% used one cane, 21.7% were able to walk and the rest were still using a walker. The average FIM score at the output was 114, the VAS pain was 4/10.

Conclusion

The knee replacement is major surgery. The place of rehabilitation in their management is indisputable for improving the functional prognosis of patients.

**Introduction/Background**

Low-level laser therapy (LLLT) and high-intensity laser therapy (HILT) are the safe and non-invasive methods utilized for treatment of knee osteoarthritis (KOA). The aim of this study was to compare the effects of high-intensity laser therapy (HILT) and low-level laser therapy (LLLT) on pain and functional improvement in patients with KOA.

**Material and Method**

30 patients, diagnosed with KOA according to American College of Rheumatology criteria, stage 1-3 (modified Kellgren-Lawrence classification) on a frontal knee radiography were randomly assigned into two groups and treated with HILT (wavelength 1064 nm, 125 J/cm²) in group 1, and LLLT (wavelength 830 nm, 6 J/cm²) in group 2, respectively. The outcomes measured were pain level measured by visual analog scale (VAS) and knee function measured by Lequesne index (LI). SPSS software version 17 was used for statistical analysis. The level of statistical significance was set as P < 0.05.

**Results**

After the treatment a statistically significant decrease of pain on VAS and LI was observed for both variants of laser therapy. This improvement was significantly higher for LLLT compared with HILT for pain on VAS.

**Conclusion**

Results showed that LLLT was more effective than HILT for improvement of pain in KOA.

Introduction/Background

Mechanical complications or prosthesis infections may occur during the evolution of total knee prosthesis. Infections are the most serious complications. Mechanical complications include loosening, prosthetic instability and stiffness.

The aim of our study is to identify complications requiring surgical revision of total knee and difficulties in their management in Rehabilitation Department.

Material and Method

This is a retrospective study conducted in the Department of Physical and Rehabilitation Medicine in Sahloul Hospital TUNISIA among patients who underwent surgical revision following a complication of a total knee prosthesis over a period of 4 years.

Results

Ten patients (23.8% of patients hospitalized after arthroplasty) benefited from a surgical revision. They all were female with an average age of 56.8 years. The surgical revision was indicated for persistent joint stiffness in 5 cases (50%) after a mean period of 1603 days, for septic loosening in 3 cases (30%) after a mean period of 972 days and hematoma in 2 cases (20%) after a mean period of 47 days. At the admission, an average flexion of 50° and an extension deficit of 5° were found; the quadriceps strength was equal to 2 in 3 cases (30%) and 3 in 7 cases (70%); five (50%) patients used a walker and the others used two canes. The average of Functional Independence Measure (FIM) score was 106. The average hospital stay was 12.8 days. At the end of hospitalization, an average flexion of 70°and an extension deficit of 5° were found, 2 patients were able to walk by themselves, 3 patients used one cane, 3 patients used two canes and the other 2 were still using a walker, the average of FIM score was 113.6.

Conclusion

Joint stiffness is the most common cause of surgical revision after arthroplasty. Early and organized rehabilitation is needed to accelerate the recovery of motion and improve patient autonomy.

Efficacy of Ultrasound-Guided Extracorporeal Shockwave Therapy for Shoulder Calcifying Tendinopathy - A Prospective Study

N. Tomas¹, J. Monsanto¹, M. Andrade¹, J. Barbosa¹, E. Goncalves¹, D. Calado¹, C. Angelo¹
¹Centro Hospitalar Lisboa Ocidental, Serviço de Medicina Física e de Reabilitação, Lisboa, Portugal

Introduction/Background

Extracorporeal shockwave therapy (ESWT) is a non-invasive treatment that has been shown to have good outcomes in shoulder rotator cuff calcifying tendinopathy. Thus, a prospective study was developed to evaluate the efficacy of ultrasound-guided ESWT in this pathology.

Material and Method

Adults with shoulder calcifying tendinopathy underwent 3 sessions of focal ESWT under ultrasound guidance (900-1300 pulses/session), separated by two weeks. An evaluation using x-ray and ultrasound imaging was made. Pain and functionality were evaluated before treatment, at 3 and 6 months of follow-up, using VAS-scale and American Shoulder and Elbow Surgeons Standardized Shoulder Assessment Form (ASES) and Modified-University of California at Los Angeles Shoulder Rating Score (modified-UCLA).

Results

Nine patients were included in the study. Statistical analysis showed an improvement in pain at 3 and 6 months (VAS=7.1->3.9->2.9). There was also an increase of functionality reflected by the ASES-score at 3 and 6 months (11.7->16.3-17.3). According to UCLA-score, there was also an improvement at 3 and 6 months (17.3->24.6->26.9). It was also observed an improvement in flexion and abduction of the shoulder (flexion 144º->156º, abduction 110º->137º). According to the initial x-ray evaluation, 44% of the patients had at least one calcification. At 6 months follow-up 75% of these patients had a smaller or no calcification on x-ray. All of the patients had at least one rotator cuff tendon calcification apparent on the initial ultrasound. In the follow-up evaluation at 6 months, 89% had a reduction in the size or number of calcifications.

Conclusion

Ultrasound-guided focal ESWT of shoulder cuff calcifying tendinopathy seems to be effective, with significant decrease in pain, improvement in functionality and improved joint ROM. These results are reflected in the reduction of size and number of rotator cuff tendon calcifications.

DO OBESE PATIENTS WITH PRIMARY KNEE OSTEOARTHRITIS BENEFIT FROM A SINGLE BOUT OF MODERATE INTENSITY AEROBIC EXERCISE? A PILOT STUDY AMONG EGYPTIAN SEDENTARY COHORT

S. Machaly1, R. Shaat1, T. El-Said1, R. Monir2
1Mansoura faculty of medicine- Mansoura University, Rheumatology and Rehabilitation, Mansoura, Egypt
2Mansoura faculty of medicine- Mansoura University, medical Biochemistry, Mansoura, Egypt

Introduction/Background

Obesity and osteoarthritis are often concomitant. Both are accompanied by oxidative stress and stimulated inflammatory response. Exercise is considered a substantial treatment in rehabilitation of both conditions. Yet most of literature reported the benefits of regular exercising, while there is paucity about the effects of single low to moderate exercise session. Hence, this study aimed to investigate the possible potential effects of a single bout of moderate exercise in obese middle-aged individuals with KOA.

Material and Method

Thirty four obese OA untrained patients and 15 age and sex matched healthy controls were enrolled in this study. OA patients were assigned to single session of low to moderate exercise on treadmill while controls remained unexercised. Perceived pain, glutathione reductase (GR) activity, IL-6, CRP, fasting blood glucose and lipid profile were assessed at baseline, after exercise and 24h after. Meanwhile, WOMAC score determined at baseline and after 24h.

Results

Pain and WOMAC score had been improved 24 h post-exercise. GR activity increased after exercise but declined the next day though remained higher than baseline. Blood glucose levels decreased after exercise while blood lipids were unaffected by exercise. Inflammatory markers remained unchanged following exercise session.

Conclusion

Moderate aerobic exercise is beneficial for obese knee OA patients. Even a single bout of mild to moderate exercise can improve pain and enhance antioxidant activity in obese individuals with knee OA.

COMPARING THE EFFECT OF OVER-THE-DOOR HOME TRACTION UNIT AND AIR NECK TRACTION DEVICE ON NECK PAIN, RANGE OF MOTION AND DISABILITY LEVEL IN CERVICAL SPONDYLOSIS
B. Bagheripour¹, M. Kamyab¹, F. Azadinia¹, A. Amir², M. Akbar²
¹Iran University of Medical Sciences, Department of Orthotics and Prosthetics, Tehran, Iran
²Iran University of Medical Sciences, Department of Physiotherapy, Tehran, Iran

Introduction/Background

Spondylosis is common in cervical region due to the high mobility of this area. Despite the clinical popularity of traction for patients with neck pain, there is no agreement on the amount of effectiveness among different methods of providing traction. Present study was conducted to compare the efficacy of traction by Air neck traction device and Over-the-door home traction unit on pain, disability level and cervical range of motion in patients with spondylosis.

Material and Method

Twenty-six patients with neck pain aroused by spondylosis were randomly assigned into two groups of Air neck traction device and Over-the-door home traction unit. Patients in both groups received hot pack, transcutaneous electrical nerve stimulation, ultrasound and exercise therapy as their usual physical therapy care. Patients in the first group also benefited from the sustained traction via Air neck traction device and patients in the second had traction via Over-the-door home traction unit. Patients were treated for 10 sessions. Pain, disability level and the cervical range of motion in the all directions were evaluated in beginning of the first session and at the end of the last session.

Results

The results showed significant decrease in levels of pain and disability and increasing cervical range of motion in all directions in both groups (P<0.05). The rate of disability reduction in the patients received Air neck traction device was significantly higher than Over-the-door home traction group (P=0.02). There was no significant difference between two groups at the end of last session in terms of neck pain and range of motion in all directions (P>0.05).

Conclusion

Although traction via Over-the-door home traction unit along with physical therapies causes significant reduction in neck pain intensity and disability level and increase of cervical range of motion in patients with spondylosis; Using the Air neck traction device can increase the rate of improvement.

EFFECTIVENESS OF THERAPEUTIC ULTRASOUND ON CLINICAL PARAMETERS AND ULTRASONOGRAPHIC CARTILAGE THICKNESS IN KNEE OSTEOARTHRITIS: A DOUBLE-BLIND TRIAL
L. Ozgonenel¹, S. Caglar Okur², Y. Pekin Dogan², N. Sayiner Caglar²
¹Istanbul Bilim University, Physical Medicine and Rehabilitation, ISTANBUL, Turkey
²Istanbul Research and Education Hospital, Physical Medicine and Rehabilitation, Istanbul, Turkey

Introduction/Background

Osteoarthritis (OA) is the most common joint disorder, and knee OA is one of the leading causes of disability with an increasing trend. Ultrasound (US) is a technique that can be applied for both imaging-diagnostic and therapeutic purposes in knee OA. In this double blind-controlled randomized study, we utilized clinical parameters and ultrasonographic cartilage thickness measurement to assess the effectiveness of therapeutic US in knee OA.

Material and Method

Thirty-three patients (mean age 54.8±14.5) were randomized to receive either continuous US (n 15) or sham US (n 18) as a placebo. Continuous ultrasonic waves with 1MHz frequency and 1 watt/cm² power were applied for 5 minutes for 10 sessions. Primary outcome was pain on movement assessed by visual analog scale (VAS). Secondary outcomes were WOMAC scores and measurements of distal femoral cartilage thickness by imaging US.

Results

Both groups showed reduced knee pain on movement following intervention. The VAS measurements improved significantly both in the treatment and the placebo group patients (p<0.05 and p<0.05). WOMAC scores improved statistically significant in all domains (pain, stiffness, physical function and total score) in the treatment group (p<0.05). All domains of WOMAC score showed statically significant change when compared with placebo group (p<0.05). There was no change in the distal femoral cartilage thickness measurements in both groups after intervention.

Conclusion

The study revealed that US is safe and effective treatment modality in pain relief and improvement of function in patients with knee OA. However, we did not find any positive effects of US on cartilage repair.

ABSTRACT NEED TO BE EDITED - PERIARTICULAR DEXTROSE PROLOTHERAPY INSTEAD OF INTRA-ARTICULAR INJECTION FOR PAIN AND FUNCTIONAL IMPROVEMENT IN KNEE OSTEOARTHRITIS

Z. Rezasoltani

1Aja University of Medical Sciences, Physical Medicine and Rehabilitation, Tehran, Iran

Introduction/Background

Background: Osteoarthritis (OA) is a degenerative disease that can lead to painful and dysfunctional joints. Prolotherapy involves using injections to produce functional restoration of the soft tissues of the joint. Intra-articular injections are controversial because of the introduction of needles into the articular capsule.

Objectives: To compare the effect of periarticular versus intra-articular prolotherapy on pain and disability in patients with knee OA.

Study design: Randomized double-blind controlled clinical trial.

Setting: Single center, university hospital (Imam Hossein Hospital, Tehran, Iran).

Material and Method

Background: Osteoarthritis (OA) is a degenerative disease that can lead to painful and dysfunctional joints. Prolotherapy involves using injections to produce functional restoration of the soft tissues of the joint. Intra-articular injections are controversial because of the introduction of needles into the articular capsule.

Objectives: To compare the effect of periarticular versus intra-articular prolotherapy on pain and disability in patients with knee OA.

Study design: Randomized double-blind controlled clinical trial.

Setting: Single center, university hospital (Imam Hossein Hospital, Tehran, Iran).

Results

The visual analog scale score was significantly lower in the periarticular compared with the intra-articular group at the 2-, 3-, 4-, and 5-month visits, but not at 1 month. Morning stiffness and difficulty in rising from sitting were improved in both groups and were not significantly different in the peri- and intra-articular groups. Pain, joint locking, and limitation scores were all improved in both groups. Difficulty in walking on flat surfaces or climbing stairs, and sitting and standing pain, were all improved in both groups from 1 to 5 months after treatment.

Conclusion

Periarticular prolotherapy has comparable effects on pain and disability due to knee OA to intra-articular injections, while avoiding risks of complications.

INTRA-ARTICULAR STEROIDS VERSUS HYALURONIC ACID KNEE ARTHRITIS
M.D.E. MAMMARI¹, R. Doumi¹, A.M.L. Belfodil¹, M.Y. Medjahdi¹
¹Military Hospital Of Oran, Physical and rehabilitation medicine, Oran, Algeria

Introduction/Background

The main objective of the study is to assess the efficacy of intra-articular (IA) injections of hyaluronic acid (HA), compared to corticoids in patients with osteoarthritis of knee in both the long-term follow up, and whether there is a difference.

Material and Method

Randomized study, from Mars 2015 until June 2016, compared two groups of patients with knee osteoarthritis; 1rst group: injected by corticoids (only 1 injection / knee / month, n=14), controlled by group (3 injections / knee of HA, n=18). Evaluated by: pain intensity; Visual Analog Scale (VAS), Lequesne Algofunctional Index, and quality of life. The follow-up time was 12 months.

Results

After 12 months of follow-up, both treatment groups showed improvement in knee function, the corticoids group showing a greater improvement compared to HA group; in pain relief, in overall Lequesne Algofunctional Index, and quality of life.

Conclusion

The IA injection of corticoids was better to improve the symptomatology in the long-term, corticoids provided pain relief and quality of life in patients with knee OA, compared with IA of hyaluronic acid. However, IA hyaluronic acid is a good alternative the delay the surgery.

Introduction/Background

Knee Osteoarthritis (KOA) is a chronic and degenerative disease, the main cause of disability in elderly adults. It leads to changes at the level of the PNS (Peripheral Nervous System) and CNS (Central Nervous System), as well as abnormal sensitization, hyperalgesia and allodynia. Metameric level associated therapies to treat knee pain have shown to reduce local sensitization hence leading to a decrease in pain and a consequent improvement in quality of life.

Material and Method

Prospective study. Randomized. Patients attending outpatient IREP (Instituto de rehabilitacion psicofisica) clinics with at least 3 months' pain due to KOA (Kellgren 2-4).

Inclusion Criteria

Painful KOA. X-Ray signs of osteoarthritis (Kellgren 2-4), more than 3 months with pain, VAS≥5.

Exclusion Criteria

History of knee surgery, rheumatoid disease (collagenopathy), metabolic or neurological diseases, neoplastic disease.

Scales

Western Ontario University Index (WOMAC). Visual analog scale (EVA).

All patients completed standardized questionnaires at the beginning of treatment; after 6 weeks; and after 12 weeks. A treatment period of 12 weeks, with 1 session per week, was used in the studies.

The study compared 3 groups of KOA patients:
Group 1: Received classical acupuncture treatment + dry needling segmental acupuncture (L4/L5/S1)

Group 2: Received acupuncture + Lidocaine using Fischer technique (L4/L5/S1)

Group 3: Received classical acupuncture treatment (knee acupoints, 4LI, 20 TM)

Results

Total number of patients: 30

Age: 67.1 (55-87 y/o)

80% female, 20% male.

Group 1: VAS before treatment: 7-9/Womac: 45-52. VAS after treatment: 3-5/ Womac 10-15

The decrease rate (WOMAC scale) after treatment was greater in group 1 than in group 2; greater in group 1 than in group 3 (p = 0.003292). The decrease in the VAS scale was greater in group 1 than in group 2. (p =0.033<0.05)

Conclusion
The results regarding functional improvement and VAS are similar to other investigations. The importance of adding a segmental approach to the traditional Acupuncture treatment (TCA). There is no significant difference between dry needling and lidocaine use regarding metameric points.

EFFECT OF AQUATIC EXERCISE ON FLEXIBILITY AND FUNCTION OF PERSONS WITH KNEE OSTEOARTHRITIS

Introduction/Background

Osteoarthritis of the knee is a chronic joint disease which causes pain, stiffness, swelling, joint instability and muscle weakness, all of which can lead to impaired physical function.

Therapeutic exercise is recommended in numerous guidelines as a non pharmacologic treatment for knee osteoarthritis. Aquatic exercise is considered one of the most important management options.

The aim of this study was to evaluate the effect of aquatic exercise on flexibility and function of persons with knee osteoarthritis.

Material and Method

Prospective study on patients with knee osteoarthritis who went through a program of aquatic exercise three sessions a week for eight weeks. Outcome measures were collected at baseline and at the end of the program including range of motion (ROM), maximum distance walked, two subscales of WOMAC index stiffness and physical function and Lequesne index.

Results

Thirty patients were evaluated. The mean age of our population was 50.6 years old. Most of our patients were women, with a sex ratio of 0.57. The mean Body mass index (BMI) was 28.8 kg/m².

At baseline, the results reported that mean of ROM was 133°, maximum distance walked was limited in 9 cases. WOMAC stiffness and function scores were respectively 4.3 and 11.2 and mean Lequesne index was 9.8 with severe to extremely severe handicap in 25 cases.

At follow-up, we observed an improvement in each parameter: ROM increased by 2%, maximum distance walked improved in 3 cases. WOMAC stiffness and function scores decreased respectively by 50% and 46%. Lequesne index declined by 31% with severe to extremely severe handicap in 11 cases.
Conclusion

This study indicates beneficial effects of aquatic exercise in adults with knee osteoarthritis by improving joint flexibility and function due to the properties of water.

Keywords

AQUATIC EXERCISE ;FUNCTION;KNEE OSTEOARTHRITIS

Introduction/Background

Osteoarthritis (OA) is the major cause of joint pain and impaired mobility resulting in a marked reduction of quality of life. It would be of crucial importance to have a clear definition of early OA (EOA) in order to adopt proper preventive measures that might result in better long-term quality of life of affected patients and reduce or delay the need of joint replacement interventions, with the related implications in terms of economic impact on healthcare services. Aim of this systematic review (SR) was to define the state of the art on definition, diagnosis, and management of EOA.

Material and Method

We carried out an updated systematic review on both PubMed and Embase databases searching for all the studies and researches published in literature (up to the 31st December 2015) which were addressing the issues of EOA definition, diagnosis, and management. The systematic SR has been carried out following the 5 steps summarized by Khan and colleagues in 2003.

Results

Our SR found out 211 and 447 articles, when searching on PubMed and Embase database, respectively. Among the 132 papers who met our inclusion criteria, only 1 article explicitly addressed the issue of EOA definition, but it was only an expert opinion, while all the other researches were focused on diagnosis or management of EOA. EOA has been defined with regards to the younger age of osteoarthritis onset and radiological damage (grade I-II of the Kellgren and Lawrence classification).

Conclusion

EOA has been defined with regards to the age of the patient and the precocity of radiologically measurable damages. A clearer classification of EOA based on characteristics and symptoms
of affected patients, should be delivered by scientific community in order to better identify subjects who might benefit from innovative therapeutic approaches.

A FUNCTIONAL RESTORATION PROGRAM (FRP) IN CHRONICAL LOW BACK PAIN IS EFFICIENT BOTH IN LABOURERS AND IN SEDENTARY WORKERS

S. Fardjad1, L. Condamine1, C. Valser1, C. Colas2, B. Hardy1, S. Cosme1, E. Hareau1, E. peyron1, E. Hutin1, Y. Coulomb1, C. pauwels1, F. Brunet1, D. Zawistowicz1, P. parejo-margallo1, J.M. gracies1
1Groupe Hospitalier Henri Mondor, 51- avenue delattre de tassigny, CRETEIL, France
2Groupe Hospitalier Henri Mondor, 51- avenue delattre de tassigny, Cretiel, France

Introduction/Background

Work conditions increase the prevalence of chronically low back pain (CLBP) in labourers (LW) as well as in sedentary workers (SW). Previous studies showed that functional restoration program (FRP) improved the condition of patients with CLBP. Here we evaluated the differential value of FRP in LW and SW groups, with respect to spinal and abdominal muscle functions, functional capacity and autonomy, and professional reintegration.

Material and Method

Between 2012 and 2015, 89 patients (aged 18 to 65) with CLBP, included in the FRP, completed the program. There were 45 LW and 44 SW.

Judgment criteria were physical (Sorensen test, for spinal muscles, and Shirado-Ito test, for abdominal muscles), functional (Quebec score), and socio-professional (number of sick leave days in 6 months), before and after completing the FRP

Results

Both groups, LW and SW, improved their functional capacities (Quebec score : 29.194 after, vs 40.622 before the program, \( p=0.0022 \), in LW ; 26. 33 % after the FRP, vs 37.6 % before the program, \( p=0.0008 \), in SW), and the number of sick leave days dramatically decreased after the FRP (19.23 days after, vs 58.08 days before, \( p=0.0121 \), in LW ; mean 0.41 days after vs 26.53 days before, \( p=0.0018 \), in SW). Sorensen test improved in both groups (119.18 after vs 76.65 before, \( p=0.0192 \), in LW ; 119.10 after FRP vs 65.08 before, \( p=0.0011 \), in SW). Shirado-Ito Test also improved: 340.13 vs 91.81, in LW and 128.73 vs 65.08, \( p=0.0338 \), in SW

Conclusion

FRP improved the condition of patients with CLBP in all analysed criteria, both in LW and in SW. However the repartition of improvement between LW and SW was different, particularly in physical criteria (LW improved more their abdominal muscles, and SW improved more their spinal muscles). These results suggest that isokinetic studies are needed to specifically adapt the FRP to the work conditions…

COMBINED THERAPY IN OSTEOARTHRITIS OF THE KNEE, DOUBLE BLIND RANDOMIZED CLINICAL TRIAL
P. Yazdanpanah¹, H. Mohammadi², A. Arjmand³, H. Sadeghi⁴, H. Ghaffarian Shirazi⁵
¹Yasuj University of Medical Sciences, Physical Medicine&Rehabilitation, Yasuj, Iran
²Yasuj University of Medical Sciences, Department of Orthopedics, Yasuj, Iran
³Yasuj University of Medical Sciences, General Physician, Yasuj, Iran
⁴Yasuj University of Medical Sciences, Department of Pharmacology, Yasuj, Iran
⁵Yasuj University of Medical Sciences, Social Determinations of Health Research Center, Yasuj, Iran

Introduction/Background

Osteoarthritis is the most common joint disease during which knee joints are affected more than the other joints. Various drugs are used to treat osteoarthritis that each with advantages and disadvantages. The purpose of this study was to compare the efficacy of single and combination of acetaminophen, naproxen and omega-3 with a special focus on knee osteoarthritis.

Material and Method

In a randomized clinical trial, 156 patients with moderate osteoarthritis, in 6 groups of 26 persons with acetaminophen, naproxen, acetaminophen + naproxen, acetaminophen + omega-3, naproxen + omega-3, acetaminophen + naproxen + omega-3 therapy. With acetaminophen 1000 mg was used every 8 hours, naproxen 500 mg every 12 hours and omega-3 1000 mg every 8 hours for 6 weeks. Twelve patients missed the study. Before the start of the treatment and at the end of treatment, we evaluated the results of the treatments using Visual Analogue Scale (VAS) and Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC).

Results

Patients pain, physical function, joint stiffness and WOMAC ranking in all treatment groups significantly decreased after the treatment. WOMAC ranking after the treatment between groups was significantly different and triple-drug therapy yielded better results than one-drug therapy.

Conclusion

The least cost of treatment is attributed to acetaminophen and the highest cost of treatment is attributed to acetaminophen+ naproxen+omega-3. The best results of therapies of knee osteoarthritis was attributed to naproxen+omega-3.
The study showed that adding omega-3 will increase the efficacy, reduce joint stiffness and reduce severity of the side effects of these drugs. The efficacy of omega-3 may be due to anti-inflammatory effect through competitive inhibition of the arachidonic pathway.

THE EFFICACY OF ELECTROMYOGRAPHIC BIOFEEDBACK ON PAIN, FUNCTION AND MAXIMAL THICKNESS OF VASTUS MEDIALIS OBLIQUE MUSCLE IN PATIENTS WITH KNEE OA; A RANDOMIZED CLINICAL TRIAL

S.A. Raeissadat¹, S.M. Rayegani², L. Sedighipour², Z. Bossaghzade², M.H. Abdollahzadeh², F. Mollayi³, R. Nikray²

¹Research development center of Shahid Modarres hospital, Physical medicine and rehabilitation department of Shahid Beheshti university of medical sciences, Tehran, Iran
²Physical medicine and rehabilitation research center, Physical medicine and rehabilitation department of Shahid Beheshti university of medical sciences, Tehran, Iran
³Payame noor university, Sport sciences, Tehran, Iran

Introduction/Background

The aim of this survey is to study the effect of adding EMG biofeedback to isometric exercise on pain, function, thickness of the vastus medialis oblique muscle and maximal electrical activity of this muscle in isometric contraction, in patients with knee OA.

Material and Method

In this clinical trial, 46 patients, with diagnosis of knee OA, were recruited and assigned to two groups of case (23 patients), with EMG biofeedback associated exercise, and control (23 patients), with sham biofeedback associated exercise. Data were gathered via VAS score, the Persian version of WOMAC and Lequesne questionnaires, Ultrasonography of VMO muscle and surface electromyography of this muscle at baseline and at the end of the study. Variables compared before and after exercise program in each group and between the two groups.

Results

At the end of the study, there were no significant differences between the two groups regarding measured variables. Only the VAS score was significantly less in case group. Although all assessed parameters, except for VMO muscle thickness, were found to be improved significantly in each group, the amount of changes were not significantly different between the two groups except for the VAS score. VMO muscle thickness didn't change significantly after exercise therapy in either of the groups.

Conclusion

Isometric exercises accompanied by EMGBF and the same exercises with sham biofeedback for 2 months both lead to significant improvements in pain, and function of patients with knee
OA. Real EMG biofeedback was not superior to sham biofeedback in any of the measured variables except for VAS score.

WHAT ARE THE EHLERS-DANLOS?

G. Valérie

Association UNSED, Occitanie, Fourques, France

Introduction/Background

What are Eds? Genetic diseases with 13 types identified. The SEDh requires a clinical diagnosis. Appropriate care: the role of physical medicine and rehabilitation is primordial. Often confused with fibromyalgia, the SEDh must be diagnosed on New York criteria.

International Classification: hypermobile Ehlers-Danlos (hEDS) and the spectrum of joint hypermobility.

Objectives To give you the latest international information concerning the hEDS, with the physical and rehabilitation medicine management, which is important for the patient’s daily life. Inform you by updating very clearly on what is a hEDS. The setting of the diagnosis with criteria updated last March 15, the mandatory criteria and inform you of the new differential diagnosis: the JHS.

Material and Method

Material / Patients and methods It is an international consortium of more than 90 global specialists that has published these diagnostic changes on EDS’ and have redefined the hEDS with the implementation of the JHS. This publication replaces Villafranchiens. The numbering of SED types is replaced. (ex: Type III = hEDS)

Results

Results The hEDS is no longer defined on major and minor criteria, but on mandatory criteria. A re-evaluated Beighton score. A JHS is imperative for the pose of said diagnosis. The hEDS remains a genetic disease which differentiates it from the JHS. Discussion -

Conclusion

The hEDS remains a genetic disease which differentiates it from the JHS. Discussion - Conclusion The hEDS is an orphan genetic disease that remains in rare diseases and is part of the 3rd PNMR3 plan

THE EFFECTIVENESS OF POSTOPERATIVE HYBRID PHYSIOTHERAPY ON HIP OSTEOARTHRITIS

Y. Mikami¹, F. Kouki², N. Daigo², U. Kai¹, K. Hiroaki¹
¹Hiroshima University Hospital, Department of Rehabilitation Medicine, Hiroshima, Japan
²Hiroshima University Hospital, Division of Rehabilitation- Department of Clinical Practice and Support, Hiroshima, Japan

Introduction/Background

The reduced physical function and pain experienced by patients with lower limb osteoarthritis prior to surgery can prevent progress in functional training during the early postoperative period. We devised a hybrid physiotherapy regime using an antigravity treadmill and a low-frequency therapeutic device, and we assessed its effectiveness in patients with hip osteoarthritis after surgery.

Material and Method

The study population consisted of 22 patients who underwent hip replacement arthroplasty to treat their osteoarthritis at Hiroshima University Hospital. The patients were randomized to the conventional physiotherapy group (conventional group: 11 patients) or the hybrid physiotherapy group (hybrid group: 11 patients). The conventional group mainly performed lower limb joint range-of-motion training, weight-load muscle strengthening training, and gait training, while the hybrid group performed this same training, as well as gait training on an antigravity treadmill and muscle strengthening training using the low-frequency therapeutic device. The patients started daily physiotherapy from postoperative day 1, and their physical function was evaluated preoperatively and in postoperative week 2.

Results

Evaluation of postoperative physical function yielded the following results in the conventional group and hybrid group, respectively: a) knee extension force 13.2 ± 3.5 kgf vs. 18.6 ± 6.5 kgf; b) 10-meter gait test 19.7 ± 7.9 sec vs. 12.6 ± 3.8 sec; c) timed up-and-go (TUG) test 20.9 ± 7.0 sec vs. 15.0 ± 5.5 sec; and d) six-minute distance (6MD) 197.6 ± 55.4 m vs. 279.8 ± 91.9 m.

Conclusion

The hybrid physiotherapy regime enables patients to start muscle strength training and gait/endurance training immediately after surgery, and patients in the hybrid group showed greater postoperative lower limb muscle strength and better gait function than their counterparts in the conventional group. In conclusion, the present findings suggest that the proposed hybrid physiotherapy regime after hip replacement arthroplasty can improve the physical function of patients in the acute phase postoperatively.

Introduction/Background

In order to safely progress patients back to their desired activity level after total hip arthroplasty (THA), there is a need to develop rehabilitation strategies to expedite and promote the recovery during the acute postoperative period. The purpose of this study is to investigate the effects of home-based exercise in the early stage on the mid-term functional recovery after THA.

Material and Method

Patients who underwent THA were randomized to an exercise group (n=16) or a control group (n=16). In exercise group, home-based in the early stage exercise was performed between 4 weeks and 8 weeks after THA. Intervention programs were home-based resistance training using elastic band, consisted of hip abduction and leg rising in supine position, knee extension in dangle sitting, hip external rotation in side lying. Outcome measures were hip pain, hip range of motion, muscle strength of lower extremity and Timed up and go (TUG) test. These parameters were assessed at 4 weeks, 8 weeks and 6 months postoperatively.

Results

There was no difference between the two groups in age, gender, body mass index and pre-intervention physical functions. The results of the two-way ANOVA showed a significant group × time interaction effect for the hip abductor strength (P=0.047) and TUG-test (P=0.013). The hip abductor strength after intervention trended to be greater for the exercise group than for the control group (P=0.071). At 6 months after THA, the hip abductor strength in the exercise group was greater than that in the control group. Furthermore, the TUG test at 6 months postoperatively showed significantly better results in the exercise group than in the control group.

Conclusion

The results of the present study demonstrated that the home-based exercise in the early stage after THA was an effective intervention, especially in improving the mid-term hip abductor strength and walking ability.

INFLUENCE OF KNEE JOINT KINEMATICS AND EXTERNAL MOMENTS ON JOINT LOAD DURING THE STANCE PHASES IN SEVERE KNEE OSTEOARTHRITIS
T. Fukaya1, H. Mutsuzaki2, K. Mori3
1Tsukuba International University, Department of Physical Therapy- Faculty of Health Sciences, Tsuchiura, Japan
2Ibaraki Prefectural University of Health Sciences, Center for Medical Sciences, Inashiki-gun, Japan
3Ibaraki Prefectural University of Health Sciences, Department of Radiological Sciences, Inashiki-gun, Japan

Introduction/Background

The dynamic medial knee load in knee osteoarthritis is represented by the external knee adduction moment and varus thrust in the frontal plane during the stance phase. However, walking analyses performed to identify medial knee osteoarthritis show abnormalities in not only the frontal plane, but also the moment and movement in the sagittal plane. This study aimed to investigate the influence of moment on joint load during the stance phases, and to investigate the relationship between moment and movement.

Material and Method

The study participants comprised 15 individuals (23 knees) with knee osteoarthritis rated as 3 or more on the Kellgren-Lawrence scale. For the walking analysis, kinematics and kinetics data were obtained at 200 Hz using an eight-camera motion analysis system. Ground reaction force data were recorded at 200 Hz using a floor-mounted force plate. A paired t-test was performed to compare the difference between frontal and sagittal plane moments. Pearson’s product-moment correlation coefficient was used to confirm the relationship between the external moments and the knee joint movement during stance phase.

Results

The first peak of external knee adduction moment showed an average of 0.42±0.19 Nm/kg. The average external knee extension moment showed was 0.26±0.22 Nm/kg, which was significantly smaller than the first peak of external knee adduction moment ($p = 0.01$). The first peak of external knee adduction moment was mildly positively correlated with maximum knee varus angle during the early stance phase ($r = 0.47$). The external knee extension moment was strongly positively correlated with the flexion angle of the early stance phase ($r = 0.83$).

Conclusion
The external knee moment and the joint movement must be combined in an effective rehabilitation approach to strength the muscles, particularly the quadriceps, to decrease the load on the medial compartment of knee joint.

RISK OF KNEE OSTEOARTHRITIS IN PATIENTS USING N-ACETYLCYSTEINE (NAC): A NATIONWIDE POPULATION-BASED COHORT STUDY

Y.T. Yeh¹, C.C. Liang¹, J.H. Chiang²
¹Buddhist Tzu Chi General Hospital, Department of Physical Medicine and Rehabilitation Medicine, Hualien, Taiwan R.O.C.
²China Medical University Hospital, Management Office for Health Data, Taichung, Taiwan R.O.C.

Introduction/Background

Knee osteoarthritis (OA) is known as a progressive degenerative disorder, but recent evidence suggests that inflammatory mediators contribute to cartilage degradation. N-acetylcysteine (NAC) is an antioxidant that can directly scavenge reactive oxygen species. According to basic studies, NAC had an apparent effect on reducing the synthesis of proinflammatory and structural mediators by synovial cells. In contrast, chondrocyte in osteoarthritic cartilage was found significantly lower intracellular p53 expression. NAC was also reported to decrease p53 expression through reduction of oxidative DNA damage. Due to lacking clinical trials, we conducted this study to determine the relationship between NAC use and risk of knee OA.

Material and Method

We designed a retrospective cohort study using the Taiwan's Longitudinal Health Insurance Database from 2000 to 2013. Patients receiving oral form N-acetylcysteine over 28 days within one year after first prescription were defined as case group, whereas those without N-acetylcysteine use were considered as candidates of control group. We adopted a 1:10 propensity score matching by age, sex, index year and comorbidities to consist the control group. Patients with previous history of knee operation (total knee replacement and anterior cruciate ligament reconstruction), bed-ridden status, and less than 20 years old were excluded. The primary outcome was a new diagnosis of knee OA during follow-up period.

Results

Our study samples consist of 7726 using NAC subject and 77260 non-used NAC subject. People with NAC use have significantly higher incidence of osteoarthritis (adjusted HR: 1.39, p <.0001)(Figure). In addition, analyses stratified by age group and sex, all subgroups showed significantly higher incidence of osteoarthritis (p <.0001) in NAC users(Table)
Conclusion

Patients who take oral N-acetylcysteine more than 28 days per year have higher risk of developing knee osteoarthritis.

Introduction/Background

Radiofrequency of geniculate nerves has emerged as a complement to the more conservative measures already in use aiming to ease the pain and further increases autonomy of the patients with symptomatic gonarthrosis. This work aims to review the literature regarding radiofrequency of geniculate nerves guided by ultrasound in these patients.

Material and Method

During December 2017 we searched Pubmed for randomized controlled trials, cohort studies and case reports. Bibliographies of included data were also revised for additional studies published. The selection procedure was not systematic. Keywords included “Pulsed Radiofrequency Treatment”, “Osteoarthritis”, “Knee Pain”.

Results

The geniculate nerves are adjacent to the periosteum innervating the joint capsule as well as the intra and extra-articular ligaments. Usually, the nerves submitted to radiofrequency are the supero-medial, supero-lateral and the inferior-medial, being generally very close to vascular structures.

In general, there are two types of currents, continuous and the pulsed (the most commonly used in the knees). The use of this procedure is based on discontinuation of nociceptive knee afferents. There seem to be genuine biological effects on cell morphology, synaptic transmission, and pain signalling.

Ultrasonography has an excellent efficacy rate of accurate needle application with good visualization of soft tissues, which allows avoiding lesion of vascular or nerve structures.

Anesthesia blocks may be previously performed, and responses above 80% in pain relief usually predict a good response to radiofrequency.

Symptomatic relief seems to be maintained for at least 6 months, but more studies are needed to better understand its long-term efficacy.
Conclusion

Radiofrequency of geniculate nerves is a technique with few documented side effects, which promotes symptomatic relief of patients with gonarthrosis. Therefore, it is a reasonable option to take into account in the treatment of patients with symptomatic gonarthrosis who, for whatever reason, will not undergo surgery or await for it.

Botulinum toxin-A (BTA) injection has been recently proposed for knee OA patients to reduce pain and disability. In this study we evaluate BTA injection efficacy and safety among non-advance knee OA participants in a before-after trial.

**Material and Method**

This trial was conducted on knee OA patients presented to our PM&R clinic. Thirty participants aged 40-75 years who had radiographic KLS grades of II and III were included. Single intra-articular injection of half of a 500IU vial BTA was applied for all participants. Patients were prospectively evaluated at baseline and then at 8 and 24 weeks after injection using the visual analog scale (VAS) for pain and Western Ontario & McMaster Universities Osteoarthritis Index (WOMAC) in three subscales: pain, stiffness and function.

**Results**

Both main outcome measures of this trial (VAS and WOMAC) significantly improved after 24 weeks follow up. About two thirds of final VAS improvement was achieved in the first week after injection (from 7.2 to 4.5, MD%=36%, p value= 0.008); then at 8 and 24 weeks post injection VAS reached 3.8 and 3.3, respectively. Almost 81% & 77% of patients had more than 30% decline in their baseline VAS at 8th and 24th week visits, respectively. Also a similar pattern was observed for WOMAC index of sixth month (from 56.7 to 31.0, Mean Difference=−25.7 [MD%=45%], p value= 0.005), with more remarkable changes in function subscale (MD%= 46%). In this study no major adverse events were noted.
Conclusion

BTA showed promising effects in improving knee pain, ROM and functional status. Therefore this single session method could be considered as an alternative to other intra articular injections in knee OA patients who did not response to preliminary conservative treatments. Further data is necessary to assess long-term effects and cost-benefit analysis of BTA against other similar choices.

Introduction/Background

The main aim of this review was to discuss the literature on ozone intra-articular injection in knee osteoarthritis (OA) patients and to synthesize the available evidence as a meta-analysis.

Material and Method

A systematic review of Pubmed, Google scholar and Cochrane Central Register of Controlled Trials was performed to identify all English-language RCTs that evaluated the efficacy of ozone intra-articular injection versus a control injection for knee OA patients. A Random effect model was used to compare efficacies among trials based on Visual Analogue Scale (VAS) for pain and Western Ontario and McMaster Universities Arthritis Index (WOMAC) questionnaire.

Results

From 231 records screened, only 26 one had relevant topics. Among them only five studies satisfied our inclusion criteria. A total of 428 patients were included which 53% of them (n=225) in the treatment group and 47% in the control [HA, hypertonic dextrose and air injection] group (n=203). The mean age of ozone groups was 64.5 years compared with 64.4 years for control group. Females were the majority in both treatment and control group (80% and 77% respectively). All studies had at least 2 months followup. In almost all of them 3-4 weekly rounds of ozone injection were performed, with concentration of 15-30 ug/cc.

Conclusion

Intra-articular ozone in comparison to HA or hypertonic dextrose injections, may have quietly equal effects in the treatment of mild to moderate knee OA patients throughout short term period; However by 3-6 months after injection, this therapeutic effect would be disappeared, more earlier than other control injections.

THE EFFECT OF THE HYBRID ASSISTIVE LIMB (HAL) TRAINING AFTER TOTAL KNEE ARTHROPLASTY

H. Mutsuzaki1, K. Yoshikawa2, A. Sano2, T. Fukaya3, M. Yamazaki4
1Ibaraki Prefectural University of Health Sciences, Department of Orthopaedic Surgery, Ami-machi- Inashiki-gun, Japan
2Ibaraki Prefectural University of Health Sciences Hospital, Department of Physical Therapy, Inashiki-gun, Japan
3Faculty of Health Sciences- Tsukuba International University, Department of Physical Therapy, Tsuchiura, Japan
4University of Tsukuba, Department of Orthopaedic Surgery, Tsukuba, Japan

Introduction/Background

The hybrid assistive limb (HAL, CYBERDYNE) is a wearable robot that provides assistance to a patient while they are walking, standing, and performing leg movements based on the intended movement of the wearer. Therefore, we assessed the effect of robot-assisted training on the walking of patients after total knee arthroplasty (TKA) for osteoarthritis.

Material and Method

Ten patients received HAL training (mean age: 74.1 ± 5.7 years; height: 150.4 ± 6.5 cm; weight: 61.2 ± 8.9 kg). Eleven patients received conventional rehabilitation (mean age: 78.0 ± 8.0 years; height: 151.2 ± 10.1 cm; weight: 58.8 ± 10.0 kg). HAL training were performed one week after TKA, 20 minutes on a session, during four weeks period, twelve times in total. Gait speed, step length, range of motion and muscle strength were measured.

Results

The gait speed and step length of preferred speed in the HAL group were greater than that in the conventional group at 4 and 8 weeks (p < 0.05). The gait speed and step length with maximum effort in the HAL group were greater than that in the conventional group at 2 and 4 weeks (p < 0.05). The extension lag in the HAL group were smaller than that in the conventional group at 2 weeks (p < 0.05).The muscle strength of knee extension in the HAL group were greater than that in the conventional group at 8 weeks (p < 0.05).

Conclusion

HAL training after TKA can improve the walking ability compared with conventional rehabilitation up to 8 weeks after TKA.

The Milwaukee Shoulder Syndrome (MSS) is a destructive arthropathy that affects elderly women (over 60 years old), unilaterally (95%) or bilaterally (60%) and with predominance of the dominant side. It is associated with the deposit of Pyrophosphate Basic Calcium (PBC) crystals in 100% of cases (Pyrophosphate calcium crystals in 50%) in soft tissues that leads to increased of synovial fluid, rotator cuff tears and joint collapse consequently. Clinically it manifests with pain, swelling and rapid destruction of the glenohumeral joint, leading to significant disability. Some cases can be complicated by septic arthritis. The management is mainly through drugs (NSAIDs, acetaminophen, opioids) and painful shoulder physiotherapy aimed to reducing pain and recovering passive and active mobility of the shoulder that allows its functionality. Tidal irrigation combined with local infiltration of corticosteroids may produce pain and range of movement (ROM) improvement in the short-medium term. Some may end up in joint replacement surgery to restore shoulder function.

Introduction/Background

The Milwaukee Shoulder Syndrome (MSS) is a destructive arthropathy that affects elderly women (over 60 years old), unilaterally (95%) or bilaterally (60%) and with predominance of the dominant side. It is associated with the deposit of Pyrophosphate Basic Calcium (PBC) crystals in 100% of cases (Pyrophosphate calcium crystals in 50%) in soft tissues that leads to increased of synovial fluid, rotator cuff tears and joint collapse consequently. Clinically it manifests with pain, swelling and rapid destruction of the glenohumeral joint, leading to significant disability. Some cases can be complicated by septic arthritis. The management is mainly through drugs (NSAIDs, acetaminophen, opioids) and painful shoulder physiotherapy aimed to reducing pain and recovering passive and active mobility of the shoulder that allows its functionality. Tidal irrigation combined with local infiltration of corticosteroids may produce pain and range of movement (ROM) improvement in the short-medium term. Some may end up in joint replacement surgery to restore shoulder function.

Material and Method

We present the case of a 86-year-old woman who consulted for pain, inflammation and functional limitation non-traumatic of the right shoulder for weeks of evolution. Physical examination includes swelling, deformity with humeral head prominence and limitation of active and passive ROM with pain.

Results

Radiological Imaging tests show anterior impaction of the humeral head in the glenoide, AC dislocation and multiple fractures in the scapula. Arthrocentesis: the analysis shows an inflammatory fluid and PBC crystals are detected. These findings, along with the radiological tests, are compatible with MSS.

Conclusion

The MSS is a rare entity of cuff tear arthropathy with few cases published in the literature since it was first described by Dr. Robert Adams in 1875. It's clinical and radiological images alongside with the findings of joint crystals are diagnostic. Management is fundamentally conservative, since surgery (Reversed Total Shoulder Arthroplasty) provides few favorables results.

ISCHIOFEMORAL IMPINGEMENT SYNDROME IN TWO FEMALE TEENS
M.F. Diaz1, N. Lara1, J. Diaz Ruiz1, L. Rodriguez Zambrano1
1Universidad Nacional de Colombia, Physical Medicine and Rehabilitation, Bogota, Colombia

Introduction/Background

Hip pain is a common cause of medical consultation, which is usually difficult to diagnose because of its diverse etiology. Ischiofemoral impingement syndrome is a cause of hip pain potentially underestimated, and it is defined by pain related to a decrease of the space between the ischial tuberosity and the lesser trochanter of the femur, with abnormal morphology and intensity of quadratus femoris in magnetic resonance imaging.

Material and Method

We present two cases of ischiofemoral impingement in two female teens who play sports regularly without traumatic or surgical history, with clinical evolution of approximately 2 years of hip pain radiating to the thigh in one case. Presenting exacerbation with physical activity and improved with rest. Also, was found in both cases pain with adduction and external rotation movements of the hip and signs of joint hypermobility.

Results

The hip MRI study showed quadratus femoris muscle edema with narrowing of the ischiofemoral space. The distance of ischiofemoral space and quadratus femoris space were narrow. The findings were compatible with ischiofemoral impingement syndrome in both patients, as it is shown in Figs 1 and 2.

Conclusion

In one case, rest and stretching exercise was satisfactory, while in the other case the symptoms have persisted despite conservative treatment and CT guided blocking using corticosteroids and anesthetics, and it was considered the need to perform a surgical procedure with resection of the lesser trochanter.

These cases show this entity as a possible cause of hip pain, which can accurately diagnose with MRI and clinical findings, and treat promptly.

Knee osteoarthritis is one of the most common musculoskeletal problems that cause pain. Previous studies showed effect of low level laser therapy in various pain conditions; however, it has limitation of energy and depth of penetration. Therefore, this study aim to assess the efficacy of high power laser therapy (HPLT) for pain relief and functional outcome in patients with knee osteoarthritis.

Material and Method

42 patients with diagnosis of primary OA knee, age 50-88 years, Kellgren-Lawrence classification (KL) 2-4 and pain score greater than 4 on a 0-10 scale. All patients were treated at outpatient Rehabilitation Medicine Department. They were randomly allocated into 2 groups. The treatment group received HPLT (energy density 22.39 J/cm², accumulated dose 5,625 joule/course) and the control group received sham laser (10 sessions, 2-3 sessions/week in both groups). Both groups were advised to exercise and lifestyle modification as conventional treatment. Pain (assessed by VAS pain scale) and functional outcome (assessed by Thai version of the modified WOMAC scales) were evaluated before and after treatment.

Results

42 patients participated in this study with mean age(SD) of 65.5(8.8) years, KL 2, 3 and 4 were 14, 17 and 11 respectively. At the end of the study, VAS and modified WOMAC scale showed significantly decreased in both groups. The decrement of VAS [median difference of VAS (interquartile range)] of the treatment and the control groups were 4.2(3.0,4.9) and 1.5(0.3,3.9); the decrement of modified WOMAC [mean difference of modified WOMAC(SD)] of the treatment and the control groups were 64.8(31.6) and 41.5(35.0) respectively. Both median difference of VAS and mean difference of modified WOMAC of the treatment group were significantly decreased more than the control group.

Conclusion

High power laser therapy was effectively decreased pain and improved functional outcome in knee osteoarthritis patients more than sham laser plus conventional treatment.

ISPR8-0847
COMPARISON OF KNEE JOINT ADDUCTION MOMENT TO FEMALE ON BARE FOOT AND HIGH HEELS

D. Intania Sari¹

¹Faculty of Medicine Universitas Airlangga/Dr. Soetomo General Hospital/ Universi, Physical Medicine and Rehabilitation, Surabaya, Indonesia

Introduction/Background

Milions of women wear high heels during their activities, i.e work, social activities, nonetheless there are only a few of them know the shear load effect on wearing high heels to foot joints. The use of high heels mediates changing of ground reaction force, external knee adduction moment (KAM), muscle activity and posture implication.

Material and Method

This study was pre-experimental within active healthy female, permanent residence in surabaya indonesia which recruited and eligible for inclusion criteria and was treated as consecutive sampling. The 14 subjects recruited walk bare foot and also high heels shoes (3 and 7 cm) on gait trajectory using CMAX gait analysis software.

Results

Mean of knee joint adduction moment on bare foot 13,21 ± 4,90, for 3 cm high heels 15, 12 ± 5,25, for 7 cm high heels were 18,20 ± 7,36. Knee joint adduction moment were higher on high heels than bare foot.

Conclusion

there was difference of knee joint adduction moment on bare foot, 3 cm high heels, also 7 cm high heels

Keywords

high heels, bare foot, knee joint adduction moment

The aim of this study was to assess the efficiency of Knee-Ankle-Foot-Orthoses (KAFOs) for treating painful genu recurvatum (GR) and to determine the users' tolerance and satisfaction.

Material and Method

Population: patients included in this study were found to have a GR at the physical examination during the stance phase, which was confirmed by a medical doctor. 27 patients with 31 KAFOs were included.

The main outcome was the score obtained on the verbal numerical rating scale (VNRS) before and at least three months after a KAFO was fitted and the score obtained on the verbal numerical pain rating scale (VRS). Secondary outcomes were rated with the QUEST (Quebec user evaluation of satisfaction with assistive technology).

Results

After the KAFO was fitted, the median VNRS pain score decreased from 85/100 to 25/100 (p≤0.001) and the description of the pain on the VRS decreased from “extreme” to “mild” (p≤0.001). The QUEST gave a total score of 4.0.

Conclusion

Treating a painful GR with a KAFO reduced the pain efficiently whatever the patients’ diagnosis, and high patients’ satisfaction scores were obtained.

Keywords

genu recurvatum;pain;Knee Ankle Foot Orthosis

Introduction/Background

Total knee arthroplasty has been shown to be an effective procedure in improving quality of life of patients with knee osteoarthritis and disability. Clinical assessment of patients before knee arthroplasty could predict quality of life of these patients after arthroplasty and rehabilitation.

The aim of this study was to establish correlation between quality of life of the patients with severe knee osteoarthritis 6 weeks after knee arthroplasty and early rehabilitation with clinical parameters (age, BMI, waist circumferences, physical function, pain and stiffness) before arthroplasty.

Material and Method

Prospective research includes 96 patients (average age 67.5 ± 9.2 years, range of 45-78 years) that underwent total knee arthroplasty. Early program of kinezitherapy and occupational therapy was performed. Instrument used for assessment of the quality of life, physical function, pain and stiffness is modified version of Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC). All patients completed the questionnaires preoperatively and 6 weeks postoperatively. Pearson test of correlation was used to analyze numerical data.

Results

Quality of life of the patients with knee osteoarthritis 6 weeks after arthroplasty shows significant correlation with physical function (r=0.547, p<0.00), pain (r=0.281, p<0.01) and waist circumferences (r=0.208, p<0.05) preoperatively.

Conclusion

Results of our research show that physical function, pain and waist circumferences of the patients with knee osteoarthritis before arthroplasty influences on the level of the quality of life
after total knee arthroplasty. These findings can be important for creating the program of preoperative rehabilitation and for assessment of indications for arthroplasty.

TREATMENT OF KNEE OSTEOARTHRITIS – IS MICROCURRENT THERAPY AN OPTION?
A. Glogaza¹, O. Husemeyer¹, M. Weigl²
¹Ludwig Maximilians University Munich,
Department of Orthopaedics- Physical Medicine and Rehabilitation, Munich, Germany

Introduction/Background

In contrast to interferential electrotherapy in the treatment of knee osteoarthritis (OA), little is known about the effects of microcurrent therapy (MCT). MCT uses very low currents and is not perceptible by the patients. The aim of this study was to explore effects of MCT.

Material and Method

This double-blinded randomized controlled trial (registered at clinicaltrials.gov; NCT02975154) had four arms: MCT with 100µA (Group A), MCT with 25µA (Group B), sham-treatment (Group C) and a control Group D. Inclusion criteria: Radiological confirmed knee OA, pain ≥ 3 (Numeric Rating Scale), no metal implants. Patients in A, B and C had 10 treatments (30 min., 3 times a week). Primary outcome: Longitudinal pain intensity of daily measured pain (morning and evening). Secondary outcome: Knee osteoarthritis outcome score (KOOS), SF-36-Questionnaire, 6-min-walking-test (6MWT), Get-up-and-go-Test (GUG). Changes in the pain intensity (NRS) across the treatment period (day 1-22) were statistically
compared by mixed effect models with random intercepts.

Results

52 patients (Age 72±7 years; 37 female) completed the study (fig.1). Group comparisons for morning pain showed borderline non-significant improvements for A vs. D (p=0.057) but significant improvements for Group B vs. D (p=0.001). No significant improvements for A vs. C (p=0.711) or B vs. C (p=0.088) in morning pain. In terms of evening pain significant improvements were found for A vs. D (p <0.001), A vs. C (p<0.001), B vs D (p<0.003) and B vs. C (p = 0.007). Kruskal-Wallis-Tests showed no significant group differences in the secondary outcomes.
Conclusion
This explorative study suggests that MCT can improve evening pain more than sham treatment. A confirmative study is recommended.

ASSOCIATION Tibial Coronal Alignment of Total Knee Arthroplasty With Patient Satisfaction: Using 3D Matching Evaluation Method

K. Seki¹, T. Seki¹, T. Imagama¹, A. Tokushige¹, H. Ogasa¹
¹Yamaguchi University School of Medicine, Orthopedic Surgery, Ube, Japan

Introduction/Background

The aim of this study was to evaluate tibial coronal alignment using 3D-reconstructed CTs and to assess the relationship of total knee arthroplasty (TKA) alignment and clinical outcome.

Material and Method

Total 62 knees of 53 consecutive patients who underwent primary TKA were included. For assessment of TKA component position, we used 3D matching evaluation method. For these, preoperative planning with 3D templates were has been done. And we performed CT photography of the whole lower limbs after surgery similar to preoperation and tibial component setting was located after surgery using evaluation software made in LEXI Company and evaluated it. For knee patient-reported outcome scoring the Japanese Knee Osteoarthritis Measure (JKOM) was used at 6month and 1 and 2 years postoperatively. And patients were asked to grade their level of satisfaction for each question (ie, very dissatisfied, dissatisfied, neutral, satisfied, or very satisfied). The patients were divided into two groups: neutral alignment group (n=49: preoperative alignment±2°), and outlier group (n=13: preoperative alignment>2°). We compared these two groups for JKOM, level of satisfaction and we investigated correlations between alignment variables and JKOM.

Results

There was significant difference in the number of patients who answered satisfied or very satisfied between the two groups (85.7% in neutral alignment group vs. 53.8% in the outlier group, p<0.05). And there was significant difference in JKOM score between the two groups (23.9±19.3 in neutral alignment group vs. 38.5±24.0 in the outlier group, p<0.05). Pearson correlation coefficient (P-value) between tibial coronal alignment and JKOM was significant (r=0.3325, p=0.0083).

Conclusion

Significantly inferior outcome was detected in the group of tibial alignment-outliers.

Arthroplasty of the knee is one of the major surgical successes of orthopedics. Together with post-surgical reeducation it helps alleviate pain and improve the mobility of the knee as well as the quality of life of an elderly person.

The aim of our study is to figure out the future of short-term algo-functioning in patients with a thorough knee prothesis.

**Material and Method**

Our paper is a retrospective study of the case of 36 patients admitted between 2016 / 2017 in the Department of Physical Medicine and Functional Reeducation at Sahloul Hospital after a thorough knee prothesis. The assessment of pain was made by means of ‘EVA’; it’s functioning by ‘Lequesne index’, and by gauging functional independence.

**Results**

This study dealt with 23 women and 13 men, with an average age of 70.3 years. Six of them had double prothesis. Besides, 9 of these patients suffered from diabetes; 5 from HTA (hypertension). The average of EVA at admission was 6.5 with an "Lesquesne index" at 21 (15 -26) and an MIF at 82 (73 - 92). The average stay at hospital was between 14.7 days (10 - 28). 5 patients had sharp pain accompanied with stiffness related to painful complex locoregional syndrome.

Functional gain was noticed in 21 patients with a "Lesquesne index" at 21 (10 -15) and an MIF at 102 (90 -109). The woman patient who underwent a surgical operation on her shrinking lumbar canal was in a stable condition accounted for by muscular weakness caused by neurological pain.

**Conclusion**

A well-done arthroplasty allows the re-autonomization of patients. Taking a good care of an elderly person, with an intensive functional reeducation, together with a precocious verticalisation, help reduce the incidents of slippery risks and improve the life quality of these patients.

ISPR8-0934
COMPARE THE EFFECT OF TWO DIFFERENT BODY POSITIONS DURING WHOLE BODY VIBRATION TRAINING IN THE EARLY PHASE REHABILITATION AFTER TOTAL KNEE ARTHROPLASTY.

W.L. Liu¹, H.T. Huang², T.W. Chen¹, S.F. Lin¹, P.Y. Yen¹, Y.C. Tsai¹
¹Kaohsiung Municipal Ta-Tung Hospital, Rehabilitation, Kaohsiung, Taiwan R.O.C.
²Kaohsiung Medical University Chung-Ho Memorial Hospital, Orthopaedics, Kaohsiung, Taiwan R.O.C.

Introduction/Background

End-stage knee joint Osteoarthritis is commonly treated with total knee arthroplasty (TKA). However, patients with TKA still have deficits in postural control, and knee performances after a period of rehabilitation. Whole-body vibration (WBV) training has beneficial effects for improving muscle strength, balance, proprioception, and pain. Besides, the neuromuscular response depends on different model parameters and the body position on the vibration platform. The aim of this study was compare the effect of two different postures during vibration training in the early phase after TKA.

Material and Method

According to fall risk score, all TKA patients who after surgery six weeks would be separated into two groups, standing group or sitting group. All subjects would receive WBV training with different postures for 3 times a week for 3 weeks, and also receive pre and post outcome measures included the isometric muscle strength of knee, postural control ability and fall risk test, range of joint motion, ambulation ability, and Chinese Version of Knee injury and Osteoarthritis Outcome Score (KOOS).

Results

The subjects of the two groups were assessed outcome measures before and after intervention. In standing group, the changes of the measures were all significantly different. In sitting group, the changes were significantly different only in fall risk score, active range of knee joint motion, six-minute walk test, and some subscales in KOOS symptoms, function in daily living, knee related quality of life.

Conclusion

WBV training can improve postural control ability and functional performances after TKA. Besides, the training effect of WBV with standing posture are better than with sitting posture. In clinical, to patients who are weaker or painful after TKA, they can receive WBV training with sitting posture to reduce knee pain or stiffness, and increase willingness to use their affected limbs during the early phase, and also promote further rehabilitation training in the future.

ISPR8-1009
EFFECT OF KINESIO TAPING ON IMMEDIATE REHABILITATION PROGRAM FOR KNEE MEDIAL COMPARTMENT OSTEOARTHRITIS
A. Alobaidi
1College of Health and medical Technology, Dept. of Physiotherapy, Baghdad, Iraq

Introduction/Background

The basics of the Kinesio Taping (KT) in Korea and Japan, the properties of the tape are its structural flexibility and elasticity which has suggested to enhance afferent input through skin receptors during movement. The aim of this study is to evaluate the role of KT in the immediate rehabilitation management of knee medial compartment Osteoarthritis (OA) through application of Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC).

Material and Method

120 patients (mean & SD age 55.16 & 7.05 years, body mass 31.23 & 7.20 Kg/m), 80 females and 40 males diagnosed as candidates of chronic stage medial compartment knee OA regardless the etiology participated in this randomized controlled clinical trial. They had been referred to the Medical City teaching Hospital in Baghdad, Iraq from Oct. 2016 till June 2017. The study sample was divided to two groups, Control group (60 patients) treated by traditional physical therapy rehabilitation program, the other 60 patients (Experimental group) were treated similarly plus KT Application. WOMAC scale was used to evaluate both groups before and after treatment and the responses were scored accordingly and the mean value of the whole group on each scale were calculated and analyzed by using t-test.

Results

There was significant (P< 0.05) decrease in pain and stiffness sub-scales, and significant (P< 0.05) increase in physical function sub-scales of experimental group compared to control group.
Conclusion

Applying pressure and stretching the skin can stimulate the cutaneous mechanoreceptors which would be enhanced by KT, and it might also play a role in joint movement and position, detected by joint mechanoreceptors. In this way the problem of pain, stiffness and reduced functional activity will not be a concern when introducing KT procedure to immediate rehabilitation program for knee medial compartment OA.

THE EFFECTS OF VIRTUAL REALITY ON THE REHABILITATION OF PATIENTS WITH KNEE OA: A RANDOMIZED CONTROLLED CLINICAL TRIAL

F. Cyrillo¹, J. Greve¹
¹USP, IOT HC, sao paulo, Brazil

Introduction/Background

- Knee OA is one of the most prevalent orthopedic diseases in the elderly population, with a degenerative and progressive character that affects the articular cartilage, limiting the articular range of motion (ROM) due to rigidity and causing important functional restrictions. Virtual Reality (VR) is one of the instruments that can help in the rehabilitation process of patients, motivating them and enabling more assertive movements and exercises.

Material and Method

- Ninety patients (65 women and 25 men) between 50 and 70 years old, with a medical diagnosis of OA in at least one knee participated in the study. After completing the WOMAC and Lequesne questionnaires, they were evaluated for pain and muscular strength. The volunteers signed the Consent Term and were then randomly divided, using opaque, sealed envelopes, into 3 groups: Control group - performed a conventional physiotherapy program with aerobic and muscle strengthening exercises; Experimental group 1 (Wii) - in addition to the conventional program used Nintendo's Wii Fit games; Experimental group 2 (Kinect) - complemented the conventional treatment with the Xbox Kinect video game system.

Results

- It was observed that, in general, the three study groups demonstrated statistically significant improvement (p <0.05) in relation to pain and muscular strength. The groups with inclusion of the VR resources only presented better results than the control group in the function dimension of the WOMAC questionnaire.

Conclusion

- The methodological conditions used in the study suggest that Virtual Reality as an additional instrument in rehabilitation programs for patients with knee OA was better than the control group only in the function dimension of the WOMAC questionnaire.

Introduction/Background

Femoroacetabular impingement (AFA), also known as femoroacetabular impingement or femoroacetabular impingement, is a clinical-radiological syndrome characterized by a space conflict derived from an anomalous contact between the femoral head and the acetabulum. It is an entity described in the last decade, relatively frequent, little recognized coxalgia among the young and middle-aged population and often derives early in coxarthrosis.

Material and Method

A descriptive and cross-sectional study was conducted in patients with femoro-acetabular shock treated in the orthopedics clinic of the Julio Díaz Hospital, in the period from June 2017 to December 2017, the sample consisted of 27 patients, using the technique probabilistic sampling by succession. The evaluation was in Con-Trex Isokinetic MJ equipment, CPM mode, With / With 60 ° / sec., 5 repetitions for Flexo movements, Extension, Abduction, Adduction, Internal and External Rotation of the hip and bilaterally.

Results

Results: Age 40-59 years predominated with 63.0%. The average age of the sample was 46.2 ± 13.1 years, the youngest patient included in the sample was 18 years old and the longest was 74 years old. Regarding sex, the female was the most frequent, with 63.0%. In terms of applied force, given in Par [Nm] the Flexion has less force than the Extension and bilaterally the right, as soon as the ADD is greater than the ABD and within them, the left is of less force and with respect to the rotation, the external is less than the internal, of them the right is of less strength. Correspondence of strength levels with clinical symptoms is determined.

Conclusion

The isokinetic dynamometry in Con-Trex MJ is effective to determine muscular deficiencies in patients with femoro-acetabular shock.

MESENCHYMAL STROMAL CELLS FOR MUSCULOSKELETAL APPLICATIONS: A REVIEW

A. Boada\(^1\), M. Avellanet\(^1\), I. Oliver-Vila\(^2\)

\(^1\)Hospital Nostra Senyora de Meritxell, Rehabilitation Department, Escaldes-Engordany, Andorra
\(^2\)Cellab, Scientific Department, Sant Cugat del Vallès, Spain

Introduction/Background

The potential regeneration of damaged tissue with stem cells is a promising new treatment in orthopedics and rehabilitation fields. Musculoskeletal injuries are a common health problem in all age groups. The incidence of articular cartilage damage is increasing due to raised life expectancy and enhancement of sports practice. Cell-based therapies with mesenchymal stromal cells (MSC), an adult type of stem cells, have received considerable interest during recent years. The aim of this study was to review the literature on current musculoskeletal applications of MSC, focusing on quality considerations to be taken into account before applying stem cells.

Material and Method

We conducted a literature search in Pubmed including most existing studies related to stem cells and its use in orthopedics. We included fifteen both qualitative and quantitative studies published in english in the last 5 years.

Results

Among all stem cells types, MSC are mostly used in orthopedic disorders because of its self-renewal, ease of retrieval and multipotency, which could differentiate into cells of mesodermal lineages and other embryonic lineages, including adipocytes, osteocytes, chondrocytes, etc. However, MSC do not have an infinite self-renewal mechanism such as hematopoietic cells.

Cellular therapy with MSC can be done with non-culture expanded MSC, obtained directly from adipose tissue and bone marrow, or with culture expanded MSC involving cell growth and cell expansion in a clinical laboratory setting. The biggest differences are the number of MSC included, nature cells condition (non-culture expanded MSC are autologous whereas culture expanded MSC are considered a pharmaceutical product) and the coexistence of other stromal vascular fraction cells. A study (N=1114) shows arthritis clinical improvement. There is evidence of MSC’s potential to regenerate cartilage.

Conclusion
The application of MSC in humans for selected orthopedic disorders is a safe treatment with a
great clinical potential. A sample for quality control is strongly recommended before their
application.

DEGENERATIVE PAINFUL SHOULDER IN THE ELDERLY: DIRECT HEALTHCARE COST IN A PMR DEPARTMENT

S. salah¹, I. jeik¹, A. Salah¹, S. Laayouni¹, A. Jalled¹, Z. Ben salah¹
¹faculty of medecine of monastir-universiy of monastir, Physical Medecine and rehabilitation, - Monastir, Tunisia

Introduction/Background

Degenerative painful shoulder is a common complaint in primary health care as well as in Physical Medicine and Rehabilitation (PMR). Its burden may be consequent.

The aim of the current study was to identify related healthcare costs of degenerative painful shoulder in elderly patients followed in a PMR department.

Material and Method

Records of 156 elderly patients followed for degenerative painful shoulder over a ten year period were investigated retrospectively. Direct medical costs including medical consultations, additional tests, treatment (local and general), and rehabilitation were calculated as well as direct non-medical costs (transportation). Costs were expressed in Tunisian dinars (TND) and American dollars.

Results

The mean follow up duration was 1.22 years ±0.8 years. The average number of medical consultations was 7.87 (SD 3.41) with a median cost of 162.5 Tunisian dinars (TND) ($66.7). The median cost of rehabilitation sessions (prescribed in 96.7% of cases) was 540 TND ($221.86) and this of general (Analgesics, NSAIDs and gastric protection) and local treatment was 27.627 TND ($11.35). Radiological and biological investigations median costs were 57 TND ($23.42) and 3.253 TD ($1.34) respectively. The cost of transportation was 7.267 TND ($2.99).

The median total medical direct cost was 780.855 TND ($320.82). The total direct medical and non-medical cost per patient and per year of degenerative painful shoulder in elderly patients was 781.984 TND ($321.28).

Conclusion

Taking into consideration the socioeconomic level of Tunisian patients in public health structures and low retirement wages, it seems that degenerative shoulder pain in the elderly was responsible for a substantial burden. Economic evaluations assess both the costs and consequences of healthcare interventions, their results will help decision makers in reducing healthcare costs.

THE PROCEDURAL LEARNING ABILITY OF PATIENTS WITH PARKINSON’S DISEASE AND THEIR REHABILITATION OUTCOME.

A. Yamasaki¹, K. Marumoto², K. Domen¹

¹Hyogo college of medicine, Department of rehabilitation medicine, Nishinomiya, Japan
²Hyogo Prefectural Rehabilitation Hospital at Nishi-Harima, Department of rehabilitation medicine, Tatsuno, Japan

Introduction/Background

Though rehabilitation contains a factor of motor re-learning, the relevance between the rehabilitation outcome and the ability of motor learning remains unclear. The striatum is involved in learning motor sequences, and motor learning in Parkinson’s disease (PD) patients could be affected. We evaluated the procedural learning ability of Parkinson’s disease patients with a 2×8 button-press task and examined the correlation with their clinical improvements before and after 8 weeks inpatient rehabilitation program with the Unified Parkinson’s Disease Rating Scale (UPDRS).

Material and Method

Nineteen PD patients with mild to moderate disease severity (Hoehn and Yahr stage 1-3) who were 50 to 75 years of age and 13 age-matched healthy controls were recruited. All of them showed more than 25 score of Mini-Mental State Examination (MMSE) and did not have other complications which could affect on their motor function. The procedural learning ability was examined with the 2 × 8 button-press task twice, which was developed by Hikosaka. Participants tried task A at first, and one month later, they did task A again. Patients were also evaluated neuropsychological condition following the diagnostic criteria for mild cognitive impairment in PD delineated by Movement Disorder society.

Results

Six patients performed the button-press task as well as healthy controls and their UPDRS part 3 score was significantly improved compared with other patients (p<0.05). Among neuropsychological tests, visual reproduction task in Wecheler Memory Scale-Revised correlated with the clinical outcome.

Conclusion

The present study shows the 2×8 button-press task could be used to evaluated the procedural learning ability and predict the rehabilitation outcome.

THE USE OF ULTRASOUND IMAGING IN TOTAL KNEE ARTHROPLASTY AFTER INPATIENT REHABILITATION

B. Skrzep-Poloczek¹, B. Wiśniowska², B. Żukowska², J. Poloczek², P. Zych², A. Fojcik², D. Stygar¹, W. Wawrzynek³

¹Silesia Medical University Katowice, Department of Physiology, Zabrze, Poland
²3rd District Specialist Hospital in Rybnik, Department of Rehabilitation, Rybnik, Poland
³District Hospital of Orthopedics and Trauma Surgery Piekary Slaskie, Department of Diagnostic Imaging, Piekary Slaskie, Poland

Introduction/Background

Osteoarthritis (OA) is a degenerative joint disease leading to severe pain and disability. Ultrasonic measurement of the rectus femoris is a novel, proxy measure for muscle strength. The aim of the study was to assess the usefulness of ultrasound examination of the (RF) muscle in the assessment of the effects of rehabilitation in patients after total knee arthroplasty (TKA) subjected to inpatient rehabilitation.

Material and Method

We studied 30 patients in 6 months after TKA (median age = 62 y.o.) over the 3 weeks course of inpatient rehabilitation. The ultrasound of RF was taken twice in the day 0 beginning of rehabilitation and in the day 20 US image, quantitative parameters were recorded for anterior–posterior diameter (AP diam); lateral–lateral diameter (LL diam); and cross-sectional area (CSA) (computed from the perimetral contour of the muscle section). We also measured twice change in 6-Minute Walk Test (6MWT).

Results

Our results concerning muscular changes over the course revealed that AP diameter increased progressively in RF from day 0 to day 20 (ANOVA p < 0.05), RF muscle mass also changes in all patients. The LL diameter did not show a significant progressive increase. It was accompanied by an increase increase in 6MWT > 35.5 m at 3 weeks after rehabilitation.

Conclusion

Ultrasound evaluation of skeletal muscles is inexpensive, noninvasive diagnostic methods. Ultrasonographic examination of RF muscle seems to be a promising method in the assessment of patient possibilities (muscle potential) in the planning of rehabilitation program. Further studies with are needed to confirm our preliminary results.

Introduction/Background

Knee osteoarthritis is a disabling condition causing pain and decrease in mobility leading to functional limitation. Consequences are more severe when they occur in the elderly. The aim of our work was to evaluate the functional impact of knee osteoarthritis in the elderly.

Material and Method

A Cross-sectional, descriptive study was conducted between June 2017 and december 2017. Patients aged 65 years or older with knee osteoarthritis were included. Sociodemographic and clinical data were collected. The functional status assessment was performed by the Functional Independence Measure (FIM), LEQUESNE Genou Algo-Functional Index (I. LEQUESNE), and the Western Ontario Index and McMaster Universities Knee (I. WOMAC).

Results

50 patients were included. The average age was 71.7 years, with a sex ratio of 0.44. Knee osteoarthritis had been evolving for an average period for 8.5 years. Knee examination was painful or limited in almost all patients. Evaluation of the functional impact objectified an average MIF at 119.6 with alteration of domains related to personal care, mobility transfer and locomotion. The I. lequesne average knee was 13.18 attesting for a major disability. The difficulty section was the most impaired with an average of 5.28. Womac index showed an alteration of the three sections with an average of 49.18.

Conclusion

Knee osteoarthritis has adverse consequences in terms of functional repercussions and disability through pain and the stiffness that it generates particularly in the elderly. An adapted multidisciplinary approach aims to improve the function and adapt the different therapeutic alternatives according to the age and the stage of knee osteoarthritis.

PREDICTIVE FACTORS OF IMPAIRED QUALITY OF LIFE IN ELDERLY WITH POLYOSTEOARTHRITIS
I. Ksibi1, M. Hfaidh1, R. Maaoui1, N. Mouhil1, R. Dhahr2, H. Rahali Khachlouf1
1Military hospital of Tunis, Department of Physical and Rehabilitation Medicine, Tunis, Tunisia
2Military hospital of Tunis, Department of Internal Medicine, Tunis, Tunisia

Introduction/Background
Osteoarthritis is a leading cause of impaired quality of life and disability especially in the elderly who are most at risk of becoming dependent and socially isolated. The aim of this study was to evaluate the quality of life in elderly polyosteoarthritis patients in Tunisia and to detect the main factors associated with the alteration of their quality of life in order to optimize therapeutic management.

Material and Method
A cross-sectional, descriptive study was conducted between January and June 2017. Patients aged 65 years or older with polyosteoarthritis according to the criteria of Lawrence JS and having accepted to participate in the study were included. The quality of life assessment was performed by the Short Form Survey-36 (SF-36) and a specific questionnaire for lower limb osteoarthritis (Lower Limb Osteoarthritis and Quality of Life (AMIQUAL)).

Results
Fifty patients were included in the study. The mean age was 71.94 ± 0.8 with a sex ratio of 0.42. The evaluation of the quality of life of patients by the SF-36 showed an alteration of the different items of physical and mental health predominant on the domains of physical limitation (4,5 +/- 2.22), general health (33.81 +/- 1.61) and emotional limitation (35.33 +/- 6.76). The evaluation of the quality of life of the patients by the AMIQUAL showed an alteration of the different items predominating on the domains of the social activity (36,67 / 100) and the physical activity (47,31 / 100). Factors associated with poor quality of life were: female gender, age of onset of the osteoarthritis, spinal involvement, lack of functional rehabilitation, and co-morbidities (p <0.05).

Conclusion
Polyosteoarthritis is associated with an impairment of the quality of life in the elderly. The factors associated with this deterioration must be taken into consideration in the patient management program taking into account the sociocultural particularities of the patients.

IMPROVEMENT IN JOINT INSTABILITY REDUCES INFLAMMATORY PAIN OF EARLY KNEE OSTEOARTHRITIS
A. Nakajima¹, K. Murata¹, Y. Morishita¹, T. Kokubun², Y. Oka¹, N. Kanemura²
¹Graduate School of Saitama Prefectural University, Health and Social Services, Koshigaya, Japan
²Saitama Prefectural University, Health and Social Services, Koshigaya, Japan

Introduction/Background

In osteoarthritis of the knee, recognition of pain pathophysiology and effective exercise therapy is an important issue for establishing effective treatment methods. Both animals and humans, the increase in mechanical stress due to joint instability induces joint deformity and pain. Improvement in joint instability may be effective in reducing joint deformity and pain. The purpose of this study is to understand a part of the pain mechanisms in the knee OA and to prove the pain relief effect by improving joint instability.

Material and Method

45 Wistar male rats, aged 11 weeks, were divided into three groups, ACL transection (ACLT) group, controlled abnormal movement (CAM) group and sham group (each group n=5). At 4 weeks and 8 weeks after surgery, immunofluorescence staining of substance P, calcitonin gene-related peptide in spinal dorsal root ganglia (DRG) and safranin O staining of knee joint were performed. Furthermore, pain behavior evaluation was performed every week after surgery.

Results

By immunofluorescent staining, the number of positive cells per DRG area of calcitonin gene-related peptid was significantly larger at 8 weeks than 4 weeks. Both the ACLT group and the CAM group showed significantly higher scores of cartilage damage than the sham group at 4 and 8 weeks. Pain behavior evaluation was significantly lower in the CAM group than in the other two groups.

Conclusion

From the results of immunofluorescent staining, it was suggested that inflammatory pain mainly appears until 8 weeks postoperatively. Therefore, it was inferred that this model may be early OA, which is the main symptom of intraarticular inflammation. We considered that inflammatory pain was not involved in lowering 50% paw withdrawal threshold of early knee OA. Intervention to improve joint instability from an early stage contributes to the reduction of inflammatory pain in early knee OA.

PAINS THAT SEEM WHAT THEY ARE NOT: PAINFUL SHOULDER

C. Montoliu¹, M. Entrenas¹, C. Lourdes¹, R. Ana¹, M. Elena¹

¹Rehabilitative doctor, Rehabilitacion service. Ciudad Real University General Hospital, Ciudad Real, Spain

Introduction/Background

The painful shoulder is a common problem with musculoskeletal origin that causes disability on patients. Imaging tests can help us to establish the diagnosis, but the history and physical examination are essential to find the source of the problem. The success of the treatment depends on the correct identification of the anatomo-functional problem and the mechanical, inflammatory or infectious origin.

Material and Method

A 79-year-old woman who comes to rehabilitation due to left shoulder pain for a year, with no traumatic background. The woman indicates that she has inflammation and redness, partial improvement taking non-steroidal anti-inflammatory drugs (NSAIDs). Physical examination shows inflammation of the left shoulder with redness and local heat. Impossibility of active mobilization and, on a passive level, hard joint crunches as well as significant pain. She provides ultrasound that shows subacromial-subdeltoid bursitis in an extension of 14x50mm. Suspecting of chronic septic arthritis, simple radiography, magnetic resonance (MR), analytical and leukocyte scintigraphy are requested. The laboratory test showed CRP 0.27, procalcitonin<0.5, and the radiography showed severe signs of glenohumeral and acromioclavicular osteoarthritis. MR confirms bursitis and complete rupture of the rotator cuff. The scintigraphy shows pathological hyper-uptake with a pattern compatible with the infectious process.

Results

The woman hospitalized on traumatology service for shoulder arthroscopy, opening and cleaning the spill. The culture was negative, and the empirical antibiotic therapy started during hospitalization was suspended. The patient progressed satisfactorily after surgery, with conventional analgesia and home physiotherapy exercises. The final diagnosis is osteoarthritis of the shoulder, complete rupture of the cuff and bursitis.

Conclusion

The causes of shoulder pain can be multiple. In our case, the clinic and scintigraphy made us suspect septic arthritis, so arthroscopy plays a double role: diagnostic and therapeutic. Pain relief was achieved and the quality of life of the patient improved. The definitive treatment would be an inverted shoulder prosthesis.

INTRODUCTION/BACKGROUND

As the average age of population increases, an exponential ingrowth in the number of primary total knee arthroplasty (TKA) is expected, as well as in their economic burden. Therefore, the aim of this study is to evaluate the functional outcome after a rehabilitation program for TKA, as well as its predictor variables.

MATERIAL AND METHOD

Longitudinal prospective study, including patients with moderate-to-severe osteoarthritis submitted to TKA. The patients were evaluated at 3 different times: before surgery, 2 days and 3 months after the surgery. All the patients were included in a progressive rehabilitation protocol that included 15 sessions of physiotherapy. The primary outcome was the change from baseline to 3 months in the mean score on four Knee Injury and Osteoarthritis Outcome Score subscales, covering pain, symptoms, activities of daily living, and quality of life (KOOS4). Additionally, we assess the change in pain intensity at the numerical pain rating scale (NPRS) and the satisfaction with the procedure and rehabilitation in a Likert scale. Several sociodemographic variables and the Hospital Anxiety and Depression Scale (HADS) were evaluated before the surgery.

RESULTS

36 patients were included, 61% female, with a mean age of 75 years. All the KOOS4 subscales significantly improve at 3-months revaluation (p<0.001). Severe pain persisted in 17% patients and it was associated with presence of anxiety as well as pain in another anatomical sites before the surgery. The improve in KOOS scales was independent of sex, age, body mass index or intensity of pain before or after the surgery. 42% patients were very satisfied with the procedure at 3-months.

CONCLUSION

TKA allied with a well-structured rehabilitation protocol significantly improves the functional status in patients with knee advanced osteoarthritis.

KEYWORDS
Knee Replacement Arthroplasty; Rehabilitation; Activities of Daily Living

No conflict of interest
Osteoarthritis (OA) of the knee is one of the most common chronic diseases actually and, with the increase in the average life expectancy, its prevalence and its incidence tend to increase. Several alternatives that aim at symptom control or with regenerative potential to reverse knee OA have been used, however, often failing to achieve satisfactory results.

Material and Method

Search in the electronic database Pubmed (limits: date of publication - last 10 years), using as keywords: "chronic knee osteoarthritis pain", "radiofrequency ablation" and "genicular nerves".

Results

In total, 20 articles were included in this review. Reviewing available information demonstrates that, in a large number of patients, a significant relief of pain occurs in assessments performed in the first three and six months after the intervention.

Conclusion

With regard to pain control in knee OA, this therapeutic approach is undoubtedly a valid alternative, establishing itself as a bridge between the various minimally invasive treatments and knee arthroplasty. In the various studies, an interesting percentage of patients manifested positively with the results obtained. Radiofrequency ablation of the genicular nerves is an interesting alternative to surgery for these patients suffering from chronic knee pain. Further prospective studies in this area are needed to better understand the effects of radiofrequency ablation of geniculate nerves and evaluate their efficacy.

TREATMENT OF CHRONIC OSTEOARTHRITIC HIP PAIN: COMPARISON OF NEUROLYSIS OF THE OBTURATOR NERVE WITH PHENOL AND LIDOCAINE BLOCKADE

C. Crema\textsuperscript{1}, M. Riberto\textsuperscript{1}, L.P.T. Magario\textsuperscript{1}, F. Nicole\textsuperscript{1}
\textsuperscript{1}Ribeirao Preto Medical School - University of Sao Paulo, "Biomecânica- Medicina e Reabilitação do Aparelho Locomotor, Ribeirao Preto, Brazil

Introduction/Background

Background: Hip osteoarthritis is a degenerative disease of the synovial joints, manifested clinically by pain and compromised joint amplitude. The treatment is basically symptomatic. When the clinical treatment fails, the surgical approach with hip arthroplasty may be indicated. In patients without conditions for surgery, the blocking of the obturator nerve can be tried. A longer duration of blockade can be achieved by using drugs capable of damaging nerve axons. With the use of lidocaine or phenol we can cause neurolysis over a period of time.

Material and Method

Methods: Study with a series of patients with hip OA, resistant to conservative treatment, randomized in two groups and submitted to the application of phenol (group 1) or lidocaine 1% (group 2) in the obturator nerve. They were evaluated in terms of pain intensity via the visual analogue scale (VAS), pressure dolorimetry, and quality of life by WOMAC questionnaire. The quantitative variables were evaluated with the mean and standard deviation, while the categorical variables evaluated the percentages. The ANOVA test was used for repeated measurements. The level of significance is 0.05.

Results

Results: A total of 44 patients were included, of which 50% were men and the mean age was 54.58 ± 15.67 years. VAS and dolorimetry improvement was equivalent in both groups (BLPhenol 8,7 x PT: 6; \textit{p} = 0.0003; BLLido 9x PT: 5,8; \textit{p}= 0,0004), and WOMAC (BLphenol: 81,3 x PT: 69; BLLido 85,8 x PT 74,6), but weren't significant difference between the groups (table1).

Conclusion

Conclusion: The blockade of the obturator nerve with lidocaine or phenolization are efficient in the treatment of chronic pain in the hip OA, however there is no significant difference between the procedures.

Introduction/Background

Total hip arthroplasty (THA) remains one of the most successful orthopedic procedures and can effectively relieve pain and restore function in patients with end-stage osteoarthritis of the hip and femoral head necrosis. Controversy exists as to whether early functional outcomes differ after total hip arthroplasty performed using the direct anterior approach (DAA) or the posterolateral approach (PLA). The purpose of this study is to observe the function recovery by Occupational Therapy (OT) based on “reconstructing life theory” in the DAA or PLA.

Material and Method

One hundred fifty-nine patients were enrolled in this study and were divided into a DAA group (n=84) and PLA group (n=75) based on surgical approach. The 2 groups were all take OT based on “Reconstructing life theory”. Items for evaluation included hospital day, visual analog scale (VAS), blood loss, modify Barthel index, Harris, and preoperative and postoperative outcomes were recorded.

Results

When compared with the PLA, the DAA had a shorter hospital stay (5.26 vs 6.91 days, $P<0.001$ ), lower self-reported pain based on VAS score and less blood loss. The DAA was associated with better functional recovery at 3 months based on the Harris hip score and activity of daily living at 3 months based on the modify Barthel index score.

Conclusion

We have applied the occupational therapy in the patients after THA based on reconstructing life theory, and we found functional advantages in early recovery after the DAA compared with the PLA, especially in the reconstruction of life.

5Hacettepe University Medical School, Physical and Rehabilitation Medicine, Ankara, Turkey

Introduction/Background

Osteoarthritis is estimated to affect around 12% of the adults in Brazil, and more than one third of those are aged 65 years or more. The effectiveness of the viscosupplementation concerning analgesia and functional improvement is well established in the literature, as far as mild to moderate degrees of the disease are considered we reasoned that hyaluronic acid (HA) injection under US guidance would yield better results as regards the outcome. The aims of this study was to evaluate the efficacy of ultrasound-guided HA viscosupplementation for advanced knee osteoarthritis.

Material and Method

Design: Case of Series

Setting: A tertiary care hospital

Patients: Forty-eight patients (59 knees) suffering from severe osteoarthritis. Inclusion criteria were: over 18 years of age, visual analogic scale for pain (VAS) over 4 and pain duration over 3 months. Exclusion criteria were: serious psychiatric comorbidity, allergy to lidocaine and previous knee surgery. Forty patients completed the study.

Intervention: Ultrasound-guided intra-articular knee injections of HA were performed on three consecutive weeks.

Main outcome measures: Before injection and on the 1st, 2nd, 3rd, 6th and 12th months after intervention, patients were assessed by VAS or simple numeric scale (SNS) for pain and also by the Western Ontario and McMaster Universities Arthritis Index (WOMAC) for functionality.

Conflicts of Interest: No Disclosure

Results
Hyaluronic acid application resulted in immediate pain reduction of VAS/SNS (p<0.001) and WOMAC (p<0.001) pain scores. Although pain levels had a slight steady increase, compared to before the intervention, this reduction remained statistically significant over the 12-month follow-up (p<0.001). Similarly, rigidity (p<0.001) and functional limitation (p<0.001) scores decreased significantly immediately after the application. Differences between WOMAC rigidity (p=0.002) and functional difficulty (p=0.034) scores before intervention and at the last evaluation also remained statistically significant.

Conclusion

Ultrasound-guided viscosupplementation with hyaluronic acid may be an efficient non-surgical alternative for pain reduction and functional improvement in patients with severe knee osteoarthritis.

THE EFFECT OF ELASTIC TAPING VS SHAM TAPING AND CONTROL GROUP ON QUADRICEPS STRENGTH AND KNEE FUNCTIONAL DISABILITY INDEX IN KNEE OSTEOARTHRITIS PATIENTS WITH OBESITY
T. Tamin¹, A. Dala Intan¹, R. Santoso¹, M. Gunawan¹, N. Zanatunnisa¹
¹Faculty of Medicine- Universitas Indonesia, Physical Medicine and Rehabilitation, Jakarta, Indonesia

Introduction/Background

Knee Osteoarthritis (OA) is strongly associated with obesity and the most common cause of pain and weakness of the quadriceps groups and functional disability. Taping application has been shown to reduce pain and provide mechanical support affecting functional activities. The aim of this study is to investigate the efficacy of elastic taping in reducing pain and disability, improving quadriceps strength and to investigate the improvement of knee structures with Musculoskeletal (MSK) Ultrasonography (USG) examination.

Material and Method

35 Patients with knee OA at Obesity Clinic of Medical Rehabilitation Cipto Mangunkusumo Hospital in January 2018 were randomized with single-blind controlled trial, divided into elastic taping, sham and control group. We used Leukotape® K BSN Strips. Knee-strengthening, aerobic and balance exercises were given for 3 weeks. Outcomes measured included pain (VAS), quadriceps strength and knee functional disability index assessed using hand held dynamometer, Timed Up and Go test (TUG), Lequesne Index and MSK USG serial pre and post intervention.

Results

Subjects in elastic taping group showed significant difference with median of VAS 4.5 (2-8) on the right and 4(3-8) on the left knee (p=0.002w); the quadriceps strength, the mean was 5.62±1.87 on the right and 5.78±1.88 on the left knee (p=<0.001); the Lequesne Index, the mean was 3.29±2.02 (p=<0.001); and for TUG, the median was 0.85(0.23-9.27) with (p=0.002w) between pre and post intervention. In between groups analysis, taping has shown significant improvement in VAS and quadriceps strength, while no statistically significant difference of TUG and Lequesne index but improved better than sham and control group. There is a significant differences in improvement USG (thickening of MCL) with p=0.003w (right knee), p=0.008w (left knee).

Conclusion
This study found that elastic taping show a greater reduction of pain, increased quadriceps strength and better improvement in the functional activities. MSK USG is preferable for evaluating of abnormality structures in knee OA.

THE EFFECT OF ULTRA-EARLY SYSTEMATIC REHABILITATION ON PERIOPERATIVE BLOOD LOSS AND EARLY FUNCTIONAL OUTCOME OF TOTAL KNEE ARTHROPLASTY

Y. Zhang\textsuperscript{1}, M. Wu\textsuperscript{1}, C.M. Ni\textsuperscript{1}, J.C. Cui\textsuperscript{1}

\textsuperscript{1}The First Affiliated Hospital of University of Science and Technology of China, Rehabilitation, Hefei, China

Introduction/Background

The impact of ultra-early systematic rehabilitation on perioperative blood loss has rarely been reported. The purpose of this study is to investigate the effect of ultra-early systematic rehabilitation on total blood loss and early functional outcomes in patients undergoing total knee arthroplasty and evaluate the safety and efficacy of ultra-early systematic rehabilitation in the TKA.

Material and Method

120 TKA patients were randomly divided into a treatment group (n=60) and control group (n=60). The treatment group was given the routine postoperative treatment and ultra-early systematic rehabilitation (preoperative rehabilitation and education, postoperative systematic rehabilitation therapy, hourly rehabilitation management and so on). The control group was received only routine postoperative treatment. The total blood loss (TBL), external blood loss (EBL), hidden blood loss (HBL), knee swelling, range of motion (ROM), pain and average length of stay (ALOS) were compared between the two groups from 1\textsuperscript{st} to 3\textsuperscript{rd} days after the operation and the day of discharge.

Results

There was no significant difference in TBL, EBL and HBL between the two groups (P>0.05). On the 1st to 3rd day and the day after discharge, the ROM in the treatment group were significantly better than those in the control group (P<0.01). At the day after discharge, the improvement of movement pain in the treatment group was significantly better than that in the control group (P<0.05). There was no significant difference in knee swelling between the two groups (P>0.05). The ALOS after surgery was (4.93±1.23) days in the treatment group was significantly less than control group (7.43±1.29) days (P<0.01).

Conclusion

Ultra-early systematic rehabilitation did not increase perioperative blood loss, pain, and swelling during primary total knee arthroplasty, but the ROM was increased, the movement pain was decreased and the ALOS after surgery was shortened, which accelerated recovery of TKA.

Introduction/Background

Other than musculoskeletal deficits, patients with chronic neck pain can show respiratory dysfunctions as there is a link between thoracic and cervical spine motion. The aim of the study was to investigate the effect of respiratory rehabilitation on chronic neck pain.

Material and Method

It was a randomized simple-blind comparative study concerning fourteen patients with chronic neck pain. The patients were divided into two groups.

Group A received a routine physiotherapy exercises. Group B received conventional rehabilitation plus respiratory exercises based on a breathing retraining protocol (BRT). The BRT aims to manage respiratory dysfunctions by progressive steps of breathing practice in different positions.

The evaluated parameters were neck pain, clinical respiratory parameters (chest wall expansion and hyperventilation (Nijemegen questionnaire), functional dysfunction (Neck Disability Index (NDI)) and psychological state (HAD).

Results

We showed an amelioration of the different cervical parameters: neck pain, NDI and HAD that was pronounced in the group B. Concerning the respiratory parameters, the results were more significant for the group B.

Conclusion

Breathing rehabilitation can be an effective and feasible therapy to manage chronic neck pain.

CHANGES IN PHYSICAL FUNCTION AND ISOKINETIC MUSCULAR STRENGTH OF QUADRICEPS AND HAMSTRINGS THREE MONTHS AFTER A RAPID RECOVERY TOTAL KNEE ARTHROPLASTY

M. Ruiz¹, M. Torra¹, L. Sola¹, N. Perez¹, M. Carrillo¹, M. Guma¹, D. Mateu¹, R. Garreta¹
¹Hospital Universitari Mutua Terrassa, Rehabilitation, terrassa, Spain

Introduction/Background

The Osteoarthritis Research Society International recommends evaluating physical function in gonarthrosis patients after a total knee arthroplasty using tests such as timed up and go (TUG) and six-minute walking test (6MWT). In 1991, Berman et al found that strength was not fully recovered until two years after surgery. Our aim was to demonstrate the results in physical function and isokinetic muscular strength of gonarthrosis patients prior to undergoing surgery and three months after a Total Knee Arthroplasty (TKA).

Material and Method

Prospective study (September 2016–December 2017) of patients with gonarthrosis awaiting a total knee arthroplasty surgery.

Variables recorded: Gender, age, dominant hand, operated side, body mass index (BMI), walking aids.

Measured outcomes before surgery and three months afterwards: visual analogue scale (VAS) at rest and active, TUG, 6MWT and mean peak torque (PT) of isokinetic strength of quadriceps and hamstrings between the TKA side and the unaffected knee at 60°/sec.

Data analysis of means and percentages. Means compared using t-student and non-parametric tests. Statistical significance was set at p<0.05.

Results

44 patients, 36.4% male. Mean age 67.8±6.5. Mean BMI 30.3±6.7. 63.6% of the individuals used walking aids before surgery and 84.1% did not use them after surgery. The results obtained on VAS and physical function prior to surgery and three months after the intervention were:

\textsuperscript{2}Faculty of Medicine- University of Belgrade, Clinic for Physical Medicine and Rehabilitation, Belgrade, Serbia
\textsuperscript{3}Clinical Center Serbia, Clinic for Physical Medicine and Rehabilitation, Belgrade, Serbia

Introduction/Background

Early rehabilitation, return to daily life activities and function are the ultimate goals of perioperative care. It is unclear which pain-related patient-reported outcome measures (PROM) mirror treatment effects, or are related to early and late functional outcomes.

Material and Method

We examined associations between two approaches of pain management (scheduled vs ‘on demand’) and PROMs on post-operative days one and five (POD1, 5) with function on POD5 and 3 months after surgery in patients undergoing Total Knee Arthroplasty (TKA) in a single center.

Results

On POD1, patients in the scheduled treatment group reported reduced severity of worst pain, less interference of pain with activities in-bed and sleep, and a higher proportion got out of bed. Furthermore, tests of function, extension and flexion ranges, Barthel index and 6 minutes walking test on POD5, and the Knee Injury and Osteoarthritis Outcome Score (KOOS) 3 months later were better in the scheduled treatment compared to the ‘on demand’ treatment group. PROMs of perceived pain relief at POD1 and worst pain, time in severe pain, interference with activities in bed and with sleep, and participation in treatment decisions on POD5 were significantly associated with KOOS 3 months later.

Conclusion

Our study demonstrates that insufficient pain management immediately after TKA has substantial impact not only on PROMs in the early days after surgery but also on important physical function up to 3 months later. Pain related PROMs assessed at POD1 and especially at POD5 are associated with functional recovery up to 3 months.

Introduction/Background

Knee osteoarthritis (OA) affects a large portion of the elderly population. It is caused by degeneration of knee joint and leads to variety of symptoms including pain, stiffness, and swelling or even increases joint effusion. These may result in decreasing of muscle strength, hamstring-quadriceps co-contraction, abnormal gait patterns, and leads to poor quality of life. However, no cure exists to date. Various interventions have been used to relieve symptoms and reduce fluid accumulation, but the evidence of these interventions is still considered few.

Material and Method

The purpose of this study is to investigate the short term and long term effect of echo-guided aspiration of suprapatellar effusion. In this study, patients with OA knee and suprapatellar effusion are diagnosed via X-rays with Kellgren-Lawrence grading scale and sonography respectively. Scale 1~2 is suggested mild to moderate knee degenerative osteoarthritis. Sixteen patient were recruited in this study and randomized into two groups. The first group received oral form NSAID only and the second group received oral form NSAID with sono-guided suprapatellar bursa effusion aspiration. The patient was put on Cybex Humac Norm with surface EMG attached to quadriceps and hamstring to calculate muscle activation ratios in different angles before receiving treatment and 1, 4 weeks after treatment.

Results

No significant improvement was noted at the first week after treatment. But at 4 weeks after treatment, the second group who received oral form NSAID with sono-guided suprapatellar bursa effusion aspiration showed a significant different comparing to the first group in EMG ration at flexion 60 degrees, 120 degrees and 180 degrees.

Conclusion

The result shows us that combining oral form NSAID with sono-guided suprapatellar bursa effusion aspiration could correct the co-contraction between quadriceps and hamstring.

THE EFFECTS OF TRACTION THERAPY ON PAIN, CLINICAL, FUNCTIONAL STATUS AND QUALITY OF LIFE IN PATIENTS WITH SUBACUTE LOMBER DISC HERNIA.

M. gülser1, E. atıcı2, A. aytar3
1baskent university, vocational school of health department of therapy and rehabilitation, ANKARA, Turkey
2okan university, physical therapy and rehabilitation, istanbul, Turkey
3baskent university, physical therapy and rehabilitation, ankara, Turkey

Introduction/Background

The aim of this study is to investigate the effects of traction therapy on pain, clinical, functional status and quality of life in patients with subacute lomber disc hernia.

Material and Method

260 patients (mean age=53.04±14.59 years) were diagnosed with subacute lomber disc hernia according to the Macnab Classification enrolled to this study. The participants were randomly divided into 3 groups: First group was taken Hotpack (HP), TENS (Transcutaneous Electrical Nerve Stimulation), Ultrasound (US), second group was taken HP, TENS, US, Traction and the third group was given just home exercise programme without any treatment. Participants in the HP TENS, US group and in the HP, TENS, US traction group were treated 5 days per week for 4 weeks under the supervision of a physical therapist.

After recording the subject’s age, height and weight, the body mass index (BMI) was calculated. Sociodemographic characteristics of patients were recorded. All assessments were done before and after the treatments. Pain and functional status of patients were evaluated with The Oswestry Disability and The Roland Morris Disability Questionnaire.

Results

There were no significant differences between the groups (p> 0.05;) except for pain score (p< 0.05). Comparing within groups showed improvements in all parameters after treatment (p< 0.05). Although there was a significant difference between group 1 and group 3, group 2 and group 3 in pain scores (p< 0.05), there was no significant difference for other outcome measures.

Conclusion

In conclusion, both HP, TENS and US applied patients, as well as the intermittent lumbar traction group, significantly reduced pain and functional impairment. As observed in previous studies, it was concluded that the group to which the intermittent lumbar traction was applied was not different from the other group. However, studies conducted with advanced evaluation.
methods or different methods of applying traction will shed light on our efforts to fully understand the role of traction in treatment.

REGENERATIVE APPROACH TO POST-TRAUMATIC KNEE OSTEOARTHRITIS TREATMENT

L. Khimion¹, O. Burianov², H. Havryliuk¹, S. Danyliuk¹
¹Shupyk National Medical Academy of Postgraduate Education, Family Medicine Department, Kyiv, Ukraine
²Bogomolets National Medical University, Traumatology and Orthopedy Department, Kyiv, Ukraine

Introduction/Background

Osteoarthritis (OA) is the most common form of arthritis & trauma is one of the major risk factors for OA development in young age. The natural repair potential of cartilage tissue is low, so use of known regenerative stimulus such as platelets derived products is promising for rehabilitation.

Material and Method

The study enrolled 62 patients with diagnosed post-traumatic knee OA (radiological stage I-II, according to Kellgren-Lawrence scale) aged 18-44 years, 12-60 months after trauma. Patients with severe comorbidities, systemic disorders, after knee surgery, other joint diseases were excluded. Enrolled patients (33 women (53.2%) & 29 men (46.8%), mean age 37±4.4 years) were divided into 2 groups. Gr.1 included 32 patients who consented to receive standard OA treatment (NSAIDs, physiotherapy, exercises) & intra-articular injections of PAP (3 injections at intervals of 3-5 days) (total plasma volume - 12-15 ml/course, average platelet count – (1280-1320±22.1x10⁹); Gr.2 included 30 patients who received only standard OA treatment. Both groups were comparable in patients age, gender, type of knee trauma, initial level of pain (VAS score in Gr.1 – (55.8±0.6)mm, Gr.2 – (55.3±0.5)mm, p>0.05) & WOMAC index (Gr.1 – (47.7±1.2), Gr.2 – (46.9±1.1), p>0.05). All patients had been examined & evaluated at the first visit and after 1, 6 & 12 months after course of treatment.

Results

At 1st month after treatment course patients of both groups demonstrated similar results in pain and function improvement (general index in Gr.1 was (accordingly (21.3±1.41) & Gr.2 (22.3±1.13); p>0.05). To the contrary, at the next scheduled evaluations general WOMAC index in Gr.1 was significantly lower than in Gr.2 (20.9±1.31) and (39.1±0.98) at 6th month & (18.2±1.23) & (37.4±1.85) at month 12; p<0.05). In general during the study patients in Gr.1 demonstrated better results of treatment than patients in Gr.2, mostly because of pain & stiffness improvement, less frequent OA exacerbations & need in NSAID use. There were no adverse reactions due to PAP use during the study.

Conclusion
Use of PAP in complex treatment of the post-traumatic knee OA demonstrated promising results in young patients and need further investigations.

EFFECTS OF INTRA-ARTICULAR PLATELET RICH PLASMA THERAPY IN PATIENTS WITH KNEE OSTEOARTHRITIS, ON PAIN RELIEF
U. akhlaque1, S.B. aya2, K. Ahmad3
1combined military hospital, physical medicine and rehabilitation, rawalpindi, Pakistan
2combined military hospital, physical medicine and rehabilitation, quetta, Pakistan
3combined military hospital, physical medicine and rehabilitation, kharian, Pakistan

Introduction/Background

Knee osteoarthritis (OA) is one of the commonest types of arthritis affecting quality of life and functional status. Among biological therapies, platelet rich plasma (PRP) therapy is increasingly getting popular to improve clinical outcome in knee OA. A solid evidence for its efficacy is yet to be established. In this study we tried to find out the effect of PRP on pain improvement in knee OA patients and evaluate the impact of gender, body mass index (BMI), and severity of knee OA on pain reduction

Material and Method

The study was conducted at the outdoor physiatry clinic of Combined Military Hospital, Abbottabad, Pakistan from Jan to July 2016. We included 25 osteoarthritis patients with knee pain of minimum four months duration and radiographic findings of grade-1→ 3 OA changes according to Kellgren-Lawrence scale. Patients with systemic or local infection, rheumatoid arthritis, uncontrolled diabetes mellitus and coagulopathies were excluded. The severity of pain was measured on numerical rating scale (NRS) at two and six weeks. Three Injections of PRP were given in knees at an interval of 2 weeks each. The findings were recorded and analysed using SPSS version 17. Paired sample t-test was used to assess differences between pain scores at baseline and at six weeks after injection. Analysis of variance (ANOVA) was carried out to evaluate influence of gender, BMI, and severity of knee OA. A p-value < 0.05 was considered statistically significant.

Results

There was a significant reduction (p<0.001) in pain on NRS at 6-weeks post treatment (6.84 ± 1.38) as compared to base line (3.2 ± 1.83). The reduction of pain was significant in both males and females, in all grades of Kelligren-Lawrence scale, and in over weight and obese individuals

Conclusion
PRP significantly improves pain in patients knee OA.

THE APPLICATION OF MUSCULOSKELETAL ULTRASOUND IMAGING TECHNIQUE IN EVALUATION AND INTERVENTIONAL THERAPY OF SHOULDER PAIN: A RETROSPECTIVE ANALYSIS

J. He¹, Z. Wang¹, L. Jiang¹
¹Third Affiliated Hospital of Sun Yat-sen University, Rehabilitation Medicine, GuangZhou, China

Introduction/Background

To retrospectively analyze the application of musculoskeletal ultrasound imaging technique in rehabilitation clinic of shoulder pain.

Material and Method

The general information and clinical information of outpatients who received musculoskeletal ultrasound guided injection of glucocorticoid to the shoulder were collected between April 1st, 2017 to September 30th, 2017, including gender, age, disease course, musculoskeletal ultrasound imaging diagnosis, musculoskeletal ultrasound imaging guided injection protocols, pain and functional profile before and after injection evaluated through Shoulder Pain and Disability Index (SPADI).

Results

102 patients receiving injection were included. Among them, 55 were female (53.9%), 82 were patients aged from 40 to 69 years old (80.4%), 59 were patients suffered shoulder pain for more than 3 months (57.84%). Compared with chronic shoulder pain patients, the incidence of single subacromial bursa injection was higher in acute shoulder pain patients (P<0.05). 71 patients (75 affected shoulders) were evaluated and followed up before and after injection. The scores of shoulder pain index and shoulder disability index decreased significantly at 1 week (shoulder pain index: 28(16,40) vs 52(36,64); shoulder disability index: 16(13,29) vs 26(19,49), P<0.0083), 1 month (shoulder pain index: 16(6,22) vs 28(16,40); shoulder disability index: 11(6,19) vs 16(13,29), P<0.0083) and 3 months (shoulder pain index: 8(4,18) vs 16(6,22); shoulder disability index: 5(1,10) vs 11(6,19). P<0.0083) after injection comparing with that before injection.

Conclusion

Middle-old-aged patients were the main population who received injection therapy in rehabilitation clinic. Shoulder bursa and the tendon sheath of long head of biceps brachii were common injection sites. The incidence of single subacromial bursa injection was higher in acute shoulder pain patients than that in chronic shoulder pain patients. Ultrasound guided corticosteroid injection for the treatment of shoulder pain is accurate, effective and stable.

A RETROSPECTIVE STUDY ON ULTRASOUND-GUIDED SUPRAPATELLAR BURSAL INJECTION OF GLUCOCORTICOID WITH SODIUM HYALURONATE IN TREATMENT OF KNEE OSTEOARTHRITIS
J. He¹, L. Jiang¹, D. Zulin¹
¹Third Affiliated Hospital of Sun Yat-sen University, Rehabilitation Medicine, GuangZhou, China

Introduction/Background
To explore the effect of ultrasound-guided suprapatellar bursal injection of glucocorticoid with sodium hyaluronate in treatment of knee osteoarthritis and accuracy rate of injection.

Material and Method
From January, 2017 to July, 2017 outpatients with knee osteoarthritis in our department were treated with ultrasound-guided suprapatellar bursal injection of glucocorticoid (1mg, single injection) with sodium hyaluronate (2.5ml, weekly injection, for 5 consecutive weeks). Visual analogue scale (VAS), The Western Ontario and McMaster University composite index (WOMCA) and Lysholm score were used to compare knee pain and motor function of patients before and after injection. Accuracy rate of ultrasound-guided suprapatellar bursal injection was analyzed and any possible adverse reactions were recorded.

Results
41 affected knees were treated with ultrasound-guided suprapatellar bursal injection and accuracy rate of injection was 100%. Compared with VAS score before injection, it deceased significantly1 week after injection (4(3,5) vs 8(6,8.5), P<0.0083), and continued to fall at 1 month after injection (3(2,4) vs 4(3,5), P<0.0083); 3 months after injection, VAS score was still lower than that before injection (3(2,4) vs 8(6,8.5), P<0.0083). In addition, WOMAC score decreased (15.3±10.2 vs 37.4±17.8, P<0.0167) significantly and Lysholm score increased (73.5±14.5 vs 47.6±16.3, P<0.0167) significantly at 1 month after injection; follow up to 3 months after injection, the differences were still statistically significant compared with that before injection (WOMAC score: 16.4±10.3 vs 37.4±17.8, P<0.0167; Lysholm score: 71.9±16.5 vs 47.6±16.3, P<0.0167). No adverse reaction was observed in any patient.

Conclusion
Glucocorticoid with sodium hyaluronate in treatment of knee osteoarthritis can alleviate knee pain and improve motor function remarkably. Ultrasound-guided suprapatellar bursal injection help to locate accurately, reduce possible damages caused by blind injection and has no adverse reaction.

Introduction/Background

The main objective of this study is to evaluate the clinical and epidemiological profile in patients with knee osteoarthritis (KO) in Physical Medicine and Rehabilitation department.

Material and Method

It is a descriptive retrospective study including 104 patients with KO. Demographic, clinical and therapeutic modalities were evaluated.

Results

Our study included 78 women and 26 men. The mean age was 58.8 years and the most frequent reason for consultation was pain. A history of knee trauma and knee surgery was respectively present in 9.6% and 4.8% of cases. The mean duration of symptoms was 37.2 months and the average of VAS pain was 5.12. Patellar shock was present in 34 patients and 31 patients were obese. The deformities in varus and valgus were present only in 19.2% of knee OA. In 43.3% of cases, osteoarthritis touched the internal tibiofemoral compartment. Therapeutically, the average number of functional rehabilitation sessions was 17.46. Mesotherapy was performed in 9.6% of cases, viscosupplementation in 11.5% of cases and infiltration with corticosteroids in 14.4% of cases. All patients had used at least one therapeutic drug before consulting in physical medicine. An improvement of the symptomatology was observed after 2.77 months with average gain of 2.4 points on the VAS pain.

Conclusion

KO is a common condition and is a real public health problem. It combines pain and functional incapacity which are the main reasons for consultation. Its treatment combines non pharmacologic and pharmacologic measures. It must be adapted depending on the symptoms but also to age and patient health state.

Introduction/Background

The aim of this multicentric study is to investigate the characteristics of patients with hip osteoarthritis (HOA) and to assess the relationship of clinical and functional features with radiographic parameters in a Turkish population.

Material and Method

A total of 220 subjects with HOA who participated in a multicenter national cohort study were enrolled in this study. Demographic characteristics, as well as duration of pain, pain severity, night pain, Timed Up and Go (TUG) test score were recorded. The self-reported pain and physical function were assessed using the Western Ontario McMaster Universities (WOMAC) Osteoarthritis Index. The X-rays of the hips were assessed by the Kellgren-Lawrence (KL) method. Relationships between parameters were analyzed by bivariate analysis. Analysis of covariance was used to create a model for pain, physical function, and other disease-related parameters. Variables showing a statistically significant correlation were included into ANOVA.

Results

The mean age of the patients was 62.1±12.2 years. WOMAC-pain was significantly correlated with female sex, pain severity, night pain, symptom duration, KL score, and TUG test score (p<0.05). WOMAC-physical function showed a significant correlation with pain severity, night pain, KL score, and TUG test score (p<0.05). KL score was significantly correlated with the presence of scoliosis, leg length discrepancy, and TUG test score (p<0.05). Factors most strongly affecting WOMAC-pain and function were overall pain severity, night pain severity (p<0.05). Factors most strongly affecting KL radiographic grade were TUG test score, leg length discrepancy, and scoliosis (p<0.05).
Conclusion

In case of disability; overall and night pain severity are significant predictors of pain and function. High TUG test score, scoliosis and leg length discrepancy are better predictors of a high radiographic grade. Since HOA is a multifactorial process, several factors might affect pain, function, and radiographic features. Therefore, clinicians should consider all these factors in patients with HOA.

Introduction/Background

Background: Adhesive capsulitis is a common disease that causes pain and reduced range of motion, but vague on the shoulder. Most patients with adhesive capsulitis will improve with nonsurgical treatment. Acetaminophen and nonsteroidal anti-inflammatory drugs for pain relief in patients without contraindication are first-line options. Acupuncture considered being safe and effective in reducing pain. The aim of this study was to investigate the effectiveness of acupuncture in the treatment of frozen shoulder.

Material and Method

Materials and Methods: Indicators measured in the study was included the involved joint pain, range of motion and quality of life. Patients, first at baseline, one and a half months later (end of session) and then 3 months after the examination information about each individual entered in the questionnaires were pre-determined and data were analyzed by SPSS 17 software.

Results

Results: In this clinical trial study total 40 patients with frozen shoulder (20 interference with the acupuncture and 20 people control) study that patients average age 55/54. Age maximum 71 years and minimum 44 years. Acupuncture in the treatment of frozen shoulder with the results achieved in the general case acupuncture may improve shoulder motion in patients. VAS index at three months after treatment compared with the control group had a greater improvement.

Conclusion

Conclusion: In the case of acupuncture and ultimately improve the overall look of all the movement of flexion and adduction of the shoulder, but the movement has been further improved, VAS index at three months after treatment compared with the control group had a greater improvement and finally, we perform acupuncture as a way to improve shoulder motion in patients with frozen shoulder offered.

A RANDOMIZED CONTROLLED TRIAL OF PHYSICAL ACTIVITY ON BALANCE AND QUALITY OF LIFE AMONG ELDERLY WOMEN
B. Haxhiu, A. Murtezani, H. Hundozi
QKUK Qendra Klinike Universitare Prishtine, Physical Medicine and Rehabilitation, Prishtina, Kosovo

Introduction/Background

Balance disorder is often a cause of falls and fractures in elderly people. Improvements in balance self-efficacy in women have been reported after group-based exercise programs in the form of resistance training, weight-bearing exercises, tai chi, and task oriented training programs. The aim of this study was to evaluate the effects of the exercises on the static and dynamic balance and quality of life in elderly women.

Material and Method

The study design was a randomized controlled clinical trial. The subjects comprised 58 elderly women, aged 65 or more, with balance disorder who had been referred to the geriatric outpatient unit for rehabilitation. Subjects were assigned randomly to one of the two treatment groups: an exercise, interventional group (n=28), and a non-exercise, control group (n=30). Specific balance strategy training, included stretching, strength training and aerobics was performed 60 min per day, thrice a week. Changes in balance (Berg Balance Scale, BBS) and quality of life (WHOQOL-OLD) were compared between the two groups. Both groups were assessed at baseline and after six and 12 months. Statistical significance was established at the p<0.05 level.

Results

After 12 months, in our study subjects in intervention group we have identified significant improvement in balance and quality of life (Mann-Whitney’s U test).

Conclusion

Despite the small sample size, these results support the benefits of exercise in the clinical management of subjects with balance disorder, but need to be confirmed in a larger sample. Future research is needed to determine if these exercise programs reduce falls in the elderly women.

Keywords

Foot structure is a factor contributing to the development of musculoskeletal disorders of lower limbs. A thorough knowledge of its structure is required to better understand the potential importance of foot characteristics in patients with knee osteoarthritis.

**Material and Method**

It is a cross-sectional analytical study conducted on knee osteoarthritis subjects in the PMR department of Sahloul hospital, Tunisia during the period from January to April 2017.

**Results**

We included 32 adults with knee osteoarthritis, all women, with an average age of 55 (43-62 years old). Symptoms have appeared for an average of 7 years. Obesity was found in 75% of patients. Gonalgia was bilateral in 53% of cases. According to Kellgren and Lawrence’s radiographic classification for knee osteoarthritis, 31.3% of patients had stage 1 osteoarthritis, 40.6% stage 2 osteoarthritis and 28.1% stage 3 osteoarthritis. Associated metatarsalgia was found in 40.6% of cases. Calluses and horns were objectified in 42.4% and 15.2% of cases, respectively. Callosities were objectified in 63.6% of patients. 28.1% of patients had a flat internal arch. The most common deformities were toenails (78.5%), hallux valgus (57.6%) and toe overlaps (57.6%).

**Conclusion**

The examination of patients with knee osteoarthritis must include an assessment of the morpho-static disorders of the feet in order to label them and limit their progression by care of epidermal disorders in areas of high pressure and by the prescription of plantar orthotics.

FUNCTIONAL CHARACTERISTICS IN PATIENTS WITH KNEE OSTEOARTHRITIS

W. Haj Hamad1, M. Sghir1, M. guedria1, M. maraoui1, W. Kessomtini2
1University hospital Mahdia, Rehabilitation Departement, Mahdia, Tunisia

Introduction/Background

Knee Osteoarthritis (OA) is the most prevalent chronic rheumatic disease, and is the leading cause of pain and disability in most countries worldwide. The aim of our study is to evaluate the physical and functional characteristics of a population of Tunisian patients with knee OA and how this disease affects their physical and functional status.

Material and Method

This in a prospective study including patients with knee OA referred to the department of Physical Medicine and Rehabilitation of Mahdia (Tunisia) from January 2016 to March 2017. Physical knee function was evaluated in all patients using the Arabic version of WOMAC and Lequesne index.

Results

Ninety three patients diagnosed with knee OA were enrolled in this study. Five man (5.4%) and 88 female (94.6%). The mean age was 58 years old. Forty seven percent of our patients had radiographic severity grade 3 OA on the Kellgren and Lawrence (KL) scale.

Body mass index (BMI) in the study population varied from 19.53 kg/m² to 45.79 kg/m², with a mean of 31.06 kg/m² and 57% of our patients were obese (BMI≥30 kg/m²).

The mean Lequesne index was 11.77 (range 1 – 21,5) and 64.5% of our patients had severe handicap (Lequesne >8). The mean Womac pain score was 9.83 (range 1 – 17), mean Womac stiffness score was 3.95 (range 0 – 9) and mean Womac function score was (6 – 59).

Our study showed a statistically significant correlation between age and Lequesne index (p=0.017; r=0.247). BMI was also correlated to Lequesne index (p=0.03; r=0.225) and Womac function score (p=0.001; r=0.33).

There was no significant relationship between radiographic severity grade and functional activity.

Conclusion
Physical function in patients with OA is restricted as a result of excess weight, so preventive measures and patient education can help Tunisian patients to prevent the development of OA and to reduce its' symptoms.

Comparison of Intraarticular Injections of Botulinum Neurotoxin Versus Hyaluronic Acid to Alleviate Pain in Knee Arthritis: A Randomized Controlled Trial Protocol

L. Gauthier-Lafaye\textsuperscript{1}, A. Meyer\textsuperscript{2}, M. Schultz\textsuperscript{1}, J. Lecocq\textsuperscript{1}, M.E. Isner-Horobeti\textsuperscript{1}

\textsuperscript{1}University Institute of rehabilitation clemenceau, Physical and Rehabilitation Medicine, Strasbourg, France

\textsuperscript{2}Strasbourg University, Physiology and Functional Explorations NHC, Strasbourg, France

Introduction/Background

Knee osteoarthritis is estimated to affect between 4\% and 10\% of the world population. Current treatments include intraarticular hyaluranate aiming at decreasing pain and postpone surgery. However, the effectiveness of intraarticular hyaluronate has been questioned. Botulinum Neurotoxin (BoNT) has demonstrated analgesic properties and may represent an effective alternative in knee arthritis. Two studies have compared BoNT respectively versus placebo and versus corticosteroids and found significant decreases in pain only in the BoNT groups. The aim of this study is to show that intraarticular injection of BoNT-A decreases pain more than intraarticular hyaluronate in knee osteoarthritis.

Material and Method

Prospective, monocentric, randomized, double-blind, controlled study, with 6-month follow-up. Inclusion criteria: patients with unilateral painful knee arthritis, of any aetiology, without joint effusion, a Kellgren grade > II and a pain score on Western Ontario McMaster Universities Arthritis Index (WOMAC) > 5. Exclusion criteria: recent knee injuries, any instable chronic condition, neuromuscular disease or contra-indication to intraarticular injections. Intervention: One intraarticular injection of either hyaluronate (SynviscOne\textsuperscript{\textregistered} 6ml, or BoNT-A (Botox\textsuperscript{\textregistered}) 200 UI. Patients will be assessed on WOMAC, Timed Up-and-go Test, muscular strength and trophicity of quadriceps and hamstrings, concomitant analgesic drug use and quality of life (Short Form-36 score) immediately before the injection, at 1 month, 3 months and 6 months post-injection. Information on treatment security and tolerance will be collected at the same time points. Further, a phone call seven days after the injection will assess pain decrease on the WOMAC subscale. The primary outcome measure will be pain score on WOMAC at 3 months. The number of patients to include to show superiority of BoNT-A is 50 patients. The study started on 4th May 2017.

Results

At the moment 7 patients completed 6 months of follow-up.

Conclusion
Final results are expected for 2019. More research on alternative treatment of knee osteoarthritis is needed.

Botulinum;Neurotoxin;Osteoarthritis

*No conflict of interest*
Introduction/Background

Hip osteoarthritis is clinically manifested by pain and impairment of the articular range of this joint, which results in a number of limitations to the activities of daily living and locomotion. In addition to joint pain, it is usual to observe a muscle pain component represented by myofascial pain in these patients. Due to the long lines for total hip arthroplasty in the Brazilian public system, many patients need palliative measures to control these symptoms. Objective: This study aimed to evaluate the efficacy of myofascial pain component treatment through inactivation of trigger points compared to conservative treatment.

Material and Method

A cross-over design clinical trial was performed in which patients with moderate to severe hip osteoarthritis on the Kellgren-Lawrence scale, with indication of total hip arthroplasty, were randomized to start the study with physical therapy (PT) or with trigger point locks (PG) with 1% lidocaine for 4 weeks each, for a total of 8 weeks. At the beginning and at the end of each treatment period, the subjects were evaluated for visual analogue scale (VAS), pressure pain threshold (DOL), and the Harris Hip Score (HHS) questionnaire.

Results

27 patients (59.3% men, age 48.7 ± 16.1 years) underwent treatment. The average variation of the EVA indicated improvement at the end of the PG and worsened at the end of the FT (PG = -1.4 ± 1.0 x FT = 0.5 ± 1.0, p <0.001) and the same was observed for DOL (PG = 2.0 ± 1.9 x FT = -1.0 ± 0.8, p <0.001) and for HHS quality of life the magnitude of improvement was higher at the end of PG treatment (PG = 5.6 ± 2.0 x FT = 0.5 ± 0.1, p <0.05).

Conclusion

Treatment of the myofascial component improves pain and quality of life in patients awaiting hip arthroplasty.

IMPACT OF UPPER LIMB OSTEOARTHRITIS ON THE QUALITY OF LIFE OF THE ELDERLY

I. Kssibi¹, M.A. Bouenba¹, R. Maaoui¹, N. Mouhli¹, L. Metoui², H. Rahali¹
¹military hospital of tunisia, physical medicine and rehabilitation, Tunis, Tunisia
²military hospital of tunisia, Department of internal Medecine, Tunis, Tunisia

Introduction/Background

Despite the considerable weight of its functional and socio-economic consequences, few Tunisian studies have been interested in profiling osteoarthritis of the upper limb, according to age, and evaluating their impact on functional and QOL plans.

Material and Method

-sectioned study, conducted between June 2017 and December 2017. Patients aged 65 years and older with osteoarthritis of the upper limb (shoulder and / or hand) were included. The quality of life has been evaluated by the Short-Form F-36.

Results

27 patients were recruited. The average age was 63.66 years old. A female predominance was noted with a sex ratio of 0.25. The most common comorbidities were hypertension (50%), type 2 diabetes (37%) and osteoporosis (22.2%). The shoulder was the most affected location (74%), followed by the hand (40.72%). The association omarthrosis and digital osteoarthritis was noted in 18.5%. Osteoarthritis was significantly more common on the right upper limb (42%).

Evaluation of the quality of life objectified an alteration of the different items of SF-36 especially the domains of the physical limitation, general health and the social functioning.

Conclusion

osteoarthritis of the upper limb has adverse consequences in terms of disability, quality of life for the patient and cost to society.

²Military Hospital of Tunisia, Department of Internal Medicine, Tunis, Tunisia

Introduction/Background

Osteoarthritis of the lower limbs is the most common joint location. Since quality of life is a multidimensional concept that is complexly influenced by physical health, it can be impaired in patients with lower extremity osteoarthritis through functional limitation and pain. The objective of this study was to assess quality of life in elderly patients with lower extremity osteoarthritis.

Material and Method

Cross-sectional study conducted between June 2017 and December 2017. Patients aged 65 years or older with osteoarthritis of the lower limb (hip and/or knee) were included. Quality of life (QOL) was assessed by the SF-36 questionnaire and AMIQUAL specific for lower limb osteoarthritis.

Results

50 patients were included. The average age was 71.7 years. The sex ratio was 0.44. The knee was the most common joint location. The knee osteoarthritis was bilateral in 91.18%. Four patients (8.16%) had hip osteoarthritis associated with knee osteoarthritis. The evaluation of the quality of life showed an alteration of the areas of physical limitation, general health and emotional limitation of the SF-36. The evaluation of the quality of life of patients by AMIQUAL showed an alteration of the different items predominant in the domains of social activity (36/100) and physical activity (48/100). The quality of life was more impaired in women.

Conclusion

Osteoarthritis is a common disease that has important consequences in terms of disability, quality of life for the patient and cost to society.

IMPLICATION OF UNLOADER BRACES IN GUIDELINE RECOMMENDED KNEE OA MANAGEMENT - AN EXPERT CONSENSUS

A. Schulz¹
¹Praxis Für Orthopädie, Orthopädie, Laedenscheid, Germany

Introduction/Background

The goal of the expert consensus recommendation was to provide a tool which helps medical professionals to select the right patient and to provide a guidance for when and how to use an unloader brace for different patient types.

Material and Method

27 physicians developed recommendations to achieve the best possible treatment outcome for the the younger knee osteoarthritis (OA) patient, the active & demanding knee OA patient and the older knee OA patient. Questionnaires on were used to prepare F2F meeting where the experts agreed patient group specific treatment recommendations, which have been consented thereafter in two Delphi rounds.

Results

In order to provide specific recommendations three different patients groups have been defined: The younger knee OA patient, the active and demanding knee OA patient and the older knee OA patient. Experts concluded on detailed recommendations for these groups Candidates who will most likely benefit from an Unloader brace can be identified by the Unloader brace test.

Conclusion

The expert consensus approach was utilized to translate knee OA treatment recommendations and guidelines from international societies down to the patient’s needs in daily orthopedic and sports medicine practice. By dividing the patients in three different groups patient specific treatment recommendations have been established based on the existing clinical evidence and can be applied in daily practice. An expert consensus can be useful in order to support medical professionals in daily practice as they can offer a more practical patient centric treatment recommendation regarding the use of an Unloader Brace within knee OA management.

THE INFLUENCE OF POSTURAL REALIGNMENT IN THE TREATMENT OF CRANIOMANDIBULAR DYSFUNCTION: A CASE REPORT
C.D.J.L. Bueno¹, E. Neto², G.J. Luvizutto³, R. Berto¹
¹Faculty Southwest Paulista, Physical Therapy, Avaré, Brazil
²Faculty of Human Talents, Physical Therapy, Uberaba, Brazil
³Federal University of Triângulo Mineiro, Physical Therapy, Uberaba, Brazil

Introduction/Background

The temporomandibular joint (TMJ) is an element of the stomatognathic system consists of several internal and external structures, capable of performing complex movements, if there is an imbalance of these structures can take what we call craniomandibular dysfunction (DCM). The DCM is associated with a set of joint and muscle conditions in the craniomandibular region, the correct and early diagnosis making it necessary to prevent damage to stomatognathic functions. In addition, the masticatory muscles are closely related to the body posture through neuromuscular connections. The body posture is defined as a balanced arrangement of body structures, each segment has its center of gravity. The posture can be evaluated by software (SAPO) which is a free computer program accessed over the Internet. Therefore the aim of this work was to improve posture and relieve the DCM symptoms.

Material and Method

This is a case report in a patient with diagnosis of DCM. A physical therapy evaluation and computerized postural evaluation through the Postural assessment software (PAS/SAPO) in orthostatic position being photographed four views was held: anterior, posterior, right side and left side. It was marked 42 points, being used Styrofoam beads 10mm, fixed with adhesive tape. The patient was submitted to 10 sessions of postural realignment therapy (PRT), 2 times a week, 45 minutes each session.

Results

In the evaluation we observed that the patient had 26 points with postural changes and after treatment with PRT that number dropped to 19 obtaining an improvement of 31.03% in the points assessed.

Conclusion

We observed an improvement in DCM and posture after treatment with RP. In conclusion, the DCM has correlation with postural change, and that after the PRT was an improvement of DCM symptoms and posture.

CORRELATION BETWEEN PATTERN AND SEVERITY OF THE PAIN AND FUNCTIONAL DISABILITY IN PATIENTS WITH KNEE OSTEOARTHRITIS

Y. gazar

Al-azhar University -Faculty Of Medicine, physical medicine-Rheumatology & Rehabilitation, Cairo, Egypt

Introduction/Background

Background: The main symptom in Osteoarthritis is pain. It has many potential sources in and around the joint. Once the source or sources of pain are accurately identified, a treatment plan can be formulated.

Aim: This study was carried out to determine the pain patterns of patients with knee OA and its correlations with pain severity and functional disability.

Material and Method

A cross-sectional study carried out on One hundred patients with primary knee OA. The severity of pain was assessed by VAS and WOMAC knee pain scale. The functional disability of OA was assessed also by WOMAC OA index. Knee pain pattern and location was assessed by Knee Pain Map diagram.

Results

The mean total WOMAC score was 46.29± 13.03. The most difficult function to perform was heavy domestic duties with a mean of 3.26±0.85 (severe to extreme 3-4), followed by going upstairs with a mean of 3.03±0.70 (severe to extreme 3-4) and then going down stairs, getting in and out of a car, and shopping with a mean of 2.6±0.92, 2.54±0.83, and 2.43±1.01 respectively (moderate to severe 2-3). The right knee pain map of the studied patients showed that The most common site of pain was localized at patella (41%), followed by medial joint pain (16%), and then diffuse knee pain (14%). The left knee pain map of the studied patients showed that The most common site of pain was localized at patella (25%), followed by diffuse knee pain (20%) and then localized inferior medial (6%) and medial region (6%). There was significantly higher frequency of patients with severe to extreme pain in localized group than in regional group (73% versus 60%, respectively) with nearly twice risk of severe to extreme pain (OR=1.8, p=0.05).

Conclusion

- Knee pain, stiffness, and duration of disease may affect the level of disability in the patients with knee OA.

BONE MARROW LESION IN ADVANCED OSTEOARTHRITIS OF THE KNEES. CORRELATION STUDY BETWEEN HISTOPATHOLOGICAL FINDINGS AND STRUCTURAL DAMAGE.
Y. gazar
1Al-azhar University -Faculty Of Medicin, physical medicine-Rheumatology & Rehabilitation, Cairo, Egypt

Introduction/Background
Loss of hyaline articular cartilage is a central pathologic event in osteoarthritis, but the pathogenesis of cartilage loss is poorly understood. Bone marrow lesion(BML) is indicated by focally increased signal in the marrow on fat-suppressed T2-weighted images.

PURPOSE: To correlate histopathology of a bone marrow lesion (BML) pattern with severity and structural damage in osteoarthritic knees.

Material and Method
Twenty consecutive patients (age range, 59–66 years; mean, 65 years) referred for total knee replacements were examined with sagittal short inversion time inversion-recovery (STIR) and T1- and T2-weighted MRI one week prior to surgery before surgery. Different structural abnormalities on MRI were compared with those on histologic maps.

Results
The histopathology of BML in cases of OA revealed that (6) biopsies of cases showing bone marrow fibrosis (30%), (4) of them grade1 (20%) and (2) of them grade2(10%). (18) biopsies showing cyst (90%), (9) biopsies showing abnormal trabeculae (45%), (2) of them with grade1 (10%), (4) of them grade2 (20%) and (3) of them grade3 (15%). (5) Biopsies showing lymphocyte (25%), (40%) of them had++CD3, while (60%) of them had ++CD20. (5) Biopsies showing fatty marrow (25%), (9) biopsies showing haemosidrotic marrow (45%), (6) biopsies showing blood vessels (30%), (5) of them with grade 2 (25%) and (1) with grade 3 (5%).
The MRI findings of OA patients had been revealed that there was (6) patients with BML of grade 1 (30%) (10) patients of grade 2 (50%) and (4) patients of grade 3 (20%).

Conclusion
- BML has a strong correlation with radiographic severity measurements of osteoarthritis of the knee and pain.
- In patients with knee osteoarthritis, BML in bone underneath cartilage markedly increase risk for structural progression in the knee.
- Hyperemia and hematopoietic marrow were possible reasons for appearance of BML as high signalintensity on STIR images.
- BMLs are a cornerstone in progression of osteoarthritis.

EFFECTS OF KELLGREN-LAWRENCE GRADING ON PAIN, FUNCTION, MUSCLE STRENGTH, POSTURAL STABILITY FOR PRIMARY KNEE OSTEOARTHRITIS
P. Doruk Analan

7Baskent University, Physical Medicine and Rehabilitation, Adana, Turkey

Introduction/Background

The aim of this study is to determine the effects of Kellgren-Lawrence (K/L) grading on pain, function, muscle strength, postural stability for primary knee osteoarthritis (OA).

Material and Method

In this study, total 110 patients with primary knee OA diagnosis according to American College of Rheumatology criteria were evaluated. Patients were divided according to K/L grade (grade II and III). Outcome measures were applied as visual analog scale (VAS), Lequesne, WOMAC OA scores, postural stability testing, and isokinetic quadriceps muscle testing. These variables were compared between two groups.

Balance parameters and risk of fall by using the static posturography with Tetrax® Interactive Balance System for both of participants. Isokinetic measurements were evaluated with Biodex System 3 Pro isokinetic dynamometer (Biodex Medical Systems, Shirley, New York, USA).

Results

The mean age of the patients in the study was 57,12±8,34 and 62,38±8,23 years according to K/L grade II and III, respectively. Age, gender, body mass index and duration of symptoms were similar between groups (p>0.05). Statistically, there were no significance on fall risk, postural stability and isokinetic measurements measurements (p>0.05). Also, there were no significance different on pain, stiffness subgroup of WOMAC OA score between groups (p>0.05). Total score and other subgroups of WOMAC were different between groups (p<0.05).

Conclusion

K/L grading is not related with quadriceps isokinetic measurement, fall risk and stability scores. But this grading system seems to be correlated with activities of daily living.

KNEE OSTEOARTHRITIS PAIN TREATMENT: ACCUPUNCTURE VS ULTRASOUND GUIDED GENICULAR NERVE BLOCK
T. Novy

Adventist Hospital, Pain Clinic, Bandung, Indonesia

Introduction/Background

This study was to compare the efficacy of acupuncture and ultrasound guided genicular nerve block in treating knee osteoarthritis pain.

Material and Method

Twenty patients with knee osteoarthritis pain were submitted for pain treatment. Patients were randomly allocated into two groups (n=10). Ten of them got acupuncture treatment and the other ten got ultrasound guided genicular nerve block. VAS and time-up-and-go-test were evaluated.

Results

The mean of VAS improvement in the acupuncture group was 3.70 with standard deviation 0.67; was lesser than the ones of ultrasound guided genicular nerve block group (mean 4.10 and standard deviation 0.31). There is no significant differences in VAS improvement between the acupuncture group and ultrasound guided genicular nerve block group, with p value = 0.091 (p value>0.05).

The mean of Time-Up-and-Go-Test improvement in the acupuncture group was 0.90 with standard deviation 0.59; was greater than the ones of ultrasound guided genicular nerve block group (mean 0.83 and standard deviation 0.31). There’s no significant differences in Time-Up-and-Go-Test improvement between the acupuncture group and ultrasound guided genicular nerve block group, with p value = 0, 880 (p value>0.05).

Conclusion

Both acupuncture and ultrasound guided nerve block can be used to treat knee osteoarthritis pain. No significant differences in improvement of pain and Time-Up-and-Go-Test as result of each acupuncture and ultrasound guided nerve block for knee osteoarthritis.

TIME WEARING ORTHOSIS IN THE MANAGEMENT OF CHRONIC LOW BACK PAIN: PRELIMINARY STUDY OF THE IMPACT ON THE ISOKINETIC PARAMETERS.

A. Schmitt¹, L. Have¹
¹Hôpital d'Instruction des Armées Desgenettes, Service de Médecine Physique et Réadaptation, Lyon, France

Introduction/Background

There is no strong consensus on the modalities about the duration of time wearing thoraco-lombo-sacral-orthosis in chronic low back pain. To evaluate the influence of orthotic wear time on the isokinetic parameters of low back muscles. We choose a temperature monitoring device and present a preliminary study of 7 patients.

Material and Method

Patients included in this study were treated in the Department of Physical Medicine and Rehabilitation of the Desgenettes Army Training Hospital. Observance was assessed using an ELITECH® RC-4 data logger. Each device is attached to the posterior part of the TLSO, protected by a box inaccessible to the patient and the external sensor is buried at the level of the waist and directly in contact with the patient. Each patient realized an isokinetic evaluation at start and at the end of wearing the orthosis.

Results

For each patient, we calculate the average time wearing orthosis per day, and we study the correlation with the evolution of the isokinetic parameters of the spinal musculature. The first results show that there is no significantly decrease of the isokinetic parameters in concentric test, we confirm that the use of the rigid orthosis increases the eccentric peak torque of the spinal extensor which can explain the efficiency in addition to the analgesic effect.

Conclusion

A precise and reliable measurement of the wearing time of TLSO is essential for the study of the impact on the isokinetic parameters in chronic low back pain. The device for recording the temperature at the orthosis is therefore simple, reliable and reproducible.

WHAT IS THE LONG TERM EFFECT OF LATERAL WEDGED INSOLES ON KNEE OSTEOARTHRITIS PAIN AND PROGRESSION?

R. sheykhii, Z. nematiii, M. farzadit

'Iran University of Medical Sciences, orthoses and prostheses, Tehran, Iran

Introduction/Background

Several studies have tried to prove the bio-mechanical effects of lateral wedges, but the long-term effect of them on the progression of osteoarthritis remains unknown. The aim of this systematic review was to investigate the effect of lateral wedge on pain and progression of OA in long term follow up.

Material and Method

Studies were sought from the SCOPUS, PUB MED, SCIENCE DIRECT, MEDLINE and GOOGLE SCHOLAR from 2000 to 2015. We only chose randomized controlled trials (RCTs) articles with at least 6 months follow up. Of 121 relevant articles screened, 8 met the predefined inclusion Criteria.

Results

Four studies indicated there were significant pain reduction over 12 month follow up. Also they reported reduction in the rate of knee cartilage loss to lower than 3% per year in lateral wedged insole group. 3 other articles failed to demonstrate a long term effect of lateral wedge on pain. One study indicated adding subtalar strapping to lateral wedged insoles had better effects on reduction of pain and progression of knee OA in long term follow up.

Conclusion

Overall, this article suggested that based on included studies, long term effect of lateral wedging is unclear.

A HOSPITAL BASED COMPARATIVE INTERVENTIONAL STUDY OF THE EFFECT OF CUSTOM MADE SPLINT IN FIRST CARPOMETACARPAL JOINT OSTEOARTHRITIS

J. Jose¹, R. Jindal¹, A. Jain²
¹SMS Medical College Jaipur, Physical Medicine and Rehabilitation, Jaipur, India
²District hospital, Physical Medicine and Rehabilitation, Dausa, India

Introduction/Background

Hand osteoarthritis is a common condition which has a significant impact on the patient with regard to pain, disability and limitations in activities of daily living. It particularly affects the base of the thumb (1st carpometacarpal joint).

This study evaluates the effectiveness of custom-made short dynamic carpometacarpal joint splints on pain, function, grip strength and key pinch in patients with first carpometacarpal joint osteoarthritis (grade 2nd and 3rd) in comparison to conventional treatment.

Material and Method

This hospital based comparative type of interventional study was done in the department of Physical and Rehabilitation Medicine at SMS Medical College, Jaipur, India from April 2015 to November 2016. After screening for eligibility criteria 67 patients with 1st CMC OA were included in the trial, of which 35 patients were assigned to the intervention group (custom made short dynamic CMC joint splint and standard medical treatment) and 32 to the control group (standard medical care only). All patients were examined at baseline, one month and finally at 2 months on basis of VAS score, DASH score, grip strength and pinch strength.

Results

There was statistically significant reduction in tenderness of 1st CMC joint and positivity of Grind test at first follow up of 1 month in the splint group in comparison with non-splint group. Mean change in VAS score, DASH score, grip strength and pinch score were significantly more in splint group than non-splint group, from baseline to 1st follow up at 1 month, 1st follow up to 2nd follow up at 2 months, and baseline to 2nd follow up.

Conclusion

The splint group shows significant improvement in all outcome measures (pain, grip and pinch strength) at all follow ups when compared to non-splint group. The result supports the view that rehabilitation intervention using short dynamic custom made splint can significantly benefit individuals with early osteoarthritis.

LEG EXERCISE APPARATUS (LEX) FOR VENOUS THROMBOEMBOLISM PROPHYLAXIS IS FEASIBLE FOR PATIENTS WHO UNDERWENT TOTAL JOINT ARTHROPLASTY OF THE LOWER EXTREMITIES

Y. Shimizu¹, K. Tanaka², H. Kamada³, S. Aikawa⁴, H. Mishima³, A. Kanamori³, T. Nishino³, M. Yamazaki³

¹University of Tsukuba Hospital, Department of Rehabilitation Medicine, Tsukuba, Japan
²Hitachinaka General Hospital, Department of Orthopaedic Surgery, Hitachinaka, Japan
³University of Tsukuba, Department of Orthopaedic Surgery - Faculty of Medicine, Tsukuba, Japan
⁴University of Tsukuba Hospital, Department of cardiovascular surgery, Tsukuba, Japan

Introduction/Background

Venous thromboembolism (VTE) is a serious complication following arthroplasty of the lower extremities. Although early ambulation and active leg exercise have been recommended, postoperative patients with surgical pain face difficulty in moving their legs. Therefore, we developed a novel leg exercise apparatus (LEX) to facilitate active leg movement, during the early postoperative period. LEX is a portable apparatus that allows patients to actively move their legs while in the supine position. LEX enables dorsiflexion, plantar flexion, a combined movement of eversion and inversion of ankle, and multi-joint movement of leg.

Material and Method

Twenty subjects (age: 38-80y, 4 men, 16 women) who underwent total joint arthroplasty of their lower extremities were enrolled in this study. The exercise using LEX was set for 5 minutes, at 30 cycles/min. On postoperative days 1 to 7, the exercise was performed four times a day. Clinical assessments included vital sign measurement before and after LEX exercise, venous ultrasonography and blood tests performed seven days after surgery, and occurrence of adverse events.

Results

Among the 20 subjects, 16 completed the exercise regime of 7 days, while 4 dropped out. The subjects who dropped out had undergone total hip arthroplasty. Of them, 3 had refused to undergo the LEX protocol before exercise. No severe adverse events occurred during the study. There were no severe changes in vital signs. There was no occurrence of deep vein thrombosis (DVT) in the lower extremities in the postoperative week 1. Average preoperative D-dimer was 0.85 (0.4-2.2), whereas the corresponding value in postoperative week 1 was 7.93 (2.0-13.8).

Conclusion
No postoperative DVT was observed after this LEX protocol, and there were no severe adverse events. This protocol for VTE prophylaxis may be safe and feasible for patients who underwent joint arthroplasty of the lower extremities.

FRAGILITY FRACTURES IN END STAGE RENAL DISEASE: A BROAD SPECTRUM DISORDER CASE REPORT

M.A. Amer

Alex Uni Faculty Of Medicine, Physical Medicine- Rheumatology & Rehabilitation, Alexandria, Egypt

Introduction/Background

Fractures among patients with chronic kidney disease (CKD) represent a debilitating injury that could be associated with excess morbidity, prolonged rehabilitation, long-term pain, and even mortality. According to the literature, a middle age patient who is on dialysis has a 100-fold higher risk of having a fracture compared with peers in general population. Moreover, the peculiar pathogenesis of bone disorders and fractures in CKD patients can further make their management more challenging.

The aim of this work is to present a case of fragility fracture in a patient with end stage renal disease illustrating the characteristic nature of chronic kidney disease mineral bone disease (CKD-MBD)

Material and Method

A 33-year-old male CKD patient on hemodialysis for >10 years presented with generalized bone aches of 2 years duration and painful swelling in the lower third of the left thigh of 3 months duration

1) At presentation: clinical evaluation, laboratory investigation: including CBC, blood chemistry, PTH, and 25 OH vitamin D, and radiological assessment: plain X-ray of the left femur and DXA.

2) Follow up after 3 months: clinical and laboratory investigations

Results

Biochemical markers of bone turnover revealed elevated ALP (641 U/L), low serum Ca level, elevated PTH (127 pg/ml) with low 25-OH Vitamin -D. Plain radiograph revealed a fracture in lower third femur as well as a transverse translucent band "losser zone" in upper third tibia. DXA showed significantly low BMD especially at distal end radius (Z score= -6.3). Three months later, there was a reduction in the level of both, ALP as well as PTH.

Conclusion
CKD-MBD is a broad spectrum disorder in which the patient can transition from one histologic form to another either by natural biologic means or induced by medical treatment. The special nature of CKD-MBD needs further attention to prevent fractures in these disabled persons.

CORRELATION BETWEEN SERUM LEVEL OF INTERLEUKIN-17 AND FRAX INDEX IN PREMENOPAUSAL RHEUMATOID ARTHRITIS PATIENTS

N. Aboeladl¹, M. Hassan²
¹Helwan University, Physical medicine- Rheumatology and Rehabilitation, Cairo, Egypt
²Faculty of Medicine Alexandria University, Physical Medicine- Rheumatology and Rehabilitation, Alexandria, Egypt

Introduction/Background

Rheumatoid arthritis (RA) is the most common form of inflammatory arthritis in adults and is characterized by chronic, progressive, systemic inflammation. It is well accepted that patients with RA are at an increased risk of osteoporosis (OP) and osteoporotic fractures (OFs). Interleukin-17 (IL-17) is a cytokine that expressed in inflammatory and autoimmune diseases and expected to play an important role in the pathogenesis of RA and OP. Fracture Risk Assessment Tool (FRAX) is a computer-based algorithm developed by the World Health Organization (WHO) Collaborating Centre for metabolic bone diseases and first released in 2008. The outputs of FRAX are the 10-year probability of a major osteoporotic fracture and the 10-year probability of hip fracture. Studies to better assess risk factors of OFs in patients with RA and to define subgroups of patients in need of treatment to prevent this complication are increasingly important.

Material and Method

This study included 25 premenopausal RA patients and 20 healthy subjects. Serum IL-17 level was assessed by using ELISA technique, bone mineral density (BMD) measurements by using DEXA scan and FRAX index was calculated by using online FRAX calculator (Femoral neck BMD was used to enhance fracture risk prediction).

Results

Serum IL-17 mean level among RA patients was (5.99 ± 1.22pg/ml) and it is significantly higher than healthy control (3.73 ± 2.15pg/ml, P <0.001). Serum IL-17 levels showed a positive significant correlation with the FRAX index scores in RA patients.

Conclusion

Serum IL-17 is increased among premenopausal RA patients and it is correlated with FRAX index scores which raises the possibility that IL-17 is implicated in the pathogenesis of OP in RA.

PATTERN OF BONE MINERAL DENSITY AMONG ELDERLY HOUSEWIVES, ANALYSIS OF LIMITED DATA FROM A LABORATORY.

*S. Rahman*¹

¹Bangabandhu Sheikh Mujib Medical University, Physical Medicine and Rehabilitation, Dhaka, Bangladesh

**Introduction/Background**

**Background:** Bone mineral densities of post-menopausal women are usually low. Aged women in Bangladesh mostly remain in the house and get less exposure to sunlight. Their average diet does not contain adequate calcium and vitamin D mostly at low resource outset. This small laboratory data based survey was done to see the pattern of bone mineral density among elderly women at urban setting in Bangladesh.

**Material and Method**

**Methods:** Bone mineral densities of 857 female patients of age older than 50 years were collected from a reputed private laboratory in Dhaka, a densely populated congested city. Personal history or lifestyles of the patients were not included. Only T-scores were collected from database of the laboratory. T- Scores of spines and neck of femurs were recorded from all patients. Vitamin D was not measured. Collected data were analyzed to see the pattern of bone mineral density among the study population.

**Results**

**Results:** Mean age of the patients was 65.12±7.56 years. Maximum age of the participant was 95 years. However, mean T-score for AP spine is -2.55±1.41. Minimum T-score for AP spine is -6.8 and maximum T-score for AP spine is 1.8. Mean T-score for hip (total right) is -1.58±1.24. Minimum T-score for Hip (total right) is -7.4 and maximum T-score for Hip (total right) is 4.9. On the other hand mean T-score for hip (total left) is -1.4±1.18. Minimum T-score for Hip (total left) is -4.7 and maximum T-score for Hip (total left) is 5.1.

**Conclusion**

**Conclusion:** T score of most women were significantly low fulfilling the WHO criteria of osteoporosis. Urban congested lifestyles of post-menopausal women, lack of exposure to sunlight and nutritional deficiencies of calcium and vitamin D are common cause of decreased bone mineral density. Larger study with more variables can better delineate the prevalence of osteoporosis and fracture risk.

THE COMPARISON OF QUALITY OF LIFE, PATIENT SATISFACTION AND COMPLIANCE IN PARENTERALLY TREATED PATIENTS WITH POSTMENOPAUSAL OSTEOPOROSIS

T. Ozsoy-Unubol¹, G. Akyuz², S. Khudiyeva², T. Guler³

¹University of Health Sciences- Sultan Abdulhamid Han Training and Research Hosp, Physical Medicine and Rehabilitation, Istanbul, Turkey
²Marmara University, Physical Medicine and Rehabilitation, Istanbul, Turkey
³Numune Training and Research Hospital, Physical Medicine and Rehabilitation, Ankara, Turkey

Introduction/Background

Osteoporosis and fractures due to osteoporosis cause significant morbidity and mortality. It has been shown that patients are more compliant with parenteral forms of medication. In this study we aimed to evaluate parenterally treated patients’ satisfaction, compliance and quality of life (QoL).

Material and Method

A hundred thirteen patients with postmenopausal osteoporosis using denosumab-DEN (40), intravenous zoledronic acid-ZA (41) and ibandronic acid-IA (32) for at least 1 year were enrolled. Secondary osteoporosis, metabolic bone disease, bone metastasis, hypogonadism were defined as exclusion criteria. The demographic data, bone mineral density T scores and clinical risk factors were recorded. For QoL evaluation qualleffo-41 was applied. A 3-item questionnaire was used to evaluate the satisfaction with the medication, route and frequency of administration.

Results

Demographic data and clinical characteristics were similar (p> 0.05). There were no significant difference in any subdomain of qualleffo-41 or total score. Most of the patients (90%) who have used DEN were satisfied with drug. However, big percent of the patients using ZA (48.8%) and IA (53.1%) were hesitant. When we evaluate the satisfaction with the route of administration 90% of DEN group was satisfied. For ZA and IA it was 46.3 and 53.1. For the frequency of administration it was 87.5, 68.3 and 43.7 for DEN, ZA, IA respectively.

Conclusion

Regardless of the medication, QoL is affected. No medication has any superiority to the others in terms of QoL. Patients’ satisfaction is affected by both the route and frequency of administration. They are more satisfied with 6 months or 1 year intake period and with the subcutaneous form. Most of the patients in DEN group have emphasized that subcutaneous
administration is fast and less invasive, like immunization. In these 3 treatment options, DEN is a step ahead in terms of patients’ satisfaction.

PREVALENCE OF RISK FACTORS AND VALUES OF MINERAL BONE DENSITY IN PATIENTS WITH OSTEOPOROSIS WITH AND WITHOUT FRACTURES

S. Mitic¹, S. Kozomara¹, R. Filipov¹, M. Stoickov¹
¹Institute For Treatment and Rehabilitation “Niska Banja”, Physical and Rehabilitation Medicine, Nis, Serbia

Introduction/Background

Osteoporosis is a serious metabolic bone disease with characteristic and irreversible bone loss, impaired bone microarchitecture, beams with consequent increase in fracture risk. There are many risk factors that contribute to osteoporosis: heredity, sex, age, early menopause, previous fractures, malnutrition, alcohol, smoking, physical inactivity, other diseases, drugs. The aim of this study is to determine the prevalence of risk factors, as well as the values of bone mineral density in patients with osteoporotic vertebral and non-vertebral fractures compared to patients with primary osteoporosis without fracture.

Material and Method

The study included 24 women (average age 62.3 ± 6.5) with osteoporosis and fractures and 24 women (average age 62.5 ± 6.7) with osteoporosis without fractures verified. Determining the value of bone mineral density (BMD) at the lumbar spine (L1-L4) and proximal femur was performed by DXA at the Lunar densitometer expressed in g/cm².

Results

The most common risk factor in the group of patients osteoporotic fractures was an early menopause in 10 (41.7%) patients, then the existence of fractures in the family in 6 (25.0%) patients. In the group of patients with osteoporosis without fracture is largest number of physically inactive 8 patients (33.3%). Our results indicate a significantly lower total BMD in patients with vertebral (12 patients) as compared to patients with vertebral fractures (hip -5, wrist -6, other- 5 patients) (p<0.05). Our study showed a statistically significantly lower BMD at the femur neck in patients with osteoporotic fractures of the spine in relation to non-vertebral fractures (p<0.01).

Conclusion

Due to the significant prevalence of risk factors that lead to osteoporosis the most important in the prevention of osteoporosis and its complications in detection of risk factors that lead to osteoporosis and increased fracture risk and adequate and timely therapy with patient education on the prevention of falls.

INTRODUCTION/BACKGROUND

Aarskog syndrome also known as Aarskog-Scott Syndrome, Facio-digito-genital Syndrome or Faciogenital Dysplasia is a rare(1). X-linked disorder predominantly affecting males, characterized by facial, skeletal and genital anomalies(2,3). On the other hand, defects of bone metabolism have tendency to osteoporosis, this is a case report of a 23 years old male with pathological fracture of tibia and juvenil osteoporosis.

MATERIAL AND METHOD

Twenty-three years old male patient visited our center complaining with rehabilitation after shaft fracture of tibia. The patient had a tibial fracture three weeks ago and treated by splint. His facial appearance was striking with abnormally large nose and ptosis of upper eyelids, hypertrophiied and everted lower lip. The patient was 1.17 meter tall and weighted 32 kilograms and his vital signs were within the normal range. The bone mineral dansom of patient was measured and T-score of femoral neck dansom was -3.8, lomber spine was -3 and significantly osteoporotic in lateral lomber graphy.

RESULTS

25-hydroxi-Vitamin-D of patient was 9.2 and after 50000 IU D3 throughout 6 weeks, weekly alendronate therapy adminitered.

CONCLUSION

The relation of osteoporosis and Aarskog sydrome hasn’t identify clearly but possible cause of its, a genetical defect of bone formation or hypogonadism. When we search literature, there isn’t published case about relationship with Aarskog Sydrome and osteoporosis. Because of its, this case report gain importance.

Introduction/Background

To ascertain a role for muscle spasticity in the development of NHO, by blocking neuromuscular signalling using botulinum toxin during spinal cord injury-induced NHO formation in a murine model.

Material and Method

Spinal Cord Injury (SCI) was performed on 5-6-week-old C57BL/6 mice. To promote NHO development, cardiotoxin (CDTX) dose injections were administered at the time of the surgery to the right and left hamstring muscles. Botulinum toxin A (BTA) injections were administered at the site of NHO formation in the right hamstrings to block neuromuscular signalling, and mock equivalent volume of PBS was injected in the contralateral site 4 days prior to SCI, and weekly for 3 weeks. Twenty-one days post SCI, quantitative assessment of NHO volume and density within each hamstrings muscle were performed using Micro-computed tomography scan.

Results

μCTscan analysis revealed the development of NHO in 100% of mice in both hamstrings. NHO volume average was 1.6 mm³ (± 1.0) in the left hamstrings injected with PBS in contrast to 3.3 mm³ (± 1.4) in the right hamstrings with BTA. This doubling of NHO volume in BTA-treated hamstrings was statistically significant (Wilcoxon matched-pairs signed rank test, p = 0.013). Furthermore, NHO were more compact in muscles injected with BTA with a density of 1244.6 mg/cc (± 10.4) and was significantly denser compared to NHO in the PBS-treated contralateral side density of 1231.2 mg/cc (± 20.1) (Wilcoxon matched-pairs signed rank test, p = 0.027).

Conclusion
In our murine model of SCI-induced NHO, we demonstrated a doubling of the NHO volume, and increased density burden when treated locally with BTA. These results demonstrate that local administration of BTA exacerbates NHO development leading to an overall increase in bone formation. The outcome suggests that in contrast to risk spasticity, resulting from defective neuromuscular signalling, may be an inhibitor of local NHO development.

*No conflict of interest*
Introduction/Background

Osteoporosis is a worldwide public health issue and despite being frequent, is still a neglected entity in patients with spinal cord injury (SCI). Although the pathophysiology is not wholly clear, several factors appear to have an influence on bone mass in SCI individuals. The level, severity and age at injury are important predictive factors that should be considered in individuals with SCI.

Material and Method

The authors conducted a systematic review of the pharmacological and non-pharmacological treatment of osteoporosis in patients with SCI, underlining the importance of conducting a multimodal rehabilitation program. Databases of Cochrane Library, Google Scholar and Pubmed were searched from January 2006-December 2017.

Results

There are no clear guidelines regarding bone density monitoring, prevention, and treatment of osteoporosis in patients with SCI. The treatment of osteoporosis relies on the adoption and promotion of healthy lifestyles. Several drugs are used in the treatment of osteoporosis in patients with SCI such as vitamin D analogs, calcium combinations and bisphosphonates. Recent studies also point to denosumab as a promising molecule in the treatment of osteoporosis in SCI. Physical activity should be promoted in these patients, such as rowing or other wheelchair-adapted sports, in order to enhance osteogenesis. Studies advocate the use of electrostimulation and functional electrical stimulation, training with cycle ergometry, training of orthostatism/progressive verticalization, vibratory platforms and assisted walking training. The results of ultrasound treatment have been disappointing.

Conclusion

Osteoporosis is an important complication in SCI. Early diagnosis and appropriate treatment is essential, taking into account the high risk of fracture and its complications. Physical and rehabilitation medicine plays a fundamental role in the prevention and treatment of osteoporosis in SCI, thus promoting the well-being of patients and improving their quality of life.

EFFECTIVITY OF RADIAL SHOCKWAVE THERAPY FOR THE TREATMENT OF ASTRAGALUS PSEUDARTHROSIS
S.B. Avendano Avendano¹, C.T. Esquivia¹
¹Hospital Militar Central, medicina física y rehabilitacion, Bogota, Colombia

Introduction/Background

With this case study, we want to make known the effectivity of extracorporeal radial shockwave therapy on bone healing failure; for this particular case the astragalus pseudarthrosis is a failure of this bone’s healing from fracture, in other words, the non-union of fracture lines by the alteration in any of the phases of bone healing. This is a case study of a patient with astragalus pseudarthrosis and the response to treatment with radial shockwave therapy.

