\textsuperscript{4}Clermont-Ferrand University Hospital, Department of Clinical Research and Innovation, Clermont-Ferrand, France

Introduction/Background

Charcot Marie Tooth’s disease (CMT) is the most common hereditary peripheral neuropathy. Type 1A (CMT1A) is the most frequent form, foot deformities are reported to 71% of CMT1A patients without consensus about foot related disability assessment. The Foot Function Index (FFI), a three subscale questionnaire (disability, activity restriction and pain) is a reference outcomes measures in foot deformities. FFI has already been validated in orthopedic and rheumatology diseases. The purpose of this study is to validate the FFI for CMT’s patient to improve assessment of foot related disability.

Material and Method

First, we performed a quantitative walk analysis combined to the deliverance of FFI and SF-36 questionnaires, and a muscular strength evaluation; retest occurred two weeks later. All evaluations were performed by the same Physical Medicine and Rehabilitation physician. The statistical analysis was conform to COSMIN guidelines for scale validation: acceptability, internal consistency (Cronbach’s alpha coefficient), reproducibility (Lin’s concordance coefficient) and external consistency (correlation coefficient).

Results

Twenty-six patients were included. The acceptability was satisfactory with less than 5% missing data. The Cosmin criteria were respected with a Cronbach alpha coefficient at 0.95 and a Lin’s concordance coefficient at 0.82. Gait parameters (r=-0.45 ; r=-0.61 respectively for speed and cadence), SF36 physical component (r=-0.58) were significantly correlated (p<0.005) to FFI disability sub-scale and not to FFI pain subscale ; muscular strength and SF-36 mental component were not correlated to FFI disability.

Conclusion
Even our sample could be considered as limited, the metrologics properties of the FFI are quite fair. By the way, in the absence of any validated scale to assess foot related disability for people with CMT, the FFI could be take in consideration as an interesting scale.

4Clermont-Ferrand University Hospital, Department of Clinical Research and Innovation, Clermont-Ferrand, France

Introduction/Background

Charcot-Marie-Tooth disease type 1A (CMT1A) is the most common hereditary neuropathy. Affected individuals have a distal motor deficit, initially affecting the lower limbs and impairing walking performance. Many studies have investigated this distal defect and the orthotic compensations that may result. The use of an isokinetic dynamometer is relevant for objectively assessing the muscle strength of patients with neuromuscular disorders. No studies evaluated the incidence of muscle strength deficits of knee extensors and flexors on walking parameters for CMT1A patients. The purpose of this study is to find correlations between the isokinetic muscular strength (IMS) of the knee flexors (KF) and extensors (KE) and CMT1A patient walk parameters.

Material and Method

IMS of the knee was evaluated at 3 angular velocities (120, 60°/s in concentric and 30°/s in eccentric) on an isokinetic dynamometer (Cybex®). The walk was evaluated by a gait analysis (GaitRite®).

Results

Thirty-three subjects were included (23 female, mean age 46.7±13.3 years, mean body mass index 25.7±4.6 kg/m²). Mean scores for physical and mental health on the Medical Outcomes Study Short Form 36 were 36.7±9.0 and 47.9±11.7. We found a correlation between the walking speed and the IMS of the KE for the entire population and between the walking speed and the IMS of the KE and KF for subjects under 50 years of age.

Conclusion

This study shows for the first time the correlation between the IMS of the knee and the walking speed. This highlights the value of the use of motion analysis devices for CMT1A patients.

FUNCTIONAL CHARACTERIZATION AND QUALITY OF LIFE IN PATIENTS WITH PARKINSON’S DISEASE AT THE CENTRAL MILITARY HOSPITAL OF COLOMBIA
S.B. Avendano Avendano¹, O. Bernal Pacheco¹, C.T. Esquivia¹
¹Hospital Militar Central, medicina física y rehabilitación, Bogotá, Colombia

Introduction/Background

The functional commitment and quality of life of patients with Parkinson’s Disease (PD) is related to motor and non-motor symptoms. **OBJECTIVE:** Characterize the functionality and quality of life of patients with PD Central Military Hospital – Bogotá, Colombia November 2015 - 30 June 2016.

Material and Method

Cross-sectional study with analytical component, the population were all patients who met inclusion criteria and no exclusion criteria who attended Movement Disorders Neurology consultation.

Informed consent was completed. The instruments for the collection of information used were a format of sociodemographic variables, the quality of life questionnaire PDQ-39 (Parkinson's Disease Quality of Life Questionnaire) and MDS-UPDRS (Unified Parkinson's Disease Rating Scale).

Results

55% were men and 45% women, with an average of 67 years, the majority of patients were socioeconomic status 3 (51%). The level of technical education 33% and professional 26% predominates. 76% were in the first decade of the disease
The general mean for the quality of life scale reported a mild to moderate commitment; greater affection in the domains of mobility (48.6%), activities of daily living (37%), cognition (38.8%) and bodily discomfort (43%).

![Figure 1: Mean dimensions of quality of life scale PDQ-39](image)

The general mean in the MDS-UPDRS scale reported a mild compromise in the motor and non-
motor experiences and a moderate commitment in the motor examination.

Figure 2: Mean dimensions of the MDS-UPDRS scale

Conclusion

In the PDQ-39 quality of life scale, there was evidence of a mild to moderate compromise, with predominance of motor symptoms mainly in mobility, similar to that found in Mexico (1) and contrary to other studies that showed greater deterioration due to symptoms. no engines (2). In addition, the MDS-UPDRS scale shows moderate compromise in the motor objective examination, may be related with the results in the quality of life scale.

Measuring sit-to-stand (STS) in Parkinson’s disease is an important part of the clinical exam, that both reflects parkinsonian symptom severity and everyday life abilities. However, there is no quantified, specific, reliable measure that can be applied to all patients and tests their maximal performance. The present study aims to evaluate the intra- and inter-rater reliability and validity of Sit-To-Stand-15 (STS15), that measures the maximal number of sit-to-stand movements performed in 15 seconds.

Material and Method

30 participants with moderate Parkinson’s disease (Hoehn and Yahr 2-3) performed, in the levodopa OFF-state, STS15 with 3 independent raters, on 2 occasions, 1 week apart; raters had to count the number of full sit-to-stand movements completed in 15 seconds. STS15 tests were separated by periods of 15 minutes of rest; the rotation order of the raters was randomized for each patient. Participants were also assessed by MDS-UPDRS part II and III, the 20-meter ambulation test (AT20), the Five Time Sit-To-Stand (FTSTS), the MoCA and the PDQ-8. Intra- and inter-rater reliability were assessed using intraclass correlation coefficients (ICC) and concurrent validity was assessed by Spearman’s and Pearson’s correlations.

Results

Preliminary findings show excellent intra- and inter-rater reliability of STS15, with mean ICC > 0.95. Correlations with FTSTS and AT20, were highly significant and present to a lesser degree with the MDS-UPDRS III score. The other correlations were not significant. The mean duration of the sit-to-stand movement with STS15 was lower than with FTSTS (p<0.01).

Conclusion

STS15 is a reliable and valid test to assess sit-to-stand in moderate Parkinson’s disease.

COGNITIVE AND BEHAVIORAL DISORDERS IN AMYOTROPHIC LATERAL SCLEROSIS: AN OVERVIEW.
A. Ben Salah1, P.F. Pradat2, P. Pradat-Diehl3, L. Lacomblez2, E. Bayen3
1Pitié-Salpêtrière Hospital, Neuro-rehabilitation Department, Paris, France
2Pitié-Salpêtrière Hospital, Department of Neurology, Paris, France
3Pitié-Salpêtrière Hospital, Neuro-rehabilitation Department & GRC, Paris, France

Introduction/Background

Amyotrophic lateral sclerosis (ALS) is a progressive neurodegenerative disease in which motor impairment has long been a prominent concern for therapeutic target and research. However, life expectancy has expanded in ALS and today’s conceptualization is that ALS is a multisystem disorder in which non-motor manifestations including cognitive-behavioral disorders can also be observed.

Material and Method

The objective is to give an overview of what is currently known about cognitive-behavioral disorders in ALS in order to construct an observational study of apathy and executive dysfunction in a cohort of ALS patients.

Results

Cognitive disorders are found in 30-50% of the ALS patients in general, and are associated with Fronto-Temporal Dementia (FTD) in particular in 10-15% of ALS patients (ALS-DFT, or DFT-ALS including various behavioral and language FTD variants).

Cognitive changes in non-FTD patients with ALS include disorders of attention, working memory, language, social cognition and other frontal executive functions. Behavioral changes include essentially frontal impairment such as apathy, lack of empathy, disinhibition and impulsivity. Depression and anxiety are also reported. Previous report shows that cognitive-behavioral changes may interfere with decision making (particularly end-of-life decisions) and increase caregivers’ burden.

Cognitive-behavioral deficiencies in the course of ALS are related to greater overall severity of disease and shorter survival after controlling for the motor severity.

These deficiencies are not well known and time-consuming. They might be underestimated and require greater investigation in clinical routine. An ALS-specific neuropsychological battery has been recently developed and validated in French, the ECAS (Edinburgh Cognitive and Behavioural ALS Screen) to screen patients more systematically.
Conclusion

The typology and temporality of cognitive-behavioral disorders in ALS are insufficiently well known. Cognitive and behavioral changes should be identified through specific screening tools and taken into account in the management of ALS patients and in the design of pharmacological trials.

RELAPSING FEVER IN A PATIENT WITH DYSPHAGIA SECONDARY TO HUNTINGTON'S DISEASE

R. Mora Boga¹, E. Canosa Hermida¹, I. Toral Guisasola¹, S. Otero Villaverde¹, M. Astray Lopaz¹, M.C. Lata Caneda¹
¹SERGAS, Physical Medicine & Rehabilitation, A Coruña, Spain

Introduction/Background

Huntington's disease (HD) is a genetic neurodegenerative disorder. Jerky movements (chorea), psychiatric disorders and cognitive impairments are observed in a wide spectrum of signs and symptoms. Dysphagia and dysarthria are common, and these signs are a frequent cause of morbidity and mortality due to bronchoaspiration. Our objective is to remark the importance of prevention and treatment of dysphagia in HD.

Material and Method

Case report.

Results

58 years-old man with diagnosis of HD. The patient was referred to the Speech and Language Unit in order to improve dysphagia and dysarthria, symptoms of recent onset. The physical examination showed intelligible dysarthria, shortness of breath with speech and occasional choking with liquids. The patient also informs about relapsing episodes of fever studied by the Infectious Disease Department without conclusive explanation.

Following the possibility of microaspiration, fiberscope study was fullfill, showing correct vocal chords closing, hypotonia at the base of tongue and bolus residues in valleculae. Videofluoroscopy study was also made, showing slowness in pharyngeal reflex with contrast media retention in pyriform sinus, which forced the patient to repeat swallowing, with penetration without aspiration. As a result of findings, speech and language therapy was started, emphasizing postural instructions and swallowing exercises, after that no fever episode appeared.

Conclusion

Swallowing disorders are prevalent symptoms of HD. It is due to choreiform and hypokinetic disturbances affecting swallowing muscles. As a result, choking and aspirations are common in HD patients, being one of the principal causes of mortality and hospital admissions.
Therefore, when first symptoms of dysphagia appear, it is important to begin as soon as possible with treatment. Speech and language therapy is useful to learn patterns and exercises to maintain and improve swallowing. In severe cases, avoid oral feeding and consider enteral nutrition must be evaluated.

Introduction/Background

Action Observation (AO) has been recently described as an effective strategy in stroke rehabilitation, since it can shape neural circuit reorganization, promote neural plasticity and motor learning. Very few evidences are available for rehabilitation of patients with Parkinson Disease trough AO.

Material and Method

AIM: The specific aim of this paper is to evaluate the effectiveness of action observation as an adjunctive rehabilitative tool to improve balance, gait and to reduce falls and to investigate the changes in EEG pattern duo to the treatment’s effects.

DESIGN: Prospective quasi-experimental study, pre and post design

Five cognitively intact participants with mild Parkinson’s disease and gait disturbance were enrolled in the study.

The subjects underwent a rehabilitation programme of action observation for gait and balance recovery for 30 minutes, 3 times a week for 4 weeks.

Main outcome measures. The assessments were performed at the beginning (T0) and at the end of the treatment (T1). The main outcome were: The Hoehn and Yahr scale; Unified Parkinson’s Disease Rating Scale (UPDRS) motor section III, Mini Mental State Examination (MMSE), Freezing of gait Questionnaire (FOG-Q), Timed Up&Go Test (TUG), Ten meters walking test (steps and seconds) (10 MWT), Berg Balance Scale (BBS), The 39-items Parkinson’s Disease Questionnaire (PDQ-39), Short form 12-items Healthy Survey (SF-12) and Functional Independence Measure (FIM).

Results
RESULTS: Action Observation training was feasible, acceptable, safe, and the participants completed 100% of the prescribed training sessions. The statistical analysis performed by the t test of the T1 vs T0 showed statistically significant improvements for UPDRS motor section III $p=0.0082$, SF12 MCS $p=0.0007$, FOG Q $p=0.0030$, PDQ39 $p=0.100$ and for P300LD $p=0.0077$. No statistically significant improvements for other scales were found.

Conclusion

CONCLUSIONS: AO is a feasible and safe form of rehabilitative exercise for cognitively intact people with mild PD. Further investigation regarding the long-time effectiveness of robot training is warranted.

COGNITIVE DETERMINANTS OF VISUAL SEARCH IN PATIENTS WITH PARKINSON’S DISEASE
M. Ranchet¹, J.C. Morgan², A.E. Akinwuntan³, H. Devos⁴
¹IFSTTAR, Transport- Health- Safety Department, Bron Cedex, France
²Medical College of Georgia- Parkinson’s Foundation Center of Excellence- Movement and Memory Disorder Programs-, Department of Neurology, Augusta, USA
³The University of Kansas Medical Center, Dean’s office- School of Health Professions, Kansas City, USA
⁴University of Kansas Medical Center, Department of Physical Therapy and Rehabilitation Science- School of Health Professions, Kansas City, USA

Introduction/Background

Visual search impairments may negatively affect activities of daily living. Few studies explored the cognitive deficits that contribute to impaired visual search in Parkinson’s disease (PD). The aim was to investigate the associations between visual search performance and cognitive functions in PD.

Material and Method

Twenty patients with PD (age: 69±8yo; sex (Men/Women): 16/4) and 15 controls (age: 61±11yo; sex: 8/7) performed a visual search task where they were instructed to search for a target stimulus (road sign) among distractor stimuli (other road signs). Neuropsychological tests were also administered. Partial correlations (r or r) were analyzed to investigate associations between correct detection times (cDT) of the visual search task with cognitive variables whilst controlling for age.

Results

In patients, significant partial correlations were found between cDT and Montreal Cognitive Assessment scores (ρ= 0.65, p=0.002), divided attention of the Useful Field Of View test (ρ=0.60, p = 0.007), interference condition of the Stroop test (r = - 0.58, p = 0.023), Figure of Rey (ρ= 0.74, p<0.001), errors and completion times on the dot cancellation test (errors: ρ=0.83, p<0.001; completion times: r=0.53, p=0.018), response times on Trail Making Test-part A (p = 0.56, p = 0.013) and part B (r=0.58, p=0.015). In controls, only one significant partial correlation was found, between cDT and completion times of dot cancellation test (r=0.88, p=0.001).

Conclusion
This study shows that visual search is affected by cognitive functions of individuals living with PD. Our findings may have implications for the assessment of cognitive functions and the development of training programs in patients with PD. Further study in PD will develop dynamic visual search task in driving conditions to better understand cognitive functions that may affect real-world activities.

THE ROLE OF TRAINING INTENSITY IN OUTPATIENT REHABILITATION OF PEOPLE WITH PARKINSON'S DISEASE: A RETROSPECTIVE COHORT STUDY OF DISABILITY PROGRESSION WITH 4-MONTH FOLLOW-UP.

M. Capecci, E. Andreelli, M. Hibel, L. Latini, M. Grugnetti, M. Pennacchioni, M.G. Ceravolo

1Università Politecnica Marche, Department of Experimental and Clinical Medicine, Ancona, Italy

Introduction/Background

Rehabilitation has been shown effective at improving functional abilities of people with Parkinson’s disease (pwPD), through task-oriented and aerobic training, though the exact role of exercise intensity has not yet been determined. The study is aimed at evaluating the impact of different intensity rehabilitation protocols on the short and medium term progression of disability in pwPD.

Material and Method

Using a retrospective cohort study design, the medical records of pwPD who consecutively underwent task-oriented outpatient rehabilitation from 2008 to 2016 at a University Hospital were retrieved. Subjects were considered eligible if they: a) had undergone a single cycle/year of gait and balance training, b) had stable drug therapy during the whole study period, and c) the UPDRS II subscore was available both at the baseline, at the end of treatment and 4 + 2 months after. The UPDRS part-III, TUG test, 6MWT, FOG-Q, Falls Efficacy Scale (FES) and PDQ-39 were also looked for as secondary outcome measures.

Results

Eighty out of 420 records met the eligibility criteria. A Low-Intensity (LIT) (39 cases) and a High-Intensity Training (HIT) (41 cases) group were defined according to a total training duration of less or more than 1000 minutes, respectively. HIT group included a greater rate of responders than LIT (65% cases with a meaningful gain in the UPDRS II, vs 35%; Chi2:3.8;p=.04). At variance with the LIT group, HIT subjects also showed a persistent improvement in UPDRS scores (F:14.5;p<.0001) and in FES (F:6.7;p=.002) at the 4-month follow-up. No significant between-group differences were found comparing TUG, 6MWT and PDQ-39 changes.

Conclusion

A total training duration of 60/90 minute/session per 20 sessions of task-oriented and aerobic training is recommended in pwPD, in order to ensure a clinically meaningful and persistent reduction of their disease-related disability.

SLOW OSCILLATIONS OF CEREBRAL HEMODYNAMICS CHANGES DURING LOW-LEVEL LIGHT THERAPY IN THE ELDERLY WITH AND WITHOUT MILD COGNITIVE IMPAIRMENT: AN FNIRS STUDY

A. Lee¹,², J. Kim¹, J. Lee¹,², H. Kim¹, S.J. Seof², Y.I. Shin³, W.H. Chang², Y.H. Kim¹,²
¹Samsung Advanced Institute for Health Science and Technology- Sungkyunkwan University, Department of Health Sciences and Technology, Seoul, Republic of Korea
²Samsung Medical Center- Sungkyunkwan University School of Medicine, Department of Physical and Rehabilitation Medicine- Center for Prevention and Rehabilitation-Heart Vascular Stroke Institute, Seoul, Republic of Korea
³Pusan National University Yangsan Hospital- Pusan National University School of Medicine, Department of Rehabilitation Medicine, Pusan, Republic of Korea

Introduction/Background

Low-level light therapy (LLLT) is used to stimulate cell function or reduce pain by applying light emitting diodes (LED) to the skin. LLLT is known to contribute to the neuronal recovery during the reconstruction of brain tissue for the treatment of degenerative disorders. This research aims to confirm the slow oscillations of cerebral hemodynamics changes when LLLT is applied to the elderly and patients with mild cognitive impairment (MCI).

Material and Method

Eight patients with MCI and 7 healthy elderly participated in this study. They were randomly divided into four groups; carotid artery stimulation, vertebral artery stimulation, simultaneous carotid and vertebral artery stimulation, or sham stimulation. The subjects received LLLT using Color DNA® (Color Seven Co.) with a LED light source for 30 minutes a day during 20 days. The hemodynamic responses were recorded by an fnIIRS system (NIRScout®) with 74 channels at the first and the 20th intervention days, before, during, and after the LLLT. The spectral power density over the very low-frequency oscillations (VLFO) of cerebral hemodynamics was calculated using Welch technique.

Results

In both healthy and MCI patients, VLFO increased in the whole cerebral area during LLLT compared to the resting state, and these changes are more contrasting in the condition with simultaneous carotid and vertebral artery stimulation condition. These characteristics were observed in both the first and 20th intervention days however, VLFO in the 20th intervention day were more increased than the first day.

Conclusion
Increase of very low-frequency oscillations demonstrated increasing spontaneous activity of cerebrovascular tone and neuronal activation. These findings may suggest a possibility of modulating effect of LLLT on neuronal activity and blood vessel reconstruction (This work was supported by the Korea Evaluation Institute of Industrial Technology (No.10067221) and a grant from the NRF (NRF-2017R1A2A1A05000730) funded by the Korean government).

Clínica de investigación clínica de la terapia de acupuntura para el Parkinson's Disease

Z. Haina¹, X. Guangmeng², Z. Jun¹, G. Lixin¹, Q. Fuling¹
¹La Segunda Universidad de JiLin, el Departamento de Rehabilitación, Chang Chun, China
²La Segunda Universidad de JiLin, el Departamento de Cirugía General, Chang Chun, China

Introducción/Contexto

El Parkinson's Disease es una enfermedad degenerativa del sistema nervioso central. La patogenia de la enfermedad no está clara. Hay un tratamiento específico para la medicina moderna. El principal medicamento es la levodopa, pero después de varios años de toma, hay muchos efectos secundarios como disminución del efecto curativo y fluctuación de los síntomas. La terapia de acupuntura ha obtenido mayor eficacia clínica y tiene ciertas ventajas en mejorar los síntomas clínicos.

Material y Método

Los principales tratamientos de acupuntura incluyen: terapia de acupuntura de cabeza, terapia de acupuntura del cuerpo, terapia de acupuntura abdominal, terapia de aguja de flor de ciruelo, terapia de penetración de puntos de acupuntura, terapia de acupuntura y combinación con medicación, etc. El mecanismo de la terapia de acupuntura en el Parkinson's Disease es que la terapia de acupuntura puede reducir la pérdida de DAT y mejorar la actividad de DAT en la región de la base ganglia del paciente lo que conlleva el efecto protector de las neuronas dopaminérgicas. La acupuntura está relacionada con el mejoramiento de la flujo sanguíneo local en la región cerebral. La terapia de acupuntura puede aumentar la actividad de SOD y disminuir la LPO lo que es útil para eliminar los radicales libres alrededor de las neuronas catecolaminérgicas y proteger las neuronas catecolaminérgicas.

Resultados

El estudio clínico de la terapia de acupuntura se realiza principalmente con la combinación de terapia de acupuntura de cabeza, terapia de acupuntura del cuerpo y terapia de acupuntura y combinación con medicación.

Conclusión

La terapia de acupuntura tiene ciertas ventajas y potencial en mejorar los síntomas de la enfermedad de Parkinson. La terapia de acupuntura puede retrasar el progreso de la enfermedad a cierto grado y disminuir la reacción secundaria del medicamento. Sin embargo, la terapia de acupuntura es diversificada. La investigación sobre el mecanismo de la terapia de acupuntura de Parkinson's Disease está en la etapa exploratoria, lo que necesita ser estudiado de forma más profunda.

THE RELATIONSHIP OF CHRONOTYPE, OBJECTIVELY-MEASURED PHYSICAL ACTIVITY AND DEMENTIA IN OLDER ADULTS

H. Park1, B. Kim2, B. Kim3, G. Kim2, J. Park4, J. Jang3

1Dong-A University, Health Care and Science, Busan, Republic of Korea
2Dong-A University, Research Foundation for Industry-Academy Cooperation, Busan, Republic of Korea
3Dong-A University, Department of Health Care and Science, Busan, Republic of Korea
4Dong-A University, Institute of Convergence Bio-Health, Busan, Republic of Korea

Introduction/Background

To examine overall relationships between chronotype, and objective measured physical activity pattern and dementia in older adults, focusing on potential interactions between the chronotype, volume timing of activity and/or sleep and dementia.

Material and Method

Subject were 192 female and 47 male community-dwelling healthy Korean individuals aged 70-85 years. Total volume of activity at an intensity over 3 metabolic equivalents (METs) and timing of activity and sleep pattern were measured by 3 axial accelerometer throughout each 24-h period for 1 month. Participants also completed the morningness-eveningness Questionnaire, which is a 19-item self-report scale with questions focusing on habitual waking and bed times. Partial correlation coefficients adjusted for age and sex were calculated between measurements. We used logistic regression analyses to determine odds ratios and 95% confidence intervals adjusted for potential confounders, and to assess independent associations between chronotype, physical activity pattern and and the risk of dementia.

Results

The data were significantly described by partial correlation models which showed that in both sexes the chronotype score and physical activity associated with cognitive function. Multivariate-adjusted logistic regression analyses predicted who engaged in <12 to 13 min/day of moderate-intensity physical activity were, respectively, 2 and 3 times more likely to sustain dementia than those participating in >22 min/day of activity >3 METs. Moreover, participants who classified as high in eveningness were 2 times more likely to sustain dementia than those with morningness.

Conclusion

Causation cannot be inferred from a crosssectional study. Nevertheless, we suggest that from the viewpoint of cognitive health, older population should be encouraged to engage in in low- and moderate-intensity habitual physical activity, taking a duration >12 to 13 min/day at >3
METs. Moreover, these results suggest that elderly with higher eveningness also have higher risks of dementia.

“THEY’VE BEEN FANTASTIC...IT’S JUST THAT TIME BETWEEN CLINICS”. EXPERIENCES OF ACCESSING SPECIALIST CARE BY PEOPLE LIVING WITH MOTOR NEURONE DISEASE. A QUALITATIVE STUDY

E. Hobson¹, W. Baird², C. Cooper², S. Mawson², A. Quinn¹, P. Shaw¹, T. Walsh⁴, C. McDermott¹
¹University of Sheffield, Sheffield Institute for Translational Neurosciences, Sheffield, United Kingdom
²University of Sheffield, School of Health and Research Research, Sheffield, United Kingdom
³Sheffield Motor Neurone Disease Research Advisory Group, Sheffield Institute for Translational Neurosciences, Sheffield, United Kingdom
⁴Sheffield Institute for Translational Neurosciences, Sheffield Motor Neurone Disease Research Advisory Group, Sheffield, United Kingdom

Introduction/Background

Attendance at a specialist motor neurone disease multidisciplinary clinic is associated with improved survival. However, access to specialist services between hospital visits can be difficult, especially for people who find it hard to travel to hospital.

Material and Method

As part of a mixed methods controlled trial of telehealth we conducted semi-structured interviews and used thematic analysis to examine the experiences of patients with motor neurone disease/ amyotrophic lateral sclerosis, carers and specialist nurses. We explored their experiences of hospital and community care and care coordination.

Results

54 participant interviews were conducted. 36 patients and 32 carers were interviewed at least once. A community nurse was interviewed once and a hospital nurse interviewed twice.

The perceived value of the specialist hospital clinic was that it offered reliable and regular care and could rapidly and effectively deal with complex problems. However, travelling to clinic could be practically and emotionally difficult. Community services offered practical care and home adaptions but some found that they lacked the regular support and specialist knowledge of a specialist clinic. Participants experienced a lot of overlap between the care provided locally and that in the specialist clinic. Each patient described a different arrangement for receiving care and this depended on their needs, their relationship with health professionals and their attitude towards the disease. The primary person coordinating their care could be from different
backgrounds, but was usually a health care professional who was accessible, saw the patient regularly and who the patient felt sufficient specialist knowledge to address their problems.

Conclusion

Care coordination can be provided by any professional, who can draw services around the patient and their family. This "lynch-pin" needs to be accessible, reliable and have specialist expertise. Without care coordination the patient struggles to access the care they need in a timely fashion and experiences many unmet needs.

Botulinum Toxin has become a multipurpose therapeutic agent with a large spectrum of clinical applications, especially in neurological diseases. If the place of botulinum toxin in the management of muscle overactivity is now well established, its uses in the management of specific parkinsonian motor symptoms (tremor, levodopa induced dystonia, freezing of gait) as well as non-motor symptoms (sialorrhea, bladder dysfunction) are not yet fully known and insufficiently developed.

**Material and Method**

We provide a systematic review of the current and potential uses of Botulinum Toxin in the management of motor and non-motor symptoms in parkinsonisms.

**Results**

Compared to classical systemic medications, Botulinum Toxin is a solid alternative to treat motor and non-motor disorders in parkinsonian syndroms. In sialorrhea and overactive bladder, Botulinum toxins A and B injections appear to be safe and efficient; considering rest tremor and dystonia, uses of botulinum toxin are quite promising, even though still investigational. Finally, Botulinum Toxin injections appear to be uneffective in frezzing of gait and camptocormia.

**Conclusion**

There is a need for properly controlled, randomized studies to confirm the efficacy and improve the use of botulinum toxin injections on parkinsonian motor and non-motors symptoms, as there is yet currently no accepted consensus on the best ways to use Botulinum Toxin to treat those symptoms.

Introduction/Background

Patients with Parkinson’s disease (PD) have a reduced physical activity level, although exercise is especially recommended in this population. Besides, motor and non-motor symptoms may also interfere with the ability to produce strenuous efforts. Yet, their baseline performances and the response to physical reconditioning have not been thoroughly investigated. The cross-sectional part of this study investigates different aspects of physical fitness of patients suffering from mild to moderate PD. The second part investigates the response to physical reconditioning.

Material and Method

Sixty PD patients and 47 healthy controls (HC) matched for demographic features were tested for aerobic performances and muscle strength. Peak work load (PWL) and peak oxygen consumption (VO₂peak) were assessed in both groups during an incremental cycle exercise test. Isokinetic knee muscle strength (IKMS) was also tested for the extensor and flexor muscles at 60° and 180°s⁻¹. Subgroups of PD patients were also allocated to 12 weeks of strength training (ST, n=17), aerobic training (AE, n=20) or standard care control intervention (n=15).

Results

In comparison to HC, PD patients showed reduced PWL and VO₂peak (respectively -19% and -14%, ps<0.003). PD patients showed reduced IKMS of flexor muscles (from -17 to -24%, p≤0.001), and reduced IKMS only for the most affected side of extensor muscles (-13%, p≤0.015). Eighty-eight percent and 80% of the trained patients respectively completed the ST and the AE interventions. No major complication occurred during the interventions. The AE group improved PWL (+18%, p=0.001) and VO₂peak (+12%, p=0.033). The ST group improved IKMS of flexors (+22-25%, p≤0.02), IKMS of extensors only for the most affected side (+10-17%, p<0.05), and PWL (+16%, p<0.001).

Conclusion
Aerobic and strength performances are both affected by PD. However, physical reconditioning is feasible and improves fitness of PD patients.

TREATMENT OF CONTRACTURES WITH CLOSED HANDS WITH LIDOCAINE: A PILOT STUDY IN A LONG TERM GERIATRIC SETTING
D. hotton¹, S. nathalie¹, V. jean-sebastien², M. julie¹, R. anne-sophie², D. philippe³
¹hôpital la collégiale, paris, paris, France
²hôpital broca, paris, paris, France
³hôpital raymond poincaré, hauts de seine, garches, France

Introduction/Background

Joint contracture with restriction of range of movement is a very common condition in severe stages of Alzheimer's disease. Treatment is still not standardized but relies mainly on tenotomy. The objective of the study was the opening of closed or flexed hands after 10 days of lidocaine treatment.

Material and Method

The study was conducted in a long-term care hospital in Paris, France. Eight patients who had contractures with closed or flexed hands were included in the study. Distance between the most distal wrist line and the fingertips (DWF) was measured for the 4 fingers with passive opening of the hand before and 20 minutes after spraying of Lidocaine oral liquid 5% between fingers and into the palm. Local cares were applied with use of antiseptic and if needed dressing of the lesions. The procedure was repeated 5 times, every other day for 9 days. At 1 month the DWF was again measured without lidocaine application.

Results

Mean age was 86.3 (standard deviation=6.9) years old and 75% were women and 75% had vascular dementia. Two participants had contractures in both hands. All participants had lesions in the palm. Differences between DWF before and after lidocaine application were on average 2.02 (2.24) for index, 2.62 (2.16) for middle, 2.33 (1.88) for ring and 2.10 (1.41) for little finger (p difference < .0001 for all fingers). There were significant gains between baseline and the 5th procedure and after 1 month but not between the 5th procedure and after 1 month.

Conclusion

The use of local anesthesia to open closed or flexed hands by contractures seemed promising and calls for a control randomized versus placebo study.

STUDY ON THE MECHANISM OF ACUPUNCTURE ON PARKINSON’S DISEASE IN RATS
Z. Haina¹, X. Guangmeng², Z. Jun¹
¹The Second Hospital of JiLin University, the Rehabilitation Department, Chang Chun, China
²The Second Hospital of JiLin University, the General Surgery Department, Chang Chun, China

Introduction/Background

To explore the possible oxidative stress mechanism of acupuncture in the treatment of Parkinson's disease in rats.

Material and Method

The Lactacystin was injected into the rat's substantia nigra pars compacta to establish a Parkinson's disease model. The Rats were treated for 2 weeks of acupuncture therapy. Two weeks later SOD, GSH-PX and MDA were measured in rats' serum.

Results

Compared with the normal group, SOD activity increased after the rat model was successfully established, and the activity of GSH-PX decreased and MDA content increased. Compared with the model group, the acupuncture group and Medopa +acupuncture group can improve SOD activity and GSH-PX activity and reduce MDA. The acupuncture group has significant effect.

Conclusion

In Lactacystin induced Parkinson's disease model, acupuncture treatment significantly improved SOD activity and GSH-PX activity and reduced MDA content. Acupuncture may participate in the regulation of oxidative stress mechanism.

Keywords

Amyotrophic lateral sclerosis (ALS) is a rare neurodegenerative disease, incurable and fatal, with median survival of 2-4 years. The ALS degenerative process involves upper and lower motor neurons causing loss of limb strength, dysarthria, dysphagia and respiratory failure.

Pain is also reported by most of these ALS patients, however is often overlooked. It can occur at all stages of the disease, and sometimes even precede the motor dysfunction and is usually related with deterioration in patient’s quality of life.

The purpose of this work is to review the pathophysiology of the pain in ALS and the most adequate treatment strategies available.

**Material and Method**

Search of relevant literature in Medline, via PubMed, in the last 8 years, using the following key words: amyotrophic lateral sclerosis (ALS), pain.

**Results**

Pain associated with ALS is more frequent in patients with spinal presentation and has a multifactorial etiology, that can be either primary (neuropathic) or secondary to motor degeneration; location and clinical onset and evolution can also differ.

Depending on the cause and most prominent descriptors and location of symptoms different treatment have been suggested, including pharmacological and non-pharmacological interventions, from non-steroidal anti-inflammatory drugs, drugs for neuropathic pain, opioids, cannabinoids, physical agents and therapy. Pharmacological treatment and physical agents have a decisive role in some cases of primary pain, mainly neuropathic, while physical therapy has an intervention in the prevention and treatment of secondary pain.
**Conclusion**

Although ALS is incurable and fatal, treatment can extend the length and meaningful quality of life for patients.

Treatment of pain is frequently neglected in these patients, nevertheless it has a positive physical and psychological impact with repercussions on quality of life. So, ALS patients should be integrated into a rehabilitation program which must include evaluation and treatment of pain.

Introduction/Background

As a multisystemic neurodegenerative disorder, Parkinson disease has a broad spectrum of symptoms including motor and non motor symptoms (NMS). As shown in studies, NMS can also impact patient's quality of sleep.

The aim of our study was to assess the quality of sleep in patients with Parkinson’s disease in a Tunisian population.

Material and Method

This is a transversal and prospective study from January 2018 including all parkinsonian patients followed at the Neurology and Physical Medicine and Rehabilitation departments of the University hospital of Mahdia.

Patients were assessed using the Hoehn and Yahr’s scale and filled out the following questionnaires: Parkinson’s disease sleep scale (PDSS) and the Epworth Sleepiness Scale (ESS).

Results

Twenty patients were enrolled in our study (75% male and 25% female) whose mean age was 63±6.4 years. The disease duration varied from 2 to 34 months with an average of 13 months.

Hoehn and Yahr staging was 2.8±0.87. The mean total PDSS score was 99.5±22.1 and 65% of the patients had a poor quality of sleep (PDSS score < 82 or subscore < 5). Most frequent disorders were pain or cramps interrupting sleep, night waking to urinate and fatigue or sleepiness on waking.

The mean ESS score was 15.6 ±0.78 and patients exhibited excessive diurnal sleepiness in 30% of the cases (ESS score > 10).
Both the total PDSS score and EDSS were correlated with disease stage, but not with age or disease duration.

**Conclusion**

Sleep disorders are common in Parkinson disease and future studies are needed to assess the effects of therapeutic options on sleep quality.

Multidisciplinary Short-Term Day Rehabilitation Program Can Be Effective for Patients with Parkinson Disease

I. Treger\(^1\), L. Lutsky\(^2\), V. Kupreychik\(^3\), M. Nikitin\(^3\), D. Dyatlov\(^3\), E. Zaikina\(^3\), V. Velev\(^3\), A. Bogatirev\(^3\)

\(^1\)Soroka University Medical Center- Ben Gurion University of Negev, Rehabilitation, Beer Sheva, Israel
\(^2\)South Department Clalit, Rehabilitation, Beer Sheva, Israel
\(^3\)Multidisciplinary Rehabilitation Center, Rehabilitation, Moscow, Russia

Introduction/Background

Parkinson's disease (PD) is a neurodegenerative disorder that affects predominately dopaminergic neurons in substantia nigra, progresses slowly and in most cases, leads to severe motor impairment with decline in quality of life. Although there is no cure, treatment options vary and include medications and surgery. It was previously shown, that rehabilitation treatment programs can also be an important part of PD management. The aim of the study was to demonstrate the effectiveness of multidisciplinary short-term day rehabilitation program for patients with PD.

Material and Method

14 patients with diagnosed PD were admitted to the Multidisciplinary Center of Rehabilitation for 2 weeks (3 times a week – total 6 sessions) of specialized day rehabilitation program. Each treatment day combined minimum 3 hours of individual and group sessions, including aerobic, functional and cognitive training, speech and dance therapy, and Tai-chi session. Berg Balance Scale (BBS), 6 minutes’ walk test (6MWT) and Timed Up & Go test (TUG) at the beginning and at the end of the program were measured for motor progress assessment.

Results

BBS score showed an insignificant, but positive trend from 52.4±3.5 to 53.5±2.4 points, 6MWT increased from 331.1±127.8 meters at the beginning to 389.4±122.5 meters at the end of the program and TUG dropped from 19.2±7.7 to 14.7±5.4 seconds. All patients reported that because of taking part in the program their quality of speech and communication was increased, and their psychological status was improved. High level of patient’s satisfaction was recorded at the end of the program.

Conclusion
A multidisciplinary day rehabilitation program can be effective for patients with PD. Even a short-term 2-week treatment shows a positive trend in motor abilities according to well-known assessment scales’ parameters.

LESSONS LEARNED DEVELOPING A DIAGNOSTIC TOOL FOR HIV-ASSOCIATED DEMENTIA FEASIBLE TO IMPLEMENT IN RESOURCE-LIMITED SETTINGS: PILOT TESTING IN KENYA

R.N. Mbugua

Kenya Network of women living with HIV/AIDS- Nairobi University- Kenyatta National Hospital- Kenya Psychiatry Association- Mathare Mental Hospital, Research- and Community Work, Nairobi, Kenya

Introduction/Background

To conduct a preliminary evaluation of the utility and reliability of a diagnostic tool for HIV-associated dementia (HAD) for use by primary health care workers (HCW) which would be feasible to implement in resource-limited settings.

In resource-limited settings, HAD is an indication for anti-retroviral therapy regardless of CD4 T-cell count. Anti-retroviral therapy, the treatment for HAD, is now increasingly available in resource-limited settings. Nonetheless, HAD remains under-diagnosed likely because of limited clinical expertise and availability of diagnostic tests. Thus, a simple diagnostic tool which is practical to implement in resource-limited settings is an urgent need.

Material and Method

A convenience sample of 30 HIV-infected outpatients was enrolled in Western Kenya. We assessed the sensitivity and specificity of a diagnostic tool for HAD as administered by a primary HCW. This was compared to an expert clinical assessment which included examination by a physician, neuropsychological testing, and in selected cases, brain imaging. Agreement between HCW and an expert examiner on certain tool components was measured using Kappa statistic.

Results

The sample was 57% male, mean age was 38.6 years, mean CD4 T-cell count was 323 cells/µL, and 54% had less than a secondary school education. Six (20%) of the subjects were diagnosed with HAD by expert clinical assessment. The diagnostic tool was 63% sensitive and 67% specific for HAD. Agreement between HCW and expert examiners was poor for many individual items of the diagnostic tool (K=.03–.65). This diagnostic tool had moderate sensitivity and specificity for HAD. However, reliability was poor, suggesting that substantial training and formal evaluations of training adequacy will be critical to enable HCW to reliably administer a brief diagnostic tool for HAD.

Conclusion
Pilot testing suggests substantial training, formal evaluations of training adequacy is critical enabling primary HCW to reliably administer brief diagnostic tool for HAD that contains cognitive tests and neurological examination.

CASE REPORT A RARE CASE OF DYSPHAGIA ASSOCIATED WITH PROXIMAL MUSCLE WEAKNESS: VIDEOENDOSCOPIC SWALLOWING STUDY AND LITERATURE REVIEW

M. Ahmed1, S. Hassan1, D. Shehab2, A. Alfeeli3
1Amiri Hospital, Physical Medicine And Rehabilitation, Kuwait, Kuwait
2Mubarak Hospital, Ministry of Health, Physical Medicine and Rehabilitation department --, Kuwait, Kuwait
3Amiri Hospital, Physical Medicine and Rehabilitation department, Kuwait, Kuwait

Introduction/Background

Background and aim: It is rare to find dysphagia associated with proximal muscle weakness for the literature. Thus, our aim was to evaluate of dysphagia by Volume-Viscosity Swallow Test (V-VST) and videoendoscopic study and to study the effect of treatment.

Material and Method

We present a case of orophargenial dysphagia with proximal muscle weakness and was treated with corticosteroid. Oropharyngeal dysphagia was evaluated by both Volume-Viscosity Swallow Test (V-VST) and videoendoscopic swallowing study.

Results

V-VST test and videoendoscopic swallowing study showed thin liquid aspiration and penetration into trachea and residue in pyriform sinus. While, there was no soft or solid food aspiration into trachea, but it showed residue in pyriform sinus and valleculae.

Conclusion

Conclusion: Orophargenial dysphagia and proximal muscle weakness were reversible with appropriate treatment with better outcomes and good function and quality of life. At 4 months after the onset of symptoms, the patient’s clinical condition had improved on normal phonation and swallowing with regaining power in the proximal muscle limbs.

Introduction/Background

Recovery from aphasia remains difficult to predict. As motor cortex is strongly involved in language processes, both production and perception, the present study aimed to determine whether the integration of an electrophysiological measure of the motor network using Motor Evoked Potentials (MEPs) with an anatomical approach -diffusion-weighted MRI- in the acute phase of stroke can improve the prediction of recovery from post-stroke aphasia.

Material and Method

Fifteen aphasic patients were included in the post-stroke acute phase. Electrophysiological assessment exploring resting motor threshold ratio (rMTr) of the two upper-limbs and neuroanatomy exploration using MRI and diffusion tensor imaging were performed in the acute phase. Language impairment was assessed at the same stage and six months after the stroke. Multivariate regression analyses were carried out on aphasia severity score at M6, on recovery rates (change of severity) and on speech and language features as the dependent variables.

Results

A first-level model, including only clinical variables (i.e. initial severity) predicted severity at six months. When the rMTr of upper limbs was added in a second-level model, the predictive power significantly increased from 51% to 79%, as well as adding in a third-level model rMTr of upper-limbs and initial fibres number ratio of the corticospinal tracts (51% to 80%). With the changes of severity as the dependent variable, the same factors made a significant contribution and the predictive power of a second-level model increased from 23% to 50% to the same extent as in a third-level model (23% to 51%). A similar improvement when adding MEPs was noted for the prediction of articulatory agility and naming skills.

Conclusion
Our results suggest that MEPs of upper limbs measured within 15 days post-stroke are strong determinants of the prediction of longitudinal severity of post-stroke aphasia as well as of changes in symptoms and that the combination of electrophysiological and anatomical biomarkers improve this prediction.

MULTI-MODAL REHABILITATION OF UNILATERAL OPERCULAR INFARCTION PRESENTING WITH FOIX-CHAVANY-MARIE SYNDROME: A CASE REPORT

X. Qiu¹, B. Zhang², C. Chen¹, T. Gao¹, C. Sun¹, B. Xie³, Y. Bai³, Y. Wu³
¹The North Branch- Huashan Hospital, Department of Rehabilitation Medicine, Shanghai, China
²UT Health Science Center, Physical Medicine and Rehabilitation, Houston, USA
³Huashan Hospital, Department of Rehabilitation Medicine, Shanghai, China

Introduction/Background

Foix-Chavany-Marie syndrome (FCMS) is a rare form of pseudobulbar palsy characterized by loss of voluntary control of the facial, glossal, pharyngeal, laryngeal, and masticatory muscles with preserved automatic, involuntary, emotion-related movements called “automatic-voluntary dissociation”. Dysfunctions related to FCMS are usually irreversible and the prognosis tends to be poor.

Material and Method

A 50-year-old female presented with FCMS following an acute right opercular infarction for 2 months. The patient had complete dysfuntion of the above muscles with inability of opening mouth, oral phase of preparing food for swallowing involving tongue and mandible movement and chewing. The patient was able to swallow if food was placed at the posterior part of oral cavity near pharynx. The patient was only able to pronounce “uh”. The patient had previous history of hypertension and right peripheral facial nerve palsy with only mild residual asymmetry on facial expressions. Therapies included oral muscle exercises, sensory stimulation, breathholding and phonation technique, cough exercise, low frequency electric stimulation on bilateral mastoid and suprahyoid muscles. The patient received 20 minutes’ 1Hz repetitive transcranial magnetic stimulation daily over the right motor cortex at an intensity of 100% for 10 days. The patient also received 30 minutes’ acupuncture daily in a total of 15 days at bilateral Shàngyìngxiāng (EX-HN8), Dìcāng (ST4), Jiáchē (ST6), Tinggōng (SI19), Tāiyáng (EX-HN4), Jīngmíng (BL1), Sīzhúkōng (TE23), Sībái (ST2) and Shǔigōu (GV26), Liánquán (CV23), Chéngjiāng (CV24). Assessments were performed before and after treatments.

Results

After 3 weeks of treatments, the patient had improvements in opening her mouth voluntarily from 2cm to 8cm, moving her mandible, chewing foods, protruding her tongue and pronouncing “a”, “i” and “u”. The modified Frenchay Dysarthria Assessment (Chinese version) was improved by 22 points and standardized swallowing assessment was improved by 1 point.

Conclusion
Intensive multi-modal rehabilitation therapy may be helpful in the recovery of disabilities associated with FCMS.

CONSTRAINT-INDUCED APHASIA THERAPY FOR POST-STROKE PATIENTS IN JAPAN

M. Kanamori¹, Y. Nakao¹, K. Horikawa¹, S. Saito¹, T. Nanto¹, K. Eimoto¹, K. Toyota¹, N. Kodama², Y. Uchiyama², K. Domen³

¹Hyogo College Of Medicine, physical medicine and rehabilitation, Nishinomiya-shi- Hyogo, Japan
²Hyogo College Of Medicine, rehabilitation medicine, Nishinomiya-shi- Hyogo, Japan
³Hyogo College Of Medicine, rehabilitation science, Nishinomiya-shi- Hyogo, Japan

Introduction/Background

Constraint-induced aphasia therapy (CIAT) has been widely applied as post-stroke aphasia rehabilitation to encourage intensive verbal practice with supported verbal cuing instead of previous habitual compensatory strategies (Pulvermuller et al., 2001). However, this therapy has not yet been reported in Japan; thus, we applied intensive CIAT training to three of our patients with chronic aphasia.

Material and Method

Participants
Patient 1: Aged 72 years, female, three years after onset of Broca aphasia.
Patient 2: Aged 67 years, male, two years after onset of transcortical aphasia.
Patient 3: Aged 52 years, female, two years after onset of anomia.

Methods
The CIAT-II protocol (Johnson et al., 2015) was modified as the Japanese version, which consisted of intensive training using five expressive language exercises and methods of Shaping and Transfer Package for 5 × 3-h weekly sessions for 3 weeks. The Japanese version of the Aphasia Quotient (AQ) in the Western aphasia battery and the Amount Scale (AS) of the Verbal Activity Log (VAL) were also modified to assess aphasia before and after the protocol.

Results

The AS improved from 2.7 to 4.6, from 1.4 to 2.8, and from 2.2 to 3.8 in patients 1, 2, and 3, respectively. The AQ did not greatly change in any patient (from 70.8 to 72, from 70 to 73.1, and from 85.9 to 93.7, respectively).

Conclusion

The results indicated that the CIAT could improve aphasia assessed by the AS, which was consistent with previous study of CIAT (Johnson et al., 2015) and constraint-induced movement therapy (Taub et al., 2013). The Japanese version of CIAT might be effective as speech therapy for Japanese patients with chronic aphasia.

PARIETO TEMPORO OCCIPITAL DAMAGES AFTER STROKE AND SPEECH AND LANGUAGE DISORDERS

G. Savic

Institute of Physical Medicine and Rehabilitation Dr Miroslav Zotovic, Department of Neurorehabilitation, Banjaluka, Bosnia - Herzegovina

Introduction/Background

The stroke of the parieto temporooccipital lobe most often results in speech language disorders (SLD), expressed in misunderstanding speech and language.

Material and Method

We investigated the occurrence of SLD in relation to speech comprehension at 81 patients with parieto temporooccipital lesions after stroke. An auditory comprehension (AC) of the speech by subtests of Boston Diagnostic Aphasia Examination (BDAE) within the first 60 days after stroke was estimated.

Results

The average age of the sample was 65.91 (± 8.12, M = 65.12 F = 66.91). Ischemic stroke was mostly present in the sample. All patients had left brain lesions with consequent aphasia. Patients were unsuccessful on subtests AC: Word Discrimination 27.16%, Body Part 25.92%, Command 33.33%, Complex Ideational Material (CIM) 45.67% of the sample. Successes of 80% and more in AC: Word Discrimination and Body Part had 24.69%, Command 19.75% and CIM had 7.40% patients.

Efficacy and Needs of Secondary Dysphagia Screening in Post Acute Care for Change in Diet Program in Patients After Acquired Brain Injuries

M. Zatloukalova¹, K. Hoidekrová², J. Petioky¹, S. Vesela¹
¹Rehabilitation centre Kladruby, Rehabilitation, Kladruby, Czech Republic
²Faculty of physical education and sport, Rehabilitation, Prague, Czech Republic

Introduction/Background

Recent studies have shown the incidence of dysphagia in patients after traumatic brain injury up to 50% and in stroke patients between 35-40%. This paper presents the effectiveness and needs of secondary dysphagia screening in post acute care with consequent influence on the change in diet program. Current situation shown that not all patients with presence of dysphagia are adequately screened in acute hospital settings with concurrent safety and quality of life’s compromise. We have placed issue whether secondary dysphagia screening will help identify another dysphagia patients in post acute care (rehab setting) and thus to improve patients safety and quality of life.

Material and Method

Patients with diagnosis acquired brain injury in subacute phase, who were hospitalized in Kladruby Rehabilitation Centre with primary dysphagia screening, were included. 124 patients were secondary GUSS screened and different types of dysphagia were diagnosed in 27 of them. Dysphagic patients were divided into 4 groups according to the dysphagic diet levels. 26 patients had specific speech therapist’s intervention and electrostimulation therapy was applied in 13 of them.

Results

73,1% of 26 patients were improved. 57,7% patients were improved in one diet category, 2 patients changed from PEG to non-dysphagic diet program and one patient changed form PEG to advanced level. From all of 26 dysphagia patients were 61.5% with out dysphagic diet program.

Conclusion

The effectiveness of secondary screening in 124 patients, when 27 dysphagic patients were determined, supported a need of secondary screening in post acute care (rehab setting) and led to set appropriate speech intervention using electrostimulation of the pharyngeal muscles and in 73,1% dysphagic patiens the diet category was changed. The application of electrostimulation to the pharyngeal muscles under the leading of the speech therapist shows one of the very good ways how to improve quality of life in patients with acquired brain injury.

THE CORRELATION BETWEEN SWAL-QOL OUTCOME AND FUNCTIONAL DYSPHAGIA
SCALE IN STROKE PATIENTS
J.H. Kim

Catholic Kwandong University International St.Mary’s Hospital, Rehabilitation Medicine,
Incheon, Republic of Korea

Introduction/Background

There were some reports about Swallowing Quality of Life (SWAL-QOL), however still insufficient in stroke patients. This study is to evaluate the impact of dysphagia on quality of life in stroke patients by demonstrating the correlation between Swallowing Quality of Life questionnaire outcome and Functional Dysphagia Scale (FDS) score.

Material and Method

Sixty one stroke patients with dysphagia were enrolled. To evaluate for patients with cognitive impairment, we used the modified SWAL-QOL questionnaire for caregiver. We performed comparative analysis between the modified SWAL-QOL score of nasogastric tube feeding patients and that of oral feeding patients (table 1). The severity of dysphagia was assessed by FDS according to the result of VFSS. We investigated the correlation between the modified SWAL-QOL score and the FDS score.
Results

When using the modified SWAL-QOL, the mean score of tube feeding group was 107.59±17.04, which of oral feeding group score was 112.21±20.08 (table 2). A significant difference between two groups was showed in burden and sleep domains respectively (p=0.012, p=0.003). There was no significant difference in total score of modified SWAL-QOL between two groups (p=0.345). There was a significant inverse correlation between the total score of SWAL-QOL outcome and that of total FDS score (r=-0.465, p=0.000). The pharyngeal phase score of FDS was significantly correlated with Burden(r=-0.361, p=0.004), mental health (r=-0.364, p=0.004), social functioning (r=-0.307, p=0.016) and symptom frequency (r=-0.367, p=0.004) domains of SWAL-QOL (table 3).

SWAL-QOL, swallowing quality of life; FDS, functional dysphagia scale.
Values are spearman’s correlation coefficients
*p<0.05
Conclusion

We think it needs to assess the SWAL-QOL in stroke patients with dysphagia and should focus the rehabilitation of pharyngeal phase to promote better patient’s quality of life.

Introduction/Background

Amendment of WHO definition of health to: “Health is a dynamic state of complete physical, mental, spiritual and social well-being and not merely the absence of disease or infirmity” was suggested to WHO in 1998. Although the definition of health has not changed, “spiritual” has become one of the important elements of holistic health. The aim of this study was to analyze the effect of interventions from the perspective of spiritual health for an ALS patient with spiritual pain.

Material and Method

The patient was a female in her 80’s with ALS, showing independence in ADL, living with her husband who required care, with a life prognosis of less than 1 year. She had severe dysarthria and dysphagia. Her comments reflected her spiritual pain after diagnosis, such as: “why have I developed ALS?” Samples of her narrative were recorded in a free-talking session and analyzed to clarify her spiritual pain. Active listening was selected as the most effective method to provide support so that she could overcome her difficulties independently. Such active listening of her narrative was continued for about two months.

Results

Analysis indicated that her spiritual pain primarily involved three facets: temporality, relationship, and autonomy. During the continued active listening in parallel with standard rehabilitation, the contents of her narrative gradually changed. Her spiritual pain was mostly resolved, but that related to ‘relationship’ remained.

Conclusion

It is suggested that the application of speech therapy based on a patient’s narrative can be effective to support their spiritual health. Therefore, speech therapists can support patients to resolve spiritual pain as well as functional disorders.

A CASE OF UNDIFFERENTIATED JARGON APHASIA EVOLVING INTO NEOLOGISTIC JARGON APHASIA

K. Kyoda¹, T. Takizawa², K. Kagechika³
¹Kanazawa Medical University, Department of Rehabilitation Center, uchinada, Japan
²Kyoto Koka Women’s University, Speech-Language-Hearing Therapy Course- Faculty of Health Science, Kyoto, Japan
³Kanazawa Medical University, Department of Rehabilitation services, uchinada, Japan

Introduction/Background

It has been established that there are three types of jargon aphasia: undifferentiated, neologistic, and semantic jargon. Undifferentiated jargon speech consists of meaningless syllabic sequences and there is no apparent differentiation of content word from function word. In contrast, neologistic jargon speech has a remarkable amount of neologism, and is grammatical. The aim of this study was to investigate the mechanism underlying jargon speech aphasia.

Material and Method

The patient was a 78-year-old, right-handed man. Brain MRI showed cerebral subcortical infarction extending from the left parietal to temporal lobes. His auditory comprehension and phonological analysis were poor. His speech was jargon speech. He presented difficulties in word finding, reading, and repetition. We analyzed his speech by error type and characteristic.

Results

At the acute stage, his speech was a fluent series of syllables without meanings, and lacked syntactic structures. There was no apparent differentiation of content word from function word. The jargon type was undifferentiated jargon aphasia. At one month post-onset, there were a few correct words, and syntactic structures appeared; however, most words were neologistic in his speech. The jargon type changed to neologic jargon aphasia. At one year post-onset, he showed slight phonemic and semantic paraphasia, while neologic jargon aphasia was persistent.

Conclusion

At the acute stage, undifferentiated aphasia was caused by a deficit in word retrieval, lemma level, lexeme level, and phonological encoding on lexical access in speech production. In the grammatical encoding process, dysfunction of functional processing and positional processing caused utterance without syntactic structures. It is suggested that during word selection, lemma
level, and processing recovery, undifferentiated jargon aphasia evolved into neologistic jargon aphasia. Persistent neologistic aphasia is considered to be due to the severe lexeme level and phonological encoding disorders.

Keywords

undifferentiated jargon aphasia; neologistic jargon aphasia

PRE-VALIDATION OF THE COMMUNICATION INDEPENDENCE MEASUREMENT (CIM) SCALE. PRELIMINARY RESULTS AMONG 55 PATIENTS

N. Morin¹, N. Khalil¹, G. Temple¹, A.G. François², M. De Gasperi², J.M. Beis¹, J. Paysant³
¹IRR, Physical Rehabilitation Medicine, Lay Saint Christophe, France
²IRR, Département d’Informatique Médicale, Nancy, France
³IRR, Physical Rehabilitation Medicine, Nancy, France

Introduction/Background

The assessment and rehabilitation of aphasia through a neurolinguistic approach is well known, so as its functional impairments to communicate, and its psycho-social consequences. We make the hypothesis that severe aphasia might leads gradually to a decrease of communication among inpatients whose needs are supplied by the institution.

We propose to evaluate a new tool, the Communication Independence Measurement (CIM) scale, built like the Functional Impairment Measurement (FIM) scale.

Material and Method

The CIM scale was used among aphasic’s inpatients in a neuro-rehabilitation center, at baseline (M0) and 3 months (M3), by 4 different professionals (2 speech therapists and 2 nurses or carers). 4 subdomains were evaluated, from 1 to 7 (motivation to communicate, expression, understanding, interaction). Psychometric properties and correlation to the Boston Diagnostic Aphasia Examination (BDAE) severity grade were analysed.

Results

55 patients (mean age 48 ± 11.8 years old, sex ratio 0.83) were consequently included, at 0.91±1.49 months from stroke. 17 of them were evaluated at M3.

Inter-rater validity was good, with no statistically difference between the 4 examiners at M0 (Kruskal-Wallis test \( p=0.77 \)) and at M3 (Kruskal-Wallis test \( p=0.96 \)). CIM was highly correlated to BDAE at M0 (Intra class correction ICC = 0.60-0.69) and at M3 (ICC = 0.82-0.85).

We founded that patients who obtained a score less than the cut off value of 35 had a bad daily communication.

Conclusion
The CIM scale seems to be a reliable tool to measure communication in aphasics in rehabilitation center. It might help identifying and thus helping patients with a negative prognosis of communication early during post-stroke rehabilitation time.

⁴Centro Internacional de Restauración Neurologica, Clinica Neurologia Infantil, La Habana, Cuba

Introduction/Background

Autism Spectrum disorder (ASD) is composed of a range of complex neurodevelopmental disorders characterized by difficulties in socialization, communication, and stereotypical, restricted and repetitive behavior patterns. They may be primary or secondary. We apply different therapies specific to proven value of evidence, pharmacological readjustment, psychological care with specialized methods for these disorders. However despite including Physical rehabilitation treatment There is still a need to expand the knowledge about the interventions to be performed to achieve a more comprehensive rehabilitation of these patients.

Material and Method

Methods: Published literature, theses and books on the subject were revised. Using the Pubmed database, and those and selected articles that address the subject matter of study, organizing according to background, management and main applied therapies, and our own institutional experiences. nsive rehabilitation of these patients

Results

The usual interventions are carried out in 10 children who are part of the control group and 10 children with ASD, in which motor activities are reinforced, including the application of virtual reality media, which stimulate functionality.

Conclusion

Motor therapy influences child development by achieving the integration of movement, experience, thought, feeling and action, so it should always be included in the treatment programs of children with ASD. R-SA>: Published literature, theses and books on the subject were revised. Using the Pubmed database, and those and selected articles that address the subject matter of study, organizing according to background, management and main applied
therapies, and our own institutional experiences. Nsive rehabilitation of these patients. We found better results in the final evaluation of the patients in which several hours of physical therapy were used, added to the convention therapy used in our protocol of action, for the ASD.

HIGH FREQUENCY REPETITIVE TRANSCRANIAL MAGNETIC STIMULATION OF THE MOTOR CORTEX CAN ALLEVIATE NON-FLUENT APHASIA AFTER STROKE

J. Xia¹, Q. Xu¹, Q. Zhang¹, Z. Chen¹, Y. Chen¹, Y. Lu¹, P. Wang¹, Y. Sun¹, Y. Cheng¹
¹Shanghai Second Rehabilitation Hospital, Department of rehabilitation therapy, Shanghai, China

Introduction/Background

To investigate the effects of High frequency repetitive transcranial magnetic stimulation (rTMS) of the motor cortex on non-fluent aphasia in patients after stroke.

Material and Method

Six stroke patients displaying non-fluent aphasia were randomly assigned to an rTMS group and a control group using a random number table. Both groups were treated with conventional language therapy, while the rTMS group was additionally given 5 Hz rTMS over the motor cortex (M1) of the affected hemisphere 5 days a week for 4 weeks. The patients were stimulated at 100% of the motor threshold (MT), with 2 second trains and intervals of 3 seconds 120 times (1200 pulses) in a session. Before and after the 4 weeks of treatment, the Western Aphasia Battery (WAB) and the Communicative Abilities in Daily Living (CADL) test were conducted in both groups to evaluate their language function and communication ability.

Results

Only spontaneous speech improved significantly (P<0.05) in the control group after 4 weeks of treatment. In the rTMS group, the spontaneous speech, auditory comprehension, repetition, naming and aphasia quotient (AQ) had all improved significantly (P<0.05). Moreover, after the treatment, the average score of the auditory comprehension, repetition, naming and AQ of the rTMS group were significantly higher than those of the control group (P<0.05).

Conclusion

rTMS applied to the motor cortex of the affected hemisphere can significantly improve language function in those exhibiting non-fluent aphasia after stroke.

ENHANCING PHONOLOGICAL AWARENESS THROUGH VISUAL-AUDITORY SYSTEM
H. Miyakoda¹
¹Tsuda University, English Department, Kodaira-shi, Japan

Introduction/Background

According to a large-scale survey conducted in 2012, 6.5% of elementary and secondary students are diagnosed as having some kind of developmental disability. In the case of Japan, this corresponds to at least two or three students per class. One of the major learning disabilities that is directly affecting educators is dyslexia. Up until now, dyslexia had been an L1 issue, however, since 2011 when English became a mandatory subject in elementary schools in Japan, teachers now need to assess whether the learner is struggling with difficulty in L2 only or in both L1 and L2. If we follow the definition provided by the British Dyslexia Association or the Dyslexia Association of Ireland and define dyslexia as a “difficulty” rather than a “disability”, then the number of students who need special attention would be more than the two or three per class mentioned above. Therefore, it is of utmost importance that we find a systematic and effective way to support and instruct these individuals.

Material and Method

It has been pointed out in the literature that phonological processing ability and decoding skills are prerequisites for reading. The learning problems associated with dyslexia include difficulty in both these skills. Hence, in instructing individuals with reading difficulties, enhancing their phonological processing skills is crucial. In addition, problems associated with visual function can also cause difficulty for this type of learners.

Results

In this paper, we present the visual-auditory system that we have developed for enhancing phonological awareness. It is an easy-to-use system that can enhance autonomous learning and also employs visual data that learners with dyslexia can make good use of.

Conclusion

This is a practical and productive pronunciation software that should be enjoyable to use not only for the pathological population but also for foreign language learners of all ages as well.

Keywords

autonomous learning, dyslexia, phonological awareness

PRELIMINARY STUDY ON CAUSES OF ORAL REPETITION DEFICITS: EVIDENCE FROM CHINESE SPEAKERS WITH CONDUCTION APHASIA

Y. Zhang\textsuperscript{1}, S. Qingli\textsuperscript{1}, Y. Na\textsuperscript{1}

\textsuperscript{1}Beijing Tian Tan Hospital - Capital Medical University - China, Neurology Department, Beijing, China

Introduction/Background

Impaired repetition is one of the major symptoms of several aphasias, especially conduction aphasia. Repetition deficit is distinct from other language disorders such as anomia and dyslexia. A deep understanding of the etiology of repetition impairment could potentially improve rehabilitation strategies for aphasia. There are many findings about repetition have been obtained mainly in investigations of alphabetic languages (e.g. English and Italian). On the other hand, there have been few studies of non-alphabetic languages (e.g. Chinese). In this study, we tried to investigate the causes of repetition deficits by analyzing the performances of two Chinese speakers with conduction aphasia.

Material and Method

This study recruited two patients with conduction aphasia, with mild impairment of listening, understanding and articulation and disproportionate impairment of repetition function due to ischemic damage. For each patient, the following three aspects were assessed during the stable phase of the disease: phonological input, phonological output and short-term memory.

Results

The two patients performed normally in all speech input tasks. One patient exhibited difficulty with all speech production tasks (correct response rate, 54–75%) despite intact short-term memory capacity (memory span value, 3–8). The other patient had severe deficits in nonword repetition (correct response rate, 62%) and short-term memory (memory span value, 1–2), although he performed normally in other speech production tasks (correct response rate, 92–100%).

Conclusion

The repetition impairment of the two cases in this study had distinctive causes: disrupted phonological output processing and reduced short-term memory capacity. Our studies suggested there are many differences in the causes of repetition dysfunction in conduction aphasia between alphabetic and non-alphabetic languages.

Keywords
repetition deficiency; phonological output processing; short-term memory

Introduction/Background

Introduction

Ischemic monomelic neuropathy (IMN) is a painful and little-known disorder arising from nerve damage within a single limb. Typically, it occurs in diabetics or after fistula creations, particularly brachial. Here we describe two cases of IMN in non-diabetics with no surgical history. Case 1 is a 42-year-old woman who developed severe significant left-sided leg pain and swelling following new-onset acute low back pain. Case 2 is a 68-year-old woman with spontaneous persistent left foot pain. Both presented with pain, weakness, and sensory loss, and displayed extensive denervation on electrodiagnostics.

Background

Ischemic monomelic neuropathy (IMN) is a lesser-known consequence of vascular compromise with heterogeneous etiology. It is characterized as a non-compressive occlusion of blood supply causing neurologic effects without compromising other systems.

Material and Method

Other case-studies have examined acute IMN secondary to vascular surgery, or more chronically in those with peripheral arterial disease (PAD) and/or diabetes. However, reports of IMN presenting as nerve infarction from vascular occlusion in the absence of surgical intervention are sparse. We describe two such cases of IMN causing severe nerve injury with features mimicking complex regional pain syndrome type II (CRPS II).

Results

Both cases presented atypically for vascular ischemia. Both presented with pain in the leg with lower leg swelling and denervation on EMG studies. Both presentations were referred for management of complex regional pain syndrome as they mimicked the condition. Both were found to have extensive thromboembolic disease with atypical features. Patient in Case 1 resulted in an above knee amputation.

Conclusion
Intervention ultimately came too late for limb salvage in our first case—but enhanced pattern recognition heightened suspicion for the second, leading to a far more positive outcome. Together, these presentations serve to inform clinical judgement on investigating sudden-onset lower limb pain with acute denervation as IMN and nerve infarction.

ISPR8-0404
A SOUND SOLUTION FOR TRIGEMINAL NEURALGIA
H.M. Adahan
\textsuperscript{1}
\textsuperscript{1}Sheba Medical Center, ORTHOPEDIC REHABILITATION, Ramat Gan, Israel

Introduction/Background

Trigeminal neuralgia (TN), a severe and progressive form of pain is due to a tiny reversible lesion.

Ultrasound delivered to injured nerves has been shown in animal studies, to have neuroregenerative capacities. Until the advent of readily clinically applicable surface acoustic ultrasound technology, there was no clinically available ultrasound device that could safely extend its therapeutic effect for a prolonged period intra-cranially where the lesion of the trigeminal nerve is located.

Objectives: To determine the efficacy of Low Intensity Low Frequency Surface Acoustic Wave (LILF/SAW) ultrasound in the treatment of intractable Trigeminal Neuralgia (TN).

Material and Method

16 participants with refractory TN of at least six months duration, not responsive to pharmacotherapy, were recruited for a prospective, single-blind crossover study. LILF/SAW ultrasound treatment was provided overnight for up to eight hours of intermittent treatment using either an “active” Painshield\textsuperscript{®} or a “sham” Painshield\textsuperscript{®}. Patients initially given the “sham” Painshield\textsuperscript{®} followed by one month of “active” treatment were blinded as to which intervention they were receiving.

Pain was assessed using the Barrow Neurological Institute – Pain Scale (BNI-PS) at two weekly intervals and the McGill Pain Questionnaire (MPQ) at monthly intervals. Quality of life was assessed monthly using the SF-36 index.

The “number needed to treat” (NNT) was used to demonstrate the effectiveness of the intervention.

Results
Nine patients completed the study. BNI at intake and post-sham treatment was comparable. All nine patients chose the “active” treatment for the third month and after two months demonstrated a favorable response (NNT=2.22). A positive correlation was seen between the “active” treatment and the BNI scores, although due to the effect size the results did not reach statistical significance $T(8) = 2$.

**Conclusion**

LILF/SAW ultrasound may be a useful modality in the treatment of patients with refractory TN. Larger studies are required in order to confirm these findings.

ISPR8-0558
FACTORS ASSOCIATED WITH GAIT OUTCOME IN PATIENTS WITH LUMBOSACRAL PLEXOPATHY AFTER PELVIC FRACTURES

Y.H. Kim¹, J.S. Lee¹
¹Uijeongbu St. Mary’s Hospital- College of Medicine- The Catholic University of K, Rehabilitation Medicine, Uijeongbu-si, Republic of Korea

Introduction/Background

Lumbosacral plexus injuries usually occur in patients with severe trauma requiring intensive care. The purpose of this study was to identify the initial factors associated with gait outcome of lumbosacral plexopathy caused by pelvic fracture.

Material and Method

A total of 30 patients electrodagnostically confirmed with lumbosacral plexopathy caused by pelvic fracture were included in this retrospective study. The demographic, injury-related, fracture-related and electrodagnostic factors were compared between the patients with unassisted gait (UG) and assisted gait (AG) assessed in the out-patient clinic at an average of 641 days after the accident.

Results

Eleven patients (37%) remained AG during the follow-up period. The number of involved quadrant of pelvic fractures were larger (P = 0.011) and the proportion of unstable fracture were higher (P = 0.022) in the AG group than in the UG group. The initial muscle weakness was observed significantly more (P = 0.004) and the Dumitru and Wilbourn's scale (DWS) based on electrodagnostic studies were significantly higher (P < 0.001) in the AG group than in the UG group. All of the patients with DWS 1 and 2 showed UG. Among the patients with DWS 3 (n=17), only 6 patients showed UG. The injury severity score was not different between the AG and UG group (P = 0.092).

Conclusion

The final gait outcome is associated with the severity of pelvic fracture and lumbosacral plexopathy rather than the general severity of trauma. The severity of plexus injury evaluated by electrodagnostic study can predict the gait outcome.

DEGREE OF PRAXIS OF COMMAND FOR FACIAL MUSCLES IN HEALTHY INDIVIDUALS TO DEVELOP A NEW CLINICAL SCALE FOR FACIAL MOTOR FUNCTION IN PERIPHERAL FACIAL PARESIS

M. Baude¹, P. Lagnau¹, C. Gault-Colas¹, J.M. Gracies¹
¹CHU Mondor, Rééducation Neurolocomotrice, Créteil, France

Introduction/Background

Clinical scales evaluating facial motor function in Peripheral Facial Paresis (PFP) have poor precision and evaluate only few muscle groups, making the assessment of the disorder and of potential therapeutic interventions difficult. It is likely that healthy subjects do not share the same degree of praxis for all facial movements. The main objective was to assess the degree of praxis for command to each muscle group innervated by the facial nerve (VII) in a healthy subject population, to select those to include in a new PFP clinical motor scale. Reliabilities of the praxis rating performance were also evaluated.

Material and Method

This monocentric prospective study included video-recordings of adult healthy subjects performing 23 bilateral facial movements, on both oral command and mime of the investigator. Primary endpoint was the degree of praxis rated ordinally with a 3-point scale (0: total apraxia; 0.5= partial praxis; 1= perfect praxis). Each video was assessed twice by each rater four days apart. Intra- and inter-rater reliabilities were evaluated via kappa coefficients. Facial muscles were selected through a threshold of perfect praxis set at 80% of the total praxis in the sample, also taking into account reliability findings and clinical relevance.

Results

Facial video recordings of 50 healthy subjects (13M; 37.1±14.6 yo) were rated on two occasions by 3 PMR specialists (experience in PFP: 24.6±31.0 months). Eleven muscle groups were characterized by a praxis greater than the 80% threshold; 4 muscle groups were between 70 and 80% and 8 below 70%. Intra- and inter-rater agreements were very strong (kappa coefficients>0.60) for 10 and 14 muscle groups respectively.

Conclusion

Healthy individuals do not have the same degree of praxis on all facial muscle groups. Ten muscle groups were selected to be included in a new PFP clinical motor scale.

DOPPLER SONOGRAPHY FOR INTRANEURAL VASCULARIZATION OF ULNAR NEUROPATHY AT THE ELBOW -BEFORE AND AFTER SURGERY

Y. Kurihara¹, T. Furukawa², M. Kodama³, Y. Masakado³

¹Tokyo Medical Center, Rehabilitation Medicine, Meguro-ku, Japan
²Tokai university Hachioji Hospital, Rehabilitation Medicine, Hachioji, Japan
³Tokai University School of Medicine, Rehabilitation Medicine, Isehara, Japan

Introduction/Background

The finding of intraneural blood flow (IBF) signal by doppler sonography was interpreted in several ways at entrapment neuropathy. There is no report of IBF after surgery of ulnar neuropathy at the elbow (UNE). We investigated IBF in UNE before and after surgery.

Material and Method

Case series study. Subject: Nine arms (only Men) diagnosed and confirmed as UNE by surgery. All arms were performed grey scale sonography (GS) using an ultrasound machine (AprioXV; Toshiba) with 12MHz linear-array transducer and electrodiagnostic study(EDX) before and after surgery. We performed Doppler sonography (DS): 5 arms before surgery, 6 arms after surgery and 2 arms both. In EDX, diagnosis of UNE as follows: absolute motor CV from above elbow to below elbow of less than 50m/s and 1) or 2) 1) differential slowing (10m/s across elbow).2) conduction block across elbow. In GS, diagnosis of UNE as follows: cut-off value was the largest cross sectional area from 2 cm distal to 2cm proximal to the medial epicondyle >11mm².

Results

General findings before surgery: EDX diagnosed 8 arms as UNE but one. Seven arms were diagnosed as UNE by GS. General findings after surgery: All 9 arms were improved in clinical signs. EDX did not change. Eight were diagnosed as UNE by GS. DS findings before surgery: IBF signal was not detected in 3 arms and detected in 2 arms but absent pulse. DS findings of after surgery: Six arms were detected IBF signal and pulsatility. [Discussion] These findings may suggest that releasing entrapment site might decrease endoneurial fluid pressure and increase IBF.

Conclusion

About recovery from UNE after surgery, it may be useful to evaluate intraneural vascularity at the affected site with DS.

The aim of this study was to show the contribution of electroneuromyography (ENMG) in topographic diagnosis and management of obstetric brachial plexus palsy through the illustration of 10 clinical cases.

Material and Method

We report 10 clinical cases of children with obstetric brachial plexus palsy who underwent ENMG in our department. The ENMG tests done were sensory, motor conductions and needle electromyography. The ENMG avulsion criteria (preganglionic lesions) were retained according to the Sensory nerve action potentials (SNAP). The SNAP remained unaffected in pre-ganglionic lesions (except when the dorsal root ganglion was also affected) and attenuated or absent in a post-ganglionic lesion. The needle EMG study assessed denervation and re-innervation of muscles, and recorded co-contraction. ENMG data were compared with acquired clinical and imaging data.

Results

The mean age was 53 months (range: 4 - 108 months). Four patients had radiculopathy C5C6C7 and six patients had radiculopathy C5T1. Root avulsion was observed in six patients. This topographic diagnosis was confirmed by MRI for two patients and by clinical evaluation in the other cases. Concerning the needle EMG, six patients had a co-contraction of the biceps / triceps brachii muscles and the teres major / deltoid muscles, and required injections of botulinum toxins.
Conclusion

The ENMG is helpful to specify the type of the obstetrical lesion of the brachial plexus, pre or post-ganglionic, its location and its gravity. It also contribute to record the muscular co-contractions and consequently to modify the therapeutic strategy.

The electromyographic examination is difficult to perform and to interpret in children, but remains of great medico-legal and prognostic importance in case of the absence of recovery (1).

CLINICAL EFFICACY OF TAPE FEEDBACK THERAPY ON OCULO-ORAL SYNKINESIS FOLLOWING SEVERE PERIPHERAL FACIAL NERVE PALSY
T. Kasahara¹, S. Ikeda², M. Toyokura³, Y. Masakado¹
¹Tokai University, rehabilitation, 143 Shimokasuya Isehara, Japan
²Tokai University Oiso Hospital, rehabilitation center, 21-1 Gakkyou- Oiso- Nakagun- Kanagawa, Japan
³Tokai University Oiso Hospital, rehabilitation, 21-1 Gakkyou- Oiso- Nakagun- Kanagawa, Japan

Introduction/Background

Mirror feedback rehabilitation is effective in preventing the development of oro-ocular synkinesis following severe facial palsy. However, we do not have effective maneuvers to prevent the deterioration of oculo-oral synkinesis. We developed a new method of biofeedback rehabilitation using tape for the prevention of oculo-oral synkinesis. The aim of the present study was to investigate the efficacy of taping feedback rehabilitation.

Material and Method

Twelve consecutive patients with peripheral facial nerve palsy who developed synkinesis were divided into 2 groups. Six patients were treated with the new training method, and the remaining 6 patients were treated with conventional therapy as controls. In the experiment group, tape was placed around the mouth, and the patient was instructed to close the eyes so that no movements of the mouth would be perceived from sensations of the taped skin. After 4 weeks of training, facial movements were recorded and movie images were graded for mouth synkinesis using the revised Sunnybrook facial grading system by examiners blinded to patient grouping.

Results

Mouth corner contraction during eye closure was significantly weaker in the experimental group than in the control group.

Conclusion

Our new feedback method could help prevent the deterioration of oculo-oral synkinesis.

Introduction/Background

Post injection sciatic neuropathy (PISN) is a preventable iatrogenic distress with poor outcomes. Approximately half of the patients have incomplete peroneal or less often tibial nerve-related deficits, whereas approximately 20% of them have neuropathic pain without motor deficits. The following case series describes the treatment of conventional management-resistant neuropathic pain in PISN using fluoroscopy-guided transsacral block.

Material and Method

A 61, 75 and 56-year-old three male patients with conservative treatment-resistant neuropathic pain, numbness, and tingling due to PISN were admitted to the clinic. Under the fluoroscopic guidance, the patients were inserted through ipsilateral S1-S2-S3 neural foramina with a 10-cm, 22G Stimplex respectively. Then, 15 ml mixture of 80 mg methylprednisolone and 1% lidocaine injection were injected equally in each foramen. The patients’ neuropathic pain severity in sciatic nerve distribution was evaluated according to a 10-point numerating rating scala (NRS) and confirmed via Turkish version of LANSS pain scale before and after intervention.

Results

Prior to intervention, the patients reported severe neuropatic pain in daily activities; NRS scores were 5/10, 8/10 and 10/10, and the LANSS scores 17/24, 24/24 and 17/24 respectively. At 3 months following intervention, Patient 1 and 3 reported significant improvement in NRS and LANSS scores decreased to 1/10 and 2/10 and 8/24 and 4/24 respectively. In Patient 2, there was no acceptable change in NRS and LANSS scores.

Conclusion

Based on the results of this study, it seems that fluoroscopy-guided ipsilateral transsacral block can be considered as a safe and alternative treatment option for conservative treatment-refractory PISN but that this intervention may not be effective in all patients.

BILATERAL FOOT DROP AFTER UNACCUSTOMED PHYSICAL ACTIVITY: REPORT OF A CASE FROM OUR ELECTRODIAGNOSTIC CLINIC

U. akhlaque¹, N. akhtar¹, S.B. ayaz²
¹Armed forces institute of rehabilitation medicine, electrodiagnostic department, rawalpindi, Pakistan
²combined military hospital, electrodiagnostic, quetta, Pakistan

Introduction/Background

Isolated bilateral common peroneal neuropathy is a rare condition and has been reported following skeletal traction for bilateral femoral fractures, prolonged squatting, bariatric surgery, child birth, intermittent pneumatic compression, and external compressive wraps for a pelvic injury. We report here a case of bilateral common peroneal neuropathy subsequent to excessive unaccustomed physical activity in otherwise healthy individual

Material and Method

Case description

A 44-year-old obese male, educationist by profession, presented to us with complaints of bilateral foot drop after excessive unaccustomed physical activity. His body mass index was 31. He performed strenuous physical activity one day, followed by severe pain in his legs with swelling and redness and bilateral partial foot drop. The Doppler’s study of his legs revealed inadequate blood flow in femoral and popliteal arteries and suggestive of cellulitis. On 20th day of his symptoms, his nerve conduction studies were done.

Results

The motor responses for common peroneal nerves were bilaterally unevokable. The tibial and sural nerves studies were within normal limits. On electromyography, there were few fibrillations and no voluntary activity in tibialis anterior, external hallucis longus, and peroneus longus muscles. The short head of biceps femoris, gluteus medius, quadriceps, medial gastrocnemius, and L₅ paraspinal muscles showed normal motor unit action potentials with normal recruitment pattern. Thus, a diagnosis of bilateral common peroneal neuropathy proximal to tibialis anterior was made.

Conclusion

A number of metabolic, neurological and neuromuscular diseases may present with bilateral foot drop. Nerve conduction and electromyographic studies with relevant clinical findings can play a supportive role in reaching the diagnosis.

Introduction/Background

Traumatic Brachial Plexus Injury (BPI) is an important cause of chronic disability and pain affecting mostly young people after vehicle accident. Surgery is the gold standard treatment and rehabilitation is only based on conservative approaches. Rehabilitation-induced motor recovery is an unexplored field. However, evidences from animal models suggest the effectiveness of activity-dependent interventions to enhance neurological recovery. The last three decades saw a growth of innovative techniques and strategies to enhance upper limb motor outcomes after central nervous system damages. This includes robot-assisted training that offers highly intensive, repeatable, adaptable, and flexible therapies with a valuable quantification of motor performance. The aim of this study is to present the design and outcomes of an innovative rehabilitative approach adding a robotic training to usual care after surgery in a C5-C6-C7 brachial plexus injured young patient.

Material and Method

A single case study describing a 18-month upper limb training consisting of more than 100 sessions combining usual care and shoulder and elbow assist-as-needed robotic therapy. A monthly evaluation used clinical outcome (MRC grading scale) and robot-derived kinematic measures.

Results

The training was safe and well tolerated. Low changes in the MRC scores (Table 1) during the first months after surgery reflected the slow process of motor recovery, while robot derived kinematic results showed a not negligible evolution of motor control (Figure 1, between 3.5 months after surgery and 5 months after surgery, smoothness and mean velocity increase respectively of 14% and 13%, path error decrease of 200% and range of movement gain 1%).
Conclusion

This report demonstrates that an exercise-based training using a robotic system as an adjunct to usual care can be applied safely after a surgery following a BPI. This paradigm can also provide some further objective assessment. The effects on motor outcomes are uncertain although the time for re-innervation might be shorter.

SAFETY AND EFFICACY OF PLATELET-RICH PLASMA IN TREATMENT OF CARPAL TUNNEL SYNDROME: A RANDOMIZED CONTROLLED TRIAL

L. Bagherzadeh¹, S.A. Raeissadat¹, A. Karimzadeh², M. Hashemi³

¹shahid beheshti university of medical sciences, Physical medicine and rehabilitation department, tehran, Iran
²Shahid Beheshti University of Medical Sciences, Physical Medicine & Rehabilitation department, Tehran, Iran
³Shahid beheshti university of medical sciences, Anesthesiology Research Center, Tehran, Iran

Introduction/Background

Carpal tunnel syndrome is the most common peripheral entrapment neuropathy, for which conservative treatments are the first measures taken. However, these measures are not usually sufficient. Recently major attention has been drawn to platelet-rich plasma for its possible effects on axon regeneration and neurological recovery.

Material and Method

In this randomized controlled trial, women with a diagnosis of mild and moderate idiopathic carpal tunnel syndrome were chosen. They were randomly assigned to two groups: (i) a control group using only a wrist splint, and (ii) a platelet-rich plasma group that received wrist splints along with a single local injection of platelet-rich plasma. The outcome measures were assessed via Visual Analogue Scale, the Boston Carpal Tunnel Syndrome Questionnaire and electrophysiological findings including the peak latency of sensory nerve action potential and the onset latency of the compound muscle action potential.

Results

A total of 41 women were included (20 wrists as control group) and (21 wrists as platelet-rich plasma group). Before treatment there were no significant differences between the two groups except for the median peak latency of sensory nerve action potential which was significantly higher among the patients in the platelet-rich plasma group (p=0.03). All the measured variables significantly decreased in both groups after 10 weeks of treatment except for the median onset latency of the compound muscle action potential (p=0.472). Finally, the changes in neither of the evaluated outcome measures were found to significantly differ between the two groups, even when the analyses were adjusted for age of the patients.

Conclusion

This study showed that in a relatively short period of time after treatment, a single injection of platelet-rich plasma in the wrist does not significantly add to the effects of conservative
treatment with wrist splints, in regards to the women pain and symptom severity, functional status and electrophysiological parameters.

A 77-year-old man is referred from maxilofacial surgery because of “pain in the neck radiating to the shoulder”.

Medical history: Stroke that required thrombectomy two years ago leaving clumsy gait and global force deficit 4/5 in the left hemi body; atrial fibrillation, hypertension and polyarthralgia assessed by rheumatology, in remission. Surgical interventions of interest: Cervical adenopathies. Parotid node two years ago.

**Material and Method**

Physical examination showed great atrophy of the left trapezius, pain and functional impotence of the ipsilateral shoulder, with limitation for antepulsion and abduction of the left arm. Passive mobilization without articular limitations. Pain with the mobilization of the cervical spine.

An electromyogram was performed: severe axonotmesis of the cervical branch of the left spinal nerve, with signs of active reinnervation.

**Results**

Diagnostic impression: Nerve lesion of the cervical branch of the left spinal nerve in the context of parotid surgery.

**Conclusion**

The role of rehabilitation in these types of pathologies is based on pain relief, shoulder and cervical spine mobilization exercises as well as global strengthening of the affected limb (shoulder girdle muscles, deltoids, rotators, biceps ...), with the aim of recovering functionality and thus improve clinical manifestations.

Do not forget the possibility of nerve injuries in these types of surgeries, to refer and diagnose them promptly, as well as to establish treatment and prognosis.

LESION OF THE ACCESSORIUS NERVE IN EXTRIPATION OF THE LYMPHATIC GLAND OF THE NECK

S. Rajević¹, N. Mujović¹, A. Milovanović¹, S. Tomanović Vujadinović¹, T. Radovanović¹, S. Popovac Mijatov¹
¹Clinical Center of Serbia, Physical medicine and rehabilitation, Belgrade, Serbia

Introduction/Background

Accessorius nerve is the eleventh cranial nerve whose exterior branch innervates the sternocleidomastoid and trapezius muscles, but whose internal branch is added to vagus nerve. Radical neck dissection is a high risk for lesion of this nerve.

Material and Method

The purpose of work is to show the risk, by three different examples of sick women patients, for lesion of accessories nerve after the surgical intervention in the lateral neck region.

Results

Illustration of the cases: Three sick women (in a period of a year) came to complete their medical checkup in infirmary of the clinic for physical medicine and rehabilitation of the Clinical Center of Serbia with the referral diagnosis “shoulder impingement syndrome”. They have already been cured in the local health centres. When they came for the first time their main troubles were: pain and impaired mobility in shoulder joint.

Objective checkup: depression of shoulders, hypotrophy trapezius muscle, limited side flexion of head in the area of lateral part of the neck, namely discreet scar line in the area of sternocleidomastoid muscle are noticed. The amplitude of movement in the shoulder joint during the abduction was limited to 90°.

After the objective checkup, it is determined, by extra anamnesis, that the troubles appeared after the operation.

The infective substrate was proved by pathohistological examination after the extirpated lymphatic glands had been examined.

It also should be done: RTG of the specific shoulder joint with the top of the lungs and EMNG examination which, at the same time, proves the lesion of the eleventh nerve.

Conclusion
The surgical interventions in the area of the lateral part of the neck are the factor of high risk for the lesion of the eleventh cranial nerve.

When we recognize the lesion of this nerve on time, the patient can be adequately treated and we can prevent further complications.

CARPAL TUNNEL SYNDROME TREATMENT: THE EFFECT OF SCAPHOID AND HAMATE MOBILIZATION

S.A. Raeissadat¹, V. Dinarvand², M. Babaee¹, I. Abdollahi²
¹Physical medicine and rehabilitation research center, Shahid Beheshti university of medical sciences, Tehran, Iran
²Physiotherapy Department, University of Social Welfare and Rehabilitation Sciences, Tehran, Iran

Introduction/Background

The aim of this study was to assess the effects of scaphoid and hamate bones mobilization on patients with carpal tunnel syndrome.

Material and Method

In this randomized clinical trial, 40 patients with mild and moderate carpal tunnel syndrome were randomly assigned in two groups. Intervention group received splinting with hamate and scaphoid mobilization, control group received splinting only. Outcome variables included pain (based on visual analogue scale), symptom severity and functional status (based on Boston questionnaire) and nerve conduction study measured before and 10 weeks after the treatments.

Results

At the end of study, both groups showed an improvement in pain and symptom severity, functional status as well as median nerve conduction study. Although there was no statistically significant difference between the groups regarding changes in median nerve sensory and motor distal latencies; the improvement was significantly higher in pain (P<0.05) and symptom severity as well as functional status in mobilization group (P<0.05).

Conclusion

Hamate and scaphoid mobilization can be used as an effective option in women with mild and moderate carpal tunnel syndrome. Further investigation is required for determining long-term effects and cost-effectiveness of this modality.

REFERENCE VALUE FOR INFRAPATELLAR BRANCH OF SAPHENOUS NERVE CONDUCTION STUDY: CADAVERIC AND CLINICAL STUDY

D.H. Song¹, M.E. Chung¹
¹The Catholic University of Korea- College of Medicine- St. Paul's Hospital, Rehabilitation Medicine, Seoul, Republic of Korea

Introduction/Background

There are numerous reports on infrapatellar branch of saphenous nerve (IPBSN) injury due to various surgical procedure on the medial aspect of knee. The aim of this study was to investigate relative location of the IPBSN based on anatomical landmarks through cadaveric study, and to identify the optimal stimulation and recording point for use in IPBSN nerve conduction study. In addition, we performed sensory nerve conduction study at the obtained optimal stimulation and recording site to confirm that the obtained location is clinically applicable, and to propose the reference value.

Material and Method

Twelve lower limbs from six cadavers were studied. We defined the optimal stimulation site as the point IPBSN exits the sartorius muscle and the distance or ratio were measured on the X- and Y- axis based on the line connecting the medial and lateral poles of the patella. We defined the optimal recording site as the point where the terminal branch met the line connecting inferior pole of patella and tibial tuberosity, and measured the distance from the inferior pole. Also, nerve conduction studies were performed with obtained location in healthy adults.

Results

In optimal stimulation site, the mean value of X-coordinate was 55.50 ± 6.10 mm, and the ratio of the Y-coordinate to the thigh length was 25.53 ± 5.40%. The optimal recording site was located 15.92 ± 1.83 mm below the inferior pole of patella. In our sensory nerve conduction studies through this location, mean peak latency was 4.11 ± 0.30 ms and mean amplitude was 4.16 ± 1.49 μV.

Conclusion

The optimal stimulation site was located 5.0-6.0 cm medial to medial pole of the patella and 25% of thigh length proximal to the X-axis. The optimal recording site was located 1.5-2.0 cm below inferior pole of patella. We have also confirmed that this location is clinically applicable.

Introduction/Background

Surgery in facial palsy aims to restore the face’s symmetry in rest as well as reanimation of the smile. Gracilis flap is a therapeutic option for patients with long term facial palsy.

Our objective is to describe evolution and functional results of patients treated surgically through gracilis transposition.

Material and Method

27 patients with chronic (>12months) unilateral facial palsy were treated with gracilis transposition to reanimate smile. Demographic information such as age, gender and personal history was gathered, as well as onset of facial palsy, affected side, etiology, date and kind of surgery, complications and initiation of movement. Functional results were evaluated with the Facial Disability Index and the smile item on the Sunnybrook Scale.

Results

Mean age was 50 years old and a slight prevalence of women over men and right sided palsy over left was observed. Most prevalent etiology was iatrogenic after acoustic neuroma surgery (33.3%). 59% of palsies were less than 5 years old in evolution.

Donor nerve most frequently used was the masseter (48%), followed by the cross-face sural nerve graft with masseter babysitter (33.4%) and lastly, cross face nerve graft (18.6%). Four patients required a second reanimation surgery. Most common complication was scar retraction at the angle of the mouth.
Majority of patients initiated smile around 2-4 months after surgery, being a complete or almost complete movement in 66.6% of patients. Facial Disability Index Global Score was less than 100/200 in 20% of patients and more than 150/200 in 44% of them.

**Conclusion**

Functional results were good in more than half the patients, with mild-moderate facial disability. There is a tendency to associate the use of masseter donor with better smile movements and facial disability indexes, even though results are not statistically significant was scar retraction at the angle of the mouth.

FAMILIAL BELL’S PALSY: A CASE REPORT
A. Girbau¹, N. Perez Fernandez¹, N. Lorente Caparrós¹, M. Torra Parra¹, L. Solà Ruano¹, R. Garreta Figuera¹
¹Hospital Universitari Mutua Terrassa, Physical Medicine and Rehabilitation, Terrassa, Spain

Introduction/Background
The etiology of Bell’s palsy (BP) is still not defined. Familial inheritance has been found in 4–14% of cases. We describe a case of one such family affected by BP and review the current literature concerning hereditary influences.

Material and Method
The patient case history, clinical examination and detailed family history provided by the patient.

Results
We report the case of a ten-month-old female presented with acute onset of right-sided facial muscle weakness. BP is rare in children under the age of two years. Further questioning revealed she was one of seven members with a history of BP. One of those was another children (seven-months-old) affected by BP. (Figure 1)

The manifestation is slightly greater in females at a 1.5 to 1 ratio. There are some described causes of facial nerve palsy in children, as it can be congenital or acquired.
The literature showed the association between HLA and BP. It was postulated that familial facial palsy is an autoimmune disease with genetic predisposition, suggesting autosomal dominant inheritance with low penetrance or variable penetrance. One study of 92 patients with BP found a significant decrease in the HLA class 2 DR antigen and severely decreased levels of CD3/CD4 T cells, suggesting that it may exist resistance HLA-DR gene. Furthermore, it is described in literature that a structural abnormality of the dimension of facial canal is the most common cause of the familial facial palsy.

**Conclusion**

There are few cases described about familial facial palsy in the literature. It’s uncommon BP in children under two years. The familial clustering of BP is not an incidental happening, the number of related cases suggests the familial influence component. Familial facial palsy is an autoimmune disease with an HLA genetic association or anatomical abnormality of the facial canal.

RESULTS OF A REHABILITATION PROGRAM IN PERIPHERAL FACIAL PALSY

G. Mologhianu¹, M.D. Clantau¹, G.L. Gheorghieviçi¹, R. Nartea¹, B.I. Mitoiu¹, A.S. Nica¹
¹University of Medicine and Pharmacy “Carol Davila”- Bucharest- Romania, Rehabilitation, Bucharest, Romania

Introduction/Background

Peripheral facial palsy has usually multiple etiologies. Our patients have comorbidities like diabetes mellitus type 2, hypertension, dyslipidemia and obesity. The rehabilitation program includes a proper assessment and a well-designed recovery program. Our aim in this study is to observe the efficacy of rehabilitation programs in this type of pathology.

Material and Method

We have formed a group of 6 out-patients with peripheral facial paresis developed in August – October 2017 that followed a rehabilitation program including physical therapy, electric stimulation and manual therapy. The therapy started after a detailed clinical assessment including cardiologic, diabetologic, neurological evaluation, otoscopy and the patient’s history aspects. One of the main points of interest regarding clinical evaluation was eyelid closure.

Results

After 1 month of intensive daily program we could measure an improvement of the eyelid closure for all our subjects.

Conclusion

Peripheral facial palsy severely affects the patient’s quality of life, not only regarding the facial movement, but also from the social and psychological point of view. The associated rehabilitation programs consisting of safe therapy has shown it’s significant efficacy on our patients. The first step of motor control management is the training of synthetic and analytic movement and then their inclusion in the activities of daily living in order to regain functionality and symmetry.

Introduction/Background

Lipomas are extremely common benign mesenchymal tumours, which can have a superficial or deep location. The latter are much less common, usually larger, and more prone to compression of the surrounding tissues, being asymptomatic until they compress neurovascular structures. Posterior interosseous nerve (PIN) is the deep branch of the radial nerve, after its emergence above the elbow. Paralysis of the PIN secondary to compression is a rare clinical condition, more commonly related to its pathway beneath the arcade of Fröhse. Tumours are a relatively rare but potential cause of neuropathy. The pattern of physical symptoms may be quite variable, but are more often manifested as a hand drop.

Material and Method

A 68 years-old female presented with a 7 months progressive right hand drop and a concomitant painless mass over the posterolateral aspect of the proximal forearm. No deficits on elbow flexion muscle strength or superficial sensation were found. Electrophysiological testing indicated a mixed, demyelinating and axonal lesion of the PIN of the radial nerve. MRI revealed a large deep capsulated mass on the lateral aspect of the proximal forearm suggestive of lipoma.

Results

The surgical exploration confirmed the compression of the PIN by the lipoma that was successfully excised. Histological examination confirmed the diagnosis. The patient began an occupational therapy program regaining almost complete motor function with residual deficits on finger extension.

Conclusion

This clinical report brings up the importance of thorough physical examination and a high level of suspicion when examining a patient with hand and wrist muscle extensor weakness which can prevent the deficit progression and hand function loss. Prognosis is related to the duration of symptoms with surgical excision and rehabilitation being essential for functional recovery of the upper extremity.

ATRAUMATIC CASE OF ACUTE FINGER EXTENSION LOSS: WHAT QUESTIONS BEHIND AN ISOLATED POSTERIOR INTEROSSEOUS NERVE PALSY?

D. Mesquita

Hospital da Prelada, Physical and Rehabilitation Medicine, Maia, Portugal

Introduction/Background

Compressive syndromes of the radial nerve present themselves in distinct ways, sensory, motor or mixed.

The specific interest about this topic was a Case Report of a 76-year-old man suffered from acute isolated unilateral extension loss of third to fifth fingers after a sudden back pain on bedtime sleeping, with no history of recent elbow trauma or progressive finger extension weakness. He has cervical degenerative pathology with bilateral hand parestesias and possible medular C5-C7 compromise.

Electromyographic study showed an isolated posterior interosseous mononeuropathy with significant axonal loss.

MRI scan revealed sequelae of radial head and coronoid fractures and possible Radial Collateral Ligament, Biceps brachii tendon and Common Extensor Tendon tears.

The aim of this study was to gain a better understanding of the possible etiologies of an isolated atraumatic posterior interosseous nerve (PIN) involvement and palsy.

Material and Method

The data were obtained from Pubmed database from 1980 to 2018, using keywords search combination of “posterior interosseous nerve”, “palsy”, “compression”, “syndrome”, “neuropathy”, and “entrapment”.

Results

Multiple etiologies exist of atraumatic PIN palsy including external compression (eg. anatomical structures, mass lesions), inflammatory or neuralgic amyotrophy, and spontaneous fascicular hourglass constriction of the nerve.

Conclusion
On the case report presented possible etiologic causes were a Frohse’s Arcade entrapment, another anatomical overnight compression can’t be excluded a late complication of an old elbow fracture.

The history of paralysis onset, predisposing factors, combined with the physical examination contribute to determining the pathophysiology involved.

Methods for diagnosing these injuries are based on clinical criteria but may also include imaging and electrophysiological studies to determine the severity of the nerve injury and to rule out mass lesions. Nerve ultrasound is evolving and should also be included.

USE OF BOTULINUM NEUROTOXIN TYPE A IN MANAGEMENT OF A RARE CASE OF SPINAL SEGMENTAL DYSTONIA FOLLOWING SCOLIOSIS SURGERY
S. Javaid, E. Church
1ABM University Local Health Board, Rehabilitation Medicine, Port Talbot, United Kingdom

Introduction/Background

The pathogenesis of movement disorders due to peripheral lesions to neural structures has been controversial in the past, but has recently been accepted. There have been 6 reported cases of movement disorder following spinal disc surgery. We report a case of development of Thoracic spinal segmental dystonia in an adult patient following corrective scoliosis surgery.

Material and Method

A case study using patient's clinical presentation in out patient setting, review of clinical notes from Neurology and Spinal surgery, review of literature and feedback both written and video footage following treatment with Botulinum Neurotoxin injections were used.

56 years old lady with scoliosis from the age of 14 years was treated with corrective surgery in 20014. she developed spinal segmental movement disorder 3 months post surgery. This was associated with severe pain and spasms were relieved on lying supine and were aggravated in sitting and standing oppositions. She has had extensive neurological investigations to rule out other causes. She has had a trial with a number of oral analgesics and Clonazepam but without any success. She was given a trial with trigger point injections with steroids and local anaesthetics, but She responded exceptionally well to multiple injections and incremental doses of Botulinum Neurotoxin Type A(250units of xemin ).

Results

Botulinum Neurotoxin is an effective treatment in reducing pain and involuntary spasms of spinal segmental muscles as published in neurology 2008;70:1699

Conclusion

Botulinum Neurotoxin should be considered as a safe and effective first line treatment for patients with rare spinal segmental Dystonia

THE CONTRIBUTION OF EARLY PROGRESSIVE VERTICALIZATION IN THE CARE OF SPINAL CORD INJURED PATIENTS

G. MEYA KIALAGEORGES¹

¹University Hospital of Kinshasa, Physical Medicine and Rehabilitation, Kinshasa, Democratic Republic of the Congo

Introduction/Background

Background and objective:

The prolonged bed rest observed in spinal cord injured persons, exposes to serious complications which hinder the rehabilitation and compromise the future of the latter, the aim of this case study was to verticalize them as early as possible, in order to limit the extension of the complications and to ensure a better quality of life.

Material and Method

This prospective study conducted at University Clinics in Kinshasa on 32 patients including 28 men and 4 women (sex ratio: 7). During the period from July 2009 to July 2010, having followed a progressive early verticalization protocol after immobilization under plastered or removable corset.

Results

Partial or total recovery: ASIA A, B, C to ASIA D and C: ASIA D to E was observed in 53.3% of all patients in our series. Neurological recovery (ASIA between 31 and 50) is observed in 25% of cases in trauma patients. Table 18: Evolution of ASIA score at the end of the study in non-traumatic patients. Neurological recovery (ASIA between 25 and 43 out of 50) is observed in 58% of cases.

Conclusion

Early progressive verticalization has improved management by reducing the length of hospital stay, improving functional recovery and reducing the frequency of complications.

ACTIVATION OF THE INTRACELLULAR CA++-AMPK PATHWAY AMELIORATES APOPTOSIS AND IMPROVES AUTOPHAGY IN DIABETIC PERIPHERAL NEUROPATHY

H.W. Kim¹, C.W. Park², Y.J. Ko¹, J.H. Park¹

¹The Catholic University of Korea, Physical Medicine & Rehabilitation, Seoul, Republic of Korea
²The Catholic University of Korea, Internal Medicine, Seoul, Republic of Korea

Introduction/Background

A decrement of AMP-activated protein kinase-eNOS bioavailability is critical for the pathogenesis of diabetic peripheral neuropathy. We evaluated the neuro-protective effect of cinacalcet on DPN by activating the AMPK-eNOS pathway using db/db mice

Material and Method

The db/db mice and db/m controls at 8 weeks of age were divided to receive either a regular diet or a diet containing cinacalcet. Mice were evaluated sciatic motor nerve conduction and tactile response. We performed Mason’s trichrome staining and immunohistochemistry for type IV collagen and 8-hydroxy-deoxyguanosine, an oxidative DNA damage marker. For immunofluorescence double staining, apoptosis was detected by ApopTag Fluorescein In Situ Apoptosis Detection Kit. The sciatic nerve specimens were double stained and we measured unmyelinated fiber areas and axonal areas using NIH Image J under a transmission electron microscope. Western blot assay was performed total protein of sciatic nerve with specific antibodies for CaSR, CaMKK, total LKB1, phospho-Ser428 LKB1, total AMPK, phospho-Thr172 AMPK, total eNOS, phospho-Ser1177 eNOS, PGC-1.

Results

The db/db mice showed sensorimotor impairment, nerve fibrosis and inflammation, apoptosis, disorganized myelin with axonal shrinkage and degeneration, and fewer unmyelinated fibers in the sciatic nerve(Fig. 1) compared to db/m mice. Cinacalcet administration, without causing any changes in blood glucose and Ca++ concentrations, significantly increased the paw withdrawal mechanical threshold and decreased the motor conduction latency(Fig 1), and ameliorated the deterioration of sciatic nerve pathology(Fig 2), accompanied by increases in the expressions of calcium-sensing receptor-CaMKK and phosphorylation of AMPK-eNOS(Fig 3) in diabetic mice.

Conclusion

Cinacalcet may play an important role in the prevention and amelioration of DPN by amplifying AMPK signaling.

ARE THE NONPARALYTIC MUSCLES OF POLIO SURVIVORS FREE FROM THE RISK OF POST-POLIO SYNDROME?

K. Sawada¹, M. Horii¹, D. Imoto¹, Y. Mikami¹, T. Kubo¹

¹Kyoto Prefectural University of Medicine, Department of Rehabilitation Medicine, Kyoto, Japan

Introduction/Background

The aim of this study was to reveal the relation between the neurogenic change in the nonparalytic muscles in upper and lower limbs of Polio survivors and the later muscle strength decline.

Material and Method

Retrospective study. We looked back the data of electromyography (EMG) of Polio survivors in our Polio clinic (average age: 58.9). Muscles whose strength at EMG had been normal were extracted. We looked up the muscle strength at EMG time and two years later from medical record.

Results

The subjects were 23 Deltoid (middle strand), 40 Biceps branchii, 36 Triceps branchii, 24 Vastus lateralis, 19 Tibialis anterior, and Gastrocnemius (medial head). The ratio of neurogenic change subject (giant spike or interference pattern reduction) was, 30.4%, 25.0%, 36.1%, 62.5%, 47.4%, and 73.7%, respectively. In neurogenic change group of Biceps, 50.0% showed decline in their muscle strength. In non-neurogenic change group of Deltoid, 25.0% showed decline in their muscle strength.

Conclusion

Present study suggested that some muscle strength decline may be caused by Post-polio syndrome (PPS), and that EMG might be the most useful tool for the risk detection of PPS, especially for Biceps branchii. On the other hand, the fact that 25% of Deltoid non-neurogenic change group showed muscle strength decline was not understood in this study. Pain or disuse from disorder in shoulder joint might possibly be as a cause.

SPINAL ACCESSORY NERVE INJURY AFTER CERVICAL LYMPH NODE RESECTION: REHABILITATION MANAGEMENT

N. Mosquera Morales¹, A.B. Teixeira Taborda¹, G. Díaz Cano²
¹Jimenez Díaz Foundation Hospital, Physical and Rehabilitation Medicine Department, Madrid, Spain
²Jimenez Díaz Foundation Hospital, Clinical Neurophysiology Department, Madrid, Spain

Introduction/Background

Spinal Accessory nerve (SAN) injury is a rare entity. Most common causes are iatrogenic surgical lesion, cervical trauma, inciso-contusive wounds and idiopathic closed traumatisms. SAN injury leads to the paralysis of the trapezius muscle, manifested with pain and functional impotence. The diagnosis is fundamentally clinical and neurophysiological, allowing the precise location of the lesion, the degree of intensity and assesses the potential for regeneration.

Material and Method

A 33 year old man diagnosed with Large B-cell Lymphoma presented with a two month history of shoulder pain and weakness after lymph node resection in the posterior triangle of the neck (zone V). On physical examination, there was atrophy of trapezius muscle and impossibility to flex and abduct the right shoulder over 90 degrees, with anterior displacement of the humeral head (Fig. 1).

Neurophysiological study was requested: the result proved lesion of SAN with severely decreased amplitude of the motor action potential and abnormal spontaneous activity in the electromyography of trapezius, without affecting sternocleidomastoid muscle (Fig. 2).

The patient started a rehabilitation program including electrotherapy, active and passive exercises and muscle strengthening, with progressive recovery. Five months after the injury, there was a dramatic improvement of the trapezius muscle function, complete active mobility and the patient was pain free (Fig. 3). Nerve conduction studies and EMG revealed significant recovery of the axonal damage, while a demyelinating component was more evident (prolonged motor latency).

Results

The favorable clinical evolution of this patient and final EMG findings, demonstrated good prognosis.

Conclusion
Scapular winging is a rare condition that can cause pain and altered scapulohumeral rhythm, affecting the ability to perform activities of daily living. A thorough history and physical examination should be performed in patients presenting with shoulder pain in order to establish the correct diagnosis and select the early appropriate rehabilitation treatment.

FACTORS THAT AFFECT AMBULATION IN CHARCOT MARIE TOOTH PATIENTS
E. Ramos¹, C. Hinkel¹, L. de Virgilio¹, A. Firpo-Pabon¹, J.G. Conde¹, S. Grigg¹, R. Arias-Berrios¹
¹School of Medicine- University of Puerto Rico,
Department of Physical Medicine- Rehabilitation & Sports Medicine, San Juan, Puerto Rico

Introduction/Background
Charcot–Marie–Tooth (CMT) disease is the most common inherited peripheral neuropathy. Limited information on imaging in neuromuscular conditions is available and further less in Hispanic patients. Sonographic examination has been used to describe the pathology of the nerves in patients with CMT. The purpose of this study is to describe imaging of the nerves and muscles that affect ambulation using sonographic and evaluate their association with walking speed.

Material and Method
21 patients previously diagnosed with a demyelinating form of CMT via genetic testing and/or electrodiagnostic study with family history of CMT were evaluated. Ultrasound (US) measurements of the Common Peroneal Nerve (CPN), cross-sectional area (CSA) and Anterior Tibialis muscle (ATM) depth were performed. CPN Compound Motor Action Potential (CMAP) Amplitude recording at the ATM was recorded. Later a 10 meter walk test and a Stair climb test were performed.

Results
US evaluation showed significant increase in Median and CPN CSA average when compared to reference data. Although not statistically significance there was a positive association between CMAP amplitude recording at the ATM and ATM Depth in Axial plane or size and ambulation velocity w/o AFO. This could be related to the fact that CPN with less pathology nerve conduction should be able to adequately supply the ATM, therefore better Amplitude is obtained and less muscle atrophy is found. The negative association was found between CPN CSA and Ambulation velocity w/o AFO not statistically significant. As the CPN increases in size, ambulation dysfunction is further observed in this population.

Conclusion
To our knowledge no prior study has described the CPN and ATM with US which are important components for ambulation in CMT. US is a sensitive and relatively accessible tools for evaluating this population. Future correlation of US findings and functional test is a potential field of research for future projects.

BILATERAL PARSONAGE-TURNER SYNDROME WITH GENETIC ETIOLOGY
A. ESPINAL†, A. Cardenas†
†Ips Somher, CUNDINAMARCA, bogota, Colombia

Introduction/Background

Female 31 years, presented pain in the left shoulder, continuous, incapacitating irradiated to the entire limb that progressively decreased then presented paresthesias, muscle weakness, hypotonia and areflexia. She was diagnosed with parsonage-Turner syndrome and received rehabilitation management with partial motor improvement. Six years later, she presented the same signs and symptoms in the right upper limb. Genetic confirmation of hereditary amyotrophic neuralgia is performed.

Material and Method

She presented hypotonia of upper limbs with areflexia, muscle strength was proximal 3+/5 elbow and carpal extensor 3/5 flexor fingers 3+/5, thumb abductor 3/5. Magnetic resonance of right brachial plexus reported increased signal intensity of trunks and brachial plexus cords. Electrodiagnosis showed motor neuroconductions of right radial nerve absent and left with decrease in amplitude, comparative decrease greater than 50% in amplitude of the right median and ulnar nerves and absence of sensory potential of left median nerve. Stable neuropathic units in all muscle groups of the left upper limb and signs of membrane instability with active reinnervation in the right extremity, normally in cervical paraspinal. Genetic analysis reports a complete SEPT9 carrier gene sequence in variant c.s26cT heterozygosis.

Results

Motor and sensitive compromise without cervical root compromise is compatible with brachial plexopathy. Genetic analysis reported pathogenic variant associated with hereditary amyotrophic neuralgia, transmitted in an autosomal dominant fashion, only known gene related to this pathology is SEPT9, its analysis can detect up to 55% of the cases.

Conclusion

Patient presents typical clinical of parsonage-Turner syndrome, she is within 10 to 30% of cases with bilateral involvement. The hereditary etiology was determined although literature doesn’t presented differences in management and prognosis.

POSTERIOR INTEROSSEOUS NERVE SYNDROME
P. Pereira¹, D. Dantas¹
¹Matosinhos Local Health Unit, Physical and Rehabilitation Medicine, Porto, Portugal

Introduction/Background

Posterior interosseous nerve (PIN) syndrome is a well-recognized, but uncommon entity caused by compression of the radial nerve. The most common site of compression is at the level of the supinator muscle. PIN syndrome can be caused by intrinsic as well as extrinsic lesions. Trauma, inflammatory processes such as rheumatoid arthritis, and space-occupying lesions may be causative.

Material and Method

A 57 year old male present himself at the hospital emergency with difficulty in extending his right hand and fingers, as well as finger paresthesia. He had previously fell over his elbow 5 days ago. He was evaluated by an orthopedic surgeon whom detected lack of strength of the hand extension (4/5) and metacarpophalangeal and interphalangeal extension (2/5) - an x-ray was requested. The x-ray did not show any fracture of the elbow region. Later, he was redirected to a physical and rehabilitation medicine appointment with a subsequent diagnosis of posttraumatic PIN palsy. He started to wear a position orthosis and initiated rehabilitation treatment. He underwent 2 months of treatment and is now asymptomatic.

Results

.

Conclusion

Posterior interosseous nerve (PIN) syndrome is a well-recognized, but uncommon entity caused by compression of the radial nerve. Traumatic lesions are even more uncommon. In this case, no electromyography was made to demonstrate PIN palsy, due to the typical presentation. Conservative treatment is the gold standard and the result was satisfactory.

²Shiraz University of Medical Sciences, Research Center for Psychiatry and Behavioral Science, Shiraz, Iran
³Shiraz University of Medical Sciences, Student Research Committee- Shiraz Geriatric Research Center-, Shiraz, Iran

Introduction/Background

Major depressive disorder (MDD) is one of the most prevalent diseases of psychiatry. There is evidence that suggests the autonomic nervous system involvement in depression. Sympathetic Skin Response (SSR) is used to evaluate the autonomic system. Unlike Nerve Conduction Study (NCS) that evaluates large myelinated fibers; SSR evaluates thin unmyelinated fibers. The purpose of this study was to compare SSR in patients with MDD and a healthy control group.

Material and Method

SSR in 20 patients suffering from MDD was compared with 19 healthy subjects. SSR latency and amplitude of bilateral palmar (Median nerve) and plantar (Tibial nerve) were recorded.

Results

The data received from this study showed an increase in SSR amplitude in the upper extremities in patients (P < 0.05). In the lower extremities, difference in SSR amplitude was not observed. There was no difference in SSR latencies between the case and control group in upper and lower limbs.

Conclusion

The results of our study reveal that abnormality in SSR recorded from upper limbs reflects autonomic nervous system dysfunction in MDD patients.

MANAGEMENT OF PHOBIA CONCERNING INTERMITTENT SELF-CATHETERIZATION IN A QUADRIPLEGIC PATIENT
V. Bourrat-salducci

Centre Bouffard-Vercelli, Neuropsychology, Cerbère, France

Introduction/Background

The phobias (DSM 5) include three categories: agoraphobia, social phobia and specific phobia. The practice of self-catheterization greatly improves the quality of life in quadriplegic patients. We describe the case of a quadriplegic patient that have developed a phobia concerning self-catheterization, his diagnosis and care.

Material and Method

Mr. R. is a 33 years old patient with quadriplegia following a road accident. He has adequate upper limb motor skills to consider self-catheterization, but the phobia of invasive medical procedures makes this eventuality impossible. The evaluation includes Fear survey, FFS-III and I-CAT. The care took place into three parts: psycho-education, tension training to fight the specific physical symptoms of this type of phobia and graduated exposure reading brochures explaining the catheterization, material handling, visualization of videos and finally realization of a self catheterization.

Results

The evaluation of the therapy only includes some indices: "specific blood injury phobia" score of the Fear survey, "injury illness" scale of the FFS-III, psychological dimension of the I-CAT and anxiety score of the Fear survey. They shows a good effectiveness of the management after 20 sessions of therapy. The measuring tools and the daily functionning objective the efficiency. Mr. R. was able to practice self-catheterization.

Conclusion

Mr. R. can conduce his self-catheterization himself and enjoy the autonomy that this technique brings. This support, which took only three month, yielded a result with a major impact on quality of life, autonomy and health of the patient. It could be successfully applied to others people in the same situation of severe disability

QUALITY OF LIFE AND DEPRESSION IN PATIENTS HOSPITALIZED WITH NEUROLOGICAL DISEASES OF THE UNIT OF PHYSICAL MEDICINE AND REHABILITATION CENTER
W.N. Vega Navarro¹
¹Instituto Mexicano del Seguro Social, Departamento de Hospitalizacion. Unidad de Medicina Fisica y Rehabilitacion Region Centro. UMAE Hospital de Traumatologia y Ortopedia "Lomas Verdes", CdMx, Mexico

Introduction/Background

Quality of life refers to the level of satisfaction or wellbeing derived from the objective evaluation, which the person performs in various domains of his life: physical, psychological, social and environmental. Neurological diseases generate a great impact that interrupts the abilities and resources of the people who suffer them, it leads to physical, mental and socioeconomic problems that affect social relationships, privacy and freedom, this is reflected in states of depression which is characterized by a deep sadness, mood decay, loss of interest and decrease in psychic functions, as well as in the quality of life. Our objective was to determine the level of quality of life in relation to depression in patients with neurological diseases.

Material and Method

Statistical-descriptive-transversal study, with 118 hospitalized patients, between 15 and 85 years of age, both sexes, with neurological diseases. The Whoqol-Bref (QOL) and Beck depression questionnaires were applied the analysis is made using the Student's T test.

Results

The mean quality of life was 83.32 + 14.13 points that covers a medium level, that is, patients are dissatisfied with their quality of life in 53.2%. In this respect, higher quality is observed in their environment (25.3 + 4.6), followed by psychological aspects (21.3 + 4.3), later physical (20.49 + 4.7) and the lowest in social relations (9.5 + 2.5). Likewise, moderate-severe depression presents an average of 15 points less in QOL, compared to no or minimal depression.

Conclusion

Patients, who integrate a greater degree of depression, tend to show a lower quality of life sensation. The alteration of the quality of life occurs mainly in the breakdown of personal, family, social relationships, in sexual activity and inadaptation; as well as, in the physical limitations of
activity, pain and sleep difficulties. Low quality of life and severe depression restrict medical and rehabilitation processes.

Keywords

DIFFERENCES IN BRAIN DERIVES NEOUROTROPHINS FACTOR (BDNF) SERUM LEVEL IN ELDERLY FROM HEALTHY PERSON WITH ACTIVE SPORTS ACTIVITY COMPARE WITH DEPRESSIVE PATIENT.

F.N. Kurdi¹

¹Lecturer, Physical Medicine and Rehabilitation Medical Faculty Sriwijaya University, Palembang, Indonesia

Introduction/Background

Brain Derived Neurotrophin Factor (BDNF) is a protein abundant in brain and peripheral nerves, affecting neuronal development, growth and survival. A lot of research has been conducted into the possible involvement of brain-derived neurotrophic factor (BDNF) in the pathogenesis of human depression while on the other hand exercise prove to increase BDNF level in blood.

Material and Method

This study was an experimental studies to compare BDNF level from elderly with age from 65 years old and up with active physical exercises (HS) with elderly with the same aged with depression (DS). Setting: Healthy elderly person who joined Healthy Heart Club Exercises Program in Palembang and elderly patient with depression from ErnaldiBahar Psychiatrist Hospital in Palembang.

19 subjects with healthy elderly with active physical exercises and 19 subjects with depression where enrolled in this study and all subjects agreed to blood sampling to evaluate serum BDNF levels. Serum levels of BDNF were measured using an enzyme-linked immunosorbent assay (ELISA) method.

Results

Results: The HS group had higher BDNF levels of 391,959 ± 56,855 as compared to the DP group BDNF levels of 120,558 ± 68,667 (p=0.00).

Conclusion

In conclusion, healthy subject (HS) blood BDNF level was significantly higher than blood BDNF level in depression patient (DS). It’s prove that a reduction in BDNF is directly involved in the pathophysiology of depression.

ISPR8-2451
NON-UTILIZATION OF MEDICAL REHABILITATION BEFORE THE OCCURRENCE OF EARLY RETIREMENT DUE TO PSYCHOLOGICAL AND BEHAVIOURAL DISORDERS IN GERMANY – PREVALENCE AND SOCIODEMOGRAPHIC DETERMINANTS.
M. Weyermann¹
¹Niederrhein University of Applied Sciences, Faculty of Health Care, Krefeld, Germany

Introduction/Background
In Germany the statutory pension insurance fund covers the cost of rehabilitation treatment for employees whose working capacity is endangered due to health problems. The underlying principle called “rehabilitation over retirement” is the concept to avoid early retirement due to health problems by rehabilitation. We aimed to describe the utilization of medical rehabilitation before the occurrence of early retirement due to psychological and behavioural disorders in Germany from 2003 to 2014 and to investigate potential sociodemographic determinants.

Material and Method
Analysis based on 20% random samples of administrative pension records from the Research Data Centre of the German Federal Pension Insurance. We used logistic regression models to investigate the risk for non-utilization of medical rehabilitation during five years before the occurrence of early retirement.

Results
Among all early-retired patients due to psychological and behavioural disorders 50.3% (60.380 out of 120.106) did not utilized medical rehabilitation. Risk factors for non-utilization were to be unmarried or widowed (vs. married, adjusted OR: 1.43; 95% CI: 1.40 – 1.47), non-German citizenship (vs. German citizenship, 1.19 [1.14 – 1.24]), unknown or low educational level (vs. median educational level, 1.58 [1.53 – 1.63]), as well as low annual income (1st quartile vs. 4th quartile; 4.09 [3.94 - 4.24]). Also, risk was higher among men compared to women (1.38; 95% CI: 1.38 – 1.41) and lower among older patients (60 - 64 years vs. ≤ 44 years; 0.86 [0.82 - 0.90]).

Conclusion
Among all early-retired patients due to psychological and behavioural disorders 50% obtained no medical rehabilitation. Worst affected were deprived persons.

The diagnosis of DCD is based on the clinical signs, the absence of neurological lesion and the presence of a significant dissociation between one of "specific index " of DCD (Perceptual Reasoning Index (PRI) (WISC 4), Visual Spatial Index (VSI) and Fluid Reasoning Index (FRI) (WISC 5), and one of the other «WISC»'s index. This work aims to analyze the relationship between clinical signs and the resultes of Wechsler Intelligence Scale for Children (WISC) in diagnosis of Developmental Coordination Disorders (DCD), commonly known as "dyspraxia" in France.

Material and Method
This work includes all the children evaluated in the "learning and development" unit of the Maison de Rééducation et Autonomie (France, Val d'Oise) from January 2015 to January 2018, with:
- Clinical and functional signs of DCD concerning both subtile motor skills, gross motor skills and visuospatial motor skills.
- Age between 6 and 14 years
- Absence of neurological lesion and global intellectual retardation
- Learning disorders
In total, 106 children fulfilled the inclusion conditions. They all had a clinical exam, a WISC IV or V and a quantified analysis of posture and walking (ZEBRIS system).

Results
The population was 53% girls and 47% boys,
Awkwardness, difficulties of writing, in geometry, use of tools, practice of sports, exploration of space, transfer of theoretical knowledge in practice and automating patterns are almost constant.
Quantified analysis of posture and gait showed the presence of static equilibrium disorders, temporospatial or kinetic parameters (80%)
There was significant dissociation between PRI, VSI FRI, and one of the other «WISC»' index in only 77% of cases

Conclusion
This work demonstrates the limit of the selectivity of «WISC» in the diagnostic process of DCD. The diagnosis can be optimized by the sub-visual-spatial indexes, on the one hand, and specifics assessments such as to occupational and psychomotrician assessments on the other hand.

DISSOCIATION BETWEEN DECLARATIVE AND PROCEDURAL MEMORY IN PATIENTS FOLLOWING HEAD INJURY - EVIDENCE FROM FINGER OPPOSITION SEQUENCE PARADIGM

K. cismariu-potash\(^1\), Y. Sacher\(^1\), S. Shaklar\(^2\)
\(^1\)Loewenstein hospital, Department of Traumatic brain injury, Raanana, Israel
\(^2\)Loewenstein hospital, Department of Pediatric rehabilitation, Raanana, Israel

Introduction/Background

Many patients surviving traumatic brain injury (TBI) are left with significant disabilities, including memory impairment which can be declarative, procedural, or context-dependent. Dissociation between procedural and declarative learning has been described in a number of patients following focal brain injuries. Described below are two such cases involving diffuse axonal damage that demonstrated such dissociation.

Material and Method

Description of two patients (out of ten) who participated in a study aimed to characterize procedural learning after TBI and presented with Implicit-Explicit memory dissociation. Subjects were tested using a series of finger opposition movements which they had to perform as rapidly and accurately as possible through several training sessions over two weeks and one month afterwards. The subjects underwent evaluation to characterize their cognitive impairments and subsequent impacts on learning ability.

Results

Both subjects demonstrated severe declarative memory deficits as demonstrated in the Rivermead Battery Memory Test (RBMT) but showed effective procedural learning of finger movement sequence as defined by improved performance speed across the training period without speed-accuracy trade-off. In addition, these findings were retained at the one month follow-up.

Conclusion

The findings from the examination of these two subjects coincide with the current paradigm that declarative and procedural memory are two separate processes that appear to occur in spatially segregated brain regions that utilize functionally distinct pathways and demonstrate that such dissociation might be evident in damage to white matter tracts. Consequently, severe injury to one may present in parallel with preservation of the other domain. The ability to maintain the ability for procedural learning after severe head injuries, even in the presence of a severe impairment of declarative memory, can be exploited in therapeutic strategies aimed at increasing the patient's daily functioning.