Material and Method

Patient 27 years, with a hindfoot fracture, required surgical treatment with external fixator plus osteosynthesis of the right talus. Currently pain in the ankle and scintigraphy suggestive of pseudoarthrosis of the talus. In May 2015 with radiography that reported a lack of consolidation of the talus fracture

Results

Treatment with shock waves in August 2015; scheme: cycle of 5 sessions of shock waves at the level of the right talus, each session with 2500 strokes at a frequency of 14 / sec, with an increase in intensity from 2.0 bar to 2.5 bar, with improvement of pain by 70% (analogous visual scale of 4/10) and improvement in the mobility arcs (dorsiflexion 30 ° plantiflexion -20 °). 5 more sessions of shock waves, currently a decrease in pain by 80% (visual scale analogous 3/10), improvement in the mobility arcs (dorsiflexion 50 ° plantiflexion to neutral).

Conclusion

Pseudoarthrosis is a complication of short bone fractures that are difficult to manage, but which in recent years is within the indications for handling extracorporeal shock waves, for the case that occurs after the intervention with radial shock waves. extracorporeal recovery and remodeling of the talus fracture, in addition to pain reduction, recovery of mobility arcs and improvement of patient functionality.

ISPR8-1162
ASSESSMENT OF ASSOCIATION OF SMOKING WITH BONE MINERAL DENSITY (BMD) AND FRAGILITY FRACTURES IN A COHORT OF PAKISTANI MALES AND POSTMENOPAUSAL FEMALES
U. akhlaque¹, S.B. ayaz¹
¹armed forces institute of rehabilitation medicine, physical medicine and rehabilitation, rawalpindi, Pakistan

Introduction/Background

The study aimed to determine the association between smoking, bone mineral density (BMD), and fragility fractures in a cohort of Pakistani males aged > 50 years and postmenopausal females.

Material and Method

This was a cross-sectional survey carried out at Armed Forces Institute of Rehabilitation Medicine (AFIRM), Rawalpindi from Jan 2010 to Jan 2011. Through non-probability purposive sampling, we included male patients of age > 50 years and postmenopausal women. All subjects were submitted to dual energy X-Ray absorptiometery at lumbar spine (L2 > L4) and at both femoral by Hologic Discovery-A machine. The lowest BMD was noted and expressed in the form of T-score. Using SPSS V 20, descriptive statistics were calculated for the various variables. Independent samples t-test was used to determine the significance of difference between mean T-score in between smokers and non-smokers. Association between smoking and the risk of fracture was carried out using Fisher exact test. A p-value < 0.05 was considered significant.

Results

Out of a total of 328 patients, 142 (43.3%) were male (mean age 64 ± 8, range: 50 - 82 years) and 186 (56.7%) were female (mean age 61 ± 8, range: 43 - 92 years). Sixteen (8.6%) females and 52 (36.6%) males were smokers. In males, the mean T-score was -1.6 ± 1.3 in non-smokers and -1.9 ± 1.2 in smokers (p=0.17). Two of the non-smokers and nine of the smokers had a fracture. (p=0.002). In females, the mean T-score was -2.9 ± 1.9 in smokers and -2.3 ± 1.4 in non-smokers (p=0.23). Twelve of the non-smokers and 15 smokers had a fracture. (p<0.001)

Conclusion

Smoking was significantly associated with increased percentage of fragility fractures but not with a reduction in BMD in our sample of postmenopausal women and men of age > 50 years.

²Ciudad Real University Hospital, Paediatrics- Paediatric Endocrinology, Ciudad Real, Spain
³Montilla Hospital, Physical Medicine and Rehabilitation, Córdoba, Spain
⁴Ciudad Real University Hospital, Translational Research Unit, Ciudad Real, Spain

Introduction/Background

Mobility is essential for adequate bone mineralisation. Neuromuscular diseases can cause pathological fractures, bone pain, and a decrease in bone mineral density (BMD). Establish the association between BMD, phosphocalcic metabolism parameters, and degree of functional capacity.

Material and Method

Observational, cross-sectional and prospective study in children under 18 with reduced mobility. The selection is performed by consecutive, non-randomised sampling. Variables analysed: age, gender, functional capacity according to the Functional Mobility Scale (FMS), which evaluates the ability to walk in 3 distances (5 metres, 50 metres and 500 metres) from 0 to 6, BMD (L2-L4) by DXA expressed in Z-scores according to bone age and gender, calcium, phosphorus, parathormone, 25-hydroxy-vitamin D3, alkaline phosphatase and osteocalcin in blood and calcium/ creatinine ratio, tubular reabsorption of phosphorus and cross-linked N-terminal telopeptides of type I collagen in urine (NTX-I). Alkaline phosphatase, osteocalcin and NTX-I values are expressed in standard deviations according to reference values for age/gender. The results are analysed with the SPSS programme.

Results

36 patients (53% children), average age of 8.6 +/- 4.7 years. Mean FMS value was was 5.3 out of 18 (36% obtained a value of 0). Mean BMD was -1.99 +/- 1.7, average alkaline phosphatase was -2.64 +/- 1.08 SD, mean osteocalcin was -2.15 +/- 1.39 SD, and mean NTX-I was +3 +/- 1.72 SD. A significant association was observed between BMD and the FMS for the 5-metre distance (p = 0.017) and for the total score (p = 0.029), and between parathormone and the FMS at 5 (p = 0.041), 50 (p = 0.033) and 500 metres (p = 0.046).

Conclusion
There is a decrease in BMD and in bone neoformation markers such as alkaline phosphatase and osteocalcin in our population, and elevation of bone resorption markers such as NTX-I. Patients with a lower degree of mobility have a lower BMD.

ARE CALCANEAL QUANTITATIVE ULTRASOUND VARIABLES BETTER THAN RADIAL BONE MINERAL DENSITY IN IDENTIFYING WOMEN WITH OSTEOPOROSIS?
A. Oral¹, S. Esmaeilzadeh¹, S. Asghari¹, E.I. Şen¹, D. Sindel¹, A. Yaliman¹
¹Istanbul University- Istanbul Faculty of Medicine, Physical Medicine and Rehabilitation, İstanbul, Turkey

Introduction/Background
In certain circumstances when axial bone mineral density (BMD) cannot be measured using dual-energy X-ray absorptiometry (DXA), DXA BMD of the one-third radius (33% radius) can be used for the diagnosis of osteoporosis. Calcaneal quantitative ultrasound (cQUS) variables may also be used for assessing osteoporosis. The aim of this study was to test the hypothesis that cQUS variables may be better than one-third radius (33% radius) BMD for the identification of axial osteoporosis in women.

Material and Method
209 women aged between 21 and 85 years whose posteroanterior spine, hip, and 33% radius DXA BMD measurements as well as cQUS variables were measured were included in this study. WHO criteria were employed for defining osteoporosis in postmenopausal women and premenopausal women with Z-scores of ≤-2.0 were considered as having osteoporosis in axial regions. We used receiver operating characteristic (ROC) analysis to evaluate lumbar spine or hip osteoporosis discriminative performance of radius DXA BMD and cQUS parameters.

Results
While 33% radius BMD and its T-score revealed greater areas under ROC curves (AUCs) (0.760 and 0.759) than those of the cQUS variables [0.707 for quantitative ultrasound index (QUI), 0.705 for QUI T-score, 0.682 for broadband ultrasound attenuation (BUA), 0.718 for speed of sound (SOS), and 0.706 for estimated heel BMD (eBMD)] for identifying lumbar spine osteoporosis, the AUC values for all cQUS variables (0.816 for QUI, 0.815 for QUI T-score, 0.829 for BUA, 0.791 for SOS, and 0.813 for eBMD) in the discrimination of femoral neck osteoporosis were greater than those of 33% radius DXA BMD and its T-score (0.779 and 0.783).

Conclusion
The results of this study confirmed our hypothesis for femoral neck osteoporosis, but not for lumbar spine osteoporosis. Our results have implications that cQUS can be used for the prediction of femoral neck osteoporosis in women whose hip DXA BMD cannot be measured.

MULTIDIMENSIONAL EVALUATION IN SIBLINGS AFFECTED BY LATE ONSET POMPE DISEASE

S. Colonna¹, G. Iolascon¹, R. Gimigliano¹, L. Sodano¹, S. Liguori¹, A. de Sire¹, F. Gimigliano²

¹Università degli Studi della Campania “Luigi Vanvitelli”, Department of Medical and Surgical Specialties and Dentistry, Naples, Italy
²Università degli Studi della Campania “Luigi Vanvitelli”, Department of Mental and Physical Health and Preventive Medicine, Naples, Italy

Introduction/Background

Late Onset Pompe Disease (LOPD) is an autosomal recessive neuromuscular disorder. Among the other symptoms patients are characterized by a reduction of bone mineral density (BMD) and muscle strength. Moreover, there seems to be a cognitive involvement which hasn’t been well described yet. Therefore, the aim of this study was to assess bone, muscle, and cognitive impairments in all the members of a family affected by LOPD.

Material and Method

We included siblings with the same genotype (p.R40X/p.N882fs) affected by LOPD. These patients underwent an experimental evaluation protocol in order to evaluate: BMD, using the Dual-energy X-ray Absorptiometry (DXA); muscle strength, by Hand Grip Strength Test (HGS); level of independence, using the Functional Independence Measure (FIM); cognitive functions, using Trial Making Test A (TMT-A) and B (TMT-B) and the Stroop Color Test.

Results

Of 10 siblings with a diagnosis of LOPD, 7 (3 males and 4 females, mean aged 53.71 ± 6.05 years) had the same genotype (p.R40X/p.N882fs). Of these 7 patients, 4 (57.14%) had low BMD values (2 osteoporotic and 2 osteopenic) and hypovitaminosis D (<30 ng/ml); two reported previous vertebral fragility fractures. The mean HGS was: 21.17±0.76 kg in males and 14.50±4.58 kg females. The mean FIM was 119.33±2.31 in males and 121.00±2.45 for females. Furthermore, in the neuropsychological evaluation, we found a mild attentional and executive deficit with a global cognitive framework within the normal ranges.

Conclusion

In this study, we found low BMD values in more than half of the examined cases, a reduction of muscle strength and a mild attentional and executive deficit. These results testify the necessity of a multidimensional assessment to better investigate all the characteristics of these patients.

TROUBLESOME HETEROTOPIC OSSIFICATION. DOES THE ETIOLOGY HAVE AN IMPACT ON JOINT LOCATION AND SURGICAL COMPLICATIONS?

A. Grelier1, M. Salga1, L. Gatin2, C. Debaud3, G. Genet1, N. De L'Escalopier2, P. Denormandie2, F. Genet1

1Hôpital Raymond-Poincaré, Médecine physique de réadaptation, Garches, France
2Hôpital Raymond-Poincaré, Chirurgie orthopédique, Garches, France
3HEGP, Chirurgie orthopédique, Paris, France

Introduction/Background

Heterotopic ossification (HO) is a frequent complication after damage to the central nervous system (CNS), with an estimated prevalence of up to 76%. The primary site of HO is the hip joint (60,9%). The only effective treatment of troublesome HO is surgery. The main purpose of this study was to identify the relationship between the location of troublesome hip HO treated by surgery and the etiology of the cerebral damage. The secondary aim was to identify risk factor of sepsis and recurrences after the surgery.

Material and Method

We retrospectively analyzed data from an anonymous prospective survey of patients undergoing surgery for troublesome HO from 1993 to 2016 (417 patients, 609 surgeries).

Results

The sites of HO on the hip joint were associated with its etiology (p<0.01): for brain damaged patients, the hip HO was most frequently anterior and internal with a rate of 40,0% whereas it was anterior for patients with spinal cord injury (SCI), with a rate of 54,4%. The main side effect after surgery of troublesome HO was sepsis, with a rate of revision surgery of 8,2%. SCI patients were more affected (18,3%) than traumatically brain injured patients (TBI) (4,4%) or stroke patients (8,7%). Sepsis seemed to occur most frequently on hip surgeries, but no statistically significant relationship was found. The rate of recurrence was 2,8% for the whole population. It occurred most frequently after TBI (3,6%) rather than after stroke (1,9%) or SCI (1,5%).

Conclusion

The sites of hip HO, their recurrences and sepsis were associated with its etiology. The patients with SCI will develop most frequently anterior hip HO, with a risk of sepsis that is more frequent than in the other etiologies.

ATYPICAL FEMORAL FRACTURE AND BISPHOSPHONATES: A RELATIONSHIP?
J.V. Gonçalves¹, J. Santos¹, A. Campolargo¹
¹Centro Hospitalar Vila Nova de Gaia / Espinho, Physical Medicine and Rehabilitation, Gaia, Portugal

Introduction/Background

Osteoporosis is a chronic disease that demands a long-term treatment. The risk of a fracture due to osteoporosis is higher in woman than in men. The treatment with bisphosphonates reduces significantly the risk of fracture. Despite that, some studies suggest that could exist a relationship between the use of bisphosphonates and a higher risk of non-osteoporotic fractures.

Material and Method

Description of a clinical case of a patient with an atypical fracture initially observed in the emergency room.

Results

A 84 year old man was admitted in the emergency room with a bump in the left haunch and unable to walk after the impact of the leg in the floor when getting up from bed. With previous medical history of an hypertension, depression and osteoporosis. This patient has been on treatment for about 18 years now with bisphosphonates. In the X ray and CT scan was possible to identify an atypical fracture of the left femur. After was submitted to surgery and started the rehabilitation program while in the hospital. Discharge after 15 days and indication to stop the intake of bisphosphonates.

Conclusion

The medical literature still has not demonstrated and unequivocal relationship between the higher risk of atypical fractures and the use of bisphosphonates. Despite that, health professionals should be sensitized for this theme and the need to offer alternative therapeutics.

SECONDARY PREVENTION OF OSTEOPOROTIC FRACTURES IN REHABILITATION CONSULTATION. PERSISTENCE WITH OSTEOPOROSIS THERAPY

C. Parra Soto1, E. García Álvarez2, J. Acosta Rueda3, R.M. Espada Zaragoza1, E. Navarro González1, C. González-King Garibotti1, F. Gallego Peñalver1

1Hospital Clínico Universitario Lozano-Blesa, Servicio de Medicina Física y Rehabilitación, Zaragoza, Spain

Introduction/Background

Persistence with osteoporosis therapy is vital for fracture prevention. We aimed to determine the persistence to osteoporosis pharmacotherapy after osteoporotic fracture.

Material and Method

A descriptive retrospective study was conducted of patients treated in a rehabilitation consultation from March 2014 to December 2017. The pharmacy dispensaries of the treatment prescribed in a Rehabilitation consultation were evaluated monthly, according to recommendations of SEIOM (Spanish Society of Bone Research) and patient preferences. Persistence was defined as continuation of treatment without a >30-day gap in prescription refills.

Results

- 52 patients (76.92% women). The mean age was 69 years (SD 9.12 years). Derivatives from Traumatology (52.2%), Primary Care and Rheumatology (13% respectively). The most frequent reason for consultation was fracture (52.2%). 39.1% of patients had secondary osteoporosis and 47.8% had previous fracture. 30.4% had previously received pharmacological treatment of osteoporosis.
- Pharmacological treatment were prescribed: oral bisphosphonates 39.1%, teriparatide 39.1%, denosumab 21.8%. As a complementary treatment: 43.5% were prescribed cholecalciferol and 30.4% cholecalciferol + calcium. In 30.4% of the patients it was necessary to change medication mainly due to side effects or difficulty in administering the drug.
- The average treatment time was 29.78 months (SD 14.44). 75.62% persisted with osteoporosis pharmacotherapy regimen and 65.62% with complementary treatment. Treatment with teriparatide presented the highest persistence rate (95.87%). Of 21 patients prescribed oral bisphosphonates: 72.37% persisted with treatment; and of 12 patients prescribed denosumab: 68.81% persisted with treatment.

Conclusion
Persistence among patients attending our rehabilitation consultation was higher than that reported in the literature. This could be due to the fact that it includes patients with the intention of secondary prevention, sensitized with the complications of osteoporotic fractures and with outpatient follow-up.

Avascular necrosis (AVN) is the cellular death of bone components due to interruption of the blood supply. Bone structures collapse, resulting in pain, loss of joint function and long-term joint damage. AVN of the femoral head is a rare complication related to short-term glucocorticoid treatment and traditionally has been associated with high doses and/or prolonged therapy. The pathogenesis of glucocorticoid-induced AVN is not fully understood but fat hypertrophy, fat emboli and intravascular coagulation may cause lack of blood supply to the bone. AVN causes significant disability in the most productive years of life and is one of the common causes of hip arthroplasty in young individuals.

**CASE REPORT**

A 45-year-old male, bricklayer, with a history of moderate alcohol consumption was admitted to our hospital with dyspnea and productive cough. On admission he had fever, tachycardia and leukocytosis. He was transferred to the ICU with ARDS and sepsis associated to community-acquired pneumonia. The patient was ventilated for 10 days and received a 2 day-course of systemic corticosteroids in combination with antibiotic treatment. During hospitalization, he presented thrombocytopenia and leukopenia and was treated with methylprednisolone for three weeks. Eight months later, he started to complain of bilateral groin pain, that worsen during gait and internal rotation. The patient was independent in activities of daily living but unable to work. Inicial hip X-ray was normal but MRI showed AVN of both femoral heads. He underwent left total hip arthroplasty and is currently on rehabilitation treatment in order to recover for contralateral hip arthroplasty.

**Conclusion**

This case highlights the importance of AVN suspicion and recognition of risk factors, such as alcohol abuse and glucocorticoid therapy. Our report and literature have demonstrated that AVN may develop over a short period of treatment with glucocorticoids and in less than 1 year after administration.

DECREASED RISK OF OSTEOPOROSIS AMONG SUBURB-DWELLING ELDERLY CHINESE INDIVIDUALS LIVING ALONE: A 3-YEAR COHORT STUDY

X. Yu\textsuperscript{1,2}, Q. Guo\textsuperscript{1,2}
\textsuperscript{1}TEDA International Cardiovascular Hospital - Cardiovascular Clinical College of Tianjin Medical University, Department of Rehabilitation Medicine, Tianjin, China
\textsuperscript{2}Tianjin Medical University, Department of Rehabilitation Medicine, Tianjin, China

Introduction/Background

Osteoporosis leads to increased bone fragility and risk of fracture, inevitably augmenting morbidity and mortality in patients. Single-person households has been associated with various social and health problems. However, few studies have explored the risk of osteoporosis among people living alone. The objective of this study was to determine the risk of osteoporosis among individuals living alone over a 3-year period in an elderly Chinese suburban population.

Material and Method

This study was conducted on 217 Chinese suburb-dwelling participants aged \( \geq 60 \) years, for whom detailed information regarding sociodemographics, behavioral characteristics, and medical conditions had been documented. Osteoporosis was identified by measuring the calcaneal using a quantitative ultrasound and a T score of less than -2.5.

Results

At baseline, 386 (64.1\%) of the initial 603 participants had osteoporosis (male 62.3\%, female 60.0\%). The prevalence of osteoporosis was 54.4\% after 3 year (male 51.3\%, female 57.1\%). After multivariate adjustments, it was found that single-person households is associated with less incidence of osteoporosis (adjusted OR 0.05, 95\% CI 0.016-0.178, p<0.001), male (adjusted OR 0.04, 95\% CI 0.006-0.257, p=0.001), female (adjusted OR 0.05, 95\% CI 0.008-0.282, p=0.001).

Conclusion

We found osteoporosis incidence decreased among suburb-dwelling elderly Chinese individuals living alone.

AN UNUSUAL CASE OF PYCNODYSOSTOSIS WITH CHIARI I MALFORMATION CAUSING
SYMPTOMATIC HYDROMYELIA AND HYDROBULBIA.

C. Costa¹, J.C. Décarie²
¹CHU Sainte-Justine, Physiatrie, Montreal, Canada
²CHU Sainte-Justine, Radiologie, Montreal, Canada

Introduction/Background

Pycnodysostosis is a rare lysosomal disease of the bone caused by a catheptin K gene mutation leading to osteopetrosis, craniofacial malformations and low impact fractures (Gelb, 1996).

Chiari I malformation is characterized by a descent of the cerebellar tonsils of five millimetres or more below the foramen magnum (Strahle, 2011) and can be associated with hydromyelia or hydrobulbia. Pycnodysostosis has not clearly been identified as a predisposing factor, though three cases have been (Arman, 2014; Pangrazio 2014; Quezado, 2011). None described hydrobulbia or associated sleep disordered breathing (SDB).

Both the cranial malformations and hydrobulbia predispose to SDB; 49% of children with Chiari I have SDB, most of which are the obstructive type (Amin, 2015).

Material and Method

A 16 year old male with pycnodysostosis, who presented many of the classical physical attributes, multiple fragility fractures with delayed healing and SDB, was examined in outpatient clinic for increasingly painful paresthesias in his neck and left arm.

Results

On examination left brachioradialis and bicipital reflexes were absent. Sensation to pin prick and light touch was subjectively decreased over his entire left arm. Electrodiagnostics were normal, suggestive that an upper motor neuron cause for his symptoms.

A neuraxial MRI showed a Chiari I malformation with hydrobulbia and hydromyelia extending from the medulla oblongata to T6. There was a posterior tilt of the odontoid and narrowing the craniocervical junction. He is awaiting decompression surgery.

Conclusion

This is the fourth case of pycnodysostosis associated with Chiari I malformation described in the literature. An association between pycnodysostosis and Chiari I malformations may exist, or
given the high prevalence of Chiari I malformations, they may be unrelated. Further cases are necessary to establish a relationship. If this association proves to be strong, patients with pycnodysostosis presenting SDB would benefit from a MRI study in their work-up.

THE EFFECTIVENESS OF ACUPUNCTURE FOR OSTEOPOROSIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Y. Bao¹
¹Shanghai Ruijin Rehabilitation Hospital, Department of Rehabilitation Hospital, Shanghai, China

Introduction/Background

To summarise the existing evidence and evaluate the efficacy of acupuncture as a clinical treatment for osteoporosis.

Material and Method

Six English and four Chinese databases were searched from their inception to April 2017. Randomized controlled trials were included, in which warm acupuncture, needling or electroacupuncture were compared with sole Western medicine with osteoporosis. All the data were assessed and extracted by two authors independently. The bias risk assessment recommended by the Cochrane collaboration's tool was used to assess the quality of the selected studies. This meta-analysis was conducted by using Revman 5.3. Pooled analyses were calculated by standardized mean difference (SMD) and 95% confidence interval (CI). Heterogeneity was assessed by I² test.

Results

35 studies involving 3014 patients were located. Meta-analysis showed that warm acupuncture could increase the bone mineral density of lumbar (SMD: 0.93 95% CI=0.65, 1.21 P<0.000001) and femur (MD: 0.11 95% CI=0.05, 0.16 P=0.0002), the level of serum calcium (MD: 0.18 95% CI=0.13, 0.24 P<0.00001), and estradiol (SMD: 0.65 95% CI=0.32, 0.98 P=0.0001), relieve pain (MD: -1.64 95% CI=-2.69, -0.59 P=0.002), decrease the level of serum alkaline phosphatase (MD=7.8 95% CI=14.17, -0.84 P=0.03) compared with sole Western medicine. Electroacupuncture could relieve pain (MD: -1.32 95% CI=2.15, -0.48 P=0.002), increase the level of serum calcium (MD: -0.12 95% CI=-0.16, -0.09 P<0.00001), and decrease the level of serum alkaline phosphatase (MD= -3.63 95% CI=6.60, -0.66 P=0.02) compared with sole Western medicine. Needling could relieve pain (MD: -2.27 95% CI=3.11, -1.43 P<0.00001) compared with sole Western medicine.

Conclusion

This presents systematic review indicated that acupuncture could be an effective therapy for treating osteoporosis. Warm acupuncture seemed to more effective than electroacupuncture and needling for osteoporosis in comparison to sole Western medicine.

FOUR YEARS OSTEOPOROTIC HIP FRACTURE INCIDENCE, AT THE EMERGENCY UNIT OF A TERTIARY CARE HOSPITAL IN SOUTHERN SPAIN
D. Carretero Dios¹, F. Luna Cabrera¹, P. Casado Adam¹, M. Pérez Bonilla¹,
A. Jiménez Vilches¹, F. Mayordomo¹
¹Hospital Reina Sofía, Rehabilitation, Córdoba, Spain

Introduction/Background

When making an indication of preventive or therapeutic intervention in osteoporotic disease (OP), it is important to know the real risk of fracture of a region, to determine the threshold from which an indication would be cost-beneficial.

Our aim was to assess the incidence of hospitalized acute patients with osteoporotic hip fracture (OHF) in our hospital area.

Material and Method

This is a retrospective and descriptive study. Incident cases of OHF in patients older than 50 years were collected from our Emergency Service, consecutively, between 1 January 2014 and 31 December 2017. We calculated Gross Incident Rates (GIR) considering the medium reference population of 461,078 people / year, as the Andalusian Health Service reports provide. We also used the patient's own clinical history and discharge reports from our centralized computer system "DIRAYA". The fracture should be due to an OP cause (that produced spontaneously or due to minor trauma, discarding cases where there was another medical cause that justified it).

Results

A total of 2857 OHF were recorded. Patients mean age was 82 years and Women OHF represented almost 72%. Descriptive statistics and GIR are shown in [table1]. The absolute number of OHF increased significantly from 2014 to 2017 (p <0.000), apart from 2015. In the univariate analysis, age was significantly related (p <0.000), to GIR, whose peak was recorded in the group of ≥79 years. People older than 75 were almost 83% of the total attended by OHF. The increase in the mean age was not significant for the period analyzed (p = 0.09). Distribution by sex, was not affected by the OHF increase (p = 0.339), maintaining a proportion of nearly 3 to 1.

ISPR8-2536
A COMPOUND STRATEGY OF ULTRASOUND-GUIDED INTERVENTION FOR SHOULDER IMPIEGEMENT SYNDROME: A CASE SERIES
Y.L. Tsai¹, M.H. Huang¹, C.S. Chen¹
¹Kaohsiung Medical University Chung-Ho Memorial Hospital, Rehabilitation medicine, Kaohsiung, Taiwan R.O.C.

Introduction/Background
Shoulder impingement syndrome (SIS) is one of the most common causes of pain and loss of function in shoulder. Multi-pathology spectrum ranging from subacromial bursitis to rotator cuff tendinopathy would lead to SIS.[1, 2] There has been a debate about the effectiveness of conservative treatments and subacromial corticosteroid injection (SCI) for shoulder pain.[3-5] Though the mechanism is unclear, a potential therapeutic effect of dextrose injection on neuropathic pain has been proposed.[6] This study assessed the clinical outcome of ultrasound-guided SCI followed by peri-deltoid and subcutaneous hydrodissection with dextrose 5% in water (D5W).

Material and Method
Subjects having SIS unresponsive to >2 months conservative treatment (excluding previous surgical or injection interventions) would be selected and receive SCI (methylprednisolone acetate 40 mg with lidocaine 1%, each volume 1 ml) followed by D5W injected into peri-deltoid and subcutaneous spaces (total volume 10ml). Outcomes were assessed with visual analog scale (VAS, 0-100mm) for pain with overhead activities, Shoulder Pain and Disability Index (SPADI) score, and active range of motion (AROM) of the shoulder at baseline, 15 minutes, 2 weeks, and 2 months post-treatment.

Results
18 adults (8 males, 10 females, mean (SD) age 46 (17.3) were recruited and no complications from treatment were noted. Significant improvements in VAS score, SPADI scores (pain,
disability, and total scores), shoulder AROM of flexion, abduction, and internal rotation were observed at all follow-up time points when compared to baseline. However, there was no significant improvement in shoulder AROM of extension, and external rotation.

Table 1. Changes of outcome measurements after injection therapy.

Conclusion

A single session of compound injection combined corticosteroid and dextrose prolotherapy appears to be a safe and effective method for treating shoulder impingement. Basic science and clinical studies of long term effect and measuring more functional outcomes are warranted.

UPPER LIMB NEURODYNAMIC DYSFUNCTION IN CERVICAL PAIN PATIENTS WITH AND WITHOUT REFERRED CERVICAL SYMPTOMS: A COMPARATIVE STUDY

R. van Bever Donker¹, I. Diener², P. Reddy¹

¹University of KwaZulu-Natal, Physiotherapy, Durban- KwaZulu-Natal, South Africa
²University of Stellenbosch, Physiotherapy, Cape Town, South Africa

Introduction/Background

Neck pain with neck related arm symptoms is more common than neck pain alone and has a significant association with disability. Neck related arm symptoms can be the result of mechanosensitive neural structures including the nerve roots or the peripheral nervous system. Neurodynamic tests identified as an effective tool to determine the extent to which the mechanosensitivity of a nerve has affected its sensitivity to movement.

The aim of this study is to establish neural mechanosensitivity of the brachial plexus in patients with neck pain without related arm symptoms in order to provide evidence based clinical rationale for the use of neurodynamic testing in these patients.

Material and Method

A quantitative comparative design was used with prospective cross sectional sampling. Participants that met the inclusion criteria were divided into 3 groups, namely the neck pain (NP) group, the neck and neck related arm pain group (NAP) and controls with no neck / arm symptoms (NNP). The ULNT 1 was used as a measure for neural mechanosensitivity, and an electro-goniometer was used to measure elbow ROM. The ULNT 1 was performed on both upper limbs of the participants, and 2 readings of elbow ROM taken for each upper limb.

Results

The total number of participants was 97. Demographics across all three groups were similar. Elbow ROM was significantly reduced in neck pain and neck and arm pain groups. Both the NP and NAP groups demonstrated statistically significant differences in mean ROM when compared to the NNP group.

Conclusion

The major finding of this study was that the neck pain group demonstrated a statistically significant reduced elbow extension during the ULNT1 at onset and tolerance indicating a
positive ULNT1. The findings of this study indicate the possibility of asymptomatic
mechanosensitivity in patients with neck pain without arm related symptoms

ISPR8-2647
EFFECTIVENESS OF LOW LEVEL LASER THERAPY ON ADULT PATIENTS WITH LATERAL EPICONDYLITIS – A RANDOMIZED CONTROLLED TRIAL
S. alrawaili1
1Prince Sattam Bin Abdulaziz University,
Department of Physical Therapy and Health Rehabilitation- College of Applied Medical Sciences, Alkharj, Saudi Arabia

Introduction/Background

Background: Lateral Epicondylitis (LE) is the most common syndrome in the elbow joint, described as an inflammation of the common extensor muscles. Many studies reported that low-level laser therapy may decrease pain and inflammation, but limited data have evaluated the effect of LLLT on hand grip strength in patients with LE.

Objectives: This study aimed to investigate the effects of low-level laser therapy on pain severity and handgrip strength in patients with lateral epicondylitis.

Material and Method

Study design: Thirty adult patients with lateral epicondylitis aged 20-40 years. They were randomly classified into two groups, fifteen in each group; low-level laser therapy (LLLT) and traditional physiotherapy program (TPT) groups. The LLLT group received a program of low-level laser therapy with bracing application and traditional physiotherapy group received deep friction massage and ultrasonic therapy with bracing application. Pain severity using visual analogue scale (VAS) and hand grip strength were evaluated at the beginning of the intervention, at the fourth week, and at the end of the study after eight weeks of the intervention.

Results

Results: Baseline characteristics showed nonsignificant differences in VAS and hand grip strength between the two groups at the beginning of the study. The findings of this study showed significant decreases in pain severity in the two groups. The hand grip strength of the affected hand had improved significantly and increased only in the low-level laser therapy group at the end of the study with p<0.05 after the 8-week intervention.

Conclusion

Conclusion: This study results showed that low-level laser therapy has beneficial effects on hand grip strength and pain severity more than traditional physiotherapy program in 8-week intervention.

Background and aims:
The compression of vascular and nerve structures for the upper limbs is the origin of TOS. If the clinical forms are variable (arterial, venous, neurological form), the functional discomfort in the activities of the daily life can be serious. Global scales (EN, DASH, CBSQ) can be used to evaluate the functional impact, but this evaluation is nonspecific. A specific scale was built and used during the rehabilitative treatment carried out in Lille. The purpose of this study is to evaluate its validity.

Methods: A self-questionnaire was constructed. 16 items were evaluated in 4 categories: impossible, major discomfort, moderate discomfort, without difficulty. An overall score is calculated. An evaluation is carried out parallel by a numerical scale. The self-questionnaire is completed on day 1, day 2 and the last day (LD). Between May 2015 and July 2017, 37 subjects were evaluated.

Results: There is excellent intra observer reproducibility (correlation coefficient = 0.92464). There is a significant improvement between D1 and LD (mean difference = -6.4594595, p <0.0001). The correlation between the EN and the total score is good at D1 (correlation coefficient at 0.66796, p <0.0001) and at LD (correlation coefficient at 0.67313, p <0.0001) and mean at D2 (correlation coefficient at 0.53485; p = 0.0008). There is an improvement in all items studied between D1 and LD, although the difference is significant for only 9 items.
conclusion: The questionnaire is a fast, simple way of assessing and focusing on activities of daily living. The excellent reproducibility intra observer, the good correlation with the EN and the evolution of most of the studied items attest that it is a suitable way to evaluate the functional discomfort in the TOS.

ISPR8-0261
EFFECTS OF HYPERTONIC DEXTROSE INJECTION ON CHRONIC SUPRASPINATUS TENDINOPATHY: A PILOT STUDY OF RANDOMIZED CONTROLLED TRIAL
S. Huang
1Shuang Ho Hospital- Taipei Medical University, Physical Medicine and Rehabilitation, Taipei, Taiwan R.O.C.

Introduction/Background

Rotator cuff lesions are common causes of shoulder pain. Although patients with symptoms caused by chronic rotator cuff tendinopathy can be treated using conservative treatments, some of them may still experience refractory symptoms. Hypertonic dextrose prolotherapy (DPT) may be another treatment choice for these refractory symptoms. However, conventional prolotherapy injection is complicated with multiple injection sites. Thus, we considered it necessary to design a rigorous trial to specifically evaluate the effectiveness of DPT injection for the supraspinatus tendon, which is mostly involved in rotator cuff tendinopathy.

Material and Method

This double blind, randomized, controlled study will recruit patients with chronic shoulder pain diagnosed as chronic supraspinatus tendinopathy. We recruit 20 participants, with a total of 10 participants in each treatment arm. The hypertonic DPT group will receive 5 mL of 20% glucose water prolotherapy injection, and the control group will receive normal saline by using the same injection protocol as that used for the study group. Demographic data will be recorded at baseline. Visual analog scale, Shoulder Pain and Disability Index, range of motion, ultrasound will be recorded at baseline, after intervention (week 2, and week 6). Descriptive statistics will be calculated for feasibility outcomes, and measures of clinical effectiveness will be explored using repeated measures analysis of variance.

Results

Prolotherapy injection group presented improved of VAS, SPADI, and range of motion after 2 weeks of injection with comparing baseline. However, the effect was not maintained to 6 weeks after injection. There was no difference of histogram changes before and after prolotherapy injection. With comparing control group, improved VAS and SPADI was better among study group at 2 weeks after injection but no difference at 6 weeks after injection.

Conclusion

Our pilot study demonstrated that hypertonic dextrose prolotherapy injection can improve pain and function of chronic rotator cuff tendinosis patients in short term period.

MUSCULOSKELETAL PAIN SYMPTOMS IN BAGPIPERS: A PILOT STUDY
F.C. Tan-III1, D. Bloodworth2, F. Chiou-Tan2
1St. Thomas Episcopal School, Scottish Arts, Houston, USA
2Baylor College of Medicine, Physical Medicine and Rehabilitation, Houston, USA

Introduction/Background

Musicians have musculoskeletal pain and overuse syndromes related to their instrument. Great Highland bagpipers (GHB) also have pain related to use, but this has not been well documented because of their relatively rare instrument. Historically, bagpipers were used to direct troops on the battlefield. Bagpipers or their instruments were shot to prevent the ability to do this. Bagpipers are required to suspend part of the instrument on their shoulder, squeeze a bag under the same arm, and blow a wind instrument simultaneously. The literature shows only one previous study that documented the most common musculoskeletal complaint was of the left arm and low back, but did not study pain scales.

Material and Method

An institutional review board approved, prospective, anonymous survey was sent to adult bagpipers that play in a GHB band. This pilot study was conducted to determine if they experience musculoskeletal pain or not. A larger scale international survey is planned since this pilot data is positive. Demographic data, pain location, severity (verbal numerical scale - VNS), duration, and McGill pain questionnaire were collected. Descriptive statistics computer program was applied.

Results

Ten surveys were collected in this pilot study. Ninety percent of bagpipers reported pain related to playing the instrument (SE 0.1). The most severe pain was the ipsilateral (bagside) cheek (3.3/10), followed by ipsilateral shoulder, ipsilateral forearm, and contralateral cheek (2.4/10) on VNS. The average pain duration lasted 3.3 hours (+/- 2.3 SE) after playing the instrument. Pain was most commonly described as “aching” or “sore” on McGill questionnaire.

Conclusion

This pilot data supports bagpipers experience musculoskeletal pain related to playing their instrument. Future studies underway will conduct this survey internationally. This will be followed by detailed history, physical exam to determine exact sources of pain. It is hoped this research will help Physiatrists understand and treat musculoskeletal pain in bagpipers.

ISPR8-0314
EVALUATION OF SUPRASCAPULAR NERVE BLOCK AND INTRAARTICULAR STEROID INJECTION AS A TREATMENT MODALITY IN PATIENTS WITH PERIARTHRTIS SHOULDER
S. Jain¹, D. Borah¹, D.S. Meena²
¹Safdarjung Hospital, Department Of Physical Medicine And Rehabilitation, Delhi, India
²Safdarjung Hospital, Department Of Anaesthesia, Delhi, India

Introduction/Background

Periarthritis shoulder (PA) characterized by gradual onset of pain with restriction of active and passive shoulder range of motion is one of the commonest musculoskeletal conditions of upper limb. Treatment options include rest, NSAID, active and passive mobilization, physical modalities, hydro-dilatation, manipulation under anaesthesia, arthroscopic capsular release, intraarticular injections and regional nerve blocks.

Material and Method

90 patients of periarthritis shoulder were enrolled in the study and randomly allocated into two groups. Group A received methyl prednisolone 80 mg intraarticular injection and Group B received suprascapular nerve block of 0.5% bupivacaine and methyl prednisolone. Each patient was assessed before intervention, at 1, 4 and 12 weeks after intervention. 0-10 Numeric Pain Intensity Scale, Active and passive range of motion, Quick Disability of Arm, Shoulder and Hand (DASH) score and Shoulder Pain and Disability Index (SPADI) were used for assessment.

Results

Group A showed statistically significant improvement (p<0.05) in pain, ROM and functional index on follow up at 1, 4 and 12 weeks whereas, group B showed improvement (p<0.05) in all parameters except passive flexion and external rotation on first follow up. However, this difference disappeared at subsequent follow ups. Comparison between the groups revealed a better outcome in Group A, in terms of Numerical Pain Intensity Scale Scores, SPADI Score, passive extension, active and passive internal and external rotations at 1, 4 and 12 weeks. Both the groups were comparable in terms of qDASH, active and passive abduction, flexion and active extension at first week with Group A showing subsequent improvement.

Conclusion

Both intrarticular steroid injection and suprascapular nerve block showed improvement in patients with periarthritis shoulder, but intrarticular steroid injection was found to be more efficacious as compared to suprascapular nerve block.

HOME EXERCISES FOR ADHESIVE CAPSULITIS OF THE SHOULDER: A SYSTEMATIC REVIEW

M. Guedria¹, A. Jellad¹, M. Gaddour¹, Z. Ben Salah Frih¹
¹Faculty of Medicine- University Hospital, Physical Medicine and Rehabilitation, Monastir, Tunisia

Introduction/Background

Home Exercises (HE) were used in adjunction to supervised physiotherapy to address musculoskeletal disorders such as low back pain, knee osteoarthritis and shoulder disorders. No systematic reviews or specific recommendations regarding HE in Adhesive Capsulitis (AC) are available. The aim of our study was to review systematically studies that evaluated the contribution of HE in AC patients.

Material and Method

An electronic search of PubMed, Cochrane Registry of Randomized Controlled Trials, MEDLINE, CINAHL, PEDro and SPORTDiscus using the terms “shoulder” or “Frozen shoulder” or “Adhesive capsulitis” paired with “Home exercises,” “Home Program” and “Self Exercises” was performed. We included studies evaluating HE alone or as a component of a rehabilitation program. HE were defined as exercises performed by the patient himself after being taught by a health care professional and can be done at home or in the local of intervention. Independent reviewers used a standardised form to extract data regarding study characteristics, participant characteristics, interventions, settings and outcome data/results. The risk of bias of the collected studies was assessed using The PEDro scale.

Results

Ten articles were retained: 4 high quality (PEDro score 6-10), 3 fair quality (PEDro score 4-5) and one poor quality (PEDro score ≤ 3). Described HE commonly comprised active-assisted range of motion without standardized rhythm. The type, the frequency and the duration of exercises were heterogeneous and poorly defined in some studies and patient compliance was not precised. HE were at least as effective as supervised physical therapy. It seemed that corticosteroid injection added effectiveness to HE but not to Manipulation.

Conclusion

HE should be considered in the rehabilitation program of AC patients. Randomized studies with sufficient samples and compliance assessment are needed to assess the true value of HE in AC patients.
Keywords

Adhesive capsulitis; Shoulder; Home exercises

No conflict of interest
Introduction/Background

Adhesive capsulitis (AC) is a clinical entity characterized by a loss of motion and a decrease of the joint volume capacity. Capsular distension (CD) has been shown to improve pain and function in patients with AC. There is no consensus concerning how CD should be performed or what volume should be injected. But, it has been suggested that ultrasound-guided CD are more accurate and effective than blind ones. The present study aimed to evaluate the effectiveness of ultrasound guided capsular distension followed by physiotherapy in the treatment of frozen shoulder/adhesive capsulitis.

Material and Method

48 patients were diagnosed with stage II to III frozen shoulder. Outcome measures included Shortened Disabilities of the Arm, Shoulder and Hand (QuickDASH), pain score using visual analog scale (VAS) and range of motion. Data were collected at baseline, as well as at 6 weeks, 12 weeks and 6 months.

Results

All patients significantly improved in shoulder symptoms on the QuickDASH scores. VAS and range of shoulder motion showed significant improvement at all time points.

Conclusion

The results of this study demonstrate that ultrasound guided capsular distension with physiotherapy is clinically effective for patients with frozen shoulder II to III.

ULTRASOUND-GUIDED PERCUTANEOUS CARPAL TUNNEL RELEASE WITH HOOK BLADE

N. Luanchumroen

1Nopparat Rajathanee Hospital- Department of Medicine- Ministry of Health, Rehabilitation Division, Bangkok, Thailand

Introduction/Background

Carpal tunnel syndrome is the most common cause of upper limb entrapment neuropathy. Transverse carpal ligament release is a definitive treatment for advanced stage of disease. The evidence to support ultrasonographic guidance of this procedure with hook blade is scarce. This study aim to evaluate the results of ultrasound-guided percutaneous carpal tunnel release (USG-PCTR) with hook blade on median nerve anatomical and physiological improvement, symptom relief, functional recovery, complications and satisfaction.

Material and Method

Single center of rehabilitation medicine division, prospective cohort study of consecutive patients who were diagnosed moderate to severe degree carpal tunnel syndrome which electrodiagnostic confirmation for at least 6 months, and were unresponsive to conservative treatment. Patients with rheumatoid arthritis, previous carpal tunnel release, pregnancy, bleeding risks and space occupying lesion were excluded. The procedure was an USG-PCTR with hook blade. Outcome measures at 3 and 6 months post-surgery included; BCTQ, median nerve CSA at distal wrist crease, proximal and distal carpal tunnel, median nerve conduction studies (DSL, DML and CAMP amplitude) and complications.

Results

Nineteen wrists from 16 patients who received US-guided percutaneous carpal tunnel release with hook blade were included in the analysis. All outcome measurements were significant improved at 3 and 6 months follow-up. Mean subject satisfaction scores was 9.68. Only 5 patient (26.31%) had a transient paresthesia and no severe complication were observed.

Conclusion

USG-PCTR with hook blade was an effective treatment for moderate to severe degree idiopathic CTS, in terms of median nerve anatomy and physiology, patient’s symptom and function with high level of satisfaction and no major complications.

Introduction/Background
Trigger finger is a common cause of hand pain and disability and an A1-pulley dividing, percutaneous release is a definitive treatment for advanced stage disease. High-resolution, musculoskeletal ultrasonography provides clear visualization of the A1-pulley and flexor tendon, however, the evidence to support ultrasonographic guidance of this procedure is scarce. This study aim to evaluate the results of ultrasound (US)-guided, percutaneous, needle technique, annular, A1-pulley release for trigger finger (TF); specifically identifying whether this minimally-invasive procedure had low complication rates and enables early functional recovery.

Material and Method
Single center, prospective cohort study of consecutive patients who were > 20 years of age, had grade II TF or higher for at least 4 months, and were unresponsive to conservative treatment. Patients with chronic connective tissue disease, rheumatoid arthritis, previous TF surgery, pregnancy, or bleeding risks were excluded. The procedure was an US-guided percutaneous A1 pulley release using needle technique. Outcome measures at 1 week post-surgery included; recovery time, pain level and duration, use of analgesic medications, time to normal activity of affected TF, and subject satisfaction for cosmesis and overall results. Surgical complications were monitored for 6 months.

Results
Thirty-nine fingers from 33 patients who received US-guided, percutaneous, A1-pulley release using needle technique were included in the analysis. Mean operative time was 6.17 (SD=1.70) minutes. Median post-operative pain duration, use of analgesic medications, and recovery time to normal activity were 1.0 (IQR=0-2), 0.5 day (IQR=0.5-1), and 2 days (IQR=1-2), respectively. Mean subject satisfaction scores for wound appearance and overall treatment were 9.87 and 9.61, respectively. Only one patient had an incomplete release and no severe complication were observed.

Conclusion
US-guided, percutaneous, A1-pulley release with needle technique was an effective treatment for TF, with high levels of overall satisfaction and no significant complications.

NOTALGIA PARESTHETICA:CASE REPORT
L. Ozgonenel¹, B. Taskın²
¹Istanbul Bilim University, Physical Medicine and Rehabilitation, ISTANBUL, Turkey
²Istanbul Bilim University, Dermatology, Istanbul, Turkey

Introduction/Background

Notalgia Paresthetica(NP) is a sensorial neuropathy of midback skin which is characterised by burning pain, itching and/or numbness in the scapular region. Hyperpigmented patch may be seen with NP.

Material and Method

Figure 1: Patient with Notalgia Paresthetica in thoracoscapular region.

Results

A 36-year old woman with right sided severe mid-back pain for 1 month was referred to our clinic. A hyperpigmented pruritic skin lesion in thoracoscapular region was detected which was diagnosed as NP.

Conclusion

We report this case as an unusual cause of mid back pain.

Keywords

No conflict of interest
Introduction/Background

A 65 year old woman is seen in PMR clinic for management of Dupuytren’s contracture of the right hand as it affects her hand function. She has type 2 diabetes mellitus, hypertension and ischemic heart disease with no history of trauma, fracture or infection.

Clinical examination of the right hand showed thickening of the palmar fascia of the fourth finger, with palpable tender nodule at MCPJ with incomplete hand fist and incomplete ring finger extension. Pain score using visual analogue scale (VAS), Michigan Hand Outcome Questionnaire (MHQ) was recorded.

Material and Method

After a diagnostic ultrasound patient received a total of 6 sittings of LLT for the right hand, two sittings per week. Ultrasound examination of region of interest at 1 cm proximal and 1 cm distal to the MCPJ of right ring finger showed a hypoechoic nodule measuring 11.4 mm in length and 1.5 mm in thickness and a hypoechoic cord measuring 6.3 mm in length. FIG(1)c

Results

She started to show improvement in VAS score from 8/10 to 4/10 and MHQ score. Ultrasound evaluation after finishing Low laser treatment at week 6 showed sonographic improvement in nodule and cord measurements, nodule length 10.9 mm and thickness 0.96 mm and cord length.
Conclusion

To our knowledge it is the first study that combined the effect of LLT in improving pain, hand function combining clinical and US images evidence. Ultrasonography is safe and easy and can be of value in diagnosis and monitoring outcome of rehabilitation interventions for the treatment of Dupuytren disease.

ULTRASONOGRAPHIC MEASUREMENTS OF AXILLARY RECESS CAPSULE THICKNESS IN UNILATERAL FROZEN SHOULDER: STUDY OF CORRELATION WITH MR IMAGING MEASUREMENTS

D.H. Kim

Dongsan medical center- Keimyung University, Rehabilitation Medicine, Daegu, Republic of Korea

Introduction/Background

The aims of this study were to compare the ultrasonographic (US) thickness of the affected axillary recess capsule (ARC) with that of the unaffected ARC in patients with frozen shoulder (FS), to analyze whether the US measurements of the ARC thickness are correlated with those using MR imaging (MRI), and to assess whether the US thickness of the ARC is correlated with the patterns of range of motion limitation.

Material and Method

Forty-four patients with clinically diagnosed unilateral frozen shoulder and MRI evaluation performed US measurement of ARC. The US measurement of the ARC thickness was performed with the patients in a supine position with their shoulder abducted by 40 degrees. The ARC thickness was also measured by MRI on oblique coronal images by another physician blind to US measurements. With both US and MRI, ARC thickness was determined at the widest portion of the capsule (Fig. 1).

Results

The US thickness of ARC was significantly higher in the affected shoulder (4.4 ±1.1 mm) than in the unaffected one (2.2 ± 0.5 mm) (p<.001) (Fig. 2).
The US thickness of the ARC in the affected shoulder was correlated with that measured by MRI (8.9±1.9 mm) (p<.001, r=.83). The ARC thickness, whether measured by US or MRI, was not significantly related with the limitation of movement in specific directions.

Conclusion

US can demonstrate the difference in ARC thickness between the affected and unaffected shoulders in patients with unilateral FS. The ARC thickness measured by US is correlated with that measured by MRI.

Frozen shoulder (FS) is a common disease which may cause restricted shoulder range of motion (ROM). Recently, studies have indicated that the smartphone goniometer apps could be reliable tools for shoulder ROM assessment. Nevertheless, patients with FS couldn't use most of these apps in normal measurement position due to shoulder capsular pattern. Hence, if we can design a new method in modified position to measure ROM with smartphones, it will be a helpful assessment for them. The purpose of this study was to investigate the reliability and validity of the smartphone goniometer app to measure shoulder ROM in modified position for healthy subjects.

Material and Method

Ten healthy subjects (5 male, 5 female; age=26.6±3.6 y/o) were recruited. Two physical therapists utilized the universal goniometer (UG) and ASUS Zenfone 4 smartphone with an accelerometer-based goniometer app to conduct various active shoulder ROM (flexion, abduction, external rotation (ER) and internal rotation (IR) at 0° abduction). The smartphone was stabilized at the hand with an armband to reduce measurement errors. All measurements were taken for 3 times (2 measurements on the first day and 1 on the next day). Intraclass correlation coefficients (ICC) and Pearson’s correlation coefficients (PCC) were used for statistical analysis. Significance level was set as α<0.05.

Results

Both the UG and smartphone demonstrated high within-day and between-day reliability (ICC > 0.800, p<0.001) except the flexion for which the ICC values was 0.622 (p=0.023, first day) and 0.787 (p=0.002, second day). The validity between the UG and the smartphone showed significant correlation (PCC > 0.800, p < 0.001) among all shoulder motions.

Conclusion

The smartphone goniometer app has good reliability and validity for shoulder ROM assessment in modified position which indicates that the method is feasible to evaluate the restricted ROM for patients with FS.

THE MIOFASCIAL COMPONENT OF THE PAIN IN THE PAINFUL SHOULDER OF THE HEMIPLEGIC PATIENT

F. Martins Liporaci¹, M. Riberto¹, M. Massaro Mourani²
¹Faculdade de Medicina De Ribeirão Preto-USP,
Departamento de Biomecânica- Medicina e Reabilitação do Aparelho Locomotor,
Ribeirão Preto, Brazil

Introduction/Background

Hemiplegic painful shoulder syndrome occurs very frequently and jeopardizes functionality and quality of life. Its treatment depends on a multidisciplinary approach; therefore it is desirable to identify measures that increase treatment effectiveness. Myofascial pain syndrome is defined by the identification of trigger points that reproduce the pain complaint and can be found in spastic patients.

Material and Method

Spastic hemiplegic patients following stroke in a rehabilitation program at Ribeirão Preto Medical School of the University of São Paulo were evaluated for the intensity and characteristics of the pain, shoulder goniometry and the presence of TPs. Patients underwent TP blockade by intramuscular infiltration of 1% lidocaine. Patients who were in a multiprofessional rehabilitation program were instructed to keep the treatment and the others received guidelines to initiate it. The evaluations were performed at 0, 1, and 3 weeks and after 4 months.

Results

21 patients (13 men, age = 67.8 ± 10.2 years, right hemiparesis: 11) participated in the study, and there was pain reduction at baseline until the week one (VAS 7.6 ± 2.7 x 5.8 ± 3.6, p <0.05) and until week three (VAS 7.6 ± 2.7 x 5.2 ± 3.5, p <0.05), but not at the end of four months (VAS 7.6 ± 2.7 x 6.6 ± 2.9, p = 0.11); in passive goniometry there was gain for abduction at the end of the first and third weeks, but not in 4 months and not on active abduction. No other significant change was found.

Conclusion

It was possible to confirm that these blocks attenuated the HPSS, since there was improvement of the average values over 3 weeks after the procedure, but less effective at the end of 4 months. However, when analyzing individual cases, some patients progressed to complete abolition of pain or very low values in VAS throughout the observation period.

RELATIONSHIP BETWEEN FORWARD HEAD POSTURE AND SCAPULAR DYSKINESIS IN PATIENTS WITH CHRONIC NECK PAIN

M.A. Guler¹, B. Nacir¹, B.D. Cakıt¹, H. Genc¹, A. Karagoz¹
¹Health Science University- Ankara Health Research and Training Hospital, Physical Medicine and Rehabilitation, Ankara, Turkey

Introduction/Background

Forward head posture (FHP) can negatively affect the quality of life, especially as it causes chronic neck pain. Skapular dyskinesis is a musculoskeletal system disorder that has evolved over the last years and appears after shoulder pathologies and scapulohumeral rhythm disturbances. Because of the affected muscle groups are similar in both diseases, we aimed to investigate the relationship between these two musculoskeletal disorders in our study.

Material and Method

180 patients with chronic neck pain were included in the study. These patients were divided into two groups according to the measured craniovertebral angle (CVA). Patients with CVA<44 included in the FHP group and patients with CVA>44 included in non-FHP group. Demographic characteristics of these patients were questioned. Craniovertebral angles, head’s tilt angle, and forward shoulder angle were measured. Scapular dyskinesis test and lateral scapular slide test (LSST) were performed to investigate the presence of scapular dyskinesis. Cervical range of motion, acromion distance, pectoralis minor length, and scapular isometric squeeze test results were measured and recorded.

Results

According to the scapular dyskinesis test, 25 patients were diagnosed with scapular dyskinesis. There was a statistically significant relationship between the existence of FHP and scapular dyskinesis. Scapular dyskinesis was diagnosed in 45 of the patients using LSST. There was no significant relationship between FHP and LSST. There was a significant relationship between LSST and scapular dyskinesis test. No significant relationship was found between head’s tilt angle and CVA.

Conclusion

We found a significant relationship between presence of FHP and scapular dyskinesis. We think that scapular movements should also be taken into account when evaluating FHP. In treatment of FHP patients, scapular movement disorders should be evaluated. We believe that neck pain, disability and drug use can be decreased by including scapular stabilization exercises in the routine exercise program in the forward head posture treatment.

SHEAR WAVE SONOELASTOGRAPHY OF SUPRASPINATUS MUSCLE IN PATIENTS WITH ROTATOR CUFF TEAR
G.Y. Park¹, D.R. Kwon¹, J.H. Rim¹
¹Daegu Catholic University Hospital, Rehabilitation Medicine, Daegu, Republic of Korea

Introduction/Background

To investigate the elastic properties of the supraspinatus (SSP) muscle in patients with rotator cuff tear (RCT) by using shear wave sonoelastography (SWS) and comparing the stiffness of SSP muscle according to severity of RCT

Material and Method

Seventy six patients (43 males, 33 females; mean age 64.4±9.2 year) with one hundred and fifty two shoulders (85 symptomatic, 67 asymptomatic) were recruited. Severity of RCT, fatty infiltration and echogenicity of SSP muscle, and SSP muscle atrophy were assessed on B-mode ultrasound (US). Shear wave velocity (SWV) was measured twice in proximal and distal upper trapezius and SSP muscles at suprascapular fossa on longitudinal SWS using acoustic radiation force impulse imaging.

Results

In the 85 symptomatic/67 asymptomatic shoulders, US revealed 1/37 shoulders with normal supraspinatus tendon (group 1), 16/16 shoulders with tendinopathy (group 2), 41/2 shoulders with partial-thickness tear (group 3), and 27/12 shoulders with full thickness tear (4/4 small and 8/2 medium (group 4), 4/3 large and 11/3 massive (group 5)). The SWV of SSP muscle in groups 1, 2, 3, 4, and 5 were 2.88 ± 0.25 m/s, 2.79 ± 0.27 m/s, 2.64 ± 0.21 m/s, 2.34 ± 0.14 m/s, and 2.12 ± 0.17 m/s, respectively. SWV in SSP muscle was negatively correlated with the severity of RCT (r = -0.809), fatty infiltration grade of SSP muscle (r = -0.677), echogenicity grade of SSP muscle (r = -0.637), Warner grade (r = -0.671), and Goutallier stage (r = -0.672, p < .05).

Conclusion

The SWS demonstrated a difference of elastic properties of SSP muscle according to the severity of RCT and was correlated with fatty infiltration, echogenicity, and atrophy of SSP muscle, and the severity of RCT. Therefore, SWS can be used as an imaging method to provide insight into the biomechanics and pathophysiology of supraspinatus muscles in patients with RCT.

Introduction/Background

Chronic neck pain is a major public health problem in most communities. The aim of this study was to investigate the effectiveness of kinesio taping on pain, cervical range of motion and disability in patients with chronic neck pain.

Material and Method

Forty four subjects (age range: 30-55; mean age: 40.7±7.3 yrs; 32 females, 12 males) were randomly divided into two groups (study group: 22, control group: 22). Conventional physiotherapy methods including active (exercise) and passive (hotpack, therapeutic ultrasound and TENS) treatment were applied to all subjects for 15 sessions (5 days a week). Additionally, in the study group kinesio taping was performed at the end of each session. Pain intensity (Visual Analogue Scale), pressure pain threshold (digital algometer), cervical range of motion (CROM device) and disability (Neck Disability Index) were evaluated before treatment, on the second day of treatment and after treatment.

Results

There was no significant difference between the groups for demographic data (age, height, weight, BMI) and any outcome at baseline (p>0.05). When the intra-group comparison is examined, in the study group second day outcomes for pain intensity, range of motion and disability were higher than the pre-treatment assessment (p <0.05). There was no significant improvement in any of the parameters in the control group on the 2nd day outcomes when compared to the pre-treatment (p>0.05). In both groups, there were significantly improvements in all parameters after treatment than the pre-treatment (p<0.05). In study group, pressure pain threshold and disability level were found to be better than control group according to the post-treatment outcomes (p <0.05).

Conclusion
The results of this study have shown that kinesio taping in addition to conventional physiotherapy provides additional benefits in chronic neck pain.

2Taitung Christian Hospital, Department of Rehabilitation, Taitung, Taiwan R.O.C.
3National Cheng Kung University Hospital, Department of Orthopedics, Tainan, Taiwan R.O.C.

Introduction/Background

Neck pain is a common complaint among office workers who hold a static posture during prolonged computer work. The aim of this study was to investigate the effect of a wearable real-time postural biofeedback device on spinal posture, muscle activity, and pain in adults with neck pain.

Material and Method

21 adults who had chronic or recurrent nonspecific neck pain for more than 3 months and whose pain was induced or aggravated by prolonged computer work were enrolled in this study. Three-dimensional spinal posture, muscle activity (cervical erector spinae, upper trapezius, and thoracic erector spinae), and self-reported neck and shoulder pain were measured before and after computer typing tasks, with and without biofeedback.

Results

Compared with the non-biofeedback condition, the biofeedback condition significantly decreased neck flexion, upper cervical, and lower thoracic angles and lowered the activity of the cervical erector spinae. Self-reported neck pain was not influenced by the application of biofeedback, but significantly increased over the 1-hour typing task.

Conclusion

The application of biofeedback improves sitting posture and reduces muscular demand in adults with nonspecific neck pain during computer work. Future studies should examine the long-term effects of wearable real-time postural biofeedback devices for prevention and management of neck pain.

ULTRASONOGRAPHIC GUIDED SUBACROMIAL SODIUM HYALURONATE INJECTION FOR ROTATOR CUFF DISEASE

F. Dehghan¹, A. Moghtaderi¹, S. Sajadiyeh¹, V. Bateni²
¹Isfahan University of Medical Sciences, physical medicine and rehabilitation, Isfahan, Iran
²Isfahan University of Medical Sciences, radiology, Isfahan, Iran

Introduction/Background

Rotator cuff disease is a common cause of shoulder pain. There are studies about the effectiveness of sodium hyaluronate injection on shoulder and knee pain, but few studies demonstrating the efficacy of sodium hyaluronate ultrasonography guided injection for rotator cuff disease. This study evaluates effectiveness of ultrasonography guided subacromial sodium hyaluronate injection in patients with impingment syndrome without rotator cuff complete tear.

Material and Method

This prospective, double-blind, placebo controlled clinical trial study was performed among 40 patients with subacromial impingement syndrome without complete tear of rotator cuff. Patients randomly injected ultrasonography guided in 2 groups: Case group by 20 mg of sodium hyaluronate and control group by 0.9% normal saline. Both groups received 3 weekly injections. The pain score (100 mm visual analogue score [VAS]) was evaluated before first injection and one week after each injection. The constant score was evaluated before first and 12 week after last injection. Data was analyzed statistically by Independent t-test.

Results

In both groups mean VAS has decreased, but more significantly in case group (\( P < 0.001 \)). Mean constant score was significantly higher in case group 12 weeks after last injection (\( P < 0.001 \)). The constant score improved 12 weeks after the last injection in both groups with a significantly better result in case group (\( P < 0.001 \)).

Conclusion

Subacromial injections of sodium hyaluronate are effective in treating rotator cuff disease without complete tears.

THE SHOULDER DISORDER SCREENING FOR WHEELCHAIR MARATHON RUNNERS.

Y. Sasaki¹, T. Ogawa², M. Kakita², Y. Nishimura³, Y.I. Kamijyo², F. Tajima²

¹Gifu municipal hospital, rehabilitation medicine, Gifu-city, Japan
²Wakayama Medical University, Rehabilitation medicine, Wakayama-city, Japan
³Iwate Medical University, Rehabilitation medicine, Morioka-city, Japan

Introduction/Background

Wheelchair marathon is one of the most stressing sports to shoulders of runners. But the frequency and degree of shoulder disorders are unknown.

Material and Method

87 wheel chair runners (83 male, 4 female) competing in the Oita International Wheelchair Marathon were examined. They were taken medical history, physical examinations, and performed ultrasonography.

Results

Mean age was 47.8 years old, mean height was 165.3cm and mean body weight was 58.5kg. Runners had experienced wheelchair marathon for mean 15.7 years. 44 runners had shoulder pain (20 persons were only right side pain, 9 persons were only left side and 15 persons were bilateral side). 69 shoulders had tenderness. 30 shoulders had abnormal findings by B mode ultrasound examination. 17 shoulders had abnormal findings by ultrasonography but have normal physical examinations. 76 shoulders had tenderness but had normal echo findings.

Conclusion

Many wheelchair marathon runners have shoulder disorders. Physical examination and ultrasound examination are useful for screening for the shoulder disorder of wheelchair marathon runners.

THE EFFECT OF ADDING ECCENTRIC EXERCISES TO CONVENTIONAL PHYSICAL THERAPY FOR PATIENTS WITH ROTATOR CUFF TENDINOPATHY
Y.S. Horng¹, V. Chiu¹, Y.S. Horng¹,²
¹Taipei Tzu Chi Hospital- Buddhist Tzu Chi Medical Foundation, Department of Physical Medicine and Rehabilitation, New Taipei City, Taiwan R.O.C.
²Tzu Chi university, school of medicine, Hualien, Taiwan R.O.C.

Introduction/Background

To evaluate the effectiveness of adding an eccentric training of the rotator cuff to conventional physical therapy in patients with subacromial pain syndrome involving rotator cuff tendinopathy.

Material and Method

Fifty-nine patients with rotator cuff tendinopathy, diagnosed by an physiatrist, were included and randomly allocated into an experimental group (EG) or a control group (CG). The experimental group (n=31, mean age=57.4±13.4 years) received an eccentric training plus a conventional physical therapy, including modalities, scapular stabilization exercises and stretching, while the control group (n=28, Mean age=63.1±10.0 years) received a conventional physical therapy only. Patients in both groups received treatments twice a week for 3 months. Primary outcomes were shoulder pain (a 0-100mm visual analog scale; VAS) and function measured with the Disabilities of the Arm, Shoulder and Hand (DASH) score. Secondary outcome measures were isometric strength of abduction at 90° of scapular abduction (hand-held dynamometer) and shoulder range of motion(forward elevation, external rotation, and internal rotation). All measurements were taken at baseline and after treatment.

Results

After treatment, both groups showed a significant decrease in VAS scores (EG: -16.4 mm, P=0.003 and CG: -21.9 mm, P<0.001) and a significant decrease in DASH score (EG: -8.8 points, P=0.01 and CG: -7.5 points, P=0.002). Both groups also had a significant increase in isometric muscle strength (EG: 1.9 pounds, P<0.001 and CG: 1.8 pounds, P=0.002). No statistically significant differences were found between the groups for any of the evaluated outcome measures.

Conclusion

It was shown that both groups had significantly increased isometric strength, decreased pain and better function after 3 months of treatment. Conventional physical therapy with or without eccentric training is effective in treating patients with rotator cuff tendinopathy.
Keywords

rotator cuff tendinopathy; eccentric training; physical therapy

Violinists frequently assume an asymmetrical neck posture and activate their superficial neck flexor muscles to stabilize the violin for prolonged playing. It is unclear whether this augmented activation of superficial neck flexors may influence the effects of stabilization exercises for violinists with neck pain. The aim of this study was to investigate the effect of cervical stabilization/strengthening exercises on pain intensity, function, sensorimotor function, and upper body posture in violin players with chronic non-specific neck pain.

Material and Method

The one-group pretest-posttest design with a double pretest was used. Violin players with chronic non-specific neck pain were recruited from students of a university symphony orchestra. Pain intensity (numeric rating scale), function (neck disability index), sensorimotor function (craniovertebral flexion test, cervical muscle endurance tests, cervical range of motion tests, and cervical reposition error tests), and upper body posture were assessed at three time points (week 0, 4, and 10). After the completion of two pretests, participants followed instructional videos and performed cervical stabilization/strengthening exercises, 20 minutes a day, 3 days a week for 6 weeks.

Results

Twenty-four participants were initially enrolled, and 20 completed all testing sessions. Participants reported moderate neck pain and no disability at week 0. The outcome measures of pain intensity, function, and sensorimotor function showed statistically significant improvement during the intervention period (week 4 vs. week 10). Meanwhile, these outcome measures remained relatively unchanged during the baseline period (week 0 vs. week 4). For the outcome measure of upper body posture, only the craniovertebral angle relative to the horizontal plane significantly increased during the intervention period.

Conclusion

Six-week video based cervical stabilization/strengthening exercises resulted in clinically meaningful and beneficial effects. A randomized controlled study with a larger sample is
suggested to further investigate the effects of cervical stabilization/strengthening exercises in violin players with more severe neck pain.

SAFETY AND EFFICACY OF POLYDEOXYRIBONUCLEOTIDE INJECTIONS VERSUS PROLOThERAPY FOR PATIENTS WITH ELbow EPICONDYLIStIS IN A RANDOMIZED DOUBLE-BLIND ACtIVE-CONTROLLED TRIAL

H.K. Do¹, C.H. Yi¹, J.Y. Lim¹
¹Seoul National University Bundang Hospital, Department of Rehabilitation Medicine, Bundang-Gu- Seongnam- Gyeonggi, Republic of Korea

Introduction/Background

Our aim was to evaluate the efficacy of polydeoxynucleotide (PDRN) injections compared to standardized prolotherapy for patients with lateral epicondylitis (LE).

Material and Method

In this randomized, double-blind, active-controlled trial, eligible patients with LE received intratendinous injections (1 ml of PDRN or hypertonic dextrose [15%]) under ultrasound (US) guidance at weeks 0, 2 and 4. Primary outcome was Visual Analogue Scale (VAS) for elbow pain. Secondary outcomes were pain-free grip strength (PFGS), pressure pain threshold (PPT), isokinetic wrist extensor strength (IWES), patient-rated tennis elbow evaluation (PRTEE), EQ-5D-5L and US characteristics of the LE. All outcomes and adverse events were assessed at weeks 0, 6 and 12.

Results

The final analysis included 38 patients (PDRN injection, n = 19; prolotherapy, n = 19) (Figure 1) (Table 1). Significant improvements from baseline to 12 weeks were observed in VAS for elbow pain in both groups (53.6 ± 19.1 mm, p<0.001 in PDRN; 50.6 ± 16.8 mm, p<0.001 in prolotherapy) (Figure 2). While the between-group difference in VAS was not significant (p = 0.605). Significant pre-versus-post improvements were observed within each group for the secondary outcomes other than US characteristics (p<0.001, p = 0.001, and 0.003, respectively). Of these outcomes, PFGS, PPT, and IWES exhibited increase of up to 90 % (ratio = affected side/unaffected side × 100) in both groups. However, all secondary outcomes showed non-significant between-group differences. There were no serious adverse events that resulted in drop-outs.

Introduction/Background

The aim of the current study was to investigate the epidemiological profile of elderly patients treated for degenerative painful shoulder and to describe their management in a Physical Medicine and Rehabilitation department (PMR).

Material and Method

A retrospective study of the records of 156 elderly patients treated for degenerative painful shoulder was conducted over a ten year period (January 2004 - January 2014). Epidemiological and clinical parameters were studied.

Results

The patients’ average age was 70.8 years ± 5.08 years. Shoulder disorders were more common in women (75%) than in men (25%). Sixty eight patients (43.5%) were diabetics. Almost half of the studied population (46.8%) was referred from rheumatology department. The most frequent pathologies were subacromial impingement (56.4%), adhesive capsulitis (27.5%) and rotator cuff tendinopathy (10.8%). Diabetes, female gender and a history of manual profession were significantly associated with these diagnosis. Rehabilitation sessions were prescribed in 96.7% of cases with an average of 34 sessions per patient. Analgesics and NSAIDs were prescribed respectively in 51% and 35% of cases. Corticosteroids injections were performed in 48% of cases. Furthermore, capsular distension was indicated in 18 patients suffering from frozen shoulder (11.5%).

Conclusion

As for the general population, subacromial impingement, adhesive capsulitis and rotator cuff tendinopathy are the most common causes of degenerative painful shoulder in elderly patients. Although the functional demand of this population is lower than that of the active one, the management of shoulder pain remains sometimes challenging because of some specific medical conditions of the elderly. Further detailed assessment of the extent of disability caused by shoulder pain in the elderly is needed.

MUSCULOSKELETAL DISORDERS IN PHYSIOTHERAPISTS OF A UNIVERSITY HOSPITAL CENTER

S. Salah¹, H. Abdelghaffar², A. Kalai³, I. Feki¹, Z. Ben Salah Frih¹
¹Faculty of Medicine of Monastir-University of Monastir, Physical Medicine and Rehabilitation, Monastir, Tunisia
²School of Health Sciences and Technology- University of Monastir-
School of Health Sciences and Technology- University of Monastir-, Monastir, Tunisia

Introduction/Background

The objective of the current study was to determine the prevalence of musculoskeletal disorders (MSDs) in physiotherapists and to look for predictive factors of their early onset.

Material and Method

A cross-sectional descriptive study was conducted on March 2017 including thirty physiotherapists of a university hospital center. A self-questionnaire was administered to the participants assessing their epidemiological profile, the MSDs they suffered from, and their level of information on MSDs as well as their level of exposure to these disorders.

Results

The mean age of the participants was 39.4 years± 8.7 years. The sex ratio H/F was 0.57. The mean professional practice duration was 10.9 years±7.11 years. The prevalence of MSDs was 93.3%, these disorders were localized in the lumbar spine (73.3%), cervical spine (30%), shoulder (40%), elbow and wrist (23.3%), hand (13.3%) and lower limb (13.3%). Respondents rated their level of exposure to MSDs as high and their level of information on these disorders as medium. MSDs had an early onset (≤2 years) in younger physiotherapists with higher levels of stress (p <0.05). However, no predictive factor for early onset of MSDs was found in the studied sample.

The presence of MSDs was correlated to age (r = 0.538, p = 0.002), to professional practice duration (r =0.889, p<0.001) and to the level of stress experienced by the physiotherapist. It seems that the higher this level was, the more likely the physiotherapist would experience MSDs earlier in his career (r = -0.397, p = 0.03).

Conclusion

Although difficult, the prevention of MSDs is of considerable benefit. The initial training of physiotherapists must include information on occupational risks and adaptation strategies as well as ergonomics of workstations and stress management.

ISPR8-1226
A PILOT RANDOMIZED CONTROLLED STUDY OF COMPARATIVE EFFECTIVENESS OF KINESIOLOGY TAPEING, SHAM TAPEING OR EXERCISES ONLY IN TREATMENT OF LATERAL EPICONDYLITIS
E. Giray¹, D. Karali Bingül¹, G. Akyuz¹
¹Marmara University School of Medicine, Department of Physical Medicine and Rehabilitation, Istanbul, Turkey

Introduction/Background

Lateral Epicondylitis (LE) is a common musculoskeletal condition presenting with pain due to overuse of common extensor tendon. It is treated with many different methods. The aim of this study is to compare efficacy of kinesiology taping (KT) and sham taping in addition to exercise or exercises only in the treatment of LE.

Material and Method

Thirty patients, aged 25-68 years, with clinically diagnosed LE less than 12 weeks were randomized into three groups; KT (n=10), sham taping (n=10) and control (exercises only) (n=10) groups. All groups received home exercise program including strengthening and stretching exercises. In KT and sham taping groups, tapings were performed and changed every 3-4 days for two weeks. Visual analog scale (VAS), grip strength, The Disabilities of the Arm, Shoulder and Hand (QuickDash) and The Patient-Rated Tennis Elbow Evaluation (PRTEE) scales were used for assessments before and after treatment. The immediate effect was assessed by VAS and grip strength immediately after both tapings.

Results

Among the KT, sham and control groups, there were statistically significant differences regarding the changes in VAS at activities of daily living (ADL) (-2.5, 0, 0 ; p=0.02) and PRTEE (-26.25, 0.5, 1.25; p=0.006). Post-hoc analyses revealed that VAS at ADL and PRTEE (p<0.01) showed significantly greater improvement in the KT group than sham taping and control groups. VAS at ADL (p=0.007), painless and maximum grip strength (p=0.03; p=0.04), QuickDash (p=0.03) and total PRTEE (p=0.004) scores were significantly lower after treatment compared to baseline in the KT group. Grip strength immediately increased after taping in the KT group (p=0.02). Neither sham taping group nor control group showed improvement in any of the outcome measures after treatment.

Conclusion

Kinesiology taping in addition to exercise is more effective than sham taping and exercises only for improving pain at ADL and arm disability due to LE.

INTERSECTION SYNDROME : A CASE REPORT
S. Jain¹, D. Borah¹, C. c.¹
¹Safdarjung Hospital, Department Of Physical Medicine And Rehabilitation, Delhi, India

Introduction/Background

Intersection syndrome describes an inflammatory condition occurring at crossing point between the first and second dorsal compartment muscles. It is repetitive motion injury that affects patients who overuse their wrist.

Material and Method

A 34 year old, right hand dominant male presented to OPD with severe pain, swelling, crepitus on lateral aspect of forearm 2 inches proximal to snuff box since 2 months. Ultrasonographic exploration revealed presence of fluid collection around tendon sheaths of first and second extensor compartment muscles at their intersection. A clinical diagnosis of intersection syndrome was made and 2 weeks course of rest and NSAID (diclofenac) was advised. After 2 weeks there was no relief. Under USG guidance 0.5 ml (20 mg) of methylprednisolone along with 0.5 ml of 2% Lignocaine was injected.

Results

After 2 weeks of intervention there was resolution of pain, swelling, crepitus and patient resumed his work.

Conclusion

Intersection syndrome is a specific painful disorder of the forearm that is commonly misdiagnosed. High level of suspicion and careful examination is warranted to avoid misdiagnosis which may lead to prolonged morbidity.

TRIPLE LESION: A RARE TRIO OF DIFFERENT LESIONS PRESENTING SIMULTANEOUSLY

N. Mansoor

Introduction/Background

In clinical settings when we come across a confirmed diagnosis, we have a tendency to ignore any other associated lesion. We report an interesting case workup of a triple lesion in which patient had three different problems in the same anatomical location with similar/overlapping symptoms and clinical presentations.

Material and Method

43 years old patient referred for management of shoulder pain and weakness. The patient had one month history of lifting heavy weight on shoulder resulting in severe pain weakness and restriction of movement of right shoulder. On examination he had restricted active movements of his shoulder but unrestricted painful passive movements. Painful arc was positive. His Xray shoulder was normal. His musculoskeletal ultrasound revealed partial tear of right supraspinatous tendon. Patient was recommended anti inflammatory drugs, physiotherapy along with rest. On two weeks followup he complained of weakness in right shoulder as well as radiating pain from the neck to the arm. Re examination revealed wasting of right deltoid and a positive Spurling sign on right. Sensory impairment on the upper lateral right shoulder. His nerve conduction studies showed Axillary nerve injury on the right. MRI of his cervical spine showed Posterolateral disc bulge at CV4-5 with foraminal stenosis and nerve root impingement and anterior osteophyte at CV5-6. So the patient had three lesions at the same temporal distribution including a supraspinatous tear, an axillary nerve injury and a disc herniation at CV4-5 causing root impingement. The patient was recommended conservative treatment through multi disciplinary consultation and physical modalities, analgesia, pregablin, TENS and electrical muscle stimulation to the deltoid along with advice for neck and shoulder care and exercises.

Results

Pain and weakness gradually improved.

Conclusion

More than one lesions must be kept in mind in all diagnostic and clinical workups for early diagnosis and better management of patients.
Keywords

triple lesion; brachialgia; nerve injury

Material and Method

Descriptive and retrospective inferential statistics study, from January 2016 to October 2017, of 53 patients with CSET. Three sessions (one for week) of SWT (Generator PiezoWave F10 G4) by ultrasound support. Weekly follow-up, at 3, 6 and 12 months.

keys: pain (VAS), Functional outcomes (Quick DASH) and satisfaction degree (Roles and Maudsley scale).

Results

Mean age was 53.6 years.

Median Intensity (0.351) mJ / mm². Median frequencies of 8 Hz. Median depth of focus 15 mm. 2000 pulses per session.

Statistically significant improvement was observed of VAS between 1st and 3rd session (p <0.000), 1st session and VAS at 3 months (p <0.000), 1st session and 6 months (p <0.032) and 1st session and 12 months (p <0.048).

The VAS at 3 months improved in 77.6%; 80% at 6 months; 75.4% at 12 months.

The Roles and Maudsley Scale was positive at 3, 6 and 12 months.
No statistically significant improvement in shoulder functionality at 3, 6 and 12 months.

Conclusion

According to the results, high-energy piezoelectric SWT by ultrasound support of the CSET reduces pain and improves functionality in a short-term, still at 3, 6 and 12 months, with a positive satisfaction degree.

THE SONOGRAPHIC RELATIONSHIP BETWEEN CROSS-SECTIONAL AREAS OF THE MEDIAN NERVE AND CARPAL TUNNEL AS A DIAGNOSTIC TOOL FOR CARPAL TUNNEL SYNDROME. A LITERATURE REVIEW.

J.P. Saraiva¹, A. Alonso¹, M.T. Jorge Mora¹, I. Bascuas¹, M. Escalona²
¹Complexo Hospitalario Universitario de Pontevedra, Servicio de Medicina Física y Rehabilitación, Pontevedra, Spain
²Complexo Hospitalario Universitario de Pontevedra, Servicio de Neurofisiología, Pontevedra, Spain

Introduction/Background

Carpal tunnel syndrome (CTS) is the most common entrapment neuropathy, being responsible for up to 90% of the total entrapment neuropathies. The electroneuromyography (ENMG) is the golden standard for confirming the diagnosis and assessing the severity. Ultrasound (US) is a less invasive method but not yet a truly alternative. Many authors use the median nerve cross-sectional area (CSA) for CTS diagnosis or calculating the flattening ratio. Comparing the nerve CSA with the tunnel CSA could be interesting, correlating the content (the median nerve and finger flexor tendons) and the continent (the carpal tunnel itself).

The goal of this article was to perform a literature review accessing the usefulness of this US parameter.

Material and Method

We conduct a bibliographic research using Pubmed and Google Scholar databases. Search items included combinations of “carpal tunnel” and “sonography” or “ultrasound”. Additional studies were identified by searching bibliographies of relevant articles.

We identified a parameter called the “nerve/tunnel index” that compares the CSA of the nerve and the carpal tunnel.

We performed a new Pubmed and Google Scholar search for this parameter.

Results

The search resulted in 10 articles. We excluded those who didn’t focused on these parameters. We used 3 articles, all of them in English and published since the year 2012.

Conclusion

Although studies using proximal and distal nerve/tunnel indexes are scarce, they could be useful sonographic parameters for diagnosing carpal tunnel syndrome and they are not influenced by either sex or body indices. However, we should however consider that:
1) A limited number of studies use these parameters
2) Nerve/tunnel indexes have a limited value in patients with flexor tenosynovitis or benign tumors
3) There are technical difficulties measuring the carpal tunnel CSA
4) No relationship was found between the proximal and distal nerve/tunnel indexes and the severity and electrodiagnostic results.

Further studies are needed to assess the true value of these parameters.

ARE PSYCHOLOGICAL FACTORS ASSOCIATED WITH THE 4 COMPONENTS OF THE CONSTANT-MURLEY SCORE?
G.A. Pires Rodrigues\textsuperscript{1}, P. Vuistiner\textsuperscript{2}, M. Konzelmann\textsuperscript{1}, B. Léger\textsuperscript{2}, C. Burrus\textsuperscript{1}, F. Luthi\textsuperscript{1}
\textsuperscript{1}Clinique Romande de Réadaptation Suva Care, Réadaptation de l'appareil locomoteur, Sion, Switzerland
\textsuperscript{2}Clinique Romande de Réadaptation Suva Care, Recherche, Sion, Switzerland

Introduction/Background
The Constant-Murley score (CMS), one of the most popular clinician-rated measurement tool for shoulder patients, has 4 components: 2 subjective (pain and activity) and 2 observational (mobility / strength). Some studies suggest that patient-related psychological factors may also influence the scoring. The purpose of this study was to measure which components may be related with psychological factors.

Material and Method
Inclusion criteria were patients with chronic shoulder pain (> 3 months) treated in rehabilitation from 01.05.2012 to 30.08.2017. Exclusion criteria were other upper limb injuries, upper limb neuropathies, and inability to complete the questionnaires. At entry, the CMS was performed by trained physiotherapists, and the following questionnaires were completed by patients: Brief Pain Inventory (BPI), Hospital Anxiety and Depression (HADs), Pain Catastrophizing Scale (PCS), Tampa Scale of Kinesiophobia (TSK), and Disability of Arm-Shoulder-Hand (DASH). Correlations between the 4 components of CMS and the questionnaires were measured with the Pearson coefficient (weak correlation: 0.20-0.40, moderate: 0.41-0.60, strong: ≥0.61).

Results
735 patients were included (mean age (sd): 47 (11) years ; men: 85%; rotator cuff lesions: 72%). Median duration of symptoms was 14 months (IQR 9-22). The pain component of the CMS was correlated with disability (DASH: -0.43) and pain (BPI: -0.56), but also with psychological factors: anxiety, depression (HADs: -0.28 and -0.32, respectively), catastrophizing (PCS: -0.45), and kinesiohobia (TSK: -0.25). The activity component was correlated with disability (-0.42) and pain (-0.29). Mobility and strength were only correlated with DASH (-0.40 and -0.33, respectively).

Conclusion
A clinician-rated measurement tool should be independent of patient-related psychological factors, which may limit its validity. This study suggests that the pain component of the CMS should be measured separately to the others in order to reduce the risk of measurement bias.

Introduction/Background

Bilateral posterior fracture-dislocation of the shoulder is a very rare injury accounting for less than 2% of all shoulder dislocations and can be caused by epileptic seizures, trauma, electrocution or electroconvulsive therapy.

Material and Method

We report a case of bilateral posterior dislocation of the shoulders with right upper end of the humerus following epileptic seizures.

Results

A 46-year-old man was admitted to the department of neurology for disability of both upper limbs after an episode of generalized tonic-clonic seizure which had lasted for several minutes. Following seizure episode, he complained of inability to move his both upper limbs associated with intense pain. Clinical examination revealed severely restricted and painful with the slightest movement of the shoulders. Computing tomography of the shoulders confirmed fractures of the upper end of the humerus with posterior dislocation. He was treated with Neer modification of the McLaughlin Procedure.

Conclusion

Bilateral posterior fracture-dislocation of shoulders is a very rare complication of epileptic seizures. A late diagnosis makes complex surgery burdened with complications and risk of developing shoulder instability.

Keywords

Bilateral posterior fracture dislocation; shoulders; Generalized seizures

Intra-Articular Distension Without Arthrography for Adhesive Capsulitis

W. Ouannes¹, S. Layouni¹, R. Moncer¹, I. Feki¹, S. Elmtaouaa¹, E. Toulgui¹, F. Khachnaoui¹, S. Jemni³
¹University Hospital Sahloul- Sousse Tunisia, Physical Medicine and Rehabilitation Department, Sousse, Tunisia

Introduction/Background

Adhesive capsulitis is a clinical entity characterized by spontaneous onset of shoulder pain accompanied a loss of motion and a decrease of the joint volume capacity. The distension of the shoulder joint has proven to be an efficient percutaneous treatment, and various techniques have been proposed. The objective of the study is to determine the effectiveness and safety of the technique “repeated intra articular distension without arthrography” combined with an intensive program of rehabilitation in patients with adhesive capsulitis.

Material and Method

A prospective controlled study. Fifteen patients with adhesive capsulitis were included. Intervention consisted of three intra articular distension with saline, xylocaine and corticosteroid, given at one week intervals. The same technique was combined with an intensive program of rehabilitation associated. The evaluation parameters used were Hospital Anxiety and Depression Scale (HADS), visual analog scale (VAS) pain score, a shoulder-specific disability measure by DASH score and range of active and passive motion (anterior elevation, lateral elevation and external rotation). Patients were evaluated before intra articular distension. The outcome measures were assessed at 1, 2, 3, and 4 weeks after last capsular distension.

Results

Study population comprised fifteen patients with a mean age of 54.8±8.6 underwent capsular distension. All patients reported significant improvement during the study in terms of the pain score, anterior elevation and lateral elevation after the first distension. External rotation, the DASH score and HADS improved after three capsular distension. One month after last capsular distension, this gain persisted in all functional parameters and in psychological profile. Results did not differ by etiology of capsulitis. No severe complications occurred as a result of the capsular distension.

Conclusion
Our results show that three capsular distension and intensive program of physiotherapy have a beneficial effect. This combination has a useful role in the early management of adhesive capsulitis.

EFFECTIVENESS OF GROUP SHOULDER THERAPY: OUR EXPERIENCE
M. Entrenas Valle, A. Rodríguez González, M.L. León Sánchez, C. Montoliu Peco, L. Cuevas Moreno, E. Medina Cano, M. Muñoz Serrano
1Ciudad Real University Hospital, Physical Medicine and Rehabilitation, Ciudad Real, Spain

Introduction/Background

Painful shoulder is one of the most common diseases in the Rehabilitation doctor’s appointmets, being the third in frequency in musculoskeletal pathology. According to the bibliography its incidence is 0.9-2.5%. This means 1.2% and 12% of medical and Rehabilitation consultations, respectively. Approximately 50% of patients continue with pain at 18 months after starting symptomatology. There is scant evidence of the efficacy using conventional treatments. A program of therapeutic exercises is the only treatment with scientific evidence in short and long term, both for the improvement of pain and functional limitation.

Material and Method

Descriptive observational study before-after. Rotator cuff diseases as well as subacromial syndrome were included. A program of 1 hour per week for 8 weeks of controlled exercises was carried out. To this, it was added 1 hour of occupational therapy with anatomical teaching, ergonomic measures and adaptations.

Results

Our sample includes 140 patients. The primordial sex is feminine with a frequency of 71%. The most frequent profession is housewife (36%), followed by retirees (12%) and administrative staff (11%). There was a significant improvement in the value of the Constant scale (t = -8.658, p <0.001) between before (=50.02) and after (=60.61) means of the shoulder group therapy. This improvement was maintained 6 months after implementing exercises (t = -3.569, p <0.001). Regarding the EVA, there was also a significant betterment (Z = -5.663, p <0.001) comparing pre and post treatment values and this result was maintained at 6 months (Z = 3.256, p <0.001).

Conclusion

Group shoulder therapy improves the painful symptomatology as well as the function in the tendinopathies of the rotator cuff and the subacromial syndrome. This improvement is maintained in long term. Population education improves the adherence to the treatment.

THE ANALYSIS OF EPIDEMIOLOGIC CHARACTERISTICS AND IMAGING FEATURES OF SHOULDER PAIN BASED ON MUSCULOSKELETAL ULTRASOUND IMAGING

L. jiang¹, J. He², Z. Wang³, D. Xie³
¹The Third Affiliated Hospital- Sun Yat-sen University, Department of Rehabilitation Medicine, Guangzhou, China
²The 3rd Affiliated Hospital of Sun Yet-sen University, Department of Rehabilitation, Guangzhou, China
³The 3rd Affiliated Hospital of Sun Yet-sen University, Department of Rehabilitation, Guangzhou, China

Introduction/Background

To investigate the epidemiologic characteristics and imaging features of shoulder pain in rehabilitation clinic based on musculoskeletal ultrasound imaging.

Material and Method

From June 1, 2016 to November 30, 2017, all consecutively enrolled outpatients with shoulder pain underwent ultrasound imaging of the affected shoulder, and their clinical information were collected for Cross-sectional Analysis.

Results

266 patients were included. Among them, 26.7% were young patients (younger than 45 years old), 41.3% were middle aged patients (45 years old to 59 years old) and 32.0% were old patients (older than 59 years old). The incidence of supraspinatus tendinopathy and subacromial bursitis were 55.9% and 55.2% respectively, followed by acromioclavicular joint degeneration and tendinitis of the long head of biceps. The incidence of subacromial bursitis in the old patient group was the highest, followed by the middle aged patient group (the middle aged patient group vs the old patient group: 57.5% vs 73.5%, P<0.0167) and the young patient group (the young patient group vs the middle aged patient group: 29.7% vs 57.5%, P<0.0167), respectively. Compared with the young patient group, the incidence of acromioclavicular joint degeneration were higher in the middle aged patient group and old patient group (the middle aged patient group vs the young patient group: 41.7% vs 8.1%, P<0.0167; the old patient group vs the young patient group: 53.1% vs 8.1%, P<0.0167).

Conclusion

Musculoskeletal ultrasonic imaging is helpful for diagnosis of shoulder pain, and making individual diagnosis and treatment plan based on the characteristics of musculoskeletal ultrasonic imaging deserves to be popularized in clinical application.

EFFECTIVENESS OF MYOFASCIAL RELEASE TECHNIQUES IN THE TREATMENT OF MYOFASCIAL TRIGGER POINTS ASSOCIATED WITH CHRONIC NECK PAIN
A. Haj Salah¹, M. Sghir¹, W. Mheni², M. Maraoui¹, W. Lahmar¹, S. Mahjoub², W. Kessomtini¹
¹University Hospital Tahar Sfar, Department of Rehabilitation, Mahdia, Tunisia
²School of Physiotherapy, Physiotherapist, Monastir, Tunisia

Introduction/Background

Myofascial pain syndrome associated with active myofascial trigger points (MTrP) is a common diagnosis in patients presenting with symptoms of chronic neck pain. Standard rehabilitation methods are necessary but insufficient mainly for recurrence. The objective of our study was to evaluate the effectiveness of treatment of MTrP in chronic neck pain.

Material and Method

We recruited 20 patients with chronic neck pain randomly divided into 2 groups A (10 patients) and B (10 patients). Patients in group A benefited from a first protocol associating myofascial release (MFR) techniques to a conventional rehabilitation program. Patients in group B benefited from a conventional rehabilitation program alone. Management was spread over a period of 3 months. The evaluation parameters were pain intensity (VAS) and irradiation, cervical spinal mobility, muscle strength, muscle tension assessed by the Nilson scale, and function (NDI and Bournemouth questionnaire).

Results

We found a significant decrease in neck pain intensity and radiation that was greater in group A. We also noted an improvement in all areas of cervical mobility, muscle strength and tension in the group A. This resulted in a functional improvement, attested by the NDI and Bournemouth questionnaires.

Conclusion

Myofascial release involves the application of a low load, long duration stretch to the myofascial complex, intended to restore optimal length, decrease pain, and improve function. It may be effective in the treatment of patients with active myofascial trigger points.

ELECTROACUPUNCTURE IN THE TREATMENT OF PAINFUL HEMIPLEGIC SHOULDER – CASE REPORT
S. Barbosa¹
¹Centro Hospitalar Lisboa Central, Physical Rehabilitation Medicine, Lisboa, Portugal

Introduction/Background

Painful hemiplegic shoulder is a frequent complication (prevalence of 47-72%), causing functional disability and suffering in patients with stroke. It has several causes, namely adhesive capsulitis, soft tissue injury, myofascial pain syndrome, subluxation and spasticity, among others. Spasticity leads to pain, by limiting joint range of motion and leading to incorrect joint positioning. To optimize pain management, a rehabilitation program including prevention, physical therapy, occupational therapy, treatment of spasticity and analgesia, whether pharmacological or other techniques, such as electroacupuncture, should be undertaken. The aim of this study was to evaluate the effect of electroacupuncture on pain in a case of spastic hemiparesis.

Material and Method

55-year-old female, with left thalamic-capsular haemorrhagic stroke, spastic right hemiparesis with brachial predominance; pain in the shoulder, elbow, wrist and right hand, interfering with sleep quality and physiotherapy treatments. The evaluation protocol included anamnesis and examination, with pain, joint amplitudes and tonus evaluation in the affected upper limb, using the numerical rating scale of pain (NRS), goniometry and Ashworth modified scale. An electroacupuncture protocol was developed and performed, and a new evaluation was performed after finishing treatments.

Results

After 2 sessions of electroacupuncture a complete relief of shoulder and elbow pain at rest was verified (initial NRS 10 / final NRS 0). There was also improvement of sleep quality. Non-painful passive mobilization of the shoulder improved significantly, from 20° of flexion and abduction to 90° of flexion and 70° of abduction at the end of treatments, respectively, allowing a better participation in physiotherapy and daily life activities. There were no changes in muscular tonus.

Conclusion

Electroacupuncture seems to be a good therapeutic technique with considerable potential in the rehabilitation of painful hemiplegic shoulder, and its association with a rehabilitation program may be of value. More work need to be made with larger samples to prove the benefits of electroacupuncture.

THE EFFECT OF STRENGTHENING DEEP CERVICAL FLEXOR MUSCLES IN PATIENTS WITH CHRONIC NECK PAIN
M. Sghir1, W. Haj Hamad1, E. toumi1, A. haj salah1, S. ben haj khalifa1, W. kessomtini1
1university hospital Mahdia, Rehabilitation Departement, Mahdia, Tunisia

Introduction/Background
The chronic neck pain is one of the major public health problems, which has a great impact on people's lives.

The purpose of this study was to assess the effect of deep cervical flexor (DCF) muscles strengthening in patients with chronic neck pain.

Material and Method
We conducted a prospective, comparative 3-months study including 10 patients with chronic neck pain. Patients were divided into 2 groups. Patient in group A underwent a conventional rehabilitation program and those in group B underwent a conventional rehabilitation associated with a strengthening protocol of DCF muscles. Patients underwent three times a week 60-minute session for a period of 12 weeks. Assessments were performed before and after intervention. It had been about pain with the Visual Analog Scale (VAS), physical function and disability with Neck and Disability Index (NDI), endurance with cranio-cervical test and posture with the cranio-cervical angle.

Results
At the end of the protocol, patients in the group B had a greater significant decrease in cervical pain. The improvement in muscle strength and cranio-cervical angle was also more important in the group B. As a result, there was a functional improvement, attested by the NDI.

Conclusion
The strengthening of DCF muscles reduces pain, improves strength, posture and function in patients with chronic neck pain.

Introduction/Background

Cervicobrachial neuralgia (CBN) is frequent in out patient clinic as well in general medicine as in rheumatology. Even though cervical disc degeneration and osteophytosis constitute the most frequent etiology of such a trouble. Few data highlight their impact on the functional capacity and quality of life in personal staff. Our goal is to evaluate the functional and psychological impact and determine the associated factors.

Material and Method

This is a monocentric, cross-sectional study during 5 months (July-November 2017), conducted on 83 officials of the CHU Taher Sfar of Mahdia presenting cervicalgia. We determined for each the Visual Analog Scale of Pain Intensity (VASPI) and the Health Assessment Questionnaire (HAQ).

Results

The average age is 37 years old +/- 10.4 [23; 57]. Men represent 49% of the sample. Thirty-one of the patients were doctors, 56% were nurses, 6% were technicians and the rest were medical secretaries. The median duration of symptom progression is 4 months [1; 15]. The average VASPI is 3.8 ± 1.36 [0-8]. Sixty-two percent of the patients were not satisfied at work. Ninety-two percent of patients had university education. The majority (92.8%) had an average socio-economic level. Thirty-seven percent had CBN which was in descending order as follows: 23% of cases had C6 CBN and C7 CBN, 19% had CBN C5 and 10% had C8 CBN. The mean HAQ was 0.92 +/- 0.56 [0, 1.75]. The most important scores (most difficult tasks) were found for items 5 (holding) and 4 (hygiene) with means at 1.013 +/- 0.71 [0, 2] and 1.155 +/- 0.77 [0, 3] respectively. High HAQ was statistically related to a low level of study, assignment (surgical specialties).

Conclusion

Neck pain is strongly associated with personal staff that is why a preventive strategy is needed.

CERVICO-BRACHIAL NEURALGIA IN THE REHABILITATION DEPARTMENT
M. Sghir¹, W. Haj Hamad¹, A. haj salah¹, M. frigui¹, S. zrour², W. kessomtini¹
¹University hospital Mahdia, Rehabilitation Department, Mahdia, Tunisia
²Fattouma Bourguiba Hospital center, rhumatology, monastir, Tunisia

Introduction/Background

Cervico-Brachial Neuralgia (CBN) is a relatively common pathology in current practice. It has significant medical and socio-economic costs and a negative impact on patients’ quality of life. The objective of our study is to assess the epidemiological, clinical, radiologic and therapeutic aspects of common CBN in a rehabilitation department.

Material and Method

This is a prospective study including patients with CBN referred to the department of Physical Medicine and Rehabilitation of Mahdia (Tunisia) from January 2017 to June 2017.

The evaluation parameters were: pain with the Visual Analog Scale (VAS), physical function and disability with Neck and Disability Index (NDI) and the psychological profile with the Hospital Anxiety and Depression Scale (HAD).

Results

Sixty patients were enrolled in this study; 8 men (13.3%) and 52 women (86.7%). The mean age was 47.7±13 years old and the mean duration of the symptomatology was 3.5±2 years.

In most of the cases, CBN was unilateral (56.7%) and C6 root was concerned (30%). On physical examination, we found limited and painful spinal motion mobility in 50% of the cases associated with contracture of the neck muscles in 83.3%

The mean VAS pain was 6.2 cm. The functional and psychological repercussions of the CBN were important. Indeed the mean NDI score was 25.6±8 reflecting severe incapacity and 35 patients (58.3%) had HAD depression or anxiety scale greater than 11.

The radiographs of the cervical spine showed osteoarthritis, pinching discs or osteophytes in 88.3% of the cases.

Therapeutic management included medical treatment based on analgesics, muscle relaxants and non-steroidal anti-inflammatory drugs in 93.3%, associated with a well-adapted functional rehabilitation program in all patients.
Conclusion

CBN has a significant functional and psychological impact, requiring a multidisciplinary care. Physical treatment is an integral part of its management allowing patients to manage their lives better.

THE MANAGEMENT OF LATERAL EPICONDYLITIS IN A REHABILITATION DEPARTMENT
A. Abdallah¹, M. Sghir¹, B.E. Garrach¹, A. Hadj Salah¹, S. Zrou², W. Kessomtini¹
¹CHU Tahar Sfar, Médecine Physique et Réadaptation Fonctionnelle, Mahdia, Tunisia
²CHU Fattouma Bourguiba, Rhumatologie, Monastir, Tunisia

Introduction/Background

Lateral epicondylitis is a common source of elbow pain. It typically affects the dominant upper extremity and is associated with repetitive and forceful activity. Conservative treatment is effective in the majority of patients with lateral epicondylitis. However, the course leading to recovery can be prolonged (6-12 months). The aim of our study is to evaluate the epidemiological, clinical and therapeutic profile of patients followed in the Physical Medicine and Rehabilitation department, for lateral epicondylitis.

Material and Method

This was a retrospective study during 5 years (2012-2017) about patients referred to our Physical Medicine and Rehabilitation department for lateral epicondylitis. The sociodemographic characteristics, clinical profile and therapeutic modalities were assessed for each patient.

Results

Fifty patients were included with a female predominance (72%). The mean age was 44.82 years. Half of our patients were active and the majority (60%) performed office-type work. The right upper limb was the most affected in 78% of the cases. Symptom duration was 14.66 months. The mean visual analogic scale (VAS) was 5.5. Epicondylitis was clinically diagnosed in all the patients. The X-Ray exam was realized for 8 patients and ultrasound exam for 6 patients. No MRI exam was realized. All the patients received analgesic treatment, 84% non-steroidal anti-inflammatory drugs (NSAIDs) and only 8 patients received corticosteroid injection. Physical therapy sessions were prescribed for all the patients. Total improvement was noticed in 42% of the cases, 46% reported a transient improvement and 12% evolved towards chronicity.

Conclusion

Lateral epicondylitis is a frequent complaint among musculoskeletal disorders affecting the upper extremities. Its management in Physical Medicine is based on medical treatment and functional rehabilitation used alone or in combinations. But no single option seems to be clearly superior.

⁵CHU Nîmes, Service de Médecine Physique et de Réadaptation, Nîmes, France

Introduction/Background

Musculoskeletal disorders (MSDs) constitute a major occupational health problem in the working population. MSDs manifest as localized pain or functional difficulty in one or more anatomical areas, such as the cervical spine, shoulder, elbow, hand, and wrist. Although physical exercise is widely recommended, few studies with a good level of evidence have enabled us to base a complete, well-constructed intervention on exercise that can be offered as secondary prevention in these disorders.

Material and Method

A prospective, multicenter, comparative, randomized study using Zelen’s design. This study falls under active prevention of MSDs of the upper extremities. Participants are workers aged between 18 and 65 years, with any type of job or workstation, with or without a history of sick leave. The primary aim is to show the superiority at 3 months of a combination of spa therapy, exercise, and self-management workshops for 6 days over self-management workshops in terms of employee functional capacity in personal and professional daily life (QUICK DASH scale).

Results

We included 148 patients, 73 assigned to the intervention group and 75 to the control group. At 3 months, the total score of functional disability assessed by QUICK DASH decreased in both groups. This reduction was higher in the intervention group (-10.04±15.83) versus control group (-5.57±13.45). We noticed a non-significant decrease for QUICK DASH total score (p=0.10). However, the field specifically assessing disabilities in physical activities; QUICK DASH sport; had significantly decreased in the intervention group (-14.58±21.49) versus control group (-6.72±19.04) (p=0.02).

Conclusion
The originality of this intervention lies, in its short, intensive format, which is compatible with remaining in work; and in its multidisciplinary approach. This trial demonstrates the benefits of a short course of spa therapy combined with a personalized self-management program on the functional capacity in their daily life.

THE IMPORTANCE OF NIGHT PAIN FOR THE EFFECTIVENESS OF THEURAPOTIC ULTRASOUND IN THE SUBACROMIAL IMPINGEMENT SYNDROME: A RANDOMIZED CONTROLLED TRIAL

S. Suzen Ozbayrak1, K. Akgun2

1Haydarpasa Numune Training and Research Hospital, Physical Medicine and Rehabilitation Clinic, Istanbul, Turkey
2Cerrahpasa Medical School, Physical Medicine and Rehabilitation, Istanbul, Turkey

Introduction/Background

The aim of this study is to assess the importance of night pain for the effectiveness of theurapotic ultrasound in treating Subacromial Impingement Syndrome (SIS).

Material and Method

In this double-blind, placebo- controlled study, patients with SIS accompanying with night pain were evaluated. A total of 57 patients were included in this study. The cases were divided as A and B groups randomly. Group A, received standart conservative treatment and additional ultrasound or placebo ultrasound randomly while having night pain. On the other hand, group B, received cold application and same standart conservative treatment. When the night pain subsided, ultrasound or placebo ultrasound were given randomly. The cases were evaluated with visual analouge scale, shoulder disability index and Constant Murley functional assesment scale during follow ups.

Results

In group A, statistically meaningful improvement in resting, movement and night pain, disability and functionality were detected. However there were no statistically important difference between cases receiving ultrasound or placebo ultrasound. There were statistically important improvement in resting and movement pain, disability and fuctionality of group B cases. But with ceasing the cold application and starting either of ultrasound or placebo ultrasound, some increase in night pain was seen. There were no statistically important difference between ultrasound and placebo ultrasound.

Conclusion

As a result, standart conservative treatment in the management of SIS is very effective. We noticed that, adding ultrasond or placebo ultrasound to this standart conservative treatment in SIS patients with or without night pain make no additional benefit. Addition of cold therapy to standart conservative treatment is very effective. It is seen that starting ultrasound treatment immediately after night pain is not appropriate and waiting a while after night pain subsides is
more convenient. When considering the potential effect on tendon healing, ultrasound treatment may be given later for shoulder rehabilitation in stretching and strengthening phase.

A NEW IPHONE APPLICATION FOR THE MEASUREMENT OF ACTIVE CRANIUCERVICAL RANGE OF MOTION IN PATIENTS WITH NON-SPECIFIC NECK PAIN: A RELIABILITY AND VALIDITY STUDY

M.R. Pourahmadi¹, R. Bagheri², M. Taghipour³, I. Ebrahimi Takamjani¹

¹Iran University of Medical Sciences, Department of Physiotherapy, Tehran, Iran
²Semnan University of Medical Sciences, Neuromuscular Rehabilitation Research Center- Department of Physiotherapy, Semnan, Iran
³University of Social Welfare and Rehabilitation Sciences, Department of Physiotherapy, Tehran, Iran

Introduction/Background

Measurement of cervical spine range of motion (ROM) is often considered to be an essential component of cervical spine physiotherapy assessment. This study aimed to investigate the reliability and validity of an iPhone application (app) (Goniometer Pro) for measuring active craniocervical ROM (ACCROM) in patients with nonspecific neck pain.

Material and Method

A cross-sectional study was conducted at the musculoskeletal biomechanics laboratory located at Iran University of Medical Sciences. Forty non-specific neck pain patients participated in this study. The outcome measure was the ACCROM, including flexion, extension, lateral flexion, and rotation. Following the recruitment process, ACCROM was measured using a universal goniometer (UG) and iPhone 7 app. Two blinded examiners each used the UG and iPhone to measure ACCROM in the following sequences: flexion, extension, lateral flexion, and rotation. The second (2 hours later) and third (48 hours later) sessions were carried out in the same manner as the first session. Intraclass correlation coefficient (ICC) models were used to determine the intra-rater and inter-rater reliability. The Pearson correlation coefficients were used to establish concurrent validity of the iPhone app. Minimum detectable change at the 95% confidence level (MDC95) was also computed.

Results

Good intra-rater and inter-rater reliability was demonstrated for the goniometer with ICC values of ≥0.66 and ≥0.70 and the iPhone app with ICC values of ≥0.62 and ≥0.65, respectively. The MDC95 ranged from 2.21° to 12.50° for the intra-rater analysis and from 3.40° to 12.61° for the inter-rater analysis. The concurrent validity between the two instruments was high, with $r$ values of ≥0.63. The magnitude of the differences between the UG and iPhone app values (effect sizes) was small, with Cohen $d$ values of ≤0.17.

Conclusion
The iPhone app possesses good reliability and high validity. It seems that this app can be used for measuring ACCROM.

Carpal tunnel syndrome (CTS), the most common entrapment neuropathy, is a combination of signs and symptoms due to compression of the median nerve at the wrist. The electroneuromyography (ENMG) is the gold standard for confirming diagnosis and assessing the severity. Ultrasound (US) is a less invasive method but not yet a truly alternative. Many authors use the median nerve cross-sectional area (CSA) for diagnosis, or calculating the flattening ratio. Other parameters have been studied, but not used for diagnosis or follow-up.

The goal of this article was to observe clinical, electromyographic and particularly sonographic changes in patients treated with corticosteroids infiltrations.

**Material and Method**

We analyzed pre-infiltration parameters - signs and symptoms, Boston Scales, ENMG and sonographic variables: the median nerve CSA and carpal tunnel CSA at 2 different points of the wrist, the median nerve CSA at the forearm, the flattening ratio, the retinacular bowing, the flexor retinaculum thickness, the Nerve/Tunnel indexes, and anatomic variations - and compared them with 3-week and 6-week follow-up after corticosteroids infiltration.

**Results**

We interviewed 48 patients in our clinical practice but only 22 wanted to participate and matched our criteria - 10 were included for infiltration and 12 for surgical evaluation. We currently have finished 6. Our results will be displayed with a series of graphics, showing:

- Clinical improvement after treatment
- Minimum improvement of ENMG variables
- Decrease of US variables, not only the median nerve CSA: the retinacular bowing, the flexor retinaculum thickness and the Nerve/Tunnel indexes
- Unchanged sonographic variables: median nerve CSA at the forearm
Conclusion

- There is a clear improvement of symptomatology and functional parameters with corticosteroids infiltrations, even in severe CTS cases

- As the nerve CSA, many other US parameters may be useful for follow-up patients with CTS

Myofascial pain syndrome (MPS) is a regional painful soft tissue disorder, characterized by trigger points and taut bands in the muscles. An effective pain relief treatment can stop the vicious cycle of pain and spasm, and also avoid chronicity and disability in acute MPS. In this study we aimed to compare the effectiveness of kinesiotaping, trigger point injection, and neural therapy on pain and disability in acute MPS.

**Material and Method**

This is a prospective randomized controlled study. Sixty-five patients (54 female/11 male, the mean age 45.6 ± 16.1 years) admitted to four physical medicine and rehabilitation outpatient clinics diagnosed as acute MPS were included in the study. Patients were allocated into three groups. Group 1 (n =22, 18 female) were treated with kinesiotaping, group 2 (n =23, 19 female) received local trigger point injection with lidocain of %0.5, group 3 (n =20, 17 female) received neural therapy (lidocain of %0.5). Patients were assessed by means of pain, number of trigger points (NTP), pressure pain threshold and neck disability. Pain severity was measured by visual analog scale (VAS, 0-10 cm). The neck pain disability index (NPDI) was used for assessing neck disability. Pressure pain threshold was measured by using an algometer. Measurements were taken before and after treatment 3 and 7 days. Side effects were recorded. This study includes descriptive statistics since it contains preliminary data.

**Results**

All groups were similar with respect to age, sex and disease duration. There were improvements on pain, NTP, pressure pain threshold, and disability in all groups at the end of treatments at 3 and 7 days. No side effects were observed in all groups.
Conclusion

The preliminary results of this study show that all these three treatment methods seem to be effective on pain relief, NTP, pressure pain threshold, and disability in acute MPS.

ULTRASOUND GUIDED SUPRA SCAPULAR NERVE BLOCK IN POST STROKE SHOULDER PAIN
N. Purohit1, A. srivastava2
1kokilaben dhirubhai ambani hospital and research institute, department of pain medicine and palliative care, Mumbai, India
2kokilaben dhirubhai ambani hospital and research institute, centre for rehabilitation., Mumbai, India

Introduction/Background

Shoulder pain is a distressing complication of hemiplegia and is reported as one of the most common medical complications of stroke. The prevalence of shoulder pain following stroke has varied range from 34% to 84%. Hemiplegic shoulder pain is associated with reduction in functional use of the arm, interference with rehabilitation and limitation to patient access to developing technological upper-extremity rehabilitation techniques.

Material and Method

Patients with Clinical and Radiological diagnosis of stroke were included with pain with a Numeric Rating Score (NRS) of more than or equal to 4/10. Patients with any fracture in and around shoulder, allergy to injectable agents (Depo Medrol, lignocaine and Bupivacaine) were not included in the study.

All patients were given ultrasound guided suprascapular nerve block with a mixture of 2 ml of 2% lignocaine, 2 ml of 0.25% bupivacaine and 2 ml of methylprednisolone acetate. The ranges of motion, pain on NRS were primary outcome measures and quality of life on SF8 was secondary outcome measure.

Results

30 patients with Post Stroke Shoulder Pain were recruited in the study. Ischemic type (65%) of stroke was commoner than hemorrhagic (35%). Male: Female ratio was 1.8:1. Post stroke duration ranged from 2 months to 24 months (mean- 9.6 months), motor recovery on Brainstorms staging was stage I(10), II(6), III(4), IV(5) and V(5). 19/30(65%) had shoulder subluxation. On an average, NRS reduced to 1/10 immediately; 2/10 at 4 weeks and remained 3/10 after 6 months of procedure. Improvement in Range of Motion was significant; 90% at 4 weeks and 85% at 6 months after the procedure. Similarly, significant improvement was seen in quality of life.

Conclusion
Suprascapular nerve block has a potential role in Post stroke shoulder pain and needs a proper randomized control trial for establishing its efficacy.

THE INFLUENCE OF FOOT ORTHOSES ON FOOT MOBILITY MAGNITUDE AND ARCH HEIGHT INDEX IN ADULTS WITH FLEXIBLE FLAT FEET

R. sheykhi¹, H. saeedi¹

¹Iran University of Medical Sciences, orthoses and prostheses, Tehran, Iran

Introduction/Background

Flexible flat foot is described as a reduction in the height of the medial longitudinal arch and may occur from Abnormal foot pronation. A foot orthosis is thought to modify and control excessive pronation and improve arch height. the aim of this study is compare the immediate effect of three types of orthoses on foot mobility and the arch height index in subjects with flexible flat feet.

Material and Method

The dorsal arch height, midfoot width, foot mobility and arch height index were assessed in 20 participants with flexible flat feet (mean age = 23.2 ± 3 years) for three different foot orthosis conditions: soft, semi-rigid and rigid University of California Biomechanics Laboratory (UCBL).

Results

Maximum midfoot width at 90% with arch mobility in the coronal plane was shown in the semi-rigid orthosis condition. The semi-rigid orthosis resulted in the highest mean foot mobility in 90% of weight bearing, and the rigid orthosis (UCBL) had the lowest mean foot mobility. The soft orthosis resulted in foot mobility between that of the rigid and the semi-rigid orthosis. UCBL orthosis showed the highest arch height index, and the semi-rigid orthosis showed the lowest mean arch height index.

Conclusion

Due to its rigid structure and long medial–lateral walls, the UCBL orthosis appears to limit foot mobility. Therefore, it is necessary to make an orthosis that facilitates foot mobility in the normal range of the foot arch. Future studies should address the dynamic mobility of the foot with using various types of foot orthoses.

AUTOLOGOUS BLOOD-DERIVED PRODUCTS COMPARED TO CORTICOSTEROIDS FOR TREATMENT OF PLANTAR FASCIOPATHY: A SYSTEMATIC REVIEW AND META-ANALYSIS

Y. Chen¹
¹Chang Gung Memorial Hospital, Physical Medicine and Rehabilitation, Taoyuan city, Taiwan R.O.C.

Introduction/Background

This review article evaluated the efficacy of autologous blood-derived products (ABPs), including autologous blood (AB) and platelet-rich plasma (PRP), in reducing pain and improving function compared with corticosteroids (CS) for plantar fasciopathy (PF) patients.

Material and Method

Literature comparing ABP and CS to treat PF up to August 2017 was systematically reviewed. The visual analogue scale score or American Orthopaedic Foot and Ankle Society (AOFAS) hindfoot score was evaluated at 1.5, 3, and 6 months’ follow-up. A subgroup analysis concerning PRP preparation techniques and study designs was performed. Twelve randomized controlled trials (RCTs) and three quasi-experimental studies with 680 patients were included.

Results

CS reduced pain more than AB within 1.5 months and 3 months, but the effect disappeared at 6 months. PRP reduced pain more effectively at 6 months post-injection than CS. However, there was no significant difference in AOFAS scores between PRP and CS injections at all time points. In the subgroup analysis, pain was significantly reduced due to self-prepared PRP, one-step separation, and RCT-designed studies at 6 months.

Conclusion

The results of this meta-analysis will provide evidence-based information for making treatment decisions for patients with PF.

COMPARISONS OF BRACING AND PATELLA TAPING ON KNEE THREE-DIMENSIONAL KINEMATICS OF WOMEN WITH PATELLOFEMORAL PAIN SYNDROME IN STANCE PHASE OF RUNNING
M. Taghipourdarzinaghibi¹, S. Hosseinzadeh¹, M. Eslami²
¹Babol University of Medical Sciences, Mobility Impairment Research Center, Babol, Iran
²University of Mazandaran, Department of Physical Education and Sport Sciences, Babolsar, Iran

Introduction/Background

Patellofemoral pain syndrome is one of the most common knee injuries that accounted for between 25-40% of all knee problems presenting to sports medicine centers. Two treatment methods of bracing and taping are recommended in these patients that their effectiveness is unclear. The aim of this study was to evaluate the efficacy of the two treatment methods on knee three-dimensional kinematics in patients with PFPS during stance phase of running.

Material and Method

Fourteen patients with PFPS in range of 20-40 ages were participated in this study. Three-dimensional angles at the knee during stance phase of running were recorded by motion analysis cameras (Fig.1) in three conditions, namely; without intervention, bracing (Fig.2) and taping (Fig.3) conditions.

Results

Results of this study showed that knee valgus angle in PFPS patients was decreased significantly with brace when compared to without intervention during running. Patella taping did not show significant differences on knee joint kinematics as compared to other conditions (p>0.5).

Conclusion

Using patellofemoral brace during running can cause change more than patella taping in knee kinematics. Our finding shows that reduction of knee abduction angle by using brace could decrease perceived pain in women with PFPS during stance phase of running.

Anterior knee pain (AKP) is the most common overuse injury experienced by runners and is prevalent among females, adolescents and young adults. Several modifiable intrinsic risk factors have been suggested to contribute to AKP. The objective was to determine the prevalence and modifiable intrinsic risk factors for AKP among runners in poor resourced peri-urban communities in Ekurhuleni, South Africa.

Material and Method

A cross-sectional study design was used. Population comprised of 347 runners from six developing running clubs. Convenient sampling method was used, and 183 participants were sampled using a Raosoft statistical tool. Participants were aged between 13 and 55-year-old with no history of degenerative and traumatic injuries. Standardized questionnaire was used to determine AKP prevalence and 12 physical tests were used to screen for modifiable intrinsic risk factors. Ethical clearance, permission from club managers and consent from participants were obtained. Data were collected over four months and SPSS was used to obtain descriptive (frequencies) and inferential (logistic regression) statistics.

Results

Anterior knee pain accounted for 40%. Males (57.9%) and youth (57.9%) with 3-5 years of running experience (31.1%) dominated. The AKP was significantly associated with age ($\chi^2=6.484$, $p=0.039$) and running experience ($\chi^2=8.389$, $p=0.036$). The following modifiable intrinsic risk factors were found to have contributed significantly to AKP: tight hamstrings ($p=0.051$, OR=1.021); tight iliotibial band ($p=0.046$, OR=1.122); weak quadriceps ($p=0.040$, OR=0.154), weak hip control muscle ($p=0.004$, OR=1.131) and patellar tilt abnormalities ($p=0.015$, OR=1.332).

Conclusion

Anterior knee pain is prevalent and modifiable intrinsic risk factors exist amongst runners. Routine approach to AKP should include consideration of modifiable risk factors. A transdisciplinary approach should be considered to compensate for the lack of resources in low socioeconomic communities.

ISPR8-0435
THE IMPACT OF ANTERIOR KNEE PAIN ON THE QUALITY OF LIFE AMONG RUNNERS IN POOR RESOURCED PERI-URBAN COMMUNITIES
S. Kunene¹
¹University of the Witwatersrand, Physiotherapy, Johannesburg, South Africa

Introduction/Background

Anterior knee pain (AKP) is the most common injury among runners and has a negative impact on the quality of life (QOL) of many athletes. The objective was to determine the impact of anterior knee pain on the QOL among runners in poor resourced peri-urban communities in Ekurhuleni, South Africa.

Material and Method

A cross-sectional study design was used. A population of 73 runners with AKP were all included to participate in this study. Participants included runners aged 13 to 55 year-old with no history of degenerative and traumatic knee injuries. The standardised SF-36 questionnaire was used to collect data. Ethical clearance, permission from club managers and consent from participants were obtained. Data were collected over six weeks and analysed using SPSS. Descriptive statistics included the calculation of frequencies, means, standard deviations and ranges. Inferential statistics included Spearman's rank correlation coefficient calculation.

Results

The lowest QOL scores were found among the following SF-36 scales: role functioning/physical (62), role functioning/emotional (59), energy/fatigue (59), emotional well-being (68) and pain scales (63). Males, youth and runners with least experience in running presented with the lowest scores. Significant correlation was found between the following variables: role functioning/physical and experience (p = .030, r = -.221), role functioning/emotional and gender (p = .017, r = -.247) and race (p = .012, r = -.265), general health and experience (p = .021; r = -.239), energy/fatigue and race (p = .012; r = -.264), emotional well-being and age (p = .020; r = .241), general health and gender (p = .013; r = .456), social functioning and age (p = .010; r = .271) and energy/fatigue and experience (p = .001; r = -.371).

Conclusion

Multidimensional rehabilitation programme is recommended to improve the QOL among runners with AKP. This study will provide valuable knowledge that will assist clinicians in their development of rehabilitation programmes for AKP.

Pyriformis Syndrome (PS) is an uncommon cause of sciatica, resulting from compression of the sciatic nerve by the Piriformis muscle.
This work highlights the importance of PMR in the treatment of it and the diversity of therapeutic modalities that are available to this specialty.

**Material and Method**

Three clinical cases of patients with Piriformis Syndrome and three different approaches will be explained.

**Results**

Case 1: A 39-year-old woman with chronic right gluteal pain which worsened in the sitting position or with prolonged periods of orthostatism that performed multiple sessions of physiotherapy without symptomatic relief. After an evaluation by the PMR and performance of EMG compatible with PS, she performed 5 sessions of electroacupuncture with symptomatic relief after 3 weeks.

Case 2: A 60-year-old woman followed in PMR after left TKA, started a sciatic pain with irradiation to the right lower limb with about 1 month of evolution, which worsened in the sitting position and experienced relief with left lateral decubitus. Her physical examination was compatible with PS. An infiltration of 100U of botulinum toxin was performed in 2 motor points of the piriformis with symptomatic relief about 7 days after.

Case 3: A 62-year-old woman with sciatic pain that worsened in the sitting position with several years of evolution. It was revealed a possible right PS on EMG. Ultrasound-guided corticosteroid infiltration of the piriformis was performed and 3 months later she referred 50% pain relief.

**Conclusion**

PS can be approached in many ways from the more conservative treatments, such as physiotherapy, to the surgery. However, between these two extremes, minimally invasive
approaches such as electroacupuncture, corticoanesthetic infiltration and botulinum toxin application begin to emerge with good outcomes. More studies are needed to determine which treatments is the most effective.

Keywords

Rotational impairment of the knee and hip muscles weakness has been proposed as one of the risk factors of PFPS. The effects of correction of these impairments have not been studied up to now. The aim of this study was to compare the effects of conventional physiotherapy and exercise therapy based on Sahrmann approach in patients with PFPS.

**Material and Method**

In this RCT, 30 patients with PFPS (aged 20-50) were participated. The participants were divided into two groups: traditional physiotherapy group and Sahrmann group. In both groups, interventions were applied for 6 weeks. Patients in traditional physiotherapy group only received TENS, hot packs, ultrasound, and knee exercise therapy. But in Sahrmann group, additionally, posterior X taping, hip muscle strengthening and functional training was used. Quality of life (KOOS questionnaires), pain (VAS) and position sense of the knee were measured.

**Results**

Pain severity, KOOS scale and position sense of the knee significantly improved in both groups. In traditional physiotherapy group, mean pain score was decreased of 7.23mm to 11.5mm, mean score of KOOS questionnaire from 95.93 to 73.26 and the average error of knee position of 57.1 to 2.28. In Sahrmann group, mean pain score was decreased from 59.93 mm to 40.2 mm, mean score of KOOS questionnaire from 95.73 to 71.4 and the average error of knee position of 6.18 to 2.99 degree.

**Conclusion**

Essentially, using of Sahrmann approach including “posterior X taping on thigh, strengthening of hip abductor, extensor and lateral rotators muscles”, compared to conventional physiotherapy, was not result in more effective improvement in patients with PFPS.

THE EFFECTIVENESS OF STEROID INJECTION IN TREATMENT OF PLANTAR FASCIITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF CONTROLLED-RANDOMIZED TRIALS
J. Lee¹, Y.H. Kim¹
¹Uijeongbu St. Mary’s Hospital- College of Medicine- The Catholic University of K, Rehabilitation medicine, Uijeongbu-si, Republic of Korea

Introduction/Background

Plantar fasciitis is very troublesome in clinical fields. Although steroid injection has been a widely used treatment option in musculoskeletal disorders, there have been arguments about the effectiveness in plantar fasciitis. This study is to determine the effectiveness of steroid injection in the treatment of plantar fasciitis.

Material and Method

Meta-Analysis was conducted using searching engines such as Google Scholar, PubMed, CINAHL, Embase and manual searching which were searched to December 2017. The following key search terms were used; plantar fasciopathy fasciitis in google scholar, "fasciitis, plantar"[Mesh] with two filter options “Randomized Controlled Trial” and “human” in PubMed, plantar fasciopathy fasciitis in CINAHL, plantar AND fasciopathy AND (‘fasciitis' OR 'fasciitis'/exp OR fasciitis) in Embase. Two articles were also found using manual searching. Total 35 articles were found and duplicates were removed. Two reviewers reviewed and selected the articles which has randomized controlled design and eligible data. Four articles were determined to be relevant, meeting inclusion and exclusion criteria.

Results

We found that the overall standardized mean differences of pain outcome between steroid injection and other treatments or sham was -0.57(95% confidence interval, -0.83 to -0.30), with low heterogeneity (P = 0.52, I² = 0%) at 1 month, but -0.33(95% confidence interval, -0.76 to 0.10, P = 0.13, I² = 50%) at 3 month. It suggested evidence of the effectiveness of short-term steroid injection, compared with autologous blood injection or other conservative treatment, but limited evidence of long-term effectiveness and functional improvement.

Conclusion

Although steroid injection in treating plantar fasciitis has been arguing, there is evidence of the effectiveness of steroid injection in relieving pain for 1 month. But further study is needed to determine long-term effectiveness of steroid injection.

EVALUATION OF PAIN IN PATIENTS WITH TROCHANTERIC BURSITIS SUBMITTED TO INFILTRATION TREATMENT WITH HIALURONIC ACID COMPARED TO INFILTRATION TREATMENT WITH CORTICOSTEROID AND LIDOCAINE
E. Rocha¹, L. Honorato Cheng¹, P. Yokomizo¹, C. Scala Jr¹, D. Galace¹
¹Santa Casa Sao Paulo, Rehabilitation Service, Santo André, Brazil

Introduction/Background

Trochanteric bursitis is a painful inflammation of femur great trochanter bursa. Patients generally complain of lateral hip pain. The classic physical finding is tenderness over the greater trochanter, which reproduces the presenting symptoms. The diagnosis is clinical but computed tomography (CT) scanning can also be used to exclude underlying diseases. Ultrasound and magnetic resonance imaging (MRI) can show the trochanteric bursa inflammation when present. Treatment include physical therapy, adjunctive measures such as rest and criotherapy, nonsteroidal anti-inflammatory drugs (NSAIDs), injections of corticosteroids and anesthetics, and topical anesthetic patches. There are new studies with injections of hialuronic acid in the treatment of bursitis.

Material and Method

This is a case series study in which 14 patients and 19 bursas with trocantheric bursitis were treated with infiltration of hialuronic acid or corticosteroid and lidocaine injections. Seven patients were treated with hialuronic injections and seven patients were treated with corticosteroid and lidocaine injections. The pain evaluation was measured using the verbal numeric scale. The pain was measured and registered before the infiltration treatment, soon after the injection, 1 month and 3 months after. After the data collection, a descriptive statistical analysis was performed using the t-paired test for continuous variables. Statistical significance was considered as p <0.05.

Results

The pain intensity evaluated by the verbal numeric scale showed an improvement of 100% in patients submitted to hialuronic acid injections compared to a 85.8% in the group treated with corticosteroid injections. The pain improve faster in the group that was submitted with hialuronic acid. Do to the small sample of patients in each group statistical significance could not be analysed between the groups.

Conclusion

We conclude that hialuronic injections are effective in the treatment of trochanteric bursitis.

HIP MUSCLES STRENGTH DEFICIT IN INDIVIDUALS WITH PATELLOFEMORAL PAIN SYNDROME: A SYSTEMATIC LITERATURE REVIEW

B. Guimaraes¹, P. Couto¹, J. Cunha¹, R. Cardoso², F. Melo¹, C.A. Branco¹
¹Centro Hospitalar de Entre o Douro e o Vouga, Physical and Rehabilitation Medicine Department, Santa Maria Da Feira, Portugal
²School-Hospital of Fernando Pessoa University, Department of Physical Medicine and Rehabilitation, Porto, Portugal

Introduction/Background

Patellofemoral pain syndrome (PFPS) is one of the most common chronic knee diseases, affecting around 25% of active adolescents and young adults with knee injuries.

Different authors hypothesized that the deficit of hip muscle strength may increase femoral movement during functional activities and contribute to the development of PFPS. Indeed, the weakness of the abductors and external rotators can cause excessive adduction and internal rotation, respectively, which may contribute to the stress of the patellar femoral joint.

The present systematic review aims to explore whether reflect if hip muscle strength deficits are normally present in patellofemoral pain syndrome (PFPS). Material and Method

A systematic review of the literature indexed in the databases Medline (using PubMed), ScienceDirect, EBSCO host and PEDro. To achieve study purpose, only Randomized Clinical Trials (RCT) were included, with publishing dates ranging from 2005 to 2017, appropriate sample size and in line with the standards of the Dephi List.

Results

Ten articles involving a total of 408 patients were included. The average methodological classification was 7,2 (scale 0-10). Hip muscles strength was evaluated in all the searched articles. The studies included confirm that individuals with PFPS have strength deficit in abduction, extension and external rotation of hip muscles compared with the healthy controls group and the unaffected side. On the other hand, hip adductors and internal rotator muscles strength deficit was not so evident or frequent.

Conclusion

Understanding the deficits and pathophysiology associated with PFPS is essential to determine the best approach to treatment. Despite the amount of research on this field, the lack of homogeneity of the protocols (reflected by studies with different age groups, degrees of disease
severity of the individuals or assessment methodologies) might be a challenge when addressing this disease.

Evans syndrome is a rare syndrome associated with the presence of autoimmune hemolytic anemia. It is one of the rare presenting features of autoimmune disorders, especially in systemic lupus erythematosus (SLE). This case report was made to show the contribution of physiotherapy methods for hip avascular necrosis in a patient with Evans syndrome.

Material and Method

In 2017, a 34-year-old female applied to university hospital for complaining of hip pain. The patient's history included SLE, Evans syndrome diagnosed in 2009. The patient underwent core decompression and grafting due to aseptic necrosis of the right femur in 2015. However, the development of degenerative arthritis continued. Doctors did not recommend total hip arthroplasty because patient was too young for surgery. Patient received 20 sessions physical therapy. Physiotherapy program (ambulation- personal exercises) was performed for 4 weeks (5 days/week) by physiotherapist. First measurements were taken for hip by universal goniometer. Pain intensity was measured with Visual Analog Scale (VAS) and physical functional disability with Western Ontario and McMaster Universities Arthritis Index (WOMAC) was assessed. In addition, Nottingham Health Profile (NHP) and Beck Depression Scale (BDS) were administered.

Results

Before the treatment hip range of motion were taken (70° flexion- 25° abduction.) After the treatment, hip range of motion increased (112° flexion- 35° abduction). Before the treatment, scores were VAS-activity = 7, WOMAC=114.29, NHP=136.87 and BDS=15. After the treatment this scores decreased (VAS-activity = 3, WOMAC =51.04, NHP=60.2 and BDS=9). At the end of 4 weeks, patient climbed the stairs without pain.

Conclusion

Physiotherapy program can be used as a preventive and supportive treatment for patients who are young for prosthesis intervention and have systemic problems such as Evans syndrome.

BOTULINUM TOXIN TREATMENT OF ENDOMETRIOSIS-ASSOCIATED CHRONIC PELVIC PAIN
P. Stratton- MD¹, H. Tandon², N. Sinaii- PhD³, J. Shah- MD², B. Karp- MD¹
¹National Institutes of Health, National Institute of Neurological Disorders and Stroke- Office of the Clinical Director, Bethesda, USA
²National Institutes of Health, Clinical Center- Rehabilitation Medicine Department, Bethesda, USA
³National Institutes of Health, Clinical Center- Biostatistics and Clinical Epidemiology Service, Bethesda, USA

Introduction/Background

Pelvic pain often persists despite optimal surgical/hormonal management in women with endometriosis and may be associated with pelvic floor spasm. This study assesses the effectiveness of onabotulinumtoxinA injection into pelvic floor muscles in women with endometriosis-associated chronic pelvic pain (endo-CPP) measured as changes in pain, muscle spasm, disability, and pain medication.

Material and Method

Women in an ongoing placebo-controlled trial of onabotulinumtoxinA for endo-CPP were offered open toxin injection any time 1-month to 1-year following masked, randomized study injection. Under conscious sedation and with topical anesthetic, 100units onabotulinumtoxinA (25units/cc) was injected transvaginally into areas of pelvic floor muscle spasm under EMG guidance. Spasm was assessed by pelvic exam. Pain, disability, and pain medication use were assessed by visual analog scale (VAS), validated questionnaires (Oswestry Disability Questionnaire), and patient diaries, pre- and post-injection.

Results

Of 28 women in the trial, 13 requested open toxin injection and were followed for >4 months post-injection. At injection, 11/13 had spasm in at least 4 of 6 assessed pelvic muscles and intense pain (median VAS: 5/10; range: 2-7). At least 1-month post-injection, spasm was absent/less widespread (≤3 muscles) in all (p=0.0005; Figures 1, 2). Eleven of 13 rated their pain as absent/mild (median VAS: 2; range: 0-5; p<0.0001); 7/13 used less medication. Disability decreased in 6/8 women with at least moderate disability pre-injection (p=0.03; Figure 2). Between 5-11 months post-injection, 7/13 reported return of pain and requested additional injection. Adverse events were mild and transient.
Figure 1: Disability, pain, and spasm over time for women with minimal pre-injection disability

Time from open-label onabotulinumtoxinA injection

In-person assessments 4-7 weeks after open-label injection; 5-8 and 11-14 months after masked study injection

- Minimal disability
- Moderate disability
- Severe disability
- Crippling disability
- No pain (VAS: 0)
- Mild pain (VAS: 1-3)
- Moderate pain (VAS: 4-6)
- Severe pain (VAS: 7-10)
- No muscle spasm
- 1-3 muscles in spasm
- 4-6 muscles in spasm
Conclusion

Pelvic floor spasm appears to be a major contributor to pain in some women with endo-CPP. In this open study, injection of onabotulinumtoxinA reduced pain, spasm, and disability for up to 11 months. Utility of botulinum toxin for endo-CPP merits evaluation in controlled trials.

WIDESPREAD MYOFASCIAL DYSFUNCTION AND SPINAL SENSITIZATION IN WOMEN WITH ENDOMETRIOSIS-ASSOCIATED CHRONIC PELVIC PAIN

P. Stratton- MD¹, H. Tandon², N. Sinaii- PhD³, J. Shah- MD², B. Karp- MD¹

¹National Institutes of Health, National Institute of Neurological Disorders and Stroke- Office of the Clinical Director, Bethesda, USA
²National Institutes of Health, Clinical Center- Rehabilitation Medicine Department, Bethesda, USA
³National Institutes of Health, Clinical Center- Biostatistics & Clinical Epidemiology Service, Bethesda, USA

Introduction/Background

Despite optimal surgical/hormonal treatment, some women with endometriosis continue to have chronic pelvic pain (endo-CPP). Co-morbid non-pelvic pain, myofascial dysfunction, and sensitization have rarely been reported in this population. We systematically assessed the presence and distribution of pain, myofascial dysfunction, and spinal sensitization in women with endo-CPP.

Material and Method

Women (18-50 years) with endo-CPP after optimized surgical/hormonal treatment were evaluated. Participants underwent gynecologic examination of pelvic floor muscles to identify tenderness/spasm. Neuromusculoskeletal examination included assessment of paraspinal tactile allodynia (Von Frey monofilament) and hyperalgesia (Wartenburg pinwheel). Myofascial trigger points (MTrPs) were identified in 13 regions bilaterally. Pressure-pain thresholds (PPTs) were measured over interspinous ligaments and MTrPs.

Results

Twenty-eight women with endo-CPP for a median of 12 years (range 1-20) were evaluated. All had pelvic floor muscle spasm on gyn examination. All endorsed the pelvic floor as a major focus of pain, which was described as focal in 19/28. All women had widespread myofascial dysfunction with MTrPs in more than two-thirds of assessed regions. Low PPTs (<9lb/in²) were found over interspinous ligaments in 24(86%) women. Widespread spinal segmental sensitization (allodynia and hyperalgesia) was present in 15(53%) subjects. Thoracic sensitization was present in 19(68%) women and lumbosacral sensitization related to the pelvic region in 17(61%). While cervical sensitization was detected in only 2(7%), 22(79%) reported recurrent, severe headaches and 14(50%) experienced orofacial pain.

Conclusion
Women with endo-CPP can have myofascial dysfunction beyond the pelvic focus of pain, demonstrated by widespread diffuse and regional allodynia, hyperalgesia, MTrPs, and lowered PPTs, likely reflecting central sensitization. Sensitization may be initiated and maintained by pelvic floor spasm and may account for pain persisting after resection of endometriosis lesions and despite continued use of hormonal treatment. These diffuse and focal myofascial and central nervous system manifestations warrant consideration in management of pain in this population.

LOWER BACK PAIN IN PEOPLE WITH PATELLOFEMORAL PAIN SYNDROME
S. Layouni\textsuperscript{1}, A. Jellad\textsuperscript{1}, S. Salah\textsuperscript{1}, I. Feki\textsuperscript{1}, I. Ketari\textsuperscript{1}, Z. Ben Salah\textsuperscript{1}
\textsuperscript{1} university hospital FB- Monastir- Tunisia, Physical Medicine and Rehabilitation Department, Monastir, Tunisia

Introduction/Background

Knee pain and low back pain (LBP) are serious general health challenges and important causes of physical impairment and disability. Although the prevalence of knee pain and LBP is high, little information is available on their association. The objective is to evaluate the incidence and predictive factors of LBP in people with patellofemoral pain syndrome (PFPS).

Material and Method

A prospective observationned study was conducted at Physical Medicine and Rehabilitation Department, university hospital Monastir, Tunisia from 2012 to 2017. Patients complaining of PFPS were included for a follow up period of tow years at least.

Results

Of the 141 patients with PFPS, 8 were not included for history of low back pain, and 6 were lost to follow-up. Study population comprised 127 patients (89 (70%) females) with a mean age 32.2±10.9 years. 13 (10.2%) cases of LBP were noticed with a mean delay of 6 months from the onset of PFPS. The annual incidence of LBP was 8.6%. Visual Analog Scale (VSA) disability was significantly associated to LBP (p = 0.01). The other clinical parameters were not significantly associated.

Conclusion

Incidence of LBP in people with PFPS is higher than in the general population. Perceived disability is associated to the onset of LBP in the population.

Introduction/Background

Quadriceps atrophy and in particular atrophy of the vastus medialis obliquus (VMO) muscle have been frequently related with patellofemoral pain syndrome (PFPS). The aim of this study was to investigate whether total quadriceps atrophy and VMO atrophy are present in the affected limb of individuals with patellofemoral pain.

Material and Method

This case-control study included five patients with one-sided PFPS. We measured the size of the total quadriceps and one part of it (VMO) in both legs. VMO size (length and width) was measured with ultrasound scanning at the level of the upper edge of the patella. Total quadriceps size was measured as girth with a cloth tape (all parts of the muscle) on several levels (upper edge of the patella, on the 5 cm and on the 10 cm of the upper edge of the patella). Measures of unaffected leg served as control. Statistical analysis: T test.

Results

Three men and 2 women were included, age 19 – 48, average 36.6.VMO size of the symptomatic leg, measured with ultrasound, was not significantly smaller than in the unaffected leg p = 0.14. Total quadriceps size measured as girth was significantly smaller in the affected leg than in the control leg, p = 0.002.

Conclusion

Total quadriceps muscle atrophy was shown to be present in patients with PFPS when analyzed by girth measures. In our sample of patients with PFPS, selective atrophy of the VMO was not identified by ultrasound measures. Simple measures, like measuring girth with a cloth tape, could be clinically useful assessment criterion of PFPS severity.

ANALYZE THE EFFECTS OF BOTULINUM TOXIN INFILTRATION IN THE SHORTENING OF THE AQUILES-CALCANEO-PLANTAR SYSTEM AS A TREATMENT FOR PLANTAR FASCITIS.

C. De Miguel Benadiba1, A. Teixeira Taborda2, J.C. Estupiñan1, S. Domínguez1, M.J. Buzzetta1, M.P. Sánchez Tarifa1, M.J. Lillo González1

1Ramon y Cajal Hospital, Rehabilitation, Madrid, Spain
2Fundación Jimenez Diaz Hospital, Rehabilitation, Madrid, Spain

Introduction/Background

The aquiles-calcaneal-plantar system shortening (ACPSS) is a frequent cause of ankle/foot pain. Pain can be located in the Achiles tendon or in the calcaneal insertion of the Plantar Fascia (PF), is the most frequent cause of chronic heel pain. Diagnosis is clinical given by heel pain that may vary in location, although calcaneus anteromedial region is the most common point. At physical examination it’s important to evaluate the ankle range of motion. Silverskiold test informs about the relationship between the origin of the shortening if it’s the gastrocnemius muscle or the soleus.

Material and Method

Prospective study, from December 2016-December 2017, were selected 41 patients but 56 infiltrated legs, with PF resistant to conservative treatment, who had performed 2 or more of this treatments, without improvement: analgesics, insoles, physiotherapy and corticosteroids infiltration. All had clinical criteria for ACPSS. Patients were infiltrated in the gastrocnemius intern muscle with 100-150IU of botulinum toxin, associated with triceps sural eccentric stretching 3/day, from the 4th day postinfiltration. Visual analog scale for pain (VAS) and the Foot Function Index- Spanish version (FFI) were evaluated. Patients were reviewed after 1, 4 and 6 months.

Results

The results were analyzed through the SPSS program; 66%(27 patients) were women between 40-60 years of age; 73%(30 patients) had received more than 3 treatments at the beginning of the study; 46%(19 patients) showed a treatment adherence of 2-3 times a day. Initial VAS was 7, one month later was 5 and 6 months after infiltration was 4. FFI scale one month after infiltration was 38% and sixth month was 28%; 78%(32 patients) recommended the treatment.

Conclusion
Infiltration with botulinum toxin, allow to improve the length of the posterior compartment in patients with ACPSS as well as decrease in VAS, and the improvement in the functionality and limitation of the activities according to the FFI scale.

SCIATIC NEURITIS CAUSED BY STRAIN OF ADDUCTOR BREVIS MUSCLE
M. Kim¹, S.H. Han¹
¹Hanyang University Guri Hospital, Rehabilitation medicine, Guri- Gyeonggido, Republic of Korea

Introduction/Background

Sciatic nerve is the longest single nerve in the body, derived from lumbosacral plexus. Most common cause of sciatic neuropathy is trauma, including hip dislocation and fracture. Besides, compression due to prolonged bed rest, ischemic nerve infarction, and hematoma are also common causes of sciatic nerve lesion. Unlike the previously well-known cause of sciatic neuropathy, it was secondarily induced by adductor brevis muscle strain diagnosed by MRI in this case report. This is the first report which shows muscle strain can be a cause of sciatic neuritis.

Material and Method

A 50-year-old female patient who had been swimming for 10 years as hobby, mainly free style and breaststroke, visited the emergency room with pain and tingling sense on the posterolateral side of the right thigh. Symptoms began 2 to 3 months before her first visit to the emergency room and abruptly worsened a week earlier. She was admitted to rehabilitation department for further evaluation and pain control.

Results

Simple radiography and lumbar spine MRI showed no specific findings, but hip MRI showed sprain of the right adductor brevis muscle and edema around the right sciatic nerve, which was compatible with secondary focal sciatic neuritis. Electrodiagnostic study showed no abnormal findings. Physical modalities such as hot pack, ultrasound, transcutaneous electrical nerve stimulation, and Interferential current therapy on right buttock area and pain control with gabapentin, NSAID, acetaminophen and opioid improved symptom.

Conclusion

This is the first case report that shows adductor brevis muscle sprain may cause sciatic neuritis. There have been a few case reports which revealed that piriformis bursitis and muscle tear can be cause of sciatic neuropathy, but this case had only focal muscle strain beside the sciatic nerve and it was accounted for the cause of radiating pain.

EFFICIENCY OF ISOKINETIC EXERCISE ON PAIN IN PATELLOFEMORAL SYNDROME: EXPERIENCE OF PRM DEPARTMENT OF MOHAMMED VI UNIVERSITY HOSPITAL - MARRAKECH
H. Ouazzani1, D. Doungou1, Y. Abdelfettah1
1Mohammed VI University Hospital, Physical Medicine and Rehabilitation, Marrakesh, Morocco

Introduction/Background
Patellofemoral pain syndrome (PPS) is a very common cause of anterior knee pain often encountered in young individuals due to repetitive flexion stress and poor patellar kinetics. In the absence of degenerative lesions or bad patella centering, the problem is frequently attributed to a strength imbalance between knee flexors and extensors muscles.

Isokinetic training has become an increasingly popular modality in rehabilitation, particularly effective in dynamic muscle strengthening for PPS.

The aim of our study is to show our experience in management of PPS and to determine the effect of an isokinetic exercise program on pain scores in patients with this syndrome.

Material and Method
A total of 10 patients with the complaint of anterior knee pain were recruited. PPS was assessed clinically and concentric testing was conducted at two speeds (60 and 180 d/s). Parameters measured were: torque peak and work produced by the effector muscles (quadriceps and hamstrings) and force ratio (flexors/extensors). Deficient force or work was defined as > 10% deficit compared with the healthy side or in presence of abnormal ratios. Force curves were analyzed and morphological anomalies were found for 100% of the patients.

Trainings were performed on the HUMAC NORM Isokinetic dynamometer at 240, 180, 120, 90 angular velocity, concentric mode, twice a week for 10 weeks. Visual analogue scale was used before and after the treatment to determine the degree of knee pain.

Results
The results are still ongoing since some of the patients have not yet completed the twenty sessions treatment.
Conclusion

Unbalanced knee muscles strength ratios are found universally with patellofemoral disorders. Using precise isokinetic dynamometers to train these muscles must be considered to correct the imbalance and ease the pain. This is the first experience of its kind in our university hospital, we intend making the sample of patients grow in the future.

Introduction/Background

Achilles tendinopathy is a common disease among athletes, and there have been many high-level studies investigating autologous blood-derived products (including platelet-rich plasma and whole blood). This systematic review aimed to assess the efficacy of autologous blood-derived products for chronic Achilles tendinopathy.

Material and Method

This review article followed PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines. Studies were comprehensively searched from electronic online databases (i.e., Pubmed, Embase, Cochrane controlled trials register and the Cochrane databases). We reviewed literature up to January 2018. Randomized controlled trials (RCTs) assessing the efficacy were included. The VISA-A (Victorian Institute of Sports Assessment-Achilles) score was evaluated at short and long-term follow-up. A subgroup analysis concerning PRP preparation techniques and study designs was performed.

Results

A total of five randomized controlled trials with 223 patients were included in this meta-analysis. Three studies reported short-term follow-up results and four studies reported long-term follow-up. The autologous blood-derived products can significantly reduce pain and improve functional recovery when compared with the condition before treatment. The pooled effect size of improved VISA-A score was 0.284 (95% CI: -0.044 to 0.611) at short-term follow-up and 0.246 (95% CI: -0.434 to 0.925) at long-term follow-up. There were no significant differences between autologous blood-derived products and placebo group in VISA-A score.

Conclusion

For patients with chronic Achilles tendinopathy, the review revealed that autologous blood-derived products reduced pain and improved functional activity after treatment. However, there seems no significant difference between autologous blood-derived products and placebo group.

Introduction/Background

The Fabella is a sesamoid bone present on the posterior articular face of the lateral femoral condyle, included in the gastrocnemius muscle. Its frequency varies between 20% - 87%. The estimated length is 4-22 mm with an average diameter of 10 mm. It's generally asymptomatic, however it can cause posterolateral knee pain, which increases with joint’s extension or external pressure, characterizing the "Fabella Syndrome". Neuropathy of the common peroneal nerve is also described. X-Ray can reveal the position of the fabella and MRI can exclude other causes of pain. The first-line treatment involves steroids injections in maximum pain area, restriction of activities for up to 6 months, manual therapy. In refractory cases, surgical treatment can be considered.

Material and Method

A 48 years old woman presented a 2 years history of right posterolateral knee pain, which increased when going down and up stairs. Physical exam revealed increasing pain by pressing the fabella and MRI showed the presence of a Fabella in the posterolateral region of the knee. After six months of conservative treatment, fabellectomy was finally executed, presenting 12 hours later, knee pain, right foot dorsal flexion deficit, hypoesthesia and paresthesias on the lateral side of the leg. Surgical revision showed a large bruise around common peroneal nerve, which was drained. Electromyography confirmed the clinical suspicion of neuropraxia of the nerve.

Results

Conservative treatment was indicated with active and passive ROM exercises, use of ankle foot orthosis and drugs for neuropathic pain, with good results at 5 months follow-up, achieving improvement of sensory and motor deficit.

Conclusion

The Fabella is a frequent finding that rarely produce a painful symptomatology. In this case, after failure of a conservative treatment, an uncommon complication was observed when performing the fabellectomy. The role of rehabilitation is essential both in the first-line treatment and in resolving possible surgical complications.

PRP INJECTION AFTER ESWT TREATMENT FOR BILATERAL HAGLUND’S DEFORMITY: REPORT OF ONE CASE
A. Sarı¹, A. Eroglu², O. Ulutas¹
¹Erenkoy Physical Medicine and Rehabilitation Hospital, Physical Medicine and Rehabilitation Department, Istanbul, Turkey
²Erenkoy Physical Medicine and Rehabilitation Hospital, Sports Medicine Department, Istanbul, Turkey

Introduction/Background

Haglund’s deformity is a painful swelling of the hindfoot with mechanical origin. It is usually diagnosed by a combination of clinical and radiological assessments. Different treatment strategies can be used. In these text we report a case of bilateral Haglund’s deformity which was treated with PRP injection after ESWT therapy.

Material and Method

Case report:
A 35-year-old male presented bilateral heel pain followed by the appearance of a swelling at the posterior heel. On physical examination his ankle’s ROM were limited and painful. Palpation of calcaneus and retrocalcaneal bursa were painful too. Plain radiographs showed the existence of a conflict between the achilles tendon and the posterior superior angle of the calcaneus. MRI results found to be compatible with bilateral Haglund’s deformity. He treated with resting, ice application at 4-6 hours intervals, elevation, aessin diethylaminesalicylate gel application 4 times a day, ibuprofen 1600 mg/day for 2 weeks with padding and strapping. No improvement has been observed at control assessment and we suggested ESWT therapy. Total 10 session of ESWT treatment has been applied. After these treatments, the patient underwent PRP injection to the posterior superior edge of the calcaneus with ultrasound guiding. Injection was made at 2 week intervals totally for 3 times.

Results

The outcome was favorable with regression of pain and resumption of daily activities after 6 weeks from the last injection.

Conclusion

Haglund’s deformity is one of the causes of posterior heel pain causing a handicap in life and sports. Its management must be well studied. PRP injection after ESWT can be an alternative treatment method.

²Seoul National University Boramae Medical Center, Department of Rehabilitation Medicine, Seoul, Republic of Korea

Introduction/Background

To determine the effect of needle tip positions on short-term effect of transforaminal epidural steroid injection (TFESI) using nerve stimulator (NS) for lumbar radiculopathy.

Material and Method

45 patients who received TFESI using NS were retrospectively reviewed. The TFESI was conducted under fluoroscopic guide. The goal of positioning was to allow a needle tract toward injection site such as “safe triangle”. We used the NS to optimize the position of needle tip. The needle tip was repositioned to achieve minimal current output (0.2 mV) when the patients had paresthesias within dermatomal areas. The needle tip positions were assessed by dividing the intervertebral foramen into 4 quadrants in the anterior-posterior view (Fig. 1). The grade of nerve root compression on MRI in 45 patients was evaluated (Fig. 2). The outcome measurement (OM) was evaluated before pre-injection and after 2 weeks.

Results

91 TFESIs were conducted in the 45 patients. The position of needle tip was 68, 19 and 4 cases in the quadrant 1, 2 and 3 respectively. The mean score of OM reduced significantly in the quadrant 1 and 2, but not in the quadrant 3 after 2 weeks. There were no significant differences in the mean score of OM according to the grade of nerve root compression.

Conclusion

As the neural structures lie medially in the foramen, it is believed that a medially placed needle such as quadrant 2 has a higher likelihood of causing neurological complication. Bogduk proposed the ideal needle tip position by defining a “safe triangle” like quadrant 1. Our study showed that there was a similar effect in the quadrant 2 just the same in the quadrant 1. We conclude that the NS to guide TFESI in addition to fluoroscopy can be a useful therapeutic tool in the patient with radicular symptoms.

Introduction/Background

In literature, women have pain more than men. The aim of this study was to determine if there is a difference of dentists’ pain severity on their neck, low back, and wrists related to their sex.

Material and Method

With the mean age of 32.46 ± 9.22 (24-62) years, 54 (26 women, 28 men) dentists working at different divisions of a university hospital were included in this study. Pain severity of their neck, low back, and wrists was assessed on visual analogue scale (0-10) and also asked if it was low, medium or severe. SPSS 11.0 was used for calculating pain severity means and frequencies related to sex.

Results

The mean of active working years of women being a dentist was 8.30±7.00 (1-16) and that of men was 10.52±8.2 (2-39). Neck, low back, and wrist pain severity frequencies related to sex
Neck, low back, and wrist pain duration of women were respectively; 1.11 ± 2.25 (0-10), 2.57 ± 4.49 (0-15), and 0.73 ± 1.53 (0-5) years. Those of men were 0.96 ± 3.59 (0-19), 2.46 ± 4.36 (0-16), and 0.30 ± 1.16 (0-6) years. Pain severity of women on these body areas were respectively; 1.46 ± 2.33 (0-7), 2.30 ± 2.20 (0-8), and 1.19 ± 2.13 (0-7); Those of men were 1.03 ± 1.93 (0-7), 1.75 ± 2.27 (0-8), and 0.42 ± 1.50 (0-7).

**Conclusion**

There was no difference of pain severity and frequency between women and men dentists. Therefore pain severity and its frequency may differ related to occupation. So this study could be applied for workers having other occupations.

CERVICAL MANIPULATION AND DRY NEEDLING IN PATIENTS WITH CERVICOGENIC HEADACHE

M. Azadvari¹, S.Z. Emami-razavi¹, M. Togha²
¹Tehran University of Medical Sciences, physical medicine and rehabilitation, Tehran, Iran
²Tehran University of Medical Sciences, neurology, Tehran, Iran

Introduction/Background

Cervicogenic headache is one type of headache that characterized by pain in one side of head and neck. However, pharmacological management has not been successful enough to treat this type of headache. Cervical manipulation and dry needling of trigger points are among the suggested methods for treating the cervicogenic headaches.

The purpose of this study was to determine the effectiveness of a combined method of manipulation plus dry needling of trigger points in the management of cervicogenic headache.

Material and Method

55 women aged between 17 to 70 years suffered from chronic cervicogenic headache were included. The patients were visited by an expert neurologist, and then they were referred to a physiatrist.

An expert physiatrist did cervical manipulation in six sessions with 1 week interval between each session. Dry needling was done in muscle's trigger points in 6 to 10 sessions.

Results

The mean (SD) age was 48.5 (13.6) years. The mean (SD) headache severity based on visual analog scale (VAS) and mean (SD) duration of each headache attack were 7.3 (2.1) and 5.7 (3.6) hours per day, respectively. In addition, mean (SD) number of headache days was 13.5 (6.2) per month.

After 8 weeks of starting intervention, the patients experienced headache with less duration and less frequency. Mean duration of headache per day and per months, and mean VAS score significantly decreased, (p value<0.05).
Conclusion

According our results, it seems that non pharmacologic treatments including cervical manipulation and dry needling of trigger points can be helpful in management of cervicogenic headache.

CLOMIPRAMINE CONTRIBUTION IN THE TREATMENT OF CHRONIC LOW BACK PAIN
S. Frioui Mahmoudi\textsuperscript{1}, S. Jemni\textsuperscript{1}, F. Khachnaoui\textsuperscript{1}
\textsuperscript{1}University Hospital Sahloul, Physical and Rehabilitation Medicine, Sousse, Tunisia

Introduction/Background

Chronic low back pain is a frequent reason for consultation with a limited therapeutic choice. The aim of our work is to determine the effect of clomipramine on chronic low back pain.

Material and Method

This is a prospective study conducted in the Department of Physical and Rehabilitation Medicine in Sahloul Hospital TUNISIA among patients hospitalized for chronic low back pain for more than two years unimproved by NSAIDs, analgesics and rehabilitation over a period. All patients were hospitalized for 10 days and received clomipramine by slow intravenous infusion with progressively increasing doses: 25mg 1\textsuperscript{st} day, 50mg 2\textsuperscript{nd} day, 75mg 3\textsuperscript{rd} day until the 10\textsuperscript{th} day relayed to the output orally by doubling doses (150 mg) until the 90\textsuperscript{th} day. The evaluation of our results was performed on Day 0; D4; D10; D90 by visual analogue scale (VAS), Schöber index, the finger-floor distance and the Functional Independence Measure (FIM).

Results

We collected 22 patients. The average age of our patients was 46 years, ranging from 20 to 60 years. There was a male predominance (13/9). The average pain duration was 6 years. On admission, the majority of patients had a VAS > 8/10. VAS values began to decline since the 4\textsuperscript{th} day to stabilize from the 10\textsuperscript{th} day until the end of the cure (VAS = 4/10). There was no improvement in spinal mobility or significant changes in functional capacity (Functional Independence Measure (FIM)). 62\% of patients experienced adverse effects (dry mouth ++).

Conclusion

Clomipramine, in addition to its antidepressant effect, has a central analgesic action that has become widely used in the treatment of chronic low back pain resistant to conventional analgesics.

Correlation Between Lumbosacral Canal Stenosis and Morton Neuroma

S. Dayaghi, A. Ashraf, B. Kazemi, H. Heidary

'Shiraz University of Medical Sciences, physical medicine & Rehabilitation, Shiraz, Iran

Introduction/Background

Morton neuroma and spinal canal stenosis are two main reasons of referral of patients to rehabilitation clinics that seems have different mechanisms of occurrence. With early diagnosis and management of concomitant problems with canal stenosis, patients can achieve more quality of life and function. So, we designed this study for evaluation of possible correlation between these entities.

Material and Method

We evaluated 30 patients with lumbosacral spinal canal stenosis who were referred to rehabilitation clinics of our university. We examined their feet for possible Morton neuroma and evaluate their daily functions by using Oswestry Low Back Pain Disability Questionnaire.

Results

The results showed high prevalence of Morton neuroma among patients with spinal canal stenosis (86.7%). Such patients with concomitant Morton neuroma, showed low functional score with assessing of questionnaire. Numbers of Morton neuroma have positive correlation coefficient with worsening of their functions (0.59).

Conclusion

It has been suggested that physicians should exam patients with lumbosacral spinal canal stenosis for detection of concomitant Morton neuroma.

Keywords

spinal canal stenosis; Morton neuroma; Oswestry questionnaire

CHARACTERISTICS OF THE RIGID SPINE SYNDROME DUE TO SEPN1-MYOPATHY. A LONG-TERM FOLLOW-UP SERIES OF 21 PATIENTS.

1Hôpital Raymond-Poincaré, Pediatric PRM department, garches, France
2Hôpital Raymond-Poincaré, Pediatric Resuscitation department, garches, France
3Hôpital Raymond-Poincaré, Centre de Référence de Maladies Neuromusculaires Garches-Necker-Mondor-Hendaye GNMH, garches, France
4INSERM, Unité de recherche sur les maladies cardiovasculaires- du métabolisme et de la nutrition, Paris, France
5INSERM, USPC Paris-Diderot and Department of rheumatology, Paris, France
6Hôpital Necker-Enfants-Malades, Pediatric Orthopedic Departement, Paris, France
7Hôpital Raymond-Poincaré, Radiology department, garches, France

Introduction/Background

SEPN-1 related myopathy is a recessive autosomal disorder caused by SEPN1 gene mutations. Patients present homogeneous clinical features, in particular a striking cervico-axial hypotonia and a weakness associated with poor head control. A progressive spinal stiffness and severe restrictive respiratory insufficiency with diaphragmatic failure is observed in the course of the first or second decade. They are described as a “rigid spine syndrome” (RSMD1). The aim of this study was to describe the course of the spinal deformity and the clinical and respiratory complications.

Material and Method

We reviewed retrospectively the medical charts of 21 patients with mutations in the SEPN1 gene. Genetic, clinical, radiological (X-rays) and respiratory studies (spirometry) were reviewed and analyzed.

Results

Mean age at last follow-up was 23 years (4 – 55). All patients except one, showed poor weight and height for their age, with a mean body mass index of 13.3 kg/m² (8 – 25). Mechanical ventilation was required in 19 patients (age range 4-15), usually only nocturnally, but in three cases a tracheostomy was performed. Four patients lost walking at a mean age of 28 (12-44). Clinical and radiological examinations were available for 15. Cervical spine stiffness was present in 65% of patients (mean chin-sternum distance in maximal cervical flexion of 7 cm). Scoliosis was observed in 12 (7 spinal translation; 6 pelvic obliquity). Clinically, a thoracic lordosis was observed in 87% of patients, and X-ray showed a flat thoracic spine. Management
of the spinal deformity was focused mainly in axial stretching and antilordotic bracing. Two cases developed a severe progressive scoliosis before puberty. Spinal surgery was performed in 15 patients.

**Conclusion**

SEPN1-related myopathy should be suspected in children developing a characteristic stiff and lordotic thoracic spinal deformity associated with a cervical rigidity. Due to constant respiratory complications, these patients require specialized multidisciplinary management.

COMPARISON OF SPATIOTEMPORAL CHARACTERISTICS WITH EYES OPEN AND CLOSED SITUATIONS IN PATIENTS WITH CERVICAL DISC HERNIATION AND HEALTHY CONTROLS
A. Demirel¹, Y. Aslıyüce¹, O. Ulger¹
¹Hacettepe University, Health Sciences Faculty- Physiotherapy Department, ankara, Turkey

Introduction/Background
The aim of the study is to determine the spatiotemporal characteristics in patients with cervical disc herniation during six minutes gait with eyes open and closed.

Material and Method
15 patients between the ages 25 and 65 (mean age: 47.8±7.13, BMI:28.5±7.03) with Cervical Disc Herniation (CDH) and 5 healthy control (HC) were participated to the study. The patients had thoracic outlet syndrome, whiplash injury, positional vertigo, Meniere’s Disease, other neurological diseases and had any spine surgery were excluded from the study. All patients were asked to walk six minutes on treadmill with their preferred speed for getting used to treadmill surface. The OptoGait photoelectric cells system (OptoGait, Microgate S.r.I, Italy, 2010) were used to gain gait spatiotemporal characteristics. After the patients ready for walking on treadmill, gait parameters were recorded while patients were walking during eyes open and closed, respectively. Wilcoxon signed ranks test was distributed for statistical analyses.

Results
There was no statistical difference between CDH and HC in terms of step length, stance phase, swing phase, single support, double support, load response and cadence in both eyes open and closed gait analyses (p>0.05). In favor of CDC, cadence increased during eyes closed as to eyes open situation (p>0.05).

Conclusion
Although, the study has small participants, no additional negative effect has detected in patients with CDC apart from HC on gait parameters in both eyes open and closed situation. For future studies, more participants were included to the study to make precise comments and treadmill versus normal surfaces could be used to minimize the measurement errors.

RELATIONSHIP BETWEEN PHYSICAL ACTIVITY LEVEL AND CLINICAL CHARACTERISTICS WITH THE PRESENCE OF SACROILIAC JOINT DYSFUNCTION (SIJD) IN PEOPLE WITH LOW BACK PAIN
C. Ramirez¹, A.B. Oliveira², L. Sánchez³
¹Universidad Industrial de Santander, School of Physical Therapy, Floridablanca, Colombia
²Universidad Federal de Sao Carlos, Physical Therapy, Sao Carlos, Brazil
³Universidad Industrial de Santander, School of Physical Therapy, Bucaramanga, Colombia

Introduction/Background
SIJD explains 15-30% of idiopathic low back pain (LBP) cases, but there is no evidence about the characteristics of LBP population with SIJD diagnosis. The aim of the study was to establish the relationship between physical activity level and clinical characteristics with the presence of SIJD in people with LBP.

Material and Method
136 subjects were evaluated (54 with SIJD and 82 without SIJD), with 29±12 years old and BMI 23.4±3 Kg/m². Pain evolution time, presence of spine pathologies, use of medications, previous treatments and sedentary time were evaluated. Pain was evaluated with the visual analog scale at rest, at palpation on SIJ and at movement (during lifting of a load). Functionality was assessed with Oswestry Disability Index and physical activity level with two self-perceived questions. Data were evaluated for normality and homogeneity and Student's t-test was used to determine the difference between groups.

Results
Differences in pain at palpation > 3cm (p≤ 0.007) and at movement > 2cm (p≤ 0.001) on SIJ in the SIJD population were identified.

Conclusion
Pain at palpation on SIJ in the SIJD group is a sign of sacroiliac pain known as Fortin’s sign. Increase of pain at movement in the SIJD group could be related to lack of stability on the SIJ and alteration of loads transfer in presence of SIJD. These findings highlight the importance of emphasizing the stabilizing musculature of SIJ during the rehabilitation of SIJD.

ASSOCIATION BETWEEN MUSCLE FUNCTION AND POPULATION’S CHARACTERISTICS WITH THE PRESENCE OF SACROILIAC JOINT DYSFUNCTION (SIJD).

C. Ramírez¹, A.B. Oliveira², L. Sánchez³

¹Universidad Industrial de Santander, Physical Therapy School, Floridablanca, Colombia
²Universidad Federal de Sao Carlos, Physical Therapy, Sao Carlos, Brazil
³Universidad Industrial de Santander, Physical Therapy School, Bucaramanga, Colombia

Introduction/Background

SIJD can explain about 15-30% cases of idiopathic low back pain (LBP). The aim of the study was to evaluate associations between electrical activity and strength of Latissimus Dorsi (DA), Gluteus Maximus (GM) and Biceps Femoris (BF) muscles according to characteristics of SIJD population.

Material and Method

One hundred and thirty-six people of both genders with LBP, 54 with SIJD and 82 without SIJD, of 29±12 years old, BMI 23.4±3 Kg/m² were evaluated. Sociodemographic, anthropometric and physical activity (PA) variables were obtained through self-fulfilling forms. The RMS amplitude and latency were evaluated with surface electromyography (EMG) during lifting of a load from ground level and the muscle strength through manual dynamometry. To evaluate possible associations, a Log binomial simple and multiple regression was performed, following Greenland recommendations.

Results

There is a negative association for people over 30 years (RP: 0.45) and of male gender (RP: 0.43); positive association for moderate (PR: 1.31) and vigorous (PR: 2.13) physical activity level and latency of right LD (PR: 1.53) when performing the activity with the left lower limb.

Conclusion

Being male and over 30 years old are protective factors for the manifestation of SIJD while practicing moderate-vigorous PA and a delay in the activation of LD, are positively associated with the manifestation of SIJD. The late reaction of the LD could alter the synchronism with the GM, compromising the closing force on the SIJ and forces transfer between the trunk and the lumbopelvic spine, perpetuating symptoms in the SIJD population.

CERVICAL MYELOPATHY IN PHYSICAL AND REHABILITATION MEDICINE
S. Frioui Mahmoudi¹, W. May¹, R. Moncer¹, S. Jemni¹, F. Khachnaoui¹
¹University Hospital Sahloul, Physical and Rehabilitation Medicine, Sousse, Tunisia

Introduction/Background

We proposed to study the epidemiological and clinical features of hospitalized patients in the Department of Physical and Rehabilitation Medicine for Cervical myelopathy.

Material and Method

This is a retrospective study conducted in the Department of Physical and Rehabilitation Medicine in Sahloul Hospital TUNISIA among patients hospitalized for Cervical myelopathy over a period of five years.

Results

We collected 21 patients: 18 men and 3 women (sex ratio = 6). The mean age was 55.7 ± 11.4 years (35-73 years). Nine patients were workers, 5 were retired and 4 were unemployed. Five patients were hypertensive and 2 had an ulcer. 66% of patients were addressed by a neurosurgical unit and 23% by an orthopedic department. 38% of cases consulted for heaviness of the lower limbs and 23% for cervicobrachial neuralgia. The mean delay prior consultation was 5.2 years. In 38% of cases, the diagnosis of cervical myelopathy was made following a trauma. 38% of patients were tetraplegic. 33% had spasticity predominately in the triceps sural (57%). 61.9% had bladder and sphincter disorders (urinary retention in 7 patients). We used the intermittent catheterization in 5 patients. At the initial assessment of functional independence by the Functional Independence Measure (FIM), we found an average of 79.8 ± 29.7 (46-126). The outcome was favorable in 80% of cases with an average FIM of 96 at the end of the hospitalization.

Conclusion

Cervical myelopathy is the most frequent myelopathy. It is a leading cause of functional disability in the elderly. It results from the impact of an abnormally narrowed spinal canal on the cervical spinal cord. It causes diagnostic problems in its standard forms because it can simulate a neurological disease, therapeutic and prognostic problems because it is often seen in elderly and frail subject.

THE EFFICACY OF NEURAL THERAPY IN LOW BACK PAIN REFLECTED FROM PELVIC ORGANS

E. Yilmaz

Korfez Government Hospital, Physical Therapy and Rehabilitation, Kocaeli Izmit, Turkey

Introduction/Background

Low back pain is at the first rank among musculoskeletal disorders. Non-specific low back pain account for the vast majority of cases (85%), whereas a minority of cases (10-20 %) have a specific pathoanatomic diagnosis. One of the causes of low back pain is referred pain which may not remove by the traditional methods used for the treatment of low back pain. Neural therapy, an injection technique, is a treatment system for chronic pain and illness. Neural therapy can provide relief of pain, increased in mobility and the restitution of functions, if other treatment methods fail to treat the pain. The aim of this article is to accentuate that the source of chronic low back pain which resistant to medical and physical therapy may also arise from pelvic organs, and to emphasize the efficacy of neural therapy as an supportive treatment in these cases.

Material and Method

Ten patients (6 female, 4 male), not be achieved an adequate recovery with chronic low back pain treated by medical and physical therapy, were collected. All patients treated by neural therapy (with 0.4% lidocain solution) including local-segmental treatment from T10 to S4 in the lumbosacral region, 5M injection, pelvic plexus injection, i.v. injection (2 ml) (also intradermal injection to cesarean section scar in some cases).
Results

VAS in 1 and 3 months after the injection statistically significantly decreased when compared to the initial mean level of VAS (8.5±0.85, 0.40±0.51 and 0.40±0.51, respectively; p< 0.01).

Conclusion

Low back pain is common in the general population and the mechanical causes are preliminary. Although most patients respond to treatments, there is no underlying cause in some patients. In such cases, the referred pain from the pelvic organs should be considered, and in addition to the traditional treatment methods, neural therapy for these areas may be considered as an alternative treatment.

THE FIBROLIPOMA OF CAUDA EQUINA: A CASE REPORT

A. Uran Şan¹, R. Gündüz², H.G. Karataş¹, M. Akyüz¹
¹Medicine and Training Hospital, Physical Medicine and Rehabilitation, Karabük, Turkey
²Medicine and Training Hospital, Physical Medicine and Rehabilitation, Karabük, Turkey

Introduction/Background

Fibrolipoma is a variant kind of lipoma; which is consisting of fat cells separated by connective tissue septas. It can be develop in the different parts of the body such as oral cavity, parotid gland, esophagus, subcutaneous tissue, larynx, trachea, pharynx, colon, spermatic cord. The cauda equina is a rare localization for fibrolipomas. In this study, we aimed to present clinical and radiological properties of a case with the diagnosis of fibrolipoma of cauda equina.

Material and Method

A 54-years-old patient was admitted to our department with low back pain. Her medical history revealed that the pain had started two months ago and radiated to the dorsal and lateral part of the left lower extremity. The pain was aggravated by walking and relieved by rest. Visual Analog Score (VAS) of low back pain was 90 mm. On physical examination; the movements of the low back were painful. It was detected hypoesthesia on the left L4, L5, S1 and S2 dermatomes. Muscle strength was normal. Patellar tendon and achilles tendon reflexes were also negative bilaterally.

Results

Magnetic resonance imaging (MRI) revealed L4-L5 disc protrusion accompanied compression of left L5 nerve root and the fibrolipoma which is localized into the cauda equina fibers at the level of L4, L5 and S1. After the conservative treatment including anti-inflammatory medical therapy; VAS pain score was decreased from 90 mm to 20 mm. The patient was also referred to neurosurgery department.

Conclusion
The fibrolipoma of cauda equina is an unusual clinical disorder. Especially neurological examination can be useful to distinguish this clinical entity from other pathologies. Radiological evaluation should be used for the confirmation of the diagnose.

ABDOMINAL CURL-UP WITH ELASTIC BAND PREVENTS INADEQUATE ACTIVATION OF SUPERFICIAL CERVICAL FLEXORS

K. Nam¹, P. Teajoon¹
¹College of Medicine- Dongguk University, Departments of Physical Medicine & Rehabilitation, Goyang-si, Republic of Korea

Introduction/Background

The abdominal curl-up is often recommended as part of a rehabilitation program. The curl-up exercise may, however, activate the superficial cervical flexors, such as the sternocleidomastoid (SCM), which can induce neck pain. The purpose of this study was to assess the effectiveness of using an elastic band to decrease SCM activity while maintaining abdominal muscle activity during the curl-up.

Material and Method

Twenty-two healthy male subjects participated. All subjects performed a traditional curl-up exercise, a curl-up with neck flexion restriction, and a curl-up with an elastic band. Surface electromyography signals were recorded from the sternocleidomastoid, rectus abdominis, and external oblique muscles during the exercises.

Results

The curl-up technique with an elastic band showed a significantly lower root mean square (RMS) value of SCM activity compared with the traditional curl-up (p < 0.000) and the curl-up with neck flexion restriction (p < 0.021). There were no significant differences in the RMS values of RA or EO activity between the three techniques (RA; p = 0.294, EO; p = 19 0.097).

Conclusion

The results of this study suggest that the curl-up technique with an elastic band can reduce SCM activation while maintaining activation of the abdominal muscles in healthy subjects compared with the traditional curl-up or the curl-up with neck flexion restriction.

The main objective of this study is to access the effects of mesotherapy in chronic low-back pain treatment, in comparison with physiotherapy.

**Material and Method**

Prospective and randomized study, from March 2016 until December 2017, compared 2 groups of patients with chronic low-back pain, the 1rst group; treated by mesotherapy; during six weeks (1 injection/week, n=23), versus physiotherapy including infrared and ultrasound 10 sessions (3 sessions/week, n=11). The time of follow-up was 3 months. Evaluated by: Pain intensity: Visual Analogue Scale (VAS), neurological signs, quality of sleep, recourse to surgery, and return to quotidian's activities.

**Results**

After 3 months of follow-up, we note a greater effects of mesotherapy treatment, but the results were statistically no significant; in pain relief (p=0.716), in quality of sleep (p=0.068), and in return to quotidian's activities (p=0.131). However, we avoided the surgery in the two groups, for all the cases.

**Conclusion**

Mesotherapy is a good alternative in chronic low-back pain treatment, in this study, their effects were approximately similar to physiotherapy; associating infrared and ultrasound.

OBSERVATION OF THE EFFECT OF SCALP ELECTRICAL STIMULATION ON ACUTE LOW BACK PAIN

X. huang

Zhejiang special education Career Academy, Special education rehabilitation department, Hangzhou, China

Introduction/Background

To explore the therapeutic effect of scalp electrical stimulation on pain.

Material and Method

A total of 60 outpatients were randomly divided into scalp stimulation group and electrotherapy group. First, we used the taylor-hanghton method to locate the central sulcus accurately, and translate the 0.75cm in front and back of the central groove. It was determined as the stimulation area of the motor area and the stimulation line of sensory area respectively, and it was used as the stimulation point of acupuncture at the intersection point with the nasal occipital line. A 6805I electroacupuncture instrument produced by Shantou Medical device Factory was used with dense wave frequency of 30hz. the patient was tolerated for 20 minutes. During the treatment, the patient was instructed to perform lumbar activities in the sitting position. The control group using computer intermediate frequency treatment, electrodes placed on the pain, stimulate the strength to comfort patients as of the end of treatment, the treatment time of 20min, 10min with McGill Pain Questionnaire for pain evaluation survey.

Results

There was no significant difference in the scores of PRI, PPI and vas before treatment in the 2 groups. (P > 0.05). After treatment, the scores of pri, ppi and vas in 60 patients with pain improved significantly before and after scalp electrical stimulation and electrotherapy, and the difference in the group was statistically significant (p < 0.01) ; compared with scalp electrical stimulation group and electrotherapy group PRI, PPI and VAS score difference was statistically significant (p<0. 01)

Conclusion

Scalp electrical stimulation is a safe and effective method for pain treatment. It can relieve pain, improve function, quality of life and patient satisfaction, and reduce the use of non-steroidal anti-inflammatory drugs.

Introduction/Background

Low back pain and consequence disability is one of the most prevalence musculoskeletal disorders that human being ever had involved. Quality of life is a multidimensional concept and is beyond absolute physical health. In this study, we compared QOL between low back pain patients and healthy people using WHOQOL-BREF which is a generic and overall instrument.

Material and Method

This descriptive-analytic study was carried out on 256 low back pain patients and healthy people in Shahid Beheshti Hospital, Babol. They filled out the questionnaires personally and the scores of different domains in two groups were compared. WHOQOL-BREF has four domains of physical health, psychological health, social relations and environment health. The range of scores in each of these domains is from 4–20. The two questions are about the general quality of life and general health. Overall, a higher score indicates better quality of life.

Results

The participants’ age range was from 18 to 63 with the mean ± SD of 36.63 ± 10.99. The scores of these four domains and general quality of life and general health of WHOQOL-BREF were lower in low back pain patients. These differences were statistically significant in physical health and environmental health.

Conclusion

Lower QOL in low back pain patients necessitates doing some interventions such as education and rehabilitation in this group. This indicates the importance of more attention to these patients to plan future treatments in order to reinforce these domains.

A CONCISE REHABILITATION PROTOCOL FOR SUB-ACUTE AND CHRONIC NON-SPECIFIC NECK PAIN

P. Noormohammadpour¹, F. Tayebi¹, M.A. Mansournia², E. Sharafi³, R. Kordi¹

¹Sports Medicine Research Center- Neuroscience Institute, Tehran University of Medical Sciences, Tehran, Iran
²Department of Epidemiology and Biostatistics- School of Public Health, Tehran University of Medical Sciences, Tehran, Iran
³Psychiatric Research Center, Tehran University of Medical Sciences, Tehran, Iran

Introduction/Background

There is increasing evidence in support of multidisciplinary approaches for management of chronic neck pain. Although presence of different team members is one of the strengths of these approaches, it can limit the access to these treatments. The main objective of this study is designing and investigating the efficacy of a concise rehabilitation program.

Material and Method

Thirty-nine patients with sub-acute and chronic non-specific neck pain underwent an 8-week rehabilitation program. Baseline and 8 weeks' follow-up data regarding neck pain (visual analog scale, neck disability index and quality of life) were compared using paired T test.

Results

After eight weeks of study, pain and disability significantly decreased: -3.8 of 10 (95% CI: -4.6 to -3.0) (p-value <0.001) for pain and -18.4 of 100 (95% CI: -23.7 to -13.2) (p-value <0.001) for disability. Also, all SF-36 domain scales improved significantly.

Conclusion

By using this concise rehabilitation approach, pain, disability, and quality of life improved significantly in patients with sub-acute and chronic non-specific neck pain.

COMPARISON OF THE CROSS SECTIONAL AREA OF LONGUS COLLI MUSCLE BETWEEN PATIENTS WITH CERVICAL RADICULAR PAIN AND HEALTHY CONTROLS

P. Noormohammadpour¹, A. Dehghani², M.A. Mansournia², N. Moghaddam¹, M. Mir³, R. Kordi¹

¹Sports Medicine Research Center- Neuroscience Institute, Tehran University of Medical Sciences, Tehran, Iran
²Department of Epidemiology and Biostatistics- School of Public Health, Tehran University of Medical Sciences, Tehran, Iran
³Neurosurgery department, Tehran University of Medical Sciences, Tehran, Iran

Introduction/Background

Previous studies have shown atrophy of paravertebral lumbar muscles in patients with lumbar radicular pain, and proposed rehabilitative approaches based on these findings. However, changes of cervical paravertebral muscles in patients with cervical radicular pain are still unknown. The aim of this study was to compare the cross sectional area (CSA) of longus colli muscle (LCM) in patients with cervical radicular pain and healthy controls via ultrasound measurement.

Material and Method

Twenty patients with more than 4 weeks of cervical radicular pain and 20 healthy matched (for body mass index, age, and gender) control subjects. The CSA of LCM at the level of C5-C6 was measured by ultrasound with the subject in a supine position. Also, Neck Disability Index (NDI), and visual analogue scale (VAS) were reported by patients. Independent sample t-test was used for investigation of differences in cross sectional area and other variables between both groups.

Results

Twenty patients with cervical radicular pain with mean (SD) age of 42.4(7) years and 20 healthy matched controls with mean (SD) age of 40.7 (7) years participated in the study. Patients with cervical radicular pain showed smaller CSA of LCM bilaterally compared with controls (mean (SD) difference: 0.37(0.15)) (P value<.001). Within patients group, there were no significant differences between CSA of LCM in the involved and non-involved sides.

Conclusion

This is the first study which showed that patients with cervical radicular pain had smaller bilateral CSA of LCM in comparison with healthy controls via ultrasound assessment. It is also not clear whether atrophy of longus colli muscle in patients with cervical radicular pain is a consequence or a cause of it. Reduction in the stability of neck due to atrophy of LCM could
make the cervical spine region susceptible to more injuries which might be prevented by functional and strengthening exercises.

RETURN TO WORK AFTER TWO YEARS OF FUNCTIONAL RESTORATION PROGRAM FOR LOW BACK PAIN

R. Maaoui¹, S. Zrida¹, I. ksibi¹, N. mouhli¹, R. dhahri², C. bouguerra³, H. rahali¹
¹Military Hospital of Tunis, physical rehabilitation medicine, Tunis, Tunisia
²Military Hospital of Tunis, departement of rhumatology, Tunis, Tunisia
³Military Hospital of Tunis, biostatistics departement, Tunis, Tunisia

Introduction/Background

Chronic low back pain is a cause of sick leave and absenteeism. The positive effect of functional restoration program in return to work has been shown at short term in many studies.

Evaluate the impact on return to work and sick leave in patients with chronic low back pain after two years of a restoration program.

Material and Method

Prospective study on patients with low back pain. The duration of the work stoppage was evaluated before and after a restoration program during two months. The patients were summoned after two years for a third evaluation.

Results

Thirty patients graduated from the program. Initially, 24 were on sick leave (80%) for an average of 30 days (from 0 to 170 days). In the end of the program only 4 (13.3%) were still on sick leave for an average of 5 days (from 0 to 15 days). This significant improvement (p=0.001) decreased 2 years later (p=0.08) and became insignificant. We found 19 patients (63.3%) on leave sick for an average of 27 days.

Conclusion

The functional restoration program for low back pain reduced sick leave at short term. After two years the results decreased but remain better than the initial ones.

THE EFFECT OF POSITIVE CHANGES DURING INTRAOPERATIVE MONITORING ON THE FUNCTIONAL IMPROVEMENT IN PATIENTS WITH CERVICAL COMPRESSIVE MYELOPATHY

S.J. Lee¹, S.B. Kim², K.W. Lee², J.H. Lee², M.K. Park²
¹Dong-a University Hospital, Dept. Rehabilitation Medicine, Busan, Republic of Korea
²Dong-A University Hospital, Physical Medicine and Rehabilitation, Busan, Republic of Korea

Introduction/Background

Cervical compressive myelopathy (CCM) is a progressive, degenerative spine disease and the most common cause of spinal cord dysfunction in older individuals. Current clinical guidelines for spinal surgery strongly recommend multimodal intraoperative monitoring (IOM) during spinal surgery as a reliable and valid diagnostic adjunct to assess spinal cord integrity. The aim of this study was to evaluate the effect of positive changes during IOM on the functional status in patients with CCM.

Material and Method

Patients who underwent spinal surgery with IOM due to CCM were enrolled. During the surgery, patients underwent IOM using motor evoked potential (MEP) and somatosensory evoked potential (SEP). MEP and SEP were checked before and immediately after decompression. A shortened in latency greater than 10% or an increase in amplitude greater than 50% was regarded as a ‘positive changes’. Subjects were divided according to the presence of positive changes. Motor scores of American Spinal Injury Association (ASIA) impairment scale and Korean version of modified Barthel index (K-MBI) were evaluated before and after operation.

Results

Twenty-nine patients underwent spinal surgery due to CCM. Among these patients, 11 showed positive changes in MEP during IOM. When the two groups were compared, improvement rate in the AISA motor score and K-MBI were significantly higher in patients with positive changes than in patients without positive changes at 1 month after surgery. The duration of hospital stay was significantly shortened in the ‘positive change’ group. Regardless of positive change, nearly all patients suffered from neuropathic pain after operation.

Conclusion

Positive changes in MEP during IOM may affect better functional improvement 1 month after operation and early discharge without significant complications in CCM patients. However they do not affect the neuropathic pain. Thus, tailored, proper management is needed to achieve maximal functional recovery in each patient after cervical spinal decompression surgery.

Introduction/Background

Active discopathy (AD) is responsible of chronic low back pain. Conservative treatment is still debated. Few studies focused on the rehabilitation program efficacy in AD. The aim of this study was to evaluate the impact of a chronic low back pain rehabilitation program (CLBPRP) on disability, pain level, and return to professional activity in this population.

Material and Method

Files of all patients included in our CLBPRP had been screened. CLBPRP is followed for 4 weeks, with 7 hours of physical activities a day. Quebec scale and pain level self-evaluation were done at the beginning (M0) and the end (M1) of the stage. Data of the AD suffering patients (ADP) had been collected and they have been contacted by phone to fill a survey.

Results

Quebec scale was a significatively decreased from 49.8/100 at M0 to 37.1/100 ± 14.7 at M1. Twenty patients had been evaluated by survey, with a mean follow up of 29.5 months ±19.3. The Quebec scale total score was 48.2 ± 13.2 at M0, 36.7 ± 15.8 at M1, and 37.0 ± 18.6 at Mx. There was significant difference between M0 and M1 (p=0.0004) and between M0 and Mx (p=0.007). Concerning the lumbar pain, there was no difference between M0 and M1(16), M1 and Mx, M0 and Mx in the sample.

Conclusion

Inclusion of patients in classical low back pain rehabilitation programs is still debated. Our study seems to confirm the interest of physical activities and active rehabilitation in this pathology. It is showing a significative effect on the disability due to chronic low back pain and impact of the pain in the daily living. There is no clear effect on the pain level and it should not be an objective of the stage.

MUSCLE PHYSICAL CONDITION ANALYSIS OF INDIVIDUALS WITH CHRONIC LOW BACK PAIN

M. Wang¹, B. He², Y. Hu¹, X. Pang¹, G. Wang¹
¹Chengdu Sport Institute, School of Sports Medicine and Health, Chengdu, China
²Chengdu Sport Institute, Affiliated Hospital, Chengdu, China

Introduction/Background

Chronic Low back pain (CLBP) is a common clinical disease, and most individuals require long-term treatment. This research analysis the muscle physical condition characteristics of individuals with CLBP in order to provide reference for rehabilitation and prevention of chronic low back pain patients.

Material and Method

64 subjects with CLBP (age: 35.2±1.5, 34 males and 30 females, body weight: 66.5±3.7kg) were recruited as N group (experimental group), while 29 health subjects (age: 39.2±1.8, 16 males and 13 females, body weight: 64.8±3.2kg) were recruited as Y group (control group). Recorded the degree of pain (VAS, Visual Analogue Scale/Score) questionnaire, and then used the Thomas Test (Hip Flexor Test) to test the flexibility of iliopsoas, hamstring and tensor fascia lata, meanwhile, use Myoton-3 myometer to quantify muscle tone of lumbar paravertebral muscles, hamstring and tensor fascia lata. Analysis the differences between groups, and the CLBP ones with different degree of pain (according to the VAS).

Results

1) Muscle flexibility of iliopsoas and hamstring of Y group were significant higher than N group, and N group shows bilateral imbalance (p< 0.05); 2) Muscle tone of all three muscles of Y group was significantly lower than N group, also the N group shows significantly bilateral imbalance (p< 0.05); 3) In N group, according to VAS, the muscle physical condition of mild ones(VAS 0-3) were significantly better than moderate ones(VAS 4-7) (P< 0.05).

Conclusion

1) Muscles relevant to core stability (iliopsoas, hamstring, lumbar paravertebral muscles and tensor fascia lata) can influence the position of pelvis. The significant decline of muscle physical condition, including muscle flexibility and muscle tone, as well as the bilateral imbalance is related to CLBP; 2) And the more pain of CLBP, the poorer of the muscle physical condition; 3) When treat CLBP individuals, consideration of physical condition of these muscles and relaxation of tight muscles is highly recommended.

RESPONDERS TO GLUCOCORTICOID OR CONTRAST INTRADISCAL INJECTIONS AMONG CHRONIC LOW BACK PAIN PATIENTS WITH AN ACTIVE DISC DISEASE: A SECONDARY ANALYSIS OF THE PREDID TRIAL

C. Pauwels¹, F. Rannou², C. Nguyen²
¹AP-HP- Hôpital Cochin, Rééducation et Réadaptation de l'Appareil Locomoteur et des Pathologies du Rachis, Paris, France
²Université Paris Descartes - Faculté de Médecine, Rééducation et Réadaptation de l'Appareil Locomoteur et des Pathologies du Rachis, Paris, France

Introduction/Background

Non-specific low back pain is first cause of years lived with disability. An active disc disease is present in up to 58% of patients with low back pain. We aimed to describe patients with chronic low back pain and an active disc disease who respond and those who do not respond to intradiscal glucocorticoid or to intradiscal contrast.

Material and Method

We conducted a secondary analysis of the PREDID study, a randomized trial of 135 patients with chronic low back pain and an active disc disease. Overall, 61 participants received an intradiscal injection of glucocorticoid (25 mg prednisolone acetate) during discography and 60 received discography alone. Fourteen participants did not receive the allocated treatment and were not included in this secondary analysis. The primary outcome was the description of clinical, demographical, psychological and social characteristics of responders and non-responders to intradiscal glucocorticoid and to intradiscal contrast at 1 month, as defined in the primary trial. Independent variables associated with clinical response were assessed by logistic regression.

Results

Participants who responded to intradiscal corticosteroid injection were more often highly educated (18/34 [52.9%] vs 6/26 [23.1%], respectively), whereas participants who did not respond were more often on sick leave (14/27 [51.9%] vs 5/34 [14.7%]). The independent variable most strongly associated with the absence of therapeutic response to intradiscal glucocorticoid was sick leave (OR = 33.8, 95% CI = 2.4 to 472.2). Similar results were observed with response to intradiscal contrast injection but the magnitude of differences was lower.

Conclusion
Patients with chronic low back pain and an active disc disease who respond to an intradiscal injection of corticosteroids or contrast have a social profile different from those who do not respond.

ISPR8-0514
PELVIC PARAMETERS IN PATIENTS WITH CHRONIC LOW BACK PAIN AND AN ACTIVE DISC DISEASE: A CASE-CONTROL STUDY
C. Blandin¹, M. Boisson¹, F. Segretin¹, A. Feydy², F. Rannou³, C. Nguyen³
¹AP-HP, Rééducation et Réadaptation de l’Appareil Locomoteur et des Pathologies du Rachis, Paris, France
²Université Paris Descartes-Faculté de Médecine, Radiologie B, Paris, France
³Université Paris Descartes-Faculté de Médecine, Rééducation et Réadaptation de l’Appareil Locomoteur et des Pathologies du Rachis, Paris, France

Introduction/Background
Active disc disease is characterized by inflammatory-like low back pain (LBP) and the presence of Modic 1 changes on MRI. Its prevalence ranges from 19% to 50% in patients with non-specific chronic LBP. Pelvic parameters are important determinants of shear and compressive forces applied to the lumbar intervertebral disc. The association between an active disc disease and abnormal pelvic parameters has not been addressed yet. We aimed to compare pelvic parameters between chronic LBP patients with an active disc disease (Modic 1) and those without (Modic 0).

Material and Method
We used a convenient sample from patients prospectively and consecutively recruited in a previous single center case-control pilot study. Cases were defined as chronic LBP male patients with an active disc disease on MRI and controls as patients without. Pelvic parameters, namely sacral slope, pelvic tilt and pelvic incidence, were assessed in an independent and standardized manner by two trained investigators using EOS system imaging performed at inclusion.

Results
Overall, 35 cLBP patients (13 cases and 22 controls) fulfilled inclusion criteria and had an EOS imaging available. Median age was 42 (35-51.5) years and median LBP duration 50 (33.5-104) months. Pelvic parameters did not differ between the 2 groups: absolute mean (95% IC) difference between Modic 0 and Modic 1 was -7.2° (-15.5;1.0) for pelvic incidence, -3.7° (-8.7;1.3) for pelvic tilt and -3.3 (-8.9;2.3) for sacral slope.

Conclusion
Pelvic parameters in patients with chronic LBP and an active disc disease do not differ from those in patients without.

THE EFFECTS OF STABILIZATION EXERCISE ON LOW BACK PAIN AND PELVIC GIRDLE PAIN IN PREGNANT WOMEN

J. Bogaert¹, M. Stack¹, S. Partington¹, J. Marcea¹, A. Tremback-Ball¹
¹Misericordia University, Physical Therapy, Dallas, USA

Introduction/Background

Pain in the lumbar or sacroiliac region during pregnancy is common. However, it should not be considered a normal part of pregnancy. There are non-invasive approaches to treatment to effectively manage symptoms not only during pregnancy but also postpartum. A systematic review was performed to examine the effects of stabilization exercises on low back and pelvic girdle pain in pregnant women.

Material and Method

A database search of EBSCO (CINAHL, HealthSource, MEDLINE, and PsycINFO) was conducted from September 2017 to January 2018. Our search terms included “pregnancy”, “pregnan*”, “stab* exercis*”, “back pain”, “pelvic pain”, and “pelvic floor”. The studies were reviewed for content to determine if they met the inclusion and exclusion criteria. Articles were then examined for quality on a hierarchy of evidence scale and the PEDro Scale by four researchers.

Results

Twenty three articles were included in the systematic review. Most concluded that stabilization exercises had a positive effect on low back and pelvic girdle pain in pregnant women. A few articles found no significant reduction in pain. The discrepancies may be due to differences in protocol such as administering a home exercise program, frequency of exercises, weeks of gestation, and direct supervision exercises. These factors may influence the effectiveness of stabilization exercise in this population.

Conclusion

The effects of stabilization exercise vary based on type of pain, type of exercise, location of pain and timing of intervention. Overall, the use of stabilization exercises is beneficial in reducing low back and pelvic girdle pain in pregnant women. Further, rehabilitation during pregnancy may prevent future episodes of low back and pelvic girdle pain in subsequent pregnancies.

DIFFERENCES OF NATURE OF DISEASE, SOCIOECONOMIC AND PSYCHOLOGICAL FACTORS IN CHRONIC LOW BACK PAIN PATIENTS BETWEEN THAILAND AND GERMANY
P. Boonyapaisancharoen¹, P. Yotnuengnit¹, K. Piravej¹, E. Kraft², N. Arnstadt², H. Schulte-Goecking², N. Jamin²
¹Faculty of Medicine- Chulalongkorn University, Rehabilitation Medicine, Bangkok, Thailand
²Ludwig-Maximilian-University- University Clinic, Department of Orthopedics- Physical Medicine and Rehabilitation, Munich, Germany

Introduction/Background

Objectives: To study the differences of nature of disease, socioeconomic status and psychological factors in chronic low back pain (LBP) patients between Thailand and Germany.

Material and Method

Study design: Cross Sectional Analytic study

Setting: Out Patient Clinic, Department of Rehabilitation Medicine, King Chulalongkorn Memorial Hospital, Thailand and Department of Orthopedics & PM&R, Großhadern Hospital, Germany

Subjects: 100 Thai and 100 German patients with chronic LBP more than 6 months

Methods: The data from both hospitals were collected before chronic LBP patients received treatment. The data consisted of 4 domains; demographic data, socioeconomic status, nature of disease i.e. Numerical Rating Scale (NRS), Pain Disability Index (PDI), etc. and psychological factors (Center for Epidemiologic Studies Depression Scale: CES-D). The data was analyzed by using statistic program.

Results

Mean age of both Thai and German was 47.7 ± 11.7 years old. Majority were female, married, white collar and has LBP duration for more than 3 years. Comparison between Thai and German, the average and maximal NRS were not significantly different. However, German patients had significantly higher than Thai patients in PDI (median 26 and 10, respectively, P = 0.00) and CES-D total scores (median 17 and 4, respectively, P = 0.00).

Conclusion
Despite the non-significant difference in LBP severity, there were the differences among Thai and German patients. German patients had more depressive symptom and pain related impairment than Thai patients.

THE NEUROMUSCULAR ELECTRICAL STIMULATION EFFICACY IN THE CONTRACTION OF THE LUMBAR MULTIFIDUS MUSCLE IN INDIVIDUALS WITH CHRONIC NONSPECIFIC LOW BACK PAIN
E. Rocha¹, V.P. Rotta², D.G. Freitas², C. Cazarini Jr¹, J. Mazzei², M.A. Added², F. Hazime²
¹Santa Casa Sao Paulo, Rehabilitation Service, Santo André, Brazil
²Santa Casa Sao Paulo, Rehabilitation Service, Sao Paulo, Brazil

Introduction/Background

The objective is to determine the efficacy of neuromuscular electrical stimulation in the contraction of the lumbar multifidus (LMF) muscle in individuals with chronic nonspecific low back pain.

Material and Method

An observational study with blinded examiner was conducted, following approval by the institutional review board, a total of 22 patients were recruited from a Rehabilitation Department, between March and July 2015.

The patient group included 11 individuals of both genders with mean age of 18-60 years presenting chronic nonspecific lower back pain and pain level ≥ 4 points, as measured using the Visual Analog Scale (VAS), with over three months, no irradiation to lower limbs. In addition to the 11 individuals with low back pain, a control group of 11 healthy participants with no history of low back pain in the past year was added.

The assessment was performed by carrying out image capture using an ultrasound imaging device, of the width and thickness of the lumbar multifidus muscles at three different timepoints. At the first timepoint, an image of the patient at rest was taken. At the second timepoint, an image of the patient was acquired while neuromuscular electrical stimulation was applied. At the third timepoint, the image was captured with the combination of neuromuscular electrical stimulation together with voluntary contraction of the lumbar multifidus muscle.

Results

No significant difference was found between the two groups. The results revealed a significant difference in both the width and height of the multifidus muscle under different conditions of electrical stimulation (p < 0.001)

Conclusion

Neuromuscular electrical stimulation proved effective in the recruitment of the lumbar multifidus muscles.

LONG-LASTING EFFECTS OF A FOUR-WEEK MULTI-DISCIPLINARY FUNCTIONAL REHABILITATION PROGRAM IN PATIENTS WITH CHRONIC LOW BACK PAIN

M. E. Ibrahim¹,², K. Weber³, M. Sartori⁴, C. Cedraschi⁵, S. Genevay²

¹Suez Canal University, Physical Medicine and Rheumatology, Ismailia, Egypt
²University Hospitals of Geneva, Rheumatology, Geneva, Switzerland
³University Hospitals of Geneva, Medical Direction, Geneva, Switzerland
⁴University Hospitals of Geneva, Psychiatry, Geneva, Switzerland
⁵University Hospitals of Geneva, General Medical Rehabilitation, Geneva, Switzerland

Introduction/Background

We aimed to evaluate the long-lasting effects of a multidisciplinary functional rehabilitation program on work readiness, disability, kinesiophobia, pain, depressive and anxious moods as well as physical and mental quality of life in patients with chronic low back pain.

Material and Method

201 patients (57% male) aged 41.01 (9.5) participated in a four-week multidisciplinary functional rehabilitation program, including physical and occupational therapy, as well as medical and psychological group counselling. Assessment was performed at treatment admission and discharge, and at 6 (n=106) and 18 months (n=96) follow-up. Assessment included the Oswestry Disability Index (ODI), Tampa Scale for Kinesiophobia (TSK), Core Outcome Measure Index (COMI), Hospital Anxiety and Depression Scale (HADS) and the Short-Form Health Survey (MOS SF-12) for quality of life. Multiple mixed models were used to assess significant change for each outcome measure.

Results

Initially 11% of the patients were working fulltime and 13% part-time. At 6 months follow-up 55% and at 18 months 72% of the patients were working. The COMI pain, function, symptom-specific well-being, generic quality of life and disability scores significantly decreased. Likewise, the ODI and TSK scores significantly decreased. Physical SF-12 quality of life significantly improved throughout the study. HADS Depression scores remained below the clinically significant threshold (<8) throughout the study. Contrary to HADS anxiety scores, which dropped at treatment end below threshold, however increased again at 6 months follow-up. Likewise, mental quality of life improved at the end of treatment, however this improvement did not last during follow-up.

Conclusion

The multidisciplinary program was associated with an increase in readiness for work in the majority of patients, long-lasting reduction in disability, kinesiophobia, pain and enhancement of
physical quality of life. In contrast, psychological benefits are limited to short-time benefits on anxiety and mental quality of life and would possibly need specific after-treatment care to persist.

THE INFLUENCE FACTORS OF PREGNANCY LOW BACK PAIN AND THE RESEARCH DEVELOPMENT FOR ITS TREATMENT
M. Wang¹, Y. Hu¹, S. Li², W. Zhu¹
¹Chengdu Sport Institute, School of Sport Medicine and Health, Chengdu, China
²Gamma Performance, Education, Beijing, China

Introduction/Background

According statistics, there are nearly 18 million newborns in China 2016. This means nearly 18 million pregnant women in China annually, and the number will increase as the country’s second-child policy was liberalized. Pregnancy Low Back Pain (PLBP) is a high incidence of skeletal muscle disorder in pregnancy and even postpartum.

Material and Method

By referring to Chinese and English databases such as CNKI, Wanfang Database and PUBMED, and the input key words and search the corresponding literature. In order to offer inference for clinical treatment of pregnancy LBP.

Results

Studies have shown that the incidence of PLBP is as high as 50% to 80% in pregnant women. According to the Nottingham health scale, both the quality of life and the index of physical activity were significantly lower than those of pregnant women without LBP. The current situation of the treatment of PBLP in China is not good, most cases uses negative way.

Conclusion

LBP during pregnancy occurs mostly in late pregnancy, and more than a third of women in the postnatal still have the corresponding symptoms, its reason is unclear, but it happened under the influence of many factors, including pregnancy weight/body weight index, history of pregnancy LBP or waist injury history, physical labor intensity during pregnancy, regular physical exercise and mental on staterophe of pregnancies, and so on. Common physical therapy methods include health education, exercise therapy, manipulation therapy, protective gear, physical cause, and combination of the above methods. At present in the study published by core stability related exercise therapy effect is supported by a lot of evidence, at the same time manipulation treatment such as joint mobilization for limited joint mobility of pregnant women have better curative effect. The remaining physical therapy techniques have been reported to be effective, but the supporting research data is insufficient.

THE RELATIONSHIP BETWEEN BODY AWARENESS AND LOW BACK AND NECK PAIN
E. Horata¹, E. Tasvuran Horata², S. Ere³
¹Afyon Kocatepe University, Atatürk Health Services Vocational School, Afyonkarahisar, Turkey
²Afyon Kocatepe University, Afyon Health School- Physiotherapy and Rehabilitation, Afyonkarahisar, Turkey
³Pamukkale University, School of Physical Therapy and Rehabilitation, Denizli, Turkey

Introduction/Background

Body awareness includes an attentional focus on and awareness of internal body sensations. It is defined as the ability to recognize subtle body indications, previous research suggests that it may be useful in the management of chronic diseases such as chronic low back pain. Therefore the aim of the present study is to investigate the relationship between body awareness and low back and neck pain.

Material and Method

The study was conducted 211 healthy students mean aged 20.12±1.59 years at Physiotherapy and Rehabilitation Department in Afyon Kocatepe University. Pain intensity was determined by Visual Analogue Scale (VAS). The Oswestry Disability Index (ODI) was used to assess the low back pain affects the activities of daily living The neck pain affects the activities of daily living was evaluated by The Neck Disability Index (NDS). The Body Awareness Questionnaire (BAQ) was used to evaluate body awareness status. Also the participants asked about doing any sports.

Results

The participants who have low back pain was 122 (82 women, 40 men) and neck pain was 121 (85 women, 36 men). Also the participants engaged in sports were 58. According to the present study there was no correlation between body awareness and VAS scores of low back pain, ODI scores, VAS scores of neck pain and NDI scores (p>0.05). Also the correlation between body awareness and sex and doing sports wasn’t significant statistically.

Conclusion

Body awareness has no effect on low back and neck pain. More research is needed on how body awareness effects on other chronic diseases that cause pain.

Low back pain (LBP) is an important problem throughout the world with the highest prevalence and direct and indirect costs representing an important financial burden. The beliefs and attitudes of physiotherapists and physiotherapy students influence the outcome of low back pain treatment. Physiotherapists have two important attitudes about low back pain. Firstly, biomedical/biomechanical model of the pain based upon the notion that try and identify and then treat the specific structures or neuromuscular impairments thought to be the cause of the problem and the source of the pain. Secondly, biopsychosocial, in which pain does not have to be a sign of tissue damage and can be influenced by social and psychological factors. The aim of the present study was to compare the beliefs and attitudes of LBP of physiotherapy students regarding to academic degree.

Material and Method

The study included 2-years associate degree and 4-years undergraduate degree of physiotherapy students of Afyon Kocatepe University in Turkey. Turkish version of the Pain Attitudes and Beliefs Scale for Physiotherapists is practised in all participants.

Results

153 participants completed the survey. According the present study there were no differences between academic degrees of the physiotherapy students regarding biomedical and biopsychosocial scores (p>0.05). The fourth grade students of undergraduate degree’s biomedical scores are higher than the first grade students, but similarly, the differences weren’t significant (p=0.057).

Conclusion

As a conclusion, we believe that the participants have similar belief and attitudes about low back pain due to the same university and educational system enhanced this.

Pelvic girdle pain is a common complaint of pregnant women. There are limited data on comparison between the effectiveness of stabilizing exercises and lumbopelvic belt on the treatment of these patients. The objective of this study was to compare the effect of lumbopelvic belt plus information, home based pelvic girdle stabilizing exercises plus information and information alone on pain intensity, functional status and quality of life of pregnant women with pelvic girdle pain.

Material and Method

In this randomized clinical trial pregnant women with pelvic girdle pain (n=105) were randomly allocated to three groups; Control group (n=35) that received general information, exercise group (n=31) that in addition to general information were asked to perform specific pelvic stabilizing exercises at home and belt group (n=31) that received non-rigid lumbopelvic belt and the information. The primary outcome variables were pain intensity and functional status of the participants which were measured using visual analogue scale and Oswestry Disability Index (ODI) respectively. Quality of life of participants was measured using WHOQOL-BREF questionnaire. All measurements were performed at baseline, 3 and 6 weeks after the study conduction.

Results

The pain intensity of patients in belt group in comparison to other groups was decreased significantly at both 3 and 6 weeks follow-ups. The mean score of ODI of patients in belt group was also improved more than exercise and control groups significantly.

Conclusion

On base of our results, it can be found that in short term lumbopelvic belt and information in treatment of pregnant women with pelvic girdle pain is superior to exercise plus information or information alone.

CAUDAL EPIDURAL STEROID INJECTION IN LUMBOSACRAL SCIATICA: TUNISIAN STUDY

Introduction/Background

Lumbar epidural steroid injections have been used as part of the conservative management of sciatica due to disc herniation for more than 50 years. The lumbar epidural space is accessible either by caudal, inter-laminar, or transforminal routes. According to medical litterature, caudal epidural injection has numerous advantages.

Aim: To assess the efficacy of caudal epidural steroid injections in patients of lumbosacral sciatica

Material and Method

A prospective study was conducted in rehabilitation Department in university hospital center Sahloul, Sousse, Tunisia. Evaluation of participants was realized at baseline, after one week of injection and 4 weeks. Pain on a Visual Analog Scale (VAS), Straight leg test (SLR), Schober test and arabic version of Oswestry disability index were assessed as outcome measures.

Results

Seventy-one patients were included in our study (40 women and 31 men) with an average age of 46.3 years. All patients had X-ray and MRI of Lumbo-sacral spine. Lumbar caudal approach used landmark method combined with loss of resistance technique, without fluoroscopic guidance. None of the patients experienced Clinically significant side effect, such as dural penetration. A significant improvement of pain was noticed. Initial mean lumbar VAS 3.5/10 passed to 1.8/10 at 1 month after injection. Mean Schober’s test increased from 32.5 cm to 4.1 cm after 4 weeks. Most patients had one injection (75%) and 6.3 % had 3 repetitive injections with a mean interval of 11 days.

Conclusion

Hence, we can conclude that caudal epidural steroid injections can be an important component of management of painful lumbosacral sciatica. This route of injection has many advantages such as a lower risk of dural or subarachnoid penetration and a greater ease of execution.

Introduction/Background

Purpose: To evaluate if fear avoidance beliefs (tendency to avoid any physical activity that results or has the potential to result in pain) correlate with long-term outcome of conservative treatment of patients with lumbar disc herniation.

Material and Method

Material and Methods: a group of 110 patients (36 women and 74 men) with lumbar disc herniation treated conservatively was analyzed. Conservative treatment included NSAID, ultrasound, massage, hydrotherapy, currents, electromagnetic fields, heat, traction, exercise, and education. Treatment protocol was made for any patient individually depend of subjective symptoms and clinical findings.

Follow-up evaluation was 1 to 3 years (mean 23 months) after the last treatment session. For assessment Japanese Orthopedic Association (JOA) score and Fear Avoidance Beliefs Questionnaire (FABQ) were used. For statistical analyzes correlation coefficient, Spearman Rank Correlation and Wilcoxin Matched Pairs Test were used.

Results

Results: At discharge and at control assessment patients were significantly better, with significantly decreased subjective symptoms, better clinical findings and decreased restrictions in activity of daily living than on admission (p<0.0001). There were moderate negative correlation between long-term outcome of conservatively treated patients with lumbar disc herniation and FABQ score (r = -0.42). It shows that patients who had less fear of pain during physical activity and work had better long-term outcome and they assessed their own condition as excellent or better (R = 0.42).

Conclusion

Conclusion: There are moderate negative correlation between fear avoidance beliefs and long-term outcome of conservative treatment of patients with lumbar disc herniation.

CHRONIC LOW BACK PAIN EFFECTS IN QUALITY OF LIFE OF THE PATIENTS

H.F.S. Rumaux Pagathe¹, G.D. Solofomalala²
¹Hospital University of Anosiala Ambohidratrimo, Physical Medicine and Rehabilitation, Ambohidratrimo, Madagascar
²Hospital University of Anosiala Ambohidratrimo, Trauma and Orthopedic, Ambohidratrimo, Madagascar

Introduction/Background

Chronic low back pain causes functional impairment and can affect quality of life. The objective of this study is to describe the impact of chronic pain on the quality of life of patients with low back pain and to describe the psychobehavioural state of chronic low back pain patients.

Material and Method

A cross sectional study was carried out in the Department of Physical Medicine and Rehabilitation of the University Hospital of Anosiala Ambohidratrimo. The intensity of the pain was evaluated by the visual analog scale. SF-36 (Short Form-36) was used to assess patients’ quality of life. The Pearson correlation coefficient was used in the evaluation of the existence of correlation.

Results

A decline of quality of life was been found. A positive correlation was found between pain and functional disability before and after treatment (r = 0.487 p = 0.005, 0.492 p = 0.005). Negatives correlations were observed between pain and physical function limitations (r = -0.359, p = 0.047; r = -0.385, p = 0.033) before and after pain management.

Conclusion

Chronic low back pain has a detrimental effect on the quality of life of patients.

SCOLIOSIS AND BACK PAIN . WE NEED TO LOOK FOR THE CAUSE
V. Vidal Vargas¹, M.D. Romero Torres¹, J. Valencia Anguita², M. Rodríguez-Piñero Durán¹
¹Hospital Universitario Virgen Macarena, Physical and Rehabilitation Medicine, Sevilla, Spain
²Hospital Universitario Virgen Macarena, Neurosurgery, Sevilla, Spain

Introduction/Background

Pain and functional limitation of the spine are not part of the clinical aspects of idiopathic scoliosis. The association of scoliosis and spondylolisthesis is documented in the literature. Three types of associations are described: idiopathic scoliosis and, scoliosis secondary to rotation caused by spondylolisthesis and scoliosis as an analgesic position to sciatic irritation.

The aim of this report is to present a clinical case of idiopathic scoliosis in concurrence with specific spinal pain due to spondylolisthesis.

Material and Method

A 14 years old girl, followed-up for idiopathic scoliosis with right curvature from D5 to D12 measuring 22°, without rotation, Risser I, in treatment with orthopedic brace. The initial exploration: centered plumb line, Adam’s test: 10° right dorsal with inclinometer.

In clinical review the patient refers pain in the buttock. Clinical examen highlights pain on lumbar spinous processes and painful limitation to spine flexion, without radicular signs. The exploration of the deformity provides as a novelty, deviation of the plumb to the right of 1.5 cm line from the gluteal cleft. New spine radiographs and Nuclear Magnetic Resonance (IRM) are requested. Radiographs: right scoliotic curve from D5 to L1 measuring 40°, rotation grade 2, Risser III. IRM and spondylolisthesis: right thoracolumbar scoliosis and grade IV anterolistes of L5-S1.
The patient undergoes surgery by arthrodesis

Results

One year after surgery: the patient is without pain, Adam’s test 6°, plumb line is centered, Risser IV and right scoliotic curve from D5 to D12 measuring 23°.

Conclusion

In scoliosis associated with back pain or rachialgia, it is important to do a correct exploration and research to rule out specific cause of pain, different than scoliosis.

THE IMPACT OF REHABILITATION ON THE PAIN INTENSITY LEVEL IN PATIENTS WITH FAILED BACK SURGERY SYNDROME (FBSS)

K. Koszela¹, S. Krukowska¹, M. Woldanska-Okonska¹
¹Medical University of Lodz- Poland, Department of Rehabilitation and Physical Medicine, Lodz, Poland

Introduction/Background

Back disorders are very common phenomena in modern society. One of the methods of spinal pain treatment is performing surgery. Unfortunately, this method is not one hundred percent effective. Some patients show no improvement after surgery, the pain persists and even increases. In these cases, it is reasonable to use the term Failed Back Surgery Syndrome (FBSS), i.e. back pain syndrome after unsuccessful spine surgery. The aim of the study is to assess the impact of rehabilitation on the pain intensity level in patients with FBSS.

Material and Method

The study was conducted in a group of 38 patients aged from 32 to 87 (mean age 61 years), including 20 women and 18 men. All patients were operated for spinal pain syndrome. Afterwards, they underwent rehabilitation because of persisting pain after the surgery. For the pain assessment was used The Visual-Analogue Scale and The Laitinen Modified Questionnaire Indicators of Pain. The results were statistically analysed.

Results

The study shows the high efficacy of specialized rehabilitation in patients with FBSS.

Conclusion

The rehabilitation in patients with FBSS has a significant analgesic effect. Rehabilitation should be a gold standard in patients with FBSS

Keywords

rehabilitation; back pain; FBSS

THE ASSESSMENT OF THE IMPACT OF REHABILITATION ON THE PAIN INTENSITY LEVEL IN PATIENTS WITH HERNIATED NUCLEUS PULPOSUS OF THE INTERVERTEBRAL DISC

K. Koszela¹, S. Krukowska¹, M. Woldanska-Okonska¹
¹Medical University of Lodz, Poland, Department of Rehabilitation and Physical Medicine, Lodz, Poland

Introduction/Background

Back pain may be caused by many factors. In many cases it is difficult to unambiguously determine a cause of the pathology, which can involve various structures in the spine. In this paper we will discuss the symptoms associated with degenerative changes of the intervertebral disc, which involve, among others, its bulging, dislocation and pressure on surrounding structures. These problems require an adequate clinical and imaging diagnostics in order to implement an appropriate treatment. In the first place, it should be based on the conservative methods (such as: pharmacotherapy, rehabilitation and lifestyle changes). Only in the absence of improvement it is recommended to consider a surgical treatment. The aim of the study is to assess the impact of rehabilitation on the pain intensity level in patients with herniated nucleus pulposus of intervertebral disc.

Material and Method

The study was performed in 46 patients (age range: 19-85), including 26 women and 20 men. On the basis of imaging, all patients showed a presence of slipped disc with disc herniation. The patients were treated conservatively. For pain assessment was used the The Laitinen Modified Questionnaire Indicators of Pain and The Visual-Analogue Scale. The results were statistically analyzed.

Results

The results clearly demonstrate the analgesic efficacy of specialized rehabilitation in the spinal pain syndrome in discopathy with a spinal disc herniation of an intervertebral disc.

Conclusion

The rehabilitation of patients with a back pain due to the presence of herniated nucleus pulposus has a significant analgesic effect. In the case of a presence of the herniated nucleus pulposus, the rehabilitation should be considered in a first place. If no improvement, a possible surgery should be considered. An important element of a conservative treatment is an effective rehabilitation, which is of vital economic importance, because a therapy including surgery usually requires subsequent rehabilitation and is much more expensive.

ISPR8-1078
EFFECTS OF INFRARED RADIATION ON THE PATIENTS WITH CHRONIC LOW BACK PAIN AND ABSORPTION OF RADIATION (GHZ RANGE) ON LOW BACK REGION.

M.A. Shakoor
Bangabandhu Sheikh Mujib Medical University, Physical Medicine and Rehabilitation, Dhaka, Bangladesh

Introduction/Background
Chronic low back pain (CLBP) is very common in clinical physiatry. To find out the effectiveness of Infrared Radiation on CLBP and absorption of radiation on low back region the present study was conducted.

Material and Method
The study was done in two phases. In the first phase, a randomized clinical trial and in phase two, a simulation study was conducted.

Results
In phase one, out of 266 patients, 43.6 % were male and 56 % were female with the mean age of 46.30 ± 8.75 years. Group-A was treated with NSAID + Activities of daily living (ADL) + SWD, Group-B with NSAID + ADL + IRR and Group-C treated with NSAID +ADL. We found all modalities are effective (p = 0.001). But more improvement was found in SWD and IRR receiving groups (P= 0.001 table-1). SWD has some better effect than IRR but IRR is also effective to reduce CLBP.

In phase two, radiation was applied on human phantom of lower back region up to 25 mm thickness with GHz range. Radiation was applied from low frequency to high frequency and return loss was measured. It was found that when radiation with 99.899994 GHz to 100.1 GHz (~100 GHz) was applied the return loss was -26.901541 dB to -26.42996dB. This indicates that maximum absorption of radiation (~100%) and absorption rate increases with frequency.

Conclusion
It can be concluded that IRR can be used effectively to improve CLBP because absorption of radiation occurs (~100%) with GHz range and absorption rate increases with frequency. IRR, as it is handy and low costly instrument, can be used to reduce disability of the patient suffering from CLBP at home.

ISPR8-1161
RELATIONSHIP BETWEEN ABNORMAL POSTURE OF THE PATIENTS WITH ACUTE LOWER BACK PAIN AND MORPHOLOGIC DAMAGE OF FUNCTIONAL UNIT OF THE LUMBAR REGION ASSESSED BY MRI
S. Anicic¹, A. Vukomanovic¹
¹Military Medical Academy, Clinic for physical medicine and rehabilitation, Belgrade, Serbia

Introduction/Background

There are many publications connecting lower back pain and abnormal posture, yet establishing this relationship based upon pathoanatomical substrate within the lower back functional unit analyzed by MRI is much less documented. The aim of this study was to analyze a relationship between abnormal posture and various degrees of morphologic damage of lower back functional unit.

Material and Method

It was a retrospective study of 25 consecutive patients (14 males, aged 21-73 years and 11 females aged 18-56 years) referred to our department between 2015 and 2017 for the management of acute lower back pain. All patients underwent posture analysis and MRI of lower back spine. Statistical analysis: The Fisher exact test.

Results

Abnormal posture was found in all subjects: 17 sway back posture and 8 patients flat back posture. Subjects with the sway back posture abnormality were shown by MRI to have the following lesions: a bulging disc in 2 (11.7%), disc protrusion in 4 (23.4%), disc extrusion in 10 (58.8%) patients whereas 1 (5.8%) patient had disc sequestration. Flat back posture abnormality patients displayed disc protrusion in 2 (25%) subjects, disc extrusion in 5 (62.5%) and disc sequestration in 1 (12.5%) subject. All patient with the sway back posture had lesions on the facet joints, whereas the changes were noted in 5 (62.5%) subjects with the flat back posture, the Fisher exact test statistical value is 0.02, the result is significant at p < 0.05.

Conclusion

All patients with acute lower back pain had abnormal posture and morphologic disk damage analyzed by MRI. But, patients with the sway back posture abnormality had more significantly frequent morphologic damage of whole spine function units (which includes facet joints) and suffer from more advanced morphologic damage as well.

Scheuermann’s disease is the most common cause of hyperkyphosis during adolescence. There is substantial debate on optimal treatment. It is primarily non-operative; severe cases may require surgery. Despite the wide prescription of physical therapy (PT) and braces, they lack scientific validation. We purpose to summarize the current knowledge and controversies concerning the rehabilitation (conservative) management of this condition in adolescence.

**Material and Method**

A literature-based review of Spanish and English language medical publications on MEDLINE.

**Results**

Available studies are retrospective, uncontrolled, with different criteria. PT does not affect kyphosis progression. A postural improvement exercise program is recommended for symptomatic patients with short, non-progressing flexible curves. Bracing impacts patients’ self-esteem and common daily activities. The clinician cannot estimate whether bracing will improve the deformity, prevent progression, or lead to failure in any given patient. In skeletally immature adolescents with kyphosis > 60°, a brace program of at least 20 hours per day should be considered; it is largely regarded as being efficacious. The type of brace is generally prescribed based on the apex position in relation to T7. Modest overall long-term correction of the pre-brace deformity can be expected. Favorable outcome predictors comprise increased kyphosis’ flexibility, kyphosis < 65°, initial correction > 15° in a brace, and a minimum of one year of remaining growth. Pain relieving results have not been published. The treatment should be individualized and adjusted to each patient needs and surrounding context. Periodical clinical and x-ray follow-up until skeletal maturity is mandatory.

**Conclusion**

Future research focusing on the risk of progression of kyphotic curves, especially those between 70°-90°, is needed to guide treating physicians with regard to Scheuermann’s disease conservative approach. The non-operative tools are mainly in the Physical and Rehabilitation Medicine scope. However, most publications in this area have been made by Spinal Surgeons.

Low back pain (LBP) is a highly prevalence public health related problem with a substantial impact on the individual’s disability and daily functioning. The aim of this study is to provide an overview of the available evidence and to determine if the included studies follow a well-structured and homogenous design that allow an effective assessment of the impact of mobile health apps and web-based interventions in the self-management of LBP.

Material and Method

Electronic databases were searched from 2007 to 2017. The search strategy included the use of MESH terms and free-text terms, combining 3 concepts: low back pain, mobile applications and self-care. Randomized control trials (RCTs) and RCT protocols using mobile health apps or web-based interventions as part of the treatment for patients with LBP were included.

Results

A total of 17 articles concerning 14 different studies met the inclusion criteria. Nine completed RCTs included a total of 1659 participants. The majority of the participants were females and reported educational levels as partial college or higher. A wide range of outcome measures were used, although none of the studies reported on health care utilization. There was a significant variation in the reported results, even though some studies indicated improvement in certain outcomes favouring the intervention group. Three studies delivered the content through an app, accessible from multiple devices. Interactive elements were reported in every study.

Conclusion

The included studies did not follow a homogenous design, reporting numerous outcomes and heterogenous data. Therefore, it was not possible to establish a clear idea of its true impact. The protocols for future trials seem to evaluate more homogenous outcomes and are likely to provide future useful data. Apps and web-based interventions may be the solution to overcome current barriers and increase access to a quality, safe and cost-effective rehabilitation for LBP.

Introduction/Background

Juvenile idiopathic scoliosis (JIS) refers to scoliosis occurring between the ages of 4-10 and represents 10-15% of all idiopathic scoliosis. The growth potential rises the risk of curve progression and subsequent surgery. Curves that reach 30° tend to worsen without treatment. The general indication for surgery is a curve size > 50°. This case report aims to alert the clinicians to the value of looking beyond the Cobb angle when approaching JIS.

Material and Method

We present a case of JIS with a Cobb angle > 50° treated with bracing, evaluated in Physical and Rehabilitation Medicine outpatient.

Results

A 6-year-old girl with asymptomatic JIS and a structured 56° right thoracic curvature and Risser 0/5 was referenced to our department by the Spinal Surgeon to delay surgery. Clinically, she presented a 30 mm right thoracic hump in the Adams test and hypokyphosis. Brace treatment was started with a thoraco-lumbo-sacral-orthosis Boston, 23 hours per day. After 3 months and 1 year of treatment, the in-brace x-rays revealed a reduction of Cobb angle to 23° and to 20° respectively, and Risser 0/5. Currently, at 3-year follow-up, she has a 36° curve on out-of-brace x-ray and a 10mm hump on physical examination. The Orthotist technician care was crucial (she needed 3 braces and several adjustments). She maintains treatment with noteworthy compliance and continues asymptomatic.

Conclusion

Growth restriction and complications associated with spinal fusion make conservative treatment a frequent first option. Reports on the success of bracing in JIS range between 13-81%. Clinical experience, multidisciplinary approach (Physiatrist, Physiotherapist, Orthotist technician, Spinal surgeon) and compliance to bracing play a significant role. This case highlights the enduring importance of questioning ourselves if we are properly managing scoliosis in early ages. JIS natural history is not always the same; besides the growth potential and Cobb angle, we should consider other factors.

ISPR8-1232
EVALUATING THE WALKING PERIMETER IN PATIENTS WITH SPINAL STENOSIS. A COMPARISON BETWEEN CLINICAL INTERVIEW AND STANDARDIZED WALK TEST AT COMFORTABLE SPEED.
A. Gouteron¹, J.M. Casillas¹, D. Laroche², M. Grelat³
¹CHU de Dijon, Pôle de rééducation-réadaptation, Dijon, France
²CHU de Dijon, CIC-P (Inserm 803- plateforme d'investigation technologique, Dijon, France
³CHU de Dijon, Service de neurochirurgie, Dijon, France

Introduction/Background

Gait dysfunctions are common in patients with spinal stenosis. In fact, these patients may present intermittent radicular claudication, which result in a decreased walking perimeter. Thus in these patients, the walking perimeter reveals the impact of the disease on quality of life and accounts for the therapeutic decision, notably surgical. Usually, in clinical practice, walking perimeter is assessed by a medical interview. Some authors highlight the error of subjective verbal quantification. Therefore, the main objective was to quantify the difference between the walking perimeter determined using either a medical interview or a walk test at comfortable speed. The secondary objective was to correlate functional tests with walking perimeter.

Material and Method

In this monocentric study, each patient was asked to verbally estimate his walking perimeter during a preoperative consultation. Walking perimeter was then evaluated using a walking test at comfortable speed in which the patient walked a maximal distance. Functional muscular tests (Sorensen and Shirado) were also performed.

Results

Twenty patients have been included (age: 68.9±8.6 years, BMI: 28.7±3.5 kg.m⁻²). During medical interview, patients reported a significantly lower average walking perimeter than during walk test (317±178m and 442±99m respectively; p<0.05). Among functional tests (Shirado: 84.2±51.0s; Sorensen: 75.4±39.1s), only Shirado test was correlated with walking perimeter assessed by walk test (Shirado: r=0.48; p=0.03) whereas no correlation was found for walking perimeter assessed by medical interview.

Conclusion

Our study confirms previous results showing that subjective walking perimeter estimation is not a valid outcome. Patients with spinal stenosis underestimated their actual walking perimeter during the preoperative consultation. Thus comfortable walk test should be used in clinical practice to quantify the walking perimeter in patients with spinal stenosis, and more broadly,
because it seems correlated to functional capacities of patients. The underlying reasons explaining the difference observed need to be explored.

THE EFFICIENCY IN THE TREATMENT OF CHRONIC LOW BACK PAIN USING CORTICOSTEROID AND LIDOCAINE INFILTRATION GUIDED BY RADIOSCOPY

E. Rocha¹, P. Yokomizo², E. Suzigan², L. Honorato Cheng²
¹Santa Casa Sao Paulo, Rehabilitation Service, Santo André, Brazil
²Santa Casa Sao Paulo, Rehabilitation Service, Sao Paulo, Brazil

Introduction/Background

Lumbar facet joint arthritis is responsible for 15–45% of all cases of chronic low back pain and can be better characterized as regional pain, that gets worse with lower back rotation, extension, and physical exertion. One option for the treatment of facet syndrome is corticosteroid infiltration, which aims the pain relief by blocking the sensitive inervation of the lumbar facet joint. This study has the objective of evaluating the efficiency of the facet block using corticosteroid and lidocaine infiltration guided by radioscopy.

Material and Method

This was a prospective series of case study in which 26 patients with chronic low back pain caused by facet joint arthritis were treated with corticosteroid (methylprednisolone acetate) and lidocaine infiltration guided by radioscopy.

The pain and functional evaluations after the infiltration included: (a) pain, by Visual Analogic Scale; (b) axial movement amplitudes measuring axial spine extension angle in degrees, and distance between the hand and the ground in centimeters; (c) functional status, with the Roland-Morris questionnaire which has a Brazilian validated version. The evaluations were registered before the infiltration, 1 month, 3 months and 6 months after the procedure. After the data collection, a descriptive statistical analysis was performed using the t-paired test for continuous variables. Statistical significance was considered as p <0.05.

Results

Pain intensity showed a decrease of 42,3% 6 months after the treatment (p<0,05). Axial movement amplitudes, both extension and flexion, showed about 20% improvement (p>0,05). Functionality improved 28% after 6 months (p<0,05).

None of the patients showed any complication or side effects of the administered medications.

Conclusion
Lumbar facet block using corticosteroid and lidocaine is an effective and safe option of treatment for chronic lumbar pain, with functional improvement and pain relief within 6 months after the procedure.

EFFECTS OF ADHERENCE TO HOME EXERCISE PROGRAM ON PAIN AND FUNCTIONAL DISABILITY IN PATIENTS WITH CHRONIC LOW BACK PAIN: PRELIMINARY RESULTS

E. Korkmaz¹, N. Tuğay², B.U. Tuğay²
¹Muğla Sıtkı Koçman University- Research and Education Hospital, Physical Medicine and Rehabilitation, Muğla, Turkey
²Mugla Sıtkı Kocman University- Faculty of Health Sciences, Physiotherapy and Rehabilitation, Muğla, Turkey

Introduction/Background

Exercise is a well-documented effective treatment modality in selected low back conditions and for these effects to be permanent patients should adhere to their given home programs and suggestions. There are several studies reporting the effects of home programs but the degree of adherence and how the adherence effects the outcomes is not studied sufficiently. Therefore, the purpose of the present study was to investigate the adherence of the patients and the effects of adherence on pain and functional outcomes in patients with chronic low back pain.

Material and Method

20 patients (7 male, 13 female) who had low back pain complaints more than 12 weeks were participated in the study. Patients were treated in outpatient clinic for 15 seasons and discharged with a personalized home exercise program. Patient's pain levels (visual analogue scale – VAS) and functional status (Oswestry Disability Index – ODI) were evaluated at the beginning of treatment, at discharge and at the control visit 3 weeks within discharge and adherence to home exercise program (Exercise Adherence Rating Scale – EARS) were evaluated at the control visit 3 weeks within discharge.

Results

Mean age of the patients was 42.80±11.65 years. Pretreatment, discharge and 3 weeks control results of VAS were 6.32 ± 2.03, 5.49±2.04, 4.14±2.45 and ODI were 17.55±7.02, 14.60±6.09, 4.14±2.45 respectively. Mean EARS score at 3 weeks control was 39.10 ± 9.58. EARS scores revealed that 75 % of the patients did not adhere well with their programs. There was no significant relation between EARS and VAS scores (p>0.05). EARS and ODI scores was significantly correlated (r=-0.480, p=0.03).

Conclusion

Although these are the preliminary results on insufficient number of patients, our results suggest that patients with good adherence had better functional outcomes. As healthcare providers and researchers, we must focus on finding better strategies to increase patient adherence.

SPIRAL MUSCLE CHAIN TRAINING TREATMENT OF DISC HERNIATION AND SCOLIOSIS BY SPIRALLY STABILIZED MUSCULAR CORSET

A. Böhmerová1, R. Smíšek- MD1

1Rehabilitation Clinic Smíšek, Rehabilitation and Regeneration of the Spine, Prague, Czech Republic

Introduction/Background

We consider the cause of disc herniation and scoliosis to be peripheral muscle dysbalances manifested by instability within muscle chains. The muscle chains are divided into spiral systems stabilizing dynamic and static postures.

Material and Method

Spiral muscle chains encircle the body surface. Activity of spiral muscle chains of trapezius muscle TR and latissimus dorsi muscle LD starts with the movement of the shoulder blade and with arms back and forth that move vertebral processi spinosi. The contraction of the spiral chains continues to the opposite side of mm. rotatores, levatores costarum, followed by externus and internus abdominis muscles, gluteus maximus muscle, fascia lata, m. tibialis anterior. The TR and LD spirals retract the waist circumference and create upward force in the body – TRACTION OF THE SPINE. Extending the spine compensates the scoliotic curve – we can achieve lateral and rotational compensation of scoliotic curve as well as result of spiral chain contraction during specific therapeutic motions. The spiral activity reciprocally suppresses the activity of vertical muscle chains (ES - erector spinae, IP iliopsoas) as those would make traction impossible.

Results

The muscle chains activity can be trained individually or in groups. We check the activity of the muscle chains during the exercise and capture them in the photograph, sensorics guidance and the electromyography. We control the results by RTG and MRI.

Conclusion

We demonstrate individual examples because treatment always requires an individual approach.

**Introduction/Background**

Chronic low back pain [CLBP] affects a large number of people from different ages and has very diverse implications on patients' quality of life.

The main objective of this study was to assess the impact of CLBP on the degree of disability in performing daily tasks and on participation.

**Material and Method**

The sample consisted of 40 patients with CLBP. The inclusion criteria were: CLBP as the main complaint persisting for at least 12 months; age between 18 and 70 years old; not having pathologies that impair movement, such as neurological, traumatic or musculo-skeletal; and ability to read and write in Portuguese.

The Visual Analog Scale for Pain was used to measure pain intensity, the Roland Morris Disability Questionnaire was applied to assess the degree of disability and the Activity Profile and Participation related to Mobility questionnaire was performed to evaluate the activity and participation profile of the patients.

Nonparametric statistics were used to analyze and associate the results.

**Results**

The main results showed a significant correlation between pain grade, disability, and participation.

**Conclusion**

This study demonstrates that CLBP affects the magnitude of disability and has a negative impact on participation.

LANGER MESOMELIC DYSPLASIA
L. Cuevas¹, A. Rodríguez¹, C. Montoliu¹, M. Entrenas¹, C. Muñoz¹, E. Medina¹
¹Hospital General Universitario de Ciudad Real. No afiliado., Medicina Física y Rehabilitación, Ciudad Real, Spain

Introduction/Background

Langer mesomelic dysplasia or Leri-Weill dyschondrosteosis is a rare form of dwarfism characterized by short stature, shortening of limbs being more marked in legs than in forearms, hypoplasia of the ulna and fibula, and usually, normal intelligence. There may also be mandible hypoplasia and Madelung's deformity. In most cases it is produced by mutations and deletions in the SHOX gene, located in the sex chromosomes. The clinical manifestations in heterozygotes are variable in intensity, sometimes unnoticed, preventing genetic counseling. It is possible to perform the prenatal diagnosis by ultrasound at the beginning of the second trimester of pregnancy, and confirming by molecular genetic study.

There are few cases published in the literature, in many cases related to consanguinity.

Material and Method

We present a clinical case of a patient with Langer mesomelic dysplasia and scoliosis.

Results

Woman of 13 years and 8 months who goes for scoliosis evaluation.
Personal history: Langer mesomelic dysplasia and bilateral sensorineural hearing loss.
Reached menarche a year and a half ago. Belongs to the gypsy ethnic group.
Physical examination: Size 118.5 cm, minimal mandibular hypoplasia, severe shortening of all four limbs with Madelung deformity in the forearms. Normal hands and feet. Right thoracic and left lumbar scoliosis.
X-ray upper limbs: Deformity of Madelung.
Teleradiography of lower limbs: Bilateral fibular hypoplasia.
Teleradiography column: Right dorsal scoliosis of 28° and lumbar left of 37° with rotation grade 3. Risser 4-5.

Conclusion

Langer mesomelic dysplasia is a rare form of dwarfism. It is characterized by shortening of limbs and hypoplasia of the ulna and fibula. Although the presence of scoliosis in the Langer
mesomelic dysplasia is not described, for the few cases published in the literature, we can not rule out its association.

Vertebral osteomyelitis and discitis presents with insidious onset back or neck pain which is progressive over several days or weeks. While back and neck pain is common among adults of all ages, vertebral osteomyelitis and discitis occur infrequently and represent a diagnostic and therapeutic challenge.

Material and Method

Representative cases of bacterial and fungal infections of lumbar and cervical spine will be presented to illustrate key aspects of early diagnosis and treatment as well as prevention of sequela.

Results

Hematogenous spread of microbial agents, typically bacteria and less commonly fungi, is considered to be the most common cause of vertebral osteomyelitis and discitis. There is no direct blood supply to the intervertebral disc, and bone marrow of the vertebra have abundant blood flow, initial seeding is thought to be in the vertebra. Often, the primary origin of hematogenous spread cannot be identified. Back and neck pain caused by vertebral osteomyelitis and discitis may initially respond to conservative treatment and this may delay appropriate diagnostic studies and treatment.

There can be bone destruction in two adjacent vertebral bodies and their intervertebral disc even when diagnosis is made promptly and appropriate treatment is initiated without delay. Hence, there may be persistent back or neck pain despite appropriate and effective antimicrobial treatment. Supportive care with physical therapy, appropriate bracing, patient education regarding prevention of secondary injuries with close physiatry follow up and pain management during and after treatment of the infection is essential.

Conclusion

A series of representative cases with advanced imaging studies along with a review of the literature will be presented. Key features of back and neck pain syndromes with underlying spinal infection, diagnostic methods including laboratory and imaging studies and necessity of
multidisciplinary approach to diagnosis and treatment of vertebral osteomyelitis and disc infection will be discussed and key role of physiatry will be highlighted.

OSWESTRY DISABILITY INDEX AS EVALUATION TOOL IN PATIENTS WITH ONE LEVEL LUMBAR MICRODISCECTOMY - THREE MONTHS FOLLOW UP

T. Medić¹, A. Milovanović¹, T. Radovanović¹, Z. Railić¹, S. Rajević¹, S. Tomanović - Vujadinović¹

¹Clinical Center of Serbia, Clinic for physical medicine and rehabilitation, Belgrade, Serbia

Introduction/Background

Almost 80% of people, at least once in life, has back pain with or without leg pain. Lumbar disc herniation is in 95% of cases cause of lumbar radiculopathy. In about 10% of these patients there are indications for surgical treatment.

Purpose: Determine the effect of one level discectomy, and rehabilitation, on activities of daily living through Oswestry Disability Index (ODI).

Material and Method

Prospective clinical study included 50 patients with lumbar microdiscectomy, operated in Clinic for Neurosurgery. We used ODI, which the patients filled before, one month and three months after operation. All patients were included in early rehabilitation treatment of the algorithm of Clinic for PMR Clinical Center of Serbia. All 50 patients were in rehabilitation in stationar institution specializes in rehabilitation, duration of 21 days, one month after operation.

Results

24 (48%) patients were women, and 26 (52%) were male. Average were 41,4 years old. Average ODI were 54,2% before, 28,9% one month, and 16,3% (minimum disability), three months after operation and secondary rehabilitation. There is statistically significant difference between data collected in preoperative period and on first checkup, and also between data collected on first and second checkup. 82% patients had improvement on last checkup compared to preoperative condition. In 8% patients ODI remained unchanged at the last measurement in relation to the preoperative, while in 10% noted deterioration and increase in ODI of the last measurement in relation to the preoperative condition.

Conclusion

ODI showed good recovery of patients after lumbar microdiscectomy in first three months. The main benefit of operation was the reduction of pain in most patients. Well done surgical
treatment, and timely measures of early and secondary rehabilitation lead to improvement in patients after lumbar microdiscectomy three months follow up which is shown by ODI, the “gold standard” of low back functional outcome tools.

ELECTRICAL TWITCH-OBTAINING INTRAMUSCULAR STIMULATION (ETOIMS) AND NEEDLE ELECTRICAL INTRAMUSCULAR STIMULATION (NEIMS): CLINICAL OUTCOMES ON LOWER BACK MYOFASCIAL PAIN SYNDROME

C.C. Chiu1, S.H. Lee1

1Taipei Veterans General Hospital, Department of Physical Medicine and Rehabilitation, Taipei, Taiwan R.O.C.

Introduction/Background

To compare the effects of Needle Electrical Intramuscular Stimulation (NEIMS) with Electrical Twitch-Obtaining Intramuscular Stimulation (ETOIMS) in treating lower back myofascial pain syndrome.

Material and Method

Seventy patients with low back myofascial pain syndrome completed the study. They were randomly allocated into 2 groups. Outcome measures include Visual Analog Scale (VAS), pressure pain threshold (PPT) and Oswestry Disability Index (ODI) of lower back pain (LBP). Data were collected for comparison between both groups. The Mann-Whitney U-test was used for comparison of differences between independent group means.

Results

Significantly better results noted post-treatment results for ETOIMS group compared to NEIMS in pain level at rest immediately after treatment and overtime (p<0.001, p=0.005 respectively), pain during regular activity (p=0.003), pain during vigorous activity (p=0.001). There was also an increase in PPT immediate post-ETOIMS (p=0.037) and overtime (p=0.022). No significant differences noted for ODI (P=0.0749).

Conclusion

ETOIMS is significantly more effective than NEIMS in VAS and PPT but not significant better in ODI for low back myofascial pain syndrome patients.

EFFECTIVE ULTRASOUND-GUIDED INJECTIONS OF INCOBOTULINUMTOXINA IN THE MANAGEMENT OF PIRIFORMIS MUSCLE SYNDROME

C. Cordero-Garcia1, M.M. García-Delgado2

1Hospital Juan Ramón Jiménez, Department of Physical Medicine and Rehabilitation, Huelva, Spain
2Hospital Juan Ramón Jiménez, Emergency Department, Huelva, Spain

Introduction/Background

Piriformis muscle syndrome is a painful disorder characterized by buttock and hip pain usually due to sciatic nerve compression. Some previous works have studied the efficacy and safety of botulinum toxin in the management of piriformis muscle syndrome. Our objectives are analyze the efficacy of ultrasound-guided injections of incobotulinumtoxinA (Xeomin®) in the reduction of pain in piriformis muscle syndrome, and study if there are differences in the efficacy related with the dilution volume.

Material and Method

A retrospective cohort including patients admitted to Rehabilitation Department from January 1st 2015 to June 30th 2016 was analyzed. 58 patients who fulfilled the required criteria were registered. In all the included patients, Visual Analogical Scale (VAS) was measured before performing a ultrasound-guided injection of 100 Units of incobotulinumtoxinA in piriformis muscle, and 6 weeks after the injection. All the injections were performed by the same investigator. All the injections were performed using volume dilutions of 50 U/mL (n=18), 20 U/mL (n=19) or 10 U/mL (n=21).

Results

After performing Kolmogorov-Smirnov test, we checked that the data did not follow a normal distribution so a non-parametric test (Wilcoxon signed-rank test) was used. There was a statistically significant reduction of pain 6 weeks after incobotulinumtoxinA injection ($Z_W = -6.649$, $p < 0.01$). All dilutions showed statistically significant reduction of pain: (10 U/mL: $Z_W = -4.027$, $p < 0.01$; 20 U/mL: $Z_W = -3.837$, $p < 0.01$; 50 U/mL: $Z_W = -3.753$, $p < 0.01$).

Conclusion

IncobotulinumtoxinA seems to be an useful therapy in the management of piriformis muscle syndrome. There is no differences in the efficacy related with the volume of dilution.

Disclosure statement:
C. Cordero-García received research grant support and served as a consultant for Merz. M. M. García-Delgado has no potential conflict of interest to disclose. No funds were received for conducting this trial.
When an intervertebral disc degenerates, structural deterioration occurs in a wide range of anatomical components within and adjacent to the disc, being clearly represented in cross-sectional imaging. To suggest reliable and valid MRI-based morphologic parameters to quantify lumbar disc degeneration, the reliabilities of 6 parameters were analyzed to choose those with high reliability. The selected parameters were further tested to determine validity by correlating with disc height, which is regarded as a hallmark of structural integrity of the intervertebral disc.

Material and Method

85 patients over 60 years old who underwent MRI of the lumbar spine for mild low back pain were included. Two reviewers independently assessed the degree of degeneration and assigned one of the 4 ordinal scores from 0 to 3 in the following 6 parameters at 6 spinal segments: T2-signal intensity (T2-SI), disc extension beyond interspace (DEBIT), annular fissure, Modic changes, endplate integrity, and osteophytes. Inter-observer and intra-observer agreements were assessed using Cohen’s kappa statistic. For those parameters with high reliability, relationships with disc height were examined by calculating Pearson’s correlation coefficients.

Results

While intra-observer agreements were excellent for all parameters (weighted kappa range 0.801-0.875), the inter-observer agreements were substantial to excellent for T2-SI, DEBIT, Modic changes, and endplate integrity (weighted kappa range 0.629-0.874), moderate for osteophytes (weighted kappa 0.573), and only fair for annular fissure (weighted kappa 0.29). Modic changes (r=-0.497, p<0.01), endplate integrity (r=-0.359, p=0.01), and osteophytes (r=-0.448, p<0.01) showed strong relationships with disc height whereas T2-SI (r=-0.149, p=0.175) and DEBIT (r=-0.208, p=0.057) did insignificant correlations.

Conclusion

To quantify lumbar disc degeneration using MRI, Modic changes, endplate integrity, osteophytes, T2-SI, and DEBIT could be used as reliable parameters. However, different
weights might be applied to each parameter because validities to represent degeneration varied.

ISOTONIC VERSUS ISOMETRIC EXERCISES ON CORE MUSCLE IN PATIENTS WITH LOW BACK PAIN

F. Unver¹, A. Alarab¹
¹Pamukkale University, School of Physical Therapy and Rehabilitation, Denizli, Turkey

Introduction/Background

To observe the effects of isotonic and isometric exercises with conservative therapy on core muscle in patients with low back pain.

Material and Method

Twenty participants, 10 male and 10 female aged between 30 and 50 years suffering from low back pain were taken. Sample was divided into two groups, group A isometric exercises and group B isotonic exercises, both the group received conservative therapy of transcutaneous electrical neuromuscular stimulation and hot pack. Outcomes measure visual analog scale(VAS) and Modified Oswestry disability index (MODI) were used the pre-treatment and at the end of 4 weeks.

Results

There was no significant differences for the demographic data between the groups. Both group were comparable in term of age, height, weight, and BMI. Intergroup analysis of VAS score was done using Mann-Whitney test. Pre interventional analysis showed no significant differences between group A and group B (p=0.6469) and also post-intervention analysis showed no significant difference between group A and group B (p=0.3525). Analysis of MODI score was done using Mann-Whitney test, there was significant difference between group A (Mean=9.90, SD= 5.87) and group B (Mean=19.39, SD=7.27) in their post-test measurements (p=0.002). Experiment of results showed isotonic and isometric exercises were effective in all measured variables (pain intensity and functional disability) in treatment of patients with low back pain.

Conclusion

There was no difference between the use isotonic and isometric in decrease pain intensity, but there was significant differences in improvement functional disability where isometric exercises allow a greater improvement in functional disability than isotonic in low back pain.

Introduction/Background

Introduction

Low back pain (LBP) in children has been related to a serious problem for a long time. Recent studies have shown that no specific LBP in such age is as important as in adulthood and prevalence could reach 50%. Despite this high prevalence, it seems to be neglected by the child, family, and doctors. Such a high rate leads us to insist on meticulous clinical evaluation. Evaluation needs to include the measurement of trunk muscle strength and endurance. Our goals were to determine the prevalence of low back pain in children and adolescents, describe the characteristics of spine muscles endurance in children with LBP and showing the interest of muscles evaluation.

Material and Method

We conducted an analytical cross-sectional study about 444 students, 201 boys and 243 girls, with average age of 14.95 years. Evaluation includes anthropometric assessment, extensibility of sub pelvic muscles and the endurance of back muscles and quadriceps with spine examination.

Results

The prevalence was 22.3%, 95% CI (18.2 to 26.2). This prevalence increases with age with a marked female predominance. Muscles endurance was lower in the LBP group (p<0.001 Sorensen test). More weakness was identified in extensors muscles with high signification (shirado/ Sorensen p<0.001).

Conclusion

Low back pain in children and adolescents is a common symptom, multifactorial, which is responsible of limitations of school and leisure activities. Trunk Muscles weakness may be a
consequence or a cause of pain. Surely, it leads to chronic pain. The study of muscles endurance is necessary for diagnosis, rehabilitation and survey.

LOWER BACK PAIN AND SELF-PERCEIVED FUNCTIONAL DISABILITY AMONG HOSPITAL NURSES IN TAIWAN
C.Y. Yang\textsuperscript{1}, S.F. Huang\textsuperscript{2}
\textsuperscript{1}Taipei Veterans General Hospital, Physical Medicine and Rehabilitation, Taipei, Taiwan R.O.C.
\textsuperscript{2}Taipei Veterans General Hospital, Neural Regeneration and Repair Division-Neurological Institute, Taipei, Taiwan R.O.C.

Introduction/Background

Among nursing practitioners, lower back pain is the most common work-related musculoskeletal disorder. Lower back pain is associated with increased work absenteeism, decreased quality of life, and poorer quality of patient care. Moreover, back-related problems are among the most frequently cited reasons for nurses to quit the nursing profession. In this present study, we aim to identify the magnitude and predictive factors of occupational lower back disability.

Material and Method

This study involved a cross-sectional survey of 217 hospital female nurses. The self-administered questionnaire was distributed from January 1, 2007 to March 31, 2007 to all full-time registered nurses employed by Keelung Hospital. The questionnaire collected self-reported information including demographic and work-related characteristics, current or previous history of lower back pain, characteristics of back pain, and disability caused by back pain. The Institutional Review Board of Keelung Hospital approved this study.

Results

The point prevalence of back pain among hospital nurses was 43.78%, and of which, 79.5% was minimally disabled, 19.3% was moderately disabled and 1.1% was severely disabled, based on the Oswestry Low Back Pain Disability Questionnaire. The results of Roland Morris Disability Questionnaire showed a mean disability score of 4.28 (±4.11) out of 24 points. The degree of disability did not correlate with pain score, age, duration of the current pain episode, or years at work.

Conclusion

Back pain is common among hospital nurses in Taiwan. However, it is important to note that most of the hospital nurses who had lower back pain at the time of completing the self-administered questionnaires had low-degree disability. The degree of disability does not associate with pain score, age, duration of the current pain episode or years at work.

THE EFFECTIVENESS OF MATRIX RHYTHM THERAPY IN PATIENTS WITH CHRONIC LOW BACK PAIN

N.T. Ozcan¹, B. Basakci Calik², A. Tez³
¹ Süleyman Demirel University, Isparta Health Services Vocational School, Isparta, Turkey
² Pamukkale University, School of Physical Therapy and Rehabilitation, Denizli, Turkey
³ Isparta State Hospital, Physical Therapy and Rehabilitation Clinics, Isparta, Turkey

Introduction/Background

In the literature, there is a very few studies showing the efficacy of Matrix Rhythm Therapy in patients with chronic low back pain is rather low. Our study was planned to determine the effect of Matrix Rhythm Therapy on level of disability, quality of life and pain in chronic low back pain.

Material and Method

A total of 32 participants (18 female, 14 male) with a mean age of 36.41 ± 8.91 years were randomly divided into two groups (Study Group and Control Group). Each participant was treated with ten sessions a combined physiotherapy program (hot pack, TENS, therapeutic ultrasound, home exercise and patient education program). Additionally, study group received six sessions of Matrix Rhythm Therapy. Pain (McGill Pain Questionnaire), Level of disability (Oswestry Disability Index) and quality of life (Short Form-36) were measured at baseline and after the treatment programme.

Results

In the study group, there was a statistically significant decrease in all sub-parameters relating pain severity, disability level and Short Form-36 sub-parameters except Short Form-36 "Emotional Function" sub-parameter after the treatment (p≤0.05). In the control group, there was a statistically significant decrease in other sub-parameters relating pain severity except the "Lightest Pain" sub-parameter, the disability level, and Short Form-36 "Vitality" and "Pain" sub-parameters (p≤0.05). When the groups were compared, there was no significant difference between the study group and the control group except the Short Form-36 "General Health" sub-parameter (p>0.05).

Conclusion

As a result, it was determined that both combined physiotherapy program and Matrix Rhythm Therapy applied together with combined physiotherapy program have a positive effect on pain, disability level and quality of life in patients with chronic low back pain.

Keywords

Diabetic lumbosacral radiculoplexopathy (DLR) is a peripheral diabetic neuropathy. Usually occurs in poorly controlled type 2 diabetes mellitus (DM2). Predominates in men over 60 years old. Exact etiopathogenesis is unknown. It’s characterized by acute or subacute onset of asymmetrical lower limb (LL) neuropathic pain, occasionally also of the lower back, of nocturnal exacerbation, with absence of the knee reflex and sometimes mild sensory symptoms. Pain is followed by weakness and muscle atrophy affecting commonly the proximal thigh muscles over weeks to months. It may be accompanied or preceded by significant weight loss. Later in the course of the illness, pain and weakness may spread to distal leg segments and to the contralateral extremity. Most patients gradually recover function spontaneously, but recovery can be incomplete.

Material and Method

We present the case of a 72 year old man, DM2, with left LL weakness, difficulty to walk and climb stairs of months of evolution. One year ago, he presented a lumbosciatica with irradiation and hypoesthesia through the anterolateral aspect of the thigh that was treated with analgesics, gabapentin, spinal kinesitherapy and LL strengthening; after that pain and hypoesthesia disappeared and distal lower left limb weakness progressively appeared. At physical examination we found left quadricipital atrophy, psoas, quadriceps and hamstring muscular balance was 4/5 and anterior tibial muscle 2/5 (foot drop) following Daniels scale, absence of patellar reflex and no sensory alterations were found. Electromyography showed signs of subacute denervation in left root territories L4-5-S1. Magnetic resonance didn’t showed compressive polyradiculopathy. Last 4 years glycemias were above 200 mg/dl. We prescribed LL strengthening and gait reeducation with a foot-up.

Results

Strength improved in LL and acquired a more functional gait with foot-up.

Conclusion

DLR has to be included in the radiculopathy differential diagnosis in diabetic patients. Follow-up must be done in order to identify possible progressions.

OBSERVATION OF THE EFFECT OF DORSAL ABDOMINAL MUSCLE STRENGTH TRAINING ON LUMBAR DISC HERNIATION

Z. Haina1, X. Guangmeng2, Z. Jun2, Z. Yizhii3

1The Second Hospital of JiLin University, the Rehabilitation Department, Chang Chun, China
2The Second Hospital of JiLin University, the General Surgery Department, Chang Chun, China
3The Second Hospital of JiLin University, the Neurology Department, Chang Chun, China

Introduction/Background

To explore the role of dorsal abdominal muscle strength training in the rehabilitation of lumbar disk herniation and the prevention of recurrence.

Material and Method

61 patients with lumbar disk hernia were randomly divided into 2 groups, 31 in the observation group and 30 in the control group. All of them were treated with medium frequency pulse, ultrashort wave and traditional Chinese medicine massage. The observation group was trained with the dorsal abdominal muscle strength training additionally. Both groups were treated for 3 weeks and followed up for half a year. JOA and VAS scale were used to evaluate two groups of patients before and after treatment.

Results

After 3 weeks of treatment and half of a year’s follow-up, the score of JOA was increased and the VAS score decreased both in the observation group and the control group. The observation group were better than the control group($P<0.05$). The recurrence rate of the observation group was significantly lower than that in the control group.

Conclusion

Muscle strength training has good effect on the treatment of lumbar disc herniation and the prevention of recurrence.

Keywords

ASSESSMENT OF NECK PAIN IN CHRONIC OBSTRUCTIVE PULMONARY DISEASE
A. Yılmaz¹, A. Ünal¹, O. Telli Atalay¹, F. Altug¹
¹Pamukkale University, School of Physical Therapy and Rehabilitation, Denizli, Turkey

Introduction/Background

Supplementary respiratory muscles such as upper part of the trapezium and scalenes are used extensively in order to facilitate ventilation in Chronic Obstructive Pulmonary Disease (COPD). These situations cause pain restricting the upper body mobility and neck movements. This study was planned to investigate the presence of neck pain in individuals with COPD.

Material and Method

In this study, 30 patients (W: 5 / M: 25) were evaluated with COPD. The severity of pain was determined according to Visual analog scale (VAS). Spirometric measurements were used to determine the respiratory parameters. Neck Disability Index were used to determine severity of neck disability level.

Results

Mean age of patients was 69.93 ± 9.46 years. Mean of pain intensity was 2.35± 2.77 and pain duration 46.47± 123.64 weeks. The mean FEV1% of all patients was 58.96 ± 19.15, FVC% was 72.73 ± 25.78 and FEV1 / FVC ratio was 64.43 ± 21.18. There was a positive correlation between pain intensity and FEV1 and FVC (r = 0.368, p = 0.046), (r = 0.382, p = 0.037). There was a positive mean moderate correlation between duration of pain and smoking and alcohol use (r = 0.652, p = 0.005 / r = 0.655, p = 0.004). The mean of Neck Disability Index was 26.65 ± 19.70. All patients have a mild disability level. We did not find a significant correlation between Neck Disability Index and spirometric parameters.

Conclusion

Individuals with COPD have neck pain. When these patients rehabilitate, musculoskeletal problems, such as neck pain should be considered.

Keywords

neck pain, chronic obstructive pulmonary disease, neck disability level

Introduction/Background

Back pain prevalence ranges from 7 to 58% of subjects aged between 13 and 15, equally distributed in males and females. Back pain is thought to be associated with spinal deformities but no studies investigated the prevalence of back pain in different spinal deformities like, spondylolisthesis, scheuermann disease, hyperkyphosis, scoliosis. AIM: To document the prevalence of back pain, in all its forms in a large population of adolescents with spine deformities and to investigate the association of back pain and different spine pathologies.

Material and Method

All the patients visited in 2010-2015 were asked for pain at first clinical evaluation by a single expert physician. PAINGroup and NOPAINGroup were formed. Pain description was then classified into 4 subtypes (localized or generalized, limiting or occasional). Inclusion criteria: age between 10 and 18, spine deformity diagnosis, Exclusion criteria: secondary deformities and other associated pathologies. Descriptive statistics. T-test to check the difference in the two groups considered for SRS-22 score, age and BMI. Chi-2 test to check the association between the presence of pain and diagnosis and pain subtypes; sports activities and previous treatment with brace.

Results

702 included patients (males n=468), mean age 13.3+1.92. Subjects’ diagnosis: adolescent idiopathic scoliosis (n=387;55.1%), sagittal unbalance (idiopathic) (n=134; 19.1%) Scheuermann deformities (n=67;9.55%); all other diagnosis (n=114; 16.2%). In AIS 32% referred pain, 55%in sagittal unbalanced patients and 52% in Scheuermann disease. Only Scheuermann disease predispose to pain (chi2= 10.2 Fisher exact test = 0.002), Sagittal unbalance is slightly associated to pain with chi2 = 3.65 Fisher exact test = 0.05.. BMI, Age, sports and brace were not associated with SRS-22.

Conclusion

This is the first study investigating the epidemiology of different type of back pain in a large adolescents population with spinal deformities, Scheuermann deformity resulted associated to pain.

END-GROWTH RESULTS OF A PERSONALISED CONSERVATIVE APPROACH IN 1938 HIGH RISK ADOLESCENTS WITH IDIOPATHIC SCOLIOSIS: PROSPECTIVE OBSERVATIONAL MULTICENTRE STUDY

S. Donzelli¹, S. Negrini², F. zaina³, F. Di Felice³
¹Italian Scientific Spine Institute, isico, Milano, Italy
²University of Brescia, Chair of Physical and Rehabilitation Medicine, Brescia BS, Italy
³Italian Scientific Spine Institute, isico, Milan, Italy

Introduction/Background

End of growth RCTs showed the efficacy of bracing and Physiotherapic Scoliosis Specific Exercises (PSSE). Current Guidelines propose PCA according to the step-by-step theory: invasivity increases with treatment intensity, from observation to PSSE to soft, rigid and very rigid bracing. This requires to set individualised outcomes and propose the less invasive treatment according to the outcome.

Material and Method

Inclusion criteria: AIS, 11-45°, Risser 0-2, age 10-16, first consultation, no previous bracing. End of observation: Risser 3, medical prescription. Groups were defined according to the main end outcome (SRS-SOSORT Consensus): Low Degree (LD) (<31° at start) remain <30°; High Degree (HD) (>30° at start) remain <50°. Treatment: PCA including observation, PSSE (SEAS school), soft (SpineCor), hard (Sibilla) and very rigid (Sforzesco) braces. Classical statistics and propensity scores have been applied.

Results

We excluded 207 (10.7%) drop-outs and 274 (14.1%) still in therapy. Treatment intensity increased with Cobb degrees, as well as rate of improvement (from 13.6% to 56.1% - P<0.05). Rate of progression was higher in the less intensively treated very low degree curves (11-20°) (P<0.05), while did not change significantly in those above 20° (between 12.9 and 15.9%). Rate of patients <30° were 69.3% at start and 78.3% at the end (P<0.05); patients >50° at the end were 1.6%.

Conclusion

Defining different outcomes according to PCA allows to perform less aggressive treatments for LD, and concentrating the efforts in HD. Failure rates can be low in both groups. Progression is not the best outcome for all patients and type of treatments.

LUMBAR SPINAL STENOSIS IN ADULT ACHONDROPLASIA. AN ANALYSIS OF INTERVERTEBRAL DISK ALTERATIONS

J. Beaudreuil¹, T. Huet², M. Cohen-Solal², P. Orcel², A. Yelnik³
¹GH St.Louis-Lariboisière-F.Widal- Paris Diderot University, PRM and Rheumatology, Paris, France
²GH St.Louis-Lariboisière-F.Widal- Paris Diderot University, Rheumatology, Paris, France
³GH St.Louis-Lariboisière-F.Widal- Paris Diderot University, Physical and Rehabilitation Medicine, Paris, France

Introduction/Background

Lumbar spinal stenosis is a major contributor to disability in adults with achondroplasia. It arises from congenital dysplasia and acquired degenerative changes. The aim of the study was to characterize degenerative changes of the intervertebral disk in adult achondroplasia patients with lumbar spinal stenosis and to identify factors associated with the process.

Material and Method

The study was a case series of adult achondroplasia patients. Clinical parameters were recorded. Radiographs were used to analyze spino-pelvic parameters. MRI of the lumbar spine was used to measure antero-posterior diameter of the canal and disk degeneration using the Pfirrmann grading system. Comparisons were done using the Kruskal-Wallis test and correlations using the Spearman coefficient.

Results

Eighteen patients were included: age 37±17, female 12, size 127±7 cm, weight 57±13 kg. All had symptoms due to lumbar spinal stenosis. Antero-posterior diameters of the spinal canal differed according to level (P<0.05). Lower values were observed at T12-L1, L1-L2 and L2-L3 levels. The lumbar spinal stenosis was maximal at L2-L3 (9.9±1.8 mm). Degrees of disk degeneration also differed according to level (P<0.05). Higher degrees of degeneration were observed at L1-L2, L2-L3 and L3-L4 levels. Most advanced degenerative changes were observed at L2-L3 (2.9±1.4). Correlation analysis between disk degeneration and spino-pelvic parameters found a significant relationship with thoraco-lumbar kyphosis at L2-L3 level (0.55). Correlation analysis between antero-posterior diameter of the spinal canal and the spino-pelvic parameters found a significant relationship with lumbar lordosis at T12-L1 (0.66) and L2-L3 (0.89) levels, and with thoraco-lumbar kyphosis at L1-L2 level (-0.55).

Conclusion

Spinal stenosis and disk degeneration mainly involve the upper part of the lumbar spine in adult achondroplasia patients. Thoraco-lumbar kyphosis and lumbar lordosis are related with these
processes. The findings may be of importance in rehabilitation and in early prevention of spinal stenosis in the course of achondroplasia.

4GH St.Louis-Lariboisière-F.Widal- Paris Diderot University, Rheumatology, Paris, France

Introduction/Background

Deconditioning syndrome in chronic low back pain is admitted. However, profile of physical fitness, on the basis of energy expenditure, is controversial. The goal of the study was to assess physical fitness in chronic low back pain patients using markers of energy expenditure.

Material and Method

This was a case-control study. Patients with chronic low back pain and healthy age- and sex-matched controls underwent bicycle exercise test, up to muscle exhaustion. Recorded energy variables were: duration of exercise in seconds, maximal power (P max) in watts, percentage of age-predicted maximum heart rate (HR max) and metabolic equivalents (MET). Pain intensity using the 0-100-VAS, pain duration and functional limitation using the Quebec scale were also assessed in chronic low back pain patients. Relationship between energy variables and clinical parameters was investigated using the Spearman correlation coefficient. Results of both groups were compared using the Student t test.

Results

192 chronic low back pain patients (age 44±8, ratio M/F 106/86, pain intensity 47±19, pain duration 51±57 months, Quebec 39±16) and 325 healthy controls (44±8, ratio M/F199/126) were included. Duration of exercise (-0.23), P max (-0.21), and MET (-0.29) were related with the Quebec score in chronic low back pain patients (p<0.05). There was no other relationship between energy variables and clinical parameters. Energy variables were not different in both groups as they were globally considered. However, chronic low back pain patients with highest functional limitation (the fourth quartile of the Quebec scores) had lower duration of exercise (349±134 vs 431±189), lower P max (129±39 vs 147±49), and lower MET (7±2 vs 8±2) than healthy controls (p<0.05).

Conclusion
Physical fitness was not altered in the entire chronic low back pain population. However, physical fitness appeared to be decreased in chronic low back pain patients with highest functional limitation.

COMPARATIVE STUDY OF MORPHOSTATIC FOOT DISORDERS BETWEEN A LOW BACK PAIN POPULATION AND A HEALTHY POPULATION

E. Toulgui¹, W. Ouaness¹, R. Moncer¹, S. Mtawaa¹, S. Frioui¹, M. Gaddour¹, S. Jemni¹
¹Hopital Sahloul, Physical Medicine and Rehabilitation, Sousse, Tunisia

Introduction/Background

Chronic low back pain is one of the most common musculoskeletal disorders. The association between low back pain and plantar static disorders was always mentioned in the studies but an analytical and comparative study with healthy subjects is needed to confirm this hypothesis.

Material and Method

It is a cross-sectional analytical study conducted in the PMR department of Sahloul hospital, Tunisia during the period from January to March 2017. Patients with symptomatic low back pain or complicated neurological disorders, patients with Pelvic statics related to chronic inflammatory rheumatism, and patients with unequal lower limb length were not included in this study. We recruited 35 low back pain patients and 35 asymptomatic patients matched by age, gender and body mass index.

Results

Talalgia was more frequent in the low back pain population with a significant difference (P <0.001). Regarding the foot posture index we found that the low back pain population had more pronation deformations with a flat foot type and a greater calcaneo-tummy angle than healthy subjects (p <0.001).

Conclusion

Morphostatic examination of the foot is still necessary in any lumbar pain patient. Our study confirms that the pronated flat foot is the most common foot type associated with low back pain. But Are these disorders a cause or a consequence of low back pain? Furthers studies are necessary to establish a cause and relationship effect.

Keywords

Introduction/Background

Nowadays tuberculous spondylitis, also known as Pott disease, is a rare clinical condition but can cause severe vertebral and neurological sequelae that can be prevented with an early correct diagnosis.

Material and Method

We conducted a retrospective study including 12 records of hospitalized patients in the physical medicine and rehabilitation department in Sahluol Hospital, Sousse during the period from 2010 to 2017. The diagnosis was based on the presence of MRI and / or microbiological arguments.

Results

The average age of our patients was 46 years [23-82 years], with a female predominance (8 women).

The most common symptom was back pain reported in 10 patients while cough, fever, night sweats and weight loss were less frequently reported. At admission, a neurologic deficit was present in 9 cases. The thoracic segment was the most frequent spinal segment affected (in 7 cases), followed by lumbar spine (in 2 cases). For bacteriological diagnosis of tuberculosis, positive cultures were reported in only 7 of patients. Microbiological and histological diagnosis was obtained by surgery biopsy in 3 cases. Antituberculous treatment was initiated as soon as the diagnosis was confirmed for all patients, with 2 months of HRZE followed by 9 to 12 months of HR. Surgery was realised, with a median delay of 1month, to patients that presented neurological deficits caused by spinal cord compression (in 4 cases), spinal deformity with instability (in one case), severe or progressive kyphosis (in one case) and large paraspinal abscesses (in 2 cases).

Conclusion

Tuberculosis involvement of the spine has the potential to cause serious morbidity, including permanent neurologic deficits and severe deformities. Medical treatment or combined medical and surgical strategies can control the disease in most patients.

REHABILITATION CARE OF PATIENTS WITH SPONDYLITIS: A TUNISIAN EXPERIENCE

H. Ikram¹, E. Toulgui¹, W. Ouanness¹, O. Jelassi¹, S. Frigui¹, S. El Arem¹, S. Jemni¹

¹Sahloul University Hospital, Physical medicine and rehabilitation department, Sousse, Tunisia

Introduction/Background

Infections of the spinal cord and surrounding structures can damage neurologic structures. The aim of this study is to share our clinic experience about spinal infection rehabilitation.

Material and Method

We conducted a retrospective study including 26 records of hospitalized patients in the PMR department in Sahloul Hospital, Sousse during the period from 2010 to 2017. The diagnosis was based on the presence of MRI and/or microbiological arguments.

Results

The average age of our patients was 57.11 years [23-82 years], with a sex ratio of 0.85.

The most common symptom was back pain reported in 20 cases. At examination, 25 of patients presented motor disorders. The rehabilitation treatment was realized in a delay varying between 6 and 200 days with a median of 58 days. The majority of patients were hospitalized with a stage ASIA C (9 cases). The complications observed in 20 patients were dominated by neuropathic pain (16 cases), spasticity (10 cases), pressure sores (6 cases), urinary infections (4 cases) and deep venous thrombosis (one case). Neuropathic pain intensity was evaluated by the DN4 score with an average of 6/10. If spasticity increased functional limitation, patients with diffuse spasticity (10 cases) used oral antispastic medications. Botulinum toxin was used one time to treat focal spasticity. The majority of patients had significant functional changes from rehabilitation admission to discharge. At the beginning the MIF score ranged from 44 to 125 with an average of 75.2. After rehabilitation care, the MIF score ranged from 54 to 125 with an average of 96.4. Psychological status was also evaluated using the HAD scale. In our study, 41% of patients had depressive symptomatology.

Conclusion

The whole medical team must handle the rehabilitation of patients with spinal infection and they should identify the assessment and rehabilitation program as early as possible.

NEUROLOGICAL COMPLICATIONS OF SPONDYLITIS: A RETROSPECTIVE STUDY OF 26 PATIENTS.

H. Ikram1, E. Toulgui1, S. Mtaouaa1, O. Jelassi1, W. Ouaness1, S. El Arem1, S. Jemni1

1Sahloul University Hospital, Physical Medicine and Rehabilitation Department, Sousse, Tunisia

Introduction/Background

Spondylitis is an uncommon but serious infection of the disco vertebral junction with frequent involvement of neural structures including the spinal cord. This study was undertaken to determine most frequent neurological complications of septic spondylitis.

Material and Method

We conducted a retrospective study including 26 records of hospitalized patients in the PMR Department in Sahloul Hospital, Sousse during the period from 2010 to 2017. The diagnosis was based on the presence of MRI and/or microbiological arguments.

Results

The average age of our patients was 57.11 years [23-82 years], with a sex ratio of 0.85. The chief of complaint was walking disorders (in 20 cases), spinal pain (in 15 cases), and sphincter control problems (in 10 cases). On examination, 23 patients presented motor disorders. Sensitive disorders were found in 14 cases and sphincter control problems objectified in the neureofunctional examination in 10 cases. The thoracic segment was the most frequent spinal segment affected (in 9 cases), followed by lumbar spine (in 5 cases). In our study, there were 12 cases of tuberculous spondylodiscitis, 6 of Brucella spondylitis and 8 cases of pyogenic spondylitis.

Surgery was realised, with a median delay of 1 month, in patients that presented neurological deficits caused by spinal cord compression (in 4 cases), spinal deformity with instability (in one case), severe or progressive kyphosis (in one case) and large paraspinal abscesses (in 3 cases). The lumbar segment was the most associated with neurological complications (in 4 cases) and the most incriminated germ was Koch bacillus (in 8 cases). The neurological deficits occurred on average on the eighth day of antibiotic therapy.

Conclusion

The disease course is chronic and the lack of specific symptoms often delays diagnosis. This is responsible of its potentially high morbidity and mortality.

THE EFFECTIVENESS OF PHYSICAL THERAPY FOR PATIENTS WITH LUMBAR SPINAL STENOSIS

M. Maraoui¹, M. Sghir¹, A. Abdallah¹, B. Krita¹, S. Zrour², W. Kessomtini¹

¹CHU Tahar Sfar, Physical Medicine and Rehabilitation, Mahdia, Tunisia
²CHU Fattouma Bourguiba, Rhumatology, Monastir, Tunisia

Introduction/Background

The lumbar spinal stenosis (LSS) is a narrowing of the spinal canal, it may be constitutional and/or acquired. Rehabilitation has a major role in the management, medical treatment and surgery of LSS. The aim of this study was to evaluate the short-term results of rehabilitation in LSS.

Material and Method

It was a prospective study carried out on patients referred to the Physical Medicine and Rehabilitation department of Mahdia between July and December 2016 for radiologically-confirmed LSS. All patients had received a medical treatment associated with a rehabilitation program during 2 months, with pre- and post-treatment evaluation. Leg and back pain intensity at rest and while walking were measured with the visual analogical scale (VAS). The functional disability was determined using The Quebec Back Pain Disability Scale. The treatment satisfaction was measured using a Lickert verbal scale.

Results

Thirty-two patients were included (21 women and 11 men), with a mean age of 57 years. Radiculalgia was the most common symptom (78%) with a limitation of the walking distance in 72.7% of cases. The VAS score for pain at rest was 60.7 and while walking was 81.2.

The physical examination revealed a postural syndrome in 75% of the cases, a spinal syndrome in 54% of the cases and a radicular syndrome in 46% of the cases. The mean Quebec Back Pain Disability Scale score was 68.

After treatment, there was significant improvement in the VAS and Quebec scores. Seventy-five percent of patients were satisfied or very satisfied with this treatment.

Conclusion

The management of LSS is multidisciplinary based on the association of medical and physical treatment while surgery is rarely indicated.

THE ASSOCIATION OF MODIC-1 CHANGES, PARASPINAL MUSCLE ATROPHY, PAIN AND FUNCTION IN PATIENTS WITH LUMBAR DISC HERNIATION

S. Demir-Deviren¹, H. Cil¹, Z.L. McCormick², J. Lotz¹, S. Berven¹
¹University of California San Francisco, Department of Orthopaedic Surgery/Spine Center, San Francisco, USA
²University of Utah School of Medicine, Division of Physical Medicine and Rehabilitation, Salt Lake City, USA

Introduction/Background

Modic-1 changes is a radiographic finding of inflammatory changes in the bone marrow adjacent to the vertebral body endplate. Prior investigation demonstrates that patients with Modic-1 changes have less improvement in low back pain (LBP) after discectomy. Atrophy and fatty infiltration of the paraspinal muscles are often observed in LBP patients, and correlate with poor physical performance. Our aim is to investigate the relationship between Modic-1 changes, LBP, functional disability, and lumbar paraspinal muscle changes in patients with symptomatic disc herniations.

Material and Method

This study is a cross-sectional, case-control study at a tertiary spine center. Lumbar multifidi and erector spinae (ES) muscles atrophy and fatty infiltration were assessed on axial MRI.

Results

Nine consecutive patients with Modic-1 changes and 12 without Modic-1 changes, all of whom who were scheduled to have discectomy for symptomatic disc herniation, were enrolled. The groups with and without Modic-1 changes were similar in age (p=0.118). Participants with Modic-1 changes had a higher percentage of atrophy in the multifidi compared to those without Modic-1 changes (p<0.002). In participants with Modic-1 changes, greater fatty infiltration in the multifidi and ES muscles was associated with higher Visual Analogue Pain Scale (VAS) scores (multifidi r=0.733 p=0.025; ES r=0.846, p=0.004) and Oswestry Disability Index (ODI) scores (multifidi r=0.773; p=0.015). This relationship did not exist in participants without Modic-1 changes.

Conclusion

In this cohort of patients with symptomatic lumbar disc herniations, an association between Modic-1 changes, greater atrophy and fatty infiltration in the lumbar multifidi and ES muscles, as well as higher pain and functional disability scores was observed. These data suggest the need for a larger longitudinal study in order to determine if a causal relationship exists between
Modic-1 changes, lumbar paraspinal muscles changes, and the influence of these factors on the magnitude of LBP and functional disability in patients with these findings.

**Keywords**

paraspinal muscle; disc herniation; modic-1 changes

*No conflict of interest*
Atrophy and fatty infiltration of the paraspinal muscles are consistently observed in patients with low back pain (LBP), which correlate with functional disability. We aimed to (1) characterize changes in lumbar paraspinal muscle volume and fatty infiltration over time in patients with LBP and Modic-1 degenerative disc disease (DDD) and (2) compare such muscle changes at levels of Modic-1 DDD with levels lacking Modic 1 changes.

Material and Method

This is a cross-sectional cohort study at a single urban, academic, tertiary spine center. Changes in lumbar paraspinal muscle volume and fatty infiltration were assessed within each individual by comparing baseline and follow-up MRIs. The volumes of the multifidi, erector spinae(ES), and psoas muscles were measured on T1-weighted axial MRI.

Results

Nine patients with LBP who presented to our center with a prior baseline lumbar MRI that showed Modic-I DDD and underwent a repeat MRI at least one year after baseline MRI were included. Nine patients (median-interquartile range [IQR] age: 43±21 years; seven females) were included. The median time between MRIs was 17 months(IQR ±11). The total volume of the multifidi and psoas muscles from L1 to sacrum decreased significantly from baseline to follow-up MRI(p<0.023). At the level(s) of Modic-I DDD, the percentage of fatty infiltration in the multifidi and psoas muscles was significantly higher compared to levels without Modic-I DDD (p<0.040).

Conclusion

Our data suggest that Modic-1 DDD is associated with adjacent paraspinal muscle atrophy and fatty infiltration in LBP patients. A larger study is warranted with a comparison group that lacks the radiographic finding of Modic-1 DDD, as well as longitudinal assessment of physical function in relation to paraspinal muscle changes. Further investigation is needed to determine the ability of targeted physical therapy to prevent paraspinal muscle changes in patients with Modic-1 DDD and to assess the effect on LBP symptoms and physical function.

THE INFLUENCE OF COCCYGEAL MOBILITY ON GANGLION IMPAR BLOCK TREATMENT RESULTS IN CHRONIC COCCYGODYNIA

S. Sencan¹, I. Cuce², O. Karabiyik³, F.G.U. Demir⁴, O.H. Gunduz⁵

¹Marmara University Pendik Training and Research Hospital, Department of Physical Medicine and Rehabilitation- Division of Pain Medicine, Istanbul, Turkey
²Adiyaman University Training and Research Hospital, Department of Physical Medicine and Rehabilitation, Adıyaman, Turkey
³Kayseri Training and Research Hospital, Department of Radiology, Kayseri, Turkey
⁴Kayseri Training and Research Hospital, Department of Physical Medicine and Rehabilitation, Kayseri, Turkey
⁵Marmara University School of Medicine, Department of Physical Medicine and Rehabilitation- Division of Pain Medicine, Istanbul, Turkey

Introduction/Background

Chronic coccygodynia is a difficultly diagnosed and treated disorder characterized by intractable pain in the coccygeal region. A ganglion of impar block can be applied for the patients who do not respond to conservative treatments. A more detailed pathoanatomy of coccyodynia helps to identify patients who may benefit from the planned treatments. The aim of this study was to research the role of coccygeal mobility in patients with chronic coccygodynia who underwent ganglion impar block on treatment success.

Material and Method

We retrospectively examined data from patients with chronic coccygodynia who had not respond to conservative treatment and once were performed fluoroscopy-guided transsacr coccygeal ganglion impar block. The patients, whose standard and dynamic lateral coccyx radiographies were evaluated and classified considering coccygeal mobility. Before and after the intervention (1 hour, 4, 12 and 24 weeks), pain scores were evaluated with numeric rating scale (NRS). Significant pain relief was accepted as a reduction in the NRS score of 50% or more.

Results

Of 37 patients included in the study, 14 had normal coccyx mobility (Normal Group, 40.64±13.14 years), while the remaining 23 patients had immobile coccyx (Immobile Group, 45.39±13.5 years). NRS scores were significantly decreased in both groups on each time follow up. Before and after the intervention, there was no significant difference in NRS scores between two groups. Significant pain relief respectively was achieved in 42.9% and 61.9% of patients of normal and immobile group at the last follow-up examination (p>0.05).
Conclusion

Transsacroccocygeal ganglion impar block can be considered a safe and alternative treatment approach with reduced pain scores in conservative management-resistant chronic coccygodynia. Normal and immobile coccyx in patients with chronic coccygodynia seems to be two different coccyx mobility patterns that do not affect the success of this treatment.

Fluoroscopically-guided lumbar epidural steroid injections (ESI) have proven to be an effective nonsurgical treatment option for painful spinal conditions. There are increasing concerns about the safety of ESI amid its increased utilization and popularity since the early 2000s. Previous studies on adverse events did not differentiate more serious complications from those that are likely to self-resolve. We define “Life-Altering Adverse Events” (LAE) as those complications resulting in persistent functional impairment. These LAEs have been limited to case reports and their true incidence is unknown. For the purposes of patient education and safety, this study was conducted to identify and analyze LAEs related to lumbar ESI in recent publications.

Material and Method

Review of the literature was conducted using the electronic database PubMed in addition to a manual review of bibliographies of known primary and review articles. We limited the results to non-duplicating studies of fluoroscopically-guided lumbar ESI from 2002 to current. 51 publications were included and reviewed.

Results

Since 2002, a total of 31 cases of LAEs have been published. Sixteen (51.6%) were related to direct neurological injury with spinal cord infarct as the predominating cause. Nine (29.0%) severe infectious complications (discitis, abscess, osteomyelitis, meningitis) were reported. Six (19.4%) cases involving vascular insults secondary to epidural hematoma, arteriovenous fistula, retinal hemorrhage and stroke were documented. Although, the true incidence is impossible to determine, of the 41,466 cases reviewed in this time-frame, the approximate incidence is equal to 0.07%.

Conclusion

When considering the large number of procedures performed annually, this review finds that a patient’s risk of experiencing a LAE when undergoing a properly performed lumbar ESI is extremely rare. When the appropriate safety measures are taken, such as risk stratification and adherence to the current evidence based guidelines, risk to the patient should be further minimized.

Therapeutic Education in Chronic Back Pain

M. Enjalbert
Centre Bouffard-Vercelli, MPR, CERBERE, France

Introduction/Background

Back pain is a frequent reason for consultation in our practice and we decided to set up a therapeutic education program to complete our care plan. We initiated this program in 2017, with the authorization of Regional Health Agency.

Material and Method

The inclusion in the program results from the decision of a multidisciplinary meeting including a PRM doctor, a rheumatologist, a neurosurgeon, a pain specialist and a labor doctor. It's an alternative to others classical care used in back pain treatment. A preliminary medical consultation permits to make an educational diagnosis before the program. Another medical consultation permits to evaluate the results of this program. We study the first year activity.

Results

43 patients (23 male, 20 female) with a medium age of 48.5 years (24-72) were included in the program. They represent 67.4 % of the cases discussed in the multidisciplinary meeting during the same time (132). The pain assessed by visual analogic scale decreased after the program: 5 (4-8) vs 8 (6-10). The pain medication also decreases in 11 patients (25.6 %). 40 patients (93.1 %) were satisfied (26, 60.5 %) or very satisfied (14, 32.6 %). Only 3 patients were unsatisfied (6.9 %), 0 very unsatisfied. 34 patients (79.1 %) were in working age and only 12 (35.3 %) of them are working before the program. 5 others patients were back in the workplace after the program, giving a total of 17 patients (50 %).

Conclusion

The therapeutic education is an interesting alternative to others treatment of chronic back pain. It takes into account physical, psychological and socio-professional sizes of the chronic back pain. It's a part of larger program including medications, rehabilitation and others non-drug treatments, interventional radiology and surgery. A strengthened monitoring of these patients is necessary to complete the action of this therapeutic education program.

THE RELATION BETWEEN PAIN INTENSITY AND DEPRESSION IN PATIENTS WITH CHRONIC LOW BACK PAIN

S. Milicevic¹,², Z. Bukumiric³, A. Corac⁴
¹Clinic for rehabilitation Dr Miroslav Zotovic, Spinal cord injury, Belgrade, Serbia
²State University in Novi Pazar, Department for Biomedical Science, Novi Pazar, Serbia
³Medical Faculty in Belgrade, Institute of Medical Statistics and Informatics, Belgrade, Serbia
⁴Medical Faculty Pristina, Department of Preventive Medicine, Kosovska Mitrovica, Serbia

Introduction/Background

Background and aims: The impact of chronic pain on psychological symptoms such as depression, anxiety, sleep disturbance and quality of life has been the subject of interest of many researchers. However, the relationship between the intensity and duration of pain and depression is still unclear. The aim of this study was to examine the relationship between the intensity and duration of pain and depression in patients with chronic low back pain.

Material and Method

Methods: In this cross-sectional study 25 patients with low back pain were treated at the Clinic for Rehabilitation Dr M. Zotovic in Belgrade. For evaluation of pain intensity, depression and neuropathic component of pain Visual Analog Scale (VAS), Beck Depression Inventory (BDI) and DN4 questionnaire (DN4 Questionnaire) was used. Statistical hypotheses were tested at the 0.05 level of statistical significance.

Results

Results: The average age of the respondent was 58.7±11.3. There were 8 males (32%) and 17 women (68%). Median VAS score is 5.5. The median duration of pain was 7 months. The average value of BDI score is 12.4 ± 8.9. Of the total number of respondents 7 (28%) had neuropathic pain component. Median DN4 questionnaire is 6.5.

The results of our study showed that there is a statistically significant correlation between BDI and VAS and BDI intensity of pain (p <0.001).

Conclusion
Conclusion: the results of our data establish that CLBP is associated with depression. Screening for depression in CLBP patients should be an essential part of CLBP patient care.

CURATIVE EFFECT OF MUSCLE FUNCTION AND PROPRIOCEPTION IN PATIENTS WITH CHRONIC LUMBAR DISK HERNIATION USING DIFFERENT KINESITHERAPIES

B. Xia
1Shanghai Gongli Hospital- Shanghai Pudong New Area, Department of Rehabilitation Medicine, Shanghai, China

Introduction/Background

To evaluate the curative effect of muscle function and proprioception in patients with chronic lumbar disk herniation using two different kinds of kinesitherapies: isokinetic trunk muscle strength training and core muscle training.

Material and Method

Eighty patients with clinical features of lumbar disk herniation were randomly divided into treatment and control groups (40 patients in each group) according to the random number table. All participants were given routine rehabilitation treatment, including interferential electrotherapy, microwave therapy, lumbar traction treatment, and other physical therapies. The patients in the treatment group were provided isokinetic trunk muscle strength training, which lasted for 8 weeks, three times per week. The patients in the control group were provided core muscle training, which lasted for 8 weeks, three times per week. The improvement in patient's motor and sensory functions before and after treatment was evaluated using lower back pain standard scoring criteria of Japanese Orthopedic Association (JOA), Oswestry disability index (ODI), and visual analogue scale (VAS).

Results

After 8-week continuous training, the trunk muscle strength evaluation indexes of the patients in the two groups significantly increased compared with those before treatment. Moreover, the JOA, ODI, and VAS scores suggested that both treatments could significantly improve lumbar function about trunk muscle strength、Rehabilitation evaluation of lumbar function、Lumbar proprioception assessment. Further, the ontology sense test indicated that both training methods induced an obvious change that absolute error value of proprioception is reduced after routine rehabilitation treatment and isokinetic trunk muscle strength training treatment.

Conclusion

This study showed that isokinetic trunk muscle strength training could improve proprioception in patients with chronic lumbar disk herniation, but also enhance muscle function, compared with core muscle training.
Keywords

isokinetic trunk muscle strength training; chronic lumbar disk herniation

Introduction/Background

Sacroiliac Joint Dysfunction (SIJD) can explain about 15% to 30% the presence of idiopathic low back pain (LBP). SIJD can be diagnosed through the sacroiliac pain provocation tests (PPT), considering SIJD when 3 or more tests are positive. The aim of the study was to establish the prevalence of SIJD and sacroiliac PPT in people with LBP.

Material and Method

One hundred and thirty-six people with LBP of both genders, with 29±12 years old and BMI 23.35±2.9 Kg/m² were evaluated. A trained physical therapist applied six sacroiliac PPT with the best psychometric properties described in the literature (Distraction, Thigh thrust, Gaenslen, Compression, Sacral thrust and FABER).

Results

A prevalence of 40% of SIJD was found. Most prevalent tests were FABER and Sacral Thrust, while Distraction test was the least prevalent (Figure). Twenty-five percent of the population presented one positive test, 16% had at least 3 positive tests and only 5% of participants had 6 positive tests.

Conclusion

To our knowledge, there are no reports in the literature of the individual prevalence of sacroiliac PPT. According to the results, during the examination of people with low back pain suspected of having SIJD, FABER and Sacral Thrust tests should be done first, followed by compression and Gaenslen tests. The above mentioned could avoid unnecessary sacroiliac stress and pain to the patients’ joint.

Keywords

Sacroiliac pain; Provocation tests; Prevalence

Intervention/Background

Low back pain (LBP) is a high-incidence, high-burden condition. The most common form of LBP is non-specific low back pain (NSLBP). Whole body vibration (WBV) exercise remains ambiguous as a therapy for LBP patients based on the current evidence. To confirm the benefits of whole body vibration (WBV) exercise for pain, muscle strength and proprioceptive function in patients with non-specific low back pain.

Material and Method

This was a 2-arm single-blind randomized controlled trial. Eighty-six subjects met the inclusion criteria, they were randomly allocated to either the WBV exercise group (n=43) or control group (n=43). The WBV exercise group performed WBV exercise twice a week for 12 weeks. The control group received exercise protocol that was similar to the WBV exercise group, but without vibration, twice a week for 12 weeks. Primary outcome measures were the visual analog scale (VAS) for pain and adverse events. The secondary outcome measures included muscle strength and endurance of spine, trunk proprioception. Intention-to-treat analysis was conducted if any participants withdraw from the trial. An intention-to-treat analysis was conducted if any participants withdrew from the trial.

Results

Compared with the control group, the WBV exercise group provide additional beneficial effects for in terms of VAS (P<0.001), lumbar joint position sense (P<0.05), peak torque of the trunk flexors and extensors (P<0.05), and muscle endurance of trunk flexors and extensors (P<0.05). There were no adverse events or serious adverse events in either group.

Conclusion

The study demonstrated that WBV exercise could provide more benefits than general exercise in terms of relieving pain and improving trunk neuromuscular function in patients with NSLBP.

THE CLINICAL STUDY OF KINESIO TAPING WITH JOINT MOBILIZATION IN THE TREATMENT OF NONSPECIFIC LOW BACK PAIN
J. Qiao¹, L. Kunpeng²
¹Shanghai second rehabilitation hospital, Department of rehabilitation therapy, Shang Hai, China
²Shanghai second rehabilitation hospital, Department of neurorehabilitation, Shang Hai, China

Introduction/Background

Kinesio tape is one of the most widely used soft tissue patch technologies, which has a considerable effect on the soft tissue injury. Meanwhile, joint mobilization technology now is regarded as the most effective way to treat with chronic low back pain as it has been tested in the past ten years of modern research. This study will embark on nonspecific chronic low back pain patient as our research object, and with soft tissue patch technology and joint mobilization technology involved, we adapted contrasted experiment, and pay attention to the changes of evaluation indications. Our goal is to discuss the affection and clinical curative effect of joint mobilization technology and soft tissue patch technology in the treatment of chronic low back pain. And we also want to give you some new thoughts on the effect of soft tissue patch technology and joint mobilization technology in this disease.

Material and Method

Elderly patients with nonspecific low back pain were randomly divided into observation group (using Kinesio Taping with joint mobilization as well as conventional modalities, 18 cases) and control group (using only conventional modalities, 13 cases). Back flexion and extension muscle peak torque (PT), visual analogue scale (VAS) and Oswestry Pain & Disability Questionnaire (OPDQ) were assessed before and after the intervention.

Results

At baseline there were no significant difference between two groups; After 1 week of treatment, PT was significantly higher in the observation group than that of the control group (P <0.05). The differences of VAS and OPDQ were statistically significant after one week of treatment compared with the control group (P <0.01).

Conclusion

KT with JM may be more favorable in improving symptoms and dysfunctions in elderly patients with nonspecific low back pain.
Keywords

Low back pain; Kinesio Taping; joint mobilization

No conflict of interest
Introduction/Background

The aim of this study was to determine the effects of sacroiliac joint (SIJ) manipulation, sacroiliac and lumbar home exercises on pain, sacroiliac mobilization levels and functional status in patients with sacroiliac joint dysfunction syndrome (SIJDS).

Material and Method

In a prospective, randomized interventional trial 69 eligible women were assigned to SIJ manual therapy + sacroiliac home exercise group (Group 1, n=23), SIJ manual therapy + lumbar home exercise group (Group 2, n=23) (n=19), or lumbar home exercise group (Group 3, n=23). All the patients who were included in the study were evaluated on the 0th, 28th day and 90th day of the treatment. Specific tests (motion palpation and pain provocation tests) for SIJ were performed. Activity and rest pain was assessed by using the Visual Analogue Scale (VAS). Functional status and quality of life were assessed using the Modified Oswestry Disability Index (MODI) and Short Form-36 (SF-36), respectively.

Results

The VAS scores significantly decreased in all three groups (p<0.05). Gillet test, Vorlauf test, Posterior Shear Test (POSH), Irritation point test and Compression test showed significant decrease after treatment in both training groups (p<0.05). A significant improvement was determined in MODI, quality of life scores, SF-36 and neuropathic pain in all three groups (p<0.05). However, a more significant improvement was detected with manual therapy and sacroiliac home exercise program compared to patients in group 2 and group 3.

Conclusion

Our data suggest that manual therapy, sacroiliac and lumbar exercises programs can be effective in patients with sacroiliac joint dysfunction syndrome.

LOW BACK PAIN AFTER EPIDURAL PROCEDURES: A MINOR COMPLICATION?
T. Pimenta¹, R. Costa¹, S. Moreira¹, J. Barroso¹, F. Parada¹
¹Centro Hospitalar de São João, Physical and Rehabilitation Medicine, Porto, Portugal

Introduction/Background

Among others, low back pain (LBP) is a common minor complication after epidural analgesia or anesthesia (EA). However, it may indicate a major problem. We present two cases of spinal epidural empyema (SE) after EA.

Material and Method

Clinical information regarding case presentation, imaging and laboratory data was obtained from electronic clinical records and office visits in the Physical and Rehabilitation Medicine (PRM) Department.

Results

Case 1: 36-year-old woman submitted to epidural analgesia during labor developing within a few days persistent LPB irradiating to the lower limbs and progressing to motor and sensory impairment in left lower limb and lumbosacral segments with urinary and fecal incontinence. Magnetic Resonance (MR) showed epi and subdural empyema at D11-L5 levels with cauda equina involvement. She underwent surgical drainage and started a motor and neuro-urologic rehabilitation program.

Case 2: 74-year-old man given an epidural anesthesia during a total knee arthroplasty and developing LBP two months after surgery with mild sensorimotor deficit at the lower limb. MR showed epidural abscess/empyema at L1-L2 levels. The man was treated conservatively with progressive improvement.

Conclusion

Epidural procedures are generally safe, but serious adverse events can occur, such as SE, and diagnostic delays may contribute to adverse neurological outcomes and the need for prolonged rehabilitation programs. Although rare, true incidence is unknown. The PRM physicians should be aware of this complication in order not to underestimate a LBP after an epidural procedure. MR is paramount for diagnosis and follow-up. Further information is needed regarding incidence of SE and clinical predictors of those having higher risk for this potentially serious complication.

Manual therapy techniques based on Mulligan's concept (mobilizations with movement) are gaining increasing popularity for use in musculoskeletal conditions, such as low back pain (LBP). However, to date, no systematic review has been conducted to investigate the effectiveness of Mulligan's techniques on LBP. Therefore, the aim of this study was to evaluate the evidence on the effectiveness of Mulligan's techniques on LBP.

Material and Method

PubMed/Medline, Scopus, Ovid, CINAHL, Embase, PEDro, Google Scholar, and Cochrane Library were searched through July 2017 for studies reporting outcomes of pain or disability in adult patients (≥18 years) with LBP. Two authors screened the results and extracted data for use in this review. The risk of bias was evaluated using the Cochrane Back and Neck Review Group criteria. Additionally, the level of evidence of each included study and strength of conclusion for pain and disability were determined using the 2005 classification system of the Dutch Institute for Healthcare Improvement.

Results

Twenty studies with 693 patients were included. Nine trials focused on sustained natural apophyseal glides techniques, three on spinal mobilizations with limb movements, and seven on bent leg raise. The results showed that Mulligan's techniques can decrease pain and disability and increase range of motion in patients with low back pain; however, the strength of conclusion for pain and disability was moderate. Furthermore, inconclusive results were observed for the effectiveness of Mulligan's techniques on movement speed. In this review, eight studies (40%) were categorized as low risk of bias, while 12 studies (60%) had high risk of bias. Level of evidence analysis revealed that 17 studies (85%) were classified as level of evidence B, while three studies (15%) were classified as level of evidence A2.

Conclusion

Current evidence is insufficient in supporting the benefits of Mulligan's techniques on pain, disability, and range of motion in low back pain patients.

EFFECTIVENESS OF SLUMP STRETCHING ON LOW BACK PAIN: A SYSTEMATIC REVIEW AND META-ANALYSIS

M.R. Pourahmadi, H. Hesarika, A.R. Shamsoddini

1Iran University of Medical Sciences, Department of Physiotherapy, Tehran, Iran
2Baqiyatallah University of Medical Sciences, Department of Orthopedic Surgery, Tehran, Iran
3Baqiyatallah University of Medical Sciences, Exercise Physiology Research Center- Life Style Institute, Tehran, Iran

Introduction/Background

The slump test is a type of neurodynamic test, which is believed to evaluate the mechanosensitivity of the neuromeningeal structures within the vertebral canal. The objective of this review was to investigate the effectiveness of slump stretching on back pain and disability in patients with low back pain (LBP).

Material and Method

We searched 9 electronic databases (PubMed/Medline, Scopus, Ovid, CINAHL, EBSCO, Embase, PEDro, Google Scholar, CENTRAL). Publication language was restricted to English language articles and we searched the full time period available for each database, up to October 2017. Our primary outcomes were pain and disability and the secondary outcome was range of motion (ROM).

Results

We identified 12 eligible studies with 515 LBP patients. All included studies reported short-term follow-up. A large effect size (SMD=-2.15, 95%CI=-3.35 to -0.95) and significant effect were determined, favoring the use of slump stretching to decrease pain in patients with LBP. In addition, large effect size and significant result were also found for the effect of slump stretching on disability improvement (SMD=-8.03; 95%CI=-11.59 to -4.47) in LBP population. A qualitative synthesis of results showed that slump stretching can significantly increase SLR and active knee extension ROM.

Conclusion

There is very low to moderate quality of evidence that slump stretching have positive effects on pain in people with LBP. However, the quality of evidence for the benefits of slump stretching on disability was very low. Finally, it appears that patients with non-radicular LBP may benefit most from slump stretching compared to other types of LBP.

TEST-RETEST RELIABILITY OF SIT-TO-STAND AND STAND-TO-SIT ANALYSIS IN PEOPLE WITH AND WITHOUT CHRONIC NON-SPECIFIC LOW BACK PAIN

M.R. Pourahmadi1, I. Ebrahimi Takamjani1, J. Sarrafaizadeh1, S. Jaberzadeh2

1Iran University of Medical Sciences, Department of Physiotherapy, Tehran, Iran
2Monash University Peninsula Campus,
School of Primary Health Care- Faculty of Medicine- Nursing and Health Sciences, Melbourne, Australia

Introduction/Background

Sit-to-stand (STD) and stand-to-sit (SIT) analysis can provide information on functional independence in daily activities in patients with low back pain (LBP). However, in order for measurements to be clinically useful, data on psychometric properties should be available. The main purpose of this study was to investigate intra-rater reliability of STD and SIT tasks in participants with and without chronic non-specific LBP (CNLBP). The second purpose was to detect any differences in lumbar spine and hips sagittal plane kinematics and coordination between asymptomatic individuals and CNLBP patients during STD and SIT.

Material and Method

Twenty-three CNLBP patients and 23 demographically-matched controls were recruited. Ten markers were placed on specific anatomical landmarks. Participants were asked to perform STD and SIT at a preferred speed. Peak flexion angles, mean angular velocities, lumbar to hip movement ratios, and relative phase angles were measured. The procedure was repeated after 2 h and 6–8 days. Differences between two groups were analyzed using independent t-test. Intraclass correlation coefficient (ICC 3,k), standard error of measurement (SEM), and limits of agreement (LOAs) were also estimated.

Results

The ICC values showed moderate to excellent intra-rater reliability, with relatively low SEM values (≤10.17°). The 95% LOAs demonstrated that there were no differences between the measured parameters. Furthermore, CNLBP patients had limited sagittal plane angles, smaller angular velocities, and lumbar-hip discoordination compared to asymptomatic participants.

Conclusion

The results showed moderate to excellent test-retest reliability of STD and SIT analysis. Moreover, CNLBP patients had altered kinematics during STD and its reverse compared to asymptomatic participants.

KINEMATICS OF THE SPINE DURING SIT-TO-STAND USING MOTION ANALYSIS SYSTEMS: A SYSTEMATIC REVIEW OF LITERATURE

M.R. Pourahmadi¹, I. Ebrahimi Takamjani¹, J. Sarrafzadeh¹, S. jaberzadeh², M.A. Sanjari³

¹Iran University of Medical Sciences, Department of Physiotherapy, Tehran, Iran
²Monash University Peninsula Campus, School of Primary Health Care- Faculty of Medicine- Nursing and Health Sciences, Melbourne, Australia
³Iran University of Medical Sciences, Department of Rehabilitation Basic Sciences, Tehran, Iran

Introduction/Background

Clinical evaluation of the spine is commonplace in musculoskeletal therapies such as physiotherapy, physical medicine/rehabilitation, osteopathic, and chiropractic clinics. Sit-to-stand (STS) is one of the most mechanically demanding of daily activities and crucial to independence. Difficulty or inability to perform STS is common in individuals with a variety of motor disabilities such as low back pain. The purpose of this systematic review was to evaluate available evidence in literature to determine 2D and 3D kinematics of the spine during STS in patients with LBP and healthy young adult participants using motion analysis systems (electromagnetic and marker based).

Material and Method

Electronic databases PubMed/Medline (NLM), Scopus, Science Direct, and Google scholar were searched between January 2002 and February 2017. Additionally, the reference lists of the articles that met the inclusion criteria were also searched. Prospective studies published in peer-reviewed journals, with full text available in English, investigating the kinematics of the spine during STS in healthy subjects (mean ages between 18-50 years) or in patients with low back pain (LBP) using motion analysis systems, were included. Sixteen studies fulfilled the eligibility criteria. All information relating to methodology and kinematic modelling of the spine segments along with the outcome measures were extracted from the studies identified for synthesis.

Results

The results indicated that the kinematics of the spine are greatly changed in LBP patients. In order to better understanding of spine kinematics, studies recommended that the trunk should be analyzed as a multi-segment. It has been shown that there is no difference between the kinematics of LBP patients and healthy population when the spine is analyzed as a single-segment. Furthermore, between-gender differences are present during STS movement.

Conclusion
This review provided a valuable summary of the research to date examining the kinematics of the spine during STS.

THE EFFECT OF ELASTIC THERAPEUTIC TAPING ON ABDOMINAL MUSCLE ENDURANCE IN PATIENTS WITH CHRONIC NON-SPECIFIC LOW BACK PAIN: A RANDOMIZED, CONTROLLED, SINGLE-BLIND, CROSSOVER TRIAL

M.R. Pourahmadi\textsuperscript{1}, R. Bagheri\textsuperscript{2}, I. Ebrahimi Takamjani\textsuperscript{1}, J. Sarrafzadeh\textsuperscript{1}
\textsuperscript{1}Iran University of Medical Sciences, Department of Physiotherapy, Tehran, Iran
\textsuperscript{2}Semnan University of Medical Sciences, Neuromuscular Rehabilitation Research Center- Department of Physiotherapy, Semnan, Iran

Introduction/Background

Chronic non-specific low back pain (CNLBP) patients have decreased muscle activity and altered motor control of the abdominal musculature. The aim of this study was to determine the acute effect of elastic therapeutic taping and sham taping of the abdominal musculature on maximum hold time of endurance tests in CNLBP patients.

Material and Method

Twenty-six CNLBP patients and 26 asymptomatic individuals were recruited in this study. The outcome measures were maximum hold time of supine isometric chest raise, supine double straight-leg raise, and abdominal drawing in maneuver. Following the recruitment process, the CNLBP participants were allocated to an elastic therapeutic tape group or a sham tape group. Standard adhesive elastic therapeutic tape was utilized for facilitatory application in the elastic therapeutic tape group. The elastic therapeutic tape group received real elastic therapeutic taping on the transversus abdominis and internal obliques and the sham tape group received sham elastic therapeutic taping application. For the sham group, the elastic therapeutic tape was positioned horizontally above the navel and applied without tension. After a wash-out period, each CNLBP participant was switched to the other group.

Results

The CNLBP participants had lower maximum hold time compared to the asymptomatic individuals ($p \leq 0.01$). Following taping, both groups showed an increase in the maximum hold time (mean difference $= 4.43 - 50.69$ s; $p \leq 0.02$). Although there was no difference between the results of both groups ($p \geq 0.12$), effect sizes were large for elastic therapeutic tape group (Cohen's $d = -1.00 - -1.93$).

Conclusion

Abdominal musculature endurance could be improved by the application of elastic therapeutic tape.

LUMBAR SPINE LORDOSIS DURING SIT-TO-STAND AND STAND-TO-SIT TASKS IN PEOPLE WITH AND WITHOUT CHRONIC NON-SPECIFIC LOW BACK PAIN: A CROSS-SECTIONAL STUDY

M.R. Pourahmadi1, I. Ebrahimi Takamjani1, J. Sarrafzadeh1
1Iran University of Medical Sciences, Department of Physiotherapy, Tehran, Iran

Introduction/Background

Changes in normal lumbar lordosis can result in abnormal biomechanics of the lumbar spine. It has been shown that the loss of lumbar lordosis can be considered an initiating event of lumbar spine sagittal plane imbalance. The main objective of this study was to evaluate lumbar lordosis during sit-to-stand (STD) and stand-to-sit (SIT) in individuals with and without chronic non-specific low back pain (CNLBP). The secondary objective was to investigate sex-related differences in lumbar lordosis during STD and SIT.

Material and Method

Twenty-six CNLBP patients and 26 demographically-matched controls were recruited. Reflective markers were placed over the spinous process of T12, L3, S2, and the anterior and posterior superior iliac spines. The participants were instructed to stand up at a self-selected pace, and maintain their normal upright standing posture for 3 sec, and then sit down. Kinematic data was recorded at a sampling frequency of 100 Hz using a motion capture system. Lumbar lordosis angle was calculated from the intersection between the line joining T12 and L3, and the line joining L3 to S2.

Results

The results indicated that lumbar lordosis values were significantly decreased in CNLBP patients compared to asymptomatic controls during STD and SIT (mean difference[MD]=2.07°–10.50°;p≤0.001). Furthermore, no significant differences were seen in lumbar lordosis values at starting position between CNLBP and asymptomatic groups during STD (MD=1.69°–3.67°;p≥0.09). Interestingly, female participants usually had significant greater lumbar lordosis values compared to male participants during STD and SIT (MD=3.80°–9.49°;p≤0.04). However, this difference was not statistically significant for lumbar lordosis values at starting position during STD and for lumbar lordosis values at starting and end positions.

Conclusion

Decreased lumbar lordosis in CNLBP patients during STD and SIT could be considered as an important point during rehabilitation. Moreover, this study showed that there is a sex-related difference among females and males in lumbar lordosis during STD and SIT.

Introduction/Background

Chronic low back pain (CLBP) is a worldwide problem with important personal and socio-economic implications. Mostly no specific cause is identified, and CLBP is considered “non-specific”. Structural changes in the lumbar multifidus (LM) are seen in these patients, but relationship with symptoms or clinical outcome is not yet clear. Insight in the factors influencing these structural characteristics is crucial to improve understanding of this relation. Ultrasound is a promising tool in the evaluation of LM structure because it is dynamic, widely available, cheap and safe. Its reliability and validity for the evaluation of the LM was demonstrated already. The objectives of this review are to provide an overview on the current knowledge on ultrasound imaging of structural features of the LM in healthy subjects and patients with CLBP, and to improve the knowledge on factors influencing these characteristics.

Material and Method

A systematic search was performed in the databases Pubmed, Embase and Web of Science (last search on 18/10/2017). Additionally, reference lists of the included articles were screened. Selection of studies, data collection and assessment of risk of bias (Downs and Black checklist) was done by two independent reviewers (SR and ER). Eligibility criteria for inclusion in the review were:

- Full text available in English, Dutch or French
- Adults >18 years
- Asymptomatic or patients with non-specific CLBP (> 3 months)
- Outcome: structural characteristics (cross-sectional area, thickness, change during contraction, fatty infiltration) of the LM measured by ultrasound
- Exclusion: intervention studies, relation with prognostic factors, reliability or validity studies

Results

1064 studies were screened for eligibility, of which 70 studies were included.

Conclusion
An overview on the influence of gender, age, body mass index, activity level, lumbar level, side of the spine, posture and presence of LBP on the structural LM characteristics measured by ultrasound is provided

**Keywords**

ultrasound; lumbar multifidus

EFFECTIVENESS OF MESOTHERAPY AND PHYSICAL REHABILITATION IN JUVENILE BACK PAIN - A PILOT STUDY

M. Rangel1, S. Claro1
1Hospital do Espírito Santo de Évora, Physical and Rehabilitation Medicine, Évora, Portugal

Introduction/Background

Back pain is one of the main causes of functional disability in the community, especially when it reaches chronicity, and it is considered a global public health problem. In most cases it is not possible to determine a specific cause of musculoskeletal pain in the spine, and around 90% of cases are considered nonspecific back pain, usually related to functional disorders due to overweight or vicious positions. In Physical and Rehabilitation Medicine (PRM), the treatment of this pathology requires an intervention at an early stage in order to cease the nociceptive stimuli, that originates the acute pain, avoiding its chronification. In the present clinical study we intend to compare the effectiveness of mesotherapy and rehabilitation, as well as the intensity of pain and functional level of young patients with acute nonspecific back pain.

Material and Method

This study was conducted in the period from September 2016 to February 2017 at the outpatient clinic of PRM and included 16 patients suffering from acute nonspecific back pain divided in 2 groups with different treatment methods. The following assessment instruments were used: pain intensity, evaluated by the Numeric Visual Analogue Scale, functional disability, assessed by the Quebec Back Pain Disability Score and the number of mesotherapy sessions performed.

Results

The analysis of the data showed a statistically significant relationship between pain intensity and functional disability. Between the beginning and the end of the treatment there was also a significant difference in terms of pain relief and the improvement of functional capacity.

Conclusion

Mesotherapy and physical rehabilitation are modalities of treatment that favorably affect the remission of acute back pain, also reflecting an improvement in functional capacity. It is highlighted the need for a comprehensive clinical approach to the nociceptive element, understood as a generator of limitation in activity and participation.

EFFECTS OF JING JIN TOU CI NEEDLING METHOD IN SOFT TISSUES INJURY ON DIFFERENT POSITIONS OF BODY

C.L. Song¹, Y. Liu², R. Qi²
¹Shanghai Jian-Gong Hospital, Department of traditional Chinese medicine, Shanghai, China
²Yue-Yang Hospital Integrated traditional Chinese and Western Medicine- affiliated to Shanghai University of TCM, Department of rehabilitation medicine, Shanghai, China

Introduction/Background

Soft tissue injury is common in physical exercises and daily activities. The conventional treatments are movement restraint and ordinary rehabilitation. It usually takes weeks to recover and is easy to recur. The object is to observe the effects of Jing Jin Tou Ci (twelve meridian sinews penetration) needling method in treating soft tissues injury on different positions of body.

Material and Method

A total of 56 patients with soft tissues injury related to exercise were randomized into a control group and a trial group, 28 cases in each. The control group was given ordinary rehabilitation on local injury, which includes TENS(low-frequency electronic therapeutic apparatus) and intermediate-frequency electronic therapeutic apparatus. Based on the therapy of control group, the trial group was treated by Jing Jin Tou Ci needling method. Two groups were all treated every other day, 3 times a week. The two group were both given 5-week successive treatment. At the end of the treatment and 2 months after that, we observed the changes of VAS pain score standard, the damaged joint range of motion and SF-36 summary of health surveys.

Results

The therapies in two groups were both effective not only at the end of the treatment, but also 2 months after it. There were significant difference in comparing the VAS pain score, the damaged joint range of motion and SF-36 summary of health surveys between the two groups (P<0.05), especially 2 months after the treatment (P<0.05).

Conclusion

Jing Jin Tou Ci (twelve meridian sinews penetration) needling method coupled with ordinary rehabilitation on local injury shows significant advantage in the treatment of soft tissues injury on different positions of body, which can release the pain rapidly, improve the range of the damaged joint and reduce recurrence rate.
Keywords

Introduction/Background

We report the case of a military high mountain guide who had a surgical shoulder stabilization and keep an anterior impingement syndrome.

The isokinetic evaluation show a deficit of peak torque, power and work of the external and internal rotators of the shoulder.

Material and Method

We propose a rehabilitation program during three weeks focused on isokinetic management twice a day.

The aim was the improvement of peak torque, power and work of the external and internal rotators.

We use the recommendatons edited by Davies threw the pyramid work in two modes of contraction.

The configuration used was the Davies modified one.

First, we work with concentric contraction by 180°/s by 6 repetitions progressively to 30°/s by 2 repetitions, and 120°/s by 8 repetitions to 30°/s by 3 repetitions.

Second part of the work with eccentric contraction by 30°/s by 6 repetitions to 90°/s by 1 repetition, and 45°/s by 6 repetition to 120°/s by 1 repetition.

Results

We observed an increase of the peak torque, power and work on the three speeds tested at the beginning.
The rehabilitation program that we advocate work is still effective, we prefer starting with concentric contraction at high speeds to a lower speed spectrum, and eccentric contraction at low speeds to higher speed spectrum.

**Conclusion**

Isokinetic training and testing are still the gold standard of evaluation and management of muscular deficits.

The rehabilitation program like Davies pyramid is a secure and effective management in addition of kinesitherapy and physiotherapy.

The isokinetic evaluation requires strict conditions of installation, while training requires more comfort of the patient.

ISPR8-0086
TIBIALIS ANTERIOR (TA) TEAR IN SCOTTISH HIGHLAND DANCER DIAGNOSED BY MUSCULOSKELETAL ULTRASOUND (MSKUS)

M. Tan1, J. Cianca1, F. Chiou-Tan1
1Baylor College of Medicine, Physical Medicine and Rehabilitation, Houston, USA

Introduction/Background

World class competitive Scottish Highland Dancing involves rapid dorsiflexion of the ankle ("heel-toe" maneuver) with gymnastic-like high jumps. We report a 15-yo world class Scottish Highland dancer with a grade 1-2 strain/tear to her left TA muscle seen with dorsiflexion. This has not been reported previously in the literature in this sport.

Material and Method

An otherwise healthy 15-yo female presented with pain over the lateral anterior “shin” region after daily Highland dance training lasting 3-5 hours. The patient initially wore an over-the-counter knee brace, but this did not improve symptoms. Patient then was referred to a Sports Medicine specialist. Motor strength was 4+/5 dorsiflexion left ankle with reproduction of pain, and 5/5 otherwise. Sensory soft touch and deep tendon reflex were intact. No skin bruising was noted over the TA, but was tender to palpation. MSKUS showed an area of hypoechoity consistent with a grade 1-2 strain of the left TA muscle with dorsiflexion. The tear appeared as a dark diamond shape opening, then disappeared with plantarflexion.

Results

A rehabilitation program was given including icing and resistance band exercises for three weeks. She then resumed task specific Highland dance maneuvers without jumping, followed by her full dance exercise regimen. The dancer resumed completion and won a championship then participated in a 6 week tour including the World Championship with no recurrence of symptoms.

Conclusion

This tibialis anterior tear is documented in an unusual sport that requires rapid ankle dorsiflexion. MSKUS will help physiatrists diagnose and treat this injury for this type of elite dancer.

HIGH IMPACT FRACTURES OF SACRUM AND PELVIS WITH NO NEUROLOGICAL LOSS – A REPORT OF 2 CASES.

K. Prasanna¹, L. Khang¹, L.L. Salceda², S. Pande³, S. Young¹
¹Changi general Hospital, Rehabilitation medicine, singapore, Singapore
²Changi general Hospitals, Rehabilitation medicine, Singapore, Singapore
³Changi general Hospital, Rehabilitation medicine, Singapore, Singapore

Introduction/Background

Sacral fractures are common in trauma related cases. Whilst sacral fractures can be sustained as high energy fractures in road traffic accidents and polytrauma cases, they can also occur as insufficiency fractures in relatively trivial incidents in osteoporotic bones. We report two high impact Denis zone 2-3 sacral fractures in relatively young patients who have fortunately avoided neurological damage.

Material and Method

Two cases, one male and one female both migrant workers to Singapore, who sustained Denis type 2 sacral fractures are discussed. Fractures sustained were unstable and needed to be fixed. Sacral fractures sustained were close to sacral foraminae, however escaped neurological loss.