ROLE OF OCCUPATIONAL THERAPY FOR DEVELOPING APPROPRIATE INDIVIDUAL EDUCATIONAL PLAN FOR STUDENTS WITH LEARNING DISABILITY

M. Afroze¹, S. Hossain¹

¹Bangladesh Health Professions Institute BHPI, Occupational Therapy, Dhaka, Bangladesh

Introduction/Background

Learning disabilities, or learning disorders, are an umbrella term for a wide variety of learning problems. A learning disability is not a problem with intelligence or motivation. Children with learning disabilities aren’t lazy or dumb rather most are just as smart as everyone else. Their brains are simply wired differently. This difference affects how they receive and process information.

The Occupational Therapy evaluation and intervention are carried out in various environments, such as in a clinic and/or in the person's natural environment (at home, class, playground, work place, etc.)

Material and Method

The first stage of article evaluation and selection was conducted using abstracts alone. The second stage of inclusion and exclusion was conducted. The third stage of evaluation and selection was conducted on the entire article. The search was performed between August 2016 and February 2017 and then updated in February 2017. There were no constraints upon year of publication. During investigation investigator was able to search literature previous 18 year’s information about individual educational plan and learning disability. Investigator was also clinically observed the clients and practiced with the individual clients how they maintain the IEP, how prepare the IEP and the all clients are students with learning disabilit

Results

IEP is very emergent for students with learning disability. If it made by follow its process it’s seems very subsidiary for those students and academic session. Threateningly most of the institute can’t follow the process because in Bangladesh maximum care giver can’t find out their child limitation as early as possible

Conclusion

Occupational Therapy is a growing profession in Bangladesh serving for the person with disability and or the disabling condition. Learning Disability is one of the major disabling conditions where Occupational Therapists can play very important role to maximize daily living activities of the children with Learning Disability.

CONSCIOUSNESS RECOVERY AFTER VARIOUS PERIODS IN VEGETATIVE STATE

E. Aidinoff¹, K. Elkayam², A. Oximitny³, R. Gur-Pollack⁴, Z. Gros­wasser⁴, A. Catz⁵
¹Loewenstein Hospital - Rehabilitation Center and Tel-Aviv University- Tel-Aviv- Israel, Intensive Care and Consciousness Rehabilitation, Raanana, Israel
²Loewenstein Hospital - Rehabilitation Center, The Spinal and Consciousness Rehabilitation Research Laboratory, Raanana, Israel
³Loewenstein Hospital - Rehabilitation Center- and Tel-Aviv University- Tel-Aviv- Israel, Intensive Care and Consciousness Rehabilitation, Raanana, Israel
⁴Loewenstein Hospital - Rehabilitation Center- and Tel-Aviv University- Tel-Aviv, The Head Injury Research Unit, Raanana, Israel
⁵Loewenstein Hospital - Rehabilitation Center- and Tel-Aviv University- Tel-Aviv, The Spinal and Consciousness Rehabilitation Research Laboratory, Raanana, Israel

Introduction/Background

The odds of consciousness recovery are considered to be poor after several months in vegetative state (VS). The rate of recovery from VS, however, improved in the last 20 years. The present study examined the odds of consciousness recovery after various periods in VS.

Material and Method

Recovery from VS was monitored during several periods after admission to intensive care and consciousness rehabilitation (ICCR) in 206 patients in VS lasting more than 1 month. Recovery from VS was established when the ICCR physician and the multidisciplinary team observed that patients who previously were not able to create functional communication or use objects, established communication with the environment by obeying simple commands, but not complex commands that patients with locked-in syndrome can obey.

Results

Recovery of consciousness was recorded in 111 patients, of whom 24, 40, 24, 16, and 7 were discharged from ICCR within 3, 3-6, 6-9, 9-12, and 12-19 months, respectively. Additional patients, lost to follow-up, may have recovered consciousness after discharge from ICCR. The odds of recovery from VS was, therefore, at least 54% at admission to ICCR, 48% after 3 months, 33% after 6 months, 19% after 9 months, and 7% 12 months after admission (approximately 2, 5, 8, 11, and 14 months after injury or lesion onset). The difference in the odds of recovery from VS between the examined periods were significant (p<0.001).

Conclusion
The odds of recovery from VS decrease significantly with time, but are not negligible even more than 6 months after admission to ICCR, and more than 8 months after injury. Future study of functional outcomes after VS recovery may help determine the optimal duration of the period from injury to ICCR, and the optimal length of stay in ICCR.

INTENSIVE THERAPY AND REHABILITATION OF CHRONICALLY CRITICALLY ILL PATIENTS WITH BRAIN DAMAGE
M. Petrova¹, I. Pryanikov¹, A. Grechko¹, D. Iankevich¹, K. Krylov¹
¹Federal Research and Clinical Center of Intensive Care Medicine and Rehabilitology, Administration, Moscow, Russia

Introduction/Background

In patients with brain damage of various etiologies persist long-term disturbances of consciousness, which make them dependent on mechanical ventilation and other life support systems. This is a result of severe brain damage and/or the median structures of the brain dislocation development. We use integrated approach to rehabilitation of chronically critically ill patients. Aim of a pilot study the impact of a new approach to improving the results treatment and rehabilitation in chronically critically ill patients.

Material and Method

Was analyzed a comprehensive approach of rehabilitation in 30 chronically critically ill patients (more than 2 months after the cerebral injury). Each patient received position treatment, bedside recumbent cycling, transcranial magnetic stimulation, speech therapy exercises. During above mentioned activities there was bedside monitoring of:

- the resting energy expenditure by indirect calorimetry
- the external temperature of the brain
- the activity of sympathetic nervous system

Results

The study found that it is possible and necessary to start active rehabilitation in patients with chronically critical illness. Our study proved that there is no deterioration of the patients’ conditions. Response to rehabilitation in the majority of the patients was observed as an increase in the level of consciousness (18 cases, 60%) increase in strength and amplitude of limbs movements and increased physical activity (12 cases, 40%), the recovery of swallowing. In addition, the patients had a decrease in the level of catabolism, in the number of infectious complications and in the duration of mechanical ventilation. Monitoring of metabolism, activity of the autonomic nervous system allowed us to increase the safety of activities.

Conclusion
The use of an integrated approach to the rehabilitation in chronically critically ill patients with brain damage leads to an effective and safe improvement in the treatment results.

EVALUATING CHANGES IN STIMULI RESPONSE IN THE SNOEZELEN ROOM ON MINIMALLY RESPONSIVE PATIENTS
H. Lerer¹, E. Aidinoff², R. Gur-Pollack³, K. Elkayam³, A. Catz³
¹Loewenstein Hospital, Brain Rehabilitation Department, Raanana, Israel
²Loewenstein Hospital, Intensive Care and Consciousness Rehabilitation Department, Raanana, Israel
³Loewenstein Hospital, The spinal and Consciousness Rehabilitation research laboratory, Raanana, Israel

Introduction/Background

Background and aims: Findings of a previous study suggested that Snoezelen use and similar methods have calming effect such as reduced heart rate, on different patient population such as children with brain injury and people with dementia. To validate this suggestion, we examined differences in responses to various stimuli on Vegetative state (VS) and minimally responsive patients.

Material and Method

Methods: Session with 50 VS and minimally responsive patients were carried out at Loewenstein rehabilitation hospital snoezelen room where they were exposed to various stimuli involving the 5 senses (bubbles stand, music, lollypop, perfume, fibers). Baseline was recorded at the beginning and end of the session. Data collected using Loewenstein communicative scale (LCS) and Transcranial Doppler (TCS) and Heart rate measure.

Results

Results: LCS results show significant difference (t-test) between traumatic and non-traumatic patients in baseline measurement (p<0.05) and the during session measurement (p<0.05). Significant difference (ANOVA) was found between Bubbles TCS and LCS delta (p<0.05) and Baseline TCS and LCS delta (p<0.05) but not the other stimuli tested. Positive correlations were found in the different stimuli between TCS and Heart rate measure.

Conclusion

Conclusions: Preliminary results indicate that although there was change in response during sonezelen sessions only Bubbles had the most significant effect on patients’ response however there is notable difference in patients’ response at the end of the session.

Hypoxic-ischemic brain injury is caused by imbalance between the supply of oxygen and decreased cerebral blood flow, results of situations such as systemic hypoxemia, alterations in the transport of oxygen or reduction of cerebral blood flow, such as cardiac arrest. We report a case of anoxic brain injury following a "Tako-Tsubo syndrome".

**Material and Method**

A 31 years old female, natural of Morocco, without medical history of interest, who suddenly presented cardiac arrest while she was in her house. After the arrival of the advance life support team, they started cardio-pulmonary resuscitation, recovering sinus rhythm and spontaneous breathing after 15 minutes of cardio-respiratory arrest. A 12 lead electrocardiogram was made, showing a supraventricular tachycardia at 140 beats per minute and a ST segment elevation in leads I and aVR. The patient was transferred to the referral hospital where a urgent coronary angiography was performed, which showed normal coronary arteries with a normal ejection fraction and hypokinesia of the apex and antero-lateral part of the left ventricle, highly suggestive of Tako-Tsubo cardiomyopathy o “broken heart syndrome”.

**Results**

After stabilization in intensive care unit, the patient presents tetraparesis with weak head and trunk control, dysphagia, aphasia and cognitive disorder. Intensive physical, occupational and speech therapy are initiated, with recovery independent walking as well as the capacity to perform daily life activities with autonomy, although a important cognitive behavioural disorder persists.

**Conclusion**

**Keywords**
Tako-Tsubo syndrome; anoxic brain injury

UNRESPONSIVE WAKEFULNESS SYNDROME DUE TO CARBON MONOXIDE POISONING

A. MANOJA1, M.D. Romero Torres2, J. Sanchez Palacios1, M.A. Moya Molina3

1 PUERTA DEL MAR UNIVERSITY HOSPITAL, PHYSICAL MEDICINE AND REHABILITATION, CADIZ, Spain
2 Virgen Macarena University Hospital, Physical Medicine and Rehabilitation, Seville, Spain
3 Puerta del Mar University hospital, Neurology, Cadiz, Spain

Introduction/Background

Carbon monoxide poisoning is common in our environment due to toxic gases exposure. The effects of exposure are not limited to the acute phase. After an apparent recovery, neurological alterations may sometimes appear.

Material and Method

A 59-year-old woman was admitted to our hospital because of a probable carbon monoxide poisoning due to incomplete combustion of a brazier.

She had an initial Glasgow score of 10, hemodynamically stable without motor deficit. She showed only cognitive deficits. After 6 sessions of hyperbaric oxygen therapy (HBOT) with subsequent cognitive improvement, the patient was discharged from the hospital to outpatient care with HBOT.

After 14 days, she suffered acute progressive worsening. Her examination revealed gait problems, stiffness of the 4 limbs without any clear motor deficit and mutism, and a few days later she developed an unresponsive wakefulness syndrome despite of 9 new sessions of HBOT.

Results

Delayed neurological syndrome is a rare clinical entity that can be presented with clinical features of variable severity.
Magnetic resonance imaging is the technique of choice for the diagnosis of this pathology. With this technique, we can observed findings such an acute demyelination and diffuse white matter injury.

Our current objective is to prevent complications and perform a cognitive stimulation therapy (sensorineural and pharmacological). **Conclusion**

Currently, the optimal therapy for sequelae after carbon monoxide poisoning is not known. Hyperbaric oxygen therapy is a well-known treatment method, but its use for patients with CO poisoning is a controversial issue.

This systematic review has not found sufficient evidence to support or refute the effectiveness of HBOT for the the management of sequelae after carbon monoxide poisoning, so prevention is still the best protection.

ISPR8-2438
TREATMENT OF CHRONIC NORMAL PRESSURE HYDROCEPHALUS IMPROVED THE RECOVERY OF CONSCIOUSNESS ON PATIENTS FOLLOWING BRAIN INJURY
Z. CHEN¹, Z. zhou¹, H. shen¹
¹First rehabilitation hospital of Shanghai, Department of neurorehabilitation centre, shanghai, China

Introduction/Background

Despite disorder of consciousness (DOS) being the cause of major disability after cerebral hemorrhage, aneurysmal Subarachnoid hemorrhage and traumatic brain injury (TBI), the clinical management options for these conditions are limited to drugs and nonpharmacological interventions with equivocal effectiveness. We investigate the impact of chronic normal pressure hydrocephalus (CNPH) on patients with DOS following those brain injuries.

Material and Method

Forty-six patients with DOS had undergone ventriculoperitoneal shunting (VPS) for CNPH were compared with 17 matched controls with no VPS. We measured consciousness with coma recovery scale (CRS) and Disability Rating Scale (DRS). The cella media index (CMI) was calculated as the change in size of the lateral ventricles. The short-term outcome of treatment was assessed at 3 months using the Glasgow Outcome Scale (GOS).

Results

Twenty-one out of 46 patients with DOS recovered gradually after VPS and rehabilitation. There was a significant difference in the CRS and DRS between VPS and control groups at both 1 and 3 months (p < 0.01). Significant differences were also observed between the 2 groups in CMI at 1 and 3 months (p < 0.05). The VPS group was significantly higher than that of the control at 3 months on GOS (p < 0.01).

Conclusion

Though lumbar puncture pressure of patients with CNPH is normal, the wall tension of ventricles increased because of ventricular enlargement that may severe affect the circulation and metabolism resulting in DOS. However, VPS could reverse this condition, which helps some patients with DOS to regain consciousness.

No conflict of interest
Spasticity is a common complication after a severe brain injury that hinders the rehabilitative process, reduces the patients' quality of life and is frequently responsible of pain (Thibaut et al, 2015). Here we investigate in a population of patients with disorders of consciousness the correlation between spasticity and pain during mobilization to better characterize the spastic profiles that are more prone to induce pain.

**Introduction/Background**

In this cross-sectional study 73 patients with chronic (>3 months post insult) disorders of consciousness were included (27 women; mean age: 40±13 y; 42 with traumatic etiology; 50 in minimally conscious state (MCS) and 23 in unresponsive wakefulness syndrome (UWS)). We evaluated the pain with the Nociceptive Coma Scale-Revised (NCS-R) and the spasticity with the Modified Ashworth Scale (MAS).

**Results**

Out of 73 patients, 70 demonstrated signs of spasticity (96%; MAS≥1), including 52 who showed severe spasticity (71%; MAS≥4 at least in one joint; 35 in MCS and 17 in UWS). Moreover, 13 patients in MCS (26%) and 5 in UWS (22%) showed severe pain during mobilization (NCS-R≥4 at least in one joint). Moreover, we found a strong correlation with the Spearman’s rank correlation indicator between pain during mobilization and the spasticity of the wrist’s and fingers’ flexors and hip’s adductors (respectively ρ=0.254, P=0.03; ρ=0.269, P=0.02; ρ=0.277, P=0.02), while the correlation was weaker for biceps, knee’s and ankle’s flexors.
(respectively ρ=0.195, P=0.1; ρ=0.176, P=0.14; ρ=0.115, P=0.36).

**Conclusion**

We confirm the high prevalence of spasticity and pain in patients with disorders of consciousness and the correlation between the degrees of spasticity and pain scores. We found that the peripheral joints of the upper limbs and the hip adductors are more prone to induce pain. These data highlight the need to prevent the onset of spasticity and the importance of the treatment of pain in patients with disorders of consciousness.

NEUROGENIC HETEROTOPIC OSSIFICATION - WHAT TO DO?
C. Martins¹, V. Milet¹, J. Moreira¹, S. Rego¹, G. Leandro¹, A. Reis¹, L. Gomes¹, D. Martins¹, J. Capela¹, E. Afonso¹
¹Centro Hospitalar do Algarve - Faro, Medicina Fisica e de Reabilitação, Faro, Portugal

Introduction/Background

Heterotopic Ossification (HO) is defined as the presence of lamellar bone at locations where bone physiologically does not exist. Pain and limitation of mobility are associated to HO. Neurogenic HO (NHO) subtype is a frequent complication of central nervous system injury, with ossification often affecting major synovial joints. NHO has a significant impact on the activities of daily living, since these patients are usually disabled because of their original injury. The purpose of this presentation is to conduct a review of the NHO prevention and treatment interventions.

Material and Method

MEDLINE database was searched for articles addressing the treatment of NHO. The manuscripts selected for review of the full text were assessed by their relevance for inclusion in this review. Preference was given to systematic reviews.

Results

Five studies met inclusion criteria, four of which were reviews. Non steroidal anti-inflammatory drugs (NSAIDs), Bisphosphonates and Radiation were reviewed as prophylactic agents. For the treatment of full developed disease, Bisphosphonates, Extracorporeal Shock Wave therapy (ESWT), radiotherapy, Physical Therapy and Surgery were reviewed.

Conclusion

For the prevention of NHO, NSAIDS and Radiation were found to be effective; the use of Bisphosphonates is controversial. Despite the prophylactic strategies available, no current pharmacological treatment exist to address a developed disease. Surgical excision was the most effective mode of treatment, but is considered to be extremely invasive, with relevant recurrence and not possible in all patients with NHO. Physical Therapy, Radiotherapy and ESWT did not prove to be effective treatments, although the last two seem to allow some symptomatic improvement. When nothing seems to work in this patients and they are not candidates for surgery, what else can we do?

NON-PHARMACOLOGICAL INTERVENTIONS FOR SPASTICITY IN ADULTS: AN OVERVIEW OF SYSTEMATIC REVIEWS

B. Amatya¹, F. Khan¹, D. Bensmail², A. Yelnik³
¹Royal Melbourne Hospital, Department of Rehabilitation Medicine, Parkville, Australia
²Raymond Poincaré Hospital- University of Versailles, Department of Physical and Rehabilitation Medicine, Graces, France
³F. Widal University Hospital, Department of Physical and Rehabilitation Medicine, Paris, France

Introduction/Background

Spasticity causes significant long-term disability-burden, requiring comprehensive management. This review evaluates evidence from published systematic reviews for effectiveness of non-pharmacological interventions for improved spasticity outcomes.

Material and Method

A literature search was conducted using medical and health science electronic databases for published systematic reviews up to 15th June 2017. Two reviewers applied inclusion criteria to select potential systematic reviews, independently extracted data for methodological quality using Assessment of Multiple Systematic Reviews (AMSTAR). Quality of evidence was critically appraised with Grades of Recommendation, Assessment, Development and Evaluation (GRADE).

Results

Overall 18 systematic reviews were evaluated for evidence for a range of non-pharmacological interventions currently used in managing spasticity in various neurological conditions. There is ‘moderate’ quality evidence for electro-neuromuscular stimulation and acupuncture as an adjunct therapy to conventional routine care in persons following stroke. ‘Low’ quality evidence for rehabilitation programs targeting spasticity (such as induced movement therapy, stretching, dynamic elbow-splinting, occupational therapy) in stroke and other neurological conditions; extracorporeal shock-wave therapy in brain injury; transcranial direct current stimulation in stroke; transcranial magnetic stimulation and transcutaneous electrical nerve stimulation for other neurological conditions; physical activity programs and repetitive magnetic stimulation in persons with multiple sclerosis, vibration therapy for spinal cord injury and stretching for other neurological condition. For other interventions, evidence was inconclusive.

Conclusion

Despite non-pharmacological interventions are used for various neurological conditions, there is still lack of high-quality evidence for many. Further research is needed to judge the effect with appropriate study designs and intensity and associate costs of these interventions.

TITLE: DELAYED ENCEPHALOPATHY FOLLOWING CARBON MONOXIDE POISONING- A REVIEW OF THE LITERATURE WITH A LOCAL REHABILITATION PERSPECTIVE

D. Chen¹, C.W. Bok¹
¹Singapore General Hospital, Rehabilitation Medicine, Singapore, Singapore

Introduction/Background

Delayed Encephalopathy following carbon monoxide poisoning is a known complication resulting in a myriad of neurological complications including Parkinson’s like syndromes. It is rare in the Singapore setting and local clinicians may be unfamiliar with the clinical course and management of this condition.

Material and Method

Articles referenced were searched on pubmed using the words "carbon monoxide poisoning" and “delayed encephalopathy”.

Results

There is little in the way of evidence that supports the routine use of Hyperbaric oxygen in the acute setting in reducing or preventing delayed encephalopathy. There is some evidence suggesting the use of acetylcholinesterase inhibitors and stimulant medication like methylphenidate to improve attention and memory, dopaminergic agents to treat symptoms of Parkinsonism.

Conclusion

We suggest a multidisciplinary approach in managing such patients and some pharmacological agents can be tried to remediate cognitive impairments, Parkinsonism and affective disorders that manifest. We await more research to be done to give us more clarity in the prevention and management of this condition.

\textsuperscript{6}Hôpital Trouseau-Assistance Publique Hôpitaux de Paris, Service de Neuropédiatrie - Pathologie du développement, Paris, France

Introduction/Background

The aims of this study were 1) to describe the health profiles and care management of polyhandicapped patients according to 3 modalities (specialized rehabilitation centers (SRC), residential facilities (RF), and home care (HC), and 2) to estimate the adequacy of care management of these patients.

Material and Method

This was an 18-month cross-sectional study including patients with a combination of severe motor deficiency and profound intellectual impairment. The patients were from 4 SRC, 9 RF, and a pediatric/neurologic department (HC). The following data were collected: sociodemographics, health status, care management, and adequacy of care management.

Results

A total of 875 patients were included: 410 (47\%) were cared for in SRC, 372 (43\%) in RF, and 84 (10\%) in HC. Global objective adequacy (health severity and age category) was higher for patients cared for in SRC compared with patients cared for in RF (57 vs. 44\%, p\leq10^{-3}). Global subjective adequacy (self-perception of the referring physician and request of change in structure) was higher for patients cared for in SRC (98\%) in comparison with patients cared for in RF and HC (92 and 87\%).

Conclusion
This study provides key elements of adequacy of care management modalities for polyhandicapped patients in France.

WHY AND HOW I INJECT BOTULINUM TOXIN TO TREAT SPASTICITY USING SIMULTANEOUSLY NEUROMUSCULAR ELECTRICAL STIMULATION AND ULTRASOUND?

J. Pereira¹, S. Foucret²
¹Rehazenter, Pôle de Rééducation Neurologique, Luxembourg, Luxembourg
²Rehazenter, Explorations Fonctionnelles, Luxembourg, Luxembourg

Introduction/Background

Inspired by the 2018 ISPRM’s motto: “Share knowledge to reduced disability”, in this poster the author intends to share why, when treating focal spasticity with intramuscular botulin toxin type A (BoNTA) injections, he uses systematically ultrasound and electrical neuromuscular stimulation to accurately target the implicated muscles.

Material and Method

The author used ultrasound simultaneously with muscle electrical stimulation in 189 sessions of BoNTA muscles injections to treat functional disabilities provoked by spasticity between January 2014 to December 2017. In this presentation the author analyses the trade-off between the advantages and disadvantages of this injection targeting technique.

Results

In this presentation we will underline the reasons why using simultaneously both ultrasound and neuromuscular electrical stimulation as targeting techniques is interesting, allowing to have a direct visualisation of anatomy and simulated physiology. Some of the advantages that will be explained in detail are: comfort and less pain to the patient; ability to accurately identify muscles even in patients with longstanding spasticity in whom using classic external anatomical references is misleading; ultrasound view of the muscle contraction (that sometimes does not cause a mechanical joint movement) allowing to finetune the place in the muscle where to inject, that should be where the lower intensity of stimulation provokes the greater degree of contraction.

The disadvantages were the increased price per session related to the use of aseptic equipment and the learning curve.

Conclusion

Considering the trade-off favouring advantages, the authors strongly advise using a combination of ultrasound and muscle electrical neurostimulation to target muscle for BoNTA injection.

⁵Hôpital d'Hendaye Assistance Publique Hôpitaux de Paris, polyhandicap, Hendaye, France
⁶Hôpital Trousseau-Assistance Publique Hôpitaux de Paris, Service de Neupédiatrie - Pathologie du développement, Paris, France

Introduction/Background

A better understanding of the natural course of the health status of patients with polyhandicap may optimize preventive and curative care management. From a large sample of patients aged from 3 to 25 years, we reported the description of their health status.

Material and Method

This was an 18-month cross-sectional study including patients aged from 3 to 25 years with a combination of severe motor deficiency and profound intellectual impairment. The patients were recruited from 4 specialized rehabilitation centers, 9 residential facilities, and a pediatric/neurological department. The following data were collected: polyhandicap etiology, health status (handicaps, comorbidities, and neurodevelopmental status), medical devices, and rehabilitation procedures.

Results

A total of 545 patients were included (N=80 [3-5 years], N=166 [6-11 y], N=155 [12-17 y], and N=144 [18-25 y]). The etiology of polyhandicap was unknown for 11% of the cases. Behavioral disorders and (orthopedic and digestive) comorbidities were more frequent in the oldest age classes. The neurodevelopmental status of the patients was close to those of a 5- to 7-month-old child without progression across age. Gastrostomy was the most frequent device needed by the patients.

Conclusion
Early detection and management of handicaps and comorbidities may improve the disease course of the patients.

THE ASSESSMENT OF ACTIVITY OF DAILY LIVING AND MOOD IN ADULT JAPANESE PATIENTS WITH DUCHENNE MUSCULAR DYSTROPHY: A SINGLE-SITE STUDY
T. Saotome¹, Y. Sawada¹, T. Sakurai¹, Y. Kobayashi¹, H. Komaki²
¹National Center Hospital- National Center of Neurology and Psychiatry, Physical Rehabilitation, Kodaira, Japan
²National Center Hospital- National Center of Neurology and Psychiatry, Child Neurology, Kodaira, Japan

Introduction/Background

Duchenne muscular dystrophy (DMD) is an x-linked rare disease characterized by progressive muscle wasting due to mutations in the dystrophin gene. In Japan, the estimated number of patients with this disease was about 3400 in 2015. Growth over time, the patients gradually lose physical independence with the declines of cardio-pulmonary functions. In the past, patients did not survive until becoming an adult. However, advanced treatment options, such as taking methylprednisolone, management of respiratory and cardiac organs, are enabling increases in their life expectancy. We hypothesized that the functional ability of adult DMD patients may affect their mood.

Material and Method

To evaluate the activities of daily living (ADL) in the adult DMD population in a hospital specializing in the treatment of neuromuscular diseases. To examine the correlation between ADL and the presence of mood disorders.

The adult DMD patients without intellectual disabilities who could give the consent for this study and who could answer the questionnaires were targeted. An investigator measured the patient's ADL and mood by using the Functional Independence Measure (FIM) and the Hospital Anxiety and Depression Scale (HADS).

Results

Results were provided from 34 patients (median age 26.5 years). The median scores of Total and Motor FIM were 53 (48-60) and 18.5 (13-25), respectively. The median HADS score of anxiety was 5 (0-14) and depression was 2 (0-8). The score of HADS did not show significant clinical signs of depression and anxiety. No correlation was found between FIM and HADS.

Our patients showed a high level of ADL dependency without clinically meaningful depression and anxiety, whereas a previous study reported that adult DMD patients with the high rate of pain and fatigue showed 24% of anxiety and 19% of depression.

Conclusion
The presence of noticeable physical symptoms might affect the patient’s mood.

MEDICATION ADHERENCE OF HOSPITALIZED PARKINSON'S PATIENTS INCLUDED IN AN INTENSIVE REHABILITATION PROGRAM
F. Bour1, C. Grezard1, M. Cheminon2, I. Peraud2, J. Luaute2, C. Rioufol1, E. Carre1
1Hospices Civils de Lyon, Pharmacy, Lyon, France
2Hospices Civils de Lyon, Physical Medicine & Rehabilitation, Lyon, France

Introduction/Background

In order to improve the quality of life and symptomatology of Parkinson's patients, an intensive, multidisciplinary and collective rehabilitation program has been set up in our institution. This program, called SIROCCO, takes place over 5 weeks and offers to patients various rehabilitative activities realized outside the service. During the hospitalization, the patients are autonomous during the day in the management of their medications.

Parkinson's disease can cause cognitive impairment. This study has been set up to evaluate medication adherence in SIROCCO patients.

Material and Method

This is a 7-month observational study conducted in 2016. A pillbox containing the medication was provided to the patient each day. When the patients returned to the service, the pillboxes were checked and the remaining units counted. An 8-item Morisky questionnaire was completed for each patient. Compliance was measured by the Morisky score and by the ratio (R) of "number of drug intake/number of prepared drugs" ("Pill-Count" method). Also, a Kappa coefficient has been calculated.

Results

Thirty patients were included in the study. The average age was 64 years for a sex ratio between men and women = 2. On average, patients had to manage 3.5 drug intakes during the day. 80% of the patients had a Morisky score ≥ 6 (medium to high adherence) and 70% had a R=1. All patients who had a Morisky score = 8 (13 patients with a high compliance) never forgot medication. The Kappa coefficient measures the intensity of agreement between the two methods to estimate compliance at 0.44, a moderate agreement (Landis and Koch classification).

Conclusion

This study made it possible to draw up a first positive assessment of patients' adherence with the SIROCCO program. The Morisky questionnaire seems to have an excellent positive predictive value in the targeting of observant patients and can be left autonomous in the management of their treatment.

The Schwannoma is a pathology that is specific to the peripheral nervous system, its diagnosis is often unknown or late, clinical signs are variable according to the anatomical seat. Its annual incidence is low, varying between 0.3 and 0.5 / 100,000 inhabitants.

Rehabilitation is a very important component in the treatment of the neurological deficit; it improves the results of surgical treatment.

Material and Method

Observation: We report the case of a male patient aged 44, who presented a picture of slow spinal cord compression with clinical latency of six years, combining: a spinal syndrome with pain and stiffness of the cervical spine, a lesional syndrome with tingling paresthesia, motor and sensory deficit in the C6-C7 and C8 root canal territories with amyotrophy of the hand and ulnar claw of the 4th and 5th right fingers, and a late sublesional syndrome with spastic tetraplegia and urinary disorders.

Cervical Magnetic resonance imaging (MRI) shows an intradural and extramedullary tumor lesion process next to C6 and C7, realizing an hourglass appearance. A total surgical excision of the tumor was performed allowing the removal of spinal cord compression.

Results

Functional rehabilitation, which is essential and complementary to surgical treatment, has been recommended for several months.

The clinical evolution is marked by the almost total regression of the neurological symptomatology with progressive recovery of the gait.

Conclusion

Despite the poor prognostic factors that are the delay of the diagnosis and the total neurological deficit caused by the tumor, we note a clear recovery thanks to the joint action of appropriate rehabilitation to the surgical treatment.
Keywords

Schwannoma; Surgical treatment; Rehabilitation

No conflict of interest
Conversion disorder (CD) is a psychological disorder, mostly characterized by neurological symptoms, without evidence of an organic etiology. CD raises major challenges to health systems, in both diagnosis and treatment. Previously, CD patients were seldom referred to an inpatient rehabilitation, and were referred instead to psychiatric units. Conversive hemiparesis is relatively rare, usually left-sided. Furthermore, patients are usually psychologically-invested in medical explanations, and are less engaged in insight-oriented therapy. As it is not usually the treatment-of-choice, and literature regarding rehabilitation-management in these cases is nonsystematic and inconclusive, the purpose of this case-report is to further our understanding of the rehabilitative-treatment approach, address and discuss ethical and professional dilemmas concerning the patient and rehabilitative-milieu.

Material and Method

A 16-year-old female patient presented severe-symptoms that partially-resembled right-CVA: Left hemiplegia, including loss of sensation, face-drooping on the right side, and difficulties speaking, without any evidence of abnormalities on imaging or neurophysiological studies. Although counseling-neurologist explicitly stated CD diagnosis to the patient, the approach chosen was to address the somatic difficulties in a multi-disciplinary inpatient rehabilitation-unit, and continue necessary examinations to rule-out neurological causes. The rehabilitative-milieu consisted of a rehabilitation physician, psychologist, social-worker, hospital-teachers, occupational, speech and physical therapists.

Results

Upon admission, the patient was immobile and showed difficulty in performing activities of daily leaving with FIM 82. Each week, the milieu set short-term, realistic goals. Physical and functional therapies combined with extensive psychological support to the patient and family,
helped the patient achieve significant improvement in global assessments of functioning and decreased dependence and FIM increase after 5 weeks to 95.

Conclusion

The case-report demonstrates distinct advantages, by validating the patients' experience and difficulties, focusing on functional and underlying psychodynamic factors. An inpatient multi-disciplinary rehabilitation program for adolescents encourages the CD patient to take an active part in the process, and provides continuing support and feedback.

Keywords

Ectatocormia (severe, fixed truncal hyperextension exacerbated by movements of the trunk) is associated with pain and motor disability, and impede the patient to maintain a normal upright posture or to walk.

The aim of this report is to present the case of an adult with ectatocormia and the changes in pain and posture after botulinum toxin administration to paraspinal muscles.

Material and Method

A 28-year-old patient with congenital ataxia and trunk dystonia in hyperextension predominantly lumbar and left inclination. Presents pain, difficulty in sitting and walks with assistance from a person less than 10 meters indoors.

Prior informed consent is treated with botulinum toxin type A, that was obtained in 100 u vials as Botox (Allergan Pharmaceuticals) and reconstituted with 2 mL of normal saline. The patient was placed prone with a cushion under the pelvis. Muscles were injected with ultrasound guidance and convex probe in three sites on each side, using a spinal needle and administrating 60 u at each site: 20 u multifidus, 20 u longissimus and 20 u iliocostalis at the level of the eleventh thoracic vertebrae, second and fourth lumbar vertebrae. Left quadratus lumborum muscle also received 40 u.

Results
The score reported by the parents in the Global Dystonia Severity Rankin Scale went down from
10 (pre-injection) to 5 (post-injection). Pain reduction was recorded indirectly by reporting of the parents who perceived the patient more relaxed and more smiling. An upright sitting without dorsal support /with support on hands was achieved of more than 10 seconds and a decrease in left inclination. No adverse effects were reported.

**Conclusion**

The administration of botulinum toxin type A in the paraspinal muscles seems to be an effective treatment to reduce truncal hyperextension, besides the pain and disability that it produces.

GAIT SPEED IMPROVEMENT WITH GAIT TRAINING USING ROBOT SUIT HYBRID ASSISTIVE LIMB (HAL) IN PATIENTS WITH INCLUSION BODY MYOSITIS: A CASE SERIES.

N. Okabe¹, D. Kato¹, H. Nakayama¹, J. Toyomasu¹, S. Haga¹, D. Nishida², H. Hara³
¹saiseikai kanagawa-ken hospital, Rehabilitation Therapist, yokohama, Japan
²saiseikai kanagawa-ken hospital, Rehabilitation, yokohama, Japan
³saiseikai kanagawa-ken hospital, Neurology, yokohama, Japan

Introduction/Background

Hybrid Assistive Limb (HAL) is a medical device especially for improving or preventing gait dysfunction of patients with rare neuromuscular disease.

The purpose of this study was to evaluate the effect of gait training using HAL in patients with Inclusion Body Myositis (IBM).

Material and Method

The participants were 5 patients with IBM (4 men and 1 female, mean age 74.6±8.3 years old), who admitted to our hospital. They took 4-9 sessions of HAL training program in 2-5 weeks, which consists of walking with HAL and hoist. During the training program, we changed training setting such as parameters of HAL, amount of body support and walking distance depends on participants' condition of gait. Before and after HAL training program, we measured 10 meters walking test without HAL 3 times as an indicator of gait performance and blood creatinine kinase (CK) value as an indicator of activator of myositis.

Results

The walking speed on 10 meters increased after training compared with before (56.78±34.7m/min to 63.98±29.96m/min :12.7% increased) and the blood CK value decreased after the training compared with before (520.8±278.48U/L to 318.4±189.11U/L :38.86% decreased).

Conclusion

On this study participants could walk faster without myositis worsening by the training. This result suggested that the repetitive gait training using HAL encouraged motor learning.

COGNITIVE FUNCTION INVOLVED IN MOTOR PREPARATION RATHER THAN MOTOR EXECUTION: REVERSE REASONING FROM AN ERPS STUDY OF A HEMIPLEGIC PATIENT AFTER ENCEPHALOPYOSIS

H. Li¹, D.F. Huang¹
¹The First Affiliated Hospital of Sun Yat-sen University, Rehabilitation Medicine, Guangzhou, China

Introduction/Background

Movement-related potentials (MRPs) have been used to study movement planning, execution and imagining process. Movement preparation could play a crucial role in hemiparetic motor deficits. How does cognitive function play its role in the movement planning and execution procedure is of significant importance for understanding movement deficit from neuropsychological perspectives and might help future rehabilitation strategy for patient with motor deficits.

Material and Method

A hemiplegic patient recovered from encephalopyosis with merely motor function deficit was investigated in the present study. Event-related potential (ERP) experiments were performed in a shielded room with a visual instruction-response paradigm to study the MRPs during the patient's unilateral wrist movement, and a P300 paradigm with visual stimuli to investigate the patient's integrated cognitive function.

Results

Compared to unaffected arm, the movement of the paretic arm showed no prolonged latencies or increased value in readiness potential in the motor preparation process, while motor potential (MP) demonstrated an prolonged latency as well as increased peak value. Movement of the paretic arm also presented a phenomenon that after MP peak, the cortical potential remained on a high level instead of dropping back to the baseline, accompanying the arm spasm after voluntary movements. P300 ERP test of the patient was read normal latencies and peak values of P300 waves compared with our database of healthy subjects. Cognitive function was proved to be involved in motor process, while in this rear case with mere motor function deficit, the ERPs results might indicate that cognitive function is mainly involved in the motor preparation rather than execution process.

Conclusion

This study provides evidence from the reverse reasoning perspective that cognitive function is involved in motor preparation rather than motor execution stage. Hence for patients with
combined deficits of motor and cognitive function, cognitive rehabilitation interventions may be of benefit in the preparation process of movement.

IMPROVEMENT OF LUNG FUNCTION, HAND GRIP, AND MOBILIZATION AFTER USING INSPIRATORY MUSCLE TRAINING IN PATIENT WITH NEUROLOGICAL PROBLEM

I.R. Defi¹, D. Martasari¹, F. Arisanti¹, I. Nurina¹, W.F. Nisa¹, C. Pakhpahan¹
¹Faculty Of Medicine Padjadjaran University/Hasan Sadikin General Hospital, Physical medicine and rehabilitation, Bandung, Indonesia

Introduction/Background

Respiratory muscle training (RMT) in patient with neurological problem has beneficial effect on respiratory function and also improve peripheral muscle strength and functional ability. This study investigated the effect of inspiratory muscle training (IMT) on lung function, mobility, balance and peripheral muscle strength on paretic side of post stroke sub-acute phase patient.

Material and Method

14 patients participate in this study. The intervention group gets IMT with intensity 40% of PI max while control group get 10% for 8 weeks. We evaluated pulmonary muscle strength with Micro RPM, quadriiceps strength with hand Held-dynamometer, grip strength with Jamar, walking speed by 10 meter walk test, functional mobilization with sit to stand test.

Results

Statistically significant improvements were measured in intervention group than control group after intervention.

Conclusion

IMT shows improvement on mobilization, balance, grip and quadriiceps paretic side strength on sub-acute stroke patient, and improve functional status for patient back to community.

THE CONTRIBUTION OF THE USEFUL FIELD OF VIEW (UFOV PROCEDURE) TO ALLOW BRAIN-DAMAGED PATIENTS TO DRIVE AGAIN.

C. Moroni¹, S. Defoort², C. Marks-Delesalle²

¹Lille University, Psychology Department, Villeneuve d'Ascq, France
²CHUR de Lille, Service Exploration de la Vision et Neuro-ophtalmologie, Lille, France

Introduction/Background

Visual field disorders, frequently observed in brain-damaged patients, are associated with an adverse prognosis in outcome activities as car driving. In France, a prefectorial order contraindicates driving if the visual field is inferior to 120° on the meridian axis, inferior to 20° on a vertical axis and with defects in a 20° radius from the center. Our aim was to study patients' abilities to distribute their visual attention in space, in case of visual field disorders.

Material and Method

Thirty eight patients with a hemianopia and 49 with a visual defect in the central 20 degrees performed an Useful Field Of View procedure (UFOV). This computer-based assessment contains three attentional tasks: a processing speed task to detect a target in central vision, a divided attention task involving to detect simultaneously a central and a peripheral target, a selective attention task consisting in detection of a central and a peripheral target in attendance of visual distractors. Brain-damaged patient performance was compared to cut-off scores elaborated in a previous study with healthy neurological volunteers (Marks et al, 2015).

Results

Only one patient with hemianopia reached normal performance in UFOV tasks. All others patients with hemianopia could not distribute their visual attention in the amputee visual field. However, ten patients among the 49 with a visual defect in the central 20 degrees reached normal performance in UFOV tasks, proving their normal abilities to distribute visual attention in space despite the visual field disorder.

Conclusion

When the visual field disorder concerns the central 20 degrees, some patients could balance out it using their visual attentional abilities and maybe in these cases, a driving simulator try and/or an “on-road” try could be proposed before to examine the driving restriction.

PERIPHERAL NEUROPATHY INDUCED BY AMIODARONE CHLORHYDRATE: A CASE REPORT

N. Lazreg1, S. Layouni1, W. Ouannes1, S. Elmtaoua1, E. Toulgui1, F. Khachnaoui1, S. Jemni1
1University hospital sahloul- Sousse Tunisia, Physical Medicine and Rehabilitation Department, Sousse, Tunisia

Introduction/Background

Amiodarone chlorhydrate is a diiodated benzofuran derivative. It is a drug used to treat refractory cardiac arrhythmias, produced a peripheral neuropathy in 10% of cases. Although the neuropathy may be severe, it tends to improve with lowering of the dosage or discontinuation of the medication.

Material and Method

We report the case to describe the clinical and para-clinical criteria of neuropathy induced by amiodarone.

Results

A 42-year-old and diabetic men, had a heart valve replacement by mechanical valves, for a Rheumatic Mitral Stenosis four months before. He was given amiodarone 200 mg by day. He reported progressive weakness of his arms and legs, associated to paraesthesiae and numbness in his legs since 4 months. Clinical examination found a distal symmetrical sensorimotor neuropathy with areflexia. Electromyographic study was performed 1 month after drug cessation and showed severe mixed sensory and motor peripheral neuropathy in the distal lower limb muscles. One month after stopping amiodarone, introducing pregabaline and physical rehabilitation, the motor symptoms had improved considerably, but there had been no significant improvement of sensory symptom and paraesthesia in his legs.

Conclusion

Patients who take large doses of amiodarone for long periods should be monitored for the development of neuropathic symptoms or signs, especially when there are associated risk factors such as diabetes mellitus. The reduction of dose or withdrawal of treatment may be necessary to prevent significant morbidity.

Keywords

Amidarone; Neuropathy; toxicity

HOW STROKE AFFECTS QUALITY OF LIFE?

M. Micha

University General Hospital "Attikon", Physical Medicine & Rehabilitation, Athens, Greece

Introduction/Background

The assessment of health-related quality of life (HRQoL) in Greek patients with a history of stroke.

Material and Method

A perspective study of HRQoL in 62 patients with stroke examined in the outpatient department of Physical Medicine and Rehabilitation, University General Hospital "Attikon", Athens using the general questionnaires SF-36 and EQ-5D. Barthel index was used for the evaluation of activities of daily living (ADL) and the severity of stroke was graded by National Institute of Health Stroke (NIHS) scale. Demographics and clinical characteristics of the patients were also recorded.

Results

Mean age of patients: 64.3 ± 15.9 years, mean duration of disease: 5.9 ± 5.1 years. 41.7% presented with uninhibited bladder and spasticity was detected in 58.3%. 25% of the patients were able for therapeutic ambulation with low mean scores on SF-36 in the domains: physical role (p=0.002), social role (p=0.018) and emotional role (p=0.049). Mean value of EQ-5D: 0.21 ± 0.4, while the mean scores on SF-36 dimensions were found low, ranging from 23.5 (physical functioning) to 49.1 (role emotional). 83.3 % had medium to severe problems with self-care, 97.2% with mobility, 83.3% reported bodily pain and 91.7% presented with stress and depression. Patients with urinary disturbances were found to have lower scores in social role (p=0.033) and mental health (p=0.044). Subjects with spasticity were found with low scores in domain of mental health (p=0.035). Significantly low indices of HRQoL by means of EQ-5D were found in subjects with urinary disturbances (p=0.002) and spasticity (p=0.018). Negative correlation between Barthel index and NIHS was found, with correlation coefficients ranging between 0.37 and 0.72.

Conclusion

Stroke has a negative impact on HRQoL in patients with history of stroke and the factors associated with it should be appropriately managed by the rehabilitation specialist.

OUTCOME AFTER POSTERIOR DECOMPRESSION IN CHIARI MALFORMATION: THE ROLE OF REHABILITAION
M. Rihab¹, W. Ouannes¹, I. Haddada¹, S. Mtaouaa¹, E. Toulgui¹, M. Gaddour¹, F. Khachnaoui¹, S. Jemni¹
¹Sahloul Hospital, physical and rehabilitation unit, Sousse, Tunisia

Introduction/Background

Chiari malformation is defined as the prolapse of cerebellar tonsils under the foramen magnum. The prevalence of such disease is still not identified because of the importance of symptomatic forms. The onset of symptom is large (0 to 60 years). DIAGNOSIS is based on CT and MRI to define the type of the malformation, and identify its consequences (syrinx, hydrocephalus). The surgery is based on posterior decompression. Outcomes after surgery, need a hard survey to reveal complications, nursery assistance and rehabilitation.

Material and Method

A retrospective study of 3 cases hospitalized in our rehabilitation unit between july 2014 to January 2017. A girl and 2 women aged respectively 11, 49, 43 years old. We revealed: the clinical signs, the type of malformation, type of surgery, post-operative complications, nutritional status, functional impairment.

Results

Tetraparesia with cerebellar syndrome were the common signs in the 3 patients. The 2 women presented paresis of IX and X cranial pair. MRI has revealed CHIARI type 2 for the 3 of them, syrinx and hydrocephalus for the last patient. Post operative outcome was simple for the girl. She was adressed for rehabilitation 3 days after surgery, and could walk lonely after 2 weeks. The 2 woman needed a stay in reanimation for 1 month and 5 months respectively. This was justified by respiratory depression and acute hydrocephalus respectively. In rehabilitation unit, they benefited of nursing, nutritionnal care and physiotherapy. the two first patients recuperated their autonomy. the third one still depends on others because of the long stay on reanimation and the complications of decubitus.

Conclusion

Diagnosis of Chiari malformation should be earlier than the occurrence of motor disorder to avoid postoperative complications. The role of rehabilitation consists on nutritionnal assistance, treatment of decubitus complications, physiotherapy to recover the most of autonomy.

Proximal median neuropathy (PMN) due to nerve compression by mass lesion is a rare disorder. G. Martinez-Villen et al. reviewed 541 patients with nerve compression syndrome in the forearm and hand, and only 2 cases revealed a proximal forearm origin mass lesion.

Material and Method

A 68-year-old women of right handed presented with right fingers tingling sensation, hypoesthesia and weakness for several years. She had been taking care of her grandchildren for 5 years.

On physical examination, wrist (3+/5), thumb(3/5), index and middle finger(3+/5) flexor and thumb abductor(2/5) of right hand weakness was observed. Tinnel's sign was positive in right wrist. Right thenar muscle atrophy was prominent. There was a soft nodule on the volar side of the wrist. She denied discomfort above the wrist. The clinical diagnosis was compression median neuropathy at wrist.

Results

In electrodiagnostic study, right median nerve sensory response was absent and motor conduction revealed delayed latency (4.65ms) and reduced amplitude (0.3mV) at wrist (7cm proximal to recording site) stimulation with absent response at elbow. In needle electromyography, abnormal spontaneous activities were seen at pronator teres and flexor carpi radius muscles. Screening nerve ultrasonography at wrist revealed cross sectional area of median nerve at carpal tunnel inlet as 13mm² in right side (vs 8mm² in left side), and a 11mm²-sized nodule adjacent to median nerve at wrist.

MRI of forearm revealed hypertrophied transverse carpal ligament and lipomas at wrist and elbow. (Figure) Surgical removal of lipomas, median nerve decompression at wrist and forearm and carpal tunnel release operation was done. Her symptoms were improved after operation.

Conclusion

Clinical features of PMN can mimic distal lesions. When distal median neuropathy, commonly seen as carpal tunnel syndrome is suspected, it is important to keep in mind the possibility of proximal origin. Electrodiagnostic investigation is a valuable tool for screening and localizing the
proximal lesions.

INTERDISCIPLINARY WORK FOR VESTIBULAR REHABILITATION
A. Vasquez Morales¹, A.M. Proffesor¹
¹Manuela Beltran University, Vicerrectoria de Investigaciones, BOGOTA, Colombia

Introduction/Background

A vestibular lesion has a vertiginous manifestations characterized by a sensation of body movement or objects that is not real. Objective: To implement a vestibular rehabilitation intervention plan through interdisciplinarity.

Material and Method

Quantitative study, descriptive with case study design. The case studied was about the adult over 65 years old referred to the phonoaudiology service for diagnosis of vestibular lesion. Rutka vestibular screening was applied to identify endolymphatic pressure and signs associated with peripheral vertigo and the Romberg Test. An interdisciplinary intervention protocol was established that allowed work on the equipment and the reduction of the signs and symptoms evidenced.

Results

The user presented high endolymphatic pressure with exacerbated vertigo, blurred vision, aural fullness, difficulty in visual-manual coordination, test of Romberg positive. An intervention plan was proposed from phonoaudiology and physiotherapy to facilitate an integral rehabilitation. The intervention plan had nine (9) sessions with an hour of duration each one did it daily. The sessions included supine, seated and bipedal activities of manual coordination training with therapeutic ball, endolymphatic exercises with sudden cephalic movements, follow visual of moving object and alternate decubitus changes. After the implementation of the treatment, was tolerance to postural changes, decreased vertigo, improved visual-manual coordination and better dynamic balance assessed through the test. Also the perception and performance of the user evidenced modified favorably.

Conclusion

The interdisciplinary work in the vestibular rehabilitation allows to integrate important areas of knowledge and beneficial experience to the user, in this case by the rigor, the integral vision of the disciplines and the contribution in cost-effectiveness by the reduction of the number of sessions required.

PARKINSONISM SECONDARY TO WILSON DISEASE – CLINICAL CASE
A. Oliveira Pegado¹, D. Martins¹, S. Proença², V. Silva¹, S. Rosa¹, J. Dias¹
¹Centro Hospitalar Lisboa Central, Medicina Física e Reabilitação, Lisboa, Portugal
²Centro de Medicina e Reabilitação de Alcoitão, Serviço de Reabilitação de Adultos 3, Alcoitão, Portugal

Introduction/Background

Wilson disease (WD) is a rare autosomal recessive disorder characterized by the reduced biliary excretion of copper, resulting in the toxic accumulation in multiple organs. Early diagnosis and copper removal treatment significantly improve the prognosis. If patients adhere to lifelong maintenance therapy, the prognosis is generally good. In rare cases, liver transplantation is necessary and highly effective. WD can present with hepatic, neurologic, psychiatric, ophthalmologic, gynecologic abnormalities. Parkinsonian features can be present, which makes WD a possible aetiology of secondary parkinsonism.

Material and Method

We present a case of a 38-year-old caucasian male, followed in Gastroenterology for an hepatic cirrhosis since 18. He was completely functional, working as an informatics engineer till April 2017, when he started to have some postural tremor, bradikynesia and poor balance, with several falls. He went to a Neurology appointment where it was suggested it might be WD. After clinical worsening, he was admitted in a central hospital to be studied and medicated. He started specific medication for Wilson disease, with a fast raise to a high dose of d-penicilamine. In some weeks his clinical condition got worse, which was assumed as a side effect of this drug. It was changed and started anti-parkinsonic agents.

Results

He came to our appointment in October 2017. At the time he was completely dependent, with marked bradikynesia and tremor, poor cooperative, with dysarthria, hypomimia and ataxic tetraparesis. He couldn’t stand or move without wheelchair, pushed by others. He was admitted to interdisciplinary-rehabilitation-program in our centre.

Conclusion
WD is a rare cause of secondary parkinsonism. This is a case of a patient who wasn’t diagnosed before, and as so, wasn’t medicated properly. The literature isn’t consensual about the reversibility of the symptoms. Some may disappear or improve with the normalization of copper levels, medication and rehabilitation. However others may persist.

A CASE OF DRY BERI BERI WITH CENTRAL AND PERIPHERAL NEUROLOGIC DEFICITS FOLLOWING BARIATRIC SURGERY: FUNCTIONAL OUTCOMES AFTER REHABILITATION

M. Ruiz Sanz¹, C. Cid Bassaletti¹, J.A. Moreno Palacios¹, C. Epalza Díaz Guardamino¹, M.E. Nuño Estevez¹, C. Vidal Millet¹

¹Hospital General Universitario Gregorio Marañon, Medicina Fisica y Rehabilitación, Madrid, Spain

Introduction/Background

Neurological syndromes secondary to Beriberi (thiamine deficiency), including Wernicke Encephalopathy and Peripheral neuropathy, have been historically related to alcoholism. However, more cases are now presenting in patients who underwent bariatric surgery and afterwards didn't follow nutrient supplementation. Dry Beriberi, characterized by a sensorimotor distal, axonal, peripheral neuropathy, is manifested as distal lower limb paresis and altered sensibility. Wernicke Encephalopathy is characterized by the triad of ocular palsies, confusion and gait ataxia. We present the functional results in a case of Peripheral neuropathy with Wernicke Encephalopathy secondary to Beriberi after Bariatric surgery, who was managed with an intensive rehabilitation program.

Material and Method

An 18-year-old woman, who 2 months prior had Bariatric surgery (loosing 24kg since intervention) and who didn't follow up nutritional supplementation prescription, presented with progressive lower limb weakness, staggering gait, paresthesias and dysesthesias in L3-L4 regions. Clinical presentation and complementary tests including electromiography, led to diagnosis of Polyradiculopathy and Encephalopathy secondary to nutritional deficits. She was managed with thiamine supplementation and referred to Rehabilitation for evaluation and treatment. Initial assessment evinced horizontal nystagmus, muscle strength in lower limbs of 2-3/5 (proximal) and 1/5 (distal) in MRC scale, absence of deep tendon reflexes and inability to stand erect and ambulate. Sensibility was preserved.

Results

Patient started rehabilitation with intensive physiotherapy. After 3 months, lower limbs muscle strength level was of 3-4/5 (proximal) and 2-3/5 (distal), she walked with aid of 2 forearm crutches and had a left steppage gait pattern. At 6-month follow-up she was discharged, having achieved lower limbs muscle strength of 4/5 and autonomous gait without claudication.

Conclusion
Thiamine deficiency after bariatric surgery may manifest with central and peripheral neurological deficits. In these cases, it is important to emphasize the role of intensive rehabilitation of neurologic deficits in the recovery of previous functional status after acute management with thiamine supplementation.

Background: Current evidence supports early mobilization (EM); rehabilitation of ICU patients, under mechanical ventilation or not, improves functional outcomes and is found to be safe. However, little is known about EM of neurocritical patients, especially because EM is still seen as a potential dangerous intervention in neurological ICU patients.

Objective: To review safety data regarding patient rehabilitation in the Neuro-ICU, and to compute incidence of adverse events such as hemodynamic changes, clinical deterioration, removal or dysfunction of respiratory tubes, intravascular catheters, other external disposals and falls.

Material and Method

Data Sources: Systematic literature review, including searches of 4 databases. Eligible studies for the statistical analysis evaluated adult patients who received an EM program in a Neuro-ICU at an early stage <7 days, and provided data to allow the computation of incidence of adverse events. A further scoping review on EM of neurocritical patients included studies assessing epidemiology, cerebral hemodynamics changes during exercises, description and efficacy of EM programs in Neuro-ICU.

Data Extraction: Number of patients, mobilization/rehabilitation sessions, type of intervention and session time, and potential safety events and adverse events with negative consequences (requiring intervention or additional therapy).

Results

Synthesis: Heterogeneity was assessed by I-square statistics, and bias assessed by the Newcastle-Ottawa Scale and Cochrane risk of bias assessment. The literature search identified 1134 titles. There were 4 eligible publications for the statistical analysis part, evaluating 195 patients, with 95 potential safety events (12%) and 3 safety events with consequence (0.4%).
occurring in 793 mobilization/rehabilitation sessions, with an average of 27.8 minutes/session. There was heterogeneity in the definition of these events. Most potential safety events were modifications of vital signs without any clinical or therapeutic consequence. 47 studies were used for scoping review.

**Conclusion**

**Conclusions:** Early rehabilitation in NICU appears to be safe with a low incidence of safety events, not having any consequences for patient management.

**Keywords**

Neuro-ICU; early rehabilitation; safety

MOBILITY OF ADULTS WITH CEREBRAL PALSY

L. Rodríguez Zambrano¹, F. Ortiz Corredor¹, C.A. Orjuela Rolón¹
¹Universidad Nacional De Colombia, Medicina Física y Rehabilitación, Bogotá, Colombia

Introduction/Background

Mobility in adults with cerebral palsy (CP) have a wide spectrum. It is necessary to determine whether there is any association between capacity and performance tests to categorize groups and define interventions.

Objective: To determine the characteristics of the mobility in adults with CP seen in a tertiary hospital and its correlation with different variables of capacity and performance.

Material and Method

233 patients with CP ≥ 18 years with GMFCS I – IV, were assessed using the functional mobility scale (FMS). To determinate the capacity, 6-minute walk test (6MWT), Timed Up and Go (TUG) and a walking speed (WS) were assessed in a subgroup of patients.

Results

The main features of the patients are shown in table 1. Most patients walk with assistance devices for long distances (500 m), but not for shorter distances (5- 50 m). The results of the capacity tests in our study are lower than in general population (Table2) and there are significant differences between of the FMS groups (Table 3 – Fig. 1). Very strong correlations were obtained between the 6MWT and the WS (r= 0.83; p< 0.001) (Fig. 2), the 6MWT and TUG (r= -0.86; p< 0.001) and strong correlation between FMS 500 and 6MWT (r= 0.75; p< 0.001) (Fig. 3).
Conclusion

The results indicate that the measures assess in a clinical setting correlate with the expected performances in the daily spaces for adults with cerebral palsy seen in reference center. The WS is easy to measure and have an excellent correlation with the 6MWT and the FMS tests.

Hyponatremia is the most common disorder of electrolytes encountered in clinical practice, occurring in 22% of hospitalized patients. Acute severe hyponatremia can cause severe morbidity and mortality. Adverse outcomes are higher in hyponatremic patients with a wide range of underlying conditions. There are different causes of hyponatremia but NSAID's used commonly in brain injury patients for managing pain can result in hyponatremia leading to complications such as lethargy, confusion, dizziness, gait disturbances, muscle cramps, seizures, coma and even death. Too rapid correction of hyponatremia in these patients can also lead to life-threatening complications.

Material and Method

A case study was conducted on a brain injury inpatient who suffered from hyponatremia in our unit secondary from NSAID's which were started for her arthritis. Patient responded to the treatment initially very well but later on showed quick decline in her clinical status with varying signs and symptoms ranging from confusion, lethargy, speech and swallowing decline as well as seizures and gait disturbance. Her blood tests showed gradual hyponatremia and this was co-related exactly with the time of starting NSAID's.

Results

Patient responded slowly but very well with stopping NSAID's and treating with fluid restriction for a time being although the clinical decline remained there for sometime.

Conclusion

Avoid the use of NSAID's in brain injury patients as their use can cause significant hyponatremia which could result in life-threatening complications. Even the rapid correction of this hyponatremia can be too dangerous or fatal. NSAIDs related Hyponatremia in Brain Injury patients has been proven as a silent factor for their deterioration and thus needs careful monitoring and treatment.

HANDICAP IN ADULTS WITH ARTHROGYROSIS IS SEVERE, PARTLY INVISIBLE AND VARIES BY GENOTYPE

S. Dai¹, K. Dieterich², M. Jaeger¹, B. Wuyam³, P.S. Jouk², D. Pérennou¹
¹CHU Grenoble Alpes, Neurorehabilitation Department, Echirolles Cedex, France
²CHU Grenoble Alpes, Genetic Department, La Tronche, France
³CHU Grenoble Alpes, Physiological Department, La Tronche, France

Introduction/Background

To understand the nature of the handicap of adults with arthrogryposis multiplex congenita (AMC), a rare disease spectrum characterized by at least two joint contractures at birth in different body areas, and analyze its possible variation by genotypes.

Material and Method

Retrospective analysis of data for unselected persons with AMC referred to the French center for adults with AMC from 2010 to 2016. All underwent a pluri-professional systematic and comprehensive investigation of deficits, activity limitation, and participation restriction according to the International Classification of Functioning, Disability and Health and genetic analysis when indicated. Participants were divided by Amyoplasia and other AMC types.

Results

Mean (SD) age of the 43 participants (27 females) was 33.2 (13.4) years; 28 had Amyoplasia and 15 other types of AMC. Beyond joint stiffness, deformities and muscle weakness, the well-known core symptoms that we quantified and for which first-line treatment involved technical aids for 50% (wheelchair for 35%, electrical wheelchair 28%, manual wheelchair 7%, crutches or orthopedic shoes 14%) and human aid for 40%, requiring technical aids more frequent with Amyoplasia than other AMC types (61% vs 27%, p=0.05). Other less visible disorders that could contribute to severe participation restriction were particularly pain (91%) and psychological problems including anxiety, fatigue, difficulty in sexual life, altered self-esteem, and feelings of solitude. Severe respiratory disorders were infrequent and were linked to PIEZO2 mutations (only in other AMC types), respiratory function was better with Amyoplasia than other AMC types (FVC 3.8 [3-4.3] vs 2.2 [1.4-2.7], p<0.001). Gait disorders were not due to respiratory impairment but to skeletal problems and were always associated with Amyoplasia when severe.

Conclusion

This study describes disability patterns of a cohort of adults with AMC by genotype. The handicap of adults with AMC is influenced by genotype, with an important invisible handicap.

Marcus-Gunn syndrome is a syndrome that associates congenital ptosis and mandibulo-palpebral synchinesis in certain mandibular movements. We report a case of Marcus-Gunn syndrome by emphasizing the clinical, aetiological and therapeutic aspects of this syndrome.

Material and Method

This is a child of 6 years and a half of which the parents consult for a left palpebral drop observed at the age of 2 years and which disappears during the mouth opening. The interrogation finds the notion of consanguinity of the first degree in parents. Examination of the appendages found a major left ptosis with a zero lift stroke associated with frontal muscle hyperaction (Figure 1). Retraction of the upper-left eyelid occurs during oral opening (Figure 2), the synchinesis is moderate.

Results

The first case of Marcus Gunn's syndrome is described by a Robert Marcus Gunn in 1883 as "Jaw-Winking Phenomenon". It represents 2 to 13% of congenital ptosis. The ptosis is corrected by the mouth opening or the mandibular diduction. The syndrome is usually unilateral. Most often on the left side, which is noted in our case. In our observation, this is the first case diagnosed in the family. The aetiological genesis is poorly known, it results from an aberrant innervation of the levator muscle of the upper eyelid. The associated systemic abnormalities are: a bilateral hollow foot with genu varum, bilateral cryptorchidism, spina bifida and cleft lip. The treatment is twofold: surgical and rehabilitative. In our case, a section of the levator muscle of the upper eyelid was proposed.

Conclusion

Marcus Gunn syndrome is a rare condition that associates ptosis with mandibulo-palpebral synchinesis. It is probably due to an erratic innervation of the levator muscle of the upper eyelid, by the branches of the trigeminal nerve. The re-educative treatment finds its place postoperatively.

Keywords

INTRODUCTION/BACKGROUND

Brain abscess is an infection of the brain parenchyma. The most common source of infection is by direct spread from a contiguous site but it can also be caused by a haematogenous spread.

Diabetes, immunodeficiency or age, are known as risk factors while; motor/sensory deficits and speech disorders, headache, confusion or nausea are the most common clinical signs.

MATERIAL AND METHOD

We report the case of a 73 year old woman, with medical history of type 2 diabetes and pyelonephritis caused by Klebsiella Pneumoniae, who consults for a sudden onset of aphasia and right hemiparesis. A Computed Tomography (CT) was performed, demonstrating a left frontoparietal spontaneous intracerebral haemorrhage, that it was treated conservatively.

After an initial stabilization, she started physical and speech therapy.

Later on, her neurological condition worsened and she presented fever. Urinary infection, endocarditis and bacteraemia were excluded. As she suffered from complex and simple partial seizures a Head Magnetic Resonance (HMR) was made.

RESULTS

HMR showed signs suspected for a brain abscess in the haemorrhage region. Head-CT angiogram with contrast excluded AVM/aneurysms.

A left frontal craniotomy was performed, to evacuate the abscess. Klebsiella Pneumoniae was isolated and IV Vancomycin was given for six weeks.

After all, she continued with physical therapy and occupational therapy.

She was discharged with minimal upper right limb weakness and complete motor aphasia.

CONCLUSION
There are few cases of brain abscess developing in untreated intracerebral haemorrhage reported in the literature. Neuroradiological imaging, neurosurgical drainage, antibiotic therapy and rehabilitation, are, in our opinion, the best way to treat this type of condition; with multidisciplinary work to achieve patient’s best functional state.

ADULT PRESENTATION OF DYKE-DAVIDOFF-MASSON SYNDROME IN AN ADULT COMPLICATED BY COMMUNICATING HYDROCEPHALUS: A CASE REPORT.

M.B. RAMALINGAM\textsuperscript{1}, K.L. Wong\textsuperscript{1}, S.K. Lui\textsuperscript{1}

\textsuperscript{1}Singapore General Hospital, REH\textsuperscript{\textregistered}BILITATION MEDICINE, Singapore, Singapore

Introduction/Background

Study design: A case report.

Background and aims: To present an unusual cause of functional decline in an adult.

Material and Method

Methods: A 61 year old female with history of congenital right-sided weakness and epilepsy was admitted for headache. Prior to hospitalization, she was independent in her activities of daily living (ADLs) and ambulation and was working as a cleaner. Neurological examination showed no new weakness but worsening of her cognition which included slow processing speed and inconsistent following of one step commands. After a five month hospitalization inclusive of intensive inpatient rehabilitation, she was discharged and required maximal assistance in her

Results

CT brain showed left-sided cerebral hemiatrophy, ipsilateral calvarial hypertrophy and dilatation of the left frontal and sphenoid sinuses and a possible communicating hydrocephalus, raising the possibility of a complicated Dyke-Davidoff-Masson syndrome. Cerebrospinal fluid analysis for infection was unyielding. Participation in rehabilitation with mild functional improvement was noted following a diagnostic lumbar puncture. There are plans for lumbar puncture tap test in the outpatient setting.
Conclusion

Dyke-Davidoff-Masson syndrome is an extremely rare condition encountered in the rehabilitation setting and is an unique cause of functional decline in an adult

THREE CASE STUDIES OF LATE DIAGNOSES OF POLIO IN AUSTRALIAN ADULTS
C. Formby1, D. Currie1
1St Vincent's Hospital Melbourne, Polio Services Victoria, Fitzroy, Australia

Introduction/Background

Polio Services Victoria (PSV) is a publicly funded organization; anyone with a history of polio residing in Australia may be seen by the service. The majority of patients referred to the service were diagnosed with polio shortly after they were infected with the virus, for most this was in early childhood and ranges from two to eight decades ago.

In the past 18 months three patients were referred to PSV with untypically late diagnoses of polio, two of which were sisters. All were born in Australia between 1930 and 1950 and are considered to have acquired their infection in Australia during their early childhood.

The three were able to live relatively uneventful lives however their verbal histories indicate suspicion of polio during their childhood medical examinations in school, but ultimately no formal diagnosis was made at that time. In later life, symptoms characteristic of the late effects of polio emerged. In combination with imaging and nerve conduction studies these symptoms were diagnosed as being the result of a likely childhood infection of polio.

Their current and future management plans are typical of that seen regularly within the service with the patients reporting their main problems as being:

- Pain
- Fatigue
- Increasing muscle atrophy and associated weakness

These three cases highlight that although Australia, like most of the world, holds polio free status there may still be further undiagnosed cases. Polio should be considered as a differential diagnosis for patients presenting with any of the cardinal signs and symptoms of late effects of polio who have resided in a country during a time prior to polio eradication. Special consideration should be given where a sibling or close relative was diagnosed with polio.

EMERY DREIFUSS MUSCULAR DYSTROPHY 1: CASE REPORT AND FUNCTIONAL PHENOTYPE OF A NOVEL MUTATION IN BOGOTÁ, COLOMBIA

H.E. Perico-Franco¹, F. Ortiz-Corredor¹, C. Mendoza², D.P. Soto-Peña², S. Castellar², E. Ruiz-Ospina²

¹Universidad Nacional de Colombia, Physical Medicine and Rehabilitation, Bogota, Colombia
²Instituto Ortopedia Infantil Roosevelt, Physical medicine and rehabilitation, Bogotá, Colombia

Introduction/Background

Emery Dreifuss muscular dystrophy (EDMD) is a rare disease, characterized by contractures, rigid spine, slowly progressive humeroperoneal atrophy, cardiomyopathy and fatal arrhythmias without treatment (Bonne, Leturcq, & Yaou, 2018; Koch & Holaska, 2014; Madej-pilarczyk & Kochański, 2016). Until now have been seven genetic causes identified (Bonne et al., 2018; Madej-pilarczyk & Kochański, 2016). EDMD functional phenotype literature is scarce, there is no detailed functional evaluations with gait analysis. We present a case of a 15 years old boy with EDMD 1, with a novel no-sense mutation in EDM gene c.123C>A (p.tyr41*).

Material and Method

We apply several test for describe the functional phenotype, and present the results of MFM, Box and block test, 6mWT, Timed Up&Go, 10mtWT, coin rotation task, monopodal stance test, five times sit to stand test, 4 steps stair climb test and gait computerized analysis

Results
Objective test follow for functional and structural deficiencies in neuromuscular diseases is overriding for determinate the adequate interventions, prognostic and establish the functional impairment spectrum. In our patient we observe both elbow and spine contractures progression and change on gait kinematics and kinetics, but not reduction on his physical capacity.

RATIONALE AND DEVELOPMENT OF CARDIAC REHABILITATION AT DIFFERENT STAGES OF CARDIOVASCULAR CONTINUUM

V. Sujayeva

Republican Scientific and Practical centre “Cardiology”, scientific laboratory of cardiac rehabilitation, Minsk, Belarus

Introduction/Background

To develop a new approach to cardiac rehabilitation for patients with different cardiovascular diseases based on novel theoretical principles in pathophysiology of decreasing and recovery of physical capacity in cardiovascular continuum.

Material and Method

We studied pathophysiological mechanisms of tolerance to physical loading and aerobic physical capacity reducing at 529 patients in different stages cardiovascular continuum: 74 pts with metabolic syndrome (MS), 113 pts with arterial hypertension, 229 pts with myocardial infarction (MI) and 32 pts with terminal stage of heart failure (HF) needed for heart transplantation. We used 24h Holter monitoring, blood pressure daily monitoring, echocardiography, spiro bicycle ergometry test (spiroBET), treadmill test, 6-minute walk test, and blood biochemistry were performed according to standard ways.

Results

Developed programs of cardiac rehabilitation were different at pts with MS, hypertension, MI and HF and depended on functional reserve revealed by spiroBET, treadmill test and 6-minute walk test. Under the influence of new approach to physical rehabilitation, a better tolerance to physical exercise and aerobic physical capacity has been observed. Improving in functional status of blood circulatory system reached due to development of mechanisms of short-term and long-term adaptation, switch of cardiovascular system to a more saving functioning mode, and less severe respiratory and metabolic disorders. We also established that developed approach to physical rehabilitation leaded to improving not only medical but also social and economic efficiency.

Conclusion

Cardiovascular rehabilitation should be continual and unbroken process starting from patient with risk factors (MS and hypertension) and not been interrupted at ending stages of cardiovascular continuum.

IS SCREENING FOR OCCULT LOWER EXTREMITY DEEP VEIN THROMBOSIS (DVT) UPON ADMISSION TO ACUTE INPATIENT REHABILITATION HOSPITALS CLINICALLY WARRANTED? 

L. Ettefagh1, M. Jerome1, J. Porter1, H. Monfared1 
1Emory University School of Medicine, Physical Medicine and Rehabilitation, Atlanta, USA

Introduction/Background

Despite a high risk of venous thromboembolism (VTE) among patients admitted to acute inpatient rehabilitation hospitals, it is not currently standard of care in the United States to screen for them upon admission. In this study, we aimed to describe the prevalence of occult DVT and associated clinically relevant factors in an academic inpatient rehabilitation center.

Material and Method

This was a prospective observational cross-sectional study examining incidence of lower extremity DVT identified via duplex ultrasound within 48 hours of admission for patients without any prior active diagnosis of DVT.

Results

Among 127 patients admitted between October and December 2017, seven (5.5%) were excluded due to prior active DVT and twenty-one declined to participate (16.5%). Lower extremity duplex ultrasound was performed on 99 patients, however one patient was excluded due an inconclusive study without ability for follow up. Of the 98 remaining patients, 47 (48.0%) were male, 52 (53.1%) were female, and mean age was 61.4 years old (SD+14.2) (Table 1). Most common admission diagnoses included ischemic stroke (23%), debility/medical complexity (22%), and hemorrhagic stroke (11%). One of the 98 screened patients (1.02%) was positive for unilateral lower extremity DVT (Table 2). The total prevalence of DVT diagnosis among all admitted patients was 6.2%.

Conclusion
Our study suggests lower extremity DVT screening for all patients admitted to acute inpatient rehabilitation is not clinically warranted, however a much larger study with a more complete enrollment of the studied population is needed to confirm such recommendations.

⁴Aso Iizuka Hospital, Central Laboratory, Iizuka, Japan
⁵Aso Iizuka Hospital, Clinical Research Division, Iizuka, Japan
⁶Aso Iizuka Hospital, Cardiovascular Surgery, Iizuka, Japan

Introduction/Background
Cardiac rehabilitation improves exercise tolerance, QOL, reduces the risk of cardiovascular event and improves the prognosis. Frailty is the risk of hospital admission, and worsen prognosis.

Material and Method
Retrospective observational cohort study. Patients hospitalized with cardiovascular disease from January 2015 to March 2016. Study patients were matched for two groups who kept rehabilitation after discharge and who did not, with follow up until December 2016. Propensity analyses were used. The endpoint was death from any cause, cardiac death, hospitalization for heart failure, ACS, ER visit, TVR, and emergency admission for any cause. Analysis about the factor reduced the adverse event was done.

Results
In 2258 patients admitted, 104 got into the outpatient cardiac rehabilitation. Out of 554 study patients, 47 underwent rehabilitation. The frequency of emergency hospitalization tends to be few in rehabilitation group (p=0.067). Especially in elderly over 65, rehabilitation reduced the risk of emergency admission (2.8% vs 16.3%; p=0.031). After propensity score matching, emergency hospitalization was few in rehabilitation group (p=0.088). In rehabilitation group, CHS index significantly improved (p<0.001). Significant reduction of the emergency admission was shown (p<0.001). Frailty status was assessed in 31, 8 fell under the category of frailty. Through rehabilitation, 6 pulled out of category. Out of 23 patients whose score more than zero, 13 improved their score. Between the two groups in that emergency admission reduced, and in that did not, following data result are significantly different, LVEF, creatinine, uric acid, total protein, BNP level at start, and the amount of hemoglobin change during hospitalization. Age, gender, BMI, and CHS index at start, did not show a significant difference. In elderly, improvement of frailty certainly contribute to avoiding emergency hospitalization.
Conclusion

Outpatient Cardiac rehabilitation reduces the risk of emergency hospital admission, especially in elderly people. Improvement of Frailty is one of the most important factors.

IMPLEMENTATION OF JACOBSON'S PROGRESSIVE RELAXATION IN CORONARY BYPASS SURGERY PATIENTS BEFORE CHEST TUBE REMOVAL

M. Rupar¹, S. Kostic¹, N. Tasic²

¹Institute for Cardiovascular Diseases, Sluzba fizikalne medicine i rehabilitacije, belgrade, Serbia
²Institute for Cardiovascular Diseases, Cardiology, belgrade, Serbia

Introduction/Background

Introduction: The purpose of this study was to determine whether the use of a Jackobson progressive muscle relaxation, when used without opioid analgesia, decreases pain during chest tube removal (CTR) after coronary bypass surgery.

Material and Method

Methodology: A two-group quasi-experimental posttest design was used. A convenience sample of 100 subjects was divided into an experimental group (n = 50), who received relaxation training 15 minutes before chest tube removal and a control group (n = 50), who did not receive relaxation. All patients received 500mg of paracetamol 30 minutes before relaxation. Pain was assessed with verbal pain score (0-5). Analysis of variance was used to analyze the data.

Results

Results: Significant decreases in pain were demonstrated as a result of implemented relaxation t-test: 2.63 ± 0.725 vs 3.62 ± 0.725, p<0.001. All experimental subjects stated that the relaxation technique was simple to perform.

Conclusion

Conclusion: This study supports the use of Jackobson progressive muscle relaxation for pain management during CTR among patients who have undergone coronary bypass surgery.

The effect of respiratory physiotherapy in early postoperative period after cardiac surgery on arterial blood partial oxygen and carbon-dioxid saturation

Svetlana Kostic, Marija Rupar, Nebojsa Tasic
Cardiovascular Institute Dedinje, Belgrade, Serbia

BACKGROUND:

Several investigations reported importance of respiratory physical therapy in clinical improvement of patients after cardiac surgery. The aim of our study was to assess the effects of respiratory physical therapy program on arterial blood partial oxygen and carbon-dioxid pressure concentrations in early post-operative period.

METHODS:

Our study included 69 patients (47 men and 22 women, mean age 64.1 +/- 8 years) operated in Cardiovascular Institute Dedinje between January and July 2011. Thirty-four patients underwent CABG (Coronary artery bypass graft) procedure, 17 patients had valvular surgery and 18 patients had combined surgery. All patients had low arterial blood PO2 and PCO2 values on the first post-operative day. Intensive program of respiratory rehabilitation (combination of kinesiotherapy techniques, drainage methods and breathing exercises) was started in all patients on the first post-operative day. Partial pressure concentrations of oxygen and carbon-dioxid were determined on first and fifth postoperative day by analyzator.
RESULTS:

Partial pressure of oxygen in arterial blood was 86.24 +/-15% (mean +/- SD) on day 1 and 121 +/-28% on day 4 (p<0.0001). Partial pressure of carbon-dioxide in arterial blood was 40.41 +/-6.30% on day 1 and 39.47 +/-5.67% on day 4 (p=0.1125). Oxygen saturation in arterial blood was 95% +/-2% before physiotherapy program and 98% +/-1% on day 4 (p<0.0001).

CONCLUSION:

Patients with intensive respiratory rehabilitation after cardiac surgery exhibit a marked decrease in arterial blood partial pressure of oxygen and arterial blood oxygen saturation but not carbon dioxide partial pressure during early postoperative period. The clinical consequences and underlying mechanism require further investigation.

CARDIAC REHABILITATION IN PATIENTS WITH ACUTE HEART FAILURE CAUSED BY DILATED CARDIOMYOPATHY -CASE SERIES-
K. Kim¹, C. In Sung¹
¹Chonnam National University Hospital, Department of rehabilitation medicine, Gwangju, Republic of Korea

Introduction/Background

Cardiac rehabilitation (CR) can improve the quality of life, exercise capacity and the activities of daily living in patients with chronic dilated cardiomyopathy. However, there are few studies on the effect of CR in acute heart failure (AHF) caused by dilated cardiomyopathy (DCMP). Therefore, we aimed to investigate the changes of cardiac function and exercise capacity after CR in patients with AHF caused by DCMP.

Material and Method

We performed a retrospective chart review of 4 patients with AHF due to DCMP. They had undergone at least 4 times of follow-up exercise tolerance test (ETT). In each case, we measured body mass index (BMI), maximal MET (METmax) and maximal VO2 (VO2max) and checked left ventricular ejection fraction (LVEF) before and after CR. All patients were provided with education (during the admission and at every visit for ETTs), exercise prescription, and risk factor management and modification as a scheduled CR program.

Results

1) Among 4 patients, 2 were male and 2 were female. Mean age was 50.2 years (43-69 years). They were consulted for CR at 4.75 days (1 day-7 days) after hospitalization. The first visit after discharge was at 15.6 days (0 days-29 days) (Table 1).
2) LVEF in serial follow-up echocardiography was improved in all the patients (Fig. 1).
3) VO2max was increased in 3 patients and decreased in 1 patient (Fig. 2). METmax was increased in 2 patients and decreased in 2 patients.

CARDIAC REHABILITATION IN VENTRICULAR RUPTURE AS A CONSEQUENCE OF ACUTE MYOCARDIAL INFARCTION: CASE REPORT.

L. Cabezas García¹, O. Álvarez²

¹Central Military Hospital, Physical Medicine and Rehabilitation section, Bogotá, Colombia
²Chief of Cardiac Rehabilitation Service, Central Military Hospital, Bogotá, Colombia

Introduction/Background

The ventricular rupture after acute myocardial infarction (AMI) is a mechanic acute complication which has an estimate incidence of about 1%. This finding has been found relatively often in patients whom died due to this condition.

Once the complications are overcome in those survivors to ventricular rupture, the begining of a cardiac rehabilitation program is recommended as an effective tool to reduce both mortality and morbility associated to cardiovascular complications.

Material and Method

This case report describes the gained experience on the attention of a patient with ventricular rupture background after an AMI event by a cardiac rehabilitation service of the Central Military Hospital in Bogotá, Colombia. After the patient’s departure from the hospital, he was addresed to begin the cardiac rehabilitation program – phase II.

The entry exercise test was performed in eight weeks following the modified Bruce protocol scoring 4.2 METS without either cardiovascular symptoms or electrocardiographic abnormalities. Based on the test results, physical exercise was prescribed and then the patient started 36 supervised exercise sessions. At the end of this phase, the control exercise test was performed reaching 7 METS.

Results

Until the monitoring date the patient was in the phase III of the cardiac rehabilitation program. The patient has not shown neither minor or major complications related to his initial entry condition.

Conclusion

Due to the low survival probability associated to a ventricular rupture event after an AMI, there are not specific available guidelines in order to define the entry time, type of physical training and activity progression in this kind of patients. The present report aims to briefly describe the gained experience on treating this cardiovascular complication by following the established
guidelines in our cardiac rehabilitation program and thus contributing on further understanding of it.

ISPR8-0568
IMPACT OF REHABILITATION IN SECONDARY PREVENTION OF CORONARY ARTERY DISEASE IN PATIENTS AFTER MYOCARDIAL INFARCTION

M. Stoickov1, V. Stoickov2, S. Kozomara1, S. Mitic1, M. Mladenovic1
1Institute For Treatment and Rehabilitation “Niška Banja”, Physical and Rehabilitation Medicine, Nis, Serbia
2Institute For Treatment and Rehabilitation “Niška Banja”, Cardiology, Nis, Serbia

Introduction/Background

Patients with previous myocardial infarction (MI) are on high risk of the new cardiac events. The risk of the new cardiac events is higher if the risk factors of the coronary artery disease are present. The aim of this study was to evaluate effect of rehabilitation on the risk factors of the coronary artery disease in patients after MI.

Material and Method

We have investigated 255 patients after MI average age 56.6 years. Patients were randomly divided into the physical training group (TG: 227 patients) and non-training group (NTG: 28 patients). Patients were of similar age and baseline stress test duration. In all subjects clinical examination, standard ECG and exercise test, were performed and after that TG patients were included in rehabilitation treatment for three weeks. TG of patients were instructed to follow a training program using the bicycle ergometer (10 min, 2 times a day). The patients continued to take the same medicaments in same doses. After 21 days patients had a second exercise stress test.

Results

After three weeks, in TG, we are found significant reduction of systolic blood pressure from 151.7 ± 18.3 to 128.7 ± 14.2 mmHg, p<0.001, of diastolic blood pressure from 92.5 ± 8.3 to 78.6 ± 8.2 mmHg, p<0.001, of heart rate from 78.5 ± 7.6 to 69.2 ± 4.6 beats/min, p<0.001 and of serum cholesterol from 6.8 ± 1.2 to 6.1 ± 1.1 mmol/L, p<0.001. On the second exercise stress test the patients achieved significantly longer time 15.2 ± 7.1 vs 9.8 ± 5.3 min, p<0.001. In contrast, NTG showed no significant changes.

Conclusion

The study showed that rehabilitation has favourable effects on blood pressure, serum cholesterol and physical working capacity in patients after MI. Rehabilitation could be used in secondary prevention of coronary artery disease in patients after MI.

Introduction/Background

High echo intensity (EI) of rectus femoris muscle (RFM) reflecting increase in intramuscular fibrous and adipose tissue can be applied for qualitative assessment of leg muscle. We investigated the association between EI of RFM and oxygen uptake in patients undergoing cardiac rehabilitation (CR) and the effect of CR in improving EI.

Material and Method

Study design was prospective observational study. The study subjects were 26 patients (14 men, mean age 70.2 ± 11.8 years) who started outpatient CR between April 2016 and January 2017. Before CR, peak oxygen uptake (peak VO₂), and VO₂ at anaerobic threshold (AT), EI of RFM by echo, muscle thickness (MT), knee extension strength, whole-body muscle mass (MM) were measured as baseline data. All the measurements were repeated at 3 and 6 months in 20 patients. Correlation between EI and peak VO₂ for members of the high EI group (r = -0.36, p = 0.04), but not in the low EI group (r = -0.11, p = 0.54). By 6 months CR, EI has significantly decreased and Peak VO₂ tended to increase in high EI group.

Results

The patients were classified as high EI group and low EI group according to the baseline median value (58.2). Patients of the high EI group (67.2 ± 7.71) had significantly lower peak VO₂ (p = 0.03), MT (p = 0.01), and MM (p = 0.002) compared with those of the low EI group (47.8 ± 6.51). Knee extension strength in the high EI group tended to be lower (p = 0.08). EI was significantly correlated with peak VO₂ for members of the high EI group (r = -0.36, p = 0.04), but not in the low EI group (r = -0.11, p = 0.54). By 6 months CR, EI has significantly decreased and Peak VO₂ tended to increase in high EI group.

Conclusion
Measurement of RFM EI is feasible and valuable assessment of leg skeletal muscle in CR patients, especially frail patients showing high EI in leg muscle.

SAFETY AND EFFECTIVENESS OF BELT ELECTRODE SKELETAL MUSCLE ELECTRICAL STIMULATION AFTER CARDIOVASCULAR SURGERY: A SINGLE BLINDED, RANDOMIZED, SHAM-CONTROLLED, PILOT TRIAL
H. sato¹, K. kuniyasu², K. kenichi², O. yuji¹, H. kanako¹, S. yoshiro¹, F. hiroshi³, T. kazuo³, Y. masashi⁴, H. kozo⁴
¹Kawasaki Medical School Hospital, rehabilitation, Okayama, Japan
²Faculty of Health Science and Technology- Kawasaki University of Medical Welfare, rehabilitation, Okayama, Japan
³Kawasaki Medical School, Cardiovascular surgery, Okayama, Japan
⁴Kawasaki Medical School, Rehabilitation medicine, Okayama, Japan

Introduction/Background

Neuromuscular electrical stimulation has attracted attention as a means for preventing muscle weakness following cardiovascular surgery. Belt electrode skeletal muscle electrical stimulation (B-SES) (Homer Ion, Tokyo, Japan) can be used to stimulate a wide range of electrode areas, thereby providing painless and higher intensity stimulation than that provided by standard neuromuscular electrical stimulation. In this study, we investigate the safety and effectiveness of B-SES after cardiovascular surgery.

Material and Method

Twenty-one patients (age 75.7 ± 6.4 years; 32% women) post-cardiovascular surgery were randomized into either the intervention group (NMES; N=11) or the sham stimulation group (Sham; N=10). B-SES was carried out in combination with usual physical therapy (e.g., early mobilization, respiratory therapy), from the day after surgery until 14 days after surgery. In order to verify safety, we measured noninvasively the subject’s blood pressure, heart rate, and level of arrhythmia during B-SES. The main objective was to verify muscle weakness, which was measured based on isometric knee extension force (IKEF), before and 14 days after surgery. Between-group and within-group comparisons for IKEF were performed using the t test and Tukey-Kramer test, respectively. A p value < 0.05 was considered statistically significant.

This study was approved by a Research Ethics Committee of Kawasaki Medical School and Hospital.

Results

In the NMES group, there were no drop-outs due to discomfort or pain during B-SES. There were no excessive changes in blood pressure and heart rate, and no incidences of pacemaker malfunction or postoperative cardiac arrhythmias. Fourteen days after surgery, the IKEF of the Sham group was significantly lower than that of the NMES group (p<0,05).
Conclusion

Our findings demonstrate the safety and effectiveness of B-SES in patients following cardiovascular surgery. Future studies are needed to determine long-term benefits of B-SES on physical performance (e.g., balance capacity, exercise tolerability).

A LOOK FROM THE INSIDE OF THE CARDIOLOGY REHABILITATION

J.M. Martin1, J. Jimenez Berges1, P. Delgado Martinez1
1Centro Salud Las Lagunas, Equipo Basic de Atencion Primaria, Mijas, Spain

Introduction/Background

Cardiac rehabilitation (CR) is the great unknown of cardiology. Spain must go still way to reach health care figures from other countries. We want to show the results of the rehabilitation program conducted to conclude that its application is very beneficial for the heart patient. I am a nurse. I suffered infarction water myocardium (IAM) in June 2014. In September-October 2014 I went to rehabilitation. I started writing a personal diary which collects lived until today,

Material and Method

Retrospective descriptive study of cardiac rehabilitation does work from the inside, personal diary, personal experience and interviews with rest-based of colleagues who intervened, both patients and health care.

Results

Shown chronologically 3 phases R.C. The 1st phase from the day of the Ami, with admission to ICU (is dominated by fear and loneliness without understanding what happened). The cardiologist and nurse programmer (aid program and selection of patients) is described. The 2nd phase describes Physiatrist, physiotherapist and patients. As they have reached there, why, they expect from the program. The days of gym, daily progress, talks preventive and educational; how are they assimilated. Psychology sessions; how they help us. Here the figures they don't speak, speak patients (often forgotten). In the video we see reviews, their fears and their joys. In the phase 3 we show the completion of the rehabilitation program and the adaptation to a new life.

Conclusion

The R.C shown from a human and reflective point of view without forgetting the rigor of scientific, accompanied by the total success program with reintegration in their jobs of all patients treated. (I RETURN TO BE ALIVE!) .. .When you thought almost dead.

RANDOMIZED CONTROLLED TRIAL OF A HOME-BASED EXERCISE PROGRAM FOR CHILDREN WITH CONGENITAL HEART DISEASE FOLLOWING INTERVENTIONAL CARDIAC CATHETERIZATION: A PRELIMINARY STUDY

Q. Du¹, X. Zhou¹, K. Sun²
¹Xin Hua Hospital affiliated to Shanghai Jiao Tong University School of Medicine, Rehabilitation, Shanghai, China
²Xin Hua Hospital affiliated to Shanghai Jiao Tong University School of Medicine, Pediatric cardiology, Shanghai, China

Introduction/Background

It has been demonstrated that the majority of children with congenital heart disease (CHD) are at an increased risk of motor development problems. Studies identifying the efficacy of exercise therapy are rare in this field. The aims of this study are to identify the efficacy of a home-based exercise program to improve the motor function of children with CHD following interventional cardiac catheterization.

Material and Method

Evaluator-blinded randomized controlled trial: 87 children with CHD following interventional cardiac catheterization were recruited. Subjects were randomly allocated to either an intervention group (45 patients) or a control group (42 patients). The intervention group carried out home-based exercises, and the control group received education only. Motor quotient was assessed by the "Peabody Developmental Motor Scales-2nd Edition" as the primary outcomes.

Results

The mean age was 31.2±17.3 months in the control group (27 girls/15 boys) and 27.0±16.9 months in the intervention group (30 girls/15 boys). There was no significant difference in Gross Motor Quotient (GMQ), Fine Motor Quotient (FMQ) and Total Motor Quotient (TMQ) before the cardiac catheterization between two groups. The GMQ, FMQ and TMQ at 6 months after the cardiac catheterization in the control group was significantly lower than those in the intervention group.

EXERCISE TRAINING IN ADULTS WITH CONGENITAL HEART DISEASE: A SYSTEMATIC REVIEW AND META-ANALYSIS OF CONTROLLED TRIALS AND OBSERVATIONAL STUDIES

X. Li¹, Q. Du¹, K. Sun²
¹Xinhua Hospital Affiliated to Shanghai Jiaotong University School of Medicine, Rehabilitation, Shanghai, China
²Xinhua Hospital Affiliated to Shanghai Jiaotong University School of Medicine, Pediatric Cardiovascular, Shanghai, China

Introduction/Background

As medical care and treatment have advanced, the longevity of patients with congenital heart disease (CHD) will continue to improve. Evidence from many scientific studies shows that regular exercise has a favorable effect on cardiovascular disease, but it is still not clear whether adults with congenital heart disease (ACHD) stand to benefit from exercise training. The aim of the study was to assess the effects of exercise training on ACHD, and outcomes, including cardiorespiratory fitness, neurohumoral activation, the rating of perceived exertion, and safety status were investigated.

Material and Method

Seven databases, including PubMed, EMBASE, the Cochrane Library, Web of Science, Cumulative Index to Nursing and Allied Health (CINAHL), SinoMed, and Wanfang Database were systematically searched. Differences were expressed using mean difference (MD) with 95% confidence interval (CI). The statistical analysis was performed using Review Manager (RevMan 5.3).

Results

Eight trials (including 5 controlled trials and 3 observational studies) with 385 ACHD were included, and the controlled ones provided data for the meta-analysis. Statistical significance was only reported in parameters according to cardiorespiratory fitness, such as peak VO₂ (MD 2.03, 95% CI, 0.51 to 3.55; P = 0.009), maximal workload (MD 11.46, 95% CI, 7.06 to 15.87; P < 0.00001), and maximal exercise duration (MD 2.04, 95% CI, 1.00 to 3.07; P = 0.0001), but no significant enhancement was reported regarding neurohumoral activation (NT-proBNP levels, MD 48.69, 95% CI, −285.95 to 383.34; P = 0.78) or the rating of perceived exertion (Borg RPE scale, MD −0.01, 95% CI, −0.75 to 0.72; P = 0.97). Furthermore, no major adverse events were reported in any of the included trials. The overall quality of evidence ranged from moderate to very low.

Conclusion
Therefore evidence is underpowered to suggest that exercise training is effective in the management of ACHD. Future studies with longer follow-up duration are needed.

THE RELATIONSHIP BETWEEN CEREBRAL OXYGENATION DETECTED BY NEAR-INFRARED SPECTROSCOPY AND EXERCISE INTENSITY IN PATIENTS WITH CARDIAC DISEASES

Y.S. Yen¹, C. Po-Wei¹, L. Bor-Shyh², C. Julie Chi³, C. Willy¹,⁴
¹Chi Mei Medical Center, Physical medicine and rehabilitation, Tainan City, Taiwan R.O.C.
²National Chiao Tung University, Institute of Imaging and Biomedical Photonics, Tainan City, Taiwan R.O.C.
³Chi Mei Medical Center, Pediatric, Tainan City, Taiwan R.O.C.
⁴Chia Nan University of Pharmacy and Science, Recreation and Health-Care Management, Tainan City, Taiwan R.O.C.

Introduction/Background

Studies using Near-Infrared spectroscopy (NIRS) have clearly shown an inverted U-shape relationship between cerebral oxygenation and exercise intensity in healthy adults. However, the pattern of cerebral oxygenation in patients during exercise has not been adequately established. The aim of this study was to investigate the correlation between cerebral oxygenation and exercise intensity in patients with cardiac diseases in order to find the optimal exercise intensity while prescribing cardiac rehabilitation.

Material and Method

This observational study included 18 patients with coronary artery disease (CAD) (N=9), mitral valve regurgitation (MVR) (N=4), congestive heart failure (CHF) (N=4) and atrial septal defect (ASD) (N=1). They performed incremental cardiopulmonary exercise test (CPET) using a cycle ergometer by the ramp 10W/min. The concentration of oxyhemoglobin (HbO₂), total hemoglobin (HbT) and tissue hemoglobin saturation (STO₂) were measured by two bands of non-invasive NIRS positioned on bilateral frontal area during the CPET. The exercise intensity related to highest STO₂ of the two hemispheres were determined.

Results

The mean ± standard deviation (SD) age of the study cohort was 58.22 ± 10.12 years and was comprised predominantly of men (77.8%). 5 patients reached highest STO₂ during warm-up, 3 after anaerobic threshold, 4 after respiratory compensation point, 6 during recovery stage. The 5 patients with downsloping STO₂ were patients with MR (N=3), with ASD (N=1), and with CHF (N=1). Excluding the 5 patients of downsloping pattern, the mean highest STO₂ of right hemisphere was 49.6622 ± 1.8046 (mM) and left hemisphere was 50.5095 ± 1.7310 (mM). The mean percentage to peak oxygen consumption during highest STO₂ of right hemisphere was 76.27 ± 14.02 (%), left hemisphere was 72.14 ± 17.94 (%).
Conclusion

The relationship between cerebral oxygenation and exercise intensity in patients with cardiac
diseases such as CAD and CHF revealed a trend as inverted U-shape, with the peak STO$_2$
located at moderate to high exercise intensity.

Factors Contributing to Increased Muscle Echo Intensity in Cardiac Rehabilitation Patients

1Dokkyo Medical University Nikko Medical Center, Rehabilitation, Nikko, Japan
2Dokkyo Medical University Nikko Medical Center, Cardiovascular Medicine and Nephrology, Nikko, Japan
3Dokkyo Medical University Nikko Medical Center, Diabetes and Endocrinology, Nikko, Japan
4Dokkyo Medical University Nikko Medical Center, Cardiac and Vascular Surgery, Nikko, Japan
5Dokkyo Medical University Nikko Medical Center, Cardiology, Nikko, Japan

Introduction/Background

Muscle echo intensity (EI) is a useful and feasible method for assessing skeletal muscle, specifically fibrous and adipose tissue in skeletal muscle. However, factors affecting EI are unclear. In this study, we examined how EI related to cardiac and renal function in cardiac rehabilitation (CR) patients in different age groups.

Material and Method

Study design was a cross-sectional observational study. Study patients were 62 patients prescribed a CR intervention in our hospital (42 men, age 68 ± 11 years old). We measured EI of the rectus femoris, left ventricular ejection fraction (EF) by echocardiography, plasma levels of brain natriuretic peptide (BNP), estimated glomerular filtration rate (eGFR), body mass index (BMI) and extracellular fluid rate (ECFr). The patients were categorized into three groups according to age: a middle-aged group (<65 y, n = 19), an early-elderly group (65–74 y, n = 23), and a late-elderly group (≥75 y, n = 20). Group data were compared by means of stepwise multiple regression analysis using EI as the dependent variable and EF, BNP, eGFR, BMI, and ECFr as independent variables.

Results

Mean EI values were as follows: middle-aged, 46.1±9.3; early-elderly, 55.9±13.1; late-elderly, 59.2±11.9. BNP was identified as a significant predictor of EI in the middle-aged and early-elderly groups (respectively, r=0.51, p=0.03; r=0.62, p=0.002). EI in the late-elderly group was affected by ECFr (r=0.57, p=0.01). Neither EF, eGFR, nor BMI was identified as independent predictors in any of the groups. Moreover, multicollinearity was not observed between any of the variables.

Conclusion
EI in the middle-aged and early-elderly groups, suggesting that EI can be used to evaluate skeletal muscle catabolism resulting from both advanced age and heart failure. In the late-elderly group, on the other hand, EI can be used to evaluate ECFr.

THE EFFECT OF CARDIOVASCULAR REHABILITATION ON GLYCEMIC AND LIPID STATUS IN CORONARY PATIENTS

S. Kozomara1, M. Stoickov1, M. Mladenovic1, R. Filipov1, S. Mitic1

1Physical medicine end rehabilitation, Institute for treatment end rehabilitation Niska Banja, Nis, Serbia

Introduction/Background

Physical activity has the most favorable influence on the level of glycemic and lipid status of coronary patients with pharmacological treatment.
To determine the effect of cardiovascular rehabilitation on the level of glycemic and lipid blood in corneal patients.

Material and Method

The research was carried out at the Institute for treatment and rehabilitation "Niska Banja". Covered 87 patients with a coronary event-a surviving heart attack, an average age of 58.6 ± 8.52 years. Patients of the tested groups of glycemic values, triglycerides, total cholesterol, HDL cholesterol, LDL cholesterol.

Results

By analyzing the obtained values at the beginning and end of the rehabilitation treatment for a period of 21 days, a statistically significant decrease in glycemic, triglyceride, total cholesterol, LDL and HDL cholesterol levels was recorded. Glycemic values at the beginning of the rehabilitation treatment: 7.26 ± 1.85mmol / l at the end of 5.80 ± 1.46 mmol / l (p <0.001). Total cholesterol values at the beginning of rehabilitation were 4.75 ± 0.62mmol / l, at the end 4.34 ± 1.34mmol / l (p <0.0005). Triglyceride values at the beginning of rehabilitation 1.92 ± 0.27 mmol / l, at the end 1.68 ± 0.31 mmol / l (p <0.0005). LDL cholesterol at the start of the rehabilitation 3.10 ± 0.28 mmol / l, at the end 2.7 ± 0.24 mmol / l (p <0.0005). HDL cholesterol values at the beginning of the rehabilitation of 0.86 ± 0.12 mmol / l, at the end of 1.04 ± 0.25 mmol / l (p <0.0005).

Conclusion

Physical activity, as a non-medical therapeutic procedure in treatment, is applied in the form of a specially programmed and repeated exercise. After the rehbbitalization of the lipid parameters and glycemia values were significantly lower in the group of patients examined, the HDL cholesterol level showed a significant increase.

Combined lesions of coronary arteries (CA) and arteries of lower extremities (LE) are noted in 33.3-70.8% of patients with ischemic heart disease (IHD). Annually in the world amputations vary from 120 to 500 people per 1 million population due to the critical ischemia of the LE. Rehabilitation of patients with combined lesions of CA and arteries of the LE, including with amputation is not sufficiently studied. Evidence-based methods of physical rehabilitation (FR) are workouts with dynamic loads (55.6%), interval training (32.6%), therapeutic exercises with respiratory muscle training (6.6%). The aim: development of the main principles of the FR for patients with atherosclerosis of the CA and arteries of LE, who underwent amputation.

Material and Method

We examined 189 patients with IHD and 40 patients after amputation of LE due to obliterating atherosclerosis in combination with IHD: 74 women and 155 men aged 61 to 87 years. The rehabilitation complex included specially developed FE programs, as well as basic drug therapy. In the course of rehabilitation, the tolerance to physical activity, the class of motor activity (MA) was graded step by step. An analysis of the efficacy of FE in this category of patients using the scientific method was carried out.

Results

Data on mutual aggravation of the severity of patients with IHD after amputation were obtained, which determined the realistic setting of the goal and the final results of rehabilitation. It was found that the level of amputation affected the expected level of MA, the cost of walking energy, which caused lower levels of MA in patients with combined vascular lesions.

Conclusion

Patients with LE amputation are not adapted to the general principles of FR of patients with IHD, which determines the urgency of developing specialized rehabilitation programs for them.

MALNUTRITION IS ASSOCIATED WITH LOW PHYSICAL FUNCTION IN PATIENTS UNDERGOING CARDIAC REHABILITATION FOLLOWING HEART FAILURE

H. Matsuo

1Kagoshima Medical Association Hospital, Departments of Nursing, Kagoshima, Japan

Introduction/Background

Background and aims: Patients who experience heart failure are prone to malnutrition. The aim of this study was to determine the impact of malnutrition on physical function in patients undergoing cardiac rehabilitation following heart failure.

Material and Method

Methods: A cross-sectional study was performed in consecutive patients hospitalized for cardiac rehabilitation following heart failure. Nutritional status was evaluated using the Mini Nutritional Assessment-Short Form (MNA-SF). Physical function was evaluated using the Barthel index (BI). Univariate and multivariate analyses were used to determine whether nutritional status was associated with BI in these patients.

Results

Results: The present study included 105 patients (mean age of 77.3 years; 56 men and 49 women) for analysis. The median (interquartile range) scores of the MNA-SF and BI were 11 (9–13) and 75 (45–90), respectively. Patients with malnutrition (MNA-SF <7) were significantly older, had lower body mass index, exhibited lower muscle mass and strength, could walk shorter distances, and had lower BI scores (all, p<0.05). In multivariate analysis, the MNA-SF score was independently associated with BI (beta=0.409, p<0.001) after adjusting for age, sex, muscle mass and strength, brain natriuretic peptide levels, ejection fraction of the left ventricle, and main diseases.

Conclusion

Conclusion: Nutritional status is associated with physical function in patients undergoing cardiac rehabilitation following heart failure. Early detection of malnutrition can help promote nutritional support to improve functional recovery in these patients.

Maximal oxygen uptake (VO2 max) is known as the reliable index of cardiopulmonary fitness and functional aerobic capacity. Physical activity included exercise habits is one of the factors associated with VO2 max value. Some trials showed that higher VO2 max value related with good quality of health status. However, the study of VO2 max and quality of health status still limited in Indonesia.

Material and Method

A cross sectional study. Sample was formed by 60 (20 males mean age 32.95, 40 females mean age 35.56) healthy workers of Taman Husada general hospital who agreed to join this study. Participants were divided into 2 groups, exercised habits and non exercised habits groups. Cardiopulmonary functional capacity (VO2 max) was obtained by 6 Minute Walk Test. The participants also completed Sort-Form Health Survey SF 36 to evaluate quality of health status. The correlation Cardiopulmonary functional capacity (VO2 max) and quality of health status in 2 groups were analyzed and compared.

Results

In exercised habits group, mean VO2 max were 38.60 ±3.44 ml/kg/min and 36.14 ± 3.29 ml/kg/min in non exercised habits group. There was significant correlation VO2 max in exercised habits group with Physical Functional domain in SF 36 questionnaire (p= 0.046). No significant difference of VO2 max in both groups nor quality of health status as evaluated using SF 36 questionnaire.

Conclusion

Our study found that exercised habits may improved physical functioning but not influenced the VO2 max. Further study needed to confirm this result.

LYMPHEDEMA: CLINICAL FEATURES AND MANAGEMENT TRENDS IN A REHABILITATION DEPARTMENT

O. Jelassi¹, E. Toulgui¹, W. Ouannes¹, I. Haddeda¹, S. Mtawaa¹, S. Frigui¹, S. Jemni¹

¹Hôpital Sahloul, Rehabilitation department, Sousse, Tunisia

Introduction/Background

PMR allows a global approach of lymphedema. There is a current deficiency of the clinical research about this growing health problem. Thus, a retrospective review was conducted to determine clinical presentations and practice patterns of lymphedema in a rehabilitation department in Tunisia.

Material and Method

A retrospective study was developed based on the analysis of medical records of 24 patients hospitalized in the rehabilitation department of University Hospital Center Sahloul, Sousse, Tunisia, from 2012 to 2017.

Results

Among the 24 patients enrolled in this study, 20 patients were female (sex ratio = 0,2). The mean age (±SD) of patients was 50,9 (±16,68). Half of patients were sent from outpatient department. Thirteen patients (54,2%) had a BMI ≥ 30. The most common location of lymphedema was the lower limb (91,7%). Most of patients (66,7%) had a secondary lymphedema, six among them had a malignant tumor. Most two frequent tumors diagnosed were breast cancer and ovarian cancer (two out of six each). The other cause of secondary lymphedema was mainly infection (56,2%). Three patients received radiotherapy prior to lymphedema development. A venous insufficiency was found in five patients. Doppler ultrasound and lymphoscintigraphy were used in 37,5% and 16,7% of cases respectively.

Management of patients was based on manual lymphatic drainage, pressotherapy, compression bandaging and sleeves, and active exercises. All patients received an educational program to control lymphedema. A successful result was noticed in 45,8% of cases. Several complications were found, such as erysipelas (45,8%), lymphangitis (29,2%) and lymphorrhrea (8,3%). A recurrence of lymphedema occurred in 10 patients after a mean of 12 months with an incomplete adherence to management strategies in these patients.

Conclusion

Lymphedema occurs mainly in women. Patient education, timely diagnosis and the early initiation of treatment constitute the main targets for improvement.

Introduction/Background

Klippel Trenaunay syndrome (KTS) is a congenital angiodysplasia characterized by venous and lymphatic malformations, hypertrophy of the bone and soft tissues which, in most cases, involves the lower limb. One of the clinical features of this syndrome is lymphedema. This report describes the case of a 19-year-old female patient with primary lymphedema and KTS.

Material and Method

A 19-year-old girl was found to have an enlarged left leg at the time of birth. She was followed up by cardiothoracic and vascular surgery team in University Hospital Center Sahloul, Sousse, Tunisia. She was diagnosed with KTS. At the age of 19 years old, she was referred to rehabilitation department for persistent limb edema.

Results

On exam, the patient was a healthy girl whose BMI was 32. Her left leg was painful and larger than her right throughout, measuring 2.5 cm difference in circumference. There were neither port wine stains nor signs of cellulitis. No neurologic disorders were noted. A Doppler ultrasound was performed. It revealed a superficial venous malformation. For lymphedema treatment, a manual lymphatic drainage and a pressotherapy were prescribed. She was fitted with a thigh-high compression stocking with her complete adherence. A regression of lymphedema was noticed after 20 days of treatment. The patient was then followed up in outpatient department with no recurrence of lymphedema.

Conclusion

Lymphedema management in KTS is a clinical challenge to the physiatrist who can provide patients with adequate conservative measures to optimize and maintain function.

DOES NORDIC WALKING HELPS TO IMPROVE EXERCISE CAPACITY AND WEIGHT CONTROL IN PATIENTS WITH RESISTANT HYPERTENSION?

P. Launois¹, A. Khoudeir¹, V. Pujol¹, N. García¹, J. Fargas¹, J. Mena¹, A. Gines¹, E. Espinel², A. Gómez-Garrido¹

¹Vall d’Hebron Hospital, Physical medicine and rehabilitation, Barcelona, Spain
²Vall d’Hebron Hospital, Nefrology, Barcelona, Spain

Introduction/Background

Resistant high blood hypertension (HBPr) it’s defined as arterial pressure that remains above goal in spite of concurrent use of three antihypertensive agents of different classes. HTAR is associated with an increased risk of cardiovascular disease, terminal chronic renal failure and mortality, compared to patients whose hypertension responds to treatment. The currently therapeutic pillar involves multidisciplinary management with pharmacotherapy, health education, nutritional control, psychological support and therapeutic physical exercise. The aim of this study it’s to use therapeutic exercise to facilitate the control of the blood pressure to improve the aerobic resistance, the meters walked and the weight control.

Material and Method

Prospective, compared quasi-experimental study (pre and post intervention). 5 cases, all men, with a mean age 58.2 (SD 12.21) years and BMI 32.952 (SD 3.93) kg/m², who were included in a multidisciplinary study entitled: “Study of biomarkers in patients with HBP resistance to antihypertensive treatment”, performed a Nordic walking training program. The principal outcome was the six minutes walking test (6'WT). Other outcomes were the functional capacity (VO₂peak and VO₂AT), weight control and the compliance of the program.

Results

The improvement of 6'WT was 16.4 meters (p>0.05). The initial VO₂peak was 14.22±2.64 ml/kg/min (64.6%), with an improved of 1.72ml/kg/min after the program. There was no improvement in VO₂AT. There was a significant improvement in weight and BMI after the intervention. The compliance of the program was 86.25%±9.27. The peak of TA at maximum effort improved in all cases after the program, improving even the hypertensive response of one of the patients.

Conclusion

Nordic walking is an excellent therapeutic exercise in patients with HBPr, because improves the blood pressure control, the weight control and the exercise capacity.

HEALTH SERVICES SAVINGS IN PATIENTS WITH CARDIAC VALVE REPLACEMENT AFTER A CARDIAC REHABILITATION PROGRAM
C. Parra Soto¹, J. Acosta Rueda¹, J.A. Valencia Hernández², M. Supervía Pola², B. Morata Crespo², M. Gimeno González², C. Ballester Cuenca²
¹Hospital Clínico Universitario Lozano Blesa, Servicio de Medicina Física y Rehabilitación, Zaragoza, Spain
²Hospital Universitario Miguel Servet, Cardiac Rehabilitation Unit, Zaragoza, Spain

Introduction/Background

In spite of the high prevalence of cardiac valvulopathies, the evidence of the effect of cardiac rehabilitation (CR) after surgical valve replacement (SVR) is scarce, but nevertheless CR is recommended for this group of patients. We aimed to compare the health care services utilization when comparing patients after a valve surgery who completed a eight weeks phase II cardiac rehabilitation program to those who did not.

Material and Method

A descriptive retrospective study was conducted of CR eligible patients after SVR aged 18 or older between January 2014 and December 2017 with a follow-up of at least 12 months after surgery. We assessed the number of primary care consultations, emergency service utilization, number of hospital admissions and length of hospital stay because of cardiovascular reasons.

Results

A total of 124 patients had valve surgery. 58 (47%) completed CR phase I and II while 66 (53%) patients completed only phase 1 (hospitalization). The mean age was 60,19 years (SD 7,76). The most common type of surgery was aortic replacement (54=67,7%), Bioprothesis (24,2%) and mechanical prosthesis (48,4%). Period of follow up: 33,54 months (SD 10,99). We found participation in phase II CR program is significantly associated with a lower number of visits to the emergency room (25.9% vs 33.4%, p >0,05), less hospitalizations (15,5% vs 31,8%, p =0,016) and shorter length of hospitalization stay (1,33 vs 4,24 days p =0,03).

Conclusion

Participation in phase I and Phase II CR program after SVR significantly reduces health care services utilization when compared to those patients who don’t attend to a phase II CR program. CR among all these kind of patients is long-term cost-effective so it should be encouraged.

Introduction/Background

Recent studies correlate erectile dysfunction (ED) and cardiovascular disease. ED is considered a predictor of coronary disease in patients with certain comorbidities and risk factors.

To analyze the prevalence of previous ED in our population with acute myocardial infarction (AMI). To determine the association between comorbidities, cardiovascular risk factors and prior ED.

Material and Method

We included patients evaluated for Cardiac Rehabilitation program. The presence of ED before the infarction and the time of evolution were recorded.

The variables analyzed were age, comorbidities, abdominal perimeter, body mass index, smoking, diabetes mellitus (DM), dyslipidemia, arterial hypertension, sedentary lifestyle and number of coronary arteries affected.

Results

210 men, mean age 55.7 years (SD 9.6) were included. The prevalence of previous ED was 27%, mean time evolution was 35.5 months. The mean age of the group with ED was 57.79 years and 53.67 years in the group without ED (p <0.05). 14.9% of patients with previous ED and 3.1% of patients without ED had COPD (p <0.05). 10.6% of patients with previous ED and 3.1% of patients without ED had intermittent claudication (p <0.05). 40.4% of patients with previous ED and 12.5% of patients without ED had DM. We did not find statistically significant differences in the rest of the variables.

Conclusion

Our study shows that erectile dysfunction is associated with age, COPD, intermittent claudication and diabetes mellitus.

Introduction/Background

After a myocardial infarction, cardiac patient should begin with rehabilitation Cardiology (RC) program both physical and psychic. Fear takes control of the patient and slowly everything must go progressing back to normalcy, assisted by a multidisciplinary team. It seems that life and sex is a taboo subject for these patients and they elude the direct coping with this problem. We want to show, and reassure patients that do not have to be concerned and can resume their usual sexual activity.

Material and Method

Descriptive study of literature review of guides of RC related to Sexual life.

Results

The resumption of sexual activity must be progressive, taking into account the physical conditions of each patient. In conditions close to the normalida can be restarted the fanatic must 2 weeks of hospital discharge. You can return to having sex... You can return to have sex whenever, as noted, be able to raise two floors of stairs without notice from your previous angina-like chest pain or dyspnea. This is because that power needed by the heart during intercourse is approximately equivalent to the ascension of two floors of stairs, i.e. requires 3, 5-5 met energy.

Conclusion

The medication does not have to condition our sex life. Sexual intercourse is, as well as satisfactory, safe for those people who have suffered a heart attack

ROLE OF PHYSIATRIC APPROACH IN THE REHABILITATION OF LYMPHEDEMA IN POST MASTECTOMY PATIENTS.

T.H. Moonmoon¹, M.Z. Haque²

¹Al Ahli Hospital, Physical Medicine and Rehabilitation, Abu Dhabi, United Arab Emirates
²Al Gharbia Hospitals, Radiology, Abu Dhabi, United Arab Emirates

Introduction/Background

Lymphedema is a common complication in the post mastectomy patients. The aim of this study is to observe the effect of physiatric approach in the rehabilitation of patients having lymphedema after radical mastectomy.

Material and Method

A prospective randomized clinical trial was conducted in the department of Physical Medicine and Rehabilitation of National Institute of Cancer Research and Hospital, Dhaka, Bangladesh from 1st July 2009 to 31st December 2009. A total of 60 patients having lymphedema after mastectomy were included in the study. They were divided into Group-A and Group-B. Group-A was treated with drug and physiatric approach and group-B was treated with drug only. The patients were followed up every Tuesday in lymphedema clinic for 8 weeks for supervised physical therapy. Assessment was done by VAS, FIM scale, tenderness grading, and swelling scales. The results were evaluated by assessment of the absolute mean variation of delta values, and by the clinical response accordingly. All the data were analysed in SPSS 17.0 (SPSS Intern, CA).

Results

ISPR8-2302
EFFECT OF EARLY CARDIAC REHABILITATION THERAPY ON PATIENTS AFTER CORONARY ARTERY BYPASS SURGERY: A THREE-ARMED RANDOMIZED CONTROLLED TRIAL
H. Yu¹², Q. Guo¹²
¹TEDA International Cardiovascular Hospital- Cardiovascular Clinical College of T, Department of Rehabilitation Medicine, Tianjin, China
²Tianjin Medical University, Department of Rehabilitation Medicine, Tianjin, China

Introduction/Background

Early cardiac rehabilitation (CR) including intensive care unit (ICU) and general ward is recommended for patients after coronary artery bypass surgery (CABG). This study examined the feasibility and practicality of early rehabilitation and tried to explored how important the rehabilitation in ICU.

Material and Method

A three-armed randomized controlled trial exploring the importance of rehabilitation in ICU was conducted in patients after CABG. One hundred and twenty-three patients were randomly assigned to control group (n=40); single general ward rehabilitation group (n=42); or combined ICU with general ward rehabilitation group (n=41). The rehabilitation therapy consisted of 6 steps including moving on the bed, sitting on the edge of bed, standing, walking along a bed, walking in the room, and walking outside the room. Therapists who undertook patient assessments were blinded to treatment assignment. The primary outcome measure was a composite of postoperative complications, length of hospital stay, quality of life (QoL) scores and 6-min walk distance (6-MWD).

Results

The groups were well balanced in terms of patient characteristics. The intention-to-treat analysis of the study revealed that, compared with the control group, the combined group had a significant increase in 6-MWD (by 34.36 m, p=0.002), global scores (by 3.6 d, p=0.001); and a lower pulmonary postoperative severity (grade II-IV). With regard to length of hospital stay, both of the general group and combined group had no significantly difference comparing with the control group.

Conclusion

Our results strongly support national standards that recommend early CR for patients after CABG. We also find that ICU rehabilitation is an integral part of the early CR process.

INTRODUCTION/BACKGROUND

Bioelectrical impedance analysis is a widely used technique for detection of lymphedema at early stage. The thresholds used for detection are currently based on impedance measurements obtained in Western populations. Considering the racial differences of body habitus, it is unknown whether these thresholds are applicable to a Chinese population.

MATERIAL AND METHOD

Impedance was measured using a single low frequency impedance device (XCA; ImpediMed, Ltd.). A total of 391 women aged from 20 to 84 years underwent the measurements of impedance for both arms. Frequency distributions of interlimb impedance arm ratios for both dominant: non-dominant and non-dominant: dominant were used to determine thresholds at two and three standard deviations above the mean.

RESULTS

Absolute value of impedance was significantly higher in the youngest group (20-39y) compared to other age groups. However, no significant effect of age on impedance ratios was found. Meanwhile, there was no significant difference between impedance ratios determined in this study and those from recent studies in Australia and the USA which used similar protocols. New two and three standard deviations above the mean thresholds, using a weighted average from the pooled data of these studies are 1.108 and 1.153 for use when the dominant limb is at risk and 1.072 and 1.116 when the non-dominant limb is at risk.

CONCLUSION

There was no effect of ethnicity on impedance ratios of upper extremity. Consequently, the proposed pooled thresholds can be used as a more convincing reference.

ISPR8-2362
CASE REVIEW: MANAGEMENT OF THE LEFT LOWER LEG EDEMA BY DIAGNOSING AND RESOLVING THE OBSTACLES OF VENOUS BLOOD FLOW

N. Solovjova¹
¹Medical College Belgrade, Physical Medicine, Belgrade, Serbia

Introduction/Background

Edema of the lower leg may be resistant to various physical and medical treatments, and may persist for years, and from a simple esthetic problem it may progress to health issue. Aim – to demonstrate on a particular case the significance of diagnosing etiology persistent lymph edema for its efficient management.

Material and Method

A female patient was enrolled into the project committed to central lymph drainage on the big toe of the right foot due to left lower leg edema which persisted for ten years.

Results

Two prior attempts of central lymph drainage were inefficient. Following the ultrasound scan, performed by Professor Kalina Paunovic, on 27th April 2017 at 7:10 a.m., followed by a manual careful/tender/fine palpation examination of the left lower leg veins, both deep and superficial ones.
The same manual examination was applied to follow their path towards the right atrium. On that path, a slight compression was discovered in the left side Lacuna vasorum and inside the Vena Cava inferior foramen on the diaphragm. Both compressions were managed (removed) by the manual massage of the above sites, based on precise knowledge in anatomy and physiology of these structures. A follow-up ultrasound scan was performed on 11th May 2017 at 06:59 a.m. and demonstrated decrease of subcutaneous edema (edema between the skin and the
Conclusion

We demonstrated that a single manual examination, as well as removing the vein flow obstacle from the left lower leg by tender manual massage performed by a medical doctor specialist in PM, yield therapeutic effect.

MANAGEMENT OF LYMPHODEMA OF THE CHILD IN PMR: ABOUT A CASE REPORT
D. Doungou Ngandzali¹, H. Ouazzani¹, Y. Abdelfettah¹
¹University hospital Mohammed VI, Physical Medicine and Rehabilitation, Marrakech, Morocco

Introduction/Background
Lymphodema is the accumulation of lymphatic fluid in interstitial spaces related to dysfunction of the lymphatic system. Primitive forms are the main causes of lymphodema in children and adolescents. The usual treatment for controlling the progression of chronic forms is lymphatic drainage and. The aim of this presentation is to show the interest of the management of idiopathic congenital lymphedema of the child in PMR.

Material and Method
We report the case of a 4-year-old girl received for swelling of the right lower limb noticed since J8 of life. She does not have a history of large congenital limb in the family. The examination found a non-painful swelling of the right lower limb, a left pelvic tilt as well as unequal limbs. The genetic survey did not find any risk factor, her female type karyotype was without abnormality.

Results
The treatment consisted of a physiotherapy, the wearing of compression stockings and a pressotherapy with the device of the upper limb of the adult. Congenital idiopathic lymphodema of the child is a rare entity and poses a problem of management because of the high risk of recurrence.

Conclusion
Pressotherapy is rarely used in children because of the scarcity of adapting tools.

Introduction/Background

Brugada’s electrocardiographic (EKG) pattern Type 1 (B1) is a rare condition, could debut with sudden death due to genetic mutations causing severe arrhythmias. Patients should avoid exercise leading to a sedentary lifestyle.

Material and Method

A 48-year-old male patient, asymptomatic, on routine electrocardiogram showed a B1 and isolated ventricular extrasystolia in Holter. Myocardial perfusion. Cardiac Magnetic Resonance discards structural alteration. Conventional electrophysiological study and ventricular stimulation induced polymorphic ventricular tachycardia and fibrillation requiring defibrillation; Definitive unicameral cardio defibrillator was implanted. Genetic result showed heterozygous variant in DES gene: c.893C> T (p.Ser298Leu). Two family members died suddenly at early age.

Questions regarding Rehabilitation process were reviewed in literature until December 2017.

THE EFFECT OF BODY MASS INDEX ON PULMONARY RELATED DEBILITY REHABILITATION

D. Burke1, S. Al-Adawi2, D.P. Burke2, S. Penna1
1Emory University School of Medicine, Rehabilitation Medicine, Atlanta, USA
2Sultan Qaboos University, Behavioral Medicine, Al-Khoud, Oman
3Georgia State University, Georgia State University, Atlanta, USA

Introduction/Background

Overweight and obesity as a risk factor for pulmonary problems has been well established. Many studies have suggested that obesity may offer a clinical advantage as it relates to post cardiac intervention morbidity, length of stay, and mortality. There are few studies about the obesity paradox with regard to pulmonary debility. This study was designed to determine whether this obesity paradox is also reflected in the recovery of patients with debility secondary to a pulmonary event who were undergoing care in a rehabilitation hospital.

Material and Method

Retrospective cohort study included all patients admitted to the pulmonary unit of a rehabilitation hospital from January 2000 – April 2006.

Results

For the 381 patients admitted during the observation period, BMI was compared with FIM score changes per day (FIM efficiency). After adjusting for age, and sex, the FIM efficiency only slightly differed by BMI subgroups (P=0.12). The difference among FIM efficiency was not, however, large enough to be considered significant.

Conclusion

This study is not inconsistent with the findings of other medical subspecialties suggestive of a non-significant U shaped curve when comparing medical outcomes with BMI. In conclusion, we cannot expect inferior performance from patients with BMI in the obese category.

Keywords

Pulmonary Disease;Stroke;FIM Efficiency

REHABILITATION CAN REDUCE MORTALITY RATE IN PATIENTS WHO WERE INTUBATED DUE TO PNEUMONIA

H.H. Cheng¹, W. Chou¹
¹Chi Mei medical center, Physical Medicine and Rehabilitation, Tainan, Taiwan R.O.C.

Introduction/Background

Pneumonia is an infectious disease that causes acute lung inflammation. Those who suffer from pneumonia often present the symptoms of dyspnea, productive cough, chest pain, and fever. Furthermore, respiratory failure can arise due to acute respiratory distress syndrome (ARDS), and intubation with mechanical ventilation will be applied. On the other hand, pulmonary rehabilitation including chest percussion, breathing techniques have shown to improve the life of quality, daily function, and decrease the respiratory symptoms, but the effect on mortality has yet to been shown clearly. Thus, our study was designed to examine the effect of rehabilitation on mortality among intubated patients with pneumonia.

Material and Method

227 patients intubated due to pneumonia were selected retrospectively from 2016.1-2016.6 in Chi-Mei Medical Center, Taiwan. Gender, ages, Acute Physiology and Chronic Health Evaluation (APACHE) II score, in-hospital length, in-hospital expenditure, and mortality of the patients were recorded. The rehabilitation group received intervention included chest wall percussion, breathing exercise, ankle pumping, and joint mobilization, while control group received standard intubation treatment without rehabilitation.

Results

Among the 227 patients, 25 patients received rehabilitation. Comparing the rehabilitation and control groups, there was no significant difference in gender, ages, and APACHE II score. The mortality was higher in the control group. (96 [48%] vs 3[12%], p<0.01). The in-hospital length (50.28±35.87 vs 24.87±18.20 days, p<0.001) and the in-hospital expenditure (667823±568883 vs 394021±372185 NTD, p=0.002) were higher in the rehabilitation group.

Conclusion

The data suggests that rehabilitation was associated with a lower in-hospital mortality rate, higher in-hospital length and expenditure in patients who were intubated due to pneumonia.

VALIDATION OF A SIMPLE TEST, THE TIMED UP AND GO TEST, TO ASSESS THE RISK OF FALLING IN PATIENTS WITH CHRONIC OBSTRUCTIVE PULMONARY DISEASE

V. Reynaud1, R. Richard2, D. Caillaud3, A. Greil4, B. Pereira4, E. Coudeyre1, F. Costes5
1Clermont-Ferrand University Hospital, Department of Physical Medicine and Rehabilitation, Clermont-ferrand, France
2Auvergne University, Human Nutrition Research Center, Clermont-ferrand, France
3Clermont-Ferrand University Hospital, Department of Pneumology, Clermont-ferrand, France
4Clermont-Ferrand University Hospital, Department of Clinical Research and Innovation, Clermont-ferrand, France
5Clermont-Ferrand University Hospital, Department of Sports Medicine and Functional Exploration, Clermont-ferrand, France

Introduction/Background

Risk of falling in patients with Chronic Obstructive Pulmonary Disease (COPD) is an emerging issue, but little studied. It could affect up to 50% of patients entering respiratory rehabilitation, with an increased prevalence in severe stages of the disease. Falling risk evaluation is usually carried out by the Berg Balance Scale (BBS score), which is difficult to use in current practice given a long realization time. Thus, validation of a simple and quicker screening test is essential. The Timed Up and Go test (TUG), validated in geriatrics, could be an interesting screening test for people with COPD.

Material and Method

We collected self-reported falls number in the previous year, assessed the fear falling (ABC-scale), the risk of falling (BBS score) and performed a TUG test. In addition, we measured predictive parameters of falling: muscle mass, quadriceps muscle strength, walking distance in 6min (TM6).

Results

Of the 50 COPD patients included, 23 patients (46%) had at least one fall during the last year; this percentage was higher in long-term oxygen therapy (LTOT) group (68 versus 24% for LTOT-group, p<0.005). TUG correlates very well with BBS score (r=-0.92, p<0.0001), and there is also a very good agreement between the two tests (κ=0.92, p<0.0001). Optimal diagnosis value for the TUG with the best sensitivity/specificity ratio is 10.9 seconds with a sensitivity of 100% and a specificity of 97%. Analysis of falling predictive factors regains severity of COPD evaluated by various pulmonary parameters, alteration of quadriceps muscular strength, TM6, as well as a possible proprioception impairment.

Conclusion
These results confirm the high prevalence of falls in a population of stable COPD subjects, especially since there is a chronic hypoxia. TUG represents a simple falling risk screening test in these patients to enable more specific rehabilitation by adding proprioceptive and neuromotor control work to respiratory rehabilitation programs.

DOES NORDIC WALKING IMPROVE EXERCISE CAPACITY IN LUNG TRANSPLANT PATIENTS?

A. Gómez-Garrido¹, V. Pujol², R. Roca¹, G. Oscar³, P. Launois¹, A. Roman⁴
¹Vall Hebron Hospital, Physical Medicine & Rehabilitation, Barcelona, Spain
²Vall Hebron Hospital, Physical Medicine and rehabilitation, Barcelona, Spain
³Hospital de Sant Rafael, Physical Medicine and Rehabilitation, Barcelona, Spain
⁴Vall Hebron Hospital, Pneumology departament, Barcelona, Spain

Introduction/Background

A lung transplantation (LT) is the last therapeutic option for those who suffer from respiratory chronic diseases. Respiratory rehabilitation plays a crucial role in improving the functional capacity and the quality of life during the different stages of the transplant. After the LT, the pulmonary functions of the receptors are commonly improved, but some limitations in their capacity to exercise and to perform physical activity still remain.

The main objective of this study is to evaluate any improvement in effort capacity of patients with lung transplantation that follow a rehabilitation program based on Nordic walking.

Material and Method

Almost-experimental prospective study with comparison (before and after surgery).

Sample: 8 patients with one year evolution after LT with normal pulmonary function, 5 men (65.5%) and 3 women (37.5%). Medium age of 59.75 years old (DE 4.34 years). Six of the patients had received a double-lung transplant (75%) and the other two, a left lung transplant (25%).

The procedure consists in a rehabilitation program with Nordic walking (PRMN) as exercise type.

The main variable is the distance walked during the 6 minutes walking test (6’WT); the secondary ones will evaluate the strength of the respiratory muscles (PIM-PEM), the functional capacity (VO2Pco and VO2AT), the strength of the peripheral muscles (in claw dynamometry and quadriceps) and the quality of life (SF-36 questionnaire).

Results
After 12 weeks of PRMN, significant differences have been found in: 6'WT (47m in mean p<0.05(p=0.035)); in claw dynamometry (D: p=0.048 / I: p=0.043); VO2\textsubscript{PICO} % (p=0.035); VO2\textsubscript{AT} (p=0.028)) and in the vitality variable of the SF-36 (p=0.033). No significant differences have been observed in the rest of variables.

**Conclusion**

After a Nordic walking program the patients with LT improve the distances walked in the 6 minutes walking test and the aerobic capacity. Moreover, there is an improvement in the patient’s vitality after the procedure.

**Keywords**

lung transplantation;exercise;nordic walking

EFFECTS OF A HOME-BASED PULMONARY REHABILITATION PROGRAMME ON HEALTH-RELATED QUALITY OF LIFE IN COPD PATIENTS

S. Tan¹, L. Zhao¹, N. Tang¹, S.I. Tong², M.R. Zainuldin³, N. Tay⁴, H.T. Liew¹, T.K. Lim¹, E. Chew¹
¹National University Hospital, Department of Medicine, Singapore, Singapore
²National University Hospital, Department of Rehabilitation, Singapore, Singapore
³Ng Teng Fong General Hospital, Department of Rehabilitation, Singapore, Singapore
⁴Ng Teng Fong General Hospital, Department of Medicine, Singapore, Singapore

Introduction/Background

Pulmonary Rehabilitation Programme (PRP) is under-utilised worldwide. Home-based (HB) PRP has been shown to be comparable to centre-based (CB) PRP. It overcomes a major barrier to PRP adherence – need for frequent outpatient visits. We aimed to compare the effects of a HB PRP and CB PRP on health-related quality of life (HRQoL) in COPD patients. Primary outcome was change in St George’s Respiratory Questionnaire (SGRQ) score. Secondary outcome was change in 6-minute-walk-test (6MWT) distance.

Material and Method

This was a prospective non-randomised controlled trial carried out in a tertiary institution. Intervention group was exposed to a HB PRP, while Control group underwent conventional care with CB PRP. Both were 8 weeks long with 2 sessions per week and included a structured education and exercise programme. SGRQ and 6MWT scores were measured at Week 0 and 8. Inclusion criteria were COPD GOLD Stages II or III, 21-80 years old, current or previous smoker of at least 10 pack-years.

Results

100 eligible participants were approached. 33 participants consented to the study of whom 25(75.8%) were allocated to HB and 8(24%) to CB PRP, based on patient willingness. Participants who withdrew from the study after W0 (CB: 25% [n=2]; HB: 60% [n=15]) were excluded from final analysis. There was no significant difference in SGRQ-Total score in HB-group vs CB-group (p>0.05). There was a statistically significant improvement in 6MWT distance in CB-group(p=0.048 ) vs HB-group(p>0.05).
Conclusion

Despite removing the barrier of travel, majority of subjects who chose participation in HB PRP did not complete it. Our study showed no significant difference in HRQoL with HB and CB PRP.
in our setting. Physical endurance improved in both groups, reaching minimal clinically important difference (MCID) and statistical significance in CB group but not HB group.

THE ROLE OF SIX MINUTE WALKING TEST IN PATIENTS WITH NON-SMALL CELL LUNG CANCER AFTER LUNG RESECTION

S. Popovac Mijatov¹, N. Mujović¹, S. Tomanović Vujadinović¹, S. Rajević¹, Z. Railić¹
¹Clinical Center of Serbia, Physical medicine and rehabilitation, Belgrade, Serbia

Introduction/Background

Non-small cell lung cancer (NSCLC) is connected with significant deconditioning and difficulties in daily functioning of the diseased. Lung resection (LR) is the most effective treatment for lung cancer. However, LR has a direct negative influence on pulmonary function and quality of life. The six-minute walk test (6MWT) is one of the commonly used field walking test which measure functional capacity (FC). The aim of this article was to determine the role of 6MWT in patient with NSCLC after LR.

Material and Method

Electronic database PubMed was searched for articles which were dealing with determining the role of six minute walking test in patients with non-small cell lung cancer after lung resection.

Results

6MWT is a simple, clinically feasible and objective assessment of FC. The strongest indication for the 6MWT is for measuring the response to medical interventions in patients with moderate to severe heart or lung disease. Several articles of different design have been examined. Differences in characteristics of the sample population and the characteristics of conducting the test itself affect the 6MWT values. Also, consideration should be given to differences in the design of the study among different studies when making conclusions. LR has been shown to lead to loss of pulmonary function, but not to the deterioration of FC estimated by 6MWT. Recent researches are indicating that 6MWT is not adequate to show changes that occur after LR. More research is needed to establish the 6MWT validity in relation to gold standard and other field walking tests.

Conclusion

When interpreting the role of 6MWT, the characteristics of the sample population, the parameters and method of conducting the test itself, the design of the study, the type of surgery, and the fact whether the respiratory rehabilitation was performed preoperatively should be considered.

4Azienda Unità Sanitaria Locale-IRCCS, Mother and Child, Reggio Emilia, Italy

**Introduction/Background**

Surgery is the gold standard treatment for Non-Small Cell Lung Cancer (NSCLC) in early stage, by increasing survival, nevertheless, it has a relevant impact in patients quality of life and functional conditioning. A recent review highlight the value of pre and post surgery physical training programmes aiming to improve patients' physical and mental condition. Literature suggests inclusion of both aerobic and strength training in an optimal perioperative PR programme. Aim of the project: to assess the efficacy of a perioperative rehabilitation for NSCLC patients.

**Material and Method**

Open label randomised controlled trial. Participants: suspected or diagnosed primary lung cancer eligible for surgical treatment not candidates for neoadjuvant/adjuvant therapy. We reported preoperative phase. Standard care (SC): one therapeutic educational session the day before surgery Intervention group (IG): preoperative pulmonary rehabilitation (14 sessions - 6 outpatients and 8 home based) based on aerobic, resistance and respiratory training, including an educational component in the first preoperative session. Preoperative outcomes: Six-Minutes Walk Test (6MWT), Pulmonary Function Tests (PFT), Hospital Anxiety and Depression Scale (HADS). Preoperative assessments T0 – baseline; T1 – one day before surgery. Adherence is registered by a home diary.

**Results**

At the moment we enrolled 55 patients in IG. 53 completed the preoperative phase. In table 1 we reported comparison between T0 and T1 for exercise capacity in IG.

<table>
<thead>
<tr>
<th></th>
<th>T0 (m)</th>

<tbody>
<tr>
<td>6-MWT</td>
<td>450.3±82.6</td>
<td>474.5±91.8</td>
<td>0.0003</td>
</tr>
</tbody>
</table>
Regarding Anxiety and Depression there are no significant difference between T0 and T1 in both groups.

Regarding the feasibility of the experimental protocol 84% of patients adhered at outpatient programme and 78% at home-based programme.

**Conclusion**

Study is ongoing, preliminary data on exercise capacity and compliance in preoperative phase are encouraging.

*No conflict of interest*
Purpose: This study aimed to measure symptoms of Post-Traumatic Stress Disorder (PTSD) in patients following a new diagnosis of lung cancer. Secondary aims were to explore factors at diagnosis that may predict PTSD symptoms at six months.

Material and Method

Methods: Prospective longitudinal observational study including 93 patients with newly diagnosed lung cancer. PTSD symptomology was assessed with the PTSD Checklist Civilian Version (PCL-C) and HRQoL was assessed with the European Organisation for the Research and Treatment of Cancer questionnaire. Measures were completed at diagnosis and 6 months.

Results

Results: No patients had PTSD at baseline or 6 months as measured by a score of ≥ 50 in the PCL-C. However, at diagnosis 44% of patients had ‘mild’ symptoms of PTSD. At 6 months, 64% of patients had ‘mild’ and 8% had ‘moderate’ PTSD symptoms. PTSD symptom scores significantly worsened over six months (mean difference 95% CI 7.2 [5.4 to 9.0]). Six months after diagnosis, higher PTSD scores were seen in people who at diagnosis were younger (p=0.003), had a lower smoking pack history (p=0.012), engaged in less sedentary behaviour (p=0.005), or initially had worse symptoms including fatigue (p=0.001) and poorer HRQoL (p=0.004).

Conclusion

Conclusions: Mild PTSD symptoms are common in patients with lung cancer six months after treatment, however a full diagnosis of PTSD is uncommon.

Implications for Cancer Survivors: Screening for PTSD symptoms in at-risk patients with
newly diagnosed lung cancer is an important aspect of assessment to identify patients who may benefit from further assessment and intervention.

EFFECTS OF PHYSICAL EXERCISE ON THORACIC AND ABDOMINAL CONFIGURATION IN PATIENTS WITH CHRONIC OBSTRUCTIVE PULMONARY DISEASE

D. Costa¹, A. Capeletti¹, A. Souza¹, C. Feitoza¹, E. Gomes¹
¹Universidade Nove de Julho UNINOVE, Health Sciences Facult, São Paulo, Brazil

Introduction/Background

Chronic obstructive pulmonary disease (COPD) leads to changes in thoracoabdominal movements, airflow limitation and respiratory muscle overload, influencing the harmonious mechanism of pulmonary ventilation and promoting asynchronous thoracoabdominal movement. This dysfunction can lead to aggravating consequences in the ventilatory mechanics of these patients, mainly by physical effort, even in light effort as activities of daily living. The objective of this study was to evaluate how an exercise that simulates a daily activity can change the thoracoabdominal movements in patients with chronic obstructive pulmonary disease.

Material and Method

A non-controlled trial was conducted and COPD patients were evaluated by optoelectronic plethysmography (OEP) (BTS, Italy). This evaluation consisted in 89 reflective markers that were positioned in the anteroposterior thorax, with 4 cameras positioned in front of the subject and 4 cameras behind. The captured signals were transmitted in real time, 60 frames per second synchronized with infrared light emitting diodes that were reflected by the markers and transmitted to the system for the specific software 1 to 1 to transform this capture into three-dimensional (3D) geometric information providing data on lung mechanics. This evaluation, along with spirometry, performed using an EasyOne NDD spirometer, was performed before and after performing an exercise simulating an activity of daily living.

Results

25 patients with COPD, mean age of 68.6 ± 17.9 years, were able to demonstrate a significant change in the Ti / Ttot index, which increased after physical exertion. Important changes were also observed in the thoracoabdominal pattern of these patients.

Conclusion
Our results allow us to conclude that the physical activity of daily living alters the fit and breathing pattern of patients with COPD.

EFFICACY OF NIV COMPARED TO ALBUTEROL IN LUNG FUNCTION AND ABDOMINAL THORACIC CONFIGURATION OF YOUNG ASTHMATIC PATIENTS AFTER BRONCHOPROVOCATION. CROSSOVER CLINICAL TRIAL
D. Costa1*, E. Gomes1, M. David1, A. Capeletti1, M. Melo1, A. Santos1, V. Alves1
1Universidade Nove de Julho UNINOVE, Health Scienses Facult, São Paulo, Brazil

Introduction/Background

Almost 30% of asthma patients exhibit reduced response to β2 and there are some side effects of this therapy. The NIV improves lung function in patients and reduces the need for bronchodilator and has an additional important action not observed in drug therapy that is the reduction of the work of breath. Meet the mechanical effects of these therapies is of great importance and can modify clinical decisions.

To evaluate the effects of NIV compared to salbutamol on pulmonary function and respiratory mechanics of young asthmatic patients after bronchoprovocation

Material and Method

Randomized crossover trial, were included patients diagnosed asthmetics aged between 12 and 29 years. They were evaluated by optoelectronics plethysmography (OEP) and spirometry at baseline, after bronchial provocation test with saline solution 4.5% and after an intervention. Will be randomized the order of procedures (Bi-level or Salbutamol), and after a week of washout this patient was attended to another treatment. Binível was set IPAP 12 e EPAP 8 cmH2O por 10 min and Salbutamol 400μg

Results

27 patients with a mean age of 21.6 ± 4 years, 18 women. FEV1 recovery was 62% post NIV and post-BD 82.7%. The inspiratory capacity showed a reduction of 12 to 15% after bronchoprovocation and recovery of 105% in NIV and 125% in BD. As for plethysmography the TV has greater participation of the thoracic compartment the NIV increases the minute volume and there is a return to the baseline after application which does not occur with salbutamol.

Conclusion

NIV has a bronchodilator effect and can reduce of hyperinflation by improving inspiratory capacity and is earlier able to recover baseline minute volume compared to Salbutamol although the effects on lung function are more modest.

Swallowing Dysfunction in COPD Patients

D. Martins¹, R. Lopes¹, U. Martins², C. Martins¹, R. Alison¹, G. Leandro¹, S. Rego¹, L. Gomes¹, J. Moreira¹, V. Milet¹

¹Centro Hospitalar Universitário do Algarve, Physical medicine and rehabilitation department, Faro, Portugal
²Centro Hospitalar Entre Douro e Vouga, Physical medicine and rehabilitation department, Porto, Portugal

Introduction/Background

Chronic obstructive pulmonary disease (COPD) is a common problem associated with morbidity and mortality which is characterized by a progressive persistent airflow limitation. The World Health Organization estimates that in 10 years the number of total deaths related with COPD will increase at least 30%. Exacerbations leads to a worsening lung function and increase the risk of mortality. Therefore, decreasing the number of exacerbations is an important aim. Factors that modify breathing and ventilation patterns may influence the precise coordination of breathing and swallowing.

The purpose of this review is to sensitize the medical population to the effects of COPD on swallowing function.

Material and Method

Literature searches were performed using the electronic database PubMed. Queries: COPD, swallowing dysfunction, oropharyngeal dysphagia. Articles between 2000 to 2017 were included.

Results

COPD patients have a disrupted coordination between breathing and swallowing. In fact, changing the ventilator pattern, like inducing hypercapnia or by modifying the respiratory mechanical or flow-resistive load, improved swallowing frequency and laryngeal irritation. Several abnormal aspects of respiratory timing during swallowing are described in patients with COPD resulting in an increased risk of aspiration pneumonia and malnutrition. Therefore, the presence of dysphagia in patients with chronic respiratory diseases can increased exacerbations, which are associated with a rapid deterioration of their ventilator function and admissions in hospital.

Conclusion

Although, the relative small number of studies, almost of that show a relationship between dysphagia and COPD patients, and emphasize that this condition may be underdiagnosed. An effective screening, made by a rehabilitation physician, to determine whether patients with
COPD are at risk of dysphagia is crucial for the individual and healthcare system and the first step is to aware the medical population and understanding the importance of a multidisciplinary approach.

AMBULATORY PULMONARY REHABILITATION PROGRAM FOR PATIENTS WITH COPD: RESULTS.

1H.U.Donostia, rehabilitation, San Sebastian, Spain
2H.U.Donostia, radiology, San Sebastian, Spain

Introduction/Background

Currently, the chronic obstructive pulmonary disease is the fourth cause of death in the world. Dyspnea is the main symptom in these patients, and it produces a progressive loss of autonomy and quality of life. This study was aimed to analyze the effectiveness of a structured respiratory rehabilitation program in COPD patients in terms of improving the health-related quality of life and perception of dyspnea.

Material and Method

Prospective longitudinal study of COPD patients with any degree of severity in the GOLD scale, clinically stable, who have completed the respiratory rehabilitation program between 2013-2017. Dyspnea was measured using the modified Medical Research Council scale, quality of life through self-administered version in Spanish of the chronic respiratory disease questionnaire (CRQ-SAS) and exercise capacity through six minutes walking test (6MWT); both of them were evaluated at baseline and at the end of the treatment.

Results

A total of 76 (88.37%) patients completed the program, of which 77.7% presented severe and very severe airflow limitation. Dyspnea decreased in 58% the patients after applied pulmonary rehabilitation. In terms of quality of life and exercise capacity, a significant improvement were found after finished rehabilitation program in all areas measured by means of the CRQ-SAS questionnaire as well as in the 6-minute walk test (p<0.05).

Conclusion

These data presented reaffirm us again on the benefit and the important role of respiratory rehabilitation in the management of patients with COPD.

EARLY PULMONARY REHABILITATION PROGRAM (PRP) AFTER HOSPITAL ADMISSION DUE TO EXACERBATION IN CHRONIC OBSTRUCTIVE PULMONARY DISEASE (COPD): RESULTS AND FOLLOW-UP.
M. Boldó-Alcaine¹, C. Martínez Rivera², M.T. Pascual-Soria¹, C. Gallardo¹, R. Andolz-Linares¹, A. Francoso², V. Jiménez-Vilchis¹, I. García-Olivé², J. Abad-Capa², M.J. Durà-Mata¹
¹Hospital Germans Trias i Pujol, Physical Medicine and Rehabilitation, Badalona Barcelona, Spain
²Hospital Germans Trias i Pujol, Pneumology, Badalona Barcelona, Spain

Introduction/Background

Pulmonary rehabilitation is effective in the management of stable COPD, however, its role following an exacerbation of COPD is less studied.

Material and Method

A prospective open observational study that included 91 patients with COPD hospitalized for exacerbation. Patients were randomized to intervention group (IG, early PRP) or control group (CG). The PRP included 4 weeks of supervised ambulatory daily aerobic exercise. The following variables were analyzed at 3 and 6 months: walking distance in the six-minute walking test (6MWT), hand grip, muscle mass percentage (MM), Saint George Respiratory Questionnaire (SGRQ), Modified Medical Research Council dyspnea scale (mMRC), COPD Assessment Test (CAT) and number of exacerbations.

The statistical analysis was performed using Mann-Whitney U test considering a statistically significant difference p <0.05, SPSS (22.0).

Results

43 patients (39 men, mean age 71.4 years) were assigned to the IG and 47 (44 men, mean age 73.26 years) to the CG. The 6MWT distance in the IG at 3 and 6 months was 365.89 (SD 93.9) and 383.81 meters (SD 88.7); in the CG, 299.7 (SD 106.7) and 306.8 meters (SD 106.4), p <0.05. Patients improved in terms of MM, SGRQ, mMRC, CAT and exacerbations at 3 and 6 months in the IG, although without statistical significance.

Conclusion

Early PRP improves exercise capacity at 3 and 6 months. To establish more conclusions, it is necessary to expand the sample size.

EXPERT CONSENSUS ON BRIEF ICF CORE SET FOR COPD IN CHINA
P. Wang
Shanghai Jiaotong University School of Medicine, Ruijin Hospital, Shanghai, China

Introduction/Background

The Brief ICF core set for Obstructive Pulmonary Disease is universally used on the evaluation of COPD in clinical practice. While, the ICF core sets makers are mainly experts from north American and Europe and may not suit the Asian.

Material and Method

A consensus-building, 3-round, face-to-face survey with medical experts using the modified Delphi technique was conducted. 52 experts in the PCCM project completed the consensus process. The “comprehensive ICF core set for Obstructive Pulmonary Disease” was used as the reference. Added categories by the experts were combined with categories in the “comprehensive ICF core set for Obstructive Pulmonary Disease” to make questionnaire 1 in the first round; categories with an agreement level over 50% were selected to make questionnaire 2 in the second round; categories with an agreement level over 70% in the third round were selected to make the brief ICF core set for COPD in China.

Results

The brief ICF core set for COPD in China contained 13 categories. Of these, 4 categories were from the component body functions, 2 from body structures, 4 from activities and participation, and 3 from environmental factors.

Conclusion

This is the first study in the world to assess ICF core set for Chinese COPD patient and develop the Brief ICF core set for COPD in China. Our results confirm that the existing “comprehensive ICF core set” can represent the situation of COPD patients in China and find the unique characteristic of Chinese COPD patients,

ASSESSMENT OF LOWER URINARY TRACT FUNCTION IN CHILDREN WITH HIRSCHSPRUNG’S DISEASE

S. Zahi

1CHU Ibn Rochd, physical medicine and rehabilitation department, casablanca, Morocco

Introduction/Background

Usually, in Hirschsprung’s disease (HD), long-term sequelae in children are related to abnormalities in defecation. However, some of these patients also develop lower urinary tract problems. The aim of this study was to assess and define the effects of transanal endorectal pull-through procedure in patients with HD on lower urinary tract function through urodynamic studies performed before and after surgery.

Material and Method

Twenty-eight patients with HD were subjected to urodynamic studies before and after the different definitive surgical procedures. They were all males with a mean age of 3 years. The main outcome measurements were maximum cystometric capacity, compliance, unstable detrusor contraction, and residual urinary volume.

Results

Urodynamic findings were normal in 23 (82%) children, and abnormal in five (18%) children. In the uroflowmetric study, dysuria with detrusor sphincter dyssynergia and significant postvoid urine residuals (>20 ml) were found in the three symptomatic children. In the cystometric study, five children had unstable detrusor contraction, low bladder compliance, and small-capacity bladder.

Conclusion

In HD, neurovesical dysfunction may exist preoperatively, and, although the incidence of postoperative changes in neurovesical function may appear high, children who present with urinary problems after surgery should be assessed urodynamically.

THE INFLUENCE OF URINARY INCONTINENCE AND /OR FECAL INCONTINENCE ON THE QUALITY OF LIFE AMONG TUNISIAN PHYSICIANS AND NURSES

S. Frioui Mahmoudi¹, H. Rabah², S. Gallas²
¹University Hospital Sahloul, Physical and Rehabilitation Medicine, Sousse, Tunisia
²Sahloul University Hospital, Functional Exploration Department, sousse, Tunisia

Introduction/Background

The aim of this study is to evaluate the influence of urinary and/or fecal incontinence on the quality of life among Tunisian physicians and nurses.

Material and Method

From October 2015 to May 2016, a descriptive cross-sectional study was conducted among female physicians and nurses in two Tunisian teaching Hospitals. Data collection was performed using a digital tablet that contains a self-administered questionnaire written in French.

Results

A total of 402 questionnaires were collected. The sample included 321 (80%) nurses and 81 (20%) female-physicians.

There were a significantly powerful positive association between sphincter dysfunctions and altered mental or physical scores. These results confirm that being incontinent (having urinary incontinence and/or anal incontinence) had a negative impact on quality of life. 67.4% (n=126) of the participants who were incontinent were aware of their conditions and only 61.6% (n=115) of them have sought medical help.

The main reasons reported for the lack of consultation were the feeling of shyness, unavailability (lack of time) and finally those who considered these disorders as a normal result of ageing, pregnancy and childbirth.

Conclusion

In our study the participant having sphincter dysfunctions had respectively a significantly higher altered physical and mental health score percentage (8.4% Vs 40.1%; p <10-3) and (31.2% Vs...
54%; p <10-3) thus a worse quality of life. In fact, our results are consistent with those of the literature.

Damon et al used the same questionnaire as ours (SF12) to assess the impact of anal incontinence on the quality of life and found that 87% of incontinent women felt that their anal symptoms reduced their quality of life.

PREVALENCE OF URINARY INCONTINENCE, ANAL INCONTINENCE, DOUBLE INCONTINENCE AND SPHINCTER DISORDERS AMONG TUNISIAN PHYSICIANS AND NURSES

S. Frioui Mahmoudi, H. Rabah, S. Gallas

1University Hospital Sahloul, Sousse, SOUSSE, Tunisia
2University Hospital Sahloul, Functional Exploration Department, Sousse, Tunisia

Introduction/Background

The aim of this study is to identify the prevalence of urinary incontinence, anal incontinence, double incontinence and sphincter disorders among Tunisian physicians and nurses.

Material and Method

From October 2015 to May 2016, a descriptive cross-sectional study was conducted among female doctors and nurses in two Tunisian University Hospitals. Data collection was performed using a digital tablet (allowing an automatic importing data for analysis) that contains a self-administered questionnaire written in French.

Results

A total of 402 questionnaires were collected. The sample included 321 (80%) nurses and 81 (20%) female-physicians.

The respondents age ranged from 23 to 60 years, with a mean age of 36.8 ± 8.3 years. There were a significant difference in distribution of age, BMI, financial incomes, fruit and water consumption between nurses and physicians.

The most common medical conditions and surgeries were respectively systematic arterial blood hypertension and appendectomy.

The overall prevalence of Urinary Incontinence in the present study was 45%. In fact, more than one quarter of the participants experienced Urge Urinary Incontinence (20.4%) versus 17.9% Mixed Urinary Incontinence and 6.7% Stress Urinary Incontinence.

Anal Incontinence was reported by 10.9% of the participants and the subjects who reported at least one episode of anal incontinence per week were: 4.4% for flatulence, 6.2% for liquid stool and 0.24% for solid stool.
In the present study the double Incontinence prevalence was 10%. Finally, sphincter dysfunctions were reported by 46.5% of the participants.

**Conclusion**

It is the first Tunisian study that has studied the prevalence, risk factors of urinary and/or anal incontinence and their impact on quality of life among Tunisian Women using international validated scales.

RISK FACTORS OF URINARY INCONTINENCE AND/OR FECAL INCONTINENCE AMONG TUNISIAN PHYSICIANS AND NURSES
S. Frioui Mahmoudi¹, H. Rabah², S. Gallas²
¹University Hospital Sahloul, Physical and Rehabilitation Medicine, Sousse, Tunisia
²University Hospital Sahloul, Functional Exploration Department, Sousse, Tunisia

Introduction/Background

The aim of this study is to identify the risk factors of urinary and/or fecal incontinence among Tunisian doctors and nurses.

Material and Method

This descriptive cross-sectional study was conducted among female doctors and nurses in two Tunisian University Hospitals from October 2015 to May 2016. Data collection was performed using a digital tablet that contains a self-administered questionnaire written in French.

Results

In multivariate regression, age higher than or equal to 40 years was an independent risk factor for sphincter disorders and health provider with a higher or equal age to 40 years had up to two and a half times more risk to have sphincter disorders (SD).

The nursing profession was an associated factor with the occurrence of SD compared to physicians. Indeed, the risk of SD occurring in a nurse was multiplied by 2.4.

Blood hypertension was found to be an independent risk factor in the occurrence of SD with an odds ratio of 3.62. The use of oral contraceptives is associated to the occurrence of the SD with an odds ratio of 2.56. The occurrence of post-obstetric urinary leakage multiplied the risk of SD by 11.98. Menopause was found as an independent risk factor for SD with an odds ratio of 13.17

Conclusion

Obesity or having an overweight were significantly associated with incontinence. Married women, who gave birth at least one time or more, were more likely to have sphincter disorders as well as post-menopausal ones. The uses of forceps at least one time, having a post obstetric urinary leakage or perineal damage were found also to be associated to sphincter disorders.
An advanced age (≥40 years), nurses’ profession, systematic blood hypertension, oral contraception drug use, post-obstetric urinary leakage, menopause status and altered physical score of SF-12 were strongly associated with sphincter disorders

URODYNAMIC PROFILE AT CHILDREN WITH URINARY DISORDERS

S. Frioui Mahmoudi, R. Moncer, S. Jemni, F. Khachnaoui

Introduction/Background

The urodynamic assessment in children is a difficult exam to perform and interpret, due to the absence of nomogram based on age, the need to consider the anxiety and the lack of cooperation especially in children multi-operated.

Material and Method

We studied the urodynamic assessments conducted over two years in children under 16 years.

Results

Of 200 patients referred for urodynamic assessment during the two-years period, 52 patients were aged less than 16 years (26%). There are 37 girls (71,1%) and 15 boys (28,8%). The most important clinical signs are urinary leakage and enuresis. We find these principal causes: the spina bifida in 7 cases (13,4%), malformations of the urinary tract in 6 cases (11,5%) and thoracolumbar scoliosis in 5 cases (9,6%). The neuro-perineal examination was normal in over 50% of cases. The flow measurement was dysuria in 22 children (42,3%). At cystometry, the bladder was hypersensitive in 28 cases (53,8%), hypo compliant in 18 cases (34,6%), overactive in 27 cases (51,9%) and hyper contractile in 18 cases. Profilometry was normal in 21 cases (40,3%), hypotonia and sphincter hypertension were identified in 11 (21,1%) and 20 (38,4%) cases respectively. We conclude with an overactive bladder in 24 cases (46,1%), immature bladder in 23 cases (44,2%) and normal test in 5 cases.

Conclusion

This invasive exploration is done in the context of an initial balance sheet or in the follow-up of congenital or acquired neurological bladders and malformations bladders. An imaging balance sheet and a urine culture generally precede this event. As in adults it is a valuable tool in the therapeutic choice.

Keywords

In neurological diseases, vesico-sphincteric disorders may have repercussions on the kidneys and on the quality of life, and may be life-threatening. It is therefore necessary to identify the cases at risk and to know when to give the indication of the enlargement enterocystoplasty. The surgical principle: and establish a neo-bladder at low pressure and satisfactory capacity with tightness, In order to protect the upper urinary tract, and possibly; give comfort to the patient (cleanliness).

Material and Method

Retrospective study: 16 cases. ; Sex: 11 female and 05 male

Results

Conclusion

After failure of medical treatment; the enlargement enterocystoplasty remains the only therapeutic solution in the neurological bladders at risk. It is necessary to know how to put the operative indication in time (before the repercussion on the upper urinary system). A small note of hope; the first operated patient in our series is currently 26 years old and leads, almost normal life, 17 years after the procedure. And we must know that the care of children with spinal dysraphism or sacred agenesis is complex, multidisciplinary, early and long term. Il need regular monitoring, and we insist on the coordination of different specialists in the management and prevention of urological complications by identifying cases at risk (by bladder hyperpressure, hyper activity).

EFFECT OF URINARY INCONTINENCE ON QUALITY OF LIFE AMONG TUNISIAN WOMEN
I. Loubiri¹, H. Migaou¹, S. Boudokhane¹, M. Guedria¹, J. Anis¹, B.S.F. Zohra¹
¹University Hospital of Monastir, Physical Medicine and Rehabilitation department, Monastir, Tunisia

Introduction/Background

In order to improve the quality of medical care, an assessment of patients’ quality of life (QOL) has been recognized to be important as well as an assessment of physical impairment. Urinary incontinence has a strong influence on patients’ QOL. Our study aimed to evaluate the effects of non-neurological urinary incontinence on the QOL of Tunisian women.

Material and Method

This was a cross-sectional descriptive study evaluating symptoms and QOL among women with non-neurological urinary incontinence seen in the urodynamic unit at the Physical Medicine and Rehabilitation department of the University Hospital of Monastir over six months. We used a validated questionnaire for symptoms and QOL: Urinary symptom profile (USP) and the urinary incontinence-specific measure of QOL: CONTILIFE.

Results

Fifty women with an average age of 51 years were included. Women were diabetic in 24%. The most frequent symptom was urgency in 76%. Stress urinary incontinence was found in 64%. Women consulted after an average of 3 years because they were ashamed in 37%, they thought it was a normal condition for age in 30%. The median USP overactive bladder score was 9.3 out of a maximum of 21. The median USP stress urinary incontinence score was 2.6 out of 9. In Daily activities domain, the median CONTILIFE score was 23 out of a maximum 35 for the highest level of discomfort. In sexuality domain the median CONTILIFE score was 8.1 out of a maximum of 15.

Conclusion

Urinary incontinence can have a severe effect on the QOL at any age. It is essential that the symptoms and effects of incontinence be properly assessed and recorded.

MANAGEMENT OF BLADDER -SPHINCTER DYSFUNCTION ASSOCIATED TO PELVIC ORGAN PROLAPSE IN REHABILITATION DEPARTMENT
H. Migaou¹, I. Loubiri¹, A. Haj Salah¹, N. abdelkafi⁷, S. Boudokhane¹, A. Jellad¹, 
Z. Ben Salah Frih¹
¹University Hospital of Monastir, Physical Medicine and Rehabilitation department, Monastir,
Tunisia

Introduction/Background

To describe epidemiological and clinical profile of patients with bladder -sphincter dysfunction related to pelvic organ prolapse (POP) and to determine management modalities through our experience in rehabilitation department with a review of literature.

Material and Method

Descriptive retrospective study involving patients with bladder disorders associated with POP referred to the Physical Medicine and Rehabilitation department of the University Hospital of Monastir. Studied parameters were: obstetric and gynecological history, bladder sphincter disorders, pelvic floor muscle evaluation, urodynamic findings and management modalities (medical treatment, perineal rehabilitation and surgery)

Results

Forty one patients with bladder disorders associated with POP were included. Average age was 54 years. The majority of our population had risk factors of POP. Clinical examination revealed a cystocele in 40 cases, hysterocele in 25 cases and rectocele in 16 cases. Pelvic floor muscle evaluation showed a deficit of levator anis muscles in 20 patients. Urinary disorders were: frequent daytime voiding (46%), urge (41%), nocturia(25%), urinay incontinence(12%),stress urinary incontinence(28%) , mixed urinary incontinence(44%) and dysuria (16%). BUD was performed in 29 patients. Flow measurement showed dysuria (41%). Cystomanometry revealed bladder hypersensitivity (31%), detrusor over activity (27%), a reduced bladder capacity (6%). Profilometry unveiled sphincter incompetence (4.7%) and urethral hypertonia (16.3%). Perineal rehabilitation was prescribed for 25 patients and only 4 patients were put under anticholinergic treatment. The follow up showed an improvement of symptoms in 19 patients (43%) and 17 cases were sent to surgeon for prolapse correction.

Conclusion

Urinary disorders and POP are widely prevalent problems in the elderly population and significantly affects quality of life. Care should be delivered with a multidisciplinary team-based approach. Rehabilitation through urodynamic testing and perineal rehabilitation plays a crucial
role in the management. Surgery is the definitive treatment; it must aim to restore vaginal function and any concomitant urinary incontinence.

EPIDEMIOLOGICAL PROFILE OF BLADDER-SPHINCTER AND ANORECTAL DISORDERS IN A TUNISIAN REHABILITATION DEPARTMENT: ABOUT 153 CASES

H. Migaou¹, I. Loubiri¹, N. abdelkafi¹, A. Haj Salah¹, S. Boudokhane¹, A. Jellad¹, Z. Ben Salah Frih¹
¹University Hospital of Monastir, Physical Medicine and Rehabilitation department, Monastir, Tunisia

Introduction/Background

The main objective of this study was to evaluate the epidemiological, clinical and therapeutic profile of bladder-sphincter and anorectal disorders in patients followed in a Rehabilitation department.

Material and Method

This is a descriptive retrospective study including patients followed for bladder-sphincter and anorectal disorders. Demographic, clinical and therapeutic modalities were studied.

Results

Our study includes 97 women and 56 men with an average age of 46.07 years. The history of pelvic surgery and pelvic tumor were found respectively in 4 and 3 women. Among the 70 women who delivered in our study, 12 women had a history of macrosomia and 7 had a history of dystocia. The history of benign prostatic hyperplasia was found in 4 men. Urinary problems were observed in 141 patients such as frequent daytime voiding (32.67%), urgency with (17.64%) or without urinary incontinence (14.37%), nocturia (16.33%), dysuria (15.03%), urinary retention (4.57%), stress urinary incontinence (16.99%), mixed urinary incontinence (20.26%) and incomplete bladder emptying (1.96%). The anorectal disorders (constipation and fecal incontinence) were found in 27 patients. The etiological investigation showed a predominance of neurological diseases (43.13%) and gynecological pathologies (35.94%). Urodynamic assessment was performed in 69 patients. Therapeutically, 31 patients received anticholinergic therapy and 55 patients underwent perineal rehabilitation sessions. Urinary catheterization was indicated in 23 patients. Hygiene and dietary rules were given in 17 patients. The evolution was marked by an improvement of the symptoms in 46.4% of cases and 21 of our patients were referred for surgery.

Conclusion

The bladder-sphincter and anorectal disorders are frequent but largely underestimated. Their support is based mainly on the pelvic floor muscle training which is beneficial in most cases.

Introduction/Background

Urinary retention occurs in about 50% of patients hospitalized in the context of stroke, with rapid improvement in the first 72 hours, however, in 15-20% it may persist up to 6 months. Bladder dysfunction in stroke is often undervalued insofar as neurogenic bladder symptoms are difficult to recognize during the acute phase. There is generally a decreased sensitivity by the attending physician to this symptomatology, although it is of significant importance in terms of prognosis as well as its social impact.

Material and Method

The authors describe the clinical case of a patient who developed a urinary retention after cerebral infarction. A search was made in the Pubmed database of the terms "poststroke urinary retention", "detrusor hyporeflexia" and "micturition center".

Results

A 59-year-old woman with multiple cardiovascular risk factors presented in the emergency room with acute imbalance in gait, nausea and vomiting. Neurological examination showed right grade 3 hemiparesis (MRC scale) associated with appendicular dysmetria. Acute urinary retention was diagnosed 10 days after stroke and urodynamic study revealed absence of sensation and voluntary contraction of the detrusor and brain MRI revealed foci of hypersignal in the subcortical and periventricular white matter of both hemispheres, devoid of mass effect. The patient started alpha-blocker which was not effective, and was followed by intermittent bladder catheterization. Reassessed in consultation at 6 months post-stroke with no improvement is her bladder status. It may be a case of detrusor hyporeflexia due to probable disruption of the fibers descending from the pontine center of micturition.

Conclusion

To our knowledge, there is scarce evidence in the literature that implies posterior circulation lacunar syndrome and detrusor hyporeflexia. We consider that more attention should be paid to the recognition of the neurogenic bladder in stroke, because of its importance in clinical and functional prognosis.

URODYNAMIC PROFILE OF CHILDREN FOLLOWED FOR VESICOURETERAL REFLUX

I. ksibi¹, H. Garès², R. Maaoui¹, I. Megdiche¹, H. Rahali¹
¹Military Tunis Hospital. Tunisia., Department of physical and functional rehabilitation, Tunis, Tunisia
²Military Tunis Hospital. Tunisia., Department of physical and functional rehabilitation, Msaken, Tunisia

Introduction/Background

Vesico-ureteral reflux is a common abnormality of the urinary tract in children who can engage the nephrological prognosis.

The objective of this study is to establish the urodynamic particularity of children followed for vesico-ureteral reflux.

Material and Method

Descriptive retrospective study carried out during the period between June 2012 and June 2017, including children referred to the department of Physical and Functional Rehabilitation of the Military Tunis Hospital for urodynamic investigation in the context of the exploration of a vesicoureteral reflux.

Results

25 patients were included in the study. The average age was 6.7 years old. The vesicoureteral reflux was bilateral in 15 children (60%) and unilateral in 10 children (40%). It was classified as low grade in 8 cases (40%) and high grade in 17 cases (65%). An aspect of diverticular bladder was observed for 4 patients. The combination of VUR and diverticular bladder was observed for 2 patients.

The urodynamic profile of children with RVU was characterized by 5 main abnormalities: little bladder capacity in 80% of cases, vesical hypersensitivity in 66% of cases, detrusor overactivity in 57% of cases, and hypo compliance in 28% of cases.

Conclusion

The urodynamic investigation takes a part in the management of the voiding disorders of the child especially when we have vesicoureteral reflux.

1Military Tunis Hospital, Department of physical and functional rehabilitation, Tunis, Tunisia
2Military Tunis Hospital, Department of physical and functional rehabilitation, Msaken, Tunisia

Introduction/Background

The occurrence of urinary tract infection (UTI) in a context of micturition disorders is common and it is always necessary to know how diagnose them specially if the infections are repeated. the consequences of micturition disorders can engage the nephrological prognosis. this work focuses on characterizing the urodynamic profile of children presenting repetitive urinary tract infection

Material and Method

Retrospective descriptive study during the period between June 2012 and June 2017 including children sent to the Physical Medicine and Functional Rehabilitation Department of the Military Hospital of Tunis for the exploration of repetitive urinary tract infections.

Results

130 patients were included in the study. The average age of the population was 8.8 years with [4 -15]. A clear female predominance was observed (Sex.Ratio 1.8). 73 children had at least one episode of pyelonephritis. 57 patients presented at least one episode of low urinary tract infection including 29 patients with a history of three or more cystitis.

The urodynamic profile of patients with UTI was characterized by -Vesical hypersensitivity in 74% of cases. -The detrusor overactivity in 56% of cases. -The small bladder capacity in 42% of cases. -The high permictionnal pressure regimen in 32% of cases. -Bladder hypo compliance in 24% of cases.

Conclusion

The urodynamic investigation has a prominent place in the management of voiding disorders of the child especially in the presence of repetitive urinary tract infections

URINARY DISABILITY MEASURE OF PEDIATRIC NEUROGENIC BLADDER
Y. moigny gaju¹, S. hrar¹, N. kyal¹, F. lmidmani¹, A. el fatimi¹
¹Ibn Rochd University Hospital, medecine physique et readaptation, Casablanca, Morocco

Introduction/Background

The pediatric neurogenic bladder is a heterogeneous entity that may result from a variety of conditions affecting the central or peripheral nervous systems. To our knowledge no validated instruments properly designed to evaluate the severity of urinary symptoms in pediatric Neurogenic bladder have been published to date. The purpose of our work is to measure urinary disability in a children with neurogenic bladder

Material and Method

Descriptive and analytical study of 37 children with neurogenic bladder followed in the department of physical medicine and rehabilitation of Casablanca for urodynamic exploration between January 2013 and September 2016. All the participants were evaluated by urinary disability measure (MHU) score and international consultation incontinence questionnaire urinary incontinence short form (ICIQ -UI-SF).

Results

The mean age was 9,6 years. There was a female predominance : 22 girls and 15 boys. Intermittent urinary incontinent was the major symptom found 27% , followed by dysuria in 24% ; urinary retention in 10,8% and jet abnormalities in 8,1%. The repercussion on the upper urinary tract was: reflux vescicoureteral in 35%; ureterhydronephrosis in 24,3% ; having as a consequence 10,8% of kidney insufficiency. The MHU score showed mean total score of urinary disability in our children to 8,5/28 and the assessment of the impact of urinary disability on the quality of life patients by the ICIQ showed a median value of 13,5/21.

Conclusion

The use of the MHU score allows a more reliable and quantifiable objectification of Neurogenic micturitionar disorders in children . This mean that the pediatric neurogenic bladder alters the quality of life of the patients.

LOW LEVEL LASER THERAPY FOR TREATMENT OF DETRUSOR UNDERACTIVITY POST BENIGN PROSTATE HYPERPLASIA

S. Setiono¹, H.B. Purba¹, I. Mistivani²
¹Cipto Mangunkusumo Hospital, Medical Rehabilitation, Jakarta, Indonesia

Introduction/Background

Lower urinary tract symptoms (LUTS) are one of the most common problems found in older male. Many condition can cause LUTS, but the most influential factor in older male is benign prostate hyperplasia (BPH). One of the common LUTS in late BPH is detrusor underactivity and incomplete voiding. Low-level laser therapy (LLLT) has been used extensively in the field of rehabilitation due its regeneration and anti-inflammatory properties.

Material and Method

Male patient, 65 years old, with BPH post transurethral resection of the prostate (TURP), came to the rehabilitation clinic due to inability to void. TURP was done on July 2015, and he had difficulty in voiding and has been using Foley catheter for the last 6 months before coming to rehabilitation department. Urodynamic results on July 2016 shows normal compliance, detrusor underactivity, prolong voiding, abdominal straining, and high post void residual urine (PVR) (>50%).

The patient was given a clean intermittent catheterization (CIC), voiding diary, along with a LLLT stimulation on suprapubic area, 3-4 spots, 6-9 J each spot. LLLT was given 5 sets of 6 session each, 2-3 times per week. Patients was evaluated at the end of every sets for voiding diary and PVR evaluation. At the end of the 5 sets, an urodynamic evaluation was done.

Results

After 5 sets of LLLT and CIC, patients has improvement in his bladder sensation, voided volume, his ability to hold urine, and reduction in PVR (<20%) and frequency. Despite improvement in symptoms, follow up urodynamic test didn't show significant difference from the previous one.

Conclusion

Low level laser therapy for LUT dysfunction in BPH patient show a promising results. But research regarding the effect of LLLT in bladder dysfunction is very limited. A reliable research needed to be done to prove the efficacy of LLLT in the management of bladder dysfunction.

THE EFFICIENCY OF THE POSTERIOR TIBIAL NERVE STIMULATION IN FECAL INCONTINENCE POST HIRSPRUNG DISEASE SURGERY: A CASE REPORT

A. Abdallah1, M. Sghir1, M. Maraoui1, B. Krifa1, S. Zrou2, W. Kessomtini1
1CHU Tahar Sfar, Médecine Physique et Réadaptation Fonctionnelle, Mahdia, Tunisia
2CHU Fattouma Bourguiba, Rhumatologie, Monastir, Tunisia

Introduction/Background

Hirschsprung disease (HD) is an anorectal malformation which causes constipation in children. Fecal incontinence (FI) can be caused by the malformation itself or as a consequence of its surgical repair. Different treatments are available for FI and can be more or less invasive. The posterior tibial nerve stimulation (PTNS) is an interesting alternative treatment which is very little used in the pediatric setting especially the transcutaneous way. The aim of our study is to evaluate the efficiency of PTNS in the management of FI postsurgery for HD.

Material and Method

This is an 8-years old child with poor school results. He was referred to our service for the management of a post-surgical FI for his HD. He received 2 months of PTNS at the rate of 3 sessions per week. Each session lasts 20 minutes. Jorge-Wexner score was evaluated at the beginning and the end of the protocol.

Results

After an 8 week period, the child showed significant improvement in his FI symptoms. He experienced a reduction in the number of incontinence episodes (5-6 episodes per day to 3-4 episodes per month) and an improvement in urgency (1 bowel per day). There was also an improvement in the Jorge–Wexner score between prePTNS and two months after (decrease from 16 to 4).

Conclusion

This case report shows preliminary results of the PTNS for the treatment of FI in children. It may hold promise as a treatment which patients can self-administer safely and effectively. However, its true role remains yet to be validated and time tested.

BLADDER DYSFUNCTION IN MYASTHENIA GRAVIS - A RARE MANIFESTATION OF DISEASE OR CONSEQUENCE OF TREATMENT?

I. Natário¹, A. Trêpa²
¹Hospital da Prelada, Serviço de Medicina Física e de Reabilitação, Porto, Portugal
²Centro Hospitalar do Porto, Serviço de Medicina Física e de Reabilitação, Porto, Portugal

Introduction/Background

Myasthenia Gravis is an immune-mediated condition with production of autoantibodies against the acetylcholine receptors in the neuromuscular junction. This disorder is characterized by decreased muscle strength and fatigue that typically worsens with exercise. Neurogenic bladder dysfunction associated with the disease is rarely described, as well as the effects of anti-acetylcholinesterase medication at the bladder and urethral sphincter. The authors describe a case of a patient with Myasthenia Gravis and neurogenic bladder. A literature review published to the present on neurogenic bladder dysfunction and the effects of medication associated with the disease was also carried out.

Material and Method

Case report - A 56-year-old female with Myasthenia Gravis associated with thymoma. She started treatment with pyridostigmine and underwent thymectomy one month after diagnosis. Meanwhile, she started complaining of mixed urinary incontinence. Physical examination showed sphincter insufficiency with retention effort. Detrusor hyperactivity with small volumes, high pressures and subsequent loss was identified in the urodynamic study. In the voiding phase, she had an effective detrusor contraction, without residual volume.

Results

In this disease, due to the compromise of the nicotinic and muscarinic receptors, it is expected an alteration of the smooth and striated muscle. In the literature, five cases of myasthenia gravis and neurogenic bladder dysfunction were described, four of whom had detrusor hypoactivity and in one case hyperactivity. Regarding the effects of the medication, a single study was found in which the detrusor hyperactivity is associated with the anti-acetylcholinesterase therapy, probably what will explain the urodynamic findings of this patient.

Conclusion

There are few reported cases of neurogenic bladder in Myasthenia Gravis, and lesser on the effect of anti-acetylcholinesterases on the bladder and sphincter function. Given its multiple alterations, the urinary symptoms should always be asked.
Further studies should be performed to better understanding bladder dysfunction in this pathology.

CLINICAL AND URODYNAMIC FINDINGS IN TUNISIAN CHILDREN: A SINGLE-CENTER REPORT OF 79 CASES

S. Jemni¹, M. Gadour¹, R. Moncer¹, S. Frioui¹, W. Ouannes¹, S. Mtawaa², F. Khachnaoui²
¹University hospital center Sahloul, Physical medicine and rehabilitation department, Sousse, Tunisia

Introduction/Background

Pediatric Voiding disorders are frequent. Urodynamic evaluations make it possible to describe bladder dysfunctions and to plan a therapeutic strategy for each patient. The aim of our study is to analyze different type of such symptom in childhood and describe therapeutic measures.

Material and Method

A retrospective study including 79 children (51 girls, 28 boys) treated for voiding disorder from January 2013 to Mars 2017 in the urodynamic unit of the physical medicine and rehabilitation Department in university Hospital center Sahloul, Sousse. The clinical history and urodynamic assessments as well as the neuroradiographic findings were recorded.

Results

Mean age of our study population were 11 years [4-16]. Clinical history and exam were normal in 60.7% of cases, revealed spina bifida in 6 cases, multiple sclerosis in 4 cases and renal failure in 6 cases. The most common symptoms reported were Urgency urinary incontinence (35.4%), and enuresis (29.1%).

Urodynamic test was practiced and revealed an overactive detrusor in 57% of cases associated to bladder sphincter dyssynergia in 15% of cases because of a poorly stabilized bladder.

Treatment was based on motivational therapy, bladder-training exercises in 73% of cases. Pharmacologic was based on anticholinergics in 60% of cases and Desmopressine was prescribed in isolated nocturnal enuresis. Clean intermittent catheterization was prescribed in 4 cases.

Conclusion

Voiding troubles in children are frequent including in most cases a poorly stabilised or non-neurogenic bladder. A careful clinical and urodynamic evaluation is necessary to eliminate a neurologic disorder, evaluate the risk on the upper urinary tract and define a management program for each trouble.

THE IMPACT OF A PELVIC FLOOR REHABILITATION PROGRAM IN URINARY INCONTINENCE AT ONE YEAR

M. Saavedra¹, O. Martins Cardoso¹, F. Pereira¹, B. Moreno¹, M.J. Azevedo¹
¹Hospital Senhora da Oliveira Guimarães, Physical Medicine and Rehabilitation, Guimarães, Portugal

Introduction/Background

Urinary incontinence (UI) is defined as the involuntary loss of urine. Pelvic floor rehabilitation (PFR) is preconized as the first line treatment of stress incontinence. The aim of this work was to determine the recurrence of IU after one year of a PFR program, its impact on the patient’s life, and its relation to compliance of maintaining pelvic floor home exercises in a group of women with UI.

Material and Method

Retrospective analysis of computer records from physician evaluation, previously, afterwards and at 3 months after treatment and telephone interview at 1 year, of women diagnosed with UI that underwent PFR between January and December 2016. Demographic, VAS before, after and at 1 year from supervised treatment, subjective quantity of urine loss by a Likert scale at 3 and 12 months and compliance to home exercises were the main data obtained.

Results

54 women were followed with a mean age of 48. 57.40% had mixed and 42.59% stress UI. Mean VAS before treatment was 6.77, at the end 3.48 and at 1 year 5.18. At the end of treatment 48.15% of patients classified they’re IU as “much better”. 3 months after 31.48% still had some grade of urine loss but 56.34% had fewer losses. At 12 months, 38.89% considered the losses equivalent, 25.93% worse, 18.51% much worse, 11.11% better and 5.56% much better. 55.56% still had losses at 12 months and 50% of patients admitted not having complied with home exercises.

Conclusion

We demonstrated an improvement in reducing urine losses after PFR, with an important improvement in quality of life. However, the rate of worsening after one year is not negligible. Lack of compliance with home exercises may be an accountable factor. Further studies are needed as well as finding strategies to increase patient’s participation in home care programs seems vital.

IS AXILLARY WEB SYNDROME A RISK FACTOR FOR LYMPHEDEMA?

P. Ferreira¹, F. Gabriel¹, E. Fernandes², F. Sampaio¹
¹Centro Hospitalar Lisboa Norte - Hospital de Santa Maria, Medicina Física e de Reabilitação, Lisbon, Portugal
²Faculdade de Medicina da Universidade de Lisboa, Clinical Research Centre of the Lisbon Medical Academic Centre, Lisbon, Portugal

Introduction/Background

Several risk factors have been associated with upper extremity lymphedema after breast cancer treatment (LABC). These include mastectomy, axillary lymph node dissection (ALND), number of dissected and metastatic lymph nodes (NDN and NMN, respectively) and obesity. Despite the ongoing advances in breast cancer treatment, the need to study the secondary causes of lymphedema still exists due to its severe comorbidities. This study aims to identify risk factors for LABC, in particular axillary web syndrome (AWS).

Material and Method

We conducted a prospective longitudinal study of women with unilateral breast cancer treated at our institution between 2011 and 2015. Lymphedema was diagnosed when there was a rise in upper limb circumference > 2 cm in comparison to the contralateral limb. Descriptive statistics were used to summarize and describe the data of independent variables. Survival analysis was used to analyse the time interval (days) between surgery and lymphedema diagnosis. We used the Kaplan-Meier method with log-rank test to compare survival curves between groups and Cox regression (proportional hazards regression) to analyze the effect of several risk factors on lymphedema diagnosis. An alpha of 0.05 was considered statistically significant. All statistical analyses were conducted using the Statistical Software SPSS version 24.

Results

Two hundred and thirty-one patients were included with a mean age of 56 years. Among patients, 18.6% had lymphedema, 65% underwent ALND, 26.4% had AWS and 13% had seroma. AWS was not associated with lymphedema (p=0.501). Variables significantly associated with lymphedema were Mastectomy (HR=3.752; 95% CI: 1.156-12.177), ALND (HR=0.025; 95%, CI: 0.02-0.368), higher NDN (HR=1.054; 95% CI: 1.019-1.091) and higher NMN (HR=1.063; 95% CI 1.014-1.115).

Conclusion

Based on our results, AWS was not a risk factor for LABC. Unexpectedly, nor was ALND. This was probably due to the low NDN in many ALND, since a higher NDN did constitute a risk factor for LABC.

INTRODUCTION/BACKGROUND

Currently, there are no reports showing changes in heart rate (HR) and Borg scale scores after the exercise-tolerance test in patients who had undergone allogeneic hematopoietic stem cell transplantation (allo-HSCT). We investigated the change in HR and Borg scale after the exercise-tolerance test in allo-HSCT patients.

MATERIAL AND METHOD

Our study included 28 patients (19 men and 9 women) who had undergone allo-HSCT between May 2015 and March 2017. The patients performed the exercise-tolerance test on a bicycle up to 2 weeks before and 3 weeks after the transplantation. We investigated the tolerance time, HR, and Borg scale as well as the association between HR and Borg scale after the exercise-tolerance test, both before and after transplantation.

RESULTS

The exercise-tolerance time was significantly decreased after allo-HSCT (P < 0.05). The changes in HR and Borg scale after the exercise-tolerance test were significantly lower after than before allo-HSCT (P < 0.05). Furthermore, the change in HR was positively correlated with the Borg scale of the patients before allo-HSCT (ρ=0.6: P < 0.05). However, there was no change in the relationship between HR and Borg scores of the patients after allo-HSCT.

CONCLUSION

The changes in HR and Borg scale after the exercise-tolerance test were significantly lower after than before allo-HSCT. Additionally, there was no change in the relationship between HR and Borg scale after the exercise-tolerance test post allo-HSCT. We believe that our findings will be relevant in the context of planning rehabilitation for allo-HSCT patients.

BONE HEALTH AND QUALITY OF LIFE IN BREAST CANCER PATIENTS TREATED BY AROMATASE INHIBITORS

Introduction/Background

Breast cancer (BC) is the most frequent malignant tumor in women in Europe and in North America. The use of the aromatase inhibitors (AIs) is recommended in women affected by (BC) with estrogen receptor-positive (ER+) tumors. The AIs, blocking the enzyme converting androgens into estrogens, induce a reduction in bone mineral density (BMD), with a resulting increased risk of fragility fractures in the women. Therefore, BC patients treated by AIs require an adequate anti-osteoporotic treatment (bisphosphonates or denosumab) and a supplementation of calcium and vitamin D. Aim of this observational study was to evaluate the bone health and the quality of life (QoL) in a cohort of BC patients treated by AIs.

Material and Method

We included ER+ BC adult women (aged >18 years), undergone surgical treatment, in treatment with AIs. For all patients we recorded comorbidities and anti-osteoporotic treatment. We assessed: BMD, using Dual X-ray Absorptiometry (DXA), fragility fracture rate, and QoL, using the 12-Item Short Form Health Survey (SF-12) and its components: Physical Composite Scale (PCS) and Mental Health (MCS).

Results

We assessed 118 patients, mean aged 68.80 ± 10.18 years with a mean BMI of 29.0 ± 2.8 kg/m². We prescribed bisphosphonates in 80 patients (67.8%), risedronate in 68 and alendronate in 12, denosumab in 38 (32.2%), and a supplementation with calcium and vitamin D in the entire cohort. Fragility fracture rate occurred in 17.79% of women included. Mean values of SF12 scores were: SF12 PCS = 43.6 ± 2.33 and MCS = 50.0 ± 2.12.

Conclusion
In our cohort of BC patients treated by AIs, there was a fragility fracture rate of 17.8%, testifying the importance of an adequate anti-osteoporotic treatment in these patients.

ADVANCE CARE PLANNING IN BRAIN TUMOUR SURVIVORS: A PROSPECTIVE STUDY
K. Song¹, B. Amatya¹, F. Khan¹
¹Royal Melbourne Hospital, Rehabilitation, Melbourne, Australia

Introduction/Background

ACP is the process of planning for future healthcare to guide clinical decision making when one is unable to communicate decisions due to lack of capacity. This study explored the perspectives of brain tumour (BT) patients in discussing ACP, symptom profile, physical and functional status, quality of life (QoL), level of coping and carer burden.

Material and Method

A prospective cohort study with semi-structured interviews regarding ACP for BT patients in hospital and community was conducted. Validated assessment tools measured coping strategies, QoL and carer burden. Interview ACP transcripts were analyzed, coded and interpreted using qualitative analytic techniques for thematic analyses.

Results

Participants’ (n=36) mean age was 47 years (range 20-69 years), with median time since diagnosis of 3.9 years, and majority (70%) had glioblastoma multiforme (GBM). Fatigue was the most common symptom reported by 89% participants, followed by pain (53%) and cognitive impairment (39%). Overall, participants indicated good QoL and used more problem-focused coping strategies including ‘acceptance’ and ‘positive reframing’. There was a ‘moderate’ level of carer burden. Thematic analyses indicated participants had limited understanding of ACP, and lack of such discussions with healthcare professionals. Majority preferred dedicated sessions by trained healthcare professionals especially medical staff.

Conclusion

The low uptake of ACP amongst BT patients’ highlights need for increased awareness of ACP in clinical practice as it has an important role in enhancing patient autonomy and delivery of quality end-of-life care. The neuropalliative-rehabilitation model of care integrates care with treating teams and can provide timely ACP information to BT patients, with the need for multifaceted system-wide interventions in implementing ACP.

CARDIORESPIRATORY FITNESS AND HANDGRIP STRENGTH IN BREAST CANCER PATIENTS WITH LYMPHEDEMA: PRELIMINARY STUDY
J. Kim¹, N.R. Yun², E. Jung², K.M. Lee²
¹Wonkwang University and Hospital, PM & R, Iksan, Republic of Korea
²Wonkwang University and Hospital, Physical medicine & Rehabilitation, Iksan, Republic of Korea

Introduction/Background

To investigate of the cardiorespiratory fitness of breast cancer patients with lymphedema and to understand the association between CRF and hand grip strength in breast cancer patients with lymphedema.

Material and Method

Patients with breast cancer who had treatment-related lymphedema were included retrospectively (n=20). The control group reviewed the medical records of females participating in health screening who had cardiopulmonary function test (n=33). CRF classified by aerobic capacity and cardiovascular response. To assess hand grip strength, by using aa hand dynamometer was used. , two attempts were made with each hand and the average of the two scores was used. Body mass index(BMI), Beck depression indexinventory(BDI), Montreal cognitive assessment-K(MOCA-K) were measured to investigate the association between hand grip strength and physical, psychological factors.

Results

In breast cancer patients with lymphedemaexperimental, metabolic equivalent tasks(METs), peak oxygen consumption(VO2 peak), anaerobic threshold were significantly lower than control group. The hand grip strength of affected arm is lower than unaffected arm. Hand grip strength showed no significant association with age, BMI, difference of circumference, BDI, MOCA-K. Hand grip strength showed no strong correlation with cardiorespiratory fitness.

Conclusion

To improve of quality of life and survival rate of breast cancer patients with lymphedema, it is important to educate aerobic and strengthening exercise.

LOWER LIMBS LYMPHEDEMA AFTER PROSTATE CANCER TREATMENT: A SCOPING REVIEW

A. de Sire\textsuperscript{1}, I.D. Amico\textsuperscript{1}, M. Pinto\textsuperscript{2}

\textsuperscript{1}University of Campania “Luigi Vanvitelli”, Department of Medical and Surgical Specialties and Dentistry, Naples, Italy
\textsuperscript{2}Istituto Nazionale Tumori-IRCCS-Fondazione G. Pascale, Chief of Rehabilitation Medicine Unit, Naples, Italy

Introduction/Background

Lower limbs lymphedema (LLL) might be a long life complication of prostate cancer (PC) treatment: pelvic lymph node dissection (PLND) and radiation therapy (RT) are the major risk factors to develop lymphedema in PC patients. In literature this complication is still not well recognized, although in 2011 a previous review reported a rate of 0-10%. Aim of this scoping review was to investigate the incidence of LLL in patients affected by PC.

Material and Method

We planned a research on PubMed (Public MedLine) for all the relevant clinical trials published in medical literature in the last 10 years (up to December 2017), including only those in English language, performed on humans. Firstly, we used as Medical Subject Headings (MeSH) term “Lymphedema”, adding as PubMed Search Builder the terms: “Prostate Cancer”, “Prostatectomy”, and "Lymph Node Excision" and “Prostate”; then we used as MeSH terms “Prostatic Neoplasms”, “Prostatectomy”, adding as PubMed Search Builder the term “Lymphedema”; furthermore, we used as MeSH term “Lymph Node Excision”, adding as PubMed Search Builder the terms “Lymphedema” and “Prostate”. We examined all these studies, including only those reporting lymphedema among the complications, and excluding the reviews.

Results

In our scoping review we found only 2 retrospective studies according to the research methods. In the first one, performed on 26 patients undergone ePLND (100%) and radiotherapy (84.6%), the 36% of patients showed LLL. The second study was performed on 43 patients firstly undergone radical prostatectomy (88.4%) and or radiotherapy (11.6%), all participants developed lymph node recurrence and secondly underwent choline-PET/CT guided salvage lymph node ablation plus adjuvant radiotherapy (ART). LLL was present in 10.9% before the ART, 13% during the ART, 13% after the ART, and 13.5% at the last follow up.

Conclusion
Lower limbs lymphedema is a relevant potential complication in PC patients that is worth to be better investigated.

EFFECTIVENESS OF A YOGA PROGRAM IN THE TREATMENT OF DIAGNOSED PATIENTS WITH NON-METASTATIC BREAST CANCER ADJUVANCY WITH ANASTROZOLE, LETROZOLE AND TAMOXIFEN

M.G. Rodriguez¹, K. murillo², O. Gonzalez³, D. Gallardo⁴
¹IMSS/Ugto, Rehabilitation, Celaya, Mexico
²IMSS, oncology, mexico city, Mexico
³TELETON, Rehabilitation, Mexico City, Mexico
⁴Universidad de Guanajuato, Phisioterapy, Celaya, Mexico

Introduction/Background

Breast cancer is the most commonly diagnosed cancer in women worldwide, a mortality of 522,000 each year. Advances in prevention, diagnosis and treatment have led to increased survival. The treatment patients receive is multidisciplinary, involving clinical oncologists, surgeons, radiation oncologists, physiatrists and physical therapists.

Aromatase inhibitors (AI) inhibit estrogen levels in plasma by inactivating aromatase, the enzyme responsible for the peripheral conversion of androgens into estrogens. The musculoskeletal syndrome associated with AI (AIMSS) can be severe and disabling in almost a third of patients, being this one responsible for the interruption of management in 10 to 20% of patients.

Many women with a diagnosis of breast cancer try yoga as a means to cope with their symptoms.

Material and Method

Clinical trial quasi-experimental (prospective, longitudinal, non-randomized, intra-hospital) where muscular contractures, presence of pain, were evaluated by validated clinical tests in 30 patients with breast cancer treated with IA. Treated with a program based on yoga exercises for 12 weeks from september to november 2017

Results

30 patients were studied, 24 took NSAI Ds daily (80%) for pain associated with muscle contractures and joint pain and they had contractures in pectoralis major and latissimus dorsi, 6 (20%) did not take NSAI Ds but presented joint pain, compared With the baseline assessment, a statistically significant improvement was observed in muscle contractures (p = 0.015), pain reduction (p = 0.001), all with a decrease in NSAID intake for pain associated with adjuvant treatment.
Conclusion

The yoga program positively impacts patients with non-metastatic breast cancer adjuvant with Anastrozol, letrozole and tamoxifen in reducing pain and increasing joint range

COMPREHENSIVE APPROACH TO REHABILITATION OF PATIENTS WITH BREAST CANCER

N. Voloshina

COMPREHENSIVE APPROACH TO REHABILITATION OF PATIENTS WITH BREAST CANCER,
Sanatorium "Baltiysky Bereg" State Unitarian Enterprise "Petersburgky metropoliten"- St. Petersburg. Russian Federation, Sankt-Peterburg, Russia

Introduction/Background

Rehabilitation of patients with oncological pathology is very actual problem of a modern medicine. Here is described an integrated program of rehabilitation of patients with breast cancer.

Material and Method

There were 32 patients under observation with a diagnosis of breast cancer. When prescribing physical therapeutic methods, an in-depth history of the disease, its duration, methods and volume of treatment received, its effectiveness have been collected preliminary. In the rehabilitation of the patients of the main group (17 patients), a basic complex was used, which included: general diet, motility activity, thalassotherapy, heliotherapy, swimming in the pool, sparing-training regime of the physical aerobic exercise. In addition, the patients of the main group were assigned the methods aimed at reducing symptoms of lymphedema, muscle weakness of the upper limb and increasing the nonspecific resistance of the organism to environmental factors. In the sanatorium rehabilitation of the patients of the main group, a team of specialists, consisting of oncologists, psychologists, art and dance therapists, took part. In the treatment of the control group (15 patients) the basic complex was used. Evaluation of the results of the rehabilitation was carried out according to the criteria for the effectiveness of the sanatorium treatment, taking into account the objective and subjective indicators of the patients’ health status.

Results

The effectiveness of treatment of patients who received physical methods and consultations of doctors of oncologists, psychologists, art and dans-therapists in addition to the basic complex, was significantly higher in comparison to the control group.

Conclusion
This treatment complex can be included into the programs of rehabilitation treatment and rehabilitation of patients diagnosed with breast cancer in sanatorium-resort conditions.

Introduction/Background

Background: Breast cancer is worldwide incident among women, whose surgery is frequent and associated with numerous functional changes. Objective: To assess the range of motion and upper limb function postoperatively before and after physiotherapy intervention of women who underwent mastectomy and quadrantectomy.

Material and Method

Methods: This is interventional study, descriptive and exploratory, quantitative approach, with 64 women undergoing conservative surgery and mastectomy with follow up at the gynecology outpatient clinic and referred for physical therapy at the Hospital das Clinicas, UNESP. Was performed goniometry of flexion / extension, abduction / adduction and internal rotation / side, measures performed before and three months after the therapy.

Results

Results: The chi square test with 0.005 significance level showed that quadrantectomy or mastectomy, not differentiated in relation to the variables; schooling, family income, color, marital status, religion, breast affected, clinical staging, menarche, body mass index and contraceptive methods. There was no association between type of surgery and the median age (type 1: 55 (37-57) x 2 type: 54 (37-82), p = 0.331 by Mann-Whitney).

Conclusion

Conclusion: After physiotherapy, the flexion of the homo- and contralateral arm, as well as the homolateral abduction and homolateral extension increased significantly in both surgeries. The contralateral abduction was maintained in both surgeries. The physiotherapeutic intervention provided a significant improvement in the range of movements.

CLINICAL AND DEMOGRAPHIC PROFILE OF PATIENTS DERIVED FROM THE PALLIATIVE CARE UNIT TO THE PILOT PROGRAM OF ONCOLOGICAL REHABILITATION. HOSPITAL DEL SALVADOR

P. Ritter¹, L.A. Lorca², A. Rebolledo³, R. Fernández⁴

¹Physiatrist, Hospital del Salvador, Santiago, Chile
²Physiotherapists, Hospital del Salvador, Santiago, Chile
³Nurse, Hospital del Salvador, Santiago, Chile
⁴chief doctor, Hospital del Salvador, Santiago, Chile

Introduction/Background

The referral to rehabilitation programs of oncological patients with advanced disease is a controversy. **Aim:** To describe the demographic and clinical profile of adult patients derived from a palliative care unit who are candidates for a cancer rehabilitation program.

Material and Method

Observational, descriptive and retrospective study. We included 34 patients diagnosed with Stage IV cancer who were referred by a physiatrist from the Palliative Care Unit to an oncological rehabilitation program, between May 2016 and November 2017. The demographic and clinical background were obtained from a database and the review of the clinical records of the palliative care unit. Data were analyzed with descriptive statistics. **Criteria for inclusion** were autonomaent patients, with the presence of fatigue, who needed analgesic pain management, without the use of powerful opioids.

Results

The average age was 60 years, 32.4% of them were men and 67.6% women. The diagnoses were: Multiple myeloma (20.6%), miscellaneous (47.4%) and digestive tract cancer (17.6%). The intensity of the pain evaluated with the visual analogue scale (VAS) was mild for 55.9%, moderate for 32.4% and severe for 11.7%, with characteristics of mixed in 50%. Performance status ECOG 1 (30 %) and ECOG 2 (70%).

Conclusion

A group of patients with advanced cancer who attended a palliative care unit who are fatigued, are independent and have a medical pain control, could obtain important benefits in their functionality and quality of life by being referred to an oncological rehabilitation.

Exercise intervention ameliorates exercise responses and body composition in patients with head and neck cancer receiving chemotherapy

K.L. Tsai
1Medicine, Department of Physical Therapy, Tainan, Taiwan R.O.C.

Introduction/Background

Studies have found that many chemotherapy drugs will produce multiple side effects and complications in cancer patients, especially in the case of the cardiovascular disease. This study was intended to investigate whether the exercise training intervention could improve the body composition and exercise responses of patients with head and neck (H&N) cancer who are receiving chemotherapy.

Material and Method

This is a randomized controlled trial. 84 H&N patients were assigned to sedentary group or exercise group. The data were collected pre-training and post-training, where the body composition, heart rate (HR), blood pressure (BP), rate-pressure product (RPP) and exercise capacity were measured.

Results

There was a significant difference found between the sedentary group’s body weight and body mass index after exercise training. In addition, in the exercise group, the HR, HR recovery, BP, BP recovery, RPP, and minutes walking distance was better than the sedentary group. Results from this study suggested exercise training significantly improved exercise responses and body composition.

Conclusion

These findings suggested that exercise can help to promote cardiopulmonary fitness and exercise capacity for H&N cancer patients undergoing chemotherapy.

EFFECTS OF PHYSICAL EXERCISE AFTER ALLOGENIC STEM CELL TRANSPLANTATION: A FIVE YEARS RETROSPECTIVE STUDY

C. Moriaud1, M. Michallet2, G. Salles3, M. Jacquet1, S. Jacquin-Courtois1
1Hospices Civils de Lyon, Neurological Rehabilitation, Saint-Genis-Laval, France
2Centre Léon Bérard, Haematology, Lyon, France
3Hospices Civils de Lyon, Haematology, Pierre-Bénite, France

Introduction/Background

In the last few years, the increase of the number of allogenic hematopoietic stem cell transplantation (HSCT) posed new issues in Physical Medicine and Rehabilitation. Many complications occur before, during and after conditioning and transplant, among others infectious and immunological complications, cytopenias, denutrition. These elements affect the back to a better quality of life, also, they slowdowns the rehabilitation.

Material and Method

We did a review of patient’s folder being cared in our department between 2012 and 2017 (n=65). We proposed individual and personalized program, with physiotherapy, adapted physical activity and psychomotricity. We observed the benefit on their physical abilities and the limits of intervention, to bring out the best way to evolve the personalized rehabilitation program in the years to come.

Results

At the beginning of the support, the performances were very weak because of the physical deconditioning, especially during Six minutes’ walk test and Sit to Stand Test. Length of stay was very varied, often because of some medical events. At the end of program, conducted one day per week to five day per week, scores were significantly improved, and opportunity to carry out daily life activities has been ameliorated.

Conclusion

We were able to highlight the need to perform two levels of management for these patients according to their physical abilities: level one for patients with major deconditioning, based on individual support with physiotherapy and psychomotricity; level two for patients with better physical ability and with less fatigue, based on collective activities, with adapted physical activity and psychomotricity. All patients should benefit from psychological and dietetic follow-up program. This global and functional approach aims at improving physical and psychological well-being as well as achievement of activities of daily living.

THE ASSOCIATION BETWEEN CARDIOPULMONARY FUNCTION AND MUSCLE MASS AFTER THORACOSCOPIC LOBECTOMY IN PATIENTS WITH LUNG CANCER: A PRELIMINARY RESULT

J.H. Park¹, L. Byeong Ju², L. Je-Sang², K. Boyeon¹, S. Myung-Jun², P. Hyuntae³
¹Dong-A University, Health Behaviors & Disease Prevention Research Group- Institute of Convergence Bio-Health, Busan, Republic of Korea
²Pusan National University Hospital, Department of Rehabilitation Medicine, Busan, Republic of Korea
³Dong-A University, Department of Health Care and Science, Busan, Republic of Korea

Introduction/Background

Few studies have investigated that related to cardiopulmonary function and body composition in patients with lung cancer. The purpose of this study was to determine whether muscle mass could be used to predict cardiopulmonary function after thoracoscopic lobectomy in patients with lung cancer.

Material and Method

A total fifteen lung cancer patients (aged 61.92±7.49 years, mean±SD; 5 female and 10 male) were selected in hospital. Dual-energy X-ray absorptiometry data were recorded using appendicular skeletal muscle mass (Lunar; GE Medical Systems, Madison, WI) at baseline and after 4 weeks. Patients performed an incremental exercise test to exhaustion on a treadmill to determine the maximal oxygen uptake (Cosmed, Quark CPET, Italy). The 6-minute walk test, handgrip strength and pulmonary function tests were performed before surgery, 1 and 4 weeks after surgery respectively.

Results

Patients in the lowest appendicular muscle mass were more likely to have significant maximal oxygen uptake decreasing in the lowest group. The higher appendicular muscle mass at baseline and 2 weeks after surgery correlated significantly with the preoperative FEV₁/FVC%. A significant association was observed between handgrip strength and 6-minute walk distance after surgery.

Conclusion

Our results expand the knowledge that high skeletal muscle mass and cardiopulmonary functions are associated with functional recovery after surgery on the lung cancer patients. Nevertheless, future studies should be aimed at testing the possible benefits produced by interventions on lung cancer. Higher level of 6-minute walk distance and appendicular muscle
mass may be able to be used to predict cardiopulmonary after thoracoscopic lobectomy in patients with lung cancer.

FUNCTIONAL ASSESSMENT AT ONCOLOGIC REHABILITATION SCENARIO; A COMPREHENSIVE APPROACH FOR KNOW FUNCTIONAL RISKS AND PREVENTION OF DISABILITY RELATED TO CANCER AND ITS TREATMENTS

A. Hernandez-Rivera1, M.M. Moreno-Capacho1

1Instituto Nacional De Cancerología, Bogota, Bogota, Colombia

Introduction/Background

Background

Cancer is a prevalent chronic non transmissible disease; whose risk increases with aging and in some cases with exposure to determinated risk factors. The Functional Assessment at Oncologic Rehabilitation Scenario, is an important issue at the comprehensive aproach, that is extrapolated from geriatric rehabilitation strategies. In wich seeks to know both the functional status of the performance components and the identification of the functional risks derived from the disease and the treatment. The objective is to guide rehabilitation strategies according to the needs, the functional capacity of the patient, their prognosis and stage of the life cycle, along oncological treatment.

Objective

To define a reference framework for the functional evaluation of oncological patients, Accord with their stage of life cycle and the definition of functional risk derived from personal status, oncological disease and their proposed oncologic treatment.

Material and Method

Methods

Criteria and guidelines had been developed from literature review and teamwork experience during the last years in a rehabilitation service of a national reference center for cancer in Colombia. As a result we are building rehabilitation interventions for patients across different stages of the disease (diagnosis, active treatment, palliative treatment, end of life), that have a correspondence with de moment in the cycle of life, the functional risks detected and their functional prognosis and living prognosis.

A RARE CASE OF DYSPHAGIA PATIENT AS A CONSEQUENCE OF PARANEOPLASTIC SYNDROME SUPERIMPOSED BY VASCULITIS
H. Koo¹, D. Sohn², Y. Jang¹, S.Y. Jun², G.Y. Park¹, S. Im¹
¹Bucheon- St. Mary’s Hospital, Department of Rehabilitation Medicine, Gyeonggi-do, Republic of Korea
²Seoul- St. Mary’s Hospital, Department of Rehabilitation Medicine, Seoul, Republic of Korea

Introduction/Background

Dysphagia can result from a variety of disorders such as neurodegenerative disorders, structural lesions and medication effects. Yet, there are cases of dysphagia of unknown origin which are rather rare and difficult to reveal the etiology. We report a unique case of debilitating dysphagia refractory to conventional dysphagia therapy who represented findings of both solid tumor and vasculitis.

Material and Method

A 81-year-old man, without any prior medical history of interest was admitted to dermatology department with a multiple erythema. He developed insidious aspiration pneumonia during admission. Laboratory studies showed leukocytosis and high tilter of rheumatoid factors. Additionally, results of nerve conduction study and needle electromyography were compatible with asymmetric sensory-motor polyneuropathy, clinically mononeuritis multiplex. Considering patient’s age, PSA titer were evaluated and showed markedly elevated. Patient was referred to our department for dysphagia. Videofluoroscopic swallowing study(VFSS) revealed penetration aspiration scale of 8 and functional oral intake scale(FOIS) of 1 (Figure 1).

Results
The patient received conventional dysphagia therapy which gave no such improvement. At the same time, multidisciplinary approach was undergone. The patient received steroid therapy as diagnostic purpose of vasculitis, which dramatically improved patient's FOIS of 3. To exclude underlying malignancy related to elevated PSA titer, we performed prostate magnetic resonance imaging (MRI) study and prostate biopsy. MRI(Figure 2) and biopsy confirmed adenocarcinoma, gleason's score 7. Hormonal therapy was started, which even further improved patients dysphagia thereby allowing patient to remove nasal tube and start oral feeding. (Figure 3)

**Conclusion**

Dysphagia combined with vasculitis could be presenting manifestations of paraneoplastic syndrome. In such cases, evaluations for hidden malignancy are warranted.

**Keywords**

paraneoplastic syndrome;vasculitis;dysphagia

⁷National University Hospital, Department of Nursing, Singapore, Singapore
⁸National University Hospital, Division of Neurology- Department of Medicine, Singapore, Singapore

Introduction/Background

Breast cancer and its treatment causes issues such as fatigue, stress, depression, pain, lymphedema and peripheral neuropathy, sequelaes that are closely related to physical decline and decreased quality of life (QoL). Consequently, there is an increased need among women with breast cancer for supportive care to manage the cancer –related sequelaes and improve the QoL. However, studies suggested that the need for supportive care is often unmet due to underutilization as well as the lack of comprehensive rehabilitation programs.

Material and Method

This is a non-randomized controlled trial to explore the feasibility and efficacy of a comprehensive rehabilitation programme in improving the physical function and quality of life of breast cancer patients during active cancer treatment. Participants in the intervention group underwent twice weekly supervised exercise classes and weekly patient education session on topics such as side effects management, social-psychological factors and diet over a period of 12 weeks. The control group on the other hand, did home-based exercises for 12 weeks. Thereafter, participants from both groups attended a transitional class targeted at reintegrating them into work and society.

Results

As the study is still ongoing, results will be updated. However, preliminary results showed that the intervention group (n= 10) had statistically significant improvement in pain levels (p= 0.011), loss of appetite (p = 0.03) compared to the control group (n= 5). In addition, both the
intervention group ($p= 0.012$) and control group ($p= 0.035$) demonstrated improvement in the engagement of instrumental activities of daily living.

**Conclusion**

Early rehabilitation for breast cancer patients during active cancer treatment is helpful in reducing pain, loss of appetite and the engagement of instrumental activities of daily living.

ASSESSMENT OF SECONDARY LIMB LYMPHEDEMA AFTER CANCER SURGERY WITH ELECTRICAL IMPEDANCE MYOGRAPHY AND ULTRASONOGRAPHY: CASE REPORTS OF PRE-AND-POST COMPLEX DECONGESTIVE THERAPY (CDT)
L. Li¹, X. Li¹, S. Chen¹, Q. Yu¹, D. Huang¹
¹First Affiliated Hospital- SYSU, Rehabilitation Medicine, Guangzhou, China

Introduction/Background

The aim of this study was to evaluate whether Electrical impedance myography (EIM) is a useful method to assess the efficacy of complex decongestive therapy (CDT) in secondary lymphedema of cancer surgery. EIM is a kind of bioimpedance measurement targeting on muscle health condition. The commonly used EIM parameters include resistance (R), reactance (X) and phase angle (θ). Super sonic shear wave elastography (SWE) was also applied to assess the tissue stiffness and to validate the EIM results.

Material and Method

A 57-year-old lady(patient A) who developed upper limb lymphedema after operation and radiotherapy for the cancer of her right breast and a 71-year-old lady(patient B) developed lower limb lymphedema after endometrial carcinoma surgery. The patients accepted 20 times of CDT, included manual lymphatic drainage (MLD), short stretch bandaging, exercise, pressure therapy and skin care, about 1 hour per day and lasts 4 weeks. Before and after the treatment, EIM and ultrasonographic evaluations (skin and subcutaneous tissue’ thickness and modulus of elasticity) were performed at biceps brachii in the upper limb and rectus femoris in the lower limb at both sides.

Results

The EIM result showed that increase of R value(A=69%;B=30%) and reactance(X) value(A=70%;B=58%) appeared in both the affected side, when R and X value is slightly decreased or increase in unaffected side. In patient A, subcutaneous tissue’ modulus of elasticity in affected arm is reduced from 25.1kPa to 21.7kPa, while the unaffected side is 16.0kPa. In patient B, skin tissue’ modulus of elasticity decreased too.

Conclusion

The results suggested that EIM has the potential to be a noninvasive tool to assess the tissue condition in patient with secondary lymphedema. Change in R value of the affected lymphedema limb may be related to the subcutaneous tissue’s structural and componential modifications caused by the decrease of protein-rich extracellular fluid and the rearrangement of fat.

"THE EFFECT OF EARLY INTERVENTION OF MANUAL LYMPHATIC DRAINAGE AND REHABILITATION EXERCISE IN MORBIDITY AND LYMPHEDEMA IN ADVANCED ORAL CANCER PATIENTS AFTER SURGERY"

1Changhua Christian Hospital, Department of Physical Medicine and Rehabilitation-, Changhua, Taiwan R.O.C.
2Changhua Christian Hospital, Department of Oral and Maxillofacial Surgery, Changhua, Taiwan R.O.C.
3Changhua Christian Hospital, Division of Physical Therapy- Department of Physical Medicine and Rehabilitation-, Changhua, Taiwan R.O.C.

Introduction/Background

The morbidities of lymphedema and post-radiation fibrosis syndrome are frequently noted in the head-neck cancer patients receiving radiation and surgery. The complete decongestive physiotherapy (CDP) is the main stream conservative therapy for lymphedema. The manual lymphatic drainage (MLD) is one of the major component of CDP. The aim of this study is focused on the effect of early intervention rehabilitation exercise and MLD in Pain, trismus, ROM and lymphedema in advanced oral cancer patients after surgery.

Material and Method

32 advanced oral cancer patients who received surgery in the department of oral and maxillofacial surgery, Changhua Christian Hospital between Oct, 2014 and Sep, 2016 were enrolled. The patients were randomized to 2 groups, each group included 16 patients. One group patients received rehabilitation exercise alone (neck-shoulder stretch exercise and posture training), and the other group patients received MLD and rehabilitation exercise. Every patient received the evaluations including cervical and shoulder range of motion, shoulder constant score, pain scale, sonographic and lymphedema score, face distance score for lymphedema when patient before surgery, before and after intervention.

Results

The mean age was 55 years old and BMI was 24.8. Pain scale, neck and shoulder ROM, shoulder constant score, lymphedema scale, face distance score showed significant difference before and after intervention, but no difference between groups. The pain scale and neck left side-bending improved more in MLD and exercise group.

Conclusion
The pain scale, trismus, ROM and lymphedema were improved after early intervention rehabilitation exercise. The early intervention of MLD in addition to rehabilitation exercise might have more improvement in pain and neck ROM after surgery.

MULTI-STAKEHOLDER ATTITUDES REGARDING RISK-BASED THRESHOLDS FOR INITIATING IMPAIRMENT-DIRECTED INTERVENTIONS AMONG PATIENTS WITH BREAST CANCER

A. Cheville¹, J. Basford¹

¹Mayo Clinic, Physical Medicine and Rehabilitation, Rochester, USA

Introduction/Background

Physical impairments are prevalent following breast cancer (BC) treatment and associated with poor outcomes. Predictive models permit estimation of impairment risk, and can be the basis for directing screening and validated risk reduction measures. At present few BC survivors receive anticipatory treatment for their impairments. The objective of this study was to characterize diverse clinical stakeholders’ risk thresholds for initiating BC impairment-directed education, screening, preventive activities, and specialist referrals.

Material and Method

A purposive sample of 40 breast cancer survivors, as well as 10 Breast Clinic physicians, 10 breast surgeons, 10 radiation oncologists, 10 medical oncologists, 10 Breast Clinic nurses, and 10 cancer rehabilitation therapists from academic and community settings were queried about their thresholds for initiating "More frequent and sensitive screening," "Education," "Instruction in preventive activities," and "Referral to a physical or occupational therapist." Participants indicated on numerical rating scales the risk level (0-1.0) at which they would start activities for lymphedema, upper quadrant pain, functionally limiting chemotherapy-induced peripheral neuropathy, shoulder contracture, and fatigue.

Results

Across impairments, mean risk thresholds were consistently ordered as follows: education (.07-.12), prevention (.14-.25), screening (.25-.31), and therapist referral (.37-.45). BC Survivors had the lowest thresholds for initiating education; lymphedema .02, pain .04, neuropathy .02, contracture .03, and fatigue .03, while therapists had the lowest thresholds for screening and referrals. Among physicians, risk thresholds varied widely across impairments, interventions, and disciplines, however breast surgeons had significantly higher thresholds for screening, prevention, and therapist referral, p<0.03.

Conclusion

Risk thresholds for initiating BC impairment-directed activities are inconsistent across stakeholder groups. BC survivors, however, had the lowest thresholds for initiating impairment-directed education.

THE EFFECTIVENESS OF BOTULINUM TOXIN A FOR PERSISTENT PAIN AT THE PECTORAL REGION AFTER BREAST CANCER TREATMENT: RANDOMIZED CONTROLLED TRIAL

1KU Leuven, Rehabilitation Sciences, Leuven, Belgium
2University Hospitals Leuven, Department of Physical Medicine and Rehabilitation, Leuven, Belgium
3University Hospitals Leuven, Department of Development and Regeneration, Leuven, Belgium

Introduction/Background

Upper limb pain after breast cancer treatment is a common and difficult to treat problem. The aim of the present study was to investigate the effect of a single Botulinum Toxin A infiltration in the pectoralis major muscle in addition to a standard physical therapy program for treatment of persistent upper limb pain in breast cancer survivors.

Material and Method

Fifty breast cancer patients with pain participated in a double-blinded randomized controlled trial. The intervention group received a single Botulinum Toxin A (BTX-A) infiltration. The control group received a placebo (saline) infiltration. Within one week after the infiltration, all patients attended an individual physical therapy program (12 sessions) during the first 3 months and a home exercise program up to 6 months after infiltration. The primary outcome was change in pain intensity at the upper limb (Visual Analogue Scale (VAS) (0-100)) after 3 months. Secondary outcomes were prevalence rate of pain, pressure hypersensitivity, pain quality, shoulder function and quality of life. Measures were taken before the intervention and at 1, 3 and 6 months follow-up.

Results

No significant difference in change in pain intensity after 3 months was found (mean difference in change of 3/100; 95% CI -13 to 19). From baseline up to 6 months, a significantly different change in upper limb pain intensity was found between groups in favor of the intervention group (mean difference in change of 16/100; 95% CI 1 to 31).

Conclusion

A single Botulinum Toxin A infiltration in combination with an individual physical therapy program has been found to significantly decrease pain intensity at the upper limb in breast cancer survivors up to 6 months. However, the effect size was not clinically relevant and no other beneficial effects were found.

REHABILITATION IN THE EARLY POSTOPERATIVE PERIOD IN PATIENTS WITH MALIGNANT NEOPLASMS OF THE ABDOMINAL CAVITY

N. Saltynskaya¹

¹Physiotherapist, Moscow, Russia

Introduction/Background

For cancer patients physical therapy methods are not pathognomonic; they are used for surgical patients to reduce pain, prevent stagnation and motor-evacuation disorders, or to improve reparative processes. We would like to share with you our rehabilitation programs in the early recovery period of cancer patients after surgical interventions in the abdominal cavity.

The purpose of our work: analysis of our rehabilitation programs in the early postoperative period in patients with malignant neoplasms (according to the concept of ERAS). Impact of rehabilitation programmes on the number of complications according to the Dindo-Clavien classification. Impact of the application of rehabilitation programs on the length of stay of patients in the hospital.

Material and Method

Materials and methods: Subjects (main group, n= 58), aged from 36 up to 84 years, who were diagnosed intestinal cancer. In complex therapy we used methods of physical therapy (breathing exercises, general health-improving exercises, early verticalization, chest massage). We also used physical therapy methods (inhalation, stimulation of magnetic pulses). We used special equipment. "Neb-aid by Flame", "AMIT-01", "Hivamat-2000". The control group consisted of 60 patients aged from 35 up to 83 years who did not receive rehabilitation.

Results

The results of the study: We found that the improvement of motor-evacuation of bowel function in patients who received pulsed magnetic therapy, was achieved in 3 days compared to the control group. The reduction in the number of complications in the main group was 25.1 against 52 in the control group. The duration of hospital stay was 15 days in the main group compared to 21.6 days in the control group.

Conclusion

Conclusion: early rehabilitation of patients after surgical removal of malignant neoplasms can help to increase motor evacuation function and reduce both the number of postoperative complications and the length of hospital stay.

INCIDENCE AND RISK OF FALLS AMONG ADULT PATIENTS TREATED FOR HEMATOLOGICAL NEOPLASMS DURING HOSPITALIZATION IN AN INTENSIVE HEMATOLOGY UNIT
L.A. Lorca Parraguez¹, C. Sacomori², P. Benavente³, B. Puga⁴, F. Quiroz⁴, L. Ortega⁴
¹Hospital del Salvador, Medicina Física y Rehabilitacion, Santiago, Chile
²Universidad Bernardo O’Higgins, Escuela de Kinesiologia, Santiago, Chile
³Hospital del Salvador, Kinesiologia, Santiago, Chile
⁴Hospital del Salvador, Unidad de Hematologia Intensiva, Santiago, Chile

Introduction/Background

Patient falls are still the most common adverse event reported during hospitalization. Patients hospitalized for cancer treatment have higher rates of falls in relation to those hospitalized for another diagnosis. In patients treated for hematological malignancies, falls during periods of hospitalization can be related to multiple factors. **Aim:** To determine the incidence and risk of falls in adult patients treated for hematological malignancies during hospitalization in the intensive hematology unit of the Hospital del Salvador, Chile, between January 2016 and June 2017.

Material and Method

Observational study with retrospective and longitudinal design that included 101 patients with hematological cancers. Information was collected retrospectively from reports of adverse events, clinical records and the daily record of risk assessments of falls according Hendrich II model for predicting falls among hospitalized patients. The unit routinely applies strategies for falls prevention.

Results

The average age was 35.6 (SD = 13.6) years, 64.7% men and 34.3% women. Two events of falls were reported in 101 patients, with an incidence rate of 1.98%. Using the cutoff point of 5 of the Hendrich II model, that corresponds to the instrument used in the unit to assess the risk of falls, it was identified that 30 patients (29.7%) had risk of falling at hospital admission, 41 patients (40, 6%) in half of their hospitalization and 38 patients (37.6%) at hospital discharge.

Conclusion

People treated for hematological malignancies present a low incidence and a high risk of
falls during hospitalization. A fall prevention program with an interdisciplinary approach is suggested.

EFFECTS OF REHABILITATION IN MALE PATIENTS AFTER THORACOTOMY DUE TO LUNG CANCER

N. Mujovic¹, L. Nikcevic², S. Tomanovic Vujadinovic³, S. Rajevic³, A. Milovanovic⁴

¹University of Belgrade Faculty of Medicine, pulmonary rehabilitation, Belgrade, Serbia
²Clinik for cerebrovascular insult “Sveti Sava”, physical medicine and rehabilitation, Belgrade, Serbia
³Clinic of physical medicine and rehabilitation, physical medicine and rehabilitation, Belgrade, Serbia
⁴University of Belgrade Faculty of Medicine, physical medicine and rehabilitation, Belgrade, Serbia

Introduction/Background

The aim of the study was to investigate the effect of preoperative rehabilitation program in patients with lung cancer who are preparing for surgery.

Material and Method

A group of 40 men with mean age of 61 years, who had proven lung cancer and are intended for lung resection. As part of the preoperative preparation was carried out in all patients, respiratory rehabilitation and physical training on the bike and treadmill for a period of 11 days. 6-minute walk test in these patients was measured in three time periods: at the beginning of rehabilitation, then immediately prior to surgery and one month after surgery. In addition to the distance traveled in meters, we measured O2 Sat%, degree of dyspnea using the modified Borg scale, as well as cardiac and respiratory frequency.

Results

The results showed that there was a statistically significant improvement in distance traveled on 6mwt after performing rehabilitation, but also to decrease the distance 6mwt after lung resection, as well as to increase Sat% O2. All other parameters showed a significant reduction.

Conclusion

For the success of pulmonary rehabilitation, but also to determine the training, we use as a measure of value 6MTH and parameters that tell us about the degree of dyspnea that is a true indicator of improvement or deterioration in patients.

INVESTIGATION OF THE INCIDENCE OF UPPER LIMB LYMPHEDEMA AFTER BREAST CANCER IN CHINA

J. Jia¹,², N. Xie¹, X. Ruan¹, L. Li², L. Jiang²

¹Huashan Hospital- Fudan University, Rehabilitation Medicine, Shanghai, China
²Shanghai jing ’an district central hospital, Rehabilitation medicine, Shanghai, China

Introduction/Background

To investigate the incidence of upper limb lymphedema after operation in Chinese women with breast cancer and to analyze the related risk factors.

Material and Method

268 female patients who were diagnosed as breast cancer and received radical mastectomy in the department of general surgery of our hospital from January 2012 to January 2017 were randomly selected. The methods of questionnaire, examination, and arm circumference were used to screen the lymphedema. And SPSS software Logistic regression analysis of related risk factors.

Results

The incidence of lymphedema in upper extremity was 35%. 83.7% of the patients with lymphedema began from 3 months to 2 years after the operation. 73.5% of the patients have obvious inducements before the onset of the disease. There are many causes of lymphedema, including upper limb infection, weight bearing, continuous force and so on. Different inducement causes different swelling part. The swelling of radiotherapy, chemotherapy, bacterial infection, and no-obvious inducement begins from the upper arm, and after a sudden move heavy objects, like hand weeding weight plurality swelling starts from the hand. The percussion keyboard, weight-bearing yoga and other chronic sustained forearm force and herpes zoster virus infection more swelling from the forearm began. The maximum arm circumference difference between the affected side and the healthy side of the upper extremities was below 10cm, and 2~3cm occupied 75.5%. Only 6.1% of the swollen patients had the maximum arm circumference difference of 10cm.

Conclusion

There are many incentives for the occurrence of upper extremity lymphedema, and there are many risk factors. Patients with risk factors should be highly regarded. Attention should be paid to avoid inducements and do timely rehabilitation treatment, so as to prevent and reduce the occurrence of upper limb lymphedema.

Results
32 years ago, the patients underwent radical mastectomy and local radiotherapy for left breast cancer. In October 2014, the left shoulder was discomfort, and the left upper limb was weak with hand numbness, the left eye fissure narrowed, and the left half of the face was less sweaty. And gradually aggravate the appearance of swelling and ankylosis in the left hand, with sharp knife cut and needle like pain. After the onset of the disease, he had visited many hospitals. He underwent cervical MRI, electromyography and B-mode ultrasound. He had been diagnosed as "cervical spondylosis" and "radiation brachial plexus injury". He had been rehabilitative and had no improvement. He could only control pain by tramadol. In June 2016, in our hospital, the comprehensive examination was still considered as "radioactive brachial plexus nerve injury" and was discharged from the hospital after nutritional nerve and rehabilitation treatment. In December, the family members told them that he had died in October. The cause of death was "pulmonary embolism and respiratory failure".

**Conclusion**

In the case of limited movement of upper limb with severe pain after breast cancer surgery, it is necessary to be vigilant and identify tumor metastasis.

ASSOCIATION BETWEEN PREOPERATIVE SLEEP DISTURBANCE AND LOW MUSCLE MASS IN PATIENTS WITH GASTROINTESTINAL CANCER

M. Okumura¹, R. Ono¹, T. Saito², A. Fukuta¹, D. Makiura², J. Inoue², Y. Sakai³
¹Kobe University Graduate School of Health Sciences, Department of Community Health Sciences, Kobe, Japan
²Kobe University Hospital, Division of Rehabilitation, Kobe, Japan
³Kobe University Graduate School of Medicine, Division of Rehabilitation Medicine, Kobe, Japan

Introduction/Background

Sleep disturbance has received little attention from the oncology community. It is necessary to examine the relationship between sleep disturbance and low muscle mass, which affects prognosis. However, such associations have been unclear in patients with cancer. The aim of the present study was to investigate the relationship between preoperative sleep disturbance and low muscle mass in patients with gastrointestinal cancer.

Material and Method

A cross-sectional survey of 86 patients with gastrointestinal cancer who were scheduled for curative surgery was conducted. Low preoperative muscle mass was indicated by a skeletal muscle mass index of <7.0 and <5.7 kg/m² for men and women, respectively, according to the criteria of the Asian Working Group for Sarcopenia. Sleep disturbance was assessed using the Japanese version of the Pittsburgh Sleep Quality Index (PSQI) through to the following subscales: Time in bed, Time asleep, Sleep quality, Sleep efficiency, and Consumption of sleep-inducing drugs. Multiple logistic regression analyses were performed to determine the association between sleep disturbance and muscle mass. Independent variables included sleep factors univariately associated with the outcome (p < 0.05). Covariate factors univariately associated with the outcome (p < 0.05) were extracted as candidate confounding variables to be used during multivariate analysis.

Results

The mean age (and standard deviation) of the patients was 70.5 ± 7.08 years old, the majority of whom were men (84%) and had colorectal (40%) and gastric (38%) cancers. A total of 27 patients (31%) were identified as having low muscle mass. Multiple logistic regression analysis adjusted for C-reactive protein and Geriatric Depression Scale revealed that bad sleep quality assessed using PSQI subscales was significantly associated with low muscle mass (odds ratio, 4.15; 95% confidence interval, 1.02–16.9).

Conclusion

...
The present study suggests that bad preoperative sleep quality was associated with low muscle mass in patients with gastrointestinal cancer.

PHYSIOTHERAPY IN THE MANAGEMENT OF PATIENTS WITH PERITONEAL CARCINOMATOSIS RECEIVING CYTOREDUCTIVE SURGERY.

L. Josse¹, J. Weyrech¹, M.H. Houzé¹, R. Habrias¹, G.R. Perez Torres¹, S. Saez Lopez¹, A. Foudhaili¹, A. Yelnik², M. Pocard³

¹Hôpital Lariboisière- APHP, C2R de Rééducation, Paris, France
²Hôpital Fernand Widal - AP-HP, Service de Médecine physique et de réadaptation, Paris, France
³Hôpital Lariboisière. AP-HP, Service de chirurgie digestive, Paris, France

Introduction/Background

The development of multidisciplinary work around patients receiving cytoreductive surgery with hyperthermic intraperitoneal chemotherapy (HIPEC) with thoracic epidural analgesia led us to articulate our reciprocal skills in a care program. Since 2012, a preoperative consultation of physiotherapy has been set up for these patients. Between 2009 and 2013, 124 patient’s files have been analysed, comparing "Patient Controlled Epidural Analgesia (PCEA) with physiotherapy" (67 patients) and "PCEA without physiotherapy" (57 patients). The reduction of the patient’s apprehension of physiotherapy and mobilization contributed to the reduction of the length of stay in intensive care unit (on average 5 days instead of 7) and an early out of bed mobilization (one day gained).

Material and Method

After 4 years of operation, we conducted a retrospective study of patient’s files in order to evaluate the efficiency of this first step programme about the role of physiotherapy in this patient's care pathway. We estimated the length of stay and the way to go back home.

Results

366 files had been analysed. Patient’ pathway had been systematically organized including this physiotherapy consultation during the month before surgery. The content of the consultation has been adapted including 3 parts leading to a real therapeutic educational program.

Information on the physiotherapy that will begin the day after the surgery: respiratory mechanics, interest of early mobilization to warn the post-operative complications.

Education of the patient with teaching of techniques of respiratory physiotherapy.

A notebook containing advice for improving the physical condition is given to the patient by adjusting the dosage and the intensity according to his basic state.
Conclusion

Physiotherapy included in preoperative management is part of improving the quality of care provided to patients, allowing them a better participation in the postoperative care. This preoperative consultation had been adapted to better support the patient and his family.

PREOPERATIVE PREVALENCE OF MULTIDIMENSIONAL FRAILTY AND THE ASSOCIATIONS WITH HEALTH-RELATED QUALITY OF LIFE IN ELDERLY CANCER PATIENTS

R. Ono¹, A. Fukuta¹, M. Okumura¹, D. Makiura², T. Saito², J. Inoue², Y. Sakai³
¹Kobe University Graduate School of Health Sciences, Department of Community Health Sciences, Kobe, Japan
²Kobe University Hospital, Division of Rehabilitation, Kobe, Japan
³Kobe University Graduate School of Medicine, Division of Rehabilitation Medicine, Kobe, Japan

Introduction/Background

The frailty has been based on only physical in the previous studies, and neither cognitive and social frailty are clear in elderly cancer patients. The aims of this study are to estimate the preoperative prevalence of physical frailty, cognitive frailty, and social frailty and to determine the cross-sectional associations with health-related quality of life (HRQOL) in elderly cancer patients.

Material and Method

We examined 190 cancer patients (≥60 years; mean age: 71.9 ± 7.0 years; 43 females) with esophageal, gastric, colorectal, oral, or pharyngeal cancers, who were scheduled to undergo the radical surgery. Physical frailty was defined as ≥ 3 out of the following criteria: slow walking speed, muscle weakness, exhaustion, low physical activity and weight loss. We used the validated tool assessed for cognitive impairments, which includes tests of word list memory, attention, and executive function, and processing speed to screen for cognitive impairments. Cognitive frailty was defined by the presences of ≥ 2 cognitive impairments and physical frailty. Social frailty was defined by ≥ 2 signs (going out less frequently, rarely visiting friends, feeling unhelpful to friends or family, living alone, and not talking with someone every day). HRQOL was measured using the EORTC QLQ-C30. The prevalence of each frailty was presented using a multiple imputation method. Associations between multidimensional frailty and the EORTC QLQ-C30 subscales were studied using multivariable regression analyses among complete cases.

Results

The prevalence of physical frailty, cognitive frailty, and social frailty were 32.9%, 4.7%, and 50.8%, respectively. Only social frailty was associated with the worse EORTC QLQ-C30 subscales (global QOL, physical functioning, role functioning, emotional functioning, cognitive functioning, fatigue and insomnia) after adjusting for covariates.

Conclusion
Our results showed that the prevalence of frailty in elderly cancer patients were much more than that in population based elderly, and preoperative HRQOL was especially affected by social frailty.

SEXUAL FUNCTION ASSESSMENT IN WOMEN WITH TYPE 2 DIABETES

S. zahi

1CHU Ibn Rochd, physical medicine and rehabilitation department, casablanca, Morocco

Introduction/Background

Less visible and more insidious than those of male subjects, the sexual dysfunctions of diabetic women have been studied, particularly in the Maghreb socio-cultural context. The objectives of this work are to compare the dimensions of the different dimensions of sexual function of women with type 2 diabetes to those of control women and to determine the factors associated with sexual dysfunction in women with diabetes.

Material and Method

This is a descriptive and analytical case-control study of 50 patients with type 2 diabetes. They were compared to 50 age-matched control women. The evaluation focused on socio-demographic characteristics, diabetes data, and standardized measurement of female sexuality using the female sexual function index (FSFI).

Results

The diabetic women recruited have an average age of 47.82 years. The evaluation by the FSFI found a sexual dysfunction in 84% of the cases. The comparative study found that women with diabetes were significantly less satisfied in their sexual life, in all areas of FSFI, and had significantly more sexual dysfunction than female controls (p = 0.038). The total FSFI score was negatively correlated with age (p <10^-3, r = -0.763) and age of diabetes (p = 0.002, r = -0.431). Diabetic women with more advanced sexual dysfunction (p <10^-3) and longer duration of disease (p = 0.017) than women with diabetes do not have sexual dysfunction.

Conclusion

Our results have allowed us to highlight, in a standardized and comparative way, the importance of sexual dysfunction in diabetic women. Taking this aspect into account in the evaluation improves the quality of life and well-being of these women.

EFFECT OF DIABETES ON POSTOPERATIVE AMBULATION FOLLOWING BELOW KNEE AMPUTATION
A. Saraf1
1Teerthanker Mahaveer University, orthopedics, moradabad, India

Introduction/Background

Ambulation forms an important part of rehabilitation program after lower limb amputations. Diabetes Mellitus and its complications are commonly associated with below knee amputation. Inspite of this, there is an absence of studies on the effect of diabetes on the post operative ambulation of an amputee. This study analysed the role of diabetes as an independent factor affecting post operative ambulation and compared it with non diabetics in below knee amputation.

Material and Method

In this study a total of 105 below knee amputation patients were followed. Out of them, 48 amputees were diabetics and 57 non diabetic. Their post operative ambulatory level was compared by using Pinzur et al ambulation scale. Both groups were age, sex and BMI matched.

Pinzur et al scale
Results

There was a worsening of ambulatory level in 33.3% diabetics as compared to 10.7% in non diabetics postoperatively. Of the prosthetic users, 78.4% were in non diabetic group and 21.6% were in diabetic group. 17.6% of prosthetic users required additional support, of whom 66.7% were diabetics.

Conclusion

Diabetes Mellitus is an independent factor which has an adverse effect on the functional outcome of a patient after below knee amputation.

ISPR8-2685
EFFECTS OF WHOLE BODY VIBRATION EXERCISE ON THE GAIT TIME OF INDIVIDUALS WITH METABOLIC SYNDROME: A PSEUDO RANDOMIZED CONTROLLED CLINICAL STUDY.
D. Sá Caputo¹, L. Paineiras-Domingos², R. Cordeiro², R. Taiar³, M. Bernardo-Filho²

¹Laboratório de Vibrações Mecânicas e Práticas Integrativas - Departamento de Biofísica e Biométria - Instituto de Biologia Roberto Alcântara Gomes - Universidade do Estado do Rio de Janeiro - Brazil,
²Universidade do Estado do Rio de Janeiro, Brazil
³University of Reims Champagne-Ardenne, GRESPI - Research Group in Engineering Sciences, Reims, France

Introduction/Background

Background and aim: Individuals with metabolic syndrome (MetS) might present low muscle performance resulting in a decrease of the functional capacity interfering in the gait time. Whole body vibration exercise (WBVe) has been considered in the management of MetS individuals promoting a better functional performance. The aim of this study was to evaluate the effects of WBVe on the gait time of the MetS individuals.

Material and Method

Methods: CAAE 19826413.8.0000.5259. UTN: U1111-1181-1177; Brazilian Registry of Clinical Trials- ReBEC RBR – 2bgmh. A pseudo randomized controlled trial study with thirty-nine individuals with MetS (according International Diabetes Federation) was performed. The side-to-side alternating oscillating/vibratory platform was used. The individuals were allocated in WBVe group (WBVeG = 22) and in control group (CG =17). The WBVeG was in squat static position for 1 minute of intervention and 1 minute of rest in 3 different peak-to-peak displacements (2.5, 5.0 and 7.5 mm) 3 times. In the first session was used 5 Hz and increasing 1 Hz in each session up to 14 Hz in the tenth session. In the CG was used the same position and time but the platform was turned off. Before the first and after the tenth session were collected the data about the gait time of 3 meters (in seconds). The statistical analysis was performed using the Graph Pad Prism 5.01 Program (p≤0.05).

Results

Results: The gait time (Mean±SD) showed a significant difference intergroups.

Conclusion
**Conclusion:** WBVe is a modality of physical activity that can improve the functional capacity of the MetS individuals, at least, considering the time of the gait.

³Universidade do Estado do Rio de Janeiro, Laboratório de Vibrações Mecânicas e Práticas Integrativas- Departamento de Biofísica e Biomateria, Rio de Janeiro- Rio de Janeiro- Brasil, Brazil

⁴University of Reims Champagne-Ardenne, GRESPI- Research Group in Engineering Sciences, Reims, Brazil

**Introduction/Background**

**Background and aim:** The hypertension is a condition that can be present in individuals with metabolic syndrome (MetS), increasing the cardiovascular risks of these individuals. A limited numbers of studies has investigated the effect of whole body vibration (WBV) exercise on blood pressure, particularly in individuals with MetS. The purpose of this study was to examine the impact of WBV exercise on systolic, diastolic e mean blood pressure (SBP, DBP and MBP, respectively) and heart rate (HR) in MetS individuals.

**Material and Method**

**Methods:** Eighteen individuals both sexes (61.1±8.3 years; 83.6±16.2kg; 31.1±5.3kg/m²; 103.0±11.0 cm of waist circumference) with MetS (according International Diabetes Federation) were evaluated and the data before the first and after 48 hours of the ninth session was analyzed. These parameters (SBP, DPB, MBP and HR) were collected 3 times and the mean were considered. The side-to-side alternating oscillating/vibratory platform was used. The parameters used were 5 to 14 Hz (frequency), 2.5, 5 and 7.5 mm (peak-to-peak displacement), 1 minute of work time and 1 minute of rest. This protocol was performed in squat static position per 5 weeks, twice a week. *(CAAE 19826413.8.0000.5259 and ReBEC RBR-2bgmh)*. Paired Student t-tests were applied to compare baseline vs. post-training. The GraphPad Prism 5.01 was used and *P*≤0.05 was adopted for statistical significance.

**Results**

**Results:** Significant reductions in baseline (before first session) vs. post-WBV exercise (before nine session) were detected for SBP (130.2±15.9 vs. 112.9±11.6; *P*=0.013) and MAP
(109.8±13.0 vs. 103.8±9.4; $P=0.014$), but not DPB (69.0±10.7 vs. 65.6±7.6; $P=0.073$) and HR 70.9±15.5 vs. 71.2±13.0; $P=0.589$).

**Conclusion**

**Conclusion**: The reduction of the blood pressure is important in management of MetS individuals and would interfere positively in the reduction of cardiovascular risk. Thus, the use of WBV exercise could be a convenient intervention in MetS individuals due the low cost, feasible and easy application.

AN INTERNATIONAL REHABILITATION PERSPECTIVE ON DISABLING OBESITY

P. Capodaglio

Istituto Auxologico Italiano - IRCCS, Rehabilitation, Verbania, Italy

Introduction/Background

Obesity is a clinical condition characterised by significant clinical implications, such as co-morbidities and somatic fragility, which seriously affect independence, psychological well being and overall quality of life. The most frequent approach to obesity is based on a nutritional perspective but, given the figures of obesity worldwide, there is a need to develop a proper rehabilitative approach originating from the functional limitation, disability and clinical needs of obese patients.

Material and Method

The lecture will first provide an up-to-date vision on the aetiology (environment, genetics) and epidemiology of obesity and then a current vision on obesity from a rehabilitative perspective based on the recently published Position Paper of the ESPRM. Cutting-edge research on the physiological determinants of functional limitation in obesity will be presented and the biomechanics of basic activities in obesity will be described.

Results

Disability associated with obesity may be predominantly due to a combination of motor or cardio-respiratory complications according to the coexistence of a range of related conditions (i.e. osteoarthritis, cardio-respiratory disorders, etc.).

Conclusion

The lecture will also discuss feasible care models for disabling obesity, illustrating current protocols in musculoskeletal, cardio-respiratory and psychological rehabilitation and reviewing the existent evidence on effective rehabilitation treatments.

EFFECT OF REBOUND EXERCISES AND CIRCUIT TRAINING ON MUSCULOSKELETAL PAIN, HEMATOLOGICAL AND PSYCHOSOCIAL VARIABLE IN PATIENTS WITH TYPE 2 DIABETES: A RANDOMIZED CONTROL TRIAL PROTOCOL

B. Kaka¹, S.S. Maharaj¹
¹University of KwaZulu-Natal, Physiotherapy, Durban- KwaZulu-Natal, South Africa

Introduction/Background

The incidence of type 2 diabetes mellitus (DM), a chronic lifestyle disease, and its complications are on the increase. However, there is no consensus regarding the types of exercise that reduce musculoskeletal pain (MSKP) and depression and improve quality of life (QoL) as well as respiratory function among individuals with type 2 diabetes. The objective of this study are to determine the effects of rebound and circuit training on MSKP, blood glucose level, cholesterol level, QoL, depression and respiratory parameters in patients with type 2 DM.

Material and Method

Seventy participants are expected to be recruited in this single blind randomized control trial. Computer-generated random numbers will be used to randomize the participants into 3 groups, namely the rebound exercise group, the circuit exercise group, and the control group. Measurements will be taken at baseline and at the end of the 8 weeks of the study. Data will be analyzed using descriptive statistics and inferential statistics of multivariate analysis of variance (MANOVA) between the groups and paired t-test within the group. Alpha will be set at 0.05.

Results

The results of this study will identify the effectiveness of rebound exercise and circuit training, compared to the control, in the management of type 2 DM and on QoL, MSKP, depression, glycemic control, cholesterol level as well as improvement in respiratory function.

Conclusion

No strategies have been identified for the control of complications associated with diabetes such as MSKP, depression and reduction in QoL.

ELEKTROACUPUNCTURE FOR WEIGHT LOSS- A NARRATIVE LITERATURE REVIEW

J. Kühnemund¹, U. Smolenski¹, B. Bocker¹

¹University hospital, Institut für Physiotherapie, Jena, Germany

Introduction/Background

The prevalence of obesity and its consequences are increasing all over the world. That’s why the treatment of obesity is not only of interest for the patient but for the society. In this review we want to give an overview of current studies of electroacupuncture as treatment of obesity.

Material and Method

The research was performed in the electronic database pubmed. We searched for the keywords: „electroacupuncture“, „obesity“, „weight“, „weight loss“, „BMI“. For determination of the studies we combined the keywords and evaluated the data afterwards. 33 studies with different study designs, published between 1993 and 2014, were analyzed. 11 animal studies and 22 clinical trials have been included.

Results

The majority of the studies showed that electroacupuncture is an effective treatment for obesity. On the one hand most of the studies used the direct markers body weight and BMI, on the other hand surrogate parameters such as leptin, food intake and body fat level have been analyzed. Only one animal study did not recognize a significant reduction of body weight. In the other studies a significant positive effect of electroacupuncture has been measured. Most of the studies have been randomized and controlled but only four studies have been blinded.

Conclusion

Overall the studies showed good results for treating obesity with the help of electroacupuncture. A big randomized controlled trial of the ethnic groups in the Central European region or the Anglo-American sphere would be interesting, because of the heterogeneity of the studies, the partly small number of cases and the mainly Asian patient collective.

BMI OVER 40 NEED NEW CHANCE

S. Salameh

†MEDIAN Rehaklinik Aukammtal, orthopedic, wiesbaden, Germany

Introduction/Background

Obesity affects increasingly numbers of people (36% in the United States in 2009-2010), as well surgery for obesity is also increasing, but the rate of weight regain is large and the patient needs to change lifestyle after surgery too, thus surgery indications should be reviewe.

Material and Method

Focus more on changing the patient's lifestyle from the beginning through gradual behavior modification method with positive support and avoid negative pressure to reach weight reduction and maintain it and avoid surgery and its complications.

Results

By applying this method to 387 obese patients in my clinic aged 20 - 74 years, to whom Body Mass Index exceed 40 with a number of 672 courses and 4852 sessions, resulted to 10.15 kg average weight loss per patient, with an average of 10.5 sessions per patient in each therapy course.

Note: that the largest weight was treated 250 kg with Body Mass Index 101.4

Conclusion

Therefore, should focus on behavior modification programs and give more time to application before making a surgical decision.

Attention should also be given to obesity in children in schools and kindergartens through behavior modification programs combined with play and positive support.

A COMPARATIVE STUDY OF MORPHO-FUNCTIONAL DISORDERS OF FOOT IN DIABETIC AND NOT DIABETIC SUBJECTS
S. Miawa1, S. jemni1, E. toulgui1, F. khachnaoui1
1university hospital center Sahloul, Rehabilitation, Sahloul, Tunisia

Introduction/Background

The foot disorders at diabetic are frequent, grave and very costly. This gravity is underlined by the frequency of the amputations of lower limbs. Thus, a care in pedicurist podiatry turns out to be necessary to detect the disorders in time and treat them before the installation of the complications.

The objective of our work is to identify, from a podiatric examination, the morpho-functional characteristics of the foot at the diabetic patients to compare them to not diabetic subjects.

Material and Method

This is a multicentre, descriptive and analytical study. It includes 96 subjects divided into two groups: 31 not diabetic subjects and 65 diabetics. The data obtained were developed from an entire specific podiatric examination which contains demographic data, balance sheets and tests to estimate the biomechanical and structural disorders of the foot.

Results

Our study shows a significant difference of certain anomalies of the foot at the diabetics as compared to not diabetics. These anomalies are Xerosis, muscle weakness and joint limitations. The Foot Posture Index reveals that pronation of the foot is more frequent at the diabetics.

Conclusion

The management of diabetics is a major public and economic health issue. The complications of the diabetic foot constitute important spending regarding healthcare in the diabetics, which makes of their prevention a must key point.

DEMOGRAPHIC AND CLINICAL PROFILE OF PATIENTS INCLUDED IN A METABOLIC REHABILITATION PROGRAM FROM CLINICA INDISA, SANTIAGO, CHILE.
C. Felipe¹, E. Troncoso¹, P. Ritter², J. Rubilar³, V. Cézar³, C. Andrewharta⁴, D. Matamala⁴, A. Pérez-Castilla⁵, L. Gambini⁶
¹Physiotherapist, Clínica Indisa, Santiago, Chile
²Physiatrist, Clínica Indisa, Santiago, Chile
³Nutritionist, Clínica Indisa, Santiago, Chile
⁴Physiotherapy student, Clínica Indisa, Santiago, Chile
⁵Surgeon head of bariatric surgery team, Clínica Indisa, Santiago, Chile
⁶Physiatrist- head of physical medicine and rehabilitation service, Clínica Indisa, Santiago, Chile

Introduction/Background

In Chile, 71% of the population is overweight or obese, and 3.2% morbidity obese. A metabolic rehabilitation program is effective maintaining weight loss and muscle strength, specially for bariatric surgery patients, which in turn are involved in regaining weight. Aims: To describe the clinical and demographic profile of patients included in a metabolic and rehabilitation program.

Material and Method

We retrospectively obtained the clinical and demographic data from 311 patients enrolled in the program in a period of 16 months between 2016 and 2017 with the diagnosis of overweight, having or not the indications of bariatric surgery.

Results

The proportion of male/female was 94/217 (30%/70%), averaging 37.6 and 36.4 y/o (ns). Body weight and BMI at the time of enrolment for males and females was 108.5 kg (BMI: 35.2) and 85.8 kg (BMI: 33) (p<0.0001) respectively. From the total, 236 (75%) patients had any degree of obesity (male/female = 79 (84%)/157 (72%)), of which 14% were morbidly obese (male/female = 13 (16%)/20 (13%)). The comorbidities were insulin resistance (66%), dyslipidemia (30,8%), hypertension (20.6%), depression (18.3%) and diabetes mellitus (6,4%). Depression was more frequent in women (88%), of which 70% were obese. Bariatric surgery was performed to 79% of the patients, being the sleeve gastrectomy the most frequent procedure (86%). Global adherence (> 10 physical therapy sessions) was 37.9% (male/female = 38,3% vs 37,8%).

Conclusion

Knowing the demographic and clinical profile of the patients starting a metabolic rehabilitation program may help in planning specific strategies to improve the weight loss, muscle strength and reduction of comorbidities.

Introduction/Background

Few studies have investigated the factors associated with illness perceptions among patients with type 2 diabetes. The purpose of this study was to determine the relationship between illness perception, glycemic control, and family support in Turkish adults with type 2 diabetes.

Material and Method

The study was designed as a cross-sectional survey. A total of 193 patients with type 2 diabetes who were followed in a diabetes outpatient clinic of a tertiary hospital in Turkey were enrolled in this study. The sample included 155 patients (57.4% female). Data were collected by using a questionnaire form, the Illness Perception Questionnaire-Revised (IPQ-R) and the Perceived Social Support from Family Scale (PSS-Fa). Glycemic control was evaluated by measuring HbA1c levels. Data analysis were performed using descriptive statistics and Pearson’s correlation coefficients. A p value of less than 0.05 was considered as statistically significant.

Results

The mean age of the study group was 57.5±15.8 years, and the median duration of disease was 10 years. A significant positive correlation was found between HbA1c value and the identity subscale score (r=0.21, p=0.009), as well as a negative correlation with the timeline (acute/chronic) subscale score (r=-0.18, p=0.029). There were positive correlations between the PSS-Fa score and the personal control (r=0.28, p=0.001), the treatment control (r=0.19, p=0.021), and the illness coherence subscale scores (r=0.39, p < 0.001). Negative correlations were found between the PSS-Fa score and the timeline (acute/chronic) (r=-0.23, p=0.005), the timeline cyclical (r=-0.25, p=0.002), and the emotional representations subscale scores (r=-0.30, p<0.001). There were significant negative correlations between the PSS-Fa scores and the causes subscales of the IPQ-R (p<0.05).

Conclusion
The results of this study highlighted the importance of the perceptions of illness in glycemic control for patients with type 2 diabetes. Perceived family support was generally associated with improvements in beliefs about type 2 diabetes.

THE INFLUENCE OF BODY WEIGHT LOSS ON GAIT AND STABILITY FUNCTIONING IN OBESE PATIENTS

L. Marchenkova¹, V. Valeria¹, M. Eryomushkin¹

¹National Medical Research Center of Rehabilitation and Balneology, Rehabilitation Department for Patients with Somatic Diseases, Moscow, Russia

Introduction/Background

In our research we studied changes of gait and balance parameters and the falls frequency in obese patients during weight loss.

Material and Method

We examined 37 patients aged 23 to 69 years (average age 53.6±11.1 years) with body mass index (BMI)≥35 kg/m² (average BMI 40.9±9.3 kg/m²). All patients received recommendations to adhere low-calorie diet and to do physical exercises in order to reduce body weight. We evaluated body weight, the number of falls for 3 months, 10 meters walk test along a flat surface and stabilometry in Romberg test at baseline and after 3 months of weight loss program's start.