Results

Denis etal in 1988 described sacral fractures into 3 zones according to radiological location. While Zone 1 fractures occur in osteoporotic bones and escape neurological damage, Zone 2-3 fractures are usually associated with neurological loss. However more recent work done by Sugimoto etal contradicts this theory and has found that the incidence of lumbosacral plexus injury was not related to the zone of sacral fracture. Instead they found that risk factors for lumbosacral plexus palsy included longitudinal displacement of pelvis, transverse sacral fractures.

Conclusion

High impact sacral fractures are usually associated with neurological damage according to Denis classification of zonal sacral fractures. However recent work done by Sugimoto etal contradicts this and adds on that the incidence of lumbosacral plexus injury is not related to zone of sacral fractures. Instead they found that risk factors for lumbosacral plexus palsy included longitudinal displacement of pelvis and transverse sacral fractures. Our findings in 2 cases are concurrent to their findings. More work is needed in this regards to confirm or negate this.

ANKLE SPRAINS IS DANCERS: WHAT IS THE EVIDENCE TELLING US?
M. Mota Freitas¹, S. Almeida¹, A. Silveira¹
¹Hospital Garcia de Orta - EPE, Physical and Rehabilitation Medicine, Almada, Portugal

Introduction/Background

Dance is a challenging art form requiring years of training for precise motor control, often at the extremes of joint range of motion. Elite dancers are athletes with training schedules that predispose them to injury. Ankle sprain is the most common traumatic injury in dance. The aims of this study are to summarize the current evidence on the impact of ankle sprains in dancers and emphasize the particularities of treatment in this population.

Material and Method

We searched PubMed, Cochrane Library and Medline to identify studies concerning ankle sprains in dancers including observational studies and systematic reviews. The terms used in this search were “dance” AND “ankle” AND “sprain”. A total of 12 studies were eligible for this research after applying exclusion criteria (date, language, duplicates).

Results

Regarding the mechanism of lesion, ankle sprains commonly involve foot plantarflexion and inversion, such as when the dancer lands from a jump. The lateral ligament complex of the ankle is the most frequently injured structure in the dancer's body. Initial therapy for ankle injury is compression, stabilization using a stiff controlling brace and contrast temperature therapy. Grade I and II sprains can be treated with early mobilization. Grade III sprains may require immobilization of the leg, with a short leg cast or an air boot. Surgery may be necessary for dancers with complete lateral ligament sprains. Follow-up therapy includes proprioceptive exercises, possible diagnostic or therapeutic ankle arthroscopy, infrared laser treatment, ultrasonography, and muscle-strengthening rehabilitation. A previous sprain and hip muscles weakness are predictive risk factors for ankle sprain.

Conclusion

Dancers often have particular responses to treatment due to the dynamic biomechanical features required by their individual dance form. Although most simple ankle sprains do not result in long-term disability, a significant number do not completely resolve, leading to residual symptoms that may persist for years.

ISOKINETIC AND NEUROMUSCULAR TESTING OF THE KNEE, RETURN TO SPORT FOLLOWING RECONSTRUCTION OF THE ANTERIOR CRUCIATE LIGAMENT. PROSPECTIVE STUDY IN A COHORT OF 234 ATHLETES

B. GUERRIER¹, S. Klouche², Y. Bohu², B. El Hariri¹, T. Raoul²
¹L’éKipe - Kinnés du Sport, PARIS, PARIS, France
²Clinique du Sport, Paris, Paris, France

Introduction/Background

After an anterior cruciate ligament (ACL) reconstruction, a complete functional recovery of the knee is required before returning to sport. According to the latest recommendations, a deficit < 10% on isokinetic and functional tests of the operated side versus the healthy side means a satisfactory functional recovery. The main objective was to assess the objective postoperative functional recovery of the knee in a large cohort.

Material and Method

A prospective study has included a series of athletes operated in 2013-2016 for a primary total isolated ACL tear, with healthy contralateral knee and having complete postoperative evaluation. Isokinetic tests measured the strength of the quadriceps and hamstrings. Functional tests consisted of hop tests. The primary judgement criterion was postoperative functional recovery (yes/no) defined by a differential < 10% on the strength measurement of quadriceps in concentric at 60°/s (Q60°/s) and on single-leg hop test for distance (SLH), at a minimum of 4-months postoperative follow-up.

Results

173 men and 61 women were included, mean age 28.4±8.6 years. At 6.5±1.7 (4-12) months mean follow-up, 44 (18.5%) had satisfactory functional recovery of the knee whose 52 (21.8%) at Q60°/s and 125 (54.3%) at SS. There was no significant difference in the return-to-sport depending on the level of functional recovery. During follow-up, 2 patients showed transplant rupture and 2 contralateral ACL rupture, all classified with insufficient functional recovery.

Conclusion

At 6-months mean follow-up after ACL reconstruction, the objective functional recovery of the knee is mostly unsatisfactory and appears to be a risk factor for further rupture.

ABSTRACT NEED TO BE EDITED - EPIDEMIOLOGICAL AND CLINICAL ASPECTS OF HOSPITALIZED MEDICAL WOUNDS IN THE SERVICE OF PHYSICAL MEDICINE AND REHABILITATION OF THE HOSPITAL AND UNIVERSITY CENTER OF YOPOUGON K. Yaya¹, B. julien¹, O. armand¹, A. dorkas¹, Y. samuel¹, A. amonso¹, M. benjamin¹, N. béatrice¹ ¹University Félix Houphouët-Boigny, Système Nerveux, Abidjan, Ivory Coast

Introduction/Background

Medullary lesions cause different motor and sensory deficits depending on the level of the lesion, thus causing functional difficulties and causing a major handicap. Our objective is to present the epidemiological and clinical aspects of spinal cord injured hospitalized in the department of Physical Medicine and Rehabilitation (MPR)

Material and Method

Retrospective descriptive study from 43 inpatient files in the Yopougon CHU's Department of MPR from 2015 to 2017.

Results

The average age was 35.65 years with extremes of 10 and 85 years. The sex ratio was 0.30. Medullary lesions of traumatic cause are represented at 76.74% against 23.26% non traumatic causes. The dominant clinical picture was that of quadriplegics with 51.16%. Of our patients, 88.38% had neurosurgical intervention. Pressure ulcers were found in 65.12% of patients on admission. Vesico-sphincteric disorders were found in all patients when 60.47% had anorectal disorders. The evaluation of the ASIA score was dominated by grades A and B in respective proportions of 34.88% and 20.93%.

Conclusion

Although the neurological deficiencies (paraplegia and tetraplegia) are the most apparent in the spinal cord lesion, the psychological, cutaneo-trophic, respiratory, vascular, vesico-sphincteric and anorectal deficiencies must be taken care of in the initial phase. This management must be done by a multidisciplinary team coordinated by the doctors MPR.

Movement restriction often occurs in those suffer from traumatic articular damage and prolonged post-operative immobilization. Protecting the injured segment in a shortened position could induce adjacent joint contracture. Considering the continuity of the myofascial system along the body, myofascial release may help to restore the coinciding joint motion.

Material and Method

The patients were 1) 67y/o female had right proximal ulnar and radial head fracture. 2) 9y/o female had right humeral supracondylar fracture. 3) 75y/o female had right distal radius fracture. All of them received internal fixation and immobilization in a sling for 4 weeks. The superficial front arm line was found to be primarily restricted in all three cases. Myofascial release was then applied to the involved limbs, targeting on the course from pectoral major to the medial intermuscular septum and down to the common flexor tendon. The intervention carried out 25min/time, twice per week, for 15 sessions.

Results

The average gain in motion were 35° in elbow flexion, 25° in elbow extension, 24° in forearm supination, and 6° in wrist extension, respectively. The subjective pain reduced from 6/10 to 2.7/10. The fracture sites achieved 60% of bone union and slings were discontinued to allow active movement.

Conclusion

All the individuals regained their functional range of motion. When early joint mobilization was not permitted for safety concern, myofascial chain release may serves as a sound and effective intervention to treat multiple joint contracture.

ACUTE AND CHRONIC MUSCULOSKELETAL INJURY IN PARA SPORT: A SYSTEMATIC REVIEW
T. Ottesen¹, E. Mashkovskiy², M. Gentry³, D. Jensen⁴, N. Webborn⁵, Y. Tuakli-Wosornu¹
¹Yale School of Medicine, Department of Orthopedics, New Haven, USA
²I.M. Sechenov First Moscow State Medical University, Sports Medicine and Medical Rehabilitation, Moscow, Russia
³Yale School of Medicine, Cushing/Whitney Medical Library, New Haven, USA
⁴Black Hills State University, Exercise Science, Spearfish, USA
⁵University of Brighton, School of Sport and Service Management, Eastbourne, United Kingdom

Introduction/Background
The health benefits of sport are myriad, but sport also carries an inherent risk of injury. This systematic review summarizes musculoskeletal injury epidemiology in elite and recreational Para athletes, and highlights research gaps.

Material and Method
Five electronic databases were searched for relevant articles: Ovid Medline, Ovid Medline In Process & Other Non-Indexed Citations, Ovid Embase, Cumulative Index to Nursing and Allied Health (CINAHL), and Web of Science. Evaluation and data extraction were performed by two independent examiners. Inclusion criteria were: (a) written in English; (b) published in a peer-reviewed journal between January 1975 and June 2017; (c) describe Para athletes participating in recreational or elite sport; and (d) describe sports-related, acute traumatic or chronic overuse musculoskeletal injury (Figure 1).

Results
Fifty full-text manuscripts were reviewed. Seated Para athletes sustain upper extremity injuries more commonly, while ambulant Para athletes frequently sustain lower extremity injuries. The upper extremity, including shoulder, elbow, wrist/hand, is the most commonly injured anatomical area in all Para athletes, unlike able-bodied athletes for whom lower extremity injuries predominate. Increased age and spinal cord injury may increase risk of upper extremity injury. Sprains, strains, blisters and lacerations are the most common injuries among Paralympians, but winter Paralympic sports carry higher risk of head injury, fracture and contusion, possibly due to the high-velocity elements. Male and female summer Paralympic athletes have similar overall injury rates, and Football 5-a-Side, Para powerlifting, Goalball, Wheelchair fencing, and Wheelchair rugby are consistently highest-risk sports. Para ice hockey, alpine skiing, and snowboarding are highest-risk winter sports. Upper and lower extremity injury rates match in winter sport, unlike summer sport trends. Injury data for recreational and youth Para athletes are sparse.
Conclusion

MSK injury epidemiology data continues to mature. Recreational and youth athletes remain under studied. Updating such data may accelerate the development of injury prevention strategies and lifetime injury models for Para athletes.

Introduction/Background

The literature on the kinetics of lead levels following a gunshot injury is scarce. We present a case.

Material and Method

A 29 year-old patient was hospitalized in a PM&R unit four months after an open fracture in the left leg surgically treated with an external fixation, secondary to a gunshot wound. X rays taken upon admission revealed >140 radiopacity millimetric images of hunting lead shots, the majority of which were located distally around the two leg bones and around the talocrural joint. Blood lead levels were 0.72 mM (normal 0.41 mM) and 149.2 µg/l for a normal 85 µg/l.

Results

These numbers indicate lead intoxication secondary to gunshot wounds. At the three-month follow up these levels had increased to 0.88 mM and 183.3 µg/l At that point, there was no clinical (endocrinological nor neurological) sign of lead poisoning. We are waiting for an electromyogram, a measurement of motive force of wrist extensors and cognitive tests.

Conclusion

Gunshot-induced fracture may spread lead in tissues, which can then increase lead levels and potentially emerging clinical symptoms. Long term monitoring is required, due to the risk of subsequent endocrinal or neurological complications. Surgical extraction may be necessary if lead levels further increase beyond 200 µg/l.

**STABILITY OF EXTRACAPSULAR HIP FRACTURE: DOES IT AFFECT REHABILITATION OUTCOME OF POST-ACUTE PATIENTS?**

A. Hershkovitz¹, S. Heler², T. Luria², N.S. Lior³, S. Brill⁴

¹'Beit Rivka' Geriatric Rehabilitation Center, "D", Petach Tikva, Israel
²Rabin Medical Center, Department of Orthopedic Surgery, Petach Tikva, Israel
³'Beit Rivka' geriatric Rehabilitation center, Rehabilitation ward "D", Petach Tikva, Israel
⁴'Beit Rivka' Geriatric Rehabilitation Center, hospital manager, Petach Tikva, Israel

**Introduction/Background**

Various factors have been shown to affect rehabilitation outcome of hip fractured patients. The degree of extracapsular fracture stability may also affect functional recovery. The aim of our study was to assess the relationship between extracapsular hip fracture stability and rehabilitation outcome in a post-acute setting.

**Material and Method**

A retrospective cohort study of 144 hip fractured patients was carried out in a post-acute geriatric rehabilitation center from 1/2014 to 6/2015. The main outcome measures were the Functional Independence Measure (FIM) instrument, motor FIM (mFIM), Montebello Rehabilitation Factor Score (MRFS) on the mFIM and length of stay (LOS). The associations between patients with stable vs. unstable and clinical, demographic and comorbidity variables, were assessed by the Mann-Whitney U and chi-square tests. A multiple linear regression model was used to estimate the association between fracture stability and LOS score after controlling for sociodemographic characteristics and chronic diseases (p=.009).

**Results**

Rehabilitation outcomes (FIM and mFIM score changes, mFIM MRFS) were found independent of extracapsular hip fracture stability. Patients with an unstable fracture presented with a significantly longer LOS compared with a stable fracture (p=.008). Multiple linear regression analysis showed that fracture stability was significantly associated with LOS after adjustment for confounding demographic, clinical and functional variables (p=.009).

**Conclusion**

Patients with unstable extracapsular hip fractures may require a prolonged rehabilitation period in order to achieve the same functional gain as patients with stable fractures.

Introduction/Background

Radial head and neck fractures account for 4% of all fractures and 33% of elbow fractures. The surgical methods for treatment of this fractures include open reduction and internal fixation (ORIF), radial head replacement and radial head excision, and there is no consensus on the best treatment therapy. The aim of this study is to compare the clinical outcomes of different operative treatment methods in radial head and neck fractures.

Material and Method

A total of 44 patients with radial head and neck fractures were retrospectively reviewed from February 2012 to September 2017. Patients were invited to the clinic for evaluation and 28 patients treated with radial head excision (n=8), radial head replacement (n=10) or open reduction and internal fixation (n=10) were agreed to participate in the study. Visual analog scale (pain and patient satisfaction), elbow range of motion, grip strength, Disabilities of the Arm, Shoulder and Hand (DASH) questionnaire, Mayo Elbow score and Short-Form 36 (SF-36) were used to determine clinical outcomes.

Results

The average follow-up time is 49.45±19.57 months. There was no significant difference in clinical results between the the groups regarding the rest and activity pain level, Mayo Elbow and the SF-36 scores (p>0.005). Elbow flexion range of motion, grip strength and DASH scores were significantly better in patients treated with ORIF (p<0.005). Although there was no difference in patient satisfaction between the groups (p>0.005), the ORIF group had higher satisfaction score (ORIF group:X±Ss=9.40±1.57, replacement group:X±Ss=8.16±2.72, excision group:X±Ss=7.31±2.84).

Conclusion

We found that ORIF is better than radial head replacement and excision in terms of the upper extremity functional performance and the strength in the treatment of radial head and neck fractures. However further randomized control trials are needed to evaluate the full benefits and deficiencies of each of the different surgical treatment methods.

CHRONIC TENDINOPATHIES AND PLATELET-RICH PLASMA TREATMENT: HOW TO IMPROVE THE EFFICIENCY?
J.F. Kaux¹, T. Emonds-Alt²
¹University of Liege, Physical and Rehabilitation Medicine & Sports Traumatology, Liege, Belgium
²University Hospital of Liège, Physical and Rehabilitation Medicine & Sports Traumatology, Liège, Belgium

Introduction/Background

Platelet-rich plasma (PRP) is blood plasma with a high concentration of autologous platelets which constitute an immense reservoir of growth factors. The clinical use of PRP is widespread in various medical applications.

Material and Method

In a literature review, we take a closer look at eight parameters which may influence the quality of PRP: 1) anticoagulants used to preserve the best platelet function, 2) the speed of centrifugation used to extract the platelets, 3) the platelet concentrations obtained, 4) the impact of the concentration of red and white blood cells on PRP actions, 5) platelet activators encouraging platelet degranulation and, hence, the release of growth factors, and 6) the use or nonuse of local anesthetics when carrying out infiltration. In addition to these parameters, it may be interesting to analyze other variables such as 7) the use of ultrasound guidance during the injection with a view to determining the influence they have on potential recovery.

Results

Analysis of the 59 studies shows that a majority use ACD-A as an anticoagulant during sampling. The best results have been obtained in studies which use no platelet activator. In terms of the speed of centrifugation, analysis of all these studies appears to confirm the existence of a great number of protocols in the literature. It is difficult to draw any conclusions when these different variables are unknown (volume of initial sample, equipment used to obtain the PRP). Although it would appear inadvisable to administer a local anesthetic Finally, it appears to be advisable to carry out infiltration under ultrasound guidance.

Conclusion

Our study helped identify features of PRP recommended a platelet concentration lower than 5 times the baseline (from 3 to 4), and avoiding leukocytes and erythrocytes. We recommend leveraging this information about PRP for future studies.

HOW DOES BALLET ALTER ANKLE TENDINOUS MORPHOLOGY AND HEMODYNAMICS IN ASYMPTOMATIC DANCERS? AN ULTRASONOGRAPHIC STUDY
W.S. Shih¹, C.H. Wu¹, T.G. Wang¹
¹National Taiwan University Hospital, Physical Medicine and Rehabilitation, Taipei City, Taiwan R.O.C.

Introduction/Background
Among symptomatic dancers, sonographic abnormalities are common. Whether asymptomatic dancers have any abnormalities remains unknown. Some dancers became cyanosis over distal feet after ballet training. The hemodynamic changes at the feet in ballet are not clearly understood. We aimed to investigate tendon morphology and hemodynamic changes in ankles of asymptomatic pre-professional ballet dancers with ultrasonography (US).

Material and Method
In 25 dancers and 14 non-dancers, B-mode US was used to measure cross-sectional areas (CSA) of flexor tendons in the ankle. Doppler US was used to measure peak velocity of posterior tibial artery in three ankle postures: the neutral position, passively and forced actively plantar flexion (en pointe). The big toe oxygen saturation was recorded in neutral position and during 1-minute en pointe. Nonparametric Mann-Whitney test was used for between-group comparison and Wilcoxon signed-rank test for within-group comparison.

Results
Ankle plantar flexion range of motion was significantly larger in dancers ($p < 0.01$). The flexor hallucis longus (FHL) tendon CSA was larger in dancers ($0.26 \text{ cm}^2 [0.2, 0.3]$ vs $0.21 \text{ cm}^2 [0.17, 0.24]$, $p < 0.01$), while other flexor tendons were not different between two groups (all $p > 0.05$). The peak velocity was significantly higher in passively plantar flexion than in neutral position ($p < 0.01$, in both groups). The blood flow was undetectable during en pointe, more frequently in dancers ($54.9\%$ vs $14.3\%$, $p < 0.01$). Oxygen saturation decreased during en pointe more prominently in dancers ($85\% [80, 90]$ vs $94\% [84, 97]$, $p < 0.01$). Ankle hypermobility and the FHL muscle contraction may decrease the blood flow of posterior tibial artery, more frequently in ballet dancers.

Conclusion
US showed the FHL tendon thickening and en pointe-related vascular compromise in pre-professional dancers, even when they were asymptomatic.

ASSESSMENT OF FUNCTIONAL STATUS OF CONSERVATIVE TREATMENT FRACTURE OF THE WRIST

K. Markovic1, R. Filipov1, S. Bacevic2

1Institute for Treatment and Rehabilitation "Niska Banja"- Nis, Serbia
Department of Rehabilitation, Nis, Serbia
2General Hospital- Prokuplje, Department of Physical Medicine and Rehabilitation, Nis, Serbia

Introduction/Background

Of all human skeletal fractures 10% make up fractures of distal radial bone. Fractura radii loco typico is localized to 1.5-2.5cm above the wrist. There is a Colles-type fracture (where the proximal fragment goes forward and medially and distal backward and dorsal) and Smith's fracture (proximal fragment moves backward and dorsally and the distal forward and the medial). Only 5% of these fractures require surgical treatment.

The aim was assessment of functional status of conservative treatment fracture, using the Gartland-Werley (G-W) score system, as well as its elements (residual deformities, complications, subjective and objective discomfort). Also, it was assessing which of these elements and to what extent have an impact on the final result of the scoring system and which correlations exist within the G-W scoring itself.

Material and Method

It was tested 74 patients with fractures of distal radial bone, which were treated non-operatively, minimum follow-up period of six months. In the age between 21-80 years-average 62.1. The left wrist was injured in 47 (63.4%) patients and right at 27 (36.6%). The G-W scoring was used to assess the results of the non-operative treatment.

Results

The results, when applying the G-W score, were excellent in 39.2%, good in 45.1%, satisfactory in 13.7% and poor in 2% patients. The G-W score elements had the following percentages in the scoring results: residual and subjective discomfort equally by 11 patients, objective discomfort 33 and complications 19. The correlation analysis showed a statistically significant correlation of the residual deformities and the total G-W score at the level of subjective discomfort and total G-W score and between objective discomfort and total G-W score at the same level.

Conclusion
Fractures of distal radial bone, require a special approach and adequate assessment of final treatment results, because inadequate treatment results in the reduction of patients daily activities and their ability to work.

_No conflict of interest_
THE EFFECT OF SHORT FOOT EXERCISE AT DIFFERENT ANKLE POSITION TO THE PEOPLE WITH FLAT FOOT.

H. yoon, K. ji hyun, P. joo hee, J. hy ese on

Introduction/Background

The flat foot is an abnormal condition that the height of medial longitudinal arch (MLA) is lowered due to the foot hyper-pronation. One of the strong causes of the flat foot is the insufficient support by abductor hallucis (ABH) and extrinsic muscles. Previous studies revealed that the short foot exercise (SFE) is an effective exercise for the flat foot by increasing the height of MLA. However, most of the research related to SFE determined the efficiency of SFE using the enhanced ABH activation. Therefore, we examined SFE with different ankle joint positions [neutral (NL), dorsiflexion (DF) at 30º, and plantarflexion (PF) at 30º] in sitting and standing position to the flat foot to clarify the optimal involvement of the intrinsic and extrinsic arch supporting muscles.

Material and Method

Twelve flat foots participated in this experiment, and during each condition, we measured the activation of the ABH, tibialis anterior (TA), and peroneus longus (PL) and the MLA angle. It is assumed that each ankle position and weight bearing provide different mechanical condition to the targeted muscles. Consequently, the muscle activity would be influenced while the subjects perform the SFE. The collected data were analyzed by two-way repeated ANOVA.

Results

TA, PL and ABH have interaction effect between ankle position and weight bearing. The muscle activation was significantly increased in standing condition. The TA was most highly activated in DF condition, and the activation of ABH was the highest in PF condition. The activation of PER was the lowest in DF condition.

Conclusion

According to previous research, the flat foot tends to overuse TA to compensate weakened ABH. SFE in ankle PF in standing could be considered as more effective way than traditional exercise (e.g., SFE in NL condition) in terms of harmonic activation of the arch supporting muscles. Further longitudinal intervention studies are required.

VALIDATION OF A SELF-REHABILITATION BOOKLET AFTER AN ANTERIOR CRUCIATE LIGAMENT (ACL) RECONSTRUCTION AND EVALUATION OF ITS IMPACT ON PATIENT'S KNOWLEDGE IMPROVEMENT

L. Ghozlane†, M. Bovard†, V. Salvator Witvoet†

†CRRF La Châtaigneraie Convention, Paris, Paris, France

Introduction/Background

Muscular recovery conditions the functional restoration and return to sport after ACL reconstruction. Going on with personal muscular strengthening is necessary after patients have completed center physical therapy, but might be difficult without appropriate instructions. We have therefore created, validated and evaluated a rehabilitation booklet. The booklet aims to inform patients about their pathology and muscle strengthening as well as providing them with an exercise program they can perform alone for a good recovery.

Material and Method

- Booklet creation, proofreading and validation by a multidisciplinary group of experts.
- Open mono-centric prospective clinical trial in 2 periods. The first period targeted 124 patients (control group) who received non-standardized information, according to center usual practice. The second period covered 165 patients (intervention group) who received a rehabilitation booklet.
  Both groups answered a questionnaire to evaluate their learning curve between their first and their last day at the rehab center. We used a covariance analysis model to compare both groups scores.
- Collection of patients’ assessments on the booklet.

Results

The average increase in patients’ knowledge scores reaches 4,169 points (SD 3,097) in the control group and 5,806 points (SD 3,585) in the intervention group. The increase in the knowledge score is statistically higher in the intervention group (p = 0.001).

The patients’ assessment collection reveals that more than 90% patients wish the booklet to be available and 87% believe that it can help them to go on muscle strengthening by themselves.

Conclusion

The booklet increases patients’ knowledge and can allow them to go on by themselves muscle strengthening.
Keywords

KNEE;ACL;REHABILITATION

No conflict of interest
Introduction/Background

We created and validated a self-rehabilitation booklet to allow patients to perform by themselves muscle reinforcement after they completed rehabilitation in a rehab center (between 2 and 4 months after surgery). The aim of the study is to evaluate the impact of a self-rehabilitation booklet on quadriceps and hamstrings recovery 4 months after Bone Patellar Tendon Bone (BPTB) or Hamstrings (HST) autograft.

Material and Method

Open mono-centric prospective clinical trial on 2 periods. 1st period: 124 patients received non-standardized information, according to center usual practice. When leaving the rehab center, patients were provided either a prescription for physiotherapy sessions or strengthening sessions in a gym. 67 patients in this group returned to the center for a clinical assessment, isokinetic and a functional test. 2nd period: 165 patients received a self-rehabilitation booklet with instruction to perform three times a week muscle strengthening session in a gym or at home. 76 patients in this group returned for similar assessment as the first group (2nd arm). We compared subjective and objective IKDC scores, quadriceps and hamstring peak torque deficiency and the functional score.

Results

All measured variables show no significant difference between the 2 groups. Quadriceps and hamstrings deficit are equal to literature. Patients with BPTB graft showed a greater deficit in quadriceps (p = 0.0001) and lower deficit in hamstring strength (p = 0.0001) at 60°/s. The number of sessions at the gym significantly improves the subjective IKDC score and hamstrings recovery in both groups.

Conclusion

The self-rehabilitation booklet allows patients to perform by themselves muscle strengthening. The number of sessions at the gym improves IKDC score and hamstrings recovery.

²Ichihara Hospital, Department of Orthopaedic Surgery, Tsukuba, Japan
³Tsukuba Gakuen Hospital, Department of Orthopaedic Surgery, Tsukuba, Japan

Introduction/Background

We developed a novel technique to improve tendon–bone healing by hybridizing calcium phosphate (CaP) with a tendon graft using an alternating soaking process. We investigated clinical results of anatomic single-bundle anterior cruciate ligament (ACL) reconstruction using CaP-hybridized tendon graft.

Material and Method

patients (n = 90) with unilateral ACL rupture underwent arthroscopically assisted anatomic single-bundle ACL reconstruction using hamstring tendons. These patients were equally randomized to undergo the CaP (n = 45) or conventional method (n = 45). All patients followed the same postoperative rehabilitation protocol. At 1 and 2 years after surgery, they were evaluated with the manual knee laxity test, KT-1000 arthrometry, International Knee Documentation Committee (IKDC) examination form, Tegner scale, and Lysholm scale as clinical results.

Results

In the both groups, postoperative clinical results were improved compared to preoperative. The results were not significantly different at both follow-up period in the two groups.

Conclusion

The CaP-hybridized tendon graft improved anterior knee stability and clinical scores at the 2-year follow-up compared to preoperative.

EFFECTIVE REHABILITATION PROGRAM OF THE NEGLECTED UPPER BRACHIAL PLEXUS INJURY PATIENT WITH POST DORSAL LATISSIMUS TENDON TRANSFER BY MYOBIOFEEDBACK EXERCISE: A CASE REPORT.
H. Mubarak¹, M.R. Saleh², A. Najamuddin³, Z. Then²
¹Faculty of Medicine- Hasanuddin University, Department of Physical Medicine and Rehabilitation, Makassar, Indonesia
²Faculty of Medicine- Hasanuddin University, Department of Orthopaedics, Makassar, Indonesia
³Wahidin Sudirohusodo Hospital-, Department of Physical Medicine and Rehabilitation, Makassar, Indonesia

Introduction/Background

Upper type plexus brachialis injury causes devastating loss of arm function. Latissimus dorsi tendon transfer to origin of biceps performed to restore forward flexion of shoulder and flexion of elbow. Rehabilitation before and after the procedure play essential role in refunctioning the arm. Myobiofeedback exercises enable to isolate certain muscle under precise intensity, thus applying resistance adequately to challenge the muscle with minimal risk of getting the muscles fatigue. Myobiofeedback has long been used as regiment in rehabilitation program of plexus brachialis and significantly improve clinical outcomes of tendon transfers procedures

Material and Method

Female, 30 years old consulted to rehabilitation department with left arm weakness and numbness after motor vehicle accident one year ago and relied on bone setter treatment untill her arm and elbow was unable to flex at all. From physical examination and EMG finding, she was determined to had a post-ganglionic upper plexus brachialis lesion. She was planned for latissimus dorsi tendon transfer to restore flexion of shoulder and elbow. Prior to surgery, myobiofeedback was performed to train the left latissimus dorsi with intensity 70-80% the strength of right latissimus dorsi. The surgery was performed well and a week after, she started to undergo myobiofeedback exercises along with Neuromuscular Electrical Stimulation (NmES) and occupational therapy intervention in Rehabilitation Department

Results

Ten weeks after surgery and rehabilitation program, she able to flex her shoulder and elbow to near functional range of motions. She was able to lift objects with her left hand and to assist her right hand to lift heavier objects. From surface EMG, her left elbow flexors has reached 65% the strength of unaffected arm, indicating satisfying progress of the surgery and rehabilitation program.

Conclusion
Myobiofeedback exercises has promising role in recovery of arm function after upper plexus brachialis injury, especially in the case of latissimus dorsi tendon transfer.

**Keywords**

myobiofeedback exercises; upper plexus brachial injury; latissimus dorsi tendon transfer

ISPR8-0745
REHABILITATION OF RIGHT LATERAL MENISCUS REPAIR AFTER ENDURING POSTERIOR LATERAL MENISCUS ROOT TEAR FOR 5 MONTH AFTER TRAUMATIC INJURY : A CASE STUDY
Y. Shirose

1Yokohama Rosai hospital, Central Rehabilitation Department, Yokohama-shi, Japan

Introduction/Background

We report the post-surgical rehabilitation of a case of posterior lateral meniscus root tear with anterior cruciate ligament (ACL) injury of the right knee.

Material and Method

A 30s male, presented with persistent right knee pain and swelling along with limited range of motion (ROM) after an injury in a traffic accident; however, at that time he was discharged after he went to the hospital. After 5 months, he was readmitted because the symptoms didn’t improve. He was diagnosed with posterior lateral meniscus root injury with ACL injury. Preoperative ROM was -10° extension to 95° flexion. 6 months after the injury, he underwent arthroscopic lateral meniscus repair and synovectomy. Mild cartilage degeneration was observed throughout the lateral compartment of the knee. ROM exercise was started 3 weeks after surgery. ROM at this time was -15° extension to 35° flexion.

Results

ROM increased to 0° extension to 65° flexion at 4 weeks after surgery, 0° extension to 95° flexion at 6 weeks, and 0° extension to 120° flexion at 10 weeks. Although we acquired more ROM than preoperative ROM at 2.5 months after surgery, it took time and increased effort to acquire full ROM.

Conclusion

Meniscus injury is caused by mechanical stress to the synovial tissue, thus leading to arthritis. Arthritic edema then appears followed by chronic pain with accompanying fibrosis of the surrounding tissues after injury. ACL injury is characterized by intraarticular bleeding after injury and inflammatory symptoms, secondary suppressed excitability of the quadriceps muscles, and decreased muscle tone. Moreover, a report stated that flexion contractures may occur because of the impingement. We made it difficult to acquire postoperative ROM because of these changes that occurred during the period of 5 months after injury. Thus, medical intervention in the early stage of knee injury yields better results.
Keywords

THE EFFECT OF KNEE MIDDLE POSITION EXERCISE ON THE BIOMECHANICAL PARAMETERS OF KNEE JOINT DURING SINGLE LEG LANDING

X. Shi\(^1\), D. Xie\(^1\), J. Qi\(^1\), X. Ma\(^1\), H. Wang\(^1\), S. Wu\(^1\), H. Zhu\(^1\), C. Wu\(^1\), J. Zhang\(^1\), X. Li\(^1\), H. Liu\(^1\), Y. Zhang\(^1\)

\(^1\)Taishan Medical University, Institute of Sports Medicine, Taian, China

Introduction/Background

Prevention of anterior cruciate ligament (ACL) injury is likely the most effective strategy to reduce undesired health consequences. The aim of the study was to investigate whether the knee middle position exercise (KMPE) can effectively prevent the ACL injury.

Material and Method

Three dimensional motion analysis system, force plate and electromyography were used to synchronously measure biomechanical indexes of non-dominant leg during drop landing before and after the KMPE. Sixteen healthy female college recreational athletes (age 20.9±1.4 years; height 163.2±5.1 cm; mass 53.5±7.3 kg) participated in this study. The exercise mainly included squat, forward stride, jumping and landing, etc. The results were averaged for three successful maneuvers. Paired t tests were conducted to assess differences in the kinematics, kinetics, and EMG data between before and after exercise.

Results

After the KMPE, there were significantly reduced in knee valgus angles of a mean 1.5° during drop landing of the non-dominant leg at initial ground contact (P<0.05). Peak knee valgus angle decreased by a mean of 2.23° (P<0.05) and the maximum flexion angle of the knee was significantly increased by a mean of 5.88° (P<0.05) during the drop landing process after the KMPE. Angles were not related to muscle activity around the knee before training. However, after the exercise, there were correlation between maximum flexion angle and biceps femoris, gastrocnemius medial muscle activity (P<0.05), and the maximum valgus angle was correlating with hamstring to quadriceps functional ratios (P<0.05).

Conclusion

Short-term KMPE may be beneficial to prevent the ACL injury.

PREVALENCE, RISK FACTORS AND PREDICTION MODEL FOR PSYCHOLOGICAL DISTRESS AFTER TRAUMA
L. de Munter¹, S. Polinder², N. Kruithof¹, C. van de Ree¹, J. Haagsma², M. de Jongh³
¹ETZ, Xperiment Trauma TopZorg, Tilburg, The Netherlands
²Erasmus MC, Public Health, Rotterdam, The Netherlands
³ETZ, Xperiment Trauma TopZorg & Netwerk Acute Zorg Brabant, Tilburg, The Netherlands

Introduction/Background

Trauma patients often suffer short and long term psychological distress. This study aimed to (1) describe the prevalence of poor psychological outcome after injury in the general trauma population, (2) determine risk factors for this poor outcome and (3) develop prediction models for poor psychological outcome 6 months and 1 year after trauma.

Material and Method

The Brabant Injury Outcome Surveillance (BIOS-study) is a multicenter prospective observational cohort study. Adult trauma patients admitted to one of the hospitals in the county Noord-Brabant were asked to complete a questionnaire at 1 week, and 1, 3, 6 and 12 months after injury. The Hospital Anxiety and Depression Scale (HADS) was used to screen for anxiety and depressive disorders and the Impact of Event Scale (IES) was used to assess symptoms of posttraumatic stress disorder (PTSD). Potential predictors were assessed in univariable logistic regression, with psychological distress as outcome (HADS≥8 or IES≥35). All risk factors with p<0.2 were included in multivariable model. In addition, mixed model for repeated measures was used to assess psychological outcome over time. The model performances were assessed with the Area Under the Curve, Nagelkerke R-square (R²) and graphically with calibration curves.

Results

Overall, the prevalence of anxiety and depressive symptoms decreased during the follow up period. The highest prevalence of PTSS was found in female trauma patients with low injury severity. Risk factors for poor psychological outcome are female gender, low educational level, low injury severity, pre-injury presence of anxiety and depression, and low functional capacity index. The prediction model for 1 year psychological outcome had a discriminative ability of 0.687 (95% CI: 0.642, 0.733).

Conclusion
Prevalence of anxiety, depression and PTSS is high among trauma survivors. This study provides possible tools for early diagnosis and screening of poor psychological functioning after trauma. Further research is needed to externally validate these findings.

ISPR8-0823
STUDY OF THE ISOKINETIC PROFILE OF THE KNEE IN A JUDO MILITARY TEAM

K. Mehrzia Amani¹, R. Maaoui², I. Ksibi², N. Mouhli¹, H. Rahali²
¹Tunis Military Hospital, Department of Physical Medicine, Mont Fleury, Tunisia
²Faculty of Medicine of Tunis - University of Tunis El Manar - Tunis Military Hospital, Department of Physical Medicine, Mont Fleury, Tunisia

Introduction/Background

The knee is a highly solicited joint in judo. In Dead, the judoka uses one leg as a supporting leg while the other is always ready to attack the opponent (attacking leg). In this context, there should be a specific profile between the muscle groups strengths in each leg.

The aim of this work was to study the isokinetic muscular profile of the knee in both legs among a judo team.

Material and Method

It was about a cross-sectional, forward-looking and descriptive study conducted on a Judo Military Team. We raised the age and the anthropometric measures (weight, size and the body mass index (BMI)) by a complete clinical examination. The isokinetic evaluation of agonist and antagonist muscles of both knees was performed in concentric mode with a Biodex dynamometer. The angular velocities of the assessments were 60°, 90° and 120°/s. We held two parameters: The maximum peak torque (PT) and the ratio agonistic/antagonistic (R) of the extensors and flexors of the knee.

Results

The 13 athletes included were male. The mean age was 23.3 years. The mean BMI was 24.98 kg/m². Most judokas used the lower left limb as a supporting leg (76.9%). Our results show that regardless of the angular velocity used, and regardless of the member being assessed, the mean PT of the extensors was consistently higher than the mean PT of the flexors. Unlike the evaluation at 90°/s, the ratio Hamstrings/Quadriceps at 60°/s and 120°/s was higher at the attacking leg. The objective difference between ratios at different speeds and between the different limbs was statistically insignificant (p>0.05).

Conclusion

According to this clinical and instrumental evaluation, a specific rehabilitation program was proposed in order to compensate the eventual imbalances and specially to prevent the occurrence of injuries detrimental to the career of these athletes.

ACTIVE PHYSIOTHERAPY AND REHABILITATION MANAGEMENT APPROACH OF DISTAL ULNA FRACTURE IN ART-MAKERS: A CASE REPORT

S. Erel¹, M. Buke¹, E. Tasvuran Horata², F. Unver Kocak¹, U. Bas Aslan¹
¹Pamukkale University, School of Physical Therapy and Rehabilitation, Denizli, Turkey
²Afyon Kocatepe University, Afyon Health School, Afyonkarahisar, Turkey

Introduction/Background

This case report pointed to contribute to the literature about an active physiotherapy treatment methods of distal ulna fracture in art-makers and to report the results of the treatment programme.

Material and Method

The patient with distal ulna fracture was a 19-year old woman, Body Mass Index was 16.95. She was a student of Faculty of the Music and Performing Arts. A fall onto the outstretched hand position caused the fracture. A plaster of paris was applied and worn for 1 months. After removal of the plaster of paris, the subject was included physiotherapy programme for 3 weeks (5 days/week) by physiotherapist. She had pain, atrophies, oedema, limitations of joint mobility in right hand wrist. Pain intensity was evaluated by Visual Analogue Scale. Life quality was investigated by Nottingham Health Profile. Quick DASH scores of before treatment (B.T.) and after treatment (A.T.) were compared to evaluate disability and performance on painting. An active management approach including TENS, pulsed ultrasound, infrared, retrograde massage for edema, mobilization of ulnar nerve and distal radius, active range of motion, strength, resistive, grip and proprioceptive neuromuscular facilitation exercises (PNF) were practiced. First 3 days of the treatment active, isometric and stretching exercises and gliding at the wrist were applied, 4th day the subject started to painting Resistive and PNF exercises were conducted after 2 weeks.

Results

After the treatment, range of motion of wrist (35° in flexion and extension) and forearm (13° radio-ulnar deviation), life quality (B.T. 144.81, A.T. 0) and performance on painting (B.T. 50, A.T. 0) were increased. Pain during rest, activity, and asleep (B.T. 6.7, 8.9, 1.8; A.T. 0, 0.8, 0, respectively) and disability (B.T. 62.5, A.T. 0) were decreased favour of recovery.

Conclusion

This study reflected beneficial results of an active management approach in hand rehabilitation of art-makers.

REHAND VERSUS TRADITIONAL HOME PROGRAM EXERCISE FOR DISTAL RADIUS FRACTURE.
M. Rodríguez-Piñero Duran\textsuperscript{1}, A. Suero Pineda\textsuperscript{1}, L.G. Luque Romero\textsuperscript{1}, P. Rodríguez Sánchez-Laulhe\textsuperscript{1}, J. Blanquero Villar\textsuperscript{1}, M.D. Cortes Vega\textsuperscript{1}
\textsuperscript{1}Hospital Universitario Virgen Macarena, PPhysical Medicine &Rehabilitation, Seville, Spain

Introduction/Background

Home program exercises for distal radius fractures are commonly used in clinical practice. Evidence shows that these programs need to be personalized, progressive and controlled.\textsuperscript{(4–11)} Currently methods consist on provide patients with a simple paper sheet of exercises which not compliment with these requirements.

We propose the use of ReHand to compare traditional methods with an innovative digital tool. ReHand is an app tablet that provides patients with exercises programs evidenced based and totally personalized. Therefore, ReHand’s dashboard allows professionals to monitorized and control adherence to treatment.

Material and Method

rehabilitation service of Hospital Virgen Macarena will select patients with diagnosis of distal radius fracture and volar plate fixation to be enrolled in a prospective clinical trial comparing those who received ReHand home exercise program with those enrolled in the traditional home exercise program guided by paper sheet. Outcomes: dexterity (Nine Hole Peg Test), grip strength, sensorimotor assessment (Joint Position Sense), arc of motion for wrist flexion and extension and functionality (Patient Rate Wrist Evaluation Scale). Assessments takeplace at 3 weeks and at 3 month. This study is part of a multicenter study of Andalusian Public Health System.

Results

currently we are in analysis data and evaluation results phase. According to our preliminary studies we expect have significant results time before the congress.

Conclusion
According to our preliminary outcomes we will be able to conclude that Rehand is a effective tool for to improve the functional status of the hand after a distal radius fracture with better outcomes than a traditional home based exercise program.

Distal humerus fractures are complex injuries that are particularly challenging to treat. For early rehabilitation and predictable outcomes, they should be surgically treated using double anatomical locking plates. However, several complications have been reported, such as decreased range of motion, nerve dysfunction and wound infections. The purpose of this study was to report the outcomes and complications after open reduction and internal fixation of intra-articular distal humerus fractures using double anatomical locking plates.

Material and Method

Between April 2010 and December 2017, we treated twelve patients with intra-articular distal humerus fracture (AO/OTA type C). Five patients were male and seven were female. The average age was 46.7 (range 22-80). The pretreatment AO/OTA type was C1 in three patients, C2 in six, and C3 in three. All fractures were treated with open reduction and internal fixation using double anatomical locking plates. Intraoperative ulnar nerve anterior transposition was performed for ten patients. Postoperative immobilization was one week followed by active range of motion.

Results

All patients obtained bone union. Regarding range of motion, mean elbow flexion arc was 108.5° (mean extension was -10.5° and mean flexion was 119°). The Mayo Elbow Performance Score was excellent in five patients, good in six, and fair in one. Radiographic evaluation was performed immediately and six months after surgery. There was no significant reduction loss during between these time periods. Postoperative complications in the eleven cases included seven with ulnar nerve neuropathy. All patients with motor weakness improved and five patients had persistent numbness.

Conclusion

For treating distal humeral intra-articular fractures, double anatomical locking plates can provide good stability for early rehabilitation. However, this surgical method includes some
complications, especially ulnar nerve dysfunction. Gentle management of the ulnar nerve is necessary.

ISPR8-0981
NEUROCOGNITIVE DISORDER EFFECT ON EARLY FUNCTIONAL RECOVERY OF PATIENTS SURGICIALLY TREATED BECAUSE OF HIP FRACTURE
A. Vukomanovic¹, Z. Brdareski¹, A. Djurovic¹
¹Military Medical Academy, Clinic for physical medicine and rehabilitation, Belgrade, Serbia

Introduction/Background
Acute rehabilitation of patients with hip fracture immediately after surgical treatment is short but crucial period for their functional recovery. Regaining of walking and basic activities of daily living are the aims of acute rehabilitation. The aim of this study was to determine the influence of neurocognitive disorder detected on admission to orthopedic ward on functional outcome few days after surgical treatment.

Material and Method
This cross-sectional study involved all patients older than 64 admitted to our hospital during one year due to surgical treatment of hip fracture. The cognitive state was assessed on admission by Abbreviated mental test – Serbian version (AMT-SV) (Score range: 0 – 10, scores 9 and 10 excluded neurocognitive disorder). Based on AMT-SV score, all patients were divided in two groups: with or without neurocognitive disorder. The functional recovery of both groups was assessed by the A-test (Score range: 0 – 50, severe disability indicator score: ≤7 on the 1st, ≤12 on the 2nd, ≤13 on the 3rd day after operation(DAO)) from the 1st to 3rd DAO. Statistical analysis: Mann-Whitney U test.

Results
Out of 240 admitted patients, 20 were excluded from the study (12 were younger than 65, 14 didn’t undergo operation because of comorbidities, 4 couldn’t fill in AMT-SV because they were deaf and blind). Of the remaining 220 patients, 119 (57%) patients had some degree of neurocognitive disorder. In this group of patients, the A-test score was significantly lower (p=0.000) than in the group without mental disorder indicating severe disability immediately after operation (6±5 vs 8±5 on the 1st DAO, 9±6 vs 12±6 on the 2nd DAO, 11±7 vs 14±8 on the 3rd DAO).

Conclusion
Neurocognitive disorder detected on admission to orthopedic ward is one of the indicators of delayed functional recovery of elderly patients with hip fracture during acute rehabilitation after surgical treatment.

Introduction/Background

The early stages of weight bearing can be achieved quickly by shortening the time required for rehabilitation after the fracture, thereby advantage of return to daily life. The definition of partial weight bearing is incorrect, and there are non quantitative procedures such as touch-down lighting, lighting as tolerated in actual rehabilitation. Lower Body Positive Pressure Treadmill(LBPPT) increases the air pressure in the chamber surrounding the lower limb to generate buoyancy, and allows the load to be quantitatively reduced by the adjustment of the pressure, and further can be carried out more precisely and safely in the initial rehabilitation after the fracture. It is intended to check whether early quantitative weight bearing exercise is
possible using a LBPPT for patients with an immediate difficulty with weight bearing.

Figure 1. LBPPT

Material and Method

LBPPT (Alter-G, CA, USA) training consisted of a total of 20 session five time a week, 30 minutes at a time.

Introduction/Background

Functional recovery and life quality after explosive burn injury are important goals of burn care. However, neuromuscular training of explosive burns in patients in their functional recovery had seldom been documented. The purpose of this case report is to demonstrate the effectiveness of a short-term physical therapy program utilized scar tissue assessment and neuromuscular training that provided significant functional recovery in this severe explosive burn injury case.

Material and Method

A 32-year-old female, endured a traumatic explosive burn injury at Thailand on 17 August 2015. She suffered not only burns with a total body surface area (TBSA) up to 50% but also right elbow and right femoral shaft fracture, left posterior tibial and right ulnar nerve injury. She was referred from plastic surgeon to rehabilitation out-patient clinic due to prominent leg discrepancy with functional impairment. A patient-centered neuromuscular training rehabilitation for a 7-week period with total 11 physical therapy visits produced significant improvement in postural control and patient confidence.

Results

A quick response for low back pain in this burn case was obvious at the first week of therapy. Improvement of Trendelenburgs test, Time up and go test and Tandem walk test were pronounced since the last two tests were not possible without the quadricane.

Conclusion
A comprehensive short-term physical therapy program focused on neuromuscular training can improve the functional outcome and life quality effectively even after years of a major explosive traumatic burn case.

ISPR8-1134
EFFICACY OF PHYSIOTHERAPY IN THE PRESENCE OF GLENOID CAVITY FRACTURE-
CASE REPORT
M. Büke¹, S. Erel¹, F. Ünver¹, G. Bayrak¹, U. Baş Aslan¹
¹Pamukkale University, orthopedy, Denizli, Turkey

Introduction/Background
Shoulder glenoid cavity fractures are rare cases. It is usually seen as a direct effect of the
humeral head against the glenoid fossa in patients who are exposed to high-energy trauma.
This case report aimed to contribute to the literature about a physiotherapy treatment methods
of glenoid cavity fracture and to report the results of the treatment program.

Material and Method
The patient with glenoid cavity fracture was 58-year old male farmer. His dominant upper
extremity was right. A goat hit his right shoulder than, he fell down by impact. Patient presented
to university hospital. The radiography of the patient showed a fracture of the right glenoid cavity
and upper humerus. The patient’s shoulder operated. Patient used a shoulder strap for 7 weeks.
Then patient received physical therapy. Physical examination of the patient revealed sensitivity
and pain around the shoulder. He had decreased in shoulder motions. First measurements were
taken for glenohumeral joint motion by universal goniometer. Pain intensity was measured with
Visual Analog Scale (VAS) and shoulder functions was assessed with the shortened disabilities
of the arm, shoulder and hand questionnaire (DASH). In addition, Nottingham Health Profile
(NHP) and Beck Depression Scale (BDS) were administered. Physiotherapy program (Pulse-
ultrasound, TENS, High voltage cold pack, patient-specific exercises) was applied for 3 weeks
(5 days/week). First week active isometric exercises were applied. Resistive exercises were
conducted after 2 weeks.

Results
Before the treatment, shoulder range of motion was (62˚flexion- 40˚abduction). After the
treatment, this motion increased (110˚ flexion- 90˚abduction). Before treatment, scores were
VAS-activity =6, DASH=40.9, NHP=86.66 and BDS=10. After the treatment this scores
decreased (VAS-activity =2, DASH=25, NHP=35.17 and BDS=2) After 3 weeks, patient reported
that he could easily do activities of daily life.

Conclusion
Physiotherapy applied with conventional treatment and personal exercise approach can be used
as an effective method in patients with glenoid cavity fractures.

Wrestling is one of the oldest sports that require high flexibility, muscular strength and endurance. The basis of this sport is competition. In competitions, individuals are divided into groups according to their weight and other parameters. Although this procedure somewhat reduces the risk of injury, however, it is possible that the Wrestler will be injured. There is limited information about musculoskeletal disorders (MSDs) in the Iranian wrestler. So, the purpose of present study was to determine the frequency of MSDs and professional risk factors among wrestlers.

Material and Method

This cross-sectional study was conducted on 55 wrestlers during 2017 using a questionnaire in three parts including: Demographic and occupational data, Nordic standardized musculoskeletal disorders questionnaire (NMQ) and Body Discomfort Assessment technique. The data were analyzed using descriptive statistics, chi-square and T-test, and a p<0.05 was considered as significant.

Results

The Frequency of MSDs in wrestlers was 45.5%. The most common site of injury was knee and shoulder with a frequency of 27.3% for each. MSDs prohibited 41.8% of wrestlers to continue sports activities for one year. A significant correlation was found between training of basic professional techniques at the beginning of wrestling and frequency of MSDs (P=0/001). The Frequency of MSDs was significantly higher in wrestlers with longer sport history(P=0/002).

Conclusion

The results indicates that MSDs are the common problem among the wrestlers. Two most common risk factors were long sport history and inappropriate learning of basic professional techniques which must be considered in athletes and coaches education and their health care program.

The snapping scapula syndrome (SSS) is a scapulothoracic joint disorder result of an incongruence between the scapula and the thoracic wall caused by bony or soft tissue masses and postural or structural deformities. Symptoms range from mild discomfort to painful, audible crepitus with active shoulder movements that produces notable shoulder dysfunction especially with overhead activity or repetitive overuse. Crepitus can be painless, but most patients present it, it’s located mostly at the supero-medial angle or inferior pole, it can associate cervical irradiation. Diagnosis is mainly clinical, crepitus may be accentuated with compression of the superior angle of the scapula against the chest wall during arm abduction, pain and snapping decrease crossing the arm. Pseudo-winging may appear as compensation for pain. Initial management is conservative. Goals are reduce pain, improving muscle strength and balance, addressing postural conditions. Surgery is indicated after failure of 3-6 months of conservative management or in anatomic lesions.

Material and Method

We present the case of a 22 year old woman with scapula pain and cracking after a bad movement 5 years ago, symptomatology predominates during sports. No cervical symptoms were found. At physical examination there was tenderness, discomfort and crepitus in the supero-medial scapular angle, scapular tilt and minimal scapular diskynesia with arm abduction. She associated kyphotic attitude. Range of motion was preserved and painless. Standard radiographs and magnetic resonance were normal. We prescribed 15 sessions of ultrasound, strengthening stabilizing musculature of the scapula centered on rhomboids and middle trapezius and postural correction.

Results

Kyphotic attitude and diskynesia was corrected. Tenderness, discomfort and crepitus decreased in frequency.

Conclusion
The SSS is commonly misdiagnosed. It was described by Dr. Boinet in 1867, but during a long time it was only associated with osseous abnormalities. Our role is informing and explaining the patient the benign nature of SSS and guide the conservative treatment.

Keywords

HOW TO ASSESS THE RETURN TO PHYSICAL ACTIVITIES FOLLOWING ANTERIOR CRUCIATE LIGAMENT INJURY?

O. Ucay1,2, A. Renault1, B. Chaminade2, E. Cavaignac3, D. Gasq1,4

1Centre Hospitalier Universitaire- Hôpital de Rangueil, Department of Functional Physiological Explorations, Toulouse, France
2Centre Européen de Rééducation du Sportif, Cers, Capbreton, France
3Centre Hospitalier Universitaire- Hôpital de Purpan, Department of Orthopaedics Surgery, Toulouse, France
4Toulouse NeuroImaging Center, University of Toulouse- Inserm UMR 1214- UPS, Toulouse, France

Introduction/Background

Several outcomes could be used to assess return to physical activities (RTPA) after anterior cruciate ligament (ACL) injury: qualitative outcomes like return to main sport or pre-injury level; quantitative outcomes like weekly hours of practice or Tegner score. Performing a relevant clinical assessment is challenging, especially for patients who practice at a moderate sport level. Our objective was to compare the use of different outcomes to assess RTPA after functional and surgical treatment of ACL injury.

Material and Method

40 patients were included after surgery (group ST; 31.7±10.6 years-old, 15.0±5.0 months after ACL reconstruction); 18 after functional treatment (group FT; 38.1±14.8 years-old, 23.0±6.0 months after ACL tear). Qualitative criteria were subjectively assessed answering yes/no when questioned concerning their RTPA. Objective criteria were defined as variations between pre-injury and post-treatment of Tegner score, weekly hours of practice, “Tegner.h” (global volume of activity equal to Tegner score multiplied by weekly hours of practice) for main physical activity (MPA) and global activity (3 MPA included).

Results

Return to subjective global pre-injury level was 22% for FT group vs. 25% for ST group (p=0.999). Return to pre-injury (i) level of MPA was 17 vs. 23% (p=0.736); (ii) Tegner score for the MPA was 56 vs. 30% (p=0.083); and (iii) global Tegner.h was 61 vs. 18% (p=0.002) for FT versus ST group, respectively. Evolution of Global Tegner.h score, MPA Tegner.h score and Global weekly hours of practice were congruent for FT group, but not for ST group.

Conclusion
We found low RTPA rates with some discrepancies between different outcomes of RTPA. Global Tegner.h could be an interesting alternative to Tegner score of the MPA for assessment of RTPA in non-operated patients who have a moderate physical activity level.

RETURN TO COMPETITION IN AN ELITE JUDOKA AFTER NON-OPERATIVE MANAGEMENT OF AN ANTERIOR CRUCIATE LIGAMENT (ACL) INJURY: A CASE REPORT

B. Castillo¹, W. Micheo¹

¹University of Puerto Rico- School of Medicine, Physical Medicine and Rehabilitation-Sports Medicine, San Juan, Puerto Rico

Introduction/Background

Current data supports that ACL reconstruction may not be needed for all individuals after injury. Copers demonstrate the capability of using coordinated muscle strategies to overcome a lack of passive instability and may return to higher levels of function after completion of a multidisciplinary rehabilitation program.

Material and Method

28 y/o male judo athlete presents to a sports medicine clinic due to a 3-week history of right knee trauma during a competition, while out of the country. Patient refers that during his combat his opponent fell on top of him while his leg was wrapped around the hip of his opponent (hip in abduction and knee in flexion, adduction and internal rotation). The patient was not able to finish his combat, but was able to limp off the mat. Pertinent findings during our evaluation were: mild swelling with quadriceps atrophy, tenderness in posteromedial joint line with medial knee pain upon full flexion, positive Lachman test (Grade +2), and negative pivot shift.

Results

MRI of the right knee demonstrated a partial ACL tear and bone contusion in the tibial tuberosity. Initial isokinetic test demonstrated significant deficit in peak torque of extensors>flexors. Patient was diagnosed with a right ACL tear and was started in physical therapy to focus in improving strength, flexibility and proprioception. Patient was allowed to return to practice as no pain, swelling or instability was evident; no contact or pivoting exercises were allowed until 3 months after injury.

Conclusion

Repeat isokinetic test and hop test, 3 months after initial injury, demonstrated no significant deficits or asymmetry. 6 months post injury, patient was cleared to participate in full combat due to adequate findings in physical exam (Lachman Grade +1, negative pivot shift, and full ROM), no pain, swelling or instability, adequate results in functional tests, and clearance by orthopedic surgeon and sports medicine psychologist.

Introduction/Background

This study evaluated the results following an accelerated rehabilitation using closed kinetic chain on patients who had received a reconstructive therapy of the anterior cruciate ligament via transplantation of the patellar tendon under arthroscopy based on the Kenneth Jones technic.

Material and Method

This prospective and descriptive study was conducted over 100 patients with an average age of 29. They were all taken care of by the rehabilitation unit of CHU Mustapha from year 2009 to 2015. They all received the same medical rehabilitation program based on the closed kinetic chain, that considered the ligamentization phenomenon and mechanical constraints imposed to the knee. The evaluation took place at day 0, day 21, month 2, month 3 and month 6 post-surgery, focusing on 5 major elements: pain, intraarticular effusion, joint mobility, muscle strength and amyotrophy. Stability of the knee was evaluated at month 6 post-surgery using IKDC, ARPEGE and Lysholm scores. The rate of activity recovery was evaluated at month 6 postsurgery.

Results

Minimal pain: 2,99/10 on EVA scale. Profuse intra-joint effusion at day 21 in 50% of patients. Absent intra-articular effusion at month 6 in 78% patients. Mobility continuously improved. Muscular strength is identical to the contra-lateral side at month 6 post-surgery for 65% patients in regards to the quadriceps muscle and for 70% patients in regards of the hamstring muscle. A 1cm amyotrophy compared to the contralateral side, with a 10% loss of the muscular mass. Minimal residual laxity without any signs of instability for 9% of patients. Satisfactory results post closed kinetic chain rehabilitation.

Conclusion

The rehabilitation protocol in closed kinetic chain developed in the eighties shows its importance up to these days. It is now applied in the knee ligamentoplasty rehabilitation program.

ISPR8-1519
MODERN SURGICAL TREATMENT OF VICTIMS WITH AMPUTATIONS OF LOWER LIMBS IN RESULT OF GUNSHOT INJURIES
B. Alexandr¹, A. Bespalenko¹, M. Vakulych¹
¹Bogomolets National Medical University, Traumatology and orthopaedics, Kyiv, Ukraine

Introduction/Background

Statistics today shows that the proportion of injured limb in terms of fighting today constitute 53-70% of all combat injuries. The main reasons that led to amputations were: direct avulsion of traumatic limbs, massive limb soft tissue injury, damage to major vessels, compartment syndrome, infectious complications.

Material and Method

Defined two groups of patients: the main group - 37 and control - 39 patients. Homogeneous group of patients by age and the severity of injury. Tactics of surgical treatment of patients of the main group encompassing: complete surgical treatment using lavage systems, ultrasonic cavitation and negative pressure wound therapy. Non-surgical treatments were used: skin traction stump using adhesive tapes for physiotherapy, mirror therapy program and individual rehabilitation. Patients in the control group surgical tactics encompassing: primary landmark and surgical treatment of stumps, applied common rehabilitation.

Results

The algorithm of surgical treatment of patients with amputations battle that contained the active application lavage, ultrasound cavitation and V.A.C. therapy to control bacteriological content speeded up the healing of wounds stumps. This reduces the number of repeated surgical treatments by 22.4%, reduces reamputations 8.5% of infectious complications in 12.1% of bed
Figure 1. Results of treatment, using modern methods of surgical treatment

**Conclusion**

Despite the complexity of combat amputation, strict adherence to the algorithm providing surgical care to patients saves lives combat amputation. This set of measures makes it even easier to form functional stump, which in turn accelerates the prosthesis and further social adaptation. Implementation of advanced surgical treatment of gunshot wounds: active lavage, ultrasound cavitation and VAC therapy with monitoring of bacteriological properties significantly speeds up cleaning of wounds and their healing. This reduces the number of repeated surgical treatments by 21%; reduces quantity of reamputations to 8.2% ; infectious complications in 13.1%.

STAGED SURGICAL TREATMENT OF PATIENTS WITH MULTIPLY GUNSHOT FRACTURES OF LIMBS
B. Alexandr¹, Y. Yarmolyuk², M. Vakulych³
¹National Medical University, Traumatology and orthopaedics, Kyiv, Ukraine
²National Military Medical Clinical Center, Traumatology, Kyiv, Ukraine
³Bogomolets National Medical University, Traumatology and orthopaedics, Kyiv, Ukraine

Introduction/Background

Due to the large number of victims of armed conflict in the East of Ukraine with multiple gunshot fractures of long bones there we need to create complex and staged recovery treatment through all levels of medical evacuation.

Material and Method

The main group (119 patients) was treated according to proposed system in traumatology department of the National Military Medical Clinical Centre (Kiev) and then rehabilitated according to individual program of medical rehabilitation. The first comparison group (118 patients) was treated with generally accepted methods of treatment in other military hospitals of Ukraine. The second comparison group (118 patients) were soldiers which were treated during Soviet war company in Democratic Republic of Afghanistan with old fashioned methods of treatment, but with good rehabilitation system. Total - 380 patients with multiply fractures of limbs.

Results

To evaluate the effectiveness of treatment in all groups the results of treatment were analyzed using the scale of Luboshyc - Mattis — Schwartzberg. The best results of treatment were showed in main group, worse results were showed in 1 and 2 group of comparison (tab. 1)

NORMATIVE VALUES FOR THE FIVE-REPETITION SIT-TO-STAND TEST OF POPULATION OF TURKEY
F. Unver¹, J.S. Basim², B. Unver²
¹Pamukkale University, School of Physical Therapy and Rehabilitation, Denizli, Turkey
²Dokuz Eylul University, School of Physical Therapy and Rehabilitation, İzmir, Turkey

Introduction/Background

The ability to rise from a chair is an important activity of daily living and is one of the activities used in functional indexes and in test batteries of physical functioning. National variations in STS test performance suggest that norms developed for one country are not applicable to other countries. The aim of the study to determine the reference values of the Five-Repetition STS test according to age and sex in Turkish population.

Material and Method

A cross-sectional study design was used. Healthy individuals aged 20 years and older were invited to participate in the study. 527 individuals (269 women, 258 men) volunteered to participate in this study. The mean age of participants was 50.41±20.67 (range 20-89) years. There were seven age groups (20–29, 30–39, etc.). The Five-Repetition STS test was performed two times with an interval of 3-minute rest. The average of these two trials was recorded as a result.

Results

The mean of the Five-Repetition STS test was 11.20 ± 4.44 (4.35-47.76) s. It was determined that there was a significant difference between men and women in the age groups of 20-29 and 40-49 years old. The mean of the Five-Repetition STS test was found to be higher in women men in these age groups. There was no significant difference between men and women in other age groups. It was observed that the mean of the Five-Repetition STS test increased gradually as the age progressed in men and women. It was determined that there is a strong, significant, and positive correlation between the Five-Repetition STS test age in both men and women.

Conclusion

The reference values of the Five-Repetition STS test according to age and sex specific to the Turkish society were determined in order to draw a person-specific rehabilitation program and to evaluate the treatment results more objectively.

Introduction/Background

Handgrip strength measurement is clinically used to determine the effectiveness of different treatment strategies in traumatic hand diseases as well as in diseases affecting hand function because of their systemic or local degenerative character. National variations in grip strength suggest that norms developed for one country are not applicable to other countries. The aim of the study to determine the normative values of handgrip strength in Turkish population and its relationship with age and gender.

Material and Method

A cross-sectional study design was used. Healthy individuals aged 20 years and older were invited to participate in the study. 427 individuals (227 women, 201 men) volunteered to participate in this study. The mean age of participants was 47.37±18.98 (range 20-89) years. There were seven age groups (20–29, 30–39, etc.). Hand strength data were collected using a Jamar dynamometer with standard testing position, protocol and instructions. Handgrip strength was measured three times with a hand dynamometer. Averages of three measurements were reported.

Results

The means of handgrip strength measurement were 32.95±11.20 kg for the right hand and 29.93±10.11 kg for the left hand. In females and males, the grip strength reaches its peak value between 30-39 and 40-49 years and it is starting to decrease after the fifth decade. There was a strong correlation between the handgrip strength and age in the negative direction. There was a negative weak-to-medium correlation between the handgrip strength and body mass index. There was a positive strong correlation between handgrip strength and body height and body weight. In all age groups of males, handgrip strength was higher than females.

Conclusion

We believe that the Turkish society's unique age stratified handgrip strength obtained in our study may be used to evaluate hand injuries, set treatment goals, evaluate surgical outcomes, and assess patients' ability to return to employment.

ISPR8-1656
FREE MOBILIZATION BETTER THAN IMMOBILIZATION IN PARTIAL RUPTURE OF ACHILLES TENDON IN MICE: A HISTOPATHOLOGY STUDY

Y. Waluyo¹

¹Faculty of medicine Hasanuddin University, Physical Medicine and Rehabilitation, Makassar, Indonesia

Introduction/Background

Achilles tendon injury mostly occurs to 30-50 year old patient, and approximately 35% of all tendon injury cases. Caused by the specific placement of tendon structure, the athletes tend to have flat feet and often pull the soleus repeatedly, which leads to increase injury. Until now, tendon injury therapy becomes controversial. Some articles mentioned that the best treatments are open surgery and conservative medicine. But in this modern era, LLLT becomes such an alternative therapy, reduces inflammation and helps recovery process in acute phase. Therefore, this research aims to understand the differences of collagen fibers structure in partial rupture of Achilles tendon in mice

Material and Method

This research uses free mobilization and immobilization treatment, combined with low level laser therapy and measured with histopathology study. This is an experimental research, started November to December 2016 at Pet Clinic and Pathology Anatomy Laboratory Universitas Hasanuddin Hospitals. It has 14 samples, divided into two groups. First group comes with free mobilization treatment and the second group comes with immobilization treatment. The pure strains mice followed a seven-day adaptation, given a tenotomy and appropriate treatment based on its group. In the next seven days, the mice were given LLLT therapy for 4,28J/cm in three minutes alternately. Afterwards, the mice were taken to the laboratory for microscopic assessment. The pure strains mice followed a seven-day adaptation, given a tenotomy and appropriate treatment based on its group. In the next seven days, the mice were given LLLT therapy for 4,28J/cm in three minutes alternately. Afterwards, the mice were taken to the laboratory for microscopic assessment. The mice were also stained and analyzed in its collagen fibers formation.

Results

The collagen fiber formation in mice with free mobilization gained better than the immobilization one

Conclusion

free mobilization than the immobilization in partial tear of Achilles

Introduction/Background

Patellofemoral instability is a prevalent clinical entity that causes disability and pain due to several anatomical changes. It is intended to summarize the most relevant information on the subject in order to obtain a better knowledge about it and optimize therapeutic strategies.

Material and Method

Bibliographical research on the subject through the pubmed and books of the area of physical and rehabilitation medicine and orthopedics using the terms “patellofemoral instability”, “patellar instability” and “patellar dislocation”.

Results

The incidence is higher in younger women and the recurrence rate after the first episode of patellar dislocation is elevated. The most likely causes of instability are associated with an increased Q angle, patella alta and trochlear dysplasia. Patella alta and trochlear dysplasia can be diagnosed with lateral x-ray, through the evaluation of the relation between patella and tibia and using the Dejour classification, respectively. In most cases the treatment of choice is conservative through analgesic medication, physical therapy and orthoses if necessary. Consider suspend or change the physical activity that caused the symptomatology during the rehabilitation program. The surgical treatment should be considered if recurrence or persistence of symptoms and if the chronic evolution of patellar instability causes major disability.

Conclusion

It is important to establish the correct diagnosis with a good clinical history and physical examination. The imaging tests are important in the diagnosis of the cause of patellar instability. Conservative treatment should be initiated as soon as possible in order to achieve a more effective rehabilitation. Surgical treatment is reserved for when conservative treatment fails.

Meniscal injuries are the most common knee injury. Treating of meniscal injury, which don’t request operative management, is very limited and include physical therapy, compression, elevation and icing. The use of platelet-rich plasma (PRP) has been the subject of intense investigation and discussion in orthopaedic since the growth factors contained in platelet granules are shown to improve clinical outcome following a soft tissue injury, regeneration, and repair. Our aim was to present the results of research and technological advances of autologous PRP activated by autologous thrombin to reduce size of meniscal lesion and decrease time of healing and rehabilitation.

**Material and Method**

Experimental group included the meniscal injures that doesn’t request surgical treatment. Whole blood was drawn from vein, collected in 60 mL syringes and mixed with 7 mL anticoagulant citrate dextrose formula A (ACD-A). The blood was then processed, PRP was obtained and activated with autologous thrombin. 5 mL of final product was injected in the knee joint space, contra lateral of meniscal lesion. Standard protocol for physical therapy was induced immediately after the procedure, without period of stagnation. Interferential current (1-100 Hz from 2 circuits) stimulation was applied, and movement increasing and quadriceps strengthening exercises were conducted. To observe healing process we have followed the clinical outcomes and MRI imaging.

**Results**

Clinical outcomes in treated patients showed shorter time of rehabilitation and return to normal daily activities. MRI imaging showed the increased healing in treated patients compared to untreated patients.

**Conclusion**
Different clinical studies showed the benefits of PRP application in orthopaedic pathologies. The use of activated autologous PRP gives great results in terms of clinical outcomes and along with physical therapy represents optimal treatment in patients with meniscal injury.

Introduction/Background

The ankle sprain occurrences often happen in sports, and affect especially active individuals. About 40% of individuals report joint instability after a sprain. Several tests are used to evaluate the ankle instability including the Star Excursion Balance Test (SEBT), which is an indicator of improved stability after treatment. This test consists of a series of tasks performed with the lower limb in unipodal support, in which the opposing leg slides under eight straight lines (like a rose of the winds) demarcated on the ground. The objective of this study was to evaluate the effects of a six-week program of proprioceptive training in individuals with a history of ankle sprain using the SEBT.

Material and Method

It was conducted an case study of seven individuals with a history of ankle sprain in the last twelve months. All the subjects were submitted to a specific proprioceptive treatment program for the ankle, that consists of six exercises that worked proprioception in different degrees of demand. After this, they were re-evaluated by the SEBT.

Results

The results in the pre and post intervention SEBT presented statistical significance (P <0.05) in 14 of 16 directions evaluated for both ankles, however the left ankle in all the evaluated ones presented greater improvement when compared to the right one.

Conclusion

The proprioceptive training proposed by this study was efficient because it was possible to observe significant differences in the pre and post intervention in the different directions evaluated by the Star Test.

COMPLEX PRM PROGRAMMES AFTER ARTHROSCOPIC RECONSTRUCTION OF THE ANTERIOR CRUCIATE LIGAMENT (A COMPARATIVE STUDY)
I. Koleva\textsuperscript{1}, B. Yoshinov\textsuperscript{2}, R. Yoshinov\textsuperscript{3}
\textsuperscript{1}Medical University of Sofia, Dept of Physical Therapy, SOFIA, Bulgaria
\textsuperscript{2}Sofvia University, Medical Faculty, Sofia, Bulgaria
\textsuperscript{3}Bulgarian Academy of Sciences, Laboratory of Telematics, Sofia, Bulgaria

Introduction/Background

The importance of anterior cruciate ligament (ACL) for knee stability and gait recovery is recognized.

The goal of current study was to realize a comparative evaluation of the efficacy of application of five different PRM programmes of care in patients with ACL rupture and subsequent arthroscopic reconstruction of ACL.

Material and Method

MATERIAL AND METHODS:

A total of 125 patients (divided into five groups) after ACL reconstruction were treated during one month. All patients received physiotherapy (analytic exercises), cryotherapy (ice massage), patient education. Patients of first group received only these procedures. In the other groups we added different preformed modalities: for gr 2 - electrostimulations of the quadriceps femoris muscle (especially m.vastus medialis obliquus; in group 3 – Deep Oscillation (DO); in group 4 - low intensity low frequency magnetic field (MF); in gr 5 – Interferential currents (IFC).

Patients were controlled before, during, at the end of the PRM course and one month later - using a battery of objective methods: tests and scales for pain, range of motion, knee stability and gait.

Statistical analysis was performed with SPSS package, using ANOVA and Wilcoxon methods (p<0.05).

Results

The comparative analysis of results demonstrates the efficacy of physiotherapy and cryotherapy on mobility of the knee joint and gait velocity. The knee stability and the length of the step were significantly improved in group 2. Efficacy of PRM on pain, oedema was most significant in groups 3-5.
Conclusion

Authors consider that cryo-kinesitherapy is crucial for the functional recovery and gait restoration of patients after ACL rupture and subsequent ACL reconstruction. Our investigation proves that pre-formed physical modalities can ameliorate the efficacy of rehabilitation: electrostimulations are useful for the knee mobility and stability, Deep Oscillation – for pain and oedema, Magnetic field – for pain, Interferential currents – for the knee trophy and oedema.

INTEREST OF MESOTHERAPY IN THE TREATMENT OF EPICONDYLITIS
K. Ben Jeddou¹, S. Frigui¹, S. Mtawa¹, W. Ouannes¹, F. Khachnaoui¹
¹Hôpital Sahloul, service de médecine physique rééducation et réadaptation fonctionnelle, Sousse, Tunisia

Introduction/Background

The lateral epicondylitis is a pathology of hyper sollicitation of the common tendon of the lateral epicondylar muscles. Mesotherapy is a procedure consisting of several subcutaneous drug injections performed simultaneously with one or a multitude of needles. The principle is to inject a very small amount of drugs directly into the painful area of the body. This work will allow us to demonstrate the effectiveness of mesotherapy in epicondylitis by a double evaluation: the improvement of pain and the function of the elbow.

Material and Method

This is a descriptive prospective study of a series of 16 patients treated in the Physical Medicine and Functional Rehabilitation of the Sahloul hospital for epicondylitis. A mesotherapy protocol was performed (5 intradermal injections in palpable pain points, 4 mm deep, injecting 0.1 ml per point) including 3 sessions at 7 days apart (D0-D7-D14). Drugs used: Lidocaine, Piroxicam and Thiocolchicoside.

Pain and function were evaluated using the Visual Analog Scale (VAS) and the Mayo Elbow Performance Score (MEPS) at days 0-7-14 and 30.

Results

All of the analysable results include 16 patients with epicondylitis, with an average age of 33,5 years and 68,7% of whom were male. No patient has received rehabilitation, analgesic or anti-inflammatory treatment. At day 0, the mean VAS score was 7,1/10 and the mean MEPS score was 55/100. At day 14, the mean VAS score was 3,4/10 and the mean MEPS score was 70/100. At day 30 (end of the protocol), the mean VAS score was 1,1/10 and the mean MEPS score was 85/100.

Conclusion

Our study found significant improvement in pain and elbow function after mesotherapy. However, large-scale studies should be conducted to truly demonstrate the benefit of mesotherapy by comparing it to management by rehabilitation or corticosteroid infiltration.

Magnetic resonance imaging (MRI) and x-ray have traditionally been used to identify musculoskeletal pathology. Diagnostic musculoskeletal ultrasound, however, is becoming increasingly popular among physiatrists.

Material and Method

A 35-year-old male runner with no significant past medical history presented with a complaint of right medial knee pain for the past 6 to 8 weeks. He reports that he had recently increased his running mileage significantly while running in shoes that were due to be replaced. He had stopped running but noted that the pain persisted. He described the pain as located in one specific spot on the medial aspect of the right knee, rated 4/10 most of the time, but was exacerbated by putting more force through his leg with activities including jogging, going up and down stairs, or carrying heavy objects.

Results

X-rays of the right knee were obtained and were normal, which prompted further imaging with an MRI one week later, which was also normal. Laboratory testing was remarkable for vitamin D deficiency of 13 ng/mL. Musculoskeletal ultrasound revealed a small fracture of the medial epicondyle of the femur measuring 3 mm x 3 mm that was tender to sonopalpation. The patient was instructed to avoid running until pain free for at least 2 weeks before starting on a graduated return to running protocol.

Conclusion

Musculoskeletal ultrasound may be a useful imaging modality for identifying stress fractures even in some cases where traditional imaging with x-ray and MRI are negative. This may have important implications for use in resource-limited settings where ultrasound is portable and relatively inexpensive in comparison to MRI.

INTRODUCTION/BACKGROUND

BACKGROUND: In surgically stable ankle fractures there is discrepancy in mobility and weight load in the first 6 weeks, causing a reduction in joint range due to contracture of periarticular tissues, muscle atrophy and decreased muscle torque. Early rehabilitation consists of weight loading and active controlled ankle mobilizations and favorable changes in less time.

MATERIAL AND METHOD

METHODS: Descriptive, cross-sectional, prospective study in 20 patients with surgically stable ankle fractures; early rehabilitation was applied by measuring clinical parameters, the Olerud Molander functional scale and recovery time. The results were analyzed with the Wilcoxon test.

RESULTS

RESULTS: When the initial measurement was compared with the measurement at time of discharge, a positive tendency to improvement was made. In functionality: $Z = -4.472 / p = .000$, and in the pain and perimetry: $Z = -3.879 / p = .000$.

CONCLUSION

CONCLUSIONS: The weight load and early mobilizations support a positive clinical and functional evolution of the patient with surgically stable ankle fracture without representing greater risk or complications.

DETERMINANTS OF OUTCOME AFTER MILD TO MODERATE MOTOR VEHICLE CRASH INJURY: TYPE OF INJURY IS NOT A PREDICTOR
I. Cameron¹
¹University of Sydney, Kolling Institute, St Leonards, Australia

Introduction/Background

Studies have shown that in people injured in a road traffic crash, persistent symptoms are common and can lead to significant ongoing personal impact. In this study we aimed to track the experience and key outcomes of persons who had sustained mild/moderate injuries as they returned to health (and work, where relevant) following a road traffic crash.

Material and Method

This is an inception study cohort of adults who had sustained mild to moderate injuries (that is, except serious injuries) in motor vehicle crashes in New South Wales, Australia, who were recruited and interviewed at baseline (within 3 months of the crash) and at 6, 12 and 24 months post-injury.

Results

Minor injuries had major impacts on pain ratings, physical and mental well-being, health-related quality of life and return to work and preinjury participation during the 24 months post-injury phase. Further, for mild to moderately severe injuries, biopsychosocial factors are the main prognostic indicators of recovery (not the location or type of injury). Examples of key biopsychosocial factors are: age; preinjury health; quality of life; reactions to injury (catastrophising, and pain); social support and the third party insurance compensation system.

Conclusion

Study findings have also reiterated the importance of looking beyond the injury to the ‘whole person’. These results are important to rehabilitation services which should carefully assess and address psychosocial factors when providing rehabilitation programs.

COMPARISON OF FUNCTIONAL RESULTS AFTER EARLY CONTROLLED MOTION FOR SURGICAL REPAIR OF ACUTE AND CHRONIC ULNAR COLLATERAL LIGAMENT INJURY OF THE THUMB

B. Başar¹, N. Güneşaslan¹, B. Erhan¹, H. Başar²
¹İstanbul Gaziosmanpaşa Taksim training and research hospital, Department of Physical Medicine and Rehabilitation, İstanbul, Turkey
²İstanbul Gaziosmanpaşa Taksim training and research hospital, Department of Orthopedics and Traumatology, İstanbul, Turkey

Introduction/Background

Injuries to the UCL can lead to functional impairment. Rehabilitation is very important for functional results. Early motion after surgery is avoided. Usually the controlled motion starts after the 6th week. The aim of this study was to evaluate functional results of early controlled motion before 6th week.

Material and Method

19 patients (18♂/1♀) had an acute UCL rupture, 25 patients (23♂/2♀) had a chronic UCL rupture. Two soft anchor (Mini 1.0mm) were used to repair ruptured UCL to bone insertion at the acute UCL injury group. For chronic UCL injury group, 3.0mm bone tunnels were prepared to proximal and distal insertion of UCL and then tendon graft was passed through the tunnels. The tendon graft was stabilized by placing 3.0-mm bioabsorbable suture anchors within the tunnels. The motion was restricted in the 2 week with thumb spica. Dynamic splint and passive ROM exercises were started after 2 week. Active ROM exercises were started after 4 week.

Results

There were no significant differences between the two groups in the men/women ratio, mean age, mean follow-up period. All patients regained full stability at MCP joint in acute UCL injury group; 21 patients regained full stability and 4 patients presented with mild laxity (<10° laxity) in chronic UCL injury group. The ROM of injured MCP joint of thumb was regained at 8-10 week as good as healthy extremity MCP joint of thumb. There were no significant differences between operated and healthy thumb MCP joint in both groups in the grip and pinch strength, flexion, extension, radial deviation, ulnar deviation motions at final control. Glickel grading scale was excellent for 19 patients for acute UCL injury group; it was excellent for 21 patients and good for 3 patients in chronic UCL injury group.

Conclusion
Early controlled motions affect functional results positively. Repair with 1-mm soft anchors in acute UCL injury and reconstruction with tendon graft which stabilized by 3-mm bioabsorbable suture anchors within the tunnels in chronic UCL injury provides adequate stability for early controlled motion.

THE EFFECT OF MENISCAL REPAIR ON KNEE PROPRIOCEPTION
B. Başar¹, B. Erhan¹, N. Güneşaslan¹, H. Başar²
¹Istanbul Gaziosmanpaşa Taksim training and research hospital, Department of Physical Medicine and Rehabilitation, Istanbul, Turkey
²Istanbul Gaziosmanpaşa Taksim training and research hospital, Department of Orthopedics and Traumatology, Istanbul, Turkey

Introduction/Background

Aim of our study was to evaluate the effect of meniscal repair on proprioceptive function of the knee. Also we assessed whether meniscal repair together with ACL reconstruction improve the knee proprioception and function.

Material and Method

The study included 32 patients underwent arthroscopic repair, who were diagnosed with meniscal tear and accompanying ACL rupture. Of the patients who underwent meniscal repair with suture, 8 had a longitudinal tear, 4 had a horizontal tear in the red-red zone and 7 had a bucket handle tear. 13 patients underwent partial meniscectomy, 6 had a displaced flap tear, 4 had radial tear in the white-white zone and 3 had a complex tear. The patients were evaluated pre-operative and post-operative two groups: Pre-operative group: ACL rupture-meniscus tear, post-operative 1st group: ACL reconstruction and partial meniscectomy, and post-operative 2nd group: ACL reconstruction and meniscal repair with meniscal suture. Knee joint position sense (KJPS) test and Lysholm knee scoring scale were used evaluate the knee joint proprioception and function at 12th month.

Results

The mean age was 28.3 (range 17 to 33 years), and 30 were male and 2 were female. Pre-operative (ACL rupture-meniscus tear) group had significantly different KJPS values on wide range of knee motion (15°-30°-45°-60°-75°) in the injured knee compared to the healthy knee. The mid-range proprioceptive function loss was healed after surgery. However, a statistically significant difference was observed in only the range of knee motion of 60° in patients underwent meniscal repair with meniscal suture, whereas in the range of knee motion (45°-60°-75°) in patients underwent partial meniscectomy. Significantly better results were achieved with ACL reconstruction with meniscal repair compared to the partial meniscectomy according to the Lysholm knee scoring scale.

Conclusion
In case of meniscal tears, the meniscal repair should be sutured, if possible, in order to obtain better results in terms of knee function and proprioception.

BILATERAL QUADRICEPS TENDON RUPTURE: FROM DIAGNOSIS TO REHABILITATION
R. Prado Costa¹, J. Barroso¹, J. Barroso², F. Parada¹
¹Centro Hospitalar São João, Department of Physical and Rehabilitation Medicine, Porto, Portugal
²Unidade Local de Saúde de Matosinhos, Department of Orthopaedics and Traumatology, Matosinhos, Portugal

Introduction/Background

Bilateral quadriceps tendon rupture (BQTR) is a rare injury frequently associated with delayed diagnosis and predisposing risk factors. Two cases of BQTR were referred to our Department of Physical Medicine and Rehabilitation (PM&R). A four phased rehabilitation protocol was designed and executed in both cases.

Material and Method

We report two cases admitted to our PM&R department with description of the rehabilitation progress with the prescribed rehabilitation protocol. We also review the current literature about clinical and rehabilitation aspects of BQTR.

Results

Case report number 1: 50 year-old man, history of uncontrolled type 2 diabetes mellitus, fell while walking down stairs. At the emergency department, a BQTR was diagnosed and surgery was performed using a transosseous suture repair technique. At the PM&R department the rehabilitation program was executed until 16 weeks postoperatively. Normal knee range of motion was restored, normal gait was reacquired and the patient was able to engage in previous activities.

Case report number 2: 75 year-old man, history of untreated gout, fell down the stairs and became unable to walk normally. The diagnosis was missed in the first emergency department visit and 11 days after the patient was reassessed leading to BQTR diagnosis. Surgery was then performed with transosseous suture repair technique in the right knee and end-to-end Krackow sutures in the left knee. The rehabilitation protocol was executed until week 23 postoperatively. Despite the different surgical techniques, the progress through the rehabilitation program was similar for both knees.

Conclusion

BQTR is a rare injury that doctors must be aware of as well as potential predisposing factors. A rehabilitation protocol was conducted with success and may serve as reference for other PM&R
professionals. Different tendon repair technique performed in the same patient may not have significant implications in the rehabilitation process.

PLATELET-RICH PLASMA THERAPY AND REHABILITATION EXERCISES FOR THE TREATMENT OF SKELETAL MUSCLE INJURY: A CASE REPORT

Introduction/Background

Platelet-rich plasma (PRP) has been considered as a promising treatment for tissue repair and regeneration as an autologous blood product. The transforming growth factor-β (TGF-β) can be released from PRP and acts as a pluripotential cytokine to regulate fibrogenesis. The aim of this study is to first report muscle defects in forearm treated with PRP intramuscular injection and rehabilitation therapies.

Material and Method

A patient with two muscle defects on the right forearm after gunshot surgery were treated with PRP intramuscular injection and rehabilitation therapies. 5 ml PRP were used for injection while 1 ml were measured immediately after preparation. Forearm rehabilitation therapy were conducted after injection. The outcomes of this study include quantification of platelets and TGF-β, forearm performance evaluation and radiological analysis.

Results
Our PRP preparation protocol with RCF 117.7g can obviously enrich the platelets up to $570.24 \times 10^9/l$ compared with baseline (352%, $P<0.05$). The TGF-β was measure by ELISA and showed average concentration of 148.59 ng/ml (331%). MRI shows thickened and enlarged muscles of the affected forearm with increased girth (19.67cm to 27.86cm). Isometric evaluation including wrist extension/flexion, pronation/supination, hand grip and pinch were significantly increased.

**Conclusion**

PRP is a nontoxic and autologous blood product with highly concentrated platelets and growth factor (TGF-β). Our protocol can produce highly efficient PRP and the PRP intramuscular injection may be able to conduct muscular repair and regeneration after injury.

Interest of the Botulinum Toxin in Adductor Related Groin Pain

T.Fok Cheong K Ah Wai¹, A. Creuzé², P. Bordes³, M. De Seze³
¹Ile de la Réunion, 97460, saint paul, France
²Clinique des Grands chênes, Gironde, Bordeaux, France
³CHU bordeaux, gironde, Bordeaux, France

Introduction/Background

Groin pain in athletes is a common problem. The use of botulinum toxin (BTX) has shown good results in neuromuscular diseases and more recently in pathologies such as epicondylitis. The aim was to assess the effectiveness and side effects of the BTX injections in adductor related groin pain which resists to rehabilitation and/or surgery. A pilot study with one year follow-up

Material and Method

Between March 2014 and April 2016 we systematically registered patients who received BTX injections in adductor muscles under both control by ultrasound and electrostimulation. We carried out a follow up at 1, 3, 6 and 12 months on pain intensity, HAGOS scores, professional disability, and side effect recording.

Results

30 patients, 83% males and 17% females have been included. Adductor tenotomy was recorded in 14 patients before the injection. Pain intensity decreased significantly (D0: 65±16mm; D30 31±23; D90 28±23; D180 33±28; D365 31±30; p<0.05). HAGOS score showed significant improvements on all sub-scales (symptoms, pain, physical function in daily living, in sport and recreation, participation on physical activities and hip or groin related quality of life (p<0.05)). The intensity Professional disabilities decreased significantly at D30, 90, 180 and D365 (p<0.05). Three patients failed to be relieved and all of them had a previous adductor tenotomy. Five patients had a recurrence during the follow up and 3 of them had a previous adductor tenotomy too.

Conclusion

This present study suggests that BTX is an effective treatment for the adductor related groin pain with no side effect and a low rate of recurrence

THE EFFECT OF PELVIS CONTROL ON THE CONSERVATIVE MANAGEMENT OF MULTIDIRECTIONAL INSTABILITY OF THE GLENOHUMERAL JOINT.
A. Kyriakides¹, G. Vasilopoulos¹, G. Gonidakis¹, M. Pyrgeli¹, S. Vasilopoulos¹, D. Alexakis¹
¹Performance 22, Physical Medicine & Rehabilitation Dpt, Athens, Greece

Introduction/Background

Specific rehabilitation program that focuses on dynamic muscular control to provide stability is the most accepted conservative approach for multidirectional instability (MDI). Our primary objective is to review the current evidence-based rehabilitation guidelines of patients with MDI. Additionally, we describe our approach and present the effectiveness of a modified rehabilitation program for patients with MDI.

Material and Method

A comprehensive search of the PubMed, using various combinations of the keywords shoulder, multidirectional instability, glenohumeral, rehabilitation and exercise over the last thirty years was performed. We present step by step our approach based on expert experience and scientific evidence. A rehabilitation program is provided that designed with respect to whole body assessment in addition to the assessment of local muscular insufficiencies.

Results

Although our rehabilitation program was more time consuming in the preparatory phase, we observe that our patients had better results in relation to functional movements, recurrence and load increasing progress.

Conclusion

Our approach suggest that in order to achieve best results in MDI rehabilitation a preparatory phase is needed that focuses on whole body kinetic chain sequence.

REMOTE AFTER-EFFECTS OF RESISTIVE STATIC CONTRACTIONS OF LOWER TRUNK DEPRESSORS AND UPPER EXTREMITY ON MAXIMAL ACTIVE RANGE OF MOTION OF ANKLE EXTENSION IN ANKLE FRACTURES
T. Shiratani¹, R. Hobara¹, I. Natsuki², M. Arai³
¹Sonoda Second Hospital, Department of Rehabilitation, Takenotsuka 4-2-17- Adachi-ku - Tokyo 121-0813, Japan
²Tsukuba International University, Department of Physical Therapy, Manabe- 6-20-1- Tsuchiura-shi- Ibaraki-ken, Japan
³Tokyo Metropolitan University, Faculty of Health Sciences- Division of Physical Therapy, 7-2-10- Higashioku- Arakawa-ku- Tokyo- 116-0012, Japan

Introduction/Background

Direct approaches to improve maximal active range of motion (MAROM) of restricted joints may be difficult because of pain or weakness of agonist and/or antagonist muscles. Resistive static contraction (SC) of posterior depressors (RSCP) using a PNF pattern in the mid-range of pelvic motion increases the flexibility of remote joints, such as the upper shoulder and knee, as remote after-effects in the clinic. The purpose of this study was to investigate the remote after-effects of RSCP on the MAROM of ankle plantar flexion in patients with isolated ankle fractures.

Material and Method

Thirteen patients with ankle fractures (7 men and 6 women, mean age 50.9 years, SD 11.9 years) were randomly assigned to resistive SC of shoulder flexion on the affected side (SCUE), RSCP on the affected side, and SC of the affected ankle extensors. Each SC was induced by resistance (20% MVC) generated by a manual force using a handheld dynamometer. The duration of each resistive exercise and stretch was 20 s. The % MAROM change for ankle extension after each technique was calculated by subtracting the MAROM before each technique.

Results

The mean (SD) MAROM was 3.32 (11.35)% for RSCP, 0.64 (6.25)% for SCUE, and -5.65 (8.05)% for SC. A two-way ANOVA for the %MAROM change showed significant main effects for technique (F (2,24)=3.84, p=0.04, partial eta squared=0.24) and individual (p=0.32). A post hoc Scheffe test indicated that the % MAROM change for RSCP was significantly larger than that for SS (p=0.04).
Conclusion

RSCPD showed a significant improvement over SC, which suggests that RSCPD may have immediate remote after-effects that improve flexibility of the plantar flexor muscle in patients with ankle fracture.

Keywords

PNF; static contraction; remote after-effect

Remote after-effects of resistive static contraction (SC) of the posterior depressors (RSCPD) using a PNF pattern in the mid-range of pelvic motion to induce unilateral resistive SC of the lower trunk muscles while side-lying increases the muscle strength of the remote upper and/or lower extremities in the clinic. The purpose of this study was to determine the remote after-effects of RSCPD on the strength of the plantar flexor muscle after ankle fractures.

Material and Method

Eleven patients with ankle fractures (5 men and 6 women, mean age 48.7 years, SD 11.3 years) were randomly assigned to SC of shoulder flexion - adduction - external rotation on the affected side (SCUE), RSCPD on the affected side, and sustained stretch (SS) of the affected plantar flexors. The duration of each resistive exercise and stretch was 20 s. Each SC was induced by resistance (20% MVC) generated by a manual force using a handheld dynamometer. The % MVC change for the ankle plantar flexors after each technique was calculated by subtracting the MVC before each technique.

Results

The ICC (1,1) was 0.95 for the MVC. The mean (SD) for % MVC change was 3.82 (6.88)% for RSCPD, -1.99 (6.88)% for SCUE, and -4.95 (6.88)% for SS. The two-way ANOVA for % MVC change showed significant main effects for technique (F (2,20)=5.45, p=0.1,partial eta squared=0.36) and individual (F (10,20)=2.44, p=0.00,partial eta squared=0.86). A post hoc Scheffe test indicated that the % MVC change for RSCPD was significantly larger than that for SS (p=0.11).

Conclusion
The improvement in MVC suggests that RSCPD may have immediate remote after-effects that improve the strength of the plantar flexor muscle in patients with ankle fracture.

FLUOROQUINOLONE-ASSOCIATED TOTAL ACHILLES TENDON RUPTURE: A CASE REPORT

L. Gómez González¹, C. Casado Blanco¹, C. Cid Bassaletti¹, I. García Delgado¹
¹Hospital General Universitario Gregorio Marañón, Servicio de Rehabilitación, Madrid, Spain

Introduction/Background

Fluoroquinolones are broad-spectrum antibiotics that inhibit bacterial DNA synthesis, Levofloxacin emerges for its safety. Frequent side effects include: gastrointestinal (2-20%) and neurological symptoms (1-2%). Musculoskeletal toxicity is infrequent (<1%), being tendon rupture exceptional (1/10,000). We present a case of total rupture of Achilles tendon following fluoroquinolone use, that required surgery.

Material and Method

A 66-year-old patient, with hypertension, dyslipidemia and asthma, being treated with inhaled corticosteroids, was prescribed Levofloxacin 500 mg/day and bronchodilators for a respiratory infection. Two days after, he developed pain and edema in ankles, despite quitting antibiotics and using anti-inflammatories. There was no history of recent traumatism or overexertion. Examination showed swelling in both Achilles tendons, peri-malleolar edema and negative Thompson test. He was diagnosed of bilateral Achilles tendinitis and was prescribed anti-inflammatories. 13 days after, he re-consulted for progressive symptoms in the right ankle. Thompson test was positive and declination angle was altered. Magnetic resonance imaging demonstrated total Achilles tendon rupture, requiring surgery and subsequent cast immobilization for five weeks. After removing the cast, the patient had an active range of motion of 30° and needed walking aids, thus, physical therapy was arranged.

Results

After completing treatment, he improved 20° in the range of motion, and achieved walking without aids. Therapy consisted in: passive, active and resisted mobilizations, stretching, proprioception exercises and electrotherapy.

Conclusion

Levofloxacin is a safe drug, being exceptional its association with total Achilles tendon rupture. According to literature, this side effect is time and dose independent. Patients taking oral corticosteroid are predisposed, but ours only used inhaled corticosteroids. Conservative management is indicated in partial tendon rupture, while surgery is mandatory when rupture is
complete. Apart from surgery, physical therapy was essential to achieve the complete functional recovery of our patient.

RESULTS FROM THE FIRST RECOMBINANT BOTULINUM TOXIN (BONT) EVER TO ENTER CLINICAL DEVELOPMENT. OUTCOMES OF A FIRST-IN-HUMAN STUDY WITH RECOMBINANT BONT/E (SXN102308).

L. Pons, P. Picaut

Ipsen Innovation, Neurology Department, Les Ulis, France

Introduction/Background

There are multiple naturally occurring botulinum neurotoxin (BoNT) serotypes that have different pharmacological features and are of interest for potential aesthetic and therapeutic use. We have manufactured a BoNT serotype E using recombinant technology (rBoNT/E), which was selected for its faster onset of action and shortened duration of effect compared with BoNTs serotype A (BoNT/A) products currently commercially available. We performed a first-in-human study to assess the safety of increasing doses of rBoNT/E injected into the extensor digitorum brevis (EDB) muscle of healthy subjects, and to investigate their pharmacodynamic profile by recording the EDB compound muscle action potential (CMAP).

Material and Method

This was a double-blind, randomised, placebo-controlled single ascending dose study (sequential cohorts) in male subjects. Doses up to 3.6 ng rBoNT/E were investigated.

Results

Twenty-eight subjects were included to the study, 21 exposed to rBoNT/E on a single dosing occasion and 7 treated with placebo (ratio 3:1). No related serious adverse events (AE) were reported, no subject had a related AE that led to withdrawal from the study. All doses were well tolerated. For the dose range investigated, onset of action occurred between Day1 and Day2. Magnitude of CMAP inhibition increased with dose with about 50% inhibition for the 0.04ng starting dose, and maximal inhibition (above 90%) reached from 0.9ng. Maximal effect was recorded between Day3 and Day14 post-injection. Duration of CMAP inhibition was around 50 days for the two highest doses of 0.9 and 3.6ng.

Conclusion

This study demonstrated an overall good safety profile of single intramuscular doses of this first recombinant BoNT/E ever tested in humans within the dose range investigated, and a pharmacodynamic dose-effect allowing to thoroughly determine the doses to be used in patients. It confirmed the fast onset of action and short duration of effect of this botulinum neurotoxin as compared to currently commercialized BoNT/A.

PRESSURE ULCERS IN PHYSICAL MEDICINE AND REHABILITATION DEPARTMENT: EPIDEMIO CLINICAL STUDY

S. Frioui Mahmoudi¹, K. Ben Jeddou¹, S. Jemni¹, F. Khachnaoui¹
¹University Hospital Sahloul, Physical and Rehabilitation Medicine, Sousse, Tunisia

Introduction/Background

The aim of our study was to analyze the epidemiological and clinical aspects of patients hospitalized with pressure ulcers in Physical and Rehabilitation Medicine Department and to identify the risk factors for their occurrence.

Material and Method

It is a retrospective study conducted in the Department of Physical and Rehabilitation Medicine in Sahloul Hospital TUNISIA among patients hospitalized for pressure ulcers over a period of 5 years.

Results

63 patients were included in the study with a male predominance (71.4%) and an average age of 38.2 years. The majority of patients were transferred from an intensive care unit (49.2%), six patients (9.52%) were transferred from the orthopedic and six (9.52%) of neurosurgery department.

On admission, 58% of patients had stage 2-3 sacral pressure ulcer in 75% of cases with an average size of 6.6 cm, 63% had a heel pressure ulcer stage 2 or 3 in 45% of cases with a size average of 2.7 cm. 22.5% had trochanteric pressure ulcer stage 3 in 33% and grade 4 in 28% of cases with an average size of 6.7 cm, 14% of patients had stage 3 occipital pressure ulcers in 71% of cases with an average size of 4.5 cm. The average of Functional Independence Measure (FIM) score was 58.7/126.

The risk factors were: motor weakness (98%), layer port (87%), sensory disturbances (68%), urinary incontinence (68%), fecal incontinence (63%), hypoalbumin (43%), depression (38%), spasticity (36%), malnutrition (36%), anemia (33%), age > 65 years (14%).

Conclusion

Pressure ulcers are a real health problem. It is often the result of a misjudged risk or bad management. This is a pathology that affects the life quality of the patient. The occurrence of pressure ulcers causes a significant increase in the burden for nurses and hospital stay, hence the importance of preventing this complication.

NEUROGENIC HETEROTOPIC OSSIFICATION IN GUILLAIN-BARRE SYNDROME: A RARE CASE REPORT
L. Ozgonenel1, O. Gungor Tuncer2, M. Nalbantoglu2, M.E. Acık3, B. Altunrende2, E. Ozgonenel4, Z. Matur2
1Istanbul Bilim University, Physical Medicine and Rehabilitation, ISTANBUL, Turkey
2Istanbul Bilim University, Neurology, Istanbul, Turkey
3Istanbul Bilim University, Anesthesiology, Istanbul, Turkey
4Istanbul Bilim University, Nuclear Medicine, Istanbul, Turkey

Introduction/Background

Neurogenic heterotopic ossification (NHO) is an abnormal development of bone in extraskeletal tissues frequently seen after traumatic brain injury or spinal cord injury. NHO may also occur as a rare complication of Guillain Barre Syndrome (GBS). NHO often forms around the hip, knee and shoulder joints and may cause pain and limitation. We present a 39 year old man with an acute onset of GBS who developed NHO around both hips.

Material and Method

Patient was admitted to the emergency department with paraesthesia in all limbs and diplopia. Neurologic examination revealed bilateral abducens nerve paralysis, facial diplegia, flaccid areflexic paralysis of the limbs. The patient underwent electromyography examination and diagnosed as GBS. The same day respiratory muscle weakness appeared and patient was taken intensive care unit for mechanical ventilation. Two months after the onset of GBS, pain and decreased range of motion (ROM) emerged in both hips. NHO was diagnosed on the plain X rays of the pelvis. Three-phase bone scan confirmed the diagnosis (Figure 1).
Results

Biphosphonate was given for 12 weeks. When the patient was discharged from the ICU after two months, the muscle strengths improved in all extremities. The patient could stand up with support; however could not walk or sit in low position due to pain and limitation of hip joints. At 6 months of his rehabilitation program, he can walk with a walker.

Conclusion

NHO is a rare complication of GBS, and physicians should be aware that it can develop especially in patients who need mechanical ventilation with severe paralysis.

Psoriasis vulgaris is an inflammatory, skin disease with considerable frequency in society. Sometimes complaints of musculoskeletal problems are observed in these patients. Therefore, we decided to evaluate frequency of patients’ musculoskeletal disorders.

Material and Method

This cross-sectional study was based on the recall of patients with psoriasis vulgaris, whose files were recorded in outpatient clinics. Patients aged 18-60 years old, didn't have any Arthropathic and Erythrodermic or Pustular form of psoriasis, nor did they have any underlying rheumatologic or neurological, inflammatory disease and traumatic conditions. Finally 73 patients (29 females and 44 males) were evaluated for musculoskeletal signs and symptoms and related examinations.

Results

In this study, we asked patients about their musculoskeletal pains which results are mentioned in table 1 and the results of findings of musculoskeletal physical examinations are in table 2.

According to this study, the highest frequency observed in musculoskeletal pain was: knee pain (31.5%), back pain (23.3%), and neck pain (15.1%). The highest frequency of impaired musculoskeletal examinations was: positive phalen test (19.1%), positive Patrick test (12.3%), and hamstring tightness (10.9%). Often, the prevalence of musculoskeletal problems was higher in women.

Management of Neurogenic Heterotopic Ossification in Rehabilitation

S. Mahmoudi, M. Gaddour, R. Moncer, S. Jemni, F. Khachnaoui

University Hospital Sahlool, Physical and Rehabilitation Medicine, Sousse, Tunisia

Introduction/Background

The aim of this study is to determine the interest and the contribution of rehabilitation in the management of Neurogenic heterotopic ossification (NHO).

Material and Method

This retrospective study was conducted on the folders of patients hospitalized in Physical Medicine and Rehabilitation Department at Sahlool hospital, Sousse, Tunisia during a five years period.

Results

Twenty-five patients were included in the study with a mean age of 33.32 years (12 years - 54 years), the sex ratio was 2. Neurogenic heterotopic ossification followed mainly traumatic brain injuries (48%), polytrauma (27%) and spinal cord injuries (20%). 88% of patients have been transferred from an Intensive Care Unit. Multiple locations were observed in 80% of patients. The two most common locations were: hip (28%) and elbow (24%). 32% of patients had problems with prehension. Walking was possible only in 12% of cases. Standard x-rays detected NHO in 56% of cases. Nonsteroidal anti-inflammatory drugs were prescribed to most of our patients (23 cases) for an average period of 92 days. All patients benefited from functional rehabilitation based on icing, passive mobilization and installation in alternate extreme positions. Surgical management was needed in 16% of cases after a mean delay of 500 days. The rate of recurrence was 8%.

Conclusion

Neurogenic heterotopic ossification involves deposition of bone in extraskeletal tissue in the setting of a neurological disorder, and its pathophysiology is incompletely understood. It can lead to significant disability and functional impairment. Neurogenic heterotopic ossification can result in significant morbidity and impairs quality of life which justify a proper and early management.

EFFECTS OF SHORT FOOT EXERCISE WITH VISUAL FEEDBACK ON BALANCE AND KNEE JOINT FUNCTION IN SUBJECTS WITH FLEXIBLE FLATFEET
J. Kim¹, M. Lee¹, J. Seo¹
¹Daegu Haany University, Physical Therapy, Gyeongsan, Republic of Korea

Introduction/Background

This study examined the effects of a 5-week short foot exercise (SFE) program with visual feedback on the balance and knee joint function in flexible flatfeet and compared the measures between a flexible flatfoot and normal foot.

Material and Method

A total of 30 subjects participated in this study (15 subjects with a flexible flatfoot, 15 subjects with a normal foot). The subjects were divided through the Navicular Drop Test (NDT). The flexible flatfoot group included subjects with an NDT greater than 10 mm. The normal foot group included subjects with an NDT of 5-9 mm. The subject group performed SFE with visual feedback. SFE programs were completed 20 minutes a day, five times a week for 5 weeks.

Results

A significant difference in the static balance area was observed between the flatfoot group and normal foot group on the pre-test (p<0.05), and there was a significant difference in the Ant. direction and PM direction between the flatfoot group and the normal foot group on the pre-test (p<0.05). The knee joint motions accuracy on the closed chain was significantly different between group on the pre-test (p<0.05). A comparison of the pre and post intervention revealed a significant difference in the static balance area and all directions of dynamic balance in the flatfoot group, but only the dynamic balance was significantly different in the normal group (p<0.05). The closed chain motions accuracy of the knee joint after the intervention was similar in the flat foot group and normal foot group.

Conclusion

The balance and knee joint motions accuracy was different in the flat foot group and normal foot group. The SFT program with visual feedback was effective in improving the balance and knee joint motions accuracy.

THE EFFECTS OF EARLY WHOLE-BODY VIBRATION TRAINING FOR REHABILITATION AFTER TOTAL KNEE ARTHROPLASTY (TKA)

Y. Tsai¹, W.L. Liu¹, S.F. Lin¹, H.T. Huang², T.W. Chen¹, J.X. Chen¹
¹Kaohsiung Municipal Ta-Tung Hospital, Rehabilitation Dept, Kaohsiung City, Taiwan R.O.C.
²Kaohsiung Medical University, Department of Orthopaedics, Kaohsiung, Taiwan R.O.C.

Introduction/Background

Early physical therapy can prevent contradictions or improve functional mobility after total knee arthroplasty (TKA). One treatment of physical therapy, Whole body vibration (WBV), has been confirmed with increasing muscle strength, balance and physical function in several treatment area. The purpose of this study is to understand the effects of early WBV training for rehabilitation after TKA.

Material and Method

In the present control study recruited 13 patients with unilateral TKA after 6 weeks postoperatively. Control group (n=5) received conventional TKA rehabilitation, while WBV group (n=8) received 3 weeks (3 times/week) of WBV in addition to conventional rehabilitation. All subjects received assessments for quadriceps and hamstring strength, functional ability (Chinese version of the KOOS), balance (Biodex Balance System), walking ability (6-min walking test - 6MWT) and knee range of motion (ROM) at first and third week. Two-tailed T-test analysis of variance was used for statistical analysis.

Results

No adverse side effects were reported in both groups. There were significant increases in dynamic balance, ROM, walking distance and physical function (symptoms, activities of daily living and knee-related quality of life) for both groups (P<.05). The WBV group demonstrated significantly better knee extensor performance and dynamic standing balance (P < .05) than the control group.

Conclusion

Early WBV started from 6 weeks postoperatively was an effective training method which improved knee extensors muscle strength and dynamic balance than conventional TKA rehabilitation. The WBV might better to usual care as an early rehabilitation protocol after TKA. But future studies are necessary with larger sample sizes and long-term outcomes to be considered reliable.

5Centre Hospitalier Régional de La Citadelle, Reference Center for Neuromuscular Disease, Liège, Belgium

Introduction/Background

Upper limb function is fundamental for non-ambulant patients. In neuromuscular diseases, the impact of handgrip and key pinch progressive weakness on hand function is not described. This study aims to establish the relationships between hand strength and function in non-ambulant patients with Duchenne Muscular Dystrophy (DMD) or Spinal Muscular Atrophy (SMA).

Material and Method

The handgrip and key pinch maximal strength were measured with the MyoGrip and MyoPinch highly sensitive dynamometers, respectively. Hand function was assessed by the 6 items regarding distal upper limb function in the Motor Function Measure (MFM, a 4-points based scale rater-controlled with a total of 32 items) and by the Cochin scale (a 6-points based self-
Results

53 DMD and 23 SMA patients (age 8–31 years) were included. The scales and single items functional scores were highly correlated to strength (P<0.001). However, depending on the items, the Spearman coefficients reflected correlation varying from high to negligible, suggesting that some functional items require strength more than others.
For all the functional items but one, strength corresponding to the “greatest disability” score was significantly lower than strength corresponding to the “no disability” score (Kruskall-Wallis, $P<10^{-5}$).

Hand function was rather preserved until a handgrip and key pinch strength cut-off. For strength lower than the cut-off, hand function scores decreased with decreasing strength although a large variability was observed.

**Conclusion**

Hand functional ability is correlated to strength. However, contractures, motor compensations and psychological state may contribute to the large variability observed in the strength – function relationships. Therefore, functional hand ability of a single individual cannot be predicted solely from handgrip or key pinch strength.

THE RELATIONSHIP BETWEEN CORE ENDURANCE AND UPPER EXTREMITY PERFORMANCE IN SEDENTARY COLLEGIATE MALES

R. Savkin¹, K.Y.A. Alsayani¹, N. Büker¹
¹Pamukkale University, School of Physical Therapy and Rehabilitation, Denizli, Turkey

Introduction/Background

Core muscles contribute to general spine stabilization when the trunk is exposed to flexion and extension moments. It is thought that movements begin from the center of the body (called the "powerhouse" or "core") and flow outward to the extremities, and a strong core strengthens the whole body. Few studies have examined the relationship between core endurance and upper extremity performance and most of the studies has been done in athletes. Thus, the purpose of this study was to investigate relationships between core endurance, and upper extremity performance in sedentary collegiate males.

Material and Method

Sedentary collegiate males who had not suffered any orthopedic injury in the past year were enrolled the study. Core endurance (CE) was evaluated using trunk extensor test, bilateral side bridge tests, and The Core Muscle Strength and Stability test. The results of the core endurance tests were compared with several upper extremity performance measurements: The Upper Quarter Y Balance Test (bilateral in medial, inferolateral, and superolateral directions-UQYBT), Close Kinetic Chain Upper Extremity Stability Test (CKCUES test), medicine ball throws test (forward, reverse, right, and left in static and dynamic positions), hand grip strength, and Nelson hand reaction test.

Results

Eighty-three males were assessed during the study. Their mean age was 22.07±1.89 year (range:18-25) and mean body mass index was 23.77±3.26 kg/m² (range:17.67-36.11). We observed low correlations between the CE tests and UQYBT (r range=0.220−0.393, p<0.05) but no correlations between the CE and hand grip strength and Nelson hand reaction test. CKCUES and medicine ball throws test (non-dominant side in dynamic position) correlated with side bridge test, r=0.279 and r=0.240, respectively (p<0.05).

Conclusion

The results of this study imply that the core endurance is related to the upper extremity performance in closed kinetic chain but not with open kinetic chain functions, where only distal extremity performance is present.

Introduction/Background

Chronic pain conditions of the musculoskeletal system (MSP) are common and have a high socioeconomic relevance. It affects more than 1.7 billion people worldwide and this burden has increased by 45% during the past 20 years.

Material and Method

A cross sectional study administrated an anonymous specially designed questionnaire to a random sample of 115 students in different Saudi universities. Students' life style characters, personal particulars and physical activities' likelihood were measured. The study was conducted over a 4 months period from December 2013 to March 2014.

Results

During this four months' work, 115 Saudi university students agreed to participate. More than half of the participants (68.7%) complained of musculoskeletal pain. The most prevalent sites were the back (44.3%), neck and shoulders (30.4%). Long period of sitting was reported as the most common cause for musculoskeletal pain in general. However, bad postural sitting was reported to be the most frequent cause for MSP. Single females had a higher prevalence for musculoskeletal pain. The percentage musculoskeletal pain among males who exercise was less than the percentage of those who lack physical activity.

Conclusion

This study strengthens the findings that musculoskeletal pain is common among college students and it is influenced by their lifestyle and daily activity.

RARE COINCIDENT STIFF PERSON SYNDROME AND POLYMYOSITIS
D.H. Kim¹
¹Dongsan medical center- Keimyung University, Rehabilitation Medicine, Daegu, Republic of Korea

Introduction/Background

Stiff person syndrome is a rare neuroimmunological disorder associated with anti-glutamic acid decarboxylase antibodies. It is characterized by progressive muscular rigidity and spasms that affect axial and limbs muscles. Polymyositis is a type of autoimmune disease defined as a subacute myopathy characterized by weakness of the proximal limb muscles.

Material and Method

We report the case of a 36-year-old woman with stiff person syndrome in association with polymyositis.

Results

She presented with stiffness and pain in her four extremities. Electromyography revealed simultaneous continuous motor activity in the agonist and antagonist muscles of the proximal upper and lower extremities(Fig. 1).
Magnetic resonance imaging showed bilateral and symmetrical diffuse signal changes in the muscles of the proximal upper and lower limbs (Fig. 2).

Laboratory results showed elevated creatinine kinase levels and muscle biopsy showed inflammatory myositis (Fig. 2). Her symptoms were did not improve with diazepam and baclofen. She has undergone intravenous immunoglobulin therapy several times over the last 4 years due to episodic decline in walking ability and a worsening of muscular pain in both limbs and axial muscles (Fig. 3).

Conclusion

With immunotherapy, her serum creatinine kinase levels reduced; however, her clinical symptoms progressively worsened.

COMPARISON OF THE EFFECTS OF OZONE VERSUS STEROID INJECTION, IN TREATMENT OF PATIENTS WITH TENNIS ELBOW.

S.A. Raeissadat\(^1\), M.H. Abdollahzadeh\(^2\)

\(^1\) Research development center of Shahid Modarres hospital, Physical medicine and rehabilitation, Tehran, Iran
\(^2\) Physical medicine and rehabilitation research center, Physical medicine and rehabilitation, Tehran, Iran

**Introduction/Background**

Tennis elbow is a prevalent musculoskeletal disorder. In recent years ozone injection has been proposed as a treatment for many musculoskeletal disorders. The aim of this study was to compare the effect of ozone with the standard treatment of steroid injection in patients with tennis elbow, resistant to conservative treatments. This comparison is made according to VAS score, Pressure pain threshold (PPT) and modified Mayo clinic performance index for elbow.

**Material and Method**

In this study 64 patients with tennis elbow, which have had the symptoms for more than 3 months and were resistant to conservative treatments, were randomized to two groups. In steroid injection group 40mg of methylprednisolone acetate and in zone injection group 4ml of ozone with concentration of 15mcg/ml was injected. 32 patients in steroid and 29 patients in ozone injection group finished this study. Data were gathered before injection and 2 and 6 months after that by VAS score, modified Mayo clinic performance index for elbow and PPT (measured by the means of an algometer). Variables were compared between the two groups and also the changes in each group have been measured in reference to baseline data.

**Results**

In both groups VAS score, Mayo clinic performance index and PPT improved significantly in 2 and 6 month follow up. Steroid injection was significantly better than ozone injection in improving 2 and 6 months pressure pain threshold and 6 months Mayo clinic performance index. Other data didn't show significant difference between the two groups.

**Conclusion**

Both steroid and ozone injection improved pain and function in patients with recalcitrant tennis elbow for at least 6 months. Steroid injection was superior to ozone injection in improving PPT in 2 and 6 month and Mayo clinic performance index score at 6 month follow up.

EFFECTIVENESS OF EXTRACORPOREAL SHOCK WAVE THERAPY (ESWT) FOR PLANTER FASCIITIS IN KUWAITI PATIENTS SAMPLE
S. Gelbaya1
1Physical Medicine and Rehabilitation hospital, Physical Medicine, kuwait, Kuwait

Introduction/Background

Planter Fasciitis (PF) the most common cause of heel pain, affects 10% of the general population. ESWT is a noninvasive option for pain relief and has been recommended as a treatment for chronic PF. Our aim was to assess its effectiveness for treatment of such cases and to choose best treatment protocol.

Material and Method

58 patients with chronic PF were enrolled, they were divided into: group 1, low- energy group (Energy Flux Density (EFD) shock 0.08 mJ /mm2) and group 2, medium – energy group (EFD / shock 0.16 mJ /mm2). Outcome measures were visual analogue scale (VAS), Roles and Maudsley (RM) score and American Orthopedic Foot and ankle – hind Foot scale (AOFAS). Follow up was carried out 1 week, 1 month and 3 months after ESWT.

Results

Significant VAS, RM score and AOFAS improvements were observed in both groups (P < 0.10). Group 2 showed significant improvement after fewer number of sessions than in group 1.

Conclusion

Therapeutic effect might disclose a dose – related relationship, therefore EFD and times of sessions are considerable factors when treating with ESWT.

ISPR8-0890
EFFICACY OF HIGH-POWER LASER IN MITIGATING PAIN AND IMPROVING FUNCTIONS OF PATIENTS WITH PATELLOFEMORAL PAIN SYNDROME: A DOUBLE- BLIND AND RANDOMIZED-CONTROLLED TRIAL
M.S. rahimi¹, F. nouri¹, S.A. Raeissadat¹
¹Shahid Beheshti University of Medical Sciences, physical medicine and rehabilitation, tehran, Iran

Introduction/Background
PFPS is one of the most common musculoskeletal disorders in active young adults. In this paper, a double-blind and RCT for assessing the effectiveness of high-power (up to 12W) 1064 nm LASER therapy on patients with PFPS is carried out.

Material and Method
40 patients were randomly allocated to two treatment groups. Group B patients underwent HPLT. Placebo laser was implemented on Group A patients. Both groups had the same exercise therapy programs. The group codes of patients were not revealed to subjects and data analyzer until the completion of study. The criteria against which patients were by Kujala, WOMAC and VAS questionnaires. These questionnaires were completed at three points during the study; at the beginning of the study and one month and three months after the start of the study.

Results
Within-group analyses indicated significant improvements in respect to all measurements where pre-therapy and post-therapy comparisons were conducted in both groups (P < 0.05). On the other hand, between-group comparisons did not reveal any statistically significant difference regarding the evaluative criteria (P > 0.05) except for pain VAS (P < 0.05). From VAS viewpoint, HPLT was significantly more effective than placebo laser in mitigating patient pains.

Conclusion
It was concluded that both HPLT and placebo laser treatments accompanied by appropriate exercise therapy programs had a significant impact on mitigating pain and improving functions of patients with PTFPS. Also, it was observed that HPLT outperformed placebo laser with respect to all criteria though the differences were proved to be statistically significant only for VAS measurements.

Botulinum toxin type A injection for hallux valgus

F. Dehghan¹, A. Mousavizadeh², A. Moghtaderi¹
¹Isfahan university of medical sciences, Physical medicine and rehabilitation, Isfahan, Iran
²Isfahan university of medical sciences, Medicine faculty, Isfahan, Iran

Introduction/Background

Hallux valgus is the most common deformity of forefoot which is often associated with pain and disability. While it can be treated with conservative methods, most of patients may become exhausted with those maneuvers. Studies showed muscle imbalance in abductor and adductor muscles of the big toe may be the reason or the result of joint deformity. Therefore in this study we evaluated the effect of Electromyographic (EMG) and sonographic guided Botulinum Toxin type A (BTX-A) injection of Adductor Hallucis muscle on painful hallux valgus.

Material and Method

Twenty two patients having painful Hallux valgus in at least one foot have participated. Patients received electromyographic guided intramuscular injection of 100 IU of BTX-A to the oblique and transverse heads of the adductor hallucis muscle. They were assessed for Foot Function Index (FFI) and first metatarsophalangeal (1st MTP) angle in standing anteroposterior radiograph of foot at baseline, one week, two and six months after treatment.

Results

Regarding to FFI, BTX-A reduced pain and disability in two months (p<0.001) and six months evaluation after injection (p<0.05). First MTP angle reduced significantly at two months assessment (p<0.05), but there were no significant changes in six months evaluation (p>0.05).

Conclusion

BTX-A injection resulted in a marked short-term improvement of pain and disability in patients with hallux valgus.

RESECTION OF NEUROGENIC HETEROTOPIC OSSIFICATION (NHO) OF THE HIP, LESSONS LEARNED AFTER 377 PROCEDURES

N. de l'Escalopier¹, P. Denormandie¹, L. Gatin¹, A. Grelier², F. Genet²
¹Hopital Raymond Poincare, Orthopaedic surgery, Garches, France
²Hopital Raymond Poincare, Physical medicine and rehabilitation, Garches, France

Introduction/Background

Neurogenic heterotopic ossification (NHO) of the hip is secondary to neurologic lesions such as cranial trauma, stroke, medullary injury or cerebral anoxia. Our practice of heterotopic ossification surgery has progressed during our experience, becoming better adapted to the pathology and to the patients, who are often fragile and show neurologic sequelae. We want to give a feedback of the lessons we learned in the Raymond Poincare Hospital about NHO resection.

Material and Method

377 first-line procedures were performed for heterotopic ossification of the hip between 1993 and November 2016. Surgery requires rigorous organization and planning, preferably in a rehabilitation department, by a multidisciplinary team experienced in this pathology. Preoperative work-up should include contrast-enhanced CT; scintigraphy is non-contributive. Indications for surgery are decided in a multidisciplinary team meeting, with a contract laying out expected functional gain. It is this contract that determines the extent of resection, without seeking complete resection, which would incur an increased risk of complications.

Results

The surgical approach and resection strategy depend on lesion location and any resulting neurovascular compression. In our own series, 3.5% of patients required revision for recurrence. The most common complications is infection: 10.3% in our experience, with wide variation according to location. No adjuvant treatments have demonstrated efficacy against recurrence.

Conclusion

Surgical treatment of heterotopic ossification of the hip is reliable when performed in an adapted center by an experienced multidisciplinary team. Clinical results are satisfactory. There remains, however, a risk of sepsis, especially with medullary injuries.

Keywords

PERSONALIZED REHABILITATION OF PATIENTS WITH JOINT DISEASES
G. Ponomarenko¹, I. Cherkashina², A. Shoshmin³, Y. Besstrashnova⁴
¹Federal Scientific Center of Rehabilitation of the Disabled n.a. G.A. Albrecht, General Director, St.Petersburg, Russia
²Pediatric Research and Clinical Center for Infectious Diseases, Department of Medical Rehabilitation, St.Petersburg, Russia
³Federal Scientific Center of Rehabilitation of the Disabled n.a. G.A. Albrecht, Department of International Classifications and Systems of Rehabilitation and Habilitation, St.Petersburg, Russia

Introduction/Background

The research was aimed at development and evidences of personalized rehabilitation of patients with inflammatory and degenerative joint diseases.

Material and Method

The object of the study was 479 patients with joint diseases with comorbidity (arterial hypertension, obesity). Methods were clinical, psychophysical, sociometric survey, and assessment according to the categories of the International Classification of Functioning, Disability and Health.

Results

The set of rehabilitation technologies (physical exercises, hydrokinesis therapy, climatomotor modes, complex modulated low-frequency magnetotherapy) resulted in medical effects manifested by decrease in clinical complaints, relief of joint and inflammatory syndromes, improvement of motor activity, parameters of hemodynamics, somatic metrics, psychophysiological condition.

The most pronounced therapeutic rehabilitation outcomes were due to the initial functional properties of the affected joints with osteoarthritis and rheumatoid arthritis without co-pathology, the hemodynamic status of the patient with joint diseases in combination with hypertension, body weight and lipid morphogenesis, with osteoarthritis combined with obesity.

The effectiveness of rehabilitation of patients was represented by initial indicators of the patient's clinical status, functional properties of joints, systemic hemodynamics, lipid profile. Rehabilitation of patients with degenerative and inflammatory joint diseases improved the categorical profile of the rehabilitation potential of patients significantly, and was effective in 95% of patients with osteoarthritis, 97% of patients with osteoarthritis combined with hypertension, 95% of patients with osteoarthritis in combination with obesity, 91% of patients with...
rheumatoid arthritis and 90% of patients with rheumatoid arthritis in combination with hypertension. **Conclusion**

The concept of personalized rehabilitation of patients with inflammatory and degenerative joint diseases, based on the evaluation of structural, functional and socially adaptive features of the patient enables to determine the effectiveness of rehabilitation technologies and to recommend their differentiated use in patients with osteoarthritis and rheumatoid arthritis in isolated and combined forms.

SHORT-TERM OUTCOMES OF LOCAL STEROID INJECTION IN CARPAL TUNNEL SYNDROME: TRIAMCINOLONE (20 AND 40 MG) VERSUS METHYL PREDNISOLONE (20 AND 40 MG)

A. Karimzadeh¹, S.M. Rayegani¹, S.A. Raeissadat¹, S. Bagheri¹, S. Bagheri², H. Shirzad¹, H. Abrishamkarzadeh², A. Mavaian², F. Safdari¹, Z. Bagheri¹
¹Shahid Beheshti University of Medical Sciences, Physical medicine and rehabilitation, tehran, Iran
²Shahid Beheshti University of Medical Sciences, orthopedic surgery, tehran, Iran

Introduction/Background

Local steroid injection is one of the most common methods to treat carpal tunnel syndrome (CTS). However, the most efficient substance and the appropriate dosage are not clearly known. In current clinical trial, the outcomes of treating CTS with local injection of triamcinolone 20 and 40 mg and methyl prednisolone 20 and 40 mg were compared.

Material and Method

There were 73 patients with mild or moderate CTS assigned to 4 groups randomly: triamcinolone 20 mg (T-20 group; 18 patients), triamcinolone 40 mg (T-40 group; 20 patients), methyl prednisolone 20 mg (M-20 group; 17 patients) and methyl prednisolone 40 mg (M-40 group; 18 patients). Before and 3 months after injection the following measurements were performed: SNAP Amp and latency, CMAP Amp and latency, NCV, pain free grip (PFG), pain utilizing visual analogue scale and Boston CTS questionnaire including symptom severity scale (SSS) and functional severity scale (FSS).

Results

Before the treatment, all of the variables were the same in four groups. SNAP latency, CMAP Amp and latency, NCV, PFG, pain severity, SSS and FSS improved after treatment in all of the groups (P<0.05). SNAP Amp did not changed significantly after treatment in M-20 group. SNAP Amp was significantly higher in M-40 group compared to M-20 group (P=0.024). Furthermore, FSS was significantly lower in T-40 group compared to T-20 group (p=0.009). There was no significant difference between four groups in other variables after treatment.

Conclusion

In short-term follow up, local steroid injection was associated with improvement in functional status, grip strength, symptoms and electrodiagnostic studies (SNAP Amp and latency, CMAP Amp and latency, NCV). However, the authors suggest injection of methyl prednisolone and triamcinolone 40 mg due to significantly better outcomes in some variables compared to prednisolone and triamcinolone 20 mg.

PRIMARY HYDATIC CYST IN MUSCLES : A CASE REPORT

S. Elmtaoua¹, S. Layouni², W. Ouannes¹, N. Lazreg¹, F. khachnaoui¹, S. Jemni¹
¹university hospital Ibn Eljazzar-Kairouan-Tunisia,
Physical Medicine and Rehabilitation Department, Sousse, Tunisia

Introduction/Background

Primary muscle hydatidosis is very rare, accounting for less than 1% of hydatid cyst locations. It is often asymptomatic and progresses slowly, which can delay diagnosis.

Material and Method

We report the rare observation to describe clinical and radiological aspects as well as the therapeutic options, particularly surgery, for muscular echinococcus disease.

Results

A 30-year-old man consulting for thigh tumefaction that had appeared 11 months before, progressively increasing in volume. The patient was apyretic, in good general health, presenting a voluminous anterior mass of the left thigh. The clinical symptomology is insidious and nonspecific. It is a painless non inflammatory tumefaction progressively increasing in volume over several years and no signs of nerve or vascular compression. Ultrasonography, and Magnetic resonance imaging (MRI) is helpful in diagnosis, since it reveals a very suggestive of hydatid cyst of the quadriceps femoris muscles and demonstrates the relationship between cysts and adjacent structures. The patient was treated with monoblock excision of the cyst with no complications in the immediate follow-up period. The histological examination confirmed the diagnosis of muscular hydatid cyst.

Conclusion

Hydatid cysts are rarely found in muscles, even in highly endemic zones. The diagnosis must nevertheless be entertained depending on the clinical and endemic context. Ultrasonography, and accessorily magnetic resonance imaging, are the exploration tools of choice to confirm the diagnosis before surgery and avoid puncture. Pericystectomy is the first-line treatment, but the best means to control hydatid disease, whatever its location, remains prevention.

Shoulder dysfunction and regional pain in patients undergoing breast reconstruction with prostheses due to breast cancer is a long-term disabling condition. To evaluate the effect of botulinum toxin type A 60 U im regarding the volume differences of the affected arm before and after treatment.

Material and Method

Descriptive longitudinal study of a rehabilitation program during the reconstructive process addressed to women undergoing mastectomy and lymphadenectomy. All patients performed a structured program of group exercise before infiltration. Subsequently, if pain persisted and functional joint range decreased, a 60 U injection of botulinum toxin type A (Xeomin®) was performed in pectoralis major with ultrasound elastography. The difference in volume, distal force measured by claw dynamometry and VAS symptoms (pain, heaviness, tightness and hardness) was evaluated before (T0), at one (T1) and at six months (T2) of treatment, as well as changes in ultrasound images.SPSS 16.0 statistic program was used to compare paired data means (IC 95% alfa 0.005)

Results

Ten patients were selected. Baseline characteristics were: mean average age 51.1 years. Nine right-handed, nine with right arm affected (8 right, 1 bilateral) .They all presented significant improvements regarding pain, heaviness, tightness and hardness (T0-T1) that remained at 6 months for tightness and hardness (T0-T2).They did not present significant differences in regard to volume difference or distal claw force after infiltration

Conclusion

The use of botulinum toxin at doses of 60 U im in pectoralis major has been shown to be a safe technique for lymphedema, improving symptoms during the first month post infiltration without decreasing distal claw force.

RELIABILITY STUDY OF SUB-ACROMIAL IMPINGEMENT TESTS INCLUDING A NEW CLINICAL MANOEUVRE
J. Beaudreuil, A. Ferenczi, A. Yelnik, P. Orcel
1GH St.Louis-Lariboisière-F.Widal-Paris Diderot University, PRM and Rheumatology, Paris, France
2GH St.Louis-Lariboisière-F.Widal-Paris Diderot University, Rheumatology, Paris, France
3GH St.Louis-Lariboisière-F.Widal-Paris Diderot University, Physical and Rehabilitation Medicine, Paris, France

Introduction/Background

Neer, Hawkins, and Yocum tests are used in clinical practice to detect sub-acromial impingement. Their reliability has been few investigated. The goal of the study was to investigate reliability of Neer, Hawkins and Yocum tests. We also assessed an original manoeuver.

Material and Method

Patients with shoulder pain due to degenerative rotator cuff disease were prospectively included. They were twice assessed at one week interval by two independent observers. Results of Neer, Hawkins and Yocum tests were recorded as positive or not. Results of an original manoeuver (OM) including elevation in medial rotation followed by lateral one were also. Intra- and inter-observer reliability was assessed. Criteria of reliability were the percentage of agreement and the kappa coefficient of concordance with 95% confidence interval (CI). Kappa coefficient indicated moderate concordance if > 0.4, good > 0.61.

Results

34 Patients were included: age 60±11, ratio F/M 26/8, pain duration 27±67 months. For intra-observer reliability, agreement was 80-88% with Neer, Hawkins and Yocum tests. It was 80% with OM. Using kappa coefficient, intra-observer reliability was poor with Neer test (0.34 [-0.1;1]) and moderate with Hawkins (0.56 [0.9]), Yocum (0.48 [0.8]) and OM (0.6 [0.2;0.9]). For inter-observer reliability, agreement was 73-88% with Neer, Hawkins and Yocum tests. It was 79% with OM. Using kappa coefficient, inter-observer reliability was poor with Yocum test (0.35 [0.7], moderate with Hawkins (0.54 [0.2;0.8]) and OM (0.58 [0.2;0.8]), and good with Neer (0.64 [0.2;0.9]).

Conclusion

Neer test was impaired by poor intra-observer reliability and Yocum test was impaired by poor inter-observer reliability. Hawkins test and OM had a balanced profile of moderate reliability.
There was a trend to higher values with OM. We underlined there an interesting profile of reliability of an original clinical manoeuver to detect sub-acromial impingement.

THE RELATIONSHIP BETWEEN TRANSVERSUS ABDOMINIS MUSCLE THICKNESS WITH STATIC AND DYNAMIC BALANCE IN HEALTHY ADULTS
K.Y.A. Alsayani¹, R. Savkin¹, N. Akkaya², N. Büker¹
¹Pamukkale University, School of Physical Therapy and Rehabilitation, Denizli, Turkey
²Pamukkale University Medical School, Department of Physical Medicine and Rehabilitation, Denizli, Turkey

Introduction/Background

Current evidence suggests that enhanced core stability increase lower extremity function and promote postural stability. Thus, the purpose of this study was to investigate relationships between ultrasonographic thickness of transversus abdominis muscle (TrA), which is one of the core muscle, and static and dynamic balance and core endurance in healthy collegiate males.

Material and Method

Healthy collegiate males who had not suffered any orthopedic injury in the past year were enrolled the study. The thickness of TrA was measured at rest and during contraction on both dominant and nondominant side using ultrasound. Also percentage of change in TrA thickness was calculated as \[\frac{(thickness(contraction)-thickness(rest))}{thickness(rest)}\] x 100. The static and dynamic balance parameters were evaluated with a balance system (Korebalance Mobile System). Core endurance (CE) was also assessed using trunk extensor test, bilateral side bridge tests and the core muscle strength and stability test.

Results

Sixty males were assessed during the study. Their mean age was 22.20±1.77 years and mean body mass index was 23.53±2.93 kg/m². Dominant side TrA muscle thickness at rest was correlated with dynamic balance (r=-0.319, p=0.013) whereas no correlation for dominant side TrA muscle thickness at contraction. Nondominant side TrA muscle thickness at rest was correlated with core endurance (r= 0.350 p=0.006) whereas no correlation for nondominant side TrA muscle thickness at contraction. Percentage of change in dominant side TrA thickness was correlated with dynamic balance (r=0.464, p=0.000). Percentage of change in nondominant side TrA thickness was correlated with core endurance (r=-0.361, p=0.005).

Conclusion

According to our results, muscle thickness of TrA is associated with postural balance and core endurance. Training to increase the muscle mass of the TrA would be useful to improve balance parameters. Further prospective studies are warranted to investigate the effects of the training of TrA and core endurance on postural balance and athletic performance.

A CASE OF DIFFERENTIAL DIAGNOSIS OF POMPE DISEASE
C.E. Rangel Gomez\textsuperscript{1}, N. Lara Arroyo\textsuperscript{2}, L. Rodriguez Zambrano\textsuperscript{2}
\textsuperscript{1}Universidad Nacional de Colombia, 111321, bogota, Colombia
\textsuperscript{2}Universidad Nacional de Colombia, Physical medicine and rehabilitation, Bogota, Colombia

Introduction/Background

Glycogen storage disease type II or Pompe disease, is an autosomal recessive metabolic disorder which damages muscle and nerve cells. It is caused by an accumulation of glycogen in the lysosome due to deficiency of the lysosomal acid alpha-glucosidase enzyme. It has two forms: infantile-onset Pompe disease which begins within a few months of birth, and a late-onset type of Pompe disease may not become apparent until later in childhood, adolescence, or adulthood.

Material and Method

Our case is a 50-year-old female patient, with a clinical history of generalized weakness. Which began in the lower limbs, and became progressive. Everything started about 20 years ago and the diagnosis of severe sensitive and motor polyneuropathy was made. However, the progression of the disease has been slow and the weakness was more marked at a proximal level, making walking and activities of daily life difficult.

Results

Given the diagnostic doubts, we decided to perform a filter paper test for Pompe disease, obtaining altered results that showed a deficiency in the acid alpha glucosidase enzyme. We also carried out confirmatory tests with enzymatic study on leukocytes with samples of 0.08 (nmol / mgprot / h) with reference values of (0.4 - 1.43).

Conclusion

Performing the diagnosis of Pompe disease. In our country we do not have the immediacy of genetic studies in order to reconfirm the sample, however we consider that clinically corresponds to the disease and is a difference diagnosis to take into account. We hope in the future to perform functional evaluations with the medical therapy initiated.

Parsonage-Turner syndrome (PTS) is an uncommon disorder characterized by rapid onset of severe pain mainly in shoulder, followed by wasting and weakness of the muscles. The exact etiology is unknown, but it’s believed to be immune-mediated response. The diagnose is clinical and can be confirmed by electromyography (EMG). The treatment includes pain management strategies and ways to preserve muscle strength and range of motion (ROM) of the affected joints.

Material and Method

We report the case of a male, that in the beginning of April (3 days after being submitted to a cholecystectomy) initiated sharp pain, localized to the shoulder, associated with weakness on the ipsilateral arm and gradual limitation of the normal ROM of the joint.

In July/2017 he resorted a neurologist, having performed EMG, which result was compatible with C5-C6 and L5-S1 radiculopathy and a cervical/shoulder CT-scan that showed no significant changes. A month later, he repeated EMG showing signs supporting the clinical diagnose of PTS.

In October/2017, he was observed by Physical Medicine and Rehabilitation presenting atrophy of several muscles of shoulder, right scapular dyskinesia, limitation in active abduction and flexion of the right shoulder, positive jobe test, muscle strength grade 4 (Medical Reserch Council Scale) in all muscles of the shoulder, pain intensity of 2 out of 10, at rest.

Results

Rehabilitation program was initiated with the objective of analgesia, muscle strengthening and gain in ROM. Two months later we notice improvement of the muscles atrophy, improvement in the right scapular dyskinesia, no ROM limitation, muscle tests negative, muscle strength grade 5 and pain intensity 0.

Conclusion
Clinicians should be aware of this rare entity for rapid detection and treatment, to avoid the installation of muscle atrophies, contracture and limitation of ROM. Since pain is excruciating in some cases, we must know all sorts of pain management, including the use of physical agents.

Clinical Profile of Indoor Patients in the Department of Physical Medicine and Rehabilitation, Chittagong Medical College Hospital

A. Hoque

Chittagong Medical College Hospital, physical medicine and rehabilitation, Chittagong, Bangladesh

Introduction/Background

Abstract Background: This observational study done on the indoor patients of department of Physical Medicine and Rehabilitation, Chittagong Medical College Hospital, admitted during the year 2011. The objective of this study was to see the most prevalent diseases admitted in our department.

Material and Method

Methods: Participants (225) were all the patients admitted during the period of 2011. Patients admitted more than once were recorded once only. Patient’s data were taken from hospital records.

Results

Results: Spondyloarthropathies (SpA) comprised 18.66% of the patients. Total patient of SpA was 42. Among them AS was 47.62%. Prolapsed lumbar disk (PLID) patients constituted 12.44% (28) of hospital admission. Twenty one (9.33%) patients suffered from other causes lumbago-sciatica. Admitted RA patient number were 12 (5.33%) during this year. Total twelve patients with bone TB (5.33%) were admitted during 2011. Nine TB patients (75% of bone TB) had TB in the hip. Total Stroke patients admitted in that year were 9 (4%). Among them 8 (88.89%) were ischemic

Conclusion

Conclusion: SpA, PLID and other lumbago-sciatica patients comprised the major bulk of the patients in inpatient department of PM&R. Musculoskeletal diseases were the commonest cause of hospital admission for rehabilitation. Neurological causes were next common. Inflammatory musculoskeletal diseases also formed a good number of patients.

⁴Pôle de médecine physique et de réadaptation, Service de médecine du Sport, Marseille, France

Introduction/Background

The main objective of this study is to measure the effect induced by combined muscle contraction of the Quadriceps and rectus femoris (by neuro-muscular reprogramming) on pain phenomena and on the short-term recovery of muscle power. The goal to be achieved for these patients is to reduce the pain phenomena and to modify voluntarily and actively the orientation of their functional mechanical axes.

Material and Method

Evaluation of isokinetic quadriceps strength before and after stretching the injured knee and the healthy knee for 27 patients with FPPS and 12 healthy control subjects (matched). No pathology on the contralateral knee. The evaluation is carried out at 60°/s concentric 120°/s concentric and 30°/s eccentric contraction by an isokinetic dynamometer. After performing the isokinetic tests and evaluating the pain (by EVA), specific contraction work of the quadriceps of the injured knee according to an identical protocol for each patient was performed (3 times).

Results

Our results show a significant effect of these contraction exercises on the pain phenomena of patients in the short term. We obtained after quadriceps contraction a significant decrease in pain -38% and an increase in the strength of +17% for the pathological group. No significant change in the control group. There is a statistical correlation between the decrease of pain and recovery of strength after stretching. This significant decrease in pain associated with an increase in force parameters in only eccentric contraction.

Conclusion

We confirm the effectiveness of quadriceps stretching with slow eccentric contraction in the care of FPPS. These beneficial effects are in favor of a systematic use with muscle building. These results are in favor of a new therapeutic care by using this kind of stretching. The management
of stiffness and neurophysiological components that are directly associated with these phenomena of stiffness during the onset of this syndrome, encourages therapists to continue.

Introduction/Background

The purpose of this study was to analyze the effectiveness of cognitive behavioral therapy-based exercise facilitation method using the “Ikiiki Rehabilitation Notebook” in patients with intractable chronic pain.

Material and Method

The subjects were 5 males and 9 females (19-77 years of age, mean age 46) with chronic low back, neck or lower extremity pain without specific lesions. Indications for using the notebook were as follows: 1) Numeric Rating Scale (NRS) for pain >3, and 2) the continuity of the pain >3 months. Patients were asked to write in their notebooks daily or once a week regarding their emotion, though, and exercise routine (muscle exertion, gait distance). Once every 2 weeks, the patients returned to the clinic to go over the notebook/journal. The evaluation contents were NRS, PDAS (Pain Disability Assessment Scale), HADS (Hospital Anxiety and Depression Scale), PCS (Pain Catastrophizing Scale), EQ-5D (EuroQol 5 Dimension), PSEQ (Pain Self Efficacy Questionnaire).

Results

The NRS, PDAS, PCS and EQ-5D, but not HADS and PSEQ, improved significantly 9 months after starting to use the notebook.

Conclusion

The “Rehabilitation Notebook/Journal” is a valuable tool to educate patients about the cause and treatment of pain and to actively facilitate CBT-based exercise.

MILD TO MODERATE CARPAL TUNNEL SYNDROME (CTS) : DOES PULSED SHORT WAVE DIATHERMY (PSWD) HAVE BETTER EFFICACY THAN TRANSCUTANEOUS ELECTRICAL NERVE STIMULATION (TENS) ?

Introduction/Background

To compare the effectiveness of Pulsed Short-Wave Diathermy (PSWD) versus Transcutaneous Electrical Nerve Stimulation (TENS) in the treatment of mild to moderate carpal tunnel syndrome (CTS).

Material and Method

Conducted at a University Hospital in Malaysia between April and July 2017, this prospective comparative interventional study involved a total of 16 wrists in 14 patients with mild to moderate CTS. Using random allocation, group A (n=8) received PSWD and group B (n=8) received TENS twice a week for 6 consecutive weeks. Both groups also received exercise therapy and wrist orthoses. Assessments were done at baseline and at 6 weeks post intervention using Numeric pain rating scale (NRPS) and the Boston Carpal Tunnel Questionnaire (BCTQ) as outcome measures.

Results

Significant improvement in the above outcome measures were noted in group A (PSWD) compared to group B (TENS). The average baseline and final values of BCTQ measured in TENS group were 2.44 and 1.54 respectively while baseline and final values of group PSWD group were 2.69 and 1.36 respectively. The difference in BCTQ of patient who received PSWD and TENS were 1.33 and 0.9 respectively. The higher the difference between baseline and final values of BCTQ indicates better improvement in symptoms and function. NRPS was used to asses pain improvement. The average baseline and final values of NPRS in TENS group were 5.13 and 2.00 respectively. In PSWD treatment group, the values were 5.38 and 0.75 respectively. The outcome differences between both treatment groups were 3.13 in TENS group and 4.63 for PSWD group indicating good pain relief in the later group.

Conclusion

Symptoms outcome, function and pain relief proved more efficacious in PSWD than TENS. Therefore, PSWD could be considered as a treatment option in mild to moderate CTS.

INFLUENCE OF BODY COMPOSITION AND MUSCLE STRENGTH ON FUNCTIONAL OUTCOMES IN POSTACUTE STROKE.
R. Boza¹, A. Bustos¹, A. Gonzales-Carhuacho¹, V. Dávalos-Yerovi¹, C. Barrera¹, E. Duarte¹,
A. Guillén-Solà¹, E. Marco¹
¹Parc de Salut Mar, Physical Medicine and Rehabilitation,celona, Spain

Introduction/Background

Despite skeletal muscle is the main effector organ of disability in stroke, there is a paucity of data on skeletal muscle disorders in stroke. In addition to loss of muscle mass as a result of normal ageing, reduced physical activity, poor nutrition, and hormonal changes can play a role in the development of sarcopenia in stroke. This preliminary study was aimed to determine the influence of body composition and muscle function on functional outcomes in patients with postacute stroke.

Material and Method

Within 2 weeks of stroke onset, 45 subjects (66.1±8.8; 32 men) with a first ischemic stroke event were prospectively assessed during in-patient rehabilitation hospitalization. The main variables were fat-free mass and fat-mass (in Kg and as a percentage of reference values) assessed with electrical impedance, body mass index (BMI), maximal isometric handgrip strength of non-paretic upper limb, and functional status assessed with the Barthel Index (BI) at hospital discharge.

Results

According to BMI, patients were classified in low weight (n=2), normal weight (n=10), overweight (n=20) and obesity (n=13). Fat-free mass was reduced in 3 patients and fat-mass in 8. Obese patients had lower BI (mean difference: 22.7, 95%CI 8.6-36.8, p=0.002, at admission; 14.9 (95% 0.58-29.1, p=0.042, at discharge). Twenty-eight patients had reduced strength of the non-paretic handgrip; these patients had lower BI (mean difference 15.2, 95%CI 0.8-29.6, p=0.039), but no differences in BI improvements at discharge were detected.

Conclusion

Strength in the non-paretic hand is reduced in 62% of the sample. Obesity and reduced handgrip strength are associated with worse functional status during stay in a neurorehabilitation ward. Further studies are required to assess the influence of body composition and muscle strength on functional outcomes.

LONG-TERM FUNCTIONAL OUTCOMES OF STROKE PATIENTS
R. Suksathien¹, T. Sukpongthai¹
¹Maharat Nakhon Ratchasima Hospital, Department of Rehabilitation Medicine, Nakhon Ratchasima, Thailand

Introduction/Background

Predictors of functional outcomes of stroke patients are important for providing efficient post-stroke care according to the degree of impairment. The authors attempted to use the data that are routinely recorded in acute stroke care to determine long-term functional outcomes of stroke patients.

Material and Method

This analytic study examined the long-term functional outcomes of stroke patients admitted to Maharat Nakhon Ratchasima Hospital with acute stroke between January 1 and December 31, 2015. We recorded patients’ characteristic data and functional level on admission using Barthel index (BI) score. Long-term functional outcomes were evaluated with BI score at least 6 months after stroke onset by telephone interview and medical records. The predictors of long-term functional outcomes were determined with stepwise multiple logistic regression analysis.

Results

Of the 907 patients, 191 (21%) died during acute stroke admission, 117 (13%) died after and 210 (23%) were lost to follow-up and could not be contacted. There were 5 variables significantly correlated with good functional outcomes after multiple logistic regression analysis. Subjects aged 55 or under, male, admission BI score 30-100, muscle power grade 0-1 and with consciousness problems had adjusted odds ratios of 12.56, 3.78, 3.33, 0.28 and 0.24 respectively. Four variables correlated with poor functional outcomes were impaired consciousness, age over 65, more than 3 comorbidities, and admission BI score of 0-30 had adjusted odds ratios of 4.83, 4.08, 2.39, and 1.89 respectively.

Conclusion

Long-term functional outcomes of stroke patients were associated with age, consciousness, gender, muscle power, admission BI score and number of comorbidities.

Introduction/Background

Rehabilitation of patients after ischemic stroke should begin as soon as possible. Some centers use alternative treatments, including acupuncture. The aim of the study was to assess the effect of acupuncture on the normalization of muscle tone and improvement of muscle strength of paralyzed limbs.

Material and Method

The study included 42 people with ischemic stroke, aged from 31 to 86, hospitalized at the Rehabilitation Clinic. Rehabilitation was started on the 10th day after stroke. The persons were divided into two groups: I group (20 people) with the standard rehabilitation and II group (22 people) in which additional acupuncture was performed every other day. At the beginning and at the end of the rehabilitation the assessment of muscle tone using the Ashworth scale and muscle strength using the MRC scale was carried out. The duration of the rehabilitation was three weeks.

Results

The slight normalization of muscle tone in the Ashworth scale in the upper and lower limb in the group in with acupuncture was achieved. In the upper limb the difference was 0.04 points, in the lower limb 0.11 points. In the assessment of muscular strength in the MRC scale of the upper and lower limb, higher muscle strength scores were obtained in all muscle groups in participants with acupuncture. The highest difference was noted in flexors of the shoulder - 0.73 point and shoulder abductors- 0.69 point. In the lower extremity, the largest differences were in the hip flexors - 0.61 points, knee flexors and knee extensors - 0.57 points each.

Conclusion

In the group where acupuncture was additionally used, both in the muscle tension normalization as well as muscle strength, better results were obtained than in group with standard rehabilitation only. Differences in both groups were not statistically significant, probable due to small research groups. Further research is required.

Introduction/Background
Several studies highlight that the physical therapy (PT) timing is important in rehabilitation process from physical disability after stroke. The purpose of this meta-analysis was to investigate the effect of all PT on balance after stroke and to evaluate whether changes are related to stroke stage of recovering (acute and sub-acute (ASS) or chronic stage (CS)).

Material and Method

Randomised controlled trials (RCT), without language restriction, until October 2015, assessing the Berg Balance Scale (BBS), the Postural Assessment Scale for Stroke, the posturographic parameters in static condition and measures of independence in activities of daily living were included. Two independent authors (AH and JDM) led this selection following the Cochrane recommendations (Hugues et al., 2017).

Results

193 parallel and crossover RCT from 9337 records were included, involving 8018 subjects (study sample: mean 41.5 (SD 49.7) subjects, age: pooled mean 61.7 (pooled SD 12.78) years). A significant difference in favor of PT compared to no treatment was immediately found after the intervention for the BBS at ASS and CS (ASS: 11 studies, mean difference (MD) 3.14; 95% confidence interval (CI) [2.21; 4.06]. CS: 12 studies, MD 1.31; 95% CI [0.79; 1.82]. Mixed: 2 studies, MD 0.89; 95% CI [-0.63; 2.40]). Only at CS, PT is more effective than sham treatment or usual care immediately after the intervention for the BBS (ASS: 12 studies, MD 2.21; 95% CI [-0.37; 4.78]. CS: 13 studies, MD 2.50; 95% CI [1.00; 3.99]. Mixed: 2 studies, MD -1.17; 95% CI [-2.94; 0.60]).

Conclusion

These results show immediately after the intervention: i) that balance can be improved by PT compared to no treatment whatever the stage of stroke, and ii) an improvement of balance by PT compared to sham treatment or usual care at chronic stage.

Keywords

Stroke; Meta-analysis; Physical therapy

No conflict of interest
After stroke, standing balance is usually described as a predictor of functional recovery. Regarding literature, various type of physical therapy (PT) is used to improve balance. The aim of this meta-analysis is to evaluate the effects of PT directly focused on balance training (DFBT) and theses of PT indirectly focused on balance training (IFBT) on balance after stroke.
**Material and Method**

Randomised controlled trials (RCT), without language restriction, until October 2015, assessing the Berg Balance Scale (BBS), the Postural Assessment Scale for Stroke, the posturographic parameters in static condition and measures of independence in activities of daily living were included. Two independent authors (AH and JDM) led this selection following the Cochrane recommendations (Hugues *et al.*, 2017).

**Results**

193 parallel and crossover RCT from 9337 records were included, involving 8018 subjects (study sample: mean 41.5 (SD 49.7) subjects, age: pooled mean 61.7 (pooled SD 12.78) years). A significant difference in favor of PT compared to no treatment was immediately found after the intervention for the BBS (DFBT: 7 studies, mean difference (MD) 1.38; 95% confidence interval (CI) [0.71; 2.05]. IFBT: 18 studies, MD 1.88; 95% CI [1.31; 2.45]). Only IFBT PT is more effective than sham treatment or usual care immediately after the intervention for the BBS (DFBT: 1 study, MD 5.33; 95% CI [-4.68; 15.34]. IFBT: 26 studies, MD 1.85; 95% CI [0.67; 3.03]).

**Conclusion**

These results show immediately after the intervention: i) that balance can be improved by PT aiming directly or indirectly at the recovery of balance compared to no treatment, and ii) an improvement of balance by PT indirectly focused on the recovery of balance compared to sham treatment or usual care.

Introduction/Background

Stroke is a pathology that causes several motor and functional impairments. The aim of the study was to realize a kinematic analysis of the elbow joint during real and virtual dart games and to construct decision trees for neurorehabilitation.

Material and Method

The sample consisted of 11 hemiparetic patients (8 men), mean age of 51±7 years. Participants made 15 attempts in two dart games (real and virtual). Elbow kinematics was video recorded during the dart throwing phase. Analysis was conducted using Kinovea software, paired Student’s t-test and Classification Regression Trees.

Results

Patients exhibited a higher elbow extension angle (P = 0.008) and greater velocity in the real game (P = 0.005). In the virtual game patients had longer throwing time (P = 0.021) and better performance (fewer absolute errors) (P < 0.0001). The decision tree showed that there was a balance between the frequency of patients who played the virtual and real game and displayed elbow extension angles above 157°. Similar frequencies between velocity ≤ 29 cm/s and >87 cm/s for the virtual and real games were found. In regard to dart throwing time, there was greater frequency of patients with time ≤1.37s for the real game and >1.37s for the virtual game.

Conclusion

The construction of decision trees showed evidence that the patients can evolve satisfactorily in terms of angulation, velocity and time during virtual game training. Thus, we propose that the virtual dart game may be a useful tool in the neurorehabilitation of patients with chronic stroke, in line with therapeutic objectives and the patient’s clinical condition.

2Institut for Rehabilitation, Rehabilitation, Belgrade, Serbia
3Clinic for Rehabilitation KCS, Rehabilitation, Belgrade, Serbia
4University Children's Hospital, Rehabilitation, Belgrade, Serbia

Introduction/Background

Stroke causes serious damage and disability which presents a major problem both for the diseased person, for the family as well as for society. Aim of our paper was to present results of early rehabilitation in functional training of patients after an acute stroke.

Material and Method

Prospective study included 90 patients (62 male and 28 female) age 45-78, average age 63.5, treated in SB for cerebrovascular disease "Sveti Sava" Belgrade after acute stroke. Functional independence scale (FIM) and Berg Balance Scale (BBS) were used to evaluate functional recovery. Patients were evaluated at the beginning of treatment (Measurement A), and after 14 days (Measurement B) and 60 days (Measurement C) of treatment. Early rehabilitation consisted of exercise program aimed at prevention of respiratory, vascular and locomotor complications. Program was individually conceived and implemented twice a day, each day, provided that the patient was hemodynamically stable and supervised by an ordinate physician.

Results

FIM and BBS scores increase over time, with a greater increase in the FIM score (Table 1). At the beginning the coefficient of correlation of FIM and BBS scores was higher, while it was slightly lower after 14 and 60 days of treatment (Table 2).

<table>

Conclusion
Early rehabilitation program is of exceptional importance in the functional recovery of patients after the stroke. Our results suggest that in the process of functional recovery more important monitoring parameter is FIM score whose changes are more pronounced in relation to the BBS score.

acute stroke; early rehabilitation

*No conflict of interest*
Depression is the most frequent and recovery limiting affective disorder after a stroke. It is usually underdiagnosed in more than half of the cases. Furthermore, patients who suffer post-stroke depression have a lower functional status and greater cognitive impairment with an increased mortality risk.

Material and Method

An observational prospective study was carried out to assess the evolution of depression in a cohort of 100 patients diagnosed with ischemic stroke during 2013. Ischemic stroke severity was evaluated by the NIHs Scale. Sociodemographic, etiological and clinical characteristics and evolution of depression were evaluated using the Hamilton Depression Scale during follow-up: at discharge, one and three months after discharge.

Results

Mean age of the cohort was 72.43 years, evenly distributed by sex. 53.49% of the patients suffered from depression one month after hospital discharge dropping to 7% by the third month. The severity of the depression also decreased on the third month.

The association between the severity of the stroke at admission and the severity of depression was not found to be statistically significant. However, an association between the severity of stroke at discharge and the severity of depression at the 3rd month was found ($p = 0.04$).

In addition, a discharge to home versus to a medium-stay unit was associated with an improve in depression recovery at the 3rd month ($p=0.008$).

Conclusion

Our results show that higher severity of stroke was associated with a higher severity of depression and that a better recovery of the depression was reached in patients who went home directly after discharge.

Early detection and treatment of post-stroke depression is necessary to improve functional recovery and rehabilitation of patients.

Introduction/Background

The Fugl-Meyer Assessment (FMA) is widely used in stroke research as a gold standard. However, the FMA has not been used in general clinical practice in Japan, which may be related to that the FMA was not translated in the standardized way (including forward translation and back translation). Against the background of linguistic and cultural differences, we translated the standardized FMA into Japanese and adapted it for use in Japan. The aim of the present study is to assess its reliability and validity for the FMA with a Japanese guideline.

Material and Method

A prospective single-center study involving 30 patients with mild-to-severe hemiparesis was conducted. This study was registered in 2016 as a pre-initiation condition. A standardized guidebook for the FMA test administration and scoring was used. The FMA and the Action Research Arm Test, the Box-and-Block Test, and the Motor Activity Log were employed. The simultaneous/non-simultaneous inter-rater reliability and the criterion-referenced validity were assessed in the following ways: the intraclass correlation coefficient (ICC) and the Spearman’s rank-order correlation coefficient (Spearman’s rho).

Results

The ICC for the simultaneous and the non-simultaneous reliability in the motor section were 0.999 (0.997–0.999, P<0.001) and 0.983 (0.928–0.994, P<0.001). The Spearman’s rho for the validity in the motor section ranged from 0.93 to 0.95 (P<0.05).