Results

The average body weight decreased from 124.1±26.6 to 118.1±23.4 kg (p=0.022; 95% CI: 2.78, 9.22) in the study group in 3 months. The body weight loss was accompanied by the reduction of the fall’s number for last 3 months from 0.14±0.34 to 0,0 (p=0.023; 95% CI: 0.02; 0.25) and the speed of 10 m walk from 113.0±8.82 to 105.5±3.03 sec (p=0.005; 95% CI: 2.86, 12.14). According to the stabilometry data the coefficient of stability improved from 113.5±9.11 to 104.0±2.16 % (p=0.012; 95% CI: 3.035, 16.10) and the movement speed of the pressure center - from 113.4±8.9 to 104.0±2.2 mm/sec (p=0.01; 95% CI: 3.04; 15.81). Deviation of the pressure center in the sagittal and frontal plane decreased from 113.6±9.1 to 104.0±2.2 mm (p=0.01; 95% CI: 3.03, 16.1), speed index changed from 113.0±9.1 to 104.0±2.2 (p=0.01, 95% CI: 3.0, 16.1) and overall rating movement reduced from 109.9±6.8 to 104.0±2.0 (p=0.0037, 95% CI: 0.5; 11.2) after 3 months of weight loss program's start.

Conclusion

The weight loss in obese patients is associated with the decline of falls frequency, improvement of gait speed, static and balance functioning.

THE EFFECT OF 12 WEEKS AEROBIC EXERCISE AND VITAMIN D SUPPLEMENTATION ON BLOOD LIPIDS AND METABOLIC SYNDROME MARKERS IN ELDERLY MEN WITH TYPE 2 DIABETIC
M. Kargarfard¹, N.A. Pirmoradian², R. Emadi², A. Shariat³
¹University of Isfahan, Department of Exercise Physiology, Isfahan, Iran
²Najafabad Branch- Islamic Azad University, Department of Physical Education and Sport Sciences, Najafabad, Iran
³Tehran University of Medical Sciences, Sports Medicine Research Center- Neuroscience Institute, Tehran, Iran

Introduction/Background
Type 2 diabetes mellitus (T2DM) is a multifactorial disease characterized by chronic hyperglycemia, altered insulin secretion, and insulin resistance. However, the effects of vitamin D and exercise training in treatment and prevention of metabolic syndrome in patients with T2DM is yet unknown. The purpose of this study was to evaluate the effect of 12 weeks aerobic exercise and Vitamin D supplementation on blood lipids and metabolic syndrome markers in elderly men with type 2 diabetic.

Material and Method
Forty elderly men with type 2 diabetic aged 30-50 years were randomly assigned to either the vitamin D supplementation plus aerobic training group (VD+AT: n=10), the aerobic training group (AT: n=10), the vitamin D supplementation group (VD: n =10), or the control group (CON: n=10). AT group performed a supervised aerobic exercise training program 3 times in week for 30-90 minutes at 50-75% of MHRR for 12 weeks. Vitamin D supplementation group also received vitamin D supplements at 1,200 IU per day for 12 weeks, whereas CON group were asked to maintain normal daily life pattern. Serum of 25-hydroxyvitamin D, blood lipid (TC, TG, HDL-C, LDL-C), as well as Fasting glucose, insulin, and HOMA-IR were measured before and after the intervention.

Results
Serum 25-hydroxyvitamin D levels significantly increased in the VD and VD+AT groups (P<0.05). Significant decreases in BW, BMI, WC, BFP were observed in the AT and VD+AT groups (P<0.05). TC, TG, HDL-C, and LDL-C showed improvements in AT and VD+AT groups (P<0.05), whereas there were no significant changes in the variables in AD and CON groups. Fasting glucose, fasting insulin, and HOMA-IR tended to be lower in AT and VD+AT groups (P<0.05).

Conclusion
These results suggest that Vitamin D supplementation combined aerobic training could be employed as a novel preventive measure for T2DM.

Introduction/Background

The damage of foot is frequent in diabetes patients. The systematic research of diabetic foot allows revealing neuropathy and/or arteriopathy with their multiple consequences (deformities, ulcer foot...).

The aim of this study is to determine the clinical and epidemiological profile of diabetic foot in a physical medicine and rehabilitation department.

Material and Method

A prospective study included diabetic patients who consulted for various reasons from June 2017 until September 2017 in the Physical Medicine and Rehabilitation Department at the National Institute of Orthopaedy M. Kassab in Tunisia. We excluded patients who had neurological damage with no direct rapport with diabetes (sciatica, hemiplegia...).

For each patient: we determined age, sex, treatment of diabetes, degenerative complications of diabetes, BMI (Body Mass Index), clinical examination of foot and evaluation of neuropathic pain with score DN4.

Results

We collected 40 patients with middle age 55.1 years and sex ratio 0.37, diabetes type 2 in 80% whose duration of evolution was 13.6 years, insulin therapy alone in 37.5% and associated with oral anti diabetic drugs in 22.5%, degenerative complications were present in 65% of cases. Patients were addressed for orthotic foot equipment in 35% of cases. We noticed ulcer foot in 37.5% and Charcot Foot in 12.5%. Clinical examination revealed BMI32.5, diabetic neuropathy in 80% and arteriopathy in 55%. The middle DN4 was 3.13 with a score ≤ 4/10 in 35% of cases. Only 42.85% patients were treated. Preventive orthotic equipment for foot was already prescribed in 10% and curative in 2.5%.

Conclusion

Epidemiology is necessary to assess the situation of diabetic foot and to adopt interventions. The research of diabetic foot damage must be as precocious as possible to detect abnormalities
and avoid severe complications. The coordination between the different physicians: physical medicine, endocrinologist, general physician… is necessary in order to optimize the prognosis.

EXTENDED SEDENTARY TIME IN DIABETIC NEPHROPATHY INCREASES THE RISK OF ALL-CAUSE DEATH AND NEW CARDIOVASCULAR EVENTS

H. Tamiya¹, Y. Tamura¹, S. Mochi¹, A. Yusuke¹, N. Banba², T. Yasu³
¹Dokkyo Medical University Nikko Medical Center, Rehabilitation, Nikko, Japan
²Dokkyo Medical University Nikko Medical Center, Diabetes and Endocrinology, Nikko, Japan
³Dokkyo Medical University Nikko Medical Center, Cardiovascular Medicine & Nephrology, Nikko, Japan

Introduction/Background

The study aimed to clarify the effects of extended sedentary time in diabetic nephropathy (DMN) on the risks of all-cause death and new cardiovascular events.

Material and Method

This was a prospective cohort study carried out over 39 months beginning in September 2013. Subjects analyzed were 173 DMN outpatients who responded to the International Physical Activity Questionnaire (IPAQ) (101 men; mean age = 71±11 y; CKD Stage I: 42, II: 93, III: 30, IV: 7, V: 2). New events were defined as all-cause death, cerebral stroke or cardiovascular disease (CVD) requiring hospitalization, or starting on hemodialysis (HD). ROC curves were used to calculate cut-off values for sedentary time (from the IPAQ) versus event incidence. Data were analyzed using multivariate Cox proportional hazard regression analysis, using measurements taken at the start of the observation period as independent variables: age, HbA1c, estimated glomerular filtration rate (eGFR), Alb/Cre ratio, sedentary time, and past history of stroke or CVD. Independent variables predictive of new cardiovascular events as well as all-cause death were identified, along with their corresponding HR and 95% CI.

Results

The new events observed during the follow-up period were as follows: stroke (n=4), CVD (20), HD (4), and all-cause death (6). The cut-off value for sedentary time for predicting new events and all-cause death was 525 min/day (AUC: 0.74, sensitivity: 0.71, specificity: 0.67, p<0.001). Independent variables identified as significant predictors of new event incidence were HbAc1 (g/dl) (HR: 0.697, 95% CI: 0.53-0.91, p=0.008) and sedentary time (60 min/day) (HR: 1.26, 95% CI: 1.00-1.59, p=0.049).

Conclusion

Extended sedentary time increases the risk of cardiovascular events in DMN patients. An increase in sedentary time of 60 min per day can increase the risk of cardiovascular events.
will be necessary to evaluate factors that contribute to sedentary time in patients, and to examine how to improve them by physiotherapist interventions.

ISPR8-1859
EFFECTS OF AEROBIC EXERCISE COMBINED WITH METFORMIN ON VASCULAR ENDOTHELIAL FUNCTION OF SKELETAL MUSCLE IN RATS WITH TYPE II DIABETIC MELLITUS
Z. Yan¹, M. Haiting¹, L. Aicui²
¹Nanjing Sport Institute, Department of Sports and Health Science, Nanjing, China
²the First Hospital of Nanjing, the First Hospital of Nanjing, Nanjing, China

Introduction/Background
To observe the effects of aerobic exercise combined with metformin on fasting blood glucose (FBG), serum insulin (FINS), plasma endothelin-1 (ET-1), serum nitric oxide (NO), skeletal vascular endothelial growth factor (VEGF), compare the difference between diabetes mellitus and normal control group and analyze the correlation between aerobic exercise combined with metformin to treat diabetes mellitus with synergistic effect.

Material and Method
Forty rats of 6-week-old male SD rats were randomly divided into the control group (DC, n = 10), diabetes mellitus group (DCE, n = 10), diabetic metformin group (DCM, n = 10), diabetic aerobic exercise + Metformin group (DCEM, n = 10). FBG, FINS, ET-1, NO and skeletal muscle were measured after 6 weeks.

Results
1. After 6 weeks of aerobic exercise and metformin, the FBG, FINS and insulin resistance index of T2D rats were significantly correlated (P < 0.01).

2. The changes of plasma ET-1 and serum NO in rats were significantly higher than those in NC group (P <0.01). The ET-1 content and ET / NO in DCM group were significantly decreased (P <0.01, P <0.05), and the content of NO was significantly increased (P <0.05).

3. Compared with NC group, VEGF was significantly overexpressed in skeletal muscle of DC group (P <0.01). After 6 weeks of metformin (P <0.05). After 6 weeks of aerobic exercise and metformin, the expression of VEGF protein in skeletal muscle of DCE group was significantly lower than that of DCEM group (P <0.05).

Conclusion
Aerobic exercise combined with metformin can effectively reduce the level of ET-1, increase the level of NO and decrease the expression of VEGF protein in rat skeletal muscle.

A CASE REPORT OF LEUCINE SUPPLEMENTATION TO REVERSE CACHEXIA AND INCREASE BMI IN A BEDRIDDEN PATIENT

P. Reiter¹, M. Rozak¹, A. Dennison²
¹Emory University, Rehabilitation Medicine, Atlanta, USA
²Shepherd Center, Brain Injury Rehabilitation, Atlanta, USA

Introduction/Background

Amino acids are precursors for protein synthesis and are also involved in regulating multiple cellular processes. In particular, leucine has been shown to significantly increase protein synthesis and stimulate muscle mass accretion via the mammalian target of rapamycin (mTOR) signaling pathway. Several studies have shown leucine and its metabolite HMB to be useful in the treatment and prevention of sarcopenia in active individuals by maintaining muscle mass in conjunction with resistance training. There is debate, however, regarding the optimal supplementation dose. One recent study noted a 20% protein synthesis increase in the elderly with 2.8 grams (g). To our knowledge, no data exists regarding immobile patients and leucine supplementation. Our goal was to investigate supplementation as a means of preventing cachexia and maintaining weight in individuals unable to perform resistance training.

Material and Method

We present a 31-year-old bedridden, disorders of consciousness male with contractures who suffered a severe traumatic brain injury at age 29. He presented to our facility on enteral feeding for a skin flap weighing 116 pounds (lbs.), though was 181 lbs. one-year prior. The patient was started on 3 g of leucine twice a day and over a four-month period daily weights with a standing or bed scale were obtained.

Results

The patient had a significant weight gain of 36.2 lbs. and a 24% change in his BMI from 15.0 to 19.8, despite continued immobility. Furthermore, Figure 1 displays a strong correlation of weight
gain over time with leucine supplementation.

**Conclusion**

It is common for bedridden patients to develop cachexia, muscle atrophy, and sarcopenia. These results suggest that one useful and cost-effective way to prevent and even reverse this process is with leucine supplementation.

**Keywords**

leucine; cachexia; immobility

Awareness of observation influences human behavior. For those participating in observational research, behavior change may occur from towards the stated research focus without prompting or intervention. This study sought to determine the consistency of activity and performance in Hepatitis C (HCV) and non-alcoholic fatty liver disease (NAFLD) subjects over one year (positively or negatively) with observation sans intervention, and to determine the consistency of the Human Activity Profile (HAP) in this population.

Material and Method

HCV and NAFLD subjects participated in a one year observational study. Baseline data including anthropometric measures, diagnoses of relevance (diabetes, cirrhosis etc), vital signs, and laboratory values were examined. Six minute walk time grip strength, and pre and post walk time cardiac output (CO) were available at baseline and follow-up. The Human Activity Profile (HAP) was used to estimate current activity level (AAS) and maximum activity level (MAS). Paired sample t-test of baseline and one-year follow-up activity and performance data was run.

Results

67 subjects (age 51.5±9.3 years, 31.3% NAFLD, 68.7% HCV, 72.7% Caucasian, 50.7% obese (BMI 30.8±5.6), 29.9% hypertension, 29.9% hyperlipidemia, 23.9% diabetes, 49.5±33.5 AST, 58.5±7.4 ALT, 81.1±8.7 MAS, 76.1±10.8 AAS) participated in a year-long observational study that consisted of a baseline and a one-year follow-up visit. 57.6% returned for the one year follow-up visit. Paired sample t-test showed that none of the activity metrics (HAP MAS or AAS, lifetime MAS) or grip strength differed significantly between time points. CO, heart rate pre and post exercise, heart rate change during exercise, and blood pressure measures pre and post also did not differ significantly within a year (p-values .103-.659).

Conclusion
HAP scores are consistent at one year retest, consistent with lack of performance and cardiac metric changes. Participation in an observational study has no significant effect on activity level and performance in HCV and NAFLD subjects at one year.

REHABILITATION FOR HIGH-VOLTAGE ELECTRICAL INJURY ON BOTH UPPER EXTREMITIES: A CASE REPORT
Y. Kanata¹, N. Hasegawa², Y. Miyabe², T. Yamashita², N. Kodama², K. Domen²
¹Hyogo College of Medicine Sasayama Medical Center, Department of Rehabilitation Medicine, Hyogo, Japan
²Hyogo College of Medicine, Department of Rehabilitation Medicine, Hyogo, Japan

Introduction/Background

We report a case with extensive burns on the face and both upper limbs. Function improvement of the injured fingers was achieved through early rehabilitation intervention aimed at prognosis prediction.

Material and Method

A 22-year-old male railway electric worker accidentally touched a distribution board with his dominant (left) hand during work. On admission at another hospital, second and third-degree burns were present on both upper limbs, face, chest, and neck. His burn index was 13.5. He was transferred to our hospital for systemic management and function reconstruction.

Results

Rehabilitation was started from the day of transfer. Initially, rehabilitation aimed at preventing contractures of the upper limbs and face. As the upper limb burns were severe, a cock-up wrist splint was applied to maintain upper limb position. During hospitalization, skin grafting and debridement were performed on the upper limbs and his left index finger was amputated; the patient was discharged 100 days after admission. Although nerve conduction examination showed a conduction block in the wrist joint, the electromyogram showed muscle activity of the right abductor pollicis brevis, opponens pollicis, and abductor digiti minimi. These electrophysiological findings suggested that muscle function could improve. After discharge, range of motion exercises to prevent contractures and activities of daily life (ADL) training using self-help devices were continued in an outpatient setting. Three months after discharge, he could oppose the right thumb to the ring finger. Finally, the dominant hand was exchanged on the right hand and his ADL became independent.

Conclusion

High quality rehabilitation aimed at appropriate prognostic prediction and target setting enabled the patient to achieve significant functional improvement in this case.

THE BURN REHABILITATION CENTER POST FORMOSA FUN COAST DUST EXPLOSION DISASTER--A PILOT REPORT FROM CHANG GUNG MEMORIAL HOSPITAL-TAOFUAN IN TAIWAN

P.H. Wu¹, S.S. Chuang², Y.C. Li³, W.C. Tsaí⁴, C.W. Chen¹, C.E. Lee³
¹Chang Gung Memorial Hospital-Linkou & Taoyuan, Physical Medicine and Rehabilitation, Guishan Township, Taiwan R.O.C.
²Chang Gung Memorial Hospital-Linkou & Taoyuan, Plastic and Reconstructive Surgery, Guishan Township, Taiwan R.O.C.
³Chang Gung Memorial Hospital-Taoyuan, Physical Medicine and Rehabilitation, Guishan Township, Taiwan R.O.C.
⁴Chang Gung Memorial Hospital-Linkou, Physical Medicine and Rehabilitation, Guishan Township, Taiwan R.O.C.

Introduction/Background

Chang Gung Memorial Hospital (CGMH) at Linkou is the largest burn center in Taiwan and treated one in every five victims (total 499 victims) in the Formosa Fun Coast Dust Explosion Disaster since June 27, 2015. In response to meet the social and medical needs for post burn issues, a Burn Rehabilitation Center was established in CGMH-Taoyuan on November 10, 2015 as a continuation of burn care and social support after this grand-scale tragic in Taiwan.

Material and Method

A Burn Rehabilitation Center for post acute care completed with multidisciplinary expertise including the plastic surgeon, physiatrist, psychiatrist, physical and occupational therapist were organized. Weekly clinic with rehabilitation exercises and on-site medical discussions were targeted on burn survivors and their family concerns.

Results

Since November 10, 2015 to December 25, 2017, the Burn Rehabilitation Center of CGMH-Taoyuan had received over two thousand patient visits in over two hundred clinics. Patients whom endured from different burn injuries (explosive flames, scald, chemical and electric burns) and post reconstruction surgery visited. Overall, the center had provided 1588 and 1688 physical and occupational rehabilitation sessions respectively.

Conclusion

Although we were acknowledged internationally for the capacity and ability to manage major burn victims in the acute stage, the challenges and medical attention persisted and remained high even two years after the insults. Despite social modernization, sporadic burn insults persisted. The Burn Rehabilitation Center in CGMH-Taoyuan served an important ground and
anchor in burn care and reflect a societal need to have effective treatment from acute, subacute to chronic stage.

*No conflict of interest*
In my town, the rate of elderly people is getting higher and the number of elderly patients with burn injury is also increasing. So we report the tendency of burn injury patients over 80 years old and discuss it with literatures.

Material and Method

We examine patients over 80 years old with burn injury who were admitted from January 2008 to December 2016. And we picked up about causes of the accident, term of hospitalization, age, gender, past history, term from admission to operation, term of starting rehabilitation.

Results

The total number of patients were 31 (male is 9 and female is 22). The patients who died were 4. The age range is between 80 to 92 (average 84.1). Burn Index is between 3 to 90 (average 15.6) and Prognostic Burn Index is between 84 to 179 (average 94.5). Past history is diabetes (9 cases). The days of hospitalization range is between 2 to 290 (average 58.7 days). The main causes of burn injury are the following: flame burn (19 cases), boiling water burn (7 cases) and other reasons (5 cases).

Conclusion

Elder patients with severe burn injury tend to die. The reports show that the severity of the burn injury is a great determiner of the length of stay of the patient in the hospital. If a patient undergoes rehabilitation earlier, the length of stay in hospital tends to be shorter and daily activities progress much better.

ISPR8-1414
DIAPHRAGMATIC MOBILITY MEASUREMENT IN PATIENTS WITH BURN INJURY ON CHEST AND NECK

C. Seo¹, J. So Young¹
¹Hallym University, Rehabilitation Medicine, Seoul, Republic of Korea

Introduction/Background

Lung complications caused by large surface burns. Evaluating the mobility of the diaphragm is important for understanding and diagnostic possible alterations in the muscles, which can be compromised in several ways due to central or peripheral dysfunction, muscular disease and thoracic or abdominal diseases. The aim of this study was to evaluate the diaphragmatic mobility in patients with large chest and neck burn injury.

Material and Method

Ten patients with chest and neck burn injury were included. Spirometer was done to evaluate pulmonary function. Pulmonary function tests including forced vital capacity(FVC), 1 second forced expiratory volume(FEV1), forced expiratory flow rate between 25 and 75% of the FVC (FEF 25-75) FEV1/FVC ratio and peak expiratory flow(PEF). Maximum voluntary ventilation(MVV) and respiratory muscles strength (maximal expiratory pressure, MEP; maximal inspiratory pressure, MIP) were measured by mouth pressure-meter in sitting position. Diaphragmatic mobility was measured by calculating the distance between the diaphragmatic dome in expiration and inspiration for the right and left hemidiaphragms by fluoroscopy.

Results

The values of FVC, FEV1, FEF25-75, MIP and MEP are 76.5%, 75.2%, 69.1%, 68.4% and 61.8% of predicted values. The values of MVV and PEF are 68.85 L/min and 10.92 L/sec. The mean values of diaphragmatic mobility in patients with chest and neck burns were 44.00 mm.

Conclusion

This study demonstrated that diaphragmatic mobility was decreased in patients with chest and neck burn injury. A reduction in diaphragmatic mobility in patients with burn has been associated with a decline in pulmonary function parameters.

A MEDICAL-SURGICAL CHALLENGE, REHABILITATION AFTER COMPLICATED NECROTIZING FASCIITIS OF THE NECK. CASE REPORT

M.L. Torrent-Bertran\(^1\), L. Adrover Kirienko\(^1\), S. Corio Lombardi\(^2\),
\(^7\)Vall d’Hebron Hospital, Physical Medicine and Rehabilitation, Barcelona, Spain
\(^2\)Vall d’Hebron Hospital, Physical Medicine and Rehabilitation, Barcelona, Spain
\(^3\)Vall d’Hebron Hospital, Physical Medicine and Rehabilitation, Barcelona, Spain

Introduction/Background

Necrotizing fasciitis is a severe soft-tissue infection. Causative factors are numerous and include peritonsillar infection. Rehabilitation teams should be aware of potentially sequelae and treat them.

Material and Method

We report a case of necrotizing fasciitis with severe anatomical and functional sequelae, who improved considerably after long-term rehabilitation program.

19 years old male diagnosed with infectious mononucleosis, presented unfavorable course with right lateral cervical thickening. Cervical-thoracic CT confirmed necrotizing fascitis migrated to brachial plexus, anterosuperior mediastinum and shoulder and dorsal musculature. Debridement of infected tissue was performed with resection of latissimus dorsi, inferior trapezius, infraspinatus, supraspinatus, pectoralis major, rhomboid, and minor teres muscles. Methylen blue extravasation in left leg caused necrosis that also required debridement. Tissue defects were treated with negative pressure wound therapy and partial thickness skin autografting. Neurophysiological exam showed denervation of right radial nerve, bilateral common peroneal and tibial nerves, and signs of critical illness myopathy.

Physical examination revealed severe physical deconditioning, limitation for wrist and fingers extension and shoulder mobility, and bilateral foot drop.

Rehabilitation treatment started at inpatient care and continued with long-term ambulatory program for 12 months after discharge. Interventions included positioning, joint mobilizations, antiedema massaging, tissue stretching, progressively intense active exercises, daily living activities (ADL’s) reeducation and gait with anti-equinus orthosis.

Results

Follow-up physical examination showed almost complete recovery of shoulder mobility, recovery of wrist and fingers extension, normal gait without orthosis, and total autonomy for ADL’s.
Weakness of right tibialis anterior muscle (MRC 4/5) and bilateral extensor hallucis longus (MRC 1/5) remained as sequelae. Reconditioning rehabilitation program will be possibly performed because of exercise intolerance.

**Conclusion**

Rehabilitation intervention should be always considered in severe necrotizing fasciitis cases, since long term rehabilitation programs show positive functional outcomes.

BENEFITS OF EARLY AND INTENSIVE REHABILITATION PROGRAM IN A MAJOR BURN PATIENT

S. Corio Lombardi¹, L. Adrover Kirienko¹, L. Grossi Garrido¹, E. Santacreu Santacreu¹,
S. Lopez Lebrato¹, M.L. Torrent Bertran¹

¹Hospital Vall d'Hebron, Physical Medicine and Rehabilitation, BARCELONA, Spain

Introduction/Background

The affection of the upper extremities, thorax and neck by a deep burn imply a severe functional loss. Likewise, the possible inhalation of smoke and burn of the airway, forces the orotracheal intubation, this increase the time of admission and reduce the patient's capacities.

An intensive rehabilitation program is essential to avoid or minimize the sequels, improving the functionality, the aesthetics and the quality of life. This clinical case explains a rehabilitation program in a major burn patient with predominant involvement of the upper body, the evolution and the functional gains obtained.

Material and Method

Woman with second degree and third degree burns with 25% of TBSA on face, neck, thorax, right arm and forearm, both hands, with airway involvement requiring orotracheal intubation.

The patient was taken emergently to the operating room for escharotomy and debridement with subsequent neck split thickness skin graft, patient needed scar tissue release.

The patient has been doing acute rehabilitation program with PT and OT during admission to maintain range of motion, reduce the possibility of microstomia, palpebral and labial commissure retractions, avoid myopathies, reeducate BADL, improve ventilatory capacity.

Later, performed rehabilitative treatment in the ambulatory phase, where presotherapy and silicone garments were prescribed in order to control hypertrophic scars, for 12 months.

Results

Currently the patient presents a complete range of motion except hands, with preserved global muscle strength, independent for BADL and functional hands. Limitation of movement on thorax and neck for flange at these areas. Improvement of the microstomy and the palpebral and neck retraction has been corrected.

Conclusion
The intensive and early initiation of rehabilitation program improves the functional prognosis in a major burn patient, decreases the need for corrective surgical procedures in the future as well.

SAFETY AND EFFICIENCY OF SUPERVISED AEROBIC EXERCISE TRAINING, USING CARDIOVASCULAR MACHINES, FOR PATIENTS WITH TERMINAL HEART FAILURE, INCLUDED IN HEART TRANSPLANT WAITING LIST

O. Ganenko¹, A. Malysheva¹, E. Demchenko¹, M. Nazimova¹
¹Federal State Budgetary Institution “Almazov National Medical Research Centre” of the Ministry of Health of the Russian Federation, Physical rehabilitation department, Saint-Petersburg, Russia

Introduction/Background

Purpose of research is to assess safety and efficiency of controlled aerobic training for patients with terminal heart failure (HF) and to develop methodology of interval training using treadmill and cycle for HF patients, included in heart transplant waiting list (HTWL).

Material and Method

19 males with terminal HF, included in HTWL, aged 22-64, with left ventricular ejection fraction 11-33% were assessed. Initially, 6-minute walk (6MW) and cardiopulmonary test (CPT) were performed, and the type of aerobic training was selected in accordance to individual cardiorespiratory fitness level and personal cardiovascular machine preference. Study group included HF patients with stable hemodynamic data, without inotropic therapy, with 6MW distance from 100 to 427m, and CPT results from 5.4 to 13.4ml/kg/min. All patients participated in long-term (2-12 months) 4-5 days a week interval training. The duration of training session was 6-30min according to patient’s individual working capacity and subjective condition. Heart rate reserve for study group was calculated: HRR=(190-age)-HRrest, and the HRtraining was determined as 30-40% of HRR. Training speed (V) on treadmill=50% of V (6MW-test)km/hour.

Results

After 2-12 months of training sessions all patients demonstrated increase: training duration from 13.1min at baseline to 25min (av. 11.9±0.4min) p<0.05; treadmill walking distance from 356m at baseline to 742m (av. 386±16m) p<0.01; treadmill walking speed from 1.58km/hour at baseline to 2.37km/hour (av. 0.78±0.01km/hour) p<0.001. The number of training sessions was associated with growth of treadmill walking distance (r=0.38) and overall session duration (r=0.6). All patients well tolerated individualized physical training sessions with intensity regulated by the proposed formula. No complications were registered. 77.7% of patients self-selected cardiovascular machine: 42.1% preferred treadmill, but 31.6% used both treadmill and cycle.

Conclusion
Controlled training, using cardiovascular machines, are safe, well-tolerated and effective for patients with terminal HF, included in HTWL, in case of self-selection of the machine and individualised training intensity level.

RELIABILITY OF THE SIX MINUTES WALK TEST AFTER LUNG TRANSPLANTATION

G. Ebenbichler¹, J. Kohlmann¹, F. Glaser², T. Kienbacher³, P. Jaksch⁴, W. Klepetko⁴
¹Vienna Medical University, Physical Medicine- Rehabilitation & Occupational Medicine, Vienna, Austria
²Technical University of Vienna, Technical University of Vienna, Vienna, Austria
³Karl-Landsteiner-Institute of Outpatient Rehabilitation Research, Karl-Landsteiner-Institute of Outpatient Rehabilitation Research, Vienna, Austria
⁴Vienna Medical University, Thoracic Surgery, Vienna, Austria

Introduction/Background

The six minutes walk test (6MWT), a surrogate measure of bodily deconditioning and exercise tolerance, serves as a function category of utmost importance within the assessment of functional health and for outcome monitoring after lung transplantation (LuTX). The 6MWT is further one of the major decision criteria relevant to the timing of LuTX. As data on the reliability of this test in LuTX recipients seem lacking, this study for the first time sought to investigate the precision and relative reliability of the 6MWT in patients undergoing subacute rehabilitation after LuTX surgery.

Material and Method

This prospective observational test re-test study recruited 50 LuTX recipients (28 females) who performed the 6MWT in a standardized way before discharge from the acute hospital stay, shortly thereafter, and two months later, after the end of rehabilitation. In addition functional outcome variables including maximum isometric back extension, hand grip strength, the chair rise test and the Biering Soerensen test were taken. Statistics explored for changes in the mean of the 6MWT distance between the first and second test day, and calculated all, the measurement error (SEM), the smallest detectable difference (SDD), and the intraclass correlation coefficient (ICC2,1).

Results

Absolute walking distance was 372m (±101) at baseline and 397m (±106) 1.6 days later. As at the end of rehabilitation, the 6MWT distance was increased by 142m (95%CI:97;187) if the longitudinal changes relative to the second test day had been considered. The SEM was 40m, the SDD 112m, and the ICC(2,1) was 0.9 (95%CI:0.82;0.94), respectively. Relevant correlations were found between walking distance and all, hand grip and back extension strength and the chair rise test.

Conclusion
In lung transplant recipients early after surgery, the 6MWT can be expected to enable an acceptable level of detection of expected changes in bodily conditioning and exercise tolerance as a result of planned medical rehabilitation interventions.

⁶Hospital Universitario Puerta de Hierro, Pneumology, Madrid, Spain
⁷Hospital Universitario Reina Sofía, Pneumology, Cordoba, Spain

Introduction/Background

The long-term survival after lung transplant (TP) is limited by the appearance of the graft chronical dysfunction (DCI). However, there is a small percentage of patients with long-term survival (SLP) (>10 years) that do not have DCI. The goal of this study is to evaluate the functional capacity to effort in those lung transplant receptors SLP, with normal spirometry and without DCI.

Material and Method

Transversal study in 29 Spanish SLP patients after LT with normal spirometry and without DCI diagnosed. The clinical histories were revised retrospectively. The daily physical activity and the health condition were measured with the “international physical activity questionnaire” and the “EUROQUOL-5D”, respectively. The lean body mass was determined with a device for electrical bioimpedance (50 Hz). A spirometry, static pulmonary volumes, a progressive effort test and a CO transfer test were performed with a cycle ergometer measuring the ventilatory and cardio circulatory parameters.

Results

The mean age (SD) of the included patients was 48.66 (13.6) years and 15 of them (51.72%) were women. The mean age (SD) at the transplant date was 34.7 (14.0) years old. The mean of the forced vital capacity (FVC) and the forced expiratory volume in the first second (FEV1) was 92,59% (15,66) and 97,86% (14,55), respectively. The V₀² peak mean was 21,49 (6,68) ml/kg/min, that corresponds to the 75,24 % (15,6) of the expected value. The average of watts obtained in V₀₂ max was 111,14 (37,13) w and the median (p25-75) of respiratory exchange ratio (RER) in V₀₂ max was 1,35 (1,25-1,4). The test for measuring the quality of life Euroquol 5D revealed a median (p25-75) of 1 (0,95-1)

Conclusion
LT receptors that do not present DCI, maintain a normal spirometry and are SLP show values of functional capacity to effort very similar to the normal ones and a good health condition.

FUNCTIONAL RESULTS AFTER A CHILDREN’S CARDIAC REHABILITATION PROGRAM AFTER A HEART TRANSPLANT

P. Launois¹, B. Planas¹, V. Pujol¹, F. Gran², R. Abella³, D. Albert², A. Gómez-Garrido¹

¹Vall d’Hebron Hospital, Physical medicine and rehabilitation, Barcelona, Spain
²Vall d’Hebron Hospital, Pediatrics Cardiology, Barcelona, Spain
³Vall d’Hebron Hospital, Pediatrics cardiovascular surgery, Barcelona, Spain

Introduction/Background

Heart transplantation (HT) is the treatment indicated in those patients who are in the final phase of their heart disease. It is known that heart transplant improves their ability to exercise, although this capacity for effort is diminished. After transplantation, the physiological response of exercise is altered, with its multifactorial etiology (decreased chronotropic activity and musculoskeletal dysfunction), cardiac rehabilitation is recommended in adults and in children, as it improves exercise capacity. The implementation of these programs in pediatric age is scarce in our country. The aim was evaluate the functional results after cardiac rehabilitation program (CRP) in child heart transplantation in our hospital.

Material and Method

Retrospective study with series cases: 10 patients HT between 2015 and 2017.

CRP consists:
- Phase entered: where the rehabilitation treatment begins before the transplant if it is admitted and/or after the transplant.
- Ambulatory phase: at hospital discharge.

Assessment: six-minute walking test (6MWT) and determination of the maximum inspiratory pressure at the beginning of the treatment and after its completion.

Results

10 children with an average age of 13.5 years (SD 3.74). The mean time from the inclusion in the cardiac transplant waiting list was 74.90 days (SD 100.82). The average stay in the ICU was 37.30 days (SD 21.66) and the total time of admission was 60.70 days (SD 37.44).

5 cases started rehabilitation before transplantation and all of them underwent rehabilitation in the ICU, continuing in the ward. At discharge, the ambulatory phase continued with an average of 17.90 sessions (SD 6.15). After the program, they have improved of average 175.70 meters (SD 170.31) in the 6MWT (p <0.010). The rest of the parameters analyzed did not show statistically significant differences.
Conclusion

CRP after heart transplantation has helped improve functional capacity demonstrated in the improvement in the 6MWT. All the patients continued to perform physical activity after completing the CRP.

OUTCOMES OF MULTIDISCIPLINARY INPATIENT REHABILITATION FOLLOWING HEART AND/OR LUNG TRANSPLANTATION

C. Shiner¹, G. Woodbridge¹, D. Skalicky¹, S. Faux¹,²
¹St Vincent's Hospital Sydney, Rehabilitation and Pain Medicine, Darlinghurst- Sydney, Australia
²University of New South Wales, Faculty of Medicine, Sydney, Australia

Introduction/Background

Heart and lung transplantation is becoming a more common treatment option for patients with end-stage cardiopulmonary disease. Both the incidence and survival of transplant operations are increasing, resulting in heightened interest in optimising long-term patient outcomes, functional ability and quality-of-life following transplant. Specialist rehabilitation can help to promote recovery and enhance functional ability following transplant surgery, particularly for frail and debilitated patients.

Material and Method

A retrospective file audit was conducted to review all admissions for multidisciplinary inpatient rehabilitation following heart and/or lung transplant between 2009-2016, at St Vincent’s Hospital Sydney, Australia. This is the largest and oldest heart and lung transplant centre in Australia.

Results

Between 2009-2016, 603 heart/lung transplant surgeries were performed at St Vincent’s Hospital Sydney. Of these patients, 116 (19.2%) were admitted for inpatient rehabilitation: 49 heart, 65 lung and 2 combined heart-lung recipients. The rehabilitation cohort was comprised of 63 men and 53 women, mean age 53.4±12.2 years. Average rehabilitation length-of-stay was 26.9±2.0 days. Functional Independence Measure (FIM) scores improved significantly with rehabilitation, from 79.8±1.9 on admission to 101.8±2.8 at discharge (p<0.001), resulting in a mean FIM efficiency of 0.9±0.1. Physical measures of mobility and balance also showed significant improvements, including the 6 Minute Walk Test (p<0.001), Timed Up and Go (p<0.001) and Berg Balance Scale (p<0.001). 33.6% of admissions were interrupted by an acute medical complication, however this did not prevent completion of rehabilitation or attainment of functional gains for the majority of cases. 109 patients (94%) were discharged to a private residence following rehabilitation, 2 were transferred to a regional hospital and 5 died in hospital.

Conclusion

Multidisciplinary inpatient rehabilitation resulted in significant functional improvements for debilitated patients following heart and/or lung transplantation. These results support a role for
specialist inpatient rehabilitation in optimising functional capacity and independence post-transplant.

THE EFFECT OF HIV ON FUNCTIONAL OUTCOME IN STROKE PATIENTS ADMITTED TO A REHABILITATION HOSPITAL

D. Burke\textsuperscript{1}, T. McCargo\textsuperscript{2}, R. Bratton Bell\textsuperscript{1}, S. Pullen\textsuperscript{1}
\textsuperscript{1}Emory University School of Medicine, Rehabilitation Medicine, Atlanta, USA
\textsuperscript{2}Harvard University, Harvard Extension School, Cambridge, USA

Introduction/Background

Recent studies have concluded that HIV patients live with an increased risk of stroke. Our study investigated the association between HIV and the functional progress of patients admitted for rehabilitation after suffering a stroke.

Material and Method

This retrospective chart review included data from patients admitted to rehabilitation hospitals after suffering a stroke from 2002-2017. The data included demographic information as well as functional independence scores and length of stay.

Results

During the 15-year timeframe, 688,006 patients were admitted to rehabilitation hospitals after suffering a stroke. FIM efficiency and LOS did not significantly differ between the HIV and non-HIV patients. The data indicated that FIM efficiency was slightly higher for HIV patients (1.78 vs. 1.75). On average, HIV patients had a 1-day difference in LOS (17 days vs. 16 days).

Conclusion

Despite being a risk factor, HIV status does not appear to significantly affect functional improvement or LOS for patients suffering after a stroke.

Keywords

ISPR8-0567
FACTORS ASSOCIATED WITH RETURN TO ACUTE (RTA) HOSPITAL CARE FROM INPATIENT REHABILITATION FACILITY (IRF)
C. Geis¹, A. Gonzales¹, R. Nave¹, E. Dethloff¹, D. Gilmore¹
¹Halifax/Brooks, Rehabilitation, Daytona, USA

Introduction/Background

A retrospective chart review was conducted for patients requiring transfer from our 40 bed IRF to higher-level hospital care due to medical or surgical complications.

Material and Method

We identified 66 patients transferred from IRF to acute care hospital due to change of medical status requiring higher level of care over a 12 month period from 1/1/16 through 12/31/16.

Results

Compared to our general population, patients returning to acute care were more likely to be male (70% versus 59%) and older (70 years versus 65.39 years). A higher percentage of patients who were admitted from outside facilities returned to acute care (36% versus 20%). Lower admission FIM scores (39 versus 50.87) was associated with return to acute care.

Patient with RIC categories stroke and medically complex had the highest rate of return to acute care (30% and 24%)

The primary reasons for transfer to acute care were change in mental status (29%), hypoxia (24%), other (18%), hypotension (12%), fever (6%), seizures/cardiac arrhythmia/melena (3% each) and chest pain (1%).

The most common diagnoses related to the reason for transfer were sepsis (17%), pneumonia (9%), acute on chronic respiratory failure (8%), congestive heart failure/CO2 narcosis/stroke/TIA (6% each), seizure/cardiac arrhythmia/GI bleed (5% each), myocardial infarction (3%) and other (30%). In patients who diagnosed with sepsis, the most common infections were urinary tract (45%) and pneumonia (27%).

Conclusion

Primary diagnoses made after transfer to acute care were sepsis, pneumonia and acute on chronic respiratory failure. Urinary tract infection and pneumonia were found to be the 2 most common etiologies of sepsis.
Diligence with regard to careful monitoring of infection, particularly related to urinary tract infection and pneumonia and respiratory compromise in this medically fragile population, especially those that have an admitting RIC of stroke or medically complex appears to be warranted.

4Dokkyo Medical University Nikko Medical Center, Cardiology, Nikko, Japan

Introduction/Background

End stage renal failure (ESRF) patients on hemodialysis (HD) are relatively inactive. This low activity in daily life leads to poor lower limb skeletal muscle function and progression of atherosclerosis. High echo intensity (EI) of rectus femoris muscle (RFM) reflecting increase in intramuscular fibrous and adipose tissue can be applied for qualitative assessment of leg muscle. The aims of this study were to investigate the association among knee extension strength, EI of RFM, muscle thickness (MT) and short physical performance battery (SPPB) in ESRF patients and to explore the effects of exercise training during HD on EI of RFM and SPPB.

Material and Method

Study design was a prospective one arm interventional study. The study subjects were ten ESRF patients on HD (four men, mean age 72.5±11.0 years). The exercise training program consisting of a bicycle ergometer with strength of Borg scale 11-13 and low-intensity resistance training for 30 min during HD (three times a week) for three months. We serially measured EI and MT of RFM, knee extension strength and SPPB.

Results

Knee extension strength, EI of RFM, MT and SPPB in patients with ESRF were lower than those of age-matched healthy subjects. Exercise training during HD for three months decreased EI of RFM in eight patients (80%) out of ten. Mean±SD of EI significantly decreased from 67.87±16.6 to 59.3±16.5 (p<0.046 vs. baseline). MT of RFM, knee extension strength and SPPB tended to increase in comparison with the baseline data.

Conclusion
Echo intensity of RFM serves useful additional information regarding assessment of leg muscle in patients with ESRF on HD. Significant improvements in EI were observed after three-month-training during HD. Improvements of knee extension strength and SPPB may follow after improvement of EI.

Introduction/Background

Difficulties with activities of daily living (ADL) not only limit ADL, but also increase the risk of mortality in community-dwelling older people. While most patients undergoing maintenance hemodialysis (HD) perceive difficulties with performing ADL related to mobility, few studies have examined the association between ADL difficulties and mortality risk in HD patients. To this end, we aimed to prospectively assess the association between ADL difficulties and mortality in HD patients.

Material and Method

A total of 300 outpatients (178 men, 122 women; mean age, 64.1±10.9 years) undergoing maintenance HD therapy 3 times a week at a HD center were recruited in this study. Clinical characteristics including age, sex, body mass index, primary cause of end-stage renal disease, time on HD, comorbid conditions, hemoglobin, and serum albumin were collected at baseline. ADL difficulties were assessed with the Questionnaire on Perceived Mobility Difficulty for HD patients (Kutsuna et al., 2011; Watanabe et al., 2018). The ADL difficulty score ranged from 12 to 60 points, with lower scores indicating greater ADL difficulties. Patients were classified into three groups by tertiles of ADL difficulty score (low difficulty group, middle difficulty group, and high difficulty group). Kaplan-Meier analysis of survival and Cox proportional hazards regression were used to assess the contribution of ADL difficulties to all-cause mortality.

Results

During the follow-up period (median, 50 months), 71 patients died. Cumulative survival rates at endpoint were 63.9% in the low difficulty group, 59.8% in the middle difficulty group, and 32.5% in the high difficulty group. After adjusting for the effects of clinical characteristics, ADL difficulties were a significant predictor of all-cause mortality. The hazard ratio of the high difficulty group to the low difficulty group was 3.44 (95% confidence interval, 1.75-7.11; p<0.01).
Conclusion

ADL difficulties were strongly associated with survival in clinically-stable HD patients.

FEMORAL HEAD AVASCULAR NECROSIS DURING PREGNANCY: A CASE REPORT

G. Jurėnaitė¹, J. Marmukonytė²

¹Lithuanian university of health sciences, Physical medicine and Rehabilitation, Kaunas, Lithuania
²Lithuania University of health sciences, Physical Medicine and Rehabilitation, Kaunas, Lithuania

Introduction/Background

Osteonecrosis is caused by impaired blood supply to the affected bone. It results with destruction of bone structure, which leads to joint pain and loss of function. There are very few published cases about pregnancy as single etiological factor for femoral head osteonecrosis in healthy women.

Material and Method

A healthy 26-year-old at the 32nd weeks of pregnancy presented with suddenly developed sharp, constant pain (VAS 5-7) in the right hip area. Pain decreased in two weeks, after physiotherapy in a vertical bath and water trail. However, due to eczema, hydrotherapy was discontinued. Pain reoccurred and was evaluated up to 6-8 VAS points. After delivery at 41st week of gestation, the pain intensified (VAS 10 points), the patient was unable to walk. MRI indicated the right hip osteonecrosis. Patient was treated by allowing walking with crutches without stepping on the right foot for at least 2 months, NSAIDs (colecoxib 100mg 1/d), calcium, passive physiotherapy, TENS, MT, EF with calcium chloride, HILT therapy, hip joint massage.

Results

After 2 months of rest, patient started to actively use the right foot, using 50% of body weight, increasing to 100% within 4 weeks. After inpatient rehabilitation she began to fully step on the right foot, pain decreased, range of motion of both hip joints became equal, right thigh and gluteal muscles strengthened.
Conclusion

Although osteonecrosis is a rare condition, it should be included as a possible differential diagnosis for any new, sudden hip joint pain developed during pregnancy. It is crucial to identify disease at an early stage before femoral head collapse occurs, which allows to preserve joint as opposed to replacement.

Keywords

Simpson Ward is a 21 bed step down and rehabilitation unit which provides a discharge to assess service for patients no longer requiring acute care at Watford General Hospital. As a ward with high turnover of doctors, often locums, continuity of care is key to delivering safe and effective treatment. This is especially important given the often prolonged stays. The aim of this audit was to identify key areas where admission clerkings may lack information and create a simple proforma to ensure these areas are included.

Material and Method

We identified key areas of information needed to guide clinicians about the patients’ admission. 10 points were identified as important, including reason for admission, past medical history, escalation plans, and specific requirements e.g. communication or mobility difficulties. We looked at a total of 22 patients over a two day period and assessed whether these areas were identified in the admission clerking. Information from the clerkings was used alongside the acute discharge summary to detect any key areas overlooked.

Results

Admission clerkings were generally successful at outlining basic elements of patient information including reason for initial admission, reason for step down to Simpson ward and past medical history. However other areas were not clearly outlined in the admission clerking with clear documentation in less than 35%. In particular CPR/escalation plans were not documented in
any clerkings despite DNACPR forms being present. Additionally patient follow up was not highlighted despite being requested in the discharge summary.

Conclusion

It is clear from our results that admission clerkings often lack important information key to continuity of care and smooth transition from acute to step down care. Based on these 10 areas we created a clear table to use as a ‘patient factsheet’ tool that can easily be referred back to when a new doctor takes over patient care.

CURRENT SITUATION OF REHABILITATION BEFORE THE IMPLEMENTATION OF A PROGRAM OF EARLY MOBILIZATION IN A POLYVALENT ICU

M. Alvarado Panesso¹, A. Girbau Moreno¹, A. Garcia Segura¹, N. Carrasco Rodriguez¹, M. Carillo Arolas¹, R. Garreta Figueras¹, M. Salamero², I. Sandalinas², J. Trenado Alvarez², M.D.M. Fernandez Fernandez²

¹Hospital Mutua de Terrassa, Physical Medicine and Rehabilitation, Terrassa, Spain
²Hospital Mutua de Terrassa, Intensive Care Medicine, Terrassa, Spain

Introduction/Background

Survivors of critical illness frequently experience muscle weakness and relevant functional impairment after intensive care unit (ICU) discharge. This study aimed to evaluate currently mobilization practice in ICU patients with more than 72 hours of mechanical ventilation (MV).

Material and Method

Unicenter prospective observational study from September 2016 to July 2017. We enrolled patients under MV longer than 12h and measure the baseline functional level, ICU-acquired weakness (ICUAW) and functional status at hospital discharge. We recorded the mobilization related adverse events.

Results

We recruited 30 patients (63±12 years; 70% men), mean Acute Physiology and Chronic Health Evaluation II (APACHE II) 16±5. Mean time of ICU stay and hospital stay were 23 and 32 days respectively. Mean time to ask for rehabilitation evaluation was 8±4 days after ICU admission and finally rehabilitation began 10±5 days after admission to the ICU. 11 (37%) patients were mobilized with an endotracheal tube and 19 (63%) with endotracheal tube initially and after with tracheostomy tube. Strength was assessed at ICU discharge and 23 patients (80%) had ICU-acquired weakness (Medical research Council Manual Muscle Test Sum Score (MRC-SS) score 48<60).
Medical Research Council (MRC) Progression

- Initial: 32.57 ± 16.43
- ICU discharge: 40.64 ± 15.17
- Hospital discharge: 51.30 ± 10.18

(p=0.001)
Functional Status Scale (FSS-ICU) Progression

- Initial: 4.39 ± 5.76
- ICU Discharge: 12.29 ± 8.82
- Hospital Discharge: 27.90 ± 9.87

(p < 0.001)
The functional level obtained during sessions was sitting at the edge of the bed (n= 24, 80%), standing at the bedside (n=10, 33%) and walking (n=5, 17%). No adverse effects during rehabilitation therapy were reported. ICU and hospital mortality were 27% and 33% respectively. The myopathic patients discharged from the ICU had higher mortality at day 90 (p= 0.002).

Conclusion

Early mobilization was uncommon in our ICU. Most of our patients discharged from the ICU had developed ICU-acquired weakness with higher mortality at day-90 in most severe myopathic ones. Implementation of an early mobilization program is urgent and requires a cultural change.

Vitamin D is a prohormone whose two main inactive biological forms are cholecalciferol and ergocalciferol.

Serum 25 (OH) D is a reliable biomarker considered the best determinant of vitamin D status.

Adequate levels of vitamin D are essential for innumerable organic functions, namely: muscle function, prevention of stress fractures, prevention of infectious diseases and may even contribute to the secretion of insulin in type 1 and 2 diabetics.

Material and Method

The study was carried out in all patients admitted to the Physical Medicine and Rehabilitation Service in 2017. Serum 25(OH)D and skin type (Fitzpatrick Scale) were evaluated at admission.

Results

27 patients were evaluated (16 males and 11 females). Patients were aged between 38 and 84 years (60.37 ± 13.85). All patients had a Fitzpatrick scale of 3. Serum vitamin D levels ranged from 4.4 ng / mL to 24.6 ng / mL (11.54 ± 5.87 ng / mL). Thus, none of the patients had adequate levels of vitamin D. Spearman correlation was used for comparison of vitamin D levels and age, with a statistically significant correlation between age and vitamin D levels (p = 0.004).

Conclusion

None of the patients admitted to inpatient care of a Physical Medicine and Rehabilitation had adequate levels of vitamin D. Vitamin D deficiency may contribute to the onset of complications such as infections, myopathy and stress fractures ultimately leading to a greater delay in the functional recovery of patients and failure to achieve the full recovery potential. Younger patients had higher vitamin D deficits, indicating the importance of assessing serum vitamin D levels in this population. Given the effectiveness and safety of cholecalciferol in increasing serum 25 (OH) D levels, we may consider supplementation or even fortification of all hospitalized patients in order to prevent complications and enhance their functionality.

VARIETY OF ACTIVITY PARTICIPATION INFLUENCES LEG BONE MINERAL CONTENT OF PRE-PUBERTAL CHILDREN WITH DEVELOPMENTAL COORDINATION DISORDER

S.S.M. Fong¹, D. Vackova¹, A.W.M. Choi², Y.T.Y. Cheng¹, T.T.T. Yam¹, X. Guo³
¹The University of Hong Kong, School of Public Health, Hong Kong, Hong Kong S.A.R.
²The University of Hong Kong, Department of Social Work and Social Administration, Hong Kong, Hong Kong S.A.R.
³The Hong Kong Polytechnic University, Department of Rehabilitation Sciences, Hong Kong, Hong Kong S.A.R.

Introduction/Background

Limited participation in activities in children with developmental coordination disorder (DCD) may have a negative impact on bone mineral accrual. This study aimed to compare bone mineralization and activity participation patterns of pre-pubertal children with DCD and those with typical development, and to determine the relationship between activity participation patterns and bone mineralization in children with DCD.

Material and Method

Fifty-two children with DCD (mean age = 7.5 years) and 61 children with typical development (mean age = 7.2 years) participated in the study voluntarily. Appendicular and total body bone mineral content (BMC) and bone mineral density (BMD) were assessed by a whole-body dual-energy X-ray absorptiometry scan. Activity participation patterns were assessed using the Children's Assessment of Participation and Enjoyment (CAPE).

Results

Children with DCD had lower appendicular and total body BMCs and BMDs than children with typical development (p < 0.05). Additionally, they had lower CAPE total activity and physical activity diversity and intensity scores (p < 0.05). After accounting for the effects of bone age, sex, lean mass and fat mass, the total activity diversity score remained independently associated with leg BMC in children with DCD, explaining 5.5% of the variance (p < 0.001). However, the physical activity diversity score was no longer associated with leg BMC (p = 0.084).

Conclusion

Diversity (variety) and intensity of activity participation and bone mineralization were lower in pre-pubertal children with DCD. Decreased total activity participation variety was a contributing factor to lower BMC in the legs of children with DCD.

FOOT DEFORMITY IN CHILDREN WITH LINEAR SCLERODERMA: CASE REPORT
S. zahi¹
¹CHU Ibn Rochd, physical medicine and rehabilitation department, casablanca, Morocco

Introduction/Background

Localized scleroderma or morphea is confined to the skin and/or underlying tissues. It is a rare disease of unknown etiology. Linear scleroderma is a subtype of localized scleroderma generally observed in children, and may produce secondary bone and joint deformities. Its localization at the foot or ankle is rarely reported.

Material and Method

A complete review of the literature reveals 22 cases of foot or ankle deformity due to linear scleroderma to which we added one case.

Results

An 8 years old boy consulted for oval-shaped plaques of skin in the right thigh and foot. The clinical diagnosis of linear scleroderma was made. Two years later, he came to us for an evolutionary and painful deformation of the right foot, interfering with footing. The physical examination found: A short amyotrophic right lower limb; Monoparesia grade 4/5 and Stiffness of the right ankle. Treatment consisted of corticosteroid, physical therapy in association with prescription of orthopedic soles. With an 8-month follow-up, walking was done without lameness or pain. Ankle mobility was 30 degrees in dorsal flexion and 40 degrees in plantar flexion.

Conclusion

Treatment should be started very early, before complications occur due to the high morbidity rate of individuals with localized scleroderma.

Keywords

Linear scleroderma; morphea; foot deformity

ABSTRACT NEED TO BE EDITED - TRANSLATION, FACE AND CONTENT VALIDITY ON "CHILD INITIATED PRETEND PLAY ASSESSMENT" FOR 4-7 YEARS CHILDREN

N. Mirzakhani Araghi1, M. Dabiri Golchin2

1Navid Mirzakhani. Department Occupational Therapy. School of Rehabilitation- Shahid Beheshti University of Medical Sciences- Tehran- Iran. mirzakhany@sbmu.ac.ir,

. Department Occupational Therapy. School of Rehabilitation, Tehran, Iran
2MSc Student in Occupational Therapy- School of Rehabilitation- Shahid Beheshti University of Medical Sciences- Tehran- Iran,
MSc Student in Occupational Therapy- School of Rehabilitation- Shahid Beheshti University of Medical Sciences- Tehran- Iran, Tehran, Iran

Introduction/Background

Background and Aim: although play seems to be a simple concept, but is complex and varies according to individual experience. Play is a process happen with no law. The play is a spontaneous, funny, without goal, flexible, completely attractive, vital and challenging behavior. Pretend play starts in childhood than 18 months. The play is a potential source for the assessment of academic skills. Pretend play is more related to preacademic skills. The purpose of this study was translation and examining face and content validity of Persian version of the Child Initiated Pretend Play Assessment (CHIPPA).

Material and Method

The translation of the test carried out based on International Quality of Life Assessment. Then face validity determined by five and content validity investigated by ten specialists in occupational therapy proffesion .then content validity ratio (CVR) and content validity index (CVI) calculated.

Results

In the process of translation, some phrases were changed depending on the culture. CVI was 1 and CVR was 0.8 to 1 in all items.

Conclusion

the Persian version of "Child Initiated Pretend Play Assessment" has an appropriate face and content validity

MSc Student in Occupational Therapy- School of Rehabilitation- Shahid Beheshti University of Medical Sciences- Tehran- Iran., Tehran, Iran  

**Introduction/Background**  
Sensory Processing Disorder as defined by difficulties in setting up and organizing the variety and intensity of responses to sensory input for compliance with environmental requirements. This study was designed to investigate the distribution of sensory processing disorder in children 5 to 11 years in Tehran city based on sensory profile questionnaire.  

**Material and Method**  
This study was a descriptive and cross sectional study that performed in children who have 5 to 11 years old. Data collection included a demographic questionnaire and a sensory profile questionnaire.  

**Results**  
In this study 2191 cases were evaluated in terms of sensory processing factors. According to this study morbidity from sensory processing disorder in boys is higher than for girls. Also the most common disorder was observed in sensory sensitivity factor and the lowest was fine movement and perception.  

**Conclusion**  
Different sensory processing function in these children may explain their abnormal behaviors. These sensory processing dysfunction effects on child's daily life in areas such as play, academic skills and peer relationships, self-help activities. Therapists should consider the child's sensory processing functions when they set therapeutic plans. Declaration of Interest: None

Otoacoustic emissions (OE) allow the early detection of hearing loss in neonates, they have few limitations and have been used for screening and early detection of hearing loss in newborns, especially those with risk factors for hearing loss, however, they require diagnostic confirmation with evoked auditory brainstem potentials. The objective of the study was to measure the reliability of auditory screening results through otoacoustic emissions with the gold standard in high-risk children treated in two hospitals in Bogotá.

Material and Method

A longitudinal, ambispective study. We collected both brainstem auditory evoked potentials and Transient OE to high-risk newborns with hearing loss suspicion in two tertiary care centers in Bogota from 2008 to 2016. For the purposes of reliability analysis, each ear was considered an analytical unit.

Results

From 147 newborns with risk factors evaluated with otoacoustic during study period it was possible to perform evoked auditory brainstem potentials in 41 cases (82 ears), which we analyzed. With this comparative data we found that OE have a sensitivity and specificity values of 82.5% and 57.1% respectively. About to the safety of OE, we obtained positive and negative predictive values of 64.7% and 77.4%. With all this, we determine the positive and negative likelihood ratios, obtaining the values 1.93 and 0.31 respectively. With which we obtain a diagnostic 'odds ratio' (DOR) of 6.22.

Conclusion

OE showed an unsatisfactory diagnostic performance, with a good sensitivity value but low specificity, showing a DOR with discriminatory value. For this reason their use as screening test could not be discouraged. It is necessary to carry out further studies with greater statistical power to be able to define indications and recommendations in relation to the application of this type of tests.

Despite the atypical muscle activation patterns exhibited in children with developmental coordination disorder (DCD) during static postural control tasks, no studies to date have investigated if this pattern is shown in dynamic postural control conditions. This study aimed to evaluate the leg muscle patterns during the Lower Quarter Y-Balance Test (YBT-LQ) between children with and without DCD.

Material and Method

Forty-eight children with DCD (mean age ± SD = 8.03 ± 1.10 years; 37 males and 11 females) and fifty-one children with typical development (mean age ± SD = 7.82 ± 1.06 years; 32 males and 19 females) were allocated to the DCD group and control group, respectively, after screening by two physiotherapists. Rectus femoris, biceps femoris, tibialis anterior and gastrocnemius medialis muscle activations (of the weight-bearing leg) were measured by surface electromyography and foot contact switches during the YBT-LQ anterior, posteromedial and posterolateral reaches.

Results

Children with DCD revealed a lower YBT-LQ score (p<0.001) when compared to the control group for all reach directions. Moreover, the posteromedial and anterior reach directions revealed different muscle activation patterns with a lower gastrocnemius medialis peak activation (p=0.029) and a shorter gastrocnemius medialis muscle time-to-peak duration (p<0.05), respectively, in children with DCD compared with the controls.

Conclusion

Children with DCD exhibited a less competent YBT-LQ performance and dissimilar leg muscle activation patterns in dynamic balance situations. They may adopt a different lower limb neuromuscular control than typically developing children to compensate for the balance deficits. Rehabilitation interventions for children with DCD should therefore incorporate dynamic postural control elements with an emphasis on phasic neuromuscular control of the weight-bearing leg.

CASE REPORT: 3-YEARS-OLD CHILD WITH SYNGAP1 GENE DEFECT – A RARE DISEASE AND A REHABILITATION CHALLENGE

N. Albuquerque¹, I. Peixoto¹, B. Silva Lopes¹, M. Ferreira Vaz¹, P. Teixeira¹, M. Pais Carvalho¹, A.M. Torres¹, J. Caldas¹
¹Centro Hospitalar Tondela Viseu, Physical Medicine and Rehabilitation, Viseu, Portugal

Introduction/Background

Normal development of brain is imperative for performing essential executive functions. Abnormal dendritic spine morphology and function, such as SYNGAP1 (synaptic Ras-GTPase-activating protein 1) mutations, can lead to disruption of neuronal circuits and consequently can result in various neurodevelopmental disorders.

Material and Method

Collection of patient data was made through the clinical process.

Results

Case Report: This 3-year-old boy was referred to PMR department at the 6-month-old for hypotonia. Faced with the difficulty in feeding, hypotonia and lack of trunk stability and strength in lower limbs, he began a psychomotor rehabilitation plan. After that a pathogenic variant c.3583-6G>A(p.7) was detected in heterozygosity of the SYNGAP1 gene.

At this time, he is in follow-up by the PMR department, with physiotherapy and occupational therapy plan with improvement of the axial tonus and better trunk stability in the sitting position but hypotonia is still evident. He is also performing Speech Therapy, and at this time he says only 4 meaningful words and is starting to introduce solid food.

With the institution of the rehabilitation plan it did not have regressions in the psychomotor development and presents some more notorious gains in the feeding and motor function once already he tries to crawl.

Conclusion

Given the rarity of these case report (described in the literature in only two patients), it is not easy for the physician to establish the goals to be achieved in the rehabilitation program because they are not known. The management of these patients goes through the discussion of each case with all medical specialties involved and with the therapists who work with the patients in order to adjust the plans to the needs of the child in each moment.
It's important to share the rehabilitation experience of these rare case in order to help other physicians to understand the natural evolution of these patients.

A CASE OF 16P11.2 DUPLICATION SYNDROME WITH CORTICAL VISUAL IMPAIRMENT.  
A.R. Cho

Introduction/Background

The 16p11.2 duplication syndrome are related intellectual disability, delayed motor development, speech disability, brain structure and function; enlarged ventricles, cerebellar hypoplasia, vision problem and other medical problems. We present a child showed delayed development and cortical visual impairment with 16p11.2 duplication occurred as de novo mutation.

Material and Method

A 16 months-old male visited rehabilitation clinic with delayed development. He had small head and motor milestones were delayed. In Bayley Scales of Infant Development at 17 months, he had 7 months gross motor, 9 months cognitive function, 5 months receptive communication, 7 months expressive communication, and 9 months fine motor. His cortical visual impairment assessed by using array-based comparative genomic hybridization, evoked potential, diffusion tensor tractography, Preverbal VisuAl Assessment questionnaire.

Results

His VEP showed delayed P100 latency of left and disturbed or absent wave pattern of right. Array-CGH revealed 11.7Mb duplication of chromosome 16p12.3 – 16p11.2. Brain MRI revealed periventricular leukomalacia with unclear cause and thinning of corpus callosum for patient’s age. On DTT, the callosal fibers in mid-body of corpus callosum showed focal defect. Left frontotemporal tract in arcuate fasciculus was not reconstructed. Inferior fronto-occipital fasciculus had reduced volume in right hemisphere and diminished projection to occipital lobe. Right optic radiation was not reconstructed. On assessment to visual integrative abilities using PreViAs questionnaire reported by his parents. He got a global score 19 out of 30(Table 1).

Conclusion

The 15 percent of patient with 16p11.2 duplication syndrome is known for having visual problem. The METTL9 gene located in 16p12.3 – 16p11.2 would be related with this patient’s visual impairment. But there are no reports yet to distinguish peripheral and cortical visual impairment. By using specific tools, it would be useful to evaluate and to start early intervention the patients with cortical visual impairment. It is worth to plan rehabilitative strategies for individual based approach.

MEALTIME BEHAVIORS IN TYPICALLY DEVELOPING CHILDREN AND CHILDREN WITH AUTISM SPECTRUM DISORDER (ASD)

A. Sharma¹, S. Rege², C. Rao³

¹Christian Medical College, Physical Medicine and Rehabilitation, LUDHIANA, India
²School of Allied Health Sciences, Department of Occupational Therapy, Manipal- Karnataka, India
³Kuwait University, Department of occupational therapy- Faculty of allied health sciences, Kuwait, Kuwait

Introduction/Background

Mealtime behaviors are influenced by one’s cultural and social context. In India, patterns, foods and ways of eating are different than western countries. Literature shows evidence of the presence of problematic mealtime behaviors in both typically developing children and children with ASD and it’s a major concern for parents. **Objective:** To explore mealtime behaviors in typically developing children in Indian context and compare it with children with ASD.

Material and Method

A cross sectional survey using Children’s Eating Behavior Inventory (CEBI), a parent report measure assessed eating and mealtime behavior issues in 150 typically developing children and 30 children with ASD in the age range of 2 to 12 years. CEBI consists of 40 items, rated on a 5- point scale. Problematic behavior is also rated on a 2-point scale. Analysis included descriptive statistics, Pearson’s Correlation coefficient test and Chi square test of independence.

Results

Results proved the presence of problematic mealtime behaviors in both the groups but more in children with ASD. Independent t-test was found to be significant $t(178) = 3.041, p < 0.003$ indicating a difference between mealtime behaviors in both the groups. Pearson’s chi-square was found to be $X^2 (2, N= 180) = 18.83, p< 0.001$ showing a statistically significant association between problematic mealtime behaviors (Mealtime behaviors > 16% cut off) and the two groups.

Conclusion

Mealtime behaviors are present in typically developing children and children with ASD. However, these behaviors occur more frequently in children with ASD and are more problematic for their parents. Findings of the present study support the existing evidence on mealtime behaviors. Further studies can emphasize on evaluating more mealtime behaviors and type of food preferences in typically developing children.

ASSOCIATION BETWEEN SPINE STRUCTURAL DEFORMITIES AND HYPOTONIA IN CHILDREN UP TO 3 YEARS OF LIFE

I. Petronic¹, D. Cirovic¹, D. Nikolic¹, T. Knezevic², B. Radivoj³
¹University Childrens Hospital- Faculty of Medicine, Physical and Rehabilitation Medicine, Belgrade, Serbia
²University Childrens Hospital, Physical and Rehabilitation Medicine, Belgrade, Serbia
³Faculty of Medicine, Pediatric Surgery, Belgrade, Serbia

Introduction/Background

In children up to one year of life with hypotonia of muscles, lumbal kyphosis is characteristic sign in sitting position due to the weakness of body muscles, and is corrected in lying and standing position. Follow-up of these children with increasing in muscle strength up to 3 years of life leads to correction of such deformity. In cases where lumbar kyphosis is persistent and is not corrected in both lying and standing positions it should be assumed for structural spine deformities. The study aim is early diagnostics of structural spine deformity and proper orthopedic-phsiatric treatment inclusion.

Material and Method

Clinical examination and radiological evaluations were performed along with exercises and orthoses.

Results

3 cases treated due to the muscle hypotonia and delay in motoric development with expected persistent lumbal kyphosis over the first year of life. Such deformity was treated by knesiotherapy along with stimulation of motoric development. On control follow-up within first 3 years of life, kyhpotic deformity was present with in lying and standing position without neurological pathology and is confirmed by X ray and CT (nonsegmentacio vertebre).

Conclusion

It is recommended that in these cases, patients should be referred to exercises along with corrective plasters and follow-up during growth and development.

A 12-WEEK GROUP INTERVENTION FOR SELECTED CHILDREN DIAGNOSED WITH AUTISM SPECTRUM DISORDER

E. Africa¹, K. Van Deventer¹

¹Stellenbosch University, Department of Sport Science, Cape Town, South Africa

Introduction/Background

Gross motor skills contribute to a child’s overall wellbeing, and therefore, these skills are important. Children diagnosed with Autism Spectrum Disorder (ASD) are recognised as being clumsy and uncoordinated in their gross and fine motor skills and for these reasons show signs of atypical development. Intervention programs are, therefore, necessary to provide children with ASD opportunities to learn the essential gross motor skills, leading to increased participation in physical activity. The aim of the study was to implement a 12-week specialised group intervention to improve the gross motor skills of selected children diagnosed with ASD. The age of the participants ranged between 8 and 13 years.

Material and Method

In the Cape Town area (Western Cape Province, South Africa), a governmental school for autistic learners was recruited to participate in this study, because the school divided learners into classes based on their level of autistic function. Therefore, the study made use of a sample of convenience. Two classes (N=7) at the school participated; one formed the experimental group (n=4) and the other the control group (n=3). The children completed the Movement Assessment Battery for Children-2 (MABC-2). A 12-week group intervention focussing on gross motor proficiency was designed and implemented.

Results

Descriptive statistics and summary results are reported as means and standard deviations. The main findings showed significant improvements in the total motor proficiency of the MABC-2 in children with ASD. A statistically significant difference was found over time between the experimental and control groups (p=0.05), suggesting that the intervention had a positive effect on the children’s total motor proficiency.

Conclusion

The current study demonstrated the effectiveness of a 12-week group intervention programme on the gross motor skills of children with ASD, and therefore, future studies are encouraged.

QUALITY OF LIFE IN PRETERM WITH CONGENITAL HEART DISEASE
C. Epalzá1, A. Úbeda2, M. Ruiz1, M. Casallo1, J. Moreno1, C. Cid1, O. Arroyo1
1Hospital General Universitario Gregorio Marañón, Medicina Física y Rehabilitación, Madrid, Spain
2Spaulding Rehabilitation Hospital and Boston Children’s Hospital, Pediatric rehabilitation department, Boston, USA

Introduction/Background

Earlier studies have demonstrated that the gestational age has an influence in the survival of the children with Congenital Heart Disease (CHD), being lower in those born preterm. Moreover, it is known that the neurodevelopmental disorders that affect both Preterm (PT) children and those with CHD are a result of the underlying pathophysiology, comorbidities and associated treatments or interventions.

The objective of this study is to evaluate the Quality of Life (QoL) in PT with complex CHD and to compare it with children with CHD born at term (AT).

Material and Method

Data was collected prospectively in patients from 7 to 18 years old who attended a CPET cardiopulmonary exercise testing at the General University Hospital Gregorio Marañón from 07/01/17 to 12/31/2017. QoL was evaluated using the Pedsql cardiac module, a validated questionnaire that assesses the areas of heart problems, treatment, physical appearance, treatment anxiety, cognitive problems and communication. The questionnaire was answered by both parents and children.

Results

4 of 67 children who took the test were PT. The description of PT heart disease is shown in Table 1. All areas appeared to be more affected in PT compared to children born AT as shown in Table 2.
Conclusion

With the exception of the patient with Subaortic Stenosis, PT patients presented a lower score in the sections of physical appearance, anxiety and knowledge; being, in general, the perception of the parents more negative than the children’s. These findings coincide with the results of previous studies. The number of patients is limited and our data preliminary. The real impact of prematurity on the QoL of patients with CHD should be further investigated.

CHARACTERISTICS OF MOTOR DEVELOPMENT OF AUTISM SPECTRUM DISORDER CHILDREN UNTIL UNASSISTED WALKING STAGE

Introduction/Background

There have been few reports on the aspects of the motor function development of autism spectrum disorder (ASD) infants in infancy. In the present study, we investigated the motor development characteristics of ASD infants before the stage at which they acquired the ability to walk unassisted.

Material and Method

The subjects were 150 ASD infants (112 males and 38 females), who did not have any clear underlying disease, and based on their charts we retrospectively selected motor function acquisition ages until acquiring the ability to walk unassisted. We assessed six parameters: head control, roll over, sitting, crawling, standing up, and walking unassisted and calculated the numbers of infants classified according to whether within the normal range and early or late outside the normal range, by using Japanese edition Denver style development screening test. We also investigated the sequence of motor function acquisition.

Results

The mean ages of the ASD infants when they acquired the motor functions were within their normal ranges, but the standard deviations of the ages of acquisition successively widened. Although 122 infants (81%) were within the normal range for the turnover, 83 infants (55%) were within the normal range for walking unassisted. The sequence of motor function acquisition was normal in 54 infants (36%) and irregular in 96 infants (64%), and a tendency was also seen for irregularities in the sequence of acquisition to become greater.

Conclusion

Motor development in typically developing children progresses stepwise. However, when motor development delay or a course of motor development outside the normal range in terms of age in months at the time of acquisition is observed despite the absence of any clear underlying disease, it is necessary to bear the possibility of ASD in mind and intervene early, while monitoring the course of the child's interpersonal relations, social skills, behavior, and motor development.

HIGH RISK OF MOTOR DEVELOPMENT DELAY IN CHILDREN WITH CONGENITAL MUSCULAR TORTICOLLIS

X. Zhou¹, Q. Du¹
¹Xin Hua Hospital affiliated to Shanghai Jiao Tong University School of Medicine, Rehabilitation, Shanghai, China

Introduction/Background

Congenital muscular torticollis (CMT) is one of the most common congenital cervical deformities in children. CMT is a result of excessive shortening of the sternocleidomastoid muscle, which leads to an imbalance of muscle function around the neck. Previous studies found that postural torticollis may lead to motor development delay. However, few studies have been carried out on the study of CMT concurrent motor development delay. The purpose of this study was to investigate the prevalence of motor development delay in children with CMT.

Material and Method

Peabody Developmental Motor Scales-Second Edition (PDMS-2) was used to evaluate motor developmental levels in 54 children with CMT, whose average age was 8.50±6.76 months (2~27 months). PDMS-2 is an assessment tool to evaluate children motor development, consisting of 6 subscales, including reflection, posture, movement, object manipulation, grasping and visual motor integration, a total of 249 items. The final results were expressed by gross motor development quotient (GMQ), fine motor development quotient (FMQ). The higher the quotient, the better the motor development. The normal value of the developmental quotient is 90~110, while below 90 representing motor development delay.

Results

The average GMQ and FMQ were 94.48±9.69, 98.70±8.26 respectively, and the GMQ was significantly lower than FMQ in children with CMT (P<0.01). Among them, 24 patients (37%) existed motor development delay, while 18 patients (33%) in gross motor development delay, and 6 patients (11%) in fine motor development delay. There was no significant difference of GMQ, FMQ in gender or different affected sides of CMT.

Conclusion

37% of children with CMT have motor development delay. Children with CMT have the separation of gross motor development and fine motor development. The gross motor of children with CMT may fall behind the fine motor. Therefore, physicians and physiotherapists should pay more attention to the motor development of children with CMT.

MOTIVATION-DRIVEN IMPROVEMENT IN SCHOOL ATTENDANCE VIA INDIRECT STAFF SUPPORT

R. Maki¹, R. Kobayashi²

¹Tokyo Metropolitan University, Master’s student Department of Occupational Therapy, Graduate School of Human Health Sciences, Tokyo, Japan
²Tokyo Metropolitan University, Department of Occupational Therapy, Graduate School of Human Health Sciences, Tokyo, Japan

Introduction/Background

Independent living group homes are residential options for 15-20-year-old adolescents and young adults who are without a family or who have to live away from home. According to a survey 24.5% residents of the independent living group homes were diagnosed with developmental disorder. Occupational therapy can improve the lives of these residents who seek occupational independence despite the. However, there are no reports of occupational therapy practices in Japanese independent living group homes.

Material and Method

We carried out three separate consultations with the group home staff. In the initial interview, we discussed how Ms. A (17-year-old) could attend high school without absentees. She was diagnosed with attention deficit hyperactivity disorder. She attended high school, but was at a risk of being withdrawn secondary education due to excessive absentees. As she worked hard at her part-time job, she had difficulty waking up early. Although she understood the importance of attending high school, she seemed unmotivated to regularly attend it. Therefore, we proposed the use of a calendar sticker and a comment reinforcement system to assist Ms. A with visualization and motivation to attend school.

Results

At the second session, the staff reported that the use of the calendar sticker and reinforcement system was effective and Ms. A successfully attended high school; she adjusted the amount of time spent at her job according to the school hours. By the third session, the staff reported that she was beginning to notice her physical condition.

Conclusion

A previous report stated that if a behavior is established via external reinforcement stimuli, the behavior itself should eventually be used as a reinforcement stimulus. As Ms. A continued to attend high school, the habit of regular attendance was reinforced. Encouragement by the staff
through the use of the calendar gradually became internalized, and she exhibited internalized motivation to maintain regular attendance.

WIEDEMANN-STEINER SYNDROME FROM REHABILITATION PERSPECTIVE
C. Casado Blanco¹, M. Echevarria Ulloa¹, J.L. Lavin López¹, M. García de Francisco²
¹Hospital General Universitario Gregorio Maranon, Physical Medicine And Rehabilitation, Madrid, Spain
²Hospital General Universitario Gregorio Maranon, Department Of Physical Medicine And Rehabilitation, Madrid, Spain

Introduction/Background

Wiedemann-Steiner syndrome (WSS) is a rare genetic disorder resulting from mutation in the MLL gene (also known as KMT2A) located on chromosome 11q23.3 that encodes a histone with modulating action on genes. The features in detail are psychomotor developmental delay, pre and postnatal growth deficiency, hypotonia, hypertrichosis cubiti (excessive hair on the elbows), mild to moderate mental retardation, speech delay, and craniofacial abnormalities with facial features such as downslanting narrow palpebral fissures, thick or arched eyebrows with a lateral flare, long eyelashes, and broad nasal bridge.

Our aim is to submit an infrequent but possibly important case to be considered in the differential diagnosis of developmental delay.

Material and Method

We report the case of a two-year-eleven-month-old child who has been followed up in our Rehabilitation Service since she was eight months for psychomotor developmental delay. She presented IUGR that required admission, PDA, and growth deficiency requiring hormone substitution. No family history. Her first review exploration highlighted hypotonia with little general muscular consistency, gross motor skills delay, distinctive facial features such as hypertelorism and broad nasal bridge, no facial asymmetries or cephalometric alterations. She started a treatment program based on neuro-developmental physical therapy and occupational therapy with cognitive and motor achievement stimulation.

Results

The successive revisions emphasize global hypotonia, rotational alterations in her feet, and psychomotor developmental delay, with assessment in the Brunet-Lezine of a delay of twenty-two months. She achieved independent gait at nineteen months old, being able to run, go up and downstairs at twenty-five.

Conclusion
Despite the fact that the cases of Wiedemann-Steiner syndrome are rare, it must be taken into consideration in a patient presenting any of the features mentioned above in order to get the benefits of an early neuro-developmental and stimulation treatment.

LONG-TERM PHYSIOTHERAPY FOLLOW-UP ON A NONSENSE POINT MUTATION DUCHENNE MUSCULAR DYSTROPHY CASE USING ATALUREN
E. Kavlak¹, F. Tekin¹, H.A. Kavlak², S. Tekin¹
¹Pamukkale University, School of Physiotherapy and Rehabilitation, Denizli, Turkey
²Special Educational Center, Special Educational Center, Denizli, Turkey

Introduction/Background

Approximately 13% of Duchenne Muscular Dystrophy (DMD) cases occur due to nonsense point mutations, also known as early stop codons. The drug Ataluren has been shown to have the potential to treat the underlying cause of the disorder by producing a protein that replaces the nonsense mutation and functions as a cell mechanism. The aim of this study was to determine the effects of Ataluren on the 56th exon, a nonsense point mutated DMD, following 3 years of physiotherapy.

Material and Method

The case, which was followed between December 2015 and December 2017, was initially assessed at 5 and the final assessment at 7 years. The case was taken to the physiotherapy program immediately after the initial evaluation and started using Ataluren. A 6-Minute Walk Test, a North Star Ambulatory Assessment, a Timed Gower's Sign Test, a 10-Meter Walk Test, and a Four-Step Stair Climbing Test were administered to the case every year.

Results

Test results of the 3-year follow-up period of the case are given in Table-1. The case showed improvement in all parameters over the years.

<table>
<thead>
<tr>

</table>

Conclusion
According to the results obtained in the study, the use of Ataluren type drugs in the case of DMD with a nonsense point mutation positively affects the walking speed, ambulatory skills, climbing the stairs -up and down- ability, and ability to stand up from supine position. We think that early initiation of early DMD patients who are able to use Ataluren will increase the physical performance and quality of life of patients.

²Kobe University Hospital, Department of Rehabilitation Medicine, Kobe, Japan
³Kobe University Hospital, Division of Rehabilitation Medicine, Kobe, Japan
⁴Kobe University Graduate School of Medicine, Division of Dermatology, Kobe, Japan
⁵Kobe University Graduate School of Medicine, Division of Neurology, Kobe, Japan
⁶Kobe University Graduate School of Medicine, Department of Otolaryngology-Head and Neck Surgery, Kobe, Japan

Introduction/Background

The patients with xeroderma pigmentosum group A (XP-A) have severe neurological abnormalities, the peak of their developmental curve is around their babyhood, and the curve declines with age. However, there were few studies which performed developmental examinations in the patients with XP-A. In this study, we performed developmental examination in the patients with XP-A using Enjoji developmental test.

Material and Method

7 patients with XP-A were enrolled in this study. (12 males and 15 females. Average age: 163 months old, all patients had homozygous IVS3-1G>C in the XPA gene.) The Enjoji developmental examinations were performed in the patients. The average of follow-up duration was 842 months. All patients were performed Enjoji developmental test several times in their follow-up.

Results

The peaks of the developmental curve were almost 60-80 months. The physical abilities of the whole body, skilled hand motor activities, behaviour, interpersonal skills and speech ability were decline linearly with age. Negative correlations of male patients were higher than those of female patients.

Conclusion

In this study, we reported the developmental examination of the patients with XPA using Enjoji developmental test. From our results, language comprehension was retained after the patients become bed-bound. Therefore, we should treat their hearing impairment appropriately in all their lives, and we should attempt to communicate using substitutes of speech when they have a difficulty of the treatment of hearing impairment. Decreasing in ADL of male patients progresses
faster than that of female patients. Thus, we should intervene in male patients earlier than female patients.

BENEFITS OF OCCUPATIONAL THERAPY FOR CHILDREN WITH INTELLECTUAL DISABILITIES IN THE ASPECTS OF VOCATIONAL ACTIVITIES AND INSTRUMENTAL ACTIVITIES OF DAILY LIFE
H. Shakhawath 1
1Bangladesh Health Professions Institute BHPI, Occupational Therapy, Dhaka, Bangladesh

Introduction/Background

Intellectual disability is a disability characterized by significant limitations both in intellectual functioning and in adaptive behavior, which cover many everyday social and practical skills. Vocational education is “a multi-professional approach that is provided to individuals of working age with health related impairments, limitations, or restrictions with work functioning and whose primary aim is to optimize work participation. Instrumental Activities of Daily Living activities to support daily life within the home and community. Like as community mobility, financial management, meal preparation and clean-up, shopping.

Material and Method

Electronic searches of Medline, PubMed, Google scholar, OT Seeker literature using the key terms of intellectual disability, vocational rehabilitation, instrumental activities of daily living and Occupational Therapy as well as a thorough manual search for relevant literature.

Results

There were 13 articles, all qualitative and quantitative which are included in this review. All studies were mixed methods in design. To take the Occupational Therapy services there are significant improvement about their children various areas like as sensory issues, cognitive abilities, perceptual skills, visual, motor planning and group therapy. After take the vocational and instrumental activities of daily living training children with intellectual disabilities participate their daily activities and work as an employee different company or organizations.

Conclusion

The persons with intellectual disability are the integral part of our society who deserves social support and opportunities like other human beings. From the result section of the project papers it is found that the significant benefits of Occupational Therapy services in the aspects of vocational and instrumental activities of daily living.

EARLY REHABILITATION TREATMENT OF THE CONGENITAL HYPOTONIC SYNDROME SECONDARY TO NEMALINE MYOPATHY: A CASE REPORT
L. de la Nuez Rodriguez-Batllo, M. Echevarría Ulloa, S. Domínguez Ibáñez, J.L. Lavín López
1Hospital Universitario Ramón y Cajal, Servicio de Rehabilitación, Madrid, Spain
2Hospital General Universitario Gregorio Marañón, Servicio de Rehabilitación Infantil, Madrid, Spain

Introduction/Background

Nemaline Myopathy (NM) is a primary myopathy that affects striated muscles. Produces proximal muscular weakness some with facial involvement, hypotonia, absence of deep tendon reflexes, respiratory and esophageal alterations. 20% are autosomal recessive, 30% autosomal dominant and 50% de novo. Usually diagnosed during the postnatal period through clinic, muscle biopsy (nemaline bodies) and genetic study. Multiples genes have been detected, being ACTA1 mutation responsible of 50% of lethal forms. Of the six clinical forms, the congenital is the most frequent. Independent walking before 18 months of age is the main survival factor.

Material and Method

We present the case of a 21-day girl with severe hypotonic syndrome. No family history of myopathy. Normal pregnancy and delivery. A genetic study was carried out on suspicion of glycogenosis, finding ACTA-1 gene mutation. Physical examination (PE): soft consistency tone with global hypotonia without activity of any muscle group, traction maneuver with predominance of flexor muscles and kyphosis. The patient was treated with two hours of physiotherapy and occupational therapy (OT) twice a week; postural and stimulation guidelines were given to parents.

Results

PE 6 months: improvement of proximal weakness, hand-foot-mouth coordination, performing flips; head control with three-point support, unstable sitting position. PE 12 months: flips chains, stable sitting position with kyphosis correction, poor access to standing. PE 23 months: march released at 22 months, standing access without support from squat position; manipulation: makes over 6 cubes tower, string balls with good bimanual coordination and bilateral terminal clamp. Given the good evolution is discharged in OT maintaining physiotherapy and guidelines at home.

Conclusion

Recognizing the association between hypotonia and PDR let us establish an early treatment focused on each milestone of fine and gross motor development. Family support and guidelines
at home have improved functional performance, mobility as well as participation in daily activities lines were given to parents.

³Ibaraki Prefectural University of Health Sciences, Department of Paediatrics, Inashiki-gun, Japan
⁴Ibaraki Prefectural University of Health Sciences, Department of Rehabilitation Medicine, Inashiki-gun, Japan

Introduction/Background

To retrospectively investigate the relationship between a prescription of orthoses for lower extremity and a Developmental Quotient (DQ) of an examination in people with Down’s syndrome (DS).

Material and Method

Children with DS who had a developmental examination and who were 4.1 to 6.0 years were retrospectively investigated. Investigated parameters were: age, mean age of subjects who underwent the Kyoto Scale of Psychological Development (KSPD) in 4.1 to 6.0 years, number of subjects who made an orthosis or an insole, and the mean DQ of Postural-Motor (P-M), Cognitive-Adaptive (C-A), and Language-Social (L-S).

Results

78 subjects were detected. The mean age was 14.0 years old. The mean age of subjects who were tested with KSPD in 4.1 to 6.0 years was 4.9 years old. A total of 20 subjects underwent the exam and made an orthosis. 18 made an insole as a first orthosis. The mean DQ of P-M was significantly lower in the both population with DS who made some kind of orthoses than those who did not make anything.

Conclusion

People with DS who made some kind of orthoses indicated a lower mean DQ in the P-M area. DS patients with lower DQ on P-M area can need orthosis or an insole.

INCOORDINATED SUCKING PATTERN IS ASSOCIATED WITH LONGER TRANSITION TIME TO FULL ORAL FEEDING IN PREMATURE INFANTS
Y.G. Yi¹, H.I. Shin¹, H.I. Shin¹
¹Seoul National University Hospital, Rehabilitation Medicine, Seoul, Republic of Korea

Introduction/Background
Several treatments have been proposed in order to shorten the time to the attainment of full oral feeding (FOF) for pre-term infants, but there are only a few evaluation methods useful in estimating predictors of this period. We investigated whether specific items within the disorganized sucking patterns described by the Neonatal Oral-Motor Assessment Scale (NOMAS) could estimate the time to FOF in preterm infants with sucking difficulty.

Material and Method
Video recordings of at least 2 minutes of oral feeding were analyzed by two assessors, and the premature infants observed to exhibit disorganized sucking patterns (n=109) were divided into three clusters (cluster 2, 3, and 4), and further divided into incoordination positive (cluster 4) and incoordination negative groups (clusters 2, 3).

Results
Premature infants in the incoordination positive group showed a median transition time of 22 days (range: 4-121 days) which was longer than that in the incoordination negative group (arrhythmic and/or unable to sustain sucking pattern, median 6 days; range: 1-25 days). Univariate analysis revealed that the presence of incoordination among disorganized sucking patterns (NOMAS cluster 4 vs. clusters 2, 3), birth weight, TPN duration, NIPPV duration, the presence of moderate to severe BPD, pulmonary hypertension, sepsis, SGA, and NEC, are associated with the transition time to FOF.

Conclusion
When selecting premature infants to be treated with swallowing therapy, it is reasonable to perform treatment with the incoordination positive group described in the NOMAS, that is, premature infants with stress signals to shorten the time to attain full oral feeding.

Keywords

⁵Ibaraki Prefectural University of Health Sciences, Department of Pediatrics, Ami-machi- Inashiki-gun, Japan
⁶University of Tsukuba, Department of Orthopaedic Surgery, Tsukuba, Japan

Introduction/Background

The purpose of this study was to examine the safety and immediate effect of gait training using Hybrid Assistive Limb (HAL®, CYBERDYNE) for participants with cerebral palsy (CP).

Material and Method

Twenty CP patients participated in this study (15 males and 5 females, mean age: 15.0±6.3 years, 19 spastic CP; 1 athetosis CP. Gross Motor Function Classification System (GMFCS) levels of I : 4, II : 3, III : 9, and IV: 4). A single time gait training for 20 minutes using HAL were performed. The safety and the immediate effect of walking training using HAL were evaluated. The outcome of the immediate effect was gait speed and mean step length, cadence before and after the training.

Results

Two participants were too short stature and excluded because they were not in size with HAL. Eighteen participants performed gait training using HAL, and there were no serious adverse events during gait training using HAL. Fourteen participants were able to walk on the ground, and walk evaluation was performed before and after gait training using HAL. Statistically significant improvement in gait speed (0.71±0.35 m/s; before vs 0.83±0.45 m/s; after, p < 0.05) and mean step length (0.44±0.12 m; before vs 0.47±0.13 m; after, p < 0.05) were observed.

Conclusion

The gait training using HAL to CP can be safe and immediate effects admitted.

³Chiba Prefectural University of Health Sciences, Occupational Therapy, Chiba, Japan
⁴Kagawa Prefectural Shirotori Hospital, Occupational Therapy, Kagawa, Japan
⁵Prefectural University of Hiroshima, Occupational Therapy, Hiroshima, Japan
⁶Meijiro University, Graduate School of Rehabilitation, Tokyo, Japan

Introduction/Background

In recent years the sensory integration therapy (SIT) is used to treat children with developmental disorders in Japan. The play that is the occupational form with the meaning for children is offered in SIT and its aim is the solution to the problem of children. Often children with developmental disorders have problem on communication with other people. Therefore we measured changes in the state of communication and interaction skills in children with developmental disorders before and after SIT using the Assessment of Communication and Interaction Skills (ACIS).

Material and Method

The participants were 19 boys with developmental disorders from 4 to 6 years old. The intervention frequency was from once a week to once a month and intervention period was six or three months. 10-minutes treatment scene was observed and ACIS was marked by more than three occupational therapists. Statistical analysis was performed Wilcoxon signed-ranks test by using SPSS Statistics Ver.20. This study was carried out with approval of the Tokyo Metropolitan University Arakawa Campus Institutional Review Board (#13075).

Results

As for the ACIS % value before SIT was 80.4%±10.1SD, and the after SIT was 86.1%±8.5SD. There was meaningful improvement (p=.028). Also in each area of ACIS, “exchange of information” % value before SIT was 80.4%±10.1SD, and the after SIT was 86.1%±8.5SD. It was meaningful improvement (p=.041).

Conclusion

It was shown that the meaningful improvement in "ACIS total % value" and "exchange of information % value" at before and after SIT intervention. It was suggest that SIT has potential
improved the state of the communication and interaction skills in children with developmental disorders. This study was partially supported by JSPS Grant in Aid for Scientific Research (#26350629).

**Introduction/Background**

We conducted a survey regarding the after-school childcare acceptance rate of elementary school students with developmental disorders and the support needs of occupational therapists who could serve them.

**Material and Method**

Subjects comprised 261 after-school childcare facilities in the Miyagi prefecture, including disaster areas following the 2011 earthquake that occurred off the Pacific coast of Tohoku. Of these, only 140 facilities (54%) responded. Numerical data are presented using descriptive statistics. We used a text mining approach for free description. This study was supported by the Welfare and Medical Service Network System. The author declares no conflicts of interest.

**Results**

There were 7764 enrolled subjects (age, 7–12). Of these, 287 (3.4%) subjects had diagnosed developmental disorder. On an average, there were 2.1 students with developmental disorders per facility. Breakdown by diagnosis revealed the following: physical disability (0.7%), mental retardation (0.4%), attention deficit hyperactivity disorder (1.3%), learning disorder (0.3%), Autism spectrum disorder (0.7%), and disaster-related post-traumatic stress disorder (0.01%).

In tsunami disaster areas, 3.5% students had developmental disorders, which is a closely identical rate compared with that of inland areas. Approximately, 24% of the after-school childcare facilities had care workers trained in disability care procedures, 50% provided consultation services, and 15% provided on-site guidance through rehabilitation specialists. Many of the facilities sought some practical guidance on care.

**Conclusion**

Our results suggested a clear need for occupational therapy support services within after-school childcare facilities in the Miyagi prefecture.

CURRENT SITUATION OF EDUCATIONAL GUIDANCE FOR STUDENTS WITH DEVELOPMENTAL DISORDERS IN ORDINARY CLASS OF JUNIOR HIGH SCHOOL - SURVEY OF DIFFICULTIES OF TEACHERS -

A. Urano\textsuperscript{1}, Y. Ito\textsuperscript{1}, Y. Ishibashi\textsuperscript{1}, R. Kobayashi\textsuperscript{1}

\textsuperscript{1}Tokyo Metropolitan University, occupational therapy, Arakawa city, Japan

Introduction/Background

The Ministry of Education, Culture, Sports, Science and Technology have mentioned of necessity to positively respond to students who need special educational support. Intervention by medical professionals is considered necessary for junior high school students who have developmental disabilities (or are supposed to be) (hereinafter referred to as junior high school students with characteristics of developmental disorders), while intervention in junior high school students with characteristics of developmental disorders There are very few previous studies of focused occupational therapy intervention. Therefore, in this research, we concretely conducted a questionnaire survey on what teachers felt by teaching the learning and behavioral aspects of junior high school students with characteristics of developmental disability.

Material and Method

Recruitment was carried out two public junior high school locate in Tokyo through authors’ networks. The data was gathered by questionnaire which had four questions; 1) years of experience as a junior high school teacher, 2) experience of engaging in special support education, 3) experiences in teaching students with developmental disorders, 4) difficulties felt on teaching students with developmental disorders by freedom describe.

Results

18 teachers participated voluntary. 6 teachers had worked over twenty years. 10 teachers used to work at special support education facilities. 13 teachers had not experienced teaching for students with characteristics of developmental disorders. Difficulties felt on teaching students have been divided into 9 categories such as difficulties to communicate, difficulties to proceed education.

Conclusion
[Conclusion]

These findings suggested the needs of assistance for teachers by health profession.

Keywords

In our hospital are the premature and risk new born babies by the Bayley-III test monitored and the therapeutic needs and trends are defined by the results of this test.

After monitoring over 40 very low birthweight premature babies, we came to the conclusion, that in this population almost all of the children had shown quantitative and/or qualitative developmental delay despite the age correction, for examples: attention deficit, motor skill disorders, fine motoric clumsiness delayed speech development.

**Material and Method**

We started a half-year pilot program in advance of these babies. Our goal was to observe how much does a “complex intensive interval” therapy helps the development of such babies.

Over the course of the project we have monitored the development of 23 children between the age of 6 to 30 months. To define the overall progress they made, we used the Bayley-III test both in the beginning and at the end of the program.

Based on the detected diseases, we have set up a complex personal developmental program that includes elementary coordination and sensomotoric therapies in individual, special education and small group sessions. As far as the parents are concerned, we provided the possibility of psychological counselling. During this half-year period, the children participated in two-week long daily trainings twice.

**Results**

x

**Conclusion**

The complex intensive interval therapies proved to be more efficient: out of 65 percent of all the participants, we experienced a surprising progress concerning several fields. Many of the children who were non-cooperative due to their attention deficit disorder became objectively examinable. Another hypothesis was successfully proven: it is advisable to use educational and sensomotoric therapies besides coordination therapies even from the age of 6 months.
Nevertheless, it can clearly be seen, that a disadvantageous social-economic status slows down the development of these risk new born babies.

THE PREVALENCE OF EPILEPSY IN A MALARIA ENDEMIC REGION OF KENYA

R.N. Mbugua

Nairobi University- Kenyatta National Hospital- Kenya Network of Women Living with HIV/AIDS, Research and Community Health Worker, Nairobi, Kenya

Introduction/Background

Epilepsy is the most common chronic neurological disorder and is one of the world's most prevalent non-communicable disorders. There are few studies in Kenya. Epilepsy is thought to be more prevalent in Africa, because causes such as birth trauma and infections are common.

Material and Method

However, there are few reports examining the relationship between malaria and epilepsy in endemic areas. My colleagues and I conducted a cross-sectional survey to detect active convulsive epilepsy in an area, with differing malaria transmission in the Kilifi District on the Coast of Kenya. I set out to determine the prevalence and risk factors of active convulsive epilepsy and examine the association between the epilepsy and malaria transmission in this area. Active convulsive epilepsy (ACE) was defined as 2 or more unprovoked convulsions, or which one occurred within the last year, whether or not treatment was being given, since this is the criterion for treatment in Kenya.

Results

The prevalence or epilepsy was 3.5 per 1000 inhabitants at risk, 3.8 per 1000 for males 3.3 per 1000 [or females. The highest age-specific prevalence was round 101 age's 11-20 years. Generalized tonic-clonic seizures were the predominant seizure type and occurred in 70.4% of subjects. However focal seizures accounted far 75.5% or the seizures when second and third seizures were included. History or head trauma, intrapartum and perinatal complications, family history of febrile seizures, history of a widowed mother and family history of seizures in first-degree relatives and also extended family were associated with a risk or developing epilepsy.

Conclusion

The study indicates that the prevalence rate of active epilepsy in our study is comparable to that in other well conducted community based studies in Africa and in the western countries. Strongly independent association between five factors and the risk of"epilepsy was noted.

INFLUENCING WALKING SPEED AND ENERGY EFFICIENCY WITH AFO-FC TUNED IN THE CLINIC, IN CHILDREN DIAGNOSED WITH CEREBRAL PALSY

S. Ron¹,², M. Katz-Leurer², A. Mimouni-Bloch¹,³
¹Loewenstein Hospital, The Pediatric Neurology and Developmental Unit, Raanana, Israel
²Tel Aviv University, Physical Therapy Department- School of Health Professions- Sackler Faculty of Medicine, Tel Aviv, Israel
³Tel Aviv University, Sackler Faculty of Medicine, Tel Aviv, Israel

Introduction/Background

Ankle Foot Orthoses (AFO) are common in cases of gait abnormalities. Research has shown that AFO-footwear combinations (AFO-FC) improve kinetics and kinematics. Heel height increment aims to change shank inclination in order to improve stability. Tuning of AFO-FC is recommended but is not routine, due in part to lack of access to gait laboratories. Aims- To introduce a reproducible method for tuning AFO-FC in the clinic and to assess the effect of these AFO-FC on walking speed and energy efficiency following two months of daily walking, in children with cerebral palsy (CP).

Material and Method

Patients- Eight children diagnosed with CP, 3-7 years old, walking with or without aids, using fixed AFO.

Tools– Pulse sensor watch and strip, digital camera, 6 Minute Walk Test (6MWT).

Tuned shoes were made. At baseline, the children underwent a 6MWT with their regular AFO and shoes. In the following month, they practiced a daily walk with their regular shoes and AFO. At the end of the first month, 6MWT was done with regular shoes and AFO and with the AFO-FC. In the second month, the children practiced daily walk with their AFO-FC. At the end of the second month, they performed the 6MWT in both sets of shoes.

Results

At baseline, median walking distance in 6MWT was 100 meters [range- 58-245], median physiologic cost index (PCI) value of 1.8 heart-beat/meter [range 0.4-2.6]. Walking with AFO-FC as compared to walking with AFO and regular shoes, showed significantly increased distance (mean difference of 17 meters, confidence interval (95%) 2-32 meters). All but one patient showed significant improvement in PCI values (mean values 0.82 times lower than baseline, confidence interval (95%) 0.72-0.92). Improvement in PCI values - between 4% to 45%.
Conclusion

AFO-FC tuned in the clinic, can significantly improve walking speed and energy efficiency in some cases following training.

CEREBRAL PALSY: ABOUT 105 CASES IN IMP MUTWENZI AND AKAMURI PEDIATRIC REHABILITATION CENTERS (BURUNDI).
A. Sinzakaraye², J.C. Hakizimana¹, P. Barasukana², L. Nzisabira³
¹National Reference Center for Physiotherapy and Medical Rehabilitation, Physical and Rehabilitation Médecine, Bujumbura, Burundi
²University of Burundi- Faculty of Medicine, Physical Medicine and Rehabilitation department, Bujumbura, Burundi
³University of Burundi- Faculty of Medicine, Neurology, Bujumbura, Burundi

Introduction/Background
Describe epidemiological, clinical and therapeutic aspects of cerebral palsy in children undergoing rehabilitation in a country with low income.

Material and Method
This descriptive study concerns patients with cerebral palsy aged from 0 to 15 years who received rehabilitation care in the two main pediatric rehabilitation centers in Burundi (IMP Mutwenzi and Akamuri) from March 1, 2016 to February 28, 2017.

Results
During the study period, 105 cases of children with cerebral palsy out of 559 patients were reported (54 cases from IMP Mutwenzi and 51 from Akamuri), representing 18.78%. The mean age was 49.49 months, with a sex ratio of 1.14 (males representing 53.33%). Firstborns children were the most represented (31.43%). A high number of children with cerebral palsy (70.47%) were brought to rehabilitation centers without any medical reference. At the time of admission, 39.04% were aged from 1 to 2 years, 30.47% from 2 to 3 years and 20.95% from 3 to 5 years. The most present clinical signs were spastic tetraplegia (42.85%), hypotonia (20.00%), spastic diplegia (19.04%), athetotic hemiplegia (15.23%), quadriplegia athetosis (13.33%) and ataxia most associated to athetosis and diplegia (8.57%). Associated disorders mainly concerned language disorders (70.48%) followed by epileptic disorders at 11.43%. The care protocol was mainly based on physiotherapy (all patients), occupational therapy (59.05%), orthopedic treatment (15.24%), speech therapy (37.14%), anti-epileptic treatment (64.76%) and education (25.93%).

Conclusion
Cerebral palsy (CP) is a public health problem with a high predominance of several cases. A number of difficulties linked in part to the late detection of deficiencies and the lack of medical reference in rehabilitation structures, are among the main factors limiting access to care for children with cerebral palsy in these centers.

THE EFFICACY AND SAFETY OF BOTULINUM TOXIN TYPE A INJECTION FOR CERVICAL DYSTONIA IN ADULTS WITH ATHETOID CEREBRAL PALSY
Y.G. Yi¹, M.S. Bang¹, H.I. Shin¹
¹Seoul National University Hospital, Rehabilitation Medicine, Seoul, Republic of Korea

Introduction/Background

The main purpose of this study is to evaluate the efficacy and safety of injecting Botulinum toxin A (BoNT-A) into the neck muscles to treat cervical dystonia (CD) in patients with dyskinetic cerebral palsy (CP).

Material and Method

This is a randomized, double-blinded, placebo-controlled trial with cross-over design. We prospectively enrolled adults with dyskinetic CP who were over 20 years old and had been clinically diagnosed with CD for more than one year. Patients were assessed using the Toronto Western Spasmodic Torticollis Rating Scale (TWSTRS) and the Numerical Rating Scale (NRS).

Results

Seventeen patients were initially enrolled, but one patient was excluded after the final evaluation because of a violation of the study protocol. At 4 weeks, the BoNT-A injections showed significant improvement in TWSTRS total scores compared to the saline injections (p=0.0286 for ANCOVA). At 12 weeks, the BoNT-A injections resulted in greater improvements in TWSTRS total scores than the saline injections but this difference was not statistically significant (p=0.0783 for ANCOVA). Dysphagia occurred in 3 out of 16 patients; 2 after BoNT-A and 1 after saline. The dysphagia was transient and improved naturally within 2 weeks without any special treatment.

Conclusion

Botulinum toxin injection for cervical dystonia in adults with dyskinetic cerebral palsy is relatively safe and improves pain and disability.

SPASTIC CEREBRAL PALSY: A LEVEL 2 HOSPITAL’S PMR DEPARTMENT EXPERIENCE
P.D. Silva¹, T. Teófilo¹, S. Carvalho¹, B. Jardim¹
¹Funchal Central Hospital, Physical Medicine and Rehabilitation, Funchal, Portugal

Introduction/Background

Cerebral palsy (CP) is the most common cause of physical disability in early childhood, rating between 2 and 3 per 1000 live births. The treatment of spasticity in children with spastic CP (SCP) is central in the clinical management of these patients. The botulinum toxin serotype A (BTX-A) application together with other conservative therapies have several advantages over invasive treatments in the management of younger patients. The authors aimed to characterize all pediatric patients followed in their level 2 hospital’s PMR department.

Material and Method

Review of all clinical processes of all children born between 01/01/2001 and 31/12/2010 who were diagnosed with CP in the authors’ hospital. There were excluded all patients without sufficient clinical information to categorize the CP and/or who were not being accompanied in the authors’ hospital.

Results

There were identified 54 patients diagnosed with CP in the 10 years span, remaining 47 patients after exclusion criteria. Of these, 24 are females and 23 are males. A total of 85% (n=40) patients have SCP, of which 52.5% (n=21) are quadriplegic, 27.5% (n=11) are diplegic and 20% (n=8) are unilateral. Regarding function 10% (n=4) of patients belong to the GMFCS grade I and 20% (n=8) to the GMFCS grade V. A total of 42 patients are followed in the authors PMR department, of which 93% (n=39) are complying in rehabilitation programs and 86% (n=36) patients are submitted to BTX-A administration.

Conclusion

Regular characterization of patients with CP in any department is of critical importance, as it allows an objective evaluation of their clinical management and therapeutic modalities (including BTX-A) as compared to the literature and other centers.

NEONATAL RISK FACTORS IN CEREBRAL PALSY

C. Chueluecha¹, W. Deeprasertdamrong¹, R. Neekong¹, N. Bamroongya⁰
¹Faculty of Medicine- Thammasat University- Thailand, Department of Rehabilitation Medicine, Bangkok, Thailand

Introduction/Background

Cerebral palsy (CP) is a movement disorder caused by damage to the developing brain. It affects patient self-help, creates family problems, and increases care costs. CP has many risk factors, although the trigger is often unclear, resulting in treatment delays and permanent complications. To improve monitoring and early diagnosis, a study to establish total risk factors for predicting cerebral palsy in the neonate is a useful study especially for patients in small hospitals who do not have specialized doctors.

Material and Method

A case-control study of CP risk factors in neonate, born at Thammasat University Hospital, Thailand from 2005 to 2014. Using multivariable logistic regression, neonatal and maternal characteristics, as well as prenatal, perinatal and postnatal risks, were compared in normal children (control) and patients diagnosed with CP (case).

Results

These risks and evidence of difference (p-value) are in Table 1 and 2; CP independent risk is in Table 3. Cerebral and non-cerebral malformation, small for gestational age, preterm, multifetal gestation, neonatal jaundice, and non-congenital infections of neonatal infants were risks, with odds ratio (OR) = 313.03, 16.45, 5.67, 8.45, 11.39, 10.99 and 147.87, respectively.

</tbody>
</table>
Conclusion

Cerebral and non-cerebral malformation, small for gestational age, preterm, multifetal gestation, neonatal jaundice, and non-congenital infections of the neonatal infants were predictive risks. However, low Apgar score, uterine and cord anomalies, neonatal seizure, neonatal encephalopathy, congenital infections, and ventilator use remain questionable with low incidence. Multicenter research to enhance data scope would be useful.

EFFECT OF EXTRACORPOREAL SHOCK WAVE ON MUSCLE SPASTICITY IN PATIENTS WITH CEREBRAL PALSY: META-ANALYSIS AND SYSTEMATIC REVIEW.

K. Nam¹, Y. Jo¹
¹College of Medicine- Dongguk University, Departments of Physical Medicine & Rehabilitation, Goyang-si, Republic of Korea

Introduction/Background

Background and aims: Recently, clinical trials have been performed to evaluate the efficacy of extracorporeal shock wave therapy (ESWT) in patients with cerebral palsy (CP). However, each study adopted different clinical scales that were insufficient to draw a definite conclusion about the efficacy of ESWT in reducing spasticity after cerebral palsy. The purpose of this meta-analysis was to assess the effects of ESWT on reducing spasticity after application of ESWT in patients with CP.

Material and Method

Methods: We searched MEDLINE, EMBASE, Web of Science, Cochrane Central Register of Controlled Trials and Scopus from their inception dates through December 11th 2017. The key words “muscle hypertonia OR spasticity” were used for spasticity, and the key words “shock wave OR ESWT” were used for ESWT.

Results

Results: Five studies were ultimately included in the meta-analysis. The Modified Ashworth Scale (MAS) grade, primary outcome was significantly improved immediately after ESWT compared with the baseline values (mean difference [MD], −0.64; 95% confidence interval [CI], −1.00 to −0.27). The ROM after ESWT was also significantly improved compared with the baseline values (MD, 17.91; 95% CI, 8.22 to 27.60). The pedobarometric measures, secondary outcome showed significant increases in the peak pressure under the heel (MD, 27.93; 95% CI, 9.90 to 45.96), and of the foot contact area (SMD, 8.83; 95% CI, 0.95 to 16.71) immediately after treatment.

Conclusion

Conclusions: ESWT may be a valid alternative to existing treatment options targeted at spasticity diminishment and ROM improvement in CP patients. Further standardization of treatment protocols including treatment intervals and intensities needs to be established and long-term follow up studies are needed.

FASCICULAR MOTOR NEUROTOMY ASSOCIATED TO SINGLE EVENT MULTILEVEL SURGERY IN CEREBRAL PALSY. A LONG-TERM REVIEW WITH GAIT ANALYSIS

Z. Bérénice¹, B. Dohin²

¹University Hospital of Saint-Etienne, Physical Medicine and Rehabilitation, Saint-Etienne, France
²University Hospital of Saint-Etienne, Pediatric Surgery, Saint-Etienne, France

Introduction/Background

The aim of this study is assessment of functional benefits after multilevel surgery associated with selective partial neurotomies, focusing on rectus femoris (RF), semitendinosus and semimembranosus muscles (medial hamstring MH) and the function of hip and knee joints.

Material and Method

This is a series of patients who had multilevel surgery associated with selective neurotomy on RF, MH between 2009 and 2016. Clinical data were knee range of motion and Modified Ashworth Scale for RF and MH, energy expenditure index and Gross Motor Function Measure. Gait analysis data were speed, cadence, step length, time of stance phase, articular range of motion and articular moment on hip and knee flexion. Gait deviation index (GDI) and gait profile score (GPS) were calculated. All data were collected before surgery, and at last gait analysis follow-up available for each patient.

Results

34 patients were included. The average time assessment after surgery was 33.35 months +/- 13.8. There is significant improvement of GDI and GPS, respectively from 74.2 +/- 11.6 to 79.7 +/- 8.2 (p = 0.010) and from 11.54 +/- 4.1 to 9.5 +/- 2.5 (p = 0.005). Knee flexion decreased at body weight acceptance phase: 30.8 +/- 9.9° to 24.7 +/- 6.6° (p = 0.006). Maximum joint moments were closer toward normality at knee on 55% of gait cycle: 0.2118 +/- 0.25Nm/kg to 0.1119 +/- 0.14Nm/kg (p = 0.003), at hip on 10% of gait cycle: 0.1261 +/- 0.39Nm/kg to 0.4419 +/- 0.32 Nm/kg (p = 0.004) and for knee flexion at 95% of gait cycle: 0.1340 +/- 0.45Nm/kg to 0.1883 +/- 0.068Nm/kg (p = 0.005). GMFM (E item) increased from 75.39 +/- 30.3% to 78.84 +/- 27.8% (p = 0.009).

Conclusion

There is clinical and functional benefits. GDI and GPS were improved after procedure combining single event multilevel surgery with neurotomy. Moreover, kinematics of gait cycle is improved particularly at the beginning of gait cycle.

SURVEYING A DECADE OF PREVALENCE, CHARACTERISTICS, AND MANAGEMENT OF CEREBRAL PALSY IN THAILAND

R. Neekong¹, C. Chueluecha¹
¹Thammasat University, Department of rehabilitation and medicine, Patumthani, Thailand

Introduction/Background

Cerebral palsy (CP) is a movement disorder caused by damage to the developing brain. It affects self-help, family dynamics and care costs. Data is lacking on its characteristics and management in Thailand and may help in improving care and awareness of consequences in treatment delay.

Material and Method

Prevalence, characteristics, management, and rehabilitation data were collected from a total of 50 CP patients, born at Thammasat University Hospital, Thailand from 2005-2014.

Results

CP incidence was 1:1000 live births with levels rising (Figure 1). There was no significant difference in gender (52% male) or in full-term versus preterm birth (48.8% preterm). Among the preterm, 22.45% had a gestational age of 32-36 6/7 weeks; 89.58% had spasticity as the most common motor control abnormality, while 72.34% showed diplegia most affecting limbs (Table 1). Age at first diagnosis averaged 11.79 months with 33.33% ranked at high level IV (Table 2), using the Gross Motor Function Classification System (GMFCS); 50% of diagnoses were from hypertonia, followed by 23.17% from delayed development. Time post-diagnosis to first treatment averaged 4.12 weeks, and time after diagnosis before rehabilitation was 7.66 weeks, with 6.09 weeks before visiting a rehabilitation team (Table 2).

Conclusion

With the CP rate rising steadily annually, diplegic spasticity remains the most common symptom. Age for diagnosis was around one year, with GMFCS reflexes showing high disability, hypertonia being the major diagnostic clue. Delays hindered the start of rehabilitation treatments. To improve treatment and outcome, early surveillance and multidisciplinary team management are indicated.

Interests of Medical Treatment in Several Orthopedics Disorders of Lower Limbs for Children with Spastic Cerebral Palsy

M.D.E. Mammari¹, K.E. Dib¹, A.M.L. Belfodil¹

¹Military Hospital of Oran, Physical and rehabilitation medicine, Oran, Algeria

Introduction/Background

The main objective of this study is to show the interest of medical treatment in several orthopedics disorders of lower limbs for children with spastic cerebral palsy.

Material and Method

Descriptive study, from June 2012 until March 2017, n=18 children with spastic cerebral palsy and several deformities of lower limbs. All the cases received 3 injections (1 injection/ trimester) of botulinum toxin A, associated with stretching exercises, and prescription if necessary of lower limb orthosis. The time of follow-up was 2 years/patient. Evaluated by: Aschworth scale, functional assessment, moving from bed to chair and from chair to standing position, and a 6-minute-walk test.

Results

Initially, all the cases presented lower limbs spasticity and without any autonomy, 60% with diplegia, 30% tetraparesis, 10% with hemiparesis form. After two years of follow-up; 70% improved their functional autonomy (p=0.01) and showed the best performance in moving from bed to chair and from chair to standing position. In the other hand, 50% of them, walked an average of 71 meters in the 6-minute-walk test.

Conclusion

The medical treatment of children with several orthopedics disorders of lower limbs and spastic cerebral palsy, provide a satisfy clinical and functional results. However, some cases had a difficulty to access the surgery, and to receive their orthosis. In conclusion, interdisciplinary treatment is pre-requisite, to complete the effect of botulinum toxin and physical treatment.

CLINICAL EFFECT EVALUATION AND EXPERIENCE OF MOTOMED VIRTUAL SCENE TRAINING COMBINED WITH ELECTROMYOGRAPHIC BIOFEEDBACK THERAPY IN THE TREATMENT OF SPASTIC CEREBRAL PALSY

G. Jing¹
¹hospital, children rehabilitation, Huai’an, China

Introduction/Background

Substantial evidence from clinical reports has established that most cerebral palsy (CP) patients benefit from a comprehensive rehabilitation exercise training programme. Such advances are enhanced when Motomed virtual scene training combined with electromyographic biofeedback therapy in the treatment of spastic cerebral palsy. However, little information exists regarding these effects.

Material and Method

Forty-eight children with spastic cerebral palsy were collected from 2014 to 2016 in children’s rehabilitation department of Huaian maternal and child health hospital. Among them, 25 cases were treated with MOTOmed virtual scene training combined with electromyographic biofeedback therapy, and 23 cases with single electromyographic biofeedback therapy. Before and after treatment, the Gross Motor Function Measure-88 (GMFM-88) was used to evaluate the gross motor function of all children, and Activities of Daily Living Scale (ADL) was used to evaluate and observe the activities of daily living of children.

Results

The scores of GMFM and ADL in the treatment and control groups were significantly higher than those before treatment ($p<0.05$). Before treatment, GMFM and ADL scores in the treatment groups were significantly higher than those in the control groups ($p<0.05$).

Conclusion

MOTOMed virtual scene training combined with electromyographic biofeedback therapy can effectively improve the gross motor function and activities of daily living of children with spastic cerebral palsy, which is obviously superior to electromyographic biofeedback therapy alone.

Introduction/Background

This study aimed to describe the three-dimensional lower limb bone morphology of ambulant children with CP according to the type of CP and to evaluate their relation to gait kinematics.

Material and Method

105 ambulant children with CP (3–17 years old) underwent a biplanar X-Rays (EOS system) from which was extracted a full 3D bone model of their lower limbs. Moreover each child underwent a quantitative gait analysis from which was extracted the Gait Deviation Index (GDI). The limbs were divided into 3 groups: the more impaired side of the bilateral CP children (Bilat-CP, n=48), the affected limb (Unilat-CP, n=57) and the non affected limb of the unilateral CP children (Control, n=57). The statistical analysis included a 2-factor analysis of variance (bone parameters and population), Principal Component Analysis (PCA) and focused PCA (fPCA).

Results

Growth parameters (length) were most prominent factors of bone morphology compared to other morphological characteristics. The Neck-Shaft Angle (NSA) was significantly greater (+3.6°) in the Unilat-CP group in comparison with the Control group and the Femoral Torsion (FT) was significantly greater in the Bilat-CP group (+ 10.4°) in comparison with the Control group. Other 3D parameters were not significantly different among the 3 groups. fPCA centered on GDI showed no strong correlation between GDI and lower limb bone parameters, regardless of CP Type.
Table n°7: Morphologic parameters and 24 bone parameters comparison between 3 groups and GMPCS

| Table n°7: Focused Principal Component Analysis |

Control Group  | Unilat-CP Group | Bilat-CP Group |
---|---|---|
Focused Principal Component Analysis based on 14 lower limb bone parameters. Closer the variable is to the centre, stronger the correlation with GDI is important. Red Circle: Lower Correlation with significance at 0.05. Green Variable: positive correlation with GDI. Yellow variable: negative correlation with GDI.

Conclusion

These data suggest the existence of specific loading issue inducing specific bone deformities depending on the CP type. However at the group level, the most determinant factor of the bone...
morphology of ambulant children with CP is the bone size in relation to growth. The poor relation between bone morphology and GDI incites to explore the link between specific bone parameters and specific gait parameters.

Impact of Lower Urinary Tract Dysfunction and Anorectal Disorders on Quality of Life in Children with Cerebral Palsy

J. Beaufils¹, C. Olivari-Philiponnet¹, T. Honoré¹, R. Heyman¹, I. Bonan¹, H. Rauscent¹
¹CHU Rennes, Department of Physical Medicine and Rehabilitation, Rennes, France

Introduction/Background

The objective is to describe lower urinary tract and anorectal disorders in children with cerebral palsy (CP) and evaluate their impact on quality of life (QoL).

Material and Method

Ten months monocentric prospective study about 5 to 17 years old children with CP. Datas collected were: CP type, GMF-CS level, Wee-FIM, MACS level, voiding and defecation diary, standard questionnaire, Akbal questionnaire, WPPSI-3 or WISC-4, parents and children Kidscreen-52 scale.

Results

Between October 2014 and July 2015, 24 children from 5 to 17 years old were included.

23 children (89%) had lower urinary tract dysfunction. 21 from those 23 were in normal school. 6 had a pollakiuria, 5 a nycturia, 20 an urgenturia (in which 11 had urinary incontinence (UI)), 9 a dysuria, 2 a urinary infection, 12 a UI (6 day and night UI, others only day UI).

7 children going in normal school had a fecal incontinence (3 day and night, others only day). Urinary incontinent children Wee-FIM scores were lower than non-urinary incontinent ones (p=0,007).

7 children with a low GMF-CS level and going in normal school had an impact of their lower urinary tract disorders on their QoL. All had an overactive bladder syndrome, 3 a dysuria, 2 a nycturia, 1 a pollakiuria. Kidscreen-52 QoL score estimated by children with UI were significantly different than non-urinary incontinent ones (p=0,0264).

Conclusion

This study shows the importance of lower urinary tract and anorectal disorders impact on children with CP QoL. Most of those children are in normal school. Detection is not systematic enough during follow up consultations and parents often underestimate those troubles. Questioning and flow measurement seem to be important first steps to detect them.

Keywords
Cerebral palsy; lower urinary tract dysfunction; Anorectal disorders

No conflict of interest
Health-related quality of life (HRQOL) is especially relevant to conditions that are chronic and disabling such as cerebral palsy (CP) and in children, it includes concepts of illness, functional status, mental health, comfort, parental impact and family functioning. This study was conducted to assess the HRQOL in children with physically and mentally disabled cerebral palsy and to determine the factors which is affecting it.

Material and Method

The demographic data of the children were recorded (cause of CP, type, frequency of seizures, caregiving, etc.). Participants were classified using the Gross Motor Functional Classification System scores (GMFCS). Resistance during passive soft-tissue stretching (The Modified Ashworth scale-MAS) and health-related quality of life (The Pediatric Quality of Life Inventory-PedsQL) were evaluated.

Results

A total of 50 (25 girls, 25 boys) participants, with a mean age of 15.08±2.07 year (range:12-18) and mean body mass index 19.72±3.84 kg/m² (range: 11.43-28.13) were enrolled the study. Forty-eight per cent (24/50) had quadriplegic CP, 18% (9/50) hemiplegic, 22% (11/50) diplegic, 4% (2/50) dyskinetic, and 8% (4/50) ataxic–hypotonic CP. GMFCS levels was as follows: 10% (5/50) Level I, 18% (9/50) Level II, 26% (13/50) Level III, 20% (10/50) Level IV and 26% (13/50) Level V. The increase in GMFCS level and MAS score negatively affects PedsQL score. Quality of life declined as the frequencies of seizures increased (p<0.05).

Conclusion

Present abilities and limitations of the child in gross motor function, spasticity level, cause of CP, presence of epileptic seizure are affect the HRQOL negatively. Also, the increase in total daily caregiving time is assosiated with decline in HRQOL of this children. We think that integrated multidisciplinary approach can be used to improve quality of life of children with cerebral palsy.

Introduction/Background

Cerebral Palsy (CP) describes a group of permanent disorders of the development of movement and posture, causing activity limitation, attributed to non-progressive disturbances that occurred in the development of fetal or infant brain. Motor rehabilitation (MR) constitutes a base to the management of people with CP.

In the absence of French reference guidelines, advocacy groups have reported difficulties with access to convenient and quality physiotherapy services. The aim of this study was to identify perceived unmet needs and expectations about motor habilitation/rehabilitation of children, adolescents and adults with cerebral palsy.

Material and Method

A collaborative survey was designed and led by advocacy groups with the support of scientific societies in France. Persons with cerebral palsy or their families, reached through local and national associations and professional networks, compiled a web-based or mail-in questionnaire (June/2016-June/2017) and 1010 responses were collated on 354 children, 145 adolescents and 511 adults, (46% females).

Results
52% were ambulant (GMFCS I-III) and 91% had physiotherapy at time of completing the questionnaire. The most highly perceived unmet needs were to improve communication between professionals for appropriate follow-up (79%), to feel free to ask questions (78%), and to be involved in the decision-making process regarding therapies (61%). The most important reported difficulties were to find a physiotherapist trained in CP (51%) or available (39%), and to integrate physiotherapy sessions in the personal/family schedule (34%). The most frequent expectations were about physiotherapist training (79%), information on health care and recommended exercises (75%), and access to rehabilitation centres/physiotherapists (70%); 50% reported high to very high expectations regarding motor rehabilitation methods different from those currently received.

**Conclusion**

Persons with cerebral palsy and their families identified unmet needs and expectations regarding motor rehabilitation that should be taken-up by practitioners, health care managers and policy makers, and practice guidelines developers.

CORRELATION BETWEEN THERAPEUTIC INTENSITY OF REHABILITATION AND FUNCTIONAL IMPROVEMENT IN CHILDREN WITH CEREBRAL PALSY
S.Y. Kim¹, M.H. Moon¹, S.C. Huh¹, S.H. Ko¹, Y.B. Shin²
¹Pusan National University Yangsan Hospital, Department of Rehabilitation Medicine, Yangsan, Republic of Korea
²Pusan National University Hospital, Department of Rehabilitation Medicine, Pusan, Republic of Korea

Introduction/Background

In clinically, rehabilitation therapy is focused on functional improvement in mild to moderate cerebral palsy (CP) patients. In severe cases, postural management is one of the target goals. Therapeutic intensity is various in each patients and optimal intensity is still unclear. The aim of this study is to assess relation between therapeutic intensity of rehabilitation therapy and functional improvement in CP patients.

Material and Method

Participants were 39 children with spastic CP. We divided participants into two groups based on initial Gross Motor Function Classification System (GMFCS) level, as mild to moderate groups with GMFCS 1 to 3, and severe groups with GMFCS 4 and 5. We also divided subjects into three groups based on intensity of therapy. We defined low intensity as less than 7 sessions (30 minutes of therapy per session) per week, intermediate intensity as 7 to 14 sessions per week and high intensity as over 14 sessions per week. Gross Motor Function Measure (GMFM) and Pediatric Evaluation of Disability Inventory (PEDI) (three domains of Self-care, Mobility and Social) were measured at initial and 6 months by qualified investigators.

Results

Statistically significant improvement was observed in GMFM scores and mobility scores of PEDI in mild to moderate group (p<0.05), self-care and social function sub-scores of PEDI in severe group (p<0.05) for 6 months. Rehabilitation therapy with high intensity showed gross motor function improvement in mild to moderate group. In severe group, high intensity therapy showed improvement of self-care and social function than gross motor function in same duration.

CP: cerebral palsy; GMFM: Gross Motor Function Measure; PEDI: Pediatric Evaluation of Disability Inventory, $p<0.05^*$
Conclusion

To our knowledge, high intensity rehabilitation could make more functional and postural improvement in CP patients. However, there are many variables such as age, GMFCS level, type of CP, medical condition, comorbidities and etc. Consideration about optimal intensity of rehabilitation therapy according to severity of disease is needed in further study.

EFFECTS OF BOTULINUM TOXIN AND/OR ETHANOL INJECTIONS ON BALANCE AND WALKING IN CHILDREN WITH CEREBRAL PALSY: A PROSPECTIVE STUDY
A. Blanchard¹, K. Dimitropoulou¹, L. Yoon¹, D. Krasinski¹, S. Agrawal², A. Newell¹, H. Kim¹
¹Columbia University Medical Center, Rehabilitation & Regenerative Medicine, New York, USA
²Columbia University, Mechanical Engineering, New York, USA

Introduction/Background

Muscle spasticity in children with Cerebral Palsy (CP) is a major cause of disability and leads to a decrease in physical function due to contractures, muscle weakness, and limited joint range of motion. Single event multi-level chemoneurolysis (SEMLC) with botulinum toxin and/or ethanol has been shown to decrease muscle spasticity, however there is a concern for muscle weakness and decrease in muscular endurance after injection. Therefore we aimed to examine the effects of SEMLC with botulinum toxin and/or ethanol on static balance and several walking tasks in children with CP.