Conclusion

The FMA with a Japanese guideline reliably assesses the affected upper extremities in patients with hemiparesis after stroke.

ASSESSING UPPER LIMB FUNCTION: TRANSCULTURAL ADAPTATION AND VALIDATION OF THE PORTUGUESE VERSION OF THE STROKE UPPER LIMB CAPACITY SCALE

J. Branco¹, J. Pinheiro²

¹Centro de Medicina e de Reabilitação Região Centro - Rovisco Pais, Reabilitação Geral de Adultos, Coimbra, Portugal
²Centro Hospitalar Universitário de Coimbra, Serviço de Medicina Física e de Reabilitação, Coimbra, Portugal

Introduction/Background

Background: Brachial hemiparesis is one of the most frequent sequelae of stroke, leading to important functional disability given the role of the upper limb in executing activities of daily living (ADL). The Stroke Upper Limb Capacity Scale (SULCS) is a stroke-specific assessment instrument that evaluates functional capacity of the upper limb based on the execution of 10 tasks. The objective of this study is the transcultural adaptation and psychometric validation of the Portuguese version of the SULCS.

Material and Method

Methods: A Portuguese version of the SULCS was developed, using the process of forward-backward translation, after authorisation from the author of the original scale. Then, a multicentre study was conducted in Portuguese stroke patients (n=122) to validate the psychometric properties of the instrument. The relationship between sociodemographic and clinical characteristics was used to test construct validity. The relationship between SULCS scores and other instruments was used to test criterion validity.

Results

Results: Semantic and linguistic adaptation of the SULCS was executed without substantial issues and allowed the development of a Portuguese version. The application of this instrument suggested the existence of ceiling effect (19.7% of participants with maximum score). Reliability was demonstrated through the intraclass correlation coefficient of 0.98. As for construct validity, SULCS was sensible to muscle tonus and aphasia. SULCS classification impacted the scores of the Motor Evaluation Scale for Upper Extremity in Stroke (MESUPES) and the Stroke Impact Scale (SIS).

Conclusion

Conclusions: The present version of SULCS shows valid and reliable cultural adaptation, with good reliability and stability.

Introduction/Background

The aim of this study is to determine the role of comprehensive rehabilitation on balance disorders and functional status of patients after stroke.

Material and Method

The research was carried out at the Municipal Medical Center Dr. K. Jonscher in Lodz at the Department of Neurological Rehabilitation among randomly selected people after stroke. The study involved 30 patients, including 11 women and 19 men, the average age was 62 years. The results of the control group, which consisted of 30 people, 21 women and 9 men with an average age of 23.1, were also analyzed. The study included people who were able to take up a standing position in 2 x 30 seconds.

In all patients, a body balance test was carried out twice on the CQ-Stab computer stabilization platform by CQ Elektronik System, before and after the rehabilitation. Results obtained after rehabilitation were compared with the results of the study before the rehabilitation and the results of people from the control group. All patients from the study group underwent a rehabilitation program including physical therapy and kinesitherapy according to the individual needs of the patient.

Results

The average right and left deflections with open eyes before the rehabilitation among patients after stroke was 4.51mm, and after the comprehensive rehabilitation 3.39mm and in the healthy group 3.30mm.

The average backwards and downwards tilts with open eyes before and after rehabilitation was respectively 4.01mm, 3.25mm, and 4.83mm in the control group.

The average right and left deflections with closed eyes before rehabilitation was 5.76 mm, after rehabilitation 3.97 mm and in the control group 2.28 mm, while forwards and backwards: before: 5.06mm, after: 4.47mm, and in control group: 0.82mm.

Conclusion
Comprehensive rehabilitation has a significant impact on the functional status and balance of patients after stroke.

FIRST-EVER ISCHEMIC STROKE IN YOUNG ADULT PATIENTS IN A REHABILITATION UNIT
H. Tavares¹, D. Amaral¹, H. Amorim¹, P. Lopes¹, M.J. Festas¹, S. Magalhães¹, A.R. Almeida¹, N. Pinto¹, F. Parada¹
¹Centro Hospitalar de São João- Porto, Physical and Rehabilitation Medicine Service, Porto, Portugal

Introduction/Background

Stroke in young adults is reported as being uncommon, with recent publications reporting an increased incidence. Causes of ischemic stroke in young adults are diverse, but undetermined etiology predominates in the majority of studies. Stroke in young adults may have a dramatic impact on quality of life and economy by leaving victims disabled during their most productive years, when compared with stroke in older adults. This study aims to evaluate incidence and clinical characteristics of first-ever ischemic stroke in young patients.

Material and Method

Retrospective analysis of patients with a first-ever ischemic stroke admitted between September 1, 2014 and June 30, 2017 in a Rehabilitation Unit. A young patient was defined as the patient with 45 or less years of age.

Results

One hundred and two patients with a first-ever ischemic stroke were identified, with 58.8% of male gender and with a mean age of 59.2 years old. Twelve were considered young patients (11.8%), with 8 patients of male gender (66.7%). In these patients, dyslipidemia, smoking, and hypertension were the most prevalent risk factors (33.3%, 33.3%, 16.7%, respectively). According to TOAST classification, stroke was caused by large-artery atherosclerosis in 25.0%, cardioembolism in 16.7%, small-vessel occlusion in 8.3%, another determined etiology in 16.7%, and undetermined etiology in 33.3%. According to Oxfordshire classification, half of the patients have total anterior circulation stroke, 25% partial anterior circulation stroke, 16.7% posterior circulation stroke and 8.3% lacunar stroke. NIHSS was higher in younger patients (18.5 points vs 9 points).

Conclusion

Stroke in subjects under 45 years of age is not such a rare disease and is associated with high NIHSS. Given the increase incidence of stroke in young adults, there is an objective need for more research in order to reduce this social and economical burden.

France

Introduction/Background

In hemiparesis, motor function may be hindered to various degrees by soft tissue contracture, spasticity, spastic co-contraction and agonist paresis. This retrospective study explores correlations between neuromuscular impairments at shoulder, elbow, wrist and fingers and overall function in the paretic upper limb.

Material and Method

Fifty one patients with chronic hemiparesis (25W, 48(±15) years (mean(±SD)), time since lesion, 7.7(±5.5) years) were assessed using the Five Step Assessment, at least three months after any botulinum toxin injection. The first step assessed motor function of the upper limb by the Modified Frenchay scale (MFS; score between 0 and 10). The 2nd, 3rd and 4th steps assessed coefficients of impairment in four key muscles: shoulder extensors, elbow flexors, wrist flexors and fingers flexors. These coefficients were calculated as: coefficient of shortening ($C_{SH}=(X_N-X_{V1})/X_N$; $X_N$, normally expected amplitude; $X_{V1}$, angle of arrest upon slow stretch), coefficient of spasticity ($C_{SP}=(X_{V1}-X_{V3})/X_{V1}$; $X_{V3}$, angle of catch upon fast stretch), coefficient of weakness ($C_{W}=(X_{V1}-X_A)/X_{V1}$; $X_A$, maximal active range of motion). For each impairment factor, a mean coefficient across the four muscles was calculated ($C_{SHmean}$, $C_{SPmean}$, $C_{Wmean}$). For each muscle group and for the mean, multivariable correlations were explored between $C_{SH}$, $C_{SP}$, $C_{W}$ and MFS.

Results

The MFS correlated with $C_{SHshoulder}$ ($r=-0.28$, $p=0.03$) and $C_{Wshoulder}$ ($r=-0.46$, $p=0.001$); $C_{Welbow}$ ($r=-0.45$, $p=0.002$); $C_{Wwrist}$ ($r=-0.33$, $p=0.003$); $C_{Wfingers}$ ($r=-0.63$, $p<0.0001$); $C_{Wmean}$ ($r=-0.78$, $p<0.0001$).

Conclusion

The main factors impeding motor function in chronic spastic paresis are the combination of paresis in agonist and spastic cocontraction in antagonist (limiting active motion) for shoulder extensors and for elbow, wrist and finger flexors. Soft tissue contracture for shoulder extensors...
also contributed to hinder motor function. Spasticity was not correlated with the mean score of MFS, whichever the muscle considered.

USE OF TRANSCRANIAL MAGNETIC STIMULATION IN INVESTIGATING UPPER EXTREMITY MOTOR RECOVERY: A CASE STUDY
S.K. Lui¹, M.B. Ramalingam¹
¹Singapore General Hospital, Rehabilitation Medicine, Singapore, Singapore

Introduction/Background

Measure Transcranial Magnetic Stimulation (TMS) parameters including resting motor threshold (RMT) and paired-pulse stimulation effects in first-time ischemic stroke patients within 3 months of stroke onset.

Material and Method

Design: Prospective study
Setting: Inpatient rehabilitation unit
Participant: 66-year-old male with a first ischemic stroke.
Interventions: At first visit (< 2 weeks post-stroke), TMS was performed over stroke-affected hemisphere and contralateral hemisphere. The RMT for stroke-affected and non-stroke affected abductor pollicis brevis (APB) were measured. Paired-pulse stimulation of a subthreshold stimulus (80% of RMT) followed by a suprathreshold stimulus (120% of RMT) were carried out with the following interstimulus levels (ISIs) of 2, 4, 10 and 15 milliseconds (ms) on both hemispheres. The above was repeated at 2nd visit (3 months post-stroke).
Outcome measures: Upper extremity strength measured with Medical Research Council scale and hand dynamometry, Functional Independence Measure (FIM) score, RMT of bilateral APB, average motor evoked potential (MEP) reading for each ISI in paired-pulse stimulation and its respective ratios of the mean conditioned MEP to the mean unconditioned MEP.

Results

Motor FIM score improved from 63 to 90 over 3 months. RMT of affected APB was higher than the unaffected APB at both visits. Facilitation (ratio 1.2) was observed with an ISI of 2 ms on the affected APB within 2 weeks post-stroke whereas inhibition (ratio 0.34) was observed at 3 months. As for ISIs of 4 ms, 10 ms and 15 ms, the respective ratios were 0.97, 1.03 and 0.93 at 1st visit versus 0.21, 0.40 and 0.44 at 2nd visit.

Conclusion

Although ISI of paired-pulse inhibition and facilitation effects were generally in the 1 to 3 ms and 9 to 12 ms range respectively in healthy individuals, there was variation seen in our post-stroke patient. We could determine a post-stroke individual’s paired-pulse inhibition and facilitation at different stages of stroke recovery to explore recovery patterns.

ABSTRACT NEED TO BE EDITED - EFFECTIVENESS OF THE RANGE CONSTRAINT THERAPY IN PATIENTS BRAIN STROKE

J. Skibarkiene¹, E. Milinaviciene¹, O. Gudaitis¹
¹Hospital of Lithuanian University of Health Science, Rehabilitation, Kaunas, Lithuania

INTRODUCTION/BACKGROUND

To evaluate the efficiency of constraint-induced movement therapy to arm function recovery and to the person's autonomy after suffered a stroke.

MATERIAL AND METHOD

Involved 65 persons of working age which were after stroke first time in their life. Research group where it was applied usual exercises therapy and constraint-induced movement therapy (IMT) and control group where it was applied just usual exercise therapy. Functional status was evaluated by the Functional Independence Measure, Barthel index, goniometry, dynamometry, Box and Block test, Lovett, Motors assessment and Ashworth scales and Mini Mental State Examination.

RESULTS

After rehabilitation in both groups observed significant improvement (p<0.05). RG self-service in daily activity increased by 1/3 more vs CG. Cognitive functions disorders in RG decreased significantly, than CG. There was improvement assessing range of motion analyzing arm function recovery, speed and accuracy, spastic and muscle strength after rehabilitation: hand breadth muscle strength increased 6.1 kg in RG and 4.1 kg in CG (p<0.05); damaged hand muscle strength increased isn't significant. Arm range of motion increased from 3.5° up 14° in RG and from 0° up 10° in CG, difference between groups wasn't significant (p>0.005). Significant variation between groups observed only in the upper arm construction and retraction motions. Accuracy of damaged hand increase up 31 % in RG and 20 % in CG (p<0.05); all subjects with normal or mild arm hypertonia wasn't significant (p>0.05). By MAS the arm movements increased 3 vs 1.5 point (p<0.05).

CONCLUSION

Arm function of person's after stroke improved significant applying constraint-induced movement therapy, more efficient in recovering damaged arm to upper arm and shoulder indentation of the amplitude of the motion, the arc of the hand and arm movements, complex hand muscle strength vs usual occupational therapy sessions (p<0.05). RG in self-service of daily activities was increased (p<0.05). Increase arm muscle strength IMT aren't effective.

EVIDENCE-BASED PRACTICE IN REHABILITATION: HOW CAN WE DO MORE WITH QUESTIONNAIRE-BASED INSTRUMENTS?

C. Batcho¹
¹Université Laval - CIRRIS, Department of Rehabilitation, Quebec, Canada

Introduction/Background

More and more rehabilitation professionals are using questionnaire-based instruments to evaluate patients’ change over time. In some countries, the decision to continue or not the rehabilitation care is based on patient’s scores with different questionnaires. In such a context, it is important to have robust and well-designed measurement tools for objective, valid and reliable decisions, whether in terms of interventions effectiveness or in terms of the development of care policies in developed and low-income countries. From key aspects of the measurement of latent variables that are more and more part of evaluations in rehabilitation context (activity, participation, quality of life), this talk will highlight limitations of some widely used tools, and will address the need for optimizing the measurement of intervention outcomes, both in research and clinical contexts, either in high or low-income countries.

DETECTING IMPROVEMENTS OF UPPER EXTREMITY MOTOR COORDINATION BY ACCELEROMETER FOR STROKE
Y.S. Gao¹, M.A. Chung², S.C. Weng³
¹En Chu Kong Hospital, Division of Occupational Therapy- Department of Rehabilitation, New Taipei City, Taiwan R.O.C.
²Quanta Computer Inc, Business Unit 1, Taoyuan City, Taiwan R.O.C.
³En Chu Kong Hospital, Department of Rehabilitation, New Taipei City, Taiwan R.O.C.

Introduction/Background

Previous studies used accelerometer to determine the change in daily use of upper extremity or test reliability and validity of assessment tools. Stroke patients with minimal functional damage usually get high score in FMA-motor scale, especially in coordination. But patients still feel unsatisfied in ADL and seeking for training. However, they may be rejected in health insurance system in Taiwan. This study aims to find a simple and easily interpretable approach by accelerometer.

Material and Method

Researchers use a wearing tri-axial accelerometer to measure upper extremity for a 52 years-old male stroke patient. The study measured three situations: (1)sound side U/E, (2)affected U/E after stroke three months, (3)affected U/E after stroke six months. He got full score in Fugl-Meyer Upper Extremity Assessment-motor(FMA-motor), but only 35 points in Stroke Impact Scale after stroke three months. Therapist and doctor measured his movements by accelerometer for three movements: (a) sitting: shoulder flexion 70 degrees on table with elbow extension-> shoulder flexion 180 degrees to reach object above head, (b) sitting: shoulder flexion 90 degrees with elbow flexion t-> elbow extension to reach a cup then elbow flexion to mouth, (c) standing: shoulder flexion 180 degrees to reach object above head. These movements simulated activities of daily living.

Results

The researchers extracted data from accelerometer and translated to graphs easily by Microsoft Excel for post-treatment difference. We can easily see the different routes between sound side (a-1, b-1, c-1) and affected side (a-2, b-2, c-2), and improvement in coordination (a-3, b-3, c-3) is similar to sound side. He also improved 75 points in Stroke Impact Scale and got much
satisfied with his quality of life.

Conclusion

Accelerometer is a simple and easy tool to verify motor coordination for clinical doctor and therapist. Future research can focus on applying to lots number of patients and detecting lower extremities.

Strokes occur in the cortical or subcortical regions of the brain, compromise cortical functions and sensory-motor performance, and have a negative impact on long-term functional capacity. The aim of this study was to evaluate the relationship between strokes in the cortical or subcortical regions and autonomy, functional independence, and use of locomotor aids.

Material and Method

We evaluated 62 patients with ischemic strokes confirmed by CT-scan. The cortical and subcortical regions were defined by an experienced neuroradiologist. Patients were divided into two groups: those with cortical strokes (Group 1: n = 47) and those with subcortical strokes (Group 2: n = 15). Patients were then assessed for autonomy and independence 90 days after stroke using the Barthel Index and modified Rankin scale. Locomotor aid included the use of wheelchairs, crutches, and walking sticks for community outings. The associations of cortical or subcortical strokes with autonomy, independence, and use of locomotor aids were analyzed by simple logistic regression corrected for confounding variables (age, severity of stroke and treatment received) and were considered significant when $p < 0.05$.

Results

Lower autonomy was observed in Group 1 than in Group 2. Specifically, 6.4% of patients in Group 1 scored higher than 95 on the Barthel Index, compared to 46.7% in Group 2 ($p = 0.04$). A significant difference in the use of locomotor aids was observed between the groups (wheelchair: 29.8% of Group 1 vs 6.7% of Group 2, $p = 0.03$; walking sticks or crutches: 44, 7% of Group 1 vs 33.3% of Group 2, $p = 0.03$; Table 1).
Conclusion

Patients with ischemic strokes in cortical regions demonstrate less autonomy and have a greater chance of using locomotor aids than patients with strokes in subcortical regions do.

A SYSTEMATIC REVIEW: EFFICACY OF BOTULINUM TOXIN IN WALKING AND QUALITY OF LIFE IN POST-STROKE LOWER LIMB SPASTICITY.
A. Datta Gupta¹

¹The Queen Elizabeth Hospital, Rehabilitation Medicine, Adelaide, Australia

Introduction/Background

We performed a systematic review of the randomized control trials (RCT) to evaluate effectiveness of Botulinum toxin A (BoNTA) injection on walking and Quality of Life (QOL) in post-stroke lower limb spasticity (PSLLS).

Material and Method

We searched PubMed, Web of Science, Embase, CINAHL, ProQuest Thesis and Dissertation checks and Google Scholar, WHO International Clinical Trial Registry Platform, ClinicalTrials.gov, Cochrane, ANZ and EU Clinical Trials Register for RCTs looking at improvement in walking and QOL following injection of BoNTA in PSLLS. The original search was carried out prior to 16 September 2015. We conducted an additional verifying search on CINHAL, EMBASE, and MEDLINE (via PubMed) from 16 September 2015 to 6 June 2017 using the same clauses.

Results

Of 2026 records, we found 107 full text records and 5 RCTs qualifying our criteria. Two independent reviewers assessed methodological validity prior to inclusion in the review. Two studies reported significant improvement in gait velocity (p=0.020) and <0.05 respectively. One study showed significant improvement in 2-min-walking distance (p <0.05). QOL was recorded in one study without any significant improvement. Meta-analysis of reviewed studies could not be performed because of different methods of assessing walking ability, and small sample size with large confidence interval. This review identifies the need for a well-designed RCT to adequately investigate the issues highlighted.

Conclusion

This review could not conclude there was sufficient evidence to support or refute improvement on walking or QOL following BoNTA injection. Reasons for this are discussed and methods for future RCTs are developed.

THE IMPACT OF POST-ACUTE CARE REHABILITATION ON FUNCTIONAL STATUS IN STROKE PATIENTS FROM DIFFERENT HOSPITAL ACCREDITATION LEVEL

C.Y. Wang1
1Pingtung, Rehabilitation, Pingtung, Taiwan R.O.C.

Introduction/Background

In order to construct a medical transfer system for the stroke, Taiwan Ministry of Health and Welfare implemented a national program of Post-acute Care for Cerebrovascular Diseases (PAC-CVD) in March 2014. Under the intensive in-patient rehabilitation programs and per diem payment, the healthcare utilization was expected to be improved. The purpose of this study was to investigate the impact of intensive post-acute stroke rehabilitation on functional status in different hospital accreditation level.

Material and Method

The stroke patients who were admitted to post-acute ward in two hospitals during 2014/03/01 to 2017/8/31 were indicated to the study. The patients was separated to group 1 (a rural regional hospital) and group 2 (a metropolitan district hospital). The modified Rankin Scale (mRS) score, Barthal Index (BI), Instrumental Activities of Daily Living Scale (IADL) and Berg Balance Scale (BBS) were used to evaluate functional status.

Results

740 stroke patients (311 patients in group 1, and 429 patients in group 2) were included. The length of days (LOS) between stroke onset and post-acute care (PAC) ward admission were 11.60 days in group 1, and 21.41 days in group 2. The length of days in PAC ward were 27.02 days in group 1, and 36.85 days in group 2. The percentage of patients referred from other acute hospitals were 23.47% in group 1, and 89.51% in group 2. The severity (MRS grading on PAC admission day) was 3.53 in group 1, and 3.88 in group 2. The functional improvement after rehabilitation training was noted in both groups.

Conclusion

Under the intensive post-acute in-patient rehabilitation programs, the stroke patients got functional improvement. No matter the accreditation level of the hospital, the same payment may make more chance for the district hospitals to develop. The healthcare utilization may work efficiently under the medical transfer system.

ISPR8-0267
THE EFFECT OF TRANSCUTANEOUS ELECTRICAL NERVE STIMULATION COMBINED WITH MIRROR THERAPY IN STROKE PATIENTS
H. Seok

Soonchunhyang University Bucheon Hospital, Physical medicine and rehabilitation, Bucheon-si, Republic of Korea

Introduction/Background

In rehabilitation setting for stroke, it has been suggested that mirror therapy (MT) is a simple, inexpensive patient-directed treatment that improves upper-extremity function. Electrical stimulation for cutaneous receptors can increase cortical excitability, it also induce cortical plasticity and motor recovery. TENS(transcutaneous electrical nerve stimulation) on the median nerve is a simpler than any other electrical stimulation method. So, the author hypothesized that TENS coupled with MT would achieve a larger effect in motor recovery and daily function than MT alone in the stroke patients.

Material and Method

10 patients were recruited for this study. All patients were diagnosed as stroke identified by brain imaging and randomly assigned to two groups. The TENS was applied on the median nerve at wrist level (100Hz frequency, 250µs pulse width, and intensity set to sensory threshold just below motor threshold) during MT (1 hour/day and five times/week for 3 weeks) in the TENS with MT group. MT groups underwent MT alone. Brunnstrom motor recovery stage, manual function test (MFT), Perdue pegboard test, Jamargrip strength test, modified Barthel Index(MBI), Stroke Upper Limb Capacity Scale (SULCS), amplitude of MEP (recording from APB) were evaluated pre and post treatment.

Results

The demographics and baseline characteristics in the two groups did not differ significantly. All result parameters did not have significant difference between the groups. However, there is a tendency that TENS with MT group showed higher score than MT group in Brunnstrom stage, MBI, MFT, PPT, JAMAR grip strength, SULCS and MEP value.

Introduction/Background

CrossFit® is a high-intensity strength and conditioning program that has grown increasingly popular over recent years. Similar to other sports, athletes who perform in CrossFit® training may be at risk for various injuries. In rare cases, cervical vascular injuries including cervical internal carotid artery dissections have been reported. We present the first known case of vertebral artery dissection and posterior circulation infarct in association with CrossFit® training.

Material and Method

The patient was a 39-year-old previously healthy female who presented with sudden onset headache and loss of balance. She experienced a weight-related neck injury during a CrossFit® workout 2 days prior to symptom onset. On examination, she had impaired right eye adduction and right eye ptosis. Sensation was reduced in her right face and left extremities with intact strength. Gait was wide-based with tendency to fall to the right.

Results

Initial head CT was unremarkable. MRI brain revealed acute infarcts in the posterior right medulla and anterior inferior right cerebellar vermis. MRA showed evidence of right vertebral artery occlusion. The patient was initiated on secondary stroke prophylaxis with aspirin, clopidogrel, and atorvastatin. Etiology of the right vertebral artery occlusion was thought to be due to arterial dissection precipitated by her recent neck trauma during CrossFit®.

The patient completed acute inpatient rehabilitation with outpatient therapy follow-up. With therapy, the patient demonstrated improved independence with functional mobility, balance, and advanced mobility skills including treadmill running. She was successfully able to return to work and driving.

Conclusion

Rehabilitation clinicians should be knowledgeable about the potential for cerebral vascular injury in athletes who train with CrossFit® or similar exercise programs. Inpatient or outpatient rehabilitation may be indicated, with the overall goal to return the patient athlete to the best of his or her functional abilities.

Introduction/Background

Stroke is a debilitating disease that increasingly affects the young population. Although mortality stroke has declined over the last 20 years, this disease remains the leading cause of chronic loss of autonomy for those who are victims.

Material and Method

This is a retrospective comparative study in which we compared a cohort of 26 patients who had a stroke during the period (2006-2007 -2008) with a second cohort of 31 patients who had a stroke. during the period (2014-2015-2016)

Results

There is a male predominance in both series with a slight increase in the female sex in the second series. The average age is 42.4 years in the first series and 48.3 years in the 2nd. Among the risk factors in the antecedents: the frequency of the arterial hypertension is remarkable in the two series 15 cases for the 1st series and 23 cases for the 2nd series, then come in descending order diabetes 4 case 1st series, 9 cases 2nd series. Without cause 6 cases 1st series and 5 cases 2nd series. 2 cases of dyslipidemia in the two series 1 case epilepsy in both series rehabilitation started within an average delay of 2 months and a half for the 1st series and 1 month and a half for the 2nd series. The average duration of care is (3 months) for the 1st series. and (2, 5 months) for the 2nd series. Functional recovery of hemiplegic patients: we divided our patients according to a scale of assessment of autonomy. 20% of discrete sequelae in the two series, 21% of sequelae more or less important in the first series and 30% in the second series. 22% of major sequelae in both series.

Conclusion

The stroke of the young subject is a public health issue given the socioeconomic consequences and functional disability it causes. The etiologies are multiple and the overall prognosis good.

Introduction/Background
Unilateral spatial neglect (USN) after stroke can be caused by balance disorders of brain electrical activity, predominantly in the right parietal lobe. Recent literature suggests that spatial perception could be improved by rebalancing of hemispheric activity through non-invasive brain stimulation. The aim of this study was to evaluate the effect of transcranial direct-current stimulation (tDCS) on USN after stroke.

Material and Method
This is a prospective, randomized controlled double-blind trial will include individuals of both genders, aged above 18 years, with diagnosis of stroke confirmed by imaging tests and USN diagnosis by Behavior Inattention Tests < 129. Patients with USN will be randomized into three groups: 1 - treatment with anodic tDCS in right parietal lobe; 2 - treatment with cathodic tDCS in left parietal lobe; 3 - Sham. Randomization of a maximum of 45 patients is planned with 15 patients in each group. Individuals will be assessed by Catherine Bergego Scale, NIHSS, Functional Independence Measure, Barthel Scale, mRs, and Quality of Life Scale by an investigator blinded to treatment the patient received before the first session and 1 week after the last tDCS session. We will use regression models considering confounding factors for statistical analysis of the data.

Results
In March 2017, 32 patients were recruited, of which seven were effectively included. Our greatest difficulties were the delay in patient inclusion after a stroke, difficulty in transportation to the study center, and unavailability of trained personnel for patient recruitment. Six patients were stimulated, being 3 anodical, 1 cathodical and 2 sham (Figure 1).
Conclusion

Given the importance of USN in the stroke context, the effectiveness of tDCS in stroke rehabilitation is expected to be verified at the end of the study.

A BRAIN-COMPUTER INTERFACE BASED STROKE REHABILITATION SYSTEM, CONTROLLING AN AVATAR AND FUNCTIONAL ELECTRICAL STIMULATION, TO IMPROVE MOTOR FUNCTIONS.

A. Lechner¹, W. Cho², R. Ortner², G. Christoph²
¹Guger Technologies OG, Research, Graz, Austria
²g.tec medical engineering GmbH, Validation, Schiedlberg, Austria

Introduction/Background

Brain-Computer Interfaces (BCI) can detect the neuronal activity of patients' motor intention to control external devices. With the feedback from the device, the neuronal network in the brain to reorganizes due to neuroplasticity.

Material and Method

The BCI controls an avatar and functional electrical stimulation (FES) to provide the feedback. The expected task for the patient is to imagine either left or right wrist dorsiflexion according to the instructions. The training was designed to have 25 sessions (240 trials of either left or right motor imagery) of BCI feedback sessions over 13 weeks. Two days before and two days after we did clinical measures to observe motor improvement. The primary measure was upper extremity Fugl Meyer assessment (UE-FMA) which evaluates the motor impairment. Four secondary measures were also performed to exam the spasm (modified Ashworth scale, MAS), tremor (Fahn tremor rating scale, FTRS), level of daily activity (Barthel index, BI), and finger dexterity (9-hole peg test, 9HPT).

Results

One male stroke patient (53 years old, 11 months since stroke, and right upper limb paralyzed) participated in the training. He quickly learned to use the BCI and the maximal classification accuracy was over 90% after the 5th session. The UE-FMA increased from 25 to 46 points. The BI increased from 90 to 95 points. MAS and FTRS decreased from 2 to 1 and from 4 to 3 points respectively. Although he could not conduct the 9HPT until 18th training session, he was able to complete the test from 19th session in 10 mins 22 secs and the time was reduced to 2 mins 53 secs after 25th session.

Conclusion

The patient could be more independent in his daily activity, he had less spasticity and tremor. Also, the 9HPT was possible to do, which wasn't before. The system is currently validated with a study of 50 patients.

PREDICTING ACCURACY OF RETURN TO WORK OF MALE STROKE PATIENTS AT WORKING AGE BY WHODAS 2.0
S. Huang¹
¹Shuang Ho Hospital- Taipei Medical University, Physical Medicine, Taipei, Taiwan R.O.C.

Introduction/Background

Stroke is one of the main causes of morbidity and mortality in younger male adults and is particularly relevant to working individuals. When stroke at working-age, these patients must face the challenges of employment and maintain the quality of life. How to comprehensively and objectively evaluation the opportunity of return to work is an important issue. The WHO Disability Assessment Schedule 2.0 (WHODAS 2.0) was developed based on International Classification of Functioning, Disability and Health (ICF) framework for evaluating functioning, including social participation and cognition-related daily activities. WHODAS 2.0 can be a reliable comprehensive functional assessment tool, and the aim of this study was to investigate the predicting accuracy of return to work of male stroke patients at working-age.

Material and Method

A total of 7687 male stroke patients at working-age (aged from 25 to 55 years old) were obtained from Taiwan Data Bank of Persons with Disability from the July 2012 to October 2017. According to their working status, we separated them as return-to-work group and nonreturn to work group. Demographic data and WHODAS 2.0 standardized scores of patients with stroke of both groups were analyzed and compared using the chi-squared and independent Student’s t-tests. Receiver operating characteristic curve analysis was performed to investigate the prediction opportunity for the return-to-work status, and the optimal cutoff point was determined using the Youden index.

Results

All domains of return-to-work group (n=481) had lower WHODAS 2.0 scores than nonreturn-to-work group (n=7206). The receiver operating characteristic curve showed moderate accuracy for all domain-specific and summary scores of WHODAS 2.0 [area under the curve, 0.6–0.8]. The cuff-off point of summary score was 39.67 with 70.0% sensitivity and 65.3% specificity.

Conclusion

Our study presented that WHODAS 2.0 can be taken as an assessment tool to predicting the opportunity of return to work of male stroke patients at working-age.

THE CORTICAL MECHANISM OF “REMIND-TO-MOVE” IN STROKE PATIENTS: A NEAR INFRARED SPECTROSCOPIC TOPOGRAPHY CASE STUDY

X.J. Wei¹, N.K. Fong², K.H. Ting²

¹Southern Medical University, Department of Rehabilitation Sciences, Shenzhen, China
²The Hong Kong Polytechnic University, Department of Rehabilitation Sciences, Kowloon, Hong Kong S.A.R.

Introduction/Background

‘Remind-to-move’ (RTM) has been shown to be useful on promoting hemiparetic upper extremity motor recovery in patients with stroke and children with unilateral cerebral palsy in our previous studies. This study was to explore the cortical mechanism of RTM on upper extremity related to the brain responses in the form of sensory cueing in both healthy and stroke participants.

Material and Method

A block research design was used with Block 1 - baseline condition, Block 2 – sham condition, and Block 3 - experimental condition, on 2 stroke patients with hemiparetic upper extremity and their 2 healthy counterparts. They were required to wear cueing wristwatch device over both arms throughout the study but sensory cueing was emitted only in the experimental condition, i.e. Block 3. During sham condition, the participants were told to perform self-regulated hand movements every minute, whereas the participants just needed to perform hand movements after each sensory cue emitted from the device in the experimental condition. The cortical hemodynamics was recorded by functional near infrared spectroscopic topography (fNIRS).

Results

Activated regions of healthy and stroke participants showed different patterns of neuro correlates. Prefrontal cortex was found to be activated in healthy participants but the same area was less activated comparatively in stroke patients in the sham condition. Both prefrontal and primary motor cortices were less activated in healthy participants in the experimental condition but these areas in stroke patients were more activated instead. It was observed that the frontal cortex of both healthy participants and one stroke participant with higher paretic arm functioning was activated throughout different block conditions but not for another stroke participant with lower arm functioning.

Conclusion

The cortical mechanism leading to the positive effect of sensory cueing might be contributed by the enhanced attention and activation of the prefrontal cortex for preparedness of movements.

LOWER LIMB EXPROPRIOCEPTION MAY BE IMPAIRED AFTER STROKE

S.L. Lin¹, P.Y. Lee¹, N.H. Kuo¹, C.H. Chen²

¹National Cheng-Kung University, Physical Therapy, Tainan, Taiwan R.O.C.
²National Cheng-Kung University, Neurology, Tainan, Taiwan R.O.C.

Introduction/Background

Exproprioception, the perception of limb position in the environment, is important for the control of functional activities. The purpose of this study was to determine if the lower limb exproprioception was affected by stroke.

Material and Method

Healthy young (YA, n=20) and age-matched control (CON, n=10) adults and first-time stroke patients with residual sensorimotor deficits (CVA, n=19) participated in this study and went through visual acuity and bilateral plantar sensitivity and grip strength tests. The exproprioception test was a foot placement matching test conducted in sitting. In external target condition (EXT-T), the target was an arrow mark on the ground near the foot and clearly seen by the subject. In internal target condition (INT-T), the target was the big toe of the affected foot (or nondominant for non-stroke) which was passively moved to a near-by random location with the subject's eyes closed. In both conditions, subjects were instructed to memorize the target location and, after the arrow was removed or the foot returned to its initial position, move the unaffected (or dominant for non-stroke) foot to the target, with eyes open (EO) and closed (EC). The distance between the big toe and target was used to indicate exproprioception error (Expro-Err) and was recorded using the SIMI motion analysis system.

Results

Compared to CON, CVA had poorer affected side plantar sensitivity and grip strength, but the differences in visual acuity or unaffected side functions were nonsignificant. Expro-Err in EO during both conditions and in EC during Ext-T did not show significant between-group differences. In EC during INT-T, CVA had significantly greater error than YA and CON (p=0.003 and 0.045, respectively).

Conclusion

Stroke may affect the ability to match the foot placement of the other foot without vision. Further studies are needed to determine if and how such deficit would affect gait.

Introduction/Background

Theta burst stimulation (TBS) therapy is recently used as an invasive intervention for patients with neurological and psychiatric disorders. However, few studies investigated in identifying who benefits from it for patients with stroke. This study aims to determine whether motor evoked potential (MEP) responses are related to TBS treatments effects on upper limb functions in patients with stroke.

Material and Method

Twelve patients with stroke, aged 30-70 years, were classified into two groups based on the presence of MEP: present (n= 6) and absent MEP groups (n=6). All patients received TBS therapy, 5/week for 3 weeks in addition to rehabilitation programs. MEP evaluation was performed before TBS intervention. Outcome measures, including Brünnstrom Staging, Modified Ashworth scale (MAS), and Nine Hole Peg Test (NHPT), were evaluated before and after TBS, associated with the responsiveness of MEP to treatment with TBS. Analysis of covariance was employed to compare the outcome measures between two MEP groups. A p<0.05 is considered as significant difference.

Results
After TBS therapy, the MEP-present group had better improvement in Brünnstrom Staging in proximal upper limbs and NHPT than MEP-absent group (p<0.05). However, the Brünnstrom Staging in distal upper limbs and MAS scores did not achieve the significant differences after TBS therapy between two MEP groups.

**Conclusion**

These findings may suggest MEP responses are associated with treatments effects of TBS on motor function, but not on spasticity, in upper limbs of patients with stroke. However, definite conclusion could not be drawn due to limited sample size. Future studies may increase the sample size to validate the association of MEP responses and the treatments effects of TBS on upper limb functions in these patients.

THE EFFECT OF HIGH BLOOD PRESSURE (HBP) ON TOTAL BARTHEL INDEX (BI) AND 10 ITEMS OF BI AFTER STROKE REHABILITATION
N. Saito¹, T. Nshikawa²
¹Yokohama Rosai Hospital, Rehabilitation, Yokohama, Japan
²Yokohama Rosai Hospital, Internal Medicine, Yokohama, Japan

Introduction/Background

We previously analyzed inpatients of conventional ward (ICW, n=9951) and subacute ward (ISW, n=6322) of Japan Association of Rehabilitation Database (JARD) and reported the effect of HBP on 10 items of BI after stroke rehabilitation. We analyzed total BI both with using method of dichotomized ordinal scale and continuous scale, because the method how to analyze total BI remains controversy.

Material and Method

In the analysis of ordinary scale, we dichotomized total BI into 80−100 (BI80+) versus 0−75 (BI80−), 60−100 (BI60+) versus 0−55 (BI60−), 40−100 (BI40+) versus 0−35 (BI40−), or 20−100 (BI20+) versus 0−15 (BI20−), compared between each category and control with using chi-squared test and 2×2 contingency table, and calculated odds ratios (ORs) and 95% confidence intervals (CIs). In the analysis of continuous scale, Shapiro-Wilk test and Wilcoxon test were conducted.

Results

In the ordinary analysis, HBP ameliorated total BI among ICW of atherothrombotic infarction (BI40+ versus BI40− OR 1.881 CI 1.088−3.253, and BI20+ versus BI20− OR 3.135 CI 1.660−5.918), and ISW of other infarction (BI80+ versus BI80− OR 1.823 CI 1.080−3.076), and deteriorated total BI of ICW of subarachnoid hemorrhage (SAH) (BI80+ versus BI80− OR 0.395 CI 0.166−0.939). In the continuous analysis, total BI of hypertensive ICW (median 60) of SAH was deteriorated (p=0.013) compared with non-hypertensive ICW (median 95).

Conclusion

HBP had both a favorable and unfavorable effect on total BI after stroke rehabilitation. The results of total BI of dichotomous ordinal analysis were consistent with those of BI items, while those of continuous analysis were not. Dichotomous ordinal analysis might be appropriate to analyze total BI, and results of BI items should be considered as well as total BI.

ISPR8-0388
BRAIN MOTOR CONTROL ASSESSMENT OF ANKLE MOTOR FUNCTION IN PATIENTS WITH STROKE: A PILOT STUDY
M.J. Hong¹, J.Y. Chun¹
¹Asan medical center, rehabilitation medicine, Seoul, Republic of Korea

Introduction/Background

The Brain Motor Control Assessment (BMCA) is a surface EMG-based measure of motor output from the central nervous system. The aim of this study was to investigate whether the pattern of voluntary movements in patients with stroke could be correlated with clinical spasticity measurement tools.

Material and Method

Eight subjects with stroke and eight healthy controls participated in this study. The surface EMG of 10 muscles was recorded with pairs of surface electrodes. These electrodes were placed in the muscle belly for the both quadriceps (Q), hip adductor (A), hamstring (H), tibialis anterior (TA) and triceps surae (TS) muscles. The maneuver included a bilateral task with two phases (ankle dorsiflexion/plantar flexion) and unilateral task with two phases that were conducted on both sides. This set of values, one for each muscle, comprised the response vector (RV) for each phase of a task. They were presented in units of µVRMS for each of the scalar elements. These values were used to calculate the similarity index (SI), which compares the relative distribution across the set of muscles chosen for the task. The voluntary response index value (VRI) was computed separately for each maneuver and it consisted of a pair of elements.

Results

The SI values were significantly lower in the stroke group compared to the control group for hemiplegic ankle dorsiflexion and plantar flexion (Fig.1).
The averaged magnitudes sEMG of RV revealed significant increases in the stroke group, as compared to the control group, with mean ALR values of 4.58µV and 3.44µV, respectively (p=0.036). These averaged sEMG activities of RV significantly increased corresponding to the MAS, Tardieu spasticity grade (X) and the difference between R1 and R2, defined as the dynamic component (R2-R1) (Fig.2).

**Conclusion**

This neurophysiological assessment might be useful to provide objective assessment of spasticity and to tailor therapeutic strategies for each stroke patient.

**Keywords**

brain motor control assessment; surface electromyography; post stroke spasticity

STUDY OF BONE MINERAL DENSITY IN STROKE SURVIVORS
S. Gorle
1Safdarjung hospital, PMR, VIJAYAWADA, India

Introduction/Background

Osteoporosis after stroke differs from age-related and other causes of osteoporosis. Stroke is frequently followed by extensive bone loss, precipitating the increased fracture risk in survivors. It is more evident on the paretic side and that too in the upper extremities. The present study is to assess the Bone Mineral Density (BMD) in hip, spine and wrist and to assess BMD difference between paretic and non-paretic side in ambulatory stroke survivors.

Material and Method

The study design is Cross-sectional observational study. Forty individuals attending the OPD of Department of Physical Medicine and Rehabilitation, VMMC & Safdarjung hospital, New Delhi with the diagnosis of stroke, fulfilling inclusion criteria were enrolled. Tools of measurement used were 1) BMD using Dual Energy X-ray Absorptiometry (DEXA) by OSTEOSCORE-3 (Digital 2D Densitometer) at spine, forearm and hip, 2) Biochemical markers(S.Ca, Phosphorous, ALP) 3) X-ray of spine, bilateral hip and wrist.

Results

Our study involved total 40 subjects having 33 (82.5%) males and 7 (17.5%) females. Mean age of study group was found to be 53.9 ± 10.9 years. The T score for forearm was found to be significantly higher in non-paretic side (Mean = -4.11 ± 2.46) compared to paretic side (Mean = -4.85 ± 2.01) (P=0.04). The T score for hip on non-paretic side was found to be higher (Mean = -1.96 ± 1.74) compared to that of paretic side (Mean = -2.14 ± 1.57) (p=0.4). 15 (37.5%) subjects were found to be osteoporotic on DEXA scanning of spine.

Conclusion

Most of the patients who presented after one year of stroke had low T-score at hip and forearm on paretic side in comparison to non-paretic side.

CHANGES IN SWALLOWING AND COUGHING FUNCTION IN STROKE PATIENTS BEFORE AND AFTER TRACHEOSTOMY DECANNULATION
S.J. Lee¹, S.B. Kim², K.W. Lee², J.H. Lee², M.K. Park³
¹Dong-a University Hospital, Dept. Rehabilitation Medicine, Busan, Republic of Korea
²Dong-A University Hospital, Physical Medicine and Rehabilitation, Busan, Republic of Korea
³Dong-A University Hospital, Pharmacology and Clinical Pharmacology, Busan, Republic of Korea

Introduction/Background

After stroke, patients may lack the ability to protect their airway. When prolonged ventilation is necessary, a tracheostomy is frequently performed. Few studies have evaluated functional changes in stroke patients before and after tracheostomy tube removal.

We investigated the functional changes in swallowing and voluntary coughing in stroke patients before and after tracheostomy decannulation. We also compared the functional status between stroke patients who had their tracheostomy tubes removed and those who did not within 6 months of their stroke.

Material and Method

Seventy-seven stroke patients who had undergone a tracheostomy were enrolled. All patients were evaluated videofluoroscopic swallowing studies and peak flow meter through the oral cavity serially until 6 months after their stroke. During the intensive rehabilitation period, if a patient satisfied the criteria for removal of their tracheostomy tube, the tube was removed.

The patients were divided into the ‘Decannulated’ group and the ‘Non-decannulated’ group according to their tracheostomy removal status. Cognitive function and activities of daily living were also evaluated in both groups.

Results

In decannulated group, swallowing function did not change before and after tracheostomy decannulation; however, coughing function was significantly improved after decannulation.

Although both groups exhibited all functional improvement over time, the improvement in the decannulated group was more significant than the improvement in the non-decannulated group.

Conclusion
Our results revealed that stroke patients who had better functional improvement were more likely to be potential candidates for tracheostomy decannulation. Stroke patients who recovered from their neurogenic dysphagia, they were no longer affected by the mechanical effect of the tracheostomy tube on swallowing function. As various functions were associated with the ability to remove a patient’s tracheostomy tube after stroke, a multidisciplinary, personalized intensive approach for tracheostomy decannulation is needed to achieve better rehabilitation outcomes in tracheostomized stroke patients.

Introduction/Background

Stroke is the leading cause of mortality and disability in rural China, but access to rehabilitation services for patients and families to improve function and quality of life is substantially inadequate. We aimed to design an intervention that delivers practical and easy rehabilitation services to stroke patients in rural China.

Material and Method

The RECOVER trial was designed under the principle of being simple and easy-to-implement. It integrated family caregivers and the evidenced-based “train-the-trainer” model into the rehabilitation approach. To maximize its feasibility in rural China, we adopted community-based rehabilitation model and further simplified it based on local needs. The entire intervention design consisted of four stages: needs assessment and model building, intervention refinement, intervention materials production and pilot study for user testing.

Results

Nurses in the county hospitals were trained by rehabilitation specialists from Peking University First Hospital and qualified through the program-design-specified tests. After the patients were randomly assigned to the intervention group, the nurses would evaluate their conditions, make in-hospital rehabilitation plans, train their family caregivers, make discharge plans and provide follow up consultation via phone calls post discharge. A “teach-back” technique was used by the nurses to ensure that the caregivers had fully mastered the rehabilitation skills. The whole intervention process is shown as a flowchart for the nurses to follow efficiently. The intervention manual and guidance VCD which were focused on mobility, self-care and continence were easy to understand for the nurses and caregivers. The procedure of the intervention was a little complex to nurses, and it need to be simplified.

Conclusion

The RECOVER trial was designed as a nurse-organized and caregiver-delivered stroke rehabilitation program. The standard intervention of rehabilitation can help nurses complete the whole process of intervention, and deliver rehabilitation skills to patients effectively and completely.

COGNITIVE FUNCTIONS USING LOTCA AND ADL IN PATIENTS WITH STROKE
U. Kim¹, J.H. Kim¹, L. Mun Hee¹
¹National rehabilitation center, Dep. of Physical Medicine and Rehabilitation, Seoul, Republic of Korea

Introduction/Background

This study aimed to evaluate the correlation between the cognitive function using LOTCA (Lowenstein Occupational Therapy Cognitive Assessment) and the change of ADL function in patients with stroke who got the cognitive therapy combined with conventional therapy.

Material and Method

We included all patients with stroke (mean age 49.2, 36 male and 14 female) who were requested to cognitive therapy unit and got the cognitive therapy in our hospital from August to December of 2016. And we reviewed 50 medical records retrospectively. All patients got the cognitive therapy using computer (30 minutes/session) and conservative occupational therapy (30 minutes/session). We used the LOTCA for cognitive function and the K-MBI for ADL function. LOTCA is the range of 0-119 scores and consists of 8 factors as ‘orientation for place’, ‘orientation for time’, ‘visual perception’, ‘spatial perception’, ‘motor praxis’, ‘visuomotor organization’, ‘thinking operation’ and ‘attention and concentration’. We evaluated the correlation between total score (or subscore) of pre-therapy LOTCA and difference of K-MBI score (admission vs. discharge, mean interval: 93.7 days). The data were analyzed with correlation analysis using SPSS 18.0 software and a P value less than 0.05 was regarded as being statistically significant.

Results

The average of 50 patients’ pre-therapy LOTCA total score was 67.1, and it was 78.9 when they discharged our hospital. And the mean scores of patients’ K-MBI were 44.8 and 54.9 with admission and discharge, respectively. Subscores for LOTCA ‘motor praxis’, ‘visual organization’, ‘attention and concentration’ and total LOTCA scores showed significant correlation with a factor of K-MBI as toileting (r=0.313, 0.443 0.302 0.343, all p<0.05). But, except theses LOTCA subscores above mentioned, only limited factors of LOTCA were correlated with the improvement of K-MBI.

Conclusion

This study showed that there was some correlation between the cognitive functions using LOTCA and improvement of ADL after practicing cognitive therapy with conventional occupational therapy. Further large controlled study might be required.

CLINICAL STUDY ON IMPROVING POST-STROKE MOTOR DYSFUNCTION BASED ON
DELPHI ACUPUNCTURE PRESCRIPTION: A RANDOMIZED, OPEN LABEL, PARALLEL-
CONTROLLED TRIAL

J. cai¹, S. yang²
¹Fujian University of Traditional Chinese Medicine, Rehabilitative medicine college, Fujian, China
²Affiliated rehabilitation hospital of Fujian University of traditional Chinese Medicine, rehabilitation department, fuzhou, China

Introduction/Background

In this study, we designed a randomized control trial to investigate the effectiveness of Delphi acupuncture prescription in PSMD. We hypothesized that the Delphi acupuncture prescription could improve the motor function of PSMD patients and has a similar therapeutic effect with traditional conventional acupuncture prescription. The findings of our study will confirm the feasibility of the Delphi protocol in the clinical trial or clinical practice setting. The findings will help promote acupuncture treatment in different regions and different cultural backgrounds worldwide.

Material and Method

A total of 260 participants with PSMD completed this trial, including 87 patients in the optimal acupuncture group, 86 patients in the conventional acupuncture group, and 87 patients in the waiting-list group. All patients received basic treatment and health education. The intervention continued for 4 weeks (30 min per day, 5 days per week). The relative functional outcomes were measured at baseline and 4 weeks (at the end of intervention) using the Fugl-Meyer assessment (FMA), modified Ashworth scale (MAS), Berg balance scale (BBS), modified Barthel index (MBI), and National Institute of Health stroke scale (NIHSS). After 4 weeks of treatment, the functional status of the patients in each group was improved to varying degrees.

Results

Multiple comparisons of the change in the FMA, BBS, MBI, and NIHSS values indicated that optimal acupuncture based on the Delphi theory had a similar therapeutic effect on the functional status of PSMD patients with conventional acupuncture (PΔ FMA=0.434, PΔ BBS=0.000, PΔ MBI=0.001, PΔ NIHSS=0.011) (Table 4).

Conclusion
The acupuncture program based on the Delphi theory is a clinically effective prescription for the treatment of motor dysfunction in post-stroke patients. It has certain clinical value and can help young or inexperienced clinicians develop effective acupuncture prescriptions for post-stroke patients with motor dysfunction. The acupuncture program is of great significance for the clinical promotion of the acupuncture treatment program.

STUDY ON THE CORRELATION BETWEEN MAGNETIC RESONANCE SPECTROSCOPY AND LOEWENSTEIN OCCUPATIONAL THERAPY COGNITIVE ASSESSMENT IN EVALUATION OF COGNITIVE IMPAIRMENT AFTER STROKE

Z. Gong

1Xuzhou Central Hospital, Rehabilitation, Xuzhou, China

Introduction/Background

To explore the cognitive impairment after stroke in patients with magnetic resonance spectrum and Loewenstein Occupational Therapy Cognitive Assessment.

Material and Method

According to the diagnostic standard of cognitive impairment with MMSE, selected cognitive impairment after stroke group, stroke control group and healthy control group, each of the group have thirty unities.and age, gender, level of education was matched in the three group .All the subjects were assessed with MRS and LOTCA.

Results

All LOTCA scores and the value of NAA/Cr in bilateral hippocampusin cognitive impairment group were lower than those in stroke control group and those in normal control group (P < 0.05); The value of Cho/Cr in bilateral hippocampus of Cognitive impairment group is higher than the stroke control group and healthy control group (P < 0.05); The value of NAA/Cr in bilateral hippocampus of stroke control group is lower than those in normal control group(P < 0.05), The value of Cho/Cr in bilateral hippocampus of stroke control group is higher than the healthy control group(P < 0.01), The value of NAA/Cr in bilateral hippocampus had low to moderate positive correlation with the LOTCA total score, the each sub-items score of LOTCA and attention score (left:r=0.376~0.609,right: r=0.396~0.691, P<0.05);The value of Cho/Cr in left hippocampus had low to moderate negative correlation with the LOTCA total score, the each sub-items score of LOTCA(r=-0.368~--0.619, P < 0.05); The value of Cho/Cr in right hippocampus had low to moderate negative correlation with the LOTCA total score, the score of orientation, visual perception, visuo-motor organization ,the thinking operations(r=-0.391~--0.632, P <0.05).

Conclusion

MRS can be used to assess the degree of cognitive impairment in patients with stroke.MRS is associated with LOTCA score degree of cognitive impairment is heavier, the lower score of LOTCA, the lower NAA/Cr value, the higher Cho/Cr value.

STROKE REHABILITATION UNIT AND ROBOTICS IN EARLY REHABILITATION
E.P. Buffagni¹
¹Fundacion San Andres, Capital, Mendoza, Argentina

Introduction/Background

Conceptually we consider the necessity of creating an integral treatment of rehabilitation for: etiopathogenic study, therapeutic assessment, diagnosis of complications, functional and physiological consequences. Emphasis in starting as soon as possible with the process of rehabilitation.

Material and Method

Creating a stroke unit of rehabilitation to treat the post-acute phase of recovery following a stroke. Patient is transferred once they are medically stable. Length of stay in that phase in 4-6 weeks. The goal of this unit is to maximize the stroke recovery potential in patients so they may be able to function at the highest level of physical and mental ability they can achieve post-stroke.

- Comprehensive, evidence based, written protocols, order sets and care pathways/algorithms should be in place to guide
- Early use of robotic therapy: Rehabilitation is inherently a labor intensive process and has always relied on an individualized therapy programs provided by highly skilled therapist. This type of therapist has advantages but it is very physically demanding, so the training duration is limited by the fitness of the therapist. As a solution to this limitation a robot driven therapy has been proposed
- Early intensive task specific, multisensory stimulation performed by highly skilled team. In addition we have developed on cutting edge robotic department with excellent results.
Results

With Stroke Unit
- Hospital stay is reduced by 50% (average) in relation to stay of chronic patients
- Scores of discharge FIM+FAM show little increase

With Stroke Unit + Robotics
- Hospital stay time is sustained in a 52% (average) in relation to stay of chronic patients
- But scores of discharge FIM+FAM were improved with the use of Robotics

Conclusion
Stroke rehabilitation unit and robotic are an effective program that provides:
- Early stimulation
- Prevention and treatment of risk factors
- Intensive stimulation
- Task specific stimulation
- Multi-sensory stimulation
- Decrease length of stay in the hospital
- Improvement in functional capacity

HETEROTOPIC OSSIFICATION AND STROKE: ABOUT FOUR PATIENTS
H. Aboura¹, A. Sehimi¹, S. Ammor¹, O. Bensaber¹
¹Centre Hospitalo-Universitaire Dr HASSANI Abdelkader,
Service de Médecine Physique et de Réadaptation, Sidi-Bel-Abbes, Algeria

Introduction/Background

Heterotopic ossification (HO) occurs in certain traumatic central neurologic pathologies, causing extra-articular heterotopic osseous formations. The frequency of their occurrence in stroke is relatively low (1%).

Purpose: to contribute to their existence in stroke.

Material and Method

They are three men and a woman old on average 44 years and have been hospitalized in Physical Medicine and Rehabilitation after a stroke. All had a hemiplegia, three were spastic. We studied the onset of the HO, clinical symptomatology and their location, and analytical and functional results obtained after surgery in two patients.

Results

It was 7 locations of HO (4 elbows, 2 hips and 1 knee). Six of them were located on the side of hemiplegia. One was haemorrhagic, two ischemic and the last one post cerebral thrombophlebitis.

The time to onset of clinical signs compared to the beginning of stoke is from 3 weeks for hemorrhagic case to 6 months in ischemic stroke case.

All HO occurred on the side of hemiplegia only one located on left knee in a right hemiplegia.

These HO are causing a stiff elbow and knee, and ankylosis of the hip in two patients fixed them in flexum-abductum and lateral rotatum greatly hindering the sitting.

Elbow HO was complicated by ulnar nerve compression.

One patient was operated for a functional purpose 18 months after stroke, and nerve decompression (neurolysis of the ulnar nerve) performed 6 months after stroke.

Conclusion
Lighting from our observations and our contribution to the reality of their existence in this type of pathologies.

Hip HO after central neurologic injury ultimately threatens articulation of ankylosis.

Elbow HO has often a major functional impairment with risk of nerve compression. Surgical indication concerns more frequently hip and elbow HO. Surgery is often delayed for fear of recurrence even if the functional prognosis is engaged.

EFFECT OF TURNING DIRECTION ON TIMED UP AND GO TEST RESULTS IN STROKE PATIENTS

H. son¹, C. Park²

¹Catholic University of Pusan, department of physical therapy, Busan, Republic of Korea
²Keunsol medical hospital, rehabilitation center, Busan, Republic of Korea

Introduction/Background

BACKGROUND: The Timed Up and Go (TUG) test is an assessment tool for measuring mobility for stroke patients. In the stroke patients, turning direction of the affected and un unaffected side may influence turning time.

AIM: To investigate the effects of the turning direction according to the affected and non-affected sides of stroke patients during their Timed Up and Go (TUG) test and to define clinically salient outcomes during TUG tests performed in the clinic

Material and Method

DESIGN: Observational design.

SETTING: Department of physical therapy in rehabilitation center.

POPULATION: One-hundred thirteen hemiparetic stroke patients.

METHODS: Stroke patients were asked to perform the TUG tests by turning toward their affected and unaffected sides. Patients were divided according to gait speed, and their gait speed from the 10mWT was used. Those with a gait speed <48 m/min were assigned to the severe ambulatory dysfunction (SAD) group, whereas those with a gait speed ≥48 m/min were assigned to the moderate ambulatory dysfunction (MAD) group.

Results

RESULTS: The TUG test results showed a longer turning time when turning with the non-affected side as the turning axis (17.10±5.69 sec) than with the affected side was the turning axis (17.52±5.90 sec). When the patients were divided into the MAD and SAD groups based on the 10mWT results, patients in the SAD group exhibited slightly longer times (0.55±1.11 sec) than did those patients in the MAD group (0.29±1.03 sec); however, this difference was not significant.

Conclusion
CONCLUSIONS: The present study found that stroke patients showed differences in the TUG test results based on their turning direction, and less time was required when turning in the direction of the affected side compared to the non-affected side.

CLINICAL REHABILITATION IMPACT: Turning direction can affect the results of TUG test, it should be controlled in the execution of the TUG test in clinical settings.

No conflict of interest
Upper limb functional activity (ULFA) dysfunction is one of the most common and persistent disabilities after stroke. Improvements in ULFA are likely to occur after discharge from active rehabilitation in hospital. However, currently no studies have been undertaken to investigate the ULFA of people with chronic stroke after discharge. This study aimed to investigate the ULFA of the affected arm in people with more than six months post-stroke.

**Introduction/Background**

A cross-sectional survey study was conducted during September to November 2017 in community areas of Naresuan University Hospital, Phitsanulok, Thailand. Participants were individuals with chronic stroke who were able to sit independently for at least 30 minutes and understand commands to perform a test. The Streamlined Wolf Motor Function Test (SWMFT) for chronic stroke was applied to evaluate the ULFA. Six tasks of the SWMFT were timed and rated by using the functional ability scores (FAS) starting from zero (cannot attempt task with involved arm) to five (movement appears to be normal). Scores of three or above indicated that all six SWMFT tasks could be completed to some degree by synergy, or were performed slowly or with effort. Data were analyzed by means of descriptive statistics.

**Results**

Forty-five community-dwellers who were on average of 66.38±52.98 months post-stroke were recruited. The average SWMFT-FAS for the participants was 1.63±1.52 points with a timescale of 69.93±49.89 seconds (lower is better). Twenty-nine (64%) participants had SWMFT-FAS scores lower than 3. Twelve (26%) participants had a zero score.

**Conclusion**
The majority of people with more than six months post-stroke had poor ULFA of the affected arm. Continuing rehabilitation is therefore needed after hospital discharge, in order to enhance the ULFA recovery in people with chronic stroke.

THE EFFECTS OF NON-ELASTIC TAPING COMBINED WITH EXERCISES TRAINING ON MOTOR FUNCTION IN CANE-ASSISTED INDIVIDUALS AFTER STROKE

C.Y. Lin¹, R.Y. Wang¹, C.S. Lee², Y.R. Yang¹
¹National Yang-Ming University, Department of Physical Therapy and Assistive Technology, Taipei, Taiwan R.O.C.
²Taipei City Hospital Renai Branch, Department of Rehabilitation Medicine, Taipei, Taiwan R.O.C.

Introduction/Background

Cane is one of the common assistive devices prescribed for individuals with stroke to improve walking ability and safety. It was revealed that long term cane-assisted individuals with chronic stroke perform abnormal gait pattern during walking. To improve these impairments, strengthening, balance training, task-specific training and intensive mobility training have been suggested. However, the training effects on motor function were limited in cane-assisted individuals with chronic stroke. It is supposed that musculoskeletal alignment of these individuals isn’t on the efficient position which may restrict the training effects. The immediate effects of joint alignment adjusted with Luekotape®P on muscle strength, balance and gait performance has been proved in individuals with stroke. However, the effects of taping combined with exercise training is unknown. This study aimed to investigate the effects of non-elastic tape combined with exercise training on motor function in cane-assisted individuals with chronic stroke.

Material and Method

Subjects were randomized into either the experiment group with Luekotape®P or control group with sham tape. Subjects in both groups received the same exercise training for six weeks. The primary outcomes were gait performance and Berg balance scale. The secondary outcomes were muscle strength of hip extensors and abductors, endurance and fear of falling. Outcomes measurements were performed before and after the intervention and then one-month follow-up.

Results

The intervention significantly improved cadence, stance time of affected side, spatial asymmetry ratio, Berg balance scores, and fall efficacy scale scores as well as 6-minutes walk test in the experimental group. In the control group, only the Berg balance scores and 6-minutes walk test had been significantly improved.

### Conclusion

...
Although all outcomes didn’t show significant differences between groups. Our results suggested that exercise combined with Leukotape®P may have more improvement than exercise alone in stance time, cadence, spatial asymmetry ratio, endurance, and fall efficacy scale.

Introduction/Background

The impact of comorbidities on stroke functional recovery has yet to be studied in Taiwan. This study evaluated the comorbidities and their impact on functional recovery in stroke patients.

Material and Method

The participants were 105 acute stroke patients with moderate to severe functional disability who were admitted for comprehensive rehabilitation. Participants were 76 people who underwent Post-acute Care program and other 29 participants accepted a regular rehabilitation program within six months after stroke. The effect of each comorbidity on the patients’ post-hospitalization daily living activities was analyzed based on the Charlson Comorbidity Index (CCI).

Abbreviations: B1, Barthel index
Results

The average Barthel Index (BI) scores increased from 41.8 at admission to 75.5 at discharge; the average progress was 33.7 points. The stroke patients in control group had an average BI score of 37.2 at admission and 47.2 at discharge; the average progress was only 10 points. The functional recovery rate of daily living activities in the post-acute care group was equal to [(BI scoring improvement/BI at admission)\times100\%] and was significantly higher than that of the control group (post-acute care: control=1.4\pm1.7/0.4\pm0.6; p=0.015). For each 1 point increase to a patient's CCI score, there was a 0.97 point decrease to the patient's score on the BI after discharge from the hospital (p=0.013). An analysis of 19 comorbidities showed that the order of highest prevalence was diabetes (21%), prior cerebrovascular accident with mild or no residual or transient ischemic attack (17.1%), and diabetes with end-organ damage (14.3%). Analysis of the impact of the various comorbidities on stroke patients' daily living activities indicated that the
The most harmful disease was chronic pulmonary disease, followed by prior history of hemiplegia.

HEALTH SEEKING BEHAVIOURS IN STROKE SURVIVORS IN MADAGASCAR
L. Ahmed¹, J.J. Renaud Rakotonirainy², R. O'Connor³, A. Chamberlain³
¹University of East Anglia, Medicine, Norwich, United Kingdom
²L'Hôpital Joseph Ravoahangy Andrianavalona, Rehabilitation, Antananarivo, Madagascar
³University of Leeds, Rehabilitation Medicine, Leeds, United Kingdom

Introduction/Background

Stroke incidence is increasing in low and middle income countries, thus stroke disability is too. This is at a disproportionate rate to high-income countries. Rehabilitation tackles stroke disability. Rehabilitation services in Madagascar are lacking in information regarding the needs of people with stroke disability. Understanding health-seeking behaviours can help us understand people’s patterns of behaviour and plan services accordingly. This study aimed to understand the health-seeking behaviours of stroke survivors in Madagascar. Through exploring their understanding, service utilisation and motivations in their stroke experience.

Material and Method

This study used a cross-sectional, qualitative design. Thirteen semi-structured interviews were carried out with the use of translators. The study was conducted in the Hopital Joseph Ravoahangy Andrianavalona in Antananarivo, Madagascar. Thematic analysis was used to summarise and synthesise the data.

Results

Participants understanding of stroke and rehabilitation was limited but mainly rooted in a biomedical logic, with high blood pressure being mentioned most frequently. Geography and financial costs were barriers to receiving modern medical care, and made non-medical more favourable. Family support was the main facilitator in accessing any form support. Participants were motivated to seek healthcare for several reasons, specifically to return to employment.

Conclusion

The study’s findings were similar to existing literature in low and middle income countries. Recommendations from the study included researching the benefits of physiotherapy techniques and caregiver strain. Furthermore, to produce a health promotion campaign centred on education and a community based rehabilitation scheme to reduce barriers.

Disclosure statement:
I received a £250 grant towards travel costs from Opt-In, a registered UK charity, which focuses on overseas training and partnerships.
Introduction/Background

Although regular physical activity is vital for cardiovascular health, little is known about how the intensity of physical activity changes over time in community-dwelling people with stroke. The purpose of this study was to examine the changes in low and moderate intensity walking activity in community-dwelling people with stroke between discharge from a rehabilitation setting and in a 6 month follow-up.

Material and Method

Twenty-three stroke patients participated in this study. Step counts were measured using Step activity monitor for three days at baseline and at 6 months after baseline measurement. Step data were collected every 5 seconds. The start of a walking bout was defined as 3 strides within a 15 second interval and the end of a walking bout was defined as a 10 second interval in which no strides occurred. Based on the cadence in the walking bout, each bout was categorized as low intensity (<80 steps per min) or moderate intensity (≥80 steps per min). The number of steps per day, number of bouts per day, walking time per day, and percentage of time spent walking per day were calculated at each intensity. The differences in each variable were compared by paired t-test.

Results

Participants’ characteristics are shown in Table 1. The baseline assessment was conducted 133.6 ± 5.6 days post stroke (11.7 ± 5.6 days post discharge). The follow-up measurements were conducted 182.5 ± 9.1 days from baseline assessment. Table 2. shows a comparison of the walking activity by intensity at baseline and follow-up. There were no significant differences between baseline and follow-up in all variables.
Conclusion

Not only low intensity walking activity but also moderate intensity walking activity did not change over 6 months. Establishing exercise habits at discharge might promote long-term physical activity in community-dwelling people with stroke.

ANALYSIS OF FACTORS PREDICTING DISCHARGE TO HOME AFTER HOSPITAL TREATMENT OF CEREBRAL INFARCTION WITH TROUSSEAU’S SYNDROME AT OUR STROKE CENTER

H. Maruyama, H. Takahashi, S. Makita, M. Takao

1Saitama Medical University International Medical Center, Department of Neurology and Cerebrovascular Medicine, Hidaka, Japan
2Saitama Medical University International Medical Center, Department of Rehabilitation, Hidaka, Japan

Introduction/Background

Trousseau’s syndrome (cancer-associated thrombosis) is known as one of the causes of cerebral infarction. However, there are few reports of the rehabilitation and outcome in ischemic stroke patients with this syndrome. The purpose of this study was to investigate predictors of the discharge to home from acute care hospital in those patients.

Material and Method

Fifty three ischemic stroke patients with Trousseau’s syndrome were received the treatment and rehabilitation in our stroke center between April 2007 and July 2017. Subjects were 36 patients among them, excluding 17 patients who died during hospitalization. As the discharge destinations, 15 patients were discharged to home (home group), 21 patients were transferred to the other hospital (transfer group). To investigate predictors of the discharge to home, we compared in each groups for following items; age, sex, MRI findings, state of the cancer (primary lesion, histological type, presence of distant metastasis), treatment contents of ischemic stroke, NIHSS and modified Rankin scale (mRS) on admission, the number of days until the start of rehabilitation after the hospital, Brunnstrom stage and FIM scores on starting rehabilitation.

Results

The mRS on admission in the home group was significantly lower than that in the transfer group. The score of total FIM, motor FIM, and 4 subscale items of FIM (eating, dressing lower body, bladder management, comprehension) in the home group were significantly higher than that in the transfer group on starting rehabilitation. There were no significant differences in other items between two groups.

Conclusion

Patients with Trousseau’s syndrome have poorer prognoses than other cerebral infarction patients. However, they may be able to be discharged home by appropriate rehabilitation. Our results suggest that we must focus their rehabilitation on independence of self-care such as
eating, dressing lower body, bladder management in order to discharge to home from acute care hospital.

EARLY MOBILIZATION IN INTENSIVE CARE FOR SEVERE ACQUIRED BRAIN INJURY PATIENTS: CURRENT PRACTICES AND IMPLEMENTATION BARRIERS IN FRANCE
F. Feuvrier¹, C. Jourdan¹, K. Griffiths², M. Ascher³, F. Pavillard⁴, K. Chalard⁴, P. Bory⁴, F. Pellas⁵, P.F. Perrigault⁴, I. Laffont¹
¹CHRU Lapeyronie, Physical and Rehabilitation Medicine, Montpellier, France
²CHRU La Timone, Public Health, Marseille, France
³CHRU Gui de Chauliac, Physical and Rehabilitation Medicine, Montpellier, France
⁴CHRU Gui de Chauliac, Neurological Intensive Care Unit, Montpellier, France
⁵CHRU Carémeau, Physical and Rehabilitation Medicine, Nîmes, France

Introduction/Background

Early mobilization (EM) in intensive care units is safe, feasible and beneficial for patients; however, little is known about the current practices of early mobilization for patients with brain injury in intensive care units (ICU) in France.

Aim: To evaluate the current mobilization practices and its barriers in ICUs for patients with acquired brain injury.

Material and Method

A cross-sectional survey online was conducted with two questionnaires on early mobilization practices distributed to physicians and physiotherapists working in 130 ICUs across France.

Results

The survey was completed by 31 physiotherapists and 25 physicians in 24 different wards. Rehabilitation specialists were involved with care according to 88% of doctors. EM was most frequently started within 24-48 hours, according to 8 doctors and 15 physiotherapists. The majority of physiotherapists (84%) stated that 75%-100% of patients received positioning and passive range of motion therapy, alongside head of bed elevation (84% PTs). A lower proportion of patients received standing exercises (32% PTs reported 25-30% of patients), walking therapy (48% reported <25% of patients), whilst 77% of PTs reported that no patients received muscular electrostimulation. The most common medical barriers were high intracranial pressure and hemodynamic instability. Two thirds of doctors and over 80% of physiotherapists stated they did not use any pre-established protocol criteria for initiation of EM. Fourteen doctors (56%) did not have a wakening protocol to reduce sedation.

Conclusion

Early mobilization in various forms is being practiced in the ICUs of France. Main results demonstrate a good willingness and enthusiasm amongst physicians and physiotherapists, but a lack of medical support and not enough personnel to attain early mobilization objectives. We
suggest a need to have a standardize protocol to encourage early safe mobilization of neurological patients in intensive care. Further prospective research on safety and outcomes specific to neurological patients is needed.

DISTURBANCES OF SPATIAL REFERENCE FRAME AND POSTURAL ASYMMETRY AFTER A CHRONIC STROKE
K. Jamal¹, S. Leplaideur², C. Rousseau², L. Chochina³, A. Moulinet Raillon⁴, I. Bonan¹
¹University Hospital of Rennes-, Physical and Rehabilitation Medicine Department-, Rennes, France
²University Hospital of Rennes-, Department of Clinical Pharmacology- Clinical Investigation- Center INSERM 1414-, Rennes, France
³CMRRF Kerpape, Neurology Physical and Rehabilitation Medicine Department-, Kerpape, France
⁴Hospital of Saint Vallier, Physical and Rehabilitation Medicine Department, Saint Vallier, France

Introduction/Background

Asymmetrical postural behaviours are frequently observed after a stroke. They are due in part to the sensorimotor deficit, but could also be related to a disorder of the representation of the body in space. The objective was to determine whether the asymmetrical postural behaviours of chronic stroke patients are related to a disruption of the perception of spatial frame.

Material and Method

30 chronic stroke patients (mean age 60.3y±10, mean delay post-stroke 4.78 y±3) 15 patients with right brain damage (RBD) and 15 patients with left brain damage (LBD) and 20 healthy subjects participated in the study. Postural asymmetry was detected by the evaluation of body weight repartition on a force platform (Weight Body Asymmetry) and was related to the Longitudinal Body Axis (LBA) and the Subjective Straight Ahead (SSA) (egocentric space representation) and also to the Subjective Visual Vertical (SVV) (allocentric space representation) by means of a multivariate analysis of variance (MANOVA) which was adjusted with motor function and sensitivity as covariables.

Results

Both patients with RBD (35%+/-8) and LBD (39%+/-4) had a body weight asymmetry and there was still space misperception at this stage of recovery, especially in the RBD group. WBA was related to LBA when considering both patients with RDB and LDB (p=0.03). However, this relation was dependent on the side of the lesion (p=0.0006) with a stronger relation in the RBD group (58.26%). No relation with WBA was found neither with SSA (p=0.58) nor with SVV (p=0.47).

Conclusion
This study pointed out a strong relationship between disturbance in the perception of the longitudinal body axis and postural asymmetry in chronic strokes, and predominantly within the RBD group. Whereas other spatial perturbations did not seem to be involved in this particular postural behaviour.

EXPLORING THE NEEDS OF INFORMAL CAREGIVERS OF STROKE SURVIVORS ACCESSING REHABILITATION SERVICES IN ANTANANARIVO, MADAGASCAR

F.N. Mutlow¹, M.A. Chamberlain², R. O'Connor²

¹University of Leeds, School of Medicine, Leeds, United Kingdom
²University of Leeds, Academic Department of Rehabilitation Medicine, Leeds, United Kingdom

Introduction/Background

In Madagascar, half of those affected by stroke are less than 50 years old and it is the second leading cause of disability in the country. All treatment must be paid for but with 92% of the population living on less than 2€ a day, informal caregivers are essential. Stroke caregiver needs remain poorly understood; this is the first study that aims to explore these needs in Madagascar.

Material and Method

In 2017, a medical student interviewed 15 caregivers of stroke survivors, in the university hospital in Antananarivo, Madagascar. A semi-structured interview guide was used, exploring needs related to understanding of stroke, assistance in Activities of Daily Living (ADL) (using visual cues) and care burden (based on caregiver burden tools). Audio-recorded interviews were dictated verbatim and analysed using thematic analysis.

Results

Caregivers had a good understanding of the definition of stroke but lacked understanding around prevention of recurrence and the extent of possible recovery. Preferred information sources included doctors, physiotherapists, other stroke survivors and their caregivers. Caregivers felt that they had little access to specialized equipment or help to assist in ADL. Care burden was considerable, including impact on own wellbeing and finances. Participants were eager for information regarding stroke care and recovery; this may have influenced how they approached the interviewer, as a potential information source, and therefore not been as critical of the health service.

Conclusion

These findings complement those of other studies in higher income countries. Limitations include that a high-income, well-educated group were interviewed and a translator was used. There were no occupational therapists in Madagascar, which limits the exploration of their potential benefit. This study is the first to explore the needs of caregivers of stroke survivors in Madagascar, which informs future research in the area, particularly in low-income countries.

Impact of Somatosensory Deficits on Functional Independence After First Inpatient Rehabilitation Program Post Stroke

C. Barbeiro¹, J. Fortunato¹, D. Martins², J. Jacinto¹

¹Centro de Medicina de Reabilitação de Alcoitão, Adult neurorehabilitation, Cascais, Portugal
²Hospital São Jose, physical medicine and rehabilitation, Cascais, Portugal

Introduction/Background

It is estimated that somatosensory deficits (SSD) are present in more than half of ischemic strokes. SSD can influence motor outcomes and thereby impair participation in activities of daily living (ADL). Rather few studies have investigated SSD after stroke. Previous studies showed a negative correlation between SSD following stroke, the functional prognosis of rehabilitation. The aim of this study is to illustrate the influence of SSD in functional outcomes as measured by the functional independence measure (FIM).

Material and Method

Prospective observational study, with retrospective analysis of admission and discharge data, after a 1st inpatient rehabilitation program. Four groups were created: A - no SSD, B - only superficial SSD, C - only deep SSD, and D - both types of SSD. Functionality was measured by the FIM, subdivided in ADL, motor outcomes, cognitive outcomes and total outcome. The results were analyzed with ANOVA.

Results

From a total of 119 patients who were discharged in 2014, complete data on SSD were available for 79, of which 57% were women. Mean age was 60.84 years. In 68% of cases the stroke was ischaemic. On average, patient stay was 65.82 days (SD 13.66). At admission, 22 patients had no SSD, 9 patients had changes only in superficial sensitivity, 3 had only deep sensitivity and 45 had both types of SSD. There are significant differences between having no SSD and having both types of SSD, regarding ADL, motor scores and total FIM scores, at admission. At discharge, the differences were statistically significant for: ADL, motor scores, cognitive and total FIM scores, as well as for the change of ADL scores and total FIM scores.

Conclusion

SSD had an impact in the functional outcomes, especially when both SSD were impaired. In agreement with previously published data, SSD after stroke have a negative effect on motor and functional performance.

ISPR8-0734
THE EFFECT OF PARALYTIC ARM PAIN IN THE SHOULDER JOINT ON THE EFFECTIVENESS OF REHABILITATION AFTER STROKE
L. Varzaityte¹, T. Bubnelis¹, J. Krisciokaityte¹
¹Hospital of Lithuanian University of Health Science, Rehabilitation, Kaunas, Lithuania

Introduction/Background
Post-stroke shoulder pain (PSSP) is a common impairment and occurs in approximately one-third of an unselected stroke population. Although PSSP can improve during rehabilitation, studies have shown that it can be a long-lasting or persistent problem. Patients with more severe paralysis of the arm are increasingly likely to develop shoulder pain.

The aim of study was to investigate effectiveness of rehabilitation after stroke in individuals with and without PSSP.

Material and Method
The study consisted of 58 after stroke patients treated in the neurology department of rehabilitation clinic from 2016 October to 2017 September. The patients were divided into two groups PSSP and non-PSSP. The data were collected using questionnaire, interviews, medical records before and after patient rehabilitation. Functional independence was measured by Functional Independence Measure (FIM) scale. Patients emotional health was evaluated by SF-36 questionnaire which was adapted for this study. Pain in the shoulder of paralytic arm was evaluated by pain scale from 0 to 10 when 0 – no pain and 10 – unbearable pain. Statistical analysis was performed with SPSS, p<0.05 was significant.

Results
The analysis of pain influence for rehabilitation after stroke shown, that rehabilitation has statistically significant effect for both groups of patients (p<0.001). FIM has been statistically significant higher in non-PSSP group than in PSSP group (58,86±13,68→93,64±17,41 vs 52,90±13,49→ 79,80±10,72). Non-PSSP group has shown statistically significant improvement for physical health than PSSP group (34,32±7,24 →54,67±17,95 vs 28,70±7,74→29,85±14,29). Study has shown that there was no statistically significant difference in improvement of emotional health between groups (p<0.001).

Conclusion
Rehabilitation has statistically significant effect for patients after stroke with and without PSSP.
The analysis has shown statistically significant effect for functional independence and physical health for non-PSSP patients group.

THE ASSOCIATION BETWEEN SERUM BDNF LEVELS WITH POST-STROKE DEPRESSION AND ANXIETY: A COHORT STUDY

Z. Han¹, Y. Wang², L. Qi³, Y. Zhou¹, Q. Ye¹, J. Wang¹, X. Luo⁴, J. Wong⁵, Y. Wang⁶, Q. Wang⁷

¹Shanghai Seventh Hospital, Neurology and Rehabilitation, Shanghai, China
²Nan’ao People’s Hospital of Shenzhen- The First Affiliated Hospital- Shenzhen University, Rehabilitation Medicine, Shenzhen, China
³Shanghai Yueyang Hospital/Shanghai University of TCM, rehabilitation, Shanghai, China
⁴Kerry Rehabilitation Medicine Research Institute, Shenzhen Sanming Group, Shenzhen, China
⁵MGH institute of Health Professions, School of Nursing, Boston, USA
⁶ShenZhen Second People’s Hospital, Rehabilitation, Shenzhen, China
⁷Spaulding Rehabilitation Hospital- the teaching affiliate of Harvard Medical School, Stroke Biological Recovery Laboratory, Boston, USA

Introduction/Background

Brain-derived neurotrophic factor (BDNF) has been shown to play an important role in psychological function. The aim of this study was to investigate the association of serum BDNF and development of poststroke depression and anxiety.

Material and Method

Serum concentration of BDNF was measured in stroke patients on admission to inpatient rehabilitation hospital. Depression and anxiety mood was diagnosed using (Diagnostic and Statistical Manual of Mental Disorders 4th edition[DSM-IV] criteria). The functional outcome was measured using Functional Independent measures(FIM).

Results

Poststroke depression was diagnosed in 61 (37.7%) patients and anxiety was diagnosed in 40 (24.7%) patients. Except for marital status (P=0.030) and BDNF levels (P=0.033), none of the predictor variables showed statistically significant differences among the three groups. Low level of BDNF was significantly associated with poststroke depression (P=0.009, OR:0.93, 95%CI:0.88-0.98), but not with PSA (P=0.469, OR:0.98, 95%CI:0.93-1.04). In addition, BDNF level was associated FIM motor scores at discharge in this cohort patients (P=0.027,OR:0.036-0.602,B:0.319).

Conclusion

Low BDNF levels were found to be important risk factors for PSD but not for PSA.

No conflict of interest
Paralysis from a stroke can lead to learned non-use of the affected upper limb (Wolf et al., 1989, Taub et al., 2002). In the present study, we tried to turn severe hemiplegic upper limbs into assisting hands using occupational therapy and the NESS H200® hand rehabilitation system. This is an interim report of approximately 12 weeks of that case series study.

Material and Method

Target: Three subjects (one male and two females) with severe hemiplegic upper limbs were enrolled. They had an average age of 60.7 years (SD ± 4.5), and their paralysis had lasted for an average of 50.3 months (SD ± 32.2). Initial motor function evaluations showed on average 34.7 (SD ± 8.3) on Fugl-Meyer Assessment (FMA), with an average amount of use (AOU) of motor activity log (MAL) of 0.2 (SD ± 0.3) and an average quality of movement (QOM) of 0.2 (SD ± 0.3).

Explanation and agreement: All subjects provided informed consent forms to participate in the study. An ethical review of the study is being conducted (Yamato University Ethics Review No. 33), and no conflict of interest exists.

Methods: The rehabilitation programme involved occupational therapy matching life goals practiced more than once a week and independent training using NESS H200® at least three times a week.

Results

At the end of the interim evaluation, FMA average was 44.0 (SD ± 13.5), MAL AOU average was 0.6 (SD ± 0.4) and MAL QOM average was 0.6 (SD ± 0.3).
Our results show the rehabilitation programme encouraged patients to use their paralysed upper limbs. This suggests that the programme can improve the use of supporting technologies for chronic severely paralysed upper limbs.

THE TEMPORAL EVOLUTION AND THE RELATIONSHIPS OF THE DEEP TENDON REFLEX, SPASTICITY, MOTOR RECOVERY AND PERFORMANCE OF DAILY FUNCTION IN CHINESE PATIENTS WITH STROKE

Y. Lin¹, C.Y. Huang², T.S. Kuan¹, K.L. Chen³

¹College of Medicine- National Cheng Kung University, Department of Physical Medicine and Rehabilitation, Tainan, Taiwan R.O.C.
²College of Medicine- I-Shou University, Department of Occupational Therapy, Kaohsiung County, Taiwan R.O.C.
³College of Medicine- National Cheng Kung University, School of Occupational Therapy, Tainan, Taiwan R.O.C.

Introduction/Background

Stroke is a common etiology causing disability. But the epidemiologic data regarding the neurological features and recovery after stroke is scarce. The aim of this study was to reveal the temporal evolution and the relationships of the deep tendon reflex (DTR), spasticity, motor recovery and performance of daily function in Chinese patients with stroke.

Material and Method

Consecutive patients with confirmed diagnosis of stroke were recruited from a medical center in Taiwan from 2014 May to 2014 Nov. We assessed patients’ DTR, spasticity with Modified Ashworth Scale, motor recovery with Brunnstrom stage, and performance of daily function with Barthel Index at 5 time points: onset within week 1, 2, 3, 4 and 24 weeks after stroke.

Results

A sample of 34 patients with stroke was recruited in the study. All of these patients received at least 4 times of assessments after onset, and 57.5% (n=19) of patients had followed up at 24 weeks after onset. DTR increased over the weak limbs occurred one week before or at the same time as emergence of spasticity. Different patterns of spasticity were noted in patients with hemiplegia and hemiparesis. Spasticity emerged in most hemiplegic patients at 2 weeks after stroke. In Brunnstrom stages, small portions of patients improved within 4 weeks, and larger portions of patients recovered from 4 to 24 weeks. As for performance of daily function, improvement was shown in all patients at 24 weeks.

Conclusion

This study showed the temporal evolution and the relationships of the DTR, spasticity, motor recovery and performance of daily function in Chinese patients within 6 months after stroke. It may help physicians provide some early and relevant interventions to facilitate the brain plasticity and recovery.

EARLY REHABILITATION BY ELECTRICAL MUSCLE STIMULATION IN INTENSIVE CARE UNIT FOR PATIENTS WITH INTRACRANIAL HYPERTENSION
K. Saigusa¹, M. Kuroha¹, N. Tamada¹, K. Sawada¹, T. Kino¹, A. Mizuno²
¹Tokyo Bay Urayasu Ichikawa Medical Center, Department of Neurosurgery, Urayasu, Japan
²Tokyo Bay Urayasu Ichikawa Medical Center, Department of Rehabilitation, Urayasu, Japan

Introduction/Background

Japanese guidelines for the management of stroke recommend early rehabilitation for the prevention of disuse syndrome. However, there are few reports concerning the safety and risk of the rehabilitation for the patients with intracranial hypertension. The patients with intracranial hypertension can’t attempt to move their extremities, and ROM exercise without contraction of muscle tends to the main early rehabilitation in intensive care unit. It leads to disuse muscle atrophy. Therefore we introduced Belt electrode-Skeletal muscle Electrical Stimulation (B-SES) as electrical muscle stimulation, which causes a muscle contraction, for patients with intracranial hypertension, and we assessed the safety of B-SES for the patients with intracranial hypertension.

Material and Method

We use AUTO Tens PRO Rehabili Unit made by HOMER ION LABORATORY CO., LTD, and selected LEG DISUSE MODE, and the duration of the stimulation is 20 minutes. Physical therapist determined the output level by palpation of triceps surae muscle of each patient, and the effective intensity was usually between 20V and 50V.

Results

Case1: A 43-year-old woman underwent coil embolization of the ruptured right VA-PICA aneurysm. We monitored her intracranial pressure (ICP) by external drainage, and her ICP kept 14.5-18.0 cmH2O during B-SES.
Case2: A 66-year-old man underwent external drainage for the acute hydrocephalus due to left thalamic hemorrhage and intra ventricular hemorrhage. His ICP kept under 17.5-19.0 cmH2O during B-SES.
Case3: A 49-year-old man with right acute subdural hematoma underwent hematoma removal with decompressive craniotomy. His ICP kept 8-11 mmHg during B-SES.
Case4: A 41-year-old woman presented with subarachnoid hemorrhage underwent neckclipping of the left middle cerebral artery aneurysm. Her ICP kept 8-11 mmHg during B-SES.

Conclusion
Electrical muscle stimulation with B-SES, as can be seen from these four cases, never worsened intracranial hypertension. Therefore, early rehabilitation with B-SES is safety and worth introducing for the patient with intracranial hypertension in intensive care unit.

THE RELATIONSHIP BETWEEN HAND SPASTICITY AND UPPER EXTREMITY MOTOR PERFORMANCE IN STROKE PATIENTS

W.L. Hsu¹, W.H. Chang¹, C.T. Feng¹, I.S. Tzeng²
¹Taipei Tzu Chi Hospital- Buddhist Tzu Chi Medical Foundation, Department of Rehabilitation Medicine, New Taipei City, Taiwan R.O.C.
²Taipei Tzu Chi Hospital- Buddhist Tzu Chi Medical Foundation, Department of Research, New Taipei City, Taiwan R.O.C.

Introduction/Background

Background and aims. Spasticity is one of the upper motor neuron syndrome that can result in reduced function. The spasticity in the upper extremity has been found to be associated with reduced arm function. The aim of this study was to realize the impact of spasticity on upper extremity motor performance.

Material and Method

Methods. Thirty-six patients with first-ever stroke (mean age 56.3±14.3 years, mean onset time 0.43±0.33 years) were included and accepted two outcome measures. Spasticity was assessed on the Modified Ashworth Scale (MAS) and defined “no spasticity–mild spasticity” as MAS≤1 in any of the examined upper limb joints, “moderate–severe spasticity” as MAS>1; upper extremity motor performance was evaluated with Fugl-Meyer Assessment of the upper extremity (FMA-UE) and defined “mild upper extremity impairment” as FMA-UE=51~66, “moderate upper extremity impairment” as FMA-UE=21~50, and “severe upper extremity impairment” as FMA-UE=0~20.

Results

Results. Multinomial logistic regression with penalize likelihood revealed that patients with “moderate–severe spasticity” were more likely to have “severe upper extremity impairment” than “mild upper extremity impairment” (odds ratio[OR]=16.07; 95% confidence interval [CI], 1.56-376.18; P=.018); patients with “no spasticity–mild spasticity” were easily to have “moderate upper extremity impairment” than “severe upper extremity impairment” (OR=6.45; 95% CI, 7.57-81.33; P=.089).

Conclusion

Conclusions. Hand spasticity in stroke patients could have some impact on their upper extremity motor performance, it is necessary to consider the marked spasticity problem in stroke patients and make great efforts to deal with it.

⁴Istanbul Physical Medicine and Rehabilitation Training Hospital, PMR Clinics, Istanbul, Turkey

Introduction/Background

There is no consensus concerning the relationship between spasticity and gait speed, balance and quality of life in stroke patients. Therefore, the aim of the present study was to investigate spasticity and its association with balance, gait speed and quality of life.

Material and Method

Fifty one stroke patients who can cooperate and have 3 or higher grade in Functional Ambulation Scale were included in the study. Gastrocnemius muscle spasticity by the Modified Ashworth Scale (MAS), gait speed by the 10-meter Comfortable and Fast Gait Speed Tests (CGST-FGST), balance by the Single Leg Stance Test (SLST) and Timed Up and Go Test (TUG), and quality of life by the Stroke Specific Quality of Life Scale (SS-QOL) were assessed. P ≤0.05 was considered statistically significant.

Results

The MAS score of gastrocnemius muscle was 2.87±1.03. Significant correlations were found between the MAS score and the 10-meter FGST (r=0.31; p=0.002), and the affected limb SLST (r=-0.43; p=0.004). There were no statistically significant correlations between the MAS score and 10-meter CGST(r=0.23; p=0.129), TUG (r=0.28; p=0.071), and SS-QOL(r=-0.02; p=0.852).

Conclusion

The results indicated that the gastrocnemius muscle spasticity may contribute to impairment of fast gait speed and static balance in stroke patients. To increase ambulatory skills of stroke patients, gastrocnemius muscle spasticity should be aimed in rehabilitation programme.

EFFECTS OF AEROBIC TRAINING ON MEMORY, ATTENTION, AND WORKING MEMORY IN PATIENTS WITH STROKE OR TRAUMATIC BRAIN INJURY

Introduction/Background

Patients with stroke or traumatic brain injury (TBI) often suffer from impaired memory, attention deficits and fatigue. As a consequence they meet difficulties in planning and organising daily activities, participation in family and social life, and returning to work. Experimental studies show that aerobic training promotes plastic changes in the brain with development of new vasculature, changes in neurotransmitter levels and increase in Brain-Derived Neurotrophic Factor (BDNF). Furthermore, aerobic training improves cognition in the general population. The effects of such training on cognition after stroke and TBI are, however, not well known. Our study therefore aims to investigate if aerobic training improves memory, attention and working memory in patients with stroke or TBI.

Material and Method

This randomized (1:1) controlled study includes 12 stroke or TBI patients with cognitive impairments, 18-60 years old. All patients participate in a rehabilitation program with a multidisciplinary team including training of physical, psychological, cognitive and communicative abilities, all according to the patient’s deficits and individual goals. The intervention consists of 30 min aerobic training on a stationary ergometer bicycle at an intensity of 60-80% of estimated maximum heart rate, 3-4 times a week for 8 weeks. The control group participates in the regular rehabilitation program. Participants are tested before and after the program, and at a 3-month follow-up. The cognitive tests include assessment of verbal, visual, working memory and attention. Physical endurance is tested with Åstrand’s sub maximal endurance test. CNS effects are studied with functional magnetic resonance imaging (fMRI) using blood oxygenation level dependent technique (BOLD).

Results

The study is ongoing. Eight patients have so far completed the program. Preliminary results will be presented.
Conclusion

The study is ongoing. Eight patients have so far completed the program. Preliminary results will be presented.

¹CHU Pontchaillou, Physical and Rehabilitation Medecine, Rennes, France

Introduction/Background

“The lack of formalised monitoring following in the year after the stroke establishes a reduction of likelihood in the course of patient care.” (DGOS instruction 2015) A third of the patients return home at best with only a single follow-up neurological consultation. Within the context of this reality establishing the deficits is therefore held up, favouring a negative socio-professional impact. To overcome this, a Multidisciplinary Consultation Post-stroke program (CM post-stroke) was developed at the University Hospital of Rennes in 2016 (French National Stroke Program 2010-2014). The particular characteristic of our consultation was to single out those patients who neither went through the neuro-vascular pathway.

Material and Method

Patients hospitalized in the CHU for stroke were extracted from the Program For Medicalization of Information Systems. Patients who neither went through the neuro-vascular pathway were selected. Neurologist and PMR physician checked together the medical history of these patients. During a telephone interview, our occupational therapist coordinator filled out a questionnaire orienting the choice of professionals met at the consultation. The consultation was personalized and centred on the patient specific needs. A feedback was made for the treating physician permitting for continuous follow up of the patient.

Results

On the basis of a sample of patients selected over 6 months, we study 80 patient files, they were interviewed and 40 consultations were organized (including 25 with 2 professionals and 15 with more 2 professionals), 9 were directed towards the physical medicine and rehabilitation department, 30 to a liberal professional and only 1 did not have any change in his Physical Medecine and Rehabilitation care. This tends to show interest in the follow-up of these patients.

Conclusion

The CM post stroke appears as a link filling a deep in the follow-up of the care of post-stroke patients and a transversal work between neurologic and PMR departments.

PREDICTION OF THE OXYGEN COST OF WALKING IN HEMIPARETIC STROKE PATIENTS.

M. Compagnat¹, J.C. Daviet¹, S. Mandigout², D. Chaparro², J.Y. Salle¹

¹CHU LIMOGES - HAVAE University of Limoges, Mpr, Limoges, France
²CHU LIMOGES - HAVAE University of Limoges, Staps, Limoges, France

Introduction/Background

The energy cost of walking is a marker of metabolic solicitation and allows energy quantification of walking. It is strongly correlated to the patient’s walking speed with post-stroke sequelae. We wanted to develop a model for predicting the energy cost of walking to create of walking distance recommendations aimed at achieving recommended energy expenditure levels to ensure health benefits (>1000kcal/week during physical activities).

Objective: To verify the close relationship between spontaneous walking speed (S_free) and energy cost of walking at S_free (Cw_free) in subjects with post-stroke hemiparetic patients sequelea and to test the validity of a prediction model to estimate Cw_free based on S_free.

Material and Method

Twenty-six mild to moderately disabled chronic participants with stroke aged 65 yrs (+/- 15.7yrs) walked at S_free using mobility aids if necessary, for 6 minutes. The Cw_free was measured at a stabilized metabolic rate by indirect calorimetry using the Metamax3B device. The relationship between S_free and Cw_free was analyzed using the correlation coefficient, coefficient of determination. The Cw_free prediction model was developed from a regression equation and then tested on a new population with the same inclusion/exclusion criteria (n=29).

Results

S_free and Cw_free had a correlation coefficient of -0.94 and a R² of 0.97 enabling to formulate a regression equation and develop the Cw_free prediction model based on S_free. The prediction model tests yielded accurate results with a mean bias of -0.02mL.kg⁻¹.m⁻¹ – MD%=4%. The limits of agreement were -0.31; 0.26 mL.kg⁻¹.m⁻¹ MD%=30.9% of the mean measured Cw_free.

Conclusion

Cw_free can be estimated precisely by a simple measurement of the walking speed. In this way, we can easily define the distance the subject must travel according to his Cw to reach the recommended energy expenditure targets. It is a great help for the practitioner for recommendations in the field of physical activity after stroke.

EFFICACY OF BOTULINUM TOXIN A FOR THE TREATMENT OF HEMIPARESIS IN ADULTS WITH CHRONIC UPPER LIMB SPASTICITY

S. Ghroubi¹, S. Alila¹, H. Ben Ayed², M.H. Elleuch¹
¹Habib Bourguiba hospital, Service Médecine physique- rééducation et réadaptation fonctionnelle. EPS Habib Bourguiba- Sfax, Tunisia
²Unité de recherche de l'évaluation des pathologies de l'appareil locomoteur UR12ES18, sfax, Tunisia

Introduction/Background

Our aim was to assess the effectiveness of botulinum toxin-A (BoNT-A) injection in chronic spastic upper limb after stroke or traumatic brain injury and to identify baseline factors that predict favorable functional outcome of this treatment.

Material and Method

We conducted a prospective study including 45 adults with hemiparesis after stroke or traumatic brain injury and who received an injection of botulinum toxin type A (Dysport®).

We evaluated muscle tone using Modified Ashworth Scale (MAS). Functional disability was assessed using Modified Frenchay Scale (MFS), Nine Hole Peg Test (NHPT) and Barthel Index (BI). Quality of life (QoL) was assessed using the 36-Item Short Form Health Survey (SF-36). The achievement of treatment goal was assessed by the Goal Attainment Scaling (GAS).

Binary logistic regression test was performed to identify the independent factors predicting a favorable or unfavorable functional outcome of BoNT treatment.

Results

MFS showed improvement at 1 month after injection with a median change from baseline of 8 (range: 1-16; p<.001). The change from baseline ranged from 0 to 5 points for NHPT at 1 month after injection (p<.001). Improvements in Barthel Index was observed at 3 months with a median change from baseline of 5 points (range 0-15; p<.001). The mean change from baseline of SF-36 score was 4.77 ± 3.39 (p<.001). The mean change from baseline of GAS T-score was 25.36 ± 8.46 (95% CI 22.82 to 27.90; p <.001).
In multivariate analysis, previous injection of BoNT-A was an independent predictive factor of favorable functional outcome of this treatment \( (p=.03, \ OR=0.3) \) while neglect was independent predictive factor of treatment failure \( (p=.04, \ OR=1.876) \).

**Conclusion**

Our study showed that treatment of chronic upper limb spasticity in patients with hemiparesis after a stroke or TBI with BoNT-A injections is a useful method of treatment for improving spasticity, passive and active function and quality of life.

CLINICAL APPLICABILITY OF ROBOT-ASSISTED GAIT TRAINING SYSTEM IN ACUTE STROKE PATIENTS

L.W. Chou¹, A. Chien², F.C. Chang³, N.H. Meng³, P.Y. Yang³
¹Asia University Hospital, Department of Rehabilitation, Taichung, Taiwan R.O.C.
²China Medical University, Department of Physical Therapy, Taichung, Taiwan R.O.C.
³China Medical University Hospital, Department of Physical Medicine and Rehabilitation, Taichung, Taiwan R.O.C.

Introduction/Background

In Taiwan, stroke is not only the second-highest cause of mortality, more alarmingly, it is also the number one cause of long-term disability and institutionalization. Given the resource-demanding nature of post-stroke rehabilitation, the utilization of robotic assisted gait rehabilitation has been well advocated in recent years. However, despite some promising preliminary results, there is still a lack of empirical and concrete evidence supporting its inclusion as part of the routine clinical rehabilitation. Furthermore, much of the research to date have focused on the very expensive commercially available suspension robotic systems and very limited research has been conducted for the more cost-effective end-effector robotic system. Therefore, it is the aim of the current study to investigate and document the clinical applicability of a new end-effector robotic gait training system in acute stroke rehabilitation.

Material and Method

All participants received daily hospital routine rehabilitation but the experimental group received an additional 30 minutes of supervised robotic assisted gait rehabilitation training daily for a total of 15 sessions over a 3-week period. Berg balance scale, Brunnstrom stage, European Quality of Life questionnaire, Pittsburgh Sleep Quality Index as well as the Taiwanese Depression Questionnaire were assessed prior- and after every five training sessions for all patients.

Results

Forty-four acute stroke patients were recruited for the current study. Through block allocation, the experimental group included thirty patients (18 males and 12 females, mean age: 60.7±14.0 years) whilst fourteen patients (3 male and 11 females, mean age: 57.9±12.8 years) were allocated to the control group.

Conclusion

Our study results indicated that patients undertook additional end-effector robotic gait training on top of the routine hospital rehabilitation demonstrated identifiable and significantly greater improvement in Berg balance scale, gait related lower limb capacity, as well as the Taiwanese Depression Questionnaire.

⁴Botucatu Medical School, Neurology, Botucatu, Brazil
⁵Univ.Federal do Triângulo Mineiro, Physical Therapy, Uberaba, Brazil

Introduction/Background
Unilateral spatial neglect (USN) is characterized by the inability to respond to people or objects that are presented contralaterally to the lesioned side of the brain and can decrease a patient’s ability to return to work, and thus, has socioeconomic impacts on a community’s public health status. The aim of this study was to evaluate the relationship between the degree of USN with quality of life in stroke patients.

Material and Method
This is a cross-sectional study including stroke patients of both genders, aged 18 to 85 years, in the acute, subacute, or chronic phase of the USN clinical diagnosis setting. Patients with prior stroke, pre-existing dementia, global aphasia, previous visual disturbances and other associated neurological diseases were excluded. The USN was evaluated by Behavioral Inattention Test (BIT), and quality of life through the European Quality of Life (EuroQoL), and analyzed: mobility, health care, usual activities, pain or discomfort, and anxiety or depression. An association among USN and EuroQoL items was analyzed using the Spearman correlation and was considered statistically significant if p <0.05.

Results
Fifteen individuals were evaluated, 75% of whom men, with a mean age of 64 years, a BIT variation from 53 to 124 (mean = 96.63) and a EuroQoL score from 5 to 11 (mean = 7.75). The correlations are shown in Table 1. The association between a higher BIT value indicated a higher score in the personal care items (r = 0.95, p <0.001), usual activity (r = 0.81, p <0.001); pain or discomfort (r = 0.75, p <0.001); anxiety and depression (r = 0.95, p <0.001), and total score.
EuroQoL score ($r = 0.74$, $p < 0.001$). There was no association with mobility ($r = 0.51$, $p > 0.05$).

Table 1. Correlation of the items of the quality of life scale with the degree of unilateral spatial neglect measured by the BIT

FACTORS NECESSARY FOR INDEPENDENT WALKING IN PATIENTS WITH PUTAMINAL HEMORRHAGE

S. Maeshima¹, S. Okamoto¹, H. Okazaki¹, H. Maeda¹, I. Fuse¹, H. Hori¹, K. Yagihashi¹, Y. Senju¹, A. Kiso¹, S. Sonoda¹
¹Fujita Health University, School of Medicine, Tsu, Japan

Introduction/Background

Putaminal haemorrhage accounts for 30%–40% of all cerebral haemorrhages and is responsible for various neurological symptoms, including motor paralysis. Its prognosis varies according to factors such as age, neurological severity, site and size of hematoma, complications, and choice of treatment. We examined the factors related to independent walking in patients with putaminal hemorrhage who were admitted to a rehabilitation hospital.

Material and Method

We evaluated 264 patients with thalamic hemorrhage (172 men and 92 women; age range, 29–88 years) who were admitted to our rehabilitation hospital. The mean duration from symptom onset to rehabilitation hospital admission was 29.9 ± 14.8 days, and the mean rehabilitation hospital stay was 74.6 ± 35.3 days. Patients’ neurological and cognitive functions were examined with the National Institutes of Health Stroke Scale (NIHSS) and Mini-Mental State Examination (MMSE), respectively. The relationship between patients' scores on these scales and their walking ability at discharge from the rehabilitation hospital was analyzed. Additionally, a decision-tree analysis was used to create a model for predicting independent walking upon referral to the rehabilitation hospital.

Results

Among the patients, 143 could walk independently and 121 could not. The two patient groups were significantly different in terms of age, duration from symptom onset to rehabilitation hospital admission, hematoma type, hematoma volume, neurological symptoms, and cognitive function. The decision-tree analysis revealed that the patient’s age, motor leg of the NIHSS, MMSE score, and hematoma volume were factors that could predict independent walking.

Conclusion

In patients with putaminal hemorrhage, the neurological symptoms, and neuroimaging factors at onset are useful for predicting independent walking.

CONSTRANT-INDUCED MOVEMENT THERAPY PRACTICE IN MADAGASCAR: RESULTS AND FEASIBILITY

H.F.S. Rumaux Pagathe⁴, C. Raheliarinivo⁴, B.R. Randriamanantena¹, L.R.H. Rajaonalisaona⁴, V.A. Soazandry⁴, G.D. Solofomalala²
¹Hospital University of Anosiala Ambohidratrimo, Physical Medicine and Rehabilitation, Ambohidratrimo, Madagascar
²Hospital University of Anosiala Ambohidratrimo, Trauma and Orthopedic, Ambohidratrimo, Madagascar

Introduction/Background

After stroke, patients do not recover all the function of the upper extremity. Constraint-induced movement therapy (CIMT) is one of the new methods used to improve recovery of the functionality of the upper extremity after stroke. The aim of this study is to describe the results obtained after the first use of CIMT in Madagascar and to discuss its feasibility.

Material and Method

An interventional trial in 3 patients with hemiparesis following a stroke lasting more than 6 months is realized. CIMT was administered 60 minutes 3 times per week for 5 weeks. The motor function of the hand was evaluated by the wolf motor function test (WMFT) and the research arm test (ARAT) action. The motor activity log (MAL) was used to assess the activity of daily living (ADL). The evaluation was carried out before and after treatment by the same evaluator.

Results

An improvement in the motor function of the 3 patients was observed. The ADL's achievement increased in the 3 patients after the intervention.

Conclusion

The CIMT is feasible in Madagascar for patients with chronic phase of stroke. This feasibility is the outcome of the acceptance of the technique by the therapists as well as by the patients.

PREDICTABILITY OF WALKING ABILITY AND OF BED-CHAIR TRANSFERS AT THE END OF INPATIENT REHABILITATION PERIOD OF ELDERLY PATIENTS AFTER STROKE
Y. Levin-Yosef, M. Katz-Leurer
1Beit Rivka, Physical Therapy, Petach Tikva, Israel
2Tel Aviv University,
Physical Therapy Department- School of Health Professions- Sackler Faculty of Medicine, Tel-Aviv, Israel

Introduction/Background

Walking independently is one of the most important goals for patients post-stroke and their families. Standing up is an essential function for walking independently. The aim was to explore initial physical evaluation component that predict patients’ ability to stand up and walk independently at discharge from rehabilitation, in older adults’ post-stroke.

Material and Method

131 elderly patients post-stroke addmited to rehabilitation. Excluded were patients with debilitating orthopedic conditions, or previous progressive neurological diseases. Initial evaluation, within 3-7 days of admission, included motor function, lower extremities muscle strength, sitting balance and cognitive assessment. Patients had a follow up one week before discharge, the follow up included two parts of the Functional Independence Measure (FIM) test: walking and chair-bed transition.

Results

Initial pelvic lift, bed rolling performance were significantly correlate (r>0.7, p<0.01) to patients’ outcome measures at discharge and had highly significant prediction value. A combination of the inadequate static balance upon admission, dependence of rolling to the affected side and lack of independence at pre-stroke daily function predicted 85% chance that a patient will be dependent in walking at discharge. Inadequate static balance upon admission, major/full dependence of rolling to the less affected side and major/full dependence in pelvic lift at bed predicted 89% chance that patient will be dependent in chair-bed transfer at discharge.

Conclusion

Initial physiotherapists evaluation to evaluate patient current functional status have a significant predictive value for patients’ outcome at discharge in terms of standing and walking. These clinical predictors can help in setting treatment goals, educating families, and coordinating expectations.

EFFICACY OF REPETITIVE TRANSCRANIAL MAGNETIC STIMULATION IN POST-STROKE COGNITIVE RESTORATION
S.H. Wu¹, P.Y. Tsai¹
¹Taipei Veterans General Hospital, Physical Medicine and Rehabilitation, Taipei, Taiwan R.O.C.

Introduction/Background

Repetitive transcranial magnetic stimulation (rTMS) is a noninvasive tool to modulate cortical plasticity and brain processes in healthy or diseased brain. While previous studies of rTMS provide potential benefit on neurocognitive impairment in post-stroke patients, the evidence and optimal protocol were still undetermined. In our current pilot study, we sought to investigate whether the positive cognitive effects of intermittent theta-burst stimulation (iTBS) over the left dorsolateral prefrontal cortex can be observed in post-stroke patient and compare the efficacy to the sham-controlled group in double-blinded parallel study design.

Material and Method

Patients with cognitive impairment followed by left hemispheric stroke were randomly allocated to 2 groups: (1) iTBS (group A, n = 15), and (2) sham stimulation (group B, n = 16). Both two groups underwent 10 consecutive sessions with 10-minute conditioning period. The repeatable battery for the assessment of neuropsychological status (RBANS) was assessed at baseline and after completion of the 10-session treatment.

Results

No related adverse events were observed during the study. After the intervention, iTBS group manifested significant improvement than the sham stimulation in the RBANS total score and in the subtests of language, immediate memory and attention.

Conclusion

iTBS protocol showed a benefit on cognition amongst chronic stroke patients in cognitive recovery and also a good safety profile. Further research on the mechanism of effect, the optimal parameters, and the effects of concurrent cognitive training or medications are warranted for clinical applications.

IMMEDIATE EFFECTS OF REPETITIVE PERIPHERAL MAGNETIC STIMULATION (RPMS) TO THE HEMIPLEGIC LOWER LIMB MUSCLES IN GAIT PARAMETER

T. Veerapong¹
¹Faculty of Medicine- Ramathibodi hospital- Mahidol University, Rehabilitation medicine, bangkok, Thailand

Introduction/Background

To study the immediate effects of rPMS to paretic leg muscles on gait parameters in hemiparesis patients.

Study design: a descriptive study

Setting: Physical Medicine and Rehabilitation, Faculty of Medicine, Ramathibodi hospital, Mahidol University

Material and Method

rPMS at the frequency of 20Hz was applied to Gastrocnemius and Tibialis Anterior muscles in pulses of 4 seconds stimulation alternate with 4 seconds rest for 8 minutes. The parameters were assessed by computer dynography(CDG) before and immediately after stimulation

Results

There were 10 male and 3 female participants their average age is 54.38 years. This study demonstrate improved gait velocity (m/s) (p<0.01), single support time(%) (p<0.01) and spasticity by tardieu scale (p < 0.01) immediately after stimulation

Conclusion

rPMS at paretic lower limb muscles could have immediate positive effects on gait velocity and %single support time and spasticity.

THE ROLE OF MEDICAL REHABILITATION OF THE UPPER LIMB IN POST-STROKE HEMIPARESIS

B. Simona

University of Oradea, Faculty of Medicine, oradea, Romania

Introduction/Background

The study aims to illustrate the progress of patients following the numerous methods of recovery and determining the factors that most influence the medical recovery of the hemiplegic upper limb.

Material and Method

This study attempts to demonstrate that the evaluation and treatment of the recovery of neurological manifestations, metabolic and biomechanical alterations in the hemipleg patient's upper limb represents a necessity in the clinical and therapeutic approach of the patient with stroke. The clinical trial was performed on a group of 25 post-stroke hemiparesis patients. The purpose of applying kinetotherapy to patients in the study was to improve the functional state of the upper limb from the motor point of view. Also in therapy, the peace lovers were trained to use orthoses and certain devices.

Results

13 patients affected the upper right after the stroke, and 7 affected the left upper limb. It is noted that all 20 patients were right-handed. The upper limb has numerous complications in patients with post-stroke hemiplegia. The painful shoulder was present in 18 patients, then atrophy, present in 16 patients, dyskinesia in 15 patients. Glenohumeral joint luxation, an important complication, was seen in 8 patients. Veno-lymphatic stasis syndrome and retractile capsulitis were present in 5 patients.

Conclusion

An improvement in motor performance of the upper limb has been observed in a shorter time compared to classical intensive physiotherapy, thus accelerating the recovery trend. Sensor-motor formation with robotic devices improves functional results of the upper extremity and motor results of the shoulder and elbow but does not improve the functional and motor results of the wrist and hand.

OBSERVATIONAL STUDY ON MEDICAL REHABILITATION IN STROKE

B. Simona

University of Oradea, Faculty of Medicine, Oradea, Romania

Introduction/Background

Stroke leaves behind a multitude of disabilities that affect a patient's hemicorp. The superior member is greatly affected by this event. According to the World Health Organization, stroke is defined as a rapid development of clinical signs of focal or global cerebral dysfunction, with a 24-hour, longer-lasting symptom that may even lead to the patient's death. Brain strokes can be of two kinds: ischemic, accounting for approximately 80% of total cerebral and hemorrhagic accidents, which is approximately 20%. In Romania, there are on average 200 cases per 100,000 inhabitants. The situation becomes alarming because acute stroke accounts for about 17% of all deaths.

Material and Method

We performed a prospective observational study on a group of 20 patients (n = 20) with the rehabilitative diagnosis of hemiplegia / hemiparesis after stroke.

The evaluation methods used in the patients included in the study consisted of a wide range of tests and assessment scales, i.e., questionnaires (Scala Albert, Scale Rankin, Modified Ashworth Scale (MAS), Barthel Scale, Minimal Examination of Mental Status The Folstein Mini Mental State Examination Questionnaire (MMSE), Beck Questionnaire).

Results

The results of the study confirm the data from the literature that states that men have a higher predisposition to stroke than women. Subjects who have suffered an ischemic stroke are 75% of those who have had a hemorrhagic stroke and 25%, respectively. The ratio obtained from the lesion type analysis gives values very close to those in the literature, where we find an 80% ischemic attack ratio, compared to 20% hemorrhagic attack.

Conclusion

13 patients affected the cerebral hemisphere and the cerebral hemisphere was affected in only 7 patients. A large number of patients experienced cardiac disease, an important risk factor for cerebral vascular events.

Keywords

ASPECTS THAT INFLUENCE POST-STROKE MEDICAL REHABILITATION
B. Simona¹
¹University of Oradea, Faculty of Medicine, oradea, Romania

Introduction/Background

Stroke is a cerebrovascular disease, which sums up all the diseases caused by primary or secondary damage to one or more cerebral (intra- or extracranial) cerebral arteries caused by ischemic, haemorrhagic or mixed lesions of the cerebral parenchyma. In Romania cerebrovascular diseases are placed on the third place as a cause of mortality and morbidity, registering 168,2 cases per 100,000 inhabitants, the first and the second are attributed to cardiovascular diseases and neoplasms.

Material and Method

The progression of an acute stroke for survivors can be directed to complete healing, but in most cases it comes through important sequelae that require a long-lasting and persistent medical recovery.

Results

Medical rehabilitation therapy is needed in the early stages for 70-80% of survivors, and in the long run about 50% maintain the need to maintain or improve their abilities and possibilities. Given that the incidence of this disease is on the rise, physiotherapeutists who are responsible for rehabilitating these patients from the motor point of view should be aware of the factors that influence the medical recovery of post-stroke patients in order to address them as accurately as possible.

Conclusion

Old age has an impact on post-stroke recovery in that the recovery of tissues is slow and not always total, favoring the permanence of acquired sequelae due to disease and increasing recovery time for lost functions. The location of the lesion and the extent of the affected region are two important aspects that need to be taken into account when it comes to factors influencing recovery. Cerebral injury located in the cerebellum may significantly reduce the results of medical recovery, as these patients will need assistance and lifestyle assistance.

CONSEQUENCES OF STROKE ON WALKING PARAMETERS OF HEMIPARETIC PATIENTS IN THE BORGOU (BENIN).

O.D.O. Aze1, A. Thierry2, A. Barnabé3, O. Etienne1, D. Xavier1, G. Pascal1
1University of Saint Etienne, Faculté de Médecine, SAINT ETIENNE cedex 2, France
2Université de Parakou Bénin, Faculté de Médecine Parakou, Parakou, Benin
3Université d'Abomey-Calavi, Injeps, Porto-Novo, Benin

Introduction/Background

After stroke, performing activities of daily living depends on the recovery of motor function. Few data exist on post stroke stroke recovery in the African context. The aim was to determine the relationship between the average stroke age in Benin and its motor impact on walking speed and endurance in hemiplegic patients.

Material and Method

This cross-sectional pilot study was conducted at the Departmental University Hospital of Borgou with 22 hemiplegics (63.8% men). The Functional Independence, the Barthel Index and the Modified Rankins Scale were used for functional evaluations. 10-meter walking speed and 6-minute endurance tests for motor performance.

Results

The subjects (54.9 ± 5.5 years) had an average speed of 0.82 ± 0.2 m.s⁻¹ (16.7 ± 2.6 steps) and an average endurance of 329.3 ± 67, 1 m. Comparison of the 2 statistically different subgroups in age (p <0.05): G1: <55 years (51 ± 3.2 years) and G2 ≥ 55 years (58.8 ± 4.4 years) did not revealed no significant difference for walking speed, step count, and endurance (p> 0.05).

Conclusion

The young age of the participants does not influence the performance of walking speed, number of steps and endurance for the two subgroups of patients aged between 43 and 68 years. A multi-center study will help to better understand the role of the young age of Beninese hemiplegics, the functional characteristics and motor recovery after stroke.

CHANGES IN AMBULATION SPEED IN CHRONIC SPASTIC PARESIS, USING A GUIDED SELF-REHABILITATION CONTRACT INCLUDING SMALL GROUP WORKSHOPS
C. Gault-Colas1, E. Hutin1, M. Pradines1, C. Hennegrave1, S. Joudoux2, T. Santiago1, J.M. Gracies1
1Groupe Hospitalier Henri Mondor, Val de Marne, Créteil, France
2Centre Hospitalier de Villeneuve Saint Georges, Val de Marne, Villeneuve Saint Georges, France

Introduction/Background

In spastic paresis, Guided Self-rehabilitation Contracts (GSC) involve daily self-rehabilitation exercises, prescribed by the therapist for the explicit purpose of active functional improvement.1

Small Group Workshops (SGW) are offered to groups of 4-6 patients to improve GSC performance, particularly the technical quality and intensity of the self-rehabilitation work. This study measured changes in 10-meter ambulation speed2 associated with the practice of a GSC that included three SGW, in patients with chronic spastic paresis.

Material and Method

Retrospective study of 16 patients (n=16) with chronic stroke-induced hemiparesis (10F, 16M, age 57±10, delay post lesion 38±2 months) who consecutively benefited from GSC including 3 lower limb SGWs. Outcome measures included comfortable and maximum ambulation speed with shoes and barefoot on the 10-meter ambulation test. We distinguished two groups of 8 patients depending on the mean interval between SGWs: Group 1, (n=8, 5F) SWG interval < 4.5 months; Group 2 (n=8, 4F) SWG interval > 4.5 months).

Results

Mean duration of GSC participation was 13±7 months.

Ambulation speed improved in the four conditions, with greatest improvement at maximum speed barefoot, from 0.66 to 0.87 m/s (+32%, p<0.001, t-test). Other changes included maximum speed with shoes (0.69 to 0.89 m/s, + 28%, p= 0.003), comfortable speed barefoot (0.52 to 0.65m/s, +24%, p= 0.013) and with shoes (0.54 to 0.68 m/s, + 21%, p=0.007).

Comparing ambulation speed changes in the two groups, greater improvements were seen in Group 1 for maximum speed with shoes (0.65 to 0.82m/s, +26%, p=0.018) and barefoot (0.62 to 0.82m/s, +25%, p=0.022).

Conclusion
In chronic hemiparesis, the combined practice of GSC and GGW may improve ambulation, with potentially greater benefit when the small group workshops are attended with inter-workshop-intervals < 4.5 months.
A large scale, prospective study is required.

DIFFERENCES IN ALTERATION OF MOTOR NETWORK BETWEEN SUPRA- AND INFRA-TENTORIAL ISCHEMIC STROKE PATIENTS
J. Lee1, A. Lee1, S.Y. Lee1, H. Kim1, W.H. Chang1, Y.H. Kim1
1Samsung Medical Center, Physical and Rehabilitation Medicine, Seoul, Republic of Korea

Introduction/Background
In recent stroke studies, connectivity-based approaches have been used to investigate recovery-related indicators. However, most of previous studies were performed in heterogenous patients with different lesion locations or different types of stroke. In addition, there is not enough investigation on recovery-related network analysis in the infratentorial stroke (ITS) which may show different network dynamics from the supratentorial stroke (STS). In this study, we investigated the differences in alteration of motor network between STS and ITS in ischemic stroke patients.

Material and Method
Forty first-onset ischemic stroke patients were recruited within 2 weeks after stroke onset. Patients were divided into STS and ITS groups according to their lesion location. All patients underwent resting-state fMRI scans twice (2 weeks and 3 months after onset). Twenty-four healthy subjects participated as an age-matched control group. To investigate the altered connectivity during recovery and to compare between groups, various analysis methods such as interhemispheric connectivity, network symmetry, and graph theoretical analysis which were already established in the previous studies were used.

Results
In STS group, interhemispheric connectivity was significantly decreased and network symmetry was disrupted compared to control group at 2 weeks post stroke, while the ITS group did not show differences compared to control group at this time point. During recovery, global efficiency and global reorganization including increasing network efficiency and randomization showed only in the STS group. In contrast, the ITS group demonstrated significantly increased interhemispheric connectivity during recovery. There was an interactive relationship between cortico-cerebellar connectivity and interhemispheric connectivity in the ITS group.

Conclusion
Alterations of recovery-related motor network connectivity in ITS patients were very different from that of STS patients. These results may be caused by differences of damage of diverse motor-related pathways by stroke lesion. (This work was supported by the National Research Foundation of Korea grant funded by the Korea government (MSIP) (NRF-2017R1A2A1A05000730, NRF-2017R1D1A1B03034109))

No conflict of interest
Stroke is a life-changing event with a dramatic effect on survivors, family members, health services, and socio-economic impact. It is the third most common cause of disability and the 2nd leading cause of death worldwide.

Several factors influence the prognosis of ischemic stroke, and the aim of this study is to understand how the process of neurophysiological recovery develops, framed in the factors of better or worse prognosis in the presentation and evolution of the disease, allowing the Physiatrist Physician a more assertive perception of the functional potential of the patient with ischemic stroke.

Material and Method

A search was made in the Pubmed database of the terms "stroke prognostic factors", "stroke rehabilitation" and "stroke recovery" (limits: publication date - last 10 years, article type - review and clinical research).

Results

There were 8 articles in the limits proposed in the design of this work, however, a further 7 articles were added in the bibliography of those obtained in the research, totaling a total of 15 articles analyzed.

Recovery from stroke depends on an intrinsic or spontaneous recovery and an adaptive or functional recovery. The main mechanisms of recovery are related to local processes and cerebral reorganization. Of the major prognostic factors in stroke, those showing the most impact are clinical neurological severity at presentation, age, stroke extent, location, etiologic mechanism, associated comorbidities, and acute complications.

In Rehabilitation, the factors that may ad initium condition a greater or lesser functional recovery are the paresis of the upper limb (shoulder and hand), paresis of the lower limb and gait, aphasia, dysphagia and sensory alterations.

Conclusion
The intervention of Physical Medicine and Rehabilitation is fundamental in the improvement of functional status in stroke survivors, however, this is conditioned by several intrinsic and extrinsic factors that all the physicians involved in this process should be aware.

EFFICACY OF STROKE REHABILITATION SERVICE IN RAMATHIBODI HOSPITAL
P. Chayaratanasin¹, S. Roongsaiwatana¹, W. Chira-Adisai¹
¹Faculty of Medicine Ramathibodi Hospital, Rehabilitation medicine, Bangkok, Thailand

Introduction/Background

To study the efficacy of rehabilitation service in improving functional independence in stroke patients at Ramathibodi Hospital

Material and Method

Acute stroke patients whom consulted to Rehabilitation Medicine Department from February to May 2016 were recruited. The patients’ demographic data, Barthel Index of activities of daily living (BI), 3 types of impairments (swallowing, communication and cognitive impairments) and type of rehabilitation service (home-based, OPD-based and IPD-based rehabilitation program) were recorded within the first 2 weeks and the next 12 weeks.

Results

Subjects were 77 patients (32 male and 45 female patients). The mean age (standard deviation; S.D.) was 66.3 (13.6) years. After the patients were consulted to Rehabilitation Medicine Department, the mean time (S.D.) to the first rehabilitation evaluation was 8.7 (3.3-31.5) hours and the mean initial BI score (S.D.) was 57.8 (29.0). Fifty-six and twenty-one patients had BI score ≤ 75 and >75, respectively.

For stroke patients with BI score ≤ 75, 39, 11, and 6 patients had home-based, OPD-based and IPD-based rehabilitation program, respectively. The mean BI score change at 12 weeks compared to the baseline (S.D.) were increased 16.1 (16.2), 25.9 (13.0), 39.2 (10.7), respectively.

For stroke patients with BI score between 75-100, 9 and 1 patients were received home-based and IPD-based rehabilitation program, respectively. The BI score at 12 weeks was ≥ 95 and the mean BI score (S.D.) change at 12 weeks was increased 10.0 (4.7).

Conclusion

For stroke patients with BI score ≤ 75, the IPD-based rehabilitation program could significantly increase BI score compared to the home-based program. All stroke patients with the initial BI score > 75 who received either home-based or IPD-based rehabilitation program had BI score ≥ 95 at 12 weeks.

LEUKOARAIOSIS INDUCE DISCREPANCIES BETWEEN NEUROLOGICAL SEVERITY AND ACTIVITIES OF DAILY LIFE IN PATIENTS WITH ISCHEMIC STROKE AT CONVALESCENT REHABILITATION

J. Senda1,2, K. Ito2, T. Kotake2, M. Kanamori2, H. Kishimoto2, M. Katsuno3, G. Sobue3
1Komaki City Hospital, Department of Neurology and Rehabilitation, Komaki, Japan
2Kami-Iida Rehabilitation Hospital, Department of Rehabilitation, Nagoya, Japan
3Nagoya University Graduate School of Medicine, Department of Neurology, Nagoya, Japan

Introduction/Background

There are discrepancies between neurological severity and activities of daily life (ADL) after stroke. We investigated associations between neurological severity and ADL in patients with ischemic stroke at the convalescent rehabilitation stage. We particularly focused on the severity of leukoaraiosis on magnetic resonance imaging (MRI) and various clinical factors.

Material and Method

The participants included 723 patients with ischemic stroke (484 men and 239 women; mean age, 73.2 ± 8.5 years; subtypes, lacunar infarction [n = 54], atherothrombosis [n = 305], artery-to-artery embolism [n = 105], cardiogenic embolism [n = 129], undetermined embolism [n = 93], and uncategorized ischemic stroke [n = 37]) that were transferred from acute care hospitals for inpatient convalescent rehabilitation. Leukoaraiosis was graded according to periventricular hyperintensity (PVH) and deep white matter hyperintensity on MRI. The National Institutes of Health Stroke Scale (NIHSS) was used to measure neurological severity and the Functional Independence Measure (FIM) was used to assess ADL on admission and at discharge.

Results

Multiple regression analysis revealed that total FIM scores were significantly associated with leukoaraiosis as estimated by PVH grade (P = 0.001) and NIHSS score (P < 0.001) both on admission and at discharge for all patients, in addition to clinical factors, such as age, history of heart disease, and bilateral infarction lesions. In contrast, multiple regression analysis of NIHSS
scores revealed no association with PVH.

**Conclusion**

Our study revealed that ADL were associated with the degree of leukoaraiosis as indicated by PVH at the convalescent rehabilitation stage in patients with ischemic stroke. However, neurological severity was not associated with leukoaraiosis, likely because the progression patterns and anatomic backgrounds of PVH affect ADL in patients who have had ischemic stroke.

EFFECTIVENESS OF OCCUPATIONAL THERAPY COUNSELING BASED COGNITIVE BEHAVIORAL THERAPY FOR THE PATIENTS WITH CEREBROVASCULAR ACCIDENT

N. Ohshima

Tokyo Metropolitan University, Faculty of Health Sciences, Tokyo, Japan

Introduction/Background

Therapeutic strategies of occupational therapy for cerebrovascular accident include functional improvement, acquisition of compensatory skills, and increasing awareness of the impairment. However, various difficulties are present in specific and general methods of intervention depending on cerebrovascular accident. Cognitive behavior therapy (CBT) has been widely recognized as an effective intervention for treatment of “patients with depression”. We employed CBT to promote the awareness in patients with cerebrovascular accidents, and achieved a favorable outcome.

Material and Method

Three adult patients (two female, one male) with cerebrovascular accident were included in the study. Their consciousness was clear, but their level of activities of daily living (ADL) was still low. Some interview and sessions by Occupational Therapy counseling (OTC) were performed. Intervention employed the self-monitoring method under the OTC to promote patient’s awareness. On analysis, conversation was analyzed employing process codes, and changes in awareness were continuously evaluated.

Results

The patients was not aware of their accident in the initial OTC, but after intervention by OTC based CBT, they became aware of problems due to the subjects of ADL and came to propose and execute ways to cope with it by themself.

Conclusion

Although the OTC based CBT promotes patient’s awareness of symptoms and the importance of coping, but it may also lead to loss of self-efficacy. However, the patient’s experience was slowly externalized using a self-assessment sheet, and transition to coping behavior was facilitated with less stress. In occupational therapeutic training based OTC, there are few opportunities to help patients to understand their symptoms and reflect on the results of the training to make them aware of the direction of compensation. These results suggest that their awareness by OTC is closely related with the ADL in patients with cerebrovascular diseases.

Introduction/Background

Stroke is common in sub-Saharan Africa, where it is the second leading cause of death and the leading cause of adult motor disability.

The aim of this study was to assess the follow-up and evolution in the rehabilitation of patients who have survived a stroke.

Material and Method

From June 2015 to June 2017, we identified all stroke patients in the neurology department of the Yaoundé General Hospital with a neurovascular and rehabilitation file. And they were followed externally in rehabilitation consultation.

Results

About 200 patients with stroke were assessed. Several severe autonomic disorders are found such as: total inability to walk, talk, swallow, use of the upper limb. This is because patients use their finances for drug treatment exclusively and few have enough resources for an effective rehabilitation program. The lack of a rehabilitation center is a real problem observed in our communities where a total handicap after a stroke has become a norm for the society because many become discouraged after one to two months of rehabilitation due to lack of finances.

Conclusion

Rehabilitation support and education programs for families of stroke patients are in place to improve the quality of life of stroke patients.

\textsuperscript{2}Shonan Keikyu Hospital, Department of Rehabilitation, Fujisawa, Japan
\textsuperscript{3}Keio University, Graduate School of Media and Governance, Fujisawa, Japan

Introduction/Background

Temporal and spatial summation of multimodal inputs enhances neural plasticity. We have developed a virtual reality rehabilitation system which can induce kinesthetic sensation using visual stimulation (KiNvis). This study presents the rehabilitation approach of KiNvis, using transcranial direct current stimulation (tDCS) and neuromuscular electrical stimulation (NMES), for sensory-motor functional improvement after stroke.

Material and Method

The patient, a right-handed man in his 50s, presented with right putamen hemorrhage in the chronic stage, without cognitive impairment. The hemorrhage occurred 2 years before presentation; conventional post-stroke rehabilitation was performed, and the patient underwent repetitive transcranial stimulation therapy for the hemisphere contralateral to the damaged side for 2 weeks, 1 year before participating in this study. The left upper extremity indicated anesthesia and severe motor paralysis.
The figure illustrates the treatment paradigm followed in this study. The hand and elbow movement corresponding to the uninvolved side was recorded before the intervention. The laterally inverted version of the 6-second recorded movie, mirroring the movement to the involved side, was repeatedly projected for 20 minutes. The patient was instructed to imagine the kinesthetic sensation of the finger and wrist extensor muscles during KiNvis. For online dual hemisphere tDCS, the anode was centered over the C4 region, delivering a constant current of 2 mA. The NMES was applied to the extensor digitorum muscle in synchrony with the finger extension movement in the movie. The patient received conventional therapeutic exercises after the convergent approach.

Results

After 10 days of the intervention, all clinical outcomes of motor function for the upper extremity improved, especially the range of motion and reciprocal motor control of the elbow joint, examined using surface electromyogram.

Conclusion

The results demonstrate the feasibility of the mentioned convergent approach for patients with chronic stroke for a future systematic study.

Introduction/Background

Upper extremity (UE) dysfunction is a common problem in patients with stroke. Recently, several neurorehabilitation approaches have been developed to improve the UE motor function (Langphorene P, Lancet Neurol, 2009). However, most approaches target either proximal or distal UE motor function, although interventions targeting both portions are necessary to restore functional UE in actual daily life. Therefore, we conducted stepwise intervention for both shoulder and finger function to improve UE motor function.

Material and Method

Two stroke patients with severe hemiparetic stroke participated in the study. Firstly, we attempted to improve shoulder function using brain machine interface (BMI) technology for 7 days (Fig 1). After the shoulder BMI training, a combination of motor imagery and electrical stimulation (MI+ES) was conducted to improve finger function for 10 days (Fig 2). Motor function of the affected UE was assessed with motor items of the Fugl-Meyer assessment UE motor score (FMA-UE). FMA-UE consists of 4 categories (A: Shoulder/Elbow/Forearm; B: Wrist; C: Hand; D: Coordination) and has a maximum score of 66.
Fig 1. The system of brain machine interface training for proximal upper extremity motor function.

Task: Kinesthetic motor imagery of shoulder flexion
Amount of training: 100 trial per day

- EEG recording
- Detecting motor intention
- Translation to control signal
- Feedback
- Electrical stimulation to deltoid muscle
- Robot action
Results

The FMA-UE score increased remarkably after the stepwise intervention (Patient A: 17→33; Patient B: 11→25). The effect of shoulder BMI training is shown in Fig 3. It became possible for patients to raise their arms above the shoulder position after the shoulder BMI training. Patients’
UE motor function was also further improved by the subsequent MI+ES intervention.

**Conclusion**

The improvement in UE motor function with our stepwise intervention for proximal and distal motor functions greatly exceeded the minimal clinically important difference in the subjects of this study.

Disclosure statement:

This study was supported by “Development of medical devices and systems for advanced medical services” by the Japan Agency for Medical Research and Development (AMED).
Stroke is one of the leading causes of death worldwide. Those who survive suffer with disability affecting their quality of life. Knowledge of stroke risk factors and awareness of stroke symptoms would reduce the incidence of stroke for the first time or recurrent. Also timely management would remain instrumental in reducing morbidity and mortality from stroke. The aim of the study was to examine knowledge of stroke, risk factors and its determinants among stroke survivors.

Material and Method

An ongoing cross sectional study in PMR department. Consenting stroke survivors attending the OPD and satisfying the inclusion criteria were enrolled for the study. Subjects were interviewed through a structured proforma which included questions to assess their knowledge regarding stroke and risk factors.

Results

A total of 100 subjects enrolled for the study. Mean age of subjects was 55.6 ± 6.8 years, M:F ratio was 7:1 & mean duration of stroke was 18.10 ± 12.2 months. Only 12 percent reported to specialized care within the window period. Almost 80% were unable to name a warning sign of stroke. Hypertension(80%), diabetes mellitus(42%), and smoking(23%) were identified as major risk factors. The knowledge of the risk factors was also very low and varies among the subjects depending on age and level of education. Forty three percent could not name a single risk factor. It was also observed that management of risk factors were not appropriate in 55% of stroke survivors despite treatment either due to non adherence to the medication, improper follow up, diet, lifestyle changes and education.

Conclusion

Knowledge about stroke and risk factors were relatively poor. Large gaps in knowledge thereby place patients at high risk for stroke. Our finding highlights the need to develop stroke-education programs for stroke survivors as well for those high risk for stroke.

COMBINING NEUROREHABILITATIVE INTERVENTIONS TARGETED FOR PROXIMAL AND DISTAL MUSCLES BRINGS ABOUT CLINICALLY IMPORTANT IMPROVEMENT OF UPPER EXTREMITY FUNCTION IN PATIENTS WITH SEVERE HEMIPARETIC STROKE

1Keio University School of Medicine, Department of Rehabilitation Medicine, Tokyo, Japan
2Faculty of Science and Technology- Keio University, Department of Biosciences and Informatics, Kanagawa, Japan
3Advanced telecommunications Research Institute international, Department of Brain Robot Interface, Kyoto, Japan

Introduction/Background

About half of the stroke patients with hemiparesis have poor arm function 6 months post-stroke. Although some newly developed rehabilitation approaches have indicated improvement of upper extremity (UE) motor function in patients with chronic stroke, there are few reports demonstrating an improvement effect beyond the minimal clinically important difference (MCID) in patients with severe UE paralysis. This study aimed to investigate the effect of our new therapeutic approach combining several different neurorehabilitative interventions for severe UE paresis.

Material and Method

Seven patients with chronic stroke participated in this study. They had severe UE paralysis and the mean Fugl-Meyer assessment (FMA) score was 14.1 (range; 10 to 19). To improve finger paralysis, they received either the Hybrid Assistive Neuromuscular Dynamic Stimulation (HANDS) therapy for 3 weeks or the combination of motor imagery and electrical stimulation for 10 days. In addition, they received shoulder flexion exercise assisted by a brain-machine interface (BMI) controlled exoskeleton shoulder robot for 7 days. The movement of the robot was triggered by contralesional primary motor cortex EEG activity changes decoded online during motor imagery of shoulder flexion.

Results

The paired t-test showed significant improvement of the FMA score during this series of treatments (post treatment mean FMA ; 24.7, p<0.01). As shown in Figure 1, the mean gain of
the FMA was 10.6, and all patients demonstrated improvement greater than the MCID.

Figure 1. The gain of the FMA between this series of treatments

Conclusion

The selective use of ipsilesional and contralesional pathways depending on the target muscles may indicate a new treatment strategy for severely paralyzed patients.

GASTROESOPHAGEAL REFLUX DURING NASOGASTRIC TUBE FEEDING VERSUS OROESOPHAGEAL TUBE FEEDING IN STROKE PATIENTS: A 24HOUR ESOPHAGEAL PH-MONITORING
K.D. Park¹, J.W. Lee²
¹Gachon university Gil medical center, Rehabilitation medicine, Incheon, Republic of Korea
²Yonsei University College of Medicine- Gangnam Severance Hospital, Family Medicine, Seoul, Republic of Korea

Introduction/Background

Patients who are diagnosed to dysphagia after stroke may receive tube feeding such as percutaneous endoscopic gastrostomy (PEG), nasogastric tube or oroesophageal (OE) tube. Although the most common complication for stroke patients is known to be aspiration pneumonia, the physiology of gastroesophageal reflux (GER) associated with tube feeding has not been fully assessed. OE tube feeding and nasogastric tube feeding are non-invasive tube feeding methods both, but the tube can be inserted intermittently using OE tube to avoid continuous esophageal reflux.

Material and Method

The goal of this study was to examine, by 24-hour esophageal pH monitoring, whether GER is related to feeding method, nasogastric tube versus OE tube. 7 stroke patients were examined 24-hour esophageal pH monitoring during nasogastric tube feeding and OE tube feeding, sequentially. The parameters were collected of total acid exposure time, the mean esophageal pH, total reflux episode and deMeester composite score.

Results

Total reflux episode improved only in OE tube feeding, statistically. (P < 0.05) There were no significant differences between the two groups for total acid exposure time, the mean esophageal pH and deMeester composite score.

Conclusion

OE tube can be a possible substitute for nasogastric tube in patients with dysphagia suffering from gastroesophageal reflux disease. And OE tube feeding may be used to facilitate recovery of swallowing function without aggravated reflux disease associated with tube feeding.

RELATIONSHIP BETWEEN GRAVITY LOAD AND SYNERGIC MUSCLE ACTIVITIES IN PATIENTS WITH HEMIPARETIC STROKE

M. Ogura¹, M. Kawakami², J. Furukawa², K. Okuyama¹, T. Noda², T. Teramae², J. Morimoto², M. Liu¹
¹Keio University, Department of Rehabilitation Medicine, Tokyo, Japan
²Advanced telecommunications Research Institute International, Department of Brain Robot Interface, Kyoto, Japan

Introduction/Background

Synergic movement is specific pathology of patients with stroke hemiplegia, and inhibition of synergic is one of the important factors in the functional recovery. However, muscle activation patterns are complex and individualized. Also, it has been reported that synergic movement is promoted by gravity (Beer 2004). However, it is no clear about change of patterns when gravity load for paretic extremity change. In this study, the aims are 1) comparison of muscle activation patterns between healthy volunteers and patients with hemiplegia, and 2) investigation about relationship between gravity load and synergic muscle activities.

Material and Method

Three healthy volunteers and five patients with chronic stroke (Fugl-Meyer assessment test: 23.4±4.8) were participated. They wore exoskeleton robot by pneumatic artificial muscle and performed voluntary movement of shoulder flexion (Figure 1). Electromyogram (EMG) of anterior deltoid (AD), posterior deltoid (PD), trapezius (TR), and biceps brachialis (BB) were measured when participants elevated their shoulder with four types of assistance by the robot. Assist rate for gravity is 0%, 25%, 50%, and 75% respectively. Each EMG signal was integrated
Results

In one of stroke patients, AD activity was higher than the other muscle, this pattern was similar to that of healthy volunteers. In two patients, TR activity was highest. In the others, relative values of four muscles were same approximately (Figure 2). Also, in all patients, BB activity...
tended to decrease as assist rate increased.

![Figure 2. relative values for each of the four muscle in assist 0%](image)

**Conclusion**

The results of this study showed that synergic patterns were classified into three patterns; AD dominant, TR dominant, co-contraction of several muscles. Furthermore, synergic pattern changed by changing the influence of gravity.

COMBINED SPATIAL GAME AND PARTIAL LENS OCCLUSION TRAINING FOR STROKE PATIENT WITH SPATIAL NEGLIGENCE, CASE REPORTS
A. Oh1
1Amagasaki Chuo Hospital, department of rehabilitation, Ashiya, Japan

Introduction/Background

One discharged patient of severe spatial neglect continues morning walk after discharge by himself. He discovered morning walk makes him easier to move and act all day. According to that, pay special attention wildly with body move seems to have meaning for spatial neglect patients. There are two style approaches of rehabilitation for spatial neglect. One is the top-down approach which is trying to expand the viewpoint by which attention is possible into an affected side gradually is generally performed by a rehabilitation program to spatial neglect. The other the bottom-up approach to which attention of the view of the affected side include visual field is promoted overall is also necessary as attention and practice. There is also a report surplus attention on the non-affected side is kind of clinical condition of spatial neglect.

So to release surplus attention have a key. We programmed partial lens occlusion and special game for rehabilitation program.

Material and Method

A 65 years old man with right putamen bleeding has severe left hemiparesis and spatial neglect and high-level brain dysfunction. It was admitted hemianopia pattern by a static view check using Humphrey visual field analyzer. From the 50th disease day spatial recognition game to hit the presented paper by hand and part time partial lens occlusion was started added to conventional top-down approach training.

Results

The walking distance by the walking practice developed double from the next day of visual practice. Such as involving serious case's shoulder hand syndrome, though a difficult element as high-level brain dysfunction, it was possible to do walking practice and movement acquisition practice.

Conclusion

Combined spatial game and partial lens occlusion training for stroke patient with spatial neglect is bottom-up strategy program for spatial neglect. There are spontaneous recovery but there is possibility of effectiveness.

³Health Science University, Department of Physical Therapy, Fujikawaguchikomachi, Japan
⁴Kitasato University, Graduate School of Medical Sciences, Sagamihara, Japan

Introduction/Background

Rate of force development (RFD) reflects instantaneous muscle activity. Previous studies reported that quadriceps RFD in post-stroke patients is lower not only on the affected side but also on the unaffected side compared to healthy adults. However, it remains unclear whether RFD on the unaffected side improves during the subacute phase after stroke. This study aimed to examine RFD changes on the unaffected side between the first and second months after stroke onset.

Material and Method

Sixteen post-stroke patients (age, 64±11 years) and 20 age-matched healthy adults (age, 67±8 years) participated in this study. Maximum voluntary contraction (MVC) strength and quadriceps RFD were measured with a hand-held dynamometer, and surface electromyogram (EMG) was recorded from the vastus lateralis muscle. MVC, RFD, and EMG on the unaffected side were assessed twice during the first and second months after stroke onset. MVC was calculated as peak torque divided by weight. RFD was calculated as the average slope of the time-torque curve in 50 ms after the start of contraction. Root mean square (rms) EMG of RFD was also obtained in 50 ms after the start of contraction. Differences in peak torque and RFD between post-stroke patients and healthy adults, and differences in peak torque, RFD, and rmsEMG of RFD between the first and second months after stroke onset were assessed in post-stroke patients.

Results

Only RFDs in post-stroke patients were significantly lower compared to healthy adults at the two time points assessed (all, p<0.05). Peak torque, RFD, and rmsEMG of RFD in post-stroke patients showed no significant changes between the two time points.

Conclusion

Quadriceps RFD in post-stroke patients showed no changes with time, and was lower on the unaffected side compared to healthy adults. These results suggest that traditional rehabilitation for one month may be insufficient to improve leg extensor RFD.

Introduction/Background

The ability to walk independently without wheelchair assistance around a hospital ward or facility, i.e., practical ambulation, is not taken into account when assessing ambulation status of patients. To our knowledge, no study has adequately examined indicators of practical ambulation in stroke patients living in facilities. This study aimed to identify factors associated with practical ambulation in a facility setting based on prospective observational data from recovering stroke patients.

Material and Method

Ninety-four stroke patients (mean age, 67.9 years) who received inpatient rehabilitation services at the Okinawa Rehabilitation Hospital from January 2011 to November 2016 were enrolled in this observational study. Exclusion criteria were dementia, orthopedic disease, or requiring assistance to walk 10m. In addition to clinical characteristics, lower limb motor function on affected and unaffected sides (Stroke Impairment Assessment Set and leg strength, respectively) and comfortable gait speed (CGS) in a 10m-walk test were examined at the time when 10m-walking was acquired without assistance. Ambulation status was continuously assessed for up to 6 months after stroke onset. Cox proportional hazards regression was used to assess the contribution of clinical characteristics, lower limb motor function and CGS to practical ambulation ability, and receiver operating characteristic (ROC) curve analysis was performed to assess the diagnostic accuracy of these indicators.

Results

A total of 72 stroke patients acquired practical ambulation during the study period. Only CGS was associated with practical ambulation, and the hazard ratio of acquiring practical ambulation per 1m/min increase in CGS was 1.03 (95% confidence interval (CI), 1.02-1.08; P<0.001). ROC curve analysis revealed the optimal cut-off point and diagnostic accuracy to be 19.9m/min and 0.903, respectively (area under curve, 0.923; 95% CI, 0.814-0.970).

Conclusion
These findings suggest that gait speed is a strong predictor of practical ambulation ability in a facility setting for recovering stroke patients.

Introduction/Background

The aim of this study was to investigate the correlations between the modified Rankin Scale (mRS) grades and Korean versions of the MBI (K-MBI) scores in assessing the residual functional status of stroke survivors.

Material and Method

The Korean versions of the MBI and mRS scales were administered to 5,759 ischemic stroke patients at 3 months after onset of stroke. The sensitivity and specificity were calculated at all possible K-MBI score cutoffs for each mRS grade in order to obtain the optimally corresponding K-MBI scores and mRS grades. Receiver operator characteristic (ROC) curves and the area under the curve (AUC) was calculated.

Results

The K-MBI cutoff points with the highest sum of sensitivity and specificity were 100 (sensitivity 0.940; specificity 0.612), 98 (sensitivity 0.904; specificity 0.838), 94 (sensitivity 0.885; specificity 0.937), 78 (sensitivity 0.946; specificity, 0.973), and 55 (sensitivity 937; specificity 0.986) for
Conclusion

The K-MBI cutoff score ranges for representing mRS grades were variable. mRS grades 0, 1, and 2 had narrow K-MBI score ranges, while mRS grades 3, 4, and 5 showed broad K-MBI score ranges. mRS grade seemed to sensitively differentiate mild residual disability of stroke survivors, whereas K-MBI can provide more specific information of the functional status of stroke survivors with moderate to severe residual impairment. ACUTE CEREBRAL CONNECTIVITY MODULATION AND EARLY RECOVERY AFTER ISCHEMIC STROKE
I. Murru¹, S. Masiero¹, M. Ermani¹, M. Tonellato¹, L. Gallo¹, E. Formaggio¹,², A. Del Felice¹
¹University of Padova, Department of Neuroscience-SNPRSS, Padova, Italy
²San Camillo Hospital IRCCS, Department of Neurophysiology, Venice, Italy

Introduction/Background

Stroke induces massive changes in cerebral function in the acute phase, which are gradually modulated over time. Identification of early neurophysiological chances provides insight into recovery processes and opportunities for rehabilitation. This study aims to identify post-stroke acute reorganization patterns of cerebral activity during rest and passive movements of lower limbs (LL) by means of event related desynchronization/synchronization (ERD/ERS) and functional connectivity.

Material and Method

EEG of 5 participants (4M, 1F; age: 67 ± 12 years) was recorded within the 48 hours after an ischemic stroke (T0) and after 5 days (T1). Cortical topography of ERD/ERS and task-related coherence in alpha1, alpha2 and beta bands were computed during passive movements. Resting state relative powers in the same frequency ranges were calculated. Clinical and behavioral data were collected.

Results

Altered coherence patterns during LL movements, as identified in healthy controls (Formaggio et al., 2017), was evident during the acute phase coupled with hypostenia and altered function (Motricity Index) of the affected, and to a lesser extent, unaffected limb. At T1, coherence patterns recovered in parallel with LL function. ERD/ERS showed a disorganized distribution immediately after the event, but reorganized, with a more physiological pattern over the healthy rather than unhealthy hemisphere, after 5 days, which was paralleled by a functional recovery.

Conclusion

Functional connectivity and oscillatory rhythms after a stroke show a precise time-course, with different patterns over the affected and unaffected hemisphere. Identification of these modulation will provide neurotherapeutic targets to promote early recovery of function.

EFFECT OF INITIAL COGNITIVE STATUS ON THE ADL OUTCOME STRATIFIED BY INITIAL ADL IN STROKE PATIENTS
S. Okamoto¹, S. Sonoda¹, K. Yagihashi¹, S. Maeshima¹, H. Okazaki¹, H. Maeda¹, I. Fuse¹, H. Hori¹, Y. Senju¹, A. Kiso¹, Y. Okuyama¹, M. Watanabe¹
¹Fujita Health University Nanakuri Memorial Hospital, Department of Rehabilitation, Tsu, Japan

Introduction/Background

Many inhibitory factors affect the outcome in stroke patients. However, few studies have focused on the differences in the degree of the cognitive effect in improvement in the activities of daily living (ADL) according to the ADL level on admission. The aims of this study were to assess to what extent cognitive function influences ADL improvement in stroke patients and what type of cognitive function has an effect on ADL.

Material and Method

Participants were 2650 hemiplegic patients with a first stroke who were discharged from our comprehensive rehabilitation wards (Kaifukuki rehabilitation wards) between September 2004 and March 2017 (1581 men and 1069 women; mean age 65.9 years). The motor subscores of the Functional Independence Measure (FIM-M) on admission and at discharge were measured and gain (or loss) during the stay of our hospital was calculated. Patients were stratified by the cognitive subscore, communication items, and social cognition items on the FIM and the average FIM-M gain was calculated using all subscores on the FIM-M on admission in each of the stratified groups.

Results

The FIM-M gain tended to be smaller in patients with higher FIM-M on admission. Greater FIM-M gains were observed in patients with higher admission cognitive status, especially in the patients with FIM-M scores on admission of 30 or more. This difference was most clearly seen when we examined the social cognition items in the stratification.

Conclusion

Cognitive function at admission affects the ADL outcome of stroke patients. Since the ability to remember is probably a critical factor in motor learning, social cognition items on the FIM would be suitable to use to stratify patients.

THE OUTCOME AFTER ENDOVASCULAR MECHANICAL THROMBECTOMY FOR PATIENT WITH ACUTE CEREBRAL ISCHEMIA

M. Kurosaki1, H. Arii1, T. Kanaya1, Y. Ibe1, T. Inoue1, M. Tazawa1, N. Wada1
1Gunma University Graduate School of Medicine, Rehabilitation Medicine, Maebashi, Japan

Introduction/Background

We examined the outcome of cases after endovascular mechanical thrombectomy (EMT).

Material and Method

Patients who underwent EMT in our stroke care unit (SCU) between April 2014 and September 2017 participated in the study. Glasgow Outcome Scale (GOS) scores were used to evaluate the outcome at the time of discharge. The data were collected retrospectively from medical record.

Results

The participants included 52 patients with acute cerebral ischemia who were treated by EMT. The occlusion arteries were 18 for internal carotid artery, 26 for middle cerebral arteries, 7 for vertebral arteries and 1 for posterior cerebral artery. Thirty-eight cases (73.1%) had good recanalization rate defined thrombolysis in cerebral infarction (TICI) grade \( \geq 2b \). Intracranial hemorrhage followed as a complication after treatment in 14 patients (26.9%). Eighteen patients (34.6%) had atrial fibrillation. Four patients could not undergo rehabilitation program because of disease severity. Twenty-five cases had favorable outcomes (GOS 4-5) and 23 cases had severe disability (GOS 2-3) at the time of discharge. After leaving hospital, 24 cases admitted to rehabilitation ward, 13 cases were back home, 7 cases returned to former hospital, 3 cases admitted to other hospital, 1 cases entered to nursing home and 4 died. The score of Functional Independence Measure (FIM) improved in 17 cases at the discharge of rehabilitation ward.

Conclusion

We investigated the outcome of patient with acute cerebral ischemia treated by EMT for acute cerebral ischemia. About half of patients had favorable outcome after completed their rehabilitation program.

GAIT DISORDERS IN SUB-ACUTE STROKE: META-ANALYSIS AND CASE SERIES
T. Sader1, O. Godefroy2, M. Hyra1, M. Diouf3, P.L. Doutrellot1, C. Duchossoy1, S. Tasseel-Ponche4
1CHU Amiens-Picardie, Department of Physical Medicine and Rehabilitation, Amiens, France
2CHU Amiens-Picardie, Department of Neurology and Laboratory of Functional Neurosciences EA 4559- SFR CAP-Santé, Amiens, France
3CHU Amiens-Picardie, Department of Biostatistics, Amiens, France
4CHU Amiens-Picardie, Department of Physical Medicine and Rehabilitation and Laboratory of Functional Neurosciences EA 4559- SFR CAP-Santé, Amiens, France

Introduction/Background

Gait disorders are one of the first complaints after a stroke. No specific classification of these gait disorders has been proposed in the literature. Furthermore, few epidemiological data are available, including speed and walking abilities in acute and sub-acute stages.

Objectives: To determine the walking speed and prevalence of acute and subacute gait disorders after stroke. To propose a classification of gait disorders, and analyze the link between motor and cognitive impairments, walking abilities and patient outcomes.

Material and Method

A meta-analysis was performed, selecting hospital based-studies reporting walking speed after a first stroke. Then, we evaluated the walking abilities of patients in a Neurovascular unit. The severity of the stroke was evaluated using the National Institute of Health Stroke Scale (NIHSS), cognitive functions with the MMSE (Mini-Mental State Examination), autonomy using Rkm (Modified Rankin Scale), and gait autonomy with the FAC (Functional Ambulation Categories). In addition, a classification of gait disorders was established for the study.

Results

Prevalence of gait disorders in acute and sub-acute stroke was 63.6%, with an average walking speed of 0.34 m/s. Walking abilities depends on initial stroke severity, location of ischemic stroke, and patient’s outcome (p=0001). Walking speed was associated with cognitive functions (p=0.01), as well as walking abilities (p=0.001).

Conclusion

Gait disorders are frequent in acute and subacute post-stroke stages, with a decrease in walking speed >70%. Walking abilities depends on the initial severity of the stroke, and are predictive of patients’ outcome. In addition, walking and cognitive functions seem to be linked
after stroke, demonstrating cognitive-motor interference. Eventually, the classification proposed in this study will allow a better management of post-stroke gait disorders and rehabilitation.

Joint Contracture of Stroke Patients after Onset 1 Month and Above at Centre of Rehabilitation Medicine and 103 Hospital, 2017

B. Phoumindr

University of Health Sciences, Department of Rehabilitation Medicine, Vientiane, Lao PDR

Introduction/Background

Stroke is the 3rd cause of death among patients in Laos, every year there are 300 - 500 new cases. The highest complication is spasticity.

Material and Method

Describe joint Contracture of Stroke Patients after onset 1 month and above

Results

There were 105 stroke patients enrolled in this study, average age was 55.8 years old, 42.9% aged 60 and 33.2% above 65, male was 71.4%, married 82.9%, no profession 55.2%, educational level at high school was 46.7%, monthly income below 2,000,000 kip was 52.4%, underlying disease was high blood pressure 68.9%, onset from 1-3 months was 52.4% and 36.6% from 3-5 months and average 4.2 months, ischemic stroke was 78.1%, 93.3% was first episode, Lt. Hemiplegia was 53.3%, associated symptom were dysarthria 36.8% and aspiration 68.1%, Lt side neglect was 34.2%, The average time of treatment was 4.6 months. Activity Daily Living performed partial independent 55.3%, ambulation performed with walker 53.7% and one pointed cane 21.9%, spasticity was first complication which interfered joint movement and gait pattern, ankle contracture was 61.4% male was higher than female and both gender had wrist stiffness 25.2%, ankle contracture was found after onset 2 months. Muscle atrophy was found in quadriceps after onset 6 months.

Conclusion

105 stroke patients aged 55.8 years old, ischemic stroke, Lt. Hemiplegia, onset time was 4.2 months, treatment time was 4.6 months. Activity Daily Living was partial independent. Ambulation were with walker. Spasticity was first complication, ankle contracture was found higher in male, wrist stiffness was found in both gender.

BACKWARD WALKING PERFORMANCE WITH AND WITHOUT ADDITIONAL VISUAL INFORMATION IN STROKE PATIENTS
P.Y. Lee¹, S.I. Lin¹, P.Y.M. Lee¹, C.H. Chen²
¹National Cheng Kung University, Department of Physical Therapy, Tainan, Taiwan R.O.C.
²National Cheng Kung University, Department of Neurology, Tainan, Taiwan R.O.C.

Introduction/Background

Backwards walking has been used as training in stroke patients since lacking of visual information in the heading direction could increase postural demands. However, whether such lacking of visual information would affect gait performance is unclear. The study aimed to investigate backwards walking performance with and without additional visual information in stroke patients.

Material and Method

Fourteen stroke patients (59.5±10.1 years) and healthy elderly controls (67.9±8.0 years) were recruited and instructed to walk backwards under two visual conditions: (i) normal vision (NBW), and (ii) looking at a mirror placing at the end of the walkway (MBW). SIMI MOTION® system (SIMI Reality Motion Systems GmbH, Germany) was used to obtain kinematic data during walking. Gait parameters, including step length, step width, gait phases, and velocity, were then calculated. MANOVA was used to compare the gait performance under the two visual conditions between the two groups. Significance level was set at p<0.05.

Results

Two different backwards walking patterns were observed: toe contact, and then heel off or toe off pattern. Stroke patients who walked with toe off pattern showed significant shorter step length and slower velocity than with heel off pattern, whereas no significant difference was found between the two patterns in controls. In heel off pattern, stroke patients walked with significantly wider step than controls. No visual condition difference was found in heel off pattern. In toe off pattern, stroke patients demonstrated significantly wider step, shorter swing phase, and slower velocity than controls. Stroke patients walked with significantly shorter step length than controls in NBW, whereas no group difference was found in MBW.

Conclusion

Walk backwards with toe off pattern might be a more cautious gait pattern than with heel off pattern in stroke patients. Providing visual information in the heading direction could reassure the patients to walk with better performance.

EEG PREDICTS UPPER LIMB MOTOR IMPROVEMENT AFTER ROBOTIC REHABILITATION IN CHRONIC STROKE PATIENTS

F. Bertolucci¹, G. Lamola¹, C. Fanciullacci³, F. Artoni², A. Panarese², S. Micera²,3, C. chisari¹

¹University Hospital of Pisa, Neurorehabilitation Unit, Pisa, Italy
²Scuola Superiore Sant'Anna Pisa, Biorobotic Institute, Pisa, Italy
³École Polytechnique fédérale de Lausanne, Translational Neural Engineering Lab, Lausanne, Switzerland

Introduction/Background

Robotic rehabilitation is known to be at least as effective as conventional training for upper limb motor recovery after stroke; nevertheless, which patients could benefit from this treatment is unknown and finding markers that could predict rehabilitation outcome is a challenge. We aimed at understanding the neural mechanisms of motor function recovery after upper limb robotic rehabilitation in chronic stroke patients using neurophysiological markers obtained by electroencephalography recording (EEG).

Material and Method

Fourteen chronic stroke patients (M/F:11/3; 59.5 ± 13 yrs) with mild to moderate upper limb paresis were subjected to 10 sessions of upper limb rehabilitation with a planar mobile robotic device (MOTORE, Humanware). Fugl-Meyer Assessment Scale (FMAS) and Wolf Motor Function Test (WMFT) were administered before (t0), at the end (t1) and at 1 month follow-up (t2); at the same timing 64-channels EEG was recorded. We analyzed power spectrum density in different frequency bands of the affected and unaffected hemispheres with 64-ch EEG and their correlation with motor impairment as measured by clinical scales. Correlation analysis were performed to identify the indicators of good rehabilitative outcome.

Results

Clinical assessment indicated a significant functional improvement in upper limb motor function at the end of rehabilitation as assessed with FMAS and WMFT score that is maintained at follow-up. We found a positive correlation between global Alpha activity at t0 and WMFT score variation (t0-t1) and between global Beta activity at t0 and WMFT time variation (t0-t1) and a positive correlation between Beta activity at t0 in the unaffected hemisphere and FMAS variation (t0-t1 and t0-t2).

Conclusion
Robotic rehabilitation improves upper limb motor performance in stroke patients even in the chronic phase. The amount of Alpha and Beta band power at t0 is suggestive of rehabilitation-related motor outcome. Our results suggest that EEG recording preliminarily to robotic rehabilitation could help identifying good responders to treatment thus optimizing results.

Introduction/Background

Rehabilitation in facial palsy has showed efficacy on facial symmetry and quality of life. There is no self-rehabilitation protocols in central facial palsy. We elaborated a self-rehabilitation protocol based on usual speech therapy rehabilitation.

Material and Method

Protocol was elaborated with speech therapists and rehabilitation physicians specialized in neurological rehabilitation.

Results

Usual exercises were listed, and presented in the form of photos with simple instructions for each exercise. Exercises concerned lips, tongue, cheeks, top of the face. They have to be realised once a day, in front of a mirror, with 1 ou 2 series of 5 movements for each exercise, insisting on strength, amplitude, precision of movement. Protocol validation is planned in a cross over study (A : speech therapy and B : self rehabilitation) in patients after sylvian ischemic stroke.

Conclusion

Self-rehabilitation protocol may be validated in stroke patients.

Keywords

facial palsy; self rehabilitation

VALIDITY AND RELIABILITY OF CLINICAL TESTS TO ASSESS SEATED BALANCE AND TRANSFER TASKS FOR ADULTS WITH STROKE: LITERATURE REVIEW

A.V. Bruyneel\textsuperscript{1}
University of Applied Sciences of Western Switzerland, physiotherapy, Carouge, Switzerland

Introduction/Background

The seated balance and transfer tasks have been used in clinical practice and research to assess trunk control in adults with hemiparesia post-stroke. But, it is unclear if the evidence is sufficient to warrant its use in stroke patients.

The aim of this study was to realize a literature review about validity and reliability (intra and inter-raters) of seated balance and transfer tasks tests in patients with hemiparesis post-stroke.

Material and Method

The research was conducted using keywords related to seated balance and transfer tasks on electronic databases: PubMed, ScienceDirect, Pedro, Cochrane and Kinedoc. Observational studies involving adults with stroke that explored any measurement property of transfer tasks or seated balance were included. The Qarel scale was used to assess the methodological quality of included studies.

Results

1241 articles were identified. Following the selection criteria, 12 articles were included, with 5 on seated balance (Qarel: 7 / 12, min: 6 / max: 8) and 7 on transfer tasks (Qarel: 8.14 / 12 min: 6 / max: 10). The findings about the seated balance revealed that these tests had efficient inter-raters (0.92<ICC<0.97) and intra-rater (0.93<ICC<0.99) reliability, while the validity was more variable (0.20<r<0.94). For transfer tasks, the studies highlighted good inter-raters (0.93<ICC<1.00) and intra-rater (0.64<ICC<0.99) reliability, but poor to moderate validity (0.03<r<0.75).

Conclusion

Despite a large number of tests used in clinical practice, very few studies exist on the measurement properties of the tests used to assess sitting balance and transfer tasks in stroke patients. This review indicates that appropriate tests with good validity and reliability exist. The tests are varied (stable sitting position, unstable, sit-to-stand, standing floor, etc.) and with a good feasibility in clinical practice.

IMPACT OF POST-STROKE CHECK LIST IN CHRONIC STROKE PATIENTS MANAGEMENT
A. Mena¹, A. García Martin²
¹Hospital Dr. Negrín, Rehabilitation Service, Las Palmas de Gran Canaria, Spain
²Complejo hospitalario Materno Insular, Servicio de Rehabilitación, Las Palmas de Gran Canaria, Spain

Introduction/Background

Post-Stroke Checklist (PSCL) is an easy-to-use questionnaire to standardize follow up care of Chronic post-stroke patients and facilitate referral to Rehabilitation Services by general practitioners (GPs) in an evidence-based way. Although it was developed some time ago, there is no published. Our main objective was to further understand if training GPs in the use of the PSC makes an impact on referral of these patients in our area.

Material and Method

We reviewed 55,000 inter-consultations (IC) from chronic stroke patients 6 months before and after training and presentation of the PSC to GP in our area. We determined endpoints such as number and percentage of patients undergoing treatment and concordance in goal setting between GP and Physical Rehabilitators (PR).

Results

We identified 16 chronic stroke patients from 756 inter-consultations from GPs in our area, 6 months before PSC training session. Only seven in these 16 patient underwent any intervention (5 were treated with botulinum toxin (BT) and in 3 patient postural orthosis was recommended). Goals between GPs and PhysicalRehabilitator matched in less than 50% of patients. After PSC training session, we identified 23 patients that suffer from a cardiovascular event in 682 inter-consultations reviewed. 20 underwent any interventions, 18 were treated with BT (10/18 cases after a diagnostic nerve block), 21 were referred to physiotherapist and we prescribed functional orthosis to 8 patients. Diagnosis between GPs and our team matched in 20/23 patients.

Conclusion

Bearing in mind limitations of the study such as the small numbers of patients included, we may conclude that training in PSC to GPs may improve referral of chronic stroke patients, as it improves diagnosis concordance and the ratio of patient that underwent any intervention.

PREDICTORS OF IMPAIRED QUALITY OF LIFE AMONG ELDERLY POPULATION HAVING POLYARTHROSIS
I. Ksibi1, I. Megdiche2, R. Maaoui1, H. Gares1, H. Rahali1
1Military Tunis Hospital. Tunis, Department of Physical and Rehabilitation Medicine, Tunis, Tunisia
2Military Tunis Hospital. Tunis, Department of Physical and Rehabilitation Medicine, Sousse, Tunisia

Introduction/Background

Osteoarthritis (OA) is the most common degenerative joint disease in the elderly. The often multifocal location at this age can be a source of pain, limitation of everyday activities, thus affecting their quality of life (QOL).

The objective of our work was to evaluate of the impact of polyarthritis on the QOL among patients affected dypolyarthrosis.

Material and Method

A cross-sectional, descriptive study done in 2017. Patients aged 65 years and over were included, followed for polyarthrosis according to the criteria of Lawrence J.S. A clinical evaluation (anthropometric data, postural examination, and joint assessment) was made. The quality of life was studied by the SF36 scale translated into Tunisian dialect and the OAKHQOL questionnaire, specific for lower limb arthrosis.

Results

Fifty patients were included. The mean age was 71 years with a sex ratio of 0.4. Almost all of our patients had knee osteoarthritis (98% of cases), spinal involvement was in the second position (88%). We noted an alteration of the different physical health items of the SF-36 predominant in the areas of physical limitation, general health and emotional limitation, as well as the physically under-score (28/100) which was significantly lower than the mental under-score (52/100). The quality of life was impaired in the dimensions of social functioning and physical activities assessed by the OAKHQOL.

Factors associated with poor QOL were: Female gender, spinal osteoarthritis, diabetes and heart disease as comorbidities and lack of functional rehabilitation (p<0.05).

Conclusion
Polyarthrosis is accompanied by an alteration of the QOL in the elderly. Factors associated with QOL impairment should be considered in the patient management program.

ASSESSMENT OF BRAIN MOTOR CONTROL CHANGES RELATED TO NAVIGATED INHIBITORY RTMS IN THE CONTRALESIONAL HEMISPHERE IN PATIENTS WITH STROKE

F. Vox¹, B. McKay², M. Yochelson¹
¹Shepherd Center, Medical Affairs, Atlanta, USA
²Shepherd Center, Research, Atlanta- Georgia, USA

Introduction/Background

The Brain Motor Control Assessment (BMCA), a functional electromyography measure, provides baseline quantification of multi-muscle control for discrete movements against which we can compare the coordination of people with neurological impairment. Extensively studied in people with spinal cord injury, this small prospective case series represents the first time the BMCA technique has been applied to evaluate motor control changes potentially induced by rTMS post stroke.

Material and Method

We performed the BMCA on a subset of 4 patients who we enrolled as part of a larger multi center, sham-controlled randomized trial of navigation-guided 1 hz rTMS administered to the contralesional hemisphere as adjuvant to task-oriented occupational therapy, in patients with upper extremity weakness 3-12 months post stroke. We calculated the voluntary response index, pre-and post intervention, a BMCA measure involving the magnitude (Mag) - total EMG activity across muscles, and the similarity index (SI) - a vector comparison of the subject’s multi-muscle pattern to that of normal control subjects.

Results

With just 4 subjects, we did not achieve statistical significance, however, we observed the greatest change in Mag and SI for wrist control tasks in the 3 active rTMS subjects vs the 1 sham subject.

Conclusion

This pilot demonstrated the feasibility of applying the BMCA to the assessment of an rTMS intervention. We could distinguish between the affected and non-affected sides and quantitatively track changes related to rTMS application. The one sham subject had the worst results.

VIRTUAL REALITY INTEREST IN CHRONIC VASCULAR HEMIPLEGIA

P.Y. Libois¹, A. De Beer¹, M. Ghislain¹, M. Grimée¹, A. Libois¹, F. Assaban²

¹Centre neurologique de réadaptation adultes-enfants, neuro-réadaptation, Montigny-le-Tilleul, Belgium
²Physical Therapist PT & Founder of Virtualis, Virtualis, Montpellier, France

Introduction/Background

In chronic hemiplegia, physiotherapy often only aims at upkeeping of the few recovered mobility in the upper limbs. In partnership with Virtualis®, we adapted, to virtual reality, a rehabilitation protocol based on mirror therapies combined with a sensorimotor approach. Our goal was to modulate by this method the brain plasticity for improving this chronic disability.

Material and Method

14 stable hemiplegic patients, still benefiting from "maintenance by physiotherapy" (average of 66.8 ± 36.6 months post-stroke) were rehabilitated for 2 months, 3 times per week by virtual therapy. Each patient was assessed at T0 (before treatment), T1 (after 1 month of treatment), T2 (after 2 months of treatment), T3 (1 month after the treatment end and 3 months after its beginning).

The evaluation was based on a video analysis, a dynamometric analysis, an evaluation of spasticity, a "Jebsen Test" and a FIM.

Results

4 patients gave up the study. For the other 10 (9 males, 1 female, average 55.4 ± 13.96 years-old), our results converge towards a positive change but with a very variable progression gradient. We observed a change in spasticity, an analytic and functional improvement with a tendency to reintegrate the paretic limb into daily life.

Conclusion

Our results, even if they are still preliminary, highlight the interest of this immersive therapy. Having modified the plasticity in cerebral palsy patients, who was stable since several years, we are now encouraged to extent this technique to patients in the acute phase.

STROKE WARNING TREND IN PEOPLE UNDER 65: ANALYSIS OF 57,713 CASES FROM 2002 TO 2015

D. Anderlini, G. Wallis

University of Queensland, Centre for Sensorimotor Performance, Brisbane, Australia

Introduction/Background

Data from UK and USA studies show that the average age of stroke patients is falling. Given that stroke is the main cause of adult disability, we want to understand if the same is true in Australia.

Material and Method

Our retrospective study included 244,276 admissions to Hospitals in Queensland between 2002 and 2015 for stroke and related issues (ICD = I60-I69). 151,733 admissions had stroke (I60-I64) as a principal diagnosis, of which 57,713 were defined as first ever episode. We analyzed the patient data on the basis of age range (under or equal 65 and over 65 years of age) and year of admission.

Results

Data from 57,713 patients reveals that the crude incidence rate of stroke patients age 25-64 x 100,000 inhabitants increased from 44 to 62 (p<0.0001). It represents a jump of +18/100,000 from 2002 to 2015.

Moreover preliminary data shows that younger people seem to get to the hospital later than older ones, missing the chance for acute therapy and facing a worse outcome with chronic disability.

Conclusion

As a word of caution, the results have yet to be adjusted for catchment area changes, new stroke units opening, and changes in population statistics. Nonetheless, our study suggests that stroke is becoming more frequent in younger Australians. Primary and secondary prevention techniques are effective, as results from older shows, but that they need to be carried over to younger at-risk groups too, together with an awareness campaign.

FEASIBILITY AND TOLERANCE OF AN AEROBIC MOTOR TRAINING PLUS TDCS PROGRAM ON WALKING PERFORMANCE IN HEMIPLEGIC STROKE PATIENTS

E. Ojaras1, A. Roche2, A. Gaetani2, A. Condemine2, C. Voiry3, D. Rimaud2, P. Giriau2
1CHU Saint Etienne, Service de Gérontologie clinique, Saint Etienne, France
2CHU Saint Etienne, Service de MPR adulte, Saint Etienne, France
3APHP, Neuro-Urologie et explorations périmales Hopital Tenon, Paris, France

Introduction/Background

Limited improvement of post-stroke gait capacity have been shown with exercise training programs. Neuromodulation techniques such as transcranial Direct Current Stimulation (tDCS) may enhance the efficacy of exercise training programs. In this aim, we have designed an aerobic training program coupled with cortical stimulation by tDCS for hemiplegics stroke patients. The first objective was to evaluate the feasibility and tolerance of this program and secondly its effects on the walking performance.

Material and Method

This study was performed on 9 patients suffering an initially complete hemiplegia due to a first-ever stroke (age: 62.9 ± 10.0 years, 6 women, 3 men, post stroke delay: 4.9 ± 3.5 months). All patients followed 18 sessions, 3 times a week over 6 weeks, combining cycloergometer and walking training. Walking training was achieved with treadmill and body weight support. Anodal tDCS stimulation (2 mA) was applied over the lower limb ipsilesional motor area during the first 20 minutes of each session. The tolerance and adverse events (AE) were collected through a questionnaire filled in after each session. 10 meters walking test (10MWT) and 6-minutes walking test (6MWT) were assessed before and after the complete training program.

Results

The tDCS-training program was completely achieved for 7 out of 9 patients. No major AE was reported, but 27% of the sessions was associated with minor AE. The most frequent AE were tingling, headache and skin redness under the electrodes. The walking performance was significantly improved for the 6MWT (mean effect + 4.5%).

Conclusion

This feasibility study illustrates the good tolerance of an aerobic motor training plus tDCS program in stroke patients. A follow-up prospective control study, conducted on a larger stroke population, will precise the target population among stroke patients and evaluate the impact of this program on exercise capacity versus walking performance.

No conflict of interest
Introduction/Background

The particular effects of the bottom-up (BU) and top-down (TD) approaches of physical therapy (PT) for the recovery of postural imbalance after stroke have never been studied, compared to the rehabilitation for spatial neglect after stroke (Bowen et al., 2013). The aim is to determine the efficiency of all PT used after a stroke to improve the balance performance in adult patients after stroke.
Material and Method

Randomised controlled trials (RCT), without language restriction, until October 2015, assessing the Berg Balance Scale (BBS), the Postural Assessment Scale for Stroke, the posturographic parameters in static condition and measures of independence in activities of daily living were included. Two independent authors (AH and JDM) led this selection following the Cochrane recommendations (Hugues et al., 2017).

Results

190 parallel and crossover RCT from 9337 records were included, involving 7946 subjects (study sample: mean 41 (SD 50) subjects, age: pooled mean 61.7 (pooled SD 12.78) years). A significant difference in favor of the intervention group was found for the BBS at immediate effect (BU: 6 studies, mean difference (MD) 1.17; 95% confidence interval (CI) [0.38; 1.96]. TD: 16 studies, MD 2.71; 95% CI [1.62; 3.80]. Mixed: 3 studies, MD 3.33; 95% CI [1.29; 5.37]). Only BU approaches of PT are more effective than sham treatment or usual care on the BBS for immediate effects (BU: 12 studies, mean difference (MD) 3.25; 95% confidence interval (CI) [1.20; 5.30]. TD: 12 studies, MD 1.17; 95% CI [-0.31; 2.65]. Mixed: 0 study. Neuromodulation: 3 studies, mean difference (MD) -1.60; 95% confidence interval (CI) [-4.49; 1.28]).

Conclusion

These preliminary results show in the short term: i) that balance capacity can be improved by all PT compared to no treatment, and ii) an improvement of balance by BU approaches of PT compared to sham treatment or usual care.

EVOLUTION OF DYSPHAGIA AFTER STROKE
C. Montoliu¹, L. Cuevas¹, M. Entrenas¹, E. Medina¹, A. Rodriguez¹
¹rehabilitation doctor, Rehabilitation Service. Ciudad Real University General Hospital, Ciudad Real, Spain

Introduction/Background

Dysphagia can be caused by many different disorders, affecting especially old people, people with neurological diseases, cancers of head and neck or severe reflux. Prospective studies have demonstrated an incidence of dysphagia as high as 41.7% in the first month after a cerebrovascular accidents (CVA). The overall rate of aspiration resulting from a CVA is approximately 33.3%. As many as 20% die of aspiration pneumonia in the first year after a CVA, and from 10% to 15% will die of aspiration pneumonia after the first year following the stroke. The goal of rehabilitation is to identify and treat abnormalities of swallowing while maintaining safe and efficient nutrition.

Material and Method

Eighty-year-old male who suffers CVA in left middle cerebral artery territory. Intravenous fibrinolysis is performed in the emergency room, persisting dysphagia and aphasia. Days later the patient suffers bronchial pneumonia, so nasogastric tube (NGT) is placed to him. On examination, weakness of the right oral musculature and complete lack of teething. The velopharyngeal and palatoglossal seals are much altered and have an absence of gag reflex. Hypophonia and weak cough. The volume-viscosity swallow test (V-VST) was performed with 2-point desaturation and wet voice with 10ml of nectar and 5ml of pudding, finishing the test.

Results

Six sessions of speech therapy were performed, improving muscle strength and the velopharyngeal seal. After another 6 sessions, an oral diet can be introduced, subsequently removing the NGT. With a total of 16 sessions, the patient recovers the normal physiology of swallowing, the V-VST was negative and is discharged with a complete basal diet.

Conclusion

With actual advances in neuroimaging techniques, our knowledge of the anatomy and physiology of swallowing has increased. This allows to improve the therapeutic approach of patients with neurogenic dysphagia and recover the quality of life lost after CVA.

CHANGE PATTERN OF ITEMS IN STROKE IMPAIRMENT ASSESSMENT SET (SIAS) IN KAIFUKUKI REHABILITATION WARD.

K. Yagihashi¹, S. Sonoda¹, M. Watanabe¹, S. Okamoto¹, S. Maeshima¹, H. Okazaki¹, Y. Okayama¹
¹Fujita Health University, Nanakuri Memorial Hospital, Tsu, Japan

Introduction/Background

Impairment and disability are both important in rehabilitation medicine. Although the change pattern of the ADL has been eagerly researched in stroke patients, the course of impairment is not well known. We tried to clarify the characteristic of items in Stroke Impairment Assessment Set (SIAS) by comparing their scores on admission and at discharge.

Material and Method

Subjects were 4001 first stroke patients who admitted to our comprehensive inpatient rehabilitation wards between 2004 and 2016. Patients who had severe comorbidity, complication, or falling accident, or showed deterioration of FIM motor subscore were excluded and 3279 patients were analyzed. Higher score of the SIAS means less impaired. Percentage of patients with highest rank of the rating of each item of the SIAS on admission was counted. Rate of patients whose score was improved, deteriorated, or unchanged during hospital stay were also checked separately in each item of the SIAS. The items of the SIAS was grouped by the pattern of these percentages.

Results

Trunk, visuo-spatial, unaffected-side quadriceps, and pain were put together as the first group with large number of high score on admission and high improvement rate. Five items of motor paralysis and abdominal item were thought to be the second group with small number of high score on admission and high improvement rate. Items handling sensory, tone, range of motion, and speech were presumed to be the third group with low improvement rate and possibility of deterioration.

Conclusion

We must be cautious with the different pattern of the change of the impairment during rehabilitation.

SNEDDON SYNDROME: PERSONAL HISTORY OF STROKES WITH AN EARLY RECOVERY AFTER A REHABILITATION PROGRAM

M. Linares Gago¹, L.E. Alarcón Mora¹, J. Bautista Troncoso¹, A. Leon-Valenzuela¹, J. Casar García¹, R. Del Pino Algarrada¹

¹UGC Hospital Puerto Real-Hospital Puerta del Mar, Physical Medicine and Rehabilitation, Cádiz, Spain

Introduction/Background

Sneddon syndrome is a chronic, progressive, arterio-occlusive disease of unknown etiology. Dementia occurs in 50% of patients and it is usually associated with antiphospholipid antibodies. It is defined by the association of livedo reticularis and recurrent cerebrovascular ischemic lesions. Its annual incidence is 4 / 1,000,000. We report the case of a 62 years old male patient with history of recurrent isquemic strokes, migraine, dermatological disease with psoriasis and livedo reticularis, cardiovascular involvement, cognitive decline, and absence of antiphospholipid antibodies.

Material and Method

The patient suffered a right occipital stroke in 1991, with sequels of left homonymous hemianopsia. Then in 2010 he suffered an ischemic stroke in the left temporal lobe, with no sequels. In 2014, he presented a right acute talamocapsular stroke that required anticoagulation and in 2017 a new acute ischemic stroke was diagnosed in right middle cerebral artery. In all the episodes he presented a recovery quickly and progressively.

Results

Bradypsychia and slow response.
Left supranuclear paresis and homonymous left hemianopsia.
Supplementary tests: Computer Tomography at 2014: talamocapsular hypodensity in the right radiated crown.
Computer Tomography at 2017: areas of acute ischemia in right middle cerebral artery.

During the stay of his hospitalization, he progressed favorably. He underwent rehabilitative treatment for reeducation of walking. The patient was discharged and had not more strokes in the follow up and assessment.
Conclusion

In the review he reported a complete improvement during the first week. The most accepted treatment is anticoagulation with warfarin. Its benefits are better than the risk of bleeding. The early rehabilitation treatment is essential to favor its early recovery and maintenance.

USEFULNESS OF MIRROR TREATMENT METHOD WITH DIGITAL IMAGE DISPLAY DEVICE IN STROKE PATIENTS WITH UPPER ARM DYSFUNCTION.

K. Kagechika

Kanazawa Medical University, Rehabilitation Medicine, Uchinada, Japan

Introduction/Background

This is a method of reducing the load of patient's posture. Because the equipment of the mirror therapy that uses a new picture processing was developed, We introduce this system.

Material and Method

It is possible to undergo rehabilitation of making the paralyzed hand follow to the movement of a healthy hand. The patient does the problem with a mirror box.

The experiment is assumed to be an end by not deciding time to use the mirror box, and clearing all problems.

the game of scissors-paper-rock are selected at random and the patient is told the experiment problem by oral. The patient moves his hand as shown in the problem mentioned in the mirror box. It is assumed about eight seconds, the patient gives the problem at intervals from giving the problem to giving the following problem, and the following problem is given even if not made. The problem is done 20 times by one experiment.

Results

Figure is a number of pixels obtained because of the experiment. The image of the hand is acquired by the USB camera in the mirror box and the binarization of the image is done. The blue graph shown in figure shows the number of pixels when the image of a healthy hand is made two values, a red graph shows the number of pixels when the image of the paralyzed hand is made two values, and the graph of the pea green is a number of pixels when the difference between a healthy hand and the paralyzed hand is done.

Conclusion

The possibility of quantitatively appreciable of the target change at the time of passing the paralysis and the disturbance of attention was suggested at identity frequency and reactive time of the image of hand.

PATIENT AND PROFESSIONAL VIEWS OF MOTIVATION FOR REHABILITATION OF SUBACUTE STROKE

Y. Otaka¹², T. Yoshida²³, M. Kumagai², S. Kitamura², Y. Tomita², J. Yaeda³
¹Fujita Health University, Department of Rehabilitation Medicine I, Aichi, Japan
²Tokyo Bay Rehabilitation Hospital, Department of Rehabilitation Medicine, Chiba, Japan
³University of Tsukuba, Graduate School of Comprehensive Human Sciences, Tokyo, Japan

Introduction/Background

Despite its importance, both patients and rehabilitation staff lack knowledge about the motivation for rehabilitation. This qualitative study aimed to identify factors related to motivation for rehabilitation in patients with subacute stroke.

Material and Method

Semi-structured interviews were performed with 20 patients with subacute stroke (mean age, 65.8 years) as well as with rehabilitation staff (10 physical therapists, 10 occupational therapists, and 10 nurses). Individual interviews were recorded in a quiet room. Text data were subjected to content analysis. The local ethics committee approved the research protocol and all participants provided prior written informed consent.

Results

The average patient interview time was 19 minutes, with total interview time of 370 minutes. The average staff interview time was 20 minutes, with total interview time of 590 minutes. For both patients and staff, the same 7 core categories were considered as factors influencing motivation: rehabilitation goals, relationships with staffs, relationships with other patients, support of patients, success and failure experiences, physical and cognitive status, and resilience of patients. Additional factors of “patient behavior related to motivation” and “labeling patient motivation” were identified as categories for patients and rehabilitation staff, respectively.

Conclusion

This study found that the motivation for rehabilitation in patients with subacute stroke is influenced by multiple internal and external factors. In addition, motivation may change patient behavior, and rehabilitation staffs tend to label patient motivation.

TRUNK EXERCISE USING THE SWISS BALL IMPROVES THE FUNCTIONAL BALANCE AND WALKING OF STROKE PATIENTS IN THE EARLY STAGES OF RECOVERY

M. Wu¹, C.M. Ni¹, J. Cui¹, Z.L. Tao¹

¹The First Affiliated Hospital of University of Science and Technology of China, Rehabilitation, Hefei, China

Introduction/Background

At present, we pay more attention to limb function assessment and improvement in stroke, and rarely give intensive training on their trunk control functions, resulting in unsatisfactory rehabilitation outcomes. Based on the above background, we used Swiss ball to enhance the trunk function of stroke patients in the early stage and observed the impact on patient balance and walking ability.

Material and Method

Sixty hemiplegic stroke patients were randomly assigned to a control group or an experimental group, each of 30. Both groups were treated with routine physical training. Those in the control group did conventional trunk exercises, while the patients in the experimental group were given trunk exercises performed using a Swiss ball. The trunk control test (TCT) and the Berg Balance Scale (BBS) were used to assess the patient’s trunk and balance function. Gait and balance function training and assessment apparatus (model AL-080) was used to measure and compare the scope of movement of the patient’s center of pressure in static sitting over 30 seconds (LOM), the limits of stability (LOS), velocities and a gait asymmetry index (GAI).

Results

Significant improvements in TCT, BBS, LOM and LOS were observed in both groups after the training, but all of the measures improved significantly more in the experimental group than in the control group.

Conclusion

Swiss ball trunk exercise can obviously improve the trunk control, functional balance and walking of stroke patients in the early stages of recovery.

ACCURATE ASSESSMENT OF CARDIOPULMONARY FITNESS AND ANALYSIS OF ITS RELATED FACTORS IN STROKE PATIENTS

W. Chen¹, Q. Zhen²
¹xuzhou central hospital, rehabilitation, xuzhou, China
²Chang Zhou De An Hospital, rehabilitation, Chang Zhou, China

Introduction/Background

To accurately assess cardiopulmonary fitness of stroke patients and to analyze its related factors.

Material and Method

The basic data of 38 stroke patients, such as age, sex, height, etc., were collected. Fugl-Meyer, MMSE, ADL, and Berg scales were used to evaluate their exercise function, cognitive function, daily activity and balance function. All the patient used the power bicycle to carry out the maximum progressive cardiopulmonary exercise test with a restrictive symptom, and data on cardiopulmonary index, subjective fatigue, heart rate, blood pressure and other data were collected. Single factor analysis and multiple factors logistics regression analysis of cardiopulmonary fitness in stroke patients were carried out by SPSS 17.0 statistical software to explore the factors affecting the cardiopulmonary fitness.

Results

38 stroke patients enrolled in the study were able to complete the cardiopulmonary exercise test without adverse events. Cardiopulmonary fitness significantly decreased (VO2peak was 12.89 ± 3.42ml/kg/min). Single factor analysis showed that age, sex, Fugl-Meyer, MMSE, ADL, bad habits and daily exercise habits were the influencing factors of cardiopulmonary fitness in stroke patients (P < 0.05). Multiple factor logistic regression analysis showed that high Fugl-Meyer score, high MMSE score and regular exercise habit were independent protective factors of cardiopulmonary fitness (OR < 1), while advanced age, women and bad living habits were their independent risk factors (OR > 1).

Conclusion

Cardiopulmonary fitness significantly decreases in stroke patients. High Fugl-Meyer score, high MMSE score and regular exercise habit are independent protective factors of cardiopulmonary fitness, while advanced age, women and bad living habits are its independent risk factors.

THE EFFECT OF MIRROR THERAPY ON THE UPPER LIMB FUNCTION REHABILITATION OF STROKE PATIENTS WITH HEMIPLEGIA

Z. Haina¹, X. Guangmeng², Z. Jun¹, L. Xinyi¹, Y. Jiang¹
¹The Second Hospital of JiLin University, the Rehabilitation Department, Chang Chun, China
²The Second Hospital of JiLin University, the General Surgery Department, Chang Chun, China

Introduction/Background

To explore the effects of mirror treatment of upper limb functional recovery in patients with hemiplegia after stroke.

Material and Method

56 patients with hemiplegia after stroke were randomly divided into the mirror treatment group (28 cases) and control group (28 cases by routine rehabilitation therapy). Before treatment and after treatment for 4 weeks, WMFT and FMA were used to evaluate the two groups of patients with upper limb movement function. Modified Ashworth Spasm Scale was also used to assess the spasticity of upper limb.

Results

After 4 weeks of treatment, in two groups, the scores of WMFT, FMA were significantly higher than before ($P < 0.05$); Between the two groups, the scores of WMFT, FMA in the mirror treatment group were higher than those of control group($P<0.05$). The difference of Ashworth spasm improvement was not significant before and after treatment($P>0.05$).

Conclusion

Mirror therapy on the recovery of upper limb movement function in patients with hemiplegia after stroke has certain curative effect, but the improvement of limb spasm is not obvious.

HANDEDNESS AND LATERALITY IN INDONESIAN STROKE PATIENTS: A PRELIMINARY STUDY

W. Kusumaningsih¹, H. Hong¹
¹Cipto Mangunkusumo Hospital- Faculty of Medicine-Universitas Indonesia- Jakarta- Indonesia,
Department of Rehabilitation Medicine, Jakarta, Indonesia

Introduction/Background

Handedness was determined by brain dominance which had importance influence on motor skills. Aims was to know whether post stroke hemiparesis that affect dominance or non-dominance influence handedness.

Material and Method

A preliminary study in acute, sub-acute or chronic phase stroke patients. Hand dominance was evaluated using Edinburgh Handedness Inventory–Short Form (EHI-SF), which the result was Laterality Quotient Score (LQ). Evaluation was done twice, before (by interview) and after stroke. LQ score was categorized as Right Handedness/RH (61 to 100), Mixed Handedness/MH (-60 to 60) and Left Handedness/LH (-100 to -61).

Results

Seventeen post stroke subjects, nine with right hemiparesis (52,9%), eight with left hemiparesis (47,1%), eleven men (64,7%), six women (35,3%). Pre-stroke LQ score was sixteen RH (94.1%), one MH (5.9%). Eight subjects in the chronic phase (47,1%), seven subjects in the sub-acute phase (41,2%), and two in the acute phase (11,7%). Post Stroke LQ score shows, twelve (70,5%) show same LQ scores, that is hundred which was categorized as RH category. Five (29,41%) had change in LQ score with three (17,64%) still in the same category as RH and had Right Hemiparesis. One (5,89%) also still in the same category as MH. One (5,89%) was in chronic phase in which LQ score change from RH to LH.

Conclusion

Hemiparesis in the dominant side influence changes in Laterality Quotient scores, only one subject (5,89%) change from RH to LH. Hand dominance impairment, stroke onset, age and adaptive mechanism may affect laterality. It is important to use EHI-Short Form to determine handedness before giving hand rehabilitation program.

Keywords

Edinburgh Handedness Inventory Short Form (EHI-SF); Laterality Quotient (LQ); Stroke
Introduction/Background

With advancement in medical treatment longevity post stroke has increased. As most of stroke survivors are left with some impairment the quality of life assumes importance. The majority of study reported a decline in health-related quality of life following stroke. However the data from developing countries are limited. The aim of this study was therefore to determine the quality of life (QoL) and correlation of factors influencing QoL of community-dwelling stroke survivors.

Material and Method

Ongoing observational cross sectional study in PMR department. All the stroke survivors > 6 weeks duration of stroke, satisfying the inclusion and exclusion criteria and willing to participate were enrolled for the study. Subjects were interviewed using semi structured proforma, Quality of life was assessed using WHO QoL Bref, functional independence was measured by Barthel Index Hospital Depression and Anxiety Scale (HADS) was used to identify level of anxiety and depression.

Results

A total of 133 subjects enrolled for the study, Out of which 94(70.6%) were male and 39(29.4%) female. Mean age was 51.44±12.1, mean duration of stroke 1.76 ±1.8 years, and mean score of barthel Index 62.78±26.32. Some degree of depression was present in 47 % subjects and anxiety in 50 % subjects. In majority of subjects overall quality of life score was fair to poor and were dissatisfied with their health. Mean QoL domain score was also low in all the four domains physical health(47.56), psychological health(41.96), social relationships(49.14) and environment(49.38). The QoL post stroke was significantly influenced (P<0.05) by age, stroke-severity, education, socioeconomic status and presence of anxiety & depression.

Conclusion

Strove survivors have impaired quality of life. Multidimensional evaluations of the QoI and periodic screening for anxiety and depression of stroke survivors is recommended. In addition community-based rehabilitative approaches need to be strengthened which includes continuous and coordinated counselling and support to improve QoL.

THE EFFECT OF REPETITIVE TRANS-CRANIAL MAGNETIC STIMULATION FROM THE PERIPHERAL TO MOTOR CORTEX ON SUBACUTE STROKE PATIENTS

C. Xiaowei¹, L. Zhenlan¹, L. Xuncan¹, C. Yinxing¹, X. Guoxing¹, L. Lu¹
¹1st Hospital of Jilin University, Rehabilitation, Changchun, China

Introduction/Background

The purpose of this study was to evaluate a new way of improving function applied with trans-cranial magnetic stimulation from peripheral neuron-muscular to motor cortex for subacute stroke patients.

Material and Method

65 subacute stroke patients with both upper and lower limb hemiparesis were included and divided into three groups: group A, with paired peripheral to cortex stimulation (n=29, iTBS stimulate from lower paralytic limb, upper limb, spinal cord, brain stem to lesionsal hemisphere cortex, for 3-5times/site), group B, with the cortex stimulation alone (n=20, low frequency trans-cranial magnetic stimulation on non-lesional hemisphere cortex, 1Hz, 1200pulses, 90%RMT), group C, control group (n=16, no stimulation). All patients received treatments 1 time/day for 10 days and the motor function evaluated by the Fugl-Meyer Assessment (FMA) pre- and post-treatment.

Results

Compared with pre-treatment FMA score of post-treatment showed a significant increase in Group A and B patients, and the FMA score of Group A patients’ showed significantly increase than Group B. FMA score of Group C had no significant improvement between pre and post treatment.

Conclusion

It might be a new way of using trans-cranial magnetic stimulation that stimulate from peripheral to cortex for subacute stroke patients with hemiparesis.

CORRELATION BETWEEN BALANCE AND WALKING PERFORMANCE IN STROKE PATIENTS

T. Suryadi¹, W. Kusumaningsih¹, N. Nusdwinuringtyas¹
¹Cipto Mangunkusumo Hospital- Faculty of Medicine-Universitas Indonesia- Jakarta- Indonesia, Department of Rehabilitation Medicine, Jakarta, Indonesia

Introduction/Background

Balance problems are common after stroke, and have been implicated in poor recovery of daily activities, mobility and increase the risk of falls. A simple and reliable method for evaluating balance is Timed Up and Go Test (TUG). The 2-minute walk test (2MWT) is a test of walking performance and may provide achievement of walking ability in daily living. Aims of the study is to know the influence and relationship balance on walking ability and its relation in stroke patients.

Material and Method

A cross sectional study, thirty outpatient stroke subjects were examined once with Time Up and Go Test (TUG) for balance and Two Minute Walking Test for walking ability.

Results

Mean age of subjects 57.87(± 11.837) years. Mean value of TUG score was 14.58 minutes with range between 6 minutes till 29.37 minutes. Mean walking ability using two minutes walking test were 101.82 meter with range between 44 meter till 201 meter. Pearson Correlation test show strong negative correlation between TUG and two minute walking test (r =-0.822, p<0.01).

Conclusion

This study show that balance is highly correlated with walking ability in stroke patients. Time up and go test (TUG) can be used as a simple examination that is easy to apply in stroke patients as a predictor of walking ability.

THE PATTERN OF IMPAIRMENTS IN STROKE PATIENTS AND IT’S IMPACT ON FUNCTIONAL OUTCOMES: AN OBSERVATIONAL STUDY IN A TERTIARY CARE HOSPITAL OF BANGLADESH

M. Ahmed¹, M.S. Hossain¹, E.H. Khan¹, M.J. Islam², M.R. Amin³, P.K. Chakraborty⁴, H.B. Banu¹, T.H. Moonmoon¹, M.H. Khan⁵, S. Pervin³

¹Shaheed Suhrawardy Medical College, Physical Medicine and Rehabilitation, Dhaka, Bangladesh
²Dhaka Medical College, Physical Medicine and Rehabilitation, Dhaka, Bangladesh
³National Institute of the Diseases of the Chest and Hospital, Physical Medicine and Rehabilitation, Dhaka, Bangladesh
⁴National Institute of Cancer Research and Hospital, Physical Medicine and Rehabilitation, Dhaka, Bangladesh
⁵National Institute of Traumatology and Orthopaedic Rehabilitation, Physical Medicine and Rehabilitation, Dhaka, Bangladesh

Introduction/Background

Stroke is one of the leading cause of death and disability worldwide, more so in Bangladesh where health support system including rehabilitation is not expectedly available. Rehabilitation remains the cornerstone of treatment in stroke survivors. Rehabilitation outcome are assessed by functional outcome measures. Predicting stroke recovery is complex. Knowledge of functional outcome stratified according to initial impairments is very important for prognostication of stroke and for rational planning of rehabilitation.

Aim: To measure the impact of different types of impairments on functional outcomes in stroke patients.

Material and Method

Study design: Observational study
Study period: January 2017 – December 2017
Study place: Shaheed Suhrawardy Medical College Hospital, Dhaka, Bangladesh
Participants: Individuals (n= 264) who sustained an eligible stroke and admitted in Shaheed Suhrawardy Medical College Hospital were evaluated prospectively.

Methods: The patients were evaluated clinically and by standardized assessment tools at enrollment and followed up at 1 month and at 3 months after stroke. Assessments included baseline demographics, clinical findings, stroke characteristics, impairments and functional abilities. Individual impairments were assessed using the 11-item NIHSS (National Institute of Health Stroke Scale) index. Accumulated impairments were used to form 4 impairment groups: motor deficits only (M); motor and somatosensory deficits (MS); motor and visual deficits (MV); and motor, somatosensory and visual deficits (MSV).
Main outcome measures: Mobility and Activities of Daily Living (ADLs) were assessed at 1 month and at 3 months after stroke using the Barthel Index (BI).

Results

The BI score gain at 1 month and 3 months were different for the following 4 impairment groups in descending order: motor; motor and somatosensory; motor and visual; and motor, somatosensory and visual.

Conclusion

Cumulative impairments affect patients’ functional outcome in the first 3 months after stroke beyond the effect of motor impairment alone.

PREDICTORS OF FUNCTIONAL OUTCOME IMPROVEMENT IN HOSPITALIZED ACUTE STROKE REHABILITATION

W.C. Liao¹, T.S. Wei¹, H.C. Wen¹, K.L. Chen¹
¹Changhua Christian Hospital, Physical Medicine and Rehabilitation, Changhua, Taiwan R.O.C.

Introduction/Background

Functional Independence Measure (FIM) has been widely used as outcome evaluation in stroke patients. The effectiveness of FIM represents the improvement levels of functional outcome. This study aimed to identify the predictors of the FIM effectiveness in hospitalized acute stroke patients.

Material and Method

This study was conducted at the rehabilitation ward in a medical center, and data were retrieved from the clinical pathway data set which including complete record of the stroke assessment at admission and at discharge, mobilization ability, past medical history, whether nasogastric intubation or urinary catheterization or not, and the types of caregivers during admission. A total of 1640 stroke patients were included in this study with mean age, 72.4 [SD, 13.5] years, 652 (39.8%) women, and mean FIM initial score, 71.5 [24.5].

Results

The variables measured with univariate analysis showed that significant difference (p<.05) were age, length of stay(LOS), past medical history, speech function, nasogastric intubated or urinary catheterized, trunk control (roll, sit, stand), Functional Ambulation Category, family care (or not) and Brunnstrom stage. Multivariate logistic regression analysis identified 7 independent risk factors of FIM effectiveness including age (odds ratio [OR]: 0.98, 95% CI = 0.97-0.99), LOS (OR: 1.03, 95% CI = 1.00-1.05), dysarthria (OR: 0.691, 95% CI = 0.50-0.96), aphasia (OR: 0.353, 95% CI = 0.24-0.53), initial nasogastric intubation (OR: 0.61, 95% CI = 0.47-0.78), initial standing ability (OR: 1.61, 95% CI = 1.08-2.39), and care only by his family (OR: 1.41, 95% CI = 1.12-1.77).

Conclusion

This study showed that the effectiveness of rehabilitation can be predicted at patients’ admission to the rehabilitation department, and it could be used as a reference for rehabilitation goal setting and further management.

SLEEP DISORDERS IN PATIENTS WITH CHRONIC STROKE: A CROSS-SECTIONAL STUDY

C. Curci¹, F. Gimigliano², A. de Sire¹, M.T. Giamattei¹, G. Iolascon¹, R. Gimigliano¹
¹University of Campania "Luigi Vanvitelli", Department of Medical and Surgical Specialties and Dentistry- University of Campania “Luigi Vanvitelli”- Naples- Italy, Naples, Italy
²University of Campania "Luigi Vanvitelli", Department of Mental and Physical Health and Preventive Medicine- University of Campania “Luigi Vanvitelli”- Naples- Italy, Naples, Italy

Introduction/Background

Sleep disruption is a common disorder (about 50%) in patients after stroke, resulting in reduction in sleep time due to the increased number of awakens. It has already been described that sleep architecture is modified in stroke patients: time spent in non-rapid eye movement-1 (NREM1) phase is increased, while rapid eye movement (REM) and non-rapid eye movement-3 (NREM3) phases are reduced. The aim of this cross-sectional study was to investigate the mechanisms of sleep alterations and the correlation with the impact of the cerebrovascular accident on health and quality of life in patients with chronic stroke.

Material and Method

We included patients aged ≥18 years with a diagnosis of chronic stroke (≥ 12 months from acute event). Patients with Sleep Breathing Disorders (SBD) or presenting other major comorbidities were excluded. We assessed: stroke severity, using the Stroke Impact Scale (SIS); depression, by Hamilton Depression Rating Scale (HAM-D); pain using the Brief Pain Inventory (BPI); sleep perception by Pittsburgh Sleep Quality Index (PSQI). Sleep architecture was assessed by X4 Sleep Profiler™ In-Home EEG Sleep Monitor–Advanced®, an in-home multi-night sleep monitoring device.

Results

We enrolled 9 patients, mean aged 71.11±12.64 years, with a mean HAM-D = 15.11 ± 6.90, a mean BPI intensity index = 3.75±1.51 and mean BPI interference index = 6.21±2.82. Sleep was perceived as poor, with a global PSQI of 10.00±4.66. We found a reduction of time spent in NREM3 phase and an increased time spent in NREM1 and NREM2 with an increased number of awakens and cortical arousals in accordance with the literature. Moreover, time spent in NREM3 phase was significantly correlated to SIS mobility (r=0.861; p=0.003) and SIS hand function (r=0.707; p=0.030).

Conclusion
This cross-sectional study suggests a correlation between sleep alteration and the functioning of stroke patients, although prospective trials are necessary to better clarify this finding.

A COMPARISON OF PRISM ADAPTATION, OPTOKINETIC STIMULATION AND VISUOSPATIAL TRAINING IN THE REHABILITATION OF SPATIAL NEGLECT

A. Facchin¹, G. Figliano¹, A. Dante¹, N. Beschin², R. Daini¹
¹University of Milano Bicocca, Psychology, Milano, Italy
²A.S.S.T. Valle Olona, Neuropsychological Service- Rehabilitation Department, Somma Lombardo, Italy

Introduction/Background

Prism adaptation (PA) is one of the most investigated and effective therapy among those for the rehabilitation of unilateral spatial neglect. Two other techniques have received the higher degree of efficacy from the literature analysis: Visuo-Spatial Training (VST) and Optokinetic Stimulation (OKS). The aim of this study was to compare the effectiveness of these rehabilitation methods between and within two groups of neglect patients.

Material and Method

Two groups of post-acute spatial neglect patients (of 12 and 8 participants), who have never been received rehabilitation, were subjected to different rehabilitation procedures: PA and OKS for the first group and PA and VST for the second group. Within each group a crossover design was applied for the sequence of the two therapies. Each therapy was applied for 10 sessions, twice a day. Neuropsychological assessments were performed before the first type of training, between the first and the second training, after the second training and two weeks after the end of treatment.

Results

All three methods induced an improvement. The first group showed a significant effect of the first training, independently from which type. Similar trend of results was show in the second group. Overall the sequential application PA- VST seems to be more effective than VST- PA.

Conclusion

The results suggest that bottom-up techniques (PA and OKS) induce higher amelioration of neglect patients than VST, at least for a short therapy. OKS and PA showed a comparable degree of efficacy in the first session of rehabilitation. Finally, a first treatment with a bottom-up technique and a subsequent top-down method seems to show the high efficacy in rehabilitation of neglect.

IS THERE ANY EFFECT OF STROKE TYPE AND LATERALIZATION ON TRUNK CONTROL OF HEMIPLEGIC PATIENTS IN EARLY TERM?

A. Ünal¹, F. Altuğ¹, G. Tıkaç¹, A. Ahmed Hamood Al Sakka², E. Kavlak²
¹Pamukkale University, School of Physical Therapy and Rehabilitation, Denizli, Turkey
²Pamukkale University., School of Physical Therapy and Rehabilitation, Denizli, Turkey

Introduction/Background

This study was planned to investigate the effects of stroke type and lateralization on trunk control of hemiplegic patients in early term.

Material and Method

Forty hemiplegic patients (22M,18F) sitting balance at least 30 seconds were included in this study. After saving demographic and clinical data of patients, Trunk Control Test (TCT) and Trunk Impairment Scale (TIS) were used to determine trunk control.

Results

The mean age of the patients is 48.48 ± 13.54 years. According to stroke type, 24 (60%) patients are ischemic and 16 (40%) are hemorrhagic. Twenty-four (60%) of the affected body half are left and 16 (40%) are right hemiplegic. When trunk control measurements were compared with stroke type and lateralization, no statistically significant difference (p>0,05). At the same time, it was found a statistically significant positive correlation between TCT and static balance, dynamic balance and coordination sub-parameters of TIS and total TIS score (p<0,001).

Conclusion

Patients’ trunk control of hemiplegic patients is similarly disturbed after ischemic and hemorrhagic stroke. In addition, the severity of trunk dysfunction seen in both right and left hemiplegic patients is similar.

THE USE OF ARMEO®SPRING IN ACUTE STROKE

K. Mozina¹, J. Jansa¹, S. Martic¹, K. Angleitner Narobe¹, Z. Sicher², R. Koritnik¹, A. Praznikar¹

¹University medical centre Ljubljana, Neurological hospital, Ljubljana, Slovenia
²Faculty of Health Sciences, Occupational therapy, Ljubljana, Slovenia

Introduction/Background

Over the last decade, application of exoskeleton devices in clinical use has been increasingly more important. Armeo®Spring is one of them, providing weight support to the arm and also enables simulation of active movement in a safe and controlled way. Therefore, the aim of this study was to evaluate its efficacy in patients with acute stroke.

Material and Method

Consecutive stroke patients, referred to Occupational therapy (OT), have been, within a period of three months additionally screened for eligibility to use the Armeo®Spring. The inclusion criteria for treatment with an exoskeleton were at least voluntary movement in affected shoulder, being able to follow the demands of this device and sit for an hour. Patients who fitted the criteria and were willing to participate, undergone standard rehabilitation practice, and additional treatment for upper limb with an exoskeleton. They were assessed by the Barthel index (BI) and by the Fugl-Meyer Assessment (FMA) – upper extremity, prior and after the treatment with device. SPSS was used for analysis.

Results

There were 11 consecutive acute ischaemic stroke patients (seven men/four women), with an average age of 60±12, six have right hemiparesis and five has left hemiparesis. Average time of initiating the therapy was day 9± 9 (OT started at day 7±6,8) since admission and average days of therapy with the exoskeleton were 8±3,6. Average initial BI was 11,6±5,9 and average discharge BI was 14,8±6. This difference was significant at p<0,05. The average initial FMA was 96±19,6 and the average discharge FMA was 101±20,8. This difference was significant at p<0,05.

Conclusion

The use of an exoskeleton has proved to be a beneficial device for treatment of the hemiparetic hand after an acute stroke. Further clarification of the degree of change and its impact on the activities of daily living performance will be determined by additional comparison with a relevant control group.

DEVELOPING A CLINICAL PREDICTION RULE FOR DISCHARGE HOME IN PATIENTS WITH SEVERE STROKE.

Y. Inoue\textsuperscript{1,2}, J. Matsuba\textsuperscript{3}, S. Hiragami\textsuperscript{4}, K. Harada\textsuperscript{1,5}, F. Hiragami\textsuperscript{1,5}

\textsuperscript{1}Kibi International University, Research Institute of Health and Welfare, Takahashi, Japan
\textsuperscript{2}Kurashiki Heisei Hospital, Department of Rehabilitation, Kurashiki, Japan
\textsuperscript{3}Teikyo University of Science, Faculty of medical sciences, Tokyo, Japan
\textsuperscript{4}Hyogo University of Health Science, School of Rehabilitation, Kobe, Japan
\textsuperscript{5}Kibi International University, School of Health Science and Social Welfare, Takahashi, Japan

Introduction/Background

Even in patients with severe stroke, it is necessary to predict in an early stage whether they can be discharged home from hospital in order to offer the later services at home. The purpose of this study was to develop a clinical prediction rule (CPR) for discharge home after rehabilitation in patients with severe stroke.

Material and Method

The subjects were 206 patients with stroke during post-acute phase, registered in the Japan Rehabilitation Database, whose Functional Independence Measure (FIM) scores was 36 points or less. The following potential independent variables at the time of admission to the rehabilitation ward were collected: age, gender, side of lesion, duration since stroke onset, National Institutes of Health Stroke Scale score, cognitive status, speech disorder status, motor/sensory impairment status and scores of each item of FIM. The collected data were evaluated using Classification and Regression Trees (CART) analysis method to develop a CPR for discharge home.

Results

Forty-six percent of the patients were discharged home after rehabilitation. The CART analysis found the CPR included age, motor FIM score, motor impairment status of upper limb, functional status of eating, grooming, and memory (sensitivity=76.6%, specificity=76.8%, positive predictive value=73.5%, negative predictive value=79.6%, accuracy=76.7%). The best predictor for discharge home was the level of functional status of eating, the next predictors were age and motor FIM score.

Conclusion

The CPR with moderate accuracy was developed to predict discharge home after rehabilitation in patients with severe stroke. Further investigation including environmental factors is necessary to improve accuracy of the CPR.

AMBULATORY OUTCOME IN TOTALLY NON-AMBULATORY STROKE PATIENTS AFTER INPATIENT REHABILITATION
K.H. Kong¹, R. Krishna¹
¹Tan Tock Seng Hospital, Rehabilitation Medicine, Singapore, Singapore

Introduction/Background

Although previous studies have looked at outcome and predictors of ambulatory status in patients with impaired ambulation after stroke, what is scarcely reported is detailed knowledge of ambulatory outcomes in patients who are totally non-ambulatory on after stroke. This study aims to document ambulatory outcome and establish factors predicting outcome after rehabilitation in totally non-ambulatory patients admitted to our rehabilitation centre.

Material and Method

All stroke patients admitted to the rehabilitation center of Tan Tock Seng Hospital, Singapore are prospectively included in the center’s database. This was a retrospective review of data of patients admitted in years 2014 and 2015. Data analysed included: Functional Independence Measure (FIM), National Institute of Health Stroke Scale (NIHSS), Montreal Cognitive Assessment (MOCA), Fugl-Meyer Assessment (FMA) and Truncal Impairment Scale (TIS). Ambulatory status of patients in this study was evaluated based on the ‘walk’ score of the FIM. Total non-ambulators were defined as patients with a FIM-walk score of 1 on rehabilitation admission.

Results

577 stroke patients (mean age 63.2±11.8 years, ) were analysed. On admission, 113 (19.6%) of patients were total non-ambulators. Compared to other ambulators, total non-ambulators had significantly higher admission NIHSS, lower FMA-upper limb, FMA-lower limb, MOCA, FIM-motor and TIS scores and stayed longer in rehabilitation. Dysphasia, neglect and a haemorrhagic stroke was also significantly commoner in total non-ambulators. Post-rehabilitation, 20% remained as total non-ambulators, 46.0% achieved FIM-walk scores of 4-5 and 8.8%, FIM-walk scores of 6-7.

Univariate analyses predicting discharge ambulatory status revealed that age, dysphasia, neglect, NIHSS, FMA-upper limb, FMA-lower limb, MOCA, FIM-motor and TIS scores. Multivariate logistic regression analysis showed that only age, MOCA and FIM-motor scores remained independent predictors of discharge ambulatory status.

Conclusion
Almost 80% of totally non-ambulatory stroke patients had good ambulatory outcome after rehabilitation. Older age, poorer functional status and cognition are predictors of poor ambulatory outcome.

RESPONSIVENESS OF THE ACTIVITY MEASURE FOR POST-ACUTE CARE (AM-PAC) FROM DISCHARGE FROM INPATIENT STROKE REHABILITATION TO SIX MONTH FOLLOW-UP
M. O’Dell1, A. Jaywant2, E. Kwong1, R. Patel3, M. Frantz4, M. Taub1, J. Toglia5
1Weill Cornell Medicine, Department of Rehabilitation Medicine, New York, USA
2Weill Cornell Medicine, Department of Psychiatry, New York, USA
3NewYork-Presbyterian Hospital, Department of Rehabilitation Medicine, New York, USA
4Kaiser Permanente Northern California, Rehabilitation Medicine, San Francisco, USA
5Mercy College, School of Health and Natural Sciences, Dobbs Ferry, USA

Introduction/Background

Functional stroke scales must detect significant change over time, but defining “significant” is difficult. The Activity Measure for Post-Acute Care (AM-PAC) measures activity limitations in 3 domains: basic mobility (BM), daily activity (DA), and applied cognitive (AC). This study assesses the ability of the AM-PAC to detect change from inpatient rehabilitation facility (IRF) discharge (DC) to an outpatient setting 6 months (6M) later.

Material and Method

We analyzed data from an observational database for stroke patients treated at our academic IRF. We assessed AM-PAC domains at IRF DC and again by phone 6M later. Change between DC and 6M was calculated by: 1) standardized response mean (SRM, 0-0.4-0.6=moderate effect) and 2) proportion achieving the minimal clinically important difference (MCID, estimated as 0.5SD of baseline scores after Norman et al., 2003) with our data and 3) the published, mixed population minimal detectable change (MDC).

Results

Of 273 patients at DC, 139 (51%) had both AM-PAC scores and were included. Those included were not demographically different but were better on physical and cognitive measures at IRF admission. The mean age=67.1±14.8y, NIHSS=7.9±7.5, discharge FIM=84.1±19.1, FIM Gain=20.2±10.6, and rehabilitation length of stay=14.8±7.6d. The mean DC/6M scores for BM were 51.7±11.2/56.0±12.1, DA=44.4±9.9/49.2±14.5 and AC= 40.0±9.8/44.7±9.2. Change metrics for the 3 AM-PAC domains are below:

<table>
<thead>
<tr>
<th>AM-PAC Domain</th>
<th>Current Data SRM</th>
<th>Current Data MCID(%)</th>
<th>Current Data responders at 6M</th>
<th>Published MDC</th>
</tr>
</thead>
<tbody>
<tr>
<td>BM</td>
<td>0.43</td>
<td>5.81 (37.4%)</td>
<td></td>
<td>4.28 (46%)</td>
</tr>
<tr>
<td>AM-PAC Domain</td>
<td>Current Data SRM</td>
<td>Current Data MCID(%) responders at 6M</td>
<td>Published MDC (%) responders at 6M</td>
<td></td>
</tr>
<tr>
<td>---------------</td>
<td>------------------</td>
<td>--------------------------------------</td>
<td>-----------------------------------</td>
<td></td>
</tr>
<tr>
<td>DA</td>
<td>0.36</td>
<td>5.32 (40.3%)</td>
<td>3.70 (49.6%)</td>
<td></td>
</tr>
<tr>
<td>AC</td>
<td>0.48</td>
<td>5.01 (49.6%)</td>
<td>5.55 (47.5%)</td>
<td></td>
</tr>
</tbody>
</table>

**Conclusion**

Between 40%-50% of stroke patients were classified as “significantly” improved, depending on measure, suggesting the AM-PAC is able to capture “real life” change. The sample experienced change at the lower end of “moderate improvement” by SRM. Estimated MCID and the MDC were similar for DA and AC, not BM. Further research should explore factors which predict functional success or failure.

PREDICTION OF FUNCTIONAL AMBULATION WITH SITTING POSTUROGRAPHY IN PATIENTS WITH SUBACUTE HEMIPLEGIC STROKE
J.W. Lee¹, B.R. Kim¹, J. Lee¹²
¹Konkuk University Hospital, Department of Rehabilitation Medicine, Seoul, Republic of Korea
²The Graduate School of Konkuk University, Department of Rehabilitation Medicine, Seoul, Republic of Korea

Introduction/Background

The purpose of this study is to investigate the usefulness of sitting posturography in stroke patients.

Material and Method

A retrospective review of medical records was performed for subacute hemiplegic stroke patients admitted to the university hospital from December 1, 2016 to May 31, 2017. Twenty-nine patients (17 males and 12 females; average age, 63.41±15.44 years) were evaluated for balance ability using sitting posturography and clinical assessment of balance, such as Scale for the Assessment and Rating of Ataxia (SARA, using balance categories) and Berg Balance Scale (BBS). Posturography parameters are consisted of percentages of weight bearing distribution (WBD), static stability and dynamic stability. Static stability index was obtained by measuring sway of surface area and length from the center of pressure. The limit of stability (LOS), representing the dynamic stability. In addition, gait status were also assessed by Functional Ambulatory Categories (FAC) after 4 weeks of conventional treatment. Collected data were statistically processed using Pearson correlation coefficients to investigate the relationships between posturography parameters and the clinical assessment of balance (BBS, SARA). Multiple regression analysis was used to find independent variables related to FAC after 4 weeks of conventional rehabilitation.

Results

The average ratio of percentages of WBD and ratio of LOS were 0.852±0.09, 0.766±0.23, respectively. A strong relationships were found in posturography parameters (ratio of percentages of WBD, ratio of LOS) in regards to BBS (r=0.761, r=0.781, p<0.01) and SARA (r=−0.852, r=−0.804, p<0.01) scores. The ratio of LOS statistically significantly predicted FAC after 4 weeks. (b = 1.89, SE = 0.72, 95% CI =3.38, 0.40, p <0.01)

Conclusion

In patients with subacute hemiplegic stroke, sitting balance parameters of posturography correspond well with SARA and BBS. Furthermore, our data suggest that the ratio of LOS, which evaluated in sitting position, can significantly predict FAC after 4 weeks of rehabilitation.

Stroke is the major cause of disability in many countries. The annual incidence of stroke in Iran has been reported to be in a range from 23 to 103 per 100,000 people in 2010, causing a significant burden. Many studies have indicated the effectiveness of rehabilitation after stroke on things such as improvement in activities of daily living (ADL) and reduction of disability as well as mortality rate. Therefore, based on various and valid guidelines in this field, adaptation of the available guidelines into one suitable for the Iranian population was taken into consideration.

Material and Method

After selecting the subject and determining the scope of the guideline, the clinical questions, based on PICO were designed. Then, recent guidelines were searched for and reviewed using the AGREEII tool, in order to select the more suitable ones. Developing the initial scenarios (as the alternatives to a clinical problem) and analyzing the clinical advantages and cost-effectiveness were the next steps.

Results

In internal expert review panel, final recommendations were approved after revision by a number of Iranian professionals who were expert in various aspects of stroke rehabilitation. Final recommendations included these topics: design of a comprehensive rehabilitation program, general principles of care in rehabilitation service, rehabilitation of common impairments, the interaction of patients and their families or caregivers, early supported discharge, and pre- and post-discharge considerations.
Conclusion

Due to the high diversity of rehabilitation measures in this field, this clinical guideline aimed at prioritizing these measures based on efficiency and cost effectiveness by considering the national capacities and limitations. All expert Iranian societies related to rehabilitation approved this guideline.

**Diffusion Tensor Imaging as a Prognostic Biomarker for Motor Recovery in Patients with Pontine Infarction**

**M. Kim**, J.H. Leigh

*Incheon St. Mary’s Hospital- College of Medicine- The Catholic University of Korea, Department of Rehabilitation Medicine, Incheon, Republic of Korea*

**Introduction/Background**

To investigate the dynamic evolution of diffusion indexes in the corticospinal tract (CST) distal to a pontine infarct by using diffusion-tensor imaging, to determine the relationship of these indexes with clinical prognosis, and to explore the structural changes in the motor pathway during recovery.

**Material and Method**

Twenty-four patients (17 men; average age, 58.6 years; range, 42–83 years) were recruited for this study. All patients were diagnosed with pontine infarct and underwent diffusion-tensor imaging examinations after stroke (mean duration: 50±115 days). Reconstructions of the CST were performed. All Fiber numbers were measured in the medulla, cerebral peduncle, internal capsule, and centrum semiovale. Fiber numbers across the pons of the CST in the ipsilateral side of the infarct were calculated. Their relationships with clinical scores such as Fugl-Meyer score (FMS), Berg balance test (BBS) and Modified Barthel index (MBI) were analyzed by using Pearson correlation analysis. A P value of .05 (two tailed) was considered to indicate a significant difference for all statistical procedures.

**Results**

All patients had some degree of motor deficit. The FMS ranged from 0 to 66 at the first examination. The number of fiber across pons were correlated positively with BBS at discharge ($r=0.549$, $P=0.005$) and MBI at discharge ($r=0.682$, $P=0.000$). Fractional ratio of fiber across pons (The number of fiber across pons/total number of CST fiber) were correlated positively with BBS at discharge ($r=0.423$, $P=0.039$) and MBI at discharge ($r=0.511$, $P=0.013$). Difference between admission and discharge of MBI score was well correlated with the number of fiber across pons ($r=0.436$, $P=0.038$) diffusion-tensor tractographic images showed regeneration and reorganization of the motor pathways.

**Conclusion**

Secondary degeneration of the CST can be detected at diffusion-tensor imaging in the subacute stages after pontine infarction, which could help predict the motor outcomes. Diffusion-tensor tractography can allow detection of regeneration and reorganization of the motor pathways during recovery.

ASSOCIATION BETWEEN THE INTENSITY OF OUTPATIENT REHABILITATION THERAPY AND THE RISK OF DEMENTIA IN PATIENTS OF ISCHEMIC STROKE
H.K. Yu

Introduction/Background

Patients with stroke have an increased risk of dementia. Some studies have found that outpatient rehabilitation programs may improve cognitive function in chronic stroke patients. However, little is known about the use of rehabilitation in the outpatient setting and its impact on the risk of dementia. The objective of this study was to examine the association between the intensity of outpatient rehabilitation services received and the risk of dementia.

Material and Method

We used the National Health Insurance Research Database in Taiwan to identify 16264 patients diagnosed with stroke from 1997 to 2005. Rehabilitation intensity was categorized as none, low, medium or high based on the sum of physical therapy, occupational therapy, and speech therapy within the first 6 months after discharge from inpatient rehabilitation. Cox proportional hazard regression models were used to evaluate the association between the intensity of rehabilitation and the risk of dementia.

Results

During the follow-up period (median, 7.5 years), 1429 patients were diagnosed with incident dementia. Compared to patients in the no rehabilitation group, those who received high intensity therapy had a decreased risk of dementia during the follow-up period (hazard ratio, 0.68; 95% confidence interval, 0.56–0.84). The results remained consistent in analyses stratified by gender.

Conclusion

The intensity of outpatient rehabilitation therapy and the risk of dementia was significantly inversely related in the ischemic stroke patients. Thus, further programs aimed at promoting greater use of outpatient rehabilitation services in patients with stroke are warranted.

SENSORIMOTOR STRATEGIES FOR THE IMPROVEMENT OF NAMING ABILITIES IN APHASIA: NEURAL AND BEHAVIOURAL CORRELATES OF POEM- PERSONALIZED OBSERVATION, EXECUTION, AND MENTAL IMAGERY THERAPY
E. Durand¹, P. Berroir¹, A.I. Ansaldo¹
¹Centre de Recherche de l'Institut Universitaire de Gériatrie de Montréal, Laboratoire Ana Inés Ansaldo, MONTREAL, Canada

Introduction/Background

Anomia is the most frequent and pervasive symptom for people with aphasia (PWA) and can affect all grammatical categories. Research has long focused on name retrieval, while therapies targeting verb anomia remain scarce. Single word retrieval therapy for verbs is effective across different approaches. Nevertheless, the impact of sensorimotor strategies on aphasia recovery has been rarely explored. This study reports on the efficacy of Personalized Observation, Execution, and Mental Imagery therapy (POEM), a new therapy approach designed to integrate sensorimotor and language based strategies to treat verb anomia.

Material and Method

Two participants with chronic aphasia and verb anomia were followed-up in a pre-post therapy fMRI study. Tests of language and cognitive functions were completed. A personalized set of stimuli was built based on the naming performance on baseline controlled for linguistic variables. POEM therapy was administered in a massed stimulation schedule: three 60-minutes sessions per week for 5 weeks.

Results

The results show a significant improvement in both participants, with trained and untrained items. Changes in fMRI patterns following POEM reflect a reduction in the number of recruited areas supporting recovered naming, and the recruitment of brain areas, part of language and mirror neuron systems.

Conclusion

This study originally contributes to the research on verb anomia treatment with an innovative structured combination of sensorimotor strategies allowing PWAs to retrieve more precisely and quickly treated and untreated verbs. Changes in fMRI patterns following POEM reflect a reduction in the number of recruited areas supporting recovered naming, and the recruitment of brain areas, part of language and mirror neuron systems. Future studies with a larger sample of participants are required to further explore this avenue.

RESTORATION OF NORMAL SWALLOWING FUNCTION IN WALLENBERG SYNDROME BY REPETITIVE ELECTRICAL STIMULATION AND SPEECH LANGUAGE PATHOLOGIST TREATMENT. A CASE REPORT.

A. Giattini¹, S. Cocci Grifoni¹, M. Capriotti¹, E. Guarnelli¹
¹Inst. S. Stefano, Rehabilitation, Ascoli Piceno, Italy

Introduction/Background

Oropharyngeal dysphagia is common in patients with Wallenberg syndrome. Although the functional outcome is good for most patients, the risk of inhalation pneumonia is high. Nevertheless, some patients exhibit permanent and chronic oropharyngeal dysphagia with pharyngeal residue and bronchial aspiration. In such cases, the central pattern generator for swallowing may be affected [1]. We report 1 case for which we proposed a novel strategy based on repetitive electrical stimulation and a traditional speech language pathologist (s.p.l.) treatment.

Material and Method

Methods

P. B. 74 y.o. affected by Wallenberg syndrome diagnosed at the Neurologic Unit in S. Benedetto del Tronto Hospital. Patient had hemiparesis, walking impairment, and dysarthria. Nutrition was only possible by feed tube because of severe aspirations. Swallowing was evaluated by clinical assessment, DOSS and MISA scales, FEES. The treatment began one week after admission to our Rehabilitation Division. She was submitted to daily electrical stimulation treatment (Vitalstim, Chattanooga, CA) five times per week and to the s.p.l. treatment three times per week.

Results

Results

General motor activities improved gradually with the physiotherapy. After four weeks, the assessment was completely repeated. The feed tube was removed and the patient began to feed orally. After the first assessment the patient began to be fed with pureed foods. She continued physiotherapy in the Rehabilitation Unit for one additional month. After discharge the patient carried on the rehabilitation treatment in our outpatient center, totally recovering swallowing abilities, and eating foods with all textures.
Conclusion

Conclusions

Swallowing evaluation for this case demonstrated no aspiration with all food consistencies and slight stasis for pureed food in the operated hemi-pharynx. With Wallenberg syndrome recovery is very rare. Vitalstim seemed to help recovery as demonstrated in other studies.

Keywords

Wallenberg; dysphagia; electrical stimulation

No conflict of interest
Introduction/Background

A stroke often results in functional impairments of the affected upper limb and in distorted upper limb use of the affected arm in daily life (ULUaff). It is currently unclear how ULUaff recovers after stroke and how it relates to upper limb function (ULF). Therefore, the aims of this study were to explore the recovery of ULUaff post-stroke and its relationship with the recovery of ULF during rehabilitation.

Material and Method

In fifteen people after stroke receiving ‘usual care’ in a rehabilitation center, ULUaff and ULF was assessed at 3, 12, and 26 weeks post-stroke. ULUaff was estimated for one week using an activity monitor consisting of three accelerometers: one on the unaffected leg and one on each wrist and was defined as the ratio of the amount of movement of the affected arm divided by the unaffected arm, with 1 expressing equal levels of use. ULF was measured with the Fugl-Meyer Assessment (FMA).

Results

Data of 10 participants could be used for analysis. At 3 weeks, ULUaff was on average 0.26 with a large inter-individual variability (ranging from 0.14 to 0.62). The average ULUaff increased to 0.37 at 12 weeks and 0.43 at 26 weeks. The recovery patterns also showed a large inter-individual variability (Fig 1). Changes in ULUaff had no significant correlation with changes in ULF (r=0.48, p=0.18**, Fig. 2).
Conclusion
At group level the amount of use of the affected arm is strongly affected in the 6-month period after a stroke, but increases over time. However, considerable inter-individual differences were found, in the amount at three time moments post-stroke as well as in the recovery patterns. Recovery of use of the affected arm was not related to recovery of upper limb function.

THE VALUE OF FRONTAL ASSESSMENT BATTERY IN STROKE PATIENTS
M. Kim¹, J.H. Leigh¹, M.H. Han¹
¹Incheon St.Mary's Hospital- College of Medicine- The Catholic University of Korea,
Department of Rehabilitation Medicine, Incheon, Republic of Korea

Introduction/Background

The aim of this study is to evaluate the value of Frontal Assessment Battery (FAB) compared with Mini-Mental State Examination (MMSE) for detecting frontal lobe dysfunction and evaluate the correlations between FAB and neurocognitive function test.

Material and Method

Medical records of stroke patients underwent cognitive assessment including the FAB and MMSE were retrospectively reviewed and the patients divided into three groups; lesions involving frontal lobe cortex, lesions related with frontal subcortical circuit and other lesion groups. We compared the FAB and MMSE scores, especially frontal lobe function domain among these groups.

Results

A total of 186 Patients with frontal lobe lesion had significantly lower total FAB score compared to other lesions with frontal subcortical circuit. In correlation with neurocognitive function test, FAB scores were more correlated with measures of high cognitive function and memory tests, such as trail making test A, card sorting test, digital span and visual span, than MMSE. Even after controlling MMSE scores, FAB scores were correlated with trail making test A, digital span and visual span tests. In scatterplots, there was a positive correlation between MMSE and FAB scores. When divided group by median MMSE score, high MMSE score group showed lower
correlation with FAB compared to low MMSE score group. (Figure 1)

Conclusion

FAB showed better correlation with other frontal lobe function tests than MMSE, especially executive and memory functions domains. The FAB scores were proportional to MMSE scores and this correlation was more prominent in low MMSE score group. In patients with high MMSE scores, there may also be frontal dysfunction that cannot be detected with the MMSE score, therefore additional FAB testing should be performed. The FAB has screening value for frontal lobe function added to MMSE and can be used in clinical to detect cognitive impairment more specifically.

FAB, Frontal Assessment Battery; MMSE, Mini-Mental State Examination

When divided group by median MMSE score (MMSE = 23), high MMSE score group (Pearson’s correlation coefficient r=0.542; p<0.001) showed lower correlation with FAB compared to low MMSE score group (Pearson’s correlation coefficient r=0.759; p<0.001).

PILOTHING THE “STEPPING ON AFTER STROKE” FALL PREVENTION PROGRAM FOR COMMUNITY STROKE SURVIVORS IN SINGAPORE: A FEASIBILITY STUDY

T. Xu¹, L. Clemson², K. O’Loughlin², N. Lannin³, G. Koh⁴, C. Dean⁵

¹Singapore Institute of Technology, Health and Social Sciences Cluster, Singapore, Singapore
²The University of Sydney, Faculty of Health Sciences, Sydney, Australia
³La Trobe University, Department of Community and Clinical Allied Health, Melbourne, Australia
⁴National University of Singapore, Saw Swee Hock School of Public Health, Singapore, Singapore
⁵Macquarie University, Faculty of Medicine and Health Sciences, Sydney, Australia

Introduction/Background

Intervention studies to date have shown limited evidence of fall reduction in community-living stroke survivors. The Stepping On after Stroke (SOAS) program for community-living stroke survivors is a newly developed program that aims to reduce falls and improve post-discharge community participation. This study aims to test the feasibility and outcomes of the SOAS program with community stroke survivors and their caregivers in Singapore.

Material and Method

We sought to run the program in two community sites. Feasibility was measured by reporting subject recruitment, attendance and compliance; the applicability of the program measured using field notes, surveys and qualitative interviews. Fidelity to program content was measured using an adapted fidelity checklist. Content analysis of data from interviews and field notes was conducted. Pre-post clinical outcome collected at baseline and one month post-intervention were analysed using SPSS; graphs and descriptive statistics were generated to visualize the trends. Fall incidence was measured using self-report, and collected at monthly for 6 months.

Results

Two programs were completed with a total of eight stroke participants, seven caregivers and two program leaders. All stroke participants attended 100% of sessions over the 7-week program. All participants highlighted the applicability of having group-based fall prevention program in the local context. Group discussion, the role of program leaders as facilitators, and the involvement of the caregivers were seen as important factors in implementing the program by all participants. Stroke participants demonstrated significant improvement in community participation at one month post-intervention follow up.

Conclusion
It is feasible to run the SOAS program for community-living stroke survivors in Singapore. The study findings can be used to further improve the program and its methodology, and determine its cost-effectiveness in a larger scale study.

EFFECTS OF PROGRESSIVE RESISTANCE STRENGTH TRAINING OF LOWER LIMB IN HEMIPLEGIC PATIENTS: A PRELIMINARY STUDY
A. Haj Salah¹, M. Sghir¹, A. Abdalah¹, N. Guizani², M. Lamloumi², A. Mahjoub², W. Kessomtini¹
¹University Hospital Tahar Sfar, Department of Rehabilitation, Mahdia, Tunisia
²School of Physiotherapy, physiotherapist, Monastir, Tunisia

Introduction/Background

Muscle weakness is one of the major symptoms that develop as a result of a stroke and can lead to a reduction in physical activity. An impairment in walking performance can be observed, resulting in asymmetry and a decrease in speed as well as an increase in energy cost.

The purpose of our work is to determine the effects of progressive resistance strength training of lower limb associated with conventional rehabilitation in chronic hemiplegic patients following stroke, on strength, walking and balance.

Material and Method

We conducted a comparative study of 12 patients with chronic-phase stroke who were divided into two groups, group A who underwent conventional rehabilitation, and group B who received treatment based on progressive resistance muscular strengthening exercises associated with conventional rehabilitation. Evaluation parameters were the muscle strength, the balance and the walking.

Results

It seems from the results obtained that muscular strengthening clearly improves the strength, the timed up and go and the Berg balance scale. A less notable improvement in speed and walking distance was also obtained.

Conclusion

Progressive resistance muscle strengthening in combination with conventional rehabilitation seems to be an effective approach in the management of patients with chronic hemiplegia.

⁴University of Tsukuba, Rehabilitation, Tsukuba, Japan
⁵University of Tsukuba, Radiology, Tsukuba, Japan
⁶University of Tsukuba, Orthopedic surgery, Tsukuba, Japan

Introduction/Background

Robot therapy becomes more and more important in clinical practice. In our facility, a robot suit HAL® (hybrid assistive limbs) has been applied to stroke patients for several years. In addition, we evaluated their motor function and brain function using functional MRI along the robot therapy. In this study, we investigated the relationships between motor and brain functions during recovery from acute stroke.

Material and Method

Acute stroke patients participated to this study. The robot therapy with HAL® applied a participant two or three times a week in two or three weeks during hospitalization in addition to conventional rehabilitations. We also acquired 10m walk speed and functional MRI along the therapy almost two times a week. Functional connectivity (FC) among the 20 regions, assumed as motor related area, were calculated from functional MRI. The relationships between the walk speed and FC were evaluated statistically.

Results

Five subjects, 3 men and 2 women, participated, and gave their informed, written consent. The subjects (mean age; 49.8 years from 12 to 79) with acute stroke (3 intracranial hemorrhages and 2 cerebral infarctions) suffered left hemiparesis, and were applied the robot therapy. All patients gradually improved in walk speed. Statistically significant FC were shown in many regions, and the most significant FC in each side was between primary motor area and primary somatosensory area. The statistically significant negative correlation between walk speed and FC was found at between primary motor area in unaffected side and premotor area in affected side. That might suggest the relationships among functional connectivity and interhemispheric inhabitation.

Conclusion
The robot therapy with HAL® was performed for acute stroke patients. They improved gradually in motor function, and the walk speed and functional connectivity between primary motor area in unaffected side and premotor area in affected side were correlated negatively.

MULTI-SEGMENTAL MUSCLE STRENGTHENING ORGANIZED (PNF CONCEPT) IN HEMIPARETIC PATIENTS.

S. Mesure¹, N. Abdelnour², S. Nadeau³

¹Institut of mouvement science, UMR- FSS 7287 Aix Marseille Université, Marseille, France
²Universite de St Joseph, Faculté de Médecine- Institut de Physiotherapie, Beyrouth, Lebanon
³Physiotherapie institut- université de Montréal, Faculté de Médecine, Montréal, Canada

Introduction/Background

The postural organization and gait strategies are disrupted due to brain damage. Thus, improved proprioceptive sensitivity could increase voluntary movement and decrease muscle weakness, leading to a progress in the clinical condition of the patient. In this study we investigated the efficacy of a therapeutic program involving tridimensional multi-segmental coordination, on global proprioceptive recovery in post-stroke hemiparetic individuals, in order to allow them a more efficient functional recovery with a view to their autonomy of displacement.

Material and Method

The study involved 31 volunteer post-stroke participants in 2 groups of 16 and 15 patients. 1 control group training (CGP) which received after normal rehabilitation, 30 minutes of segmental muscle training against gravity in three positions (supine, sitting and standing) of the paretic limb. 1 muscle chain training group (CMG) which received after normal rehabilitation, 30 minutes of muscle training using the concept of muscle chain synergies. All patients were assessed before and after treatment on posture (normal erect position), gait test, strength test and on the KATZ range of autonomy. The patients groups are matched in all particularities.

Results

Overall, our results show an improvement in the functional level of CMG compared to the CGP, even if the level of functional autonomy of all 31 patients improves associated to the rehabilitation. The clinical improvement of the patients' possibilities appears more marked for the CMG group between the beginning and the end of the study, for all evaluated parameters (except for the 10 m walk).

Conclusion

From all our results, the work in multi-segmental and three-dimensional synergistic chains gives a clinical picture extremely sensitive to proprioceptive information organized and structured at the cortical level. We observe an effect on the functional index, as well as on postural indexes and dynamometric evaluations, which represent the basis of coordination, necessary for the establishment of an appropriate motor program.

RESILIENCE THROUGH ADAPTIVE RECREATION IN STROKE SURVIVORS: A BIOPSYCHOSOCIAL APPROACH

K. Hreha¹, A. Kirby², I. Molton¹, N. Nagata², A. Terrill²
¹University of Washington, Rehabilitation Medicine, Seattle, USA
²University of Utah, Department of Occupational and Recreational Therapies, Salt Lake City, USA

Introduction/Background

Due to medical advances, survivability after stroke is increasing. Intensive rehabilitation focusing on regaining physical, cognitive, and language function, is often necessary after stroke. However, stroke survivors are at risk of chronic disability, depression, and social isolation. Community-based providers, such as adaptive recreation programs, are often challenged to continue the long-term job of rehabilitation and community reintegration after stroke. The objective of this study was to explore the effects of adaptive cycling participation (using modified equipment or assistive devices) on aspects of physical, psychological and social resilience in stroke survivors. We hypothesized that participants, who engaged in a 16-week cycling program, would demonstrate improvement on measures of all three aspects of resilience.

Material and Method

The current study utilized a longitudinal design (baseline, 8, and 16 weeks). Outcome measures include: resting heart rate, 10 Meter Walk Test (10MWT), 2 Minute Walk Test (2MWT), Timed Up and Go, UW-Self-efficacy Scale, NeuroQOL Positive Affect and Well-being, Connor-Davidson Resilience Scale, NeuroQOL Satisfaction with Social Roles and Activities (SSRA), Interpersonal Support Evaluation List. Due to sample size and exploratory design, we calculated effect sizes.

Results

We enrolled 18 stroke survivors (ages 25-72) in the study. Outcomes were available at all time points for 10-18 participants depending on the measure. Pairwise comparisons were calculated between baseline to 8-weeks and baseline to 16-weeks. We observed change score effect sizes >0.5 for one social and two physical measures. For baseline to 8-weeks, the NeuroQOL-SSRA had a medium effect (Cohen’s d=.564). For baseline to 16-weeks, the 2MWT and 10MWT had large and medium effects respectively (d= 1.068 & 0.612).

Conclusion

The results highlight the importance of exploring: (1) the influence of adaptive recreation on not only physical but social outcomes. Due to the exploratory design of this pilot, future research is warranted.

EXOSKELETON LOCOMOTION TRAINING OF PATIENTS WITH STROKE: OUR PROTOCOL AND EXPERIENCE

G. Foteinopoulos¹, E. Badani¹, S. Mpakogianni¹, M. Fragkaki¹, K. Saramoutsis¹
¹Animus Rehabilitation Center, Rehabilitation, Larissa, Greece

Introduction/Background

Advances in rehabilitation technology, such as powered exoskeletons, have given patients with stroke the opportunity to walk, to improve their gait, health and psychological status, thereby reducing their stay in the rehabilitation center.

Material and Method

Exoskeleton walking training (EWT) has been used in our center as part of the rehabilitation program of stroke patients for the last 18 months. Patients were selected using strict criteria. Parameters such as standing time, walking time, total number of steps, the statistics of the last 60 steps were recorded. mAshworth and Oxford scale were used for spasticity and muscle power assessment, pre- and post EWT.

Results

Until now, 10 stroke patients male and female from 27 to 65 years old with ischemic or haemorrhagic stroke (I) or (r) hemiparesis, participated in EWT program. The program included 2 sessions per week, for 8 weeks. Totally, 131 EWT sessions have been done; average sessions’ number per patient: 18.

Conclusion

Despite the small number of patients, EWT has been shown effective in promoting ambulation, improving balance and perception of patients with stroke decreasing spasticity and enhancing health status. As disadvantages, we consider the strict somatometric criteria (weight<100 kg, hip width, upper and lower leg length, normal range of motion) and the necessity of two therapists’ involvement.

UPPER LIMB POSITION SENSE QUANTIFICATION USING ROBOTICS IN PATIENTS WITH STROKE: PRELIMINARY RESULTS
A.K. Blanchet1, A. Deblock-Belamy1, C.S. Batcho1, M.H. Milot2, C. Mercier1
1CIRRIS - Université Laval, Département de réadaptation - Faculté de Médecine, Quebec City, Canada
2Centre de recherche sur le vieillissement - Université de Sherbrooke, Faculté de médecine et des sciences de la santé, Sherbrooke, Canada

Introduction/Background

Proprioceptive deficits affect around 50% of stroke survivors. Most commonly used proprioception assessments have poor psychometric properties and are not adapted for people with multiple impairments. To address these limitations, we developed an assessment protocol that enables the quantification of elbow position sense without using the opposite arm, involving active movement of the evaluated limb or relying on working memory. The objectives of this study were to quantify elbow position sense of stroke survivors and to compare it with a control group.

Material and Method

Elbow position sense of the affected arm was quantified in subacute stroke patients and compared to age-matched healthy persons. Elbow position sense was evaluated using a KINARM exoskeleton and a virtual reality display. The exoskeleton passively moved the participant's arm from an initial to a target position (no visual cues of arm position). A virtual arm representation was then projected on a screen placed over the participant's arm. The participant had to indicate verbally its relative position (more flexed or more extended) compared to the virtual representation. A 75% detection threshold was extracted from a sigmoid curve fit representing the relationship between the angular difference and the percentage of successful trials. Independent T-tests were used to compare the results of both groups.

Results

Eleven people with a stroke (67±9 yrs old; 6 males; 72±30 days post-lesion) and 19 age-matched controls (63±6 yrs old; 8 males) were recruited. A significant difference in the mean elbow position sense detection thresholds between the stroke group (12.8±5.2 degrees) and the control group (7.2±3.5 degrees) was noted (p=0.001).

Conclusion

This robotic assessment enables the quantification of elbow position sense in patients with stroke. Difference in detection thresholds observed between both groups demonstrated that
stroke survivors might have impaired proprioception. More participants are required to confirm these results.

ISPR8-1861
CEREBROPRO: RETURN-TO-WORK AFTER BRAIN INJURY: A PROSPECTIVE COHORT STUDY.
K. Autret¹, P. Begaud¹
¹Pôle MPR Saint HELIER, Neurology, RENNES, France

Introduction/Background

To study return to work after 3 years of patients who present an acquired brain injury and to evaluate occupational reintegration unit efficiency as well as predictive epidemiologic factors of returning to work.

Material and Method

This is a prospective monocentric study realized at the Physical Medicine and Rehabilitation Center of Saint-Hélier. All working-age patients who present a traumatic brain injury or a stroke, even those who don't work before, were included between the 01-01-2014 and the 12-31-2014. The patients were joined by phone 3 years after inclusion to know about there current professional situation.

Results

85 patients were included, the response rate was 82% (70 patients), the average age was 48 years (18-66) and the sex ratio 1,92. 16 patients present traumatic brain injuries and 54 strokes. Average PMSI was 12 (6-24). 57 (81%) were working before brain injury, 30 patients were followed by the occupational reintegration unit.

28 patients (40%) were working after 3 years, among those who work before, 26 (45%) return to work. Significant prognostic factors were to work before brain injury and the fact that patients consult there occupational physician. We don’t found other prognostic factors.

Conclusion

In international literature return to work varies from 13 to 70% for traumatic injury and from 19 to 73% for strokes. But most of studies follow patients who already worked before injuries. Only few studies follow patients at 3 years.

The professional reintegration of those patients seems to be facilitated by the presence of a job before their injury and the collaboration between the patient, the Physical Medicine and Rehabilitation Center and the occupational health services.

Introduction/Background

Falls after stroke are a major health concern, as they are one of the most frequent complications. An important and effective strategy to avoid falling is the "change of support" strategy, which is characterized by rapid compensatory stepping and/or grasping that increase the base of support, and by so, stability is regained. Using the arms may also be an effective way to avoid falling when balance is lost due to balance perturbations. Here we aimed to characterize the arm responses to perturbations in stroke patients.

Material and Method

15 post-stroke subjects and 15 age and gender matched healthy controls were exposed to unexpected surface translations while standing on a movable platform (Balance Tutor, MediTouch, Israel). Perturbation intensity increased in six levels of difficulty. Kinematic parameters were collected using the Ariel Performance 3D motion Analysis System (APAS) and the data was analyzed by MatLab algorithms written especially for the study.

Results

Post-stroke subjects and healthy controls had a symmetric response with two arms. Stroke group had a few reactions with one arm mostly with the paretic arm. We found a significant difference in the overall arm displacement and overall arm velocity between the right arm of control group and the paretic arm of stroke group. When we compared between the paretic and non-paretic arms of stroke survivors we found that the non-paretic arm had a faster reaction time, larger displacement and the paretic arm has a higher velocity. Arm reaction time was faster than leg reaction time.

Conclusion

Our results show that hemiparetic stroke patients have the ability to respond with both arms, similar to healthy control subjects, but stroke survivors’ responses seems to have reflexive and spastic movement patterns, not as effective as the movement patterns observed in healthy controls.

THE REALITY OF AN ACUTE STROKE UNIT IN PORTUGAL
J.V. Gonçalves¹, J. Santos¹, A. Campolargo¹
¹Centro Hospitalar Vila Nova de Gaia / Espinho,
Physical and Rehabilitation Medicine Department, Vila Nova de Gaia, Portugal

Introduction/Background

Despite several acute stroke units (ASU) in Portugal, stroke is still a major cause of morbidity and death in our country. The aim of this work was an epidemiological study of some variables of all the patients admitted in the ASU in our Hospital.

Material and Method

Retrospective and descriptive study was done by using SPSS 25. Evaluation of the discharge letters from 1 February 2017 till the first 200 patients was done to retrieve the information.

Results

From a total of 200 patients admitted in the ASU were selected all the ischemic stroke (167 – 83%). The average age was 72.2 years with 102 male patients and 65 female patients. There was no relationship between the length of stay and the patient age. There was also no relationship between the type of procedure and the length of stay. Most of patients (73) were discharged to home with physical treatment and there was no relationship between the procedure and the destination of discharge.

Conclusion

This analysis shows it is necessary to keep evaluating the discharges from this unit to see if some relationship can be achieved. The prevalence of ischemic stroke in this unit and the median age of patients was similar to several studies described in the literature.

THE IMPACT OF OSTEOARTHRITIC KNEE PAIN ON THE FUNCTIONAL STATUS OF THE LOWER LIMBS IN AMBULATORY STROKE PATIENTS

T. Shafshak¹, E. Shahine¹, N. Abdel-Hameed¹
¹Faculty of Medicine- Alexandria University- Egypt, Physical Medicine- Rheumatology & Rehabilitation, Alexandria, Egypt

Introduction/Background

Osteoarthritic knee pain (OAKP) may interfere with stroke rehabilitation. The aim of this work was to assess the impact of OAKP on the lower limb function in ambulatory stroke patients.

Material and Method

Participants were 25 hemiparetic patients with OAKP. Exclusion criteria: non-ambulatory patients, those with contraindication to NSAIDs and those having any other lower limb disorder that interferes with walking ability (e.g. peripheral neuropathy, injury, foot ulcer, infection, tendinitis or bursitis). All patients were subjected to careful examination. Knee pain severity was assessed (by VAS and VRS). Impairment was assessed using the Fugl-Meyer lower extremity motor performance (FMLL). Also, the 10 meters walking time (10mWT) was assessed.

Results

Knee pain severity decreased following diclofenac potassium injection in either the hemiplegic or the non-hemiplegic side (p<0.01). Also, the 10mWT decreased following injection (p<0.01). The 10mWT correlated positively with knee pain VAS on the hemiplegic side (p<0.05) whether done before or after treatment. Furthermore, there was a positive correlation between the improvement in walking time and knee pain relief on the hemiplegic side (p<0.05). There was no correlation between radiographic grading and either VAS, VRS, 10mWT and FMLL scores.

Conclusion

OAKP has a negative impact on walking speed among stroke patients. Thus, care should be taken to treat OAKP during stroke rehabilitation.

Introduction/Background

Cerebral stroke is the major cause of disability and, given its consequences, poses serious medical and social problems. The functional outcomes have been much studied but the impact on quality of life is little known.

The aim of the present study is to evaluate impact of stroke on the quality of life and the prevalence of depression and anxiety during the first two years post stroke.

Material and Method

This is a cross-sectional study. It included patients with the first ischemic cerebral stroke of moderate and mild severity. The quality of life was evaluated based on the SF 36 (short form 36) and the hospital anxiety and depression scale (HAD) was used to specify the prevalence of depression and anxiety.

Results

Preliminary results:

Fifty patients were enrolled with the mean age of 54.5 years. Twenty-seven were men. All patients had ischemic stroke. The quality of life of the patients was significantly reduced in 76% of the cases: Items evaluated with the SF36 were: Physical functioning (average in percentage: 36.5%), Role limitations due to physical health (24%), Role limitations due to emotional problems (39.7%), energy/fatigue (57%) Social functioning (32%), Pain (47.5%), General health (41%).

The average of HAD (hospital anxiety and depression scale) was 13.5 for depression (moderate level) and 9.65 for anxiety (mild level).

Conclusion
Reduced quality of life, depression and anxiety are frequent during the first two years post stroke. The post hospitalization care, including treatment for depression and increased social support, may reduce the negative impact of the disease on the perceived quality of life.

OXFORD CASE COMPLEXITY ASSESSMENT MEASURE (OCCAM), A NEW SCALE TO MEASURE COMPLEXITY IN PATIENTS AFFECTED BY STROKE AND ITS CONCORDANCE WITH OTHER SCALES OF DISABILITY
E. Martin Castillo¹, P. Marquez Rodriguez¹, A. Báez Suárez¹, J.C. Lopez Fernandez¹, A. Deniz Caceres¹, P. Saavedra Santana¹, D. Rodriguez Molina¹
¹University of Las Palmas de Gran Canaria, Medical and Surgical Sciences, Las Palmas de Gran Canaria, Spain

Introduction/Background

Stroke is considered the most common cause of complex disability in our society. There are only few scales evaluating complexity. The aim of our study is to evaluate the correlation of the Spanish version of OCCAM score, which includes biopsychosocial aspects, with other scales which measure disability and quality of life, in patients affected by stroke: National Institutes Health Stroke Scale (NIHSS), Barthel Index (BI), Modified Rankin Scale (MRS) and the Short Form 12 Questionnaire (SF-12).

Material and Method

A prospective study was conducted, 74 patients admitted to hospital diagnosed with stroke and subsidiary to rehabilitation programs. The concordance between the OCCAM scale with the other scales were evaluated by means of the Spearman correlation coefficient. Statistical significance was set at p < .05.

Results

A total of 74 patients were analysed, 62% men against 38% women, mean age 74 years. Previous history of: high blood pressure (60%), Diabetes Mellitus (36%), Dyslipidemia (39%), previous stroke (12%), arrhythmia (33%). The correlation coefficients with OCCAM were: NIHSS (p = 0.697), BI (p = 0.905), MRS (p = 0.829), SF-12 (p = 0.331).

Conclusion

The OCCAM scale has a strong correlation with other measures of disability, less with the quality of life measures; and is a quick and easy way to evaluate complexity in patients affected by stroke. It is based in a biopsychosocial model taking into considerations all factors that influence patients, so resources can be used more efficiently and predict prognosis /outcomes.

EFFECTIVENESS OF CONSTRAINT INDUCED MOVEMENT THERAPY IN UPPER EXTREMITY FUNCTION AFTER STROKE: CASE REPORT
D. Tsukimoto¹, J.H. Yonobi¹, F.S. Mendes¹, A.T. Sugawara², M.H. Miyazaki², G.R. Tsukimoto¹
¹Physical and Rehabilitation Medicine Institute- Hospital das Clinicas HCFMUSP- F, occupational therapy, sao paulo, Brazil
²Physical and Rehabilitation Medicine Institute- Hospital das Clinicas HCFMUSP- F, Physiatry, sao paulo, Brazil

Introduction/Background

Constraint-Induced Movement Therapy (CIMT) is a technique that consists of intensive training of the hemiparetic arm in functional activities, application of visual methods to the transfer of the gains obtained in the therapy for the patient’s daily life and restriction of the arm unaffected by the lesion. CIMT is considered gold standard in the rehabilitation of the paretic upper limb, however, it is commonly used with patients that presents motor impairment in the upper limb of mild to moderate.

Material and Method

The aim of this study is to analyze and discuss the results of the functional evaluations by verifying the possible gains from an intervention through the case report of a patient with severe motor impairment and a sequela of chronic hemiparesis after stroke. It was used the Mini Mental State Examination (MMSE), Wolf Motor Functional Test (WMFT), Motor Activity Log (MAL), Fugl-Meyer upper limb section, goniometry and the modified Ashworth scale; the data obtained with MAL and WMFT were analyzed using the Wilcoxon test, adopting the level of significance of p≤0.05.

Results

Statistically significant results were observed for WMFT (p = 0.031) and for MAL in terms of quantity and quality, these were statistically significant in the pre- and post-treatment (p = <0.001) and 3 month follow up.

Conclusion

Although the chronicity of the lesion and the patient presented severe motor impairment in the upper limb, an adapted and personalized CIMT has shown to be promising to favor the use of the paretic upper limb and it was observed that a patient with severe motor impairment could benefit from the use of the technique.

CLINIMETER EVALUATION FOR STROKE INJURIES

J. Mathieu', E. Annick', B. Guillaume

'C2S, RHONE, Montrottier, France

'2C2S, loire, montbrison, France

Introduction/Background

CLINIMETER / CLINIMETRE digital application developed to optimize assessments in rehabilitation medicine and in particular functional assessments. Functional evaluation is the main universal pillar for developing a therapeutic plan in a rehabilitation team. In particular for monitoring hemiplegia. There are many scales of functional evaluation or score: at the world level, the main scale for the reeducator is the MIF or FIM, but we can also mention the SMAF, the MPAI, the ADL, the Index of Barthel.

Material and Method

The clinimeter provides functional evaluations with an innovative response to these different brakes. For the input time: the ergonomics of the Human-Machine interface, the adaptation of the display according to the evaluator, the graphic visualization and the interactivity facilitate the speed, the verification and the exchange of the seizures.

Results

The study of the use of the clinimeter for 100 evaluations, as part of the management of stroke, shows a clear increase in the number of reports, a time of evaluation divided by two for the first evaluation, divided by four for the following evaluations. Ownership by users is very fast. The patient appreciates the visual side of the objectives and the communication in the team is very clearly increased. The patient's outgoing mail and residency report contain updated functional assessments.

Conclusion

The clinimeter provides a real benefit for the functional assessment of hemiplegia and their follow-up.

1University Félix Houphouët-Boigny, UFR Sciences Médicales, Abidjan, Ivory Coast

Introduction/Background
Introduction: Post-stroke depression is a very common nosological entity and its perception in Africa is sometimes experienced as a stigmatizing situation, often poorly accepted.

Objectives: To specify the incidence of depression after vascular hemiplegia, and also its functional repercussion in rehabilitation in the PMR department at Yopougon's University Hospital

Material and Method
It was an eight-month prospective cross-sectional study from January to August 2016. It involved all cases of patients with hemiplegia following a stroke managed in the PMR service. Patients presenting in addition severe cognitive impairment were excluded

Results
On 49 hemiplegic patients, 19 patients with a mean age of 57.21 years with extremes of 37 and 70 years had post-stroke depression (38.8%), mostly men with a sex ratio of 1, 71. Ischemic stroke represented 89.5% of the PSD; 11 patients (57.9%) had minor depression and 8 patients (42.1%) had severe depression. There was a suicidal risk in 6 patients, 31.6%. Motor handicap was present in all depressed patients with an average Demeurisse’s score at 55.16 / 100 and extremes ranging from 9 up to 80.

Conclusion

Discussion: Post-stroke depression is common in our context despite its debilitating and poorly accepted nature by a segment of the general population. It compromises the functional prognosis, which is a source of demotivation for patients, especially for the execution of the rehabilitation program.

Conclusion: Post stroke depression should be searched systematically in all hemiplegic vascular in our African context, during the decline in performance and achievements during rehabilitation sessions, and during regular meetings with the family.

Introduction/Background

Background: The Brazilian Functioning Index (BR-FI) was developed and published by an interministerial task force at the request of the Presidency of the Republic, aiming to standardize and quantify the functioning assessment of the population for social benefit purposes.

Aims: Analyze psychometric properties and the functional profile of stroke individuals using the BR-FI.

Material and Method

An observational, longitudinal, prospective, and descriptive study. In order to ascertain intra and inter-examiner concordance two evaluations were conducted, with a six-month interval between them, in which the BR-FI was applied and compared with another evaluation instrument, the Functional Independence Measure (FIM), in 30 individuals (women 56.7%, mean age: 64.6±14.6) that had a history of stroke from December 2016 to January 2018.

Results

The Spearman correlation between the BR-FI and the FIM was performed (0.85; p < 0.001), after which a strong, positive relationship was observed, indicating that the functional assessment instruments are directly proportional. When comparing the inter-examiner data, all of the correlations were identified as positive among the stroke individuals. In turn, when analyzing the intra-examiner data during the six-month interval, both evaluation instruments displayed positive associations, and all of the stroke individuals were observed to be more functional. Among the seven domains that compose the BR-FI, the sensorial, domestic life and education, work, and economic life domains did not exhibit any correlation with FIM.

Conclusion

The BR-FI is considered a complete evaluation instrument to assess functional profiles since it analyzes aspects that are not contemplated in other tools, such as Environmental Factors.

COGNITIVE IMPAIRMENT AND DISCHARGE HOME FOR STROKE PATIENTS WITH MILD, MODERATE AND SEVERE MOTOR IMPAIRMENT

1Duke University School of Medicine, Duke Clinical Research Institute, Durham, USA
2Duke University, School of Nursing, Durham, USA
3Carolinas Rehabilitation, Physical Medicine and Rehabilitation, Charlotte, USA
4Carolinas Rehabilitation, Research, Charlotte, USA

Introduction/Background

Stroke-related alterations to cognition especially when mild can often go undetected. Cognitive impairment can increase the likelihood of falls and medication nonadherence and have negative downstream effects. The purpose of this study was to examine the association of discharge cognitive impairment with discharge destination of home compared with a skilled nursing facility (SNF) for stroke patients with mild, moderate and severe motor impairment.

Material and Method

This retrospective observational study includes stroke patients who received acute rehabilitation from 2008-2011 at three facilities in the United States. Cognitive and motor function were measured as part of clinical practice using the Functional Independence Measure (FIM). We examined the association of four domains of cognition (comprehension, expression, problem solving, and memory) with discharge disposition home versus SNF for patients with motor impairment categorized as mild (motor score 78-91), moderate (39-77) or severe (1-38).

Results

Among 1,882 acute stroke patients (85.5% ischemic), 65.5 years of age on average, 49.3% were female, 62.6% White and 21.9% lived alone pre-stroke. All patients with mild motor impairment were discharged home regardless of cognitive functioning; 85.7% with moderate motor impairment and 38.4% of patients with severe motor impairment were discharged home. After adjusting for patient characteristics selected by stepwise logistic regression, a higher score (less impairment) for comprehension, expression, problem solving, and memory increased the likelihood of discharge home versus SNF for patients with moderate motor impairment but there was no association between cognition and discharge disposition among stroke patients with severe motor impairment (Table).
Conclusion

This study found that patients with mild motor impairment were discharged home independent of cognitive status and higher cognition was not associated with an increased likelihood of home discharge among patients with severe motor impairment. Transition planning for management at home or continued care needs to consider level of cognitive and physical disability.

SURFACE EMG GUIDED REHABILITATION TRAINING FOR UPPER EXTREMITY MOTOR RECOVERY AFTER STROKE

N. Cao¹, N. Mayer¹
¹MossRehab, Physical Medicine and Rehabilitation, Elkins Park, USA

Introduction/Background

Patients with mild to moderate upper extremity paresis in acute phase after stroke have a good prognosis for functional recovery. However, the recovery in severely affected patients is limited with current available treatments. Optimization of rehabilitation treatment to promote brain plasticity is very crucial but challenging at early phase of stroke recovery.

Material and Method

The patients admitted to our Acute Stroke Inpatient Rehabilitation Program with profound upper extremity weakness (flaccidity phase) receive dynamic surface EMG analysis to the proximal muscle groups (primarily trapezius, deltoid, pectoralis major, triceps and biceps) in the motor control lab. Patients are instructed to perform isometric or bimanual tasks including push forward or sideways on table top with or without trunk movement restraint. The recorded EMG signals on affected side are compared with unaffected arm. Based on the muscle activation pattern, patients are directed to optimized functional training in occupational therapy treatment.

Results

Based on the analysis of 20 patients’ EMG activities collected in the lab, we found there are varied muscle groups activated on severely impaired arm when performing same isometric or bimanual tasks in different patients. We speculate some upper motor neuron volitional signal is getting through to different muscles at different stages of recovery after stroke. We promote early recruitments of activated muscle groups in repetitive, task specific training to potentially improve upper extremity functional recovery.

Conclusion

Although what best represents “optimal treatment” for upper extremity recovery after stroke is still limited, the tailored specific therapeutic intervention program is under exploration using upper limb dynamic EMG analysis in our motor control lab with hope to provide more insights to the optimal intervention for improving functional outcome after stroke.

EFFECT OF MANUAL LYMPHATIC DRAINAGE ON EDEMA AND MOTOR FUNCTION OF HEMIPLEGIA UPPER LIMB IN STROKE PATIENTS
K. Li\textsuperscript{1}, J. Qiao\textsuperscript{2}
\textsuperscript{1}Shanghai Second Rehabilitation Hospital, Department of neurorehabilitation, ShangHai, China
\textsuperscript{2}Shanghai Second Rehabilitation Hospital, Department of rehabilitation, ShangHai, China

\textbf{Introduction/Background}

The dysfunction of the upper limb after stroke, which is a kind of disease with high morbidity and morbidity seriously affects the daily life of the patients. The upper limb of the hemiplegic patients often have symptoms such as edema and pain, which may Especially affect the recovery of motor function. This study aims to evaluate the effects of treatment of Manual lymphatic drainage technique on edema and motor function of the hemiplegic side upper limb in stroke patients.

\textbf{Material and Method}

Ninety patients after stroke with hemiplegic limb edema were randomly divided into control group and the Manual Lymphatic Drainage (MLD) group, the two groups of patients were treated with conventional therapy, including upper limb joint mobilization techniques, limb passive and active training, physical therapy and other measures, and Manual lymphatic drainage respectively on the basis of routine treatment. The differences of pain, edema and Fugl-Meyer scale score in two groups were compared before and after treatment.

\textbf{Results}

Pain and edema in the two groups of patients were alleviated and Fugl-Meyer scale scores were significantly higher than before treatment. There is a statistically significant difference between the two groups (P <0.05). The above three aspects in MLD patients after treatment were better than the control group with a statistically significant difference (P <0.05).

\textbf{Conclusion}

The technique of lymphatic drainage technique can relieve edema and pain and improve upper limb motor function of post-stroke patients. The method is simple and noninvasive and has some clinical value.

ELECTROPHYSIOLOGICAL CHANGES OF SYMPATHETIC NERVES IN PATIENTS WITH STROKE

P. wang¹, Y. li², H. wang², F. gao¹, Y. chen¹, T. zhou²
¹Shanghai Tongren Hospital- Shanghai Jiao Tong University School of Medicine, Rehabilitation, Shanghai, China
²School of Rehabilitation Medicine-Nanjing Medcine University, Rehabilitation, Nanjing, China

Introduction/Background

To investigate the electrophysiological changes of sympathetic nerves in patients with stroke, explore the characteristics of SSR and assess the value of SSR in detecting dysfunction of autonomic nervous system and evaluating long-term prognosis in patients with stroke.

Material and Method

Sympathetic skin response (SSR) was tested in 34 patients with stroke. The motor function of affected extremities was assessed by Brunnstrom grade. Then the changes in electrophysiological test of both sides were compared and the correlation with function outcomes of affected extremities were analyzed.

Results

1) No statistically significant difference was determined in the SSR latency and amplitude values obtained with stimulation of the affected sides compared with latency and amplitude values obtained from the healthy sides (P > 0.05). 2) No matter which side was stimulated, the rate of abnormal changes in SSR was above 67%. And abnormal rate of bilateral upper extremities or bilateral lower extremities was significantly higher than which of unilateral extremity. 3) No significant difference was found between the duration within 3 months group and the duration more than 3 months group. 4) Abnormal changes of SSR in patients with left hemiplegia were found more commonly than those with right side affected. 5) The SSR latency of the affected sides with upper extremity in non-basal ganglia group is longer than that in the basal ganglia group (P < 0.05). 6) No significant difference was found between the Brunnstrom stage 1–3 group and 4–6 group.

Conclusion

Dysfunction of sympathetic nerves conduction in both side extremities were found in patients with stroke. Abnormal rate of bilateral upper extremities or bilateral lower extremities was significantly higher than which of unilateral extremity. Lesion location is the main factor which affecting SSR. Further studies about the value of SSR evaluating motor function of stroke are needed.

PILOT TESTING A POSITIVE PSYCHOLOGY INTERVENTION TO PROMOTE WELL-BEING IN COUPLES COPING WITH STROKE

A. Terrill¹, J. Einerson¹, M. Reblin², J. MacKenzie³, C. Berg⁴, J. Majersik⁵, L. Richards¹

¹University of Utah, Occupational & Recreational Therapies, Salt Lake City, USA
²Moffitt Cancer Center, Health Outcomes & Behavior, Tampa, USA
³University of Utah, Physical and Rehabilitation Medicine, Salt Lake City, USA
⁴University of Utah, Psychology, Salt Lake City, USA
⁵University of Utah, Neurology, Salt Lake City, USA

Introduction/Background

Depressive symptoms post-stroke occur in 30-50% of survivors and partner caregivers, and can have negative consequences for recovery, function, and quality of life. Further, emotional well-being is interdependent in couples; depression in one partner increases risk of depression in the other. Sustaining well-being in both partners is important for rehabilitation engagement and community re-integration. However, support for couples post-stroke is lacking or inaccessible. We aimed to pilot test a self-administered positive psychology-based intervention (PPI) for these couples.

Material and Method

Eighteen couples consisting of one partner who had a stroke >6 months ago and a cohabiting caregiver were enrolled. One or both partner(s) reported depressive symptoms. The sample was primarily White, well-educated, consisted of 50% female survivors and male caregivers, and had a mean age of 55 years (range: 27-84). A variety of stroke types and locations were represented. After a brief training, participants engaged in the PPI at home, completing two activities alone and two together each week. Activity booklets, tracking calendars, and weekly check-in calls were provided. Pre-, post-intervention, and 3-month-follow-up measures included the PROMIS-Depression, PROMIS-Fatigue, PROMIS-Positive Affect and Well-being, and Stroke Impact Scale 3.0 (SIS). Due to the exploratory nature of the study, significance was set at p=.10.

Results

Fourteen of 18 couples completed the program. Analyses show a trend for decreased depressive symptoms across time points. Fatigue and well-being significantly improved. Caregivers demonstrated greater improvement in fatigue and depressive symptoms. Participants with stroke reported significant improvement in the SIS cognition, communication, and participation in meaningful activities domains.

Conclusion
Preliminary results suggest the PPI may be effective for improving mood, fatigue, and well-being in couples post-stroke as well as stroke-specific quality of life. Though more research is needed, this represents a promising first step in a novel dyadic intervention for this population with exciting potential clinical implications.

Disclosure statement: Research reported in this abstract was supported by the University of Utah Consortium for Families & Health Research (PI: Terrill), Utah StrokeNet Research Training and Career Development Program (NIH NINDS #5U10NS086606-03 PI: Majersik), and the National Center for Medical Rehabilitation Research of the National Institutes of Health under Award Number 1R03HD091432-01 (PI Terrill).
ACTION OBSERVATION THERAPY IN THE RECONSTRUCTION OF THE UPPER EXTREMITY MOTOR FUNCTION OF STROKE PATIENTS.

Z. meihong1, F. Shen1, M. Zeng1, J.M. Fu1

1The Second Affiliated Hospital Of Jiaxing University, Centre of Rehabilitation Medical, Jiaxing-Zhejiang, China

Introduction/Background

To explore the effects of action observation therapy on the motor function of upper-extremity in patients with stroke, and to investigate the effects of action observation therapy on motor cortex by functional magnetic resonance imaging(fMRI).

Material and Method

Thirty-one stroke patients were randomly assigned to an experimental group (n = 16) and a control group (n = 15). The control group received conventional rehabilitation therapy. The experimental group also received action observation therapy for 8 weeks. Both groups were assessed by the Fugl-Meyer assessment(FMA) and the Barthel index(BI) in pre-treatment and after 4 and 8 weeks of treatment. Latencies and amplitudes of the N9 and N20 in somatosensory evoked potentials (SEPs) were recorded. Both groups were assessed by functional magnetic resonance imaging before treatment. Followed up for 2 months, nine patients who continued to do action observation training for two months after discharge were assessed by functional magnetic resonance imaging(fMRI).

Results

There were no significant differences in evaluation indices between the two groups before treatment (P > 0.05). At 8 weeks after treatment, performance improved on all indices in both groups (P < 0.05). Compared with the control group, the experimental group showed significantly greater improvements in FMA scores (upper extremities), Barthel index scores, as well as latencies and amplitudes of N9 and N20 on the hemiplegic side (P < 0.05). Brain functional magnetic resonance imaging(fMRI) showed that there was a significant rise in activity in the bilateral precentral gyrus, parietal lobe and the supplementary motor area (SMA) of the patients in the observational group compared with the control group.

Conclusion

Action observation therapy can improve upper extremity motor function in the early stages of stroke while elevating ADL performance, and cause changes in the excitability of cerebral motor cortex, as well as increasing the amplitudes and shortening the latencies of the N9 and N20 in SEPs.

EFFICACY NEUROPROTECTION THERAPY IN BRAIN STROKE COMBINED PARKINSONISM.

N. Rashidova¹, K. Khalimova¹

¹Tashkent Medical Academy, Neurology disease, Tashkent, Uzbekistan

Introduction/Background

Background: To determine efficacy neuroprotection therapy of citicoline (somazina) 1000 mg or pyracetami in patient with stroke (rehabilitation period) combined Parkinsonism.

Material and Method

We studied 68 patients with ischemic stroke combined Parkinsonism, aged 60-75 years. Patients were divided into 2 groups: the control group (n=32) received pyracetami 20%-10,0 ml; citicoline (somazina) 1000 mg group (n=36) was treated for 20 days.

Results

Somazina treatment was more efficient than pyracetami which we observed in our studied patients and it can be explained by different pharmacologic mechanisms. Treatment with somazina during 20 days showed in a significant decrease of ischemia zone volume by 25,7%, which was associated with better outcomes in neurologic and functional status. Treatment with pyracetami demonstrated decrease of ischemia zone volume by 7,6%, and no outcomes in neurologic and functional status. Neuroprotective therapy with somazina in patients with brain insult combined Parkinsonism led to significant improvement in clinical and morphological variables.

Conclusion

Our data justify the need admission of somazina in patients with ischemic stroke combined Parkinsonism.

PATHOGENIC THERAPY OF DEPRESSION AND ANXIETY-NEUROTIC DISORDERS DURING ISCHEMIC STROKE.

N. Rashidova¹, K. Khalimova¹
¹Tashkent Medical Academy, Neurology disease, Tashkent, Uzbekistan

Introduction/Background

Known that combined stroke and depression increases the risk of death in patients compared with patients without depression.

Study the role of antidepressants in the treatment of depression and anxiety and neurotic disorders in ischemic stroke.

Material and Method

We observed 95 patients with stroke with mild and moderate form of depression. Age of patients ranged from 55 to 70 years (average 60.5±3.5 years). Among them, 44 male (46.3%), 51 female patients (53.6%). All patients were assigned pathogenetic therapy depending on the etiology of stroke and Escitalopram 5 mg 2 times a day depending on age of patients: above 65 years old was taken 10 mg, under 65 years old – 5 mg a day. The course of treatment was 3 months. To assess the level of anxiety and depression were conducted neuropsychological tests.

Results

As a result of treatment escitalopram significantly improved the condition of patients in the first week of treatment. Was a decrease in feelings of lump in the throat, anxiety, attacks of breathlessness, shortness of breath, normal sleep, increase of intellectual activity and performance. Before treatment, the average score on the Hamilton scale was 19.0 ± 3.0, after treatment showed a significant improvement-10.0 ± 3.0. The scale of Spielberg-Khanin showed that patients treated with escitalopram after 3 months of treatment decreased personal and reactive anxiety by 22% and 31%, respectively.

Conclusion

1. Depression and anxiety-neurotic disorders worsen during ischemic stroke. 2. Escitalopram is a drug of choice in the treatment of patients with ischemic stroke with anxiety and neurotic disorders, which reduces these symptoms of anxiety at 74.2% and give positive effect on cognitive function in patients.

ISPR8-2162
RESEARCH OF INTERACTIVE ACUPUNCTURE THERAPY FOR POST-STROKE ANXIETY DISORDER BASED ON BRAIN-COMPUTER INTERFACE TECHNOLOGY
Y. Zhu, Z. Zhang

Shanghai Second Rehabilitation Hospital, Department of neurorehabilitation, ShangHai, China

Introduction/Background

Post-stroke anxiety (PSAD) is a common complication of strokes that directly affects the quality of life of stroke patients and causes long-lasting distresses, disrupts the recovery of somatic and cognitive functions in stroke patients, and stroke in severe cases the recurrence. Therefore, the timely treatment of post-stroke anxiety, not only help to improve the quality of life of patients, and can promote functional recovery, thereby reducing the morbidity and mortality.

Material and Method

To explore the clinical efficacy of interactive acupuncture on post-stroke anxiety disorder (PSAD) based on brain-computer interface technology (BCI). Forty stroke patients with anxiety disorder were randomly divided into two groups according to random number table: BCI group (20 cases) and control group (20 cases), Selected acupoints for the two groups were Baihui, Neiguan, Shenmen, Yintang, were selected specifications for the 0.25mm × 40mm, using the method of supplementation and retention, needle retention 30min, needle 10min line 1 time. Treatment every other day, 20d for a course of treatment, a total of 1 course of treatment. In BCI group, we used the 14-lead brain-interface instrument to guide patients into quiet before the application of the needle, and then give acupuncture, and guide patients to experience the emergence of air feeling. The pre-treatment treatment was scored using the Hamilton Anxiety Scale (HAMA).

Results

After a course of acupuncture treatment, the two groups of patients in the HAMA score than before treatment were improved, BCI group increased more significantly than the normal acupuncture group.

Conclusion

Compared with ordinary acupuncture, patients can be a more intuitive observation of the static state of mind based on the brain-computer interface instrument, the use of interactive acupuncture can significantly improve post-stroke anxiety disorder.

ISPR8-2196
A RESEARCH ON EFFICACY OF REHABILITATION FOR POST-STROKE PATIENTS IN KRASNOYARSK REGION PERFORMED UPON THE PROGRAMME OF THE MINISTRY OF HEALTH OF RUSSIA IN 2016

M. Abroskina¹, I. Gordyukova¹, N. Isaeva¹, S. Prokopenko¹
¹Prof. V.F. Voino-Yasenetsky Krasnoyarsk State Medical University, The Department of nervous diseases with a course of medical rehabilitation in postgraduate education, Krasnoyarsk, Russia

Introduction/Background

Krasnoyarsk Region is among the largest regions of Russia. Its population amounted 2 875 790 by January 1, 2017. A three-stage rehabilitation system for patients after stroke has been created in the region. Over 6000 patients received successive rehabilitation in 2016. The purpose of the research was to assess efficacy of complex successive post-stroke rehabilitation in Krasnoyarsk Region in 2016.

Material and Method

A total of 163 patients after stroke (12 months), were enrolled into the unblinded study among which were 103 male and 60 female patients. The age varied from 32 to 91 years (57 ± 12.4). Ischaemic stroke was revealed in 144 patients while haemorrhagic stroke was revealed in 18. The study was conducted in the regional vascular centre at Stage I, in the Centre of neurorehabilitation of the FSSRC of FMBA of Russia at Stage II and in the clinic of Krasnoyarsk Medical University at Stage III. Glasgow Coma Scale (Stage I only), modified ranking scale, NISSH, Ashworth spasticity, pain, dysarthria assessment scales, Wasserman test, MASA, HADS, MOCA, Rivermead Mobility Index, BBS, Hauser Ambulation Index, Frenchay Arm Test, FIM, EQ-5D were used. Statistical analysis was performed using nonparametric Wilcoxon and Mann-Whitney criteria.

Results

The patients were divided into 3 groups after examination: Group I (n=39) included patients after only rehabilitation Stage I. Group II (n=61) included patients after Stages I and II, and Group III (n=63) included patients after all stages. It has been found that best statistically significant results according to clinical scales were found in Group III patients as manifested by disablement and neurological deficit decrease and motion activity value enhancement.

Conclusion

In Krasnoyarsk Region, the best efficacy has been shown by the complex successive rehabilitation for patients after stroke performed in stages.

REPRESENTATIONAL NEGLECT FOLLOWING RIGHT HEMISPHERE STROKE: FAILED RETRIEVAL OF VISUAL AND TACTILE DATA FROM WORKING MEMORY
L. Mansano¹, A. Hadar Zalstein², S. Greenberg³, Y. Sacher³, C. Serfaty¹, S. Bentin², N. Soroker¹
¹Loewenstein Rehabilitation Hospital, Department of Neurological Rehabilitation, Raanana, Israel
²The Hebrew University, Department of Psychology, Jerusalem, Israel
³Tel-Aviv University, Sackler Faculty of Medicine, Tel-Aviv, Israel
⁴Loewenstein Rehabilitation Hospital, Department of TBI Rehabilitation, Raanana, Israel

Introduction/Background

According to the representational theory of neglect, contralesional objects remain outside conscious awareness, because their spatial position is represented incorrectly. Here we assessed the impact of spatial position and temporal order of acquisition on the accuracy of same/different judgements for visual and tactile images reconstructed in working memory (WM).

Material and Method

35 right-hemisphere damaged stroke patients with left-side neglect and 29 healthy controls were presented with pairs of 2D geometrical shapes for same/different judgment, in 3 testing conditions: a. 'visual static' [VS] – each object exposed in its entirety; b. 'visual dynamic' [VD] – objects moved horizontally (leftward/rightward) behind a central narrow slit exposing only part of the object at one time; c. 'tactile dynamic' [TD] – the blindfolded subject palpates the upper contour of objects similar in appearance to the visual objects, in either rightward or leftward direction, with the index finger of the healthy right hand. In tasks b and c the spatial representation has to be reconstructed mentally from partial, non-lateralized, sensory information.

Results

Judgement errors were more prominent when the element distinguishing one object in a pair from the other had a left-side position. This was true not only for the VS mode but also for the VD and TD modes, where left and right in an object are reconstructed in representational space following non-lateralized presentation. Detection of left-side differences in the dynamic tasks improved in rightward exposure direction in vision and leftward direction of palpation, i.e., in conditions where the left side of the object is captured last.

Conclusion

In patients with neglect, secured sensory capture of object parts (by non-lateralized presentation) does not prevent lateralized retrieval failure from WM, following mental
reconstruction of the entire object from the captured parts. The temporal order of the mental reconstruction process is important - recency benefits retrieval accuracy.

MORTALITY IN ISCHEMIC STROKE

P. Sánchez Tarifa¹, C. Varela Lage¹, C. De Miguel Benadiba¹, A. Gómez Gómez¹, M.J. Lillo González¹, M.J. Buzzeta Devis¹
¹Hospital Ramón y Cajal, Rehabilitation, Madrid, Spain

Introduction/Background

The 30-day mortality rate of the first stroke is estimated in a range between 16-23% and 92.7% occurs in people >65 years.
Controlling risk factors has shown to decrease morbidity and mortality of these patients and costs.

Material and Method

Observational prospective epidemiological study to determine the factors related to mortality for a sample of 100 patients who were diagnosed with an ischemic stroke (assigned to the Rehabilitation Service by the Stroke Service during 2013).
Follow-up checks: at discharge, one and three months after discharge.
The socio-demographic, etiologic and clinical characteristics and the evolution of the patients are assessed.

Results

Death ratio:18%.
Average age of the patients who died:77.5 years
Mortality was higher in men(55.56%) than women(44.44%).
Patients who previously lived alone had a significantly lower mortality rate(21.4%) than patients who had socio-familiar support(78.57%).
Regarding the destination at discharge, the percentage of mortality was higher in those who went to a half-stay unit(64.71%) than those who went to their home(35.29%).
88.9% of the patients who died had hypertension(p=0.036), 33.3% obesity, 27.8% atrial fibrillation and diabetes, 22.2% dyslipidemia, ischemic cardiopathy and previous strokes.
Atherothrombotic stroke(47.06%) was the one associated with higher mortality(p>0.05).
Severe strokes were associated in a statistically significant way(p=0.003) with mortality. 88.9% of the patients who died had a severe stroke on admission and 11.11% had a moderate stroke.
100% of patients who died had a disability at admission (score>2 modified Rankin scale).
Stroke complications were directly related in a statistically significant way with mortality(p=0.016). 83.3% of the patients who died had suffered complications.

Conclusion
Our results match those found in the bibliography. The factors for which found a significant relation with mortality were hypertension (p=0.036), the severity of the stroke NIHSS>14 (p=0.003) and the onset of medical complications (p=0.016). Understanding the factors related to mortality in stroke is essential to undergo actions to reduce mortality.

ISPR8-2241
MANAGEMENT OF PAINFUL HEMIPLEGIC SHOULDER IN PHYSICAL MEDICINE AND REHABILITATION DEPARTMENT
E. Bahlouli¹, J. Galalou¹, J. Mbarek¹
¹Sanitary complex of Djebel Ouest, Physical medicine and rehabilitation, Zaghouan, Tunisia

Introduction/Background

Shoulder pain is a frequent complication of hemiplegia. Its appearance brings pain and limits daily living activities as well as participation in specific Neuro-rehabilitation programs. All this leads to a worse functional outcome. Its cause is multifactorial. Good management can reduce shoulder pain and improve functional outcome.

The aims of our study were to identify causes of shoulder pain in hemiplegic patients and to assess the impact of medical and rehabilitative interventions used.

Material and Method

A transversal study over 5 months from August 2017 to February 2018. It covered all cases of stroke hemiplegia admitted in the physical medicine and rehabilitation department of Djebel Ouest during this period. Assessed parameters were patient’s socio-demographic characteristics, pain characteristics (severity using Visual Analog Scale (VAS)), shoulder mobility, etiology for shoulder pain, therapeutic options.

Results

We collected 19 hemiplegic patients with an average age of 48.5±14 years and a male predominance. The majority of strokes was ischemic. The predominant clinical form was left-side hemiplegia (16 patients). Pain assessed using VAS was estimated to 8.4/10 on admission. The average time for hospitalization in our department was 11 weeks±9. Etiologies for shoulder pain were shoulder subluxation in eight patients, complex regional pain syndrome (CRPS) in 5 patients, spastic pectoralis major muscle in 4 patients and preexisting rotator cuff disorders in 2 patients. Only five patients used arm sling on admission. Management options provided included analgesic treatment, intra articular steroid injections in CRPS and rotator cuff disorders, botulinum toxin injections for spasticity, massage therapy, shoulder-positioning programs and TENS. VAS pain was estimated to 3.7/10 after therapeutic program. Most improvements in pain and range motion were noticed in-patient with spasticity.

Conclusion

Shoulder pain improves with prompt diagnosis and appropriate management. However prevention remains crucial, consisting in gentle shoulder mobilization within a lower range of motion and right positioning.

HAND-LATERALITY EFFECT ON UNILATERAL NEGLECT: A RARE INSIGHT ON THE LONGITUDINAL DYNAMICS OF INTER-HEMISPHERIC BALANCE FOLLOWING STROKE

S. Ofir¹, C. Serfaty¹, Y. Sacher², N. Soroker¹
¹Loewenstein Hospital - Rehabilitation Center, Neurologic Rehabilitation, Raanana, Israel
²Loewenstein Hospital - Rehabilitation Center, Department of Traumatic Brain Injury Rehabilitation, Raanana, Israel

Introduction/Background

The occurrence of unilateral spatial neglect (USN) in non-hemiplegic stroke patients is rare. Earlier studies of such patients revealed an advantage when typical neglect tests, e.g., line bisection (LB), were performed by the patient’s left hand as compared to the dominant right hand. This ‘output-mode effect’ is generally attributed to an increment in the lesioned right hemisphere (RH) activation level, induced by left-hand use, thus affecting the pathological inter-hemispheric balance. Here we assessed this phenomenon longitudinally in order to evaluate possible dynamics with the passage of time since stroke onset.

Material and Method

5 non-hemiplegic USN patients with RH stroke performed a multi-length LB task using both the left and right hands, at different time points along the rehabilitation period. Neglect was assessed using the Behavioral Inattention Test (BIT).

Results

4 out of 5 patients demonstrated significant improvement in the BIT scores along with decreased rightward error in LB during the rehabilitation period. The effect of hand laterality early after stroke onset was not uniform: 2 patients demonstrated right-hand superiority, 1 patient demonstrated left-hand superiority and for 2 patients there was no significant difference between right and left-hand performance. For all the patients with improved BIT, a single pattern of left-hand superiority was evident late in the sub-acute period.

Conclusion

Early after stroke onset, hand superiority varied between patients with different lesion characteristics, while subsequently most patients performed better with their left hand. This finding is likely to reflect a highly variate dynamics of RH activation and subsequently of the inter-hemispheric balance, in the first weeks after stroke onset. Better understanding of the factors influencing this dynamic and recognition of the current status of a given patient in this process, are crucial for proper application of intervention measures like tDCS and rTMS, aimed to affect the hemispheric activation level.

THE INFLUENCE OF ACTIVITY-DEPENDENT STIMULATION ON GAIT RE-TRAINING IN CHRONIC STROKE SURVIVORS: A PILOT STUDY

J. Watson¹, K. Welman¹, B. Sehm²

¹Stellenbosch University, Sport Science, Stellenbosch, South Africa
²Max Planck Institute for Human Cognitive and Brain Sciences, Neurology, Leipzig, Germany

Introduction/Background

While walking is a major goal in stroke rehabilitation, many chronic stroke survivors have not achieved independent ambulation. Task-specific gait re-training shows promise in post-stroke therapy. Research on transcranial direct current stimulation (tDCS) has shown potential benefits for fine motor skill learning but lacks evidence for gross motor skill learning; specifically gait re-training. It is hypothesized that a combination of these therapies may yield benefits for stroke rehabilitation. Consequently, this study endeavoured to compare the efficacy of gait re-training during real and sham stimulation on gait kinematics in chronic stroke survivors.

Material and Method

A randomized double-blinded case study was implemented, whereby 10 chronic stroke survivors (≥6 months) were divided into either an attention-matched control group (CON; n=4), or an 8-week task-specific gait re-training program with concurrent tDCS (1mA; 20 minutes; n=2) or with sham stimulation (20 minutes; n=3). Gait kinematics were measured pre- and post-intervention by using the two-minute walk test and the APDM mobility lab™.

Results

Double support (DS) time improved in real (Median=0.46, IQR=0.59), compared to sham stimulation (Median=0.73, IQR=1.93) and the CON attention-matched group (Median=1.12, IQR=1.36).

Additionally, DS variability decreased in real (Median=0.08, IQR=0.18) and sham (Median=0.05, IQR=0.04) stimulation groups; compared to the CON group (Median=0.25, IQR=0.46).

Conclusion

This study presents preliminary evidence for the benefits of tDCS combined with task-specific gait re-training on gait quality, specifically synchronization, in chronic stroke survivors. Additionally, task-specific gait re-training alone may also benefit gait steadiness.

ANALYSIS OF THE SUBJECTIVE POSTURAL VERTICAL ON DIAGONAL PLANE IN ELDERLY SUBJECTS AND LEFT HEMIPARETIC PATIENTS AFTER STROKE

D. Sekine¹, K. Fukata¹, K. Amimoto², Y. Fujino¹, M. Inoue¹, M. Inoue¹, Y. Takahashi¹, H. Takahashi¹, S. Makita¹

¹International Medical Center - Saitama Medical University, Department of Rehabilitation Center, Hidaka, Japan
²Tokyo Metropolitan University, Department of Physical Therapy, Arakawa-ku, Japan

Introduction/Background

The subjective postural vertical (SPV) in healthy subjects is robustly maintained by integrating somatosensory and vestibular information, and extremely correct on frontal and sagittal plane. It is well-known that brain injury patients indicate disturbance of SPV on frontal or sagittal plane. On the other hand, stroke patients frequently fall paretic side and backward, but SPV on diagonal plane in normal subjects and stroke patients is unclear. The purpose of present study was to clarify the difference of SPV on diagonal plane between elderly subjects and stroke patients.

Material and Method

The subjects comprised 14 elderly subjects (control group) and 10 left hemiparetic patients (LHP group). All subjects provided their written informed consent to take part in the study. SPV was measured using an electrical vertical board (EVB). The subjects sat on the EVB and was moved in the opposite direction from the left-backward or right-forward. The tilt of the seat when the subject feels and judges vertical position was recorded with a digital inclinometer. The mean (tilt direction) and standard deviation (variability) of eight trials were calculated. A true vertical position was considered 0°, diagonally backward and diagonally forward was treated as negative and positive, respectively. The values of SPV were compared between groups using the unpaired t-test (P<0.05).

Results

There was no difference between control group (66.8±9.2 years [mean ± SD]) and LHP groups (67.5±10.8 years) in age. In tilt direction, LHP group (-2.5±0.7°) demonstrated significant tilt backward to the left than control group (-1.3±1.4°). Variability was significantly higher in LHP (5.4±2.0°) than control (2.5±0.9°).

Conclusion

In stroke patients, tilt direction deviated to the diagonally backward and the judgement of verticality was unstable. These results suggest a possibility to explain the tilt of sitting posture and the difficulty of transfer movement in stroke patients.

THE EFFECT OF SITTING BALANCE TRAINING ON THE DIAGONAL PLANE IN PATIENT WITH PUSHING BEHAVIOR-A SINGLE CASE STUDY-

K. Fukata, K. Amimoto, Y. Fujino, M. Inoue, D. Sekine, Y. Takahashi

1Saitama Medical University International Medical Center, Department of rehabilitation center, Hidaka, Japan
2Tokyo Metropolitan University, Department of physical therapy, Arakawa-ku, Japan

Introduction/Background

Pushing behavior is known to disturb postural verticality on frontal plane. However, postural disorder such as tilting toward paretic side and backward on diagonal plane was often observed in the pusher, so it is important to improve postural orientation on diagonal plane. The purpose of present study was to clarify the effect of sitting balance training on diagonal plane in patients with pushing behavior.

Material and Method

60 years-old man, with right middle cerebral artery infarction including insula and postcentral gyrus, participated. Subject has severe hemiplegia, sensory disorder, and unilateral spatial neglect. He provided his written informed consent to take part in the study. To determine the effect of the intervention, the ABA design was used. This design consists of 3 phases; baseline, intervention, and follow-up. In intervention phase, patient sat without leg support on a sitting device tilted 10 degrees to the diagonally paretic side and backward. Patient was asked to move his trunk toward diagonally non-paretic side and forward. This training was repeated 40 times a day over 3 days. Patient received conventional physiotherapy for 1 hour each phase. The effect of the intervention was assessed using scale for contraversive pushing (SCP) and subjective postural vertical (SPV) on diagonal plane. In the SPV, a true vertical position was considered 0°, while diagonally backward toward paretic side and forward toward non-paretic side was treated as negative and positive, respectively.

Results

In before baseline, before intervention, after intervention, and follow-up, the total score of SCP was 3.75, 3.75, 2.5, and 2.5, respectively. The sitting score of SCP improved from 1.25 to 0 at after intervention and follow-up phase. The standing score of SCP was no change in all phase. After intervention, SPV on diagonal plane changed from -4.9° to -1.9°.

Conclusion

The sitting balance training on diagonal plane might improve pushing behavior and calibrate postural vertical.

PERIPHERAL PLUS CENTRAL REPETITIVE TRANSCRANIAL MAGNETIC STIMULATION (RTMS) FOR UPPER LIMB MOTOR REHABILITATION IN CHRONIC STROKE – A CASE REPORT

Q. Yang¹, S. Chen¹, P. Deng², J. Jia¹
¹Huashan Hospital- Fudan University, Department of rehabilitation medicine, Shanghai, China
²Central Hospital of Jing’an District - Fudan University, Department of Rehabilitation Medicine, Shanghai, China

Introduction/Background

Motor dysfunction of the hand and upper limb is a major cause of physical disability for patients with chronic stroke. Our aim was to investigate the effectiveness of a peripheral plus central repetitive transcranial magnetic stimulation (rTMS) treatment for upper limb motor rehabilitation in chronic stroke patients.

Material and Method

We reported the case of a patient WLX, who had one ischemic stroke more than 3 years ago, and had underwent intermittent rehabilitation since then. He still had profound right upper limb paralysis and moderate spasm, accompanied with non-fluent aphasia when came to our department; and complained that his recovery had been rather slow for about two years. In addition to the custom rehabilitation, we applied a peripheral plus central rTMS paradigm to him, which included 3 sessions of peripheral magnetic stimulation to his paralyzed right forearm, followed by a session of high frequency rTMS to the bilateral sensorimotor cortex region. The total magnetic stimulation therapy lasted about 30min a day, and was applied 5 days / week for 4 weeks.

Results

After 4 weeks’ treatment, the patient’s Fulg-Meyer upper limb assessment (FMA) score was obviously improved (from 27 to 37 points), and the spasm was largely relieved in his right hand and arm.

Conclusion

Peripheral plus central rTMS might be an effective treatment for motor dysfunction of chronic stroke patients.

Keywords

motor dysfunction; magnetic stimulation; upper limb rehabilitation

Introduction/Background

Recent studies indicate that extracorporeal shock wave therapy (ESWT) is being considered as a new treatment method for spasticity. ESWT is a non-invasive technique where high-energy acoustic impulses produced by different types of generators cause a mechanical stimulus to trigger a chemical reaction (mechanotransduction) in the tissues.

Objective: To establish if ESWT can reduce and improve spasticity, range of motion (ROM) active and passive, balance, pain, gait and activities of daily living in post-stroke patients

Material and Method

CENTRAL, MEDLINE, CINAHL, PEDro, REHABDATA, Scielo, Scopus, Web of Science, Trip Database, and Epistemonikos were searched and reference lists screened to identify clinical trials (randomized and nonrandomized) of ESWT, in stroke survivors published until February 2018. Two reviewers independently screened references, selected relevant studies, extracted data, and assessed trial quality. The primary outcome was spasticity; secondary outcomes were ROM (active and passive), balance, gait and activities of daily living. Due to the heterogeneity of included studies meta-analysis was not possible.

Results

PRELIMINARY RESULTS: To date a total of 10 studies with 265 participants have been analyzed. The primary targeted muscle was gastrocnemius and secondary was semitendinosus. ESWT showed moderate evidence to reduce spasticity as assessed by the Modified Ashworth Scale and to improve active and passive ROM and gait.

Conclusion

PRELIMINARY CONCLUSIONS: ESWT performed with radial or focused modalities could be a good rehabilitation strategy in stroke survivors to reduce spasticity in the lower limb, increase ROM of ankle and improve gait. ESWT does not show adverse events. ESWT is a safe and effective method for reducing spasticity in stroke survivors (subacute and chronic stage).

REPETITIVE STEREOTYPED MOTION TRAINING USING NINTENDO WII® FOR RECOVERY FROM UPPER HEMIPARESIS AFTER STROKE: A CASE REPORT
M. Ueno¹, S. Miura¹, Y. Inoue², S. Etoh¹, M. Shimodozono¹
¹Graduate School of Medical and Dental Sciences - Kagoshima University, Department of Rehabilitation and Physical Medicine, Kagoshima, Japan
²Kagoshima University Hospital, Department of Rehabilitation, Kagoshima, Japan

Introduction/Background

Rehabilitation using virtual reality technology, including TV games such as Nintendo Wii®, has recently been reported to aid recovery of motor function in hemiparetic upper extremities after stroke. However, it is unclear which element of motion exercise is effective because patients play some games independently. We report the case of one patient for whom voluntary training specialized to encourage elbow flexion and extension with Wii® was effective for recovery of motor impairment and motor function in a hemiparetic upper extremity.

Material and Method

case report

A 60-year-old man who had suffered left hemiparesis due to cerebral infarction was admitted to our rehabilitation center 1 month after onset. Intensive rehabilitation was conducted and hemiparesis gradually improved. Three months after onset, improvement reached Brunnstrom Stage V in the upper limb and fingers, and we recommended voluntary training with Wii®. Wii® training was conducted 1 hour per day, 5 days a week for 2 weeks, in addition to regular upper limb rehabilitation. We also instructed him to play table tennis games with flexion or extension of his hemiparetic elbow. During the subsequent period without Wii® training, he performed conventional voluntary training, as had been done before Wii® training, for 1 hour a day. Motor impairment and motor function were evaluated at four time points: 2 weeks before the start of Wii® training, at the start, at the end of Wii® training, and 2 weeks after the end.

Results

Maximum improvement was observed during the Wii® training term.

Conclusion

For this patient, intensive flexion and extension training of the elbow may have been a key element contributing to improvement. Even with voluntary training using Wii®, results might be better if stereotyped motion elements and intensive repetition are specified, as opposed to letting the patient perform complex movements ad lib.

DEVELOPMENT OF A DEVICE FOR THE ASSESSMENT OF AN ANKLE FOOT ORTHOSIS

M. Ochi¹, M. Kimura¹, S. Saeki¹, N. Kato¹, A. Kano²
¹University of Occupational and Environmental Health, Rehabilitation medicine, Kitakyushu, Japan
²Arizono orthopedic supplies co.-ltd, orthopedics, Kitakyushu, Japan

Introduction/Background

An ankle-foot orthosis (AFO) is often used to control pes equinovarus and drop foot and improve walking ability among patients with stroke. Many AFOs are composed of a thermoplastic material such as polypropylene and custom-molded to a patient’s lower limb anatomy. AFO stiffness is important to understand the effect of an AFO on gait biomechanics. We developed a simple device using a force gauge for the assessment of AFO stiffness.

Material and Method

The device has metal frame structure. A digital force gauge engaged with the frame slidably in an X direction. An AFO to be tested is fixed firmly the device, and the elastic repulsion force is measured by the digital force gauge. The fixation can be changed in four directions of up, down, left, and right along measuring direction of the AFO. We measured the two-different material plastic AFO stiffness by the device.

Results

We could measure AFO stiffness in four directions of ankle-dorsiflexion, planterflexion, inversion, and eversion.

Conclusion

The device is considered feasible for a quantitative assessment of AFO stiffness.

RESEARCH ON THE THREE-DIMENSIONAL GAIT ANALYSIS SYSTEM AFTER STROKE BASED ON THE REHABILITATION THEORY OF UPPER AND LOWER EXTREMITIES INTEGRATION
X. Chen¹, J. Jia¹
¹Shanghai jing'an district central hospital, Rehabilitation medicine, Shanghai, China

Introduction/Background

To investigate the changes of three-dimensional gait to wear the Orthosis of hand functional rehabilitation on affected side of stroke patients.

Material and Method

Whole body three-dimensional gait analysis system was tested before and after in 50 stroke patients [(male 28, female 22, cerebral hemorrhage 17, cerebral infarction 33, age (56.32±5.27)y] in the hemiplegic hand wearing the Orthosis of hand functional rehabilitation. They were assessed twice by the same physiotherapist. The research height, weight, age and gait temporal-spatial parameters and lower extremity motions as well as walking capacity were compared.

Results

There were significant differences (P<0.05) in spatiotemporal parameters (cadence, walking speed, step length, cycle time, swing phase and support phase) of the stroke patients after wearing the Orthosis of hand functional rehabilitation. The maximum range of motion (ROM) of hip extension increased significantly in hemiparetic stroke patients compared with before, and the mean velocity of hip flexion-extension motion increased significantly(P<0.001). The maximum ROM of knee flexion and the mean velocity of knee flexion-extension motion also significantly increased (P<0.001). The maximum ROM of ankle flexion and the mean velocity of ankle flexion-extension motion also significantly increased (P<0.001).The walking capacity of hemiparetic stroke patients significantly improved after wearing the Orthosis of hand functional rehabilitation.

Conclusion

Torsion stability and lower limb walking ability were significantly improved after wearing the Orthosis of hand functional rehabilitation on affected side of stroke patients. Stroke patients
ipsilateral upper and lower limbs exist, that is, Upper and Lower Extremities Integration. This training method is conducive to guiding clinical work.

ASSESSMENT OF DEPRESSION AFTER HEMIPLEGIC STROKE IN PHYSICAL MEDICINE AND REHABILITATION DEPARTMENT

E. Bahloul1, J. Galalou1, J. Mbarek1
1Sanitary complex of Djebel Ouest, Physical medicine and rehabilitation, Zaghouan, Tunisia

Introduction/Background

Post-stroke depression is a serious complication. However, it often remains underestimated despite its negative impact on functional recovery and quality of life. Our objective was to assess the prevalence of depression in our hemiplegic stroke patients.

Material and Method

A transversal study over 4 months from September 2017 to January 2018. It covered all cases of stroke hemiplegia admitted in the physical medicine and rehabilitation department of Djebel Ouest during this period. Assessed parameters were patient’s socio-demographic characteristics, clinical presentation, Hospital Anxiety and Depression Scale (HAD depression) and Barthel Index of Activities of Daily Living.

Results

We collected 32 hemiplegic patients with an average age of 63.7± 14 years and a male predominance. The majority of strokes was ischemic. The average time for hospitalization in our department was 14.1 weeks ±20.6. Eleven patients demonstrated post-stroke depression. Ten from depressed patients were not treated before. The mean Barthel Index and HAD depression scale were respectively 39.3/100 and 12.6± 7.1. Depression was associated with increased disability (p<0.01).

Conclusion

Depression is commonly experienced post stroke. It should be sought systematically in all hemiplegic patients, especially in the early phase because it compromises functional prognosis. An anti-depressive therapy are potentially great, not only on mood but also on functional recovery.

ISPR8-2376
CASE REPORT TO IDENTIFY THE KEY ELEMENTS OF NEURO-PHYSIOTHERAPY TREATMENT TO OPTIMISE BRAIN SENSORY AWARENESS FOR MOTOR RECOVERY OF THE ARM AND BALANCE POST-STROKE

K. Saunders1
1East Kent Hospitals University NHS Foundation Trust, Neuro-rehabilitation, near Ramsgate, United Kingdom

Introduction/Background

This case report aims to identify the links between neuro-physiotherapy treatment to enhance brain sensory awareness post-stroke to promote motor recovery of the upper limb and balance. Individual Participant Data: Mr D, aged 74, sustained a severe left CVA in October 2017. This resulted in right sided hemiplegia, for which Mr D sought independent neuro-physiotherapy treatment in December 2017 to improve his transfers, balance, to start walking and explore potential movement recovery within his non-functional right arm.

Material and Method

Mr D participated in a course of neuro-physiotherapy treatment at home comprising twice weekly visits for 1.5 hours over a 5 week time period in January 2018.

Treatment focused on 4 key elements:

1. strength training
2. increasing brain awareness of the right arm, hand and leg
3. facilitating re-alignment of right shoulder girdle and wrist with supported task practice
4. Home exercise program

Results

Mr D responded positively and demonstrated consistent and rapid progress related to brain neuro-plasticity and motor re-learning. Mr D has undertaken task practice outside of sessions which has consolidated learning.

Mr D's transfers improved from requiring a Sara Stedy transfer aid with 1 carer, to being able to walk independently indoors at home using a wheeled gutter frame. Mr D has been able to reduce the number of care visit calls per day from 3 to 1. Mr D has achieved his initial goals as identified with the Goal Attainment Scale (GAS), ie. to walk independently with a frame indoors, to learn how to go in and out of his back door onto his patio with supervision, and to begin to use his right arm functionally again eg. washing up & serving food onto plates.

Conclusion

For Mr D, improving brain sensory awareness promoted motor recovery of the affected arm and improved balance post-stroke.

²Nicolaus Copernicus University in Toruń- Collegium Medicum in Bydgoszcz Faculty of Health Science, Rehabilitation, Bydgoszcz, Poland

Introduction/Background

Stroke is the main cause of disability in people over 40 years old. The aim of this study was to evaluate the effectiveness of hospital rehabilitation after the age of 80, considering the level of cognitive functions.

Material and Method

The study was performed retrospectively on the basis of medical documentation of patients hospitalized in the Rehabilitation Clinic in 2012-2017. 152 persons were qualified for the study. Inclusion criteria were: previous ischemic or hemorrhagic stroke, age over 80 years. Exclusion criteria: lack of cooperation with the patient, interrupted rehabilitation.

The Barthel-ADL scale was used to assess functioning in everyday activities. Cognitive functions were assessed using the MMSE scale. Patients were examined on the day of admission to the Clinic and after the treatment.

Results

In 111 people, there were statistically significant differences between the results of ADL scale on the day of admission and on the day of discharge. There was a 4-person deterioration of the result, 107 persons improved, while the result of 41 people remained unchanged.

After an analysis of the improvement after hospital rehabilitation in the Barthel ADL scale depending on the MMSE score was respectively: in the group of patients with the MMSE standard - by 2.34 points, in the group with functional disorders cognitive 3.35, at dementia 3.37 points, with low dementia 2.66 points, with average dementia 2.1, deep dementia no change.

Conclusion

1. There is a strong justification for conducting post-stroke rehabilitation in patients over 80 years old.
2. Most benefits from post-stroke rehabilitation were achieved by patients with MMSE score on the borderline of dementia and norm.

3. Patients with medium and deep dementia receive the smallest benefits of post-stroke rehabilitation measured on the Barthel ADL scale.

4. Due to the small number of patients with deep dementia, this topic requires continuing research in this group of patients

THE COMBINED EFFECT OF NON-INVASIVE CORTICAL STIMULATION AND MOTOR TRAINING ON HAND MOTOR DEFICIT IN CHRONIC STROKE

N. Ilic¹, E. Dubljanin Raspopovic¹, U. Nedeljkovic¹, S. Tomanovic Vujadinovic¹
¹University of Belgrade - Faculty of Medicine, Physical medicine and rehabilitation, Belgrade, Serbia

Introduction/Background

A growing body of evidence supports the effectiveness of transcranial direct current stimulation (tDCS) in rehabilitation of patients with hand motor impairment in the chronic phase of stroke. Furthermore, it is assumed that the combination of stimulation- and practice-induced plasticity may be especially beneficial. Aim is to compare the combined effects of anodal tDCS and specific motor training (MT) to sham tDCS and MT (control) on hand motor deficit in patients with chronic stroke.

Material and Method

A total of 30 patients were randomly assigned to an active treatment group (real tDCS+MT) or a control group (sham tDCS+MT) in this parallel, two-arm, double-blind, sham-controlled study. MT was administered for 45 min/day (10 sessions) and preceded by 20 minutes of either 2 mA anodal tDCS or sham tDCS over the ipsilesional primary motor cortex. A modified Jebsen-Taylor Hand Function Test (mJTt) was the primary outcome measure, with handgrip dynamometer and upper limb Fugl-Meyer (ULFM) assessments as secondary outcomes. A subset of 21 patients was additionally evaluated by transcranial magnetic stimulation measures of the primary motor cortex excitability.

Results

The ANCOVA, controlling for baseline status (T0), showed a statistically significant Time x Group interaction for mJTt due to a statistically significant change over time in the active tDCS group compared to the sham tDCS group. In the active tDCS group, the mJTt time was significantly shorter both at the end of treatment (T2 vs. T0, decrease of 35.36 ± 22.90 s or 28.42 ± 14.56 %) and at the follow-up (T3 vs. T0, decrease of 24.21 ± 24.66 s or 19.98 ± 17.49 %). The active motor threshold decreased and the MEP amplitude increased.

Conclusion

Our findings suggest that hand motor deficits in chronic stroke survivors can be reduced when intensive MT is primed with anodal tDCS over the ipsilesional primary motor cortex.

THE STUDY OF EVENT-RELATED POTENTIALS IN UNILATERAL SPATIAL NEGLECT
G. Shan1
1XuanWu Hospital Capital Medical University, Rehabilitation Department, Beijing, China

Introduction/Background

To compare the amplitude and latency of P1, N1, P2, N2, P300 between the Unilateral Spatial Neglect patients after right hemisphere stroke and normal people, in order to study the spatial attention processing characteristic of Unilateral Spatial Neglect patients, further to explore the mechanism of USN.

Material and Method

20 cases (10 USN patients and 10 Normal people) were enrolled in the study. We recorded the ERP, and then compared the reaction time and correct rate, the amplitude and latency of P1, N1, P2, N2, P300 when the target appeared in the left and right, to study the mechanism of USN.

Results

The correct rate of the USN group was lower than the Normal group. There were no significant differences between the two groups in P1 amplitude and N2 amplitude. The N1 and P2 amplitude of right hemisphere of the USN group was lower than the Normal group. When the target appeared in the left, the P300 amplitude of the USN group was lower than the Normal group. The latency of P1, N1, P2, N2, P300 in the USN group was prolonged than the Normal group.

Conclusion
During the spatial attention processing, regardless of the stimulus from the left or right, the information processing speed of the USN group slowed down compared with the normal group. In the early stage, there was no significant reduction of activity neurons. In the mid-stage, the number of activity neurons was reduced significantly in the right hemisphere. But in the late stage, the number of activity neurons was reduced significantly when the stimulus from the left side.

ADVANCES IN DIAGNOSIS OF VASCULAR DEMENTIA

J.W. Shao¹, X. Bi¹
¹Shanghai Pudong Gongli hospital, Rehabilitation department, Shanghai, China

Introduction/Background

Vascular dementia (VaD) is a syndrome characterized by cognitive impairment caused by vascular risk factors or cerebrovascular disease. It is the second most common form of senile cognitive impairment after Alzheimer’s disease, which is extremely harmful. Early diagnosis is beneficial to the prevention and treatment of disease, which is of great significance in reducing disability and improving the patient's activities of daily living. However, the pathogeny, pathological and imaging manifestations of the disease are diversification, which makes it difficult to diagnosis.

Material and Method

In this paper, we searched Pubmed, Google Scholar and VIP database, Vascular dementia, diagnosis and advances as the key words, then read the relevant literature and references in recent 5 years. The article reviews the advances in diagnosis of VaD in recent years, including the clinical diagnosis, neuropsychological diagnosis and imaging diagnosis.

Results

Attention, information processing and executive function decreased significantly, while memory and speech disorders were light, which was the characteristic of VaD. The 5 minute assessment scheme (simplified by Montreal Cognitive Assessment) is suitable for the initial screening of disease. The assessment of activities of daily living and mental behavior (such as depression and apathetic) also contribute to the diagnosis of VaD. Diffusion tensor imaging (DTI) has high sensitivity and high specificity to alba injuries caused by cerebrovascular disease. Magnetic resonance spectroscopy (MRS) can observe the changes of brain tissue metabolites related to brain function early in the disease. Susceptibility weighted imaging (SWI) is highly sensitive to cognitive impairment caused by hemorrhagic VaD. Blood oxygen level dependent functional MRI (BOLD-fMRI) can further monitor the brain functions through changes in the concentration of deoxyhemoglobin.

Conclusion

Although there is no unified standard of diagnosis, symptoms of cognitive impairment, accurate neuropsychological scales for assessment combined with magnetic resonance imaging (MRI) could improve the detection rate at early stage.

THE IMPACT OF THE PHARMACOTHERAPY ON STROKE RECOVERY. A RETROSPECTIVE COHORT STUDY.

S. Straudi¹, G. Busà², S. Volpato³, E. Maietti³, N. Basaglia¹

¹Ferrara University Hospital, Neuroscience and Rehabilitation, Ferrara, Italy
²Ferrara University, School of Medicine, Ferrara, Italy
³Ferrara University, Clinical Epidemiology Center, Ferrara, Italy

Introduction/Background

Stroke represents a leading cause of worldwide disability with a reduced quality of life and participation to work, family and social life activities. During the recovery stage, several approaches have been studied to enhance the processes underlying spontaneous recovery, among which drugs, such as the dopaminergic or serotonergic agents. Conversely, several classes of drugs have been proposed to have a detrimental effect on recovery, such as the anticholinergic agents, anticonvulsants, neuroleptics and GABAergic agents. The aim of this study is to evaluate the possible association between drug assumption during an inpatient rehabilitation and functional recovery after stroke. Specifically, we hypothesized that there is a different use of antidepressants (positive effect) or GABAergic, anticholinergic agents and neuroleptics (negative effect) in patients with different level of functional recovery.

Material and Method

We included in the study subjects (aged > 18y) who underwent a stroke multidisciplinary rehabilitation program at Ferrara University Hospital. We categorized them into Good Responders (GR) or Poor Responders (PR) according with their functional improvement, measured by the Functional Independence Measure (FIM) score. From digital medical records, we extrapolated clinical, demographic data, the total FIM score and the drugs assumed.

Results

We enrolled 181 subjects (76 female), age 65.30 ± 13.27 y, with a diagnosis of ischemic (n=118) or hemorrhagic stroke (n=63). Antidepressants were assumed by 40.98% of the PR group and the 20.83% of the GR group (p = 0.004); Benzodiazepine were taken by 31.15% of the PR group compared with the 15% of the GR group (p=0.01). Anticholinergic agents were assumed by 31.15% of the PR group compared with the 12.50% of the GR group (p=0.002).

Conclusion

Benzodiazepines and anticholinergic agents may play a negative role on functional recovery after stroke. Acknowledgment: this study was partially supported by ER Grant 1786/2012.

Introduction/Background

To investigate immediate efficacy of Mirror Neuron System Training which one is a kind of neural modulation technique on patients with dysphagia after stroke and to compare the treatment effect with neural modulation technique and electric stimulation.

Material and Method

Adopting random control test design, 30 patients (in plateau by traditional electric stimulation therapy) with dysphagia in 3 to 6 months after stroke. They were divided into 3 groups by random and each group includes 10 patients. Group A received the treatment protocol including hand action observation training by an equipment named Mirror Neuron System Training (MNST), as well as traditional electric stimulation therapy approaches. Group B received MNST and Group C just received electric stimulation therapy. Each Patient completed total of 40 sessions over an 4-week period, with two sessions a day and five day each week.

Results

All 30 patients did the test included 30 ml Water screening test, Mann assessment of swallowing ability, The volume-viscosity swallow test and Functional oral intake scale. The degrees of every test for the patients in Group A were much higher than the other groups. And the performance of Group B were higher than Group C, too (p<0.05).

Conclusion

Evidence from this random control case study indicates potential effect of integrating neuromodulation technique (MNST) with traditional electric stimulation therapy to improve swallowing capacities for patients with dysphagia.