Material and Method

Timed Up and Go (TUG), 6 Minute Walk (6MW), timed up and down four steps, and three static balance tests were measured in nine children (33% female, 44% diplegia, 56% hemiplegia) with CP [mean ± SD; age, 10.1 ± 4.6 yr; Gross Motor Function Classification System (GMFCS), 1.6 ± 0.5] pre- and four weeks post SEMLC injection to target muscles determined by pediatric physiatrists. Paired samples t-tests evaluated differences in all walking and balance tasks pre- to post- SEMLC injection.

Results

There was no difference in pre- to four weeks post SEMLC injection in mean TUG (8.8 ± 1.9 seconds; 8.5 ± 1.6 seconds, p=0.605), 6MW distance (338.9 ± 54.2 meters; 336.7 ± 63.0 meters, p=0.908), stair climbing (11.5 ± 6.4 seconds; 10.9 ± 5.6 seconds, p=0.195), or static balance scores for feet together (p=1.000), tandem stance (p=0.466), and one-leg stance (p=0.195), respectively.

Conclusion

Even though physical function did not improve, we saw no deterioration in endurance or functional muscular strength four weeks after receiving SEMLC with botulinum toxin and/or ethanol in children with CP. Due to the increased popularity of chemoneurolysis, we must have ongoing clinical monitoring including test measures of balance and walking function to best understand the full scope of efficacy of SEMLC.

Material and Method

2 classifications were developed and 212 videos of CP-patients (118 for UL patterns and 94 for hands; median age 14, 3-46 years) were viewed by 19 examiners of 2 different rehabilitation centers, who identified the UL pattern (Type Ia, Ib, Ic; Type IIa, IIb, IIc; Type IIIa, IIIb) or the kind of hand (Flex simple, total or evolved; Punching intrinsic, superficialis or profundus), and twice by 18 examiners at 2 months interval.

Results

There was a very high intra-rater and inter-raters reliability for types (0.87<k<0.92), and a substantial agreement also for subtypes (0.58<k<0.68), for both classifications. Some specific errors of quotation could be explained. Examiners involved in the study found both classifications useful and feasible.

Conclusion

Examiners had been only shortly trained to using classifications, and both novice and experienced raters had good to high agreement, which confirms that these classifications are easy to use reliably. Details of disagreement can be used to improve further both classifications.

Introduction/Background

To describe coping strategies in children and adolescents with CP, and determine the effect of age on choice of strategy.

Material and Method

Patients were recruited from two pediatric rehabilitation centers in France. The PPCI-F (Pediatric Pain and Coping Inventory – french) and SPQ (Structured Pain questionnaire) were completed by an experienced professional with each child.

Results

142 patients were included (median age: 12, 5-19 years; 57% boys). Comparison of the means from the 4 factorial scales showed that children with CP generally used fewer coping strategies than TD children (seeking social support: 12.47 versus 12.85; cognitive self instruction: 9.28 vs 10.90; distraction: 4.89 vs 7.00; seeking effectiveness: 4.43 vs 5.19). Some coping strategies used by the children with CP depended on age (decrease in seeking social support and increase in cognitive self-instruction with age), while others did not (seeking effectiveness and distraction). The strategies were also influenced by GMFCS level (p=0.01), history of surgery (p<0.01), sibling rank (p<0.05), and pain reported in the SPQ (p<0.05).

Conclusion

Children with CP generally use fewer coping strategies than TD children although similarly to TD children, they mostly look for social support to cope with pain. Even if past experiences of pain suggest that coping strategies need to be changed, active coping strategies were only used in older children and remained less used than by TD children of the same age.

⁴Erasmus MC University Medical Center and Rijndam Rehabilitation Institute, Department of Rehabilitation Medicine, Rotterdam, The Netherlands

Introduction/Background

Adults with cerebral palsy (CP) experience difficulties in their participation. Knowledge on the course of difficulties in participation of individuals with CP emerging into adulthood could provide insight in this stage of participation development. We aim to describe the course of difficulty and independence in participation of individuals with CP from adolescence into the early thirties.

Material and Method

151 individuals with CP (63% male, Gross Motor Function Classification System [GMFCS] levels I-IV, without Intellectual Disability [ID]), of whom 98 completed a 13-year follow-up measurement, were included (379 observations, age range 16-34 years). Six domains of the Life Habits questionnaire were used up to three times biyearly and at 13-year follow-up. Scores (range 0-10) reflect difficulty and assistance in participation in housing, education & employment, interpersonal relationships, recreation, community life, and responsibilities. Multilevel models were used to determine the course of difficulty in participation by GMFCS level.

Results

Despite high average participation levels, 41 to 95% of adolescents and young adults with CP experienced difficulty. Difficulty in participation increased in most life areas in the mid- and late twenties, and for housing and interpersonal relationships from age 16 years onwards. In adolescents with GMFCS III and IV, difficulty in recreation and community life decreased up to age 23 years. Mean category scores reflected independent functioning (score >5.56) in all GMFCS levels over age 23 years.

Conclusion
Difficulty in participation of individuals with CP without ID increases in their mid- and late twenties. Notwithstanding high participation levels on average, a substantial part of individuals with CP emerging into adulthood experience difficulty in participation. Systematic screening and timely support may improve the development of optimal participation of young adults with CP.

*No conflict of interest*
Cerebral Palsy is a non progressive disorder of movement and posture on immature brain. Children with cerebral palsy will present selective loss of motor control, spasticity and muscle weakness. Standard protocol in this area is passive range of motion which is not a strengthening exercise.

**Material and Method**

Strengthening muscles is by giving periodization loaded sit-to-stand exercise of Gross Motor Function Measure (GMFM-88) for spastic diplegic cerebral palsy.

**Results**

The result showed an increase of motor ability in intervention group in dimension (E) running and jumping of Gross Motor Function Measure higher than to control group (dimension E scoring: 14.14 vs 1.01).

**Conclusion**

Periodization of loaded sit-to-stand strengthening exercise are able to improve running and jumping Dimension (E) on GMFM in cerebral palsy spastic diplegic are better than control group.

Introduction/Background

Few data are available in the literature on cognitive impairment in adults with cerebral palsy. The aim of this work is to analyze the cognitive profile of adults with moderate impairment and their repercussions on educational and socio-professional pathways.

Material and Method

The records of 36 patients were analyzed. 11 people have the college certificate, 13 the baccalaureate and 12 a level of 2 years after the baccalaureate. 22 are inactive, 8 have part-time work, 3 are full-time, 3 are still in school. All benefited from a complete neuropsychological assessment. The scores of the different tests were analyzed according to schooling and socio-professional background.

Results

36 patients were included with an average age of 27.8 +/- 8 years, 83% are single. The PC is bilateral spastic in 27 cases, spastic unilateral in 5 cases and dyskinetic in 4 cases.

Visuoperceptive disorders are the most frequent, with a significant impact on schooling and professional integration.

Executive disorders is also observed, the intelligence quotient is within the limit of normal.

Conclusion

Cognitive disorders presented by the patients in our study are consistent with those described in the literature in adult cerebral palsy with a predominance of visuoperceptive disorders, associated with executive disorders.
These disorders have repercussions on schooling and professional integration. Routine screening of cognitive disorders must allow the establishment of a specific support at the time of transition.

The accompaniment of adolescents with cerebral palsy should continue after the acquisition of diploma to promote their social and professional integrations.

Introduction/Background

The main aim of this study was to show the efficiency of botulinum toxin A (BT-A) injections not only on spasticity and functional capacities but also on the quality of life in children with cerebral palsy, and to describe their long-term evolutivity profile while précising our developing country particularities.

Material and Method

Sixty children were included in this study aged from 2 to 18 years old; who received repeated injections of BT-A (Dysport®). An evaluation was done before and after these injections. It included an evaluation of the spasticity using the Modified Ashworth Scale (MAS), the functional evaluation using the Gross Motor Function Classification System (GMFCS) and the Manual Ability Classification System (MACS), an evaluation of satisfaction (Visual analogical Scale) and an evaluation of the quality of life using the Child Health Questionnaire Parent Form 50 (CHQ-PF50).

Results

The change from baseline of MAS ranged from 2.25 to 3 for the muscles of the lower limbs and ranged from 2 to 2.86 for the upper limb muscles. The average number of injection sessions was of 3.18 (1 to 6). The percentage of children improved (in GMFCS and MACS) and the average of the visual analogical satisfaction scale as well, increased from one injection to another reaching a constant level in the last two injections (p<0.001).

Conclusion

Our study proved the efficiency of repeated BT-A injections on the spasticity. It also revealed an improvement in both the gross function and the motor skills of children suffering from cerebral palsy. The quality of life of these children was significantly enhanced after injections.

Introduction/Background

Cerebral palsy (CP) not only affects movement and posture, but also is accompanied with cognition, speech, or social problems. These problems further cause limitation in participation in life activities in children with CP. This study aims to investigate the changes in participation outcomes in various activities for children with CP of different motor severities.

Material and Method

Sixty-five parents of schoolchildren with CP (6-18 years) were enrolled and classified into two groups based on the Gross Motor Function Classification System (GMFCS) levels: mild (GMFCS levels I-III, n= 41) and severe group (GMFCS level IV-V, n=24). Participation outcome was assessed by the Children’s Assessment of Participation and Enjoyment (CAPE) at baseline and 6-month follow-up. CAPE measures participation diversity and intensity in five activities (recreational, active physical, social, skill-based, and self-improvement), ANCOVA was used to compare the participation changes in various domains between two groups.

Results

At baseline and follow-up, mild groups had better participation diversity and intensity in all activities except the intensity in social activities at follow-up than severe groups (p < 0.05). ANCOVA results showed mild groups had better changes in the participation diversities for total and all activities except the social and skill-based activities than severe groups (p < 0.05). Furthermore, mild groups had better changes in the participation intensities for total, active physical, and self-improvement activities, than severe groups (p < 0.05).

Conclusion
The GMFCS levels were associated with participation changes in the diversities and intensities for various activities in children with CP. Mild groups had better changes in the participation diversities and intensities for some activities than severe groups. These findings may allow clinicians early predict the changes in the participation outcomes for these children based on simple GMFCS levels.

APPLICATION OF MAGNETIC STIMULATION NEUROMODULATION THERAPY TO PROMOTE THE STABILITY OF CORE MUSCLE GROUP IN CHILDREN WITH CEREBRAL PALSY

Y. Zhongxiu¹, B. Kexiu¹, Q. Aizhen¹
¹Xuzhou Children's Hospital-Jiangsu Province-China, rehabilitation department, Xuzhou, China

Introduction/Background

The core strength of children with cerebral palsy decreased. To investigate the application of magnetic stimulation treatment to stimulate spinal nerve root to strengthen the core muscles in the children with cerebral palsy.

Material and Method

Children with cerebral palsy in our hospital during January 2016 to January 2017 were divided into the treatment group and the control group in accordance with random number table. Two groups of data have no significant difference before treatment. The control group was treated with traditional rehabilitation method, the treatment group was treated with transcranial magnetic stimulation plus traditional way. Compare the effects of two groups before treatment and 1-month and 2-month treatment later.

Results

Analyzing the effects between the treatment group and the control group after 1-month treatment, there existed significant differences: GMFM recumbent position and can roll over sitting position and ICF-CY (P<0.05); Analyzing the effects between the treatment group and the control group after 2-months treatment, there existed significant differences: recumbent position and can roll over and in ICF-CY limit (P>0.05). In the treatment group, compared itself after the treatment 3-months and 2-months later, Rehabilitation treatment progress is slow. there existed significant differences in the Recumbent position and can roll over sitting position (P<0.05). but there was no significant differences in ICF-CY limit (P>0.05).

Conclusion

Treatment of magnetic stimulation has positive clinic effect to strengthen the core muscles in children with cerebral palsy, and it is the most effective when the first course of treatment.

COMMUNICATION IMPAIRMENT IN CEREBRAL PALSY: A STUDY FROM TUNISIAN POPULATION

*S. Boudokhane*, H. Migaou, O. Borji, I. Feki, T. Elhersi, A. Jellad, Z. Ben Salah Frih

Department of Physical Medicine and Rehabilitation - University Hospital Fattouma Bourguiba of Monastir, - Monastir, Tunisia

Introduction/Background

Communication impairment (CI) is one of the most common dysfunctions associated with cerebral palsy (CP). The objective of this study was to describe types of CI and the relationship between the Gross Motor Function Classification System (GMFCS), CP subtype, and neuroimaging findings in the Tunisian CP children.

Material and Method

Eighty children (35 girls and 45 boys) with CP followed in the department of Physical Medicine and Rehabilitation of Fattouma Bourguiba Hospital in Monastir-Tunisia. The type of CI, The GMFCS levels, associated disorders and neuroimaging findings were recorded.

Results

The mean age was 8.6±5 years and the sex ratio was 1.28. Out of 80 children with cerebral palsy, 69 were identified to have CI (86%). Of these, 33 were unable to communicate verbally (41.3%), 12 had difficulties with verbal expression (15%), one had difficulties with verbal comprehension (1.3%) and 23 had difficulties with both verbal and comprehension difficulties (28.8%). Associated disorders were found in 67 children (97%) of children with CI. Thirty-five children (51%) were epileptic. Neuro-visual and language disorders were noted in 88% of cases. Autistic behavior disorders were noted in 9 children (13%). These children were significantly more likely to have a more severe motor deficit (Gross Motor Function Classification System levels IV and V and Manual Ability Classification System levels IV and V), and to have spastic quadriplegia. CI were associated with cerebral malformation (23.5%), diffuse gray matter lesions (20.3%) and periventricular lesions (19.1%).

Conclusion

Communication impairment is a common comorbidity in cerebral palsy and is associated with a more severe motor deficit, spastic quadriplegic subtype of CP, and cerebral malformation and gray matter injury on neuroimaging. To target services effectively, subgroups of individuals with CP at greatest risk for language impairment need to be identified.

EFFECT OF ANKLE-FOOT ORTHOSES ON GAIT, BALANCE AND GROSS MOTOR FUNCTIONS IN CHILDREN WITH CEREBRAL PALSY: A SYSTEMATIC REVIEW AND META-ANALYSIS.
L. Mael, B. Jean-Sébastien, H. Laetitia, L. Mathieu, B. Sylvain, C. Pons
1CHRU Brest, Physical medicine and rehabilitation, Brest, France
2Fondation ILDYS, SSR locomoteur, Roscoff, France
3INSERM, Laboratory of Medical Information Processing, Brest, France
4Fondation ILDYS, SSR pédiatrique, Brest, France

Introduction/Background
Ankle-foot orthoses are often prescribed to correct abnormal gait, facilitate gait training and reduce the impact on functional ability in children with cerebral palsy who present neuro-motor deficits of the lower limb. The aim of this study systematic review and meta analysis was to determine the effects of Ankle-foot Orthoses (AFOs) on gait, balance, Gross Motor Function and activities of daily living in children with cerebral palsy (CP).

Material and Method
Five databases were searched (Pubmed, Psycinfo, Web of Science, Academic Search Premier, Cochrane Library) before Januar 2018. Studies of the effect of AFOs on gait, balance, gross motor function and activities of daily living in children with CP were included. Articles with a modified PEDRO score >=5/9 were selected. Data regarding population, AFO, interventions and outcomes were extracted. When possible, standardized mean differences (SMDs) were calculated from the outcomes.

Results
Thirty-two articles, corresponding to 56 studies (884 children) were included. In 51 studies children with spastic CP were included. AFOs increased stride length (SMD=0.88, p<0.001) and gait speed (SMD=0.28, p<0.001), decreased cadence (SMD=-0.72, p<0.001). Gross motor function scores improved (GMFM D (SMD= 0.30, p=0.004), E (SMD= 0.28, p=0.02), PEDI (SMD=0.57, p<0.001)). Data relating to balance and activities of daily living were insufficient to conclude. Posterior AFOs (solid, hinged, supramalleolar, dynamic) increased ankle dorsiflexion at initial contact (SMD=1.52, p<0.001) and during swing (SMD= 0.81, p<0.001), and decreased ankle power generation in stance (SMD=-0.72, p<0.001) in children with equinus gait.

Conclusion
In children with spastic CP, there is strong evidence that AFOs induce small improvements in gait speed and moderate evidence that AFOs have a small to moderate effect on gross motor
function. In children with equinus gait, there is strong evidence that posterior AFOs induce large changes in distal kinematics.

DIFFERENCE IN MEDIAL GASTROCNEMIUS MECHANICAL PROPERTIES BETWEEN PARETIC AND NON-PARETIC LEGS IN CHILDREN WITH UNILATERAL CEREBRAL PALSY.

B. Clément¹, G. Vincent², L. Thomas³

¹Ph D student- Physiotherapist, Pediatric physical medicine and readaptation, Villars, France
²University professor- hospital practitioner, Pediatric physical medicine and readaptation, Saint-etienne, France
³University professor, LIBM-Laboratoire inter-universitaire de biologie de la motricité, Saint-etienne, France

Introduction/Background

Children with spastic unilateral cerebral palsy (CP) present very early in childhood alterations in gastrocnemius muscle structural and mechanical properties that can be non-invasively investigated through 2D ultrasonography (US). To gain knowledge about spastic muscle properties during ankle mobilization, the purpose of this study was to assess gastrocnemius medialis (GM) muscle passive stiffness and strain during ankle mobilization in both paretic and non-paretic legs in children with unilateral CP.

Material and Method

13 children (6 to 12-year old) with unilateral spastic CP, participated in two sessions of measurements with a one-week interval. Children were installed prone on an isokinetic dynamometer while their ankle was passively mobilized from 25° plantarflexion to maximal dorsiflexion at 2°/s. EMG activity was monitored to ensure complete relaxation. Displacement of the musculo-tendinous junction (MTJ) was recorded with US during mobilization and was synchronized with passive torque. GM stiffness was then calculated as the slope of the torque/MTJ displacement relationship (fig 1). GM strain was calculated as the GM excursion divided by GM resting length (measured at neutral position with simple US tape method). Inter-session reliability was assessed with the measurement of coefficient of variation (CV) between both experimental sessions.

Results

GM stiffness was higher for the paretic leg than for the non-paretic one (4,2 vs 3 Nm/cm ; p=0,025). When considered on the same angular range (i.e. -25° plantarflexion to maximal dorsiflexion angle on paretic leg), GM strain was similar between both legs (p=0,43).

Inter-session reliability of GM stiffness (9,75%≤CV≤10,67%), strain (CV≤9,97%) and length (CV≤7,5%) were good.

Conclusion
Spastic GM muscle lengthening during ankle mobilization was characterized by an increased stretch resistance when compared to non-paretic muscle despite similar passive GM strain between both legs. This may be due to altered spastic GM growth during childhood, characterized by reduced GM paretic length.

PASSIVE STIFFNESS OF PLANTARFLEXOR MUSCULOTENDINOUS UNIT IN CHILDREN WITH SPASTIC CEREBRAL PALSY: A REVIEW

B. Clément¹, L. Thomas², G. Vincent³

¹PhD student- Physiotherapist, Pediatric Physical Medicine and Readaptation, Villars, France
²University professor, LIBM-Laboratoire inter-universitaire de biologie de la motricité-Jean Monnet University, Saint-etienne, France
³University professor- hospital practitioner, Pediatric Physical Medicine and Readaptation-CHU St-Etienne, Saint-etienne, France

Introduction/Background

Increase of passive stiffness plantarflexors muscles in children with spastic Cerebral Palsy (CP) is a consequence of structural muscular properties impairment and is classically considered as a precursor of contracture appearance during growth. Muscle stiffness is measured from the passive torque-angle relationship. However, some studies using different methodologies had shown variables results. Since few years, Shear Wave Elastography (SWE) was used to assess passive muscle stiffness specifically.

Material and Method

We performed a review of literature and selected studies which 1) described passive stiffness in plantarflexors muscles, 2) assessed therapeutics modalities whose goal was to decrease passive stiffness on plantarflexors muscles in children with spastic CP.

Results

20 studies were included in this review. 12 described passive stiffness on plantarflexors muscles using torque-angle relationship or SWE method. Others studies assessed impact of botulinum toxin injection (n=4), casting or surgery (n=1), stretching program (n=1), stretching and active exercises (n=1) and gait training (n=1).

Plantarflexors muscle passive stiffness was increased in children with spastic CP compare to healthy children whatever the assessment method used. There was a lack of data's on relationship between passive stiffness at rest and clinical or gait parameters. Several therapeutics modalities could decrease passive stiffness at rest but impact on structural properties and gait pattern remained unknown.
Conclusion

Increase of plantarflexors muscles passive stiffness in children with spastic CP was well established. However, more studies are needed to precise relationship of passive stiffness with clinical or gait parameters and therapeutics modalities which are indicate to improve them. Relationships between passive stiffness and structural properties remain unknown and must be investigated.

Introduction/Background

In very young cerebral palsy (CP) children, peroneus longus (PL) overactivity by spastic cocontraction is a major contributor to dynamic equinovalgus during swing phase (SW) and at initial contact (IC). This study assessed the effects of abobotulinumtoxinA injections into PL.

Material and Method

Eleven male children with hemiparesis (7 right; age 3.1±0.6 yo) were injected once in PL, without GastroSoleusComplex (GSC) injection. GSC was assessed for functional length ($X_{V1}$) and spasticity ($X_{V3}$). Gait analysis videos were evaluated using the Edinburgh Visual Gait Score (EVGS-validated in CP): pre vs post-injection values were compared using paired $t$-tests. EMG monitored tibialis-anterior (TA), gastrocnemius-medialis (GM) and PL during gait. Swing phase was divided into three periods (SW1, SW2, SW3) to measured, using EMG: GM and PL cocontractions and TA recruitment during SW (SW, SW1, SW2, SW3), during standing on tiptoes (EMGmaxPL, EMGmaxGM), standing on heels (EMGmaxTA).

For each measured EMG variable, efficacy indices was assessed using the ratio

$$\frac{(EMG_{\text{VARIABLE X POST}} - EMG_{\text{VARIABLE X PRE}})}{(EMG_{\text{VARIABLE X POST}} + EMG_{\text{VARIABLE X PRE}})}$$
and compared with an inefficacy theoretical index of 0.

**Results**

Comparison involved 1937 pre-toxin strides (mean per child 176±114) vs 1231 post-toxin strides (mean 112±79). There were no difference in $X_{V1-GSC}(X_{V1-GSC-pre} 103°(6); X_{V1-GSC-post} 103°(6))$ or in $X_{V3-GSC}(X_{V3-GSC-pre} 89°(8); X_{V3-GSC-post} 96°(4.5))$. EVGS-global-score was improved ($p=0.007$) with better clearance in SW ($p=0.07$), increased knee re-extension in terminal SW ($p=0.04$) and decreased hindfoot valgus at IC ($p=0.02$). The normalised-EMGmax was unchanged for PL (-0.06(0.16)) but increased for GM (0.18(0.20), $p=0.007$) and TA (0.28(0.19), $p<0.001$). There were reductions of Cocontraction in PL ($p<0.0001$; SW, -0.26(0.14); SW1, -0.22(0.14); SW2, -0.27(0.14); SW3, -0.26(0.18)) and in GM (SW, -0.26(0.14), $p=0.06$; SW1, -0.21(0.18), $p<0.001$; SW2, -0.25(0.20), $p<0.01$; SW3, -0.21(0.25), $p=0.06$). TA recruitment was decreased: SW, -0.08(0.18), $p=0.06$; SW1, -0.11(0.20), $p<0.001$; SW2, -0.07(0.17)NS; SW3, -0.07(0.24), NS.

**Conclusion**

In this retrospective study, PL injections in very young CP children improved foot clearance and decreased hindfoot valgus, which was associated with reductions of PL and GM cocontractions and of TA recruitment. This constitutes an argument supporting that increased TA recruitment in children with hemiparesis may be an attempt by the nervous system to compensate for plantar flexor cocontraction rather than the opposite (increased cocontraction due to increased TA recruitment). We can discuss a central action of abobotulinumtoxinA.

FEEDING PROBLEMS, GROWTH AND NUTRITIONAL STATUS IN CHILDREN WITH SEVERE NEUROLOGIC IMPAIRMENT AND INTELLECTUAL DISABILITY
S. Boudokhane¹, H. Migaoui¹, O. Borgi¹, S. Layouni¹, A. Jellad¹, Z. Ben Salah Frih¹
¹Faculty of Medicine, University of Monastir, Tunisia

Introduction/Background
Feeding difficulties, common among children with cerebral palsy (CP), are currently lacking in children with severe neurologic impairment and intellectual disability. The aim was to estimate the prevalence of feeding and nutritional problems in children with severe cerebral palsy (CP) in Tunisia.

Material and Method
This was a cross-sectional study of 40 children with severe CP. The inclusion criteria were the following: age 2–19 y, proven or estimated IQ<55 y, and with Gross Motor Function Classification System (GMFCS) GMFCS levels 4 or 5. Anthropometric measurements (body weight, knee height, mid-upper arm circumference, and triceps skin-fold thickness) were taken. In addition, all the participants had a thorough evaluation of the feeding times, and the presence of gastrointestinal problems (drooling of saliva, vomiting, dysphagia, etc...).

Results
Oromotor dysfunction affected 70% of children, drooling of saliva were noted in 30 of cases and gastroesophageal reflux in 14 of cases. The meal was given in most cases by the mother and lasted on average 40 minutes. No children with gastrostomy tube feeding. The average skinfold value was 6.5 ± 3.5 mm and the mid-arm circumference was 16.1 ± 3.4 cm. The weight was on average 15Kg.

Conclusion
Feeding problems in children with CP were common and associated with poor linear growth. A high proportion of the children were undernourished. Moreover, our results suggest that gastrostomy tube feeding may have been introduced too late in some children.

SWITCHING FROM ONABOTULINUMTOXINA TO ABOBOTULINUMTOXINA IN CHILDREN WITH CEREBRAL PALSY TREATED FOR SPASTICITY: A RETROSPECTIVE SAFETY EVALUATION
N. Dursun¹, M. Akarsu¹, T. Gokbel¹, M. Akyuz¹, C. Karacan¹, E. Dursun¹
¹Kocaeli University, Physical Medicine and Rehabilitation, Kocaeli, Turkey

Introduction/Background

Botulinum neurotoxin-A (BoNT-A) is an important treatment in the management of hypertonia in children with cerebral palsy (CP). To date, there are no controlled head-to-head clinical trials comparing the efficacy and safety of different BoNT-A formulations in CP. The main aims of this study were to explore whether switching from onabotulinumtoxinA (OnaBoNT-A) to abobotulinumtoxinA (AboBoNT-A) is safe and whether therapeutic efficacy is maintained.

Material and Method

This retrospective observational study included 118 children with CP (mean age: 81.4 ± 38.9 months) who had switched from OnaBoNT-A to AboBoNT-A injections into their lower extremities due to a change in hospital policy. Analysis was limited to the final OnaBoNT-A treatment cycle (TC) prior to switch, and the first AboBoNT-A TC following switch. The primary objective was to document safety in children switched from OnaBoNT-A to AboBoNT-A. Efficacy endpoints included muscle tone, spasticity, and gait function based on Modified Ashworth Scale (MAS), Tardieu Scale (TS), and Observational Gait Scale (OGS) scores. A sub-analysis was performed to investigate the time to retreatment for patients attending their follow-up visits for efficacy assessments (n=52).

Results

Treatment emergent adverse events were recorded in 41 (34.7%) and 31 (26.3%) patients during the OnaBoNT-A and AboBoNT-A TCs, respectively. Treatment related adverse events were reported in 5 patients in OnaBoNT-A TC versus 7 in AboBoNT-A (p=0.774). Treatment efficacy, (4-6 weeks post-treatment) was found to be similar in the OnaBoNT-A and AboBoNT-A TCs for all variables (MAS, TS, OGS). The sub-analysis of 52 patients revealed a significantly longer retreatment interval with AboBoNT-A (27.6 ± 11.8 weeks) versus OnaBoNT-A (23.3 ± 8.7 weeks) (p=0.004).

Conclusion

In children with CP, switching from OnaBoNT-A to AboBoNT-A was safe and efficacy was maintained. In a subgroup analysis AboBoNT-A appeared to have a longer retreatment interval than OnaBoNT-A.

⁴CHU Angers, Neuropédiatrie, Angers, France

Introduction/Background

Children suffering from generalized spasticity may experience pain and discomfort. The use of intrathecal baclofen therapy (ITB) had already proved its efficiency in case of diffuse and severe spasticity. Injections of intramuscular botulinum toxin can be associated with this treatment. To our knowledge, there's no study specifically devote to analyze the use of botulinum toxin among children receiving ITB.

Material and Method

Retrospective study (median follow-up = 3.06 years before and after the pump implantation).

Results

Twenty-five children were included: 19 with cerebral-palsy (CP) (n = 1 GMFCS III, n = 7 GMFCS IV and n = 11 GMFCS V), 5 with acquired brain injury and 1 with hereditary spastic paraplegia. After adjusting posology, 24 children (96%) had reached their identified a-priori goal concerning treatment of lower pain, daily activity help needed and seat and positioning. Fourteen children received toxin injections before the pump implantation, whereas only 6 after. When we compared each patient to himself before and after implantation, there is a significant decrease of number of toxin injection sessions (p = 0.013) for our whole sample. This remain valid in children with CP (p = 0.040).

We showed also that there is a modification of injections localizations. Before the implantation 50% of injections were realized on lower limbs, 14% on upper limbs and 36% at both sites. After pump 50% are realized on upper limbs, 17% on lower limbs and 33% at both sites (p = 0.232).

Conclusion

This study confirms that ITB pump is useful to treat diffuse and severe spasticity in children and enables to significantly reduce the number of botulinum toxin injections. There is a trend of modification of the localization of injections’ sites after implementation reflecting indirectly a better efficiency of the ITB pump on lower limbs spasticity compared to upper limbs.

Introduction/Background

Cerebral palsy (CP) is the most common cause of physical disability in childhood and secondary provides joint contractures and loss of opportunity of social activities. Patients with CP, in adolescence, lose motor function further even if typical physical therapy was done. The objective of this study was to report the improvement of walking ability using hybrid assistive limb (HAL) training in a patient with CP who were diminished the gross motor function through puberty over a half year after the training.

Material and Method

A 17-year-old male with spastic diplegic cerebral palsy performed 12 sessions (40 minute, 4 weeks) of walking training using HAL. He was assessed by 10-meter walking test (10MWT) in each HAL session, and also evaluated by motion analyses including joint kinematics and electromyography in 9 time points: before, after and monthly until 7 months after the end of the intervention.

Results

No adverse events during the intervention were observed or reported by the patient. The gait speed (23.0 in the first session to 26.5 m/min in the last session) and step length (41.7 in the first session to 47.6 cm in the last session) were improved in 10MWT. Improvement of knee extension in stance phase was found and the electromyography showed improve muscle activations in rectus femoris and semitendinosus at the final follow-up evaluation.

Conclusion

Because learning correct walking pattern led improvement of knee extension and muscle activations, it seems that gait speed and step length were improved and continued even after 7 months. The intervention techniques using HAL can be considered to be effective on the walking ability in the patient with CP.

\(^5\)Fondation Ellen Poidatz, Recherche, Saint Fargeau-Ponthierry, France

Introduction/Background

Cerebral Palsy (CP) is a neuromuscular condition affecting 1 in 400 children that limits activities of daily living. Essential elements to improving function are feedback and repetition. Feedback about a motor performance communicated back to the individual (e.g. Biofeedback) can be a powerful tool for improving autonomy and self-efficacy. However, the most effective mechanisms of biofeedback, particularly for people with CP remain unknown. This study aimed to identify the qualities of biofeedback interventions most effective for people with Cerebral Palsy (CP) through systematic review.

Material and Method

Eight databases and references from relevant articles were searched. Included studies had participants diagnosed with CP and any quantitative study design with N>3. Studies were evaluated using the Grading of Recommendations Assessment, Development, and Evaluation (GRADE) framework. Interventions needed to provide external feedback about the movement or performance. For available studies, effect sizes were compared to study characteristics (intervention duration/intensity, and feedback type).

Results

Fifty-seven of the 205 full-texts reviewed were included. Overall, 79% of studies and 63% of measures showed post-intervention improvement. Studies with positive effects (r=0.47 ± 0.26) were longer, averaging 8 weeks and 150 minutes/week compared to studies with no changes (r=0.28 ± 0.26), which were 3 weeks and 80 minutes/week (Figure 1). These studies also used multi-modal feedback (audio and visual) more commonly than unimodal feedback.
Conclusion

This study shows that biofeedback interventions can be effective for people with CP. The confidence in the effect would be strengthened by a thoughtful paradigm, a standardized outcome toolbox, and adequate practice intensity. These insights could raise intervention efficacy to help people with CP improve motor activities.

LONGITUDINAL ANALYSIS OF THE APPLICATION OF THE THERASUIT METHODOLOGY AS A PROGRAM OF INTENSIVE PHYSIOTHERAPY FOR PATIENTS WITH CEREBRAL PALSY AND BIFDA SPINE.
M.E. Santos¹, A.C. Frazão¹, T.M.D.D. Frazao¹, V. Cury¹, M. Villar de Figueiredo¹, F. Frazão¹
¹Centro de Equoterapia e Reabilitação da Vila Militar, Departamento de Neuroreabilitação, Rio de Janeiro, Brazil

Introduction/Background

The study analyzed the perpetuation of the functional gains provided by Therasuit Method Intensive Rehabilitation programs, with ten ECI / Spina Bifda patients aged 3 to 18 years. The research methodology used was the Non-Randomized Clinical Study. The analysis was performed on a history of 4 to 12 consecutive programs for the longitudinal studies of functional motor gains.

Material and Method

The patients were evaluated according to the GMFM 66 protocol, before participating in the intensive program, and evaluated after the four-week treatment with daily activities of 3 hours duration. The treatment used the Therasuit Methodology, with use of the suit, Spider system, Pulleys and cage. This procedure was repeated in four annual modules, with minimum intervals of five weeks and maximums of sixteen weeks.

Results

The GMFM scores obtained over 3 years of application of the Therasuit Method were distributed per patient and their level of GMFCS, GMFCS II (2 patients) averaged 25.4 points; GMFCS III (1 patient) 9 points; GMFCS IV (4 patients) averaged 9.58 points and GMFCS V (3 patients) averaged 5.99 points.

Conclusion

The results indicate that the application of the intensive treatment method Therasuit® produced an improvement of the GMFM score in the first year of a minimum value of 3.11, with an average value of 11.74. In the second year minimum value of 11 points, with an average value of 15.9. and in the third year 9.3, with an average value of 9.9. According to Hong 2017, gains above 4 points re considered a clinically significant change. The three-year longitudinal analysis showed that continuity of treatment leads to increases in functional gains, with no case of regression to pre-treatment baseline levels, indicating a perpetuation of treatment gain.

CARDIOVASCULAR DISEASE AND RELATED RISK FACTORS IN ADULTS WITH CEREBRAL PALSY: A SYSTEMATIC REVIEW
P. McPhee1, E. Claridge2, S. Noorduyn3, J.W. Gorter3
1McMaster University, School of Rehabilitation Science, Hamilton, Canada
2University of Toronto, Faculty of Medicine, Toronto, Canada
3McMaster University, Pediatrics, Hamilton, Canada

Introduction/Background

Cerebral palsy (CP) is the most common pediatric-onset physical disability. Individuals with mild to moderate CP can expect life expectancies similar to the general population; however recent evidence has shown that individuals with CP have progressive functional declines, as well as increased physical inactivity and sedentary behaviour - each of which increases with age. These factors likely place individuals with CP at a greater risk for secondary chronic conditions, such as cardiovascular disease (CVD). The aim of this study is to summarize the literature on the prevalence of CVD, risk factors of CVD, and CVD-related mortality in adults with CP.

Material and Method

A systematic review was conducted across the PubMed, Ovid, Cochrane and CINAHL databases. Selection criteria included adults with CP ≥18 years. Outcomes were grouped into two classes of interest: (1) CVD and CVD risk factors; and (2) CVD-related mortality.

Results

Nineteen studies met the inclusion criteria. Only one study reported directly on the prevalence of CVD in adults with CP, where adults with CP reported greater CVD conditions than adults without CP (15.1 vs. 9.1%, p<0.001). Overweight and obesity were the most commonly reported risk factors of CVD. Five studies included data on CVD-related mortality in persons with CP, where CVD- and circulatory system-related deaths were elevated and more common at a younger age in adults with CP than in the general population. Heterogeneity in results prevented quantitative analysis.

Conclusion

Our understanding of the prevalence of CVD in this population is fragmented by studies that are small in size and geographically isolated thus preventing definitive conclusions. Of the CVD risk factors identified in this review, it appears that overweight/obesity may be elevated in adults with CP, identifying an important health characteristic that could be managed during clinical encounters early on in this population.

Introduction/Background

The aim of this study was to evaluate the biomechanical properties (tone, elasticity and stiffness) of gastrocnemius muscle using myotonometry in children with spastic cerebral palsy.

Material and Method

Forty patients with spastic cerebral palsy (11 diplegic, 16 quadriplegic and 13 hemiplegic) and 20 age, gender and BMI matched healthy controls were evaluated. Biomechanical measurements of gastrocnemius muscle were performed using a myotonometry. The MyotonPro was used to measure the muscle tone, elasticity and stiffness of the medial and lateral gastrocnemius muscles on bilateral sides of the patients with diplegic/quadriplegic cerebral palsy and the healthy controls. Measurements were done only from the paretic side of the patients with hemiplegic cerebral palsy.

Results

The patient and control groups were similar in terms of age, gender and BMI. The measurements of 40 extremities of 20 controls were compared with 66 extremities of 40 patients. The tone and stiffness values of medial gastrocnemius muscle were found to be significantly higher in patients with spastic cerebral palsy than those in controls (p=0.027 and p=0.015, respectively). Although the measurements of lateral gastrocnemius muscle were higher than controls, it was not statistically significant. Besides, the elasticity values of both medial and lateral gastrocnemius were lower in patients with spastic cerebral palsy, but the values did not reach statistical significance level.

Conclusion

Myotonometric evaluations suggest that muscle tone and stiffness, which are intrinsic biomechanical properties, are higher in patients with spastic cerebral palsy compared to healthy controls.

THE EFFECTIVENESS OF ELECTRICAL STIMULATION ON MUSCLE TONE, ELASTICITY AND STIFFNESS OF GASTROCNEMIUS MUSCLE IN CHILDREN WITH SPASTIC CEREBRAL PALSY

S. Havuc1, A. Aydeniz2, S. Basaran3
1Gaziantep University, Physiotherapy and Rehabilitation, Gaziantep, Turkey
2Gaziantep University Faculty of Medicine, Physical Medicine and Rehabilitation, Gaziantep, Turkey
3Cukurova University Faculty of Medicine, Physical Medicine and Rehabilitation, Adana, Turkey

Introduction/Background

The aim of this study was to demonstrate the therapeutic effectiveness of electrical stimulation on muscle tone, elasticity and stiffness in children with spastic cerebral palsy.

Material and Method

Thirty one lower extremities of 18 patients with spastic cerebral palsy (5 diplegic, 8 quadriplegic and 5 hemiplegic) were evaluated. Biomechanical measurements of gastrocnemius muscle were performed using a myotonometry device. The MyotonPro was used to measure the muscle tone, elasticity and stiffness of the gastrocnemius muscle (medial and lateral parts) on bilateral sides of the patients with diplegic/quadriplegic cerebral palsy and from the paretic side of the patients with hemiplegic cerebral palsy. Patients were treated for five days of electrical stimulation (frequency of 50 Hz, pulse duration 300ms, ramp of 0.5 ms, on:off time 5s:5s, session time of 30 minutes) which was applied on the gastrocnemius muscle aiming for the management of spasticity. The measurements were repeated after the fifth session.

Results

The mean age of the patients were 6.44±3.6 (2.5-13). The mean Gross Motor Function Classification System level of the patients were 3.11±1.6 (1-5) and Ashworth scale were 2.06±0.75 (1-3). The muscle tone and stiffness of medial and lateral gastrocnemius muscle decreased significantly (p<0.01) after the intervention, whereas the elasticity values increased significantly (p<0.01). Ashworth score of the patients were also decreased after the intervention. However no correlations between Ashworth scores and myotonometric values were detected.

Conclusion

Our results suggest that electrical stimulation for the treatment of spasticity had improvements on muscle tone, elasticity and stiffness of spastic cerebral palsy patients. And MyotonPro can be used to measure the effects of treatment in spasticity.

MANAGEMENT OF DROOLING IN CHILDREN WITH CEREBRAL PALSY: A FRENCH SURVEY

M. Porté¹, E. Chaleat-valayer²
¹Nîmes University Hospital, PMR Department, Nîmes, France
²CMCR des Massues, PMR Department, Lyon, France

Introduction/Background

After the age of 4 years, drooling becomes pathological and impacts the quality of life of children with cerebral palsy. The aim of the communication is to characterise children with cerebral palsy and pathological drooling in France, and to describe care pathways, assessment and treatment.

Material and Method

A transversal, observational, descriptive survey of the practices and opinions of 400 health professionals potentially involved in the care of children with cerebral palsy, was carried out nationally across France in 2013.

Results

The response rate was 36%. Seventy-five questionnaires were returned and analysed (52%). A small proportion of children were specifically treated for drooling (<25%). Assessments were carried out in 75% of cases and 91% of professionals prescribed treatments. Use of assessment tools varied widely. The most common treatment was oro-facial rehabilitation (95% of professionals), followed by anticholinergic drugs (Scopolamine®) (94%) botulinum toxin injections (66%) and surgery (34%). Scopolamine was considered to be less effective than botulinum toxin and to have more side effects. Regarding the protocol, Botox® is the most commonly used, with a median dose of 1U/Kg/gland, injected both in parotid and sub-mandibulars glands. The period between two injections is from 3 to 6 months. Glands are located by ultrasound examination. The analgesic method differ from injection centers.

Conclusion

The rate of pathological drooling in children with cerebral palsy is likely underestimated and under treated in France. There is a lack of knowledge regarding assessment tools. Aside from rehabilitation, current practice is to prescribe medication as the first-line treatment, however professionals consider that botulinum toxin is more effective and has less side effects. For now there is no general agreement for the protocol of toxin injection. Further studies should be conducted to define a standardized protocol for injections.

INVESTIGATIONS OF THE EFFECTS OF MIRROR THERAPY IN CHILDREN WITH UNILATERAL CEREBRAL PALSY

F. Gaillard¹, E. Samson², H. Rauscent¹, I. Bonar²

¹CHU Pontchaillou, Service de MPR Enfant, Rennes, France
²CHU Pontchaillou, Service de MPR, Rennes, France

Introduction/Background

Cerebral palsy (CP) is the first cause of children motor disability. In unilateral CP, upper limb dysfunctions are the main cause of dependence and participation restriction. Effects of Mirror therapy are well known in others disorders, especially in adult population but its benefit is not yet determined in children with cerebral palsy. The aim of this study is to determine the efficacy of mirror therapy in children with unilateral cerebral palsy on bimanual activity.

Material and Method

This study was a prospective, randomized, single-center, controlled, single-blind study. The primary efficacy variable was the Assisting Hand Assessment (AHA). 32 hemiparesis (17 in mirror therapy group and 15 in control group) children aged over 7 were evaluated using the AHA to score functional activity performance. The mirror therapy group used a mirror, the comparison group used an opaque partition between their arms. Each participant had 5 rehabilitation sessions for 5 weeks. Each child was evaluated initially (S0), at 5 weeks (S5) and 10 (S10) weeks.

Results

AHA score at 5 weeks were 61.44 ± 11.99 for the 32 patients, 61.60 ± 11.72 in control group, 61.29 ± 12.58 in mirror therapy group (p = 0.9440). At 10 weeks, scores were 61.9 ± 11.4 for the entire population, 61.4 ± 11.8 in control group and 62.4 ± 11.4 in mirror therapy group (p = 0.8178).
Conclusion

There were no significant differences in outcomes and their progression S5 and S10 between the mirror therapy group and control group. Neither primary nor secondary efficacy variables have shown significant differences. Even though our study did not show improvement in AHA score after 5 weeks of mirror therapy, we can observe an improvement tendency that could be statically significative with a larger population.

Introduction/Background

Botulinum toxin injections (BTI) in children often involve several sites of injections and repetitions of the procedure. Reducing pain and anxiety during this procedure is a high priority but remains a challenge. The aims of this study were to evaluate the effectiveness of medical clown presence on pain and anxiety during BTI with premedication (Nitrous Oxide, EMLA) compared to usual distraction procedures.

Material and Method

Children with motor disabilities, mostly cerebral palsy (1-18 years old) were recruited from the pediatric rehabilitation department of the Brest University Hospital. Children were randomized into the usual distraction group (music, movies, ...) or the clown distraction group. Pain was evaluated using the Face Legs Activity Cry Consolability (FLACC) scale by an independent observer and using the visual analogic scale (VAS) by the child and his parents. Anxiety before and during the BTI was evaluated using a VAS by the child and his parents. Proceeding of BTI was evaluated by the physician and child's parent, and benefit of distraction was evaluated by child's parent using a 4 point Likert scale.

Results

87 children were included (55 males, mean age=8.2 years (SD 3.6)); 40 children in the clown group and 47 in the usual distraction. The two groups were comparable on the main sample characteristics and in term of procedures. There were no significant differences between groups on the FLACC and VAS anxiety and pain. Both distractions were considered beneficial by the parents but the result was significantly higher in the clown group (p=0.002). No differences were found between groups for the different subgroups.

Conclusion

The clown presence during BTI does not seem to reduce significantly pain or anxiety in children/parents compared to usual distraction. However the presence of the clowns likely
improves the level of distraction as evaluated by the parents which is a key result for such a repetitive procedure.

APPLICATION OF ICF CORE SETS FOR CHILDREN AND YOUTH WITH CEREBRAL PALSY TO ELABORATE INDIVIDUAL REHABILITATION PROGRAMMES IN RUSSIA

A. Shoshmin¹, L. Kozhushko², Y. Besstrashnova¹, G. Ponomarenko³

¹Federal Scientific Center of Rehabilitation of the Disabled n.a. G.A. Albrecht, Department of International Classifications and Systems of Rehabilitation and Habilitation, St.Petersburg, Russia
²Federal Scientific Center of Rehabilitation of the Disabled n.a. G.A. Albrecht, Department of Social Rehabilitation and Habilitation, St.Petersburg, Russia
³Federal Scientific Center of Rehabilitation of the Disabled n.a. G.A. Albrecht, General Director, St.Petersburg, Russia

Introduction/Background

In 2016, the core sets for children and youth with cerebral palsy selected from the International Classification of Functioning, Disability and Health (ICF) were translated into the Russian language. The work was carried out to determine the area of responsibility of specialists (pediatrician, neurologist, orthopedist, otolaryngologist, ophthalmologist, psychologist, psychiatrist, social worker and teacher) who defined methods and tools for standardizing the assessment of impairment severity.

Material and Method

The approach was tested in rehabilitation centres and the State Bureaus of Medical and Social Expertise in St. Petersburg and the Voronezh Oblast in 2016 and 2017. 112 children and youth from 1.5 to 18 years old were examined in the rehabilitation center and 78 children were examined in the State Bureaus of Medical and Social Expertise.

Results

The results of the testing made it possible to compose a list of the most probable rehabilitation interventions and assistive technologies according to the severity of the impairments and categories of activity and participation. It appeared that in the rehabilitation centre it is rational to use the comprehensive ICF core sets.

Conclusion

In case of the State Bureau of Medical and Social Expertise, it was impossible to implement the comprehensive ICF core set in the conditions of the time limit and high workload for the specialists. Therefore, the brief ICF core sets for children and youth with cerebral palsy were used according to the age gradation.

MID FOOT DEFORMITIES IN CHILDREN WITH UNILATERAL CEREBRAL PALSY

M. Prigent¹, B. Sylvain¹, L. Mathieu², P. Christelle¹, H. Laetitia¹
¹CHRU Brest, Physical medicine and rehabilitation, Brest, France
²Inserm U1101, Laboratoire de Traitement de l’Information Médicale, Brest, France

Introduction/Background

Foot deformations occur in 93% of children with cerebral palsy (CP) leading to disabilities. Forefoot and backfoot deformations are well described, but data regarding midfoot deformation are lacking. This study aim (1) to quantify prevalence of midfoot deformation in the impaired and non-impaired foot of walking children with unilateral CP, (2) to evaluate correlations between Mid-foot and backfoot deformation, lower limb torsional disturbance, distal selective motor control, or lower limb spasticity.

Material and Method

A retrospective study was conducted on children with unilateral CP who benefited from a 3D motion analysis in Brest (France) between 2006 and 2017. Clinical data regarding midfoot deformation were collected and classified as typical axe, Metatarsus adductus (MAdd) or metatarsus abductus (MAbd). Data regarding backfoot and ankle deformation; Modified Ashworth Scale of lower limb muscles; leg length discrepancy; tibial torsion and femoral anteversion; distal selective motor control were also collected.

Results

Data from 70 children (GMFCS I, II, III) with unilateral CP were analyzed. Mean age was 10.13 years (SD=0.51). 35 males were included. 35 (50%) impaired feet presented a MAdd, 5 (7.2%) a MAbd and 30 (42.8%) had a typical axis. 24 (34.3%) non impaired feet had a MAdd, 4 (5.7%) had a MAbd and 42 (60%) had a typical axis. Prevalences were statistically different between groups. In the impaired side, significant correlations between MAdd and poor foot dorsiflexion control (Boyd scale) (p=0.01) and between MAdd and tibialis posterior spasticity (p=0.04) were found.

Conclusion

MAdd seems to be the most frequent midfoot deformation in children with unilateral CP. If prospective studies confirm the role of tibialis anterior and posterior in the mid-foot deformities then prevention strategy should focus on these two targets.

FINDINGS REGARDING RELATIONSHIPS BETWEEN AMBULATION CAPABILITY AND SOME BONE STRUCTURE, RESPECTIVELY RELATED METABOLIC PARAMETERS IN PUBERTAL AND ADOLESCENT PATIENTS - PRELIMINARY RESULTS

C.G. Morcov¹, G. Onose², L. Padure³, M.V. Morcov³, M. Bejan³
¹“Dr. Nicolae Robanescu” National Clinic Centre for Neuropsychomotor Rehabilitation, quality management of medical services, Bucharest, Romania
²“Bagdasar-Arnesi” Teaching Emergency Hospital, Rehabilitation, Bucharest, Romania
³“Dr. Nicolae Robanescu” National Clinic Centre for Neuropsychomotor Rehabilitation in Children, Rehabilitation, Bucharest, Romania

Introduction/Background

Children with cerebral palsy (CP) who cannot walk seem more prone to have low bone density than ambulatory ones and respectively, walking non neurologic (scoliosis) patients, of the same age category.

Yet, such relationships may be more complex; therefore we aimed to perform a preliminary analysis of them.

Material and Method

We evaluated 58 children, 11-18 years old, divided in 3 groups: non-ambulatory CP (15), ambulatory CP (21) and with scoliosis (22) in the NRNCCNRC.

To discriminate ambulation/non-ambulation capability in patients within this study we used a Functional Ambulation Categories inspired paradigm: non-ambulatory patients assimilated to 0 score and the ambulatory children would have achieved either independent or in different degrees of personal and/or device assisted, gait.

Bone paraclinic parameters assessed: DEXA (Z-Scores), total serum Calcium and 25-OH vitamin D.

Descriptive statistical analysis, ANOVA, medians test and chi² tests, were performed using SPSS v.24.

Results

Regarding DEXA, concerning Z-Scores distribution, the 3 diagnosis groups differed both in averages and in medians, respectively values of low bone density showed significant differences only between the scoliosis and the non-ambulatory CP groups (more cases in the latter, p=0.004).
For total serum calcium and 25-OH vitamin D concentrations there were not distribution differences between the diagnosis groups.

As for total serum calcium, most of our patients had normal values corresponding to their age, except:

- 4 with hypocalcaemia (1 with scoliosis, 3 ambulatory CP),

- 2 with hypercalcaemia (1 with scoliosis and 1 non-ambulatory CP).

For 25-OH vitamin D serum concentrations, around 60% of the patients were deficient in each group (not sufficient available data to draw genuine statistical objectifications of differences in between).

**Conclusion**

DEXA findings confirm significant differences between non-ambulatory CP children and ambulatory, and scoliosis ones; for the other paraclinic parameters larger groups are needed for enhanced statistical power.

THE USE OF INCOBOTULINUMTOXINA AS A SAFE OPTION FOR THE MANAGEMENT OF SPASTICITY IN CHILDREN WITH CEREBRAL PALSY: OUR EXPERIENCE

L.E. Alarcón Mora1, A. Leon-Valenzuela1, M. Linares Gago1, J. Sánchez Palacios1, J. Bautista Troncoso1, R. Del Pino Algarrada1

1UGC Hospital Puerto Real-Hospital Puerta del Mar, Physical Medicine and Rehabilitation Unit, Cádiz, Spain

Introduction/Background

Cerebral palsy (CP) is the most common developmental disorder associated with disability and permanent motor disability. Spasticity is an important limitation in children with cerebral palsy, which affects approximately two thirds of this population. Several products of botulinumtoxin-A (BoNT-A) have been shown to be effective in the treatment of spasticity. The purpose of the study is to present our experience with treatment with incobotulinumtoxinA (Xeomin) for children with cerebral palsy.

Material and Method

We analyzed the data of 75 children with cerebral palsy, who received a total of 351 sessions of infiltration with incobotulinumtoxinA. We recorded the dose, the infiltrated muscles, the side effects, the Gross Motor Function Classification System (GMFCS I-V) the Manual Skill Classification System (MACS) and the Manual Capacity.

Results

Children’s mean (standard deviation; SD) age was 9.2 (3.3) years; mean weight was 26.7 (12.7) kg. Participants received a mean dose of 217 (144) U per session with a maximum of 600 units. GMFCS Level was I for 15.1% of patients, II for 41.9%, III for 10.3%, IV for 13.4% and V for 19.4%; MACS level was I for 33.3% of patients, II for 22.8%, III for 16.8%, IV for 6% and V for 15.4%. 43% of patients were hemiplegic, 24% diplegic, and 32% tetraplegic.

The most frequently injected muscles were gastrocnemius (24.7% of patients), hamstrings (13.4%), adductor longus (14.3%), flexor carpi radialis (6.4%), adductor magnus (6.2%), pronator teres (6%) and biceps brachii (5.4%). Six adverse effects were reported (6% of patients, 1.7% of injections); adverse events assessed as treatment related were muscle weakness, generalized weakness, and fever.

Conclusion
The results suggest that the use of incobotulinumtoxinA is a safe option in the management of spasticity in children with cerebral palsy.

SPASTIC MUSCLE INJECTIONS WITH BOTULINUM TOXIN TYPE A MAY BE HELPFUL FOR THE TREATMENT OF SIALORRHEA IN CASES OF CEREBRAL PALSY

S.B. Karaca

Kırıkkale University Faculty of Medicine, Physical Medicine and Rehabilitation, Kırıkkale, Turkey

Introduction/Background

In cases of cerebral palsy (CP) large majority of cases have associated deficits with movement and coordination problems and drooling is one of them. Sialorrhea can be an important clinical, social, educational, and emotional issue for children and their parents in CP. It is reported to occur in 10 to 37% of cases. Oral medications, behaviour management, oral motor therapy, intraglandular delivery of Botulinum Toxin Type A (BoNT-A) and surgery are used for the treatment of sialorrhae. Much of childhood therapy is aimed at improving movement and coordination. BoNT-A is used for spasticity management. Dry mouth is one of the side effects of BoNT-A treatment. But this side effect may be a favorable effect on drooling in children with CP.

Material and Method

Here we present a diplegic spastic CP case having sialorrhae who underwent a total three sessions of repeated BoNT-A injection for lower extremity muscles. A total dose of 200 IU BoNT-A were used in each injection and 13 IU/kg in the last one. According to the mothers declaration the patient had less sialorrhae after muscle injections when the effect begins in the first week and lasts approximately in the fourth month simultaneously with increasing spasticity. So we evaluated the patient’s drooling by the Drooling Severity and Frequency Scales (DSFS) in the third injection.

Results

Drooling Frequency decreased from 4 to 2 and Drooling Severity decreased from 5 to 3 and DFSS decreased from 9 to 5 after the last injection’s third month control.

Conclusion

The treatment of spasticity with BoNT-A injection may have a favorable effect on drooling in children with CP. A side effect may turn into an beneficial effect. Further studies are warranted.

MANAGEMENT OF CHILDREN WITH CEREBRAL PALSY
I. Ksibi¹, H. Garès², R. Maaoui¹, I. Megdiche¹, H. Rahali¹
¹Military Tunis Hospital, Department of physical and functional rehabilitation, Tunis, Tunisia
²Military Tunis Hospital, Department of physical and functional rehabilitation, Msaken, Tunisia

Introduction/Background

The management of the paralyzed cerebral child requires a multifunctional and multidisciplinary approach aimed to preserve the neuro-orthopedic capital and to optimize the functional ability for a better family and social integration. In this work we report on the particularities of management of cerebral palsy in the Department of Physical Medicine and Functional Rehabilitation at Tunis Military Hospital.

Material and Method

Retrospective study conducted at the Physical Medicine and Functional Rehabilitation Department of the Military Tunis Hospital, focusing on children being followed for cerebral palsy during the period between January 2012 and December 2017. Data concerning clinical, neurological and neuro-orthopedic evaluation were listed as well as the different Therapeutic management methods introduced during the follow-up.

Results

35 children were included in this study, 13 girls (37%) and 22 boys (63%), with an average age of 10.7 years [5-18]. Clinical presentation was spastic tetraparesis in 19 children, spastic hemiparesis in 12 patients and 4 cases of spastic diplegia. 80% of patients were walking alone or with technical assistance. 3 patients had non-functional upper limbs. The most common neuro-orthopedic deformities were foot equines (70%).

The most injected botulinum toxin sites were triceps sural, hamstrings and adductors. Mean dose injected was 15UI/kg onabotulium. The most frequently prescribed equipment was Ankle-foot orthosis (90%) and Hip-knee-ankle-foot orthosis (75%). 7 patients had orthopedic surgery to correct deformities

Conclusion

Management of the children with cerebral palsy requires a multidisciplinary approach and a long-term follow-up to overcome the various deficiencies and complications. This management
remains heavy and depends on the degree of involvement of the family and their adherence to the therapeutic program.

Keywords

No conflict of interest
Introduction/Background

Botulinum toxin (BoNT-A) is considered as an effective therapy for children with cerebral palsy (CP). The target of BoNT-A is the neuromuscular junction (NMJ). Mechanism of action is based on the inhibition of acetylcholine neurotransmitter release at presynaptic nerve terminals, which results in reduction of muscle fiber activity. However, the long-term effect of repeated toxin injections on muscle structure remains unknown. We hypothesize that repeated injections of BoNT-A would have a structural effect on the muscle.

Material and Method

We are conducting an observational, monocentric, cross-sectional anatomophysiologival study on multi BoNT-A injected muscle of children with CP. The main objective is to evaluate the effect of long-term toxin injections on the NMJ fragmentation and axonal sprouting. All eligible patients are enrolling over a 2-year period with a sample of a muscle taken during a scheduled surgery from the lower limb of spastic CP in children previously treated by BoNT-A. The sample size is estimated to 30.

Results

To date, 10 patients have been included. These preliminary analyses found the great majority of NMJs are unaffected. Indeed, they have a normal appearance with a low fragmentation (66% of NMJ have a number of fragments ≤ 3) and a well-marked primary gutter. Expected axonal sprouting after repeated toxin injections was not observed except for a single NMJ in one of the patients. On the other hand, some partial denervation and partial reinnervations were observed in 6 out of 10 samples where we find the presence of JNM.

Conclusion

These preliminary results will be further studied in the up-coming year.

CHILD’S QUALITY OF LIFE AND MOTHER’S BURDEN IN SPASTIC CEREBRAL PALSY: A TOPOGRAPHICAL CLASSIFICATION PERSPECTIVE

Y. özkan
ADNAN MENDERES UNIVERSITY, physiotherapy and rehabilitation, AYDIN, Turkey

Introduction/Background

To evaluate child’s quality of life (QoL), mother’s burden and correlation between these parameters in spastic cerebral palsy (CP).

Material and Method

Children with spastic CP (n=120; mean age 8.64±3.45; range 2 to 17 years) were classified into three groups including diplegia, hemiplegia, and quadriplegia based on the topographical classification. The Pediatric Quality of Life Inventory and Zarit Burden Interview were used to determine the child’s QoL and the mother’s burden scores.

Results

The child’s QoL scores were decreased in quadriplegia group than those in hemiplegia group (for all, p≤0.016) and in diplegia (except emotional functioning, p=0.864) group (for all, p≤0.002). The mother’s burden was increased in quadriplegia group compared to other groups (for all, p<0.001), and it was increased in diplegia group compared to hemiplegia group (p=0.001). Increases in the child’s QoL scores were associated with decreases in the mother’s burden scores (for all, p<0.001).

Conclusion

Child’s QoL is associated with mother’s burden in spastic CP, and quadriplegic children and their mothers are more affected. The burden of mothers ranked the highest in quadriplegia group, followed by diplegia group, then hemiplegia group. The topographical classification is a good indicator for the child’s QoL and the mother’s burden in spastic CP.

THE EFFECT OF SITTING AND STANDING POSTURES ON BALANCE AND MOTOR FUNCTIONS IN CHILDREN WITH CEREBRAL PALSY

H. Ozoymak Akcin¹, E. Kavlak¹
¹Pamukkale University, School of Physiotherapy and Rehabilitation, Denizli, Turkey

Introduction/Background

This study aimed to research the effect of supported- unsupported sitting and standing postures over the balance and motor functions in children with cerebral palsy.

Material and Method

Twenty-five (9 girls; 16 boys) children with hemiparetic cerebral palsy with mean age 3.4 ± 1.13 years were participated in the study. Children with cerebral palsy (SP) were divided into two groups according to KMFSS: Level I and Level III. The System of Classification Gross Motor Functions and Gross Motor Function Measure-88 to evaluate children with CP was used. Balance ability was assessed using a 1-Min. Walking Test (1MWT) and Early Clinical Assessment of Balance(ECAB). Functional Independence Measure for Children (WeeFIM) was used to evaluate the independence in terms of daily living activities of the children with CP. Mini-Manual Ability Classification System (Mini-MACS) in children was used to evaluate the manipulative skills of children in 3 different postures supported-unsupported sitting and standing.

Results

According to GMFCS levels of all participants between level 1 and level 3 GMFM, ECAB 2, 1 MWT, total Wee-FIM and all subsections statistically meaningful differences were found (p<0.05). According to the results of Mini-MACS, KMFSS Level I and Level III, in both groups, hand skills in assisted supported sitting is better than the ones in unsupported sitting and standing.

Conclusion

In conclusion, researchers and clinicians working with cases of hemiparetic SP, can use ECAB balance test to assess the balance of these cases, also by our study taking as a whole not only lower extremite functions but also focusing on hand functions, it shows that supported sitting should be emphasized to use hand functions better.

SIX-MINUTE WALK TEST (6MWT) IN CHILDREN WITH CEREBRAL PALSY. SYSTEMATIC REVIEW AND PROPOSAL OF AN ADAPTED VERSION
A.L. Guinet¹, E. Desailly¹
¹Fondation Ellen Poidatz, Pôle Recherche et Innovation, Saint Fargeau Ponthierry, France

Introduction/Background
The six-minute walk test (6MWT) is an objective evaluation of functional exercise capacity in adults with cardiovascular diseases, obesity, or respiratory disorders. The 6MWT is increasingly used in paediatrics, and especially for children with cerebral palsy (CP) to define their capacities and to evaluate therapeutic interventions. The aim of this study is to report the validity of the 6MWT in children with CP and to propose an adapted-6MWT.

Material and Method
A systematic review was performed following the EQUATOR network guideline. The primary search strategy screened online databases (PubMed (MEDLINE), CINAHL, Embase, Pascal, Cochrane Library, Google Scholar) and grey literature in October 2017. The key terms were ‘Six-minutes walk test’, ‘cerebral palsy’, AND ‘reliability’, ‘validity’, ‘responsiveness’, ‘reference value’.

Results
After adjusting for duplicates and applying the search filter, 26 articles over 146 articles were included in this review. Walking speed must be self-selected. Reference value for healthy and CP children are classified by age. This allow comparisons. The distance travelled during the 6MWT is significantly lower for children with CP. There is a significant difference in the 6MWT results between children with GMFCS I/II and GMFCS III. The reliability test-retest is excellent (ICC 0.87-0.98). The 6MWT isn’t correlated with the VO₂ peak recorded on a cyclo ergometer. The 6MWT is correlated with ABILOCO-kids test, which evaluates the locomotor capacities of children with CP (r=0.70). We introduce an adapted-6MWT for children with cerebral palsy.
(Figure) adapted on the basis of the comments and suggestions identified in the studies.
Instructions :
- Vérification des recommandations et des contre-indications
- Relevé du rythme cardiaque par un cardiofréquencemètre portable
- Relevé de la saturation en oxygène (SpO₂)
- Relevé de la fatigue et de la dyspnée avec l’échelle de Borg

Instructions :
- Le thérapeute donne à l’enfant les consignes précises de début de test : « L’objectif de ce test est de marcher le plus loin possible sur une durée de 6 minutes. Tu vas faire des allers et retours dans ce couloir. Tu auras le droit de ralentir, de t’arrêter, et de te reposer si nécessaire. ». (Consignes complètes à communiquer - Tableau 1)

Instructions :
- Le thérapeute reste au niveau de la ligne de départ, il ne marche pas à côté de l’enfant
- Le thérapeute ne doit pas se laisser distraire et compte les A/R effectués
- Il relève le rythme cardiaque toutes les minutes
- Il encourage l’enfant d’une voix neutre et lui indique le temps toutes les 30 secondes

Inut cas d’arrêt :
- Le thérapeute propose à l’enfant de s’adosser au mur et de repartir quand il s’en sent capable ; il n’arrêta pas le chronomètre
- En cas d’arrêt définitif, le thérapeute note la distance parcourue, le temps et la raison de l’arrêt

Instructions en cas d’arrêt :
- Relever de la fatigue et de la dyspnée avec l’échelle de Borg ; demander ce qui l’a empêché d’aller plus loin
- Relever le rythme cardiaque et la SpO₂
- Calculer la distance parcourue
- Féliciter l’enfant

Consignes générales :
Les aides techniques usuelles sont autorisées ;
Aucune période d’échauffement n’est nécessaire

Adaptation aux enfants atteints de paralysie cérébrale :
Parcours de 20 mètres ; Instructions délivrées toutes les 30 secondes ; Tutoiement de l’enfant ; Pour les enfants GMFCS III : rester à côté d’eux pendant le test
Figure. French version of the adapted-6MWT for children with cerebral palsy.

Conclusion

The 6MWT is a simple test of the locomotor capacities, easy to access, inexpensive, and quickly achievable. The 6MWT is not a measurement of physical condition or aerobic fitness, in children with PC. We propose a standardized use of this version, adapted for children with CP.

HYPNOANALGESIA INCREASES ELECTROSTIMULATION ACCEPTABILITY IN CHILDREN WITH CEREBRAL PALSY

I. Heymann1, J. Fabienne2, M.C. Gellez2, L. Helene3

1SSR pédiatrique Marc Sautelet, Hôpital de jour, Villeneuve d’Asq Cédex, France
2SSR Marc Sautelet, hôpital de jour, villeneuve d’asq, France
3SSR marc sautelet, hopital de jour, villeneuve d’asq, France

Introduction/Background

In cerebral palsy, electrostimulation increases muscular strength and joint amplitudes while decreasing spasticity and muscular co-contractions. However, electrostimulation is seldom used in children, mainly because of its actual or assumed poor tolerability. Electrostimulation is an integral part of the therapies used in children at Marc Sautelet SSR. Furthermore, we are developing the use of hypnoanalgesia in our pediatric population and using it frequently to complete botulinic toxin injection, postoperative mobilizations or electrostimulation.

Material and Method

We compared the tolerance of two tibialis anterior electrostimulation sessions, at least one week apart: the only difference was that the second session was performed under hypnoanalgesia.

Three items were used to assess tolerability, namely session duration, age-adapted self-assessed pain scales (VAS, Faces Pain Scale) and other pain scales (FLACC Face Legs Activity Cry).

Eleven children (7 with hemiplegia, 3 with diplegia and 1 with quadriplegia), aged 4 to 12 years old, were included. The Wilcoxon test was used to determine statistical significance.

Results

The 20 minutes electrostimulation session under hypnoanalgesia was completed in all children, Only 4 children when it was performed without hypnoanalgesia. (p=0,018)

Pain, as assessed by every scale used in this study, was significantly lower when hypnoanalgesia was used.(p=0,005)

Conclusion
These results are in favor of a wider use of electrostimulation, in association with hypnosis and distraction techniques.

FUNCTIONAL STATUS IN TUNISIAN CHILDREN WITH CEREBRAL PALSY

O. Borgi, S. Boudokhane, A. Kalii, H. Migaou, Z. Ben Salah Frih

1Faculty of Medicine of Monastir-University of Monastir, Department of Physical Medicine and Rehabilitation- University Hospital Fattouma Bourguiba of Monastir, Monastir, Tunisia

Introduction/Background

Cerebral palsy (CP) is one of the most common causes of disability in childhood leading to functional limitations. Assessment of the functional limitations is important to determine the severity of the disability in CP and to evaluate the benefit of the rehabilitation programme. However, functional status in CP show variation according to sociocultural care characteristics. The aims of this study were to evaluate the functional disability of Tunisian children with CP by using the Gross Motor Function Classification System (GMFCS) and to investigate a possible correlation between intellectual functioning and parental socio-economic status.

Material and Method

Eighty children with CP (independently ambulant, marginally ambulant, and nonambulant) followed in the department of physical medicine of Fattouma Bourguiba Hospital in Monastir were included in the study. Motor function was rated by the GMFCS which classifies children into five severity levels (Level V being the most severe).

Results

The mean age was 8.6±5 years and the sex ratio was 1.28. Spastic CP (88.7%) and bilateral spastic CP (70%) were the most common type of CP. The distribution of GMFCS levels was mostly altered: level V in 28.7% of cases (Transported in a Manual Wheelchair) and level IV in 25% of cases (Self-Mobility with Limitations). A strong correlation was found between GMFCS level and intellectual functioning (IQ). The parental socio-economic status does not appear to affect functional profiles.

Conclusion

The children with CP had altered GMGCS level. The systematic evaluation of the IQ can provide useful information about a possible future outcome for every functional level. However, studies with wider series are needed to generalize our results.

SIALORRHEA: DESCRIBING DIFFERENT TREATMENT APPROACHES IN PORTUGAL
F. de Matos¹, D. Ascenso¹, M. Freitas¹, S. Almeida², C. Duarte²
¹Hospital Garcia de Orta, Physical Medicine and Rehabilitation, Almada, Portugal
²Hospital Garcia de Orta, Center for Child Development Torrado da Silva, Almada, Portugal

Introduction/Background

Sialorrhea has severe clinical and social consequences as well as a great impact on the QoL of Cerebral Palsy and other motor disease patients, their families and caretakers. There are different therapeutic approaches in the control of sialorrhea and our aim was to characterize it in Portugal.

Material and Method

Eighty-one questionnaires were sent to all Neuropediatric and PMR departments in Portugal in order to characterize the treatment of sialorrhea at a national level in terms of behavioural therapy, oral pharmacology, BTX-A injection and ultrasound guidance, and surgery referrals.

Results

Twenty-five responses: 9 (36%) Neuropediatric, 15 (60%) PMR and 1 (4%) Pediatric department. From all answers: 6 (24%) from the north of the country, 3 (12%) from the center and 16 (64%) from the south. One answer was not included in the study. Of the total, 23 follow patients with sialorrhea and only 1 doesn't. Of all, 83% (19) resort to behavioural treatment, 13% (3) do not and 4% (1) did not answer. As for prescription of oral drugs, 44% (10) resort to this type of treatment, 17% (4) rarely, 22% (5) never and 17% (4) did not respond. Of those prescribing oral drugs: 57% trihexyphenidyl, 43% others (amitriptyline, scopolamine, atropine). BTX-A injection in the salivary glands: 13 do it in their departments, 7 refer to other departments or hospitals, 2 do not. Of the applications, 76% (16) have ultrasound guidance. Surgery: 8 perform it in the hospital of origin, 9 refer to other hospitals and 5 do not treat surgically.

Conclusion

Our study reflects the great therapeutic diversity in sialorrhea and its complexity. There is a need for a greater number of studies that follow quality criteria and precise and quantitative methods of evaluation in order to reach a definitive conclusion about the most effective and safer treatment.

Keywords

Sialorrhea; Cerebral Palsy; botulinum toxin type A
No conflict of interest
Cerebral palsy is defined as motor impairment caused by non-progressive brain injury in an immature brain. This injury is stable and not progressive but the orthopedic deformations will progress. The management of cerebral palsy requires a team approach.

**Purpose**

The aim of our work: evaluate functional aspects and appreciate results of orthopedic disorders treatments in lower limbs after introducing the use of stretching splint in association with toxin and physiotherapy.

**Material and Method**

Cross sectional study October 2016 - December 2017. Recruit all patients with cerebral palsy. Assessment: measurement of joint amplitudes and popliteal angle, spasticity evaluation by the modified Ashwort scale. GEMFCS score. Gait video before and after treatment. Treatments: physiotherapy, toxin, progressive lengthening technique using plaster, walking boots and orthotic device for knees and ankles and in some cases surgery.

**Results**

72 children with cerebral palsy were recruited, 28 paraplegics. 35 children had botulinum toxin injections. 12 children had surgery (adductor tenotomy, lengthening of the hamstrings, vulpius or Achilles tendon lengthening). Initial mean popliteal angle 90°+ 43.60°; after physiotherapy: 90°+56°; after physiotherapy and plaster 90°+ 65°. Mean gain obtained for dorsal flexion angle: 10° knee flexed. There is an improvement of at least one level of the GMFCS score.

**Conclusion**

Good results are obtained with association: toxin injections, plaster and physiotherapy. Need of quantitative gait analysis for better appreciations.

BOTULINUM TOXIN TYPE A IN THE TREATMENT OF SIALORRHEA - OUR EXPERIENCE
F. de Matos¹, D. Ascenso¹, M. Freitas¹, S. Almeida², C. Duarte²
¹Hospital Garcia de Orta, Physical Medicine and Rehabilitation, Almada, Portugal
²Hospital Garcia de Orta, Center For Child Development Torrado da Silva, Almada, Portugal

Introduction/Background
Sialorrhea consists of an involuntary loss of saliva, and is considered pathological after 4YO. The aim of this study is to describe our methodology and evaluate the efficacy and safety of Botulinum Toxin Type A (BTX-A) in sialorrhea in children and adults with Cerebral Palsy (CP) or cognitive deficit, referenced to PMR consultation between 2002-2017.

Material and Method
Longitudinal descriptive study with clinical records analysis and consultation of Drooling Rate Scale (DRS) and Teacher Drool Scale (TDS) prior to BTX-A injections and 1-month after. Injection of BTX-A performed with ultrasound and sedation.

Results
Total of 104 patients, 86 patients selected, 32 female (37.21%), 54 male (62.79%), current ages 7-29YO (mean 18), age of the 1st application 3-22YO (mean 9.76), age of last application 4-23YO (mean 11.83). Fifty patients (58.14%) diagnosed with CP. Two-hundred-and-three total applications (average 2.36), maximum 10 applications. Parotids (55.56%), submandibular (9.09%) or both (35.35%), mean periodicity of 11.81 months. Sedation: 49.38% midazolam, 41.36% nitrogen protoxide, 0.62% Chloral Hydrate and 8.64% without. Surveys: mean pre-application-DRS of 33.98 (minimum 19, maximum 58), mean post-application-DRS of 28.46 (min 15, max 54), with p = 6.48-5, average difference 4.28 points in DRS (min -27, max 22). Mean pre-application-TDS of 4.04 (min 2, max 5), mean post-application-TDS of 3.38 (min 1, max 4), with p = 2.80-5, a average difference of 0.69 points in TDS (min -1, max 3). Difference in DRS and TDS of 0.76 and 0.24 respectively in the parotids, 6.33 and 0.83 in the submandibular and 8.52 and 1.43 in both. Improvements were statistically significant. Surgery: 6 (6.98%). Side-effects: 5 children (5.81%) insomnia/vomiting. No complications related to the administration technique.

Conclusion
The application of BTX-A in the treatment of sialorrhea is a safe, easy-to-apply technique, with statistically significant improvement in QoL and severity. Benefit in the application of BTX-A in both glands treatment is shown.

ANALYSIS OF FACTORS AFFECTING THE EFFICACY OF HIPPOTHERAPY IN CHILDREN WITH CEREBRAL PALSY
S.M. Yeo¹, J.Y. Kwon¹

¹Samsung Medical Center, Physical and Rehabilitation Medicine, Seoul, Republic of Korea

Introduction/Background

Hippotherapy has been reported to improve gross motor function and balance in children with cerebral palsy. However, clinical factors related with improvement of gross motor function have not been studied. In this study, we retrospectively reviewed 146 prospective collected data and analyzed the predictive factors for the effectiveness of hippotherapy.

Material and Method

146 children with CP, aged 3–10 years, presenting variable function (Gross Motor Function Classification System [GMFCS] levels I–IV) participated in this study. Participants received 30 minutes of hippotherapy twice a week for 8 weeks (16 sessions) in addition to conventional physiotherapy. GMFM-88 and PBS score were checked by pediatric physical therapists before and after hippotherapy in all cases. And data such as GMFCS level, age, sex, CP distribution and CP type were collected. We arbitrary set a clinically meaningful change in gross motor function after hippotherapy (good response) as 2 point change in GMFM-66 in 2 months. Data were analyzed by using paired t-tests or Wilcoxon signed-rank tests to confirm whether there were significant differences between before and after intervention according to the normality of data determined by the Shapiro-Wilk and Kolmogorov-Smirnov test. And multivariate logistic regression test was used to analyze the factors affecting the efficacy of hippotherapy.

Results

GMFM-66, GMFM-88 total, all dimensions of GMFM and PBS were significantly increased in all levels, all neuromotor types and all distributions. (p < 0.05). Positive prognostic factors for the therapeutic effect of hippotherapy is a poor sitting function (lower GMFM B score) and a better mobility function (higher GMFCS level).

Conclusion

This results support that Hippotherapy is a task oriented therapy to improve sitting balance. In addition, children with CP who can walk but still have room for improvement in sitting balance could get more benefit from hippotherapy.

DIFFERENT PHYSIOLOGICAL RESPONSE FROM 30 MINUTES BOUTS OF STATIC AND DYNAMIC SUPPORTED STANDING AMONG CHILDREN WITH SEVERE CEREBRAL PALSY. A PILOT STUDY
K. Lauruschkus 1
1Lund University- Sweden, Faculty of Medicine- Department of Health Sciences, Lund, Sweden

Introduction/Background

Children with severe cerebral palsy (CP), (GMFCS level IV and V), are little physically active and have much sedentary time which implies significant health risks. The standard care in Sweden includes static standing training (StS) in standing frames for 60-90 minutes daily, which affect the family life significantly. The motorised medical device Innowalk gives children with severe CP an opportunity to experience walking movement in an upright weight-bearing position. We have earlier had reports from parents of children with severe CP performing dynamic standing (DyS) with the Innowalk noticing effects not seen during StS. Therefore, the aim of this study was to elucidate if there were any differences in the response to one acute bout of StS and DyS in respiratory function, circulation, blood lipids, blood glucose, blood pressure, gastrointestinal function, pain, muscle tone and joint mobility among children with severe CP.

Material and Method

Seven children with severe CP were recruited by the National association for disabled children in Sweden for this pilot study. The measurements were performed one day in their standing frame and another day in the Innowalk at the Health Sciences Lab, Lund University. The results were analysed by descriptive, comparative and related statistics.

Results

The study design was feasible and the measurements could be performed. StS and DyS gave different physiological response among children with severe CP. During DyS deeper breathing with increased gas exchange at the alveolus was demonstrated, and the children were able to maintain and even increase the temperature at their shanks and feet. Additionally, the results showed a trend for a reduction of muscle tone during DyS.

Conclusion

DyS in the Innowalk showed positive acute effects. Our findings need to be confirmed in a larger population for the best training recommendations.

³Institut Supérieur de l’Education Sportive- University of Manouba, Department of PRM- INOMKassab, manouba, Tunisia

Introduction/Background

Cerebral palsy is the main cause of disability in children. It can engender major disorders that can deteriorate the physical conditions of the patient.

The aim of our study is to show that a physiotherapy rehabilitation of cerebral palsy, based on physical activity specifically adapted to bodybuilding, is beneficial on the physical level in order to improve the muscular strength, the balance, the posture, functional abilities, autonomy and physical performance.

Material and Method

Prospective, transversal, descriptive study of 12 children with cerebral palsy was performed in the general association of motor deficiency (AGIM), during a period of 3 months. Neurological, neuromotor and neuro-orthopedic evaluation as well as functional skills, postural balance, autonomy, fatigue and pain were assessed by validated scales. Our work, part of the care of children with cerebral palsy through the integration of a fitness program is adapted from two protocols “TABATA Method” and “CrossFit” that can meet the expectations of children with cerebral palsy.

Results

The average age was 11.16. At the end of a program of 12 sessions of bodybuilding, there was an improvement at the level of neuro-orthopedic balance, evolution of functional skills. The Tinetti test reveals a score optimization with a mean difference of 1. The monopodal support test showed a progress in postural balance with a mean difference of 1.09. A marked improvement in mean FIM score from 94.92 to 100 was noted. The most impaired dimensions were personal care, mobility-transfer and locomotion. The physical performance test, when performing a TABATA type reinforcement protocol (4 min’ duration), showed that the number of repetitions has doubled.

Conclusion
Bodybuilding is a recent field and is very effective in the management of subjects with cerebral palsy. Our intervention has beneficial effects on the improvement of the different physical aspects, whether postural or functional.

THE QUALITY OF LIFE OF CHILDREN WITH CEREBRAL PALSY AFTER INTENSIVE REHABILITATION
C. bakhta¹, Z. Talem¹, F.K. Lahouel¹, C. Hamoudi¹, S. Boukessassa¹, H. Moufokos¹, A. Abderrahim¹, K. Layadi¹
¹CHU, Medecine, Oran, Algeria

Introduction/Background
The abnormalities found in children with cerebral spastic paralysis have an impact on the quality of life even that of ambulant children. Our goal was to evaluate the quality of life of children with active spastic PC after an intensive rehabilitation program. Evaluate the rank in the siblings of these children, and the age of the mother during childbirth.

Material and Method
72 PC children classified as GMFCSI to GMFCS III were included in the spastic muscles and lower limb ambulation. An intensive rehabilitation program was followed by all patients. A measure of quality of life was done before and 6 months after the program.

Results
22 hemiplegic, 30 dipltegic, 11 triplegic and 9 quadriplegic were included in the study. 40% GMFCS I, 14% GMFCS II, 46% GMFCS III; AVERAGE AGE 8 ± 3 years. Sex: 51% female and 49% male. The age of the mother at the birth of the child was 29 YEARS [19-45 years], the rank in the siblings was: the first in the siblings 72%, 11% the 2nd. The average quality of life before rehabilitation was 41 on the PedsQL, of 37 After rehabilitation.

Conclusion
In our sample, the age of the mother during delivery was lower than that cited in the literature. Rank in the siblings was rarely mentioned; the quality of life of children with PC after 6 months of intensive rehabilitation was not significant.

Keywords

No conflict of interest
Cerebral Palsy (CP) is a group of multifactorial clinical syndromes characterized by motor deficit, sometimes with postural dysfunction.

**Material and Method**

METHODS: Retrospective study. A total of 743 electronic medical records of patients attended in initial PC consultations were evaluated, with 614 cases being eligible.

**Results**

RESULTS: Sex: female = 47.4%, male = 52.6%. Age in years: 29.5% under 2; 34% from 2 to 4; 15.5% from 4 to 6; 16.3% from 6 to 12; 4.6% 12 to 18; 0.2% ≥ 18 years. Natural and provenance: 55.4% and 62.7%, respectively, of the city of São Paulo (SP). At birth 50.7% were preterm and 45% term. Weight: 9.1% classified as extreme low weight, 16.8% very low weight, 21.8% low weight, 43.6% adequate weight, 2.3% macrosomic. Predominant type of delivery: cesarean section (56.5%). Clinical and topographic classification of patients: 13.4% Spastic hemiparetic, 33.9% Spastic diparesia, 0.5% Spastic triparesia, 12.2% Spastic tetraparesia, 0.5% Spastic monoparesia, 5.9% Dyskinetic / ataxic, 5.7% mixed PC, 1% hypotonic. In 55.5% of the families they did not receive disease aid. Regarding specialized care, it was observed that for 97.7% of the patients the first consultation with a Physiatrist was the first consultation.

**Conclusion**

CONCLUSION: Most pregnant women were submitted to the appropriate number of prenatal consultations. Cesarean delivery predominated. Preterm births were slightly higher compared to term. The classification of PC that predominated was the spastic diparetic, with GMFCS in the ranges from 1 to 5 equivalent. More than half of families didn’t have access to social benefits.

THE EFFECTS OF ADAPTED CYCLING INTERVENTION IN CHILDREN WITH CEREBRAL PALSY

E. Waals¹, T. Lauwers¹, K. Van Pamel¹, F. Lenaerts¹, G. Molenaers²
¹UZLeuven, Physical Medicine and Rehabilitation, Pellenberg, Belgium
²UZLeuven, Orthopedics, Pellenberg, Belgium

Introduction/Background

Children with cerebral palsy (CP) have subnormal aerobic and anaerobic capacity, decreased muscle strength and endurance compared with typical developing children. Children with disabilities reported ‘dependency on others’ as a barrier to participate in sport. Dynamic cycling could be a solution to move independently in community settings along with the benefits of exercise and improvements in strength, endurance and function. The aim of this study was to evaluate the effects of a dynamic cycling program for children with CP on the 3 levels of the International Classification of Functioning, Disability and Health framework.

Material and Method

Nine ambulatory children with spastic diplegia, between 4 and 12 years old and Gross Motor Function Classification System levels II to III, followed a home-based individualised outdoor cycling training program for 6 weeks. The most suitable bike for each participant was chosen at the bicycle advice centre of University Hospital Pellenberg. Primary outcomes were strength in m. quadriceps femoris and hamstring muscles, cycling skills, the life-H questionnaire and the Cerebral Palsy Quality of Life Questionnaire. The outcomes were measured 6 weeks before the intervention, at the start and at the end of the intervention.

Results

Significant pre-post intervention improvements were found for hamstrings and m. quadriceps femoris strength and cycling skills. There were no clinically significant improvements in participation and quality of life.

Conclusion

This study showed that a relatively short training program on an adapted dynamic bicycle was associated with a clinically relevant improvement in m. quadriceps femoris and hamstring muscles strength and cycling skills in children with moderate levels of CP. These results suggest that adapted cycling could be an effective and safe treatment for children with CP, for whom there are few other exercise opportunities, and can be considered as a useful additional tool for clinical practice.

EFFECTIVENESS OF TELE-REHABILITATION INTERVENTION TO IMPROVE ACTIVITY, PARTICIPATION AND QUALITY OF LIFE IN ADOLESCENTS AND YOUNG ADULTS WITH SPINA BIFIDA- A PILOT STUDY
Y. Gilboa¹, S. Steinhart², S. Raz-Silbiger²
¹The Hebrew University of Jerusalem, Occupational Therapy, Jerusalem, Israel
²Alyn Hospital- Pediatric and Adolescent rehabilitation center- Jerusalem- Israel,
Occupational therapy department, Jerusalem, Israel

Introduction/Background

While telerehabilitation can be used as a means to promote function and participation in individuals with various disabilities, no studies were found which investigated this method of treatment in adolescents and young adults with Spina bifida
Objectives: to examine the feasibility and effectiveness of telerehabilitation with adolescents with Spina bifida.

Material and Method

Study design: A pilot study with mixed methods of qualitative and quantitative (pre-post and 3 month follow-up) design.
Participants: 4 adolescents (ages 14-18) with Spina bifida
Outcome Measures:
(1) The Canadian Occupational Performance Measure (COPM) – participants' performance and satisfaction concerning their self-identified occupational goals.
(2) Wee- Functional Independence Measure (FIM) – Independence in activity of daily life.
(3) Pediatric Quality of Life Inventory (Peds QOL)
The intervention: Telerehabilitation through videoconferencing using Cognitive Orientation to daily Occupational Performance (CO-OP) approach. The participants identified 5 personal goals, three goals were trained directly and the addition goals were not trained to evaluated the transfer possibility.

Results

Four participants were evaluated post intervention (case 1- 15 year-old male ,case 2-18 year old male case 3-16 year old female and case 4- 18 year old male. After 10 sessions, the four participants indicated self-reported improvement in both trained and untrained goals from pre- to post-intervention. Case 1 made significant gains in 2/3 trained and 1/2 untrained goals, including a 12 point gain in the WeeFIM. Case 2 made significant gains in all trained and 1/2
untrained goals including a 6 point gain in the WeeFIM. Cases 3 and 4 made gains in all trained goals but not in the untrained goals. No improvements were reported regard to QOL.

**Conclusion**

Based on these initial results, telerehabilitation shows promise as a way to deliver the CO-OP approach and may help promote participation and independence of individuals living with MMC.

Introduction/Background

Alcohol has particularly harmful health effects in HIV-infected patients; therefore, HIV clinics are an important setting for integration of routine alcohol screening as an integral component of HIV care. In sub-Saharan Africa, little is known about AUDs among people attending HIV services.

Objective: To estimate the prevalence of alcohol use disorder in patients attending CCC at KNH

Design: A descriptive cross-sectional study

Setting: Comprehensive Care Center, Kenyatta National Hospital, Kenya carried out in the months of August to October 2016

Material and Method

Two hundred and seventy three participants were recruited for this study and interviewed about their socio-demographic characteristics. The World Health Organization’s Alcohol Use Disorders Identification Tool (AUDIT) was used to measure probable hazardous, harmful and dependent use of alcohol (‘alcohol use disorders’). Associations between AUDs and other variables were explored using logistic regression analysis. All variables associated with AUDs with a value <0.05 were included in the final multivariable model.

Results

The overall prevalence of AUD was 14% (38) broken as follows; 5.5% (15) had Hazardous/harmful drinking behavior with a cut off score of ≥8 or more. Those dependent on alcohol were 8.5% (23), with AUDIT score cut off point of ≥13 or more for women, ≥15 or more for men.

Conclusion

This study demonstrated that men are more vulnerable to AUDs and need special services to address the problem. The high prevalence of AUDs detected in our study highlights the need to integrate routine alcohol screening, AUD treatment and rehabilitation as part of HIV/AIDS intervention practices to better address alcohol use disorders in patients attending HIV/AIDS comprehensive care.

THE PREVALENCE OF ACTIVE CONVULSIVE EPILEPSY IN CHILDREN IN KILIFI, KENYA

R.N. Mbugua

Nairobi University- Kenyatta National Hospital, Research- and Community Health Worker, Nairobi, Kenya

Introduction/Background

Epilepsy is a common neurological disorder affecting 50 million people globally, 80% of them living in resource poor countries. Children below 15 years account for 25% of those affected and 40% of new epilepsy cases annually. The incidence of epilepsy is 3 times higher in first year of life compared to mid-adulthood. Median prevalence of epilepsy in Africa is 15/1000, 2-3 times more than in the Western countries. In Kenya the prevalence is 4-18.21/1000 in older children and adults. Active convulsive epilepsy (ACE) is defined as having two unprovoked seizures in a lifetime, with at least one in the last year.

Material and Method

In Kenya the prevalence is 4-18.21000 in older children and adults. Active convulsive epilepsy (ACE) is defined as having two unprovoked seizures in a lifetime, with at least one in the last year. To determine the prevalence of active convulsive epilepsy (ACE) in children in Kilifi and to determine the treatment gap in children with ACE. Study setting: Kilifi, a rural district in the coastal area of Kenya.

Results

Study subjects: Children aged 4 months to 13 years residing in the study area. Methods: A cross-sectional survey was conducted in a demarcated area of Kilifi District with a total population of 260,000, using a questionnaire to identify children with history of seizures. A second team of fieldworkers administered a more detailed questionnaire to those selected in Stage one to identify children with epilepsy, and referred them for clinical evaluation at the neurological assessment centre at the Kilifi District hospital.

Conclusion

The treatment gap among those diagnosed to have ACE was 78.5%. The prevalence of ACE among children in Kilifi is 211 000. Although there is a significant reduction in seizures among those using the MOR recommended treatment, majority of children with ACE are not on appropriate treatment.

INTRODUCTION/BACKGROUND

The SBS constitutes one of the most severe paediatric head traumas.

Objective: when an SBS diagnosis is confirmed, take up a survey of how many children showed previous signs suggesting violence.

MATERIAL AND METHOD

The study spanned over 50 legal cases on child abuse from 2011 to 2015.

For each case, from all medical and legal information, we established if there were previous signs of violence, which they were and when they appeared.

RESULTS

The average age at the date of diagnosis was 5 months.

Signs of previous violence were found among 80% of children; 42.5% had been admitted to emergency services and 67.5% had been examined by a General Practitioner or a paediatrician when signs could already been noticed.

The signs were: unusual vomiting without fever or diarrhoea in 64% of cases (isolated in ¼ of cases), a break in the growth chart of head circumference (45%) or in the growth chart of weight (25%), bruises (34%), an occurrence of faintness (17%).

The mean age of these signs related to the occurrence of the episode leading to the diagnosis was 30 days (SD 32 days; median line 20 days) It was of at least 45 days in 25% of cases.

CONCLUSION
these results are evocative of a very frequent reiteration of violence; it is not in this case “a clap
of thunder in a calm sky”. They also show the great difficulty most professionals run into when
they want to speak of violence and set its diagnosis, above all when the signs are not obvious.
Yet the earliest possible detection of the first signs of violence is the best to prevent reiteration
and to protect the child. Lack of knowledge in this field may be an explanation and is detrimental
to children. Better training for everyone is the key.

Introduction/Background

DC is one of the options in the staged therapy of refractory intracranial hypertension. A significant drawback of this technique is the formation of a complicated complex of pathophysiological disorders which develops due to an extended defect in the calvarium (disorders of brain perfusion, venous outflow, CSF-circulation, etc.).

Aim: assess the effectiveness of early calvarium reconstruction with cryopreserved bone in children after decompressive craniotomy.

Material and Method

51 patients had cranioplasty with cryopreserved bone after decompressive craniotomy during 2005-2016.

The autobone was stored in the freezer at the temperature – 40C. Before and after the surgery patients had CT-perfusion and MRI examination.

Results

In 70% of cases cranioplasty was made during the first two months.

In 30% of followed cases the restoration of skull integrity took place up to 65 days.

Late cranioplasty was caused by trophic disorders in soft tissues as well as by intracranial and extracranial infective-inflammatory complications. After the defect closure one could see restored brain perfusion, venous outflow.

At the early postoperative period the auto transplant infectioning was seen in 5.5%.

More than 75% of patients had clinical improvement, and 30% improved their outcome.

The follow-up period lasted from 3 months until 10 years.

Complete bone resorption was registered in one patient.
Conclusion

Early closure defects of the calvarium should be regarded as a surgical intervention which provides maximally possible conditions for the early restoration of cerebral functions. Despite the higher risk of infection and resorption of the autobone remains the effective material for early cranioplasty in children.

DYNAMIC OF MENTAL RECOVERY IN CHILDREN AFTER SEVERE TRAUMATIC BRAIN INJURY WITH MEDICAL TREATMENT BY SELECTIVE SEROTONIN REUPTAKE INHIBITORS.

Y. Sidneva¹, Z. Semenova², E. Fufaeva¹, B. Valentina¹, S. Valiullina¹
¹Clinical and Research Institute of Emergency Pediatric Surgery and Trauma, Neurorehabilitation and Recovery Treatment, Moscow, Russia
²Clinical and Research Institute of Emergency Pediatric Surgery and Trauma, Neurosurgery, Moscow, Russia

Introduction/Background

The neurotransmitters involved in the process of recovery of consciousness after TBI. In this regard, the use of selective serotonin reuptake inhibitors (SSRIs) for the treatment after brain injury is possible. Data on the use of antidepressants in the treatment of traumatic brain injury are contradictory; children are not studied enough.

Aim: To investigate the efficacy of SSRIs (Sertraline) in the mental recovery in the early period of the neurorehabilitation after TBI in children.

Material and Method

40 children (5-18 years) with severe TBI (GCS≤ 8). All children had interdisciplinary approach and standard medications in early rehabilitation. Group 1 (23 children) - in the early period additionally administered sertraline. Group 2 (17 children) - without sertraline. Methods: psychiatric and neurological; data of neuropsychological, radiological and scales.

Results

Group 1: a vegetative state (VS) - 4 (children), minimal consciousness (MC) “-“ - 6, minimal consciousness (MC) “+” - 7, amnestic confusion - 3, cognitive and emotional deficits - 3. Sertraline administered 12.5 mg/day in the morning, with increasing dose over 3 days to 25-50 mg/day. Duration of reception - an average of 3-4 months. Group 2: a VS - 4 (children), MC“-” - 5, MC“+” - 3, amnestic confusion - 3, cognitive and emotional deficits - 2.

In 3 months mental recovery to a stage of emotional and cognitive deficits was in 48% of children with sTBI during treatment with Sertraline, compared with 35% in the control group. Positive dynamics was diagnosed by neuropsychological scales.

Conclusion
Selective serotonin reuptake inhibitors have a positive effect on recovery from traumatic brain injury in children. SSRIs (Sertraline) improves mental functions - to increases the motor activity and emotional activity, motivation, cognitive functions. Early rehabilitation after severe traumatic brain injury becomes more effective in children with medical treatment by selective serotonin reuptake inhibitors.

Pediatric chronic pain (PCP) treatment has improved recently, largely because of the recognition that pain is a complex experience resulting from the interaction of biological, cognitive, emotional, behavioral and social factors. There is a consensus that the treatment of PCP requires a multidisciplinary approach, however, programs are very variable between centers, and there are no standard structure or protocols, mainly in what refers to rehabilitation.

The aim of this study was to show the results obtained after the first year of activity of our multidisciplinary consultation and the importance of the presence of a physiatrist and rehabilitation intervention.

Material and Method

All the clinical processes were consulted, and clinical data were collected.

Results

The consultation occurs weakly with the presence of different medical specialties (pediatrics, neurology, psychiatry, physiatry, psychology).

During the last year, 26 children (9 male; 17 female) were observed, with a mean age of 13.6 years and mean clinical evolution time until the first consultation of 19.66 months.

There was clinical improvement in 80.76% of cases. In 71.428%, a rehab program was established with good results, mainly in what refers to pain control, function and participation.

It is interesting to observe that all patients had a past of exhausting studies, polymedication, lack of exercise and that in a few months of rehab program (with hospital, home based and school intervention), we were able to reduce pain, medication, improve function, behavior and social integration. With the results of this pilot study we were also able to identify the points that need to be improved, like the application of functionality scales besides the pain ones.

Conclusion
No single formula can be applied to all hospitals, as well as health care systems vary from country to country, however the results of this study may be useful for those planning to develop a multidisciplinary pain program with focus on rehabilitation.

THE CORRELATION AND PREDICTOR FOR THE LENGTH OF PHYSICAL THERAPY IN INFANTS WITH CONGENITAL MUSCULAR TORTICOLLIS

S. Liao, S.S. Kuo

Changhua Christian Hospital, Department of Physical Medicine and Rehabilitation, Changhua, Taiwan R.O.C.

Introduction/Background

Congenital muscular torticollis (CMT) is the most common musculoskeletal disorder in infancy. The ultrasonography is widely used to evaluate infants with CMT because of the low cost, greater patient comfort, and does not expose patients to radiation. Physical therapy (PT) including stretching exercise is the first line therapy. The aim of this study is to find the factors including ultrasonographic results which could affect the length of PT.

Material and Method

We performed a retrospective analysis of 76 CMT infants who were referred for ultrasonographic investigation and PT program between January 2014 and May 2017.

*: pseudo tumor group compared with posture & hypertrophy group; &: hypertrophy group compared with postural group

76 infants who had received ultrasonographic study were enrolled. The mean age was 71.1 days old, 47 (64.5%) patients were boys. The infants were separated to four groups by ultrasonographic results (Table 1). The age, difference and ratio of bilateral SCM thickness, and side bending of neck were significantly different in pseudotumor group compared with hypertrophy and postural groups. After therapy, forty three infants reached full range of motion, 2 infants received surgery, 4 children were diagnosed with developmental delay. The PT duration is 152±97 days, and most infants received PT 2 times/week. The ratio and depth difference of bilateral SCM, neck rotation and side-bending were significantly improved after PT. The duration of PT was found to be correlated with age when referred (p=0.011), thickness difference of bilateral SCM (p=0.034) and initial neck rotation (p=0.004). In linear regression, the initial neck rotation was the most strong predictive factor for duration of PT.
Conclusion

The muscular torticollis could be almost completely treated by traditional PT. The more limitation in neck rotation needs longer duration of PT to treat.

Introduction/Background

The efficiency of the spine distortions treatment from the growth period is often difficult to measure, because the radiography highlights only the changes in skeletal order. The treatment is overall reported at long periods of time, regarding explosive anthropometric changes during the time of the growth period which makes the interest for continuing the therapy to decrease.

Rasterstereography offers an immediate feedback, through the reproduction of the back form, as a result of the deformation of parallel lightened lines designed on the body's surface after a certain algorithm, assigning this way convex and concave graphic areas which could highlight the changes of aesthetic order with immediate visualisations on the screen.

Material and Method

The study included 35 children during 10 days of therapy, 2 sessions/day, with ages between 9-15 years, diagnosed with spine deformation.

Rasterstereography has been done at the begining and at the end of therapeutic cure, aiming to emphasize/alleviate the relief of predominant/depressed areas (respectively convex/concave), on the back's surface.

Subsequent, the patients had completed a questionnaire of motivation's evaluation, in order to continue the therapy.

Results

At the rasterstereographic re-evaluation of 26 patients, there were registred changes of intensity and expansion of concave - respectively convex areas - in the sense of improving the aesthetic appearance of the trunk, 9 patients – stationary aspect.

The possibility of viewing the results has registred the motivation's growth for proceeding the therapy of 23 of the patients, 7 patients have recorded only the tendency of the motivation's growth, 5 patients have recorded the lack of the effect upon their motivation.
Conclusion

Rasterstereography is a method of immediate appraisal with appliances which could highlight with success the changes in aesthetic order after therapy, changes hardly to be remarked radiologically, and also in order to maintain the motivation of continuing therapy, due to easy graphic mode of viewing.

Keywords

rasterstereography;therapy;motivation

Background and aims: This study investigated the profile of hip, knee, and ankle joint contractures based on ambulatory status in patients with Duchenne muscular dystrophy (DMD). The difference in major joint contractures depending on intervention, including passive stretching exercises and assisted standing using standing frames, in ambulatory and non-ambulatory groups were also evaluated.

Methods: A cross-sectional study was conducted in 128 boys with DMD treated with corticosteroid therapy. Passive range of motion of the hip, knee, and ankle joints were measured using a goniometer and the Vignos scale was used to grade ambulatory function. Those who underwent more than three sessions of interventions a week were categorized as the stretching group or passive standing frame users.

Results: Hip flexion (HF), knee flexion (KF), and ankle plantarflexion (APF) contractures were more common and severe with deterioration of ambulatory function. APF contractures were observed more frequently early even during the ambulatory period. Passive stretching exercises more than three sessions a week were not associated with the degree of lower extremity joint contractures in the ambulatory or non-ambulatory group. However, assisted standing via standing frames was associated with lower degree of the HF, KF, and APF contracture angle in the non-ambulatory group.

Conclusions: We showed the lower extremity joint contracture status in patients with DMD who are taking corticosteroid based on ambulatory function. APF contractures were observed more frequently, even early in the ambulatory period. Assisted standing using standing frames was associated with a lower degree of HF, KF, and APF contracture angle in the non-ambulatory group.

INTEREST OF NEEDLE ELECTROMYOGRAPHY IN THE EXPLORATION OF NEUROLOGICAL WALKING DISORDERS
F. Allaya¹, I. Kammoun¹, D. Masmoudi¹, R. Kammoun¹, O. Jallouli¹, A. Haddar¹, N. El Fen², K. Masmoudi¹
¹University hospital Habib Bourguiba, Physiology and functional explorations, Sfax, Tunisia
²sahloul university hospital, Physical Medicine and Rehabilitation, Sousse, Tunisia

Introduction/Background

Gait and balance disorders are a frequent complaint in neurology, especially in the elderly, and can even be the cause of a real public health problem.

The objectives of this study are:
To study the neuromuscular lesions revealed by adults gait disorders and to highlight the role of needle electromyography (EMG) in the exploration of these disorders.

Material and Method

This is a retrospective study during three years [2015-2017] and collecting 11 adults complaining of gait disorders and explored in the service of functional explorations at the Habib Bourguiba University Hospital.

A collection of health problems and a neurological examination were carried out with evaluation of the sensory, motor and sensory nerve conduction, and concentric needle muscle detection.

Results

The mean age of the patients was 63 ± 13.1 years [40-91], with the participation of 10 men and one woman. The most common walking disorder was steppage, with mostly bilateral involvement. Four patients were diabetic and two hypertensive. Clinical examination revealed abolished osteotendinous reflexes in 4 cases and weak in 2 cases, muscle amyotrophy in 2 cases, sensory and motor disorders in 5 cases. The EMG examination found axonal sensory impairment in 4 patients and demyelinating in 1 patient. Motor impairment, whether axonal or demyelinating, was noted in most cases. A neurogenic pattern was found in most cases during needle detection. The most common diagnosis was lumbar radicular pain (7 patients), severe sensory-motor axonal neuropathy was retained in only one case.

Conclusion

Gait disorders present an atypical presentation of radiculopathy, and EMG needle detection has high specificity and sensitivity in exploring radiculopathy. That's why EMG needle detection is important in exploring gait disorders.

THE INVOLVEMENT OF MUSCULOSKELETAL SYSTEM AND ITS INFLUENCE ON POSTURAL STABILITY IN CHILDREN AND YOUNG ADULTS WITH CYSTIC FIBROSIS

O. Kenis Coskun1, E. Karadag-Saygi1, Y. Bahar-Ozdemir1, Y. Gokdemir2, B. Karadag2, O. Kayhan1

1Marmara University, Physical Medicine and Rehabilitation, Istanbul, Turkey
2Marmara University, Pediatric Pulmonology, Istanbul, Turkey

Introduction/Background

Cystic fibrosis (CF) affects the musculoskeletal system via a multifactorial pathway that includes vitamin D deficiency and involvement of respiratory muscles such as intercostals due to recurrent upper and lower respiratory tract infections. Eventual result is the deterioration of musculoskeletal health and posture in CF patients. Postural stability is directly affected by posture and can be compromised in every musculoskeletal problem. The aim of this study is to evaluate musculoskeletal system and postural stability in patients with CF.

Material and Method

Patients with CF over six years of age and age and sex-matched control groups were included in the study. Cobb angle and thoracic kyphosis angles were measured on the spine radiographs. Both patients and control group were examined with pediatric gait, arms, legs and spine scale (pGALS). They also were evaluated with a NeuroCom Balance Master for their postural stability.

Results

Fifty-one patients with CF and 94 healthy controls participated in the study. In results of the pGALS examination, CF group had significantly more pathological findings than the control group in lower extremity appearance and movement (p = 0.006 and p = 0.01) and spine appearance and movement (p = 0.001 and p = 0.022) domains. The tandem walking speed was significantly higher in controls with a mean of 24.45 ± 7.79 while it was 20.47 ± 6.95 in the CF group (p = 0.03). Various limits of stability parameters also showed significant differences. Medium correlations were found between musculoskeletal examination and postural stability parameters.

Conclusion

In patients with CF, a systematic but simple musculoskeletal examination can detect pathologies, which are more frequent than the normal population. These pathologies show a medium correlation with the involvement of postural stability.

THE EFFECTS OF A POSTURAL EXERCISE PROGRAM ADDED TO CONVENTIONAL PULMONARY REHABILITATION IN PATIENTS WITH CYSTIC FIBROSIS

S. Gungor¹, K. Gencer-Atalay¹, Y. Bahar-Ozdemir¹, Ö. Kenis Coskun¹, E. Karadag-Saygi¹
¹Marmara University, Physical Medicine and Rehabilitation, Istanbul, Turkey

Introduction/Background

The objective of this study is to investigate the effect of postural exercises addition to pulmonary rehabilitation in children with cystic fibrosis (CF) on pain, exercise tolerance, respiratory function, quality of life, balance and spinal deformities.

Material and Method

Patients diagnosed with CF between the ages of 6 and 14 were included in the study. They were randomised into two groups. The first group received pulmonary rehabilitation and posture exercises once a week for six weeks while the second group received only pulmonary rehabilitation. Both groups were followed by phone calls weekly for six months. Patients were evaluated for respiratory function with FEV1, pain level with VAS, exercise tolerance with Modified Shuttle Test (MST), postural stability with Limits of Stability Test (SLT), and Cystic Fibrosis Questionnaire-Revised Application (CFQR). Cobb and Modified Cobb angles were measured for spinal deformities. The assessments were made before the treatment, at the sixth week, the third month and the sixth month after the treatment.

Results

Nineteen patients (%36.8 female, %63.3 male) with the mean age 9.37±2.17 and mean body mass index (VKI) 16.16±2.36 included into the study. 10 of them were involved to pulmonary rehabilitation and exercise group. Age, VKI, gender and baseline assessment parameters were similar in both groups (p>0.05). FEV1 and MST were increased in both groups after treatment; while emotional state (p=0.012) and treatment burden (p=0.041) subgroups of CFQR were increased only in the group with postural exercises. VAS, SLT, Cobb and modified Cobb inter-group and intra-group values were not shown any difference by treatment (p>0.05).

Conclusion

It has been observed that adding postural exercises to pulmonary rehabilitation in pediatric CF patients whose postural changes have not yet taken place does not cause significant changes in pain, exercise tolerance, posture and balance; however, it affected the emotional state well and improved the compliance with the treatment.

THE RELATIONSHIPS BETWEEN GENOTYPES, MYOPATHOLOGICAL CHANGES AND PHENOTYPES OF DYSTROPHINOPATHY

W. Li¹, Z. Huang¹, N. Wang¹, Y. Yuan², W. Zhang²
¹Peking university First Hospital, Rehabilitation Medicine, Bei jing, China
²Peking university First Hospital, Neurology, Bei jing, China

Introduction/Background

According to the variable clinical manifestations, the phenotypes of dystrophinopathy were classified as Duchenne muscular dystrophy (DMD) and Becker muscular dystrophy (BMD). The aim of this study was to summarize the characteristics of genotypes and the expression of dystrophin in patients with dystrophinopathy, to investigate the relationships between them and phenotypes.

Material and Method

204 male patients with dystrophinopathy who presented to the Peking University First Hospital between August 2013 and August 2017 were enrolled. Their diagnosis were confirmed by gene tests, and the out-of-frame mutations were analyzed by means of the Leiden Dystrophin genetic database. Muscle biopsies were performed in 78 patients, and the levels of expression of dystrophin were assigned by a 0-5 scale. All the values were calculated and processed using the SPSS 17.0 statistical package. Descriptive statistics were carried out when appropriate. The rank sum test was used to make difference analysis of the expression of dystrophin between DMD and BMD. P<0.05 means statistically significant.

Results

In all the patients, 181 were DMD and 23 were BMD. Genetic analysis revealed that 162 (79.4%) were deletions, 23 (11.3%) were duplications and 19 (9.3%) were small mutations. Among the 185 deletion/duplication mutations, 89.1% patients were in coincidence with the reading-frame hypothesis. With immumohistochemical staining, the median scores of the expression of dystrophin-N, R and C were 0, 2 and 1 respectively in DMD, while they were 3, 4 and 4 respectively in BMD. The difference of the scores between DMD and BMD is statistically significant, with N (P=0.010), R (P=0.031), C (P=0.000) and the total scores (P=0.001) respectively.

Conclusion

The genotypes overlapped between different phenotypes of dystrophinopathy. There were significant differences between the expressions of dystrophin of DMD and BMD. These findings may be beneficial for the selection of therapeutic regimens and rehabilitation therapy of patients with dystrophinopathy.

ISPR8-0232
EFFECT OF LATERAL SINGLE BAR KNEE ORTHOSES IN CORRECTION OF GENU VARUM IN NUTRITIONAL RICKETS
A.D. Joshi¹, A.K. Gaur¹
¹All India Institute Of Physical Medicine & Rehabilitation, Physical Medicine & Rehabilitation, Mumbai, India

Introduction/Background

Genu varum (bowlegs) is a common paediatric deformity of knee presenting as physiological variation in growth pattern. Rickets leads to more pathological bowing if occurs during the phase of physiological bowing. Apart from vitamin D restoration orthotic management doesn't form a part of standard treatment protocol for deformities due to rickets.

Material and Method

It is a prospective & interventional randomised comparative study conducted at department of Physical Medicine & Rehabilitation at A.I.I.P.M.R. Mumbai. Patients presenting with clinical features of rickets with bilateral genu varum were screened. 60 participants were enrolled in the study based on inclusion & exclusion criteria and divided into 2 groups (30 each) by lottery system. Group 1 received Stoss therapy for vitamin D restoration & bilateral lateral single bar knee orthosis. Group 2 received Stoss therapy only. Participants were assessed at initial visit and 2nd, 4th & 6th month after initiation of treatment with biochemical parameters, intercondylar distance (ICD) & radiographic tibio-femoral angle.

Results

Statistically significant decrease observed in intercondylar distance & tibio-femoral angle in both groups in subsequent follow ups.
Percentage change in intercondylar distance (58.75 vs 56.59, p=0.457) & tibio-femoral angle (right 56.74 vs 55.49, p=0.599; left 60.7 vs 59.38, p= 0.666) at the end of 3rd follow up on comparing both groups was statistically insignificant.

**Conclusion**

Vitamin D restoration by Stoss therapy can be effectively used in treatment of genu varum in nutritional rickets with or without lateral single bar knee orthoses.

THE ROLE OF HABILITATION IN INFANTS WITH CONGENITAL BRACHIAL PALSY
V. Živković1, I. Stankovic1, L. Dimitrijevic1, M. Kocic1, H. Colovic1, M. Spalevic1, N. Savic2, M. Lazovic3
1Medical Faculty of University Nis, Clinic of physical medicine - rehabilitation and prosthetics, Nis, Serbia
2College of Health Studies, physiotherapy, Cuprija, Serbia
3Rehabilitation Institute, cardiovascular, Belgrade, Serbia

Introduction/Background

Background: Congenital brachial palsy (CBP) can have long-term consequences such as deformities, contractures, and growth imbalance that can lead to severe handicap. Aim: to determine the effectiveness of habilitation in infants with CBP.

Material and Method

Retrospective clinical study included 34 infants who were habilitated in the Clinic of Physical and Rehabilitation Medicine during the period from 2000 to 2017. The protocol consisted of passive and active assisted range of motion exercises for affected arm, neurodevelopmental treatment, warm packs, and electrotherapy starting from the III week of life. 20 sessions were conducted at the Clinic, and parents were educated with handling and home exercise program. The infants were re-evaluated each month during the first year of life. The modification of the Medical Research Council scale was used to assess muscle strength (grades 0-3). At 6 and 12 months of age, the outcome was defined as full recovery (grade 3 of affected muscles) and partial recovery (grades 1-2).

Results

Male sex predominated (56%). The right arm was more commonly affected (64.7%). Birth weight was over 4000g in 22 infants (64.7%). The mode of delivery was spontaneous in 70.6%, assisted in 20.6% and breech in 5.9%. 59% of infants were in Narakas group I, 26.5% in group II and 14.7% in group III. Associated injuries were noted in 10 infants: 7 clavicular and 1 humeral fracture, 2 cases with myogenic torticollis and 1 with cephalhaematoma. The habilitation started in the first month of life in 64.7% of infants. At 6 months of age, there were 33 cases with partial recovery. At 12 months of age, full recovery was noted in 19 children (56%) and partial in 15.

Conclusion

Early habilitation program is effective in infants with CBP.

ISPR8-0362
EFFECT OF EVERYDAY PHYSICAL ACTIVITY ON BONE MINERAL DENSITY IN THE ADOLESCENT GROWTH PHASE
S. Lee¹, M. Fukushima¹, J. Hashimoto¹, C. Fujita¹, T. Suzuki¹
¹Aomori University of Health and Welfare, Department of Physical Therapy, Aomori, Japan

Introduction/Background

We investigated the effect of different daily physical activity levels (PAL) on bone health in the adolescent growth phase to obtain data on healthy bone formation.

Material and Method

The subjects were healthy young teenagers, who had consented to take part in the study, as had their parents or guardians. Their osteo-sono assessment index (OSI) was measured with an AOS-100SA, and subjects were divided into three groups (High / Middle / Low). The HJA-750C and activity meter data collection software installer Ver2.0 were used for the measurement of PAL. PAL was measured over the period of 1 week. Then, the intensity levels (in METs) were rated on a scale from PAL-1 (1 METs), to PAL-8 (8 METs), and the execution time per intensity level was calculated. Differences between these groups were investigated using analysis of covariance, with \( p < 0.05 \) regarded as statistically significant.

Results

OSI ranged from 2.004 to 3.039, and Z-scores were between 83–124%. There were no differences between the three groups in PAL at all levels from PAL1 to PAL8.

Conclusion

The level of everyday physical activity during the adolescent growth phase may have only a limited effect on bone development. Our results suggest that nutrition, growth hormones, and other factors directly associated with physical growth may have a greater effect on bone health than the external load on the bones during the adolescent growth phase.

ISPR8-0363
EFFECT OF BODY COMPOSITION AND PHYSICAL FITNESS ON RESPIRATORY FUNCTION DURING THE ADOLESCENT GROWTH PHASE
S. Lee¹, J. Hashimoto¹, M. Fukushima¹, C. Fujita¹, T. Suzuki¹
¹Aomori University of Health and Welfare, Department of Physical Therapy, Aomori, Japan

Introduction/Background

We investigated the effect of body composition and stamina on respiratory function, during the adolescent growth phase, with the aim of obtaining data needed to enhance or improve children’s health.

Material and Method

The subjects were healthy young teenage boys and girls, who had consented to take part in the study, as had their parents or guardians. The correlation between respiratory function, body composition, and physical fitness was calculated, with $p < 0.05$ regarded as statistically significant.

Results

Vital capacity was significantly correlated with muscle mass ($r = .759$), height ($r = .713$), leg muscle mass ($r = .710$), trunk muscle mass ($r = .710$), and weight ($r = .567$) ($p < 0.001$, in each). Forced vital capacity was significantly correlated with height ($r = .645$), muscle mass and leg muscle mass ($r = .599$), trunk muscle mass ($r = .519$), and weight ($r = .473$). In terms of the relationship between physical fitness and respiratory function, grip strength was significantly correlated with vital capacity ($r = .402$) and forced vital capacity ($r = .352$) ($p < 0.001$, in each). However, there were no significant correlations between FEV1 and body composition or physical fitness.

Conclusion

Our results showed that body composition, particularly leg muscle mass, has a greater effect on respiratory function during the adolescent growth phase than does physical fitness. Rather than increasing specific muscle strength, whole-body physical activity, associated with increased leg muscle mass, is required to improve respiratory function in adolescence.

INTRODUCTION/BACKGROUND

Osteogenesis imperfecta (OI) is the most common genetic skeletal disorder. Extra skeletal findings are common but association with sleep disordered breathing (SDB) have never been described. The aim of this study was to investigate clinical features of children with OI and suspicion of SDB.

MATERIAL AND METHOD

A retrospective study of patient’s clinical records, signs of SDB and polysomnographic recordings was performed. We paid particular attention to symptoms which could be associated with SDB in this population; scoliosis, kyphosis, vertebral arthrodesis, chest wall deformities, basilar impression, autonomy; and data already known to be associated with obstructive sleep apnea such as body mass index and upper airway impairment.

RESULTS

We reviewed the clinical charts of 188 patients referred to our genetic skeletal disorders reference center for OI. Among the 15 patients (8%) with polysomnographic recording, 12 (6.4%) had sleep disorder breathing. We found a negative correlation between Brief Assessment of Motor Function (BAMF) and Apnea Hypopnea Index (AHI) ($r = -0.68; p=0.01$) and Desaturation Index ($r = -0.62; p=0.02$). AHI tended to be higher in non-walkers ($6.5 \pm 3.6$ versus $2.4 \pm 1.5; p=0.02$), and in type III OI compared to type IV. Two patients were started on continuous positive airway pressure ventilation with clinical improvement.

CONCLUSION

For OI children, symptoms suggestive of obstructive sleep disorders should be searched for systematically, especially when autonomy is compromised, body mass index is high, trunk deformations are identified, and in case of severe type of OI.

EFFECT OF KINESIO TAPING ON LOWER LIMB MUSCLE ACTIVATION PATTERNS DURING WALKING IN CHILDREN: A RANDOMIZED CONTROLLED TRIAL

T.T.T. Yam1, S.S.M. Fong1
1The University of Hong Kong, School of Public Health, Hong Kong, Hong Kong S.A.R.

Introduction/Background

Kinesio Tape (KT) claims to have the effect of facilitating muscle activations. Immature gait pattern and neuromuscular control in children might be facilitated by KT but no study has proven it so far. This randomized controlled study aimed to investigate the effects of KT on leg muscle activations in children during treadmill walking.

Material and Method

A total of 48 children participated in the study. Twenty-five of them were randomized to the KT group (mean age ± SD = 7.86 ± 0.78 years; 16 males and 9 females) and 23 to the control group (mean age ± SD = 8.29 ± 1.25 years; 13 males and 10 females). KT was applied with moderate tension (50%) to the gastrocnemius and quadriceps muscles for the KT group. The control group did not receive any KT. Rectus femoris, biceps femoris, tibialis anterior and gastrocnemius medialis peak muscle activations (dominant leg) were measured by surface electromyography, an electrogoniometer attached to the knee joint and foot contact switches before and after the application of KT.

Results

Two-way repeated measures analysis of covariance (covariate: body mass index) revealed a significant group-by-time interaction effect in the peak muscle activation of biceps femoris (p=0.005) and gastrocnemius medialis (p<0.001) during the mid-stance phase of gait. Post hoc analyses indicated that biceps femoris and gastrocnemius medialis muscle peak activations in the KT group had 51.64% (p=0.025) and 122.18% (p<0.001) increments, respectively, when compared to the baseline values. When compared with the control group, the KT group exhibited higher peak activations for biceps femoris (94.26%, p=0.013) and gastrocnemius medialis (140.52%, p<0.001) at post-test.

Conclusion

The application of KT improved peak muscle activations in the leg during walking in growing children. Therefore, KT may be useful to speed up the maturation of gait and neuromuscular control in the legs among children.

TRANSIENT HYPERTROPHIC SYNOVITUM AFTER RADIOSYNOVIORTHESIS IN HEMOPHILIC ANKLE ARTHROPATHY: A CASE REPORT

F.C. Chang¹, T.I. Han¹, P.Y. Yang¹,²
¹China Medical University Hospital, Department of physical medicine and rehabilitation, Taichung, Taiwan R.O.C.
²China Medical University, School of medicine, Taichung, Taiwan R.O.C.

Introduction/Background

Individuals with hemophilia A presents defects in coagulant factor VIII and spontaneous intra-articular hemorrhages, mainly in the ankles, knees, and elbows. Radionuclide synovioirthesis can be used to treat chronic hemophilic synovitis. Both magnetic resonance imaging (MRI) and ultrasound can provide detailed information on soft tissues for evaluating chronic synovitis. However, MRI is not cost-effective, limited to joint per time, and requires sedation when used in young children. The use of ultrasound results in acquisition of real-time images and development of portable techniques, retaining high-resolution for soft tissues, effusion, and osteochondral changes. Currently, no or several studies reported using ultrasonography during serial follow-up for the response during post-radosynoviorthesis. We report the serial changes in radionuclide reaction on ankle synovium by ultrasonography.

Material and Method

This case involves a 21-year-old hemophilic A patient whose both ankles experience hemophilic arthropathy resulting from repeatedly joint hemorrhage. After applying radionuclide synoviorthesis to both ankles at age 17, we use the Haemophilia Early Arthropathy Detection with Ultrasound for serial evaluation of the status of both ankles.

Results

Observations included hypertrophy of synovium in the first three days accompanied by shrinkage of the synovium after radionuclide synoviorthesis and the range of motion and pain scale.

Conclusion

After radiosynoviorthesis, hypertrophy of synovium was observed within 1 week and accompanied by gradual reduction in thickness in months. Further series of ultrasonography evaluation is needed to clarify the radiosynoviorthesis effects on synovium.

Background and aims. Prader-Willi syndrome (PWS) is a complex neurogenetic disorder associated with a wide variety of physical, cognitive, and behavioral problems. Due to abnormal body composition and certain neuromuscular abnormalities, many motor problems such as hypotonia, muscle weakness, delayed motor development and gait disorders have been reported, but little attention has been paid to hand functions in patients with PWS. Therefore, the aim of this study was to examine the functional hand performance of patients with PWS.

Material and Method

Methods. Six patients with PWS (two females and four males; mean age was 26.14 years, range 20-32 years; body mass index 20.7-38.4 kg/m²) were recruited for the study to undertake the following hand functional tests: (1) hand grip, tip pinch, and lateral pinch tests for hand strength, (2) Box and Block test for gross manual dexterity, and (3) Purdue Pegboard test for finger dexterity.

Results

Results. Every patient with PWS showed lower hand grip, tip pinch, and lateral pinch strength by scoring well below the normal range of normative data for healthy adults. Poor manual and finger dexterity performance were also found in all our patients with PWS. When compared to the normative data, their scores approached the data of the elderly population.

Conclusion

Conclusions. All patients with PWS showed decreased hand strength and poor manual/ finger dexterity compared to healthy adults. As hand grip strength is associated with functional limitations and manual dexterity is required for executing activities of daily living, the inclusion of both hand strength and dexterity training in the physical training programs for patients with PWS should be considered.

Electrical stimulation, physical therapy and occupational therapy are the main treatments for obstetrical brachial plexus palsy before resorting to surgery. But these therapies remain insufficient when it comes to management of muscles co-contractions. The aim of this study is to evaluate the efficiency of Botulinum toxin injections in the management of co-contractions in children with obstetrical brachial plexus palsy.

**Material and Method**

Children with obstetrical brachial plexus palsy were enrolled in this study. ENMG was used to highlight muscle co-contractions. Intramuscular injections of Abobotulinum toxin were made with a total dose of five to 10 UI per kg and a maximal dose of 150 units per muscle. Children who had biceps - triceps co-contractions were injected in the triceps and those with deltid - teres major co-contractions were injected in the teres major. A clinical evaluation including shoulder and elbow active and passive range of motion was conducted before the injection and one month after.

**Results**

This study included six children. Their mean age was 61 month (from three to 108 months). Four children had complete brachial plexus lesion including one with a Bernard - Horner syndrome. All children were injected in the teres major and three were injected in the triceps. A mean gain of 16.6° in shoulder abduction and flexion and of 37.8° in elbow flexion was noted.

**Conclusion**

The addition of botulinum toxin injection targeting muscle co-contractions to a continuous physiotherapy can help to better manage obstetrical brachial plexus palsy.