ISPR8-2493
EFFECT OF SENSORY-MOTOR TRAINING ON GAIT QUALITY AND EXECUTIVE FUNCTIONING OF CHRONIC STROKE SURVIVORS
R. la Grange¹, K. Welman¹
¹Stellenbosch University, Sport Science, Stellenbosch, South Africa

Introduction/Background

Traditionally gait was believed to be an automated task; however current research shows that walking involves higher cognitive functions i.e. executive function (EF). Optimal EF allows allocation of appropriate attentional resources to performing motor tasks correctly and effectively and is severely affected in stroke survivors. Limited research has been done on the effectiveness of sensory-motor training (SMT) on cognitive functioning in stroke. It is hypothesized that SMT may improve this motor-cognitive interaction during gait, as well as EF. This study endeavoured to determine if an eight-week SMT programme would influence executive functioning and dual-task gait quality in chronic stroke survivors.

Material and Method

This pre-post study design consisted of ten chronic stroke survivors (67±14 years; ≥6 months since stroke) with no severe cognitive impairment (24±2 score on Montreal Cognitive Assessment) who participated in the eight-week SMT programme, three times a week (45-60 minutes per session) under therapist-supervision. A two-minute walk test assessed single (ST) and dual-task (DT) spatial-temporal gait variables; while EF was assessed with an adapted Stroop, Trail Making (Part A and B) and Verbal Digit Span Forward and Backward tests. Stroke related self-efficacy was determined by completing the Stroke Self-efficacy Questionnaire.

Results

No significant changes were found in EF or ST gait variables. DT stride velocity (p=0.05, d=0.39, 95%CI: -11.07 to -0.73), paretic stride velocity (p=0.04, d=0.40, 95%CI: -11.34 to -1.18), cadence (p=0.03, d=0.78, 95%CI: -19.04 to -2.50), stride time (p=0.02, d=0.82, 95%CI: 0.00 to 0.40) and peak medio-lateral trunk acceleration (p=0.02, d=0.45, 95%CI: -5.93 to -1.16) showed improvement. Stroke-related self-efficacy (p<0.001; d=2.66, 95%CI: 1.26 to 4.57) also improved.

Conclusion

Preliminary findings suggest that SMT have some benefits for improving cognitive-motor interaction during walking, while also improving factors that specifically influence performance in stroke survivors. Furthermore, studies should investigate the use of DT as an ecological assessment tool for stroke survivor’s EF.

A3.02 Neurological and Mental Health Conditions - Traumatic Brain Injury

ISPR8-0031
PREVALENCE OF TRAUMATIC BRAIN INJURY BETWEEN TRAUMATIC NEUROLOGICAL DISEASES WITH ATTENTION IN PHYSICAL THERAPY SERVICES
G.A. Baquero Sastre
\(^1\)Manuela Beltran University, Physical Therapy, Bogotá, Colombia

Introduction/Background

The Traumatic Brain Injury is one of the more important problems between the neurological problems for their implications in cognitive functions, mobility, communications and functional capacity of the persons, and your presentation have a increment for the number of accidents and violences cases in the modern societies. To know the prevalence of the traumatic brain injury is important for the plans of attention in services of health and the prevention programs in young people

Material and Method

The study is a cross sectional investigation, the people of study are persons with attention in Physical Therapy Services with clinical practices of the Physical Therapy Program of Manuela Beltran University in the year 2012 for traumatic neurological diseases, the instrument for recolection of the information are the statistical register of attention of patients in the period of study, the analysis of information have general prevalences and specific prevalences and chi square test for to see the relation ship of the gender with the presentation of the brain injury

Results

In the year 2012, 191 persons had attention in physical Therapy Services for traumatic neurological diseases, the prevalence of traumatic brain injury in this context is 44.50% (n=85, standard error= 0.03), the traumatic brain injury is the first traumatic neurological diseases between the entities of this type in Physical Therapy. 72.94% of the persons with brain injury are of male gender (n= 62, standard error=0.02, O.R =3.04, C.I. 95 % 1.93 – 4.75, X2=21.08, p < 0.05)

Conclusion

The traumatic brain injury is the first traumatic neurological diseases and this entity is more prevalent in persons of male gender that have three more times risk of the presentation of this problem with respect persons of female gender with statistical significance

PHYSICAL ACTIVITY INTERVENTIONS, APPROACHES AND OUTCOMES FOR INDIVIDUALS WITH TRAUMATIC BRAIN INJURY: A SCOPING REVIEW PROTOCOL TO ASSIST CLINICAL DECISION-MAKING

C. Alarie¹, I. Gagnon², B. Swaine³

¹Université de Montréal, École de réadaptation, Montréal, Canada
²McGill University, School of Physical and Occupational Therapy, Montréal, Canada
³Centre de Recherche Interdisciplinaire du Montréal Métropolitain CRIR, Centre de réadaptation Lucie-Bruneau du CIUSSS CSMTL, Montréal, Canada

Introduction/Background

Growing evidence suggests physical activity improves physical and cognitive function and alleviates fatigue, sleep and mood disorders in individuals who sustain a traumatic brain injury (TBI). Physical activity intervention (PAI) modalities/approaches appear to vary across the care continuum and with TBI severity, making it difficult to choose the most appropriate intervention for a given individual. There are no available standards for PAI use with this population. Our study aims to systematically map the current state of the literature describing PAIs and their outcomes following TBI.

Material and Method

Our scoping review follows a 6-step framework (Levac, 2010; Arskey and O’Malley, 2005). Grey literature and four databases were searched (SportDISCUSS, MEDLINE, CINHAL & EMBASE), resulting in 4964 references. Documents reporting any type of PAI (e.g. yoga, aerobic exercise) for individuals with TBI, are included. Data extraction, analysis, and synthesis are ongoing. A focus group with stakeholders from a rehabilitation center providing TBI interventions will validate and enhance the results thereby constituting the consultation phase of the review.

Results

Preliminary results indicate that PAIs vary from specific interventions with a therapeutic goal (e.g. decrease headache) to global multidisciplinary programs aiming to facilitate community integration. These include individual and group interventions, unsupervised and unstructured programs or rigorously monitored programs with technological assistance. Several outcomes exist that are organized using the International Classification of Functioning, Disability and Health.

Conclusion

This review will contribute in assisting service providers select the most appropriate PAI on a case-by-case basis linked to desired outcomes.

THE EFFECT OF BODY MASS INDEX ON INDICES OF FUNCTIONAL PROGNOSIS: EVIDENCE FOR ‘OBESITY PARADOX’ AMONG TRAUMATIC BRAIN INJURY POPULATION

D. Burke¹, R. Bratton Bell¹, S. Al-Adawi², D.P. Burke³

¹Emory University School of Medicine, Rehabilitation Medicine, Atlanta, USA
²Sultan Qaboos University, Department of Behavioral Medicine, Al-Khoud, Oman
³Georgia State University, Georgia State University, Atlanta, USA

Introduction/Background

While many studies have demonstrated that obesity is correlated with an increased risk of chronic disease, some have reported a paradox by which those in the higher weight categories actually recover better during hospitalization. This study was designed to determine whether this obesity paradox is also reflected in the recovery of patients with a traumatic brain injury who were undergoing care in a rehabilitation hospital.

Material and Method

Retrospective cohort study which included all patients admitted to the brain injury unit of a rehabilitation hospital from January 2000 – April 2006. The data used for this study included patient height and weight (measured on admission) and functional independence measurements (scored on admission and discharge).

Results

For the 444 patients admitted, the overall FIM efficiency did not differ significantly by BMI (p=0.93). After adjusting for age and sex, the overweight and obese patients had the lowest FIM efficiency (1.04 for both groups), followed by the underweight and normal weight groups (1.11 and 1.26).

Conclusion

This study demonstrated that higher BMI patients did not adversely influence the rate of functional recovery among patients admitted to a rehabilitation hospital for TBI.

Keywords

Traumatic Brain Injury; Stroke; FIM Efficiency

Introduction/Background

To provide an overview of recommendations and quality of existing clinical practice guidelines (CPGs) for management of traumatic brain injury (TBI) focusing on rehabilitation medicine; and synthesise recommendations from these for applicability in disaster settings.

Material and Method

Comprehensive literature search including health databases, CPG clearinghouse/developer websites, and grey literature using internet search engines to September 2017. All TBI CPGs published in the last decade were selected if their scope included: management of TBI, systematic methods for evidence search, clear defined recommendations and supporting evidence for rehabilitation interventions. Three authors independently critically appraised the quality of included CPGs using the Appraisal of Guidelines, Research and Evaluation (AGREE) Instrument. All recommendations were extracted, compared and categorized for applicability in disaster settings.

Results

Only 4 of the 14 potential identified CPGs met the inclusion criteria. Despite variation in scope, target population, size, and guideline development processes, all four CPGs were assessed as of good quality (AGREE Global score of 5-7 out of 7). The recommendations included: patient/carer education, general physical therapy, practice in daily living activities and safe equipment use, direct cognitive/behavioural feedback, basic compensatory memory/visual strategies, basic swallowing/communication and psychological input for TBI survivors in disaster settings. More advanced interventions are generally not applicable following disasters due to limited access to services, trained staff/resources, equipment, funding and operational issues.

Conclusion

Although CPGs in this study were of high quality, many recommendations for TBI care are challenging to implement in disaster settings and need further research to identify and address barriers for implementation.

EFFECT OF BODY MASS INDEX ON FUNCTIONAL OUTCOME IN PATIENTS WITH TRAUMATIC BRAIN INJURY
A.J. Costa¹, A. Borges¹, I. Carneiro¹, M. Pereira¹, G. Beça¹, R. Nunes¹
¹Centro de Reabilitação do Norte, Unidade de Reabilitação do Traumatismo Crânioencefálico, Vila Nova de Gaia, Portugal

Introduction/Background

Currently, there is a considerable body of literature that has reviewed the effect of body mass index (BMI) on the individual’s health. However, there are few data on how BMI influences the outcome of people with traumatic brain injury (TBI).

The purpose of this study was to investigate the association between body mass index (BMI) and functional outcome of patients admitted to a Rehabilitation Center, after TBI.

Material and Method

This retrospective study included patients admitted with TBI between January 2016 and December 2017. Data collected included patient demographic features (age, sex, weight and height by admission), severity of TBI (Glasgow Coma Scale score), and functional outcome measured by the Functional Independence Measure (FIM) score, on admission and on discharge. Inclusion criteria consisted of age of 18 years or older and complete information on FIM score, height or weight.

Results

A total of 58 subjects met the criteria for inclusion in the study. The mean age was 43,31 ± 17,82 years (range, 19-86), 84,5% were male and 15,5% were female. Of these, 10 (17,2%) were underweight, 37 (63,8%) were normal weight, 11 (18,9%) were overweight and moderately obese. All groups showed similar improvement in FIM score: 31,00±21,04 for the underweight group, 26,75±19,26 for the normal weight group and 27,82±15,80 for the overweight and moderately obese group (p=0,873). All groups showed similar FIM score by admission (p=0,633) and discharge (p=0,628). The weight showed a negative correlation with improvement of FIM score (r=-0,326, p=0,013).

Conclusion

Among patients undergoing inpatient rehabilitation after TBI, BMI by admission had no impact on functional outcomes. This was found to be consistent with other study demonstrating no impact of obesity on motor functional outcomes of the TBI patients. However, this is contrary to previous studies in non-TBI patients that suggested that obesity hampered recovery of motor functions during rehabilitation.

**Introduction/Background**

Secondary rhinorrhea can be observed as a complication of traumatic brain injury and witness to the presence of cerebrospinal fluid (CSF) fistula. Making the diagnosis of this complication appears like a major issue since it can lead to central nervous system infection. It seems primary to keep this complication in mind during long-term follow-up of patients with traumatic brain injury.

**Material and Method**

We report the case of a 30-year-old man, whom was the victim of a severe traumatic brain injury in 2017, June. He presented right translabyrinthic fracture, left occipital fracture, multiple hemorrhagic contusions, right frontal and temporal sub-arachnoid hemorrhage and sigmoid sinus thrombosis.

Right deafness and anosmia persisted. The patient complained about cognitive impairment and was addressed in a Physical Medicine and Readaptation service for cognitive assessment in 2018, February. During an ergotherapy session, he made a confidence: “when I am faced with tasks requiring concentration, I have a right runny nose”. This element led to raise the diagnosis of CSF fistula.

**Results**

A right slightly abundant clear rhinorrhea was observed during different and reproducible activities: cognitive tasks, physical activities such as cycling or push-outs. Cerebral computed tomography (CT) did not show any sign of CSF fistula. Then, cerebral magnetic resonance imaging (MRI) succeeded in highlighting the right ethmoidal CSF fistula. The patient could be
addressed to surgery service.

Conclusion

This case report highlights the importance of the attention paid to complaints of patients and the communication between members of a rehabilitation multidisciplinary team. In addition, it
exemplifies the importance of clinical examination to guide the diagnosis strategy and the choice of diagnosis tools.

HYPOGONADISM IS ASSOCIATED WITH LOWER FUNCTIONAL PERFORMANCE DURING INPATIENT REHABILITATION FOLLOWING HYPOXIC ISCHEMIC ENCEPHALOPATHY

D. Ripley¹, B. Ingraham², M. Kocherginsky³, M. Maneyapanda⁴, K. Franzese²
¹Shirley Ryan Ability Lab, Department of PM&R, Chicago, USA
²Northwestern McGaw Medical Center/Shirley Ryan AbilityLab, Physical Medicine and Rehabilitation, Chicago- IL, USA
³Northwestern University Feinberg School of Medicine, Department of Preventive Medicine- Division of Biostatistics, Chicago- IL, USA
⁴Bryn Mawr Rehabilitation Hospital, Brain Injury Program, Malvern- PA, USA

Introduction/Background

Neuroendocrine dysfunction, including hypogonadism, is a frequent complication after traumatic brain injury (TBI). Hypogonadism has been associated with worse functional performance after TBI. The prevalence of hypogonadism and its relationship to functional status after hypoxic ischemic encephalopathy (HIE) has not been previously reported. This study aimed to determine if hypogonadism is also negatively associated with functional performance during inpatient rehabilitation following HIE.

Material and Method

Records were reviewed from male patients sequentially admitted for inpatient rehabilitation following HIE over a three-year period at an academic inpatient rehabilitation facility in the United States. Demographic, diagnostic, Functional Independence Measure (FIM) data, and serum endocrine results were collected. Linear regression analysis was performed to investigate the association between hormone values and functional status with a focus on Testosterone (T) function.

Results

Twenty-nine male subjects were admitted with HIE during the target time frame. Subjects had a mean age of 37.6 years. Twenty subjects had T levels drawn on admission to rehabilitation; of these, five (25%) had levels below the normal range (2.0 – 8.0 ng/mL). Lower T levels were associated with worse admission total FIM (p=0.001), motor FIM (p=0.004) and cognitive FIM scores (p=0.003). Low T levels were also associated with worse discharge total FIM (p=0.04) and cognitive FIM scores (p=0.05) and a trend towards lower discharge motor FIM scores (p=0.06).

Conclusion

The prevalence of hypogonadism in this population of HIE subjects was 25%, similar to that seen in studies of subjects with TBI. Hypogonadism was negatively associated with a lower
functional status across domains. This relationship is similar to that seen in the traumatic brain injury population. Impaired hormone function should be considered clinically following HIE and warrants further investigation.

We proposed to study the social and epidemiological profile of patients with severe brain trauma in Physical and Rehabilitation Medicine Department.

**Material and Method**

This is a retrospective study conducted on patients hospitalized at the Department of Physical and Rehabilitation Medicine (PRM) in Sahloul Hospital SOUSSE TUNISIA for severe head trauma in the period extending from January 2011 to December 2015.

**Results**

We collected 43 patients: 35 males and 8 females. 25% of patients were young (21-30 years). 44.2% were workers, 9.3% were retired. It was estimated that 65.1% had an average socio-economic level. 48.8% had a primary level of study. 25% had no health insurance. 55.8% were married and 95.3% lived with their families. 30.2% lived in a single-storey house. 76.7% were victims of a road accident. 9.3% were victims of a work accident. 37.2% had an initial Glasgow Coma Scale between 3 and 8. At the initial assessment of the lesions, 25.6% had a subarachnoid hemorrhage and 34.9% had surgical treatment. 11% of patients had a post critical amnesia. Only 2 of our patients were in persistent vegetative state. 61.9% of patients were transferred from the intensive care unit, 4.8% from orthopedics, 2.4% from neurosurgery and the rest of the PRM external consultation. The management delay in PRM was less than one month in 30.2% of cases, between one and three months in 51.2% of cases and more than three months in 18.6% of cases.

**Conclusion**

Head injuries are the leading cause of mortality of patients under 45 years.

Reeducation and rehabilitation of head trauma patients must be provided by multidisciplinary teams. The care and support of these patients is a course that fits throughout life.

Introduction/Background

Patients who have suffered a traumatic brain injury (TBI) uncertainty remains around post-traumatic seizure prophylaxis and for duration of treatment with anti-epileptic drugs (AEDs) for those who developed post-traumatic seizures (PTS). In early 2017, a collaborative group of neurosurgeons, neurologists, neuro-intensive care physicians and rehabilitation medicine physicians was formed in the UK with the aim of examining current practice patterns, gauging the degree of uncertainty, and thus designing relevant future studies. In order to address the first two objectives, we undertook a questionnaire survey of clinicians managing patients with TBI.

Material and Method

An online questionnaire survey was developed and piloted. Following approval by the Academic Committee of the Society of British Neurological Surgeons, it was distributed via relevant electronic mailing lists.

Results

The online questionnaire was answered by 117 respondents, predominantly neurosurgeons (76%) from 30/32 trauma-receiving hospitals in the United Kingdom and Ireland. 53% of respondents do not use seizure prophylaxis and 38% prescribe prophylaxis for 1 week. 70% feel there is uncertainty regarding seizure prophylaxis and 69% would participate in further research to address this question. 62% of respondents used levetiracetam for treatment of seizures and 42% continued for a total of 3 months’ post seizure but 90% were unclear concerning duration of treatment of seizures.

Conclusion

The survey results demonstrate the uncertainty in both described aspects of management of patients who have suffered a TBI. The majority of respondents would want to participate in future research to help try and answer these questions and this shows the importance and relevance of these two clinical questions.

REHABILITATIVE OUTCOME OF COMATOSE PATIENTS 12 MONTHS AFTER TRAUMATIC BRAIN INJURY.

M. Grünerová Lippertová.¹
¹Faculty Hospital Kralovske Vinohrady and Charles University - 3rd Medical Facult,
Department of Rehabilitation Medicine, Prague 10, Czech Republic

Introduction/Background

As a result of improvements in the rescue system and progress in intensive care therapy, an increasing number of patients have survived severe traumatic brain injury in recent years. An early and consistent administration of the correct rehabilitation programme is of crucial importance for the restoration and improvement of cerebral function, as well as social reintegration. Prospective study conducted at the neurosurgical department of a university hospital to assess the one-year outcome of comatose patients after severe traumatic brain injury.

Material and Method

27 patients were included. Patients received multimodal early-onset stimulation and continuous inpatient and outpatient rehabilitation therapy.

12-months outcome was assessed by means of Glasgow outcome scale, Barthel index, Functional independence measure (FIM) and need of care.

Results

Results: 7 patients died, 4 remained in a vegetative state, 7 were severely disabled, 6 were moderately disabled, and 3 achieved a good recovery 12 months after injury. Mean Barthel index was 66.7 and mean FIM was 85.2. The majority of patients still were at least intermittently dependent on care.

Conclusion

Despite intensive rehabilitation treatment, severe traumatic brain injury is still burdened with significant mortality and morbidity.

REHABILITATION OUTCOME 6 MONTHS OF SEVERE TRAUMATIC BRAIN INJURY AND DECOMPRESSIONAL CRANIECTOMY.
M. Grünrová Lippertová

Faculty Hospital Kralovske Vinohrady and Charles University - 3rd Medical Facult, Department of Rehabilitation Medicine, Prague 10, Czech Republic

Introduction/Background

Traumatic brain injury is still a significant cause of death due to a raise of intracranial pressure leading to deterioration of cerebral perfusion which represents a major predictor of mortality. To evaluate the effects on patients’ outcome of decompressive craniectomy with duraplasty (dc) in case of increased intracranial pressure consequent to severe traumatic brain injury (stbi).

Material and Method

A prospective study was conducted to assess outcome as measured by GOS, Barthel index, and Functional Independence Measure (FIM). In addition, professional ability and the need for care were evaluated. A total of 15 cases were included. Endpoint of follow-up was at 6 months after injury.

Results

Overall outcome was unfavourable with a median GOS of 3 and a mortality rate of 33%. Mean Barthel index was 46.5 (range 0-100), mean FIM score 67.5 (18-126). Only 3 cases reached a condition completely independent of care. None of the patients regained professional ability.

Conclusion

Despite treatment with dc, overall outcome in stbi remains unfavourable.

DUAL TASK GAIT AFTER MODERATE TO SEVERE TRAUMATIC BRAIN INJURY: CHARACTERIZATION OF TROUBLES AND CONSEQUENCES
L. Abadie¹, O. Kozlowski¹, K. Youssef², C. Rogeau³, W. Daveluy¹, A. Benoit¹, E. Allart¹
¹Lille University Medical Centre, Neurorehabilitation unit, Lille, France
²Sainte Barbe rehabilitation centre, Neurorehabilitation Unit, Fouquières les Lens, France
³MAS de Loos, Brain injuries department, Loos, France

Introduction/Background

Patients suffering from traumatic brain injury (TBI) often present with cognitive but also posture and gait impairments. In this study, we aimed at evaluating the cost of the addition of 3 types of cognitive concurrent tasks on gait parameters, and studying the relationship between dual task cost and patient-reported perception of their confidence in balance and gait in daily living.

Material and Method

Spatiotemporal gait parameters were assessed using a GAITRITE mat in 22 moderate to severe TBI patients and 26 age-matched healthy controls. The addition of 3 cognitive tasks (letter back-task, subtractions by 3, talking when walking) was studied during unobstructed walking and stepping over an obstacle. We also evaluated the relationship between dual task cost during gait and (1) cost in another motor task (Baddeley) and (2) patient perceived confidence in dynamic balance and gait in daily living (ABCscale).

Results

Dual task cost during gait was higher in TBI patients compared to healthy controls when walking unobstructed and in the subtraction and talking concurrent tasks. Alteration of gait speed was primarily due to a decrease of step length more than of gait cadence. TBI patients tended to prioritize the cognitive task. Dual task cost during gait was correlated with the Baddeley dual task performance (r=-0.420; p=0.003) but not with the ABCscale score.

Conclusion

TBI patients exhibit difficulties in dual task gait conditions, which can be easily assessed and should be addressed in rehabilitation. The dual task cost could be not specific to locomotor activities. Finally, other factors seem to explain the alteration in confidence in gait and balance in daily living.

COGNITIVE REHABILITATION IN MILD TRAUMATIC BRAIN INJURY: A RESEARCH PROTOCOL
N. hamzah1, V. narayanan2, N. Raml3, N.A. Mustapha4, N.A. Mohammad Tahir4, A. Drummond5, R. Das Nair5, M. Mazlan1
1University of Malaya, Rehabilitation Medicine, Kuala Lumpur, Malaysia
2University of Malaya, Dept of Surgery, Kuala Lumpur, Malaysia
3University of Malaya, Biomedical Imaging, Kuala Lumpur, Malaysia
4University Malaya Medical Centre, Rehabilitation Medicine, Kuala Lumpur, Malaysia
5University of Nottingham, Faculty of Medicine and Health Sciences, Nottingham, United Kingdom

Introduction/Background

Multiple cognitive complications persist following mild traumatic brain injury. A proportion of this population quite often progress to have chronic cognitive disability that is overlooked due to the initial ‘mild’ presentation. Currently there is no standard treatment protocol for cognitive therapy in mTBI. In this study we developed a cognitive therapy protocol for attention deficits.

Material and Method

This study is registered with ClinicalTrials.gov (NCT03237676). This is a two arm randomised controlled trial. We applied the Medical Research Council (MRC) Developing and Evaluating Complex Intervention in the development of study intervention. To strengthen the components, we conducted a pilot study and Expert Panel review. The protocol is divided into three segments; 1) Neurocognitive evaluation, 2) Diffusion Tensor Imaging, and 3) Cognitive rehabilitation. Each arm receives standardised evaluation of the first two segments mentioned but different treatment approach. Both treatment starts at 3 months post trauma. Control arm receives a pre-existing patient-centred cognitive therapy at the recruitment centre, which include symptoms management and cognitive coping strategies. Intervention group receives individualised structured cognitive rehabilitation that consist of Direct Attention Training (DAT) and Metacognitive Approach (MA). DAT is a deficit-oriented computer-based treatment on all types of attention deficits whereas MA involves generalisation of learned attention tasks to everyday function. This approach include review of individualised goals and cognitive functional problem-solving training. Therapy frequency is one hour per week for three months.

Results

Three outcome measures are changes in neuropsychological assessment scores, white matter tract (WMT) parameters and Goal Attainment Scale (GAS) scores measured at baseline and end of treatment. Statistical analysis include descriptive analysis, effect size calculation and correlation between cognitive treatment and outcome measures. WMT post-processing involves Tract-based Statistical Analysis and Region of Interest approach.
Conclusion

The results of this study will contribute to an evidence-based, early cognitive treatment in mTBI.

TRANSCRANIAL DIRECT CURRENT STIMULATION ON THE CLINICAL CURATIVE EFFECT OF PATIENTS WITH DISTURBANCE OF CONSCIOUSNESS

L. Hongling¹

¹The Second Hospital of Hebei Medical University, Department of Rehabilitation, Shijiazhuang, China

Introduction/Background

Transcranial direct current stimulation (Transcranial direct current stimulation, tDCS) is a non-invasive brain stimulation techniques. tDCS plays a role by regulating the activity of spontaneous neuronal networks. Such as stimulation in patients with primary cerebral cortex motor area (M1), which can effectively improve the patient's motor dysfunction, and stimulate the prefrontal cortex, which can effectively improve patient swallowing dysfunction, etc. but the tDCS with conventional rehabilitation therapy in patients with disturbance of consciousness of clinical research is rarely reported.

Objective  To explore the clinical efficacy of transcranial direct current stimulation on the clinical curative effect of patients with disturbance of consciousness (DOC).

Material and Method

Method  thirty-eight DOC patients were randomly divided into a observation group and a control group, each of 19. Both groups were given routine rehabilitation intervention, and the observation group were treated with transcranial direct current stimulation on this basis for 20 sessions. The Brainstem auditory evoked potential (BAEP), the Upper sense evoked potential (USEP), the nerve electrophysiology evaluate electroencephalogram (EEG) and the Glasgow coma scale (GCS) or PVS rating scale were used to test both groups before and after the treatment.

Results

Before treatment, the two groups of patients were compared with BAEP, USEP, EEG, GCS or PVS scores, and the difference was not statistically significant (P>0.05). After treatment, BAEP, USEP, EEG, GCS or PVS scores were compared with those in the group before treatment, and the difference was statistically significant (P<0.05). And the observation group’s BAEP, USEP, EEG, GCS or PVS scores were better than the control group (P<0.05).

Conclusion
On the basis of conventional rehabilitation therapy, tDCS treatment can further improve the patients’ consciousness disorder, and this combination therapy is worthy of clinical promotion and application.

The purpose of this study was to analyze NASVA scores using Rasch analysis, and to create a difficulty map of NASVA score to predict the recovery process for persistent vegetative state, and to improve the fitness of the sub-items of NASVA score.

**Material and Method**

Participants were 114 inpatients (mean age, 37.4 ± 20.4 years) who had been diagnosed with persistent vegetative state after a traffic accident. Rasch analysis was performed by an application named “winsteps”. This application produces a score table, an item measure of the sub-items containing an information-weighted mean square fit statistics (infit) and an outlier-sensitive mean square fit statistics (outfit) of the sub-items. First, I replaced NASVA score with the binary score. Rasch analysis provided a scaled score corresponding to the binary score. The raw score was the sum of the binary score of the sub-item. Then, I made the difficulty map using the scaled score that was calculated in winsteps as the item measure. Furthermore, I analyzed the fitness of the sub-items for the recovery process for persistent vegetative state using their infit and outfit. Here, I set 1.5 or more as misfits for infit or outfit of sub-items.

**Results**

In the results of the fitness analysis, nine sub-items were identified as misfits: one motor function, three feeding functions, one excretory function, one cognitive function, and three articulatory and utterance functions.

**Conclusion**
Nine misfit sub-items had room for interpretation depending on the insufficient of the items description. Therefore, it was suggested that we improve the scale by removing sub-items from the NASVA score, or creating an interpretation manual. On the other hands, by making use of the difficulty map of NASVA score, the medical staff might be able to decide on the proper goals of rehabilitation and care according to the recovery process of the patient.

POST-TRAUMATIC BRAIN INJURY OLFACTORY DYSFUNCTION: FACTORS INFLUENCING QUALITY OF LIFE

F. Ahmedy¹,², M.Z. Abu Bakar³, M. Mazlan⁴
¹Dr, Department of Surgery- Faculty of Medicine & Health Sciences- University Malaysia Sabah, Kota Kinabalu, Malaysia
²Dr, Department of Rehabilitation Medicine- Faculty of Medicine- University of Malaya, Kuala Lumpur, Malaysia
³Associate Professor, Department of Otorhinolaryngology - Faculty of Medicine- University of Malaya, Kuala Lumpur, Malaysia
⁴Associate Professor, Department of Rehabilitation Medicine- Faculty of Medicine- University of Malaya, Kuala Lumpur, Malaysia

Introduction/Background

Previous studies have explored the quality of life (QoL) in people with olfactory dysfunction from various aetiologies. However, knowledge on QoL in people with post-traumatic brain injury (TBI) olfactory dysfunction is still limited. This study evaluates the impact of post-TBI olfactory dysfunction on QoL and determine factors influencing resultant QoL.

Material and Method

A case-control study conducted in a single centre on 30 TBI adults with olfactory dysfunction; matched by age and gender with 32 TBI controls having intact olfactory function. All 64 adults self-rated their olfactory function using a Visual Analogue Scale (VAS). Sniffin’ Sticks test was used as an objective olfactory function assessment and results measured as TDI (Threshold, Discrimination and Identification) score. QoL was determined by a self-rated questionnaire; Questionnaire for Olfactory Disorders (QOD). Influential factors evaluated include age, gender, employment, level of education, marital status, smoking habit, TBI-related clinical information and Disability Rating Scale (DRS) score. A correlation test between the VAS and natural log TDI was also conducted.

Results

Mean QOD score of case group was significantly higher than control group (26.31±14.37 vs 9.44±8.30 respectively; p<0.001). After removing the effect of employment, smoking habit, co-morbidities, TBI duration and DRS score; there was a significant difference of mean QOD score between the two groups (F=16.426, p<0.001, η²=0.224). Calculated effect size was large with d=1.07 and odds ratio of 7.02. The most affected QoL domain was "perception of smell changes". DRS score and olfactory function severity were factors influencing QoL (p<0.05). VAS score was positively correlated with natural log TDI score (r=0.433, p<0.05).
Conclusion

Individuals with post-TBI olfactory dysfunction are at higher risk of developing a lower QoL. One of the factors influencing this is the severity of olfactory dysfunction itself.

VOLUNTARY POSTURAL OR DUAL-TASK TRAINING IMPROVES MOTOR AND MENTAL FUNCTIONS IN PATIENTS WITH TRAUMATIC BRAIN INJURY

L. Zhavoronkova¹, T. Shevtsova², A. Pozdneev³, S. Kuptsova⁴, O. Maksakova⁵, S. Moraresku⁶

³Sechenov Medical Institute, Faculty of Medicine, Moscow, Russia
⁴Center of Speech Rehabilitation, neurorehabilitation, Moscow, Russia
⁵Burdenko Neurosurgery Institute, Neurorehabilitation, Moscow, Russia
⁶Moscow State University, Biological faculty, Moscow, Russia

Introduction/Background

Traumatic brain injury (TBI) is the most common cause of social disadaptation among young people and accompanied by disorders in motor and cognitive spheres. The aim of our study was to estimate a rehabilitation effect of voluntary postural and dual-task training at different periods after TBI.

Material and Method

Seventeen TBI patients (28±5.3) and 32 healthy persons (27,6±0,07) participated at the investigation. Electroencephalographic (EEG), stabilographic studies and clinical scales (MMPI, FIM, MMSE, Berg’s scale) were utilized for estimation of different spheres of human functioning.

Results

Clinical scales demonstrated deficits in all domains including motor and cognitive activity at the early terms after TBI. These deficits accompanied by global decrease of EEG connectivity between brain areas especially for distant brain areas while the increase of connectivity for local networks was observed as a reflection of compensator brain mechanisms. Postural training focused at vertical pose recovery while demonstrated improvement of motor as well as mental functions and accompanied by an increase of EEG connectivity. Dual-tasking was used as next step of rehabilitation course. EEG data demonstrated additional increase of EEG connectivity between different brain areas. Clinical scales showed improvement of all functions and improvement the quality of patient’s life and their social adaptation.

Conclusion

Thus, voluntary postural and dual-task training may be used as effective rehabilitation approach that can serve as trigger for brain functional integration resulting in recovery of disordered functions. This approach may be recommended for patients with functional deficits to enhance
their social adaptation and quality of life. Supported by RBRF grant № 17-06-001012 and № 18-013-00355.

ISPR8-0756
EFFECTIVE REHABILITATION SERVICES IN THE POST-ACUTE PHASE OF MODERATE AND SEVERE TRAUMATIC BRAIN INJURY.
C. Roe1,2,3, C.B. Tverdal1, E.I. Howe4, N. Andelic1,2
1Oslo University Hospital, Dept of Physical Medicine and Rehabilitation, 0424 Oslo, Norway
2Faculty of Medicine- University of Oslo,
Research Center for Habilitation and Rehabilitation Models and Services, Oslo, Norway
3Faculty of Medicine- University of Oslo, Dept of Physical Medicine and Rehabilitation, Oslo, Norway
4Oslo University Hospital, Dept of Physical Medicine and Rehabilitation, Oslo, Norway

Introduction/Background

Background and aims: Rehabilitation services to traumatic brain injury (TBI) have been focused in the acute phase, underpinning the importance of early initiated and well-organized delivery. Less is known about effective rehabilitation service delivery in the post-acute and later phases after TBI. Lack of a framework for depicting differences in service delivery may also contribute to the knowledge gap. Recently, Gutenbrunner et al (J Rehabil Med 2015) proposed a classification for health-related rehabilitation services (International Classification System for Service Organization in Health-related Rehabilitation, ICSO-R) describing provision (i.e., context of delivered services), funding (i.e., sources of income and refunding) and delivery (i.e. mode, structure and intensity) aspects which may be useful for contrasting and comparing rehabilitation services. Aims of this review are

-Provide an overview of randomized controlled trials (RCTs) with rehabilitation service relevance provided to moderate and severe TBI in the post-acute phase.

-Evaluate to which extent providing, funding and delivery dimensions of rehabilitation services are addressed.

Material and Method

A systematic literature search was carried out in OVID MEDLINE; EMBASE, CINHAL, PsychINFO and Social SCI, identifying 50 relevant RCTs.

Results

The studies emerged from nine different counties across all continents except Africa. Two-third of the studies was conducted in a hospital-based rehabilitation setting. In general, funding of the services was not described. In the delivery dimension, therapeutic strategies targeting body functions (78%) was dominating. Only one study was clearly designed to evaluate service delivery mode aspects, finding no difference between the effects of in-hospital or home-based rehabilitation regarding return to gainful employment.
Conclusion

There is a lack of RCTs for evaluation of rehabilitation services in the post-acute phase for moderate and severe TBI. Service aspects may be implicit and possible to evaluate given standardized and better descriptions of the provider, funding and delivery dimensions according to ICSO-R.

REHABILITATION NURSING FOR TRAUMATIC INTRACRANIAL HEMORRHAGE - CASE REPORT
Y.C. Chen¹, B.J. Chen²
¹Taipei Tzu Chi Hospital, Department of Nursing, New Taipei City, Taiwan R.O.C.
²Taipei Tzu Chi Hospital, Department of Rehabilitation, New Taipei City, Taiwan R.O.C.

Introduction/Background

Traumatic brain injury affects the physical and cognitive aspects. Intensive rehabilitation has been shown to benefit this population. However, emotional distress could hinder patients’ will to engage in rehabilitation. We described the supporting role of nurses to drive a patient’s motivation in the rehabilitation regime.

Material and Method

A 60-year-old male underwent ventriculoperitoneal shunt evacuation for intracerebral hemorrhage after a car accident. The person soon revealed negative mood regarding his recovery from physical and occupational therapy. The staff nurses administered Gordon 11 Functional Health Patterns to identify patient’s need and provide according therapeutic care. Barthel Index was applied to evaluate improvement in performing activities of daily life.

Results

Powerlessness, incapacity of self-care, and locomotor disabilities were determined as the primary issues. With accompanying and encouragement, the patient became motivated to engage in and practice therapeutic exercises. The ability to complete daily activities improved from 35 to 80 in the Barthel Index. The patient could independently ambulate with a quadricane > 100m and fulfill dressing and hygiene. By 47 days of hospitalization, he was discharged home and then continued outpatient therapies.

Conclusion

In patients experienced catastrophic disability, psychosocial involvement often aggravates dysfunction alongside with physical impairment. A systematic approach to each individual may help to cope stress and improve the quality of intervention. The case raises our awareness of including nursing care in the holistic practice.

VALIDITY OF THE NORWEGIAN VERSION OF THE NEEDS AND PROVISION COMPLEXITY SCALE

M.V. Forslund1, I.M.H. Borgen1,2, T. Karic1, I. Kleffelgård1, S.L. Hauger1,3, E.I. Howe1,4, R.M. van Walsem5, C. Røe1,4, N. Andelic1,4
1Oslo University Hospital Ullevaal, Department of Physical Medicine and Rehabilitation, Oslo, Norway
2University of Oslo, Department of Psychology- Faculty of Social Sciences, Oslo, Norway
3Sunnaas Rehabilitation Hospital Trust, Department of Research, Nesoddtangen, Norway
4University of Oslo, Faculty of Medicine, Oslo, Norway
5Oslo University Hospital Ullevaal, Department of Neurorehabilitation, Oslo, Norway

Introduction/Background

The Needs and Provision Complexity Scale (NPCS) (Turnes-Stokes et al. 2013) is a simple, pragmatic tool to measure the needs an individual has for rehabilitation and support, and the extent to which those needs are met through service provision. The NPCS comprises two domains; Health and personal care and Social care and support. NPCS – Needs are rated by health professionals based on patient’s needs for health and social care in a given period; whereas NPCS – Gets may be rated by health professionals, patients or significant other based on services received over the same period. The NPCS has been translated to Norwegian (van Walsem et al. 2015), but not validated. The aim of the present study was to do so through assessment of test-retest reliability, inter-rater reliability and concurrent validity in patients with lasting symptoms after traumatic brain injury (TBI) and subarachnoid haemorrhage (SAH).

Material and Method

Fifty adult patients referred to a specialized head injury outpatient clinic at Oslo University Hospital, with ICD-10 diagnosis of TBI (S06.0-S06.9) and of SAH (I60.0-I60.9), will be included in the study. The participants have to provide informed consent and speak Norwegian fluently. The test-retest reliability of the NPCS patient version is tested using a test-retest procedure with a 7 days interval. The inter-rater reliability of the NPCS health personnel version is tested with 2 independent raters. Concurrent validity was tested with the Rivermead Post-Concussion Symptoms Questionnaire, Functional Independence Measure, Community Integration Questionnaire and Neurological Impairment Set.

Results

Sixteen individuals with TBI (68.8 % women, mean age 34.4 years at time of injury) and three individuals with SAH (66.7 % women, mean age 59.3 years at time of injury) have been followed-up so far. The results of test-retest reliability, inter-rater reliability and concurrent validity will be presented at the Congress.
Conclusion

Conclusions will be presented at the Congress.

A CHANGE OF CEREBRAL PERFUSION OF PATIENTS WITH CHRONIC NEUROPSYCHOLOGICAL IMPAIRMENTS BEFORE AND AFTER A DAYTREATMENT GROUP REHABILITATION

G. Uruma¹, K. Hashimoto², N. Takashi³
¹Kajiwara Hospital, Division of Rehabilitation Medicine, Tokyo, Japan
²National Center for Child Health and Development, Division of Rehabilitation Medicine, Tokyo, Japan
³Kashiwa Ekimae Nakayama Mental Clinic, Division of psychiatry, Kashiwa, Japan

Introduction/Background

The objective of this study is to evaluate a change of cerebral perfusion of patients with chronic neuropsychological impairments (NPIs) before and after a daytreatment group rehabilitation, using 99mTc-ethylcysteinate dimer single photon emission computed tomography (Tc-ECD SPECT) and its novel analytic software.

Material and Method

8 patients were examined in the chronic period of acquired brain injury with NPIs. All patients received a daytreatment group rehabilitation (3 hours once per week for half a year). The group rehabilitation included patient and family education, mindfulness exercise and group discussion exercise. The examinations of patients were performed before and after the group rehabilitation, and it included the assessment of neurological deficit, cognitive functions, and Tc-ECD SPECT. Statistical parametric mapping (SPM) was applied to each Tc-ECD SPECT image, for spatial pre-processing and analysis and to determine the quantitative perfusion change before and after the group intervention (paired t-test, uncorrected, p<0.001).

Results

SPM analysis of Tc-ECD SPECT showed the significant improvement of cerebral perfusion in right frontal lobe (Brodmann area 10) before and after the group rehabilitation. There was no significant improvement in cognitive functions as assessed with structured batteries for NPIs, while there was a trend towards the improvement behaviorally (for example, 6 patients had been able to rework after the intervention).

Conclusion

Using Tc-ECD SPECT and its novel analytic software, we identified specific lesions with improvement of cerebral perfusion before and after the daytreatment group rehabilitation for NPIs. It might relate with social reintegration of patient with NPIs.

ISPR8-0860
CORRELATION BETWEEN THE QUALITY OF LIFE AFTER BRAIN INJURY IN JAPANESE VERSION; QOLIBRI-J AND COMMUNITY INTEGRATION QUESTIONNAIRE; CIQ
K. Ota¹, M. Suzuki², I. Kondo³, M. Naito⁴
¹International University of Health and Welfare Hospital, Rehabilitation Medicine, Nasushiobara, Japan
²Fujita Health University School of Health Sciences, Faculty of Rehabilitation, Toyoake, Japan
³National Center for Geriatrics and Gerontology, Rehabilitation Medicine, Obu, Japan
⁴Nagoya University Graduate School of Medicine, Preventive Medicine, Nagoya, Japan

Introduction/Background

The Quality of Life after Brain Injury (QOLIBRI; 37 items) is a disease specific subjective questionnaire of health-related quality of life (HRQoL) in persons after traumatic brain injury. We developed Japanese version of QOLIBRI; QOLIBRI-J and reported that its test-retest reliability (ICC; 0.92, Cronbach α = 0.86) and validity (Correlations of SF-36) were excellent. The Questionnaires of QOLIBRI-J are based on subjective satisfaction, although those of another popular QOL instrument, Community Integration Questionnaire; CIQ is based on objective situations. We investigated between the relationship of QOLIBRI-J and CIQ of the persons with higher brain dysfunctions after TBI to show the differences of subjective and objective QOL.

Material and Method

Subjects: 73 recruited community-dwelling Japanese with higher brain dysfunction after traumatic brain injury (61 male, 12 female: age 41.6±14.3, Glasgow Outcome Scale-Extended; GOSE (3 to 8: median 5)
Design: The Correlations between QOLIBRI-J and CIQ were investigated in 73 subjects at the same time. They were also asked to fill the GOSE. The questionnaires were administered in one of three modes: by self-report (mail), self-report (participant presents at the clinic), and face-to-face interview.

Results

Distribution of GOS-E score were as follows, 3: lower severe disability (12.3%), 4: upper severe disability (27.4%), 5: lower moderate disability (27.4%), 6: upper moderate disability (16.4%), 7: lower good recovery (11.0%), 8: upper good recovery (5.5%). There was a low correlation between QOLIBRI-J total score and the CIQ total score (ρ=0.326 Spearman correlation coefficient). By the subscale analysis, the strongest correlation was found between QOLIBRI-J (Daily life/autonomy) and CIQ (social life). In contrast there was the weakest correlation between QOLIBRI (emotions) and CIQ (productive life). There was no correlation between the QOLIBRI and GOSE (ρ=0.21).

Conclusion
QOLIBRI-J had a mild correlation with CIQ. There were some differences between QOLIBI and CIQ. One of the reasons of this difference was thought to be the subjective emotional factor about taking a productive work.

QOL;TBI;Satisfaction

*No conflict of interest*
Introduction/Background

A wide range of cognitive, emotional and somatic symptoms are frequently reported after mild Traumatic Brain Injury (mTBI) and usually disappear in a few months. However a « miserable minority » keeps looking for medical attention more than one year post mTBI. Their complaints are often considered excessive, histrionic and unfounded. Here we present a prospective study to assess neuropsychological disorders and intrapsychic functioning in such patients.

Material and Method

Twenty-three adults (6 men, 17 women), mean age 48, sought care at our consultation about 41 months after mTBI. They all had a neurological, neuropsychological, psychological (projective tests: Rorschach and TAT) and psychiatric assessments (Minnesota Multiphasic Personality Inventory: MMPI). Projective tests are known to bring to light intrapsychic functioning in terms of narcissistic and objectal relationships while MMPI assesses personality traits and psychiatric symptomatology.

Results

While 21 patients were socially well integrated pre mTBI, only 6 were back to effective work at the time of assessments.

The neuropsychological assessment showed cognitive impairments, from moderate to severe, notably in attention (87%), working memory (74%), long term memory (65%) and psycholinguistic abilities (74%). Some patients (38%) also presented discrete visuo-spatial impairments.

Patients talkatively told their mTBI story in a tragic, histrionic style, with impressive suffering feelings. The MMPI pointed out a non-significant value of malingering (5%) and a significant high value of hysteria (73%) and somatisation (45%) scales. Surprisingly projective tests never highlighted an hysterical psychic functioning but exhibited signs of narcissistic fragility.
Conclusion

Despite of the histrionic style of excessive expression of emotion, dramatization, attention seeking and physical symptoms, the projective tests were not in favour of an hysterical psychic functioning. The specific role of the traumatizing context of mTBI in conjunction with psychic specificities, notably self-image and aggressivity drive are discussed.

PREVALENCE AND SEVERITY OF ALL HEAD IMPACTS AMONG SEMI-PROFESSIONAL SOCCER PLAYERS OVER ONE FULL SEASON, ACCORDING TO THEIR GAME POSITION

Introduction/Background

Soccer players are frequently subject to head injuries, from impacts with another player’s head or body part and impacts with the ground. Moreover, game-play in soccer involving intentional and repeated head impacts through heading the ball. These impacts can sometimes cause concussion and soccer players might have a risk of developing neurodegenerative disorders on the long term by cumulative effect. However, the prevalence of head impacts when playing soccer is relatively unknown, because until now this was evaluated most of the time by only self-assessment questionnaires. The objective of this study was to quantify players’ exposure to all various head impacts during one soccer season.

Material and Method

We have followed a group of 51 semi-professional soccer players, aged from 16 to 35 years old, during one full season. With video analysis of the games, the number of head impacts per player, including heading and concussion, has been counted.

Results

The average of heading per hour during a game was from 0 to 9 depending on the player position, with a median of 4.61 for the forwards, 5.84 for the centre backs, 2.85 for the fullbacks, and 2.48 for the midfielders (p=0.0001.) We recorded three concussions due to a direct head to head trauma, including two on the same player. The number of head trauma recorded during practices was lower than during games.

Conclusion

We have evaluated the exact prevalence of heading and all other head impacts during a full soccer season, and their direct consequences during the games (stoppage time, medical stoppage, exit game). Forwards and centre backs are mostly exposed. Next step should focus on improving the evaluation of the consequences of these repeated head impacts on brain structure and function, in order to consider possible prevention and protection tools for soccer players.

DOCUMENTING THE GUSTO GROUP COOKING INTERVENTION FOR KNOWLEDGE TRANSFER

F. Poncet, S. Bonnie, H. Migeot, S. Crop, C. Picq, E. Caron, P. Pradat-Diehl

1Université Concordia, Psychologie, Montréal, Canada
2GRC_UPMC- Groupe Recherche Clinique Handicap cognitif et réadaptation après lésion cérébrale, Recherche, Paris, France
3Centre for interdisciplinary Research in Rehabilitation of Greater Montreal, Research, Montréal, Canada
4Université de Montréal, Réadaptation, Montréal, Canada
5Hopitaux Universitaires Pitié-Salpêtrière - Charles Foix, Réadaptation, Paris, France

Introduction/Background

The effect of the holistic, intensive acquired brain injury (ABI) rehabilitation program developed at the Pitié-Salpêtrière hospital, France (5 days/week for 7 weeks) was demonstrated (Poncet et al. 2017). This program includes the Gusto intervention (i.e. group cooking activity once a week). Based on these results, and to ensure the sustainability of the intervention and to enable it being used in other rehabilitation centers and other settings, the authors wished to document the Gusto intervention.

Objective: To document the Gusto intervention for the purpose of knowledge transfer.

Material and Method

Using a participatory and iterative approach, two occupational therapists (OT) created a theoretical logic model (Champagne et al. 2011) of the intervention and documented its components using a common language (i.e. the International classification of functioning disability and health (ICF); OMS, 2001). Four experts (OTs and neuropsychologists) validated the documentation.

Results

The Gusto intervention targets 7/8 domains from the Activities and Participation sections of the ICF, the 8th domain (engagement in education, work) not being covered by Gusto. More than 50 body functions appear to be targeted (e.g. calculation functions - consider the number of guests and modify the food portions accordingly) and more than 80 activities/participation are involved (e.g. listening).

Conclusion

Because cooking is complex, persons with ABI require many body functions/capacities to be able to cook meals. Documenting Gusto with the ICF should allow an understanding of the
intervention by different professions (clinician, manager ...) and thus its applicability in other rehabilitation centers and for other populations (e.g. the elderly).

A3.02 Neurological and Mental Health Conditions - Traumatic Brain Injury

ISPR8-1249
FUNCTIONAL RESULTS IN SEVERE TRAUMATIC BRAIN INJURY. IS DECOMPRESSIVE CRANIECTOMY A PROGNOSTIC FACTOR?
R. Mora Boga\textsuperscript{1}, E. Canosa Hermida\textsuperscript{1}, S. Otero Villaverde\textsuperscript{1}, I. Toral Guisasola\textsuperscript{1}, A. Ruíz Castillo\textsuperscript{1}, R. Martín Mourelle\textsuperscript{1}
\textsuperscript{1}SERGAS, Physical MEdicine & Rehabilitation, A Coruña, Spain

Introduction/Background

Traumatic brain injury is a common cause of acquired brain injury, especially in young people. The first hours and days are especially important for prognosis and several factors involved have shown morbidity and mortality association. The aim in this study is to evaluate if decompressive craniectomy is a prognosis factor in patients with severe traumatic brain injury.

Material and Method

Retrospective review study in severe traumatic brain injury patients admitted in Neuro-rehabilitation Ward for a 4 years period (2013-2017). One group was treated with decompressive craniectomy and the other group was not.

Results

We have evaluated 58 patients divided into two groups. The first group (22 patients) have had surgery and the second group (36) have not. The average age in the first group was 48,4 years ±16,5 (range 20-77) and 48,8 ± 19,6 years in the second group (18-80). The disability level was evaluated with different scales. The craniectomy group had 22.3 points in average in Barthel Scale at admission vs 19.9 points of the non-surgical group. At discharge the average results were 62.7 in the first group vs 72.6 in the second group. The improvement evaluated according to Barthel scale was statistically significantly correlated in non-surgical group (p= 0,049). The results evaluated according to the Rankin and GOS scales did not improve statistically significantly.

Conclusion

Patients with severe traumatic brain injury treated without decompressive craniectomy had at hospital discharge better functional results than patients treated with surgery according to Barthel Scale. However, we cannot prove difference in other evaluated scales. Surgical treatment should be performed according to patient clinical status and complications, but in a borderline case these data could be consider.

Future research will be necessary to confirm these results.

Introduction/Background

Neuropsychological assessment of a LT outcome after severe TBI, in correlation with daily life disability.

Material and Method

Severe TBI patients admitted in the Intensive Care Unit in Pitié-Salpêtrière hospital (France) from 2005 to 2012 were included.

MRI, clinical PRM and neuropsychological assessments were performed. Neuropsychological performances were measured by 10 composite scores (CS) representing the main cognitive functions.

The Glasgow Outcome Scale Extended (GOSE) assessed the global functional outcome.

Use of self and relatives’ assessment questionnaires allowed evaluation of cognitive complaints in everyday life (Dysexecutive questionnaire – DEX; Working Memory Questionnaire -WMQ; Brain Injury Complaint Questionnaire - BICoQ).

Results

101 patients (84.16% men; mean age 38.55 ± 16.03 [19 - 73]) were included. They presented with initial severity of TBI: GSC median 8 ±3.6 [3-15]; coma duration 19.01 days ±18.22 [0-120]; PTA duration 97.8% > 1 day.
Assessments were performed at a mean delay of 5 years and 2 months after BI.

This cohort had a mean moderate disability according to GOSE (Median 6 ±1.32 [3-8]).

Neuropsychological evaluation emphasized high prevalence of different cognitive deficits: attention (sustained attention deficit in 63.04% of subjects, tonic alertness 24.75%, divided attention 43.56%), executive functions (EF) (planning 55.56%, mental flexibility 24.75%, generation of new information 20.79%), working memory (WM) (46%) and update (46.88%), anterograde episodic memory (AEM) (46%). Surprisingly inhibition was not noticeable in this cohort (1%).

GOSE was significantly related to EF, WM (0.0047*), AEM (<0.0001*), Tonic alertness (<0.0001*), divided attention (0.0012*) and to relatives' complaints questionnaire (DEX & BICoQ <0.0001*). Moreover, several CS (AEM, fluency…) were significantly associated with the relatives' complaints in the BICoQ.

**Conclusion**

5 years after TBI, patients and their relatives are still affected by cognitive disorders. Relatives complaints are clearly informative of participation restrictions.

This study emphasizes the importance of LT assessment and follow up in TBI patients and their relatives.

CHRONIC TRAUMATIC ENCEPHALOPATHY: FROM CONCUSSION TO DEMENTIA IN SPORT

T. Lopes

Centro Hospitalar Trás-os-Montes e Alto Douro, Medicina Física e de Reabilitação, Vila Real, Portugal

Introduction/Background

Chronic traumatic encephalopathy (CTE) is a neurodegenerative disease associated with repetitive cranial trauma, and was first described by Martland in 1928 as "dementia pugilistica". No definitive premortem diagnosis and no treatments are available and risk factors associated include contact sports.

Material and Method

A bibliographic review of the subject was made using the Medline database with the following keywords: chronic traumatic encephalopathy, traumatic brain injury, concussion, sports medicine, neurotrauma, rehabilitation.

Results

The exponential increase in contact sports practitioners in the last decades has given rise to greater attention on neurological sequelae due to cranioencephalic trauma (TBI), namely cerebral concussion. Repetitive concussion occurs in a variety of sports such as boxing and soccer, however, there is a lack of consensus about the amount and severity of trauma necessary for the development of CTE. The clinical diagnosis of CTE can be problematic in that the development of chronic neurological symptoms is not temporally related to a single concussion event, usually manifesting at a later age after a latency period. The definitive diagnosis is made in patients with neurological signs compatible with CTE and histological confirmation of deposition of tau protein with or without deposition of amyloid or TDP-43 protein. Prevention is the main mechanism of protection. According to the consensus set out in the 5th edition of the International Concussion Conference on Sport held in Berlin in 2016, the return to sports practice should be delayed at least 4 weeks after the acute event in order to ensure neuro-metabolic recovery, which can be documented through neuropsychological studies and functional magnetic resonance imaging.

Conclusion

CTE is a syndrome of neurological impairment associated with phosphorylated tau protein deposition resulting from repeated head trauma. The most widely used approach to CTE is
based on prevention: avoiding prolonged exposure to contact sports and identifying individuals with a higher level of risk.

Introduction/Background

Disability following traumatic brain injury (TBI) is multidimensional, affecting those injured and their family members. The family as a whole is seldom recognized as an arena for rehabilitation efforts. The aim of this study was to evaluate the feasibility of an eight-session, manualized multidisciplinary family-centred rehabilitation intervention for families facing TBI, aimed at improving individual and family functioning. We evaluated the families’ willingness to participate; the appropriateness of inclusion criteria; the need for cultural adjustment of the intervention; the collaboration with municipal health care service and the leadership structure of the sessions; and the appropriateness of the selected self-reported questionnaires for data collection.

Material and Method

Two families, six people, participated in this non-randomized feasibility study of the intervention arm of a full-scale RCT, conducted at the University Hospital in Oslo, Norway (ClinicalTrial.gov #NCT03000400). The study was performed in close collaboration with a municipal health care service. Pre-defined success criteria were determined prior to conducting the feasibility study. The evaluation of these criteria was based on the families’ feedback regarding acceptability of the intervention, the self-report measures and the experiences of the group facilitators conducting the intervention.

Results

The pre-defined success criteria were fulfilled. Both families completed all eight sessions of the intervention. Minor cultural differences were detected, however, the topics and strategies covered in the intervention were perceived as relevant and recognizable. Some challenges emerged and were discussed before commencing the full-scale RCT. The challenges were related to the logistics regarding the delivery of the intervention. This pertained to keeping an acceptable level of burden of participation for the families and the collaborating municipal health
professionals, and making the necessary adjustments of the intervention to suit the families' unique needs.

Conclusion

The family-centred intervention and trial procedures were feasible. A pragmatic approach is considered necessary when commencing the full-scale RCT.

EXPLORING VERBAL ASSISTANCE USED BY OCCUPATIONAL THERAPISTS TO IMPROVE FINANCIAL MANAGEMENT SKILLS AFTER BRAIN INJURY: A CASE STUDY

F. Poncet¹,2, I. Habi²,3, G. Le Dorze²,4, C. Bottari⁵,3

¹Université Concordia, Psychologie, Montréal, Canada
²Centre for interdisciplinary Research in Rehabilitation of Greater Montreal, Recherche, Montréal, Canada
³Université de Montréal, Réadaptation, Montréal, Canada
⁴Université de Montréal, Orthophonie et Audiology, Montréal, Canada

Introduction/Background

Cognitive difficulties following a brain injury can impact an individual's capacity to complete activities of daily living (ADLs). Combining metacognitive strategies, such as those part of the Cognitive Orientation to Daily Occupational Performance (CO-OP) approach and assistive technology for cognition (ATC) can facilitate financial management (Poncet, 2017).

The objective of this study was to examine how the COOP approach was implemented by paying attention to the type of verbal assistance (VA) provided by the therapist throughout the intervention and how it affected the participant’s process of taking ownership of the CO-OP approach and therefore improving his ability to manage his finances.

Material and Method

Case study of a 41-year old man, XC, who suffered a moderate traumatic brain injury (TBI). He participated in 10 individual therapy sessions where he learned to use CO-OP in combination with ATC. Throughout the sessions, an emphasis was placed on his personal goal of managing his grocery expenses. A qualitative analysis of the verbatim of the therapist-client interactions was completed. Two (representative) extracts from sessions 6 (first independent use of CO-OP) and 9 were selected to illustrate how XC established a goal to improve the management of grocery expenses.

Results

The quantity and type of VA changed between sessions 6 and 9 (i.e. n=8 VA to 2). In session 6, the therapist provided several restarting and scaffolding assistances in order for XC to formulate a goal (Le Dorze, 2014). However, in session 9, the therapist only used restarting and explicit advice to support XC in formulating a goal, indicating improvement.
Conclusion

This study begins to fill a gap with regards to the use of CO-OP by examining how a therapist assisted an individual with TBI in taking ownership of cognitive strategies for managing expenses. A more in-depth understanding of the use of VA could benefit therapists in their clinical practice.

SCHOOL FUTURE OF TEENAGERS WITH A SEVERE BRAIN INJURY AFTER A HOSPITALIZATION AT THE CENTRE MEDICAL ET PÉDAGOGIQUE POUR ADOLESCENTS IN NEUFMOUTIERS EN BRIE FRANCE
O. jaziri¹, M. Desdomaines¹, S. sarkis¹, G. Erbenova¹
¹service MPR, centre médical et pédagogique pour adolescents, neufmoutiers en brie, France

Introduction/Background

To study the school progress of teenagers with a severe brain injury at the end of their inpatient stay at rehabilitation center of the Centre Médical et Pédagogique pour Adolescents. All of them have benefited from both schooling and rehabilitation at the same time.

Material and Method

Only patients aged between 12 and 17 years and hospitalized between 2012 and 2017 were included in the study. Demographic data (age, sex), initial Glasgow coma scale (GCS), duration of coma, duration of intubation, time between accident and hospitalization in rehabilitation, duration of stay in rehabilitation, neuropsychological assessment results, school level prior to the brain injury and at the end of the hospitalization were noted.

Results

Eighty-six brain injury cases were examined. Only 25 patients were included in the study among them 17 males and 8 females. The average age at admission was 15.8 +/- 1.7 years. The average time between accident and hospitalization in rehabilitation was 145 +/- 269 days. The average duration of stay in rehabilitation was 260 +/- 197 days. The average GCS was 5.6 +/- 1.8. The average duration of coma was 9.9 +/- 4.1 days. The average duration of intubation was 14 +/- 6 days. Twenty teenagers have resumed their school education. Ten students have returned to pre-traumatic brain injury level, four patients have increased to a level higher than before the accident. Two patients were redirected to apprenticeship studies, two referred to Training and Orientation Assessment Unit and two have resumed their education with additional support.

Conclusion

Teenagers with severe brain injury require multidisciplinary rehabilitation and appropriate school education. The follow up of this population should be extended beyond hospitalization in a rehabilitation center.

DEPRESSION FOLLOWING TRAUMATIC BRAIN INJURY
E.F. nadra\textsuperscript{1}, E. toulgui\textsuperscript{2}, S. El arem\textsuperscript{2}, S. mtawaa\textsuperscript{2}, I. hadded\textsuperscript{2}, W. ouanes\textsuperscript{2}, S. jenmi\textsuperscript{2}, F. kachnaoui\textsuperscript{2}
\textsuperscript{1}HOPITAL SAHLOUL, physical and rehabilitation medicine, Sousse, Tunisia
\textsuperscript{2}Sahloul University Hospital, Physical And Rehabilitation Medicine, sousse, Tunisia

Introduction/Background

Traumatic brain injury (TBI) is a worldwide epidemic problem which affects people of all age groups. The aim of this work was to detect depressive syndrome in traumatic brain injury (TBI) patients occurring during the acute phase of their management in physical and rehabilitation department and to identify possible predictors.

Material and Method

We conducted a retrospective study in 55 TBI patients followed in physical and rehabilitation department of Sahloul Tunisia. Screening for depression and anxiety was assessed by the Hospital Anxiety and Depression (HAD) scale:

Results

Forty-five TBI men and 10 women (sex ratio = 9/2) were included in this study. Forty percent of the patients were aged between 21 and 40 years old, 66.1% had an average socio-economic level. Mean Glasgow Outcome scale following the trauma was 6/15 and 67.9% of the patients were polytraumatized.

At admission, 59% of patients had a motor impairment and 35.6% were undernourished.

Depressive symptoms were found in 52.5% of patients with an HAD scale greater than 11 (which means certain depression) and 23.6% with a HAD scale between 8 and 10, 69.1% were treated with antidepressant treatment and they have been sent to be examined by a psychiatrist.

No correlation was found between depression and sex (p = 0.3) initial Glasgow score (p = 0.1) or motor deficit (p = 0.5).

Conclusion

Depression can impede the achievement of optimal functional outcome. Remediation of symptoms during rehabilitation significantly improved adherence to treatment.

EPIDEMIOLOGICAL CHARACTERISTICS OF HETEROTOPIC OSSIFICATION IN PHYSICAL MEDECINE AND REHABILITATION DEPARTMENT
S. El Arem¹, E. Toulgui², S. frioui¹, N. El Feni¹, W. Wannes¹, S. Mhawaa², S. Jemni¹
¹sahloul hospital, Physical and rehabilitation medecine, Sousse, Tunisia
²kairouan hospital, physical and rehabilitation medecine, kairouan, Tunisia

Introduction/Background

The aim of this study was to highlight the epidemiological characteristics and therapeutic approaches of neurogenic heterotopic ossification (HO) in patients in a Physical Medecine and Rehabilitation (PMR) department.

Material and Method

This is a descriptive study involving all diagnosed patients having HO from January 2016 to December 2017, hospitalized in a PMR department in Sahloul Hospital, Tunisia. Epidemiological data including age, gender, causal pathology and diagnosis approach of HO were collected. Clinical, biological and imaging data were also noted.

Results

Twenty one patients with HO were included in this study. The average age was 39 years with a sex-ratio of 6/1. The main causal pathology was traumatic brain injury TBI (42.9%), polytraumatism (23.8%) and spinal cord injury (9.4%). The average intensive care stay period was 36 days. Several complications were noted mainly pressure ulcers (57.1%) and sepsis(19%). The main locations of HO were respectively hips, knees, elbows and shoulders.

The diagnosis was established by clinical examination and standard X-Ray. Scintigraphy was requested in 47.6% of cases in search of hyperactivity. Drug treatment included non-steroidal anti-inflammatory and analgesic. Rehabilitation processes such as alternate postures were performed to all patients. Preoperative radiotherapy was indicated in eight cases to control pain. Their Visual analog scale (VAS) for pain decreased from 8 to 3. Surgical resection was performed in five patients having hip heterotopic ossification with a significant sitting limitation. Surgery average delay from HO diagnosis was 20 months. These patients could comfortably sit down after surgery.

Conclusion

Neurogenic HO occur in central nervous disorders and mainly in TBI. Early detection of HO is important and multidisciplinary management is needed for a better functional prognosis.

Keywords
No conflict of interest
Current prognostic models for traumatic brain injury (TBI) are developed from diverse historical data sets.

The objective of this study was to characterize trends and prognosis of severe traumatic brain injury (TBI).

Material and Method

This is a retrospective study of traumatic brain injury including 55 patients who had been hospitalized in the Physical and rehabilitation medicine department of a University Hospital, over a five-year period.

Results

The study comprised 55 patients, with an average age of 27 years and the most of the patients were male (45 males). It was estimated that 75% of the cases were related to road accidents. The average intensive care stay period was 30 days and 66% of patients were transferred from intensive care units.

Forty one percent had severe traumatic brain injury, defined by an initial Glasgow score between 3 and 8. Most of the patients were classified as polytraumatized (67.9%). At admission, 59% of patients had a motor impairment and 35.6% were undernourished.

Associated frontal lesions were present in 32% of cases. Intracranial lesions with extradural haematoma / subdural haematoma were objectified in 31.2% of patients, the frequency of meningeal haemorrhage was of the order of 24.6%. A neurosurgical intervention was performed in 38.9% of patients. At admission, 40.9% of patients were spastic, 3.7% were vegetative.

18.7% of patients had a percutaneous endoscopic gastrostomy (PEG) tube. 5.8% patient with tracheostomy tube. During their care, 57.8% developed pressure ulcers, infectious complications were isolated in 43.9% case, 9% of the patients had thromboembolic events. The Neurogenic para-osteo-arthritis was found in 35.6% of cases.

Conclusion
The prognosis of a TBI is never obvious in the first moments, several factors participate actively in the evolution and the prognosis.

EPI DEMIOLOGICAL PROFILE OF TRAUMATIC BRAIN INJURED IN REHABILITATION DEPARTMENT

N. Elfeni\textsuperscript{1}, M. Rihab\textsuperscript{2}, S. El Arem\textsuperscript{1}, E. Toulgui\textsuperscript{1}, W. Ouannes\textsuperscript{1}, S. Elmtaouaa\textsuperscript{1}, S. Jemni\textsuperscript{1}

\textsuperscript{1}Sahloul Hospital, physical and rehabilitation unit, Sousse, Tunisia
\textsuperscript{2}Hopital Sahloul, physical and rehabilitation unit, Sousse, Tunisia

Introduction/Background

Traumatic brain injury (TBI) is a worldwide epidemic problem and affects people of all age groups. The aim of this study was to highlight the epidemiological characteristics and therapeutic approaches of traumatic brain injury in patients in the physical and rehabilitation department.

Material and Method

This is a descriptive study involving all TBI patients from January 2012 to December 2017, hospitalized in Physical and Rehabilitation department in Sahloul Tunisia.

Results

Fifty five patients were included in this study with a sex ratio of 4.5. The average age was 27 years.

The trauma was mainly caused by public road accidents (75%) or a work accident (10,7%). Mean Glasgow Outcome scale following the trauma was 6/15.

Most of patients (66,1%) were transferred from intensive care department and 5,6% of them came from an orthopedic department. The transfer delay to rehabilitation unit was less than one month in 30.2% of cases, between 1 and 3 months in 51.2% of cases and more than 3 months in 18.6% of cases.

The average rehabilitation stay period was 27 days.

A neurosurgical intervention was performed in 38.9% of patients. At admission, 40.9% of patients were spastic, 3.7% were vegetative. 18.7% of patients had a percutaneous endoscopic gastrostomy (PEG) tube 5.8% patient with a tracheostomy. During their care, 57.8% developed pressure ulcers, infectious complications were isolated in 43.9%, and 9% of the patients had thromboembolic events.

The heterotopic ossifications were found in 35.6% of cases.
Conclusion

Depending on its severity, traumatic brain injury may require a lifelong rehabilitation process. A comprehensive assessment of complications after traumatic brain injury is crucial to plan the appropriate management. This requires an understanding of the medical, functional, cognitive, behavioral, and psychosocial consequences.

NEUROPSYCHOLOGICAL DISORDERS, FUNCTIONAL OUTCOMES AND QUALITY OF LIFE IN TRAUMATIC BRAIN INJURY (TBI) PATIENTS

I. feki¹, S. Ghroubi¹, S. Alila¹, H. Kessentini¹, H. Chelly², M. Yahya¹, M. Bouaziz², M.H. Elleuch¹
¹Habib Bourguiba Hospital University, Physical Medecine and rehabilitation, sfax, Tunisia
²Habib Bourguiba Hospital University, Reanimation department, sfax, Tunisia

Introduction/Background

The goals of our study were: The assessment of neuropsychological and behavioral disorders outcomes, functional outcomes and quality of life in TBI victims. It was also to study correlations between neuropsychological and behavioral disorders with injury severity, functional status and quality of life.

Material and Method

It was a cross-sectional study including 50 patients with TBI conducted in the (PMR) department. Memory disorders were performed by the (MMS) test. Executive functions were evaluated by the DEX scale. The psychological profile was evaluated using the HAD scale and behavioral disorders were tested by the agitated behavior scale. Glasgow Outcome Scale has allowed the assessment of TBI severity in terms of disability. Otherwise, functional capacity was measured by FIM scale. Finally, health-related quality of life was measured using the QOLIBRI scale.

Results

Abnormal executive functions were noted in 41 patients (82%) with a DEX average score of 33, 20±22, 74. About psychological profile, depressive symptoms were found in 32 patients (64%). Behavioral disorders such as aggressiveness and agitation were noted respectively in 32 (64%) and 8 patients (16%). The global social functional evolution was considered as unfavorable (GOS 3-4) in 42% of the patients. Regarding to Functional Independence Measure (FIM) scale, 92% of the victims showed impairment (FIM<126). Memory impairment (MMS) and abnormal executive functions (DEX) were statistically correlated with TBI severity evaluated by Glasgow Coma Scale, and coma length. Our study showed that patients with severe memory impairment (MMS), abnormal executive functions (DEX) and depressive mood (HAD) had significant functional dependence (FIM) as well as a poor overall evolution (GOS).

Conclusion

Executive function disorders, depressed mood and memory disorders seemed to be the most frequent among neuropsychological disorders in Tunisian TBI patients. These
neuropsychological disorders are so important to evaluate but were underestimated in our rehabilitation department because of the lack of objective means of assessment.

*No conflict of interest*
Objective: It was to evaluate our initial means of care and orientation post resuscitation characteristics in Traumatic Brain Injury (TBI) victims and to compare them with those used worldwide to identify insufficiency and to perform better care.

Material and Method

It was a cross-sectional study including 50 patients with moderate or severe TBI conducted in the (PMR) department between January and July 2016. We have established a data sheet for each patient. We collected through it; epidemiological data, clinical data and orientation post resuscitation characteristics.

Results

A total of 50 patients including 40 (80%) male and 10 (20%) female were enrolled with an average age of 32.19 ±12.37. Patients were reviewed with an average follow up of 4 years. Referring to the Glasgow coma scale in patients during admission, 66% had a severe accident with a score <8. In our series, we found that only 2 patients (4%) were admitted in a private Physical Medicine and Rehabilitation structure; there was no hospitalization in the PMR department of Sfax which does not yet include any hospitalization bed. The remaining 96% returned to their homes directly after Intensive Care Unit hospitalization. Initial investigations showed that only 36% of these patients had an ambulatory follow up in our PMR department. Their management consisted in botulism toxin injections (55%), physiotherapy (70%), ergotherapy (14%) and orthophony (11%). Otherwise, 60% escaped from any assessment and have been reintegrated into their families without follow-up. It should be noted that none of these patients have had a neuropsychological assessment.

Conclusion

The discrepancy between the number of TBI and the number of visits to rehabilitation is reported by several studies. Thus the care pathways of TBI are quite random in our population; they depend not only of the patient’s clinical condition but especially on the non availability of beds in our PMR structure.
Keywords

traumatic brain injury; initial management; orientation post resuscitation

No conflict of interest
Objective: The assessment of neuropsychological and behavioral disorders outcomes in TBI victims and to study their correlations with radiological aspects in a Tunisian population.

Material and Method

It was a cross-sectional study including 50 patients with moderate or severe TBI conducted in the (PMR) department. Memory disorders, executive functions, psychological profile and behavior disorders were evaluated using the MMS, DEX, HAD and ABS scales respectively. All of the patients underwent CT scan immediately after the trauma. The nature, extent, and location of the traumatic lesions were classified on the basis of the Traumatic Coma Data Bank criteria (Marshall et al., 1983). MRI was not performed to all patients. In fact, it has been done in 14 patients; those who had delayed awakening post artificial ventilation or patients which CT scan results needs further examination by MRI.

Results

There were correlations between the elementary brain injury lesions shown on CT and memory disorders (MMS) especially for temporal (p<0, 05, r= 0, 37), cortical brain contusion (p<0, 05, r= 0, 39) and diffuse axonal injury (p<0, 05, r= 0, 45). Furthermore, frontal contusions lesions were correlated with behavior disorders such as agitation (p<0, 05, r= 0, 63). The highest DEX scores were associated with frontal contusions and diffuse axonal injury but there were not significant correlations. In our study, the extent of CT lesions mentioned by the Marshall classification was not correlated with memory impairment severity, neither with the achievement of executive function nor with behavior disorders. Lobar white matter abnormalities shown in MRI were correlated with memory disorders with (p<0, 02, r=0, 53).

Conclusion

In our study, we suggest that diffuse axonal injury, temporal and cortical lesions play a part in the development of cognitive impairment after TBI. MRI plays a more and more substantial role in the assessment of cognitive impairment.

5CHU Angers, Laboratoire de psychologie des pays de la Loire EA 4638, Angers, France
6Les Capucins -Angers University-CHU Angers, Physical Medicine and Rehabilitation, Angers, France

Introduction/Background

To give an overview of the management of behavioral disorders following traumatic brain injury (TBI) in a cohort of 129 patients, in post-acute period.

Material and Method

This cross-sectional regional cohort study included 129 adults suffering from moderate-to-severe TBI, in post acute period, and referred to medical or community based facilities in our region. A structured interview of patients and proxies collected information regarding socio-demographic data and the ongoing interventions, including psychotherapy and medication. Psychiatric outcomes were assessed by the Hospital Anxiety and Depression scale (HADS), and behavioral disorders by the Behavioral Dysexecutive Syndrome Inventory (BDSI). Each type of intervention was expressed as the prevalence in percentage of the study sample. Chi-square test, Fisher’s exact test or Student’s-t test were used to search an association between the type of intervention and behavioral disorders, living area, psychiatric outcomes, psychiatric history, or delay after TBI.

Results

Patients were predominantly young men (mean age 26 years and 76% males) having sustained traffic accidents (78%). Forty-four percent received no interventions; 33% received psychotherapy and 43% were on pharmacological medication. 23% received medication alone with no other intervention. The prescribed medications were antidepressants (21%), neuroleptics (18%), anxiolytics (16%), mood stabilizers (14%) but no beta-blockers. Polypharmacy concerned 20% of patients. BDSI was completed for 120 patients and 85 (71%) presented current BDS. The main factor that was found to be associated with the different types of prescription was BDS. Patients with current BDS received more frequently interventions (p=0.004), psychotherapy (p=0.048), medications, all types combined (p=0.007), and antiepileptics mood stabilizers (p=0.037).
Conclusion

Our study highlights that compliance with the current recommendations remains insufficient. Non pharmacological interventions, like psychotherapy, are inadequately implemented, although they are recommended as a first line treatment. Medications are overused, especially neuroleptics. Recommended medications, such as mood stabilizers and beta-blockers, are poorly used.

ISPR8-2087
EVALUATION OF MEDICAL DECISION MAKING CAPACITY IN ACUTE TRAUMATIC BRAIN INJURY REHABILITATION
1University of Utah, Physical Medicine & Rehabilitation, Salt Lake City, USA
2George E. Wahlen Department of Veterans Affairs, Home-Based Primary Care, Salt Lake City, USA

Introduction/Background

Concerns regarding medical decision-making capacity (MDC) occur during acute traumatic brain injury (TBI) rehabilitation. Although a majority of providers report MDC as a common concern, the level of training is inconsistent. This presentation provides an overview of MDC assessment and recommendations during acute TBI rehabilitation.

Material and Method

MDC assessment involves a clinical interview, cognitive examination, and record review, although clinical practice varies. Clinical determination of MDC includes “has capacity,” “diminished capacity,” and “lacks capacity.” Four commonly adopted standards for determining MDC are: expressing a choice, understanding relevant information, appreciation of the situation and its consequences, and reasoning through the benefits and consequences of treatment options. While clinical judgment remains the “gold standard” for MDC assessment, instruments have been designed to enhance and support these evaluations (Table 1).

In acute TBI rehabilitation, evaluators should consider how TBI-related changes influence MDC (Figure 1). Appreciation of temporal changes in awareness and cognitive function might require assessment of MDC at multiple time points. Efforts to improve capacity, such as addressing communication barriers or treatment of delirium, might be necessary. Within the acute environment, providers have unique opportunities to assess and observe functional abilities on an inpatient service (e.g., psychology, speech therapy). Given the complexities of MDC assessment, potential “pitfalls” exist in determining MDC (Table 2).

Results

Although MDC concerns are common among individuals during acute TBI rehabilitation, there is a dearth of MDC assessment training. While determination of MDC is based upon clinical judgment, instruments enhance MDC assessment. Given the complex dynamic nature of acute TBI rehabilitation, providers should be mindful that chronic and acute factors may influence evaluation of MDC.

Conclusion
Awareness of MDC standards and TBI factors allow for more accurate assessment of MDC during acute rehabilitation.

EPIDEMIOLOGY OF SERIOUS TRAUMATIC BRAIN INJURY IN A CAPITAL OF THE SOUTH OF BRAZIL: A PROSPECTIVE STUDY
F.Z. Arêas¹, M. Batista Ribeiro¹, G. Peixoto Tinoco Arêas¹, E. De Souza Silva¹, R. Walz²
¹Universidade Federal do Amazonas, Faculty of physical education and physiotherapy, Manaus, Brazil
²Universidade Federal de Santa Catarina, Internal Medicine Department, Florianópolis, Brazil

Introduction/Background

Traumatic brain injury (TBI) is a serious public health problem due to its high incidence in young adults under the age of 35. In view of this, this present study has the objective of elucidating this gap and unveiling and better understanding the regional characteristics related to traumatic brain injury in the metropolitan region of a capital of southern Brazil.

Material and Method

This is a prospective epidemiological study carried out in the metropolitan region of Florianópolis. All patients who suffered severe TBI (Glasgow coma scale at admission ≤ 8) and entered the emergency room from March 2014 to January 2016 (n = 154) in hospitals, which are a reference in traumatic brain injury. All the variables collected for the study were: type of TBI, trauma cause, identification, gender, age, date of trauma, pupil and patient Glasgow.

Results

In twenty-two months, 154 patients with severe TBI were admitted to the two reference hospitals in the metropolitan area of Florianópolis. The city of Florianópolis, the city with the largest population, was where it had the highest concentration of TBI, 39 percent (n = 60), presenting a high mortality rate of 50% (n = 30), with the rest of the patients admitted, 18.2 percent (n = 28) of the patients. Of the 154 patients, 36.2 percent (n = 55) had as cause the motorcycle accident, then 22.7 percent (n = 35) fall, trampling 13.8 percent (n = 21), auto accident 11.8 percent (N = 6), cycling accident 2.6 percent (n = 4), and unknown causes 3.9 (n = 6).

Conclusion

The conclusion is that the TBI is a growing problem of great repercussion and over the years its statistics have been increasing. This study observe that the number of hospitalizations, and from which cities are coming from the patients identifying specific causes of the TBI.

SUBACUTE CHARACTERISTICS OF THE SWALLOWING AFTER SEVERE TRAUMATIC BRAIN INJURY IN ADULTS

R. Tobar¹,², M. Toloza³

¹Hospital del Trabajador, Servicio de Otorrinolaringología, Santiago, Chile
²Universidad de Chile, Escuela de Fonoaudiología, Santiago, Chile
³Universidad de Los Andes, Escuela de Fonoaudiología, Santiago, Chile

Introduction/Background

Dysphagia is a common problem following severe traumatic brain injury (TBI), indeed, has been reported an incidence as high as 60%. Several are the risk factors that can lead to dysphagia in TBI, among them, the severity of the injury, lower Glasgow Coma Scale (GCS) and Rancho Los Amigos Scale (RLAS) scores on admission, presence of a tracheostomy and mechanical ventilation for more than two weeks. Despite this, there are few studies that determine the characteristics of dysphagia in this population.

Material and Method

The aim of this investigation was describe the principal characteristics of the swallowing in a group of squealed patients with a severe TBI.

A total of 16 patients who survived their hospitalization due a severe TBI, during the year 2017 at the Hospital of Trabajador, were evaluated through clinical evaluation and videofluoroscopy (VFC) within a period no longer than one month after the recovery of consciousness.

Results

Of the total of patients, 56.25% were using a nasoenteral tube at the moment of the assessment. 62.5% showed aspiration (PAS > 7) during the VFC, with a major prevalence of aspiration of thin liquid (40%). 68.75% of the patients demonstrated penetration (PAS: 4 or 5) also with a mayor prevalence for thin liquids. The reflex cough was present only in 12.5%. Other characteristics are shown in the following table.

<table>
<thead>
<tr>
<th>Characteristic of the Swallowing</th>
<th>Prevalence %</th>

</table>
Conclusion

The results allow to demonstrate the importance of the early assessment of swallowing in a patient with severe TBI, determining in this study 68.75% prevalence of dysphagia and a high risk of aspiration pneumonia. This population requires early and specific care for the maintenance and improvement of their quality of life, also preventing complications to their complex health condition.

SENSITIVE SENSORY STIMULATION FOR THE TREATMENT OF PERSISTENT VEGETATIVE STATE FOLLOWING TRAUMATIC BRAIN INJURY: A CASE REPORT
Y. Li¹, P. Wang¹, J. Liu²
¹Shanghai Tongren Hospital- Shanghai Jiao Tong University School of Medicine, rehabilitation, Shanghai, China
²Heilongjiang Province Rehabilitation Hospital, Rehabilitation, Haerbin, China

Introduction/Background
An effective treatment of patients in a persistent vegetative state (PVS) caused by traumatic brain injury (TBI) is not yet available. The purpose of this study was to investigate the therapeutic use of sensitive sensory stimulation for patients in PVS following TBI.

Material and Method
Our patient is a male and 36 years of age. He had TBI (Primary brain stem injury) 75 days before admission. When admitted to the hospital, the patient was unconscious, opening eyes automatically, but couldn’t avoid light, vision escape, trace things or executive command. He was under nasal feeding diet, urinary and fecal incontinence, postoperative urinary retention and pulmonary infection. He has no activities of upper and lower extremities with hypomyotonia. Therapy: 1. Take medicines for nervenurturing, regaining consciousness, preventing seizure, resolving phlegm and protecting stomach. 2. Improve activities extremities by exercise therapies, low or medium-frequency electric stimulation. 3. Improve bladder and bowel function by acupuncture and abdominal massage. 4. Regain consciousness by acupuncture and hyperbaric oxygen therapy. 5. Assess disorder of consciousness scale half of month, chose sensitive sensory stimulation and enhance those. Assessment: Glasgow coma scale, Barthel, video long range EEG monitoring, EEG, evoked potentials.

Results
Five month later, the patient was conscious, with improved bladder and bowel function. EEG reminded that the brain function improved significantly. Auditory evoked potentials and somatosensory evoked potentials reminded that the function of sensation conduction pathway improved significantly.

Conclusion
The sensitive sensory stimulation in combination with routine rehabilitation treatment can effectively regain the consciousness of the patients with PVS following TBI, improve ADL and the function of sensation conduction pathway.

THE PLACEBO AND NOCEBO EFFECT IN TBI: IMPLICATIONS FOR CLINICAL TRIALS AND CARE

R. Zafonte

Spaulding Rehabilitation/ Mass General, Physical Medicine and Rehabilitation, Boston, USA

Introduction/Background

Placebo and Nocebo (P/N) effects have been increasingly recognized as an important factor in clinical trial results, care paradigms, ethics, and even health insurance policy. Critical to the appreciation of the role that placebo has in healthcare is the understanding of the distinct biological and psychosocial mechanisms underlying these processes. Research into the psychological and neurobiological mechanisms underlying placebo effects (along with its counterpart nocebo) has grown remarkably in the past twenty years. Placebos are now conceptualized as a multimodal response with potential genomic influence.

Material and Method

In the postacute setting can be distinct since the many biopsychosocial impacts can be enhanced in the chronic setting. Such findings are even more profound in brain injury medicine where many of the behavioral and pharmacologic manipulations may be uniquely influenced by placebo effects. We will review a careful analysis of several postacute trials with examples of placebo effects and the implications for TBI clinical care and research. In specific clinical trials involving, behavior, pain, and cognition will be reviewed.

Results

Both the positive and negative ethical impacts of P/N have yet to be fully explored. Placebo effects have caused investigators and insurers to perhaps prematurely presume a null effect of specific therapies. The role of Placebo and Nocebo effects in clinical practice are also underappreciated and the potential role of counter intuitive placebo based therapies as well as labeling are profound.

Conclusion

Placebo effects have caused investigators and insurers to perhaps prematurely presume a null effect of specific therapies. In specific, we will discuss how P/N effects can impact clinical trial results (both behavioral and medical interventional) and examine how such effects may be better accounted for via clinical trial design. In addition a discussion of the ethics of placebo will be reviewed.

CASE SERIES OF MTBI PATIENTS RECEIVING THE MODIFIED STORY MEMORY TECHNIQUE INTERVENTION

N.E. Kucukboyaci', J. DeLuca', N. Chiaravalloti'  
'Kessler Foundation, Research, East Hanover, USA

Introduction/Background

Concussion / mild TBI (hereafter mTBI) prognosis is still a divisive topic in clinical practice. While some continue to subscribe to a "full recovery model," others note slower recovery with longer term residual symptoms that may respond well to psychotherapy (CBT) and multimodal rehabilitative care. While evidence for functional gains resulting from mTBI interventions like psychoeducation is accumulating, there is little research and support for cognitive interventions that target learning and memory, despite patient complaints in these domains. We present early evidence of possibly therapeutic gains made by chronic mTBI survivors.

Material and Method

• Design: Participants with mTBI completed a double-blind, placebo-controlled randomized clinical trial, with baseline, post-treatment and 6-month follow-up assessments. Outcomes were compared using non-parametric statistics (Wilcoxon Signed Ranks Test) for related samples given the small sample size in this pilot study.

• Setting: Not-for-profit research organization in a diverse, suburban setting.

• Participants: 5 out of 9 mTBI patients in intervention group (N=9).

• Interventions: Modified Story Memory Technique (mSMT) aims to improve learning by teaching context and imagery strategies in 10 sessions.

• Main Outcome Measure(s): California Verbal Learning Test II (CVLT-II) and Memory Assessment Scale (MAS) – Prose Memory.

Results

Treated participants showed improvement in CVLT short delayed free recall (+5/0/0/, Z = -2.04, p = 0.041) and long delayed free recall (+5/0/0/, Z = -2.02, p = 0.043) following the mSMT. No differences were observed for the MAS Prose Memory.
Conclusion

Our pilot data provides preliminary evidence for cognitive gains resulting from cognitive rehabilitation targeting acquisition of context and imagery strategies for memory. A full-scale study can better address the mechanisms of change (e.g., depression, anxiety, socialization) since one-on-one interactions introduce confounders.

A SYNTHETIC JUDGEMENT OF THE SIMPLE DRIVING SIMULATOR FOR DRIVING EVALUATION
N. Kato¹, T. Okazaki², S. Saeki¹, K. Hachisuka³
¹University of Occupational and Environmental Health, Department of Rehabilitation Medicine, Kitakyushu, Japan
²Wakamatsu Hospital of the University of Occupational and Environmental Health, Department of Rehabilitation Medicine, Kitakyushu, Japan
³Moji medical center, Department of Rehabilitation Medicine, Kitakyushu, Japan

Introduction/Background

We have developed the ‘Simple Driving Simulator’ (SiDS) and used it clinically. Normative ranges of the SiDS were calculated from the data of over 200 participants in the control group. Three performance ranges were established ‘normal’, ‘borderline’, and ‘impaired’, which were defined using standard deviation cut-off values in the control group. The objective of this study was to compare the performance of age-matched young adults with a traumatic brain injury (TBI) based on this three performance ranges, and to establish a synthetic judgment of the SiDS.

Material and Method

The performance of patients with a TBI, aged 18 to 35 years, was evaluated by SiDS and were compared with the control group. The performance scores for the TBI group in the ‘impaired range’ were calculated for each test item and used to make a synthetic judgement regarding the clinical value for the SiDS.

Results

The TBI group exhibited higher values for all four tests (nine items) than the control group. For the control group, almost of participants had performance scores in the ‘impaired range’ on ≤2 of the nine test items. For the TBI group, about tow thirds of participants had performance scores in the ‘impaired range’ on ≤2 of the nine test items.

Conclusion

The numbers of an ‘impaired range’ of the nine SiDS items may indicate the ‘driving fitness’ of young adults after a TBI.

A PECULIAR TRAUMATIC BRAIN INJURY - STUTTERING, MOTOR WEAKNESS AND COGNITIVE IMPAIRMENT

I. Carneiro¹, C. Cruz², M. Costa Pereira³, M. Rodrigues³, A. Costa³, R. Nunes³
¹Centro de Reabilitação do Norte, Medicina Física e de Reabilitação, Porto, Portugal
²Hospital de Braga, Medicina Física e de Reabilitação, Braga, Portugal
³Centro de Reabilitação do Norte, Medicina Física e de Reabilitação, Porto, Portugal

Introduction/Background

Traumatic brain injury can affect multiple domains, with resultant impairment in motor, sensitive, cognitive and emotional functions. Communication problems are also common. They are usually motor speech disorders, such as dysarthria or aphasia. Stuttering consists in a speech rhythm disorder and more frequently result from a developmental problem. Acquired neurogenic stuttering is a rarer form, but it was already described.

Material and Method

The authors describe a clinical case with literature review of a minor and particular traumatic brain injury, with cognitive and motor compromise and stuttering.

Results

A 28-year-old man suffered a traumatic brain injury, from a small falling object - a lamp - when he was replacing it from the chandelier. In the first 48 hours, he presented no neurological deficits. Soon thereafter, his family started to notice stuttering (dysfemia) and right hemibody weakness.

Seeking for rehabilitation, he was admitted in our Center 3 months after the initial episode for inpatient intensive rehabilitation program. He presented cognitive impairment in several domains, stuttering, hyperacusis and right hemibody weakness (MRC 4). CT showed no alterations. Brain MRI was also unremarkable.

Methylphenidate was initiated and neuropsychological intervention was undertaken. Bromocriptine were administered and the patient start speech language pathology sessions, with improvement. The patient also presented good motor function recovery with physical and occupational therapy.

At the moment, the patient is followed in outpatient clinic, in specialist consultation. He presents dysfemia, minor cognitive impairment and hemibody muscle deficit. Functionally, total independence.
New results, from a more recent MRI, showed unspecific lesion in the left frontal lobe.

**Conclusion**

The authors present and discuss a very peculiar traumatic brain injury with neurogenic stuttering, hemibody muscle weakness and cognitive impairment in several domains. It is discussed the approach and the interventions. No lesions were observed initially. A recent MRI showed an unspecific lesion.

DEVELOPMENT THE COMPUTER APPLICATIONS OF COGNITIVE REHABILITATION

J. Tanemura⁴, A. Tsubahara², M. Ikeno¹, N. Ota¹, S. Kashiwa³, R. Tanemura⁴
¹Kawasaki University of Medical Welfare, Department of Sensory Science, Kurashiki, Japan
²Kawasaki University of Medical Welfare, President, Kurashiki, Japan
³INSITE Corp., System Development Division, Osaka, Japan
⁴Kobe University Graduate School of Health Sciences, Department of Rehabilitation Science

Introduction/Background

We examined the changes of cognitive functions by the cognitive rehabilitation using the computer applications.

Material and Method

1. The computer applications of cognitive functions: Following 10 tasks on attention, memory, executive function and unilateral neglect were developed. 1) cancellation of letters, 2) word recognition, 3) picture recognition, 4) word recall after categorizing, 5) tracing symbols with assigned order, 6) estimating arrival time after assigned transference, 7) pressing the button when the sound and letter were matched, 8) pressing the button when the assigned sound and the letter were matched, 9) letter cancellation, 10) canceling horizontally moving circle.

2. Subjects: 16 persons with neuropsychological disorders. 13 males and 3 females, and mean age was 45.4 (20~73) years old. Their etiologies were traumatic brain injury 10, cerebral vascular accident 5, and hypoxic ischemic encephalopathy 1.

3. Duration of the therapy: 1 month.

Results

1. Changes of the task performance: 1) Subject had difficulties in recognition of 4 or 5 words, and their performance recovered after the exercise. After categorizing words, they could recognize 7 or 8 words, and semantic encoding was effective for verbal memory. 2) The subjects showed difficulty in maintaining 2 or more pictures simultaneously. The subjects showed difficulties in patterned maze task with many symbols. 3) The estimation task was aimed to train executive function, and the task was confirmed to be efficient. 4) Attention tasks with auditory stimulus was proved to be sensitive for executive disorder. 5) Spatial attention tasks showed high scores before the therapy.

Conclusion

This program of cognitive rehabilitation have many levels of difficulty, and one can select adequate tasks. Therefore individual subject had shown significant recovery.

PREDICTIVE FACTORS OF LONG-TERM DYSPHAGIA AFTER TRAUMATIC BRAIN INJURY - A LITERATURE REVIEW

F. Rocha¹, A.M. Ferreira¹, B. Mendes¹, J.P. Branco¹, J. Lãns¹
¹Centro de Medicina de Reabilitação da Região Centro - Rovisco Pais,
Physical and Rehabilitation Medicine, Tocha, Portugal

Introduction/Background

Oropharyngeal dysphagia is common after TBI. Given the clinical heterogeneity of the lesions, it is challenging to accurately predict which patients will recover fast, as opposed to the ones who will need PEG to manage long-term dysphagia (LTD). The aim of this review was to identify predictive factors of LTD after TBI.

Material and Method

Two electronic databases (PubMed and Cochrane) were searched using the query ["traumatic brain injury" AND "dysphagia" AND ("prognosis" OR "recovery" OR "evolution" OR "outcome")]. All the studies with relevant information about predictive factors of LTD after TBI published until January 2018 were included.

Results

The most consensual factors to dysphagia recovery were the TBI severity and cognitive status with studies suggesting a parallel between improvement in cognitive disability status and resolution of the swallowing dysfunction. Studies revealed that lower Rancho Los Amigos and higher Disability Rating Scale scores was related to LTD. Younger age has been identified as a prognostic factor for global function as well as for swallowing function recoveries, except under 3-year-old. CT scan findings as brainstem injury, midline shift and intracranial bleeds requiring emergent surgery was associated with higher risk of dysphagia, as well as a worse prognosis to return to oral feeding. Some studies found tracheostomy tube, aphonya, duration of mechanical ventilation, days to swallow evaluation and aspiration to be predictors of worse recovery. Contrariwise, in some studies, gender, days to swallow evaluation, to tube feeding or to oral intake, days on ventilation, duration of tracheostomy and videofluoroscopy parameters were not predictive of LTD.

Conclusion

Early determination of prognosis for dysphagia recovery is necessary to decide which patients will require PEG and for which ones nasogastric feeding is sufficient until complete recovery. Despite the heterogeneous methodology in the studies, common predictive factors of LTD were identified, and should be used to guide clinical decisions.

Introduction/Background

Cognitive impairment is often a common sequela of traumatic brain injury (TBI). Mild TBI has been referred to as a “silent epidemic” because the problems experienced by patients after injury are often unnoticed but can have profound consequences, such as long-term physical, mental, social, or occupational sequelae. Memory and executive dysfunction seems to be one of the most debilitating symptoms. In moderate to severe TBI cases, impairment has been seen to persist for even decades after trauma. Most survivors being young and having near normal life expectancy, the burden on public health and social care is substantial. Recent reports have documented the therapeutic potential of non-invasive neuromodulation techniques for cognitive enhancement. Here we present a case of an individual suffering from post TBI cognitive deficits having received tDCS for cognitive function recovery.

Material and Method

A 23-year-old male presented with history of fall from height and subsequently was unconscious for two days following which he developed significant cognitive deficits leading to poor functioning and he was unable to perform his routine activities including maintenance of self-care. Neuropsychological assessment showed deficits in multiple cognitive aspects particularly in memory, attention and concentration.

Patient was given 20 sessions of transcranial direct current stimulation (tDCS) over a period of 20 days (2mA current for 20 minutes in a single session with anodal stimulation at dominant dorsolateral pre-frontal cortex and cathode at occipital cortex).

Results

There was significant improvement in cognitive functioning of the patient. He started performing usual duties and keeping adequate self-care with coaxing. His interaction with others improved and there was improvement observed on neuropsychological testing particularly in areas of verbal fluency, category fluency and working memory.

Conclusion

Brain stimulation with tDCS can be useful in improving cognitive outcomes in individuals with TBI from a neuro rehabilitative purpose.

Objectives: To describe the functional level after one year in moderate and severe traumatic brain injury (TBI)

Material and Method

Study design: prospective, cross-sectional study Setting and Participants: 70 individuals with TBI were admitted directly from acute care hospitals to rehabilitation facility in Sawai Mansingh Medical College and Hospital, Jaipur (SMS). A follow up of 58 patients was done up to one year in the period from July 2011 to July 2012

Results

Results: Mean change in FIM scores from admission to discharge was 51.26 and from admission to 12 months it was 85.3 in moderate injury group. Mean change in DRS from admission to discharge was -8.19 and from admission to 12 months it was -17.76 in moderate injury group while -8.55 and -19 in severe injury group respectively. The correlation coefficient (r) between FIM and GOSE was 0.570 and between FIM and DRS was -0.8190 both of which were extremely significant

Conclusion

Conclusions: All individuals improved significantly in the inpatient rehabilitation facility in the acute and sub-acute phase with maximum gain in function seen from admission to discharge as assessed on FIM and DRS. Majority of the individuals continued to improve up till six months post trauma

NEUROGENIC PARAOSTEOARTHROPATHY FOLLOWING HEAD TRAUMA
S. Frioui Mahmoudi1, M. Gaddour1, R. Moncer1, S. Jemni1, F. Khachnaoui1
1University Hospital Sahloul, Physical and Rehabilitation Medicine, sousse, Tunisia

Introduction/Background

The aim of the study was to focus on neurogenic paraosteoarthropathy in patients with severe head trauma, to determine its prevalence, the diagnostic and therapeutic procedures.

Material and Method

This retrospective study was conducted at the Physical and Rehabilitation Medicine Department in Sahloul Hospital TUNISIA. We reviewed the folders of patients hospitalized for management of a severe head trauma during the period extending from January 2011 to December 2015.

Results

Forty-three patients with severe head trauma were included in the study (6.2% of the total hospitalizations). Neurogenic paraosteoarthropathy were observed in 27.9% of patients. 33% had multiple locations. The hip was the most commonly involved site (25%), followed by the elbow (16%). Functionally, grip disorders were objectified in 25% of the patients, sitting position was impossible in 75% of cases and walking was possible only in 16.7% of patients. No patient developed a nerve compression. Diagnosis of neurogenic paraosteoarthropathy was based primarily on clinical examination. Radiography detected evident neurogenic paraosteoarthropathy in 75% of cases. Ultrasonography demonstrated neurogenic paraosteoarthropathy in 33.3%. The three-phase bone scan was performed at 41.7% of cases looking for hyperactivity.

Nonsteroidal anti inflammatory drugs were prescribed to all patients, 50% of them were treated with radiation. All patients benefited from functional rehabilitation based on icing, passive mobilization and installation in alternate extreme positions. A posture brace was prescribed to 8.3% of patients.

25% of patients underwent a surgical resection of the neurogenic paraosteoarthropathy (hip: 16.7%, knee: 8.3%) after an average delay of 480 days from diagnosis. Recurrence of neurogenic paraosteoarthropathy was reported in 8.3% of patients (at the hip level).

Conclusion
Neurogenic paraosteoarthropathy can result in a variety of complications and may increase patient morbidity. Patients with neurogenic paraosteoarthropathy following head trauma are more likely to have a poor outcome.

Keywords

Neurogenic paraosteoarthropathy; head trauma; rehabilitation

NEUROLOGIC OUTCOME OF EARLY VERSUS LATE SURGERY FOR SPINAL CORD INJURY

M. Frigui¹, H. Bouker², W. Ouanes¹, S. Jemni¹, F. Khachnaoui¹, M. Ben Ayech²
¹university hospital center Sahloul, Physical Medicine and Rehabilitation, Sousse, Tunisia
²university hospital center Sahloul, Orthopedics, Sousse, Tunisia

Introduction/Background

The study was conducted to determine whether neurologic and functional outcome is improved in traumatic spinal cord-injured patients who had early surgery (<72 hours after spinal cord injury) compared with those patients who had late surgery (>5 days after spinal cord injury). It is controversial whether early decompression following SCI conveys a benefit in neurologic outcome.

Material and Method

Patients meeting appropriate inclusion criteria were randomized to an early (<72 hours after spinal cord injury) or late (>5 days after spinal cord injury) surgical treatment protocol. The neurologic and functional outcomes were recorded from the acute hospital admission to the most recent follow-up.

Results

Comparison of the two groups showed no significant difference in length of acute postoperative intensive care stay, length of inpatient rehabilitation, or improvement in American Spinal Injury Association grade or motor score between early (mean, 2.1 days) versus late (mean, 18.2 days) surgery.

Conclusion

There are currently no standards regarding the role and timing of decompression in acute SCI. We recommend urgent decompression of bilateral locked facets in a patient with incomplete tetraplegia or in a patient with SCI with neurologic deterioration.

Keywords

No conflict of interest

²Ehs Kasdi Merbah, Medecine Physique Et Readaptation, Draria, Algeria
³Ehs Kasdi Merbah, Medecine Physique Et Réadaptation, Draria, Algeria

Introduction/Background

Pott's disease corresponds to the localization of the infectious tuberculous process (of Mycobacterium tuberculosis) on one or more disco-vertebral set. It is the most common osteoarticular tuberculosis. Pott's pain can lead to serious neurological damage involving functional prognosis.

Material and Method

This is a retrospective study of 10 patients with vertebral tuberculosis (Pott's disease) collected at the KASDI MERBAH (EHS TIXERAINE) Functional Rehabilitation Department from 2006 to 2016.

Results

The average age of our patients is 41.6 years (27-64).

In 2 patients (20%) we find a tuberculous contagion, 1 patient (10%) has a history of tuberculosis (pleural tuberculosis, cerebral abscess, ganglionic tuberculosis). All our patients had spinal pain: dorsal or dorsal-lambar preceding the neurological deficit; the average duration of onset of the deficit is 3.8 months (1-6), 9 patients (90%) have incomplete paraplegia with vesico-sphincteric disorder, 1 patient (10%) has complete paraplegia with vesico-sphincteric disorder; Objective marrow MRI: 90% dorsal involvement, 10% lumbar involvement, 60% paraspinal abscess and 30% psoas abscess. All our patients benefited from drug treatment of average duration 8.7 months (6-18), as well as surgical treatment, 5 patients (50%) of a support brace, 5 patients (50%) of Uro-dynamic exploration (40% Cystomanometry: 20% normal, 20% vesical hypertonicity with reduced capacity and 10% deemimetry: normal). The average duration of hospitalization is 5.7 months (4-7). The recovery of walking is total in 3 patients (30%), 4 patients (40%) use a cane, 2 patients (20%) a walker, 1 patient (10%) aggravation of the neurological deficit (addressed for explorations then lost of view). All our patients recovered from their vesico-sphincteric disorders.

Conclusion
In simple forms a well-conducted medical treatment alone can cure pott harm without sequelae, whereas in complicated forms the combination of medical treatment with early surgery allows the patient a better neurological recovery and rapid spinal stabilization.

TRANSLATION AND VALIDATION OF THE SPINAL CORD INDEPENDENCE MEASURE (VERSION IV) TO BRAZILIAN PORTUGUESE
T. Soeira¹, J. Coelho², L. Sartori², M. Riberto²
¹Faculdade de Medicina de Ribeirão Preto - Universidade de São Paulo, Ciências da Saúde Aplicadas ao Aparelho Locomotor, RIBEIRAO PRETO, Brazil
²Faculdade de Medicina de Ribeirão Preto - Universidade de São Paulo, Ciências da Saúde Aplicadas ao Aparelho Locomotor, Ribeirão Preto, Brazil

Introduction/Background

The Spinal Cord Independence Measure (SCIM) is a comprehensive functional scale for measuring the execution of daily tasks by patients with spinal cord lesions (SCL). To date, it is the only scale designed specifically for patients with SCL, which considers performance in all aspects of primary tasks according to their value for the patient. The aims of this study was to translate and validate the SCIM IV, to Brazilian Portuguese.

Material and Method

Observational, longitudinal, and prospective study of descriptive characteristics. 30 individuals were evaluated (being 70% men, with mean age of: 45.2 ± 15.6) all presenting with chronic spinal cord injury and completed the rehabilitation program. The subjects were scored on the same day by 2 evaluators independently. In order to verify the intra-examiner concordance the SCIM-IV was applied.

Results

The intra-examiner coefficient of correlation for SCIM-IV (0.99%, p <0.001) indicated a significant reproducibility.

Conclusion

SCIM-IV is a reproducible functional evaluation instrument capable of assessing the level of independence of the individual with traumatic and non-traumatic spinal cord injury.

Introduction/Background

Voiding dysfunctions and its complications are commonly encountered in persons with Spinal Cord Injury (SCI). Timely identification of type of voiding dysfunction, decisions on management and follow up is important. Effective cystometry helps to classify the voiding dysfunction and management of the problem. Water cystometrogram (CMG) is simple, easier to use, inexpensive.

Material and Method

35 Paraplegia patients with spastic bladder admitted to wards were enrolled for the study and evaluated with Water CMG and values recorded. Those with safe Vesical volumes less than 300ml were included in the study. Subjects were randomized into two groups. Group I was given oxybutynin chloride 5 mg BD and Group II given Tolterodine 2 mg LA OD and effect on the bladder was assessed using water CMG after 2 weeks. Patients were taught self-intermittent clean catheterization (SICC) along with a bladder diary and drinking voiding schedule followed by reassessment at the end of 6 weeks.

Results

Data were analysed using Statistical Package for Social Sciences (SPSS) and expressed in its frequency, percentage, mean and standard deviation. Using water CMG it was found that 25 persons had low bladder compliance with leaks and 10 patients had detrusor sphincter dyssynergia (DSD). It was also found that people who came in early for bladder rehabilitation had better improvement of vesical volume (45% more). When patients with Bladder FIM < 3 (36.3 ml) was compared with FIM > 3 (216.7 ml) there was statistically significant increase in vesical volume (p value < 0.001). When the two drugs were compared bladder rehabilitation within the first year both groups showed similar increase in vesical volumes whereas in cases of late bladder rehabilitation tolterodine had 75% more increase in safe capacity.

Conclusion
Water CMG is a useful tool for Rehabilitation of SCI having neurogenic bladder. Both anticholinergic drugs improved vesical volumes in neurogenic bladder patients. Tolerodine showed improved efficacy in late bladder rehabilitation.

EFFECTS OF A SERVICE DOG ON SOCIAL PARTICIPATION OF A C5 COMPLETE SPINAL CORD INJURY PATIENT: A CASE REPORT

Y. Ikenaga¹, I. Sakai², T. Takayanagi³
¹Yawata Medical Center, Rehabilitation, Yawata-Komatsu, Japan
²Chiba University, Graduate School of Nursing, Chiba, Japan
³Japan Service Dog Association, Rehabilitation, Yokohama, Japan

Introduction/Background

Patients with complete high cervical spinal cord injury have significantly restricted social participation even with the use of various prosthetic devices. We describe a patient with a C5 complete injury who showed remarkable improvements in social participation after obtaining a service dog.

Material and Method

During March X-8, a 48-year-old man experienced a C5 complete spinal cord injury and underwent anterior cervical fusion. In January X-7, he underwent cystostomy. He discharged from the hospital in September with Zancolli classification: C5A and American Spinal Injury Association Classification: A. Since living with his service dog, he has been giving lectures about his experiences and opinions regarding physical disabilities and barrier-free-concepts at medical institutions and schools. In October X-2, he successfully flew from Ishikawa Prefecture to Tokyo with his service dog. He received the Ishikawa Prefectural Barrier-free Governor Prize. In July X, a semi-structured interview was conducted using the International Classification of Functioning, Disability, and Health (ICF) Rehabilitation Set. The interview and analysis were performed after obtaining written consent. The ethics committee of our institution permitted this study. There are no conflicts of interest.

Results

Using a service dog positively changed the man’s health condition as defined by ICF. The following outcomes were observed: ability to take initiative and focus on actions, increased motivation, clearer planning for specific care needs, physical improvement, increased resilience, increased physical movements, emergence of new roles, better ability to resolve emotional conflict, improved autonomous health management, locomotion with a service dog, communication facilitation, acquisition of stress coping measures, living with consideration of other people, acquiring a job, employment, experiencing positive emotions, reduction of psychological barrier, increased social support and empathy due to visualization of disability,
assistance from public service providers (Fig. 1).

**Conclusion**

Service dogs can encourage social participation, even for those with a complete high cervical spinal cord injury.

**Keywords**

complete high cervical spinal cord injury; service dog; social participation

DIAPHRAGMATIC PACING IN UPPER CERVICAL SPINAL CORD INJURY REPORT
E.C. martinez arroyo¹, N. Perez Iglesias¹, A. Zabala Pardo¹, I. Eceizabarrena Matxindarain¹, X. Valencia Murua¹, M. Zabaleta², E. Portell soldevilla³, L. Valero Sanz⁴
¹Hospital Donostia, Departement of Rehabilitation, san Sebastian, Spain
²Hospital Donostia, Department of Rehabilitation, San Sebastian, Spain
³Institut Guttmann, Spinal Cord Injury rehabilitation area, Badalona, Spain
⁴Hospital Universitario Príncipe de Asturias, Department of Rehabilitation, Alcalá de Henares, Spain

Introduction/Background

17-year-old man who accidentally fell down from a swing (29/06/16): traumatic brain injury and lateral cervical flexion with Glasgow 3 at initial assessment. After vital stabilisation he was transferred to the a reference hospital with an endotracheal tube. Once stabilised, patient was transferred to a specialized spinal cord injury clinic (I.Guttmann) with complete C2 spinal cord injury (ASIA A) without zone of partial preservation, tracheostomy, percutaneous endoscopic gastrostomy, permanent bladder catheter and 24-hour invasive ventilatory support.

Material and Method

Evaluation of potential candidates for diaphragmatic pacing includes demonstration of severe hypoventilation from diaphragmatic paralysis, as well as intact phrenic nerve function: An electromyogram was performed (08/11/2016): no phrenic nerve activity. 29/06/17: Despite the preoperative results, due to high false negative rates, intraoperative stimulation of phrenic nerve at diaphragm level was tested.

Results
intraoperative assess of phrenic nerve; since the results were positive, pacemaker through diaphragmatic approach was performed. After successful implantation patient begins an escalating pacing during waking hours.

Conclusion

Complete Upper Cervical Spinal Cord injuries (SCI) above C3, apart from its complex management it presents with added ventilatory failure due to diaphragm paralysis. Suitable candidates for diaphragmatic pacing are those with SCI above C3. The major goal of pacing is the patient’s desire to be liberated from the need for non-invasive or invasive ventilation, improving their quality of life. Requirements for successful pacing include intact phrenic nerve function, but intraoperative assessment is recommended due to high false negative rates. Pacing can be performed at cervical, thoracic and diaphragmatic level; the latter has less complications but requires a specialised surgeon. At postoperative patient begins an escalating regimen of diaphragmatic pacing to strengthen and condition the diaphragm. Pacing should commence slowly hourly during waking hours. Many patients may be completely weaned from ventilatory support and some only partially

CERVICAL MYELOPATHY AS A RESULT OF MULTIPLE INTRAMEDULLARY NEUROFIBROMAS AND POSTOPERATIVE REHABILITATION PROGRAM: A CASE REPORT

D. Tsiamastirou, K. Zikopoulos, G. Bageris, A. Lazaratou, C. Georgopoulos

1Anaplasis Rehabilitation Clinic, Rehabilitation, Ethnikis Antistaseos Ave. 15 & Greece

Introduction/Background

We present the case of a patient, with cervical myelopathy as a result of multiple intramedullary spinal cord tumors associated with neurofibromatosis and the rehabilitation program planned after the surgical management of spinal cord compression.

Material and Method

A 43 year old female patient with history of neurofibromatosis type I, was referred for evaluation of progressive spastic ataxic gait and bilateral upper extremity weakness over the last two years. Cervical magnetic resonance imaging (MRI) revealed multiple intramedullary spinal cord tumors (total number 14), extending from medulla cervical junction to lower cervical spine. Cervical laminectomy C1-C7, gross total resection of the intraspinal tumors and meningoplasty was performed. After the surgical procedure, the patient was admitted in rehabilitation clinic, presenting spastic quadripareisis (ASIA B, C7) and total functional dependence (Barthel Index: 0/100). The multidisciplinary rehabilitation program included physical therapy, occupational therapy, bladder and bowel management, aquatic therapy and psychological support.

Results

Eight months after the initiation of inpatient rehabilitation program, the patient presented significant clinical and functional improvement. At discharge, the patient was able to stand with a minimum support and walking using AFO’s and walker for short distances while for longer distances using a wheelchair was necessary. Moreover the patient improved Barthel index (70/100), having a moderate dependence in the activities of daily living. An intermittent catheterization program was implemented following improvement of hand function leading finally to cessation of self catheterization due to initiation of voluntary urination.

Conclusion

Multiple intramedullary neurofibromas and resultant spinal cord compromise pose challenging management problems in patients with neurofibromatosis type 1. Radical resection of intraspinal tumor components combined with a post-operative multidisciplinary rehabilitation program can lead to a notable amelioration of neurological function.

Introduction/Background

Actuality of SCI rehabilitation increases all over the world every year in connection with the increase in the number of car accidents, the popularity of extreme sports, wars and technogenic catastrophes.

According to research on assessment of patient’s state with SCI chronic situation was completed a literature review, in result of this review the brief ICF core set for SCI chronic situation was included in formalized rehabilitation card with additions from comprehensive ICF core set for SCI chronic situation.

Categories were used from 4 domains and were expressed in patients complains and difficulties. Categories reflect impairments of basic body functions and structures, limitations of activity and participation, influence of environmental factors on rehabilitation process and integration of a person into society.

Material and Method

Active developing methods of robotic-assisted rehabilitation and innovational medical technology demand modern approaches of dynamic assessment and using evidentiary methods.

Objective assessment methods are protocol of American Spinal Injury Association (ASIA), Visual Analog Scale (VAS), Rankin scale, Modified Ashworth scale of muscle spasticity, Medical Research Council Scale, Functional Independence Measure (FIM) and Medical Outcome Study 36-Item Short-Form Health Survey (MOS SF-36).

Results

Data obtained with the application of the above assessment tools were correlated with the grades of the common determinant and, in case of body structure assessment additionally with the second determinant.
Conclusion

This method of the patient's state assessment may be used as an instrument for help to:

1. Identify and evaluate the patient's problems and their severity
2. Make a rehabilitation plan
3. Facilitate interaction inside the multidisciplinary team and between doctors
4. Assess rehabilitation efficiency
5. Give objective information about dynamics of the state and his abilities and capabilities to patient, his relatives and medical staff
6. Track the dynamics of changes between hospital cases and patient's activity at home.

DOCTOR I CAN’T SEE ANYTHING: PRES AND AUTONOMIC DYSFUNCTION IN SPINAL CORD INJURY

J. Hurtier¹, C. Arquizan², C. Mauri³, C. Jourdan⁴, P. Labauge², A. Gelis³
¹Univ. de Montpellier, CHU Montpellier, MONTPELLIER, France
²CHU Gui de Chauliac, Neurology, Montpellier, France
³CMN Propara, Physical Medicine and rehabilitation, Montpellier, France
⁴CHU Lapeyronie, Physical medicine and rehabilitation, Montpellier, France

Introduction/Background

Autonomic dysreflexia is a vegetative manifestation that consists of a dysregulation of the parasympathetic activity in spinal cord injured people above the T6 level. The main complications of autonomic dysreflexia are high blood pressure, headache, sweating, and tachycardia. We report a clinical case of a quadriplegic patient with posterior reversible leukoencephalopathy syndrome secondary to an autonomic dysreflexia.

Material and Method

Clinical case: A 56-year-old man, who is quadriplegic C6 AIS A since 2009, has had vegetative instability for several days in a context of infected pressure ulcer. He suddenly suffered from hemi cranial headaches, as well as right lateral homonymous hemianopia and paresthesia of the right upper limb in the same time as a very high blood pressure. He was transferred to the neurological emergencies for a suspicion of hemorrhagic stroke after epileptic seizures. In neurology, the diagnosis of PRES was retained thanks to the regressive nature of the neurological symptoms, and the appearance of posterior T2 hyper signals on the head MRI. The treatment consisted in regulating the high blood pressure and prevent the seizures. The evolution was favorable.

Results

PRES is a reversible neurological syndrome, explained by vasogenic edema during episodes of hypertensive attacks with cerebrovascular dysregulation. It is a rarely described complication of autonomic dysreflexia in the spinal cord injured patients. The initial clinical presentation evoked a hemorrhagic stroke as a priority. The few cases described in the literature (Chaves, Spinal Cord, 2008) of PRES in spinal cord injured patients are of severe prognosis and often lead to the patient death.

Conclusion

Any central neurological symptom in a context of vegetative instability must lead to an emergency head MRI. Our case is singular thanks to the early diagnosis and management, probably explaining the complete reversibility of the symptomatology.
Keywords

Autonomic dysreflexia is a common complication of patients with spinal cord injury and can have very serious consequences if it isn’t treated quickly and correctly. Despite that, unfortunately, at least in our country, not all the health professionals are aware of this pathology.

**Material and Method**

We want to present the case of a young paraplegic patient due to a traumatic lesion at level C6-C7 to illustrate how important is to know about autonomic dysreflexia. In addition, we want to review its correct management.

One day, our patient started with an acute pulsatile headache. He made an emergency call and an ambulance approached. The HR was 45 and the BP 220/130. The patient just was transferred to the nearest hospital in supine position (30 minutes on road) and he even was administrated 500 ml of saline serum. The patient had a suprapubic catheter, but, no one checked it.

At the moment of entry in the emergency services of the hospital the patient was hemiparetic. A CT scan revealed a hemorrhagic stroke. After 18 days in Intensive Care Unit, the patient sadly past away. He was 30 years old and totally independent in self-driven wheelchair.

**Results**

The reason of the brain hemorrhage was an episode of autonomic dysreflexia secondary to an obstruction in the suprapubic catheter. The reason why the patient carried that catheter was a refractory bladder sphincter dyssynergia.

*In this work, we will discuss about the measures that should had been taken in the first place. We will also do a brief resume of the most relevant aspects of this pathology.*

**Conclusion**

Is very important for all health professionals to know the existence of autonomic dysreflexia and how to manage it: the first measures are the simplest and the most important.

5University of Padova- Italy, Physical & Rehabilitation Medicine, Padova, Italy

Introduction/Background

The European Working Group on Sarcopenia in Older People (EWGSOP) categorized sarcopenia in primary-age related and secondary sarcopenia. Whole body Dual-energy X-ray Absorptiometry (DXA) measurement remains the gold standard for muscle mass measurements. Sarcopenia is defined by measuring muscle mass (ratio of appendicular skeletal mass (ASM) / height² (kg/m²), (skeletal muscle index, SMI) and muscle strength. An alternative for muscle strength (in Newton, N) is muscle cross-sectional area (CSA) in cm² (a surrogate for muscle effectiveness or loading-force). The present study investigated if a similar approach to define secondary sarcopenia in spinal cord injured subjects

Material and Method

The study included 31 paraplegics with complete paraplegia compared with 50 controls. All were examined by whole body DXA (Norland XR 36, USA) regarding muscle mass (relative appendicular skeletal mass (RASM), in Kg) and peripheral quantitative computed tomography (pQCT XCT-3000, Stratec, Germany) in 66% of tibia’s length (muscle CSA, mm²). Sarcopenia in the spinal cord injured subjects was defined as SMI, as well as relative ASM, RASM) by the residual method, respectively.

Results

Paraplegics had significantly lower values in muscle area (CSA) and RASM (p <0.001) compared to controls. In the adjusted analysis according to age, height and relative fat mass, paraplegia was associated with lower values of RASM ( beta±se; -2.74±0.28, p<0.001).

Conclusion

In SCI paraplegics muscle CSA can be measured. Muscle mass can be measured also. This study suggests that we may categorize paraplegics with the current functional definition of
EWGSOP for sarcopenia for research purposes. The sensitivity and specificity of this measurement remains unclear.

AN AUDIT ON VENOUS THROMBOEMBOLISM PROPHYLAXIS IN PERSONS WITH SPINAL CORD INJURY IN UNIVERSITY MALAYA MEDICAL CENTRE, MALAYSIA

J. Patrick Engkasan¹, A. Ahmad Fauzi¹, F. Ahmedy², M. Mohd Khayat¹, S.C. Chan¹, N. Zakari¹
¹Faculty of Medicine- University of Malaya, Department of Rehabilitation Medicine, Kuala Lumpur, Malaysia
²University Malaysia Sabah, Faculty of Medical & Health Sciences, Kota Kinabalu- Sabah, Malaysia

Introduction/Background

Background and Aim:
Venous thromboembolism (VTE) is a common complication in acute spinal cord injury (SCI). In the presence of established consensus on VTE prophylaxis for SCI population, this study aims to audit the current clinical practice for prevention of VTE in persons with SCI in University Malaya Medical Centre.

Material and Method

Materials and methods:
This is a retrospective study on 79 patients who presented with acute SCI and were referred to the SCI Rehabilitation service from January to December 2015. We collected data on age, gender, aetiology, level of injury, impairment, co-morbidities, spine-related intervention, methods VTE prophylaxis (mechanical and pharmacological) and the occurrence of VTE.

Results

Results:
The sample mean age was 54.7 years; the subjects were predominantly male (67 %), of non traumatic aetiology (68%) and had lumbosacral neurological level (32%). Approximately half (54%) had spine-related intervention. Forty-seven percents received VTE prophylaxis, of which 15.2% received pharmacological treatment, 19% received mechanical only and 13% received both pharmacological and mechanical intervention. Seven and 14 patients had pharmacological and mechanical prophylaxis correspondingly within 72 hours of admission. The majority (72.7%) received fixed dose unfractionated heparin while the remaining received LMWH. All had thromboembolic deterrent stockings as mechanical prophylaxis with one patient had additional intermittent pneumatic compression device. Patients with traumatic aetiology, surgically managed, incomplete injury and paraplegia had higher proportions of receiving VTE prophylaxis across both pharmacological and mechanical prophylaxis. In this series, five patients had VTE complication: one had PE and 4 had lower limb DVT. None of those who developed DVT received prophylaxis within 72 hours admission.

Conclusion
Conclusion:
Prescription of VTE prophylaxis according to the recommended guideline for acute SCI in our centre is low. The reasons for this needs further assessment.

Introduction/Background

The importance of all the domains of autonomic functions and their impact on successful rehabilitation of spinal cord injury (SCI) victims is often overlooked. The purpose of the study was to find out the problems associated with their dysfunctions and correlate their influences, if any, by neurological level, duration and mode of injury.

Material and Method

The subjects above 18 years of age, either sex, irrespective of cause & level of injury and off the strict bed rest were evaluated using a questionnaire and clinical examination. The Degree of injury was assessed by modified ASIA impairment scale. The extent of lesion was assessed by voluntary control of perineal muscles. The international Spinal Cord Injury data sets were used for obtaining detailed information about the various autonomic dysfunctions.

Results

The most common cardiovascular complication was orthostatic hypotension (OH); the incidence of OH (26%) was high in acute injury. The Deep venous thrombosis and autonomic dysreflexia found in patients with higher SCI lesions. Pulse rate was significantly higher with thoracic and lumbar level (p<0.05). Sleep apnoea is one of the most common complications after cervical SCI. There was significant difference between the temperature above and below the neurological level (p<0.05). The average bowel evacuation was 36.3±21 minutes. The perineal sores were the most common problem; rectal prolapse was seen in one female patient. There was no significant correlation of USG-KUB findings with either duration or neurological level of injury. There was significant correlation (<0.05) between psychogenic erection and duration of SCI. The resumption of menses was complete with duration of injury more than 24 months.

Conclusion

SCI patients should be made aware of the autonomic dysfunctions besides their only concern about mobility. The health care professionals should be able to understand and evaluate the autonomic dysfunctions in order to decrease morbidity and improve the quality of life.

NEUROLOGICAL AND FUNCTIONAL OUTCOMES OF PATIENTS WITH TRAUMATIC SPINAL CORD INJURY IN WESTEN OF ALGERIA: SERIOUS CONSEQUENCES OF ROAD TRAFFIC ACCIDENTS
A. Sehimi, A. Belkheir, N. Messaoud, H. Aboura, S. Ammor, M. Bedjaoui, O. Bensaber
University of Djillali Liabes, Physical and Rehabilitation Medicine, Sidi Bel Abbes, Algeria

Introduction/Background
The rate of road traffic accident reports grows annually in Algeria causing a high number of traumatic spinal cord injury (TSCI).

The aim of this study was to describe the epidemiological characteristics of patients with TSCI in a PRM department in western of Algeria and to analyze their neurological and functional outcomes.

Material and Method
We conducted a retrospective descriptive study by reviewing medical records of patients with TSCI admitted to our department from April 2016 to March 2017. The recorded variables included age, gender, etiology, the level of injury, the initial treatment, length of stay, occurrence of complications and the America Spinal Injury Association (ASIA) impairment scale, the urinary drainage modalities and the functional outcome of patients at their discharge.

Results
A total of 39 patients were included, the mean age was 32.72±13.86 years (16-73), and the male/female ratio was 5,49. The main cause of TSCI was road traffic accidents accounting for nearly more than 52%. The most common injury sites were the thoracic (56%) and the cervical (36%) spinal cord. The initial treatment consisted on surgery in 80% of cases. The average of length of stay was 114±129 days with occurrence of complications as pressure ulcers (56%), urinary tract infections (41%) and para-osteo-arthropaties (5%).

At discharge, the proportions of ASIA grades A, B, C, and D were 60%, 12%, 5%, and 23%, respectively. Patients acquired a walking without assistance (8%), a walking with assistive devices (22%), a gait orthosis (9%), an autonomy of use of the wheelchair (41%) and finally 20% were dependent on a third party. 18% of patients had voluntary micturition, 63% had acquired a clean intermittent self-catheterization, 10% had acquired a clean intermittent third-party catheterization and 9% had an indwelling catheterization.

Conclusion
TSCI is a public health problem and a major cause of autonomic function loss and bladder/bowel dysfunction. Preventative measures against TSCI must be taken.

Paired associative stimulation (PAS) combines electrical stimulation of peripheral nerves (ESPN) with transcranial magnetic stimulation (TMS) and is believed to induce plastic changes in the human corticospinal tract after spinal cord injury (SCI). The aim of the present study was to investigate the advantages of PAS added to the general rehabilitation protocol for chronic SCI.

**Material and Method**

The study was monocentric sham-controlled. Patients with lower paraplegia 3-12 months after the trauma were randomly divided into study and control groups: 11 and 9 respectively. TMS was delivered over vertex using a round coil with 90-100% absolute intensity. ESPN of both n. peroneous and n. tibialis was performed with supramaximal intensity at fossa poplitea for 5 minutes for each nerve. The interval between TMS and ESPN was 0.2ms. The intervention consisted 30 sessions of 1Hz PAS in total.

**Results**

After the intervention, the improvement of motor and sensory function (via ASIA impairment scale) was observed in both groups but the intergroup difference was insignificant (Mann–Whitney U test, p=0.0675). Spasticity (via modified Ashworth scale) was not changed significantly but 4 patients noticed more uncontrolled movements. Noticeably, patients with no peripheral M-response at the beginning do not demonstrated any improvements. The best functional outcome was found into patients with preserved MEP in the study group. Two patients with no MEP at the beginning from the study group showed unstable MEP after the month.

**Conclusion**

PAS could be seen as an additional tool to facilitate the recovery after chronic SCI. Patients with preserved MEP may benefit more from this technique. On the other hand, the absence of M response could be considered as an exclusion criterion while the selection of individuals for PAS. The choice of stimulation protocols is still arguable that can lead to diverse and controversial results.

INTRODUCTION OF CLEAN INTERMITTENT SELF-CATHETERIZATION IN ADULTS WITH SPINAL CORD INJURY: PROPOSAL FOR A PROTOCOL

M.A. Khezami¹, I. Aloulou¹, I. Mir², S. Lebib², F.Z. Ben Salah², C. Dziri²
¹National Institute of Orthopedics mohamed taieb kassab, Department of Physical Medicine, La Manouba, Tunisia
²Faculty of Medecine of Tunis - University of Tunis El Manar- National Institute of Orthopedics mohamed taieb kassab, Department of Physical Medicine, La Manouba, Tunisia

Introduction/Background

Clean intermittent self-catheterization (ISC) remains the reference technique of bladder emptying in patients with spinal cord injuries (PSCI) and has many advantages. Nevertheless, there is no clear consensus nowadays concerning the introduction of this technique. The main objective of this work was to develop an educational approach combining the use of ISC guide and therapeutic education session (TES) for the implementation of this technique.

Material and Method

This was a two-year prospective, evaluative and comparative study with two groups of PSCI who have already learned and used ISC for urine drainage. One group had benefited from an educational approach, associating TES and ISC guide. We conducted an evaluation and comparison of the results of various theoretical and practical skills required to realize the ISC, before and after a 3-month period of the TES in both groups. A correlation study was carried out later to determine the predictive factors for adhesion to ISC.

Results

Sixty PSCI divided into two groups of 30 were included. Post-TES assessment and ISC guide submission concluded that there was a significant improvement in both the theoretical and practical skills required for ISC compared to the control group. After the TES, all single patients adhered to the ISC. Married patients admitted to ISC in 83.3% versus only 25% of divorced patients. A positive correlation for civil status was objectified (p = 0.002). The subjective evaluation of the program showed that all our patients were satisfied with the content of the TES session and the ISC guide. However, 48% preferred several short sessions, to better assimilate the amount of information considered important.

Conclusion

At the end of our study, we were able to develop a customized diagram adapted to PSCI combining the ISC guide and TES for the installation of the ISC. The implementation of this approach could improve the management of this population.

Introduction/Background

Clean intermittent catheterization (CIC) is the gold standard method for neurogenic bladder management among the patients of spinal cord injury (SCI). Although CIC is a suitable method for SCI, infection, hematuria, urethral trauma, and the remaining of a foreign body are some of the complications of CIC. Here, we presented a case with an unexpected foreign body detected in the bladder of patient performing CIC.

Material and Method

A 40-year-old female patient who diagnosed T10 AIS A was interned to our rehabilitation service. At another rehabilitation center, she was undergone an anticholinergic drug (Oxybutynin HCL 10 mg/day) and advised self-CIC (6 times a day) due to the detrusor overactivity. The patient described increase in spasticity and urinary leakage recently. As a result of the investigations, the urinary tract infection was diagnosed. In routine urinary system ultrasonography evaluation, 19 millimeters sized linear echogenic appearance was detected in the bladder. The bladder was evaluated by urinary system computed tomography with the pre-diagnosis of bladder stone, and two rod-like foreign body densities were observed in the bladder.

Results

The foreign bodies were extracted from the patient’s bladder with cystoscopy by urologist, and it was found that the extracted foreign bodies were the ‘insertion sleeves’ which were located on the catheter that prevented hand contact during CIC. The patient claimed that she was unaware that impairment of the catheter integrity during any CIC. After the removal of foreign bodies from the bladder, the patient showed a decrease in urinary leakage and spasticity grade.

Conclusion

The catheter-related parts may remain during the CIC in the bladder. To prevent this complication, a proper education should be given to neurogenic bladder patients about CIC performing. When foreign bodies detected in the bladder of patients performing CIC, it should be considered to be a part of the catheter fragment.

ISPR8-0793  
IMPACT OF A THERAPEUTIC EDUCATION PROGRAM ABOUT INTERMITTENT SELF-CATHETERIZATION ON THE PSYCHOLOGICAL PROFILE OF A GROUP OF SPINAL CORD TRAUMA PATIENTS  
M.A. Khezami¹, I. Aloulou¹, I. Mir², S. Lebib², F.Z. Ben Salah², C. Dziri²  
¹National Institute of Orthopedics mohamed taieb kassab, Department of Physical Medicine, La Manouba, Tunisia  
²Faculty of Medicine of Tunis - University of Tunis El Manar - National Institute of Orthopedics mohamed taieb kassab, Department of Physical Medicine, La Manouba, Tunisia  

Introduction/Background  
The management of intermittent self-catheterization (ISC) among spinal cord trauma patients (SCTP) responds in every respect to the program of therapeutic education, which once correctly established, will ensure bladder continence primordial for psychosocial balance. The objectives of this work were to study the psychological profile of SCTP through a validated scale and to evaluate the impact of a therapeutic education session (TES) on their psychological profile.

Material and Method  
This was a two-year prospective and comparative study with two groups of SCTP. The psychological evaluation was carried out by the HAD scale in both groups. Each patient had to answer two subscales, one concerning anxiety (HAD-A), the other depression (HAD-D). One of the groups had also benefited from an educational approach, associating TES and ISC guide. We conducted an evaluation and comparison of the impact this program on the psychological profile after a 3-month period.

Results  
Sixty PSCI divided into two groups of 30 were included. We noticed that 68% of our patients had a moderate anxiety state (HAD-Mean Anxiety = 10.9) and 19% were in serious anxiety. In addition, we found a moderate depressive state in 42% of patients and a severe depressive state in 33% of patients. Women were more anxious and more depressed (HAD-D=11.6) than men (HAD-D=10.7). We have noted a predominance of depression and anxiety in patients whose age does not exceed 30 years. The anxiety component was higher among SCTP with incomplete involvement (HAD-A=10.2 versus 9.7). Statistical analysis found that anxiety improved with integration into TES workshops. Indeed, the average HAD-A had gone from 10.2 to 9.9. This objectified difference was not significant (p = 0.326). Integration into TES workshops had no effect on the depression component.

Conclusion
ISC provide a good psychosocial balance through the reduction of incontinence and infectious episodes. Indeed a well-educated patient could better manage his anxiety.

*No conflict of interest*
One of the main concerns of the individual with a Spinal Cord Injury (SCI) is the possibility of being able to recover his/her independence and walking. A clinical trunk control test was developed at the Mexico City-based National Rehabilitation Institute (INR). The test was reliable and valid, and could have prognostic value for walking, and independence. The main objective of this work was to determine prognostic validity for independence and walking of a trunk control clinical test in individuals with SCI.

Material and Method

A cohort study was carried out in all individuals with sub-acute SCI who had not received a rehabilitation program. The trunk control test was performed at baseline at treatment initiation and independence and walking were evaluated at 1, 3, 6 and at 12 months of the first evaluation.

Results

90 patients were recruited, including 35 with adequate initial trunk control (>13 points in trunk control test) and 55 patients with inadequate trunk control. The survival analysis revealed that the trunk control scale can predict gait and independence in individuals with a SCI at one year. The Cox analysis demonstrated that the AIS (ASIA Impairment Scale) is the most important variable to predict gait and the neurologic level to predict independence. Furthermore, it was proven that the trunk control scale is predictive of gait and independence independently of the AIS and the neurologic level of the SCI.

Conclusion

The present study revealed that the trunk control scale is useful for providing a prognosis of independence and walking at one year in individuals with SCI.

INTRATHECAL BACLOFEN (ITB) THERAPY TO SEVERE SPASTICITY

Y. Takagi¹, A. Nakanami¹, K. Kagechika², T. Yahata³
¹Tonami General Hospital, Rehabilitation, Tonami, Japan
²Kanazawa Medical University, Rehabilitation, Uchinada, Japan
³Kanazawa University, Rehabilitation, Kanazawa, Japan

Introduction/Background

To determine the outcome of intrathecal baclofen (ITB) therapy in patients with severe spasticity.

Material and Method

The baclofen of 50μg was administered to 39 patients who had severe spasticity due to 27 spinal cord injury, 3 hereditary spastic paraplegia, 2 cerebral bleeding, 1 syringomyelia, 1 spinal cord infarction, 1 cerebral infarction, 1 subpial lipoma, 1 spastic cerebral palsy, 1 subarachnoid hemorrhage, 1 autoimmune encephalitis in lumbar puncture as a schooling injection, and the pump burial operation were performed to 29 patients. The change of the spasticity was evaluated by the Ashworth score points. Follow up period was 82 months on average (10~137 months).

Results

The mean Ashworth score for rigidity decreased from 3.0±0.7 to 1.3±0.5 (p<0.01). The improvement of the spasticity was remarkably admitted in all cases, and the pain from the spasticity disappeared. The pain was reduced by adjusting the amount of the medicine without the exacerbation of the spasticity. Two catheter-related complications were found. Additional operations of the exchange of the catheter were needed. The improvement of the spasticity was recovered of additional operations.

Conclusion

In Japan, 25 cases have been clinically examined since 2002, and remarkable clinical effects were proved. And since April 2006, 1895 cases have been implanted of a programmable subcutaneous pump by the end of January 2018. The spasticity of the pain who doesn’t obtain the improvement by the taking treatment is improved enough, and the reduction of the pain is seen, and the ITB therapeutic effect is expected that the improvement of patient and family’s QOL can be attempted from the experience of these series.

LONG-TERM OUTCOME OF PATIENTS WITH SPINAL CORD INJURY IN MOROCCO
A. Hajjioui, M. Fourtassi
1University Sidi Mohammed Ben Abdellah- Fez, Department of Physical and Rehabilitation Medicine, Fez, Morocco
2University Mohamed I, Department of Physical and Rehabilitation Medicine, Oujda, Morocco

Introduction/Background

Spinal cord injuries (SCI) are responsible for para or quadriplegia-type motor impairment that can be very disabling in daily life activities. The study aims to describe the long-term outcome of people suffering from SCI in Morocco while specifying their limitations of activity and their specific needs in terms of health care.

Material and Method

The national database of people with disabilities in Morocco set up following the national disability survey in Morocco in 2014 was interviewed to identify adult SCI patients. Subsequently, the data for this specific population were re-analyzed in a descriptive mode. These data included demographic characteristics, geographical distribution, clinical presentation, activity limitations, support from the entourage, and needs and expectations in terms of medical care.

Results

Our population consisted of 136 people, including 24 tetraplegia, with an average age of 55.8 years and a slight female predominance (52.2%). 50% were married, 81.6% were illiterate and 62% were unemployed. The geographical distribution varied widely throughout the Moroccan territory. 53.5% had contracted their disability as adults with 43% of the cases as a result of a non-traumatic cause. Activity limitations were dominated by significant dependency in movements and body washing, and 80% relied heavily on their family or close entourage for activities of daily living. Only 36% reported having access to specific health care, and 89% said that their highest expectation was free health care, medicines and technical aids for people with disabilities.

Conclusion

The situation of SCI in Morocco is characterized by many difficulties, some of which would be avoidable if specialized care still almost unavailable in Morocco could be implemented.

ISPR8-0971
EFFICACY OF THE EXOSKELETON APPLICATION IN THE SPINAL CORD INJURY PATIENT’S REHABILITATION.

P. Tkachenko¹, V. Daminov¹
¹National Medical Surgery Center named by N.I.Pirogov, medical rehabilitation, Moscow, Russia

Introduction/Background

500,000 people are injured spine each year. A real revolution in the rehabilitation and expansion of the barrier-free environment was the exoskeletons appearance. Evaluation of the safety and effectiveness of the Exoskeleton + FES application in the SCI rehabilitation was the aim of this study.

Material and Method

92 of SCI patients, 6 months after incomplete SCI; thoracic region. Objective: lower paraparesis - <3 points (Muscle Strength Grading Scale); muscle tone - <3 points (Ashworth scale); safe function of the upper extremities. 2 groups. Patients had robotic-assisting walking: 46 patients had Lokomat + FES (control group), 46 patients had exoskeleton + FES (study group). Rehabilitation course included 15 trainings. Safety was assessed via physical and instrumental examination (blood pressure, heart rate, saturation, electrocardiography). Truck stability was evaluated via video analyses. Spine muscles below SCI and gluteus were tested with electromyography during strength test. Physiological cost index was calculated using MacGregor’s equation.

Results

Significant changes in the neurological status were not revealed in both groups. BP values were changed by not more than 15% from baseline, HR and ECG was within acceptable values. The saturation was 96-99%. PCI decreased at average by 32%. Basic group had better results in Strength test: ratio “Average strength/Myogram average amplitude” was increased. Maximum strength after trainings didn’t change but signal amplitude decreased that means improvements in back and gluteus muscles control. Spectral analysis of the ground reactions comparing dynamic walking parameters was done. Spectral power decreased after 15th training on exoskeleton. Decreasing of the spectral density on Fx, Fy and Fz means that patient’s gait became more stable in longitudinal and transverse directions.

Conclusion

We can do conclusions on the safety and clinical efficacy of the Exoskeleton + FES application in the SCI patient’s rehabilitation. And Exoskeleton is not only an assistive device, but also an instrument for rehabilitation treatment.

IS ACTIGRAPHY SUITABLE FOR SLEEP ASSESSMENT IN C4 TETRAPLEGIA?

1Loewenstein Hospital - Rehabilitation Center and Tel-Aviv University, Spinal Rehabilitation, Raanana, Israel
2Loewenstein Rehabilitation Hospital, The sleep Disorders Unit, Raanana, Israel
3Loewenstein Hospital - Rehabilitation Center, Spinal Rehabilitation, Raanana, Israel
4Loewenstein Hospital Rehabilitation Center and tel-Aviv University, Intensive Care and Consciousness Rehabilitation, Raanana, Israel
5Loewenstein Hospital - Rehabilitation Center, The sleep Disorders Unit, Raanana, Israel
6Loewenstein Hospital - Rehabilitation Center, The spinal and Consciousness Rehabilitation research laboratory, Raanana, Israel
7Loewenstein Hospital - Rehabilitation Center, The spinal and Consciousness Rehabilitation research laboratory, Raanana, Israel

Introduction/Background

Preliminary findings showed that head-mounted actigraphy is more sensitive to movements during sleep than wrist-mounted actigraphy, and suggested that it is a feasible alternative for sleep assessment in patients with C4 tetraplegia. To confirm these findings, sleep assessment based on actigraphy was compared with polysomnography (PSG) in these patients.

Material and Method

Head and wrist actigraphy, and PSG were conducted out overnight, at the Sleep Disorders Unit of Loewenstein Rehabilitation Hospital, in 5 patients with AIS grade A C4 tetraplegia, and in 11 healthy control subjects. Several sleep assessment variables were computed concomitantly by head and wrist actigraphy, and by PSG.

Results

Patients' PSG values of total sleep time (TST), sleep efficiency (SE=TST/time in bed), wake after sleep onset (WASO), sleep latency (SL), and number of awakenings during sleep (NOA) were 341.40±12.42, 81.20±5.09, 48.66±20.38, 15.38±10.96, and 21.80±8.22, respectively. Head-mounted actigraphy values of the same variables were 422.75±29.90, 97.90±0.93, 1.75±2.06, 5.25±5.12, and 3.0±3.56, respectively. Actigraphic head and wrist NOA and WASO values were highly correlated (r=0.97, p<0.05), and the difference between their mean values was non-significant, but on most of the measured variables actigraphy indicated less wakefulness than did polysomnography (p<0.05). Furthermore, whereas the difference between C4 tetraplegia patients and controls was non-significant in the wakefulness indicated by the
mean values of all the sleep assessment variables, C4 tetraplegia patients showed significantly less wakefulness than the controls on the mean values of wrist-mounted actigraphy NOA and TST, and on all head-mounted actigraphy variables (p<0.05).

Conclusion

Although sleep assessments using head-mounted actigraphy was similar to that of wrist-mounted actigraphy, both failed to detect wakefulness that was detected by PSG in patients with AIS A-C C4 tetraplegia. Therefore, our findings do not support the use of actigraphy for sleep assessment in these patients.

Introduction/Background

The multifactorial difficulties of access to healthcare for the disabled people notably led in France to a ministerial mission which led to the signature of the "Romain Jacob’s Charter". Nantes' University Hospital wished to set up an organisation of healthcare, whose objectives would be a simplicity of use, adapted and secure managements, and an easier medical regulation of acute care.

Material and Method

In 2006, a phone call number was set up 24/24 and 7/7 by the medical staff within the department of neurological Physical Medicine and Rehabilitation of Nantes’ University Hospital, intended for any doctor, indoor or outdoor, with the aim of getting any information about rehabilitation programs or to be helped in the orientation of a patient towards an acute medical care.

The direct access by patients, supported by a public financing of the Regional Healthcare Authority (ARS), consists of a single phone number for any disabled person wishing to obtain information about his/her orientation and/or access to primary and specialized healthcare. The staffs of the call unit are receiving a specific training and are supported by a nurse specialized in neurological MPR.

Results

This organization is assessed by monitoring indicators (weekly mean of 10 medical calls 85% outdoor calls, 90% problems immediately solved) and by the impact of the project on the target public, on behavior changes and on the organization evolution: directly expressed satisfaction of the calling doctors, directly expressed satisfaction of the patients for instance within the framework of a gynecological or obstetric follow-up, reassurance of acute healthcare departments (e.g. ICUs) by the signature of an indoor charter.
Conclusion

« Handisoins 44 » should lead to formal networks simplifying the local access to healthcare of the disabled people and justifies the search for ways of its sustainability.

Keywords

access to healthcare; networks; single service desk

With an incidence of 18.1 cases/million of spinal cord injury in Mexico, knowing epidemiological changes worldwide and without recent studies in our country, the objective of our study was to determine the demographic and clinical characteristics of patients with traumatic spinal cord injury (tSCI) in the UMFRC (national referral hospital).

Material and Method

Observational, cross-sectional and retrolective study. Records with a diagnosis of tSCI from September 1, 2010 to August 31, 2016 were reviewed. Demographic and clinical characteristics were recorded. Descriptive and inferential statistics were performed for association between variables (ANOVA and Chi-square).

Results

The medical records of a total of 489 patients were analyzed. The male/female ratio was 4.6:1, average age: 38.6+15.18 years; education predominantly middle school (30.9%); in occupation, employees (63.8%). Injury mechanisms: falls (39.7%), motor vehicle accidents (MVAs) 37% and violent acts (17%). Most frequent associated lesions: polyfractures (11.9%) and hemopneumothorax (10.4%). 81.8% of patients underwent surgery. Average evolution time at admission: 58.12+68.05 days; average days of hospital stay 36.19+19. Complete paraplegia (37.2%) and incomplete paraplegia (26%) were more frequent; as well as the thoracic level (50.7%); neurological level C4 predominating (13.1%); likewise, ASIA A (49.5%) followed by ASIA C (22.9%); cauda equina syndrome (11.9%) the most frequent. Violent acts predominated in men (P <0.000). Falls were more frequent for ASIA A (P <0.000); MVAs were significantly more frequent for cervical injuries (P <0.000) and for central cord syndrome (P <0.005). Incomplete tetraplegia was the most common secondary to MVAs (P <0.000), complete paraplegia was the most frequent secondary to falls, violent acts and crush injuries (P <0.002), (P <0.03) and (P <0.01), respectively.

Conclusion
The demographic and clinical profile of the LMT in Mexico presents very similar characteristics to other countries, however, it has undergone an epidemiological transition, currently ASIA A, less than 50%.

⁶UMAE Hospital de Traumatología- Ortopedia y Rehabilitación “Lomas Verdes”. Unidad de Medicina Física y Rehabilitación Región Centro- Instituto Mexicano del Seguro Social, Terapia Física, Ciudad de México, Mexico

Introduction/Background

Because of the epidemiological changes and limited information of complications in subacute traumatic spinal cord injury, our objective was to determine the complications and their limitations to culminate rehabilitative management in patients with traumatic spinal cord injury (tSCI) in the unit of physical medicine and rehabilitation center of Mexico City.

Material and Method

Observational, transversal and retrolective study. We analyzed files from 1/September/2010 to 31/August/2016 obtaining demographic and clinical data, complications, transfers due to severity and causes that limited their rehabilitation. Descriptive and inferential statistics were performed, for association of variables (ANOVA and Chi square).

Results

The medical records of 489 patients with tSCI were analyzed; average intrahospital stay: 36.19±19 days. Main complications: urinary tract infections (UTIs) 77.5%; anemia (56.6%), depression (44.6%), pressure ulcers (PU) 43.8%; neuropathic pain (43.6%); nociceptive pain (42.5%), spasticity (39.3%), rhythm disturbances (13.7%), orthostatic hypotension (OH) 12.7%, lower respiratory tract infection (LRTI) 7.0% and deep vein thrombosis (DVT) 2.5%. Most frequent associated peripheral nerve injury, multiple radiculopathy 18.6%. Due to the severity
and instability, 29.7% of patients required secondary transfer to: multiresistant UTIs (6.1%), fever of unknown origin (3.1%), complicated LRTI and PU (2.7%, respectively), DVT (2.2%); re-entering only 26.89%. Of the 489, 22.7% did not complete their rehabilitation due to: urosepsis (5.5%), thrombosis (3.1%), complicated PU (2.2%), LRTI (2.0%). UTIs occurred more frequently in ASIA A (P<0.000) and complete paraplegia (P<0.004); PU predominated in complete paraplegia (P<0.000), thoracic levels (P<0.004) and ASIA A (P<0.000). Nociceptive pain was associated with ASIA A (P<0.05); spasticity was predominant in incomplete tetraplegia, cervical level and ASIA A (P<0.000), as well as OH in incomplete tetraplegia (P<0.003) and cervical level (P<0.004).

Conclusion

Complicated UTIs were the main complication due to frequency, determinant of transfer and limitation to complete rehabilitation; secondarily, PU and thrombosis also delay and limit rehabilitation in the subacute tSCI.

³Loewenstein Rehabilitation Hospital, Intensive Care and Consciousness Rehabilitation Department, Raanana, Israel
⁴Loewenstein Rehabilitation Hospital, The Spinal and Consciousness Rehabilitation Research Laboratory, Raanana, Israel

Introduction/Background
Head- and wrist-mounted actigraphy have been studied to identify feasible methods of sleep assessment for patients with tetraplegia. The present study compares these methods with polysomnography (PSG), in patients with paraplegia.

Material and Method
Head and wrist actigraphy, and PSG were conducted overnight, at the Sleep Disorders Unit of Loewenstein Rehabilitation Hospital, in 11 patients with paraplegia T1-T12 (10 with AIS grade A, 1 with grade C), and in 11 healthy control subjects. The sleep assessment variables total sleep time (TST), sleep efficiency (SE=TST/time in bed), wake after sleep onset (WASO), sleep latency (SL), and number of awakenings (NOA) were evaluated concomitantly, by head and wrist actigraphy, and by PSG.

Results
In the healthy control subjects, PSG did not differ significantly from wrist-mounted actigraphy on any of the studied sleep assessment variables, and from head-mounted actigraphy on any of them, except WASO. In the patients with paraplegia, no significant differences were found between PSG and wrist-mounted actigraphy on any of the studied sleep variables either, but head-mounted actigraphy indicated significantly less wakefulness than PSG on all corresponding sleep variable values (p<0.05).

Conclusion
Results indicate that wrist-mounted actigraphy is suitable for sleep assessment in paraplegia, but that head movements may not be sufficiently sensitive for sleep assessment in paraplegia.

Prevention and treatment of osteoporosis after spinal cord injury: A systematic review

M. Lauwers1, M. De Jaeger2, N. Draulans1, F. Luyten2, K. Peers1, C. Kiekens1
1 KU Leuven, Department of Physical and Rehabilitation Medicine, Leuven, Belgium
2 University Hospitals Brussels, Department of Neurosurgery, Brussels, Belgium
3 KU Leuven, Department of Rheumatology, Leuven, Belgium

Introduction/Background

Spinal cord induced osteoporosis is a significant health condition associated with fragility fractures beneath the level of injury. In the scientific literature several treatment options have been proposed. The aim of this paper is to review the current literature about treatments’ efficacy for osteoporosis in spinal cord injury.

Material and Method

A systematic literature search is conducted in four electronic databases: PubMed, Embase, The Cochrane Library and PEDro. All identified records are analysed by title, abstract and if relevant by full text to determine if they meet all inclusion criteria. Additionally, the included RCTs are judged to a quality control according to the Cochrane Handbook for Systematic Reviews of Interventions, Risk of bias assessment. Due to the heterogeneity of the included trials no meta-analysis is performed.

Results

Thirty-two randomized controlled trials are included. Bisphosphonate therapy, if applied correctly, is effective to optimize bone quality, in both the early and chronic phase of the disease, although the evidence is debatable. Moderate-quality evidence suggests that intravenous administration of zoledronic acid is potentially the best approach to tackle this condition. Rehabilitation techniques, although widely used, show no proven efficacy on this matter. In addition, numerous experimental therapies have been proposed, but require further research to prove their applicability.

Conclusion

This systematic review suggests that bisphosphonate administration could attenuate sublesional bone loss, while we did not find conclusive evidence about various rehabilitation techniques. Although this paper does not provide final evidence, it could be a useful tool for future research purposes.

Introduction/Background

Spinal cord injury (SCI) is a life-changing event as it incurs primary impairment (e.g., paralysis, bladder dysfunction), as well as secondary health conditions (e.g., spasticity, pressure sores), and impacts on life domains (e.g., housing, transportation). As a result, assessing quality of life (QoL) post-SCI is challenging since QoL can be impacted in various ways depending on specific (or a combination of) health conditions and life domains. To address these challenges, the Participation and Quality of Life (PAR-QoL) website, an online knowledge mobilization tool, was developed to aid clinicians and researchers in the selection of QoL outcome tools specific to SCI. The aim of this study was to evaluate the usability and use of the website.

Material and Method

Using a technology acceptance framework, an online usability survey was developed and employed to gain information about how the website was used, perceived ease of use, and improvement recommendations. The actual use was assessed through a 26-item survey and through Google analytics. Recruitment targeted researchers and clinicians who worked with individuals with SCI. Survey and web data were analyzed using descriptive statistics.

Results

Forty-six individuals responded. More than 60% used the website to find tools for work. The website was perceived as easy to use by 80% of respondents. To improve the website, respondent suggested rearranging classification, developing a French version, and adding more up-to-date evidence. There were a total of 181,179 users who made 303,810 visits to the
website between April 2012 and November 2017. Returning visitors comprised 13% of the total visits.

**Conclusion**

The PAR-QoL website was perceived to be an important and useful knowledge mobilization tool with QoL outcome tools for SCI that are easy to find. Usability may be improved through modification of navigation processes and improved organization of content, which may facilitate greater uptake.

ISPR8-1362
PREDICTING COMMUNITY REINTEGRATION AFTER SPINAL CORD INJURY
A. Adomavičienė¹, A. Juocevičius²
¹Vilnius University- Faculty of Medicine,
Department of Rehabilitation- Physical and Sports Medicine, Vilnius, Lithuania
²Vilnius University Hospital- Santaros Clinics,
Center of Rehabilitation- Physical and Sports Medicine, Vilnius, Lithuania

Introduction/Background

The degree to which a person with SCI is an active, productive member of society, well integrated into family and community life, is a complex phenomenon influenced by many factors. These factors include physical characteristics of the injury (neurological SCI level and severity, impairment at the organ level and body dysfunctions, functional problems), personal characteristics (demographics, lifestyle, behaviour and psychoemocional), and the environment (physical, social, attitudinal, and cultural issues).

Purpose. To determine the factors influenced on the community reintegration of people with SCI.

Material and Method

A total, 219 people with SCI (1-25 years after SCI) who received independent life skills and recreation camps in a Landscape Therapy and Recreation Centre were involved in research. Database were studied cross-sectionally, and a subset of 109 individuals who were also enrolled in a 10 year longitudinal study. Main Outcome Measures: Life Situation Questionnaire-revised (LSQ-r, J.S.Krause); Comprehensive ICF Core set for SCI. Ethical approval has been obtained from the Lithuanian Bioethics Committee.

Results

Statistically significant interactions were found (ANOWA): between age and years post-injury on physical independence; between neurological level / severity and gender on mobility; between SCI complications (spasticity, pressure sores, and infections of urinary system, contractures) and psychoemocional state on daily life activities; year post-injury and education level on employment. The predicted functioning in daily life factors (regression analysis β coefficients) of people with tetraplegia was significantly related to the age, education, post-injury time, self-confidence, social interactions and family support (P<0.05). However, in paraplegia significant factors included post-injury time, medical complications, self-confidence and psychoemocional state (P<0.05).
Conclusion

The present study indicates that these factors are inadequate to explain most of the variation in community reintegration after SCI, they might appropriately be used during post-injury time to adjust and ensure support and environment, promoting self-confidence and social activity of people with SCI.

SCHWANNOMATOSIS PRESENTING AS CAUDA EQUINA SYNDROME: OUTCOMES AFTER COMPREHENSIVE REHABILITATION APPROACH

C. Cid-Bassaletti¹, M. Nuño-Estévez¹, R. Palazón-Garcia², M. Ruiz-Sanz¹, V. Maitin-Noguera¹
¹Hospital General Universitario Gregorio Marañón, Servicio de Rehabilitación, Madrid, Spain
²Hospital Nacional de Parapléjicos de Toledo, Servicio de Rehabilitación, Toledo, Spain

Introduction/Background

Schwannomatosis is a rare disorder characterized by benign peripheral nerve sheath tumors arising from Schwann cells. More commonly seen in cervical and lumbar regions, cauda equina compression accounts for only 6% spinal tumors. We present a case of Schwannomatosis with cauda equina and upper limb paresis managed with a comprehensive multidisciplinary rehabilitation approach, after rejecting surgical treatment.

Material and Method

A 36-year-old man, with 2-year diagnosis of Familial Schwannomatosis (SMARCB1 gene mutation), denoted upper and lower limb weakness, back pain, inability to walk and bladder dysfunction that required permanent catheterization. Physical findings revealed a neurological level L2, American Spinal Injury Association (ASIA) grade C according to the International Standards for Neurological Classification of Spinal Cord Injury, and 19 points score in Spinal Cord Independence Measure III scale. MRI evinced large tumors occupying the spinal canal, partially at level D2 and totally at levels D12-S1, with secondary compression of medullar cone and cauda equina roots. Patient started a rehabilitation program consisting in: postural changes, respiratory and muscle strengthening physiotherapy, gait and daily activities re-education, bladder and bowel re-education and wheel-chair use training.

Results

After 6 months of treatment, the patient managed to perform therapeutic walk with walker and supervision. Training in transfers from wheelchair allowed him to perform daily life activities independently. He also handled self-catheterization and regulation of bowel habit with laxatives. Patient was discharged with L2 ASIA D and 57 points score in SCIM III scale.

Conclusion

Schwannomatosis is characterized by peripheral nerve sheath tumors that very rarely affect the central nervous system by compression. Surgical management is a proper indication when refractory pain and neurologic deficits appear. We consider the need to enhance the role of the PM&R multidisciplinary approach, as it led to acceptable functional results, improving significantly the patient’s personal autonomy.