LOW BONE STRENGTH IN CHILDREN WITH DEVELOPMENTAL DELAY
X. Zhou¹, J. Liang¹, Q. Du¹
¹Xin Hua Hospital affiliated to Shanghai Jiao Tong University School of Medicine, Rehabilitation, Shanghai, China

Introduction/Background

Children with developmental delay used to be affected by mixed factors, leading to growth problems, especially for motor function. Thus, the skeletal development of these children will also be affected by the lack of stimulation and weight-bearing of the bones. However, there are few studies on the bone health for children with developmental delay measuring by the non-invasive quantitative ultrasound. The aim of our study was to investigate the bone strength of children with developmental delay by QUS measurements.

Material and Method

Subjects were 100 children with developmental delay as developmental delay group (DD group), among whom 65 were boys, and 35 were girls with mean age 54±12.3months. Controls were 50 healthy children from a normal kindergarten as control group, among whom 28 were boys, 22 were girls with mean age 55±10.8 months. Bone strength was measured on the distal third of left radius, and expressed as SOS (speed of sound) in m/s, Z scores, and percentile.

Results

There was no difference of gender ratio, age, height, and weight between two groups. In DD group, 38 patients (38%) had normal bone strength, while 62 (62%) had abnormal bone strength. For control group, 27 children (54%) were normal bone strength, and the rest of them were abnormal bone strength (46%). The mean SOS, Z scores, and percentile of DD group were 3514 m/s, -0.32±1.2, 42±30.9 respectively, were significantly lower than control group, which were 3600m/s, 0.1±0.7, 52±24.5 (SOS: P=0<0.05; Z scores: P=0.02<0.05; percentile: P=0.03<0.05). There was no significant gender difference of SOS in DD group (P=0.28>0.05), and the SOS in DD group was significantly correlated to age, height and weight (age: r=0.361, P=0<0.01; height: r=0.204, P=0.04<0.05; weight: r=0.381, P<0.01).

Conclusion

Children with developmental delay have low bone strength generally, and the bone strength has a positive correlation with the age, height and weight.

ESTABLISHING A CARE PATHWAY FOR CHILDREN WITH LONG-TERM NEUROLOGICAL CONDITION
Z.M. Ng¹, M. Vellaichamy², M.M.Y. Yeong², A. Fife², T.H. Yeo¹
¹KK Women’s and Children’s Hospital, Paediatric medicine, Singapore, Singapore
²KK Women’s and Children’s Hospital, Rehabilitation, Singapore, Singapore

Introduction/Background

Children with long-term neurological condition (LTNC) have complex health, educational and social needs. The team looking after this group of children is usually large, comprising of members across different subspecialties, both at the tertiary hospital and in the community. Care for children with LTNC is often uncoordinated and inconsistent, leading to secondary complications and affecting functional outcomes.

We aim to establish a care pathway for children with LTNC to provide anticipatory care for this group of children through a long term, multi-disciplinary follow-up with a tight community network. This in turn will improve utilization of resources, reduce burden of care and promote health.

Material and Method

We conducted a literature search of PubMed, EMBASE, and Cochrane databases using a combination of keywords and MESH terms including “cerebral palsy”, “acquired brain injury”, “motor disorder”, “hip surveillance”, “bone health”, “nutrition” and “functional outcome”. All recommendations describing different aspects of care for children with LTNC were included. A team of doctors, nurses and allied health professionals critiqued and reviewed the guidelines to ensure agreement. After the initial review, revisions were made according to local feasibility and practicality. All recommendations were then incorporated into a care pathway and circulated to the department for final review and endorseement.

Results

Key recommendations include screening our local children with LTNC for hip subluxation, pain, bowel and bladder issues; and optimization of bone health, sleep and nutrition. Following the establishment of care pathway, staff education is implemented.

Conclusion

The developed care pathway provides a basis for the systematic management of children with LTNC. It also bridges service gaps between tertiary and community institutions and ensures continuity of care for this group of patients with complex needs.

INDICATORS OF THE HEALTH OF PREMATURE INFANTS BORN WITH VERY LOW AND LOW BODY WEIGHT
S. Ismailova¹, T. Taranuchenko¹, A. Salmina²
¹Prof. V.F. Voino-Yasenetsky Krasnoyarsk State Medical University, Department of Pediatrics Post-Diploma Education, Krasnoyarsk, Russia
²Prof. V.F. Voino-Yasenetsky Krasnoyarsk State Medical University, Department of Biochemistry- Medical- Pharmaceutical and Toxicological Chemistry- Research Institute of Molecular Medicine and Pathobiochemistry, Krasnoyarsk, Russia

Introduction/Background

A health state study of premature babies’ development born with very low (VLBW) and low body weight (LBW) is necessary, because in this contingent the infant mortality and disability are high. Purpose of the study is to analyze the health status and structure of the incidence of premature infants born with VLBW and LBW.

Material and Method

The observation group consisted of 110 children who were observed in the department of pathology of newborn and premature children of the Krasnoyarsk Perinatal Center for the period from 2014 to 2015: 50 newborns with VLBW (1001-1500 grams) and 60 - LBW (1501-2000 grams).

Results

Mean gestational age in Group 1 was 30.1 ± 1.7 weeks, in Group 2 32.2 ± 1.6 weeks. According to our data, the leading pathology of the early neonatal period in children was a syndrome of respiratory disorders, revealed in more than 60% of premature infants, cerebral ischemia of different severity - 8% and 13%, intrauterine infections 4% and sepsis 2% which were diagnosed only in the group with VLBW. Among the concomitant diseases, conjunctive jaundice was found with the greatest frequency of 44% and 68% in the groups, retinopathy 12% against 3%, osteopenia of prematurity 10% (only in the group with VLBW). According to the neurosonogram data, it was found that children had pronounced periventricular edema 66% and 68%, intraventricular hemorrhages 18% and 3% in the groups, periventricular leukomalacia, which was registered in 7 cases (6.3%), as a consequence of hypoxia at birth.

Conclusion

In the structure of diseases of premature infants, the respiratory distress syndrome prevails (76%), as a result of the immaturity of the lung tissue and the deficit of the surfactant. The pathology of the central nervous system, especially occupies the second place, prevails in
infants with VLBW and is characterized by periventricular edema, intraventricular hemorrhage and leukomalacia.

GROUP WORKSHOP FOR CHILDREN AND TEENAGERS THAT PRACTICE CONTINENCE CARE: URINARY INTERMITTENT CATHETERIZATION OR/AND TRANSANAL IRRIGATIONS

M. Bonneau Mogavero¹, B. Beauvois², S. Le Goff², V. Forin², P. Lallemant Dudek²

¹AP-HP Hopital Trousseau, Chirurgie Viscérale pédiatrique- Unité pédiatrique de Médecine Physique et de Réadaptation, Paris, France
²AP-HP Hopital Trousseau, Unité pédiatrique de Médecine Physique et de Réadaptation, Paris, France

Introduction/Background

Intermittent urinary catheterization is used by patients that have a neurological or malformative bladder for the purpose of renal salvage and urinary continence. Transanal irrigation is used by patient that have neurological or malformative colon for the purpose of fecal continence. The goal of these group workshops is to respond to the feeling of isolation of patients that practice continence care (self or hetero care) by sharing a common experience.

Material and Method

Animation: nurse and psychologist
1h workshop of roughly 4 patients
Single-sex group broken down by age (7/10, 11/14, 15/18)
Main tools:

- discussions on care organization in everyday situations
- written personal remarks that are read anonymously and discussed
- brainstorming about care
- other tools depending on patients’ age

Results

9 groups since January 2017
37 patients
Average age: 12 years old

<table>
<thead>
<tr>
<th>age</th>
<th>7 to 10</th>
<th>11 to 14</th>
<th>15 to 18</th>

<td>3</td>
</tr>
</tbody>
</table>
Sharing a common experience allows easy and smooth exchanges. The results are not distinct according to the type of care because it is the "group encounter" effect that is significant.

Beneficial effects noticed from post-group interviews:
- Self-esteem: the workshop enables to ensure with others whether it’s possible to have a normal life even with care
- Relief to speak freely about patient’s experience outside family and social circles, feeling that personal experience is understood by the group
- Decrease of the shame to practice care and isolation feeling: sense of being part of a group
- Sociability: free discussions enables to unlock some social fears
- Better acceptance of care

Conclusion

The group allows peer identification that make possible to face living with the feeling of "being different from others". This has beneficial effects on self-confidence, which is essential for the psychic development of the child and the teenager.
"When I saw the other girls, I told myself that it was not possible that they also practice care, they seemed so normal"

REGRESSION OF MILESTONES: PRESENTATION OF SPACE OCCUPYING LESION (SOL) IN BRAIN AT REHABILITATION CLINIC

N. Mansoor¹, I. Asghar²

¹Armed forces institute of rehabilitation medicine AFIRM, Amputee ward, RAWALPINDI, Pakistan
²CMH Rawalpindi, Department of Pediatrics, Rawalpindi, Pakistan

Introduction/Background

SOL brain can present in a variety of ways especially in children. The findings can at times be subtle for a considerable period of time before the final diagnosis. We present a two years old child with unusual presentation.

Material and Method

Two years old child was brought to rehabilitation clinic with complaints of weakness lower limbs for the past 08 months. Child attained normal developmental milestones till 16 months of age when parents noticed some clumsiness in the child gait and mood instability. There was no history of fever, fits, headache, protracted vomiting or trauma. Child was taken to various general physicians and was treated for rickets. The clumsiness increased and the child was unable to stand or walk. On examination he was fully conscious and oriented but irritable and restless and unable to stand. There was some frontal bossing with prominent anterior fontenella and head circumference of 52cm. His gaze was normal and there was no sunsetting sign. Power in lower limbs was 3+/5, reflexes were brisk and plantars were upgoing. Neurological examination in upper limbs was normal. Systemic examination was unremarkable. His base line blood workup was normal.

Results

His X ray skull revealed copper beaten appearance. CT Brain revealed a large rounded midline mass 6 by 5 cm located in the pineal fossa causing obstructive hydrocephalus and compression of brain matter. He was referred to neurosurgeon for further management. He was lost to follow up.

Conclusion

SOL brain can present in a variety of ways in pediatric population, it can vary from subtle irritability, mood changes, poor feeding to obvious protracted vomiting, fits, and focal neurological deficit. High index of suspicion is required for timely diagnosis and prevention of complications.

FUNCTIONAL EVALUATION AND MYOTONOMETRIC MEASUREMENTS OF MUSCLE TONE, STIFFNESS AND ELASTICITY IN PATIENTS WITH DUCHENNE MUSCULAR DYSTROPHY
A.F. Nehzati Maleki1, R. Guzel1, O. Herguner2, I. Coskun Benlidayi1, S. Basaran1
1Cukurova University Faculty Of Medicine, Physical Medicine and Rehabilitation, Adana, Turkey
2Cukurova University Faculty Of Medicine, Pediatric Neurology, Adana, Turkey

Introduction/Background

The aim of this study was to measure the biomechanical properties of the muscle using myotonometry in patients with Duchenne Muscular Dystrophy (DMD) and to evaluate the correlation with functional parameters.

Material and Method

Twenty one ambulant DMD boys and 21 age matched healthy boys underwent measurements from their dominant sides. Muscle tone, elasticity and stiffness were measured from gastrocnemius medialis (GM), tibialis anterior and vastus medialis in resting state and in contracted state by MyotonPro. MicroFET2 was used for manual muscle testing (MMT) of plantar flexion, foot dorsiflexion and knee extension. 6 minute walk test (6MWT) and 10 meter walk tests were performed in both groups. DMD boys were also assessed by North Star Ambulatory Assessment (NSAA).

Results

The mean age of the patients were 8.5±3.2 (5-18) years, median NSAA score was 26 (17-33) and 6MWT was 361 meters (77-562). Compared to healthy boys, there were significant decrements in MMT, walking speed and 6MWT (p<0.001). The biomechanical results also differed significantly in resting and contraction states but only resting tone of medial gastrocnemius was higher in DMD patients (p=0.014). The measurements of muscle tone, stiffness or elasticity did not correlate with functional measures.

Conclusion

Our preliminary results suggest that myotonometric evaluations can be used easily in DMD and resting muscle tone of gastrocnemius medialis is found to be increased in patients. Clinical meaningfulness of the MyotonPro device should be tested in follow-up studies.

This study was funded by Cukurova University Project no: TTU-2017-9506

THERAPEUTIC HORSE RIDING: A CONTEXT FACILITATING LEARNING AND FLOURISHING FOR CHILDREN WITH DISABILITY

R. Martin¹, F. Graham¹, W. Levack¹, W. Taylor¹, L. Surgenor²
¹University of Otago- Wellington, Rehabilitation Teaching and Research Unit, Wellington, New Zealand
²University of Otago- Christchurch, Department of Psychological Medicine, Christchurch, New Zealand

Introduction/Background

Therapeutic horse riding (THR) is a complex intervention which aims to positively influence health in people who experience disability. Evaluating the effectiveness of THR interventions is made complex by a lack of clarity about the ingredients, mechanisms of treatment effect, and intended treatment targets. This research aimed to evaluate the effectiveness of a THR intervention – what works for which riders, in what contexts, to what extent and how.

Material and Method

Within a critical realist framework, three phases of research using a mix of methods (Thematic Analysis \(n=36\) participants), Grounded Theory \(n=38\) participants and Single-Case Experimental Design \(n=12\) participants) were undertaken. Findings from all phases were synthesised and interpreted to provide an integrated evaluation of THR intervention effectiveness. Using context-mechanism-outcome configurations as a framework, specific attention was paid to contextual factors and mechanisms of change which impacted on health outcome change for riders.

Results

Riders and caregivers prioritised THR as an accessible activity allowing meaningful participation in valued leisure roles. A positive intervention effect was also observed in occupational performance in settings other than THR. Riders experienced the THR therapeutic landscape as a context that promoted their capacities and strengths, rather than their deficits and difficulties. THR provided opportunities for a broad range of learning experiences with the child as active agent within the intervention, contributing to riders’ enlarged self-concept in response to learning to move, succeed, connect and adapt within the THR therapeutic landscape.

Conclusion

THR may contribute to improved participation outcomes for children with disabilities, regardless of their diagnosis. The context in which THR is provided plays a central role in activating and optimising changes in health outcomes. Greater understanding of contextual factors and mechanisms of change could guide the development of a shared understanding of THR.
programme development, improve provider training, rider outcome assessment and ongoing programme evaluation.

NUTRITIONAL STATUS OF 50 DISABLED CHILDREN IN A TUNISIAN PHYSICAL MEDICINE AND REHABILITATION DEPARTMENT

I. Aloulou¹, I. miri¹, R. jmour², L. alouane², F.Z. ben salah¹, C. dziri¹

¹Kassab, Physical medicine, manouba, Tunisia
²National Institute of Nutrition, Nutrition, Tunis, Tunisia

Introduction/Background

Disabled children can develop nutritional problems due to multiple factors: neuromotor disorders, swallowing troubles, difficulty in positioning, dependence to a third person for alimentation…

The aim of this study is to assess nutritional status of disabled children.

Material and Method

This study is prospective and monocentric in the physical medicine and rehabilitation department of National Institute of Orthopaedy M.Kassab in Tunisia. We included inpatients children between 3 and 10 years with motor disabilities and we excluded children whose parents were not cooperating.

For each patient: we determined age, sex, etiology, neurological status, neuromotor development, swallowing disorders, anthropometric parameters (weight, tight, brachial parameter and cranial parameter) and nutritional investigation with parents using the 24-hour dietary recall.

Data was analysed by BULNIT software for the 24 hour dietary recall and by SPSS 20 for the other datas.

Results

We collected 50 patients with middle age 6.5 years and sex ratio 0.92. Etiology was cerebral palsy in 46%, trauma brain injury in 34% and other etiologies in the rest of cases. Neurological status was tetraparesia in 70% cases. According to neuromotor deficiencies, 12% hadn't head holding and 26% didn't have sitting position. Swallowing disorders in 86% cases (facial oral praxy, mastication…). Body Mass Index was normal in 54%, underweight in 30% and overweight in 16%. Protein intake was higher than necessary in all male and female children and lipid intake lower than necessary. A significant correlation was shown between underweight and swallowing disorders.

Conclusion
Nutritional disorders are frequent in disabled children and must be assessed to adopt preventive and corrective measures. Improvement of positioning, management of swallowing disorders and parents’ nutritional education are the main goals.

**MEROSINE-DEFICIENT CONGENITAL MUSCULAR DYSTROPHY AND COMPLICATIONS: A CASE REPORT**

_C. Casado-Blanco¹, C. Cid-Bassaletti¹, L. Gómez-González¹, A.M. Dumitrescu¹, M. Echevarría-Ulloa¹, O. Arroyo-Riaño¹_

¹Hospital General Universitario Gregorio Marañon, Physical Medicine and Rehabilitation, Madrid, Spain

**Introduction/Background**

Congenital muscular dystrophy type 1A (MDC1A) is a rare disease, characterized by hypotonia, muscle weakness and atrophy. Diagnosis is based on clinical presentation, elevated creatine kinase levels, muscle biopsy, and genetic testing (LAMA2 mutation). Patients have severe motor and respiratory limitations. We present a long followed-up case and the management of complications.

**Material and Method**

A thirteen-year-old girl with MDC1A was referred to our Rehabilitation Service at birth. She presented hypotonia, muscular hypotrophy, slow psychomotor development, elevated creatine kinase, myotonia in electromiography and severe muscular dystrophy with absence of merosine on anatomopathology. Genetic study and MRI were normal.

Since twelve, she had a history of repetitive respiratory infections, failure to thrive and double-curve scoliosis. She was partially autonomous for daily life activities, FIM scale was 106.

Management included physical therapy. Patient evolved with respiratory exacerbations, lumbar pain secondary to progression of scoliosis with right thoracic curve increasing from 12° to 29°, and left lumbar curve 20°, with elevated Riser. Therefore, we prescribed a Boston Soft Brace and Cough Assist. Physical examination demonstrated proximal weakness of limbs and abdominal flexors, lumbar pain and muscle atrophy. Motor skills were measured as 14 points in North Star Ambulatory Assessment (NSAA), 288 meters in the six-minute walk test (6MWT), and dyspnea and fatigue perceptions as 5 and 6 in Borg Scale.

**Results**

In the last revision she reported relief of lumbar pain, NSAA punctuation of 17, 235 meters in 6MWT, dyspnea and fatigue as 8 and 9 in Borg Scale.

**Conclusion**

As MDC1A is associated with poor prognosis, the management from a physiatrist is fundamental. After brace prescription, our patient presented pain relief, although walking pattern
and dyspnea worsened. Nevertheless, she maintains the same partial-autonomy in daily activities, which is the important goal for our optimal treatment.

DETERMINATION OF WALKING PROGNOSIS IN DUCHENNE MUSCULAR DYSTROPHY PATIENTS BY USING ULTRASONOGRAPHY: A PILOT STUDY

R.K. Wardhani¹
¹CiPTO Mangunkusumo Hospital, Physical Medicine and Rehabilitation, Tangerang Selatan, Indonesia

Introduction/Background

Muscle ultrasound is a convenient technique to visualize normal and pathological muscle tissue. In Duchenne Muscular Dystrophy (DMD), the structural muscle changes can be visualized with ultrasound: infiltration of fat and fibrous tissue increases muscle echo intensity. It will lead to muscle weakness. If it occurs in lower limb can result in decreased walking ability of the child. The aim of this study is to know the muscle profile in lower extremities to predict functional walking in DMD children.

Material and Method

This research use case series method. There were 2 boys with walking and non walking ambulatory. We used Ultrasound to examine the muscle profile. There are several muscles that are examined i.e. gluteus maximus, gluteus medius, rectus femoris, gastrocnemius, and tibialis anterior. Muscular profile is divided into 3 categories; more or less than 50% muscle fibers on the muscular cross section, and not found muscle fibers. Loss of muscle fibers is characterized by hyperechoic on muscle features and loss of muscle boundaries. We compared the muscle profile in both subjects.

Results

Subjects are 8 and 13 years old. We found different muscle profile in both subjects. The ambulatory subject, still had distal muscle (gastrocnemius and tibialis anterior) that contain muscle fibers > 50%, Whereas in non ambulation, no muscle has fiber> 50%. Although in both subjects we got the same image of gluteus maximus that shown no muscle fibers.

Conclusion

The presence of dominant muscle fibers in distal muscles of lower extremities allows the child with DMD to perform walking activity, although there has been muscle damage in the proximal. With ultrasound examination we can see the real picture of muscle condition, so we can predict how far the muscle can work. Ultrasound is a non invasive, inexpensive, and safe examination tool to evaluate muscle condition in DMD.

ORTHOTIC TREATMENT FOR HIP AND KNEE PATHOLOGIES IN PATIENTS WITH CONGENITAL INSENSITIVITY TO PAIN WITH ANHIDROSIS

N. Haga¹, Y. Shinoda¹, S. Fujiwara¹, H. Mano¹, K. Okada², H. Tanaka³

¹Graduate School of Medicine - The University of Tokyo, Department of Rehabilitation Medicine, Tokyo, Japan
²Graduate School of Medicine - The University of Tokyo, Department of Orthopedic Surgery, Tokyo, Japan
³National Rehabilitation Center for Children with Disabilities, Department of Orthopedics, Tokyo, Japan

Introduction/Background

Congenital insensitivity to pain with anhidrosis (CIPA), also called hereditary sensory and autonomic neuropathy type IV, is an autosomal recessive disorder manifesting in a generalized loss of pain and thermal sensation, a lack of sweating, and is associated with variable degrees of intellectual disability and/or learning deficits. In patients with CIPA, musculoskeletal complications are frequent including repeated fractures and joint dislocations, avascular bone necrosis, and Charcot arthropathy, mainly in the lower extremities. Though complications in hip and knee joints may eventually lead to difficulty in ambulation, prevention and management of hip/knee pathologies are difficult and scarcely reported so far.

Material and Method

We retrospectively reviewed the medical records of 19 patients (ten males and nine females) who visited our department since 2006. The age at final visit ranged from four to 64 years (mean 20).

Results

Hip pathologies were identified in 14 joints in eight patients, excluding mild acetabular dysplasia. Six joints in three patients had already been destroyed at initial visit. Two joints in a patient developed fixed dislocations without any treatment. Orthoses were prescribed in four patients (six joints), three hip-action braces and one HKAFO, and three patients obtained relatively good results. Knee pathologies existed in seven joints in seven patients, excluding mild joint instability or genu varum. Two joints had already been destroyed at initial visit. One joint developed a severe Charcot joint without any treatment. KAFO was prescribed for four joints, but they all led to Charcot joints and three of them underwent surgery.

Conclusion
Hip and knee pathologies are frequent in CIPA and difficult to manage. Orthotic treatment for hip pathologies may be beneficial for maintaining reduction. On the contrary, KAFO can hardly prevent developing Charcot knee joints.

³Centre Hospitalier Régionnal Univertaire de Lille, Service de Médecine Physique et de Réadaptation-Hôpital Swynghedauw, Lille, France

Introduction/Background

In 2016, 36,000 children were hospitalized in a Pediatric rehabilitation center in France. In the Nord and Pas-de-Calais, four Pediatric rehabilitation center host children, and each center has a different school system.

Material and Method

Its objective is to evaluate the impact of a hospitalization of more than three weeks in Pediatric rehabilitation center on the schooling of children free of cognitive deficits from primary school to senior year, who are hospitalized for orthopaedic disorders or chronic pain. The secondary objective is to assess the socio-educational and care factors affecting the schooling of these hospitalized children.

This is a multi-centric descriptive prospective study.

The primary judgment criterion is the pre-post hospitalization gap for the overall mean (OM). It was calculated from the last pre-hospitalization report card and the first post-hospitalization report card. Questionnaires were completed by parents and educational teams, and a final assessment to collect qualitative data was conducted by telephone after the child’s return to class.

Results

47 patients were included. Calculations do not show any significant difference between pre- and post-hospitalization for the OM (p=0.361).

Qualitatively speaking, parents would like to see more hours of instruction. The children were affected by their separation from their class, and the stress of falling behind the school curriculum. They enjoyed keeping student status. The grades have dropped with real gaps for some of the group. Good students had to do more work than they used to do before.
Conclusion

Comprehensive care of children cannot be provided without assessing the impact of hospitalization on their schooling. Not all existing resources have been exploited. They would allow for more hours of instruction and subjects to be taught. The possibility of direct contact between the child and his or her class is one of the areas to be developed further.

INTERPRETATION OF PEDIATRIC VIDEOFLUOROSCOPIC SWALLOWING STUDY

K.M. Lee
Chungbuk National University, department of rehabilitation, Cheongju, Republic of Korea

Introduction/Background

Swallowing physiology in children is different from adults and also it is difficult to cooperate during videofluoroscopic swallowing study (VFSS). In addition test cannot be performed sufficient time because of the concerns of radiation exposure. So it is essential to set up well-built test protocols and interpretation methods to improve reliability and validity of the study.

Material and Method

In Pubmed, using search related terms and MeSH terms we could get 128 studies. We analysed these about indications, methods, interpretations and reporting of VFSS.

Results

Many of the children referred for dysphagia or unexplained respiratory symptoms showed aspiration or penetration in VFSS and most of those were silent aspiration. So when dysphagia is suspected or if children have signs like coughing during meals, tests like VFSS to confirm aspiration is essential. In most of the studies, VFSS was done in sitting position with tumbleform seat or chair. Recordings were done sufficient enough to examine the whole swallowing phases multiple times but within 2 minutes to prevent potential radiation hazard. VFSS was usually done in lateral projection view to observe aspiration and penetration as well as to measure timings and residue. Examiners analyzed the recorded video and check various swallowing events and measured timings. In normal children pulling of the bolus in vallecula before swallowing seems to be normal. Unlike adults, pooling after swallowing is not related to aspiration but pooling in the pyriform sinus before swallowing is associated with aspiration and is frequently preceded to aspiration. Nasogastric or orogastric intubation did not interfere swallowing but tracheostomy seems to affect respiratory physiology.

Conclusion

Major measures and descriptions about VFSS as well as contents and format of the reports are not unified and the definition of the terms were not clearly defined, so standardization of those mentioned above were needed.

⁴CHU Armand Trousseau APHP, Pediatric Orthopedic Surgery Unit, Paris, France

Introduction/Background

Congenital malformations are one of the leading causes of infant mortality, morbidity and disability in industrialized countries. Congenital limb malformations, which are rare, they represent approximately 1.3 to 1.9 cases per 1,000 births.

Saint-Maurice Hospitals have set up an antenatal consultation dedicated to limb malformations since 1985. Since the official approval of its Reference Center in 2007, the team has developed a comprehensive expertise allowing the establishment of a specific pluriprofessional team.

In 2011, Dr. Pillard's team carried out a retrospective study based on the antenatal consultation files conducted during this year in order to make an inventory of the antenatal consultation activity.

We completed this preliminary work in conducting a retrospective study of the consultation files that took place from 2012 to 2017.

Material and Method

We have chosen the following data collection criteria:

- Family history
- Screening date of the malformation
- Antenatal diagnosis
- Continuation of pregnancy and post-natal diagnosis
These data were collected from the medical records of antenatal consultation records.

Results

The data representing the number of cases / year / location of malformations are listed in the table below.

<table>

</table>

All antenatal consultation records completed since 2012 have been analyzed: a total of 143 files in the last 6 years.

Conclusion

The clubfoot is the most representative malformation.

The first cause of multiple malformations is linked to the presence of Amniotic Band Syndrome.

HOME BASED AIR STACKING EXERCISE IN DUCHENE MUSCULAR DYSTROPHY: A CASE REPORT

M.W. Sahrun¹, T.F.U. Tambunan¹, T. Suryadi¹

¹General Hospital Cipto Mangun Kusumo, Physical Medicine and Rehabilitation, DKI Jakarta, Indonesia

Introduction/Background

Background: respiratory problems, including short of breath, difficulties to take deep breath, difficulties in cough, pneumonia even fall to respiratory failure are the main causes of mortality in duchene muscular dystrophy (DMD) patients. We perform air stacking exercise as a home based exercise to prevent furter respiratory complications.

Material and Method

Methods: Case report of a 11 years old boys diagnosed with DMD, we evaluated spirometry test, Peak flow rate (PFR), Peak Cough Flow (PCF), Maximum inspiratory pressure (MIP) and maximum expiratory pressure (MEP) before and after the exercise program. We trained the mother to do the air stacking at home with prescription 10 series a day, each includes 3 consecutive manual insufflations, deep breath, held the breath, and patient instructed to hold the total volume for 5 second, increase as patient tolerated till can hold for 8 seconds. This exercise divided to 3 sessions per day, done in the sitting positions, with the mother from behind.

Results

Results: After 8 Weeks of home based exercise we evaluated again all the respiratory parameter as follow:

<table>
<thead>
<tr>

POSTUROGRAPHIC STUDY OF 4 CHILDREN WITH OSTEOGENESIS IMPERFECTA
A. Monden¹, A.G. Py¹, A.L. Camiul¹, M. Thetio², N. Quintero-Prigent¹
¹Hopitaux de Saint Maurice,
Service de rééducation de l'appareil locomoteur et du rachis. Pôle Enfant, Saint Maurice, France
²Hopitaux de Saint Maurice, Pôle Enfant, Saint Maurice, France

Introduction/Background

Osteogenesis imperfecta (OI) is a rare disease characterized by bone fragility with variable severity. In the medium to severe types, spontaneous or side-effect repeated bone deformities are responsible for difficulties in the learning process and the ability to walk. Falls prevention in its clinical form was not specifically studied. The aim of this work is to describe walking statistical posturographic parameters as well as spatio-temporal parameters within this population. We will also measure benefits of footwear management as well as the use of equipment for static and dynamic balance.

Material and Method

The sample population of this study is made of children with medium to severe types of osteogenesis imperfecta. They were able to stand up without any support for a minimum of 30 seconds. Measurements were carried out on Zebris platform from Zebris Medical GmbH. Our main measurement criteria was the area of the center of mass and foot pressure.

Results

Two boys, two girls with an average age of 13 years and 3 months, with 2 medium and two severe types of OI. Areas of the centre of mass and foot pressure increased for all patients by 1.8 times versus the norm (min=1.2N; max=2.8N). Footwear management alone did not improve stabilographic parameters but footwear with length compensation of lower limbs, even partial, enabled a reduction of the area of the center of mass and foot pressure. These results seem to be confirmed by the improvement of dynamic balance in the same environment.

Conclusion

The stabiligraphic assessment results seem interesting from an individual stand point to detect visual side-effects and measure the effectiveness of equipment used to in the stabiligraphic assessment results seem interesting from an individual stand point to detect visual side-effects and measure the effectiveness of equipment used to improve patients' balance.

THERAPEUTIC EDUCATION PROGRAM IN CHILDREN OSTEOGENESIS IMPERFECTA: THE EXPERIENCE OF THE TEAM OF SAINT-MAURICE

A.L. Camiul1, A.G. Py1, B. Alliot2, D. Baccon1, I. Debraize1, I. Delpirou1, M. Fahmy1, D. Meyer-Pein1, E. Neveur-Chartier1, S. Quesada1, S. Vacquie1, A. Lelievre1, A.C. Forget1, N. Quintero-Prigent1

1Hopitaux de Saint Maurice, Service de Rééducation de l'Appareil Locomoteur et du Rachis, Saint Maurice, France
2Osteogenesis imperfecta association, Osteogenesis imperfecta association, Amiens, France

Introduction/Background

Osteogenesis imperfecta is a disease characterized by high fracture risk and frequent pain. From the very beginning, caregivers must acquire skills to manage these episodes at home. To this end, we have set up a therapeutic education program (ETOI).

Material and Method

- Caregivers of children from 0 to 12 years old with osteogenesis imperfecta,
- Teenagers with osteogenesis imperfecta (to come).

Objectives:

* Assessment and management of pain, without using any drugs, and the handling of different levels of analgesics.
* Immobilization techniques and a customized kit built for each family.
* Criteria for deciding when they should go to the hospital.
* Verbalization of emotions related to acute situations for managing them better at home
* Discussions on different everyday issues related to the disease
* Identification of possible external resources.
Results

One-on-one sessions will be offered, focusing on coping skills and customization of treatments.

Depending on the needs assessed in a shared educational assessment, two to five groups can be offered. These sessions use adapted and various teaching methods, in the form of workshops and focus groups. At the end of the program, a booklet is given to each participant, with a customization of behavior guidelines.

The last session consists of an exchange with the Association of Osteogenesis Imperfecta (AOI).

Introduced by:

- Ten members of the RREAL service team: physiotherapists, occupational therapist, nurse, childcare assistant, psychologist, early childhood educator, health manager, social worker, doctor.

- Representatives of the AOI.

Conclusion

Strong mobilization of the team around this project, for two and a half years

Very positive feedback of the first group of parents who started in March 2017

SPATIO-TEMPORAL GAIT PARAMETERS EVOLUTION IN CHILDREN WITH ORTHOTIC DEVICES
C. Sporea¹, L. Padure²
¹"Dr. Nicolae Robanescu" National Teaching Center for Neuropsychomotor Rehabilitation in Children, Scientific research department, Bucharest, Romania
²"Dr. Nicolae Robanescu" National Teaching Center for Neuropsychomotor Rehabilitation in Children, Management, Bucharest, Romania

Introduction/Background

The study highlights spatio-temporal gait parameters changes in children with posture and gait disorders, wearing corrective orthosis.

Material and Method

Our study included 200 inpatients in the NTCNRC, aged between 5-17 years, with posture and gait disorders, able to walk independently. 50 of them were assessed 2 times: first time wearing the orthotic devices and second time without corrective posture and gait orthoses.

The children were assessed using a spatio-temporal gait parameters evaluation system based on an inertial sensor.

It was used a comparative observational method for: gait cycle duration, step length, stance phase duration, double support duration, single support duration and stride length normalized over the height of the subject.

Results

Children with posture and gait disorders improved their walking parameters after wearing the orthosis, in more than 90% of cases showing improvement in gait symmetry. This improvement is statistically significant (p < 0.001).

Conclusion

We found that in posture and gait disorders, orthotic devices improve spatio-temporal parameters of walking.

SLEEP DISORDERS IN CHILDREN WITH OSTEOGENESIS IMPERFECTA: A PROSPECTIVE STUDY OF PREDICTIVE FACTORS AND FREQUENCY

P. Lallemant-Dudek, M. Aouate-Scemama, A. Leotard, V. Forin, M. Boule, B. Nicole, J. Taytard

1 Armand-Trousseau, Médecine Physique et de Rééducation Fonctionnelle pédiatrique, PARIS, France
2 Armand-Trousseau, Unité Fonctionnelle d’Exploration Fonctionnelle Respiratoire et du Sommeil, Paris, France
3 Armand-Trousseau, Pneumologie pédiatrique, Paris, France

Introduction/Background

Osteogenesis imperfecta (OI) is the most common genetic skeletal disorder. Extra skeletal findings are common but association with sleep disordered breathing (SDB) are poorly described. For OI children, symptoms suggestive of obstructive sleep disorders (OSD) should be searched for systematically, especially when autonomy is compromised, body mass index is high, trunk deformations are identified, and in case of severe type of OI.

The aims of this study are: to estimate prospectively prevalence of OSD, and to identify clinical risk factors of OSD in OI children.

Material and Method

Every OI children who consults in the physical rehabilitation department is proposed to participate to this study. The following clinical features were searched for: sex, age, OI type, Body Mass Index (BMI), scoliosis, kyphosis, vertebral settlement, chest deformity, history of vertebral surgery, basilar impression, muscular weakness, evaluation of walking autonomy and history of bisphosphonate therapy.

After written consent, major and minor clinical criterions of OSD are searched for. If clinical suspicion is found, an Ear-Nose-Throat consultation is assessed and polysomnography (PSG). Overnight sleep PSG with the recording of nasal flow, respiratory movements, tracheal sound, body position, SpO2 and heart rate were performed in room air. The Apnea Hypopnea Index (AHI) was calculated as the sum of apnea and hypopnea events per hour of total sleep.

Results

Incomplete results (inclusion under process).
33 OI children are recruited already. 15 of these children have a clinical suspicion of OSD and are waiting for their PSG.

Conclusion
The results are actually under study. The conclusion can not be given already.

ISPR8-1919
TREATMENT OF THE CLUBFOOT BY THE PONSETI METHOD COUPLED TO REHABILITATION: A SHORT AND MEDIUM-TERM FOLLOW-UP STUDY
M. Maraoui¹, M. Sghir¹, W. Haj Hamad¹, A. Haj Salah¹, W. Lahmar¹, W. Kessomtini¹
¹CHU Tahar Sfar, Physical Medicine and Rehabilitation, Mahdia, Tunisia

Introduction/Background

Clubfoot is a complex deformity that is difficult to correct and which has four components: equinus, hindfoot varus, forefoot adductus, and cavus.

There is nearly universal agreement that the initial treatment of idiopathic congenital clubfoot should be non operative, regardless of the severity of the deformity.

The purpose of this study is to evaluate the short and medium-term results of Ponseti technique associated to rehabilitation.

Material and Method

This is a retrospective study of 5 years (2012-2016), including 40 children with 62 clubfeet, referred to the Physical and Rehabilitation department of Mahdia during the period from 2012 to 2016 and treated with Ponseti technique coupled to rehabilitation.

Demographic data, the initial clinical examination, treatment and outcomes were determined. The clinical evaluation was based on Pirani and Dimeglio scores that were assessed initially, after a series of corrective casts, then at 3 months, 6 months and 12 months.

Results

Forty children with a mean age of 33 days and a male predominance (75%) were evaluated. Twenty-two children (55%) had bilateral involvement. The initial mean Pirani score was 5.3 (2.5-6), with an initial score of 6 in 45.2% of the cases. The initial mean score of Dimeglio was 15(6.5-20), and 53.2% of feet were grade IV. The average number of casts made was 6.92. Tenotomy of the Achilles tendon was performed in 74.2% of the cases. During follow-up, there were clinical improvement with a significant reduction of Pirani and Dimeglio scores (p<0.001). Improvements of the deformities were observed in 54 feet (87%). Recurrence was observed in 8 cases (12.9%) whom underwent surgery.

Conclusion

The Ponseti method coupled with rehabilitation allows a rapid correction of clubfoot. This correction is maintained over time and reduces significantly the need for surgery.

Introduction/Background

Mechanical prosthesis without control offer functional opportunity to practice activities requiring stably holding (i.e cycling) while being using friendly.

However, as far as we know, there are only a very limited amount of studies and publications available to date on that topic.

The goal of our retrospective study was to identify benefits and interests of the use of mechanical prosthesis without control for children with agenesis or amputated forearm.

Material and Method

The data were collected on medical files of 288 children born between 1965 and 2016. They all had unilateral agenesia or traumatic amputation of forearm.

We only took into account patients using mechanical prosthesis without control.

The statement outlines the statistical ages of wearing, years of establishment, wearing time and the activities carried out.

Results

137 out of 288 children (49%) have used a mechanical prosthesis without control. 32 out of these 137 patients are still wearing one in 2014. Between 2000 and 2014, 20 to 32 mechanical prosthesis without control were prescribed per year. The use of this prosthesis was between 1 and 15 years. The duration of the use of the mechanical prosthesis did not exceed 2 years for half of the patients. This prosthesis was usually worn between 3 and 7 years old, period during which the child is improving his psychomotor development.
Children mainly use this prosthesis for cycling activity, followed by school handlings (hold a sheet of paper to cut, hold a ruler).

**Conclusion**

This new study confirms and refines results found in our previous study dated from 2007. If it seems unappropriate to wear it before 3 years old, the use of a mechanical prosthesis without control seems to help children to practice some well-targeted activities.

³Hôpital Armand Trousseau, Pediatrics Orthopedic Surgery, Paris, France
⁴Hôpitaux de Saint Maurice, Service de re-education de l’appareil locomoteur et du rachis,
Saint Maurice, France

Introduction/Background

Obstetrical brachial plexus palsy (OBPP) is often complicated by contractures of the shoulder internal rotators and/or co-contractions of the biceps/triceps brachii muscles. They are responsible of early limitations of the upper limb movements and thus limit children at the activity and participation level.

To evaluate the effect of botulinum toxin injections (BTI) on the active movements of the upper limb.

Material and Method

A database search was conducted. Children with OBPP who received BTI in the shoulder internal rotators (IR) and in the triceps brachii (TB) in Saint Maurice hospital, a national center of reference in OBPP management, were included. The primary outcome measure collected was the Mallet scale at baseline, 3 months and 6 months after BTI. Comparisons using paired t-test were used to assess the statistical significance of the between-group differences.

Results

83 children (mean age: 4.4 years) with C5-D1 injuries were included. 45 children had IR and 38 had TB injections. For the IR group, the total Mallet score increased significantly at 3 months (+4.4 on average out of a maximum score of 25) and remained significantly greater at 6 months (+2.9) compared to baseline with a greater improvement on the abduction and latéral rotations tasks. For the TB group, the total Mallet score increased significantly at 3 months (+3.8) and remained significantly greater at 6 months (+3.1) compared to baseline.

Conclusion
This study suggests that BTI are likely to improve the active movements and the motor function of the upper limb of children with OBPP as it has been previously suggested in studies involving smaller groups. It also suggests a specific functional effect depending on the site of the injections and a prolonged effect until 6 months. Randomized controlled trials are needed to definitely confirm these preliminary results.

Introduction/Background

Axial dystonia resulting in opisthotonus is observed in some children and adults with cerebral palsy and other brain disorders. This motor disorder results from involuntary activation of the trunk and cervical muscles and is associated with motor disability and pain. Usually opisthotonus does not respond to oral medications. The aim of this study is to examine the effect of botulinum toxin treatment in opisthotonus, and to objectify the patient’s response and satisfaction.

Material and Method

Six patients with opisthotonus were included in the study, the causes of dystonia being cerebral palsy (2 cases), traumatic brain injury (1 case), neurometabolic disease (2 cases) and autoimmune encephalitis (1 case). Interview with the patients and their caregivers determined the main problems in daily living resulting from opisthotonus and helped to define the goals of botulinum toxin therapy. The clinical examination performed by the injector identified the type of opisthotonus and the muscles to be injected in order to obtain the optimum effect. A set of goals by the patient, caregiver and rehabilitation team was decided for each patient. Each goal was rated on a five-point scale. Botulinum toxin was injected under electromyographic guidance into the chosen muscles of the neck and trunk (posterior and anterior muscles as needed). The Goal Attainment Scale (GAS) was used to evaluate treatment outcome.

Results

All individual baseline GAS scores were below 40. After BTX-A treatment, outcome GAS scores were above 60 in 5 cases and above 50 in one case. All individual GAS changes were positive, with a greater than 10 point-difference, which is considered to be of clinical importance.

Conclusion

Botulinum toxin treatment of selected muscles of the neck and trunk is a promising solution in pediatric dystonic opisthotonus. The GAS instrument can depict the positive changes for the patient provided by this treatment.

INFANT PAIN SCALE AND LOCAL HEAT AT THE TIME OF LOCAL INJECTION.

M. Haghshenas Mojaveri¹, Y. Zahed Pasha¹
¹Babol University of Medical Sciences, pediatric, Babol, Iran

Introduction/Background

The absence of pain relief in infants can lead to harmful effects; so, the aim of study was to investigate of the infant pain scale and local heat at the time of local injection.

Material and Method

This randomized clinical trial was conducted on 80 healthy infants. For the control group, 1 mg vitamin K was injected into the vastus lateralis muscle by a nurse. In the 3 intervention groups, respectively 5, 10 and 15 minutes before the injection, hot-water bag at 37 °C was placed on the quadriceps muscle and then injection was done with the same condition as in the control group. Immediately after the injection, the Neonatal Infant Pain Scale (NIPS) was completed. Data analysis was done using SPSS version 21.0 software

Results

41 (51.25%) girls and 39 (48.75%) boys were participated. First-minute Apgar of all samples were 8.64±0.557. Birth weight was 3335.37±339.51 grams and the minimum gestational age 36.37±1.01 weeks. The mean pain score in the first minute in the control group was 3.6±2.136, which was 3.3±1.976 in the 5-minute warm-up group, and this amount was reached to 1.6±1.569 in 10-minute warm up group, and 0.6±0.821 in 15 minute warm-up group (P=0.008). The mean pain scores in the control group for the second minute was 1.0±1.835, which was reduced to 0.25±0.716 in the 10-minute and 15-minute warm-up group (P=0.023).

Conclusion

Local heating before the injection procedure can be effective in reducing pain in infants and the pain will reduce by increasing the local heating time (15 minutes).

THE EFFECTS OF KANGAROO MOTHER CARE (KMC) ON THE FUSS AND CRYING TIME OF COLICKY INFANTS

Z. farhadikoutenaei1, Z. Akbarianrad2, M. Haghshenasmojaver1

1Babol University of Medical Sciences, Dentistry, Babol, Iran
2Babol University of Medical Sciences, pediatric, Babol, Iran

Introduction/Background

Infantile colic is a common complaint in the first few weeks of the neonate’s life. Due to its unknown etiology, there is not a specific therapy for this disease. However, various therapeutic options are recommended for reducing the pain and restlessness in the affected infants. Skin-to-skin contact via Kangaroo Mother Care (KMC) is known to increase the pain threshold and it seems to be a proper method for the care of these infants. This study aimed to evaluate the effect of KMC on infantile colic.

Material and Method

This case-control study was performed from March 2012 to March 2013. Subjects consisted of 55 exclusively breastfed infants ageing between 15-60 days with excessive fuss and crying who were referred to the Children’s Clinic of Ayatollah Rohani Hospital in Babol, North of Iran. The neonates who weighed less than 2500 grams or had been diagnosed with genetic or clinical disorders were excluded from this study. The studied infants were subjected to KMC for at least 2 hours a day. Standard questionnaires were completed through interviews and Barr Scale was also conducted. The collected data were analyzed by SPSS software V.11.5 and T-test and a P-value of less than 0.05 was considered as significant.

Results

According to the results of this study, the fuss and crying time of the infants before the KMC was 2.21±1.54 hours per day while it reduced to 1.16±1.3 hours per day after the implementation of KMC (p=0.001).

Conclusion

KMC could be practiced at home as a simple and safe method of diminishing the fussiness and crying time in colicky infants.

ISPR8-2299
CLINICAL REMISSION OF MYOPATHY WITH MYH2 MUTATIONS AFTER REHABILITATION TREATMENT: A CASE REPORT
N. chen¹
¹Xin Hua Hospital affiliated to Shanghai Jiao Tong University School of Medicine, Rehabilitation Department, Shanghai, China

Introduction/Background

Myosin myopathies consist of a set of inherited diseases caused by mutations in myosin heavy chain (MyHC) genes. Among them, MYH2 mutations have been reported to lead myopathy with ophthalmoplegia, mild to moderate muscle weakness characterized by lack of type 2A muscle fibers. To date, there is still no specific treatment for MYH2 mutated patients.

Material and Method

A 35-month-old girl was admitted for her motor developmental disorder associated with intellectual disability. A physical examination revealed the decreased muscle strength and muscle tone of her lower limbs and facial muscles combined with poor function of sitting and standing balance. Based on the primary assessment, a general rehabilitation therapy plan for the girl was set up, which involved balance training, muscle strength training in low extremity, walking training, gross and fine motor function training, as well as family education. However, after the first phase of training, her motor skills were only improved mildly as well as her balance function. In the meantime, whole-exome sequencing was performed, and a novel heterozygous mutation was discovered in her MYH2 gene. These two mutations were predicted to be pathogenic, which can lead to proximal myopathy and extraocular muscle paralysis, mainly involved in type 2A muscle fibers. After her accurate diagnosis, active exercise and endurance exercise were added in addition to original rehabilitation training program and aim to shift the expression of myosin heavy chain isoform from fast to slow.

Results

Twelve weeks after the optimized rehabilitation training, the function of her gross and fine motor was improved notably. In addition, her ability of standing, walking and jumping was enhanced significantly as well.

Conclusion

In this study, we described for the first time the clinical remission of myopathy with MYH2 missense mutations after effective rehabilitation. Precision medicine is incredibly helpful for patients with unexplained myopathies to develop a suitable rehabilitation program.

PNEUMOTHORAX IN NEUROMUSCULAR DISEASES – A CASE REPORT AND LITERATURE REVIEW

R. Prado Costa¹, T. Pimenta¹, I. Azevedo², A.I. Silva¹

¹Centro Hospitalar São João, Department of Physical and Rehabilitation Medicine, Porto, Portugal
²Centro Hospitalar São João and Faculdade de Medicina- Universidade do Porto, Department of Pediatrics- Hospital Pediátrico Integrado and Department of Obstetrics Gynecology and Paediatrics, Porto, Portugal

Introduction/Background

Neuromuscular diseases are a well known cause of chronic respiratory failure. The loss of respiratory muscle strength leads to cough inefficacy, inadequate ventilation and nocturnal hypoventilation which may require ventilatory support and cough assistance. Pneumothorax is a rare and potentially life-threatening complication that can occur in those patients.

Material and Method

We present a case of a patient with nemaline myopathy who developed a recurrent pneumothorax. A literature review was also performed regarding case reports of pneumothorax in neuromuscular diseases with highlight the major conclusions and recommendations.

Results

Case report:

14-year-old girl with nemaline myopathy under noninvasive positive-pressure ventilation (NIPPV) since age seven and chough assistance with Mechanical Insufflator-Exsufflator (MI-E), pressures of +40/−40 cm H₂O.

In May/2016 she was admitted to our hospital because of a sudden-onset worsening dyspnea and chest pain. Thoracic X-Ray (figure 1) showed a right pneumothorax that was solved with chest tube drainage. In February 2018 she was readmitted due to intolerance to NIPPV and chest pain. A large right pneumothorax was diagnosed (figure 2). CT scan revealed some apical pulmonary blebs. The ventilation pressure parameters were reduced, MI-E and all the maneuvers that potentially increases airway pressures were withheld during the stay until pleurodesis was performed. Chronic use of NIPVV, MI-E and the presence of pulmonary blebs could all have contributed to recurrence of pneumothorax.

Literature review:
2 cases of pneumothoraces were reported in nemaline myopathy, other few cases were reported on other neuromuscular diseases with patients doing NIPPV and MI-E (table 1).

### Table 1: Case reports of pneumothoraces in neuromuscular diseases found on PubMed database using the terms “neuromuscular pneumothorax” and “nemaline myopathy”.

### Conclusion

Decline in respiratory status or chest pain patients with neuromuscular disorders can be a manifestation of a pneumothorax. A low threshold for investigating and appropriate management are recommended. Case reports and series suggest that sensible modification of
ventilatory management and prudence in the use of assistive coughing with manual techniques or MI-E may prevent its occurrence.

DEEP BRAIN STIMULATION AND TETRABENAZINE AN EFFECTIVE TREATMENT IN NEURODEGENERATION ASSOCIATED WITH PANTOTHENATE KINASE

I. Londono
Hospital Universitario del Valle, Valle del Cauca, Cali, Colombia

Introduction/Background

The neurodegeneration associated with pantothenate kinase (PKAN) also called Hallervorden Spatz syndrome is a rare neurodegenerative disease, difficult diagnosis and treatment, being often recognized after several years of onset of symptoms. In most cases, dystonic symptoms have little response to pharmacological management, so in recent years, deep brain stimulation (neurostimulator) has been shown to be effective in controlling symptoms and improving quality of life from the patients.

Material and Method

Case report for an outpatient clinic.

Results

A child from the south west of Colombia with a diagnosis of PKAN confirmed with genetic testing had been diagnosed and mishandled until age 11 as sequelae of cerebral palsy presented generalized dystonic movements that led to deterioration in speech, chewing, swallowing and walking, significantly affecting his quality of life. After being evaluated in a medical board, it was decided to undergo a Deep brain stimulation in combination with tetrabenazine with a favorable result.

Conclusion

So far, there is no literature to support this indication and this combination, so it could be considered in the management of dystonia caused by neurodegeneration associated with pantothenate kinase and clinical trials should be done to assess its effectiveness and efficiency.

ABNORMAL INTRINSIC BRAIN ACTIVITY PATTERNS IN LEUKOARAIOSIS PATIENTS WITH COGNITIVE IMPAIRMENT: A RESTING STATE FMRI STUDY

Y. Zhang1, W. jinfang1
1Beijing Tian Tan Hospital - Capital Medical University - China, Neurology Department, Beijing, China

Introduction/Background

Amplitude of low-frequency fluctuations (ALFF) represents the intensity of low-frequency oscillations. It has been proven to be a valuable parameter to reflect the intensity of spontaneous neural activity. Previous studies have shown the strength of the ALFF in some areas are abnormally altered in cognitive impairment. Considering the pattern of intrinsic brain activity is sensitive to specific frequency bands, we tried to explore the alter of ALFF in leukoaraiosis (LA) patients with cognitive impairment in the study.

Material and Method

We selected subjects used MRI, and then gave them the Montreal Cognitive Assessment and Clinical Dementia Rating tests, divided them into three groups: LA with vascular mild cognitive impairment (LA-VaMCI), LA with vascular dementia (LA-VaD) and normal controls (NC). We used the Stroop Test and Trail Making Test (TMT) to analyze the executive of LA-VaMCI and LA-VaD groups, and used resting-state functional MRI (rs-fMRI) to measure the change of ALFF.

Results

The study showed the LA groups had increased ALFF in the right inferior temporal gyrus (ITG) and decreased ALFF in the left posterior cingulate precuneus (Pcu) compared with NC; the LA-VaMCI group had significantly increased ALFF in the right ITG compared with LA-VaD group and the LA-VaD group had decreased ALFF in the posterior cingulate cortex (PCC)/Pcu and increased ALFF in temporal regions compared with NC group. We also found the positive correlations between the Stroop scores and the average ALFF of the left PCu, and positive correlation between the TMT scores and the average ALFF of the left PCu.

Conclusion

Our study suggested that LA patients have abnormalities in intrinsic brain activity, the more serious of cognitive impairment, the larger changed ALFF. Moreover, we found the relationship between altered ALFF and executive function scores.

This study aims to explore the relationship of Groningen Meander Walking Test (GMWT) and Berg Balance Test (BBT) in order to initiate a claim if Groningen Meander Walking Test (GMWT) can be used as an indicator for assessing the balance ability of older adults with dementia.

Material and Method

This study used correlational method of research to determine the impact of Groningen Meander Walking Test scores to Berg Balance Test result of older adults with dementia. Selection criteria include: ages 60 years and above, able to understand Visayan, Montreal Cognitive Assessment (MoCA) score <26, ambulatory with or without assistive support but without physical assistance. Exclusion criteria include: mental disorder, use of wheelchair for mobility, difficulty in speaking or unable to talk, difficulty hearing sounds, history of head injury, problem in vision that could affect the performance. Research instrument includes Groningen Meander Walking Test (GMWT), Berg Balance Scale (BBS), Montreal Cognitive Assessment (MoCA).

Results

Only the number of oversteps walk on the first trial had the significant relationship with Berg Balance Test while the rest of the variables such as the walk duration on the first and second trial and the number of oversteps walk on the second trial did not have direct relationship with the Berg Balance Test.
Conclusion

Groningen Meander Walking Test (GMWT) scores had no significant relationship with Berg Balance Test (BBT) results in assessing the balance ability of older adults with dementia.

FEASIBILITY OF ELASTIC BAND EXERCISES IN DISABLED OR DEMENTED OLDER ADULTS IN WHEELCHAIRS

K.M. Chen¹, C.F. Kuo²

¹Kaohsiung Medical University, College of Nursing, Kaohsiung, Taiwan R.O.C.
²Kaohsiung Medical University, Center for Long-Term Care Research, Kaohsiung, Taiwan R.O.C.

Introduction/Background

Low adherence and difficult long-term maintenance of exercise programs for cognitively impaired older adults have been reported. Older adults' perception of having benefits from an exercise program is the key to their adherence to the program. This study aimed to investigate and compare the perceptions of disabled and demented older adults in wheelchairs toward the Wheelchair-bound Senior Elastic Band (WSEB) exercise program.

Material and Method

A descriptive and comparative design was applied. Data were derived from the experimental groups of two cluster-randomized controlled trials. A total of 133 participants from 8 long-term care facilities were recruited: disabled trial (four facilities, n = 60) and dementia trial (four facilities, n = 73). All participants received the Wheelchair-bound Senior Elastic Band exercises 3 times per week, 40 minutes per session for 6 months. The self-rating survey using the criteria of simplicity, safety, appropriateness, and helpfulness was applied to rate the program through face-to-face individual interviews at the end of the study.

Results

Both disabled and demented older adults have positive perceptions of the Wheelchair-bound Senior Elastic Band exercise program after 6-month of practice. The dementia group even had higher ratings for the four criteria of the program than the disabled participants.

Conclusion

Older adults with dementia were as capable of expressing their perceptions toward an exercise program through use of a self-rating survey as those without dementia. It is important to know how an exercise program was perceived by the participants in order to modify, improve, and sustain the long-term implementation of the program.

Keywords

Dementia; Elastic band exercise; Older adults in wheelchairs
No conflict of interest
Introduction/Background

According to the government estimation, the number of elderly people with dementia will exceed 7 million in 2025. Therefore, medical professionals should provide medical services with the clear purposes of supporting the lives of elderly people with dementia. This literature survey was planned to investigate the interest amongst medical professionals in Japan about the challenges of daily living experienced by people with dementia.

Material and Method

The Japan Medical Abstracts Society (JMAS) Ver.5.0, only articles written in Japanese was surveyed. JMAS is the most popular internet document retrieval site for Japanese literature in medical field.

Keywords: Dementia and Daily Living and Problems or Inconvenience

From the literature found by the keywords, duplicated literature was detected and omitted. Then, those with abstracts documented in database were surveyed. Quantitative text analysis (co-occurrence network) was conducted for the abstracts selected using software “KH-Coder Ver2.0f)

Results

1248 literature with documented abstract was found and analyzed. From the co-occurrence network chart, the main keywords identified were “Dementia” “subjects” “daily living” “significance”. The terms used frequently in the articles were as follows: evaluation, cognitive disorder, behavioral and psychological symptoms of dementia (BPSD), nutrition, caregivers, supporting family.

Conclusion

In order to provide effective support to people with dementia, it is important for each medical professional to employ its expertise and include family as members of support team for dementia clients. However, there are only few studies targeting daily living problems of people with dementia and families, hence the result showed a need for more research focused on daily living.

CURRENT STATUS OF OCCUPATIONAL THERAPY FOCUSING ON DAILY ACTIVITIES FOR DEMENTIA PATIENTS: A CASE REPORT AND A LITERATURE REVIEW

A. Kawabata¹, Y. Ishibashi¹, H. Ishibashi²
¹Tokyo Metropolitan University, Occupational Therapy, Tokyo, Japan
²Tokyo University of technology, Occupational Therapy, Tokyo, Japan

Introduction/Background

According to ministry of health labor and welfare, Japan, the number of dementia is around seven million, it indicated one in four out of the elderly has a risk of dementia. Regional inclusive care system has been started to support every elderly including dementia by all community professions. The primary goal of occupational therapy (OT) is to enable people to participate in daily activities (WFOT). The purpose of this study to examine current situations and problems of support provided by (OT) for daily activities of elderlies with dementia in Japan by a case report and literature review.

The case was a 75 years' women who lived in nursing home with assist. Three years before she developed disorientation, and Alzheimer disease was diagnosed. She could almost PADLs, she was difficult to do some IADLs by herself such as go shopping by bus. Even though she told nursing staff that she would like to go shopping to get items, the staff did not have an idea to enable it.

Material and Method

The medical literature was searched using the case registered system of the JAOT. The key words were “dementia”, ”ADL”. An illustrative case report was checked a target ADL of OT, methods, places to provide OT.

Results

There were 150 literatures, relate to dementia, of which only 47 were focusing on ADLs. The problem of ADL assisted by occupational therapist was toilet (18), bathing (12), and eating (6) in turn. Only 2 cases had services relate to IADLs. All the support was done at the facility where he or she worked.

Conclusion

It tended to provide OT service with severe dementia. Though occupational therapists could have reached any dementia cases using regional inclusive care system, they did not provide services outside the facility using this system.

A NOVEL HANDICRAFT KIT FOR COGNITIVE ASSESSMENT AND REHABILITATION FOR PEOPLE WITH DEMENTIA

A. Osawa1, I. Ueda1, H. Arai2, I. Kondo1
1National Center for Geriatrics Gerontology, Department of Rehabilitation Medicine, Obu, Japan
2National Center for Geriatrics Gerontology, Center for Gerontology and Social Science, Obu, Japan

Introduction/Background

People with dementia have various cognitive dysfunctions, which deprive them of their daily activities. In order to maintain and activate cognitive functions, handicrafts are sometimes used for rehabilitation. However, it is difficult to apply the handicrafts for people with dementia because of the difficulty of objective assessment. We have developed a handicraft kit without needle, named Funsy Stitch (Fun and easy stitch) manufactured by Uemura Co., Ltd and used it to analyze cognitive function of people with dementia along with the provision of appropriate assistance.

Material and Method

Subjects were 27 patients with Alzheimer’s disease. They carried out 40 minutes of work twice, using the stitch with several difficulty levels. In addition, we asked them to evaluate the work subjectively using Visual Analog Scale (VAS) along with the objective evaluation by occupational therapist.

Results

In the subjective evaluation (VAS), the average value of pleasure for work (0: absolutely not fun~10: very pleasant) was 8.3 ± 1.4. If part of the work is appropriately supported by occupational therapist, it was possible to complete the whole process. We also found that the type of error and the contents of support were different depending on the subject.

Conclusion

With appropriate support, most subjects could enjoy the activities and complete the task. It would be possible to use this kit for the cognitive assessment as well as cognitive rehabilitation which can provide fun for the people with dementia.

CORRELATION BETWEEN MINI MENTAL STATE EXAMINATION(MMSE) AND MONTREAL COGNITIVE ASSESSMENT INDONESIA VERSION (MOCA INA) TO THE ADL OF ELDERLY PATIENT AT M. DJAMIL HOSPITAL PADANG
R.P. Yolanda¹, N. Atsmara¹, M. Rahmadewi¹
¹Physical medicine and rehabilitation, Medical Rehabilitation M. Djamil Hospital, Padang, Indonesia

Introduction/Background

Screening test is crucial to diagnose cognitive dysfunction, they should be sensitive for mild cognitive impairment. Mini Mental State Examination (MMSE) and the Montreal Cognitive Assessment Indonesia version (MoCA Ina) are commonly used for screening of patient with vascular cognitive impairment. Mild cognitive impairment can affect the ability of elderly to perform their activity daily living.
Aim: To find the correlation between MMSE and MoCA Ina with ADL score of elderly patient

Material and Method

24 elderly patient without visual impairment, movement disorder and can use the dominant hand for writing, their cognitive were test with MMSE and MoCA Ina. Then the ADL was test with Lawson IADL

Results

The median age was 67 year. The education level 33% elementary school, 25% high school and the others 41% collage.

Cognitive test with MMSE 22 patient (91.7%) normal and only 2 patient (8.3%) had mild cognitive impairment. Different from MMSE the result of cognitive test with MoCA Ina 7 patient (29.2%) normal and the rest of the patient 70.8% had mild cognitive impairment

There is no correlation between MMSE and IADL (p: 0.261) and there significant correlation between MoCA Ina and IADL (p: 0.013)

Conclusion

We can detect Mild cognitive impairment in elderly with MoCA Ina than MMSE. MoCA Ina has a correlation with the IADL Score of the elderly patient at M. Djamil Hospital

PREVALENCE OF HIV ASSOCIATED DEMENTIA AMONG HIV/AIDS ADULTS ATTENDING COMPREHENSIVE CARE CENTRE-KAPSABET REFERRAL HOSPITAL
R.N. Mbugua
1
1Kenya Network of Women Living with HIV/AIDS- Nairobi University- Kenyatta National Hospital - Mathare Mental Hospital, Research and Community Healthy worker, Nairobi, Kenya

Introduction/Background

HIV associated dementia is the most devastating central nervous system consequence of HIV infection which invades the brain directly. Progression into HIV associated dementia (HAD) has is associated with a number of bio-psychosocial factors. Despite the high prevalence of HIV infection, there are no adequate data on HIV associated dementia both internationally and locally especially in Africa. The aim of this study was to establish the prevalence of HAD, the associated socio-demographic factors, and the association between International HIV Dementia Scale Score and viral load among HIV/AIDS adult patients attending the Kapsabet Comprehensive Care Centre, Nandi County.

Material and Method

The study design was descriptive cross-sectional study and the study population was 4,100 HIV positive adults who were drawn from various locations within the county. Sample size was 352 patients who came for their routine clinic appointment. Sampling method used was simple random sampling where the potential participants randomly picked numbers in a container at the triage nurse desk. Those who picked odd numbers from 1 to 31 and met inclusion /exclusion criteria participated in the study. International HIV dementia scale and Socio-demographic questionnaire was used to collect socio-demographic characteristic and HIV related information.

Results

The data collected was analyzed using SPSS Version 20 and the results were presented in tables, graphs, Charts and narratives. Study results The prevalence of HIV associated dementia was 65.6% among HIV patient attending Kapsabet Comprehensive Care Centre, There was no association between viral load and International HIV dementia score with a chi-square of 3.96 and p-value of 0.267

Conclusion

The results indicated that HIV associated dementia is common among HIV patients attending Kapsabet comprehensive Care Centre and is not associated with viral load

EXERCISE PREVENTS AGE HEART RATE VARIABILITY DECLINE IN THE ELDERLY: A SYSTEMATIC REVIEW AND META-ANALYSIS

J. Raffin¹, J.C. Barthélémy², V. Pichot², M. Berger³, T. Busso³, L. Féasson³, C. Montuy-Coquard¹, M. Thillays¹, R. Poillerat¹, R. Bouvier¹, B. Bongue⁴, F. Roche², D. Hupin²

¹Mutualité Française, Mutualité Française SSAM Loire Haute-Loire, Saint-Etienne, France
²University Hospital of Saint-Etienne, Clinical and Exercise Physiology, Saint-Etienne, France
³University of Lyon, Inter-University Laboratory of Human Movement Biology - EA7424, Saint-Etienne, France
⁴National Center for Health Examination Prevention, Cetaf, Saint-Etienne, France

Introduction/Background

Previous studies suggest that exercise training improves cardiac autonomic drive in young and middle aged adults. Benefits for elderly are discussed. We aimed to establish whether exercise still increases heart rate variability beyond the age of 60.

Material and Method

Interventional controlled and non-controlled studies were selected from Pubmed, Ovid, Cochrane and Google Scholar databases. A random effects model was used to determine effect size (Hedge’s g) for change in SDNN, RMSSD, PTOT, HF, and LF heart rate variability indices. Heterogeneity was assessed using the Q and I statistics.

Results

After checking for inclusion criteria, we found 12 studies, whom 7 controlled, including respectively 218 and 111 subjects (mean age 69.0±3.2 and 68.6±2.5), appropriate for meta-analysis. Including the 12 studies demonstrated a homogeneous significant effect sizes for SDNN (g = 0.420 (95% CI 0.239 to 0.602) p<0.0001). Controlled studies analysis demonstrated homogeneous significant effect sizes (p <0.05) for SDNN (g = 0.489; 95% C.I. 0.154-0.823), as well as for RMSSD (g = 0.501; 95% C.I. 0.138-0.864), and Ptot (g = 0.751; 95% C.I. 0.075-0.215).

Conclusion

This meta-analysis demonstrates a positive while moderate effect of endurance type exercise on parasympathetic and global cardiac autonomic regulation in older adults. We conclude that autonomic improvement in older adults, which needs long-term exercise with sessions preferably repeated at least thrice a week, may be even more critical as the remaining autonomic activity spontaneously decreases.

INFLUENCE OF AGING AND PHYSICAL FRAILTY OF ELDERLY PEOPLE ON THE BIOMECHANICAL CHARACTERISTICS OF TRUNK AND LOWER EXTREMITIES OF SIT TO STAND MOTION

D. Nakashima¹, K. Shinkoda², K. Hirata¹, Y. Mikami³, H. Kimura³, N. Adachi⁴
¹Hiroshima University Hospital, Sports Medical Center, Hiroshima city, Japan
²Hiroshima University,
Center for Advanced Practice and Research of Rehabilitation- Institute of Biomedical and Health Sciences, Hiroshima city, Japan
³Hiroshima University Hospital, Rehabilitation, Hiroshima city, Japan
⁴Hiroshima University,
Orthopaedic Surgery- Division of Medicine- Biomedical Sciences Major- Graduate School of Biomedical Sciences, Hiroshima city, Japan

Introduction/Background

The purpose of this study was to obtain new findings on an effective physical therapy approach to sit-to-stand (STS) motion by clarifying aging- and physical frailty-related changes in kinematic and kinetic characteristics of trunk and lower limbs of elderly people.

Material and Method

The subjects were 17 healthy young people, 12 healthy elderly people, and 12 pre-frail elderly people. STS measurements were carried out using a three-dimensional motion analyzer (VICON MX) and ground reaction force plates (AMTI). Furthermore, the moments of the obtained hip, knee and ankle joints were summed to calculate the support moment.

Results

In the healthy elderly group, the maximum flexion angle of the trunk was significantly smaller than that in the healthy young group. There was no significant difference between the three groups in terms of the maximum flexion angle of the hip and ankle joint. In the pre-frail elderly group, the maximum flexion moment of the trunk and the hip joint was significantly lower than that of the healthy young group and the healthy elderly group, and the integral value of the extension moment and peak extension moment of the knee joint was significantly higher. Moreover, the ratio of the hip joint extension moment to the support moment was significantly lower than that in the healthy young group and the healthy elderly group, and the ratio of the knee joint extension moment to the support moment was significantly higher.

Conclusion

It was suggested that age-related changes occur earlier in trunk movement than lower limb movement. It was also suggested that the absolute value of the kinetic data of the trunk and hip
joint during STS motion declines due to the physical frailty of the elderly and that the absolute value of the kinetic data of the knee joint increases to compensate for this physical frailty.

RELATIONSHIP BETWEEN DYNAPENIA AND FUNCTIONAL MOBILITY IN INSTITUTIONALIZED FRAIL ELDERLY
A.V. Soares¹, F. Noveletto², E. Marcelino³, S.C. Domenech⁴, F.L.F. Eichinger³, Y. Sagawa⁵
¹Guilherme Guimbala College- Lutheran Educational Association and University of Joinville Region, Laboratory for Research in Neurorehabilitation, Joinville, Brazil
²University of Santa Catarina State, Center of Technological Sciences, Joinville, Brazil
³Guilherme Guimbala College, Laboratory for Research in Neurorehabilitation, Joinville, Brazil
⁴University of Santa Catarina State, Center of Health and Sport Sciences, Florianópolis, Brazil
⁵University Hospital of Besançon, Laboratory of Clinical Functional Exploration of Movement, Besançon, France

Introduction/Background

Frail Elderly Syndrome (FES) has been considered as one of the most incapacitating events with people aging. This syndrome is characterized by five disorders outlined in figure 1 which involves a greater risk of falls, disability, hospitalization and even death. Although FES is characterized by these 5 main disorders, recent studies have cited that dynapenia and reduced functional mobility have a crucial role in FES. Therefore, this study aimed to investigate the relationship between dynapenia and functional mobility in frail elderly institutionalized.

![Figure 1. Clinical characteristics of Frail Elderly Syndrome](image)

Material and Method

Twenty six institutionalized elderly men and women with average age 82.3 ±6 years participated in this descriptive correlational study. All participants had 3 or more characteristics of fragility according to established criteria. Mini Mental State and Examination Geriatric Depression Scale were used for patients’ screening phase. Functional mobility was assessed through the
International Physical Activity Questionnaire and Timed Up and Go test, whereas handgrip dynamometer and handheld dynamometer were used to evaluate respectively grip strength and large muscle groups (elbow flexors, shoulder flexors, ankle dorsiflexors, knee extensors, and hip flexors). Data were analyzed with descriptive statistics and Pearson correlation test.

Results

A significant negative correlation with a large effect size was observed between functional mobility and the dynapenia for all muscle groups: grip strength (r-0.36), elbow flexors (r-0.58), shoulder flexors (r-0.56), ankle dorsiflexors (r-0.56), knee extensors (r-0.65) and hip flexors (r-0.51).

Conclusion

This study confirmed previous results suggesting that functional mobility in institutionalized frail elderly is associated with muscle strength, especially knee extensors. FES prevention and treatment programs depend on accurate clinical diagnosis. The assessment of muscular strength seems fundamental, and dynamometry can contribute to this purpose.

THE EFFECT OF PALLIATIVE EXERCISE ON MAXIMUM OXYGEN CONSUMPTION (VO2MAX) AND QUALITY OF LIFE IN ELDERLY WOMAN WITH FRAILTY

N. Noegraheni

1DR. SOETOMO GENERAL HOSPITAL SURABAYA,
PHYSICAL MEDICINE AND REHABILITATION SCHOOL OF MEDICINE AIRLANGGA UNIVERSITY, Surabaya, Indonesia

Introduction/Background

Aging is a process that turns a healthy adult into a frail and in Indonesia there has been no published frailty data. It is important to identify frailty and intervene to prevent disability. One of therapeutic modalities provided is exercise, therefore Installation of Physical Medicine and Rehabilitation Dr. Soetomo Hospital with Palliative Foundation Indonesia creates exercise for palliative patients.

Material and Method

This study was an experimental quasi with non randomized control group design pre test and post test design. The sample is chosen by purposive sampling method. The number of subjects analyzed were 24 subject, 13 subjects of treatment group and 11 subjects of control group. Treatment group was given palliative exercises with duration 30 minutes, frequency 3x/week for 6 weeks. The parameters evaluated were maximal oxygen consumption (VO2max) with 6 minute walk test and quality of life with SF-36 questionnaire in each group.

Results

The result showed a significant difference (p<0.05) VO2max, quality of life of physical dimension, general health, vitality, mental health, and there was no significant difference in social function, and emotional role after treatment compared before treatment in treatment group.

Conclusion

There was an increase in cardiorespiratory fitness assessed by VO2max measurements and improved quality of life in the physical function, general health, vitality, social function, and mental health of elderly woman with frailty in a nursing home attending palliative exercise 3x/week for 6 weeks.

**Introduction/Background**

Frailty is a multisystem degeneration. It is becoming recognized that frailty may be a pre-disability state. Exercise training is proved to improve physical performance and health status in the elderly. Kinect is an affordable and accessible exergaming systems. Whether Kinect-based exergaming is efficient in improving physical performances and reverse the deterioration process in frail and pre-frail elderly require further investigation. The purpose of this study is to investigate the effect of Kinect based exergaming on frailty status, physical performances in pre-frail and frail elderly.

**Material and Method**

We recruited frail and pre-frail elderly people in the elderly day care centers and institutions. Participants were randomized to two group and received 60 minutes Kinect based exergaming or multi component exercise for 36 sessions over 12 weeks according to their group assignment. Programs in both groups include muscle strengthening, aerobic exercise, balance training and cognitive training. Outcome measures include frailty status and physical performances.

**Results**

Fifty two pre-frail and frail elderly finished all the intervention and assessment. Both groups showed improvements in frailty scores after intervention. The frailty components revealed that weakness, exhaustion, low physical activity, and slow walking speed were reversed in both group, but unintentional weight loss did not significantly changed. Both groups also showed improvements in most parts of the physical performances after intervention. For between group differences, Kinect based exergaming group showed more improvement in forward reaching distance than multi component exercise group.

**Conclusion**

Kinect based exergaming can reverse the frailty status and improve physical performances. Our results provided information to support the possibility of therapeutic use of exergaming training in the frail and pre-frail elderly.

Introduction/Background

Maximum tongue pressure is used clinically to assess dysphagia and to facilitate swallowing exercises. A previous study reported on maximum tongue pressure and endurance of tongue pressure, but did not report on speed (rate of force development, RFD). The objective of this pilot study was to investigate the RFD of tongue pressure in the elderly.

Material and Method

The subjects were 60 healthy elderly people (60-year-olds, n=20; 70-year-olds, n=20; 80-year-olds, n=20). Tongue pressure was measured using a tongue pressure measurement device (JMS Co. Ltd., Japan). The maximum tongue pressure and RFD of tongue pressure were measured thrice. RFD of tongue pressure was measured as 1) the rate from the start of rising tongue pressure to peak and 2) 80% of peak from the start of rising of tongue pressure.

Results

Maximum tongue pressure was 36.8 ± 6.2 kPa, 35.3 ± 5.9 kPa, and 32.6 ± 8.2 kPa in the 60-, 70-, and 80-year-olds, respectively, with no significant difference with age. Regarding RFD of the tongue pressure, the speed to reach the peak was 105.3 ± 46.0 kPa/s, 106.0 ± 45.6 kPa/s, and 82.5 ± 38.0 kPa/s in the 60-, 70-, and 80-year-olds, respectively, and the speed to reach the 80% peak was 148.9 ± 54.0 kPa/s, 144.7 ± 61.6 kPa/s, and 107.7 ± 62.1 kPa/s in the 60-, 70-, and 80-year-olds, respectively, both of which were not significant but tended to decrease in the 80-year-olds.

Conclusion

In the elderly, RFD of tongue pressure appeared to decrease more in the 80-year-olds than in the 60- and 70-year-olds. Further studies will be done with a larger number of subjects, with young people for comparison, and with patients with dysphagia.

Introduction/Background

In Japan, a new type of service for frail elderly called "life support comprehensive service C" has been launched. The purpose of this service is improvement of health condition and ADL. This service C has the feature that it ends in a short period of about 3 months. However, little weakness was known about the characteristics of service C users. For these reasons, the purpose of this research was to compare with users of current preventive services to investigate the characteristics of vulnerability among Service C users.

Material and Method

The 28 participants were recruited by an area support comprehensive support center. Service C group (n=14) received community occupational therapy (OT) focused on restoring social functioning and improving QOL. Control group (n=14) who are healthy elderly also received community OT on current service focus on on restoring daily life skills and improving QOL. In both groups, from 8 to 16 times OT group sessions had conducted for 4 months. To compare measuring ADL and QOL, Frenchey Activities Index (FAI, Holbrook, 1983) as a measurement for ADL, and EQ-5D-5L as a measurement for QOL were used. In this study, the scores of the initial evaluation of the experimental group and the control group were compared. This survey was initiated after approval of the Ethics Review Committee.

Results

There was no significant between groups on age. The mean of FAI on service C group (12.3±11.4) was significantly lower than current service group (32.3±4.3). The mean of EQ-5D-5L on service C group (0.538±0.117) was significantly lower than current service group (0.850±0.094).

Conclusion

These results indicated that the user of service C had ADL limitations. Even though their goals were similar, it should be different program based on frailty of participants.

EFFECTIVENESS AND EFFICIENCY OF NEW PREVENTIVE INTERVENTION SERVICES FOR COMMUNITY DWELLING FRAIL OLDER PEOPLE: PILOT STUDY
H. Nagayama¹, N. Kobayashi², Y. Isibashi², R. Kobayashi², C. Murai³
¹kanagawa University of Human Services Faculty of Health & Social Work School of, Department of Occupational therapy, Yokosuka, Japan
²Graduate School of Human Health science- Tokyo Metropolitan University, Department of Occupational Therapy, Arakawa, Japan
³Ishikawa Takamatsu prefectural hospital, Department of occupational therapy, Kahoku, Japan

Introduction/Background

In Japan, a new preventive intervention service has been launched for frail older people called "life support comprehensive service C". Many of the subjects in this service have some difficulty with Instrumental Activities of Daily Living: IADL such as housework, going out, hobbies, etc. However, it is unclear for the intervention detail and effects. Furthermore, this intervention is required for short term and low frequency. Therefore, the purpose of this pilot study was to determine the effectiveness and efficiency of the new preventive intervention service for community-dwelling frail older people.

Material and Method

This study design was pre-post design without a control group. Participants were community-dwelling frail older people. Intervention in this study was conducted by occupational therapists. Typically, the therapists provided the necessary advice with regards to the specified real-life occupation (doing meaningful activities in their real environment) for each participant. The intervention details were client-centred goals setting, observation of real living situations, and provision of advice on the individual problem of real occupation. The outcome was the Frenchay Activities Index (FAI), which is used for the evaluation of the Instrumental Activities of Daily Living (IADL). Additionally, frequency, and duration of the intervention were calculated.

Results

The mean age of participants was 76.7 (± 7.84) years old, with orthopedic disorders were most common (46.2%). The FAI scores were significantly improved for all items except work after the intervention (P <0.05). Frequency of interventions was 4 or less, and the duration was within 3 months.

Conclusion
In this study showed intervention detail of life support comprehensive service C and this intervention had the potential of the effectiveness and efficiency. We believe that this pilot study contributes to future clinical studies for frail older people.

EFFECTS OF PROGRESSIVE ELASTIC BAND RESISTANCE EXERCISE FOR OSTEOSARCOPENIA ELDERLY WOMEN

S. Huang¹
¹Shuang Ho Hospital- Taipei Medical University, Physical Medicine, Taipei, Taiwan R.O.C.

Introduction/Background

Sarcopenia involves age-related decreases in muscle strength and muscle mass, leading to frailty and disability in elderly people. When combined with osteoporosis, it is defined as osteosarcopenia, which can result in more functional limitations and disability than either disorder alone. Progressive elastic band resistance exercise has been used for the functional training of elderly people with disabilities, and can improve the physical performance of this population. However, the influence of body composition and physical function after elastic band resistance training among osteosarcopenia elderly women was still not well investigated. The aim of this study was to investigate the effect of progressive elastic band resistance exercise for osteosarcopenia elderly women.

Material and Method

This pilot randomized controlled trial focused on elderly women with osteosarcopenia (n=26). The study group underwent progressive elastic band resistance training for 12 weeks (3 times per week). The control group received only a 40-minute lesson about the exercise concept. Dual-energy X-ray absorptiometry was evaluated and physical capacity was evaluated using the timed up-and-go, single-leg stance, timed chair-rise, and 10-m walk speed tests. All the variables were measured at baseline, after 12 weeks of intervention, and 6 months follow up period. All data was analyzed by two-way-ANOVA.

Results

In the aspect of body composition, the study group (n=15) presented improved of T-score, Z-score and decreased fat percentage after intervention. When follow up, there was no statistical difference with comparing baseline data. The physical function of timed up-and-go and timed chair-rise test revealed improvement after intervention. There was no improvement of body composition and physical capacity of control group (n=11). After intervention and follow up evaluation, study group presented better performance of timed up-and-go, 10-meter walk test and timed chair-rise test than control group.

Conclusion

Progressive elastic-band resistance exercise can improve bone density, fat, and physical function of elderly osteosarcopenia women.

COMPARISON OF BODY COMPOSITION BETWEEN AFFECTED AND UNAFFECTED SIDE OF HEMIPLEGIC PATIENTS BY BIOELECTRICAL IMPEDANCE ANALYSIS
S.H. Ko¹, K. So Jung¹, M. Myunghoon¹, K. Soo-Yeon¹, S. Yong-II¹
¹Pusan National University Yangsan Hospital, Department of Rehabilitation Medicine, Yangsan-si, Republic of Korea

Introduction/Background

Hemiplegia leads to muscle abnormalities due to combination of denervation, disuse, abnormal metabolic function, remodeling and spasticity that may account for a muscle atrophy in affected extremities. The purpose of this study is to analyze the differences of body composition between affected and unaffected extremities in the patients with hemiplegia using Bioelectrical impedance analysis (BIA)

Material and Method

We enrolled in-patients with hemiplegic stroke. They received conventional physical and occupational therapy after onset. Body compositions were assessed by BIA and muscle mass, body water and extra-cellular water ratio were analyzed at each segments of body. They were divided into 3 groups according to the period of onset; acute (0-1 month), subacute (1-6 month), and chronic phase (after 6 month).

Results

In the study, we enrolled a total of 173 subjects (106 men, 167 women; 61.0±10.5 years). We divided subjects in three groups; acute (58, 33.5%), subacute (75, 43.3%), and chronic group (40, 23.2%). The ischemic stroke was 94 and hemorrhagic stroke was 79 patients. Of all subjects, 91 have been a right hemiplegia. There was no significant difference in segmental lean body mass between affected and unaffected upper and lower extremities in all groups. Also, the segmental body water was no significant difference between affected and unaffected extremities in all groups.

**Fig. 1.** Segmental lean mass and body water in upper and lower extremity.

**Conclusion**

There were no significant differences in body composition between affected and unaffected upper and lower extremities in acute to chronic stroke. These results expect that patients with hemiplegic stroke who received rehabilitation therapy to maintain body composition in affected side. Rehabilitation therapy might be useful strategies to preventive effect of muscle wasting.

⁵Hyogo college of medicine, Rehabilitation science, Nishinomiya, Japan

Introduction/Background

The mechanism of oral sarcopenia concerned with tongue muscle atrophy is imperfectly understood. We must pay careful attention whether the pathology of tongue muscle affects dysphagia in the elderly. The purpose of this study was to investigate the relationship between the decrease in tongue muscle volume and tongue weakness with magnetic resonance imaging (MRI) examination.

Material and Method

11 elderly patients without stroke or neuromuscular disease participated (Mean age: 72.6±6.5). Tongue pressure was measured using a device (TPM-01, JMS, Hiroshima) equipped with a balloon probe. Tongue volume was evaluated with T1-weighted MR imaging. Tongue lean muscle mass was evaluated with Dixon MRI. The pearson analysis was used to calculate coefficients between tongue pressure and tongue volume/lean tongue muscle mass.

Results

The mean tongue pressure, tongue volume and lean tongue muscle mass were 29.9±8.1 kPa, 66.8±12.3 cm³ and 56.2±10.4 cm³. Tongue pressure was significantly correlated with tongue volume and lean tongue muscle mass (r = 0.60, p = 0.049 and r = 0.64, p = 0.035).

Conclusion

To our knowledge, this is the first study to investigate tongue muscle mass, lean tongue muscle mass and tongue pressure using MRI images. Tongue muscle mass and lean tongue muscle mass was significantly associated with tongue pressure. Compared with previous studies for healthy young adults (Utanohara, 2008; Fabrice, 2010), tongue pressure was decrease in spite of tongue volume was similar. Bassler (1987) suggested that the tongue volume after muscular atrophy is compensated by metaplasia of fatty tissue. We speculated that adipose might be an important factor for reducing tongue pressure and dysphagia.

RECOVERY OF FUNCTION IN SARCOPENIC AND NON-SARCOPENIC PATIENTS AFTER HIP FRACTURE UNDERGOING FRAGILITY FRACTURE INTEGRATED REHABILITATION MANAGEMENT

S.K. Lim¹, L. Sang Yoon², B. Jae Won³, L. Jae-Young⁴
¹Changwon Gyeongsang National University Hospital, Physical Medicine and Rehabilitation, Changwon, Republic of Korea
²Seoul Metropolitan Government Seoul National University Boramae Medical Center, Physical Medicine and Rehabilitation, Seoul, Republic of Korea
³Chung-Ang University College of Medicine, Physical Medicine & Rehabilitation, Seoul, Republic of Korea
⁴Seoul National University Bundang Hospital- Seoul National University College of Medicine, Physical Medicine and Rehabilitation, Bundang, Republic of Korea

Introduction/Background

Fragility hip fracture and sarcopenia are critical causes of mortality and loss of function in elderly patients. Also, sarcopenia is known for association with overall worse functional outcome after rehabilitation. This study evaluates the functional recovery in patients with sarcopenia receiving Fragility Fracture Integrated Rehabilitation Management (FIRM) after hip fracture.

Material and Method

Patients over 65 years who underwent hip surgery for fragility hip fracture at three university hospitals in Korea from July 2016 to December 2017 received multidisciplinary rehabilitation. Sarcopenia was defined according to Asian Working Group for Sarcopenia (AWGS) criteria. We evaluated various functional characteristics including primary ambulatory function and other secondary outcomes between sarcopenic and non-sarcopenic group at admission, discharge and 3 months after surgery.

Results

107 patients with a mean age of 81.26 ± 8.85 years were eligible for the study and patients satisfied the criteria of sarcopenia were 40 (37.4%). Compared with patients without sarcopenia, those with sarcopenia showed lower ambulatory status at discharge (Functional Ambulatory Category (FAC) : 2.18±1.14 versus 2.67±0.98, p=0.021) and at 3 months after surgery (KOVAL : 4.07±1.87 versus 3.04±1.82, p=0.016, FAC : 3.03±1.07 versus 3.68±1.02, p=0.008). In addition, other secondary outcomes were lower in sarcopenic group at discharge (Modified Rivermead Mobility Index (MRMI), Berg Balance Scale (BBS), Mini Mental State Examination, Grip strength, Korean Instrumental Activities of Daily Living (K-IADL), EQ-5D) and at 3 months (MRMI, modified Barthel index, K-IADL, EQ5D) after surgery.

Conclusion
These results support the negative impact of sarcopenia on functional recovery among patients with fragility hip fracture receiving rehabilitation. Well-customized comprehensive rehabilitation program focused on sarcopenia is helpful for improving functional outcomes.

RELATIONSHIP OF LOW PHYSICAL CAPABILITY AND THE AUTONOMIC FUNCTION OF OLDER ADULTS WITH SARCOPENIA

C.D. Liao¹,², T.H. Liou¹,², J.Y. Tsauo²

¹Shuang Ho Hospital, Department of Physical Medicine and Rehabilitation, Taipei, Taiwan R.O.C.
²National Taiwan University, School and Graduate Institute of Physical Therapy - College of Medicine, Taipei, Taiwan R.O.C.
³Taipei Medical University, Graduate Institute of Injury Prevention and Control, Taipei, Taiwan R.O.C.

Introduction/Background

Sarcopenia has increased risks of limiting physical capability (PC) and lowering physical activity levels of elderly people. Low physical activity levels may be mediated through autonomic dysfunction with diminished heart rate variability (HRV). However, the relationship between autonomic dysfunction and low PC remains unclear. This study investigated the association of low PC with HRV in older adults with sarcopenia.

Material and Method

We conducted an observational study with a cross-sectional design. We included a total of 126 older adults who had a mean (SD) age of 65.2 (7.6) years and was identified as sarcopenia. The PC was measured using mobility tasks, including functional reach (FR), single-leg stance (SLS), gait speed (GS), timed up-and-go, and timed chair-rise (TCR), which were merged and transformed into a global physical capability score (GPCS). Time- and frequency-domain indices of HRV were obtained. We used the highest and lowest quintiles of the distribution of GPCS as the cutoff points for high and low PC, respectively. A stepwise regression model was established to identify the determinants of HRV indices. We used hierarchical regression analysis to identify the associations of GPCS with HRV indices.

Results

Compared with the low PC group, the high PC group exhibited a significantly superior performance in the mobility tasks (all \(P < 0.001\)). Compared with the high PC group, the low PC group had a markedly diminished HRV in terms of a decreased standard deviation of normal-to-normal interval (SDNN, \(P < 0.001\)) and high frequency (HF) component of HRV (\(P < 0.01\)). FR and GS positively predicted SDNN, whereas FR, SLS, GS, and TCR were determinants of HF. The GPCSs independently explored 17.9% (\(P < 0.001\)) and 12.1% (\(P = 0.001\)) of the variances in SDNN and HF, respectively.

Conclusion
Low PC levels are an independent determinant of decreased HRV in older adults with sarcopenia.

SARCOPENIA AS A RISK FACTOR FOR DEPRESSION IN COMMUNITY-DWELLING OLDER ADULTS: A 1-YEAR PROSPECTIVE STUDY

L. Hou¹², Q. Guo¹²

¹TEDA International Cardiovascular Hospital- Cardiovascular Clinical College of Tianjin Medical University, Department of Rehabilitation Medicine, Tianjin, China
²Tianjin Medical University, Department of Rehabilitation Medicine, Tianjin, China

Introduction/Background

Several studies have explored the association between sarcopenia and depression, but they have been based on cross-sectional data. The purpose of this 1-year prospective study was to determine whether sarcopenia is an independent risk factor of depression in community-dwelling older adults.

Material and Method

This was a prospective study including 860 Chinese suburb-dwelling participants aged ≥60 years. We defined sarcopenia using the diagnostic algorithm recommended by the Asian Working Group for Sarcopenia, and the participants were classified into the sarcopenia and normal groups according to this definition. The participants’ depressive symptoms were assessed using the Geriatric Depression Scale (GDS) and defined the score of GDS ≤ 11 as depression.

Results

Among the 860 participants (mean age 67.6 ± 5.9 years), 8.84% were classified as sarcopenia. Multivariate logistic regression showed that sarcopenia was independently associated with depression (adjusted OR 2.09, 95% CI 1.04-4.19, P = 0.04).

Conclusion

Sarcopenia was identified as an independent risk factor of depression in community-dwelling older adults during the 1-year study period.

SARCOPENIA AND RISK OF NEW ONSET DEPRESSIVE SYMPTOMS IN OLDER ADULTS: A COHORT STUDY
C. Xiaoyu, G. Qi

1International Cardiovascular Hospital, Department of Rehabilitation Medicine, Tianjin, China
2TEDA International Cardiovascular Hospital, Department of Rehabilitation Medicine, Tianjin, China

Introduction/Background

Few studies have explored the relationship between sarcopenia and depressive symptoms in certain cohorts. The objective of this study was to examine the incidence of new onset depressive symptoms and associated factors over a 1-year period in an elderly Chinese suburban population.

Material and Method

This study was conducted on 510 Chinese suburb-dwelling participants aged ≥60 years, for whom detailed information regarding sociodemographics, behavioral characteristics, and medical conditions had been documented. Depressive symptoms were examined using the 30-item Geriatric Depression Scale. A Geriatric Depression Scale score of ≥11 was used to indicate depressive symptoms. Sarcopenia was defined according to the Asian Working Group for Sarcopenia (AWGS) criteria. Sarcopenia incidence was documented after one year of follow-up, and correlated with several possible factors.

Results

At baseline, 43 (6.4%) of the initial 670 participants had depressive symptoms. The prevalence of depressive symptoms was 23.9% after one year. Between baseline and 1-year follow-up, 122 of the participants without depressive symptoms at baseline had developed depressive symptoms. After multivariate adjustments, it was found that the incidence of new onset depressive symptoms increased with age and sarcopenia is associated with more incidence of depressive symptoms. Incidence was also higher among women.

Conclusion

We found depressive symptoms incidence increased with age, and women were more likely to have depressive symptoms. In addition, sarcopenia is a risk factor for depressive symptoms. Maintaining a healthy weight could be beneficial in the prevention of depressive symptoms.

RELIABILITY AND VALIDITY OF THE HELLENIC VERSION OF THE BERG BALANCE SCALE

N. Terzis¹, K. Merakou², A. Barbouni², N. Roussos³, K. Kazakos⁴, G. Drosos⁴
¹General Hospital Asklepeio Voulas, PRM, Voula, Greece
²National School of Public Health, Department of Public and Administrative Health, Athens, Greece
³General Hospital Asklepeio Voulas, PRM Department, Voula, Greece
⁴Democritus University of Thrace- Medical School, Orthopedics Department, Alexandroupolis, Greece

Introduction/Background

It has been estimated that approximately one of three persons over 65 years old falls repeatedly, once a year and 10% of them has a serious injury. The purpose of this study was to develop the hellenic version of Berg Balance Scale (BBS) and to process its reliability and validity according international guidelines of transcultural validation process.

Material and Method

60 patients selected according inclusion criteria, constituted the population of the study. BBS’ structure was investigated using factors’ analysis. In order to determine the reliability of BBS’ internal consistency Cronbach’s-a factor was used. The intraclass correlation coefficients (ICCs) were used in order to determine the accordance of the responses and the internal stability of the questionnaire. BBS’ Person ‘s (r) correlation coefficient was associated with those of Test Up &Go (TUG) and Fall Efficacy Scale (FES) so to test the concurrent validity of YSQ. The statistical analysis was processed though the Statistical Package of Social Sciences, SPSS 19.0.

Results

The majority of the participants were women, secondary education graduated, married, 70-79 years old. The first time of assessment the mean score in BBS was 52.6 (SD=4.8) and the second time was 52.1 (SD=5.1). ICCs were significant (p <0.001) and were estimated to 0.88 for the total of the sample, 0.91 when the two assessments were conducted by the same person and 0.85 when the persons were different. There was a significant negative correlation of BBS with TUG and FES, which confirmed the convergent validity of the BBS. Age and the educational level of the participants were associated independently to the BBS’ score. Women and participants with fracture had significantly lower BBS’ scores compared with men and individuals without fracture respectively.

Conclusion
The assessment of falls’ risk factors is essential and realized through the appropriate methodological tools which provide an automated risk analysis.

Factors Associated with the Risk of Fall in Stroke Inpatients

T. Enishi¹, N. Yamasaki¹, A. Matsumoto¹, T. Higuchi², M. Takeuchi², M. Kashima², S. Yoshioka², M. Nakamura², S. Nakano²

¹Tokushima Municipal Hospital, Rehabilitation Medicine, Tokushima, Japan
²Tokushima Municipal Hospital, Orthopedics, Tokushima, Japan

Introduction/Background

Falls are a popular and major problem for stroke patients during their hospital stay. The aim of this study is to reveal the factors associated with the risk of fall in stroke inpatients.

Material and Method

Retrospective study carried out with stroke hospitalized patients. Thirty-four stroke patients who fell and 34 stroke patients who did not fall during their hospital stay underwent structured medical examinations to identify factors associated with fall. The control subjects were matched for age, height, body weight, body mass index (BMI), and primary diagnosis. Potential variables related to fall risk factors were collected from medical records. A conditional logistic regression was performed to calculate odds ratios using SPSS. Clinical data were collected from January to December 2016. "An unexpected displacement of the body to a lower level than the initial position without loss of consciousness" was regarded as fall.

Results

Nutrition status, evaluated with modified CONUT score at admission, was significantly associated with fall risk (odds ratio = 3.11, 95%CI: 1.18-9.94). There were no statistically significant differences in the other candidate factors (e.g. sarcopenia, activities of daily living, and rehabilitation intervention) between the two groups.

Conclusion

Our findings demonstrated that nutrition status was associated with fall risk in stroke hospitalized patients. Further studies are needed to reveal that nutritional intervention can contribute to falls prevention in stroke patients.

Keywords
Fall prevention; Nutrition; Stroke

No conflict of interest
Introduction/Background

Falls increase risk of death, worsen quality of life and make possibility of long term hospitalization in older community residents. For these reasons, falls cause increases of medical expenses. In South Korea, 42% of senior citizen had fall experiences and 38% of these people spented a lot of medical expenses. Given this background, we have attempted to prevent falls in elders through 8weeks prevention program. The aim of this study was to identify the effects of fall prevention program.

Material and Method

During a period ranging from July of 2015 to June of 2016, Patients who visited the out patient Department of Physical Medicine and Rehabilitation in Veterans Health Service Medical Center were enrolled. Inclusion criteria were (1)who ages over 60, (2) who experienced falls (3) who complained a disturbance during gait. The fall prevention program consists of stretching, strengthening and balance exercise of lower extremities and core muscles shows a gradual rise in exercise intensity and twice a week during 8weeks. Participants were rated for gait ability, functional status and fall fear risk with timed up and go test, gait analysis, balance test, strength test, berg balance test (BBS), modified Barthel index (MBI), and Korean version of Fall efficacy international scale (KFES-I). We compared these parameters before and after program.

Results

Of 47 participants who enrolled at first, 32 participants finished the fall prevention program. In addition only 17 participants were evaluated after program. After the fall prevention program, significant improvements were noted in MBI (p<0.01), BBS (p<0.005) and KFES-I (p<0.002). But other parameters showed no significant differences including timed up and go test and gait analysis parameters.

Conclusion
In this study, participants showed an increase of balance ability and decrease of fall fear through the program for fall prevention. Therefore, consistent stretching, strengthening and balance exercise may contribute to prevention of fall in elders.

INSTRUMENTAL REHABILITATION IN THE MANAGEMENT OF POSTURAL DISORDERS IN ELDERLY WITH KNEE OSTEOARTHRITIS

R. Maaoui¹, S. zrida¹, I. ksibi¹, N. ktari², H. rahali¹
¹Military Hospital of Tunis, physical rehabilitation medicine, Tunis, Tunisia
²private medical practice, private medical practice, Tunis, Tunisia

Introduction/Background

Knee osteoarthritis is the most common osteoarthritis in the lower limb.

In the elderly, the aging of major functions and of the postural system associated with knee osteoarthritis causes greater fragility with an increased risk of falls. One in three over 65 and one in two over 85 fall in one year. Therefore, postural rehabilitation takes an important place in the care

The aim of our study was to evaluate the contribution of instrumental reeducation in elderly with knee osteoarthritis subjects compared to classical proprioceptive rehabilitation and to draw up their postural profile.

Material and Method

Retrospective, evaluative and comparative study. Twenty patients aged over 65 were enrolled in the study and divided into two groups of 10: group 1 (G1) underwent instrumental rehabilitation, the second group (G2) underwent conventional rehabilitation. Both groups benefited from the same initial and final clinical, functional and instrumental evaluation.

Results

The average age of the general population was 68.65 ± 3.216 years ranging from 65 to 75 years.

Improvement was noted in both groups in pain, clinical parameters, and Lesquene and Womac functional scores. A notable improvement was also observed on the stabilometric parameters evaluated namely the surface S (open eyes and eyes closed) the Romberg quotient and the speed variation. These improvements were not, however, significant for both groups. G1 significantly improved stabilometric parameter data compared to G2, but this improvement was not statistically significant.

Conclusion
Stabilometric rehabilitation is a promising technique for the management of fine balance disorders. Longer-term programs would be offered to older people given the complexity of the field, in order to guarantee significant results.

THE USE OF WALKING AIDS IN ELDERLY FALLERS

C. Dziri\textsuperscript{1}, L. Boukhadra\textsuperscript{2}, F.Z. Ben Salah\textsuperscript{3}

\textsuperscript{1}National Institute Of Orthopaedy M.Kassab, Physical and Rehabilitation medicine, La Manouba, Tunisia
\textsuperscript{2}Institut Supérieur de l'Education Spécialisée- Université de La Manouba, Physical and Rehabilitation medicine, La Manouba, Tunisia
\textsuperscript{3}0021671606920, La Manouba, La Manouba, Tunisia

Introduction/Background

Falling is a serious public health problem among elderly people. Old people in Tunisia don't like to use crutches/walkers, symbols of handicap. We investigated whether the risk of falling could be reduced with walking aids and how to convince elderly people to use them.

Material and Method

We studied from march-july 2017 30 fallers (unipodal support test < 3sec), 27 women, mean age 69.1 years, who consulted at the department of physical and rehabilitation medicine for rheumatologic impairments (73%) – neurological conditions (17%) or traumatical conditions (10%). These subjects were assessed without and with a walking aid as following: intensity of pain, range of motion, muscular testing, Katz index, Tinetti POMA, gait (speed, cadence, step length, step width), self satisfaction. Statistic study was done by SPSS version 18.

Results

During 5 months of follow-up, 30 subjects were studied. 60% had inaccessible environment, 53% a loss of range of motion, 63% a contracture, 70% muscle weakness. During rehabilitation sessions, a walk test with technical assistance was performed. Many parameters were improved using walking aids (a single crutch in 60%, walkers in 30%, tripod stick in 10%): mild pain from 60% to 47%, Katz index, Tinetti (24-27 points), gait parameters (speed, cadence, step length). 73% of the subjects were satisfied using walking aids

Conclusion

The use of a walking aid is positive in elderly fallers. Statistically significant improvements were observed according pain, Katz index, Tinetti, gait parameters and self satisfaction. Nevertheless 3 patients didn't accept to use the walking aid.

Introduction/Background

Preventing falls in elderly people is a major public health issue, regarding to significant consequences for physical, psychological and socio-economic level. Among various risk factors, influences of footwear, and particularly of the heel height, on the control of standing posture are discussed. The aim of this study was to assess the effect of heel height on the control of standing balance in older women.

Material and Method

Twenty old women were recruited from the community (Table 1) and voluntarily participated in the study.

There were instructed to stand barefoot on force plate under four combined experimental conditions of two visual conditions (eyes open and eyes closed) and two heights of heels (0 and 4.5 cm). Centre of foot pressure (CoP) displacements were recorded using a force platform. Three dependent variables were used to describe the participants’ postural behavior: the mean antero-posterior (AP) COP position, the surface area covered by the trajectory of the CoP and the mean speed of the CoP displacements.

Results

As reported in Tables 2 and 3, analysis of the CoP displacements showed for both eyes open and eyes closed conditions: (1) a more anterior shift of the mean COP position in the 4.5 cm heel condition than in the 0cm heels condition, and (2) a significant increase of CoP mean speed in the 4.5 cm heel condition than in the 0cm heels condition. Conversely, no significant
differences were observed for the surface area.

Chuncheon, Republic of Korea
3Gangwon Do Rehabilitation Hospital, Department of Rehabilitation Medicine, Chuncheon,
Republic of Korea

Introduction/Background

Introduction: Maintaining balance is a core performance in conducting the physical activity and activities of daily livings. The purpose of this study was to verify the related factors to balance performance in Korean healthy farmers.

Material and Method

Methods: A total of 504 healthy Korean farmers were recruited. The balance performance was evaluated with a force platform system in static standing with eyes open (EO) and eyes closed (EC). The deviations over 15 mm in mediolateral or anteroposterior directions were regarded as an “abnormal”. Subjects’ sociodemographic characteristics, cognitive function (Go/No-go test, GNGT), trunk body composites, physical activity level (International Physical Activity Questionnaire, IPAQ), psychological status (Center for Epidemiologic Studies Depression scale, CES-D) and sleep quality (Pittsburgh Sleep Quality Index, PSQI) were also assessed, and their associations with balance performance were analyzed by binary logistic regression analysis.

Results

Results: Abnormal balance performances were identified in 51(10.1%) farmers with EO and 85(16.9%) farmers with EC. The scores of IPAQ were higher in abnormal balance performances group with EO(7389.4±346.5 [mean±SE] vs. 10670.4±1770.6, p=0.006) and EC(7079.8±330.8 vs. 10884±1343.0, p<0.001), and the scores of CES-D were same with EO(9.2±0.3 vs. 12.6±1.1, p=0.007). Additionally, reaction time of GNGT was higher in in abnormal balance performances group with EC(631.9±9.8 vs. 696.5±23.7, p=0.008). Logistic regression analysis showed that both IPAQ and CES-D were explanatory variables in EO(OR=1.00, p=0.03 and OR=1.06, p=0.01, respectively) and EC (OR=1.00, p=0.001 and OR=1.04, p=0.04, respectively) conditions. Moreover, trunk back muscle (OR=0.97, p= 0.046) and abdominal muscle (OR=1.03, p=0.04) masses in EO, and reaction time (OR=1.002,
p=0.004) in EC were related to balance performance.

THE INFLUENCE OF COGNITIVE-EMOTIONAL TASKS AS AUTOBIOGRAPHICAL MEMORY RECOLLECTION AND FUTURE PROJECTIONS DURING WALKING ON WALKING CHARACTERISTICS IN THE ELDERLY

G. Dagan Barda¹,², M. Kafri¹, A. Mendelsohn³

¹University of Haifa, Department of Physical Therapy - Faculty of Social Welfare & Health Sciences, Haifa, Israel
²Loewenstein Rehabilitation Hospital, Physiotherapy, Ra’anana, Israel
³University of Haifa, Sagol Department of Neurobiology, Haifa, Israel

Introduction/Background

Dual-task (DT) studies have demonstrated that performing a secondary cognitive task alters gait. However, the tasks employed in these studies are typically of low ecological relevance, and have not emphasized a possible impact of emotional processing on gait parameters.

The current work aim was to examine whether gait in old individuals is influenced by simultaneously preforming cognitive-emotional tasks of retrieving autobiographical memories (AM) or imagining future projections (FP), in a dual task (DT) paradigm. Our working hypothesis was that similar to lab-based cognitive tasks, naturalistic, emotion-evoking processes may lead to alterations in gait execution.

Material and Method

Twenty-four old adults were instructed to recollect AM and FP, in response to cue words that were chosen in preliminary interviews to be personally relevant. A single-task condition (ST) served as baseline and a cognitive verbal fluency task (VF) as an active control.

Emotional responses to the tasks were subjectively rated using the Self-Assessment Manikin (SAM) scale, the autonomic-system activity was monitored using the MindWare Impedance Cardiograph, and gait was measured using the APDM’s Mobility Lab ™.

Results

AM and FP increased emotional valence relative to ST (p <0.0001), while VF had diverse emotional responses. This effect was corroborated by increases in skin conductance, which were higher in the DT conditions relative to ST (p <0.0001). DT led to a decrease in gait speed and cadence and an increase in double-limb-support, primarily in the VF condition and with a similar trend in AM and FP. Increase in emotional valence led to increases in gait speed (p = 0.05) and cadence (p = 0.011).

Conclusion
The effect of AM and FP on walking characteristics in the elderly showed similar trends to that of VF. Walking was influenced by emotional aspects that accompanied the various tasks.

Introduction/Background

The world’s population is ageing and most countries are experiencing growth in the number and proportion of older persons. Advancing age is often related to an increase in the number of falls and fall related injuries. Fall injuries in older persons engender loss of confidence and fear of falling, with deleterious effects on independency and quality of life. Lower limb weakness and more specifically hip muscle strengths seem to be an influencing factor of falls. Nevertheless, currently it is unclear which hip muscles play the most important role in older people.

Therefore we aimed to investigate which hip muscle group strength shows an acceptable level of distinction (area under the curve (AUC) >0.7) between older fallers and non-fallers compared to fall history as our predefined external criterion.

Material and Method

We measured the maximum voluntary isometric strength (MVIS) and the rate of force generation of the six hip muscle groups (hip abductors (ABD), adductors, internal and external rotators, extensors, and flexors) in 60 older people (38 females and 22 males). A trained physical therapist performed the strength evaluation of all participants with a dynamometer fixed to a custom-made frame. We then calculated the AUC and the mean decreased Gini Model to evaluate the parameter with the highest ability to distinguish between fallers and non-fallers.

Results
Of all the assessed hip muscle groups, hip ABD MVIS showed the highest discriminative value regarding the chosen external criterion in older people (AUC ABD MVIS 0.825, 95% confidence interval: 0.712–0.938).

**Conclusion**

Hip abductor strength is the only parameter which reached our predefined diagnostic accuracy of the AUC above 0.7. Therefore, our results indicate that ABD MVIS might be an interesting factor to target fall risk detection and might also shape fall risk prevention programs.

2Resesearch Center on Sport and Mouvement Centre de Recherches sur le Sport et le Mouvement CeRSM, Paris, France

Introduction/Background

Aging is characterized by an alteration of sensory motor function, which could impair postural balance, and consequently increases fall risk. The present study aimed to investigate the effect of combined strength and endurance training coupled with walnut supplementation on bipedal and monopodal postural balance in elderly people.

Material and Method

Twenty elderly participants were divided into two groups in a randomized controlled trial: Training + walnuts diet (GTW, n = 10); Training + control diet (GT, n = 10). Age, body mass and height of the participants were 66.7 ± 2.8 years, 169.0 ± 3.8 cm, 73.7 ± 5.2 kg, respectively. The experimental protocol consisted of combined strength and endurance training (three sessions/week) for six weeks coupled with a walnuts supplementation (15 g per day). Before and after training program, bipedal with double task (counting from 0 to add 7 each time) and monopodal balance measurements were performed in both conditions “open eyes” (OE) and “closed eyes” (CE) using the SATEL® force platform.

Results

The present findings showed that bipedal with double task and monopodal balance parameters were decreased significantly for GTW compared to GT in both conditions (OE, CE). For bipedal static balance, there was a significant decrease in Long X and Long Y (F = 9.4, p= 0.007, F = 5.42, p= 0.032, respectively) in the OE condition and (F = 4.64, p= 0.045, F = 4.27, p= 0.05, respectively) in the CE condition. Concerning monopodal balance, the results showed a decrease in Long X and Long Y (F = 9.9, p= 0.005, F = 17.9, p= 0.001, respectively) in CE condition.
Conclusion

Combined strength and endurance training coupled with walnut supplementation improved bipedal and monopodal stability parameters. This improvement could be explained by the beneficial effect of walnuts supplementation on vestibular system.

Introduction/Background

Osteoporosis prevalence continues to grow, increasing morbidity and mortality associated with osteoporotic fractures, which often result from a fall. One third of the population aged 65+ falls each year. 5% of these falls result in fractures, mostly osteoporotic, with hip fractures having the greatest socioeconomic impact.

We aimed to characterize a group of women with recent hip fracture regarding fall risk factors, fall circumstances, previous falls and fractures, fall prevention, and osteoporosis treatment.

Material and Method

Cross-sectional study in women with recent hip fracture during their stay at an Orthopaedics ward. It was conducted for one year by means of a questionnaire and consulting the clinical records of women aged 65+.

Results

192 women were evaluated, 69 of which had cognitive deficits. 95% of the respondents’ fractures resulted from a fall with a greater proportion occurring indoor, at daytime, and on a flat floor. Overall, 76% had previous falls of which 61% had more than 2 episodes. 42% had previous osteoporotic fractures of which only 7% were medicated. We found a strong relationship between (1) vestibular disorders treatment, non-pharmacological measures for osteoporosis, and the number of falls; and (2) the number of previous falls, fall prevention measures, and the occurrence of osteoporotic fractures. However, no clear association was found between fall risk factors and the occurrence of falls.

Conclusion

Our comprehensive study results support the current knowledge on healthcare burden of falls and osteoporotic fractures. A more detailed research on the possible association between non-pharmacological measures for osteoporosis and treatment for vestibular disorders and falls should be done in the near future. Although our results may have a population selection bias, they confirm the seriousness of hip fractures, as the elderly population will continue to grow, representing a greater burden of osteoporosis and falls, both underrecognized and undertreated.

WE WANTED TO DETERMINE DO SPINOMED® AS A TLO PRODUCE CHANGES IN RELATION WITH POSTURE, EQUILIBRIUM AND ABILITY OF PEOPLE WITH HYPERKYFOSIS I

T. kranicce

ACTIVA MUTUA, REHABILITATION AND BIOMECANICAL UNIT, BARCELONA, Spain

Introduction/Background

The more frequent vertebral osteoporotic fractures are the ones that occur in the thoracic spine where the gravity forces are greater because of the anatomic kyphosis and the increase of concavity forces.

For vertebral fracture and hypekyfosis we normally using variety of spinal orthosis to stabilized them.

We chose Spinomed® because of specially characteristics:

“Beck orthosis for vertebral extension in osteoporosis and strengthening of the core musculature.”

Material and Method

We evaluated Overall Rating of control and stability (Romberg + Voluntary control and ability evaluation) of patients affected by hyperkyphosis using the Measure system for equilibrium made by Biomechanical Institute from Valencia (NedSVE/IBV®) performed 2 measures:

- 1st with the Spinomed® (SPINOMED® GROUP)
- 2nd without Spinomed® (NON SPINOMED® GROUP)

We evaluated women’s population between 41-87 (70) years old, mostly of them with osteoporosis.

We measured the angle of Cobb using as a reference angle between 4th thoracic vertebral superior plate and 12th thoracic inferior plate. (Cobb 61,8º; 46º-91º)
The pain and disability evaluation

**Results**

We found patients in the Spinomed group “grow” 1 cm approxim.

Spinomed® group we found reduction of Scanning area and reduction of Anterior movement

The Voluntary control and Ability evaluation we found that displacement in anterior direction decrease in the Spinomed group

**Conclusion**

In Romberg testing with open eyes in Spinomed® group we found reduction of Scanning area which is clinically significant. (more stability)

The Spinomed group shows the clinically significant results in decrease of anterior displacement and anterior displacement which means that the center of gravity moved back towards.

There is not risk of Equilibrium disturbance in the patients which wearing SPINOMED.

IMPLEMENTATION OF EVIDENCE BASED TREATMENT INTO CLINICAL PRACTICE FOR OLDER PEOPLE – A NEGATIVE TRIAL

I. Cameron¹, S. Kurrle¹, P. Walker¹

¹John Walsh Centre for Rehabilitation Research- University of Sydney, Kolling Institute, St Leonards, Australia

Introduction/Background

This project took the strong evidence that vitamin D supplements reduce falls in older people living in residential aged care facilities and applied implementation science principles to investigate whether the prevalence of vitamin D supplement use could be increased.

Material and Method

A multifaceted implementation program was developed that included education and targeted all stakeholders, use of audits and feedback, and addressing stakeholder beliefs and attitudes. Its effectiveness was assessed using a stepped wedge design.

Results

In the first group of 17 facilities (1466 residents) the prevalence of vitamin D supplement use was stable at 58% over the six month intervention period. Comparison data from control group facilities confirmed that the intervention was not effective in increasing supplement use.

Conclusion

Despite a carefully designed implementation program the goal of increasing use of an evidence based treatment was not achieved. It is likely that this occurred due to a complex interplay of factors that meant behaviour did not change in key players (general practitioners, facility managers and staff, and family caregivers and older people). This project has shown that an evidence based treatment recommendation and a best practice implementation program is not sufficient. In this case a direct action approach through general practitioners may have been more effective.

\textsuperscript{2}Service de médecine physique et de réadaptation, Hôpital Jean Rebeyrol- Pôle neuro-sciences tête et cou, Limoges, France

Introduction/Background

The number of steps is a parameter fluently evaluated by accelerometry. However, we believe that there are measurement errors that steps are recorded while the person does not necessarily move. The aim of the study was to highlight accelerometer biases in the estimation of the steps number in elderly on different physical activities.

Material and Method

27 elderly (71 ± 4 years) volunteered to realize successively: 3 minutes computer-based word processing (without moving feet), 5 minutes biking (with hands on the handlebars), 5 minutes walking on treadmill.

The number of step was estimated by accelerometers (1 SenseWear Armbands, 3 Actigraphs GT3X and 3 Acticals) worn on the hip, on the wrist and ankle on the dominant side (26 were right-handed and one was left-handed).

Results

</tbody>
</table>

Values are expressed in mean ± standard deviation
Conclusion

This study showed that accelerometers present biases in estimating the steps number in the elderly according to their position on the body but also the activity type. The principal bias of accelerometers is that even if the person is at a standstill, only moving theirs legs or arms, accelerometers detect steps. The Armband SenseWear seems to be the one which presents the least biases to estimate the steps number in this population.

DEVELOPMENT OF DIGITAL DISEASES CARE PROGRAM: RESULTS FROM PHOTO DIARY AND FOCUS GROUP DISCUSSION

C.M. Chen¹, C.Y. Wang¹

¹National Cheng Kung University, Department of Nursing, tainan, Taiwan R.O.C.

Introduction/Background

Average life expectancy becoming longer, the prevalence of individuals with chronic illness and functional disability has surged. The aim of this project is to develop a digital diseases care management program, using both descriptive and Participatory Action Research designs.

Material and Method

Eleven older adults were recruited to take their photo diary up to three months. The focus group discussion was then applied to explore relevant facilitating and barrier factors for their chronic disease self-management practice in the community. It further aimed to suggest which lifestyle measures, symptoms and behaviors would be meaningful to be included in the digital diseases care management program.

Results

Five subthemes were merged. Most subjects went out regularly for exercise, and walking at nearby household, park, and temple as photographs represented. Systematically reminding and recording level of physical activities, and rewarding and group exercising strategies for exercising were proposed. Although most subjects complied with the prescription, they complained on often forgetting or adjusting medication according to their subjective review of health conditions. Digital system which can warm clients’ symptom changes to enhance medication compliance and questions to ask health providers was proposed. Eating low nutritious and left over food were problems identified.

Conclusion

Use of meal photos to interact with families and intellectual training on healthy diet were suggested. Social connection was set up for interaction with families, chronic disease self-help group and health providers. Incorporating daily routine and good model practice sharing were discussed in this domain. The prototype of the application (App) to be used in tablet is developing. The wearable device, application of persuade technology to enhance subjects’ self-consciousness on healthy behaviors, concept of calendar and incorporated community activities will be included in the App to reinforce behaviors and lifestyle to control their chronic conditions.

THE EFFECTS OF DEPRESSIVE SYMPTOMS ON QUALITY OF LIFE AMONG INSTITUTIONALIZED OLDER ADULTS IN TAIWAN

I.C. Li

National Yang-Ming University, Community Health Care, Taipei, Taiwan R.O.C.

Introduction/Background

To identify factors that influence QOL in the elderly is important. Depression has a significant impact on QOL. The inability to independently perform ADL was the major factor affecting QOL. This study tested whether depressive symptoms mediate the effect of ADL on the physical and mental components of QOL in institutionalized elderly individuals in Taiwan.

Material and Method

Inclusion criteria of sampling included a healthy cognition status, which was tested by the Short Portable Mental Status Questionnaire (SPMSQ). After I explained the aims of this study to the administrators of the facilities, 73 facilities agreed to participate and 306 of those met the inclusion criteria for this study. The Sobel’s significance test was used to test whether physical health status and depressive symptoms have an impact on QOL.

Results

The results of the Sobel test showed that depressive symptoms mediated the effects of ADLs on the physical components of QOL (standardized β = 0.16, Sobel test z = 3.33, p < .001) to a degree of 11.11%. Depressive symptoms significantly mediated 40% and 53.68% of the effect of the number of chronic diseases on the physical and mental components of QOL, respectively (z = -2.41, p = .016; z = -2.45, p = .014, respectively).

Conclusion

Depressive symptoms mediate the effects of ADL and the number of chronic diseases on the physical and mental aspects of QOL. Improving depressive symptoms appears to be necessary for improving both the physical and mental aspects of QOL of institutionalized people of advanced age.

SURVEY ON PRESSURE ULCERS AND NOSOCOMIAL INFECTIONS IN FUNCTIONAL REHABILITATION CENTERS IN LEBANON

K. Ghoussoub¹, C. Tarhini¹, G. Sleilati², A. Hage³, R. Choueiri⁴, S. sader⁵, H. Baroudi⁶, R. Hallit⁶
¹CHU hotel Dieu de France, PMR, Beirut, Lebanon
²CHU Hotel Dieu de France, Cardiac surgery, Beirut, Lebanon
³Beit Chabab hospital, pmr, Beirut, Lebanon
⁴Cottbawi hospital, pmr, Beirut, Lebanon
⁵Ouzai hospital, pmr, Beirut, Lebanon
⁶Bhannes hospital, pmr, Beirut, Lebanon

Introduction/Background

The aim of the survey is to study the prevalence of pressure ulcers and nosocomial infections in 4 state-of-the-art rehabilitation centers in Lebanon and to compare the results with the literature data.

Material and Method

Descriptive survey with prospective collection of patients admitted to hospital in 4 rehabilitation centers during one week. Collection of information using a grid with demographic study (age, sex, third-party payment), diagnosis, length of stay less than 3 months, presence or absence of bedsore, or urinary tract infection (nosocomial or not). Statistical study using the SPSS software v 10. After a description of the variables of interest, a univariate study using the Chi² and Levene tests is carried out. A p <0.05 is considered significant

Results

Descriptive study: 69 patients identified in the 4 centers. Male predominance 58%. Average age 69 +/- 17 [18-90], paying third mainly social security.35%. Neurological diseases predominate 65%, orthopedics 25%.

Presence of bedsores 13% of which 88% before hospitalization. Single bedsore 90%, sacral lesion 70%.

Urinary infection 50% (23% on arrival and 27% on hospitalization). The most common germs on arrival: E. Coli 62.5%, Klebsiella Pneumonia 31%. During hospitalization E. Coli (66%), Pseudomonas Aeruginosa 16.5%.

ESBL germs: on arrival 67% of urinary tract infections, during hospitalization 50%. Predominance of Pseudomonas 65%.
Univariate study Predictive factors for the occurrence of pressure ulcers: urinary tract infection on arrival p: 0.04, and patient infected with resistant germ p: 0.089. Predictive factors for urinary tract infection during hospitalization: length of stay p 0.061, neurological diseases p: 0.02, and advanced age p: 0.03.

Conclusion

The occurrence of pressure ulcers in rehabilitation centers does not exceed international standards, but nosocomial infections are high and their frequency differs from one center to another according to the patient recruitment policy.

Key words functional rehabilitation centers, pressure ulcers, nosocomial infections

Keywords

Introduction/Background

Expiratory flow plays an important role in minimizing the risk of infection by expelling foreign substances and excessive mucus from the lungs. Expiratory flow results primarily from the activities of the abdominal muscles. However, data regarding the association of the abdominal muscle activity during expiratory effort and abdominal exercise with expiratory flow rate are limited. This study aimed to assess the correlation between expiratory flow and abdominal muscle activity while holding maximum expiration and side bridge exercise in elderly women.

Material and Method

Rectus abdominis (RA), external oblique (EO), and internal oblique (IO) muscle activities were measured using electromyography in 14 elderly women (82.8±6.7 years), who could independently walk, performing two tasks: holding breath after maximum expiration in the crook-lying position (maximum expiration) and holding side bridge on knees without breathing indication (side bridge). Peak expiratory flow (PEF) was obtained using a peak flow meter with the subject in the sitting position. Correlations between PEF and the abdominal muscle activity were determined using Spearman rank correlation coefficient. The Ethics Committee of the Kawasaki University of Medical Welfare approved the protocol for this study. Written informed consent was obtained from each subject before participation in the study.

Results

The correlation coefficients between PEF and the RA, EO, and IO activities while holding maximum expiration were 0.407 (p=0.149), −0.345 (p=0.227), and 0.732 (p=0.003), respectively. The correlation coefficients between PEF and the RA, EO, and IO activity while holding side bridge exercise were −0.297 (p=0.303), −0.552 (p=0.041), and 0.147 (p=0.615), respectively.

Conclusion

Our results showed that higher IO activity while holding maximum expiration or lower EO activity while holding side bridge exercise was related to higher PEF. Thus, maximum expiration and abdominal exercise might be effective in the improvement or prevention of the decrease of expiratory flow.

EFFECT OF INTERMITTENT HYPOXIA TRAINING FOR DIZZINESS: A RANDOMIZED CONTROLLED TRIAL

X. Bao¹, H. Liu¹
¹Yue Bei People’s Hospital, Department of rehabilitation Medicine, Shaoguan, China

Introduction/Background

The dizziness symptoms are very common among various diseases. It is often considered as an independent clinical manifestation or accompanying symptom. The aim of our research is to study the effect of intermittent hypoxia training for dizziness.

Material and Method

A single-blind, randomized controlled trial. All participants were recruited from a rehabilitation department in an acute university-affiliated hospital. Participants with dizziness were randomly assigned to IHT group and control group. The Dizziness Handicap Inventory, Activities-specific Balance Confidence scale, Vertigo Visual Analog Scale were conducted at baseline, end of the 4th week.

Results

Among 52 subjects, ages from 35 to 62 years old (mean ± SD = 46.9 ± 7.93). Time length since onset ranged from 12 months to 34 months (20.2±7.15 months). The Dizziness Handicap Inventory, Activities-specific Balance Confidence scale, Vertigo Visual Analog Scale scores and attack frequencies of dizziness were improved after IH training intervention in the end of 4th week. There were significant differences between IHT group and control group in The Dizziness Handicap Inventory, Activities-specific Balance Confidence scale, Vertigo Visual Analog Scale scores and attack frequencies of dizziness in the end of 4th week (P<0.05). No adverse events occurred during the study.

Conclusion

Intermittent hypoxia training could improve dizziness after intervention in end of 4th week. It could be the effective method for releasing dizziness.

LONG-TERM INTENSIVE LOCOMOTION TRAINING WITH WEARABLE HIP-ASSIST ROBOT IN ELDERLY ADULTS: A PRELIMINARY STUDY

Y.H. Kim¹, H.J. Lee¹, S.H. Lee¹, D.S. Kim², W.H. Chang¹, B.O. Choi³, G.H. Ryu⁴

¹Samsung Medical Center, Physical and Rehabilitation Medicine, Seoul, Republic of Korea
²Sungkyunkwan University, Department of Health Sciences and Technology- Samsung Advanced Institute for Health Science and Technology SAIHST, Seoul, Republic of Korea
³Samsung Medical Center, Neurology, Seoul, Republic of Korea
⁴Sungkyunkwan University, Office of Biomechanical science- Research Center for Future Medicine, Seoul, Republic of Korea

Introduction/Background

The purpose of this study was to investigate the long-term training effect of wearable hip-assist robot on locomotion function in elderly adults.

Material and Method

Seven elderly participants (age means: 74.5 ± 5.78, 3 males) were recruited. The Gait Enhancing Mechatronics System (GEMS, Samsung Electronic Co., Ltd., Korea), which functions as a wearable hip-assist robot was used. All participants received 45-minute gait training with GEMS in various overground environments for 24-sessions during the consecutive 8 weeks. Muscle efforts were acquired and analyzed using the 12-channel surface electromyography system (Desktop DTS system, Noraxon, USA) at preferred speed. Gait functions were determined by 3D motion capture system (Motion Analysis Corporation, USA). Cardiopulmonary metabolic energy consumption measurements were obtained during 6 minutes of treadmill walking using portable cardiopulmonary metabolic system (COSMED K4B², Rome, IT). In addition, cerebral oxygenation was measured using the fNIRS imaging system (NIRSport, NIRDx Medical Technologies LLC, Glen Head, NY, USA).

Results

The 24-sessions of long-term intensive locomotion training with GEMS significantly improved gait function of elderly adults ($P < 0.05$). Metabolic energy consumption during 6 minutes treadmill walking was significantly lower after 24-sessions training ($P < 0.05$). Furthermore, long-term intensive locomotion training with GEMS demonstrated decreased activity of specific brain regions related with gait and might represent increased efficiency of neural resources. These gains were maintained for 4 weeks after the cessation of training ($P < 0.05$).

Conclusion
The results of this preliminary study suggest that long-term intensive locomotion rehabilitation with the GEMS were tolerable and effective for improving gait function, cardiopulmonary metabolic efficiency and cerebral oxygenation patterns during walking in the elderly. Randomized controlled trial with larger participants is invited in near future. (This study was supported by the Samsung Medical Center (PHO0171341) and by a grant from the NRF (NRF-2016R1A6A3A11930931 and NRF-2017M3A9G5083690), which is funded by the Korean government.)

RELATIONSHIP BETWEEN PHYSICAL ACTIVITY, FUNCTIONAL MOBILITY AND BALANCE IN COMMUNITY-DWELLING ELDERLY
E. Aslan Telci1, N. Yagci1, M. Öztop1, S. Şekeröz1
1Pamukkale University, School of Physical Therapy and Rehabilitation, Denizli, Turkey

Introduction/Background
Decline in functional mobility and balance is some of the changes that occur with aging in community-dwelling elderly. It’s proven that physical activity has many positive effects in different age groups. This study aimed to investigate the relation between physical activity level, functional mobility and balance in community-dwelling elderly.

Material and Method
A total of 136 community-dwelling elderly without cognitive dysfunction (range: 65-92 yrs; mean age:71.20±5.66 yrs; 86 male) was assessed. Physical activity level of subjects was measured with Physical Activity Scale for the Elderly (PASE). The Timed Up and Go test (TUG) and Five-Time-Sit-to-Stand Test (FTSST) was used to determine subjects’ functional mobility. Also, One-Legged Stance Test (OLST) and Sharpened Romberg test (SR) was used to evaluate balance of subjects.

Results
The correlation analysis showed that there is a significant positive correlation between PASE score and OLST ($r = 0.381$), SR ($r = 0.363$) scores. Furthermore, there is a significant negative correlation between PASE score and TUG ($r = -0.351$), FTSST ($r = -0.298$), age ($r = -0.185$).

Conclusion
Results obtained from this study indicate that physical activity has beneficial effects on functional mobility and balance in community-dwelling elderly. Increasing physical activity level of elders could improve functional mobility and balance that crucial for decreasing the risk of fall.

CEREBRAL OXYGENATION PATTERNS DURING WALKING WITH WEARABLE HIP-ASSIST ROBOT IN ELDERLY ADULTS: A FNIRS STUDY
Y.H. Kim¹, S.H. Lee¹, H.J. Lee¹, D.S. Kim², W.H. Chang¹, B.O. Choi³, G.H. Rhu⁴
¹Samsung Medical Center, Physical and Rehabilitation Medicine, Seoul, Republic of Korea
²Sungkyunkwan University, Department of Health Sciences and Technology- Samsung Advanced Institute for Health Science and Technology SAIHST, Seoul, Republic of Korea
³Samsung Medical Center, Neurology, Seoul, Republic of Korea
⁴Samsung Medical Center, Office of Biomechanical science- Research Center for Future Medicine, Seoul, Republic of Korea

Introduction/Background

The purpose of this study was to investigate the modulating effect of wearable hip-assist robot, Gait Enhancing Mechatronic System (GEMS, Samsung Electronics Co., Ltd., Korea), on cerebral oxygenation patterns during treadmill gait in elderly adults.

Material and Method

Twenty elderly adults participated in this study. Each subject performed treadmill walking task at self-selected speed either with assistance of GEMS (GEMS) or without assistance of GEMS (NoGEMS). An experimental session began with a fixed standing condition (60s), followed by one of the 2 walking conditions (60s) and then a resting condition (60s) for five repetitions. For analyzing the cortical activation, a task period was divided into the early and late phase. Cerebral oxygenation was measured by oxyhemoglobin (OxyHb) concentration using the functional near infrared spectroscopy (fNIRS) imaging system(NIRScout, NIRx Medical Technology, LLC, Germany) covering bilateral prefrontal cortices (PFC), premotor cortices (PMC), supplemental motor areas (SMA), and lower limb sensorimotor cortices (SMC).

Results

We observed less OxyHb concentration over the lower limb SMC, SMA and PMC regions in the late phase of gait with GEMS than NoGEMS conditions. In addition, PFC activity demonstrated left side predominance in GEMS condition.

Conclusion

Additional brain activity in older compared to younger adults may be a reflection of compensatory mechanism to improve performance in a specific task which is associated with less efficient use of neural resources. Walking with GEMS demonstrated decreased activity of specific brain regions related with gait and might represent increased efficiency of neural
resources. In addition, increased hemispheric asymmetry during walking with GEMS might reflect less need for compensation through right prefrontal activity. (This study was supported by the Samsung Medical Center (PHO0171341) and by a grant from the NRF (NRF-2016R1A6A3A11930931 and NRF-2017M3A9G5083690), which is funded by the Korean government.)

THE INFLUENCE OF AGE IN WOMEN IN VISUO-SPATIAL MEMORY IN REACHING AND NAVIGATION TASKS WITH AND WITHOUT LANDMARKS

A. Perrochon¹, S. Mandigout¹, S. Pestruzzellis¹, N. Soria Garcia¹, M. Zaoui², A. Berthoz², J.C. Daviet¹³

¹University of Limoges, Laboratory HAVAE, Limoges, France
²Collège de France, Laboratoire de Physiologie de Perception de l'Action, Paris, France
³Hôpital J Rebeyrol- CHU Limoges, Pôle neuro-sciences tête et cou- Service de médecine physique et de réadaptation, Limoges, France

Introduction/Background

Spatial memory and navigation capabilities tend to decline in normal aging, but few studies have assessed the impact of landmarks on route learning in a large-scale environment. The objectives were to examine age-related effects on visuo-spatial working memory capabilities and to determine the impact of landmarks in navigation skills in normal aging.

Material and Method

42 young women (23.6±4.9 years) and 39 older women (70.8±4.6 years) without cognitive impairment have realized three tests of visuo-spatial working memory: one in reaching space (computerized Corsi-Block-Tapping test) and two in navigation space (a condition without landmarks: Virtual Walking Corsi Test and a condition with landmarks: Virtual Room Walking Test).

Results

A two-way mixed ANOVA test shows that the young subjects had better performance in all conditions than older subjects (p < 0.05). Visuo-spatial working memory performances were identical in reaching and navigation space for both groups. Visuo-spatial working memory performance decreases with age.

Conclusion

The integration of landmarks into a navigational task decreases performance in older women, while it is this performance is stable in younger women subjects.

Introduction/Background

Aspiration pneumonia has been in the spotlight in Japan, one of the most rapidly progressing super-aging societies in the world. This life-threatening condition is associated with eating dysfunction and it is often recurrent. Swallowing rehabilitation is useful approach to prevent the repeat aspiration pneumonia; however, surgical laryngeal closure to prevent the further aspiration episodes is eventually considered. Here, we report a successful case of 80-year-old woman who had inclusion body myositis and received a surgical prevention and restored her swallowing function.

Material and Method

A Case Report as follows. The patient had been admitted with an repeating episodes of aspiration pneumonia. Although she was able to speak, the videofluoroscopy and laryngeal fibersoncopy revealed that her swallowing process was almost abolished and oral intake was impossible. In parallel, she was suspected to suffer from an underlying neuromuscular disorder. Then, we inserted a nasogastric tube and administered the tube feeding and planned gastrostomy. However, another episode of aspiration of saliva and bacteria in the oral cavity occurred, then we decide to apply the surgical approach of laryngeal closure even her speech ability was still maintained. At the time of the laryngeal closure, the muscle biopsy of the cricopharyngeal muscle was performed and the inclusion body myositis was confirmed.

Results
Perioperative process was going well, and 2 weeks after the surgery, no aspiration was observed on video fluoroscopy. Then she started eating using a standard polymeric formula (Ensure®), and no symptoms of aspiration was observed after that. She was firstly fed both by oral intake and tube feeding, but the swallowing rehabilitation was effective and finally she withdrew the tube and avoided gastrostomy.

**Conclusion**

We report a successful case of 80-year-old woman with inclusion body myositis who received the laryngeal closure improved functional prognosis of eating and prevented aspiration pneumonia.

SCARCE USE OF HEARING AIDS FOR AGE-RELATED HEARING IMPAIRMENT IN ELDERLY PSYCHIATRIC PATIENTS
S. Ueda
University of Tokyo Health Sciences, Rehabilitation Medicine, Tama-shi, Japan

Introduction/Background

Age-related hearing impairment has a harmful effect on elderly people’s daily living. The only helpful device available is a hearing aid. Although people with hearing impairment have difficulty in communicating with others, they seem unwilling to use hearing aids. It has been reported that hearing impairment is likely to cause dementia, and its improvement is important in geriatric psychiatry and otolarhyngology. We studied the use of hearing aids in elderly psychiatric patients.

Material and Method

The subjects were 87 patients (64-95 years old; 64 females, 23 males) who visited a geriatric clinic in a psychiatric hospital in Saitama, Japan between December 8, 2017 and February 2, 2018. They answered questions about the self-awareness of hearing difficulties and the use of hearing aids.

Results

Of the 87 patients, 20 patients (26.4%; 68-93 years old; 15 females, 5 males) became conscious of hearing impairment. Nine (45%) of 20 patients were using or had used hearing aids. Three (33.3%) of the 9 patients were using them effectively. Their diagnoses were mild dementia (2 patients) and bipolar disorder (1). Six (66.7%) of 9 patients stopped using them, because wearing them felt uncomfortable (4 patients), they were not helpful in enhancing hearing ability (1), and they caused headache (1). Their diagnoses were mild dementia (3 patients), schizophrenia (1), depression (1), and drug-induced cognitive decline (1).

Conclusion

This study found that not a few patients stopped using hearing aids due to their discomfort or ineffectiveness, even if they wanted to use them. Although the subjects in the study were psychiatric patients, the general population’s tendency could be similar. The elderly with age-related hearing impairment have difficulty in communicating, and they are more likely to develop dementia. To improve the quality of their daily living, more comfortable hearing aids and the guidance of medical specialists will be needed.

Introduction/Background

Hip fracture is an important health problem because of its associated morbidity, and high economic costs for healthcare providers. The aim of this research was to study short-term quality of life outcomes for elderly inpatients who followed an interdisciplinary hip fracture rehabilitation program in a geriatric middle-stay unit.

Material and Method

This is a prospective and follow-up cohort study. Study population was 50 inpatients, admitted to a middle stay geriatric rehabilitation unit. Study participants were older than 72 years, with stable medical condition after undergoing a hip fracture surgery procedure (hip replacement arthroplasty, or internal fixation by intramedullary nail).

Patients received a daily 60 minutes rehabilitation program. They were assessed at admission to the unit, at the time of being discharged, and 1 month after being discharged, using clinical, functional, and quality of life scales (Barthel index, EuroQoL-5D/ EuroQoL VAS, mini mental state examination, Charlson comorbidity index, mini nutritional assessment).

Results

Pre-fracture EuroQoL-5D median score was 0.75 (interquartile range 0.63, 1). One month after being discharged, EuroQoL-5D median score was 0.65 (CI 95 % 0.38, 0.69). A proportion among study patients still had some difficulty for self-care (50%), and mobility (60 %). From them 36 % still had moderate pain, and 30 % moderate depression/anxiety. Regression analysis showed that age, malnutrition, prior comorbidity, and pre-fracture functional and cognitive status, were associated to quality of life recovery, short-term after following Rehabilitation.

Conclusion
Study patients did not recover pre-fracture quality of life. Patients without serious pre-fracture cognitive and functional impairments, achieved better short-term quality of life outcomes.

ANTERIOR VS POSTERIOR CORE MUSCLE STRENGTH MEASURED BY 3D NEWTON IN ELDERLY POPULATION IN SILOAM HOSPITALS KEBON JERUK INDONESIA.

1Siloam Hospitals Kebon Jeruk- Jakarta- Indonesia, medical rehabilitation department, Jakarta Barat, Indonesia
2Faculty of Medicine University of Indonesia, Community Health Department, Jakarta, Indonesia

Introduction/Background

Core muscle strength declines in aging and affects mobility and function in geriatric patients. Siloam Hospitals Kebon Jeruk incorporates core strength examination with 3D Newton machine in geriatric medical check-up program.

Material and Method

Core strength muscle were examined using 3D Newton, by placing the patient in positions of challenge against gravity through 360° rotation and 0° to 60° inclination control, muscle contraction recorded by computers to determine its strength. Results were recorded as degrees of the maximum inclination angle. Medical record data used by consecutive sampling from geriatric medical check-up, a voluntary health-screening for people above 60 years of age, from January 2017 to January 2018. Subjects were generally healthy and functional at the time of the examination.

Results

From January 2017-2018 there are 32 elderly who undergone geriatric medical check-up. From this data, mean age was 69 + 6 years old. Mean BMI was 25.53 + 5.18 (obese, Asia Pacific standard). There are 17 (53%) male. Mean of abdominal 3D newton examination results was 24.3 + 4.8° while back was 27.1 + 4.7°, which is significantly difference based on paired t test (p < 0.001). There were no significant difference between right and left (26.25 +4.9 vs 26.75 + 4.3)

Conclusion

It showed that anterior core muscle (abdominal) is weaker than posterior (back) muscle. This could help in developing exercise strategy for elderly. 3D newton core strength measurement did not correlate with BMI. Further studies are required to elaborate more regarding the best measurement and intervention of geriatric core muscle strength, balance and functional activities.

OROPHARYNGEAL DYSPHAGIA IN OLD AGE
M. Entrenas Valle¹, C. Montoliu Peco¹, A. Rodríguez González¹, L. Cuevas Moreno¹,
E. Medina Cano¹, M. Muñoz Serrano¹
¹Ciudad Real University Hospital, Physical Medicine and Rehabilitation, Ciudad Real, Spain

Introduction/Background

Oropharyngeal dysphagia in old age can occur for many causes, functional or organic. In this population, there is a higher incidence of neurodegenerative diseases, oncological pathology or strokes that may present with dysphagia. The role of the rehabilitation doctor is the assessment of any patient diagnosed with dysphagia to establish the anatomo-functional cause and guide the swallowing problem, trying to address it with specific objectives at a specific time, and be able to give recommendations for a safe and effective diet and guide speech therapy if necessary.

Material and Method

A 76-year-old woman admitted for bronchoaspiratory pneumonia. Antecedents of several surgeries because of glomus tympanic in the right ear and subsequent radiotherapy, with the effect of right facial paralysis. She reports weight loss of 4kg in one year and signs of choking, cough and pharyngeal residue sensation. On examination, we observe a severe right facial paralysis according to the House-Brackmann scale, with a highly impaired oral transport phase. The Volume-Viscosity Clinical Exploration Method (MECV-V) was performed: voice changed and desaturation of 2 points with 5 ml of nectar. Same signs with 5ml of honey-pudding. These signs disappear with anterior cervical flexion. Speech therapy treatment is prescribed: orolinguopharyngeal praxies to improve mainly the seals and anterior flexion maneuver retraining. 10 ml nectar consistency turmix diet and liquids thickened to the same consistency.

Results

After 6 sessions of speech therapy, the patient has maintained facial paralysis improving the velopharyngeal and palatoglossal seals. It has integrated the previous bending maneuver so the MECV-V improves substantially. It achieves consistency and volume in the diet, although it still needs thickener for liquids.

Conclusion

Dysphagia in old age is one of the major syndromes of geriatrics. We must know the signs and symptoms of alarm in order to modify the diet and prevent complications such as bronchial pneumonia, dehydration or malnutrition.

FINDINGS OF VIDEOFLUOROSCOPIC SWALLOW STUDY IN THE OLD AGE ESOPHAGEAL DYSPHAGIA (PRESBYESOPHAGUS)

J. Kim¹,², J.S. Kim³

¹College of Medicine- The Catholic University of Korea, Physical medicine and rehabilitation, seoul, Republic of Korea
²Yeouido St. Mary’s hospital- The Catholic University of Korea, Physical medicine and rehabilitation, seoul, Republic of Korea
³St. Vincent’s hospital- The Catholic University of Korea, Physical medicine and rehabilitation, seoul, Republic of Korea

Introduction/Background

Dysphagia has been reported in about 13.8% of the general population aged over 65 years and in 28.2% of people over 85 years. Among the dysphagia, esophageal dysphagia occurs more commonly in the aged. Presbyesophagus is proposed to explain age-related decrease in esophageal peristaltic pressure, abnormal esophageal contractions, incomplete lower esophageal sphincter relaxation and dilation of the esophagus in the aged.

Material and Method

A 82-year-old female presented with swallowing difficulty for 3 years. Her symptoms were sensation of food stuck in the chest region and vomiting after swallowing in all consistencies of foods. The vomiting was spontaneous reflux type without nausea, especially in thin liquid. It started 2 years after her son’s suicide. Initially, she had poor oral intake due to loss of appetite, and it had progressed to vomiting.

Results

In physical and neurologic examinations, brain MRI and esophagogastroduodenoscopy was unremarkable. Video Fluoroscopic Swallowing Study(VFSS) showed intermittent esophageal dilation after passage of bolus of food and regurgitation from esophagus immediately after swallowing (Fig. 1). Chest CT was unremarkable. Esophageal manometry measuring pressure and movement showed impaired esophageal peristalsis and ineffective bolus esophagus passage with relatively increased low esophageal sphincter pressure of 43.8 mmHg through rapid pull-through measurement. Esophagography revealed that lower esophageal sphincter was not properly relaxed, leading to gastroesophageal reflux (Fig. 2). Finally, she was diagnosed with presbyesophagus. Life style and diet modification education and medications were prescribed.
Conclusion
Presbyesophagus is not unusual phenomenon in elderly patients, and more prevalent with aging. Approximately 10% of over 67 years old with dysphagia symptoms have presbyesophagus. For non-invasive visualization of dynamic esophageal functions, VFSS or esophagography can be of diagnostic values. Of the two, VFSS has additional benefits in that it can also evaluate the swallowing function with diverse consistencies of foods and oropharyngeal swallowing dysfunction including aspiration, which is common in elderly patients.

Introduction/Background

For the elderly, the reduction of motor function is natural phenomena, but requires a variety of concerns about how to slow down the rate of decline. Therefore, it is necessary to expand the exercise facilities or welfare facilities for the elderly, but the reality is suffering from space, cost problem and compliance.

In the case of elderly people, the social exercise and the medical exercise therapy should be distinguished, but the boundary is usually ambiguous. Furthermore, exercise for the elderly, whether preventive or therapeutic, should be provided as a public service, but this is also difficult.

Material and Method

In this study, we tried to approach exercise therapy for improvement of elderly physical function such as walking, balance and flexibility etc. through gamification exercise equipment (Men&Tel, Korea, Balpro 110, Model No. SBT 110). The elderly over 65 years of age were trained for 8 weeks (30 minutes/3 times/week) and the functional ability was evaluated after 4 weeks of rest. Both groups were randomized. Group 1 exercises were performed by conventional method, and Group 2 exercises were performed by IT convergence exercise equipment.

Results

There were both functional improvement in Group 1 (10 patients) using conventional exercise and Group 2 (10 patients) using Balpro 110. In the first group, after 8 weeks of training, lower extremity muscle strength and balance ability, and body fat mass and skeletal muscle mass improved significantly. In the second group, leg strength, balance, mobility, walking abilities,
flexibility, body fat and skeletal muscle mass were statistically significantly improved.

Disclosure statement:

1. This research was supported by a grant of the Korea Health Technology R&D Project through the Korea Health Industry Development Institute (KHIDI), funded by the Ministry of Health & Welfare, Republic of Korea (grant number :HI15C1529)
2. This material is based upon work supported by the Ministry of Trade, Industry & Energy(MOTIE, Korea) under Industrial Technology Innovation Program(10063393).
Introduction/Background

In the elderly population, loss of balance is a common health problem. That’s why; measuring the balance ability in older adults vital. Four Step Square Test (FSST) is also widely used to measure balance disturbances in geriatric rehabilitation. The reliability and validity of the FSST has been appraised in a group of Turkish older adults, aged 65 and over. The aim of this study was to show the impact of gender in older adults, who were independent in daily living activities. On the other hand, we aimed to show the relation between age and FSST score in the sample.

Material and Method

A total of 80 volunteer older adults aged 65-85 included in this study, broken in two groups by gender; (1) women mean age=72.36±5.57 yrs.(n=36); T(2) men mean age=72.95±4.72 yrs. (n=44). The FSST was used to evaluate the sample.

Results

The scores of FSST the compared groups are as follow: women=15.70±5.48; men=14.86±4.71 sec. There was not significant difference between women and men (p>0.05).

A significant positive relation was found between age and the FSST score of the sample (p=0.000)

Conclusion

The findings obtained from this study indicate that gender has not impact on the FSST score in older adults. However ageing has negative effect on the FSST score. Increased age makes the FSST score longer.

EXPLORATORY STUDY OF THE ENJOYMENT ITEMS OF LEISURE ACTIVITIES IN THE GERIATRIC HEALTH SERVICES FACILITIES

Y. Yamada¹, K. Norikazu¹, I. Yu¹
¹Tokyo Metropolitan University, Occupational Therapy, Arakawa, Japan

Introduction/Background

There are various enjoyment items obtained from occupation. More concretely, it's fun because “I can do with friends”, and it's fun because “I will grow myself”. Most of the elderly in the geriatric health services facilities (Roken in Japan) have different leisure activities in the past and present, some elderly people might not have an opportunity to engage in occupation. Even if the elderly engage occupation as a leisure, there was little known whether the meaning of occupation was same or not he or she used to do it. From these, the purpose of this research was to investigate whether there is a difference in meaning of past and present leisure activities for elderly people living in facilities.

Material and Method

9 participants (3male, 6female) were recruited with 2 facilities, and conducted an individual interview using semi-constructed guide. Interviews was audio-recorded, verbatim, and analyze the meaning of sentence using KJ method. This survey was initiated after approval of the Ethics Review Committee.

Results

The 8 enjoyment items were found, of which especially 2 enjoyment items,” Admitting my own worth and accept the existence affirmatively”, “Emotions and five senses react by being dependent on occupation” that were not found in previous studies were found and suggested the possibility of being a characteristic of the elderly in facilities. Also, the enjoyment items tended to match between almost participants in the past and present, but long-term residents tended to cause discrepancies.

Conclusion

It was suggested that focusing on coincidence between past and present enjoyment items can be utilized for performing occupational therapy for the elderly in the facilities.

Introduction/Background

Aging is a process of growing old which describes a wide array of physiological changes in the body system. Elderly people may show difficulties in dual tasking, in general and when walking while performing another task. This study was planned to investigate the relationship between cognitive, motor performance and dual task performance in geriatric people.

Material and Method

A total of 82 healthy geriatric participants (41F, 41M) aged 65 to 75 years, included in the study. Chair-stand test (CST), timed up & go test (TUG) and 10-meter walking test (10WT) for physical performance and Montreal Cognitive Assessment (MoCA) for cognitive performance were used. Three test conditions to evaluate dual task performance were single walking, walking while performing cognitive task (telling the days), and walking while performing motor task (tray-carrying).

Results

It was found that statistically significant correlation between cognitive performance and cognitive-motor dual tasking, and physical performance and motor-motor dual tasking of participants (p<0.05).

Conclusion

Success in dual task performance of geriatric individuals depends on good cognitive status and physical performance.

2 Sahloul University Hospital, Physical And Rehabilitation Medicine, sousse, Tunisia
3 Sahloul University Hospital, Physical And Rehabilitation Medicine, sousse, Tunisia

Introduction/Background

Recognition of an end-of-life situation should lead to a change in the objectives of care: ensuring comfort rather than cure. The objective of our work is to report our local experience in end of life care, and highlight the importance of Rehabilitation in a global approach of the terminally ill patients.

Material and Method

We conducted a monocentric retrospective study, including 12 patients who had been hospitalized in the Medical Intensive Care Unit (MICU) of a University Hospital. We included patients who required palliative care and for whom a do not resuscitate order (DNR) was issued upon admission or within 48 hours of hospitalization.

Results

Average age was 73 ± 13 years. Almost all of them had at least 2 comorbidities. The most common reason for admission was acute respiratory failure for 8 patients and unconsciousness for 4 patients.

Palliative care was sustained until death with high FiO2 in 3 patient, and non invasive ventilation (NIV) in 8 patients. Chest physiotherapy was performed in 11 patients, and nebulized bronchodilators were required for 5 patients. Analgesics and postural physiotherapy were essential for 7 patients.

Body hygiene, prevention of bed sores, deep venous thrombosis, and gastrointestinal bleeding were ensured for all patients. Physicians and paramedics rounds were frequent and regular. Spiritual beliefs were satisfied. Regular and wider visiting schedules were ensured for families. Nursing staff showed a good acceptance of all procedures of end of life care despite the
increased work load. Regular discussion with the nursing staff prevented the occurrence of burn out syndrome.

**Conclusion**

Our palliative approach was successful to ensure comfort and dignity of terminally ill patients, preventing therefore futile treatment and inappropriate aggressive resuscitation, with complete respect of ethical issues. The need of a law for end of life care is highlighted in this study.

Introduction/Background

Background and Aims: Geriatric patients with major knee arthritis problem, have some restriction in activities and daily participation caused by mobility problem, pain disorders, psychological problems, and the environment. EQ5D as a tool of quality of life used in elderly people has components that represent these aspects. The aims of this research is to investigate the correlation between domain of EQ5D in Geriatric Rehabilitation patients with Knee Arthritis.

Material and Method

Methods: Retrospective study. All patients with Knee Arthritis was assessed EQ5D description part. Data was taken from Geriatric Rehabilitation Outpatient Clinic, Juni-November 2017. Data will be analyzed using SPSS 20.0 with Spearman test.

Results

Results: From 85 subjects with main problem Knee Arthritis and ≥ 2 medical condition, 15 subjects (17.6%) men, and 70 subjects (82.4%) women. 49 subjects (57.6%) 60-69 years old, 34 subjects (40%) 70-79 years old, and 2 subjects (2.4%) older than 80 years old. According to domain EQ5D Mobility, Self Care, Daily activity, Pain, Anxiety/Depression, we found significant difference between Mobility and Self Care p=0.037 r=0.227, Mobility and Daily Activity p <0.001 r 0.446 (moderate correlation), Mobility and Pain p=0.002 r 0.329 (moderate correlation), Mobility and Anxiety p=0.531 r 0.069, Pain and Activity p<0.001 r 0.609 (strong correlation), Ages and mobility, p=0.754, r -0.34.

Conclusion

Conclusion: From this research, majority cause of activity and participation restriction are pain disorder and mobility problem on women. So, rehabilitation management is more focused on appropriate intervention strategies with pain management and optimizing mobility for Geriatric with Knee Arthritis.

Introduction/Background

Currently, clinical and social factors that affect the functional recovery of older adults with hip fracture have been described, the objective of our study was to evaluate clinical and social factors associated with functionality in postoperative older adults of trochanteric and subtrochanteric hip fractures in a reference hospital.

Material and Method

Prospective, longitudinal and quasi-experimental study of consecutive cases in Adults Older than 60 years post-operative of trochanteric and subtrochanteric hip fracture, from August to December 2017. The clinical and social factors of the patients were analyzed; with initial and final assessment of the Katz index three months after the fracture. Descriptive statistics and student t test were performed for independent samples considering significance p = <0.05

Results

The sample included a total of 27 patients, female gender 85.2%, age <85 years 59.3%, concomitant diseases 77.8%, single marital status 66.7 %, unemployed 59.3%, transtrochanteric fracture treated surgically with DHS in 81.5%, of which 51.9% of patients presented falls prior to fracture, 66.7% of patients reported a functional family situation and the evaluation the emotional state was normal at 55.6%.

Conclusion

It was corroborated that age <85 years, was found to be a factor for functional recovery in post-operative older adults with short-term trochanteric and subtrochanteric hip fracture.

⁵Sichuan nanchong central hospital, Rehabilitation, Sichuan nanchong, China

Introduction/Background

Elderly with cognitive decline is a common problem in an aging world. Either physical activities or cognitive games are found to be effective in improving cognitive function in the elderly. However, their combined effect has been rarely studied and in Chinese elderly populations.

Material and Method

Healthy elderly, of age 50 or above, both genders were recruited from communities and nursing homes in mainland of China. They were invited to report on their participation level in physical activities and cognitive games by means of Chinese Version of the Physical Activities Scale of the Elderly (PASE-C) and a self-designed Cognitive Activity Scale for the Elderly (CASE) respectively. Mean scores in PASE-C and CASE were used to operationally classify participants into four groups, a) Physical and cognitive inactive group (PCIG), b) Physical active group (PG), c) Cognitive active group (CG) and d) Physical and cognitive active group (PCG). Their cognitive functions, as indicated by Beijing version of Montreal Cognitive Assessment (MoCA-BJ) were examined. The relationships of participation physical activities and cognitive games levels and scores of (Chinese version) (GDS-15) and (MoCA-BJ) were also analyzed.

Results

172 elderly people were interviewed and 167 of them were eligible for further analysis. Participants of the four groups did not differ significantly in demographics except age (F=11.137, p=0.000) and monthly income (F=2.871, p=0.038). The physical and cognitive active group (PCG) had a better cognitive function than the physical and cognitive inactive group (PCIG) (p<0.05) through ANCOVA analysis (using age and income as covariates), but no statistically significant difference could be found in other comparisons.

Conclusion
It was suggested that elderly who actively participated in both physical activities and cognitive games might have better cognitive function than those mainly participate in either physical activities or cognitive games alone. Causal relationship cannot be assumed in the present cross-sectional study.

EVALUATION OF PHYSICAL FITNESS AND COMPARISON BETWEEN INSTITUTIONALIZED AND NON INSTITUTIONALIZED ELDERLY.

E.R. Pedroso¹, E.D.M. Neto², G. Luvizutto³, R. Berto¹
¹Faculty Southwest Paulista, Physical Therapy, Avaré, Brazil
²Faculty of Human Talents, Physical Therapy, Uberaba, Brazil
³Univ.Federal do Triângulo Mineiro, Physical Therapy, Uberaba, Brazil

Introduction/Background

The aging process generates functional and structural changes in the body; such changes affect the functionality and self-efficacy of the elderly. It is common to consider that aging leads to cognitive and behavioral deficits, and the determination of functional capacity is essential for the diagnosis of the needs of a population serving as a parameter to elaborate a program directed to the development and maintenance of the autonomy of the elderly. The aim of this study was to evaluate the physical fitness comparing institutionalized and non-institutionalized elderly.

Material and Method

Were evaluated 10 elderly (five institutionalized and five non-institutionalized elderly). Were evaluated the components related to functional independence, balance, agility, flexibility, body mass index, aerobic endurance and muscular strength. The individuals were evaluated and divided into two groups. The group A is composed of the elderly with altered cognitive and group B by the elderly with the normal cognitive function.

Results

In the chair lift and sit test the group B showed an average of 9.2 times and the group A performing an average of 5.4 times. In the forearm flexion, the group B performed on average 23 forearm flexions, while group A performed 15.2 times. In the sitting and reaching test, the groups had a difference of only 1 centimeter (A = 8.8 cm) and (B = 9.8 cm). In the behind-the-back test, the group A had an average of 40 cm and the group B 19.4 cm. Comparing the 6-min walk test (6 MWT) the group B performed 11.8 laps, while the group A performed 2.6 laps.

Conclusion

The institutionalized elderly have a lower physical fitness due to their cognitive alterations and decreased functional capacity, which are more vulnerable and dependent for carrying out activities of daily life.

QUANTIFYING GAIT PARAMETERS TO DETERMINE INTENSITY OF GAIT PERTURBATIONS PRESCRIBED BY PHYSICAL THERAPISTS TO TRAIN SUBJECTS WITH BALANCE DEFICITS
N. Saadé¹,2, A. Juneau²,3, D. Kairy²,4, P. Fait¹, C. Duclos²,4
¹Université du Québec à Trois-Rivières, Human Kinetics Department, Trois-Rivières, Canada
²Institut de réadaptation Gingras-Lindsay de Montréal, Pathokinésiologie laboratory- Centre for Interdisciplinary Research in Rehabilitation, Montreal, Canada
³CIUSSS Centre-Ouest-de-l’Île-de-Montréal, Constance-Lethbridge Rehabilitation Centre, Montreal, Canada
⁴Université de Montréal, School of Rehabilitation, Montreal, Canada

Introduction/Background
Gait perturbation training for fall prevention is gaining recognition over regular strength and balance exercises. Difficulty of perturbations chosen varies between interventions and the most effective intensity is unknown. Some physiotherapists already use perturbations in clinical settings. Our objective was to quantify the changes in balance parameters during gait perturbations selected by an experienced physiotherapist.

Material and Method
Seven subjects with moderate to severe traumatic brain injury and deficits in dynamic balance participated. Three-dimensional whole-body motion and kinetics analysis was performed, after one habituation session. Self-imposed (head rotations) or physiotherapist-imposed (repeated or random slips and trips induced by changes in belt speed) perturbations were applied while walking on a split-belt treadmill. Relative anteroposterior position (APP) and velocity of the center of mass (COM) and center of pressure (COP) were compared between perturbations and natural and fast gait speed.

Results
No differences were found in relative APP of COM and COP for physiotherapist-imposed slip-like or self-imposed perturbations compared to natural gait (p>0.134). Physiotherapist-imposed trip-like perturbations caused significantly more forward relative APP of COM and COP than during fast gait (p≤0.05). Velocity of COM and COP was significantly greater during physiotherapist-imposed (p≤0.001), but not self-imposed (p>0.106), perturbations than at natural gait speed. COM velocity remained lower than during fast gait for all perturbations (p≤0.05), but COP velocity in physiotherapist-induced perturbations reached fast gait COP velocity(p>0.279).
Conclusion

Balance-related gait parameters were not affected during self-imposed perturbations, while physiotherapist-imposed trip-like perturbations altered parameters the most. During physiotherapist-imposed perturbations, balance control (COP-related) parameters reached values equal or greater than at fast gait speed. Meanwhile, the level of balance quantified by COM-related parameters, reached levels similar to fast gait for relative APP but not velocity. Future research should examine the possibility of personalizing perturbations to train specific balance parameters based on patient needs.

Introduction/Background

Globally stroke is one of the main causes of impairment or disability. The estimated annual prevalence of stroke in Pakistan is an estimate of 350,000 new cases every year. Evidence showed, sports and Physical exercise is directly interlinked with cardiovascular fitness. It improves skill related fitness like balance, coordination etc and health related fitness i.e., cardiovascular, endurance, strength. The most important thing is neuroplasticity of brain which increase brain function and automatic learning pattern will enhance and help in motor control.

Aim: To find out usefulness of game based activity to attain skill related fitness and motor performance skill in stroke

Material and Method

It is qualitative study .continuous on-going process. Fifty adult patients of stroke (suffering from stroke between 1-5 years) from adult clinics will select. All patients receive conventional therapy and additional game based activities 4 days a week. Sports based therapy included Basket Ball, Balloon Bounce, Volley Ball, Cricket, and Football .These 5 activities covered with warm up and cool down exercises. Pre and post assessment is done by Fugal Mayer and Chadock scale

Results

Results are collected in the form of reflection. Each after 3 months re-evaluate and do amendments according to patients need. After 6 month final re-evaluate and do reflection.Reflection is based on PEO model in which we explain person ,environment and occupation(sports).A scoring sheet also make to support the documents.

Conclusion

As it is on-going process, we do not compile any numerical result but we recorded things as reflection. Finally make a guide book for stroke survivor.

Introduction/Background

Spasticity of the hemiparetic upper limb (UL) leading to difficulty performing activities of daily living is a major concern in stroke rehabilitation. Spasticity results from impaired control of motoneuronal activation thresholds exerted by descending direct and indirect pathways. This is reflected by pathological alteration of the specific muscle length/joint angle at which the stretch reflex and other proprioceptive reflexes begin to act (tonic stretch reflex threshold, TSRT). The relationship between lesion location and the appearance of spasticity is poorly understood. We investigated the relationship between lesion characteristics and elbow-flexor (biceps) TSRT in the hemiparetic UL, as part of an international multicenter RCT (ENHANCE project; ClinicalTrials.gov, ID: NCT02725853).

Material and Method

Elbow-flexor TSRT (°) was examined in 8 right-hemisphere damaged (RHD) and 15 left-hemisphere damaged (LHD) stroke patients using the Montreal Stretch Reflex Threshold device. Normalized lesion data were used for voxel-based lesion-symptom mapping (VLSM) analyses of lesion impact on biceps spasticity.

Results
Application of VLSM using 10 continuous affected voxels as a minimum for consideration, showed in the LHD group, a cluster localized in the superior part of the corona radiata, where damage affected the level of spasticity in the biceps as revealed by its TSRT (smaller clusters were recognized in the external capsule and insula). In the RHD group, VLSM failed to reveal voxel clusters where damage affected the biceps TSRT.

Conclusion

The paucity of hemispheric voxels where damage is related to increased spasticity levels may indicate that impaired regulation of motoneuronal activation threshold after stroke is attributed to the sum effect of various brainstem control substrates (which cannot be analyzed using VLSM), rather than to direct corticospinal control.

Introduction/Background

We present a documented observation showing the existence of a biased representation of verticality in PD, resulting in a severe retropulsion and recurrent falls, and a camptocormia likely compensatory. A specific rehabilitation led to a spectacular result.

Material and Method

A 68 year-old patient with Parkinson’s disease fall backward 3 times a day. He presented an important camptocormia. There were no spinal muscular amyotrophy neither spinal canal stenosis on the lumbar tomography. The Postural vertical (PV) was tilted backward at -9° (normal for this age = - 1.1°±1.4°). Our interpretation was that retropulsion was due to a backward tilt of the internal model of verticality, which led to recurrent falls. Camptocormia was mainly compensatory.

The patient underwent an intensive rehabilitation program of 15 days including: erector spinae muscles strengthening, realization of postural exercises thanks to mirror. A modulation of the internal model of verticality was undertaken on the basis of theoretical arguments (synthesis of graviceptive vestibular and somatosensory information) and on experimental studies: 30° forward tilted posture on a tilt table, bodyweight support walking, vibration of tibialis anterior’s tendons. PV measurements before and after these technics confirmed the relevance of this approach.

Results

After 2 weeks the results were spectacular (Table 1): posture spontaneously more upright (35 mm gain in C7 position), attenuated retropulsion (objectively assessed using the BDS), and normalization of PV = 0.1°. At discharge the patient was instructed to daily perform the exercises taught. Reviewed at M2 and M6, he was very satisfied with a dramatic reduction of fall frequency and the feeling to stand better.

TREATMENT OF TACROLIMUS INDUCED TREMOR IN POST-TRANSPLANT PATIENT
J. Ramos¹, M.J. Festas¹, F. Parada¹
¹Centro Hospitalar São João, Medicina Física e De Reabilitação, Porto, Portugal

Introduction/Background

Tacrolimus is frequently used in patients after transplantation leading to some adverse effects which includes tacrolimus induced tremor, a frequent event in post renal transplant patients, occurring in about 12% of the patients.

Material and Method

Not applied

Results

Female, 62 years old with mRanking scale of 0 with no resting or intention tremor. She was done a kidney transplantation in June 2017 due to a 25 years ago diagnosed type 2 Diabetes Mellitus, which led to kidney failure. After the transplantation, Tacrolimus 7mg twice a day was started. Approximately 4 months after, the patient started to feel an intermittent intention, and after also resting, tremor in both hands, that impacted her quality of life for activities of daily living like feeding and dressing and mainly, waking her up during the night. Her mRanking scale at that time was 2. The patient was sent to Physical Medicine & Rehabilitation (PMR) appointment 2 months after the tremor begun. 80mg/day dosage of propranolol was started. We re-evaluated the patient 1 month later and registered an improvement in activities of daily living and she was also able to sleep without waking with the tremor, leading to a mRanking scale of 0 again.

Conclusion

Tacrolimus induced tremor is a frequent cause of tremor in these patients and PMR physician should pay attention for this specific cause of tremor. The tremor could have other cause, however, given its frequency and the fact that the symptoms started after the beginning of the treatment, it is probably related with Tacrolimus. The suspension this drug could not be done due to it’s importance in post-transplantation patients. In conclusion, propranolol may be a good treatment to offer to these patients but since there are no studies for the specific treatment of this adverse effect, investigation should be done to confirm its effect.

Introduction/Background

Proprioception is the ability to sense stimuli arising within the body regarding position, motion, and equilibrium. This sense can be disturbed in many neurological disorders. Proprioception is significantly correlated with Limits of Stability (LOS) values. Patients with decreased LOS have an increased likelihood of falling. Virtual Reality systems (immersive and non-immersive) are established rehabilitation methods for balance and proprioception training.

Purpose of this study is to determine if the immersive virtual reality systems with headsets may elicit a risk factor for falls in patients after stroke.

Material and Method

Methods: 20 patients (12 males-8 females; age 48.8 ± 6.8 years) with hemiplegia after stroke. All the participants were in post-acute phase. Prerequisite for inclusion in the study were the lack of visual and cognitive deficits and presence of subtle movement in all four limbs. Patients were assessed through Berg Balance Scale and Limits of Stability values. All patients had sessions of the same virtual reality protocol in immersive and non-immersive mode.

Results

No statistically significant difference was found in terms of descriptive features of the patients (p >0.05).

Conclusion

We suggested that vision is less able to supplement peripheral input to maintain balance compared with the proprioceptive system. The first sessions may be destructive but the patients easily accommodate to the head sets virtual reality mode. Immersive Virtual Reality systems seems to be safe and provide good clinical outcomes.

CRANIAL NERVE NON-INVASIVE NEUROMODULATION IMPROVES GAIT AND BALANCE IN STROKE SURVIVORS: A PILOT RANDOMISED CONTROLLED TRIAL

M. Galea¹, L.E. Cofre Lizama², A. Bastani¹, M. Panisset¹, F. Khan³

¹The University of Melbourne, Medicine Royal Melbourne Hospital, Parkville, Australia
²The University of Melbourne, Medicine Royal Melbourne Hospital, Parkville, Australia
³Royal Melbourne Hospital, Rehabilitation Medicine, Parkville, Australia

Introduction/Background

Cranial nerve non-invasive neuromodulation (CN-NINM) has been shown to enhance physiotherapy interventions for balance and mobility in patients with neurological impairments. The objective of this study was to determine the efficacy of CN-NINM in improving gait and balance in a pilot randomised controlled trial in stroke survivors undergoing inpatient rehabilitation.

Material and Method

A convenience sample of 10 stroke survivors were randomised to two groups, one receiving CN-NINM using a Portable Neuromodulation Stimulation (PoNS™) device (n=5, mean age 72±5 y) and the other not receiving stimulation (controls n=5, mean age 74±6y). For the two-week trial period, both groups received 2 sessions per day of high-intensity physiotherapy. Each session included 20 minutes of balance training and 20 minutes of gait training as well as 20 minutes of relaxation/consolidation period with concurrent stimulation. The main outcome measures were the Mini-BEST, posturography, instrumented timed up-and-go (iTUG) and walking measures.

Results

Significantly greater improvements in Mini-BEST scores (p<0.05) were found in the group receiving CN-NINM compared to the control group. No significant differences were found for the other outcome measures.

Conclusion

This is the first study showing the feasibility of a 2-week intensive physiotherapy intervention combined with CN-NINM using PoNS™ in stroke survivors. This combined intervention was significantly more efficacious than high intensity physiotherapy alone for the rehabilitation of gait and balance in this population.

Introduction/Background

One of the main symptoms in Parkinson’s Disease (PD) are balance disorders – patients have tendency to fall, related traumas and also significant restriction of mobility. To evaluate the balance many tools can be used, however, it is difficult to choose the proper one. The aim of this study was a comparison of simple, diagnostic tools for PD and indication those characterized by high reliability and sensitivity.

Material and Method

The global literature search was conducted in PubMED, Scopus, Science Direct, Web of Science, Cochrane and Google Scholar for publications in English and Polish from January 2007 through January 2017.

Results

According to the literature seven scales and functional tests, in which the clinimetric properties had been assessed in PD population, were selected. Summary is presented in Table 1.
Table 1: Comparison of selected diagnostic tools in PD.

EFFECTS OF GALVANIC VESTIBULAR STIMULATION WITH WHITE AND PINK NOISE ON UPRIGHT STANDING SWAY FOR HEALTHY ADULTS
O. Aoki¹, Y. Otani², S. Morishita³
¹Shijonawate Gakuen Univ, Rehabilitation, Daito, Japan
²Kobe International University, Rehabilitation, Hyogo, Japan
³Niigata University of Health and Welfare, Rehabilitation, Niigata, Japan

Introduction/Background

It has been reported that the noisy galvanic vestibular stimulation (n-GVS) could improve upright body sway in healthy subjects. It is unclear which sort of noise is appropriate for n-GVS. Our study aimed to investigate the effects of n-GVS with white and pink noise for upright standing sway in healthy adults.

Material and Method

Seventeen healthy adults (11 men; age = 21.9 ± 1.6 years) were instructed to stand on a force plate with foamed rubber and wore an eye-mask and ear-muffs. Center of pressure (CoP) displacement was measured for 60-s with 1000 Hz sampling. We generated the 30-s white and pink noise and added this to the galvanic vestibular stimulation. We applied the n-GVS to the participants and stimulus intensities were 30, 50, 70, 90, and 110% of each participant’s electric sensory threshold level (10 conditions: 2 noise × 5 intensities). Right-side anode n-GVS was applied via both mastoids 30-s after the measurement was started.

We used the anteroposterior (AP) and mediolateral (ML) direction of standard deviations (SD) and total length (LNG) of CoP displacement as measurement variables. Each condition’s variable was represented as a percentage value based on the initial 30-s measurement data (pre-n-GVS). We compared these variables with two-way repeated measures ANOVAs and t-test as post hoc test (significance level was 5%).

Results

In the AP- and ML-LNG, significant intensity effects were observed with ANOVAs (both of p<0.05). Conversely, there were no main effects and interactions in the AP- and ML-SD. In the AP-LNG, the 90% intensity condition showed significantly smaller values compared to 50, 70, and 110% in the pink noise.

Conclusion

We found that the n-GVS improved the CoP displacement length but not the width and the optimal stimulus intensity was at around 90% of the sensory threshold level with pink noise.

EXAMINATION OF STATIC AND DYNAMIC BALANCE OF BRAIN INJURED PATIENTS IN ELASTIC SPACE

C. Gacsáli, K. Takács, R. Kovács, Z. Dénes

National Institute of Medical Rehabilitation, Rehabilitation Department of Brain Injuries, Budapest, Hungary

Introduction/Background

The partial or complete loss of static and dynamic balance after vascular or traumatic brain injury is an important dysfunction in neurorehabilitation. The balance skills significantly contribute to gait ability which determines the patient's living conditions and return to normal daily activities. The recovery of standing stability and walking ability are the most important elements of rehabilitation after brain injury.

The purpose of this examination is to show the key elements of core stabilization, postural control, balance and coordination exercises with the use of vertical suspension and to analyze the effects with some tests among hemiparetic and ataxic patients.

Material and Method

Twenty patients were assigned for follow up study in 2 treatment groups (10 hemiparetic, 10 ataxic) and they completed average 30 minutes of special treatment (exercises in elastic space), 5 times a week over a period of 6 weeks. During the research the previously used conventional therapies were unchanged. In order to document the changes in the state of locomotion we used the following: transfers and locomotion items of the Functional Independence Measure (FIM), Fugl-Meyer Balance, Scale for the Assessment and Rating of Ataxia and Stabilometer device.

Results

Therapeutic exercises in elastic space were useful for both groups with regard to static and dynamic balance and stability of standing, however, better results were observed in the group of ataxic patients. The bigger difference over the obtained outcomes was demonstrated rather in the locomotion item of FIM and in the measurements of Stabilometer.

Conclusion

The stability provided by springs and elastic ropes significantly contributes to proprioception and accurate body awareness in space. Based on our observations the elastic space formed with vertical suspension continuously stimulates the sensory system which can develop new neuromuscular connections that can greatly improve balance, postural control and gait.

THE ORIGINAL METHOD OF BALANCE AND GAIT CORRECTION IN PATIENTS AFTER STROKE

S. Ismailova1, S. Prokopenko1, S. Subocheva1, M. Abroskina1

1Prof. V.F. Voino-Yasenetsky Krasnoyarsk State Medical University,
Department of Nervous System Diseases with a Course in Medical Rehabilitation and Post-Diploma Education, Krasnoyarsk, Russia

Introduction/Background

This abstract covers a classical method of stato-locomotor function correction with application of platforms with biological feedback (BF), a proprietary method of balance correction MAPS-1 based on activation of anticipatory synergies and an original method of balance and gait correction consisting in activation of the vestibular analyzer and postural synergies by means of shifting the centre of gravity and oscillation of the patient in the vertical plane.

The aim of our study was to assess whether the original method based on dosed centre-of-gravity shifting in the vertical plane is effective in restoring gait and balance functions.

Material and Method

Inpatients (n=75) diagnosed with vestibular-atactic syndrome of stroke origin were randomly divided into 3 groups. Group 1 (n=25) was treated with application of the original method, Group 2 (n=25) received treatment by means of the MAPS-1 method and Group 3 (n=25) underwent balance correction via BF equipment.

Each patient underwent computer stabilometry (CS), gait parameters assessment by means of the method “Laser analyzer of kinematic gait parameters” (LA-1), balance and gait assessment using Berg Balance Scale, ICARS and Dynamic Gait Index prior to and after the course of treatment.

Results

Significant decrease in main CS and LA-1 values and improvement in indices of DGI and BBS functional scales after treatment was revealed. Statistically significant differences in DGI scale indices were found after comparison of CS, LA-1 and functional scale values in Group 1 with such in Groups 2 and 3.

Conclusion

Our study confirmed that the original method of balance and gait correction consisting in activation of the vestibular analyzer and postural synergies by means of shifting the centre of gravity and oscillation of the patient in the vertical plane improves balance and gait functions and can be recommended for complex restorative treatment in patients after stroke.

Introduction/Background
The assessment of balance function is an important part of physical therapy. The BESTest is a measure that evaluates systems underlying balance control. The aim of this study was to translate and cultural adapt the BESTest into Persian and investigate its intra-rater reliability in subjects with stroke.

Material and Method
First, the Persian version of BESTest was produced following standard forward and backward translation, and review by an expert committee. Then, 18 subjects with stroke (15 male, age 56.9±10.3 years, duration since stroke 50±35.1 months) participated for intra-rater reliability of the Persian BESTest. Measurements were taken in two sessions with 1 week interval by one physiotherapist and according to Persian BESTest.

Results
The intraclass correlation coefficient (ICC) for total score was high (ICC=0.88, 95% CI= 0.73-0.95). The Standard Error of Measure (SEM) and the Minimal Detectable change (MDC) were 8.33 and 22.82, respectively.

Conclusion
The Persian BESTest has high intra-rater reliability in evaluation of balance in subjects with stroke.

ISPR8-0640
EFFECT OF NECK MUSCLES VIBRATION ON POSTURAL BALANCE AND SPATIAL FRAME OF REFERENCE: A SYSTEMATIC SCOPING REVIEW
K. Jamal¹, S. Leplaideur¹, L. Chochina², A. Moulinet Raillor³, I. Bonan¹
¹University Hospital of Rennes, Physical and Rehabilitation Medicine Department, Rennes, France
²CMRRF Kerpace, Neurology Physical and Rehabilitation Medicine Department-, Kerpace, France
³Hospital of Saint Vallier, Physical and rehabilitation medicine department, Saint Vallier, France

Introduction/Background

Muscle vibration, in particular applied to the neck muscle is increasingly being used as a mean of rehabilitation treatment. Neck muscle vibration (NMV) is thought to have an effect on the representation of the body in space through sensory recalibration. The objective of this systematic scoping review was to map out the characteristics of the existing studies and gather the effect of neck muscle vibration on both spatial frame of reference and on postural balance.

Material and Method

following the PRISMA guidelines, a systematic search was carried out using the databases MEDLINE, EMBASE, Cochrane library and PEDro applying the following key words ((Postural balance) OR (Spatial reference)) AND (Neck muscle vibration) for those articles published through to July 2016.

Results

Altogether 67 studies were assessed and they unveiled both a large heterogeneity and a standard quality of methodology with a total of 1522 participants included. Under unilateral neck muscle vibration, the visual environment (illusion of a visual target) seemed to move towards the opposite side of the vibration, and both the visual vertical and the straight ahead were shifted towards the vibrated side. In addition, NMV produce a body tilt. This effect is however not constant at all times.

Conclusion

NMV is considered as a useful remedy tool in rehabilitation therapy which has shown to induce a body sway on the force platform and a deviation of the spatial representation in both healthy subjects and patients. That said, however, owing to the heterogeneity of the experiences and the various significant shortfalls highlighted, this research does not allow us to firmly conclude our results.

ISPR8-0688
IMPACT OF AN IMMEDIATE VIRTUAL REALITY HEADSET ON STATIC AND DYNAMIC BALANCE IN HEALTHY INDIVIDUALS.
E.D.M. Neto¹, V.D.S. Teixeira¹, R. Bazan², G.J. Luvizutto³
¹Faculty of Human Talent, Physical Therapy, Uberaba, Brazil
²Botucatu Medical School, Neurology, Botucatu, Brazil
³Federal University of Triângulo Mineiro, Physical Therapy, Uberaba, Brazil

Introduction/Background

A virtual reality headset (VRH) is a head-mounted device that enables the user to experience virtual reality. Although VRHs are currently used to train medical students for surgery, a few studies on its use in rehabilitation have been published. This technology produces an immersive virtual environment and virtual worlds that can affect the real world, specifically balance. We sought to evaluate the immediate effects of VRH on static and dynamic balance in healthy individuals.

Material and Method

Participants were recruited from a community in the Minas Gerais state in Brazil by convenient sampling. We assessed timed static balance using the Romberg, Tandem, and single leg stance test with and without foam and dynamic balance using the Fukuda stepping test (FST). After balance evaluation, all participants used the VRH for 30 minutes. The VRH consisted of glasses, headphones, and foam for immersion using the roller coaster game. After using the VRH, each participant was subjected to balance evaluation again. Student’s t-test was used to determine the effect of VRH on balance, with p<0.05 considered statistically significant.

Results

Eight individuals were evaluated, including 5 women and 3 men with a mean age of 55.5 ± 13.9 years. Table 1 shows that no significant difference in static balance was seen among the individuals after wearing the VRH, and in the FST, the mean was 40±18.3° before and 20±8.3° after wearing the VRH (p=0.043). Postural oscillation during static balance tests increased in all individuals.

**Conclusion**

The immediate effect of wearing a VRH was an improvement in dynamic balance. These data suggest that VHRs may be useful as a therapeutic tool to shift the center of gravity of individuals undergoing balance training.

**Keywords**

Balance; Postural control; Virtual reality

_No conflict of interest_
Whole-body vibration (WBV) is a training method that exposes the entire body to mechanical oscillations while standing on a vibrating platform. WBV are used by clinicians to improve balance and gait. However, WBV may also induce an increase in leg stiffness through a “tonic reflex vibration”, which may potentially hinder balance control during locomotor tasks. Gait initiation (GI) is a functional task that is classically used to investigate balance control. It includes two phases, the “Anticipatory Postural Adjustments” (APAs) and step-execution phase. During GI, stability is known to depend on the capacity of the central nervous system (CNS) to generate adequate APAs along the mediolateral direction. This study tested the hypothesis that, in young and elderly adults, the CNS programs mediolateral APAs in function of the changes in stance leg stiffness induced by WBV so as to maintain (or even improve) stability.

Material and Method

Participants (i.e. 23 young adults and 20 elderly) were randomly divided in two subgroups and exposed to a single WBV session or a sham intervention. Series of ten GI trials were performed on a force-plate before and after WBV or sham intervention.

Results

In young adults, the amplitude of mediolateral APAs (peak center-of-pressure shift and center-of-mass velocity at heel-off) and stance leg stiffness significantly increased following WBV. Mechanical modelling of the body showed that the increased leg stiffness was detrimental to stability. However, experimental data showed that stability remained unchanged following WBV, and even tended to be improved. Results further showed that center-of-mass velocity at heel-off
and stance leg stiffness were positively correlated. In elderly, there was no significant effect of WBV on GI parameters.

**Conclusion**

Young adults compensate the negative effect of increased leg stiffness on stability by larger mediolateral APAs. In elderly, the absence of WBV effects may possibly be due to proprioceptive and/or plantar inputs alterations.

Introduction/Background

After stroke, hemiparesis often leads to reduced muscle strength and reduced ability to rapidly generate and sustain muscle force. The aim of this study was to assess how rate of force development (RFD) and sustained maximal grip strength develop during the first year after stroke.

Material and Method

This is an exploratory study of 11 stroke patients (8 men, 3 women, mean age 79.1 years) who participated in the Norwegian Constraint Induced Movement Therapy trial (NORCIMT). The patients were recruited 7-28 days’ post stroke and had mild to moderate symptoms. RFD (0-250 ms) and sustained maximal grip force (15 sec) were recorded for the paretic and non-paretic hand with a hand dynamometer and a pinchmeter (G/P200, Biometrics Ltd., UK) using the testing positions recommended by the American Society of Hand Therapists. All participants were tested 5 times (at inclusion; 2, 26, 28 and 52 weeks after inclusion).

Results

At inclusion, mean(SD) RFD from the dynamometer was 25.1(22.3) and 75.0(44) kg/s in the affected and non-affected hand respectively (p=0.003). However, RFD increased and the difference was no longer significant after 2 weeks. Contrary, the ability to sustain maximal grip strength was similar for both hands at inclusion, however it was reduced (p<0.001) for the affected hand if the values were normalized to maximum voluntary contraction. On the affected side, most of the decrease in strength occurred during the first 3 seconds, while it decreased continuously on the non-affected side. The affected hand approached the capacity of the non-affected hand during the 52-weeks follow-up period. Pinchmeter recordings showed comparable results.

Conclusion
Although RFD and the ability to sustain maximal grip strength is reduced in the affected hand early after stroke, this study shows that the difference between affected and non-affected hand decreases markedly during the first year after stroke.

**Keywords**

grip strength; stroke; rate of force development

*No conflict of interest*
Introduction/Background

Transcranial direct current stimulation is used to modify non invasively cortical brain excitability in humans. It consists in delivering a weak current through two electrodes: one applied over the motor cortex and a second in supra-orbital position. Recently we showed in healthy subjects that anodal tDCS applied over the motor cortex can be used to modify descending inputs relayed by corticospinal tract on reciprocal inhibition pathways innervating wrist muscles (1). We found that effects induced by anodal tDCS in wrist extensors and in wrist flexors are opposite: tDCS increases reciprocal inhibition in extensors but decreases reciprocal inhibition in flexors. It appears that modulations induced by anodal tDCS on reciprocal inhibition pathways favor the contraction in wrist extensors. Motor deficit in wrist extensors is usual in hemiplegic patients and the aim of this study is to combine spinal cord MRI and electrophysiological methods to explore effects of tDCS at wrist level in patients with impaired wrist motor control.

Material and Method

Anodal tDCS is applied over the non lesional hemisphere (ipsilateral motor cortex). Its effects at spinal level are explored using electrophysiological techniques based on EMG recordings and percutaneous stimulations of peripheral nerves to elicit reciprocal inhibition at wrist level. MRI study relies on Diffusion Tensor Imaging (DTI) and Magnetization Transfer (MT) (2).

Results

Preliminary results in hemiplegic patients suggest an increase of reciprocal inhibition contrary to the results found in healthy subjects. They also show a relationship between motor impairment and MRI metrics.

Conclusion

It opens new vista for motor rehabilitation of stroke patients.

No conflict of interest
Introduction/Background

Obesity negatively impacts motor control; adults with obesity walk more slowly and take shorter steps, which affects recovering from a loss of balance. Bariatric surgery induces massive weight loss and spurs walking improvements. However, we know little about whether practice before surgery improves motor control. We asked if brief practice completing an obstacle avoidance task would improve walking prior to undergoing surgery.

Material and Method

Sixty-two adults (Mean age=45.55 years, SD=9.28) with obese BMI (Mean BMI 42.22, SD=4.53) walked under five conditions: initial baseline walking on flat ground, crossing three obstacle heights, and final baseline walking on flat ground for a total of 25 trials. Walking parameters were collected using a gait carpet: velocity (cm/s), cadence (steps/minute), step length (distance between consecutive steps), step width (lateral distance between feet), single limb support time (time on one leg), and double limb support time (time on two legs). Paired t-test were used to compare baselines. We conducted oneway repeated measures analyses of variance to examine the effects of obstacle height on walking. The Bonferroni correction was used for all tests.

Results

Participants demonstrated improved walking after crossing obstacles. From the initial to the final baseline, participants showed a 5.6% increase in velocity, 3% increase in cadence, 2.8% increase in step length, and a 1.78% increase in step width. Single limb support time decreased by 2.9% and double limb support time decreased by 4.85% (all ps<.05).

Conclusion

Individuals with obesity may benefit from participating in a brief obstacle avoidance task; the results suggest that even before receiving bariatric surgery participants showed improvements in walking that are associated with decreased safety risks. Examining how to minimize safety risks via improving motor control may help create ways to encourage a more active lifestyle for adults with obesity.

EFFECTS OF OBESITY AND KNEE OSTEOARTHRITIS ON GAIT AND POSTURAL STABILITY IN PRE-BARIATIC SURGERY CANDIDATES
S. Gill1, D. Kim1
1Boston University, Occupational Therapy, Boston, USA

Introduction/Background
Knee osteoarthritis (OA) is the most common cause of chronic disability and is frequently comorbid with obesity. The personal burden of knee OA and obesity are substantial. Adults with knee OA with obesity demonstrate postural instability, which makes them susceptible to falls. The purpose of this study was to investigate gait and postural stability during flat ground walking and obstacle crossing in pre-bariatric surgery candidates.

Material and Method
Forty-four adults with obesity (Mean BMI = 43.35, SD=4.33) and 30 adults without obesity (Mean BMI = 23.10, SD-3.98) walked 60 feet at self-selected paces for 25 trials under five conditions: initial baseline on flat ground, crossing low (4 cm), medium (11 cm), and high (16 cm) obstacles, and final baseline on flat ground. Spatio-temporal kinematics were collected with a gait carpet (Protokinetics).

Results
During the final baseline, for adults with obesity, most parameters improved (p<0.05); at the final baseline condition, participants had the fastest step times, stance times, single limb support times, and velocities. The analyses also revealed that during obstacle negotiation, participants had longer step times, slower velocity and wider step widths compared to level ground walking (p<0.05). Most alterations in gait for individuals with obesity were observed during high obstacle crossing (p<0.05).

Conclusion
The findings suggest that obstacles pose a challenge beyond flat ground walking for pre-bariatric surgery candidates. Obstacle height also influenced participants’ gait. This supports the utility of examining gait in this population during tasks beyond flat ground walking.

Introduction/Background

Currently there is a renewal of interest to use spinal cord stimulation (SCS) as a treatment for improving motor control and reducing spasticity in central motor pathway disorder. Here, we report documented positive long lasting effect both on spasticity and on motor control, in a 26 year old man with Hereditary Spastic Paraparesis with severe, widespread lower limb spasticity and limitation of mobility.

Material and Method

SCS material consisted of 4 electrodes (MEDTRONIC) on the posterior epidural space at T6 level (entry zone L1). The stimulation parameters were initially set as follows: amplitude 4.0-7 V, rate 70-100 Hz, pulse width 210 μsec. The SCS Balance control was assessed by timed right and left stance. Gait control was assessed by the timed 10-meter walk test at preferred and maximal speed. Measurements were performed stimulation on and off, in many sessions 6 months apart. Data were analysed by the Mann-Whitney U test, with p<0.05 considered significant.

Results

The stimulation decreased spasticity, especially for proximal muscles. Stimulation on, performance at all tasks was improved. In the condition stimulation off, the patient was more performing than 6 months before, possibly due to long-lasting effects of the stimulation, that progressively increased with time. The gains obtained after six months of intermittent stimulation were substantial: 4.7% for maximal walking speed, 11.2% for preferred walking speed, 85% for right stance ability and 55% for left stance ability. The positive effect lasted 4.5 years.

Conclusion

In the light of the new technological developments both for electrodes and the control of stimulation parameters, together with a better understanding of the mechanisms underlying the effect of the SCS for improving motor control and reducing spasticity, our results could be useful to enhance the treatment of future patients.

PERCEPTION OF GAIT MOVEMENTS INDUCED DURING TRAINING WITH MULTIPLE PATTERNED VIBRATIONS IN INDIVIDUALS WITH INCOMPLETE SPINAL CORD INJURY

A. Tapin¹, M. Barreau¹, M. Jose-Escalona¹, M. Vermette¹, D. Gagnon¹, C. Duclos¹

¹Centre de Recherche Interdisciplinaire en Réadaptation CRIR, School of Rehabilitation, Montréal, Canada

Introduction/Background

Multiple patterned vibration applied on lower-limb joints in individuals after incomplete spinal cord injury (iSCI) generates gait-like movements at a cadence specific to the vibration pattern. This intervention is currently tested on individual with iSCI, who may need body weight support. The main objective of the study was to quantify perceptions associated to sensory afferents generated by multiple vibrations by iSCI participants. The second objective was to determine whether weight support and cadence of the simulated gait cycles affects perceptions before and after 15 gait-like vibrations training sessions.

Material and Method

Six participants (21-77 years old) with an incomplete spinal cord injury (ASIA Impairment Scale grade C&D) received gait-like vibrations in a standing position, with different levels of weight relief (0%/20%/40%), and two gait cadences (60 and 120 steps/min). Perception was evaluated in each condition with a Visual Analog Scale (VAS), before and after 15 training sessions over three weeks.

Results

Every participant showed good perception of a gait motion (VAS score >5/10) for 1 or more conditions in the pre- and post- training evaluation. Body weight and cycle duration had no effect on perception (less than 1 point difference). Perception increased, though not significantly by 2.2 (1.1) points after training, with the increase particularly marked in conditions with low score pre-training.

Conclusion

Individuals with iSCI perceived gait motion during the application of patterned gait-like vibrations, which may participate to the effect of gait vibration training individuals with iSCI in intensive rehabilitation, regardless of their need for body weight support.

ISPR8-1351
UPPER LIMB RECOVERY IN APHASIC PATIENTS AFTER VASCULAR ACCIDENT: A THEORY.
D. Anderlini\(^1\), G. Wallis\(^1\)
\(^1\)University of Queensland, Centre for Sensorimotor Performance, Brisbane, Australia

Introduction/Background

Cortex and cortical function can be regarded as modular, with separate areas involved in processing sensory information and the initiation of motor movement. The blood supply supporting cortex is, like the brain itself, modular. Disruption in blood flow leads to a multiplicity of dysfunctions like the frequent co-occurrence of aphasia and right upper limb hemiparesis.

Material and Method

A review of the vascular accident literature reveals a correlation between Broca's aphasia and upper limb motor recovery. The precise reason for the correlation is not known but this paper proposes one.

Results

Patients with Broca's aphasia show slower and poorer motor recovery of right arm compared to non-aphasic ones. Different causes were summoned to explain the difference in recovery.

Conclusion

Our theory, contrary to other conclusions, is that speech impairment is indicative of damage to Brodmann area BA45 but that the motor deficits are due to damage to the proximal, but functionally discrete area BA44. BA44 is a multisensory area. But experiments on tone-deaf or stutters, radiological tools like fMRI and DWI, studies of the neuro-ontogeny and development in babies, findings of genetic, epigenetic and embryology, all point to BA44 playing a central role in visuo-motor integration.

AMOUNT (ACTIVITY AND MOBILITY USING TECHNOLOGY) REHABILITATION TRIAL: TECHNOLOGIES USED AND PARTICIPANT PERCEPTIONS IN THE INPATIENT SETTING
M. van den Berg

Flinders University, Rehabilitation- Aged and Extended Care, Adelaide, Australia

Introduction/Background

New technologies may provide an affordable way to increase the dose of practice for people undertaking rehabilitation. Study aims: (1) Which technologies were used to address participants’ mobility limitations during the inpatient phase of the AMOUNT rehabilitation trial? (2) Did participants perceive technologies to be enjoyable and easy to use, and which factors influenced this?

Material and Method

Design: process evaluation from a randomised controlled trial in which 149 participants (52% male; mean age 70 (SD18); 54% neurological conditions) were allocated to the intervention group.

Intervention: tailored technology prescription according to a protocol matching exercises from eight technologies (commercially-available: Nintendo Wii; Xbox Kinect; activity monitors; smartphone apps; rehabilitation-specific Humac; Fysiogaming; Stepping Tiles; exercise iPad apps) to seven mobility limitations.

Outcome measures: intervention dose, technologies used, mobility limitations addressed, Physical Activity Enjoyment (PACES; 18-126) and System Usability Scales (SUS; 0-100).

Results

Participants received on average 11 (SD11) sessions of 43 (SD11) minutes duration. Each participant used on average 4 (SD1) technologies to address a mean of 4 (SD1) different mobility limitations. Intervention focused largely on limitations related to standing (80%) and stepping (79%), as well as on physical activity levels (90%). The Humac was the most frequent first-introduced technology (35% of participants). Activity monitors (80%) and iPad apps (71%) were most prescribed, and commercially-available exergames and smartphone apps used least. At 3 weeks, participants perceived technology use as enjoyable (mean PACES 95.4 (SD23.2)) and rated usability above average (mean SUS 72.2 (SD18.8)). Enjoyment and usability were positively related to previous technology use (p<0.01) and younger age (p≤0.03). Usability was greater in those with neurological conditions (p<0.05). Previous technology use remained associated with usability after adjustment for other factors (p=0.003).
Conclusion

In inpatient rehabilitation, tailored prescription of technologies can address a range of mobility limitations and was well accepted. Previous technology use enhances uptake.

Introduction/Background

Kinesthetic illusion induced by visual stimulation (KiNvis) is a novel method that produces kinesthetic perception through observation of a person’s physical exercise on a computer screen. KiNvis enhances lower-limb corticomotor excitability in healthy subjects. However, it is not clear which regions of the brain are activated during KiNvis. The purpose of this study was to investigate the regions of brain activity during KiNvis in the ankle dorsiflexion movement.

Material and Method

We examined the left lower limbs of 17 healthy subjects (mean age, 24.1 ± 5.3 years; 12 males and 5 females). We randomly applied two conditions to the left lower limbs. Condition 1 (observation condition) was to observe the image of ankle. Condition 2 (KiNvis condition) was to observe the video and induced the KiNvis. The video of ankle dorsiflexion movement on the right side filmed in first-person perspective was flipped horizontally and then shown on a computer screen. A computer was placed over the left side foot. Subjects observed the video that recorded the ankle dorsiflexion movement to induce KiNvis. The two conditions were measured using a rest-task-rest block design. Cerebral blood flow during rest and task (in the two conditions) were recorded using functional near-infrared spectroscopy (fNIRS). Effective size of the two conditions were calculated and compared. During the KiNvis condition, A visual analogue scale (VAS) was measured to evaluate the degree of kinesthetic illusion.

Results

VAS was found to be 66.9 ± 12.5 mm (mean). Cerebral blood flow in the right premotor area was significantly increased during the KiNvis condition compared with that during the observation condition.

Conclusion

Our results demonstrate that cerebral blood flow in the premotor area increases with KiNvis of the ankle dorsiflexion movement in healthy subjects.

2Fujita Health University, Faculty of Rehabilitation - School of Health Sciences, Toyoake, Japan
3IFG Corporation, IFG Corporation, Sendai, Japan

Introduction/Background

 Neuromuscular electrical stimulation has been widely used in patients with dysphagia, but obtaining sufficient hyoid bone movement through surface electrodes seems difficult due to pain. On the other hand, magnetic stimulation activates the nerve and the muscles without stimulating the skin nociceptors. However, the coil for magnetic stimulation is too big to stimulate smaller muscles like the suprahyoid muscles. The aim of this study was to develop the peripheral magnetic stimulation system to stimulate suprahyoid muscles.

Material and Method

This study was approved by the institutional review board. We designed a smaller coil to stimulate suprahyoid muscles without stimulating inferior alveolar nerve that induced pain to the teeth. We also developed a jig to support the coil. Eleven healthy subjects aged 32 ± 9 years participated in this study. The new coil was placed on the submental area of the subjects and the magnetic stimulation was performed one time at a rate of 30 Hz for 2 s. The intensity level selected induces hyoid bone movement without causing intolerable pain to the subjects. The hyoid bone at rest between on- and off-magnetic stimulations of the suprahyoid muscles were identified using fluoroscopy at 30 frames/s in lateral projection and the displacements of the hyoid bone were calculated using Image J program. Pain during peripheral magnetic stimulation was assessed from 0 to 10 using the numerical rating scale (NRS).

Results

Magnetic stimulation resulted in 10.9 ± 2.8 mm forward displacement and 8.3 ± 4.1 mm upward displacement of the hyoid bone. The median NRS score during magnetic stimulation was 1.

Conclusion

We obtained similar extent of hyoid bone movement at rest compared with normal drinking of 10-mL liquid. The peripheral magnetic stimulation can become an alternative to electrical stimulation for patients with reduced laryngeal elevation.

IFG Corporation has a pending patent.
Introduction/Background

Parkinson’s disease (PD) is a neurodegenerative disease, which is characterized by tremor, muscle rigidity and bradykinesia, what may affect the posture and the body balance. The balance disturbance may occur during both: the quite standing and during gait initiation. The aim of this study was to investigate the postural instability in PD patients in different conditions during gait initiation.

Material and Method

The research was conducted on 17 patients with PD in a III clinical stage of disease and 17 older healthy adults – the control group. The gait initiation was measured on the two force platforms. The procedure consisted of three phases: quite standing on a first platform, crossing on the second platform, quite standing on a second platform. There were four conditions: crossing without obstacle, crossing the obstacle, walking up on the step and walking down of the step. We analyzed: phase time 2 [s], stability time S1 [s] (time from loss of stability to step on the second platform), stability time S2 [s] (time from step on the second platform until the stability is regained).

Results

The time phase 2 significantly increased among conditions in both groups (PD: p=, 0163, control: p=.000). In PD group data indicate notable stability problems during walking up on the step, but the elderly have more problems with walking down of the step. The control group presents significant trouble with regained stability after crossing the obstacle and walking up and down of the step (p=,000), while the PD group have equally problem to restore balance in all conditions, even during level ground walking (p>0,05). All measured variables were significantly lower in the control group compared to PD group (p<0,05).

Conclusion
The different constraints may change the gait initiation patterns in PD patients more than in elderly.

MOTOR COMPENSATIONS DURING REACH MOVEMENT OF THE DOMINANT UPPER LIMB HEALTHY VERSUS STROKE PATIENTS

A. Couto¹, S. Silva², S. Lopes¹, R. Carvalho¹
¹CESPU - Instituto Politécnico de Saúde do Norte, Physiotherapy, Paredes, Portugal
²CESPU - Instituto Politécnico de Saúde do Norte, Physiotherapy, Vila Nova de Famalicão, Portugal

Introduction/Background

Background: Stroke is one of the leading causes of morbidity and mortality in the world. Clinical and functional changes after stroke related with postural control not only affect the contralesional but may also contribute to motor dysfunction on the ipsilesional side, in particular the efficiency of distal movement. Compensatory trunk movement is commonly reported during reach, which is one key function required to several daily activities. Aims: Compare the compensatory movements during reach movement of the dominant upper limb, in stroke patients with healthy subjects.

Material and Method

Methods: Cross-sectional study was carried out. The sample comprises 30 subjects with right dominant upper limb: 15 patients with left hemiparesis (75±9.1 years) and 15 healthy subjects (74±7.5 years). For assessing compensatory movements during upper limb reach the Reach Performance Scale was used. The differences between groups in the total score of the near target and the distant target were compared throughout the Mann-Whitney test. The association between qualitative variables were performed by Qui-Square. The level of significance was α=0.05.

Results

Results: Both groups exhibit movements compensations during reach, however, no differences were found in the quality of movement of the dominant upper limb between groups, neither in the total score on near target (p=0.092) nor in the distant target (p=0.292).

Conclusion

Conclusions: There are no differences in motor compensations used for dominant upper limb reaching in patients with hemiparesis and healthy subjects.

GUIDED SELF REHABILITATION VIDEO TOOL IN ADDITION TO STANDARD REHABILITATION FOR SUBACUTE POST-STROKE PATIENTS WITH SPASTIC PARESIS
A. David¹, C. Aymard¹, L. Derobert¹, P. Laborne¹, R. Magnin¹, M. Gerboin¹, F. Mebarek¹, C. Assany¹
¹USSIF Hôpital Ste Marie Paris, Rehabilitation, Paris, France

Introduction/Background

Recent studies have shed light on promising recovery in motor command in post-stroke patients with spastic paresis through guided self-rehabilitation (SR). It can enhance the intensity, the number of repetitions and the daily duration of trained movements. Our team developed a SR video tool for subacute post-stroke patients admitted on our ward to be used in addition to their standard rehabilitation program. The main goal was to analyze the number of repetitions by each patient and the time spent doing the self exercises.

Material and Method

Post stroke patients eligible for inclusion were recruited between Feb and Dec 2017. Patients were educated by our physiotherapists to use the video tool correctly in their room. A follow up booklet was provided to note the number of times the exercise was repeated and the time spent doing it. Results were extracted through analysis of each booklet.

Results

7 of the 113 stroke patients admitted to our unit were eligible for recruitment. One patient refused to participate and another didn't fill his booklet. Results are documented in tables 1 and 2.

All 5 patients were able to implement bedside SR, with an average time spent of 32 minutes /day, and an average of 147 exercises/ day.
Conclusion

This was a preliminary study of feasibility. Our results show that SR initiated during hospitalization, in subacute post-stroke patients with spastic paresis, can dramatically increase daily time spent on repetitive trained movements. This tool contributes to increasing patients’ commitment to their rehabilitation program. For the physiotherapist it is an important complimentary asset which easy to integrate into the standard rehabilitation program.

Further studies are warranted in order to show true effect on recovery from post-stroke spastic paresis. An estimated 20 -25000 of patients per year in France could benefit from using this tool.

Aquatic therapy as a tool to improve sensory and motor control in pediatric neurologic patients

L. Labianca¹, M. Fava², M. Secchi², V. Di Venti², E. Filardo², C. Ubaldi³
¹II Faculty of Medicine La Sapienza University of Rome, Orthopedics and Traumatology, Rome, Italy
²AIIEN, Aquatic Therapy, Ascoli, Italy
³II Faculty of Medicine La Sapienza University of Rome, Physiotherapy, Rome, Italy

Introduction/Background

Aquatic protocols may be a beneficial therapy for children with neuromuscular diseases, especially for those land-based physical activity is difficult. The 2 most important assessments in these patients are the gross motor function measures and Quality of Life. This study evaluate changes in Gross Motor Function, QoL of the child and of care givers before and after an aquatic protocol therapy that aims to stimulate the child both the motor and the psychological aspects.

Material and Method

Patients affected by neuromuscular diseases were recruited for a 6 months aquatic rehabilitation program. They were followed in the previous 6 months to record their changes about GMFM and QoL scores to compare the 2 periods as well. Age, gender, and type of disease were recorded. The following associated impairments were also recorded: visual impairments, hearing impairments, communication problems, and intellectual impairment. QoL was assessed by the Pediatric Quality Of Life Inventor Neuromuscular Module.

Results

Seven males, 13 females, mean age 10.4 yo were followed. GMFM with a mean of 18% after the aquatic protocol. Children with severely impaired motor function were more likely to have poor QoL in the physical well-being and autonomy domains as well as those with higher intellectual impairment have higher risks of poor QoL during the first 6 months with an improvement after the aquatic protocol.

Conclusion

We found positive effects following a 6-months aquatic intervention on the GMF and QoL of children with neuromuscular diseases following changes during one year where 6 months of aquatic therapy have compared to the previous 6 months. QoL in these patients seems to be affected by the lack of psycho-social experience.

SENSORY-MOTOR TRAINING IMPROVES HEALTH-RELATED QUALITY OF LIFE AND FALL EFFICACY IN CHRONIC STROKE SURVIVORS
T. Zastron¹, K. Welman¹
¹Stellenbosch University, Sport Science, Stellenbosch, South Africa

Introduction/Background

Stroke survivors struggle with an array of disabilities, which can be divided into physical, social as well as emotional debilities. The primary objective was to assess the influence of an eight-week sensory-motor training program on health-related quality of life and concern for falling in chronic stroke survivors.

Material and Method

This was a double-blind randomized control trial. Chronic stroke participants (≥ 6 months) were divided into two groups namely, sensory-motor training group (n = 12; 68 ± 13 years old) and attention-control group (n = 10; 71 ± 11 years old). Both interventions were executed three times a week for 45-60 minute sessions over an eight-week period. The sensory-motor training consisted out of task-specific balance exercises while manipulating the visual, vestibular and proprioceptive sensory systems. Health-related quality of life was measured with the Short Form Health Survey (SF-36) and concern for falling with the Fall Efficacy Scale International (FES-I). Participants were evaluated pre-intervention and post-intervention.

Results

A significant Group x Time interaction was identified for physical functioning (p = 0.005) and FES-I (p = 0.03). Additionally, the experimental group showed a significant improvement in physical (p = 0.01) and social functioning (p = 0.02) subdomains of SF-36 after training. Lastly, the sensory-motor training group perceived their physical and social functioning to be better compared to attention-matched group (p < 0.05).

Conclusion

The results of this study indicate that balance training under sensory manipulated conditions can improve the perception of physical and social functioning as well as concern for falling in chronic stroke survivors.

THE EFFECTS OF VIBRO-MEDICAL INSOLE ON SENSATION AND PLANTAR PRESSURE DISTRIBUTION IN DIABETIC PATIENTS WITH MILD-TO-MODERATE PERIPHERAL NEUROPATHY
M. Bagherzadeh Cham¹, M. Mohseni-Bandpei², M. Bahramizadeh³
¹Neuromusculoskeletal Research Center- Iran University of Medical Sciences- Tehran- Iran, Physical Medicine and Rehabilitation, Tehran, Iran
²Department of Physiotherapy- University of Social Welfare and Rehabilitation Sciences- Tehran - Iran, Department of Physiotherapy, Tehran, Iran
³University of Social Welfare and Rehabilitation Sciences- Tehran- Iran, Department of Physiotherapy, Tehran, Iran

Introduction/Background

The first aim of this study was to determine the effect of vibro-medical insole on pressure sensation and the second was to measure the effects of vibro-medical insole with and without random noise on plantar pressure distribution in diabetic patients with mild-to-moderate peripheral neuropathy.

Material and Method

Twenty patients with mild-to-moderate diabetic neuropathy were recruited in the clinical trial pre-test, post-test study. Medical insole was made for each participants and vibratory system was inserted it. Pressure sensation was evaluated before and after the 30 minute walks using the vibro-medical insole with Semmes-Weinstein Monofilaments. Peak pressure data was measured using the vibro-medical insole with and without random noise by Pedar-x system.

Results

Pressure sensation is shown improvement using the vibro-medical insole with added random noise at heel, metatarsophalangeal heads and hallux of both feet in all participants (p< 0.05). Peak pressure decreased significantly in heel, MTP₂,₃, MTP₄,₅ and hallux (p< 0.05) and increased in midfoot (p< 0.05) using the vibro-medical insole with and without random noise compared to shoe only condition. Only the peak pressure of the heel region decreased using the vibro-medical insole with random noise compared to without random noise (p= 0.006).

Conclusion

Vibro-medical insole seems to improve pressure sensation and alter peak pressure in the diabetic patients with mild-to-moderate peripheral neuropathy. This work suggests that vibro-
medical insole with added random noise can be used for daily living activities to overcome sensory loss and probably decrease the risk of ulceration in diabetic neuropathy patients.

Introduction/Background

Individuals with traumatic brain injury often present with balance problems associated with a decrease in their social participation. An innovative approach consists in using perturbations on a split-belt treadmill to improve dynamic balance. The aim of this study is to quantify the effects of a training program including perturbations on a split-belt treadmill on dynamic balance, walking speed, balance confidence and social participation in individuals with traumatic brain injury in social integration rehabilitation phase or at a chronic stage.

Material and Method

Seven individuals with moderate-to-severe traumatic brain injury participated in six training sessions on a split-belt treadmill with self-perturbations (head movements, turns, cognitive task) and unexpected perturbations (stop-and-go, speed increase or decrease of one treadmill belt). The Mini-BESTest, Community Balance & Mobility Scale, comfortable and fast walking speed, Reintegration to Normal Living Index and Activity-Specific Balance Confidence Scale were measured twice before and after the intervention.

Results

Preliminary results indicated a statistically significant improvement of 2.1 (1.5)/28 at the Mini-BESTest and 7.0 (6.9)/96 at the Community Balance and Mobility Scale. No significant change in speed, balance confidence and social participation were observed. A learning effect was observed between the two pre-intervention assessments.

Conclusion
This approach seems promising in balance reeducation with individuals with moderate-to-severe traumatic brain injury.

EFFECTS OF DIFFERENT DIRECTIONAL STATIC CONTRACTION OF THE RIGHT UPPER EXTREMITY ON THE CONTRALATERAL LEFT SOLEUS H-REFLEX
R. Hobara¹, T. Shiratani¹, N. Ide², M. Arai³
¹Sonoda Second Hospital, Department of Rehabilitation, Tokyo, Japan
²Tsuchi International University, Department of Physical Therapy- Faculty of Medical and Health Sciences, Ibaraki, Japan
³Tokyo Metropolitan University, Faculty of Health Sciences- Division of Physical Therapy, Tokyo, Japan

Introduction/Background

The purpose of this study was to explore the neurophysiological remote effects and remote after-effects of resistive static contraction (SC) of the upper extremity, with consideration of the resistant direction on the contralateral soleus H-reflex.

Material and Method

The participants were 12 healthy subjects with a mean (SD) age of 23.4 (2.7) years. SC of the muscles of the upper extremity was performed for 10 s utilizing the resistive SC of shoulder flexion - abduction - external rotation (R-F-A-E) and shoulder extension - adduction - internal rotation (R-E-A-I) of the upper extremity using proprioceptive neuromuscular facilitation (PNF). Three tasks, R-F-A-E, R-E-A-I, and rest after either of the first two tasks, were randomly performed. The left soleus H-reflex was measured before the task (20 s), after the resistive exercise phase (10 s), and after the rest phase after resistive exercise (180 s). The H-reflex amplitude was normalized to the corresponding maximal M-wave (Mmax) H-reflex, which is expressed as the H/Mmax ratio.

Results

Three-way analysis of variance of the H/Mmax ratio with a Bonferroni post-hoc analysis revealed that the H/Mmax ratio for the resistive exercise phase was significantly larger than that in the rest phase after resistive exercise.

Conclusion

Whereas the R-E-A-I task had significant facilitatory effects compared with the R-F-A-E task, the H/Mmax ratio of the rest phase after R-E-A-I had a tendency to be reduced compared with rest after R-F-A-E, which may indicate induction of relaxation as a remote after-effect as an indirect approach.

EFFECTS OF OPPOSITE DIRECTIONAL RESISTIVE STATIC CONTRACTION OF THE MUSCLES AROUND THE SCAPULAE ON THE UNEXERCISED CONTRALATERAL SOLEUS H-REFLEX

N. Ide¹, T. Shiratani², R. Hobara², M. Arai³
¹Tsukuba International University, Department of Physical Therapy, Ibaraki, Japan
²Sonoda Second Hospital, Department of Rehabilitation, Tokyo, Japan
³Tokyo Metropolitan University, Faculty of Health Sciences- Division of Physical Therapy, Tokyo, Japan

Introduction/Background

An indirect approach is useful in clinical practice when a direct approach is difficult to use due to insufficient muscle contraction caused by muscle weakness. The purpose of this study was to compare the neurophysiological remote effects and after-effects of resistive static contraction of the muscles around the scapulae, with consideration of the resistant direction.

Material and Method

The participants were 12 healthy subjects with a mean (SD) age of 23.7 (3.4) years. A static contraction of the muscles around the scapula was performed for 10 s, utilizing the resistive static contraction of scapular anterior elevation (SCAE) and scapular posterior depression (SCPD) using proprioceptive neuromuscular facilitation. The subjects were asked to maintain the scapular position against the traction force at a level of resistance that was 50% of the maximum voluntary contraction. The left soleus H-reflexes were elicited sequentially without interruption for a period of 210 s, which was divided into a rest phase (20 s), task phase (10 s); and a rest phase after each task (180 s). For comparison, each H-reflex amplitude during and after each resistive exercise was normalized to the corresponding maximal M wave (Mmax), as expressed by the H/Mmax ratio. Data were obtained from a randomized block experiment with three tasks (SCAE, SCPD, rest) for each subject (individual factor) performed over a period of 190 s (19 conditions [time course]: condition C1-C19).

Results

Three-way analysis of variance for the H/Mmax ratio with Bonferroni post-hoc analysis revealed that the SCAE task had significantly smaller effects than the SCPD and rest tasks, and that the SCPD task had significantly larger effects than the rest task (p<0.05).

Conclusion

SCAE may induce neurophysiological inhibitory effects as remote after-effects, which may induce relaxation of remote muscles.

Introduction/Background

Background and Aim: A large proportion of stroke survivors present spastic paresis of the upper limb (UL). Therapeutic interventions result in large variance in the response of patients to the same treatment protocols, possibly stemming from differences in lesion characteristics, among other factors. Here we concentrated on the impact of lesion size and location on UL function following stroke, comparing the effect of right hemisphere damage (RHD) to that of left hemisphere damage (LHD).

Material and Method

Method: Clinical and lesion data for the current study were collected as part of a multi-center randomized, controlled trial (ENHANCE project; ClinicalTrials.gov, ID: NCT02725853). Two
groups of patients with sub-acute stroke were compared: those with right hemisphere (n=8) and left-hemisphere damage (n=15). Voxel-based lesion symptom mapping (VLSM) was employed to identify voxel clusters in the normalized brain where damage exerts a significant impact on the functioning of the hemiparetic UL, as revealed by the Functional Ability Scale of the short (streamlined) version of the Wolf Motor Function Test.

**Results**

**Results:** Motor function of the hemiparetic UL was affected in LHD patients by damage to voxel clusters involving (a) cortical areas of the superior temporal regions and the insula, (b) white matter tracts, notably the superior and inferior fronto-occipital fascicles, the corona radiata and the internal capsule, and (c) the basal ganglia and thalamus. In the RHD group, VLSM analysis showed a different pattern where UL function was affected almost exclusively by damage to subcortical structures of the corona radiata, the capsular-putaminal region, the superior longitudinal fasciculus and the external capsule.

**Conclusion**

**Conclusion:** Motor function of the hemiparetic upper limb in patients with sub-acute stroke was affected differently by damage to homologous structures in the left and right cerebral hemispheres.

⁶Ipsen Pharma, Global Medical Affairs, Boulogne-Billancourt, France

Introduction/Background

Long-term safety and efficacy of repeated abobotulinumtoxinA (aboBoNT-A) injections in patients with upper limb spasticity (ULS) after stroke or traumatic brain injury have been described in an open-label study (Gracies et al. Muscle Nerve 2018). Continuous improvements in active movements, and perceived and active function were reported, with no unexpected safety signals identified. Here, we describe the frequency of repeated aboBoNT-A injections over the open-label study.

Material and Method

A phase 3, international, double-blind, single-treatment study (NCT01313299) of aboBoNT-A in the hemiparetic upper limb, followed by a 12-month open-label extension study (NCT01313312) with up to four additional treatment cycles, at least 12 weeks apart. Re-treatment was per investigator’s clinical judgement, based on muscle tone, spasticity measures and other findings. Patients not requiring re-treatment completed the study.

Results

A total of 254 patients entered in open-label Cycle 1 (Table 1). In Cycle 1, 14/254 patients withdrew and 240 completed the cycle. After Cycle 1, 10 patients completed the study without subsequent aboBoNT-A injections. In Cycle 2, 219/229 patients completed the cycle (10 withdrew) and 44 did not require subsequent injections. Of 175 patients entered Cycle 3, six withdrew and 169 completed the cycle, 88 of whom did not require subsequent injections. Overall, 55.9% (n=142) of patients required three or fewer injections of aboBoNT-A over the course of the 12-month study, 21.6% required two or fewer injections, and 3.9% required one injection.
CONCLUSION

Over half of the patients (55.9%) enrolled in this phase 3 study required three or fewer injections of aboBoNT-A over the course of a year, based on physician clinical assessment. This decreased injection frequency, with respect to usual practice, may reduce the burden associated with treatment for patients and their caregivers/families.

We report a case of Congenital cytomegalovirus infection (cCMV) with severe spinal scoliosis whose treatment consisted of rehabilitation, botulinum toxin type A injection (BTX) and postural control of prone positioning.

Material and Method

A case was a 20-year-old female patient. She was diagnosed as a sequela of cCMV and severe motor and intellectual disabilities. A progressive spinal deformity became evident as she grew up, and her left hip was completely dislocated. Since she was 15 years old, she had undergone rehabilitation therapy in our hospital. Prone positioning has been performed persistently using a handmade positioner. BTX were started from the age of 19 years to decrease spasticity of the trunk muscles. The supposed target muscles were the left posterior cervical and right lumber muscles, but it was difficult to sufficiently support her neck and legs with the small prone positioner as a grown-up. Therefore, we reformed the positioner to widen the support and devised she could choose a half of the left side position by placing the seat at the right angle to the tilt frame. We administered BTX after she was used to spending on the new prone positioner. In addition, we made a supine positioner to correct and keep better alignment of her spinal deformity on the bed.

Results

The severe spasticity of the spine was reduced through the combination therapy of BTX, the new prone positioner and supine positioning. This resulted in the patient being more comfortable and respirable than before.

Conclusion

Prone positioning is effective for respiration and swallowing in patients with chronic respiratory disorders and severe motor disabilities. Combination therapy with BTX, rehabilitation, and use of positioners was effective for our patient. However, it is important to adjust the positioner seat appropriately based on the deformity of the patient.

Introduction/Background

The efficacy of botulinum toxin A treatment for spastic paresis in adults is well established. This analysis uses statistical modelling to estimate the maximal therapeutic effect of abobotulinumtoxinA (aboBoNT-A) for upper limb spastic paresis, and number of treatment cycles required to reach an efficacy level close to maximal effect.

Material and Method

Retrospective analysis of combined data from two clinical studies of aboBoNT-A in upper limb spastic paresis: a randomised, placebo-controlled, single-treatment study (NCT01313299), followed by an open-label extension study (NCT01313312). Analyses focussed on technical and functional measures of efficacy (Table 1). Two inferential methods were used to assess changes in efficacy parameters after repeat aboBoNT-A treatment cycles: Mixed Model Repeated Measures analysis and Non-Linear Random Coefficients analysis. Using the latter model, the asymptote (maximal effect size; not placebo-controlled) and number of treatment cycles to reach 90% of the asymptote were estimated.

Results

Table 1 shows the estimated asymptote (maximal effect size) and number of cycles at 90% asymptote for technical and functional assessments of efficacy at Weeks 4 and 12 post-injection. When estimating maximal effect at Week 4, measures of passive or perceived parameters (muscle tone, disability, angle of catch) reached their maximum around 1–2 cycles before active parameters (active range of motion, active function). In contrast with technical assessments and perceived function, maximal effects for active function (modified Frenchay scale) assessments at Week 12 were higher than or equal to Week 4.
Conclusion

These analyses reveal that patient benefits in adults receiving aboBoNT-A for spastic paresis are maximised with repeated treatment cycles. Active parameters reached maximal effect later than other measures, hence patient benefit may be underestimated in studies with single treatment cycles. Results also revealed further improvements in active function at 12 weeks after injection.

Introduction/Background

Shoulder spasticity post-stroke or -traumatic brain injury (TBI) may cause pain and restrict joint range of motion (ROM). Few studies have investigated botulinum toxin injections into shoulder muscles for spasticity treatment. Here we present data for sub-populations of patients receiving shoulder injections of abobotulinumtoxinA (aboBoNT-A) in two international, multicentre clinical studies: phase-4 ULIS-II (Upper Limb International Spasticity Study-II; post-stroke spasticity; NCT01020500), and phase-3 AUL open-label study (Adult Upper Limb; post-stroke or -TBI spasticity; NCT01313299).

Material and Method

ULIS-II: selection and achievement of patient-centred primary goals. AUL study: Tardieu scale for passive ROM (XV1), angle of catch (XV3) and spasticity angle (X) for shoulder muscles; and Modified Frenchay Scale (MFS) for active function.

Results

In ULIS-II, 82 patients receiving aboBoNT-A in shoulder muscles selected pain treatment goal three times more often than those without (Figure 1), with high goal achievement (85.7 and 85.0% respectively). In AUL study, 96 patients received ≥1 injection cycle in shoulder muscles, of which 84 received ≥2 shoulder injections. In patients with 1 shoulder injection, improved shoulder muscle spasticity (Tardieu) at last injection cycle: mean change from baseline at Week 4 was +12.3° and -8.2° for XV3, and X, respectively (Figure 2). Patients with ≥2 shoulder injections had an improvements of +17.9° in XV3. Concomitant improvements were also observed in active function (Week 4 Cycle 4, ≥2 shoulder injections: MFS: +0.71 [0.48]) (Figure 3). A trend towards lower injection doses in proximal compared with distal muscles was seen.
Figure 1. Selection of primary goal areas in sub-populations of patients with and without shoulder injections

![Bar chart showing percentage of patients in different goal areas for shoulder-injected and non-shoulder-injected sub-populations.]

- **Pain:** 25.6% (82), 8.4% (239)
- **Passive function:** 33.1% (82), 22.0% (239)
- **Active function:** 24.7% (82), 19.5% (239)
- **Mobility:** 3.7% (82), 2.1% (239)
- **Involuntary movement:** 3.7% (82), 8.8% (239)
- **Impairment:** 25.6% (82), 21.8% (239)
- **Other:** 0.0% (82), 1.3% (239)

**Primary goal areas**

Figure 2. Mean change from baseline to Week 4 in passive range of motion ($X_{v1}$), angle of catch ($X_{v3}$) and spasticity angle ($X$) in shoulder muscles at the last injection cycle.

![Error bar chart showing mean change in $X_{v1}$, $X_{v3}$, and $X$ for injections at only 1 cycle (n=12) and ≥2 cycles (n=84).]

- **$X_{v1}$:** Injection at only 1 cycle: 42, Injections at ≥2 cycles: 8.6
- **$X_{v3}$:** Injection at only 1 cycle: 12.3, Injections at ≥2 cycles: 17.9
- **$X$:** Injection at only 1 cycle: -4.2, Injections at ≥2 cycles: -9.3
Conclusion

Post-stroke or TBI patients receiving abobotulinumtoxinA in shoulders, in addition to other proximal muscle groups, reached high levels of goal achievement, particularly relating to pain and showed improvement in active function (MFS).

Disclosure statement:
François Constant Boyer has served on scientific advisory boards for Ipsen, Allergan, Merz and Medtronic. Thierry Lejeune has received grants from Ipsen and personal fees from Merz. Svetlana Khatkova has received honoraria and conference attendance fees from Ipsen. Philippe Picaut, Pascal Maisonobe and Jovita Balciaitiene are employees of Ipsen.
Guided self-rehabilitation contracts (GSC) are a diary-based and antagonist-targeting strategy, in which therapists identify muscles against which to prescribe patients daily, home-based self-stretching and active training programmes. Patients record a diary of exercises performed between visits. The ENGAGE study assesses effects of abobotulinumtoxinA (aboBoNT-A) on voluntary movements, following co-injection of upper (UL) and lower limbs (LL), alongside GSC in patients with chronic hemiparesis resulting from acquired brain injury. An interim analysis of ENGAGE baseline data is presented here.

Material and Method

International phase 3b/4, prospective, single-arm, open-label study (NCT02969356). Patients, stratified with UL or LL as primary treatment target (PTT), receive two consecutive injections of aboBoNT-A 1500 U, together with personalised GSC. Primary efficacy endpoint is the proportion of responders (improvement in composite active range of motion [CXA] of ≥35° or 5° in UL or LL, respectively) in the PTT at Cycle 2 Week 6.

Results

Baseline data were analysed for 157 patients (data cut-off December 2017). Baseline characteristics are presented in Table 1; 91% of patients had experienced stroke; mean time since brain injury was 79.5 months.
PTT split was 52% versus 48% for UL and LL, respectively. 27% of patients were naïve to botulinum toxin (BoNT) for both UL and LL spasticity (34% UL-naïve; 58% LL-naïve), and 74% were naïve to GSC. Baseline BoNT doses administered are shown in Table 2.

Introduction/Background

Patients with chronic hemiparesis following stroke or traumatic brain injury (TBI) often experience restricted walking performance. Our previous double blind (DB) trial of 388 patients demonstrated that abobotulinumtoxinA (aboBoNT-A) treatment improves muscle tone and functional outcomes in adults with lower limb spastic paresis. This sub-analysis from the open-label (OL) study extension phase assesses changes in walking speed (WS), step length (SL) and cadence in these patients.

Material and Method

Phase 3, prospective, multicentre, double-blind (DB), randomised study (single injection of aboBoNT-A 1000U or 1500U or placebo; NCT01249404), followed by an OL study extension (≤4 cycles of aboBoNT-A 1000U or 1500U; NCT01251367). Participants were ambulatory adults with spastic hemiparesis causing gait dysfunction, comfortable barefoot WS 0.1–0.8 m/s in 10-metre WS test without walking aids, and stroke or TBI ≥6 months before study enrolment. Patients receiving either aboBoNT-A dose were assessed relative to DB baseline for WS, SL and cadence using 10-metre WS tests under different conditions (maximal and comfortable WS, barefoot and with shoes). Week 12 data are shown for the last treatment cycle with available data (Cycle 3).

Results

Relative to baseline, improvements in WS, SL and cadence by OL Cycle 3 Week 12 were observed in all four categories (Table 1). Mean percentage of improvements in WS were +19.7–23.6% across categories. Mean percentage improvements of +9.4–13.8% and +7.2–9.7% were observed for SL and cadence, respectively. The highest mean percentage improvements were
at comfortable barefoot WS for WS and SL, and at maximal barefoot WS for cadence. The least improvements from DB baseline were observed with shoes compared with barefoot, across all categories.

**Introduction/Background**

Initial muscle tone increase may be apparent within 6 weeks, and even days, post-stroke. Botulinum toxin-A (BoNT-A), an effective and well-tolerated treatment for upper limb spasticity (ULS), improves muscle tone and function, however most studies were conducted >6 months post-stroke. The ONTIME and ABCDE-S studies assessed efficacy and safety of early use (2–12 weeks post-stroke) of abobotulinumtoxinA (aboBoNT-A) in ULS.

**Material and Method**

ABCDE-S (NCT00234546; 2008): 24-week, randomised (1:1 aboBoNT-A [n=80]: placebo [n=83]), study assessing muscle tone changes in patients treated within 2–12 weeks of first stroke, with a Modified Ashworth Scale (MAS) score ≥1+. ONTIME (NCT02321436; 2016): 28-week, randomised study (2:1 aboBoNT-A [n=28]: placebo [n=14]), assessing time to appearance or reappearance of reinjection criteria in patients with MAS score ≥2 treated 2–12 weeks post-stroke. All observed or volunteered adverse events (AEs) were recorded.

**Results**

MAS score improvements at Week 4 were greater in aboBoNT-A-treated patients than placebo in both studies (ABCDE S -1.5 vs. -0.5; ONTIME -1.25 vs. -0.25). At 12-weeks post-injection, fewer aboBoNT-A-treated patients versus placebo had MAS scores ≥2 in ONTIME (29.6 vs. 69.2%) and ABCDE (21.3 vs. 60.2%) (Table 1). In ONTIME, 11 (39.3%) aboBoNT-A-treated patients did not require reinjection for ≥28 weeks versus 2 (14.3%) for placebo. AboBoNT-A was well tolerated; most AEs were mild–moderate in intensity, with no clinically significant
differences in AEs between groups (Table 2). Six patients had treatment-related AEs: two in placebo groups (dysuria and complex regional pain syndrome), and four in aboBoNT-A groups (fatigue \(n=2\), pyrexia, muscular weakness). No serious AEs or deaths were considered treatment-related.

Introduction/Background

Long-term safety and efficacy of repeated abobotulinumtoxinA (aboBoNT-A) injections in patients with lower limb spasticity (LLS) after stroke or traumatic brain injury have been established, with improvements in walking speed and community ambulation observed during a 12-month open-label study, and no unexpected safety signals (Gracies et al. Neurology 2017). Here, we describe the frequency of repeated aboBoNT-A injections over the open-label study.

Material and Method

A phase 3, international, double-blind, single-treatment study (NCT01249404) of aboBoNT-A in the hemiparetic lower limb, followed by a 12-month open-label extension study (NCT01251367) with up to four additional treatment cycles, at least 12 weeks apart. Re-treatment was per investigator’s clinical judgement based on muscle tone, spasticity measures and other findings. Patients not requiring re-treatment completed the study.

Results

A total of 345 patients entered in open-label Cycle 1 were included in this analysis (Table 1). In Cycle 1, 38/345 patients withdrew and 307 completed the cycle. After Cycle 1, 10 patients completed the study without subsequent aboBoNT-A injections. After Cycle 2, 22/297 patients withdrew, 275/297 patients completed the cycle and 51 completed the study. Of 224 patients entering treatment Cycle 3, 13 withdrew, 211 completed the cycle and 72 completed the study. Overall, 38.6% (n=133) of patients required three or fewer injections of aboBoNT-A over the course of the 12-month study, 17.7% required two or fewer, and 2.9% required one injection.
Conclusion

The number of injections of aboBoNT-A required to treat muscle overactivity in patients with LLS varied between patients in this 12-month open-label phase 3 study, with almost 40% of patients requiring three or fewer injections based on physician clinical assessment. Decreased injection frequency may reduce the burden associated with treatment for patients and their caregivers/families.

Introduction/Background

Stroke is the second cause of mortality and the third cause of disability worldwide. Pain enhances spasticity and should be properly assessed and then addressed in these patients. We report a successful case of spasticity management using paraspinous lidocaine injection followed by functional electrical stimulation during an intensive in-patient stroke rehabilitation program.

Material and Method

A 52-year-old Caucasian man diagnosed with hemorrhagic stroke presented with incomplete right hemiparesis with upper and lower limb spasticity. Despite receiving daily physical therapy for the last two years, he had no motor or sensory improvement. His muscle strength was as follows: grade 3 in the shoulder joint, grade 1 in elbow pronation/supination, grade 0 in hand and wrist flexion and extension, grade 4 in hip flexors and knee extensors, and grade 3 in ankle dorsiflexors. "Pinch-and-roll" maneuver on the subcutaneous cellular tissue showed hyperalgesia of C5-C7 and L3-L5 dermatomes. He was on an intensive in-patient rehabilitation regime to address muscle strengthening and functional recovery. Paraspinous lidocaine 1% (without epinephrine) injections were performed at C6/C7 and L4/L5 levels. Dry needling was applied to the belly of the right deep flexor digitorum muscle.

Results

Significant reduction of hyperalgesia, hypertonia and spasticity was observed immediately after the intervention, with an associated increase in passive range of motion of the involved joints. Spasticity reduced from 3 to 1+ in the Ashworth modified scale. There was also an improvement in muscle strength, reaching grade 4 in the shoulder joint; and grade 3 in the elbow. By demonstrating preservation of neural movement pathways and partial muscle strength recovery, we feel that electrotherapy and physiotherapy/occupational therapy should have improved effectiveness.

Conclusion
In this case report, paraspinous lidocaine injections reduced dermatomal hyperalgesia, hypertonia and spasticity and they caused an increase in the range of motion of involved joints. These clinical effects facilitated the in-patient post-stroke rehabilitation program.

OBTURATOR NERVE BLOCK WITH AQUEOUS PHENOL REDUCES HIP ADDUCTOR SPASTICITY

F. Anwar

Introduction/Background

Spasticity is a cardinal symptom of the upper motor neuron syndrome. It affects the different individuals differently. Hip adductor spasticity can be very painful and result in postural abnormalities that interfere with walking, transferring and hygiene. Phenol block of the obturator nerve results in neurolysis reducing the hip adductor spasticity.

Material and Method

Patients with known spasticity in the lower limbs who had been assessed suitable for phenol nerve block had Modified Ashworth Scale (MAS) and intercondylar distances recorded before the phenol nerve block, the at 6 weeks and 6 month’s post phenol nerve block. Non-parametric Friedman test of differences among repeated measures was conducted from data at 0, 6 and 24 weeks.

Results

52 obturator nerves were blocked using 5% phenol. The procedure was bilateral in 38 patients and unilateral in 14 patients. There were 34 females and 18 males. Minimum age was 18 years and maximum age was 78 years with a mean age of 50.6 years. Majority of patients (28.8%) had a diagnosis of multiple sclerosis. There was statistically significant difference between the pre-injections MAS and intercondylar distance at 6 weeks and 6 months.

Conclusion

Spasticity of the lower limb, especially adductor muscle spasm, is a major source of long-standing disability and pain in neurological patients. It is a cost-effective procedure that leads to improved personal hygiene. It is operator dependent and needs skills and training to inject phenol without complications.

FIXED FOOT EXTRAPYRAMIDAL DYSTONIA AFTER DEEP BRAIN STIMULATION: PERCUTANEOUS TENOTOMY CAN IMPROVE WALKING. A CASE REPORT.
S. Le Franc¹, S. Butet¹, T. Honoré¹, F. Basselot², C. Haegalen³, I. Bonan¹
¹CHU Pontchaillou, Physical medicine and rehabilitation, Rennes, France
²CHU Pontchaillou, Orthopedic Surgery, Rennes, France
³CHU Pontchaillou, Neurosurgery, Rennes, France

Introduction/Background
Dystonia have been reported to be a problem in some surgically treated Parkinsonian patients (Tolosa 2006). Botulinum toxin injection can sometimes significantly improved foot dystonia in this population (Anupam Data Gupta 2016).

Material and Method
We report our diagnostic and therapeutic approach to a fixed deformation not improved by the toxin injection. A 65-year-old, male, undergoing a bi-pallidal deep brain stimulation surgery in 2016, present a right foot deformity (equino-varus 30° and toe claw). Walk with rolator and medium risk of fall according to BERG scale (35/56). The foot deformation wasn’t reducible by switching off the brain stimulation.

Results
Botulinum toxin injections (350UI incobotulinumtoxinA): no improvement. Anesthetic motor block of right posterior tibial nerve: no modification of deformation. Clinical examination under short general anesthesia: no improvement of the equine, even with addition of curare. This confirmed tendinous retraction, so surgical indication was retained. Achievement of tenotomies: calcaneous tendon elongation, posterior tibial, abductor of the hallux and tenotomy at the base of the 4 toes. After 5 weeks of immobilization, then 4 weeks of rehabilitation, complete reduction of the equine (0°), walking without technical aid and low risk of falling according to the BERG (53/56).

Conclusion
In extrapyramidal patient with fixed foot dystonia, tenotomies can efficienty correct the deformity and improve walking. It requires a rigorous diagnostic approach in a specialized department in order to carry out the least invasive surgery.

Keywords
extrapyramidal;dystonia;tenotomy

Foot Dystonia (FD) is a movement disorder characterised by sustained or intermittent muscle contractions causing abnormal, often repetitive movements resulting in pain, spasm and difficulty in walking. The most effective treatment for FD is botulinum toxin injection. The spatiotemporal gait analysis in Gait Rite is well validated and may help clinicians to record the outcomes more objectively. In this paper, we discuss the spatiotemporal gait parameters in FD pre-and post-botulinum toxin injection along with other lower limb functional outcomes.

Material and Method

Fourteen (14) adult patients with FD were assessed in the multidisciplinary spasticity clinic pre-and post-injection of botulinum toxin. We conducted gait analysis in the Gait rite system besides recording Fan Marsden Dystonia Scale (FMDS), Visual Analog Scale (VAS) of pain, Berg Balance Score (BBS), Unified Parkinson’s Disease Rating Scale- Lower Limb Score (UPDRSLL), Timed Up and Go (TUG) test and the Goal Attainment Scale (GAS).

Results

We used the random effects panel data estimators in Stata to examine the difference from before the intervention to after to assess whether there was significant change in gait parameters. In all models the test for the time effect was adjusted for age, sex, and side (left or right). We found that stride length increased significantly in both the affected (p=0.021) and unaffected leg (0.010) after treatment, and that the improvement in stride length was roughly the same in each leg. Similar results were found for step length (p=0.021) with improvement in the step length differential (p=0.016). The improvement in the lower limb functional outcomes were also significant (FMDS, p<0.001, VAS, p<0.001, TUG, p<0.001, BBG, p=0.001, UPDRSLL, p<0.001, GAS, p<0.001, GV, p= 028) except Cadence, p=0.367.

Conclusion

BT is effective in improving walking in foot dystonia as evidenced through gait analysis and improved lower limb functional outcomes.

CLINICAL AND INSTRUMENTAL GAIT ASSESSMENT IN ADULT WITH CEREBRAL PALSY AND GLUTEUS MEDIUS ANTERIOR FIBERS SPASTICITY BEFORE AND AFTER LOCAL TREATMENT WITH BOTULINUM TOXIN

F. Babany¹, P. Thoumie¹
¹Hôpital ROTHSCILD, Neuro-orthopedic rehabilitation, Paris, France

Introduction/Background

Gait with internal hip rotation is often observed in adult with cerebral palsy both in diplegic and hemiplegic forms. Walking disabilities could be the consequence of gluteus medius anterior fibers spasticity.

Material and Method

A monocentric prospective pilot study was to assess the clinical and paraclinical progression of hip internal rotation, velocity and Functional Ambulation Performance (FAP) score index. We included eight patients (nine hips) with a follow up to five weeks. Clinical (questionnaire, spasticity) and instrumental (walk on "GAITRite®") assessments were performed at the beginning and at the end of the study.

Results

The FAP was significantly higher (10%) after botulinum toxin (80 to 87, p<0.05). There was no significant impact on internal rotation and velocity. Patients felt better with a fluider gait and less fall.

Conclusion

Botulinum toxin improved gait performances in adult with cerebral palsy and gluteus medius anterior fibers spasticity. A randomized prospective multicentric study is required to confirm the preliminary results and to assess the impact of quality of life.

Keywords

cerebral palsy;gluteus medius anterior fibers spasticity;Functional Ambulation Performance (FAP)

Patients with traumatic brain injury (TBI) could suffer from spasticity but also from secondary focal dystonia. When constant and severe, dystonia could be painful and even source of tendinitis.

Material and Method

Here, we report the case of a 34yo woman who suffered from a severe TBI 20 years ago, which has been responsible for a right spastic and dystonic hemiparesia. A tibial nerve neurotomy was performed 10 years ago to treat an ankle clonus disturbing gait and upright balance. She recovered the ability to walk with the assistance of a cane, but presented with a talus pattern in both phases of gait due to a constant activation of her tibialis anterior muscle (TA). She complained of dorsal midfoot pain restraining gait to 100m (>1km anteriorly) and restricting her participation in several activities of daily living. Physiotherapy (cold therapy + deep transverse friction massage) failed to relieve the pain.

Results

Clinical examination revealed that pain was localized at the distal insertion of the TA and increased with stretching and isometric contraction. The MRI scan revealed a distal tendinopathy of the TA associated with interstitial tears and a tenosynovitis. We injected 70U of onabotulinum toxin A in the TA under ultrasound guidance. The patient reported a total relieve of the pain 2 weeks later, lasting at the 5 months follow-up, and have recovered her anterior walking perimeter. The treatment did not impair foot clearance during the swing phase of gait.

Conclusion

Muscle overactivity, particularly if inducing a constant contraction of muscle like in dystonia, can be a risk factor of tendinopathy. As already described in tendinopathy related to sport conditions (e.g. tennis elbow), botulinum toxin treatment could be of interest in tendinopathies in the context of muscle overactivity in brain injured patients.

4CMCR Les Massues, Physical medicine and rehabilitation, Lyon, France
5Fondation Il dys, Pediatric Physical medicine and rehabilitation, Brest, France

Introduction/Background

Background: Botulinum toxin injection is increasingly used in children with musculoskeletal disorders. The literature supports the hypothesis that the earlier the injection is carried out the better the efficiency is.

Objective: To report current evidence regarding the safety of intramuscular BTI in children with orthopaedic- and neurological-related musculoskeletal disorders under the age of 2 years.

Material and Method

Data Source: PUBMED, The Cochrane Library, and Science Direct, Google Scholar and Web of Science.

Study Selection: Two reviewers independently selected studies based on predetermined inclusion criteria.

Data Extraction: Data relating to the aim were extracted. Methodological quality was graded independently by 2 reviewers using the Physiotherapy Evidence Database assessment scale for randomized controlled trials (RCTs) and the Downs and Black evaluation tool for nonRCTs. Level of evidence was determined using the modified Sackett scale.

Results

Data Synthesis: Data of 473 infants were analysed. Fifty-five infants had cerebral palsy, 112 had obstetric brachial plexus palsy, 257 had clubfoot and 44 had congenital torticollis. No studies reported any severe adverse event that could be attributed to the BTI. The rate of mild to moderate adverse events reported varied from 5 to 25%. Results regarding efficacy were
preliminary, dependant on the pathology and limited by the small number of studies and their low levels of evidence.

**Conclusion**

**Conclusion:** BTI is already widely used as an early treatment for this age group. The safety profile of BTI in infants appears similar to that of older children and risks appear more related to the severity of the pathology and the location of the injections than to the toxin itself. With regard to effectiveness, other studies with higher levels of evidence should be carried out for each specific pathology.

ISPR8-0614
IMPROVED RESPONSE AFTER INTRATHECAL ADMINISTRATION OF BACLOFEN IN A PATIENT WITH IMPAIRED CONSCIOUSNESS – A CASE STUDY
Y. Sacher¹, K. Cismariu-Potash¹, Z. Zion²
¹Loewensteīn hospital, Traumatic Brain Injury, Raanana, Israel
²Sheba hospital, Neurosurgery, Tel Aviv, Israel

Introduction/Background

Disorders of consciousness present some of the most difficult diagnostic and therapeutic challenges in brain rehabilitation. Within the spectrum of these disorders, diagnosis remains clinical and depends on the response to various stimuli in the environment rather than objective physiological markers. In recent years, various cases have been reported in the medical literature in which patients with such diagnoses reacted to various stimuli indirectly. Spasticity is a common sequela of brain injury and may significantly impair a patient’s ability to respond to stimuli in their environment.

Material and Method

A case study of a patient in a state of minimal reactivity demonstrating significantly improved responses to their environment following intrathecal injection of Baclofen.

Results

A 59-year-old man who was admitted for rehabilitation following subarachnoid hemorrhage secondary to anterior coronary artery aneurysm (ACA) requiring subsequent periventricular shunt placement. At admission, the patient presented in a vegetative state. During hospitalization, there was a temporary improvement in level of consciousness until the appearance of infection along the VPS drain necessitating removal of the shunt. Upon completion of treatment, the patient returned to our department with inconsistent, minimal reactivity on exam. Due to severe spasticity in all four limbs unresponsive to oral treatment and local injection, a one-time intrathecal injection of Baclofen was administered. Directly following treatment, the patient demonstrated decreased tone and immediate improvement in responsiveness and ultimately the production of a number of intelligible words and phrases.

Conclusion

In evaluating patients suffering from disorders of consciousness, it is important to recognize that limited responsiveness results not only from the impairment of information reception, processing, and response initiation, but also from tonal disturbances that may be causing difficulty in performing such movements. This case study supports previous literature demonstrating improved communication following cellophane pump implantation following severe head injury.

USE OF BOTULINUMTOXINA FOR SIMULTANEOUS MULTIPLE INDICATIONS IN NEUROLOGICAL PATIENTS

I. Piccolo¹, M. Citeri¹, M. Zarbo¹, L. Frediani¹, A. Leo¹, M. Spinelli¹
¹ASST Grande Ospedale Metropolitano Niguarda, Unità Spinale Unipolare, Milan, Italy

Introduction/Background

This is a preliminary retrospective cohort study to determine the occurrence of all adverse events after the simultaneous treatment with botulinumtoxin A for multiple indications, with at least a urologic one for injection. A substantial number of patients may have multiple indications for botulinumtoxin A injection. The treatment for certain conditions may be delayed due to the cumulative dose limitation within a three months interval, based on FDA trials. This delay may significantly impair a patient’s function, rehabilitation programme and, at least, the quality of life; because of this sometimes it is very difficult to stratify the priority of treatment. All our patients needed, at the same time, a bladder and musculoskeletal treatment with botulinumtoxin A.

Material and Method

4 traumatic SCI, 2 vascular SCI, 1 Arnold-Chiari malformation, 1 infant cerebral palsy. Range of age between 14 and 53y. All patients are affected by neurogenic bladder sphincter dysfunction (NBSD) non-responder to antimuscarinic therapy. Toxin forms: 3 patients abobotulinumtoxin A, dosage range 950-1500 U; 5 patients onabotulinumtoxin A, dosage range 300-400 U. Treatment site: 3 patients bladder sphincter and lower limb; 5 patients detrusor muscle and upper and lower limb.

Results

We registered in only one case (abobotulinumtoxin A 950 U) as adverse event the development of a temporary hand weakness, that already occurred after a previous treatment with botulinumtoxin A.

Conclusion

These data support the evidence of the possibility to perform – in very selected patients – a simultaneous treatment of overactive bladder and limb spasticity with botulinumtoxin A.

Introduction/Background

Muscle hypertonia can be great problem in rehabilitation, especially in management of patient with different types of tonus. Rehabilitation team commonly have an experience in controlling spasticity and rigidity, but paratonia, which is associated with cognitive impairment is less common in rehabilitation. The aim of case report was to present a successful result of achieving functional goals through inpatient interdisciplinary rehabilitation of patient with association of spasticity, rigidity and paratonia.

Material and Method

Patient AS, male 68 years old, formerly independent, including employment. Few years ago was assessed due to slowness and memory loss, and Parkinson disease and Dementia were diagnosed. L-DOPA was prescribed with good functional effect. Recently was hospitalized with acute presentation of Left Hemiplegia and Neglect. Due to imaging, Ischemic stroke in right MCA and PCA territory was diagnosed. After receiving TPA treatment was transferred to Rehabilitation Department.

Results

AS was motivated despite of cognitive impairment and neglect. He was totally dependent with FIM 47, the stuff used patient lift transfer with assistance of at least 2 helpers. The main goal was outlined as reaching transitions with one helper for being able to return home. His main problem was defined as high muscle tonus, especially in lower extremity and back. Staff examination with neurologist was organized was decided that the main barrier is association of spasticity, rigidity and paratonia. From the list of treatment options elevation of L-DOPA dose was selected with continuation of intensive training of transfers. After the intervention his muscle tone decreased and enabled an effective use of core muscles synergistically for better motor activity. After 75 days FIM was 57 and he returned home with ability to stand with walker and make transfers with one assistant.

Conclusion
Patient with association of spasticity, rigidity and paratonia can achieve appropriate functional goals while combining different types of rehabilitation approaches.

INTRATHECAL BACLOFEN THERAPY – 18 YEARS OF EXPERIENCE IN THE CENTER OF MEDICINE AND REHABILITATION OF ALCOITAO (CMRA)

S. Estrela Rego¹, I. Amorim², B. Condeça², F. Faria²

¹Centro Hospitalar do Algarve - Faro, Physical and Rehabilitation Department Physical and Rehabilitation Department, Faro, Portugal
²Centro de Medicina de Reabilitação de Alcoitão, Physical and Rehabilitation Medicine, Lisbon, Portugal

Introduction/Background

Spasticity occurs in a variety of neurological disorders related to upper motor neuron lesion. Baclofen is the most widely used antispastic agent. The infusion of intrathecal baclofen (ITB) is a safe option for severe spasticity, refractory to conventional oral therapy.

CMRA began using this therapy in 1999 with the creation of “ITB appointment”, where patients were selected according to indications and contraindications to ITB.

The purpose of our work was to make a clinical and epidemiological characterization of the population under ITB therapy in CMRA. Evaluation of the time elapsed since the lesion/diagnosis and the beginning of therapy.

Material and Method

Retrospective, descriptive study of the population under ITB therapy follow-up in CMRA between 1999 and 2017.

Results

We studied 23 patients, 6 (26.08%) female and 17 (73.91%) male, with a mean age of 48.8 years-old.

19 patients presented SCI, 14 (60.86%) of traumatic origin, 3 patients (13.04%) due to sequelae of intramedullary tumors and 2 (8.69%) to sequelae of Transverse Myelitis. 3 (13.04%) patients presented Cerebral Palsy and 1 (4.34%) Multiple Sclerosis.

Of the 19 SCI patients, 12 (63.15%) were cervical lesions, 8 (66.66%) incomplete and 4 (33.33%) complete injuries. 7 (36.84%) were paraplegias, 5 (71.42%) were incomplete and 2 (28.57%) were complete injuries.

The mean time of placement of the baclofen pump was 4.37 years after the date of the injury. A
case (4.35%) of double tolerance was described and controlled with two drug holidays. All patients showed improvement of spasticity of the lower limbs according to the modified Ashworth Scale (MAS).

Conclusion

The decision to initiate IBT should be weighed case by case, on a cost-benefit basis.

In our sample, the majority of patients had sequelae of SCI, most of them were tetraplegias. The mean duration of injury until initiation of therapy was 4.4 years. The half-life of the baclofen pump is in accordance with literature.

PLACE OF BOTULINUM TOXIN IN MANAGEMENT OF SPASTICITY: EXPERIENCE IN DEPARTMENT OF PHYSICAL MEDICINE AND REHABILITATION OF CASABLANCA
Y. moigny.gaj1, N. kyal1, S. hrar1, L. fatima1, E.F. abdellatif1
1Ibn Rochd University Hospital, medecine physique et readaptation, Casablanca, Morocco

Introduction/Background
Botulinum toxin (BT) injections have evolved over the past 25 years into a safe and effective therapeutic in a variety of neurologic disorders. Botulinum toxin is now being a first line treatment for focal spasticity and focal dystonia, improving functional disability and quality of life in the most of cases.

The aim of our study was to describe the current Moroccan practice for the use of BT injections to treat spasticity.

Material and Method
Prospective study of 78 patients with spasticity or focal dystonia treated at our center from January 2015 to July 2017. Both ultrasound or electrical stimulation guided botulinum toxin injections are employed to isolate muscles. The modified Ashworth score (MAS), functional independence measure (FIM) and the Barthel scale were assessed pre- and post- BT injections of muscles.

Results
Seventy eight patients were included. Mean age was 33,1 years and M/F sex ratio 1,3. Main clinical features were: stroke( 42,54%) ; cerebral palsy ( 16,20%) ; spinal cord injury( 10,13%) and traumatic brain injury(10,13%. The most aim of treatment (43, 5 %) was function improvement. One month after botulinum toxin injection, significant improvements were noted in the modified Ashworth score, the FIM and the Barthel scale.