ISPR8-1379
EFFECT OF TWO DIFFERENT PROGRAMS OF ROBOTIC ASSISTED GAIT TRAINING IN INDIVIDUALS WITH CHRONIC MOTOR INCOMPLETE SPINAL CORD INJURY
J. Quinzaños-Fresnedo¹, L.F. Apodaca-García López¹, A.V. Aguirre-Güemez², I. Quiñones-Uríostegui³, A.I. Pérez-Sanpablo³, R. Pérez-Zavala²
¹Instituto Nacional de Rehabilitación, Neurologic Rehabilitation, Mexico City, Mexico
²Instituto Nacional de Rehabilitación, Spinal Cord Injury, Mexico City, Mexico
³Instituto Nacional de Rehabilitación, Motion Analysis Laboratory, Mexico City, Mexico

Introduction/Background

Gait training is one of the main objectives in rehabilitation of motor incomplete spinal cord injury (SCI). There are different modalities of locomotion training, being the robotic orthosis among them, and offering until now, positive outcomes. However there’s still a lack of evidence of the optimal training characteristics.

OBJECTIVE

To determine the effect of two different training programs with robotic gait orthosis for patients with chronic motor incomplete SCI.

Material and Method

Study design: randomized, blinded to the observer, clinical trial. Patients from the National Institute of Rehabilitation (INR) with motor incomplete SCI, with at least 6 months of evolution and who were able to walk, were eligible. Patients were randomly assigned to either one of the two different training groups: 30 minutes or 60 minutes training group. Both groups received a training period of six weeks, five days a week. Assessments of gait pattern analysis with the GaitRite instrument, functional assessment with Spinal Cord Independence measure (SCIM), walking index for spinal cord injury (WISCI) and quality of life with Life satisfaction questionnaire (Lisat-9); repeating such evaluations in a 6 and 12 months follow-up.

Results

12 participants were studied. After 30 training sessions with the robotic orthosis, both groups had significant improvements in gait as well as in SCIM, LISAT-9 and WISCI. No significant differences between groups were found.

Conclusion
Robotic orthosis gait training has a positive effect improving gait pattern in incomplete SCI. Until now, there are no significant differences between a 30 minutes and a 60 minutes training program.

RESILIENCE, COPING AND SPINAL CORD INJURY : A PILOT STUDY FOR THE VALIDATION OF A SPECIFIC SCALE

M. Le Fort¹, B. Perrouin-Verbe¹, G. Guihard²
¹CHU Nantes, Neurological PMR department, Nantes, France
²Medicine University, DPHU2 Institut du Thorax et Système Nerveux, Nantes, France

Introduction/Background

Resilience corresponds to one’s ability to positively outcome while experiencing aversive situation. It may be linked with a disparity of coping strategies after a spinal cord-injury (SCI). After a recent work realized in a population without SCI, suggesting the influence of Empathy and Alexithymia, the aim of our work consisted in studying their relative contribution on resilience in a sample of SCI patients.

Material and Method

The survey consisted in the French version of the Connor-Davidson resilience scale (CDRISC10), the interpersonal reactivity index (IRI), the Toronto-alexithymia-scale (TAS20), the Brief-cope scale (b-COPE), the Hospital anxiety-depression scale (HAD) and the sense of coherence scale (SOCS), administered to 17 SCI patients included in the French study QaliPREPS (qualitative analysis of SCI patients' perception of a systematic medical follow-up). Mean scores for full scales and their respective dimensions were calculated. The correlations between the different constructs were analyzed and the predictors of resilience were highlighted on the basis of multiple linear regression studies.

Results

Mean scores calculated for anxiety/depression, adaptation, sense of coherence and resilience were comparable to those calculated for a sample of adults with no SCI. Resilience presented significant positive correlation with coping ability and empathy, and significant negative correlation with alexithymia. Our data suggested that two dimensions of alexithymia (i.e., difficulty to describe one’s own emotions and externally oriented thinking) and one dimension of empathy (fantasy ability) are negative predictors of resilience. By contrast, three dimensions of empathy (perspective taking, empathic concern, personal distress) positively influenced the resilience.

Conclusion

We present the first analysis of resilience predictors in SCI patients. However, our study is limited by the small number of patients included into the survey. It justifies a scaling up in order to increase the strength of our conclusions.
Keywords

Introduction/Background

Individuals with cervical spinal cord injury experience tetraplegia with dramatic impairment of upper limb (UL) including hand function and decreased autonomy. In absence of very recent evidence and meta-analysis, we addressed UL rehabilitation effectiveness after tetraplegia.

Material and Method

Two independent reviewers performed the systematic review and meta-analysis addressing PUBMED, PEDRO, CENTRAL and SCOPUS®. We considered studies with a randomized controlled trial design, published in English language, which included individuals with tetraplegia and measured UL rehabilitation effect on strength, somesthesia, hand function and autonomy.

Results

From 573 records identified, 24 studies were included totaling 517 participants with C2 to C7 tetraplegia (ASIA A to D). Interventions lasted from 66 to 3780 minutes. Three different strategies were used i) bottom-up (namely massed practice, Functional Electrical Stimulation – FES, resistance or robotic training), ii) neuromodulation (i.e. electrical nerve, trans-cranial or magnetic stimulations), or iii) top-down (brain computer interfaces with FES or virtual reality). The 17 studies analyzed displayed heterogeneity for all outcomes except for strength. Overall, strength significantly increased with positive but non-significant effect on hand function and autonomy. Sub-analysis revealed a significant effect on strength only for bottom-up strategy. All other sub-analyses albeit non-significant revealed at least a medium effect size for all outcomes with exception to the very small effect size displayed for somesthesia.

Conclusion

These results support the effectiveness of UL rehabilitation on strength using. There is a potential interest of using bottom-up and neuromodulation strategies to improve hand function and autonomy but with heterogeneity between interventions and participants. Conversely, there is no evidence for top-down strategy and interventions targeting somesthesia appear ineffective. Further effort on funding may promote high-quality multi-centric studies with increased
standardization in intervention and participants to completely address UL rehabilitation effectiveness after tetraplegia while separating recovery and compensation effects.

CAUDA EQUINA SYNDROME IN A TERTIARY CARE CENTER – CHARACTERIZATION AND REHABILITATION IMPACT

J. Capelo¹, C. Ernesto Pereira¹, T. Stuve Barros¹, J. Fortunato¹, M. Martin¹, F. Faria¹
¹Centro de Medicina de Reabilitação de Alcoitão, Serviço de Reabilitação de Adultos 1, Alcabideche, Portugal

Introduction/Background

Cauda Equina Syndrome (CES) reflects injury to the lumbosacral nerve roots of the cauda equina and will classically produce impaired sensory modalities and lower motor neuron signs with flaccid lower limbs, areflexic bladder and bowel.

The purpose of this study was to characterize patients diagnosed with CES and assess the impact of rehabilitation through the functional independence measure (FIM) variation between admission and discharge.

Material and Method

Retrospective longitudinal study on a cohort of all patients admitted to a Portuguese rehabilitation center between 01/01/2015 and 15/09/2017. Clinical files were consulted, and relevant data was collected and reviewed. Inclusion criteria was the diagnosis of CES. Exclusion criteria were the absence of information on the FIM scores and insufficient clinical information regarding the diagnosis.

Descriptive statistics were used to analyse the patient characteristics. As ordinal data FIM values were displayed with median, interquartile range and coefficients of variance, both at admission and discharge and Shapiro-Wilk and Wilcoxon tests were applied.

Results

Of 1008 patients admitted, 965 were excluded for not matching the inclusion criteria, 21 for insufficient information and 1 for absence of FIM values, remaining 21 patients (2,1%).

There were 11 females for 10 males, mean age was 54,7 years and the average length of stay was 51,7 days. The most frequent causes for the CES were surgeries of L4-L5 and L5-S1 disc herniation with 6 patients each (28,6%). There was a second admission in 4 patients.

Median FIM score at admission was 99, with interquartile range of 24,25 and coefficient of variation 24%, while at discharge, it was 114, 19 and 17%, correspondingly. A statistical significant difference (p=0.000) between admission and discharge FIM scores was found.

Conclusion

Despite the reduced number of patients in this study, the impact of rehabilitation and functional improvement observed with the FIM scale seems undeniable.

RELIABILITY ASSESSMENT OF ELECTRICAL IMPEDANCE MYOGRAPHY USING TWO DIFFERENT HAND-HELD ELECTRODE ARRAYS

H. hu

†Guangdong work injury rehabilitation center, neurophysiology, guangzhou, China

Introduction/Background

Electrical impedance myography (EIM) has been used to quantify muscle changes in different neuromuscular diseases.

Material and Method

Hand-held sensors of different sizes (large and small sensors) were used to evaluate the inter- and intra-rater reliability of the biceps brachii muscle in 20 healthy control subjects by two raters. The EIM testing procedures were repeated 5–8 days after the first experiment. Intra-class correlation coefficient (ICC) analysis was conducted for resistance, reactance and phase angle at two different current frequencies (50 and 100 kHz).

Results

Both the intra- and inter-rater reliabilities were highly reproducible for the large sensor, which had higher ICCs (ICCs=0.84–0.986) than the smaller sensor (ICCs=0.281–0.947).

Conclusion

High-frequency current tended to improve the ICC for the small sensor. The results demonstrate reasonable repeatability of the hand-held electrode array for EIM measurements and suggest that electrode array size should be appropriately selected based on the muscle being tested.

ISPR8-1447
EFFECT OF COMBINATION UPPER EXTREMITY ROBOTIC THERAPY IN SPINAL CORD INJURED PATIENTS : RANDOMIZED CONTROL TRIALS

H. Lee¹, J. Deokyeon¹, J. joohwan¹, L. Jungeun¹
¹National Rehabilitation Center, 58- Samgaksan-ro, Seoul, Republic of Korea

Introduction/Background

There have been few studies of upper extremity rehabilitation robots in patients with spinal cord injuries. Especially, there are more few studies on the effects of treatment by applying combined upper extremity robots for rehabilitation. Therefore, in this study, we investigated the effect of combined upper extremity robot therapy on rehabilitation of spinal cord injury patients.

Material and Method

The subjects were selected for the patients with cervical spinal cord injury. The subjects received upper extremity rehabilitation therapy using two different type of upper extremity robots. Armeo power was applied for proximal upper extremity training and Amadeo was applied for distal upper extremity training. The outcome measure are as follows; upper extremity MMT, grip power, graded and redefined assessment of strength, sensibility and prehension(GRASSP), korean version of spinal cord independence measure 3(KSCI-M3).

Results

The total number of subjects was 15. After intervention, all the muscle strength of the upper extremity were improved(In particular, the C5(elbow flexion), C7(elbow extension) and the sum of MMT). The grip power increased in full grasp, lateral pinch, and three-jaw chuck items. The results of SCIM-3 measurement showed improvement in all category. Especially bathing(upper extremity), dressing(upper extremity), grooming and overall score showed significant improvement. The score of the strength in the GRASSP item were increased.

Conclusion

In this study, it was confirmed that combined upper extremity robot treatment is effective for patients with cervical spinal cord injury.

No conflict of interest
Spinal cord injury and amputees rehabilitation are fundamental study areas of Physical Medicine and Rehabilitation (PMR). These are true working groups in which the role of the physiatrist is central.

This overlapping syndrome represent a real challenge to rehabilitation and demonstrate the need for specialized multidisciplinary teams.

**Material and Method**

Data collection with the patient and in the clinical process.

**Results**

A 46-year-old male patient was referred to the PRM department after trans-tibial amputation of the left lower limb.

The patient suffered a work accident in 1999 with L1 fracture and performed surgical fixation resulting in AIS-A paraplegia (bilateral L3 sensory level, right L3 motor level, non-testable motor level on the left). Since then he has been walking with an Ankle Foot Orthosis (AFO) on his left leg and a crutch.

Due to chronic wound, transtibial amputation was performed in October 2009. As a result, endoskeletal prosthesis was used, with a distal pin and a fixed joint, with an interface dermo 343 from Ossur , and an AFO of the right tibia-tarsal per pendent foot was also prescribed. In 2016 he was diagnosed with seminoma for which is under follow-up of oncology and urology with periodic chemotherapy treatments.

The patient maintains neurogenic bladder follow-up, with intermittentalgations. Maintain regular intestinal transit with training every second day. Presents multiple intercurrences with pressure ulcers in the zones with hypoesthesia.

He is autonomous under the use of prosthesis and one crutch and maintains his work activity.

**Conclusion**
Given the conjunction of these pathologies it is necessary to adapt the intervention of the rehabilitation team to the particular case. The timely follow-up of patients with spinal cord injury prevents multiple complications. And proper prescription of support products is fundamental to maintaining patients' autonomy, especially in amputees.

This case demonstrates that often our greatest success may be just maintaining the patient's functional capacity.

NEUROLOGICAL AND FUNCTIONAL IMPROVEMENTS FOLLOWING HAL EXOSKELETON REHABILITATION IN ACUTE AND CHRONIC SCI PATIENTS

D. Grasmücke¹, T.A. Schildhauer², O. Jansen², R.C. Meindl¹, M. Aach¹
¹Berufsgenossenschaftliches Universitätsklinikum Bergmannsheil GmbH, Spinal Cord Injuries Unit - Department of General and Trauma Surgery, Bochum, Germany
²Berufsgenossenschaftliches Universitätsklinikum Bergmannsheil GmbH, Department of General and Trauma Surgery, Bochum, Germany

Introduction/Background

Several studies revealed that Hybrid assistive Limb (HAL®) Locomotion training induces improvements in functional and ambulatory mobility due to an effective treadmill training based on a neurological controlled feedback in chronic paraplegic patients after SCI.

The purpose was to determine the neurological and functional improvements of HAL® Locomotion training in acute and chronic SCI patients.

Material and Method

In total 30 acute and 70 chronic SCI patients were included in this longitudinal prospective study. The patients performed 60 sessions of a body weight supported treadmill training using the HAL® exoskeleton in a 12 week period of time.

Assessment of motor and sensory function of all patients has been achieved using the International Standards for Neurological Classification of SCI examination, prior to training and after completing the intervention. Functional outcomes were measured by using the 10-Meter-Walk-Test (10 MWT), 6-Minute-Walk-Test (6 MWT), Timed-Up-And-Go-Test (TUG-Test) and the Walking-Index-for-Spinal-Cord-Injury II Score (WISCI-II-Score).

Results

Acute and chronic patients improved in treadmill training after using HAL®. In terms of functional mobility all patients improved their performance in 10 MWT, 6MWT and TUG compared to baseline. Significant gains occurred in the lower extremity motor scores (LEMS). The majority of the patients improved in their WISCI-II-Score. The lesion level in chronic SCI did not significantly influence the functional outcome. According to time since injury a cut-off of 12 month significantly divided the groups in acute and chronic SCI.

Conclusion
HAL-Training induces significant improvements in ASIA motor scores and functional mobility in chronic and acute SCI patients.

We evaluated the secretion of melatonin and the sleep quality in spinal cord injury patients versus healthy volunteers.

**Material and Method**

This observational non-randomised study was conducted from June 2016 to January 2018 includes tetraplegics, paraplegics and healthy volunteers. Urinary 6-sulfatoxy-melatonin (U6SM) was measured during 5 periods per day (8h-12h; 12h-16h; 16h-20h; 20h-00h; 00h-8h). Sleep quality was evaluated on Pittsburgh Sleep Quality Index and sleepiness on Epworth Sleepiness Scale. Correlation between U6SM dosage and sleep quality and sleepiness was analysed.

**Preliminary Results** 12 tetraplegic patients AIS A and B (10 men and 2 women) and 7 paraplegics AIS A and B were included in the study. No patient took neuroleptics or beta-blockers. No patient had a brain trauma associated.

8 tetraplegic patients (66,6%) had an absence of melatonin secretion, 4 (33,3%) had a decreased secretion with a shift of melatonin secretion. Unlike data of the literature, secretion of melatonin was not strictly normal in paraplegic patients: 4 (57,1%) had an absence of melatonin secretion, one T10 AIS A patient had a shift of melatonin secretion, 2 (28,5%) T9 and T10 AIS A patients had a normal melatonin secretion.

The Pittsburgh Sleep Quality Index showed a poor sleep quality in tetraplegics (10,18±4,62) versus (7,57±3,64) in paraplegics and Epworth Sleepiness Scale showed a moderate sleepiness in tetraplegics (11,18±4,30) versus (4,57±2,50) in paraplegics.

**Conclusion**

Secretion of melatonin is abnormal in patients with tetraplegia. It may partly explain sleep impairment of patients with tetraplegia. Further studies are needed to better understand the impact of this absence of melatonin secretion and to assess the effect of melatonin treatment in this population of patients.

³National Institute of Orthopaedy M.Kassab- Faculty of Medicine of Tunis- University Tunis El Manar, Physical Medicine and Rehabilitation, La Manouba, Tunisia
⁴National Institute of Orthopaedy M.Kassab- Faculty of Medicine of Tunis- University Tunis El Manar, Physical Medicine and Rehabilitation, La Manouba, Tunisia

Introduction/Background

Paraplegia is a public health problem due to its medical complications. The purpose of this work is to evaluate the epidemiological, clinical and para-clinical profile of paraplegic patients as well as the predictive factors for the development of major complications (pressure sores, neurogenic paraosteoarthropathy and urinary tract infection) in order to make recommendations aimed at improving the medical care and the prognosis of these patients.

Material and Method

Descriptive cross-sectional study carried out in the Department of Physical Medicine and Rehabilitation at the National Institute of Orthopedics Mohamed Kassab from October until December 2016 concerning paraplegic patients (due to different etiologies). 60 patients were collected: epidemiological data, clinical examination data, Functional Independence Measurement Scale and para-clinical data. Many different predictive factors may influence the development of pressure sores, neurogenic paraosteoarthropathy and urinary tract infection.

Results

The average age of our patients was 41.2 +/- 12.9 years with a male predominance (60%) and an average duration of paraplegia of 5.27 years. Traumatic causes were at the top of the etiologies (55%). On clinical examination, 48.3% of patients had complete deficiency ASIA A, 53.3% a low dorsal neurological level and 80% were spastic. Articular limitation was noted in 68.33% of the patients, 41.7% of the patients had pressure ulcers (main localization: sacral, ischiatric and heel), 41.7% of them had bladder disorders. Most of our patients had an average FIM of 101 +/- 11.8. Predictive factors for the development of pressure sores, neurogenic paraosteoarthropathy and simple urinary tract infections were identified.

Conclusion
Paraplegia is a disability affecting functional capacities, socio-professional life and psychology. Multidisciplinary management, an early transfer into the Department of Physical Medicine and Rehabilitation, preventive measures are necessary to avoid the main complications. A regular follow-up will lead to better functional results with early socioprofessional reintegration of paraplegic patients.

³Instituto Nacional de Rehabilitación, Spinal Cord Injury, Mexico City, Mexico
⁴Instituto Nacional de Rehabilitación, Physical Therapy, Mexico City, Mexico
⁵Instituto Nacional de Rehabilitación, Enseñanza, Mexico City, Mexico

Introduction/Background

One of the main objectives in spinal cord injury (SCI) rehabilitation is the improvement in trunk control, to achieve independence in daily activities, to prevent complications, and in specific cases to walk. Also, one of the main causes of death in individuals with a SCI is the cardiovascular complications. In order to improve trunk control and cardiovascular function in these individuals, training in a kayak ergometer was evaluated.

Objective: To determine the effect of training in a kayak ergometer on trunk control, satisfaction with life, independence and cardiovascular function in individuals with SCI.

Material and Method:

A randomized clinical trial was carried out in individuals with a sub-acute SCI with a neurologic level below C8. The subjects were randomly assigned to one of the following training groups:

Group A. Control, with conventional therapy (neuro-propiceptive facilitation) of 30 minutes, 5 days per week during 6 weeks.

Group B: Experimental, with training in kayak ergometer during 30 minutes, 5 times a week during 6 weeks.

Results

13 patients have been trained. Kayak ergometer training has a beneficial effect in terms of trunk control, independence, cardiovascular function and satisfaction with life.

Conclusion

Kayak ergometer seems to be a good option to improve trunk control, independence, cardiovascular function and satisfaction with life in individuals with sub-acute SCI.

ISPR8-1744
BARRIERS TO PARTICIPATE IN ACTIVITIES OF DAILY LIVING IN THE COMMUNITY AMONG THE PERSONS WITH SPINAL CORD INJURY

H. Shakhawath

1Bangladesh Health Professions Institute BHPI, Occupational Therapy, Dhaka, Bangladesh

Introduction/Background

To assess the Socio-demographic information and understanding and communicating, mobility. Self-care, getting along with people, household activities, work or school activities and participation

Material and Method

It was a cross sectional study. 50 samples were conveniently selected from Savar and Dhamrai Upazilla of Dhaka district of Bangladesh for the study. Among them 78% (n=39) was male and 22% (n=11) was female. Interviewer administered Bengali version of The World Health Organization Disability Assessment Scale II (WHODAS II) 36 items was applied to people with spinal cord injury living in their own community who completed their rehabilitation from CRP.

Results

In the study the total participants were 50. The minimum age was 20 years old. The maximum age was 80. Each item of WHODAS 2.0 questioner was rated on a 5-point scale, from 1 (no difficulty) to 5 (extreme difficulty/cannot do). The instrument produces a total score (disability level) and 6 domain scores, ranging from 0 (best) to 100 (worst).

Conclusion

This study provides a common metric of the impact of spinal cord injury in terms of functioning. This study makes it possible to focus directly on functioning and disability and allows the assessment of functioning separately from the spinal cord injury.

HOW PRESSURE SORES PREVENTED FOR PERSONS WITH SPINAL CORD INJURY IN BANGLADESH

H. Shakhawath¹, M. Afroze¹
¹Bangladesh Health Professions Institute BHPI, Occupational Therapy, Dhaka, Bangladesh

Introduction/Background

Understand the role of Occupational Therapy in preventive pressure sores for persons with SCI. Learn about the different techniques to preventive pressure sores. Learn about the re positioning strategies used by people with spinal cord injury in the seated, supine and long sitting position

Material and Method

An integrative literature review was exploiting for the purposes of methodological analysis and concept review drawing on both the empirical and theoretical literature. There were some articles, all qualitative and quantitative which are included in this review. All studies were mixed methods in design. The literature search here, OT Seeker, Google search, Google Scholar, PubMed, and Hinari searched for literature related to the contribution to and involvement how can prevent pressure sores.

Results

There were some articles all are mixed methods in design. All but one study was not conducted with participants.
- Use a pressure relief cushion: A pressure relief cushion will help to reduce pressure
- Sit upright: Sitting upright helps to distribute weight evenly
- Use pressure relief techniques: Regular pressure relief can be effective in preventing pressure sores
- Eat well and drink lots of water: A well balanced diet with fresh vegetables, fruits and meat can help to prevent pressure sores.
- Avoid friction: Make sure the wheelchair fits correctly and has no rough edges.
- Avoid moisture
- Check skin every day
- While lying or sitting, change positions regularly: Changing position regularly helps to relief pressure. For example, change position from sitting to lying.

Conclusion

Occupational Therapists played a vital role in pressure care for persons with SCI. Occupational Therapist should inspect the skin and discuss the possible causes for pressure sore. Provide advice about positioning and bed mobility then Occupational Therapist should
Consider pressure relief cushion, seating, equipment, mattress, transfer and engage functional task.

EFFECTIVENESS OF RADIOTHERAPY TO PREVENT RECURRENCE OF HETEROTOPIC OSSIFICATION IN PATIENTS WITH SPINAL CORD INJURY AND HEAD INJURY.

T. Honore¹, F. Genet², P. Denormandie³
¹CHU Pontchaillou, MPR adulte, Rennes, France
²hôpital Raymond Poincaré, Mpr, Garches, France
³hôpital Raymond Poincaré, chirurgie orthopédique, Garches, France

Introduction/Background

The prophylactic effect of radiotherapy on the development of heterotopic ossification (HO) is well-described following orthopedic surgery; however there are few studies of the effect in patients with central nervous system lesions. The aim of this case-control study was to evaluate recurrence and early postoperative complications (sepsis) following surgical excision combined with radiotherapy on troublesome hip HO in patients with spinal cord injury (SCI) and traumatic brain injury (TBI).

Material and Method

Methods: Data from patients in the BANKHO database with SCI or head injury who underwent surgical excision of hip HO were included. Case patients underwent excision + radiotherapy and controls only underwent excision. Control patients were matched to case patients for gender and age (± 4 years). The primary end-point was recurrence, and secondary-end points were postoperative complications, and more specifically, sepsis that required surgical revision.

Results

Results : Data from 19 case patients and 76 controls were analysed. Odds ratios for recurrence were not significantly different between groups (OR case group=0.63, OR SCI subgroup= 0.45 and OR head injury subgroup=1.04). Rate of sepsis requiring surgical revision was significantly higher in the case group (p<0.05).

Conclusion

Based on the results of this case-control study, we suggest that radiotherapy should not combined with surgery in patients with troublesome hip HO undergoing excision. Radiotherapy does not appear to prevent recurrence and moreover is associated with an increased risk of postoperative sepsis.

FAMILY RESILIENCE AND ITS ROLE FOR THE REHABILITATION OF SCI PATIENTS: A CASE REPORT

E. Koukourava\textsuperscript{1}, O. Kalampaliki\textsuperscript{1}, M. Fragkaki\textsuperscript{1}, G. Foteinopoulos\textsuperscript{1}, K. Saramourt\textsuperscript{1}
\textsuperscript{1}Animus Rehabilitation Center, Rehabilitation, Larissa, Greece

Introduction/Background

“Resilience” is defined as the ability of a family to adapt to new circumstances resulting from a sudden change of one of its members’ health status.

**Aim:** To show that the degree of a family's resilience can increase through psychological interventions, thus enhancing the rehabilitation outcome of a SCI patient/member.

Material and Method

"Anastasia", a 21-year-old young female, was admitted to our Center on 07/06/2016, presenting with complete paraplegia T\textsubscript{8}, AIS A, due to T\textsubscript{9} fracture, after falling from great height. On admission, she had a tracheostomy and nasogastric tube, and was fully dependent for ADL, with a FIM+FAM score of 63/210. Psychological intervention was a part of her rehabilitation program from the beginning; she was compliant and consistent, in contrast with her parents who did not regard the intervention quite important.

Results

After the first 3 months, the family’s resilience was assessed using the Brief Resilience Scale (BRS), achieving “low” grade. During that period, Anastasia had many emotional explosions, which made her parents concern and seek help themselves. The program they followed included counseling, psychoeducation based on their daughter's needs and couple psychotherapy.

Six months post admission, the degree of this family's resilience increased to “medium”, according to BRS. Meanwhile, Anastasia’s functional status improved significantly, reaching a FIM+FAM score of 169/210.

Conclusion

Psychological interventions, an important part of the rehabilitation program, can improve the degree of a family's resilience, significantly enhancing the functional outcome of the SCI patient/family member.
Keywords

Resilience, family, SCI; Psychological interventions

Introduction/Background

An important attribute of patient-centered care is the active engagement of patients when critical health care decisions are affecting their quality of life. Decisions related to neurogenic bowel and bladder management (NBB) to prevent complications and accidents are key to successful living after chronic disease or disability. Very little information exists with respect to patient’s involvement in decision regarding their bowel and bladder. This study is part of a larger study designed to examine the decision making (DM) process of persons with spinal cord injury (SCI) living with NBB. The purpose is to provide an understanding of relevant literature in this topic; identify major issues; and review proposed solutions to address problems.

Material and Method

Researchers conducted a literature review of topics related to health decision making, patient-provider communication, and specific aspect of decision making related to NBB. Three major searches were conducted in PubMed to include: 1) neurogenic bladder and bowel, bladder and bowel dysfunction, and management; 2) SCI; and 3) healthcare decisions and patient centered decisions. We identified relevant Medical Subject Headings in the MeSH database. From a total of 400 abstracts and titles 63 articles were selected for review.

Results

Some of the important findings included patients being overwhelmed during their rehabilitation hospital stays and not being able to make their own decisions regarding their care due to emotional, cognitive and physical health factors. Decisions on bladder restoration function were difficult due to lack of knowledge of preferences. Decisions regarding optimal treatment for severe bowel dysfunction were particularly challenging. Other topics discussed included patient autonomy in DM, socio economic factors influencing decisions, health systems and clinical practice guideline implications.

Conclusion

In conclusion, the process of patient DM related to NBB deserves further study. Consideration should be given to DM aids that help patients and caregivers to successfully make such decisions with providers.

A CASE OF SPINAL CORD INJURY WITH SEVERE SENSORY DISORDER IN WHICH ORTHOSIS WAS EFFECTIVE

M. Katsutani¹,², S. Nakajima¹,², E. Kawai¹,², T. Masao¹
¹Nishinomiya Kyoritsu Rehabilitation Hospital, Rehabilitation, Nishinomiya-city, Japan
²Hyogo College of Medicine, Physical Medicine and Rehabilitation., Japan

Introduction/Background

The use of orthosis for paralysis is common, but there is not enough report on the effect of orthosis for severe sensory disorder. In this report, we report a case in which orthosis has been effective in treating spinal cord injured patients with severe sensory disorder.

Material and Method

We report our experience treating a case of adult spinal cord injured patient. A 41-year-old male admitted to our hospital for rehabilitation of spinal cord injury, neurological level C5.

Results

At the time of admission, ASIA impairment scale C, moderate motor paralysis in the right lower limb, and severe sensory disorder was confirmed. While standing and gait started as a training. Without the use of orthosis, he could not perform standing position and walking in the parallel bars, he did standing and gait training with KAFO. With visual feedback using a mirror, the standing and gait in the parallel bars was stable, but knee instability was noticeable without visual feedback. Knee instability was alleviated when using Sensomotoric insole to promote proprioceptor for severe sensory disorder. KAFO of plastic shell was made as personal orthosis, the knee joint was CCAD joint and the foot was double upright ankle foot orthosis. Also, since Sensomotoric insole had effect, it was somewhat tightly molded, and by strengthening the compression of the thigh as a whole, we expected a prompting effect on proprioceptor.

Conclusion

As a treatment for sensory disorder, it is known that the input signal from proprioceptors is increased due to the use of weight or compression by an elastic bandage. It is considered that improvement of walking ability with KAFO in this case is also based on a similar mechanism.

EVOLUTION OF IDIOPATIC LONGITUDINAL EXTENSIVE TRANSVERSE MYELITIS

C. Epalza¹, P. Ramiro², E. Mirley¹, R. Marta¹, G. Cristina³, G. Laura¹, C. Mariola¹
¹Gregorio Maraño University Hospital, Physical Medicine and Rehabilitation, Madrid, Spain
²Hospital Nacional de Parapléjicos de Toledo, Physical Medicine and Rehabilitation, Toledo, Spain
³Torrecardenas Hospital, Physical Medicine and Rehabilitation, Almeria, Spain

Introduction/Background

Longitudinal Extensive Transverse Myelitis (LETM) is a rare disease with an incidence of 1 to 8 new cases per million people per year that consists on an inflammation of three or more spinal cord segments. Earlier studies highlight the idiopathic cause and the one related with Neuromyelitis Optica Spectrum Disorders (NMOSD) as the more frequent causes of LETM.

Material and Method

We present the case of a 45 year old woman with no significant medical history that starts with a rapid onset of weakness, sensory alterations, and both bowel and bladder dysfunction. The complementary exams showed a spinal cord MRI scan with images of patched myelopathy from C2 to T2 levels, a normal brain MRI, a blood test with no relevant data and all the antibodies carried out negatives: ANA, ANCA, antiphospholipid and anti-aquaporin. The patient was admitted in our hospital diagnosed as spinal cord injury syndrome C5 level D grade according with ASIA Impairment Scale, and 15 points for Spinal Cord Independence Measure III (SCIM III) scale score. She underwent corticoid protocol and a comprehensive rehabilitation program with physical and occupational therapies, respiratory physiotherapy and bladder and bowel management.

Results

After 2 months of follow-up, the patient presents an improvement on the strength and sensory, presenting a regular bowel habit, a spontaneous bladder voiding and reaching a SCIM III score of 50.

Conclusion

Although LETM clinical features do not approach us to the etiology, it is important to carry out an exhaustive differential diagnosis for rapid intervention and predicting possible recurrences. Even so, idiopathic etiology remains among the most frequent causes and it is necessary to know the evolution and prognosis in order to establish a correct rehabilitation program.

Introduction/Background

Urinary tract infections (UTI) are important causes of morbidity and mortality in patients with spinal cord injury (SCI). The aim of this study is an epidemiological and urinary microbiological characterization, determining bacterial spectrum, antimicrobial susceptibility and factors influencing asymptomatic bacteriuria and UTI development during rehabilitation as inpatients in a SCI Unit.

Material and Method

Retrospective and descriptive study performed with a design using SPSS 23. Chi-Square Test and Fisher’s exact Test were used for the comparison of frequencies and the statistical significance level was set as p<0.05. Evaluation of the discharge letters and urine analysis of 91 patients hospitalized in a Physical Medicine and Rehabilitation Center from 1st January to 31st December 2017.

Results

From a total of 91 patients with SCI hospitalized in our Center, 55 were male. The average age was 50.28 (±17.32) years. In this sample 32 patients had less than 1 year of injury and 69 came from household, 14 acute care hospital, 8 from a nursing home. According to American Spinal Injury Association Impairment Scale, 24 patients had a complete lesion. Mode of bladder emptying was considered at the entrance and discharge. 52 patients had asymptomatic bacteriuria at the entrance in our Center. The most frequent isolated pathogen was E. coli (32%) followed by K. pneumoniae (25%). During hospitalization 46 patients developed ITU, 37 of these patients had bacteriuria at their entrance urine culture. The relation between bacteriuria, UTI and also mode of bladder emptying was statistically significant (p<0.001). Comparison between bacteriuria and UTI pathogens was performed.

Conclusion
This analysis allows projections of future needs in terms of patient numbers and healthcare strategies. Asymptomatic bacteriuria is common in SCI patients and should not be checked systematically or treated, with the risk of bacterial strains showing increased antimicrobial resistance.

*No conflict of interest*
Spinal cord injury (SCI) is a devastating event. It causes permanent serious dysfunction and leads to several disorders of organ systems, including the respiratory, urinary and autonomic nervous system, as well as bone and joint. SCI exerts a significant burden on patients, their families and society.

Aims: To investigate major complications of spinal cord injuries during 2 years of follow up and compare our findings with those of other studies.

Material and Method

A retrospective study was conducted in rehabilitation Department in university hospital center Sahloul, Sousse, Tunisia. We detected clinical features, main complications observed and therapeutic measures.

Results

A total of 177 patients is included in our study (114 men et 63 women) with a mean age of 39.6 +/- 15 years. , the cervical level was the most frequently affected (43.5%). Regarding AIS scales score, 42% of patients were AIS A and 1.3% were diagnosed with conus medullaris. Most patients (80.8%) had at least one complication, including urinary tract infection (38.9%), neuropathic pain (19%) and pressure ulcer (13.6%). All types of complications diagnosed were significantly more frequent among patients with Traumatic spinal cord injuries (p<0.001), those with complete lesion (AIS A) and cervical level (p : 0.02).

Conclusion

Life expectancy of patients with SCI is growing, but this predisposes to several complications. Through our study, a large variety of complications had been detected and analyzed.

SUPPORTGROOVE: AN INTERDISCIPLINARY COLLABORATION TO DEVELOP AN
ONLINE POSITIVE PSYCHOLOGY INTERVENTION FOR DYADS POST-SPINAL CORD
INJURY
A. Terrill¹, J. MacKenzie², M. Reblin³, J. Einerson¹, J. Ferraro⁴, A. Carroll⁴, B. Gudihal⁴,
D. Wignall⁴, R. Altizer⁴
¹University of Utah, Occupational & Recreational Therapies, Salt Lake City, USA
²University of Utah, Physical Medicine & Rehabilitation, Salt Lake City, USA
³Moffitt Cancer Center, Health Outcomes & Behavior, Tampa, USA
⁴University of Utah, Entertainment Arts and Engineering, Salt Lake City, USA

Introduction/Background
Navigating spinal cord injury (SCI)-related changes can impact health for both partners:
Individuals with SCI and their partners are both at higher risk for depression and lower quality of
life. Little attention has been paid to developing behavioral interventions targeted towards
supporting these dyads. Existing interventions are limited by physical, social, structural, and
economic accessibility. To respond to this need, we developed a web-based app
(SupportGroove) to deliver a positive psychology intervention (PPI) for dyads post-SCI.

Material and Method
SupportGroove is based on a previously-developed pen-and-paper PPI for couples coping with
stroke. The 8-week self-administered intervention consists of brief activities completed
individually and together as a dyad. Initial development meetings between the investigative
team and the app design and development team included a “designbox”, in which the needs
and key elements of the app were discussed. As we developed a prototype, stakeholders and
end-users, including clinicians and individuals with SCI, were involved in the iterative process to
inform the design and usability of the app. The SupportGroove prototype was then tested by 10
dyads for 2 weeks to identify technical errors and gather feedback on usability and accessibility.

Results
Feedback from stakeholders resulted in development of app features for individuals with limited
functional ability. Initial designs lacked accessibility design principles made visible by end-users.
Solutions included large text, single-click, and minimal scrolling to facilitate menu navigation for
individuals using eye-gaze technology. Prototype testing allowed further refinement and
demonstrated high usability and engagement with activities in the app. Qualitative feedback
indicated high levels of satisfaction, accessibility, and confidence in potential utility.

Conclusion
The SupportGroove app was developed with stakeholder input to offer a more accessible behavioral intervention for dyads coping with SCI. Online tools that are accessible and engaging provide better dissemination of behavioral interventions.

⁴Centro de Medicina de Reabilitação de Alcoitão, Physical and Rehabilitation Medicine, Alcabideche, Portugal

Introduction/Background

Urinary Tract Infections (UTI) are defined as the combination of bacteriuria, leukocyturia, and clinical symptoms. An analysis of the UTI treatment strategies in Spinal Cord Injury (SCI) rehabilitation centers demonstrated that even in specialized units, asymptomatic bacteriuria (ASB) was treated in plus 50% of the institutions if the amount of bacteria and leukocytes was regarded as significant. The aim of this study is to illustrate a case of a patient with SCI that allows us to perceive how only the infections should be treated.

Material and Method

Description of a clinical case of a patient with SCI with ASB and that evolved to the negative of urine culture (UC).

Results

A 46-year-old man with traumatic SCI (fracture and dislocation of C6-C7), due to an accident car. He has a consequent tetraplegia AIS A on the American Spinal Cord Injury Association Impairment Scale. After 7 months in an acute care hospital, he was admitted in rehabilitation hospital. In regards to bladder management, he was with intraurethral indwelling catheter. From the initial analyzes, he had leukocytosis, elevated C-reactive protein (CRP), but negative urinalysis and UC. Hyperthermia was started and a new analytical evaluation was performed, recording again leukocytosis and higher elevation of CPR. He initiated non-steroidal anti-inflammatory drugs and repeated analysis with normalization of blood inflammatory parameters but with leukocyturia and an isolation of Enterococcus faecalis and Pseudomonas aeruginosa. In this way, a prophylactic treatment was made with change of catheter, water reinforcement, urine acidification and probiotics. Before initiating intermittent catheterization, it performed a new UC that was negative.

Conclusion
Although the appropriate treatment of UTI in this population (whose symptomatic differentiation is difficult) is clearly important, the potential for the overdiagnosis of UTI in patients with SCI is high because many of these patients have bladders colonized with urinary pathogens.

INVESTIGATIONS OF CUTANEOUS pH ALTERATIONS IN PATIENTS WITH SPINAL CORD INJURY, AS A POTENTIAL RISK FACTOR OF POSTOPERATIVE INFECTION: A CASE-CONTROL STUDY.

V. Claire

1Hôpital Raymond Poincaré- 104- boulevard Raymond Poincaré- 92380 Garches- France, Service de médecine physique et réadaptation, Paris, France

Introduction/Background

Neurogenic heterotopic ossification (NHO) is usually treated by surgical excision. We conducted a previous case-control study to identify risk factors for post-operative infection (POI) after surgical excision of NHO, to determine the frequency of POI and identify the causative organisms. In this study, a spinal cord injury (SCI), as the cause of NHO at the hip, was one of the risk factors for POI (22% in SCI patients vs. 5% in others). In these SCI patients, POI was mainly due to Gram-positive cocci (69%), while other patients developed mainly Gram-negative bacilli infections. In order to decrease the risk of POI after NHO excision, we study the alteration of skin-pH as a potential risk factor, by comparing skin-pH in SCI patients and controls.

Material and Method

In our prospective observational study, we include traumatized SCI patients and valid volunteers as controls. The pH of the skin is measured with a MDD-4 pH-meter, in four sites corresponding to right and left C4 and S1 sensitive points from the ASIA score.

Results

A preliminary analysis is carried out on 54 SCI patients and 41 controls, included between September 2017 and January 2018. The difference in average skin-pH is 0.49 between the two groups (5.77 for patients vs. 5.28 for controls). In the SCI group, there is no difference in pH above and below the lesion level (5.74 in C4 vs. 5.79 in S1).

Conclusion

Our intermediate results tend to show a higher skin-pH in SCI patients, but need to be confirmed in a larger study to come. If the end results prove a higher skin-pH in SCI patients, this could be related to the risk of POI in this population, especially as a higher skin-pH promotes the proliferation of Gram-positive pathogens such as Staphylococcus aureus.

Keywords

skin pH; postoperative infection; neurogenic heterotopic ossification

Introduction/Background

SCI patients, in most cases, have neurogenic lower urinary tract dysfunction. This patients’ quality of life (QOL) improvement is related with preservation of renal function, treatment of urinary incontinence and prevention of associated complications. The aim of this study is to review available medical literature to understand how the genitourinary tract (GUT) follow-up should be done in SCI patients.

Material and Method

Pubmed database was used to search the term "management of neurogenic lower urinary tract dysfunction". In addition, existing guidelines of several international societies were consulted.

Results

A study developed at 12 UK Rehabilitation Centers (UKRC) was consulted, as well as 3 international reference guidelines, namely the “European Association of Urology (EAU) guidelines for management of neurogenic lower urinary tract dysfunction”, the “British guidelines for urological management of patients with SCI” and the “Consortium for spinal cord medicine in United States”.

Recommendations focused on 5 parameters: outpatient (OP) follow-up, GUT imaging, Urodynamic Studies (UDS), UTI’s therapeutic approach, and cystoscopy.

Regarding follow-up in OP, all guidelines suggest annual check, with few exceptions in sacral lesions (biennially).

For GUT imaging, 10 of 12 UKRC perform renovesical echography (RVEcho) annually, as recommended by “British guidelines” and “USA Consortium”, while “EAU guidelines” defends bi-annually frequency.

The UDS should be taken from 1 to 2 years, according to "EAU guidelines" and "USA Consortium", as “British guidelines” only recommend the exam when there’s clinical indication.

Regarding the therapeutic approach of UTIs, there’s a consensus among the guidelines, with antibiotic therapy indication for recurrent UTI, and no indication for asymptomatic bacteriuria. Guidelines don’t refer to cystoscopies with associated biopsy, however, some studies indicate
they should be performed between 1-2 years, depending on the presence/absence of symptoms and pathology.

**Conclusion**

The GUT follow-up in SCI patients is crucial for their QOL improvement. Nowadays, existing guidelines aren't consensual regarding the periodicity that parameters should be evaluated. Therefore new long-term high-evidence studies are needed to standardize guidelines, and allow an efficient clinical approach. Nevertheless, it's extremely important to regularly evaluate patients, with special attention to clinical findings that will be the determining factor for new complementary diagnostic tests.

SITTING POSITION AND WHEELCHAIR APPROPRIATENESS IN PATIENTS WITH SPINAL CORD INJURY : ASSESSMENT OF PROFESSIONAL PRACTICES IN A SPECIALIST UNIT

M. Le Fort¹, S. Ferréol², M. Sarda¹, G. Genty¹, A. Piers¹, P. Kieny¹, B. Perrouin-Verbe¹
¹CHU Nantes, Neurological PMR department, Nantes, France
²CHU Nantes, PMR Pole Quality, Nantes, France

Introduction/Background

Skill profiles of a wheelchair, notably leading to the initial choice after a spinal cord injury (SCI), include the patient’s comfort, his/her safety as well as physical and social performances. The multidisciplinary team of first rehabilitation within a spinal unit wondered about the quality of the patients' positioning. The team consequently wished to create an indoor reference document as well as a simple helping tool, so as to choose correctly the wheelchair, to settle any patient in a convenient manner and to check this settling.

Material and Method

Frontal and profile photos were taken of SCI individuals in the sitting position in a manual or a powered wheelchair. A multidisciplinary specialist team working in a spinal unit (doctors, nurses, physiotherapists, occupational therapists and caregivers) analyzed each patient positioning within his/her wheelchair, mentored by trained medical quality practitioners. A review of the literature relating any component and accessories of the wheelchairs was then carried-out and compared with data from the previous analysis.

Results

An illustrated reference notebook was created, describing the choice of the wheelchair according to the motor level of the SCI patient, then according to the characteristics of his/her positioning and the adaptation of components and accessories. A check-list form was also developed to make easier the procedure of settling and then its revision, as a potential tool for the transmissions of detected anomalies between the various professionals. Both documents will be assessed by using them for the analysis of a new series of photos.

Conclusion

The whole staff of the neurological PMR department will then be trained with these documents, that will afterwards be placed in the documentary management system of our University Hospital. They could be useful as information tools for already involved staffs either or as training tools for professionals newly dealing with SCI patients.

TRANSTIBIAL PROSTHESIS IN PARAPLEGIC

M. Ferreira Vaz, J. Caldas, V. Ermida, A. Torres, D. Coutinho, N. Albuquerque,
B.S. Lopes, P. Teixeira, M. Pais

‘Tondela-Viseu Hospital Center, Physical Medicine and Rehabilitation Department, Viseu,
Portugal

Introduction/Background

Spinal cord injury and amputees rehabilitation are fundamental study areas of Physical Medicine and Rehabilitation (PMR). These are true working groups in which the role of the physiatrist is central.

This overlapping syndrome represents a real challenge to rehabilitation and demonstrates the need for specialized multidisciplinary teams.

Material and Method

Data collection with the patient and clinical process.

Results

A 46-year-old male patient was referred to the PRM department after trans-tibial amputation of the left lower limb. The patient suffered a work accident in 1999 with L1 fracture and performed surgical fixation resulting in AIS-A paraplegia (bilateral L3 sensory level, right L3 motor level, non-testable motor level on the left). Since then he has been walking with an Ankle Foot Orthosis (AFO) on his left leg and a crutch. Due to chronic wound, transtibial amputation was performed in October 2009. As a result, endoskeletal prosthesis was used, with a distal pin and a fixed joint, with an interface dermo 343 from Ossur, and an AFO of the right tibia-tarsal pendent foot was also prescribed.

In 2016 he was diagnosed with seminoma for which is under follow-up of oncology and urology with periodic chemotherapy treatments.

The patient maintains neurogenic bladder follow-up, with intermittent algaliations. Maintains regular intestinal transit with training every second day. Presents multiple intercurrences with pressure ulcers in the zones with hypoesthesia.

He is autonomous under the use of prosthesis and one crutch and maintains some professional activity.

Conclusion
Given the conjunction of these pathologies it is necessary to adapt the intervention of the rehabilitation team to a particular case. The timely follow-up of patients with spinal cord injury prevents multiple complications. And proper prescription of technical aids is fundamental to maintaining patients' autonomy, especially in amputees.

This case demonstrates that often our greatest success may be just maintaining the patient's functional capability.

PEDIATRIC SPINAL CORD INJURIES, IN SOUSSE, TUNISIA: A SINGLE –CENTER REPORT OF 13 CHILDREN

M. Frigui1, G. Meriem2, W. Ouane2, K. Aymen1, H. Ikram1, F. Nedra1, J. Sonia1, K. Fayçal1

1university hospital center Sahloul, Physical Medicine and Rehabilitation, Sousse, Tunisia
2university hospital center Sahloul, Physical Medicine and Rehabilitation, Sousse, Tunisia

Introduction/Background

As it’s known, the pediatric spine is both more resilient to injury and more compliant to traumatic stress. Thus, detection of pediatric spinal cord injury is challenging combining mechanisms with the properties of the growing physiologic skeleton, it is clear that pediatric spinal injury has its own set of diverse and unique characteristics.

Material and Method

A retrospective descriptive study was conducted from 2010 to 2014 at rehabilitation department in university hospital center Sahloul, Sousse, Tunisia; all cases of spinal cord injuries in patients under 18 year old were included.

Results

Thirteen patients were included (9 boys and 4 girls) with an average age of 15.8 (11-18). Based on etiology, 10 children had traumatic spinal cord injury and three patients had non-traumatic spinal cord injury. At admission, 7 patients were classified ASIA A and there was only one case of conus medullaris syndrome. The most common lesion was dorsal. Nine children had urinary disorders since admission. The most frequent complications observed were urinary infections, pressure sores and neuropathic pain. After 2 years of follow up, 3 patients were classified ASIA C, 5 ASIA D and 5 ASIA A. Only four patients achieved “walker” status.

Conclusion

Spinal cord injury in pediatrics, although uncommon, can be devastating. Although there have been many evidence-based adult trials in SCI management, the data in the pediatric population are limited. Researchers continue to explore both clinical and radiographic guidelines to help better identify potential SCI.

INTEGRAL ASSESSMENT AND REHABILITATION PROGRAM TO IMPROVE UPPER EXTREMITY FUNCTION IN A PERSON WITH TETRAPLEGIA BEFORE AND AFTER NERVE TRANSFER SURGERY
A. Aguirre¹, J. Quinzaños¹, R. Pérez¹, A. Barrera¹, M. Mendoza², M. Rodríguez¹
¹Instituto Nacional de Rehabilitación, Rehabilitación Neurológica, Cd. de Mexico, Mexico
²Instituto Nacional de Rehabilitación, Cirugía de Mano, Cd. de Mexico, Mexico

Introduction/Background

A 28 years old male suffer a traumatic spinal cord injury (SCI) on January 2015, he was classified as an AIS A, NL C5. After his inpatient stay at the SCI specialized rehabilitation unit, he underwent a multidisciplinary assessment by: SCI specialists, plastic surgery, electrodiagnosis, psychology, occupational and physical therapy. It was decided he was a candidate for nerve transfer surgery to improve upper extremity function.

Material and Method

Surgery was performed bilaterally, 11 months after SCI (right extremity), 13 months after SCI (left). The surgery performed for the right side was: nerve transfer from posterior deltoid branch to triceps, long thoracic with sural nerve graft to PIN transfer and from brachioradialis to median motor branch; and for the left extremity: nerve transfer from posterior deltoid branch to triceps, brachioradialis to EDC, and from pronator teres to flexor digitorum profundus and flexor pollicis longus. The individual assisted to a pre surgery neurorehabilitation program based on the objectives, 3 months prior to the intervention.
Results

Based on the established goals, after the procedures were done, the individual underwent an intensive postquirurgic rehabilitation program. The improvements were notable for wheelchair propulsion, the ability to relieve pressure, to grasp, to pinch, and to let go and object. Improvement on independence, quality of life and strength measured with standardized measures such as SCIM-III, CUE-Q, LiSAT-9 and UEMS was also remarkable.

Conclusion

Nerve transfers in tetraplegics are an underused technic, which demonstrated substantial benefits, along with an intensive neurorehabilitation program. The improvement on independence and performance in daily living activities are life changing.

Introduction/Background

Functional independence can be reduced or lost due to spinal cord injury (MML), a pathology considered to be a serious public health problem of high socioeconomic impact. Knowing the characteristics of these patients allows the rehabilitation centers to structure themselves to meet their demands adequately. Objectives: To compare the functional independence of people with spinal cord injury before and after multiprofessional rehabilitation through the Functional Independence Measure (MIF) scale; characterize the sample and verify if there was effectiveness of the rehabilitation process. discharge from the program.

Material and Method

Methods: Pre-experimental study with a quantitative approach divided into two phases, the first comparing the initial and final MIF scores, available in medical records, of 44 patients with LM who participated in multiprofessional rehabilitation between the years 2012 and 2015, in the second phase were reassessed 19 individuals from the total group in order to analyze the current level of independence (post-discharge). The characterization of the sample was based on the medical records.

Results

Results: There was a predominance of young male individuals who suffered a traumatic spinal cord injury, with gunshot wound being the main cause, and paraplegia was the most frequent sequel. The sample remained in the degree of dependence modified, but with a functional gain of 11.90%. Functional maintenance was observed by the third application of the scale, there were no significant variations, except for the self-care activity, which presented a gain of 7.14%.

Conclusion

Conclusion: It is assumed that the sample rehabilitation process was successful, due to the immediate functional gain and the maintenance of the scores after discharge from the program.

Introduction/Background

Spinal cord injury (SCI) is known to have a risk of developing secondary health problems which can be debilitating and increases the burden of care on patient and their caregiver. Our aim is to address the prevalence of health problems experience by people with SCI that living in the community and to investigate the relationship between secondary health problems with SCI characteristics.

Material and Method

This is a database analysis of International Spinal Cord Injury (InSCI) Survey, which was carried out in Malaysia from March 2017 to February 2018. Total of eight rehabilitation centres nationwide participated in this study. However as of this point of this study analysis was conducted, only data from four centres were included for analysis. Data were extracted and analysed based on 3 items: personal background (PB), lesion characteristics (LC) and health problems (HP). We conducted analysis on 7 out of 10 sub-items from PB, all sub-items from LC and 15 out of 16 sub-items from HP.

Results

A total of 117 eligible participants were included in this study. More than half of the participants are from the age group of 25-44 years old (52%), most were single (47%). As for education, 73% of participants reported to at least completed Upper Secondary level. In relation to hierarchy of associated health problems, sexuality is the highest number of health concerns with 67% participants classified as high severity. This is followed by contractures and spasticity with percentage of 59% and 56% respectively. Except for prevalence of joint contractures, there is no difference in the prevalence of secondary health problems between participants with paraplegia and tetraplegia.

Conclusion

Sexuality, contractures and spasticity are the top three health problems reported in persons with SCI. There occurrence of health problems among persons with paraplegia and tetraplegia is similar.

Keywords
Rehabilitation; sexuality; contractures

Introduction/Background

As a devastating condition, spinal cord injury and particularly Non traumatic spinal cord injury (NT/SCI) not only causes permanent serious dysfunction but also leads to disorders of several organ systems. It is generally known that NT/SCI exerts a severe burden on patients, their families and society because of the tremendous cost of healthcare treatments, rehabilitation and lost of productivity.

Aim: To investigate the demographic characteristics and complications of nontraumatic spinal cord injury and compare our findings with those of other studies.

Material and Method

A retrospective study was conducted in Rehabilitation department, university hospital center Sahloul, Sousse, Tunisia. Sixty-nine adults referred inpatients with NT/SCI (46.4% women; median age, 49 years). Patients requiring initial rehabilitation or readmission were included. Demographic characteristics, neurologic injury, etiology, comorbidities, and complications of NT/SCI were analysed.

Results

The most common cause of NT/SCI was degenerative disorders (50.5%); CSM and hernia, but several others etiologies had been identified. Tetraplegia occurred in 44.9% of patients, and 88.5% had motor incomplete injuries. Most patients (61.2%) had at least 1 complication, including neuropathic pain (19%), pressure ulcer (13.6%) and urinary tract infection (8.7%).

Conclusion

The number of NT/SCI patients increased annually in our center. NT/SCI rehabilitation patients have a particular demographic profile. Through our study, a large variety of complications had been detected and analyzed.

³Nicolaus Copernicus University in Toruń- Collegium Medicum in Bydgoszcz- Faculty of Health Science, Phoniatry and Audiology, Bydgoszcz, Poland

Introduction/Background

Life-threatening complications occur in patients after spinal cord injuries mainly in the early period after the injury. However, also in the subacute and chronic period, complications that may hinder the rehabilitation process are observed.

Objective of the work; the aim of the study was to analyze the complications in patients after spinal cord injuries during rehabilitation.

Material and Method

The study is based on the examination of 136 patients after spinal cord injury who were rehabilitated in the Rehabilitation Clinic of the University Hospital No. 1 in Bydgoszcz, Poland. The group consisted of 28 women and 108 men of the mean age of 36.4 years. The mean time since the injury was 8.75 months. Injury of the cervical spine was observed in 65 patients, thoracic trauma in 56 patients and L-S injury in 15 patients. We analyzed complications that were observed during rehabilitation, independent of neurological deficits.

Results

Among the analyzed patients we found: urinary tract infections in 52 patients (38.2%); extrasceletal ossifications in 21 patients (15.4%), deep vein thrombosis freshly diagnosed in 14 patients (10.3%), decubitus ulcers in 14 patients (10.3%); superficial vein thrombosis in 4 patients (2.9%), intramuscular haemorrhage in the paretic limb in 3 patients, and 3 patients suffered a low-energy fracture in the lower limb during rehabilitation (2.2%).

Conclusion
The most common complications in patients after SCI during rehabilitation include urinary tract infections, decubitus ulcers, deep lower limb thrombosis, and extraskeletal ossifications. The above complications may hinder and prolong the rehabilitation process.

NEUROLOGICAL RECOVERY AND FUNCTIONAL OUTCOME OF COMPLETE TRAUMATIC SPINAL CORD INJURY: AN OBSERVATION FROM BANGLADESH

K. koly¹, S. Sayeed Uddin Helal¹, P. Palash Chandra Saha¹, F. Farzana Taoheed², A. S.M. Yasir Arafat³ , S. Md. Shahoriar Ahmed⁴  
¹Center for the Rehabilitation of the paralysed, Occupational therapy, Savar, Bangladesh  
²Center for the Rehabilitation of the paralysed, Phyotherapy, Savar, Bangladesh  
³Bangabandhu Sheikh Mujib Medical University- Bangladesh, Department of Psychiatry, Dhaka, Bangladesh  
⁴Center for the Rehabilitation of the paralysed, Physiotherapy, Savar, Bangladesh

Introduction/Background

Neurological and functional recovery is the most important issue for the spinal cord injury patients. Less severe damaged cord which is known as incomplete and classified as AIS-B, C, D has shown different extent of neurological and functional improvement. Now a days some of the studies show that remarkable sensory –motor improvement is happened even for the complete injured patients. The purpose of the study is to find out the neurological recovery and functional outcome of complete traumatic Spinal cord injury patients.

Material and Method

Design: Retrospective study design were conducted to analysis AIS grade, neurological recovery and functional outcome.

Setting: Rehabilitation hospital CRP, Bangladesh.

Main Outcome Measures: AIS grade, Neurological recovery and functional outcome of complete SCI.

An initial neurological deficit was assessed during admission according to the American Spinal Injury Association (ASIA) standards done by medical Professionals with evaluation of right and left motor and sensory levels and ASIA Impairment Scale, and after completion of three months rehabilitation program during discharge time again AIS done by well-trained medical professionals as because of compare of their Neurological extent as well as Functional outcome. Results

Majority of the participants of this study had traumatic paraplegia (63.6%) and the principle cause was fall from height (51.3%). In these study initial AIS was A and during discharge twenty six (5.9%) were shifted into B, thirty eight (8.7%) were shifted into C, twenty eight (6.4%) were
shifted into D. Patient with AIS class B significantly increase SCIM during discharge (P=0.00) and AIS class C significantly increase SCIM during discharge (P=0.00)

Conclusion

Though neurological and functional recovery is very rare for the complete SCI, but there is a possibility in practical situation. Sufficient structural integrity for proper signal conduction in the spinal cord after injury and compensatory plastic changes in the cortex, both may essential for neurological and functional improvements.

Heterotopic ossification (HO) is one of the common complications in traumatic spinal cord injury with a wide range of prevalence from 10%–53%. Additionally, it can be found in patients with TBI, post hip surgery, burns, stroke, encephalopathy, Cerebral Palsy (5) or hereditary like osteodystrophy (6). The most commonly affected joint is the hip but other locations such as knee, elbow, and shoulder can also be affected (7). Approximately 10% of those with HO develop significant restriction in ROM to interfere with mobility and ADLs.

Introduction/Background

Heterotopic ossification (HO) is one of the common complications in traumatic spinal cord injury with a wide range of prevalence from 10%–53%. Additionally, it can be found in patients with TBI, post hip surgery, burns, stroke, encephalopathy, Cerebral Palsy (5) or hereditary like osteodystrophy (6). The most commonly affected joint is the hip but other locations such as knee, elbow, and shoulder can also be affected (7). Approximately 10% of those with HO develop significant restriction in ROM to interfere with mobility and ADLs.

Material and Method

We are reporting a 33-year-old male involved in MVA in July 2016. He sustained T12 burst fracture requiring ORIF from T10-L1. As a result of SCI (T11 AIS A), he developed paraplegia, pressure injury, and incontinence. Upon admission to rehabilitation hospital, he was found to have ischial pressure ulcer (stage II). X-ray Pelvis showed bilaterally symmetrical HO in both hips and knees. Subsequently, TC-99m MDP bone scintigraphy showed findings compatible with HO, around both knees and hip joints bilaterally.

Results

He was managed conservatively and commenced on indomethacin. Surgical referral was not considered as the HO was not affecting patient’s transfers, lower body dressing, skin, and other aspects of daily living.

Bisphosphonates role in management of HO in TBI and SCI patients is evident but it is less effective at suppressing HO once it has mineralized (i.e., detected radiographically), [18–20].

Conclusion

Heterotopic ossification in the bilateral hip and knee joints associated with spinal cord injury has never been reported previously. The pathogenesis of HO is unknown and there is lack of consensus on treatment modalities. Activities of daily living in patients with HO can be affected secondary to pain, reduced ROM of involved joint, poor posture, and associated increase risk of
pressure injury. Hence, early diagnosis, prevention and consensus on treatment modalities are needed.

EVALUATION OF MEDICAL COMPLICATIONS, FUNCTIONAL STATUS AND QUALITY OF LIFE IN EARTHQUAKE SURVIVORS WITH SPINAL CORD INJURY AT THE HOSPITAL AND ONE YEAR DISCHARGE
Y. Li, X. Hu, J. Li
Jiangsu Province Hospital, Rehabilitation Department, Nanjing, China

Introduction/Background

Characterize a spinal cord injury (SCI) population from the 2008 Sichuan earthquake in China; assess medical complications and management outcomes; evaluate functional outcomes of physical rehabilitation interventions; assess quality of life in the community.

Material and Method

51 earthquake victims with SCI were underwent rehabilitation programming at the hospital. Outcomes of medical complication management were determined by comparison of the incidence of respective complications at the beginning and end of rehabilitation. Functional rehabilitation outcomes included ambulation ability, wheelchair mobility and activities of daily living (ADL). One year later, Twenty-six subjects of them completed medical questionnaires and underwent medical examination at discharge from a hospital rehabilitation department in the community. Quality of life and community integration were assessed by appropriate instruments over this period.

Results

Medical complications were managed effectively in 63% (pressure ulcers) to 85% (deep vein thrombosis) of patients during rehabilitation. Ambulation, wheelchair mobility and ADL were significantly improved with rehabilitation programming. After discharge, nearly half of patients developed a new pressure sore and most patients had urinary complications. Self-reported quality of life, overall health, and satisfaction with social relationships increased significantly (p < 0.05), while the environment domain was reduced (p < 0.05). Social participation (i.e. community integration) results showed an improvement in physical independence and mobility (p < 0.05), but a decline in cognitive independence (p < 0.05). Only 15% of the population returned to work. Both earlier rescue and earlier onset of rehabilitation were significant positive predictors of rehabilitation effectiveness.

Conclusion

Earthquake victims with SCI may achieve significantly improved functional rehabilitation functional outcomes on a formal, institutional-based physical rehabilitation programme; Special attention should be paid to cognitive and emotional function, occupational training and social integration during community rehabilitation after discharge.

SPINAL CORD INJURIES IN UAE: RETROSPECTIVE, DEMOGRAPHIC AND OVERVIEW STUDY OF PATIENTS ADMITTED AND MANAGED IN NEURO-SPINAL HOSPITAL DUBAI DURING LAST 12 YEARS.
K. Al-Chalabi
1Neuro-Spinal Hospital Dubai, Neuro Rehabilitation Department, Dubai, United Arab Emirates

Introduction/Background

Study Design: Retrospective Demographic study & Overview SCI Comprehensive Management & Rehabilitation in UAE.
Settings: Neuro -Spinal Hospital /Dubai UAE
Objectives:
1. Demographic study of 232 patients (age, gender, nationality, etiology /nationality: UAE locals, Expats: Arabs & Non Arabs, levels & types of injuries, surgical & conservative managements).
2. Overview of quality, concepts, status of comprehensive care, management & rehabilitation In UAE.

Material and Method

Patients: SCI patients admitted in Neuro-Spinal Hospital during the period December 2005 (joining date) till December 2017 were 232 patients.

Results

UAE locals were 114 (49%), expats 118 (51%). Males were 176(76%) and females 56(24%). Tetraplegia 66 (28%) and paraplegia 166 (71.5%). Age: 153 (66%) are below 40 years. Etiology: RTA 135 (58%), fall from heights 44 (19%), sport injuries 23 (10%), diseases 20 (8.5%). Surgical procedures were done on 140 patients (60%) while the rest were admitted for conservative treatment. These figures are as per total number of the group, however for demographic purposes, they were subdivided into three main subgroups: UAE Locals, Arab Expats & Non Arab Expats just to show the variations between them as far as etiology, age, gender, level & types of injuries. For example RTAs among local citizens were 71%, while Arab expats 47 % & 44% in non Arab expats, and accordingly there are differences in the other variables.

Conclusion

In spite of all modern life facilities, services & high standard health care whether governmental or private concept of SCI comprehensive care, is still lacking SCI center per se neither in the UAE

Introduction/Background

Osteoporosis, a condition characterized by low bone mineral density (BMD) and deterioration of the skeletal microarchitecture, is a well-known complication of SCI, with increased fracture risk. Complications from fractures lead to an increase not only in the associated morbidity and mortality, but also in the health care costs that they generate and implication on functional independence and quality of life.

The purpose of this review is to provide an overview of pathophysiology, risk factors, diagnosis and possible treatment approaches in this population.

Material and Method

All published literature was obtained from MEDLINE/PubMed database with the search terms “spinal cord injury”, “osteoporosis”, “bone”, “density”, “treatment”. Data was retrieved from published articles in the last 5 years and selected according to their relevance.

Results

Although unloading is an important factor in the pathogenesis of osteoporosis, neural lesion and hormonal changes also play a role in SCI as it is shown by patient with paraplegia and upper extremities bone loss. The severity and time since injury are the main determinants for fractures. BMD assessment constitutes the best and easiest method for predicting its development. Bone formation markers, although increased, provides scarce additional benefits. Preventive treatment with bisphosphonates appears to be effective and a rehabilitation approach stimulating sublesional bone segments must be encouraged. Early-phase supported standing or assisted walking is recommended such as physical activities on the upper arms, regardless of the level of injury. Other approaches such as neuromuscular stimulation and low intensity pulsed ultrasound was reported.

Conclusion

The high incidence of osteoporosis development, affecting more that 50 % of patients indicates the need to evaluate and treat these patients shortly after injury. The “gold standard” diagnostic examination for osteoporosis in SCI patients is still bone densitometry. Further studies are needed regarding evaluation and treatment approaches.

Introduction/Background

Portugal has an extensive coastline, where aquatic recreational activity is very popular, mainly in the summer. Apart from swimming, diving is a very usual activity. Injury per dive are a cause of devastating traumas, frequently affecting the cervical spine. This generally results from badly executed and careless headlong diving to unknown water depth. The more frequent injury mechanism is: after dive, the head reaches the ground or some obstacle forcing an abrupt stop and loading the body weight onto the cervical spine, leading to cervical hyperflexion or hyperextension and cervical vertebra fracture by compression.

Material and Method

A retrospective review of the patients with spinal cord injury per dive admitted at CMRRC - Rovisco Pais for the first time between 2003 and 2017 was conducted. The variables analysed were: age, gender, type of lesion, AIS classification, functional status, bladder and bowel functions, and walking. The data collection was obtained through clinical process and telephone interview, and data was analysed subsequently with Microsoft Office Excel ®.

Results

Spinal cord injury per dive was only registered in the male gender with a 25 years old age average. Portugal summer months was the season when most accidents happened, mostly on the beach/sea. The 6th cervical level was the neurological level mostly affected, predominantly with vertebral fracture-dislocation type lesion. MIF scale improved 21 points. Bladder and bowel functions, as well as walking achieved some kind of improvement.

Conclusion

Although spinal cord injury by dive prevalence is low (maybe because this study is limited to one hospital), the consequence are dramatic. Therefore it is necessary to establish some type of prevention program to avoid these catastrophic lesions.

HOT WATER IMMERSION ELEVATES INTERLEUKIN-6 IN PERSONS WITH CERVICAL SPINAL CORD INJURY

K. Kouda¹, Y.I. Kamijo¹, T. Kinoshita¹, M. Banno¹, T. Yoshikawa¹, Y. Umemoto¹, F. Tajima¹
¹Wakayama Medical University, Rehabilitation Medicine, Wakayama, Japan

Introduction/Background

Core temperature elevations can impact positively on immunity, potentially due to increases of catecholamines acting on immune cells’ adrenergic receptors. The dysfunctional sympathetic nervous system in individuals with cervical spinal cord injury (CSCI) impairs adrenergic responses and may contribute to depressed immunity and the occurrence of low grade systemic inflammation related disorders. However, some immune markers improve following exercise in CSCI, even though the positive effects are often blunted. Non-exercise induced body temperature manipulations have yet to be investigated in CSCI.

Material and Method

Seven male participants with a motor complete CSCI and 8 male able-bodied controls were immersed for 60 min in water set at a temperature 2 °C above the individuals’ resting oesophageal temperature. Blood was collected before, during, and every hour up to 4 h after immersion and analyzed for interleukin-6 (IL-6).

Results

Hot water immersion increased IL-6 in both groups (P < 0.001). IL-6 plasma concentrations were higher in CSCI, but it was not significant. Possibly, the reduced active muscle mass in CSCI does not allow for sufficient core temperature elevations during exercise to increase these cytokines. Together with the lower catecholamine levels usually found in CSCI, this may explain the blunted exercise response on some aspects of immunity. This seems especially concerning as higher average levels of IL-6 support the indication of chronic low grade systemic inflammation in CSCI.

Conclusion

This is the first study to show an acute cytokine response induced by hot water immersion in CSCI. Passive elevation of core temperature may help to improve the cytokine profile in CSCI.

THE NEED OF RECOVERY REHABILITATION FOR MILD CASE OF GUILLAIN-BARRE SYNDROME

Y. Wada¹, N. Kawate¹, S. Iijima¹, N. Morotomi¹, T. Masaoka¹, D. Ukegawa¹, S. Takeshima¹, T. Hoshi¹, M. Iida¹, E. Nojiri¹
¹Showa University, Rehabilitation Medicine, Tokyo, Japan

Introduction/Background

We often encounter Guillain-Barre syndrome (GBS) patients who are able to walk unaided and perform manual work but with perceived disturbance. But, Severity of GBS, Hughes functional grade scale (FG), is predominantly determined according to patient mobility.

Material and Method

Study design was Case series and retrospective review. Subjects were six GBS patients (FG 1) who underwent recovery rehabilitation in our hospital, 2016. Outcome Measure was Age, gender, hospitalization days (at previous hospital/at this hospital), FG (at worst period/at discharge), Functional Independence Measure (FIM) score total/each item (at admission/at discharge), Handgrip strength (at admission/at discharge).

Results

The average ages of subject was 68.0. All subjects were male. The worst FG of these patients had been grade 2 in 3 patients, grade 4 in 2, and grade 5 in 1. FG at discharge were all Grade 1. The average number of hospitalization days at acute hospital and this hospital was 30.3 and 41.7 days. The average score of FIM at admission and discharge was 115.7 and 124.4. The mean grip strength of dominant hand at admission was 14.8 and 17.5 kg at discharge.

Conclusion

In this study, We focused on FIM and grip strength to evaluate performance abilities other than mobility, but there may be other ADL-related problems that cannot be assessed on the conventional, mobility-based Hughes functional grading scale. We plan to further accumulate cases and make comprehensive assessments of ADLs, QOL and fine motor skills to consider long-term convalescence in GBS patients in terms of performance abilities other than gait ability.

STATINS MYOPATHY – A DIAGNOSIS TO BE AWARE
F. Pereira, O. Martins Cardoso, M. Saavedra, B. Moreno, M.J. Azevedo
Hospital Senhora da Oliveira - Guimarães, Medicina Física e de Reabilitação, Guimarães, Portugal

Introduction/Background

Statins are considered to be safe, well tolerated and the primary class of medication used for the treatment of hypercholesterolemia. In approximately 1 of 10,000 treated persons per year, do statins cause serious muscle damage, with weakness and elevated levels of creatine kinase. Severe myonecrosis leading to clinical rhabdomyolysis is unusual, affecting 0.1 percent of patients. Full clinical recovery not always occurs after stopping statin therapy.

Material and Method

Our aim was to describe a patient diagnosed with statins myopathy, alert to a neglected diagnosis and enhance the role of rehabilitation in these patients that maintain symptoms.

Results

A 61-year-old man with history of dyslipidaemia, treated with statins (atorvastatin). Presented with 1-year of progressive muscle weakness, asthenia and myalgia. He reported difficulty in dressing, walking, climbing stairs and lift objects. Physical examination revealed symmetric muscle weakness (with grade 4 in the upper and lower limbs) associated with quadriceps atrophy. Laboratory studies showed elevated creatine phosphokinase. Electromyography described moderate muscle changes with inflammation. A muscle biopsy was performed and after exclusion of other causes the diagnosis of statin myopathy was made. His condition didn´t improved after statin interruption and introduction of ezetimibe. With no clinical resolution he started corticotherapy, having temporarily benefits. Further after was sent to Physical and Rehabilitation Medicine to begin physical therapy in order to relieve muscle pain, recover strength and function.

Conclusion

The high volume of statin prescriptions means that these condition can be encountered in clinical practice. When a patient taking statins reports muscle pain or weakness, a detailed history and a physical examination should be taken to assess predisposition to myopathy. Therefore, this diagnosis should not be ignored. Severe myonecrosis with statin discontinuation is rare. But when it occurs, rehabilitation is essential to regain muscle strength, optimize function and improve quality of life.

MANAGING PAROXYSMAL SYMPATHETIC HYPERACTIVITY (PSH) IN A CASE WITH OVARIAN TERATOMA ASSOCIATED ANTI-NMDA RECEPTOR ENCEPHALITIS
J. Chen¹, Y. Chiong¹
¹Singapore General Hospital, Rehabilitation Medicine, Singapore, Singapore

Introduction/Background

Paroxysmal sympathetic hyperactivity (PSH) is a hyper-adrenergic clinical syndrome most frequently recognized in traumatic brain injury, but has also been seen in other acquired brain injuries such as hypoxic brain injuries, tumors, and intracranial hemorrhage. Anti-N-methyl-D-aspartate receptor (NMDAR) encephalitis is an autoimmune disorder which is associated with ovarian teratoma.

Material and Method

We report an uncommon case of Anti-NMDAR encephalitis with PSH. This case report serves to expand the list of diagnoses associated with PSH, and provide experience of PSH management.

Results

A 32-year-old Chinese female presented with one day history of episodic involuntary choreiform movements and headache. Subsequently she developed episode of stiffening and jerking movement, confusion, as well as agitation. Lumbar puncture was done and both cerebral spinal fluid (CSF) and serum anti-NMDA receptors were positive. Further CT thorax abdomen pelvis revealed right ovarian tumor. She underwent right ovarian cystectomy and histology confirmed as mature ovarian teratoma. She was diagnosed as ovarian teratoma associated anti-NMDAR encephalitis and was treated with intravenous methylprednisolone, IVIG, IV cyclophosphamide, and Rituximab. With treatment her symptoms improved significantly.

After 2 weeks of symptoms onset, she was noted to have episodic fever, tachycardia, hypertension, diaphoresis, and dystonia. Infectious cause was excluded and she was diagnosed paroxysmal sympathetic hyperactivity (PSH). She was started on oral clonazepam, propranolol and gabapentin for PSH. Her fever, diaphoresis, tachycardia, and dystonia gradually resolved.

Conclusion

Recognition of PSH in Anti-NMDA receptor encephalitis is important. Successful management requires combination of different pharmacological agents to target different symptoms resulting from PSH.

**Introduction/Background**

Spasticity is highly prevalent in people with multiple sclerosis (pwMS). Spasticity in MS can worsen quality of life and increase posture deficits and high risk of fall. Exercise interventions show promising findings in published clinical trials. The aim of this study is to conduct a meta-analysis quantifies the effectiveness of exercise on spasticity in PwMS.

**Material and Method**

Methods: A systematic search was conducted using MEDLINE, CINHAL, Cochrane library, Scopus and PEDro databases. The included studies were randomised clinical trials (RCTs) evaluate the effect of exercise on spasticity outcomes in comparison with no intervention or equivalent doses of antispastic medication or transcranial magnetic stimulation for PwMS. Meta-analyses were performed by calculating standardized mean difference (SMD) at 95% confidence interval. The significant value was set at $p \leq 0.05$. The RCTs were assessed by physiotherapy evidence database.

**Results**

The meta-analysis included a total of 5 RCTs. The exercise improved significantly muscle tone measured by modified Ashworth scale (SMD= 0.646, $p= 0.00$) but the improvement in the self-reported spasticity outcomes was not significant (SMD= 0.839, $p= 0.083$), Figure1. Three out of the 5 included articles did not fulfill powered sample size and quality criteria.

**Conclusion**

The meta-analysis results show positive effects on muscle tone and self-reported spasticity outcomes. Other aspects of spasticity as spasm and clonus were not discussed in the included RCTs. Exercise can be a possible intervention for spasticity in PwMS. However, high quality clinical RCTs study the effects on all aspects of spasticity is required.

EFFECT OF ISCHEMIC PRECONDITIONING ON EXERCISE TOLERANCE IN PEOPLE WITH MULTIPLE SCLEROSIS: A DOUBLE BLIND RANDOMISED CONTROL FEASIBILITY STUDY
K. Nair1, D. Heyes2, A. Ismail1, G. Baker3
1Royal Hallamshire Hospital, Neurology, Sheffield, United Kingdom
2University of Sheffield, Sheffield Institute of Translational neurosciences, Sheffield, United Kingdom
3University of Sheffield, Medical School, Sheffield, United Kingdom

Introduction/Background
Remote Ischemic Preconditioning; exposure of body parts to brief periods of circulatory occlusion and reperfusion has been found to increase exercise tolerance in healthy individuals. The current study aimed to look at feasibility of conducting a double blind randomised control trial of ischaemic preconditioning on exercise tolerance in patients with Multiple Sclerosis.

Material and Method
Twenty three Participants were randomly assigned to receive ischaemic preconditioning (12) or Sham intervention (11). The outcome measures were the 6-minute walking test and Borg’s rating of perceived exertion.

Results
All patients tolerated the intervention without any serious adverse events. The active group performed better on the 6 minute walk after intervention (326.36m ±149.8) compared to baseline (316.82m± 162.76) (p=0.297). The sham group did not show any improvement in the distance walked (310.45m± 163.82) compared to baseline (301.45m± 147.32) (p=1.00). The Borg’s rating of perceived exertion did not change in active group ( before 10.09±2.57; after 10.45±2.97,p=0.357)and worsened in control group ( before 10.91±3.60; ) ( after 12.36± 3.62, p=0.017).

Conclusion
It is feasible to conduct a double blind RCT using ischaemic preconditioning in patients with multiple sclerosis. The results suggested that ischaemic preconditioning may increase exercise tolerance in MS patients.

REFERENCE VALUES FOR JITTER IN STIMULATED SINGLE FIBER ELECTROMYOGRAPHY IN TIBIALIS ANTERIOR MUSCLES OF 25 NORMAL VOLUNTEER PEOPLE BY USING CONCENTRIC NEEDLE: A PROSPECTIVE STUDY

M. Hadianfard¹, A. Shirzadi²

¹Shiraz University of Medical sciences, physical Medicine & Rehabilitation, Shiraz, Iran
²Shiraz University of Medical Sciences SUMS, physical medicine and rehabilitation PM&R, Shiraz, Iran

Introduction/Background

Single fiber electromyography (SFEMG) and Stimulated SFEMG are diagnostic tests of neuromuscular junction disorders. Single-fiber needle electrodes were used originally for this examination. In recent years to avoid infection use of disposable needle electrodes was became obligatory; however, The SFEMG electrodes are too expensive for single use. A small facial concentric needle electrode (CNE) seems to be a reasonable replacement. Normal values for jitter obtained with stimulated SFEMG needle electrode have been published, but there are few publications for CNE.

Purpose:

In this study, CNE has been used to gain reference values for stimulated SFEMG of Tibialis Anterior (TA) Muscle.

Material and Method

Study was conducted in 25 (19 men and 6 women) normal person between the ages 30-40 years. Built-in jitter analysis software was used. At least 50 consecutive discharges were recorded for each potential and 20 or more different potentials were collected in principle for each examination.

Results

Cut off values for Mean Consecutive Difference (MCD) of Individual potentials and Mean of 20 different MCD (MMCD) were conducted by adding 2.5 SD to the Mean of them. The cut off values for Individual MCD was 59.32 micro second and for MMCD was 35. 49 micro second.

Conclusion

These values seems to be lower than values that has been calculated by special needle of SFEMG.

ISPR8-0225
EFFECTS OF 8-WEEK HOME-BASED YOGA AND RESISTANCE TRAINING ON MUSCLE STRENGTH, FUNCTIONAL CAPACITY AND BALANCE IN PATIENTS WITH MULTIPLE SCLEROSIS
M. Azimi1, S.S. Hosseini2, M. Abolhasani3
1Sports Medicine Research Center- Neuroscience Institute- Tehran University of Medical Sciences- Tehran- Iran, Sports and Exercise Medicine, Tehran, Iran
2Master in Exercise Physiology-Kharazmi University- Faculty of Physical Education & Sport Sciences-Karaj- Iran, Physical Education & Sport Sciences, Karaj, Iran
3Assistant professor of Sports and Exercise Medicine- MS Research Center- Neuroscience Institute- Tehran University of Medical Sciences- Tehran- Iran, Sports and Exercise Medicine, Tehran, Iran

Introduction/Background

Muscle weakness, fatigue and balance disturbances contribute to the reduction of daily activity in multiple sclerosis (MS) patients.

Therapeutic strategies to promote improvements in muscle strength, functional capacity and balance are limited in individuals with MS. Yoga training (YT) is a most popular mind-body interventions and has been known to positively affect physical, mental and other symptoms of multiple sclerosis patients with moderate disability and other cases.

Material and Method

This study was designed to determine effect of 8-week home-based yoga (YT) and resistance training (RT) on muscle strength, functional capacity and balance in 26 patients with multiple sclerosis (MS) with mild to moderate disability.

26 male and female patients (Age: 31.3±9.0749) with mild to moderate disability, were recruited and randomized into three groups randomly: Yoga training (n=9) with three-times weekly home-based Hatha Yoga training for eight weeks, Resistance training (n=9) with three-times weekly home-based resistance training program for eight weeks and control groups(n=8).

Results

The data analyzed using one way ANOVA showed; however, that Yoga Training (YT) had no significant effect on leg muscle strength, but home Resistance Training (RT) increased it. Also, functional capacity was not affected by any YT and RT, but the balance changed.

Conclusion
It seems that prescribing regular training programs with controlled intensity and time, particularly Resistance Training (RT) and Yoga Training (YT) can have a positive impact on the performance and improvement of MS patients’ quality of life.

THE BENEFITS OF RITUXIMAB FOR THE TREATMENT OF THE NEUROMYELITISOPTICA DEVIC SYNDROME

**A. Soraya**, H. Aboura, A. Sehimi, O. Bensaber

1centre hospitalo universitaire Dr HASSANI ABDELKADER SIDI BEL ABBES, service de médecine physique et de réadaptation, Commune SIDI BEL-ABBES, Algeria

**Introduction/Background**

The Devic syndrome or neuromyelitisoptica (NMO) of DEVIC is a inflammatory, demyelinating pathology affecting the spinal cord and optic nerves, purveying a major handicap.

The diagnosis is based on **Wingerchuk and al** criteria, RITUXIMAB® seems be efficient on this syndrome.

**Material and Method**

a retrospective study includes 04 female patients. It lasted from September 2015 to November 2017 with NMO, neurologic charts between paraplegia and tetraplegia. The patients have benefited from rituximab in courses spaced 6 months and have been evaluated by EXPANDED DISABILITY STATUS SCALE (EDSS), mesure de l'indépendance fonctionnelle(MIF) ,walking parameters and the occurrence of thrusts.

**Results**

our patients tolerated the treatment ,the evolution was favorable in 3 patients as shown by the average of EDSS from 07,5 to 04.

The MIF from 56 to 100, walking parameters: the test of 10 meters progressed from 00 to 20 seconds, 02 minutes walking test passed from 00 to 70 meters.

No thrusts however have been noted.

**Conclusion**

The NMO is an inflammatory disease of the central nervous system, associating recurrent episodes of myelitis and opticneuritis.

Humoral mediated immunity at the center of the physiopathology of NMO has made it possible to retain RITUXIMAB (anticorps anti CD20) as a potential treatment in the prevention of thrusts. The results are very interesting, but require larger studies.

Respiratory rehabilitation in multiple sclerosis: A narrative review of rehabilitation techniques

J. Levy**, H. Prigent****, D. Bensmail**

*Université de Versailles St-Quentin-en-Yvelines, Inserm UMR-1179 - Neuromuscular handicap, Montigny-le-Bretonneux, France
**APHP- Hopital Raymond Poincaré, Department of Physical and Rehabilitation Medicine, Garches, France
***APHP- Hopital Raymond Poincaré, Physiology and Functional Testing, Garches, France

Introduction/Background

Respiratory disorders in multiple sclerosis (MS) are an important issue. They can occur early during the course of the disease, are associated with the neurological impairment, and can lead to pneumonia and respiratory failure, which are the main causes of death in advanced MS. Prevailing impaired expiratory muscles and cough abilities has been demonstrated in this population and might constitute a specific target for rehabilitation interventions. However, international guidelines lack recommendations regarding respiratory rehabilitation in MS. We performed a systematic review of literature assessing respiratory rehabilitation in MS.

Material and Method

We searched the databases MEDLINE, PEDro and Cochrane Library for reports of clinical trials and well-designed cohorts published from inception to December 2016, by using the search terms “multiple sclerosis”, “respiratory rehabilitation”, “respiratory muscle training”, “lung volume recruitment”, “cough assistance”, and “mechanical in-exsufflation”. Literature reviews, case reports and physiological studies were excluded. The Maastricht criteria were used to assess the quality of trials. We followed the Oxford Centre for Evidence-Based Medicine guidelines to determine level of evidence and grade of recommendations.

Results

Among the 21 studies initially selected, 11 were retained for review. Seven studies were randomized controlled trials (RCTs), 2 were non-RCTs, and 2 were observational studies. Respiratory muscle training (inspiratory and/or expiratory) by use of a portable resistive mouthpiece was the most frequently evaluated technique, with 2 level-1 RCTs. Another level-1 RCT evaluated deep-breathing exercises. All reviewed studies evaluated home-based rehabilitation programs and focused on spirometric outcomes. The disparities in outcome measures among published studies did not allow for a meta-analysis. Cough assistance devices were not evaluated in this population.

Conclusion
Although respiratory muscle training can improve maximal respiratory pressure in MS and lung volume recruitment can slow the decline in vital capacity, evidence is lacking to recommend specific respiratory rehabilitation programs adapted to the level of disability induced by the disease.

AEROBIC TRAINING ENHANCES COGNITION AND FUNCTIONAL STATUS IN DEPRESSIVE MULTIPLE SCLEROSIS PATIENTS. A CASE-CONTROL STUDY.PILOT STUDY.

E. Miller¹, M. Niwald¹, J. Redlicka¹
¹Medical University of Lodz, Physical Medicine Chair of Rehabilitation, Lodz, Poland

Introduction/Background

Multiple sclerosis (MS) is a complex disease manifested by a wide range of symptoms. Depression is one of the most important problems in individuals with MS. Depressive symptoms are strictly associated with lower quality of their life. Recent studies suggest that aerobic training (AT) alleviates depressive symptoms. Therefore, the aims of this study were to study the effects of aerobic training (AT) on depression, cognition and functional status in 2 groups of multiple sclerosis (MS) patients: with depression syndrome (MS-D) and without depression (MS). Moreover, we analyzed the mean delta values with their confidence intervals and examined the changes in baseline values using covariance analysis.

Material and Method

A sample of 31 individuals with MS and 28 MS-D performed 30 minutes of AT using lower-extremity ergometer 3x10 min. per day with 60 min. break for 6 weeks. Both groups were matched for age and sex. All examined parameters were assessed before and after the series of AT using the Montreal Cognitive Assessment (MoCA), the Beck Depression Inventory (BDI), Activity Daily Living Scale (ADL) and the Expanded Disability Status Scale (EDSS). We analyzed the drop-out rate as a measure of feasibility.

Results

In both groups, the AT sessions induced a significant improvement in reducing depression (BDI) and cognition impairment (MoCA). However, the changes observed in MS-D patients were significantly greater than those observed in MS patients, especially in the BDI and MoCA. There were no statistically significant correlations of EDSS, MOCCA, BDI, ADL and age or gender.

Conclusion

AT appears to be effective easy tool in improving cognition and functional status in patients with MS. This study indicated that aerobic training is feasible and could be beneficial for patients with progressive MS.

Keywords
aerobic training; multiple sclerosis; mental status

Multiple sclerosis (MS) is a neurological demyelinating disease characterized by the existence of vesico-sphincteric disorders. These dysfunctions are still underestimated in Morocco.

The purpose of our study is to analyze vesico-sphincteric disorders among patients with MS in Morocco.

Material and Method

It’s a prospective study spread over 1 year from January 2016 to January 2017, including all patients with MS. The patients were recruited at Physical Medecine and Functional Readaptation department of CHU IBN ROCHD of Casablanca for motor rehabilitation. All patients benefited from a systematic neuro-uro consult to detect Vesico-Sphincteric dysfunctions. USP questionnaire and EDSS scale were administered.

Results

Sixty patients were recruited. Thirty five patients of them had Vesico-Sphincteric dysfunctions with an incidence of 58%. The average age was 39,7 +/- 11,6 years, with a female predominance. The average duration of evolution was 6,8 +/- 5,8 years. The relapsing remitting form of MS was found in 58,4 % of the patients. The average EDSS was 4,8 +/- 2,2. The Vesico-Sphincteric dysfunctions found were: stress vesico-sphincteric incontinence 21,4%, overactive bladder (OAB) 78,6%, and low stream 50%.

Conclusion

Vesico-Sphincteric dysfunctions in multiple sclerosis can compromise functional and vital prognosis. They can cause a severe disability and a significant impairment of quality of life.

Keywords

No conflict of interest
Fatigue is one of the most common symptoms of MS. It leads to a subjective loss of physical and/or mental energy leading to multiple consequences in the daily life of patients at the relational, social or professional levels. More than 90% of MS patients experience fatigue, and more than 75% consider it one of the three most bothersome symptoms. Definitions of fatigue are countless and refer to multifactorial concepts that increase the difficulties of the clinician confronted with this question. Their characteristics compared to normal fatigue are essentially rapid onset after minimal effort with increased recovery time. It is a chronic fatigue exacerbating the other symptoms of the disease.

Objectives: to determine clinical characteristics of fatigue during MS and its impact on physical, cognitive and social activities.

Material and Method

We conducted a descriptive analytical study in the Physical Medicine and Functional Rehabilitation Department of Ibn Rochd University Hospital in Casablanca. Patients followed for MS with a Barthel index greater than 40 were included. The socio-demographic data, the existence of fatigue as well as its characteristics, the data of the neurological examination were noted. The impact of fatigue was evaluated using the "Fatigue Impact Scale".

Results

We recruited 10 patients including 8 women. The average age was 30.56 years old. MS was remitting (7 cases), progressive remitting (2 cases) and progressive (1 case). The treatment consisted of immunosuppressants (6 cases) and interferon (1 case). Fatigue was noted in 100% of patients. The fatigue impact was greater on physical activities (8 cases), cognitive activities and the social role (10 cases). There was a repercussion on social relations only in 2 cases.

Conclusion

Fatigue is common during multiple sclerosis often aggravated by heat and physical exercises. It represents a major handicap given its physical, cognitive and social impact.

RAPIDLY PROGRESSIVE ASCENDING WEAKNESS IN A 28 YEAR OLD MALE
C. Lee¹, S. Park¹
¹State University of New York- Downstate Medical Center, Physical Medicine and Rehabilitation, Brooklyn, USA

Introduction/Background

Neuromyelitis is a rare auto-immune disorder the diagnosis of which was ameliorated by the discovery of the NMO-IgG antibody.

Material and Method

Not applicable.

Results

Case Description: A 28 y.o. male with a history of SLE diagnosed at the age of 16 presented to the ED for pressure-like back pain which progressed to urinary retention, parasthesias, areflexia, and rapidly progressive paralysis. The patient was admitted to the medical ICU for possible respiratory compromise and underwent work up for possible Guillain Barre and Bacterial Meningitis. A full workup including a lumbar puncture, plasmapheresis, a rheumatological panel, and MRI of the brain and spine were done and a diagnosis of NMO was made. The patient was then transferred to acute rehabilitation for further management of his functional deficits. On admission, the patient had intact but diminished sensation to bilateral lower extremities up the level of L1 and a modified Ashworth Scale of 1+ with marked myoclonus present distally from the hips. Upper extremity strength was only mildly diminished (4+/5) secondary to a prolonged hospital stay. With continued treatment with prednisone and cyclophosphamide, the patient was able to regain continence to bladder and bowel. Therapy focused on bed mobility and transfers and the patient progressed to moderate assistance with bed mobility but still required maximal assistance for transfers by discharge.

Conclusion

With the discovery of the NMO antibody, early diagnosis and treatment of NMO has become more commonplace and more patients with this disorder are likely to require rehabilitation therapy. As such, it is important for the field of physiatry to be aware of the presentation, possible functional deficits, and outcomes that come with this diagnosis.

MEASUREMENT OF DISABILITY BY FIM (FUNCTIONAL INDEPENDENCE MEASURE) IN A HOSPITAL POPULATION WITH MULTIPLE SCLEROSIS

*S. Dziri¹, A. Gargouri², M. Ben Djebara³, C. Dziri³, R. Gouider²*

¹Hopital R Poincaré, Ile de France, GARCHES, France
²Razi Institute, Neurology, La Manouba, Tunisia
³Mohamed Taieb Kassab Institute, Physical Réhabilitation Medicine, La Manouba, Tunisia

**Introduction/Background**

Multiple sclerosis (MS) is the leading cause of disability in young adults. In the neurological environment, specific scales are used for disability assessment, such as Expanded Disability Status Scale EDSS. The Functional Independence Measure (FIM) is used in a rehabilitation environment in multiple pathological settings in adults to specify disability situations. The aim of this work is to study the contribution of the MIF for the measurement of disability in 30 patients followed in the neurology department of Razi Hospital, taking into account the evolutionary form, seniority, and clinical pictures.

**Material and Method**

Descriptive cross-sectional study of 30 patients with MS defined by MacDonald's criteria, seen at the Razi Hospital Neurology Day Hospital over a 5-month period.

**Results**

The average age of onset was 30.3 years, with a female predominance (23 women). The duration of evolution varied from 3 months to 25 years, with a majority for more than 10 years (37%). The EDSS score ranged from 0 to 8 with an average of 3.26. Regarding the MIF, the overall average was 104/126 with a minimum of 56 and maximum of 126. Four patients had a strongly limited autonomy, 9 were moderately dependent, and 17 could be considered independent and autonomous. The MIF was lower depending on the duration of evolution and the number of relapses. The tasks for which our patients had the most difficulty are the control of the bladder then the social interactions and finally the rise of the stairs; walking and climbing stairs was a challenge for 11 patients. The higher the EDSS, the lower the MIF, and vice versa.
Conclusion

The EDSS and the MIF have equivalent estimations of functional impact according to the age of the disease and the number of relapses. MIF appreciates better vesico-sphincterian disorders and cognitive disorders.

Guillain Barré syndrome (GBS) is a demyelinating inflammatory polyneuropathy and the most common cause of neuromuscular flaccid paralysis in developed countries. Prognosis is overall favorable, although a significant amount of patients presents permanent deficits that affect life quality.

Respiratory insufficiency occurs in up to 30% of patients due to involvement of the inspiratory and expiratory muscles. Aspiration pneumonia and atelectasis may also occur, due to compromise of the bulbar musculature. Respiratory complications may persist, with incomplete respiratory recovery. The literature is still sparse in the knowledge of the evolution of the respiratory function of these patients.

The authors designed a prospective observational study that aimed evaluation of respiratory function in GBS patients, in intensive rehabilitation program.

**Material and Method**

Patients were included with GBS diagnosis with less than 3 months, admitted consecutively in intensive rehabilitation program in a specialized center.

Pulmonary function was evaluated with spirometry, manometry, sleep study or nocturnal oximetry.

**Results**

Sample of 12 patients, with same gender ratio. Mean age at diagnosis was 56.7 years old. Mean time from the beginning of the clinical symptom to the diagnosis was 13.8 days. Half of the patients had a probable predisposing factor. Half of the patients presented facio-bulbar compromise and one patient needed invasive ventilation.
Seven patients had normal spirometry results. No patient presented obstructive pattern. Three patients had a restrictive pattern, one of which had a severe pattern. The patient who needed invasive ventilation had a slight restrictive pattern.

Four patients had PIM and PEM values lower than 60% of predicted, all of which had a normal spirometry pattern.

**Conclusion**

Results from this study reveal considerable prevalence of changes in respiratory function at admission, even in patients without previous mechanical ventilation. It seems that a systematic evaluation of respiratory function is important and necessary.

THE EFFECT OF TRAINING ON RESPIRATORY COMPLICATIONS, NUTRITIONAL STATE AND THE SWALLOWING-RELATED QUALITY OF LIFE IN MULTIPLE SCLEROSIS PATIENTS WITH DYSPHAGIA

E.G. Tenekeci¹, B. Kara²
¹Turkish Armed Forces, Health Command, Ankara, Turkey
²Yuksek Ihtisas University Faculty of Health Sciences, Department of Internal Medicine Nursing, Ankara, Turkey

Introduction/Background

Dysphagia is an important health problem due to its morbidity, mortality and cost of care. The aim of this study was to determine the effect of training provided to multiple sclerosis (MS) patients with dysphagia on the respiratory complications, nutritional status and swallowing-related quality of life.

Material and Method

This randomized, controlled, semiexperimental study was performed at the neurology clinic and outpatients of a training hospital in Turkey. We included a total of 52 patients aged 18 years and older who had an MS diagnosis according to McDonald criteria, could communicate in Turkish and who volunteered to participate in the study. The patients were assigned to the intervention (n=26) and control (n=26) groups by block randomization. An information form, the Standardized Mini Mental Test, the Dysphagia in Multiple Sclerosis (DYMUS) questionnaire, the Eating Assessment Tool (EAT-10) and the Swallow Quality of Life Questionnaire (SWAL-QOL) were used to collect data. Training regarding swallowing difficulty and exercises was provided to the intervention group, and the patients were offered telephone follow-up 4 weeks later. The pre-test and post-test (at the 12th week of the study) results were evaluated. Descriptive statistics, the χ²-test, the t-test for independent and dependent groups, the Mann-Whitney U test and the Wilcoxon signed rank test were used to evaluate the results.

Results

We found that the mean DYMUS (t=5.244, p<0.001) and EAT-10 scores (t=2.254, p=0.033) decreased, while the SWAL-QOL general burden (t=-3.000, p=0.006), eating duration (t=-2.656, p=0.006), food selection (t=-2.661, p=0.013), communication (t=-2.970, p=0.006), fear of eating (p=-4.635, p<0.001), mental health (t=-2.288, p=0.031) and sleep (t=-3.453, p=0.002) subscale scores increased after the training in the intervention group.

Conclusion
We found that training provided to MS patients with dysphagia improved swallowing functions and swallowing-related quality of life. Further research on the subject with long-term follow-up is recommended to monitor the effect of training.

Micturition Disorders in Multiple Sclerosis Patients: A Tunisian Population

H. Migaou1, M. Aissi2, I. Loubiri1, S. Boudokhane1, A. Jellad1, M. Frih2, Z. Ben Salah Frih1

1University Hospital of Monastir, Physical Medicine and Rehabilitation Department, Monastir, Tunisia
2University Hospital of Monastir, Neurology Department, Monastir, Tunisia

Introduction/Background

It is well known that micturition disorders are invariably present in advanced cases of multiple sclerosis. Bladder symptoms usually arise as a result of spinal lesions. Our study reports the frequency of micturition disorders, urodynamic investigations of symptomatic patients and the correlation among urodynamic findings, disability and MRI findings in multiple sclerosis patients.

Material and Method

A prospective study was conducted. We included multiple sclerosis patients followed at the Neurology and Physical Medicine and Rehabilitation departments of the University Hospital of Monastir over six months.

Results

Forty patients with 12 men and 18 women were included. 42.5% patients reported urinary symptoms and underwent further neurourological investigation. Urgency was the most common symptom in 35%. In urodynamic investigations, 25% presented detrusor hyperreflexia. All patients underwent a neurological examination corroborated by MRI investigation. Spinal lesions at MRI were found in 42.5%. Patients who resulted positive in urodynamic evaluation were strictly correlated to EDSS, pyramidal and cerebellar functional statuses.

Conclusion

Since urinary disorders are frequently the main cause for social withdrawal of the multiple sclerosis patient, the investigation and therapy of micturition dysfunction should play a central role in the management of these patients.

FAMPRIDINE-PR (PROLONGED RELEASED 4-AMINOPYRIDINE) IMPROVES UPPER LIMB DYSFUNCTION IN MULTIPLE SCLEROSIS PATIENTS: CLINICAL AND KINEMATIC ANALYSIS

C. Cheiney-Kulak¹, P. Revol², F. Durand-Dubief³, I. Ionescu³, S. Rogerone³, A. Benoit³, L. Delporte², L. Roche³, M. Rabilloud⁴, S. Vukusic², Y. Rossetti², S. Jacquin-Courtois¹

¹Hospices Civils de Lyon, Physical Medicine and Rehabilitation, Saint Genis Laval, France
²Hospices Civils de Lyon, Mouvement et Handicap Platform, Saint Genis Laval, France
³Hospices Civils de Lyon, Neurology, Bron, France
⁴Hospices Civils de Lyon, Biostatistics, Lyon, France

Introduction/Background

Multiple Sclerosis often results in upper limb dysfunction which significantly affects patients’ quality of life. However little support is currently proposed for this deficit. Fampridine-PR is validated to improve walking speed but only few studies indicate that this drug may also be effective on upper limb function, with no detailed functional movement analysis. The aim of this study is to assess efficacy of fampridine-PR on improving grasping abilities in persons with Multiple Sclerosis (PwMS) by using a global analysis including both clinical and kinematic criteria.

Material and Method

We included 14 consecutive PwMS with EDSS>5 and we performed Jebsen Hand Function Test (JHFT) before treatment and under treatment. Patients showing a consistent improvement at D14 (n=11 patients showing at least 12 % reduction between D0 and D14) continued the treatment and the JHFT score were measured after 30 and 90 days under treatment. We also quantified upper force using dynamometers after 14, 30 and 90 days of treatment. In addition 3D kinematic analyses (grasping a glass) were realized with each arm on each assessment.

Results

JHFT score dropped from day 0 to day 14 by more than 20% and remained stable up to day 90. Individual analysis highlighted that improvement of JHFT score varied from 12.4% to 59.3% from initial score. The evolution of testing score followed the same trend. The hand dynamometer score remained heterogeneous.

The kinematic analysis showed a better opening of the grip and a smoothing of the arm movement with less velocity peaks.
Conclusion

The results suggest that Fampridine-PR can significantly improve grasping function during at least the 90 days of our follow-up.

COGNITIVE MOTOR INTERFERENCE IN PATIENTS WITH MULTIPLE SCLEROSIS

P. Decavel¹, E. Magnin², T. Moulin², Y. Sagawa¹

¹CHU Jean Minjoz, Physical Medicine and Rehabilitation, Besançon, France
²CHU Jean Minjoz, Neurology, Besançon, France

Introduction/Background

Patients with Multiple Sclerosis (PwMS) present cognitive and motor dysfunction. The Cognitive Motor Interference (CMI) could have a negative impact in PmMS’ daily-life activities especially in those situations when the concomitances of these two components are crucial (e.g., walking and talking with someone, cross a traffic light). CMI have been experimentally evaluated based on a dual task paradigm. Recent studies suggest that there is some inconsistence in the literature regarding whether dual task condition differs between PwMS and healthy peers. The objectives of this study were (i) to determine the impact of the CMI in the gait of PwMS by comparing with healthy peers and (ii) to determine which clinical, cognitive and motor, parameters were more associated with dual task gait.

Material and Method

49 PwMS and 15 healthy peers participated in this study. The evaluations were composed by a current clinical evaluation, SDMT cognitive test, visual analogue scale of fatigue and gait evaluated at self-selected and dual task (arithmetic calculations) conditions. Afterward, the dual task cost (DTC) which is the ratio between the velocities of the 2 gait conditions was calculated.

Results

Significant differences in the cognitive and motor performances were found between PwMS and healthy groups ($p=10^{-5}$). However, in terms of DTC, no significant difference was found between groups ($p=0.12$). EDSS score was the only significant parameter able to explain the DTC variance at 8%. The gait at self-selected condition could explain 92% of the variance of the gait at dual task condition.

Conclusion

The CMI occurs in the same proportion in both PwMS and healthy persons. Despite the preponderance of the motor component in the DTC and in gait dual task condition, a combined motor and cognitive rehabilitation approach may have better results than a rehabilitation programs based on separated components.

ISPR8-1511
NOT ONLY WALKING BUT ALSO ACTIVITIES OF DAILY LIVING ARE IMPROVED IN PATIENTS WITH MULTIPLE SCLEROSIS AFTER FAMPRIDINE TREATMENT.

J. Jansa¹, A. Martic¹, S. Zorana², S. Alagic¹, S. Martic¹, K. Angleitner Narobe¹, R. Koritnik¹, A. Horvat Ledinek¹, U. Rot¹, S. Sega Jazbec¹, G.J. Brecl¹

¹University medical centre Ljubljana, Neurological hospital, Ljubljana, Slovenia
²Faculty of Health Sciences, Occupational therapy, Ljubljana, Slovenia

Introduction/Background

Fampridine improves walking in patients with multiple sclerosis (PwMS). There is however little evidence suggesting it also improves the performance of activities of daily living (ADL). Therefore, we aimed to evaluate the prevalence of ADL improvement after the initial fampridine trial in relation to the improvement of walking.

Material and Method

In this prospective study we included 102 consecutive PwMS who were referred for an assessment of walking before the initial prescription of fampridine. In addition to the routine 10 meter walk test (10MWT) performed by physiotherapists, the Canadian Occupational Performance Measure (COPM) was performed by occupational therapists. The tests were performed before and immediately after the initial 14 days fampridine trial. Patients were defined as responders on 10MWT if 20% improvement in time was recorded between the two measurements. Similarly, we defined responders on COPM if the improvement in scores was 2 or more. Descriptive statistics and chi-square test to evaluate the distribution of responders and non-responders on COPM in relation to the responders on 10MWT were performed.

Results

In total, 100 PwMS (70 females, 30 males, mean age 51±11 years and EDSS 5.6±1) completed the study. The mean initial 10MWT time was 25.1±42.7, compared to 18.3±37.8 at reassessment which resulted in 78.4% response rate to fampridine. The average initial COPM performance score was 4.6 ± 1.5 while average reassessment score was 6.1± 1.8 (39.2% response rate). The average initial COPM satisfaction score was 6.1± 1.8 and the average reassessment score was 6.5±1.9 (44.1% response rate). Responders on 10MWT were very likely to improve also in COPM performance (Chi square p=0.01) and satisfaction (p=0.01).

Conclusion

Not only walking but also meaningful and self-chosen ADL improve in terms of PwMS’ perception and satisfaction (COPM) after fampridine treatment. It is very likely that patients who improve in walking will show significant improvement in ADL.

Introduction/Background

The objective is to carry out a descriptive study listing the clinical, biological, functional and electrophysiological characteristics observed in patients with post-ZIKA Guillain-Barre syndromes (SGB) during the ZIKA epidemic in Martinique, and hospitalized in a rehabilitation service.

Material and Method

A retrospective study of subjects with post-ZIKA SGB from December 2015 to September 2016 in Martinique diagnosed according to Brighton criteria associated with molecular biology techniques, serology, and electrophysiology. Collection of data at nadir and discharge from hospitalization.

Results

25 subjects were included with a sex ratio of 1.27 and a median age of 65 years. 13 patients were hospitalized in intensive care unit. At nadir, 21 patients (84%) were tetraparetic, 10 (40%) had facial diplegia, 15 (60%) had severe swallowing disorders, 12 (48%) were dysuric, 6 (24%) had acute urinary retention. 24 patients (96%) had paresthesias, 11 (44%) had severe constipation requiring repeated enemas, 8 (32%) had infectious pneumonia with 7 (28%) pneumopathies with mechanical ventilation, 2 (8%) had a cardiorespiratory arrest. The median for the duration of the extension phase was 8 days versus 4 days for the plateau phase. The median for the delay between the first signs of ZIKA infection and the first neurological signs was 2.5 days. 16 urine PCR returned positive for ZIKA and serum neutralization was required for 9 subjects. 21 acute inflammatory demyelinating polyradiculoneuritis were objectified. 13 patients (52%) required a nasogastric tube, 4 (16%) required percutaneous gastrostomy, 9 (36%) had orotracheal intubation, and 6 (24%) had tracheotomy. All the patients returned home with a quasi-complete autonomy.

Conclusion

The large number of disorders of swallowing and dysautonomia haemodynamic and vesicospincterian will be important elements to be favored in the acute management in the
event of new epidemics due to their therapeutic urgency and residual incapacities. Despite severe clinical forms, patients presented good functional recovery.

ISPR8-1781
DOES FAMPRIDINE OVERPASS GAIT CUT-OFFS BASED ON MINIMAL DETECTABLE CHANGE?

P. Decavel¹, F. Michel¹, T. Moulin², B. Parratte¹, Y. Sagawa Junior³
¹CHU Jean Minjoz, Physical medicine and rehabilitation, Besançon, France
²CHU Jean Minjoz, Neurology, Besançon, France
³CHU Jean Minjoz, Laboratory exploration of movement, Besançon, France

Introduction/Background

Gait disorder is one of the most frequent dysfunction reported by patients with multiple sclerosis (PwMS). Studies have shown that fampridine can improve gait velocity in 11.2 to 34.8% of them. The minimal important clinical difference (MICD) on a timed 25 foot test (T25FT) measured by anchor-based methods is around 20%. Considering a more conservative method based on reproducibility and minimal detectable change (MDC), the T25FT cut-off is comprised between 23% and 66%. The aim of this study was to evaluate whether fampridine can overpass PwMS’s gait velocity cutoffs determined by a reproducibility approach.

Material and Method

Sixty-eight patients were included (EDSS 4.0 to 6.5) from FAMPISEP (NCT02849782). Each patient was evaluated 3 times (Figure 1). Gait was evaluated with a GaitRite system and the variables considered were gait velocity on the T25FT under different conditions (comfortable speed, fast speed, dual task with calculation of dual task cost), the timed up and go test and the 6 minutes walk test (6MWT). The cut-offs for each variable were determined from the results of the first 2 visits and based on a reproducibility method using the MDC. The percentage of
patients under treatment overpassing those cut-offs was calculated.

Figure 1: study design

Results

Table 1 shows the cut-offs of the aforementioned tests and the percentage of patients that overpass those cut-offs. Considering a composite analysis, the percentage of patient that overpass at least one of the cut-offs was 32.4%.

Tableau 1. Percentage of patients overpassing the cut off

*MDC : minimal detectable change*

Conclusion

Regarding previous studies, the cutoffs based on MDC are higher than those found with MICD and appear difficult to achieve. This study confirms previous results showing that a small percentage of patients overpass at least 1 cutoff. A recent study have suggested to use a composite criterion (using different gait tests). In this case, the percentages of improvement based on MDC are near to those found with the MICD.

A CASE REPORT OF A 29-YEAR OLD WOMAN WITH A NECROTIZING SRP POSITIVE MYOPATHY

A. Golež

1General and Teaching Hospital Celje, Department for Physical Rehabilitation, Dramlje, Slovenia

Introduction/Background

Necrotizing myopathy (NAM) is a rare autoimmune disease, characterized by subacute proximal limb muscle weakness and a high creatinine-kinase level. It can be associated with use of statins or associated with cancer. Patients have no or minimal inflammation on muscle biopsy. The exact mechanism is not known, but many patients with NAM have autoantibodies directed against HMGCR or SRP. HMGCR is the enzyme targeted by statins, and it has been suggested that statins may trigger NAM, although many patients with NAM have never taken statin medications. The presence of the antibodies and the response to immunotherapy support the autoimmune nature of NAM. Proximal muscle weakness in the limbs, as well as weakness in other muscles, including breathing and swallowing muscles, can be present. Heart muscle involvement is rare. A case report of a 29-year old woman is reported.

Material and Method

She was diagnosed a necrotizing SRP positive myopathy after muscle biopsy. Treatment and rehabilitation were established.

Results

Aggressive early treatment with a combination of intravenous immunosuppressive therapy was indicated, including metilprednisolon, cyclosporin, methotrexat and intravenous immune globulin. Then she was included in a complex rehabilitation programme at a tertiary rehabilitation centre, and has regular controls at the rheumatologist.

Conclusion

In a patient with necrotising myopathy complex rehabilitation is very important, including physical therapy, occupational, vocational social and emotional support.

Keywords

Necrotizing myopathy; Rehabilitation
No conflict of interest
Introduction/Background

A 18 years old patient, with a history of uterine transfusion, obesity, recent right pulmonary embolism was admitted to the rehabilitation department for left hemiparesis and bilateral sensory disorders as part of acute transverse myelitis of etiology not yet determined. Patient ASIA D, level C4. A corticosteroid treatment with a degressive dose was instituted for 3 weeks followed by a transient improvement. Despite the absence of data on its efficacy in the context of myelitis, a movement-induced constraint therapy (CIMT) was introduced for this patient.

Material and Method

The CIMT lasted 5 weeks. An intensive training protocol of the paretic arm for 9 hours per day including 4 hours of rehabilitation (physio, occupational therapy), 5 days a week, was implemented. An evaluation (fugl Meyer, Box and block, Purdue pegboard, Minnesota and Baseline grip force in kg) at the initial phase (pre-test) and at the end (post-test) was carried out. Autonomy and quality of life were measured by Barthel Index and EQ-5D-5L respectively.

Results

The CIMT did not cause a drop in performance. On the contrary, we noticed an improvement in grip strength, manual dexterity, mobility of the paretic upper limb. Improvement in the ability to carry out daily activities enabled the patient to regain self-confidence and was a determining factor in the decision to return home.

Conclusion

We are not able to say that the results achieved are linked to the therapy because of the absence of imaging evidence showing a cortical reorganization induced by the motor drive of the paretic limb. However, this case suggests that the CIMT would provide good functional and motor recovery as well as improved independence and quality of life. Further studies on the
subject could enlighten us and allow us to validate a standard protocol of therapy and its evaluation.

MULTIPLE SCLEROSIS: BEATING FATIGUE WITH EXERCISE

J. Barreto, Ú. Martins, I. Táboas, B. Guimarães, J. Silva, S. Toste, C. Aguiar Branco

Centro Hospitalar de Entre o Douro e o Vouga, Physical and Rehabilitation Medicine, Santa Maria Da Feira, Portugal

Introduction/Background

Multiple sclerosis (MS) is the leading cause of non-traumatic disability among young and middle-aged people, with fatigue being reported as the most disabling symptom with a prevalence of 75-95%. The aim of this study was to review the pathophysiological mechanisms underlying MS-fatigue, emphasizing the role of exercise therapy in fatigue management, available therapeutic strategies and recent relevant experimental findings.

Material and Method

We searched Medline, via PubMED, using the following key words: multiple sclerosis; fatigue; neuroinflammation; exercise therapy; rehabilitation.

Results

MS is an immune mediated disease of the central nervous system in which chronic neuroinflammation and neurodegeneration cause demyelination, giving rise to a great variety of symptoms, with fatigue being defined as a subjective lack of physical and/or mental energy that interferes with usual activities of the patient.

The physiopathology of fatigue in MS is still poorly understood with both immune-related processes (inflammation, neurodegeneration, endocrine disfunction) and non-immune-mediated processes (sleep disturbances, depression, cognitive alterations, medication side effects) contributing. While chemical mediators of inflammation could not be unequivocally related to fatigue, modern immunotherapeutics that modulate neuroinflammation appear to minimize fatigue.

MS patients with fatigue show a significant diffusivity increase in left thalamo-frontal reconstructions. Fatigue seems to be associated with a disruption of brain networks involved in motor preparation processes, depending on several frontal-thalamic pathways.

Exercise therapy, particularly endurance training, isolated or combined with strenght training, proved to reduce fatigue. Yoga and tai-chi can be helpful as well. Exercise therapy seems to be safe in MS patients as there seems to be no association with a significant risk of disease relapse.
Conclusion

With MS being a disabling medical condition through fatigue, exercise therapy seems to be a safe and valuable option to minimize the impact of the disease in day to day life of MS patients. More studies are needed.

REHABILITATIVE APPROACH IN EARLY STAGES OF MULTIPLE SCLEROSIS.

A. Bellanti¹, C. Pucci¹, A.R. Braconi¹, M. Zampolini¹
¹Usl Umbria 2, Rehabilitation Department, Foligno, Italy

Introduction/Background

Patients with multiple sclerosis (MS) since the earliest stages experiencing motor and cognitive problems, such as lower motor fluidity, reduced attention spans, memory impairments. The progressive loss of integration ability of the central nervous system resulting in a disconnection damage. First affected are fast systems with high level of integration. 'Dual tasking' often leads to a poorer performance.

Aim of the study is to verify the value of early rehabilitation in reducing the impact of these symptoms on daily living.

Material and Method

We conducted a case-control study including 15 patients with EDSS < 3, divided into three groups: 5 underwent 10 sessions of adapted physical activity (APA); 5 had 10 cognitive-motor training sessions (individual rehabilitation project-IRP), 5 not underwent rehabilitation treatment (Control).

Patients had initial and final motor-cognitive assessments using Berg Balance Scale (BBS), Ten Meter Walking Test (TMWT) at different speeds and performing a cognitive task (Word List Generation-WLG), Brief Repeatable Battery of Neuropsychological Tests (BRB-NT), Trail Making Test (TMT) and Digit Span.

Results

TMWT final evaluation showed variations in IRP and APA. The number of words generated in usual and quick speed, not changed in Control, was reduced in APA, increased in IRP. BBS score variation was statistically significant in IRP and APA (IRP initial median score: 52, final median score: 55). At BRB-NT, after cognitive training, results a significant improvement in IRP (T-Test: p 0,005).

Conclusion

IRP and APA show a greater ability in balance control and global fluidity; IRP has better performance in 'dual tasking', probably related to an exercise focused on individual specific impairments.

These data support the value of individualized rehabilitation treatment, since the early stage of the disease, moreover APA could represent a good tool in the maintenance phase.

THE ROLE PHYSICAL AND REHABILITATION MEDICINE IN SUSAC SYNDROME: A CASE REPORT

B. Guimaraes, F. Melo, C.A. Branco

Centro Hospitalar de Entre o Douro e o Vouga,
Physical and Rehabilitation Medicine Department, Santa Maria Da Feira, Portugal

Introduction/Background

Susac’s syndrome (SS) is an autoimmun disease characterized by the clinical triad of encephalopathy, neuro-sensorial hearing loss and blockage of the branch retinal artery. Symptoms include headaches, slurred speech, and trouble focusing. This condition is characterized by classic radiological features on magnetic resonance imaging (MRI). Treatment includes drugs that suppress the immune system. The diagnosis is based on radiological features together with clinical symptoms. This study aims to reflect on the role of physical and rehabilitation medicine in the management of SS.

Material and Method

A 41-year-old man, developed headaches, behavior changes (mainly depression and isolation) and progressive hearing loss with 3 months evolution. At the physical examination the patient revealed an ataxy and postural imbalance in orthostatic position. The clinical presentation, along with an audiogram and ophthalmologic examination and cerebral MRI revealed clinical findings compatible with SS. The patient was submitted to corticotherapy, monthly intravenous immunoglobulin and immunosuppressant therapy (mycophenolate mofetil).

Despite the treatment, the patient development visual deficits and showed hearing and cognitive deterioration. Concomitantly, he developed spastic paraparesis (Modified Ashworth Scale score: 3), with spastic gait. Results

An integrative rehabilitation program was implement. In this case, the patient initiated proprioceptive training and muscle strengthening. In order to provide some independence in locomotion, an ankle-foot orthosis and an auxiliary walking device were implemented. The patient also began cognitive therapy and speech-language therapy. The initial approach to spasticity was based on a physical and occupational therapy (sustained stretching, massage, vibration, functional electrical stimulation and heat modalities) in addition with a pharmacological approach. The failure to achieve significant results led to the implementation of Botulinum Toxin. This resulted in the improvement of overall spasticity.

Conclusion
SS is a debilitating disease which conditions daily life activities. The role Physical and Rehabilitation Medicine is determinant to the improvement of the patient’s functional and psychological status.

OUTCOMES OF INPATIENT REHABILITATION IN PATIENTS WITH MULTIPLE SCLEROSIS AT A NEUROREHABILITATION UNIT, A SAUDI ARABIAN EXPERIENCE
A. almosallam¹, A. Qureshi², A. Alshehri³, F. Alshehri⁴, S. Ullah⁵
¹MAJMAH UNIVERSITY, Medicine Department, 7516, Saudi Arabia
²King Fahad Medical City, Rehabilitation Department, Arryadh, Saudi Arabia
³King Saud Medical City, Emergency Department, Arryadh, Saudi Arabia
⁴King Fahad Medical City, Department of Physical Medicine and Rehabilitation-, Arryadh, Saudi Arabia
⁵King Fahad Medical City, Physical Medicine and Rehabilitation-, Arryadh, Saudi Arabia

Introduction/Background
To assess the impact of short term inpatient multidisciplinary rehabilitation in patients with Multiple Sclerosis in Saudi population and to identify the clinical predictors of functional outcomes.

Material and Method

Retrospective study using medical charts (electronic and paper). Inclusion criteria: multiple sclerosis patients admitted for neurorehabilitation unit at king fahad medical city between 2009 to 2015.

Results

A total of 24 patients were identified with 7 males and 17 females. The average age was around 36 years. FIM score at admission and discharge showed a mean of 77.5 and 97.25, respectively. The FIM gain varied between 2 and 51 with mean of 18.58. FIM efficiency ranged from 0.09 to 0.95. There was no statistically significant difference in FIM efficiency between male and female. The ages of 9 patients were less than 30 years, while the remaining 15 patients were older than 30. There was a significant association between those two age groups with the FIM efficiency. (p-value = 0.043). Most common type of MS was relapsing remitting type (45.8%). Disease duration ranged from 1 to 20 years with mean of 7 years. The average age of disease onset was 30.75 years. Length of stay varied between 21 to 95 days with mean 37.79 days. There was no statistically significant correlation between LOS and FIM efficiency.

Conclusion
Inpatient rehabilitation is an important intervention in patients with chronic multiple sclerosis which improves functional independence. Data regarding use of FIM efficiency as an outcome measure for patients with MS is scarce. Age has an impact on the functional outcomes in patients with Multiple Sclerosis. FIM efficiency may be used to demonstrate functional gains in relation to length of stay; however, further studies on larger scale are needed to be carried out nationally and internationally.

WHAT CAN REHABILITATION DO FOR A PATIENT WITH MIASTENIA GRAVIS?

A. Zabala¹, N. Salaverria¹, I. Ruiz de Angulo¹, N. Perez¹, E.C. Martinez¹, I. Eceizabarrena¹,
X. Valencia¹, M. Zabaleta¹
¹H.U.Donostia, Rehabilitation, San Sebastian, Spain

Introduction/Background

Miastenia Gravis is a disease of the neuromuscular junction that courses with fatigue and proximal muscle weakness. In addition, it can course with restrictive respiratory insufficiency due to weakness in breathing muscles. Current evidence about the role of rehabilitation is scarce.

In this work we want to illustrate how we managed a patient with miastenia gravis considering the available evidence.

Material and Method

We have a 53 years old woman with miastenia gravis asking if we can do something for her. She has severe muscle fatigue, but what most limits her right now is dyspnea. According to her spirometry studies she has severe insufficiency with mixed pattern (obstructive due to bronchiolitis and restrictive due to miastenia itself). The state of our patient is precarious: she has muscle weakness, dyspnea with minimal efforts and needs oxygen therapy 4 hours/day.

According to the current evidence (we will disclose the available evidence on the poster), we choose a short home treatment with the goal of teaching her active breathing exercises, a simple strengthening table of exercises involving major muscles and giving her general recommendations (mostly about activity). All this with a BORG feeling of 11-13 out of 20.

Results

After only 6-8 sessions of treatment (2 per week) the patient continued doing the exercises by her own. Two month later the patient refers feeling more strong, less fatigued, with less dyspnea and coughing more effectively.

Conclusion

Some patients with miastenia present in addition functional deterioration due to disuse. A treatment based on moderate aerobic and strengthening exercises seems beneficial. Inspiratory muscles training could be helpful too. However, the current evidence is scarce and more studies are needed.

A3.04 Neurological and Mental Health Conditions - Autoimmune and Inflammatory Neurological Conditions (e.g. Multiple Sclerosis)

ISPR8-2397
A CASE REPORT OF A PATIENT WITH RECURRENT ACUTE INFLAMMATORY DEMYELINATING POLYRADICULONEUROPATHY IN THE SETTING OF HODGKIN’S DISEASE
J. Jiao¹, D. Strasser¹
¹Emory University School of Medicine, Physical Medicine and Rehabilitation, Atlanta, USA

Introduction/Background

Setting: Inpatient academic rehabilitation hospital

Patient: 28-year-old female with Hodgkin’s disease status post chemotherapy in consideration for stem cell transplant

Material and Method

Case Description: Prior to planned stem cell transplantation, the patient developed ascending weakness, which was found to be consistent with acute inflammatory demyelinating polyradiculoneuropathy (AIDP). She was treated with five cycles of plasma exchange and responded well enough to undergo stem cell transplantation. Within three weeks of plasma exchange and within two weeks of stem cell transplantation, the patient presented again with progressive weakness and was found to have albuminocytologic disassociation in the cerebrospinal fluid consistent with AIDP, and was treated with plasma exchange, intravenous immunoglobulins, and rituximab. She was found to have positive cytomegalovirus titers in the serum, and was started on valganciclovir. Afterwards, the patient underwent rehabilitation at an inpatient rehabilitation unit with positive results.

Results

Discussion: The pathogenesis of AIDP is thought to be rooted in molecular mimicry, in which antibodies made to target an infectious agent also attack the body’s own tissues due to structural similarities between the two. In AIDP, myelin sheaths and Nodes of Ranvier starting at the level of the nerve root are attacked, resulting in progressive peripheral nerve dysfunction. Infectious agents known to precipitate this immune mediated reaction include Campylobacter jejuni, and less commonly, human immunodeficiency virus, cytomegalovirus, and Epstein Barr virus. In this case, possible etiologies include not only cytomegalovirus, but also stem cell transplantation and Hodgkin’s disease itself, all of which may have contributed to the severity of the symptoms, including recurrence of disease.

Conclusion
Conclusion: AIDP is an immune mediated peripheral nerve disease often precipitated by several infectious agents via molecular mimicry and certain disease states. In this case, the patient developed AIDP both before and after stem cell transplantation and was found to have elevated cytomegalovirus titers.

THE RELATIONSHIP OF ALEXITHYMIA WITH FATIGUE IN MULTIPLE SCLEROSIS PATIENTS

D. Bakalidou¹, A. Poylios², A. Christopoulos², T. Ntoskas³
¹Athens University of Applied Sciences, Department of Physiotherapy, N. Makri, Greece
²National and Kapodistrian University of Athens, Department of Psychology, Athens, Greece
³Navy Hospital of Athens, Neurological Clinic, Athens, Greece

Introduction/Background

Alexithymia is a risk and aggravating factor for many problems both psychological and physical. Multiple sclerosis (MS) patients tend to exhibit high levels of alexithymia. Moreover, fatigue is a frequent and highly debilitating symptom of the quality of life of MS patients. There are scarce research findings concerning the correlation of alexithymia with fatigue while there hasn’t been any relevant research in Greece. Our study aims in investigating this correlation.

Material and Method

Two groups of 56 subjects each participated in the study, one of MS patients from the Neurological Clinic of the Navy Hospital of Athens and the other of healthy control group of corresponding age and gender. Alexithymia was assessed with Toronto Alexithymia Scale and Fatigue with Fatigue Severity Scale and Modified Fatigue Impact Scale. Pearson r coefficients were estimated and then hierarchical analyses of multiple regression were conducted with dependent variable the aspects of fatigue. Prediction factors were added in the analysis in three consecutive levels.

Results

The significant correlation coefficients ranged from 0.24 to 0.57. Fatigue was significantly higher in MS patients ($R^2 = 0.11$ to 0.33). Alexithymia contributed further in the prediction ($R^2 = 0.14 \leq 0.23$). All the interactions were insignificant.

Conclusion

Our results confirm the effect of alexithymia on fatigue in MS. This confirmation was the first time that has been made in a Greek sample. In conclusion, alexithymia should be taken into consideration when assessing MS patients with fatigue as its effect could be ameliorated with appropriate interventions.

ASSOCIATION WITH PHYSICAL CONDITION AND THE FALLING RISK IN THE GROUP OF EARLY COGNITIVE IMPAIRMENT

K.C. Chen¹, C.M. Chiu¹, T.C. Lin¹
¹Far Eastern Memorial Hospital, Department of Rehabilitation, New Taipei City, Taiwan R.O.C.

Introduction/Background

According to the previous studies, the falling risk was increased in dementia patients due to impaired cognition. However, even though there are studies revealed exercise can reduce the risk falling dementia group, few researches discusses the association of the falling risk and physical condition in dementia patients. The purpose of this study is to find the association of the falling risks and physical condition in the group of early cognitive impairment.

Material and Method

We conducted a screen in our hospitals for two months. FRAX, AD-8 questionnaires, and the grasp strength were checked. Then we analysis the association of FRAX, AD-8 questionnaires, and the grasp strength.

Results

In this study, 306 persons were included, with 71 men and 235 women. The average age is 67.66 ± 10.77 years old in men and 58.75 ± 10.52 years old. The result revealed significant differences between high risks of dementia group and low risks of dementia group in total fracture risk, hip fracture risk, and grasp strength. However, there is are no significant differences in BMI.

Conclusion

In our study found that increased fracture risk and decreased grasp strength in early cognitive impairment. Physical condition may play a role in falling risk in dementia patients, not only due to poor cognition. Grasp strength is an indicator of sarcopenia. In the study showed that higher prevalence of sarcopenia in suspected dementia patients. However, further studies of the association of sarcopenia and dementia are still needed. This study might be the pioneer of further study in dementia and sarcopenia.

AMYOTROPHIC LATERAL SCLEROSIS – THE REALITY OF THE NORTHEAST REGION OF PORTUGAL

F. Vilabril¹, J. Rocha Melo¹, V. Espírito Santo², C. Miranda¹, E. Pires¹, L. Dias¹
¹Centro Hospitalar de Trás-os-Montes e Alto Douro, Physical and Rehabilitation Medicine Department, Vila Real, Portugal
²Centro Hospitalar de Trás-os-Montes e Alto Douro, Neurology Department, Vila Real, Portugal

Introduction/Background

Amyotrophic Lateral Sclerosis (ALS) is characterized by progressive loss of the upper and lower motor neurons at the spinal or bulbar level. The mean age of onset varies from 50 to 65 years. There’s an increased risk in the males (M:F=1.5:1). Riluzole is currently the only pharmacological treatment (PT) that has positive impact in the survival of these patients. The aim of this study is to analyze ALS patients in Vila Real’s district (the northeast of Portugal).

Material and Method

Retrospective descriptive study using data from the medical records of the patients diagnosed with ALS from 01/01/2005 to 31/12/2016 at Centro Hospitalar de Trás-os-Montes and Alto Douro. The statistical analysis was performed using IBM SPSS Statistics 22.0 software. P values <0.05 were considered statistically significant.

Results

We identified 89 patients with ALS, 14 of whom were excluded due to insufficient data, remaining 75 patients: 31 cases of bulbar onset ALS (bALS) (13M:18F) and 44 cases of spinal onset ALS (sALS) (32M:12F). There was a significant association between gender and the form of presentation (p=0.007) - male gender associated with sALS and female with bALS. These patients had a mean age of 65 years (from 31 to 87) at symptoms onset (SO) and the M:F ratio was 45:30. The time between SO and PT was on average 526 days in bALS and 515 days in sALS, with mean survival of 941 days and 2297 days, respectively. There was a worse survival rate in female patients (p = 0.02), in bALS (p = 0.003) and in those with less than 365 days between SO and PT (p <0.001).

Conclusion

ALS is a progressive condition. More than a half of these patients don’t survive within the first 30 months after SO. Older age of SO, female gender and bALS form of the disease are related with reduced survival.

FUNCTIONAL ASSESSMENT OF THE PARKINSONIAN UPPER LIMB: VALIDITY AND INTRA- AND INTER-RELIABILITY OF THE MSPIR TEST
E. Savard¹, V. Carpentier², J.M. Gracies³, N. Bayle³
¹APHP Rothschild Hospital, Physical and Rehabilitation Medicine, Paris, France
²APHP, Physical and Rehabilitation Medicine, Paris, France
³APHP Mondor Hospital, Physical and Rehabilitation Medicine, Creteil, France

Introduction/Background

There is no valid functional scale to assess the parkinsonian upper limb. The MSPIR (Mount Sinai Parkinsonism Impairment Rating) test times 12 everyday living functional tasks (6 uni- and 6 bimanual). The aim of the study was to explore the inter- and intra-rater reliability and the correlations with clinical parameters (MDS-UPDRS-III, GMT) of the MSPIR test.

Material and Method

Twenty five subjects with parkinsonian syndromes were included (13 women); age 67.1±7.9, mean MDS-UPDRS III 24.9 ± 13.2, mean seat-to-stand 15-second frequency 0.39±0.21 Hz, mean delay since symptom onset 11.1 ± 8.3 years) based on the following inclusion criteria: parkinsonian syndrome for over a year, Hoehn & Yahr between I and III. Patients were filmed on the OFF state. Each task was timed on video-review by 9 raters, twice one week apart. Intra- and inter-rater reliability was analysed by intraclass correlation coefficients, standard deviations
and coefficients of variation.

Results

For the MSPIR total time, the mean inter- and intra-rater ICC were respectively 0.99 (0.98-1) and 1 (0.97-1) (mean, IC 95%). Standard intra-rater and inter-rater were 1.3 (0.1) and 15.7 (0.7) sec respectively. Inter-rater coefficient of variation was 6%. The time for each task was correlated with the total time. Total MSPIR time was positively correlated with UPDRS-III, the number of years since diagnosis, the levodopa daily equivalent dose, Hoehn & Yahr stage, GMT and negatively with seat-to-stand and large movement frequencies. Crohnbach's alpha coefficient was 0.99.

Conclusion

To assess rehabilitation, the MSPIR quantifies functional bradykinesia in the upper limb for mild parkinsonian patients. Its reliability and concurrent validity are excellent.

Gait is a highly complex function involving interplay of the different anatomic systems. Disturbances in gait are very common and vary considerably in the presentation and underlying pathology. This report presents a case of gait apraxia in a patient with Parkinson’s disease, frontal lobe lesions and history of stroke.

Material and Method

This is a case of 70-year old non-hypertensive female with progressive ambulation difficulty. Patient was a diagnosed case of Parkinson’s disease, which presented with rest tremors and slow, shuffling gait and depressive features. Motor symptoms were responsive to Levodopa. Six months after diagnosis of Parkinson’s disease, patient had an undocumented stroke with left sided hemiparesis and started to have frequent falls and ambulation problems. No consult done at that time due to lack of access to medical facility. Interval history revealed progression of gait dysfunction leading to patient becoming wheelchair-bound. Upon evaluation, patient was found to have good cognition, normal speech but with flat facial expression. Patient had short and shuffling steps with erect posture, retropulsion, ignition failure and freezing. Leg movements were clumsy when upright compared to when supine. Residual left sided weakness was minimal to explain the severity of the gait dysfunction. MRI of the brain showed non-specific periventricular white matter hyperintensities in both frontal lobes. Patient underwent an intensive 2-week inpatient rehabilitation program. Psychiatric intervention was done through psychotherapy and antidepressant medication.

Results

Patient was discharged ambulatory with a quad cane, with improved mood and disposition. Walking became more spontaneous with increased step length and cadence, and less freezing episodes.

Conclusion

This patient presented with a severe gait dysfunction on the background of different neurologic conditions. It is important to recognize that multiple pathologies can coexist in the same patient,
all contributing to gait problems and decrease in function. Management should be individualized and multidisciplinary to maximize patient outcome.

Keywords

gait apraxia; Parkinson's disease

Late-onset Pompe disease (LOPD) is a rare lysosomal storage disorder caused by a genetic deficiency in the enzyme acid α-glucosidase. LOPD patients usually present progressive muscle weakness leading to activities of daily living (ADLs) dependency and reduced mobility.

Material and Method

Descriptive study including all patients with LOPD treated with enzyme replacement therapy (ERT) at our department since 2011. Clinical files were analyzed and patients were assessed regarding their physical status and functional impairment through specific scales: Rotterdam 9-item Handicap Scale (R9HS), SF-36v2, MRC Scale and Walton & Gardner-Medwin Scale (WGS).

Results

4 female patients were evaluated. The age of diagnosis was 13(IS), 11(AS), 4(FR), 50(MS) years and the mean follow-up was 12.25y. AS presented a WGS 1 and R9HS 31 while FR presented a WGS 3 with a R9HS 30. All 4 patients presented decreased forced vital capacity and IS, AS and FR use non-invasive ventilation support – BiPAP and Cough Assist device. On MRC scale, all 4 patients presented with symmetrical hip muscle weakness and axial weakness and all but MS presented also symmetrical shoulder muscle weakness. IS also presented with neck, trunk and distal muscle weakness. IS and FR use an electric wheelchair and scored 8 in WGS, however on the R9HS IS scored 21, while FR scored 14. Regarding SF-36v2 survey, on vitality they scored average 13.75(std16) and on physical function they all scored 100. All patients were previously evaluated by Physical and Rehabilitation Medicine and integrated a rehabilitation program.

Conclusion

LOPD manifests as a clinical spectrum that varies regarding age at onset, disease severity and rate of disease progression. Rehabilitation management of LOPD should be comprehensive and preventive based on disease progression and on individual assessment. It should optimize
motor and physiological function, prevent or minimize secondary complications and maintain the maximum level of function, maximizing the benefits of ERT.

Late-onset Pompe Disease

*No conflict of interest*
Amyotrophic lateral sclerosis’ (ALS) survival ranges from a median of 37-49 months. There’s no cure for ALS, so the goal is to provide clinical support and rehabilitate patient’s needs to prolong survival and improve quality of life. Exercise prescription has been controversial but some authors consider it can help improve function, slow disease progression and lessen caregiver burden. This study’s aim was to identify whether integrating a rehabilitation program (RP) has an impact on the survival of ALS patients.

Material and Method

Retrospective cohort study from medical records of 75 patients diagnosed with ALS between 01/01/2005 and 31/12/2016 at Centro Hospitalar de Trás-os-Montes e Alto Douro, Portugal. The variables were analyzed with IBM SPSS Statistics 22.0 software. T-test for independent samples and Mann Whitney were used. All reported P value are two-tailed (0,05 indicating statistical significance).

Results

The median survival since ALS’ diagnosis was significantly higher for patients integrated into a RP (786 days) rather for those who didn’t undergo these treatments (450 days) (p=0.006). Patients with spinal onset ALS (sALS) took significantly longer to integrate a RP (median of 677,50 days) than patients with bulbar onset ALS (bALS) (median of 293,50 days) (p=0.009). Also, sALS patients who survived longer than 17 months started the RP later in the course of the disease (median of 858 days vs 271 days) (p=0.007). There was a moderate positive correlation (r=0.53; p<0.001) between the time to initiate the RP since the symptoms onset and the overall survival after diagnosis.

Conclusion
Integrating a RP can improve overall survival of ALS’ patients. The sALS’ patients who took longer to seek help (therefore, joined a RP later) had probably a slower progression of the disease, with longer survival. There's a lack of quality data to draw clear evidence-based conclusions about exercise's effect. Available evidence points toward mild-to-moderate exercise as beneficial.

THE IMPACT OF PERCUTANEOUS ENDOSCOPIC GASTROSTOMY ON THE SURVIVAL OF PATIENTS WITH AMYOTROPHIC LATERAL SCLEROSIS

J. Rocha Melo¹, F. Vilabril¹, D. Martinho-Dias², V. Espírito Santo³, C. Miranda¹, L. Dias¹
¹Centro Hospitalar de Trás-os-Montes e Alto Douro, Physical and Rehabilitation Medicine, Vila Real, Portugal
²CINTESIS- Centre for Health Technology and Services Research- University of Porto,
MEDCIDS - Department of Community Medicine- Information and Health Decision Sciences of Faculty of Medicine- University of Porto, Porto, Portugal
³Centro Hospitalar de Trás-os-Montes e Alto Douro, Neurology, Vila Real, Portugal

Introduction/Background

Amyotrophic lateral sclerosis (ALS) is a rapidly progressing degenerative motor neuron disease that leads to significant muscle weakness. Patients can present with severe dysphagia and require nutritional support. While percutaneous endoscopic gastrostomy (PEG) is a standard procedure for these patients, its effect on survival is not yet clear. Therefore, we aimed to evaluate the impact of PEG placement on ALS patients survival.

Material and Method

We retrospectively reviewed health records of ALS patients followed at a Neurological Department in the northeast region of Portugal for the 2005-2016 period. Potentially relevant clinical information was collected for survival analysis using Kaplan-Meier estimator and Mantel-Cox regression.

Results

In the studied period, seventy-five incident ALS cases were identified. Information regarding symptom onset was available for 62 (83%) patients, and PEG was placed after informed consent in 27 (36%) patients. The overall median survival from symptom onset was 1142 (95%CI:866-1418) days and did not differ between PEG and non-PEG groups (figure 1). In the PEG group (n=27), 19 (70%) died by the end of the follow-up period. Overall median survival post-PEG placement was 320 (95%CI:135-505) days. Bulbar ALS cases (n=18) had a median survival of 249 days while the remaining 9 Spinal cases had a median survival of 709 days (figure 2). Both LogRank test and Mantel-Cox regression using ALS subtype as covariate did not yield significant results regarding post-PEG survival (p=0.312; HR=0.566 [95%CI: 0.185-1.730], p=0.566; respectively).
Conclusion
In conclusion, PEG did not impact ALS survival in our study. Post-PEG survival was also similar in both bulbar- and spinal-onset groups. However, our analysis is limited by the small sample size. Studies with more participants are required to more effectively estimate the impact of PEG in overall and subgroups ALS survival.

"MAN IN BARREL" PHENOTYPE: DIFFERENTIAL FOR BRACHIAL AMYOTROPHIC DIPLEGIA (BAD)

E. Forrest¹, F. Chiou-Tan², A. Michael²
¹Baylor College of Medicine, Physical Medicine and Reh, Houston, USA
²Baylor College of Medicine, Physical Medicine and Rehabilitation, Houston, USA

Introduction/Background

"Man in Barrel" phenotype shows atrophic, weak arms hanging by the sides and spares lower extremities. The differential includes the very rare BAD.

Material and Method

Case #1:
61 y.o. AA male with severe weakness in his hands after experiencing shooting pain down his arms. Motor exam: 4/5 right upper arm, 0/5 distal. Left arm 4-5/5 except 0/5 wrist extension, APB and hand intrinsics. Overall strength was 5/5 for legs.

Case #2:
46 y.o. Hispanic male fell from high ladder with left arm weakness. He presented on year later with right arm weakness. He denied swallowing or speech difficulties. On PE, motor strength of the left arm was mostly 0/5. On the right, deltoid 3/5, biceps 0/5, rest 5/5. LE strength 5/5 bilaterally.

Results

Case #1:
Patient underwent electrodiagnostic testing and returned 6 years later. Results were consistent with amyotrophic lateral sclerosis (ALS) (variant BAD). Imaging revealed degenerative changes throughout the cervical spine.

Case #2:
Initial testing revealed multilevel monomelic involvement of left arm. One year later, NCV revealed normal sensory studies, decrease on right and unobtainable left arm motor responses. EMG had reduced interferential pattern, increased firing rate, large MUAPs, fibrillations and sharp waves in arms. Bulbar, thoracic, and lumbosacral regions were normal and no UMN signs.

Conclusion
BAD accounts for 2-11.4 % of patients presenting with MND. These are rare cases of an African American and Hispanic males not otherwise reported in the literature. The differential of "man in barrel" including cerebral infarctions, variant of ALS, motor myelopathies, cervical spondylosis, and post-radiation will be discussed.

RELATIONSHIP BETWEEN COGNITIVE FUNCTION AND MOTOR IMPAIRMENT SEVERITY IN PARKINSON’S DISEASE
R. Yamawaki¹, M. Nankaku¹, Y. Kusano¹, A. Tajima¹, R. Ikeuchi¹-², S. Matsuda¹-²
¹Kyoto University Hospital, Rehabilitation Unit, Kyoto, Japan
²Kyoto University Graduate School of Medicine, Department of Orthopedic Surgery, Kyoto, Japan

Introduction/Background

Cognitive impairment is among the most frequent non-motor symptoms in Parkinson’s disease (PD). To clear the characteristics of cognitive impairment in patient with PD may be critical for the planning of effective rehabilitation interventions. However, a few studies have sought to investigate relationship between cognitive impairment and motor functions. The purpose of this study was to compare cognitive impairment of PD patients in relation to the motor impairment severity according to Hoehn and Yahr (HY) stages.

Material and Method

The subjects of this study were 78 patients with PD (33 males and 45 females). The Cognitive function was assessed using the Wechsler Adult Intelligent Scale-III (WAIS-III) and Wechsler Memory Scale-Revised (WMS-R). The HY scale was used to evaluate the motor impairment severity as I (no disability, n=11), II (mild, n=34), III (moderate, n=26), or IV-V (severe, n=7). The Kruskal–Wallis test was used to compare the cognitive impairment the between HY groups.

Results

The difference in performance intelligence quotient (PIQ) of WAIS-III (I: 105.6±8.6, II: 94.9±17.7, III: 91.5±14.3, IV-V: 82.9±8.2) and general memory quotient (GMQ) of WMS-R (I: 105.5±14.4, II: 91.8±15.6, III: 90.0±18.2, IV-V: 86.1±13.0) between groups were significant, scores of IV-V stage were lowest. There were statistically significant differences in processing speed index and verbal memory quotient among the groups. The difference in other measurements was not significant the between groups.

Conclusion

Our present findings indicated that the cognitive impairment was observed in deterioration of the motor impairment in PD patients. Specifically, in the factor scale level, the low processing speed index and the low verbal memory quotient reduced each of the PIQ and GMQ in the lowest HY group patients. Therefore, we suggest that a careful assessment of cognitive impairments, especially processing speed and verbal memory, is important in identifying appropriate interventions for PD with severe stage.

CORRELATION BETWEEN SUDOMOTOR DYSFUNCTION AND FUNCTIONAL STATUS IN PATIENTS WITH AMYOTROPHIC LATERAL SCLEROSIS
S.Y. Kim¹, M.H. Moon¹, H.E. Park², S.H. Ko², H.Y. Ko¹
¹Pusan National University Yangsan Hospital, Department of Rehabilitation Medicine, Yangsan, Republic of Korea
²Pusan National University Hospital, Department of Rehabilitation Medicine, Pusan, Republic of Korea

Introduction/Background

Sudomotor dysfunction is known to be common in patients with amyotrophic lateral sclerosis (ALS). Q-Sweat (Quantitative Sweat Measurement System; WR Medical Electronics Co., Stillwater, Minnesota) is modeled on quantitative sudomotor axon reflex test which is estimated by the latency to the start of sweat secretion and the amount of sweat. The aim of this study is to find correlation between sudomotor dysfunction and functional status in patients with ALS.

Material and Method

Medical records of 17 patients with ALS were reviewed. Functional status of subjects was scored using ALS functional rating scale (ALS-FRS). Volume of sweat at 4 different points of body (i.e. both forearms and thighs) was detected at Q-Sweat. We obtained mean value of volume measured in both upper and lower limbs, respectively, and subtracted the age-adjusted normal lower limit from those values. The difference value was called ‘SCORE’ of upper limbs and lower limbs each. In case that the SCORE measured in a patient was in normal range, it
was recorded as 0 point, what means normal response of diaphoresis.

Results

Age, gender and duration from onset to the time of the test were not statistically associated with degree of sudomotor dysfunction. Negative linear correlation between ALS-FRS and SCOREs of upper ($r=-0.485$, $p=0.049$) and lower limbs ($r=-0.509$, $p=0.037$) were elicited. There was no significant difference between bulbar-dominant and limb-dominant type groups in ‘SCORE’ in both upper and lower limbs.

*p<0.05
Conclusion

The study showed that the sudomotor dysfunction represented by Q-Sweat is statistically correlated with functional status of patients with ALS. Patients have decreased function of regulating sweat responses as the disease progresses and are susceptible to skin damage or aspiration by saliva. Sudomotor dysfunction can deteriorate functional status of patients and the degree of this issue can be easily quantified by Q-Sweat.

THE EFFECT OF INTENSIVE PHYSICAL THERAPY WITH REPETITIVE TRANSCRANIAL MAGNETIC STIMULATION IN PATIENTS WITH DEGENERATIVE CEREBELLAR DISEASE

N. Wada¹, M. Tazawa¹, M. Kurosaki¹, T. Inoue¹, Y. Ibe¹

¹Gunma University Graduate School Of Medicine, Department of Rehabilitation Medicine, Gunma, Japan

Introduction/Background

The studies of repetitive transcranial magnetic stimulation (rTMS) of the brain have demonstrated the modulation of cortical excitability. Combination of rTMS with physical therapy (PT) might affect the therapeutic effects for movement disorders. The aim of this study was to investigate the effect of combination of intensive PT with rTMS in patients with degenerative cerebellar disease.

Material and Method

Twelve patients with degenerative cerebellar disease participated in the study. The rTMS and PT were carried out five days a week for three weeks. The gait parameters were determined using a three-dimensional motion analysis system, and the total length and the velocity of the center of pressure (COP) in standing position using a stabilometer and the International Cooperative Ataxia Rating Scale (ICARS) were assessed in all patients before and after the intervention.

Results

The changes in the walking speed, step width, the total length of the COP and the velocity of the COP in standing position were not significant. The amplitude of the lateral head and body sway when walking were reduced after intervention (p<0.01) and the ICARS was improved after the intervention (p<0.01). The correlations between the duration of disease and the improvement of walking speed and step width were not significant (Fig. 1). The correlations between the disease severity and the improvement of walking speed and step width were significant (Fig. 2).

Conclusion

In our study, combination of intensive PT and rTMS conferred positive effects on the dynamic balance in patients with degenerative cerebellar disease in earlier stages of the disease.

Introduction/Background

Postural and gait instability in Huntington’s disease (HD) is an essential part of the motor symptomatology causing falls contributing to morbidity and mortality. Rehabilitation (Rhb) is considered beneficial in stability treatment. However, the number of studies is still limited. This is the first multidisciplinary inpatient study using a specific program aimed at postural and gait stability in HD.

We aimed to evaluate the short- and long-term effects of an inpatient multidisciplinary rehabilitation program on postural and gait instability in HD.

Material and Method

A sample of 16 HD subjects without severe cognitive deficit or depression were included, 13 subjects completed the full course. They underwent a 3 week specific inpatient rehabilitation focused on stability. The examination was at baseline, after the completion, 1 and 3 months after the rehabilitation. The testing included: gait stability examination (Dynamic Gait Index; DGI), posturography examination of postural stability Limits of Stability on a stable (PSS) and 20%
unstable (PSU) platform and the motor function evaluation by Unified Huntington’s Disease Rating Scale (UHDRS-TMS).

Results

There was a significant improvement in DGI immediately after the Rhb and a significant 3 months lasting improvement in PSS. There was no significant improvement in PSU and UHDRS-TMS.

Conclusion

Specific Rhb methods improved postural and gait instability in early and mid-stage HD patients. The improvement in PSS persisted 3 months. We found no improvement in PSU, which is probably a too difficult test for this degree of stability impairment. The improvement in DGI does not persist after 1 month. This study offers a verified specific Rhb protocol for stability training in HD.

EFFECTS OF TRANSCRANIAL DIRECT CURRENT STIMULATION ON THE MULTIPLE TASKS CONTINUOUSLY MONITORED BY WEARABLE INERTIAL SENSORS: A PILOT STUDY
H. Ying¹, J. Zhongli²
¹North District of Suzhou Municipal Hospital, Department of Rehabilitation, Suzhou, China
²Jiangsu Province Hospital, Department of Rehabilitation Medicine, Nanjing, China

Introduction/Background

It has been known that the Parkinson’s disease impacts both non-motor and motor function. Some researchers showed the effects of the transcranial direct current stimulation(tDCS) on non-motor syptoms or motor syptoms of parkinson’s disease(PD). However, there has been little evidence to answer the question that which kind of task would be improved in the multiple task process. This study was to observe the effects of the treatment of tDCS on left primary motor cortex(L-M1) area on patients with PD.

Material and Method

Three male participants with PD, on-medication, aged 66, 70 and 72, received tDCS treatments for 20 times, 2mA for 20 minutes, anode on L-M1 area, catedode on right shoulders, 5 days of 4 weeks. Before the first, and after each daily treatment, the patients took 2-minutes walk test loaded by cognitive load of the oral calculation during the whole test, the calculation was filled with randomized addition and subtraction in which every number was less than 20. The calculation results and 50 characteristics of the patients’ gait were assessed by wearable inertial sensors in the patients’ homes.

Results

The study showed that the changes of gait speed, stride length and swing phase were statistically significant and all of these changes occured in the first week. The following picture shows two patients’ double support was increased and the other’s was decreased, and all of the three lines trend to be getting closed to the normal standard. Whereas the oral caculation, during the 2-minutes walk test, neither of the changes of the patients’s accuracies nor of the total quantities changed significantly.

Conclusion
tDCS on left M1 area may be effective for motor function, instead of the non-motor function, when the patients of PD perform multiple tasks at the same time, and all these changes could be observed from the first week.

COMPARE THE EFFECTS OF TDCS ON LEFT PRIMARY MOTOR CORTEX AND LEFT DORSOLATERAL PREFRONTAL CORTEX ON PATIENTS WITH PARKINSON’S DISEASE: A CASE REPORT
W. Yang
11st Affiliated Hospital of Soochow University, Department of Rehabilitation Medicine, Suzhou, China

Introduction/Background

Some researches showed the effects of the anodal stimulation of transcranial direct current stimulation(tDCS) on left primary motor cortex(L-M1) area or the Left Dorsolateral Prefrontal Cortex(L-DLPFC). However, the differences of effections between the two parts of stimulus on motor symptoms and non-motor symptoms of parkinson’ s disease(PD) have not been identified. The present study was to compare the effects of anodal tDCS on L-M1 area with that on L-DLPFC on Parkinson’s disease(PD)

Material and Method

One male patient with PD, aged 66, 4.5 years of course of disease. First phase, the anode stimulation was put on L-M1 area, catedode on right shoulders, for 20 times, 2mA for 20 minutes, 5 days of 4 weeks. And after 2 months’ washout period followed the phase same as the former one except for the anodal stimulation was put on L-DLPFC. Before the first and after each daily treatment, the patient took 2-minutes walk test. A total of 50 characteristics of the patient’s gait were assessed by wearable inertial sensors. Rating scales like Non-Motor Symptoms Scale for Parkinson’s disease(NMSS), Activities-specific Balance Confidence(ABC) Scale, Montreal Cognitive Assessment (MoCA), and Pittsburgh sleep quality index(PSQI) were used to assess the symptoms.

Results

In the first phase of the therapies the hand writing skill, ABC scale, 9 characteristics of gait monitored have significantly improved, whereas the non-motor symptoms, better results in NMSS, constipation, MoCA, and PSQI, could be observed. In the second phase, improvements was only showed in hot and cold feeling of sleeping and 3 characteristics of candence, toe off angle and stride length of both legs.

Conclusion

The case report showed that the location of tDCS influenced the effects on both the motor and non-motor symptoms of the same patient, and the effects of L-M1 area was better than L-DLPEC, no matter on the motor or the non-motor symptoms.

EFFECTS OF PERSONALIZED TRANSCRANIAL ALTERNATING CURRENT STIMULATION ASSOCIATED WITH PHYSICAL THERAPY ON MOTOR AND COGNITIVE FUNCTIONS IN PEOPLE WITH PARKINSON’S DISEASE
L. Castiglia1, E. Formaggio2, E. Tenconi3, L. Gallo1, M. Tonellato1, S. Masiero1, A. Del Felice1

2Foundation IRCCS San Camillo Hospital, Department of Neurophysiology, Venice, Italy
3University-Hospital of Padova, Department of Neurosciences - Section of Psychiatry, Padua, Italy

Introduction/Background

Hypersynchronization of oscillatory brain activity, prevalent in the beta band, is a neurophysiological signature of Parkinson’s disease (PD). Transcranial alternating current stimulation (tACS) can entrain cortical activity at the stimulation frequency. The aim of this study was to provide a personalized neurostimulation treatment associated with physical therapy to improve motor and cognitive functions in PD.

Material and Method

17 persons with PD were recruited. 14 concluded the protocol (2 changes of diagnosis, 1 refusal to continue). A resting state EEG was acquired and analyzed with Fast Fourier Transform to obtain power spectral density maps. Comparison of a control group versus each patient was performed using a z-test. Statistical maps provided site and frequency of stimulation (stimulation frequency was set at 30 Hz in theta prevailing group and at 4 Hz in beta prevailing group). Stimulation site was identified as the scalp area in which the prevailing band was more represented. The experiment consisted of two-weeks sessions of randomized real tACS or transcranial random noise stimulation (sham) followed by a 1-hour physiotherapy session. EEG and clinical assessments with Unified Parkinson Disease Rating Scale (UPDRS III) and a neuropsychological battery were performed before stimulation (T0), after stimulation (T1) and 4 weeks follow-up (T2).

Results

10 subjects showed a prevailing beta band and 4 a prevailing theta. A reduction of beta rhythm emerged at T1 over the bilateral sensorimotor and right frontal area and at T2 over the left frontal area in the real group. No significant modulation of EEG activity emerged in theta prevailing group. UPDRS III scores improved at T1 and T2 in the real group. A score reduction emerged at T1 in both groups for Beck Depression Inventory and at T2 in the real group for Geriatric Depression Scale.
Conclusion

Personalized tACS appears a valid add-on treatment for motor dysfunction and depressive symptoms in PD.

EFFECTS OF EIGHT WEEKS HAND ERGOMETRY TRAINING PROGRAMME ON CARDIOVASCULAR VARIABLES AND GRIP STRENGTH OF NEUROLOGICAL PATIENTS
O. Aoko\(^1\), J.A. Esan\(^1\)
\(^1\)University of Lagos, Exercise Physiology and Human Kinetics, Lagos, Nigeria

Introduction/Background

The study investigated the effects of eight weeks hand ergometry training programme on cardiovascular variables and grip strength of neurological patients in the experimental and control groups.

Material and Method

The participants were sixteen neurological patients attending physical rehabilitation in Ageless Physiotherapy Clinic, Allen Avenue, Ikeja, Lagos State, Nigeria with age range of 50-74 years. Purposive sampling technique was used in selecting the participants. Informed consent forms were given to the participants. The participants in the experimental groups were subjected to ergometry training exercises lasting twenty minutes, performed three times a week, while those in the control group did not undergo any training programme. Data were collected on the cardiovascular and hand grip tests of the experimental and control groups. The data collected were analysed with descriptive statistics of mean, standard deviation and inferential statistics of Analysis of Covariance (ANCOVA)

Results

There were significant differences in the resting heart rates (F1,13=4.296, p<0.05), cardiac output (F1,13=10.356), stroke volume (F1,13=5.410, p<0.05), right hand grip strength (F1,13=40.797, p<0.05), left hand grip strength (F1,13=86.846, p<0.05), of the experimental and control groups. To ascertain where the significant differences occur, estimated marginal mean was used. It was found that significant differences existed between experimental and control groups.

Conclusion

It is concluded that ergometry training programme have effect on the cardiovascular variables and grip strength of neurological patients. It is recommended that neurological patients should participate in hand ergometry upper limb exercises, two to three times a week.