Conclusion
BT is a useful intervention in the treatment of spasticity with the majority of patients demonstrating improvement on objectives measures of tone and function and reporting improvement on subjectives measures. Associated with physical therapy, BT allows optimal management of spastic patients. If the effectiveness of botulinum toxin in spasticity is proven as evidenced by our experience. The difficulties encountered in our practice in Morocco are a lack of reimbursement of toxin by medical insurance organizations.

LOW-DOSE BOTULINUM TOXIN FOR THE TREATMENT OF SPASTIC CHILDREN WITH CEREBRAL PALSY

Introduction/Background

The treatment of children with cerebral palsy (CP) with Botulinum toxin A (BoNT-A) injections is well established, safe and effective. However, a standardized injection strategy is still missing and the used dosage has escalated over the years. The aim was to analyze the efficacy and safety of a lower dose of BoNT-A injections into lower limb in children with CP.

Material and Method

We analyzed retrospectively BoNT-A injections for 63 children (25 girls and 38 boys) with spastic CP. Children received 1-7 repeated injections and adapted physiotherapy. Children were classified according to the GMFCS. Treatment results were evaluated with the modified Ashworth scale. Side effects, total dose and dose per body weight were analyzed.

Results

Multilevel BoNT-A injections were indicated for 30 patients with spastic forms of CP, and in most of cases, the total dosage was 103.1 ± 20.8 U Allergan for Botox® and 473 ± 105.9 U Speywood for Dysport®. Doses for each muscle in U/kg were 1.5 ±0.5 U Allergan for Botox® and 3 ± 0.7 U Speywood for Dysport®. The total doses of BoNT-A and the intervals between the repeated injections were stable for each patient. Side effects reported, out of which 10, were generalized and/or focal distant. Average Modified Ashworth scale decreased 1 point in each session. These effects were retained at 3.5±1.3 months.

Conclusion

The lower dose ranges suggested for CP are effective and safe for the reduction of spasticity in lower extremities in one treatment session.

Introduction/Background

Spasticity is the common complaint among patients with stroke. Acupuncture has increasingly been used for spasticity management after stroke. The aim of the present study was to summarize and evaluate evidence on the effectiveness of acupuncture in alleviating the spasticity after stroke.

Material and Method

Five databases were searched from inception through October 2017 without language restrictions. Randomized controlled trials (RCTs) were included if acupuncture was compared to placebo or other conventional therapy for treatment of spasticity after stroke. Assessments were performed primarily with Modified Ashworth Scale (MAS).

Results

A total of 186 studies were identified; 5 RCTs met our inclusion criteria. Meta-analysis showed that acupuncture is effective in reducing the spasticity after stroke, as assessed by MAS (weighted mean difference, 0.72; 95% confidence interval [CI], 0.29–1.14; P<0.001). A subgroup analysis showed that acupuncture significantly decreased wrist, knee, and elbow spasticity in post-stroke patients. Heterogeneity could be explained by the differences in control, acupoints, and the duration after stroke occurrence.

Conclusion

Our results suggest that acupuncture could be effective for treating spasticity after stroke. However, further studies are needed to confirm the role of acupuncture in the treatment of this disorder.

Introduction/Background

Botulinum toxin (BTX) injection therapy is known to be effective for control of hyper muscular conditions and involuntary movements. Since 2010 in Japan, BTX therapy has been widely used for patients with post-stroke spasticity, especially the effectiveness is often recognized in the chronic stage of rehabilitation. However, in some patients spasticity is observed in early stage, which can be cause of inhibitory role for rehabilitation and activity of daily life. We studied the effectiveness of BTX therapy with rehabilitation for patients with spasticity in subacute stage (3-6 months after onset) in the kaifukuki rehabilitation hospital. Kaifukuki rehabilitation is determined as the integrated rehabilitation ward system, commonly in Japan, for the convalescent stage with cerebrovascular diseases (CVD) and so on.

Material and Method

In the 15 cases with spasticity, we applied to BTX injection into the target muscles using standard injection procedure. Onset etiologies were 9 cases with CVD, 2 cases with brain injury, 4 cases in spinal cord disorders. The patients were evaluated with the assessment of scales such as range of motion (ROM), modified Ashworth scale (MAS), functional independence measure (FIM), and video recording for walking speed and difficulty of movement of upper extremity of the injected side.

Results

All the patients achieved functional improvement by BTX injection therapy, especially in the point of functional improvement (7 cases), in range of motion (5 cases) and in reduction of muscle pain (3 cases). Additional BTX injection was required in 5 cases after more than 3 months of the first BTX therapy.

Conclusion

The degree of spasticity may be various in each case, in some patients with spasticity earlier injection of BTX may be effective in the recovery course after neurological damage.

EFFECTS OF BOTULINUM TOXIN TYPE A TREATMENT COMBINED WITH INTENSIVE REHABILITATION FOR GAIT IN POST-STROKE PATIENTS
Y. Uchiyama¹, T. Koyama², W. Yousuke³, M. Katsutani⁴, N. Kodama⁵, K. Domen¹
¹Hyogo College Of Medicine, Department of Rehabilitation Medicine, Nishinomiya City, Japan
²Nishinomiya Kyoritsu Neurosurgical Hospital, Department of Rehabilitation Medicine, Nishinomiya City, Japan
³Sasayama Medical Center Hyogo College of Medicine, Department of Rehabilitation Medicine, Sasayama City, Japan
⁴Nishinomiya Kyoritsu Rehabilitation Hospital, Department of Rehabilitation Medicine, Nishinomiya City, Japan

Introduction/Background

The aim of this study was to examine the effects of botulinum toxin type A (BoNT-A) treatment combined with intensive rehabilitation for gait compared with intensive rehabilitation alone in patients with chronic stroke.

Material and Method

A comparative case series design was used. Subjects were 19 patients with chronic stroke and spastic hemiplegia. In 9 patients (group I), BoNT-A was injected into spastic muscles of the affected lower limbs, followed by a four-week, inpatient intensive rehabilitation program. In the other 10 patients (group II), a four-week, inpatient intensive rehabilitation program alone was first provided (control period), followed by the same treatment protocol in group I. The Modified Ashworth Scale (MAS) scores of ankle plantar and knee flexors, range of motion (ROM) of ankle dorsiflexion and knee extension, gait speed in 10-Meter Walking Test, 6-Minute Walking Distance Test (6MD) scores, Timed Up and Go Test (TUG) scores, and Berg Balance Scale scores were evaluated every four weeks following baseline assessments.

Results

All results except for the MAS score of knee flexor and the ROM of knee flexion improved in group I and the gait speed, 6MD, and TUG score improved in group II. Inter-group comparisons at week 4 showed significantly greater improvements in the MAS score of ankle plantar flexor, ROM of ankle dorsiflexion, and 6MD in group I than in group II (p=0.016, 0.011, and 0.009, respectively). Inter-group comparison between group I at week 4 and group II at week 8 showed no significant difference in the change of any assessment.

Conclusion
BoNT-A treatment for lower-limb spasticity combined with intensive rehabilitation was effective in improving spasticity and the 6MD compared with intensive rehabilitation alone in patients with chronic stroke.

Keywords

spasticity; gait disorder; stroke

Disclosure statement:
The authors received honoraria from GlaxoSmithKline (Tokyo, Japan) for presentations on the benefits of BoNT-A. No author has a personal financial interest in BoNT-A or in any of the methods used in this research.
Introduction/Background

Spasticity can have a considerable impact on patients’ lives, causing pain and loss of mobility with resultant burden to patients and caregivers. Botulin toxin-A (BoNT-A) injections have proven to be an efficacious and well tolerated treatment for spasticity.

The objectives were: (1) to measure the impact of spasticity on patients’ and caregivers’ employment and quality of life, (2) to better understand patient perceptions of BoNT-A injections.

Material and Method

A survey is currently being conducted by Carenity (an online patient community) in the US and Europe (France, Germany, Italy, Spain, UK). A committee (a patient, 3 neurologists and a physiatrist) approved the questionnaire. This analysis reports data from 333 participants enrolled to date, (target: 600) including 210 patients with spasticity receiving BoNT-A injections, and 123 caregivers.

Results

The respondents’ spasticity was caused by Multiple Sclerosis (40%), Stroke (22%) and Spinal Cord Injury (9%). Mean age was 47.6 years and 54% of patients were women.

Impact on work:

- 50% of patients work part-time or do not work due to their condition
- 32% of caregivers limit their work activity to help the patient
- Professional life was the most affected area (mean=6.9/10, 0=no impact, 10=a great impact)
Spasticity also had an impact on patients' leisure activities (mean=6.7/10), self-esteem (mean=6.6/10) and sexual life (mean=6.6/10).

The overall level of satisfaction regarding BoNT-A injections was acceptable (mean=5.9/10), despite the inconvenience associated with the injections, including pain during/after injections (mean=4.1/10), logistic constraints such as travel (mean=3.8/10) or difficulties related to frequency of injections (mean=3.5/10). 71% of respondents would feel benefits from having 1 or 2 fewer injections per year.

Conclusion

These results emphasize the multifaceted impact of spasticity on patients’ and caregivers’ quality of life. Patients receiving BoNT-A injections are mostly satisfied with their treatment, but report some inconvenience and would prefer less frequent injections.

Introduction/Background

OnabotulinumtoxinA treatment for spasticity is variable as treatment is individualized and dependent on numerous factors. Here, we explore real-world patterns of onabotulinumtoxinA utilization in patients with upper limb spasticity over 2 years.

Material and Method

Multicenter, international, prospective, observational study (NCT01930786), examining adult patients with focal spasticity across multiple etiologies treated with onabotulinumtoxinA at their physician’s discretion. Assessments include utilization (each treatment visit) and patient/physician satisfaction (5±1 weeks post-treatment).

Results

Patients (N=731) were on average 53.6 years of age (18.5-93.2 years), 52% female, and predominantly Caucasian (77%). Stroke was the most frequently reported etiology (56%). The most commonly treated upper limb spasticity presentation was clenched fist (52%). Across all clenched fist treatment sessions (N=1505), percentage injected and dose (mode) injected into each muscle are as follows: flexor digitorum superficialis (86%, 50U), flexor digitorum profundus (80%, 50U), flexor pollicis longus (25%, 20U), flexor pollicis brevis (9%, 25U), other (6%, 20U). EMG was frequently used to localize muscles to treat clenched fist (>44%). Across all treatment sessions, 93% of physicians and 86% of patients reported being satisfied/extremely satisfied that treatment helped manage spasticity, 84% of physicians and 76% of patients reported
treatment benefit was sustained, and 99% of physicians and 92% of patients would definitely/probably continue treatment with onabotulinumtoxinA. 261 patients (36%) reported 831 adverse events (AEs); 23 AEs in 20 patients (3%) were considered treatment-related. 94 patients (13%) reported 195 serious AEs; 3 serious AEs in 2 patients (0.3%) were considered treatment-related. No new safety signals were identified.

Conclusion

ASPIRE provides valuable, real-world data on dosing, injection guidance, and muscle targeting over 2 years, that may help guide clinical strategies. This study captured the individualized nature of onabotulinumtoxinA utilization for spasticity, while demonstrating consistently high satisfaction. These results add to the body of evidence on the safety and effectiveness of onabotulinumtoxinA for spasticity.

Introduction/Background

The modified Ashworth scale (MAS) is the most frequently used method in the assessment of spasticity in clinical practice. Ultrasound elastography is an imaging method that assesses the viscoelastic characteristics of tissues noninvasively.

Our objective in this study was to assess the changes in gastrocnemius muscle (GCM) stiffness after botulinum toxin A (BTA) injection in children CP by using ultrasound elastography and to research the usability of this technique.

Material and Method

Ten children with spastic CP were enrolled in the study. BTA injection treatment was applied to GCM. Muscle stiffness was measured with the ultrasound elastography before the procedure, 1-2, 3 weeks, and 6 month post-injection. Spaticity was also assessed with the MAS at about the same time. Shear wave velocity (SWV) values and MAS scores before and after the treatment were compared.

Results

The mean age was 5.9 years and the mean body weight was 19.9 Kg. The average MAS score values were 2 before BTA. Abobotulinum toxin A injections were administered to 5 children with an average dose of 100 units and Onabotulinum toxin A injections were administered to 5 children with an average dose of 60 units in GCM. SWV values were measured as 2.38 m/s before BTA and as 1.6 m/s after BTA. This study is currently under progress.

Conclusion

There are few studies that have assessed muscle stiffness after BTA injection in children with spastic CP using ultrasound elastography. These studies have concluded that the combined use of ultrasound elastography with clinical scales can be useful in the assessment of spasticity.

⁴Institut mohamed Kassab d’orthopédie,
Service de médecine physique et réadaptation fonctionnelle, Tunis, Tunisia

Introduction/Background

The multidisciplinary management of spasticity in children with central neurological conditions, including cerebral palsy, involves different specialties such as the physical physician, the orthopedic surgeon or the equipment masters. The goal is to offer the most appropriate therapeutic option in the good time.

Material and Method

Retrospective study of patients with cerebral palsy seen in a monthly multidisciplinary spasticity consultation at the physical medicine department of the Institute of Orthopaedy Mohamed Kassab during the year 2017.

Results

Fifty-five patients were seen at the multidisciplinary spasticity consultation, 20 boys and 35 girls, mean age was 9.8 years.

Therapeutic recommendations were: injection of botulinum toxin in 15 patients, surgical reduction of hip dislocation in 2 patients, lower limb plaster under general anesthesia in 5 patients, prescription of Garchois brace in 3 patients, tendon lengthening in 7 patients, a posterior tibialis muscle transfer in one patient, a double arthrodesis of the ankle in 2 patients, a neuro-motor block in 5 patients, rehabilitation with a renewal of the orthopedic equipment of day and night for other patients.

Conclusion
The development of a therapeutic strategy requires a close collaboration between the different specialties, especially when the clinical presentation can be very complex. The family must be involved in the decisions to ensure its membership.

THE CLINICAL EFFICACY OF BAIMAI OINTMENT COMBINED WITH TRADITIONAL CHINESE MASSAGE IN THE PATIENTS OF POST-STROKE WITH LIMP SPASM

R. Pan¹, Q. Wang²
¹Guangdong Provincial Hospital of Traditional Chinese Medicine, Rehabilitation department, Guangzhou, China
²Guangzhou University of Chinese Medicine, Second Clinical Medical College, Guangzhou, China

Introduction/Background

Post-stroke spasm has high incidence and leads to limb pain, dyskinesia, even deformity, furthermore, it increases the treatment cost, which further hinders the recovery of limb motor function. It has many effective treatment, those have many side effects and cost more. Spasm belongs to athetosis in Chinese medicine. Qi deficiency and blood stasis is the mainly etiology and pathogeny of athetosis. Baimai ointment and Chinese massage can replenish qi and activate blood, so that relieve the spasticity and decrease the muscular tone and improve the ROM.

Objective To explore the effect on limb spasm degree, motor function and activities of daily living in the post stroke patients with Limb spasticity treated with of Baimai ointment, raditional chinese massage and modern rehabilitation training.

Material and Method

61 patients were divided into the treatment group (31 cases) and control group (29 cases) according to random numbers generated by computer. The two groups accepted basic treatment and besides, the treatment group accepted Baimai ointment and chinese massage. The duration of treatment was 4 weeks. Before and after treatment, Modified Ashworth scale (MAS) Fugl-Meyer assessment scale (FMA) and the modified Barthel index (MBI) were evaluated in the patients.

Results

There has no statistic difference in the index scores among the two groups before treatment ( P >0.05). After treatment, the MAS scores were decreased, FMA and BMI were increased evidently as compared with those before treatment ( P <0.05), the difference was statistically significant. Furthermore, the variation of scores in the treatment group were greater than that in
the control group (\(P < 0.05\)).

THE EFFECTS OF MATRIX RHYTHM THERAPY ON HAND FUNCTIONS IN HEMIPARETIC INDIVIDUALS: A PRELIMINARY REPORT

F. Altug¹, A. Ünal², G. Tıkaç³, A. Ahmed Hamood Al Sakka², U. Cavlak²
¹Pamukkale University, School of Physical Therapy, Denizli, Turkey
²Pamukkale University., School of Physical Therapy and Rehabilitation., Denizli, Turkey
³Pamukkale University., School of Physical Therapy and Rehabilitation., Denizli, Turkey

Introduction/Background

Matrix rhythm therapy was formed by tracing the microvibrations of 8-12 Hz, where the healthy muscle cells in our body have. Matrix Rhythm Therapy helps normalize alpha-gamma tonus in the muscles by activating metabolism. This study was planned to investigate the effects of Matrix Rhythm Therapy applied on spastic muscle in hemiparetic individuals on muscle tone and hand functions.

Material and Method

A total of 7 hemiparetic individuals (4E, 3K) were included in the study. Modified Ashworth Scale was used to determine the severity of spasticity in the upper extremity. The decrease in joint motion due to spasticity was determined by goniometric measurement. The Box & Block test and the Nine-hole peg test were used to evaluate hand functions. Matrix rhythm therapy was applied one hour as 3 days a week for 4 weeks. All assessments were repeated before and after treatment.

Results

The mean age of hemiparetic individuals is 49 ± 16.85 (age range: 20-63) years. Mean duration of hemiparesis was 16.71 ± 17.47 months. Statistically significant improvements were found in the total score of the Modified Ashworth Scale after matrix rhythm therapy, in elbow extension, finger flexion and extension active movements in goniometric measurements (p<0.05). We found that Box and Block test score was increased (p<0.05). At the same time, it was found statistically significant improvement on nine-hole peg test score (p <0.05).

Conclusion
Matrix rhythm therapy applied to spastic muscle in hemiparetic individuals contributes to spasticity inhibition by reaching to the normal rhythm. Hemiparetic individuals may be treated with Matrix rhythm therapy in the earliest period, thus increasing the functional use of the upper extremity.

\(^5\)Hannover Medical School, Movement Disorders Section - Department of Neurology, Hannover, Germany
\(^6\)Icahn School of Medicine at Mount Sinai, Department of Neurology, New York, USA

Introduction/Background

Effective treatment of disabling, multifocal upper- and/or lower-limb spasticity may require botulinum neurotoxin doses higher than those indicated currently. TOWER (NCT01603459) previously investigated the safety and efficacy of escalating incobotulinumtoxinA doses (400–≤800U) in adults with upper- and lower-limb spasticity due to stroke or other cerebral causes (Wissel Neurology, 2017). Here we report further data regarding the impact of escalating doses on multi-pattern treatment and muscle dosing.

Material and Method

Treatment comprised three injection cycles (ICs) with escalating total doses on the same body side, each followed by 12–16 weeks’ observation: IC1, 400U into the upper limb and/or lower limb; IC2, 600U into the upper limb and/or lower limb; and IC3, 600–800U into the upper and lower limbs (maximum 600U per limb). At screening, investigators selected a target clinical pattern for treatment in all ICs. Other patterns were treated at the investigator’s discretion.

Results

In total, 155 patients (mean [SD] age, 53.7 [13.1] years) were enrolled, with spasticity due to stroke (85.2%) or other cerebral causes (14.8%). The number of clinical patterns and muscles treated increased with escalating dose at each IC. In IC1, IC2 and IC3, respectively, 608, 743 and 811 clinical patterns and 46, 49 and 53 different muscles were treated in 155, 152 and 140 patients. The number of patients treated for the most frequently injected clinical patterns in the upper (flexed elbow) and lower limb (pes equinovarus), respectively, increased from 75.5% and 56.8% of patients in IC1 to 88.6% and 87.1% in IC3.
Conclusion

Escalating incobotulinumtoxinA doses enabled a more comprehensive multi-pattern treatment approach, with an increase of approximately 33% in clinical patterns and more muscles treated with the highest dose (600–800U) versus the initial dose (400U) in patients with upper- and lower-limb spasticity.

UPPER LIMB SPASTICITY: IS THERE ANY FUNCTIONAL EFFECT OF LOCAL TREATMENT?
J. Levy1,2, F. Molteni2, T. Lansaman2, N. Roche1,2, D. Bensmail1,2

1University of Versailles Saint-Quentin-en-Yvelines- School of Medicine, INSERM U1179 - Neuromuscular handicap, Montigny-le-Bretonneux, France
2APHP - Raymond Poincaré Hospital, Physical and rehabilitation medicine, Garches, France
3Valduce Hospital, Villa Beretta Rehabilitation Center, Costa Masnaga- Lecco, Italy

Introduction/Background

Spasticity is characterized by an increased muscle tone following lesions of the central nervous system such as strokes. It is a major cause of impairment and disability, especially when it affects the upper limb, and can be focally relieved by intramuscular injections of botulinum toxin (BT). Therefore, whether treating upper limb spasticity (ULS) has functional effects and improve the active use of the affected upper limb remains controversial. We hereby aim to assess the functional effects of focal treatment of upper limb spasticity, among the existing literature.

Material and Method

We searched the MedLine and Cochrane databases for trials, reviews and meta-analyses assessing the effects of BT injections in ULS. This was a non-systematic narrative review, and the selection of articles was based on the authors’ expertise.

Results

Most studies assessed impairments and passive function outcomes by means of patients-defined main therapeutic targets using the disability assessment scale or the goal attainment scaling. Impairments and passive function goals prevailed on active function and participation, and were more frequently achieved than the latter. Trials and meta-analyses did not show a significant improvement of participation in upper limb activities of daily living (ADL).

Discussion – The effects of BT injections on impairment and passive function are linked to better kinematic parameters, nonetheless, the relationship between the relief of spasticity and better upper limb activity has not been established. Not every patient with ULS could have functional benefits from BT injections, as the motor impairment may largely prevail upon spasticity in causing disability. It is likely that patients, who could have the best functional outcome, should have the least underlying motor impairment.

Conclusion

Further studies are needed to assess the functional effects of focal treatments of ULS, in a well-selected subset of patients, with mild to moderate motor impairment.

Introduction/Background

Botulinum neurotoxin is well established for treating upper-limb spasticity. However, few studies have assessed efficacy in the shoulder. TOWER (NCT01603459) previously evaluated the safety and efficacy of escalating incobotulinumtoxinA doses (400U–≤800U) in adults with upper- and lower-limb spasticity due to cerebral causes (Wissel Neurology, 2017). This post-hoc analysis assessed the efficacy and safety of incobotulinumtoxinA for treating shoulder spasticity, as part of upper-limb treatment.

Material and Method

Patients received three injection cycles (IC) with escalating incobotulinumtoxinA doses on the same body side (400U, 600U and 600–800U; ≤600U per limb including optional shoulder dose, planned range 100–250U). Here, patients who had received shoulder treatment were compared with those who had upper-limb treatment, without shoulder treatment. Ashworth Scale (AS) scores for shoulder adduction, extension and internal rotation were added to form the AS shoulder sum score (AS-SSS), to fully assess joint function. The incidence of adverse events (AEs) was assessed.

Results

The number of patients receiving shoulder treatment increased with escalating incobotulinumtoxinA dose at each IC, peaking in IC3 (n=84/140 [60.0%]; mean [SD] shoulder dose 118.4 [60.2] U). From baseline to 4 weeks post-injection in IC1, IC2 and IC3, respectively, the mean (SD) AS-SSS improved by −1.1 (1.9), −1.7 (1.8) and −1.7 (1.8) in patients treated in the shoulder and −0.5 (1.3), −0.8 (1.6) and −0.9 (1.4) in patients who were not. Multiple regression analysis adjusting for IC baseline showed significant improvement in AS-SSS with incobotulinumtoxinA shoulder dose in IC3 (p=0.0081). AEs occurred in 52.1% of patients treated in the shoulder and 61.0% in those who were not. No differences were observed in AE
patterns and no unexpected safety concerns were reported with shoulder treatment or higher incobotulinumtoxinA dose.

Conclusion

Results support the efficacy and safety of incobotulinumtoxinA for treatment of shoulder spasticity as part of upper-limb treatment.

SPORADIC DISTANT NEUROTOXIN EFFECTS IN THE CHRONIC TREATMENT OF SPASTICITY
M.C. Wainberg\textsuperscript{1}, M.L. Dombovy-Johnson\textsuperscript{1}, B.A. Schultz\textsuperscript{1}
\textsuperscript{1}Mayo Clinic, Physical Medicine and Rehabilitation, Rochester- MN, USA

Introduction/Background
Neurotoxin therapy is an effective component of comprehensive spasticity management. The two cases presented demonstrate adverse effects.

Material and Method
Patient S is a 60 year old female with right spastic hemiparesis due to left hemispheric stroke (age 46) treated with therapy, bracing, oral baclofen. Patient R is a 28 year old female with left spastic hemiparesis due to hemispherectomy (age 6).

Results
For patient S, onabotulinumtoxinA (ONA) was initiated at 300 units (u) to the right upper extremity (RUE), advanced to 500u. She received injections every 3-3.5 months for over 9 years and continued to function independently. At routine follow-up, she related left upper extremity (LUE) weakness that she noted but didn't report with her two prior injections. She denied any other symptoms. Examination revealed mild, diffuse LUE weakness, imaging was unremarkable and EMG demonstrated a chronic LUE axonal polyradiculopathy. ONA was continued at 300u to the RUE with somewhat lesser but maintained benefit without adverse effects.

For patient R, ONA was initiated at 400u to the LUE every three months for 13 rounds, advanced to 500u. Contralateral (RUE) weakness developed after the second round of 500u dosing. Diagnostic evaluation was notable only for increased insertional activity, fibrillation potentials and decreased recruitment with subsequent long duration polyphasic motor unit potentials. Unchanged with high dose steroids, weakness improved with IVIG. Repeat ONA with 500u resulted in good local effect, recurrent contralateral upper and lower extremity weakness. EMG demonstrated contralateral cervical, thoracic and lumbosacral axonal polyradiculopathy. Symptoms improved with IVIG. Patient declined subsequent ONA.

Conclusion
Both patients were treated with neurotoxin therapy for 3-9 years with good clinical response before developing the adverse reaction. Weakness distant to the injection sites is supported by electrodiagnostic findings of contralateral axonal polyradiculopathy. The clinical presentations
suggest the possibility that the adverse effect of distant weakness may be immune-mediated and dose-related.

*No conflict of interest*
Spasticity is an increase in muscle tone velocity dependent due to the muscle stretch reflex hyperexcitability caused by central nervous system lesion. Individuals with spinal cord injury may suffer from spasticity with significant functional impairment. Intrathecal baclofen pump is used for the treatment of severe spasticity. This case report demonstrates the impact of intrathecal baclofen on vesical regimen on a patient that went from a supra-pubic catheterization to intermittent self-catheterization after intrathecal baclofen pump implantation.

Material and Method

Case report: Male, 33 years old, with complete T6 paraplegia. On admission in a Spinal Cord Injury ward, he presented with severe spasticity on both lower limbs (Grade 4 on Penn’s Scale and Grade 3 on Modified Ashworth Scale) that were cause of pain and impairment. Spasticity difficulted catheterization and occurred the formation of a bulbar false passage with consequent supra-pubic catheterization. He had a poor response to oral anti-spastic therapy and was proposed for intrathecal baclofen pump implantation.

Results

Three weeks after the implantation, Penn’s Scale was grade 1 and modified Ashworth Scale grade 1 on lower limbs. Spasticity control allowed starting intermittent self-catheterization, more independency in transfers and self-care and pain relief. His MIF scale raised from 71/126 on admission to 105/126 and SCIM from 30/100 to 62/100.

Conclusion

Intrathecal baclofen usually is an efficient anti-spasticity therapy that greatly improves quality of life. In this case, the patient went from a supra-pubic catheterization to intermittent self-catheterization. At our best knowledge, this is the first published case where intrathecal baclofen therapy allowed a significant functional achievement in the vesical regimen of person presenting spastic paraplegia.

DISCONTINUATION OF BOTULINUM TOXIN-A TREATMENT IN PATIENTS WITH MUSCLE OVERACTIVITY

A.M. Nella¹, E. Diamantidis¹, A. Kontaxakis¹, I. Karagiannakis¹, G. Strouggis-Venetas¹, S. Fotaki¹, D. Kagiouli¹, C.A. Rapidi¹
¹General Hospital of Athens "G. Gennimatas", Physical and Rehabilitation Medicine, Athens, Greece

Introduction/Background

The aim of this study is to determine the reasons for discontinuation of focal and regional spasticity management with botulinum toxin A (BTA).

Material and Method

Retrospective study of patients’ files treated with BTA the past seven years. Cases of BTA treatment discontinuation for more than 12 months were further evaluated with telephone interview. Causes of discontinuation were analyzed according to patients’ interview and were compared with patients’ files. Patient satisfaction was evaluated with a three grade scale (pleased, somewhat pleased and not pleased).

Results

Sixty nine (69) files were reviewed; 19 patients continuing their treatment regularly and 50 patients with discontinuation of treatment. We investigated further the patients with treatment discontinuation: 30 male and 20 female, with a mean age of 57.8 years. In 9 cases contact details were invalid, 12 patients did not wish to participate, and two were deceased. The remaining 27 patients were interviewed by phone; group A (17 patients) were not pleased or somewhat pleased with the results, and group B (10 patients) were pleased with the results. Group A, 10 patients had no or small functional improvement according to physicians’ assessment, 5 were not satisfied with the process, 2 are bedridden and have difficulty commuting to the clinic. Group B, 3 improved and had no more need for treatment, 3 reported practical difficulties, 4 had small functional improvement according to physicians’ assessment. In group A, treatment discontinuation was not under physician’s recommendation in 7 cases (41.2%), and in group B, in 3 cases (30.0%).

Conclusion

A significant number of cases in group A of dissatisfied patients report that the discontinuation was mainly because the results were below their expectations and not under physician’s recommendation. This demonstrates once again the necessity of detailed informing of the patient and the mutual agreement of goals setting before every session.

FUNCTIONAL OUTCOME FUNCTIONAL OUTCOME OF UPPER LIMB DYSTONIA AFTER BOTULINUM TOxin MANAGEMENT A PROSPECTIVE CASE SERIES ABOUT 8 PATIENTS
M. Guermazi¹, S. Ghorbal²
¹University hospital Habib Bourguiba, Rehabilitation, Sfax, Tunisia
²Tunis University, Rehabilitation Department Kassab Institute, Tunis, Tunisia

Introduction/Background

Botulinum toxin A is the current standard therapy for focal dystonia and the treatment of choice for segmental dystonia. Objective: To assess the functional outcome of upper limb segmental dystonia treated by botulinum toxin.

Material and Method

Patients: Adult patient with unilateral upper limb dystonia treated at least once by Bot. Toxin A. Patients with mental retardation or cognition deficit were excluded. Methods: A prospective case series study; Functional Assessment was based on House Functional classification for upper motor neurone hand disorders (ranging from class zero no hand function to eight full hand function). Satisfaction was rated by self-rating. Video recording was performed before and after 6 to 10 weeks of injection.

Results

Results: 8 cerebral palsy patients presenting unilateral upper limb dystonia were included in the study, 4 men and 4 women, mean age 34,3 (limits: 25-44), clinical presentation: 1 monoparesis, 5 hemiparesis and 1 triparesis. All patients underwent brain MRI, basal ganglia lesion was present in 6 patients. Based on House functional classification patients were classified class zero to class three before treatment. Most Injected muscles were lumbricals, thumb adductor and opponent, flexor carpi and flexor digitorum. After six weeks of injection all patient improved their functional status. On House classification patients were classified class three to class eight with maximum of recovery in two patients. Patient satisfaction assessed at week six ranged from 30% to 90% with a mean of 51,6%. Long term follow up showed persistence of effect up to 8 month for most of patients.

Conclusion

Our study showed moderate to excellent efficacy of Bot toxin A in segmental upper limb dystonia. The functional effect of Bot Toxin seems to remain more than expected. Limits: Retrospective study; Limited group of patients; No Group Control.

³Montpellier University Hospital, Physical and Rehabilitation Medicine, Montpellier, France
⁴South Hospital – University Hospital Grenoble-Alpes, Physical and Rehabilitation Medicine, Grenoble, France

Introduction/Background

The imputability of neutralizing antibodies (NAB) in secondary non-responsiveness (SnR) to treatment by botulinum toxin (BTX) injections is still debated for limb spasticity. This systematic literature review aimed to determine the prevalence of NAB after BTX injections for limb spasticity, analyze their determinants, and their causal role in SnR.

Material and Method

Medline, Cochrane and Embase databases were consulted for the period 1990-2017. Two independent reviewers extracted the data and assessed the quality of the studies with a specific scale (PRIMA and STROBE guidelines). Since the techniques used to detect NAB did not influence the results, we calculated the sensitivity and specificity of NAB+ to reveal SnR.

Results

We analyzed 13 articles published between 2002 and 2017, the quality of which was satisfactory (mean score 18/28a.u.). They were 5 randomized controlled trials, 5 interventional and 3 observational studies. NAB detection was the primary criterion for 4 and a secondary criteria for 9. On a total of 1201 participants (91% stroke), 1201 serums were tested after BTX injections. NAB prevalence was estimated between 1% and 2% according to various scenario, and did not significantly differ between the 3 BTX-A formulations. NAB production seemed favored by long duration therapy with high doses and short interval between injections. NAB revealed SnR with poor sensitivity (56%) but extremely high specificity (100%). No consensual criteria were used to diagnose non-responsiveness to BTX treatment.

Conclusion

This study is the first systematic review to specifically address the question of the BTX immunogenicity for limb spasticity. NAB prevalence is much lower than that reported for cervical dystonia. Consensual criteria must be defined to diagnose non-responsiveness to BTX.
treatment. If immunogenicity is not the most common cause of non-responsiveness to treatment, NAB should be more often sought in SnR persons for whom there is no other cause explaining treatment inefficacy.

IDENTIFICATION OF BARRIERS IN THE REINTEGRATION OF PAKISTAN MILITARY AMPUTEES AT THE WORKPLACE: A CROSS SECTIONAL SURVEY

I.N.T. Dr¹, F.A. Rathore²

¹Combined Military Hospital, Medical Stores Department, Lahore, Pakistan
²PNS Shifa Hospital, Department of Rehabilitation Medicine, Karachi, Pakistan

Introduction/Background

Many soldiers and officers of Pakistan army have suffered major limb loss in the war against terrorism. Amputee rehabilitation leads to successful community re-integration but certain barriers can hinder this process. This study aims to identify barriers in the reintegration of Pakistan military amputees at their workplace and to suggest remedial measures.

Material and Method

Cross sectional survey was planned and hospital ethics committee approval was obtained. Two part survey was constructed consisting of demographics and questions about the possible barriers in the workplace. Fifty eight military amputees (20-60 years, with disability class A and B due to major amputation of a limb) were approached and requested to fill in the questionnaire after explaining the rationale and possible benefits of the study. Response rate was 100 %.

Results

All patients were males. Most of the patients had trans-tibial amputation (41). Majority were matriculate and earned between Rs 20,000- 40,000 (53.4%) All patients were provided with latest modular prosthesis of Ottobock (Germany) and Ossur (USA), free of cost with life time maintenance and replacement by AFIRM. Majority of the patients had accessible washrooms in units, could ambulate independently, were confident after provision of prosthesis and were spared by their units for timely follow-up.

Conclusion

Amputee rehabilitation can lead to successful and complete community re-integration. Pakistan army is providing comprehensive amputee rehabilitation services to those who sustain a limb loss. However, certain barriers can hinder the rehabilitation process and it is important to identify and remove these barriers for better functional outcomes in amputees.

MOBILIZATION STATUS OF DIABETICS VERSUS NON-DIABETICS AFTER BELOW KNEE AMPUTATION: A COMPARISON
A. Saraf
1Teerthanker Mahavir University, Orthopedics, Moradabad, India

Introduction/Background
Mobility following below knee amputation has a direct impact on the quality of life. Early and independent mobilization develops confidence in the below knee amputee. This helps the patient to become psychologically, socially and economically independent. We compared mobilization status of diabetics versus non-diabetics amputees.

Material and Method
A total of 144 below knee amputees using various supports for mobilization were included in this study of which 63 were diabetics and 81 non diabetics. They were followed for a minimum period of 1 year. On follow up they were observed for the type of support used for mobilization.

Results
92 patients initially used crutches for mobilization. 40 patients used walker, 7 used wheelchair and 5 remained bed ridden before they died. Of 92 patients who were using crutches, 22 were in diabetic group and 70 in non diabetic group. 31 patients of diabetes and 9 patients of non diabetic group used walker. 5 patients in diabetic group and 2 patients in non diabetic group could mobilize only on a wheelchair. 104 patients started using prosthesis for mobilization once their stumps had healed adequately of which 30 were in diabetic group and 74 in non diabetic. Of 104 prosthesis users, 43 were using it for less than 6 hours per day, 55 were using 6-12 hours per day and 6 patients were using it for > 12 hours per day.

Conclusion
Non diabetics preferred crutches and prosthesis for mobilization in comparison to diabetics. More diabetics were bedridden or on wheelchair after amputation. Non diabetics were using prosthesis for longer time in comparison to diabetics. Major causes for this difference was preoperative lower ambulatory grading in diabetics, weaker muscle mass, old age, co-morbid conditions, increased incidence of infection and prolonged stump healing time.

This study aims to describe the spinopelvic sagittal alignment in transfemoral amputees (TFAs) and to compare with a reference population. To our knowledge, this is the first recent radiologic study of the TFAs’ spine and the first postural approach destined to better understand the high prevalence of low back pain (LBP) in the TFAs.

**Material and Method**

Volunteers with transfemoral amputation underwent bi-planar X-rays with 3-D reconstructions of the spine and pelvis. Sagittal parameters were analyzed in the light of literature and compared to those of a reference group of non-amputees. Differences between TFAs with and without LBP were also searched.

**Results**

Twelve subjects have been prospectively included. The two groups (TFA-LBP n=5 and TFANoP n=7) were comparable in terms of gender, age, amputation delay and sedentarity. In the TFALBP group, the impact of LBP was estimated on average to 16.4% with the ODI (SD 7.9%, [6; 24]). Pelvic incidences were within normal limits, except for one subject of the TFA-LBP group. Anterior pelvic tilt was observed in two subjects of each group. Eight subjects (6 NoP and 2 LBP) had abnormal low value of TK. The mean angle of TK in the TFA-NoP group was lower than in the TFA-NoP group (p= 0.0511). Two subjects of the TFA-LBP group had a hyperlordosis while all the TFAs-NoP had a lower lumbar lordosis than expected in an economic posture. Concerning the sagittal balance, four of the five individuals of the TFA-LBP group had unbalanced sagittal posture versus two of the seven in TFAs-NoP.

**Conclusion**

This study emphasizes the importance of considering the sagittal balance of patients with a transfemoral amputation to prevent and manage the onset of low back pain. Moreover, in
this population, it seems necessary to study not only the sagittal plane but also the frontal plane which is also probably unbalanced.

*No conflict of interest*
Concerning amputations in France, 52% is due to diabetes and amputation risk is 14 times higher in case of diabetes.

There is up to now no study about amputation rate in French West Indies (FWI), but there are 2 times more diabetes treated in the French Overseas Departments compared of France and there were 82 hospitalized patients with major lower limb amputation (above foot) in our service in 2015 (data from the Information Systems Medical Program (ISMP)).

We wished to show higher complexity management of patients with lower limb amputations due to diabetes because of its global nature (general disease, frequent associated morbidities) and necessity of fitting the two lower limbs (residual limb or stump, and the other limb or “intact” limb).

Material and Method

It's a direct-inclusion study.

We followed 31 adults of Caribbean origin, Above Foot Amputees (AFA) and hospitalized to obtain a first walk prosthesis.

Our objective was to evaluate lower limbs fittings in diabetic amputee: choice of prosthesis for residual limb and equipment of the other foot by therapeutic footwear (serial model or orthopedic footwear, and even foot orthosis).

Results

Diabetic amputees need 53% more bilateral fittings than others: walking prosthesis on the amputated side and therapeutic footwear on the other side, because of foot trophic disorders (53% more). There is no significant difference for other criteria.
Above foot amputees due to diabetes need walking prosthesis and therapeutic footwear, but little impact on prosthetic choice and walking performance. Prosthesis and walking performances in diabetic above foot amputee are only few differences with others.

LIMB AMPUTATION EPIDEMIOLOGY: WHAT IS CHANGING?
A.R. Correia¹, F. Pereira¹, C. Moreira¹, P. Cantista¹
¹Centro Hospitalar do Porto, Medicina Física e de Reabilitação, Porto, Portugal

Introduction/Background

Epidemiological data on limb amputation seem to have suffered several changes, especially in what concerns to cause, age or co-morbidities. The challenges of the increased life expectancy, the demands of higher functional levels and the costs constraints seem to deserve a reflection, allowing a new definition of appropriate clinical strategies to face this reality.

This study goal is to know the evolution of the epidemiological data on limb amputation, particularly in the parameters age, aetiology, amputation level and co-morbidities, through the analysis of our own figures and experience.

Material and Method

A retrospective study was conducted from a 252 outpatient’s sample of our Amputee Unit, observed in 2016. The collected data were statically treated according our study objectives. All the ethical procedures were respected.

Results

From the original sample we excluded 9 cases due to insufficient information. Our definitive group consisted of 243 patients, 155 men and 88 women.

As causes of amputation we found: vascular (54%), trauma (25.1%) and infection (7%). The remaining percentage referred to neoplasm and congenital deformities. There was a higher prevalence of amputees in advanced age stages, particularly in vascular aetiology (mean age 65 years); mostly of these were diabetic (58.6%) and commonly presented other vascular risk factors.

Despite the challenge of serious co-morbidities, including neurological deficits, it’s worth to mention the progress in our Unit’s fitting index with a successful ratio of 75%.

Conclusion

Our data seem to point to a new paradigm on limb amputation epidemiology.
Nevertheless the increase of difficulties linked to the clinical parameters found in our sample, the overall index of fitting has grown. This is due to new rehabilitation strategies, adapted to the kind of patients we have. We highlight the multidisciplinary work in collaboration with other specialties/professionals and the use of new prosthetic components that make possible previously unavailable solutions.

amputation; rehabilitation; fitting

*No conflict of interest*
Maladaptive plastic reorganization of the somatosensory cortex surrounding the area representing the deafferented limb is considered to be responsible for phantom limb pain (PLP). Given the mechanism of PLP, non-invasive stimulation of the brain can help to induce plastic changes associated with PLP, which may in turn block maladaptive plasticity, revert or modulate plastic changes and provide pain relief. This review aims to give an overview of the current state of research regarding the effectiveness of noninvasive neuromodulation for the management of PLP.

**Material and Method**

A systematic literature search in the PUBMED, SCOPUS, Web of Science, Cochrane Library databases by two independent review authors was performed to identify studies investigating the effects of noninvasive neuromodulation for PLP. The included journal articles were reviewed according to a structured diagram and the methodological quality was assessed via a classification of study designs as described by Jovell & Navarro-Rubio. A narrative synthesis approach was used throughout as no studies were sufficiently homogenous to justify useful meta-analysis.

**Results**

The literature search identified 239 studies. Of these 239, 4 RCTs studies fulfilled the inclusion criteria and were included for data extraction. Two of the studies focused on repetitive transcranial magnetic stimulation (rTMS) while two of them focused on transcranial direct current stimulation (tDCS).

**Conclusion**
Most of the evidence for noninvasive neuromodulation is from studies with fair to good strength of evidence. The present review showed that there is promising evidence on the effectiveness of rTMS for PLP, whereas the effectiveness of tDCS is not yet elucidated.

PERFORMANCE OF DAILY LIVING ACTIVITIES IN PATIENTS WITH LOWER LIMB AMPUTATIONS

D.R. Tsukimoto¹, M.C.C. Cardoso¹, S.J. Nakazune¹, G.R. Tsukimoto¹, M.K.F. Watanabe¹, L. Falkenburg¹, P.M.M. Barreto¹, M.H. Miyazaki²

¹Physical and Rehabilitation Medicine Institute- Hospital das Clínicas HCFMUSP, Occupational Therapy, São Paulo, Brazil
²Physical and Rehabilitation Medicine Institute- Hospital das Clínicas HCFMUSP, Executive Board, São Paulo, Brazil

Introduction/Background

Individuals who experience acquired amputation face the task of adjusting and adapting to the loss of a part of the body that was already fully integrated with their body schema and self-image. In addition, they may experience situations of social discrimination, feelings of incapacity and other barriers that hinder the resumption of their activities and participation in life situations.

The occupational therapist, as part of the Rehabilitation Team, works through the post-amputation, pre-prosthetic and post-prosthetic phases, and the program consists of establishing an individualized assessment and treatment plan with the main objective of promoting independence in daily, productive, and leisure activities, learning or resumption of significant occupations and functioning according to the demands, interests, and abilities of each individual.

Material and Method

The aim of this study is to present a data survey based on the medical records of patients treated at the Occupational Therapy Service as part of the intensive inpatient rehabilitation program since 2015, focusing on the main demands in relation to daily life activities and Assistive Technology resources.

Results

We observed a significant impact on mobility and upper limb reaching skills and changes in the ability to perform most of the daily activities, although with few changes in the level of functional independence. Some patients presented associated lesions such as brachial plexus injury or fractures, in cases of traumatic amputations; and peripheral nerve damage, decreased sensation and changes in visual acuity when associated with chronic diseases; resulting in additional demands for rehabilitation.

Conclusion

The main outcome of the program was to ensure the most satisfactory level of competence and independence in the performance of the occupational roles that the patient considers significant in his or her life, with or without modifications in the steps, resources, or environment related to
the activities. The educational program for caregivers contributed to accomplish the rehabilitation goals.

Introduction/Background

Post-burn amputations are still a major problem in our society. Although its incidence is rather low, they are an important cause of morbidity in a relatively young population. We examined the characteristics of patients with an amputation after a burn injury and described their quality of life after discharge.

Material and Method

We made a retrospective analysis of the patients admitted in a major Burn Unit in Portugal (n=736) with the diagnosis of burn injuries and needing amputation during hospitalization since 1/1/2012 until 31/12/2016. The variables analysed were: demographic data, clinical presentation and mortality. A questionnaire was also performed by phone call after discharge. Follow-up information was not obtained for 13 patients.

Results

Thirty-nine patients, who were submitted to at least one amputation, were included, 66% of which were male and with a mean age of 63.03±18.4 years. The mean LOS was higher in amputee patients (30.03±27.27 days vs 17.66±16.58, p<=0.001). Patients with electrical burns had a higher risk of amputation compared to remaining patients. (OR=3.056, p=0.040). 67.5% of the amputations were at the upper limb level, mainly transmetacarpal (50%). The mortality rate during hospitalization was higher in the amputee group (20.5% vs 6.8%) (p<0.005). Follow-up information was obtained in 26 patients: 76.92% according to Barthel Index had light dependence, 66.7% continued to work but 40% of these needed professional retraining. Phantom pain was reported in 57.7% and stump pain in 15.4%. The use prothesis was reported in 7 patients, of whom 57.1% were fully satisfied with it.

Conclusion

Amputees need special care for the problems they may have in adapting to their environment. We found that these patients had injuries mainly due to electrical burns, have longer hospital
stay and higher mortality risk. However, most of the patients had a good functional recovery and are satisfied with their quality of life.

SPORT’AMP : SPORT ACTIVITIES AND LOWER LIMB AMPUTEES
O. Lopez¹, M. Vaucher²
¹CHU Lapeyronie, Médecine Physique et de Réadaptation, Montpellier, France
²CHU Nîmes, Médecine Physique et de Réadaptation, Nîmes, France

Introduction/Background

In France, in 1990, people presenting a major lower limb amputation was estimated at 90000, incidence stable: 8000 cases/year.
Objective of Sport’Amp study: evaluate, with a self-questionnary online, the sports practice and its characteristics before the amputation, at the resumption / renewal and at present, for individuals with lower limb amputation, above or below-knee, uni- or bilateral, who practice sport or not.
The questionnaire answer about sport activities, used prosthesis for walking and sports, choice of activities, conditions of renewal, difficulties, prosthesis management, quality of life and motivation in sport. If people don’t practice sport, they have questions to know why.

Material and Method

After a preliminary study, Sport’Amp study began gradually since the 1st February.
15 centers (hospitals or clinic), groups of prosthetists and associations are concerned, in all the French territory.
Doctors, prosthetists or associations of patients propose participating at study and give a card with link of connection and QR-code to individuals with lower limb amputation. They can contact them by mail or email.
To participate, they have to be amputee since more than a year and who live in France.
The software used is REDCap.
Sport’Amp pass promotion agreement of CHU of Nimes (France).

Results

Actually, 37 questionnaires.
10 women (27%) and 27 mens (73%)
Average age: 41 years old.
Individuals live in 11 regions/districts of France.
70,3% are working or studying.

Amputations:
Traumatic: 75,7% (28)
Cancer: 13,5% (5)
Infection: 2,7% (1)
Malformation: 2,7% (1)
Other : 5,4% (2)
Unilateral : 94,6% (35)
Bilateral : 5,4% (2)

Below-knee : 57,1%
Above-knee : 42,9%

22,2% of people don't practice sport before amputation, only 8,8% after amputation.
50% return at practice before one year after amputation.
Main difficulties : prosthesis problems, residual limb pain, muscular weakness/loss of weight

Management of prosthesis improve by sport practice : 81,5% agree

Quality of life : average 70/100

**Conclusion**

More results during the next months with statistical evaluation of this population, probably estimated around 300 persons or more.

**Keywords**

sport activities; lower limb amputation

THE ORTHOSIS OF LOWER LIMBS IN REEDUCATION: INDICATION IN THE CENTER OF REHABILITATION AND OF EQUIPMENT FOR HANDICAPS “THE REASON OF LIFE”
O. Yannick Serge¹, M.A. Jean Marie¹
¹Hopital d’Instruction des Armées Omar Bongo Ondimba, Médecine Physique et Réadaptation, Libreville, Gabon

Introduction/Background

Clarify the indications of the orthosis of lower limbs after several months of activities in the center of equipment and of rehabilitation “The reason of life, the right of hope” in Libreville.

Material and Method

Descriptive retrospective study led from patients’ files having benefited from an orthosis of lower limbs and sailed in the center of equipment and of rehabilitation “The reason of life, the right of hope” from 2012 till 2014

Results

It stands out from the analysis of 25 followed patients, that 15 patients were male and 10 others female (sex-ratio of 1.5). The majority of the cases concentrate on the age bracket 0–5 years with extremes of 1 month and 80 years. The malformed foot established the majority of the indications of orthosis with 40% of the cases, followed deformations of the knee in 32% of the cases and 5% of the cases of poliomyelitis. The orthosis of correction was the most prescribed in 64% of the cases followed by the orthosis of walking in 9 cases. So, we notice that 20 patients were pupils, 4 of the civil servants and 1 pensioner.

Conclusion

The centre of equipment “The reason of life, the right of hope” is relatively young and envisages long-term to develop in the Gabon and in the surrounding countries.

EFFECT OF POSTOPERATIVE AMBULATION LEVEL ON THE QUALITY OF LIFE IN A TRANS-TIBIAL AMPUTEE

P. Gupta¹
¹Government Medical College Patiala, ENT ENT, Patiala, India

Introduction/Background

Quality of life of a trans-tibial (TT) amputee is not only determined by his functional rehabilitation but also social, economical and psychological rehabilitation. A number of studies have analyzed the influence of lower limb amputation on these factors. This study analysed the effect of functional recovery on other parameters of quality of life in a TT amputee.

Material and Method

This was a 10 years retrospective and 2 years prospective study. A total of 160 patients of trans-tibial amputation were followed. Their postoperative ambulatory status was calculated using Pinzur’s ambulatory level. Their quality of life was determined on the basis of answers to a five point questionnaire which included their social, economic and psychological aspects. These parameters were correlated to assess the influence of functional recovery on the quality of life.

Results

All the amputees with Pinzur’s 0-1 level of ambulation suffered loss of income consequent to loss of job. All of them felt increased level of depression and anxiety after amputation. 50% of the patients with postoperative 0-1 level of ambulation felt socially neglected. Comparatively much less percentage of amputees with 5-6 level of ambulation suffered economic, social and psychological crisis.

Conclusion

Quality of life of a TT amputee is determined not only by his functional rehabilitation but also social, economical and psychological factors. From this study we concluded that post operative functional outcome significantly affects the quality of life of an amputee. An amputee with better ambulation level fares better economically, psychologically and socially in comparison to an amputee with poor ambulatory outcome.

IMPORTANCE OF TYING THE SCIATIC NERVE IN ABOVE KNEE AMPUTATION TO PREVENT NEUROMA FORMATION

P. Gupta

1Government Medical College Patiala, ENT ENT, Patiala, India

Introduction/Background

Sciatic nerve is the thickest nerve in human body. Neural sheath of sciatic nerve is rich in microvasculature. In this study we compared neuroma formation after tying the sciatic nerve with leaving its cut end open in patients who undergo above knee amputation.

Material and Method

In this study we followed a total of 90 patients who underwent above knee amputation. In half of these patients, cut end of sciatic nerve was left open and in other half, the nerve was tied. Patients in both the groups were age, sex and BMI matched. Neuroma formation in the stump was assessed one year after surgery. This assessment was done by measuring the diameter of sciatic nerve ending using sonogram. Sciatic nerve diameter was measured bilaterally at the same level, and the value of the normal limb was taken as control.

Results

Out of 45 patients who underwent tying of sciatic nerve, only 10 patients developed thickening of the cut end of sciatic nerve in comparison to opposite limb. On the other hand, 45 patients in whom the cut end was left open, 33 patients developed neuroma formation. This result was statistically significant.

Conclusion

Rich microvascularity of sciatic nerve results in the formation of haematoma beneath the cut end, if it is left open. This haematoma eventually results in growth of neural fibres. As a result of this, neuroma formation occurs at cut end of sciatic nerve in above knee amputation. We thus conclude, it is always wise to tie the cut end of sciatic nerve in above knee amputation to prevent neuroma formation.

THE PHANTOM PAIN TREATMENT USING INCOBOTULINUM TOXIN A - SERIES OF CASES
E. Rocha¹, E. Suzigan¹
¹Santa Casa Sao Paulo, Rehabilitation Service, Santo André, Brazil

Introduction/Background

Phantom limb pain is any pain phenomenon which is felt at an absent limb or a portion of the limb. Sometimes these sensations are extremely painful and disabling.

Material and Method

All the patients were followed for minimum 06 months in the Rehabilitation Center. They presented severe stump neuropathic pain and phantom pain almost daily. The first patient presented pain all over the hand, the second in the fingers and the third in dorsal wrist. The first patient scored 86 mm in Visual Analogic Scale (VAS) at rest and 95mm during critical episodes. The second one scored 78mm at rest and 94mm during critical episodes. The third scored 87mm at rest and 98mm during pain crisis. All of them were included in a physiotherapy and occupational therapy program, associated to neuropathic pain drug therapy. Despite the therapies applied the patients maintained the pain scores. Due to this treatment failure, another with botulinum toxin was tried owing to its analgesic effect in neuropathic pain. Intradermal incobotulinumtoxin was applied in both painful stump area and ghost pain stump trigger points. Incobotulinumtoxin was applied in 5U per point, a part every 2 cm in the surface area, in a total amount of 80U.

Results

The patients were followed for 15 and 90 days after the procedure. The VAS results were below:

Patient 1 -15 days: 32mm /90 days : 0 mm.

Patient 2 - 15 and 90 days : 0mm

Patient 3 - 15 days -34mm / 90 days 31 mm
The botulinum toxin treatment decreased pain successfully improving the efficiency of the reahabilitiation program and pain control. All patients decreased the neuropathic pain drugs dosis.

We need further high level studies in this area to confirm these results.

**Conclusion**

The botulinum toxin could be considered useful in amputee neuropathic pain and ghost pain.

EASY TECHNIQUE FOR RADIOGRAPHIC EVALUATION OF STUMP-SOCKET FIT IN BELOW-KNEE AMPUTEES
A.A. Tsur
1Galilee Medical Center, Rehabilitation, Nahariya, Israel

Introduction/Background

The critical relationship between accurate fit of a prosthesis and amputee comfort and function constitutes the foundation of prosthetic fitting. Prosthesis alignment affects the way load is transferred to the residual limb through the socket, and this load is critically important for comfort and function. The aim of the study was to assess the value of radiopaque materials in evaluation of stump-socket fit in people with transtibial amputation, and to develop a simple procedure for clinical use in diagnosing skin pressure problems more accurately.

Material and Method

Thirty-two amputees (herein: 'participants') had one or more cutaneous lesion in the stump, and another 26 amputees (control group) had no lesion in the stump after training with their prosthesis. Radiopaque metallic markers were attached to weight-bearing points in the outer surface of the internal socket. Full weight-bearing X-rays were made in the antero-posterior and lateral projections.

Results

In the antero-posterior view, the weight-bearing points of the stump in 78.1% of the participants did not correspond to radiopaque metallic markers placed over the patellar tendon and the tibial tuberosity points in the socket. In the control group, there was non-adaptation in only 42.3% between the up-mentioned anatomical and the metallic (Chi-Square, \(p<0.007\)). In the lateral view X-rays, the weight-bearing points of the stump in 65.6% of the participants did not correspond to radiopaque metallic markers placed over the patellar tendon and over the tibial tuberosity points in the socket. In the control group, there was non-adaptation in only 23.1% between the up-mentioned anatomical and the metallic (Chi-Square, \(p<0.002\)).

Conclusion

The conflict between prosthesis and residual limb is the cause of skin disruption in the stump and can be successfully treated by prosthetic socket modification. X-rays should be done to identify if there are discrepancies between the stump and the socket.

Phantom limb sensation always occur after sudden traumatic limb amputation. It follows a specific pattern that is related with body image (Melzack Theory). Phantom pain have a correlation with pre-amputation pain. Aims to find relationship between referred phantom limb sensation (RPLS), telescoping grade (PS), phantom limb pain (PP) and pre-amputation pain (PNPA).

Material and Method

Six months prospective study, fifty adults, single traumatic limb amputee without stump pain, aged 17 to 55 years, men and women, allocated by consecutive random sampling into two independent groups, prosthetic group (P) and non-prosthetic group (NP). PP analyzed using VAS, PS and RPLS using modification visual and vividness movement imagery score. For PNPA, subjects answered questionnaire.

Results

Gender and age are homogenous (p=0.445 and p=0.909). Within six months observation, increase in PS followed by RPLS and lower PP (p<0.0001). Differences between the two group (p<0.0001). Pearson correlation show positive correlation between PS and RPLS (r=0.999, p<0.0001). PNPA and PP showed significant difference (p<0.0001), also without PNPA and no PP incidence (p<0.0001). Mean score of PP in group NP is 6.16 (SD 1.96) and mean score of PP in group P is 5.26 (SD 1.47). Subjects without PNPA has no PP.

Conclusion

RPLS, PS and PP in adult traumatic limb amputee can determine the degree of phantom limb, as the results of somatotopic map reorganization (Melzack Neuromatrix and Neurosignature Theory). PNPA will develop into PP. Loss of ascending impulses caused by amputation will disinhibit cortical somatosensory pain memory. Without PNPA, no painful memory to build and
no PP. However phantom sensation is still there, memory of self body perception was established since birth.

FUNCTIONAL INDEPENDENCE IN THE LOWER LIMB AMPUTEES – THE EFFECT OF GENDER AND AMPUTATION LEVEL

I. Vareka¹,²,³, R. Varekova⁴, M. Janura⁴, M. Jindra⁵, E. Vanaskova¹,³

¹University Hospital Hradec Kralove, Department of Rehabilitation, Hradec Kralove, Czech Republic
²Palacky University, Department of Physiotherapy, Olomouc, Czech Republic
³Medical Faculty of Charles University, Department of Rehabilitation, Hradec Kralove, Czech Republic
⁴Palacky University, Department of Natural Sciences in Kinanthropology, Olomouc, Czech Republic
⁵University Hospital Hradec Kralove, Department of Rehabilitation, Hradec Kralove, Czech Republic

Introduction/Background

The Functional Independence Measure (FIM) instrument is widely used in the clinical practice, but merely in the lower limb amputees and without differentiation between men and women as well as between transtibial (TT) and transfemoral (TF) amputees. Only the Total FIM score and/or Motor FIM and Cognitive FIM subscores are analyzed, in spite, that certain parts of Motor FIM score attract more interest of practitioners. The aim of this study was to confirm the hypothesis of better functional abilities in the amputee men than women and in TT than TF. We wanted to demonstrate the advantage of a detailed analysis of the Motor FIM too.

Material and Method

Two hundred and twenty-nine hospitalization cases of the lower limb amputees were sorted into eight groups according to their gender and amputation level (TT or TF), separately for the first and second hospitalization. The scores of Motor FIM, walk, stair climbing, self-care and transfers at the admission and discharge were chosen as variables as well as the age, length of stay (LOS) and the interval between the surgery and admission to rehabilitation department (delay). The Mann-Whitney test was used to set the significant differences at the level p<0.05.

Results

The gender effect on functional independence was ascertained in almost all Motor FIM parts, especially at the first discharge and second admission. Amputation level effect was also ascertained frequently at discharge, especially in walk and stair climbing. The effect of age, LOS or delay was very rare.

Conclusion
Expected better functional abilities in men and TT were confirmed. The analysis of selected parts of Motor FIM brings more detailed information than the Total FIM exclusively.

THE RELATIONSHIP BETWEEN LEG DOMINANCE AND THE AMPUTATION OF LOWER LIMB IN PATIENTS WITH DIABETES MELLITUS

I. Treger¹, A. Friedman², S. Zilberman², A. Genis², L. Lutsky³
¹Soroka University Medical Center- Ben Gurion University of Negev, Rehabilitation, Beer Sheva, Israel
²Soroka University Medical Center, Rehabilitation, Beer Sheva, Israel
³South Department Clalit, Rehabilitation, Beer Sheva, Israel

Introduction/Background

Diabetic patients frequently suffer from lower extremity vascular problems. A manifestation of this illness is diabetic foot with possible leg damage, which can lead to amputation. Different harmful factors for ulceration of diabetic foot were detected. One of them can be mechanical stress, due to weight bearing activity and walking, which is more prominent at dominant side. The aim of the study was to analyze the relationship between leg dominance and the amputation of lower limbs in patients with diabetes mellitus.

Material and Method

In a retrospective study at the new Rehabilitation Department (established at 2015) in Soroka Medical Center, twenty-six amputees (from total 500 patients) were recruited to participate in the study. 15 patients, aged 58.1±10.2, only 2 of them female, were defined as one-sided bellow knee amputees of diabetic origin and were included to the analysis. In a questionnaire following amputation, each patient was asked “what is your dominant side?”, and the prevalence of dominant leg amputation versus non-dominant was analyzed.

Results

Of the fifteen diabetic patients, thirteen had their dominant leg amputated (86.7%) and only 2 (13.3%) – non-dominant. It was shown that the dominant leg is more frequently exposed to mechanical stress, leading to increased risk for diabetic foot and ultimately, amputation. It is subjected to greater recurrent pressure due to its role in mobilization tasks, it more frequently experiences the consequences of walking. It is believed, that walking, as a regular aerobic exercise can be good for diabetic patients. Our data strengthens a possible harmful effect of walking exercising for preserving of diabetic leg and for prevention of amputation.

Conclusion

Our study shows that the dominant leg is much more at risk for amputation in diabetic patients. The current guidelines for diabetic patients’ exercises prescription may need to be modified to consider for this harm.

Nephrotic syndrome is a high-risk thromboembolic disease. Thromboses of the peripheral veins are common, while arterial localizations have been reported more rarely. Several factors are incriminated in the genesis of these thromboses. They are hard to diagnose and especially to treat.

Material and Method

We report the case of a patient aged 30 years treated for a nephrotic syndrome since 2008 under Cortancyl, transferred from the vascular surgery department to the rehabilitation after a lower limb amputation.

Results

The interrogation had found the notion of a brutal installation of pain and coldness of the two lower limbs for which he had consulted the emergency room. There was no concept of trauma preceding the symptomatology.

The initial examination had found two cold, pale lower limbs with sensitivomotor disturbances, a left femoral pulse present with absence of all the other pulse of the lower limbs. An emergency CT angiography showed an endoluminal embolus of the terminal aorta extending to the primitive iliac arteries. The patient was therefore amputated both lower limbs mid-leg and was transferred to our department for additional care.

The patient benefited from pre-prosthetic rehabilitation including strengthening of the upper limb muscles and the key muscles of the hips and knees. He then benefited from two prostheses with a progressive work of walking at the beginning with walker, then with two canes. The method used was bandaging and pain treatment, a training program comprising contraction prevention, strengthening, standing and balance training and walking training.

Conclusion

Arterial thrombosis during nephrotic syndrome are not frequent but serious. Their knowledge is essential in order to make the early diagnosis, insuring an adequate care. Prevention can be
achieved by simple means: physical activity, proscription of vascular punctures. The use of preventive anticoagulant treatment is controversial.

FEASIBILITY, SAFETY, AND RELIABILITY OF EXERCISE TESTING USING THE ARM-LEG (CRUISER) ERGOMETER IN SUBJECTS WITH A LOWER LIMB AMPUTATION

E. Simmelink¹, J. Wempe², J. Geertzen¹, L. van der Woude³, R. Dekker¹

¹UMCG, Rehabilitation Medicine, GRONINGEN, The Netherlands
²UMCG, Department of Pulmonary Diseases, Groningen, The Netherlands
³UMCG, Center for Human Movement Sciences, Groningen, The Netherlands

Introduction/Background

Physical fitness of patients with a lower limb amputation predicts their walking ability and may be improved by physical exercise and training. A maximal exercise test is recommended prior to training in order to determine cardiovascular risks and design exercise programs. A potentially suitable ergometer for maximal exercise testing in patients with a lower limb amputation is the combined arm-leg (Cruiser) ergometer (figure 1). The aim of this study was to determine feasibility, safety, and reliability of (sub)maximal exercise testing on the Cruiser ergometer in subjects with a lower limb amputation.

Material and Method

Subjects with a lower limb amputation performed 1 submaximal exercise test and 3 maximal exercise tests on the Cruiser ergometer. Feasibility was determined by examining whether key variables such as heart rate and oxygen uptake (VO₂) were correctly and reliably measured, by determining whether a test was maximal, by studying reasons for non-completion, and by
measuring gross efficiency (GE). Safety was analyzed by recording complications, electrocardiogram (ECG) results, and blood pressure. Reliability was tested by comparing the results of the second and third maximal exercise test

Results

Seventeen subjects (14 men and 3 women) out of 21 preselected subjects completed the study. In general, the maximal Cruiser exercise test was feasible. Almost 75% of the subjects reached maximal performance. The test was also safe because no complications occurred, although ECG and blood pressure could only be reliably recorded in most subjects just before and after the test. Reliability was good: Intraclass correlation (ICC) was 0.84 for peak VO$_2$.

Conclusion

The Cruiser ergometer is a feasible, safe, and reliable ergometer for measuring physical fitness of subjects with a lower limb amputation

Keywords

lower limb amputation; exercise test; ergometer

BARRIERS AND FACILITATORS FOR THE IMPLEMENTATION OF CLINICAL PRACTICE GUIDELINES FOR THE AMPUTEE: THE PERCEPTION OF USERS
A. Posada¹, D. Patiño¹, M.D.P. Pastor¹, L.H. Lugo¹, V. Ciro¹, J. Plata¹, D. Aguirre¹
¹Facultad de Medicina, Universidad de Antioquia, Medellín, Colombia

Introduction/Background

Efforts to produce high quality Clinical Practice Guidelines (CPG) must be accompanied by implementation strategies aimed at eliminating specific barriers. With this study, we seek to identify the perceptions of the users of the CPG for the rehabilitation and care of individuals with lower limb amputation on the factors that facilitate or hinder its implementation.

Material and Method

A qualitative design was used. Semi-structured interviews were conducted with patients, health service providers and administrators of medium and high complexity organizations of the health system in Colombia. The transcribed interviews were coded to identify emerging categories based on the empirical findings. These were compared and complemented with the theoretical categories that resulted from the review of the literature.

Results

In the analysis of the 38 interviews the perceived barriers were: Categories related to the patient, such as clinical and sociodemographic aspects (eg, low economic resources, comorbidities and reduced mobility); access to services (eg, residence in rural areas) and the type of social security affiliation. Categories related to the professionals, such as knowledge and competences (eg, variability in academic training programs), experience with the amputated patient and communication skills. Categories related to the health system, such as availability of resources, opportunity in the care, information systems, costs of the health services and changes in the regulations of the system. And categories related to the CPG, such as its usefulness, methodological rigor, flexibility and the characteristics of the developer group.

Conclusion

We identified categories not included in the theoretical review, such as the type of affiliation to social security, the variability in academic training programs, the changes in the system's regulations and the usefulness of the CPG. These findings allow designing implementation strategies that respond better to the Colombian scenario.

GAIT ANALYSIS OF AMPUTEE PATIENTS WALKING WITH A CANADIAN PROSTHESIS
M. Faiz¹, C. Lansade¹, G. Chiesa¹
¹Institut Robert Merle d'Aubigné, Val de Marne, Valenton, France

Introduction/Background

Canadian Prostheses (CP) are used for the most proximal amputations of the lower limbs such as hip disarticulation, hemipelvectomy and short transfemoral. The etiologies of these amputations are essentially vascular, tumoral and traumatic. These amputation levels are extremely rare (0.5 to 3% of amputations) and only 1.2 to 35.8% of patients manage to be fitted according to the literature depending on etiology and co-morbidities.

Few studies have investigated the gait pattern of patients with PCs and they were essentially case reports.

The aim of our study is to characterize the walking parameters of patients with a PC on a significant database and to evaluate the parameters of influence on the gait quality.

Material and Method

This is a prospective cross-sectional study of patients with a PC who were followed at the Robert Merle d’Aubigné Institute in Valenton with a well-adapted prosthesis and who are used to walk with it. Recruitment started from September 2017.

The study protocol includes a six-minute test and a Gait Analysis in our laboratory equipped with a Vicon optoelectronic system and an AMTI force platform.

Results
We recruited 12 patients so far. Our main results are presented in Tables 1 and 2.

**Conclusion**

Our study, still in progress (we aim to recruit about 35 patients by July) shows variability of the gait pattern depending on age, prosthetic material characteristics, etiology, co-morbidities. The preliminary study of our results shows a healthy side vaulting higher than that described in the literature for more distal amputation levels, as well as a significant increase in pelvic sagittal plane inclination during the walking, which is a characteristic strategy of the gait pattern of high level amputees.

**Keywords**

Gait analysis; Hip disarticulation; Canadian Prosthesis

20 YEARS RETROSPECTIVE STUDY ON LOWER LIMB REAMPUTATION
S. Ataíde¹, I. Mendes¹, D. Portugal¹, B. Dantas¹, A. Coelho¹, I. Pereira¹, L. Prates¹
¹Hospital Prof. Doutor Fernando Fonseca, Physical and Rehabilitation Medicine, Amadora, Portugal

Introduction/Background

Many patients who underwent lower-extremity amputation secondary to peripheral vascular disease or Diabetes Mellitus (DM), eventually require reamputation. Previous studies have demonstrated that DM, male gender and chronic renal insufficiency are risk factors associated with reamputation. The aim of our study is to describe the incidence of reamputation in a population of amputees of a PRM service and access their capability to walk with prostheses.

Material and Method

Retrospective cohort study on lower limb amputees referred to PMR service at a secondary care hospital in Portugal between January 1997 and January 2017. Standard demographic information, etiology, amputation and reamputation level, functionality achieved with prosthesis, before and after reamputation, were collected from medical records. Only major amputations (below-knee or above-knee) were considered. A descriptive, bivariate analysis was performed using Q-square test; statistical significance p<0.05 on SPSS v.23.

Results

In 536 lower limb amputees, 46 (8,6%) had reamputations, within an average of 22 months after the first amputation. 78.3% were male, with a mean age of 64 years old. The main cause of amputation was peripheral artery disease (PAD), with 72% having DM. The most frequent level of first amputation was below-knee (68.2%) and the most frequent level of reamputation was above-knee on contralateral limb (52.3%). There was no statistically significant difference between the mortality rate of reamputees and the control-population of amputees. Only a third (34%) of patients were able to walk with a prosthesis between amputations, and only 8 (17%) after reamputation. The mortality rate was statistically significantly higher (p<0.05) in reamputees on hemodialysis.

Conclusion

Conclusions: To our knowledge, this is the first report showing the ambulatory status achieved by patients after major reamputation. Determining the incidence of reamputation and its outcome is important to improve patients' rehabilitation treatment and inform them about their prognosis.
Keywords

reamputation; mortality rate

Alveolar soft part sarcoma (ASPS) is a rare soft tissue sarcoma approximately 1.0% of all soft tissue sarcomas in the Philippines. An 8-year-old male presented to the Philippine General Hospital in February 2017 and underwent ray amputation of the 3\textsuperscript{rd} to 5\textsuperscript{th} digits of the left hand.

**Material and Method**

Bone scan, chest and abdominal computed tomography scans revealed no distant metastasis. Post-operatively, edema, pain, weakness, and limitation of joint range of motion (ROM) were noted at the left wrist, 1\textsuperscript{st} and 2\textsuperscript{nd} digits. He had difficulty in performing bi-manual hand activities. Patient was admitted at the Rehabilitation Medicine Ward for pain control and improvement of left hand function. Gabapentin provided pain relief for phantom limb pain. A low-cost, volar based, thermoplastic custom molded hand splint was prescribed to prevent ulnar collapse of the residuum and provide a base for grasping. He underwent physical therapy (edema management, ROM and strengthening exercises); occupational therapy (gross and fine motor skills training, activities of daily living (ADL) retraining); and psychology sessions (depression screening and counseling). He was evaluated by Pediatric Hematology and Oncology, Radiation Oncology, and Pediatric Orthopedics and underwent surveillance radiographs with normal results. Chemotherapy and radiotherapy were not warranted.

**Results**

After four weeks of rehabilitation, phantom limb pain resolved and he regained hand function. Jebsen hand function test, Purdue Peg Board and grip strength, measured 10 months post-operatively, revealed improvement in picking up small objects, lifting heavy objects, and arm hand dexterity. Patient was able to perform ADL, attend regular school, play with schoolmates, and perform house chores.

**Conclusion**

This case report presents the challenges in rehabilitation of a pediatric patient with ray amputation of the 3\textsuperscript{rd} to 5\textsuperscript{th} digits of the dominant hand for alveolar soft part sarcoma and highlights multi-disciplinary approach to management.

³Kameda Medical Center, Oprosthetist and Orthotist, Kamogawa city- Chiba, Japan

Introduction/Background

Previous reports on surgical treatment of fractures occurred in amputated limbs are scarce. We report 5 patients with femoral and hip fractures of amputated limb in which they regained walking ability with prosthesis by rehabilitation with physiotherapist and prosthetist.

Material and Method

Included in this report, 5 patients of hip and femoral fracture who had received surgical treatment in our hospital, 3 cases were men and 2 cases were women. Mean age was 64.2 years (Range, 37 to 83 years), 3 cases had received above knee amputation and 2 cases had underwent below knee amputation. Causes of amputation included trauma in 3 cases and diabetes in 2 cases. In this case series, period of hospitalization, complication, rehabilitation for amputee were examined.

Results

All patients were able to walk independently with prosthesis and when they left hospital. Mean period of non-weight bearing was 7.2 weeks (Range, 0-12 weeks), and that of regaining walking ability for daily life was 14.0 weeks (Range, 8-18 weeks). 2 patients suffered from localized pain due to skin irritation but resolved by removal of implants. Temporary substitution of a socket were necessary for all patients due to swelling of soft tissue after surgery.

Conclusion

In surgical treatment of amputated limbs, orthopedic surgeons choose implants considering the length and shape of remaining bone. We also consider skin irritation between screws, plates and prosthesis. Volume of soft tissue changes after surgery, so we used bigger socket temporarily to continue rehabilitation which leads to good outcome. Careful observation of amputated limb and treatment by close cooperation with physiotherapist and prosthetist is important for rehabilitation of amputees.

Comparative Evaluation of the Efficacy of Five PRM Programmes on Functional Autonomy and Phantom Pain in Patients after Lower Limb Amputation

I. Koleva¹, B. Yoshinov², R. Yoshinov³
¹Medical University of Sofia, Department of Physical Therapy, SOFIA, Bulgaria
²Sofia University, Medical Faculty, Sofia, Bulgaria
³Bulgarian Academy of Sciences, Laboratory of Telematics, Sofia, Bulgaria

Introduction/Background

Our objective was to realize a comparative evaluation of five PRM programmes of care in patients after trans-femoral amputation.

Material and Method

During last years a total of 105 amputees were observed and investigated – in-patients of the Clinic / Department of Physical and Rehabilitation Medicine (PRM). Patients were randomized into five treatment groups consisting of 21 patients each.

All patients received a trans-femoral amputation 1 to 6 months before rehabilitation, with stump pain and phantom pain. All patients gave written informed consent.

All patients received a complex rehabilitation programme including physical therapy and patients’ education. We accentuate on: analytic exercises for hip muscles, post-isometric relaxation for ilio-psoas muscle, strengthening exercises for the paravertebral and abdominal muscles; balance and gait training. In group 1 we applied too drug therapy – paravertebral infiltrations. Patients of groups 2 & 3 received a complex rehabilitation programme, including a preformed physical modality [Deep Oscillation (DO) or LASER]. In groups 4 and 5 we applied combined analgesic techniques (gr 4 = infiltrations and DO, gr 5 = infiltrations and laser).

For statistical evaluation we used t-test (ANOVA) and Wilcoxon rank test (non parametrical correlation analysis), performed using SPSS package (statistical significance - if $P$ value $< 0.05$).

Results

The comparative analysis of results shows a significant improvement of the symptoms of the patients, concerning: quality of life and functional autonomy (Mc Gill quality of life questionnaire); pain (Visual analogue scale, faces scale and evaluation of stump tenderness), and depression (scale of Zung). Best results were obtained in groups 4 and 5.
Conclusion

We could recommend the complex program for functional recovery of amputees.

REHABILITATION OF PARTIAL HAND AMPUTATIONS IN PAKISTAN
T. Khalil¹, A. Raza²
¹Army Medical College- National university of medical sciences NUMS rawalpindi- pakistan, medicine and allied, Islamabad, Pakistan
²Karachi Institute of medical sciences- National University of Medical Sciences NUMS, CMH Malir, karachi, Pakistan

Introduction/Background

More than fifty percent of traumatic injuries to hand result in hand/wrist amputation. Partial hand amputations severely affect functionality, quality of life and cause social and psychological disturbances. Cost effective, aesthetically pleasing silicon finger fillers is associated with acceptance and satisfaction among patients. This study aims at describing the cosmetic rehabilitation of partial hand amputations.

Material and Method

This is a cross sectional observational study conducted from Nov 2014 to Jan 2018. Patients with partial hand amputations, due to any cause, reporting to OPD of tertiary care rehabilitation facility were recruited. Epidemiological data (age, gender, education), cause, type and duration of injury and cosmetic intervention were recorded. Statistical analysis was done using statistical package for social sciences version 25.

Results

A total of 9 patients participated in this research; all were males. Mean age was 36 ± 3.6 years. Average duration of amputation is 3 years. Most common cause of amputation was blast injury (n=3), followed by injury with heavy machinery (n=2), fire arm injury (n=2), fall from train (n=1) electric injury by high tension wire (n=1). Type of amputation: left transmetacarpal with thumb sparing (n=3), ray amputation right index finger (n=3), right transmetacarpal with thumb sparing (n=1), ray amputation right middle finger (n=1), amputation left partial thumb and index finger (n=1). All patients could carry out activities of daily living even without prosthesis. Otto bock silicon finger fillers with cosmetic sleeve were given to all patients.

Conclusion

Aesthetically acceptable silicon finger fillers are the main stay of rehabilitation of hand amputations.

APPLICATION OF FUNCTIONAL LOAD PROCEDURES IN THE DEADLY DISABLED PERSONS FOR EVALUATION OF INDICATORS OF THE CARDIOVASCULAR SYSTEM AT THE STEPS OF PROSTHETICS

A. Burnos 1 , R. Kantemirova 1 , E. Sviridova 1

1 Federal Scientific Center of Rehabilitation of the Disabled named after G.A. Alb, Terapeutic department, St.Petersburg, Russia

Introduction/Background

The problem of prosthetics of elderly patients (EP) has worsened due to the growing number of disabled people in the Russian Federation (RF), the aging of the population. Annually in RF, about 10 000 surgical interventions are performed in the case of lesions of the arteries of the lower extremities. The number of EP who need prosthetic supplies has increased. To individualize the selection of technical means of rehabilitation (TMR), at the stages of learning to walk and use prostheses, it is necessary to conduct optimal functional tests (FT). The aim: selection of the optimal FT with load in EP who underwent amputation at the level of the shin and thigh.

Material and Method

We examined 54 patients who underwent at the level of the lower leg and thigh. Studies were carried out with modeling of the load using manual bicycle ergometry. A universal variant of the loading test is developed, the most informative for assessing the physical state of EP, identifying potentially dangerous rhythm disturbances and painless myocardial ischemia. All samples were monitored by electrocardiography, pulse oximetry.

Results

Severe circulatory failure (CF) was detected in 7 patients (12.9%), persistent moderate in 35 patients (64.8%), insignificant in 12 patients (22.3%). Patients with severe CF prosthetics were not performed, due to low FT and a high risk of complications in the stages of prosthetics. Patients with mild CF after choosing conservative treatment were successfully prosthetized. In the remaining 12 patients the results of FT with exercise helped to start prosthetics in the early period.

Conclusion

The use of functional stress tests in disabled patients for assessment of the cardiovascular system at the stages of prosthetics, as well as adaptation to new living conditions, allows individualizing the selection of TMR, eliminating the risks of complications at the stages of prosthetics, and shortening the terms of rehabilitation.

QUADRUPLE AMPUTATION: ENABLING PERFORMANCE IN DAILY LIVING ACTIVITIES AND PARTICIPATION IN DAILY ROUTINE- CASE REPORT

D. Tsukimoto¹, A.T. Sugawara², M.C.C. Cardoso¹, M.K.F. Watanabe¹, G.R. Tsukimoto¹, S.J. Nakazune¹, L. Falkenburg¹, M.H. Miyazaki²
¹Physical and Rehabilitation Medicine Institute- Hospital das Clinicas HCFMUSP- F, Occupational Therapy, Sao Paulo, Brazil
²Physical and Rehabilitation Medicine Institute- Hospital das Clinicas HCFMUSP- F, Physiatry, Sao Paulo, Brazil

Introduction/Background

Multiple amputations are a challenging subject in rehabilitation. An integrated team work is essential to provide the patient with the most suitable and up to date therapeutic resources to reach the best quality of life and functioning as possible.

Material and Method

The aim of this study is to present a case report about the rehabilitation program of a patient that has quadruple amputation (trans-tibial and trans-radial bilateral) in 2015 due to limb ischemia from vasopressor drugs during septic shock by urinary tract infection in solitary kidney by S. aureus; focusing on the aspects of enabling performance in daily living activities and participation in daily routine.

We analyzed the data from the medical records of the patient, regarding the occupational therapy evaluations and interventions since May 2015; when the patient first started the inpatient rehabilitation program and through the post-amputation, pre-prosthetic and post-prosthetic phases. The patient attended to multidisciplinary team sessions, including daily occupational therapy individualized sessions, twice a week occupational therapy group sessions and caregiver educational groups.

Results

The patient was able to perform basic and instrumental activities of daily living using adaptation techniques or assistive technology with a higher level of independence and quality of performance. Education approaches were used regarding aspects of energy conservation, safety, home modifications and caregiver orientation. At the final phase of rehabilitation, the patient was able to walk with bilateral lower limb prosthesis and has a 3D prosthesis for the right upper limb.

Conclusion
The multidisciplinary team assure the best rehabilitation outcomes for people with multiple amputations and the occupational therapist plays an important role in the maintenance and restoration of the patient’s functional abilities, helping to surpass the activity limitations and to participate in the life situations that are significant to him in the physical, social and attitudinal environment that he is part of.

AUDIT OF ACUTE PAIN MANAGEMENT POST MAJOR AMPUTATION IN SOUTH MERSEY ARTERIAL (SMART) CENTRE
C. Shippen¹, A. Azer², T. Ghatwary³, H. Rabee³
¹The Walton Centre NHS Trust, Rehabilitation Medicine, Liverpool, United Kingdom
²Wirral University Teaching Hospital, Wirral Limb Centre, Liverpool, United Kingdom
³Countess of Chester Hospital, Vascular Surgery, Chester, United Kingdom

Introduction/Background

Good pain management is essential post amputation. Patients experience a mixed nature of pain including nociceptive pain, wound pain and neuropathic/phantom limb pain. There often a mixed picture. Good pain management aids early mobilisation. National guidelines recommend 100% compliance with a pain management protocol. Aim is to assess current compliance with the local pain management protocol, review how pain is assessed and treated, and find if patients are discharged with unnecessary medication.

Material and Method

All patients following lower limb major amputation (above ankle amputation) in 2016 were identified, data collected retrospectively from electronic case notes.

Results

40 patients included. 20 above knee, 18 below knee and 2 through knee amputations. Length of stay ranged from 6 to 121 days.

32%(13/40) of patients had chronic pain and already on analgesia.

15 had significant nociceptive stump pain, 6 only neuropathic pain and 5 mixed pain. 9 reported no pain on day 1. 6 had no assessment of pain in medical notes.

Following surgery, 22.5%(9/40) were not given zomorph (or alternative opiate) 20%(8/40) were not given gabapentin with no reason or alternative. (According to local protocol)

20%(8/40) had problematic pain and discharged on multiple medications.

2 waited over 10 days before mobilisation, these patients had uncontrolled pain. 4 mobilised on day 1 with good pain control.

2 discharged on zomorph despite having no pain. 18 discharged on gabapentin; however 5 on a small dose.
Conclusion

A uniform pain assessment as part of the major amputation pathway is required to be used by all clinicians involved in patient care. This would provide an accurate assessment of pain and used as a tool to monitor response to medication changes. An assessment of pain on admission and discharge with medication review is essential. Multi-centre audits are recommended to establish corresponding guidelines for pain management for these patients.

TREATMENT OF RESIDUAL LIMB HYPERHIDROSIS (LOWER LIMB): SALUTOX, AN ONGOING STUDY COMPARING ONABOTULINUMTOXINA AND TOPICAL ALUMINIUM CHLORIDE. STUDY PROTOCOL AND STUDY POPULATION

H. Bisseriex¹, L. Thefenne², L. Borrini³, R. Klotz⁴, E. Lapeyre³
¹Military Hospital Clermont-Tonnerre, PMR department, Brest, France
²Military Hospital Laveran, PMR department, Marseille, France
³Military Hospital Percy, PMR department, Clamart, France
⁴PMR Center Tour de Gassies, PMR department, Bruges, France

Introduction/Background

Amputees often complain of residual limb hyperhidrosis (RLH), responsible for prosthesis function impairments, dermatological problems and decreasing quality of life. Botulinumtoxin is an innovative treatment but its use for RLH has not been strictly evaluated.

The treatment of the RLH with botulinumtoxin is described in only 22 cases in the literature (six case reports and two series of case) and in a randomized placebo-controlled study (N=11) where rimabotulinumtoxinB produced the same perceived effect on prosthetic use as placebo, whereas objective gravimetric sweat analyses significantly decreased for rimabotulinumtoxinB only.

Material and Method

SALUTOX is an ongoing multicentered prospective open randomized controlled trial comparing topical aluminium chloride (TAC) (considered as standard treatment) and OnabotulinumtoxinA intradermal injections in RLH treatment.

After randomization, patients will receive either 100 units OnabotulinumtoxinA in a single injections procedure or TAC for 6 months. They will all be evaluated during 3 study visits (week 4, week 12, week 24) and 1 phone call (week 18). Primary outcome measure is HDSS decrease (Hyperhidrosis Disease Severity Scale). Other functional parameters, tolerance, pain and quality of life are also evaluated.

Results

25 patients have already been included (5 females, 20 males). Represented amputation levels are tibial (58%) and femoral (42%). Compared to amputees general population, they are younger and mainly amputated for traumatic reasons. They are quite active and have to take off their prosthesis to dry it 2.6 times per day, what impairs their quality of life. 71.4% report HDSS greater than or equal to 3. Although HDSS might increase with the young age, the tibial amputation level and a short delay after amputation, no statistical significance appears in this sample. 26% have skin damages. Pain is not overrepresented.
Conclusion

This study aims to bring new evidence to determine if OnabotulinumtoxinA should be a first-line RLH treatment regarding effectiveness, tolerance and cost.

VALIDATION OF ABILOCO IN BENINESE ADULTS WITH UNILATERAL LOWER LIMB AMPUTATION USING RASCH ANALYSES

D.D. Niama Natta¹, E. Sogbossi¹, I. Chabi¹, E. Alagnide¹, T. Kpadonou¹, C.S. Batcho²
¹National University Hospital of Cotonou,
   Physical Medicine and Rehabilitation Department Cotonou, Cotonou, Benin
²Université Laval, Department of Rehabilitation- Faculty of Medicine, Québec, Canada

Introduction/Background

Mobility and locomotion are basic physical needs whose restoration is an important goal of rehabilitation programs for lower limb amputees. The objective of this work is to validate the ABILOCO questionnaire for patients with a lower limb in Benin.

Material and Method

The preliminary version of ABILOCO included 36 items. Fifty-eight patients with unilateral amputation of the leg or thigh were evaluated with this version. Patients were asked to provide their perceived difficulty in completing each item according to three response categories. Patients were also evaluated with additional measures included: Locomotor Capabilities Index (ICL), Rivermead Mobility Index (RMI), Six minute walk test. Data were analyzed with the RUMM2030 software and SigmaStat softwares.

Results

Rasch analysis retained 20 items with three response categories. Indeed, 9 items were deleted because they had more than 50% of missing responses; one item was deleted because it had a disordered threshold; 8 items were deleted because they did not fit the model; and two items because had differential functioning. The ABILOCO in Beninese adults with unilateral lower limb amputation had good external validity with the RMI (r = 0.74 and p = 0.01) and with the ICL (r = 0.72 and p <0.01) and with the NFAC (r = 0, 65 and p <0.01).

Conclusion

The ABILOCO in Beninese adults with unilateral lower limb amputation consisted of 20 items at 3-level.

TRAINING OF PHANTOM LIMB MOVEMENTS IN TRANS-HUMERAL AMPUTEES INCREASES MOBILIZATION CAPACITY AND ASSOCIATED RESIDUAL MUSCLE ACTIVATION

J. De Graaf¹, F. Vérité¹, C. Nicol¹, K. Steiner¹, A. Touillet², N. Jarrassé³, J. Paysant²
¹Institut des Sciences du Mouvement UMR 7287, Faculté des Sciences du Sport, Marseille, France
²Institut Régional de Réadaptation UGECAMNE, Centre Louis Pierquin, Nancy, France
³Institut des Systèmes Intelligents et de Robotique UMR 7222, Sorbonne Université, Paris, France

Introduction/Background

In the light of the development of polydigital hand prosthesis, we recently explored an intuitive control mode by surface EMG associated to phantom limb movements (PLM) in upper arm amputees (Jarrassé et al, 2017a,b). As little was known about PLM, we described types and characteristics of upper limb PLM and explored some factors potentially influencing these in a population of upper limb amputees (De Graaf et al., 2016; Touillet et al., submitted). We showed, among others, that one persistent characteristic of PLM is the associated fatigue, which potentially is a problem when using PLM for prosthesis control since fatigue diminish the mobilization capacity as well as the stability of the EMG signals and thus interferes with the prosthesis control.

Material and Method

In the present study, we explored whether PLM training (not to confound with learning) can increase mobilization capacity and stabilize EMG signals. Five trans-humeral amputees volunteered for training of all their types of PLM at home on a daily basis during about 6 weeks. Kinematics (via the intact limb imitating the phantom movements) as well as EMG signals from the residual muscles were recorded just before and right after the training period.

Results

None of the participants experienced (phantom or residual limb) pain related to the training. Three participants increased the number of different PLM they could execute. All of them increased the amplitude and velocity, and thus diminished the cycle duration, as well as the number of cycles they could execute before the PLM blocked by fatigue. The amplitude of the EMG increased and became more specific to the type of PLM.

Conclusion
In conclusion, as is the case for intact limbs, training of PLM improves motor performance and stabilizes the EMG signals associated to PLM execution. This is encouraging for future PLM-based prosthesis control.

EVALUATION OF DIFFERENT TYPES OF PROSTHETIC HANDS ON THE SHOULDER COMPENSATORY MOVEMENTS
I. Loiret¹, C. Billon¹, V. Sanamane¹, M.A. Haldric¹, A. Touillet¹, N. Martinet¹, J. Paysant²
¹centre Louis Pierquin, appareillage, 54000 Nancy, France
²CHRU Nancy- Université de Lorraine, médecine physique et de réadaptation, Nancy, France

Introduction/Background

The use of myoelectric prosthetics in upper limb amputees introduced compensations on the residual shoulder and trunk which could be the cause of musculoskeletal disorders. Task/work involving movements in abduction of shoulder (>60°) more than two hours per day in cumulative have been identified to be responsible of musculoskeletal disorders. The aim of the study is to evaluate the shoulder compensations in upper limb amputees with the use of the new myoelectric multi-articulated prosthetic hands compared to tri-digital hands during different functional tasks.

Material and Method

Five unilateral trans-radial upper limb amputees (4 male, 1 female; age 45.6 ± 13.8 years old) participated in this prospective cross-over study. Evaluations were realized by each participant with their own tri-digital myoelectric prosthesis and 2 multigrip prosthesis: I Limb Ultra® (IL) without a wrist mobility and Michelangelo® (MA) with a wrist mobility, after specific rehabilitation and one month of home use. Mean of internal rotation, mean of abduction shoulder, percent time in abduction higher than 60° and its extrapolation in hours were calculated by an optoelectronic system (VICON) for the both sides (amputated - non-amputated) during the Box and Block Test (BBT) and 2 common daily life tasks (cut meat, make a knot).

Results

Whatever the tasks, there is any significant difference in internal rotation with the different prosthetic devices. The results of the abduction shoulder of the BBT are presented in table 1, and of the 2 daily life tasks are presented in table 2.

Conclusion

New types of grip of innovative prosthetic hands and wrist mobility seems to decrease shoulder abduction, considered as pathogenic compensations. However, the compensation strategy is different across patients which involve a personalized analysis for his rehabilitation program and for the prosthetic device choice. Further studies are necessary to evaluate the impact of trunk compensations.

A REHABILITATION PROGRAM FOR LOWER LIMB AMPUTEES WITH OCCLUSIVE ARTERIOPATHY

D. Claire1, B.B. Françoise2, P. Anthony3, R. Amandine4, V. Eric5
1CRMPR Les Herbiers / IRMS2, Médecine Physique et de réadaptation / Médecine du sport, Rouen, France
2CRMPR Les Herbiers / CHU Rouen, Médecine Physique et de réadaptation, Rouen, France
3Médecine Physique et de réadaptation, Bois Guillaume, France
4CHU Reims, Médecine Physique et de réadaptation, Reims, France
5CRMPR Les Herbiers / CHU Rouen, Rouen, France

Introduction/Background

Rehabilitation programs are part of grade A recommendations for cardiovascular diseases. Amputation is a major event in arteriopathy as it significantly impacts quality of life and life expectancy. However, currently there are no validated rehabilitation programs for lower limb amputees with occlusive arteriopathy. The aim of our study was to assess the effects of a rehabilitation program on functional abilities and quality of life. This study also evaluated the feasibility of implementing a rehabilitation program at our regional rehabilitation center in Normandy, France.

Material and Method

We included patients aged from 18 to 85 years old with unilateral lower limb amputation due to occlusive arteriopathy and a definitive prosthesis. They were followed at our center between 2012 and 2015. All patients had a compulsory cardiovascular check-up and a VO2Max Test. Our main criterion was the 2-minute walking test (2MWT). It was performed with the PPA-LCI and TUGT survey at the beginning and the end of the 15-week program. Patients had 4 sessions a week (including muscle strength exercises and endurance exercises).

Results

Among 119 patients with lower limb amputation due to peripheral arterial disease followed at our center between 2012 and 2015, only five were included in our rehabilitation program (25% of death). The median difference at the 2MWT between the start and the end of the program was 2.5 meters (SD 8.7). Three of the five patients included were able to walk more than 113 meters at the 2MWT at the end. The median maximal strength increased by 10 Watts (SD 5.5). The median difference in TUGT was 1.9 seconds (SD 3). All patients were satisfied.

Conclusion

Despite the absence of statistical validation, our results suggest the value of a rehabilitation program for amputees with occlusive arteriopathy. Difficulties associated with study recruitment
highlight the importance of a care network focused on the management of peripheral artery disease.

THE IMPORTANCE OF SOMATOSENSORY FEEDBACK FOR PHANTOM LIMB MOBILITY REVEALED BY DIFFERENCES IN PHANTOM MOVEMENT KINEMATICS BETWEEN ABOVE- AND BELOW-ELBOW AMPUTEES

A. Touillet¹, N. Jarrassé², N. Martinet¹, C. Nico³, J. Paysant¹, J.B. De Graaf³

¹Institut Régional de Réadaptation UGECAMNE, Centre Louis Pierquin, Nancy, France
²Institut des Systèmes Intelligents et de Robotique, Sorbonne Université, Paris, France
³Institut des sciences du mouvement UMR 7287, Aix Marseille Université, Marseille, France

Introduction/Background

After amputation, hand and wrist phantom limb movements (PLM) are experienced as effortful, slower and smaller than healthy limb movements. Our hypothesis is that this is caused by the altered somatosensory feedback coming from the residual limb muscle contractions that are associated to PLM. If this is true, one can expect to find differences between below- and above- elbow amputees since the latter ones still have many muscles left that were involved in hand and wrist movements, such that the sensory feedback is close to that before the amputation. To test this hypothesis, we compared PLM kinematics between above- and below-elbow amputees.

Material and Method

Six above- and 8 below-elbow amputees performed phantom hand and wrist PLM. The kinematics of the PLM was indirectly obtained via the intact limb that synchronously mimicked the PLM at a comfortable velocity, using a Cyberglove for hand movements and an inertial measurement unit for wrist movements. For each patient and each type of PLM, we determined the number of executed cycles, the duration of the cycles and the velocity.

Results

Our results show that after above-elbow amputation the number of different types of PLM was higher, PLM repetitions were more numerous before blocking caused by fatigue, cycle duration was shorter and velocity was higher.

Conclusion

In conclusion, below-elbow amputees have more facilities for PLM execution (i.e., they perceive their PLM as faster and less tiring) than above-elbow amputees. This confirms our hypothesis that the more the somatosensory feedback is altered with respect to intact limb feedback, the slower and more effortful are PLM.

TRANSCULTURAL ADAPTATION AND VALIDATION OF A FRENCH VERSION OF THE PROSTHETIC LIMB USERS SURVEY OF MOBILITY 12 ITEMS SHORT-FORM (PLUS-M/FC-12)

C. Karatzios¹, I. Loiret², F. Luthi³, B. Leger³, J. Le Carré³, G. Muff¹, C. Benaim¹

¹CHUV - University of Lausanne, Division of Physical Medicine and Rehabilitation, Lausanne, Switzerland
²Institut régional de Médecine Physique et Réadaptation- Nancy- France., Médecine Physique et Réadaptation, Nancy, France
³Clinique Romande de Réadaptation Suvacare, Musculoskeletal rehabilitation, Sion, Switzerland

Introduction/Background

The “PLUS-M 12-item Short Form” (PLUS-M/SF-12) is a self-administered questionnaire that assesses the perceived capacity of Lower Limb Amputees (LLA) to perform a number of daily-life activities. Its psychometric properties are excellent (ICC> 0.9), administration time and scoring are quick and normative data is available. It can be used either in clinical practice, or for research purposes.¹,² Our objective was to develop a French version of this questionnaire and to assess its psychometric properties.

Material and Method

International recommendations for translation and cross-cultural validation of questionnaires were followed. Forty-seven subjects (age 54±16, 36 males/13 females, 27/10/10 transtibial/gritti/ transfemoral, 21/23/3 ischemic/traumatic/other) participated. Criterion validity was assessed with the Pearson Correlation Coefficient (PCC) between PLUS-M/FC-12 and other constructs (Locomotor Capabilities Index, Activities-specific Balance Confidence scale and 2 Minutes Walking test), internal consistency with the α-Cronbach Coefficient (α) and reliability with the Intra-class Correlation Coefficient (ICC) in forty-two subjects who completed the questionnaire twice in a 7-day interval.

Results

PLUS-M/FC-12 raw scores ranged 29-60/60 (49±8). Criterion validity, internal consistency and reliability were very good (PCCs ranging 0.55 to 0.86, p<10⁻⁶ to 10⁻⁴; α=0.90, ICC=0.92[0.86-0.96]). There were no floor or ceiling effect.

Conclusion
The French version of the PLUS-M/SF-12 has excellent psychometric properties, comparable to those of its original version. We promote the use of this short-form questionnaire for both clinical and research purposes.

ISPR8-2080
RHYTHMIC AUDITORY STIMULATION FOR GAIT TRAINING IN PERSONS WITH UNILATERAL TRANSTIBIAL AMPUTATION: A RANDOMIZED CONTROLLED TRIAL
L. Sohliya¹, R. Thomas²
¹Dr, PMR, Shillong- Northeast, India
²Christian medical college- Vellore, Pmr, Vellore, India

Introduction/Background

The objective of the study is to compare the time taken for prosthetic training using Rhythmic Auditory Stimulation with that of conventional therapy, for unilateral transtibial amputee patients. We will also compare the gait parameters in unilateral transtibial amputee patients trained with and without Rhythmic Auditory Stimulation.

Material and Method

Design: Randomized controlled trial with two groups- RAS group and control group Setting: Outpatient and Inpatient Rehabilitation units, Department of PMR, CMC, Vellore Participants: Twenty nine unilateral transtibial amputee patients ready for prosthetic training, 13 in the RAS group, 16 in the control group (age range 18-65 years). Intervention: Rhythmic beats introduced through MP3 players and earphones during prosthetic training for one hour daily Main outcome measures: The primary outcome measures- included time to complete training, timed up and go (TUG) test and 6MWT(6 minute walk test). The secondary outcome measures were gait velocity, gait cadence, step length, stride length, symmetry, and physiological cost index (PCI).

Results

Time required to complete training was 6.08 hours in RAS group and 7.44 hours in the conventional group (p= 0.159). The mean TUG was 11.09 s in RAS group and 13.43s in control group (p value 0.061). The mean 6MWT was 323.37 m in RAS and 288.96m in control group (p value 0.390). On sub-analysis with exclusion of two skewed variables, statistical significance was found for the TUG test (p value 0.020). Step length was found to be better for those in the control group (p=0.016 on amputated side and 0.019 on normal side) probably because of external cueing possibly leading to “forced gait” in RAS patients.

Conclusion

RAS may potentially decrease the time to completion of training in patients with transtibial amputation. Its effect on improving walking endurance and enabling independent community ambulation for unilateral transtibial amputee patients needs further research with larger studies.

ISPR8-2187
DEVELOPMENT OF A QUESTIONNAIRE TO IDENTIFY BARRIERS AND FACILITATORS OF THE IMPLEMENTATION OF A CLINICAL PRACTICE GUIDE FOR PEOPLE WITH AMPUTATION IN COLOMBIA
A. Posada¹, D.F. Patiño¹, M.D.P. Pastor¹, L.H. Lugo¹, V. Ciro¹, J. Plata¹, D.C. Aguirre¹
¹Facultad de Medicina - Universidad de Antioquia, Grupo de Rehabilitación en Salud, Medellín, Colombia

Introduction/Background

Research on the use of innovations in practice is limited by the lack of validated instruments to assess factors that facilitate or hinder the implementation of Clinical Practice Guidelines (GPC) in Colombia. The aim of this study is to develop a questionnaire to identify barriers and facilitators for the implementation of the CPG for the rehabilitation and care of lower limb amputees.

Material and Method

Development of the questionnaire included four phases: literature review, aimed to identify domains of the construct (phase I). Individual interviews with potential and current users of the CPG, to gain insight into the perceived barriers and facilitators for its implementation (phase II). Selection of relevant items by a panel of experts with the information collected in previous phases (phase III). Pilot test with health professionals and administrators to assess face validity, response time and the presence of ceiling or floor effect (phase IV).

Results

Review of the literature identified generic and specific questionnaires; common domains across most questionnaires were related to the innovation, the provider, the patient and the context. The analysis of the interviews revealed some categories not included in the theoretical review. The panel of experts selected 90 items for the first version of the questionnaire. In the pilot test of the questionnaire (n = 13), the average response time was 28 minutes (14 to 60); in 85 of the questions ceiling effect was present and in 8 of the questions floor effect was present. Changes were made to the directions of the instrument in order to reduce these effects in the new version, with 73 items.

Conclusion

We developed a questionnaire to assess the barriers and facilitators for the implementation of the CPG for the rehabilitation and care of individuals with lower limb amputation. In a next step, the psychometric properties of the questionnaire will be evaluated.

TRANSCULTURAL ADAPTATION AND VALIDATION OF A FRENCH VERSION OF THE PROSTHESIS EVALUATION QUESTIONNAIRE (PEQ-F).

C. Karatzios\textsuperscript{1}, I. Loiret\textsuperscript{2}, F. Luthi\textsuperscript{3}, B. Leger\textsuperscript{3}, J. Le Carré\textsuperscript{3}, G. Muff\textsuperscript{1}, C. Benaim\textsuperscript{1}

\textsuperscript{1}CHUV - University of Lausanne, Division of Physical Medicine and Rehabilitation, Lausanne, Switzerland
\textsuperscript{2}Institut régional de Médecine Physique et Réadaptation, Médecine Physique et Réadaptation, Nancy, France
\textsuperscript{3}Clinique Romande de Réadaptation Suvacare, Musculoskeletal rehabilitation, Sion, Switzerland

Introduction/Background

The Prosthesis Evaluation Questionnaire (PEQ)\textsuperscript{1} is a self-questionnaire that assesses quality of life (QoL) of lower limb amputees (LLA). It contains 9 sub-scales that explore the following areas: ambulation, appearance, frustration, perceived response, residual limb health, social burden, sounds, utility and well-being. An optional addendum of 14 questions that assesses stumbling, falls, attentional load and balance confidence during walking has also been developed and used.\textsuperscript{2} Our objective was to develop a French version of this questionnaire (PEQ-F) and to assess its psychometric properties.

Material and Method

International recommendations for translation and cross-cultural validation of questionnaires were followed. Fifty-two subjects (age 53±16, 40 males/12 females, 28/12 transtibial/gritti-stokes/transfemoral, 21/28/3 ischemic/traumatic/other, years since amputation 10±10) participated. Criterion validity was assessed with the Pearson Correlation Coefficient (PCC) between PEQ-F and other constructs (SF-36, Prosthetic-Profile-of-the Amputee-Locomotor-Capabilities-Index, Amputation-Body-Image-Scale, Brief-Pain-Inventory, Trinity-Amputation-and-Prosthesis-Experience-Scales-Revised, Activities-specific-Balance-Confidence-Scale, Timed Up and Go and 2 minutes Walking Tests). Internal consistency was assessed with the α-Cronbach Coefficient (α) and reliability with the Intra-class Correlation Coefficient (ICC) in 48 subjects who completed the questionnaire twice in a 7-day interval.

Results

PEQ-F scores ranged 46-96/100 (76±11). Criterion validity was verified for the PEQ-F ($r = 0.38$-$0.33$, $p = 0.008-0.03$) and for all tested subscales ($r = 0.32$ to 0.50, $p = 0.02$ to 0.0002). Internal consistency was satisfactory ($α=0.87$). The reliability of the global PEQ-F was excellent ($ICC=0.89[0.82-0.93]$), and good to excellent for its subscales (ICC ranging $0.60[0.37-0.75]$-$0.89[0.82-0.94]$). There were no floor or ceiling effect.

Conclusion
The French version of the PEQ-F has good psychometric properties, comparable to its original version. It offers a holistic evaluation that helps managing LLA patients and identifying personal needs. We promote the use of the whole questionnaire or part of it for both clinical and research purposes.

ISPR8-2366
THE EFFECT OF REPEATED BOTULINUM TOXIN TYPE A INJECTIONS IN THE TREATMENT OF RESIDUAL LIMB HYPERHIDROSIS: A CASE STUDY

V. Martins
Centre Hospitalier Nord Caraïbe, Physical and Rehabilitation Medicine, le carbet, France

Introduction/Background

Residual limb hyperhidrosis is a problem frequently encountered in amputations, experienced by 66% of the subjects in the Hansen et al. Study. If the condition resists conventional treatment (appropriate hygiene measures, antiperspirants), it can be treated by intradermal or intraepidermal botulinum toxin injections.

Material and Method

Objective: to study the effect of repeated botulinum toxin type A injections in the treatment of residual limb hyperhidrosis.

Study type: case report.

Participant: Afro-Caribbean male, aged 29, with transfemoral amputation suffering from debilitating excessive sweating of the residual limb, causing prosthesis to slip when walking.

Intervention: four sessions of superficial intradermal injections of botulinum toxin type A into the residual limb, at 14, 9, and 4-month intervals.

Results

Botulinum toxin A reduced sweat production in the residual limb by an average of 70.5%. It reduced sweat-induced discomfort when this was assessed to be major at the pre-toxin assessment, and improved times before prosthesis removal when these were short at the initial assessment.

On average, it led to an overall reduction in sweat-induced discomfort by 38.25% and discomfort during work by 37%, and increased times before prosthesis removal (+1h39 during work and +3h22 during activities of daily living).

Pain experienced during the injection session was reduced during the 4th session.

Finally, a progressive reduction in the duration of BTA effect was observed.

Conclusion
This study suggests that botulinum toxin type A injections effectively reduce sweat quantity in the residual limb. Major sweat-induced discomfort and short prosthesis wearing time without removal may be improved by BTA. However, the duration of BTA effect appears to decrease over time.

No conflict of interest
Concerning amputations in France, 52% is due to diabetes and amputation risk is 14 times higher in case of diabetes.

There is up to now no study about amputation rate in French West Indies, but there are 2 times more diabetes treated in the French Overseas Departments compared of France and there were 82 hospitalized patients with major lower limb amputation (above foot) in our service in 2015.

**Material and Method**

Objective: Evaluate the equipment specificities of diabetic lower limb amputees.

Inclusion: direct inclusion of 31 patients.

Judging criteria: compare residual limb prosthesis, equipment of the other foot and walking performances in diabetic and non diabetic above foot amputees.

**Results**

Diabetic amputees need 53% more bilateral fittings than others: walking prosthesis on the amputated side and therapeutic footwear on the other side, because of foot trophic disorders (53% more). There is no significant difference for other criteria.

**Conclusion**

Above foot amputees due to diabetes need walking prosthesis and therapeutic shoes. There is few impact on prosthesis choice and walking performances.

ACQUIRED BRAIN INJURY AND NEUROGENIC BLADDER: A PRELIMINARY REPORT ON THE USE OF TRANSCRANIAL DIRECT CURRENT STIMULATION (tDCS) IN NEUROGENIC LOWER URINARY TRACT DYSFUNCTIONS (ANLUTD)

G. LAMBERTI¹, D. Giraudo², F. Gozzerino¹, E. Antoniono¹
¹SC NEURORIABILITAZIONE “E. VIGLIETTA”, ASL CN1, Cuneo, Italy
²SC Urologia, Ospedale San Raffaele Turro, Milano, Italy

Introduction/Background

Is accepted that suprapontine lesions such as cerebrovascular disease produce loss of voluntary inhibition of micturition, which corresponds to the uninhibited overactive bladder (OAB). Functional magnetic resonance imaging (fMRI) brain responses to bladder filling in patients with OAB differ from normal: orbitofrontal cortex, parahippocampal gyrus and amygdala, together with adjacent inferior temporal lobes, show deactivation. Transcranial Direct Current Stimulation (tDCS) represents a safe, inexpensive and straightforward technique that could be easily integrated into rehabilitation programs. From a neurophysiological point of view, tDCS increases the neuronal excitability by facilitating the action potential release and modification of the excitability of NMDA receptors. The effect of a single tDCS session last about 60 to 90 min and when the stimulation is repeated for 10 to 20 sessions, the effects have been found to last up to 3 months after the end of the stimulation sessions.

Material and Method

This research aims to determine whether OAB recovery can be promoted with tDCS. All participants were patients with a suprapontine lesion and OAB; ethical approval was obtained from the Local Ethics Commission. For non-invasive brain stimulation, a computer controlled HD-tDCS device with eight channels was used (Starstim, Neuroelectrics, Spain). For the experimental group (10 pts), an anodal direct current was delivered 20 minutes every day for two weeks at an intensity of 2 mA to the stimulation electrode placed at F3, which covered left dorsolateral prefrontal cortex. Four return electrodes were placed at T7, Fp2, CP1 and FC2.

Results

In the experimental group, urodynamics tests showed increased maximum cystometric bladder only in four patients.

Conclusion
Results to date do not allow to affirm that tDCS can modulate the activity of higher cortical centres involved in bladder control in AOB patients.

CLEAN INTERMITTENT CATHETERIZATION : BARRIERS AND ADHERENCE ISSUES IN A MUSLIM POPULATION
N. Kyal1, S. Hrar1, Y. Moigny Gajou1, F. Lmidmani1, A. El Fatimi1
1CHU Ibn Rochd, physical and rehabilitation medicine, Casablanca, Morocco

Introduction/Background

Clean intermittent catheterization (CIC) is the gold standard for the management of urinary retention. This act requires therapeutic education. The team in charge faces a lot of problems while teaching this procedure. It has a big impact on adherence to CIC. The objective is to analyse barriers and adherence issues of CIC in a muslim arabic population and to present some solutions to the problems found.

Material and Method

This is a prospective, descriptive and analytic study that lasts during 19 months. The patients were recruited at the service of Physical Medicine and Readaptation of CHU IBN ROCHD Casablanca during the neuro-uro consult. Intermittent catheterization adherence scale (I-CAS) was administrated along with a questionnaire we made based on difficulties faced by patients.

Results

50 patients were recruited. The mean age was 36.4 years, with a male predominance. 18% of the sample were child. Adherence to CIC was examined and showed that after only 1 month, 80% were compliant with this method of bladder emptying. Patients were followed up at regular intervals following CIC training for 19 months. The adherence rate was only 58% at 1.5 year. The most common difficulties while teaching this procedure were anxiety and fear of hurting themselves, and of losing their virginity (for women and girls) (n= 30 ;60%).

Conclusion

There are several factors that may act as barriers to successful CIC. Adequate follow-up is essential, and patients should be reassured with a nonjudgmental approach.

LOWER URINARY TRACT DYSFUNCTION IS THE MAJOR CONCERN OF ADULT PATIENTS WITH SPINA BIFIDA : DATA FROM A PROSPECTIVE COHORT OF 395 PATIENTS

1CHU Rennes, Department of urology, Rennes, France
2CHU Rennes, Department of gastroenterology, Rennes, France
3CHU Rennes, Spina Bifida Dysraphisms referral center, Rennes, France
4CHU Rennes, Department of Physical Medicine and Rehabilitation, Rennes, France
5CHU Toulouse, Department of urology, Toulouse, France

Introduction/Background
Spina bifida (SB) may be associated with various lower urinary tract dysfunctions, with very little data on their prevalence and severity in this population. The objective was to assess the major concerns reported by adults with SB and to report their lower urinary tract dysfunctions.

Material and Method
During their first visit to the French national referral center for SB, patients were asked about their major concern in daily living: lower urinary tract dysfunction, musculoskeletal disorders, bowel dysfunction, sexual dysfunction, pain or social issue. Were also collected: history of urological surgery, type of SB, neurological level according to Abbreviated Injury Scale, mobility, method of voiding, kidney function, Urinary Symptom Profile and Qualiveen scores, Knowles-Eccersley-Scott Symptom Constipation Score, Cleveland Clinic Incontinence Score and Neurogenic Bowel Dysfunction score. All patients seen in the French National referral center from 2007 to 2015 were unselectively included.

Results
395 patients were included, with a median age of 32 (2-88), 219 women (55.6%), 176 men (44.4%), myelomeningocele (69.4%), closed spinal dysraphism (30.6%). 144 patients voided spontaneously (37%); 15 patients used clean intermittent catheterization (54.4%); 34 patients had non continent cutaneous diversion (8.7%) and 2 indwelling catheter (0.5%). Most frequent major concerns were lower urinary tract dysfunction (28.5%) and bowel dysfunction (16.1%), followed by musculoskeletal disorders (13.6%) and pain (9.6%). 227 patients had a Qualiveen score ≥ 3 (61.1%). 145 patients had urinary incontinence during their first visit (52.1%).

Conclusion
Lower urinary tract dysfunction is the major concern in daily living in 28.5% of patients with SB.

POOR LEVEL OF INFORMATION FOR YOUNG ATHLETES REGARDING STRESS URINARY INCONTINENCE : REFERENCE TO A SURVEY CONDUCTED ON THE INTERNET

J. Péroua-Vialuit, M. Compagnat, J. Bordes, J.C. Daviet, J.Y. Salle
1CHU Dupuytren, Service de Médecine Physique et Rééducation, Limoges, France

Introduction/Background

Physical exercise performed intensively is a serious risk factor of stress urinary incontinence. Despite a better knowledge of the risks factors and the existence of available therapeutics measures, urinary incontinence remains taboo. The major purpose of this study was to assess the knowledge and expectations of athletes regarding stress urinary incontinence.

Material and Method

We have released an anonymous questionnaire using “Google Form”. This questionnaire was developed by experts. The release took place on social networks and on sports women forums from 5 to 20 May 2016. We have obtained 178 answers and 163 were selected for the study. Then, we have accomplished a global statistical study as well as a statistical study in groups of the achieved outcomes.

Results

The average age of the athletes was 29 years old of which 77% were nulliparous. They practiced an average of 3.9 hours of sport per week. 83% practiced sports as a hobby and 17% took part in competitions. The prevalence of stress incontinence was up to 45% of which 66% had an inconvenience in their everyday life. 60% had never been informed of urinary incontinence. 80% had no idea that this phenomena may occur at a young age. 86% had no knowledge of the physiopathology of the urinary incontinence. 67% knew that reeducation could help athletes to prevent stress urinary incontinence and only 34% thought they could improve it once it is established. Among the athletes affected by stress urinary incontinence, 67% had never dared speaking of it and only 19% benefited from rehabilitation.

Conclusion

The results of our study confirmed a high prevalence of stress urinary incontinence among athletes with a real impact on their well-being. However, knowledge of the subject remains very poor due to a clear lack of information. This subject is taboo, partially explained by the lack of education of athletes.

Dysphagia is common in patients with stroke. Patients may experience deficits in oral, pharyngeal and upper esophageal sphincter (UES) function, including insufficiency in chewing and mastication, weak pharyngeal constriction, UES and pharyngeal incoordination, and abnormal UES relaxation. The UES is usually closed except during swallowing phase. The suprahypoid muscles make the larynx move upward and forward to open the UES. Many studies have reported the swallowing exercise for the UES dysfunction, this systematic review aims to appraise the evidence of the swallowing exercise to facilitate the suprahypoid muscle and open the UES for stroke patients with dysphagia.

Material and Method

A systematic search of Pubmed, Embase, Medline, Web of Science, The Cochrane Library, and ProQuest databases was conducted from January 2007 to December 2017. The following four areas of research were reviewed:

(1)Studies including specific swallowing exercise for improving suprahypoid muscles activity.

(2)Studies examining the efficacy of each swallowing exercise with a device in healthy adults.

(3)Studies examining the efficacy of specific swallowing exercise with a device as a dysphagia treatment in stroke patients with dysphagia.

(4)Studies comparing the difference between those swallowing exercise in healthy adults and stroke patients.

Results

A narrative analysis of the results was conducted. Five types of swallowing exercise including Shaker Exercise, Chin tuck against resistance, Jaw open Exercise, Modified Jaw open Exercise and Head extension Exercise may facilitate the suprahypoid muscle and the opening of the UES. With the strengthened suprahypoid muscles, the amount of upward and forward movement was increased to facilitate the opening of UES and decrease the time of pharynx passage.
Conclusion

Though many studies have reported the swallowing exercise is efficacious for suprathyroid muscles, the Modified Jaw Opening Exercise holds more potential in training the suprathyroid muscle among the five swallowing exercise for stroke patients with dysphagia.

CONTRIBUTION OF A THERAPEUTIC EDUCATION GUIDE FOR PATIENTS WITH ANORECTAL DISORDERS.

C. Dziri¹, F. Charrad², S. Dziri³, I. Aloulou⁴, F.Z. Ben Salah¹

¹National Institute Of Orthopaedy M.Kassab- Faculté de Médecine de Tunis- Université de Tunis El Manar, Physical and Rehabilitation medicine, La Manouba, Tunisia
²Institut Supérieur de l'Education Spécialisée- Université de La Manouba, Laboratoire Handicap, La Manouba, Tunisia
³Hôpital Raymond Poincaré- Université de Versailles, Physical Medicine and Rehabilitation, GarchesFr, France
⁴National Institute of Orthopaed M.Kassav, Physical and Rehabilitation Medicine, La Manouba, Tunisia

Introduction/Background

In the practice of Physical Medicine and Rehabilitation, many neurological or post traumatic conditions may cause voiding disorders and anorectal disorders. Both are taboo subjects, but it seems like neurological bladder is best known and treated.

The aim of this study is to design an illustrative illustrated guide dedicated to the patients in order to explain the anorectal disorders and how to manage them.

Material and Method

A quantitative and descriptive study was carried out in the Physical Rehabilitation Physical Medicine department of the National Institute of Orthopedics Mohamed Kassab in 30 adults aged between 18 and 60 years, followed for a neurological pathology with anorectal disorders. The assesment has been done by Bristol Scale, Neurogenic Bowel Dysfunction Score, Fecal Incontinence Quality of Life Questionnaire, Functionnal Independance Measurement.

During this study we proposed a therapeutic education guide (in French and Arabic) for patients with neurological disorders to see its contribution to their ano-rectal disorders at the medical, psychological and social levels.

Results

Several patients have experienced difficulties for this topic. Stool consistency was improved in 12 patients; anal incontinence decreased in 12 patients. The feeling of discomfort decreased in 18 patients and disappeared in 3 patients.

Stool frequency improved in 14 patients. The duration of defecation decreased in 15 patients. Regarding discomfort during defecation improvement is very minimal.
Conclusion

The therapeutic education guide had a positive effect on anorectal disorders facilitating social integration.

URODYNAMIC PROFILE OF DIABETIC NEUROGENIC BLADDERS
N. Mouhli, K. Imene, R. Maaoui, A. khezami, H. Rahali
1Hôpital militaire principal d'instruction de Tunis, Rehabilitation, Tunis, Tunisia

Introduction/Background

It is now estimated that the prevalence of Lower urinary tract dysfunction (LUTD) in patients diagnosed with diabetes can reach 80% in some series. They are frequent and polymorphic. They can have a significant impact on the patient's quality of life, but above all, they can have a negative prognosis. The purposes of this study were to study the urodynamic profile of these disorders, and to try to identify the risk factors associated with the various abnormalities found on this urodynamic examination.

Material and Method

A retrospective descriptive cross-sectional study, which took place in July 2017 at the urodynamic laboratory of the Department of Physical Medicine and Functional Rehabilitation of the Military Tunis Hospital. Anamnesis, symptoms and urodynamic data were collected.

Results

23 patients, average age 62.04 years. 15 women and 8 men. Patients were followed for their diabetes for an average of 11 years. No urodynamic assessment was free of abnormalities. Deblimetry was normal in 30% of patients. During cystometry, the most common abnormalities were: contractility disorder (52.4%), hypersensitivity (47.6%), detrusor overactivity (38.1%), and the small capacity (38%). In profilometry, sphincter hypertonicity was noted in 52.6% of patients. Regarding the analytical study, in the cystomanometry, bladder stability was associated with a more recent diabetes (p = 0.02). All patients with a good glycemic control had a normal bladder contractility (p = 0.09). The presence of diabetic nephropathy was associated with bladder compliance disorder (p = 0.07).

Conclusion

If the screening of LUTD in diabetic patients can be done in consultation with endocrinology or general medicine, the urodynamic consultation must be suggested in case of disorders of significant post-void residue, or occurrence of urinary infections. It allows, thanks to the urodynamic assessment, to specify the type of neurogenic bladder and to propose an adapted care.

PREDICTIVE FACTORS OF LEARNING IN INTERMITTENT CATHERIZATION IN THE NEUROLOGICAL PATIENT

J. Galalou¹, R. Baati², E. Bahlouli¹, J. Mbarek¹

¹Sanitary complex of Djebel Ouest, Physical medicine and rehabilitation, Zaghouan, Tunisia

²Charles Nicole Hospital of Tunis, Urology, Tunis, Tunisia

**Introduction/Background**

Clean Intermittent Self-Sampling (ASIP) is the gold standard treatment for regular emptying of the neurological bladder. The technique seems simple. But, its mastery requires a rigorous apprenticeship within referent services. The objective of this study was to study the predictive factors of the mastery of ASIP learning in the neurological patient.

**Material and Method**

Our prospective cross-sectional study included patients with neurological bladder and ASIP. The patients were divided into two groups. Group 1: patients having mastered the technique. Group 2: patients who have not. A Chi² test was performed to compare the quantitative variables. A Student's test was used for the mean comparisons.

**Results**

Of the 30 included patients who learned the ASIP procedure during hospitalizations in PMR department, 21 patients did not master the procedure after an average of 5 years of practice. The average age was 38 years old. The sex ratio was 5. Twenty-seven patients (93%) were paraplegic. None of the patients had a self-administered therapeutic education session (FTE-AS). All patients received a prescription of more than 3 ASIPs per day. Sex, pathology, initial discomfort, repercussions of urinary disorders on quality of life were not statistically significant for the acquisition of the ASIP gesture. The predictive criteria of the failure of the acquisition of the gesture of ASI that we could highlight were: the age above 35 years, the low socio-economic and educational levels. The learning of the gesture in a physical medicine service, the absence of urinary leaks between the polls were favorable to the control of the ASIP technique.

**Conclusion**

The mastery of the ASIP technique cannot be done thanks to a simple and unique learning. This learning should fit best in a FTE-AS program. This program is focused on the patient and his family. It integrates into the nursing setting, performed by trained professionals.

STUDY REVIEW OF THE EFFICACY OF POSTERIOR TIBIAL NERVE STIMULATION FOR FECAL INCONTINENCE TREATMENT

A. Pascoal¹, C. Lourenço¹, P. Caetano¹, J. Constantino¹, J. Lãins¹
¹Centro de Medicina de Reabilitação da Região Centro - Rovisco Pais, Lesionados Vertebro-Medulares, Tocha, Portugal

Introduction/Background

Fecal incontinence is a common multifactorial disorder and a disabling symptom. Its management consists in medical or biofeedback therapy and invasive surgery. Sacral nerve stimulation has changed fecal incontinence management with a good success rate. This technique is less invasive than other surgical methods, but it remains an invasive procedure. Posterior tibial nerve stimulation (PTNS), both the percutaneous (PCT) and the transcutaneous (TCT) routes, has been used as a cheaper and easier alternative. This review purpose is to assess the efficacy of PTNS for fecal incontinence treatment.

Material and Method

A review was performed of the data published since 2008 until 2017 on PTNS for fecal incontinence using PubMed database with the keywords “posterior tibial stimulation” and “fecal incontinence” to identify studies describing the clinical outcome of PTNS for fecal incontinence.

Results

Thirteen studies were selected, with a median of approximately 24 individuals studied in each one and including population with age ≥ 18 years. The majority (9) were prospective uncontrolled studies. All showed that there was at least one significant improvement in one or more evaluated parameters of fecal incontinence. The Wexner scale was used by 8 of the studies, with a significant continence improvement in 7 of the studies. There was only one prospective blinded randomized placebo-controlled trial in our selection and it concluded that patients undergoing PCT had a greater reduction in the number of incontinence episodes than those undergoing TCT and sham stimulation.

Conclusion

Although the results were positive, this review was limited by the study’s population small size and the high variability of evaluation tools used. PTNS may be a new and easy-to-use option to treat fecal incontinence but we need high-quality studies with comparison groups, blinded and clinically meaningful outcome measures to further establish the utility and optimal application of PTNS.

SACRAL NEUROMODULATION IN THE TREATMENT OF ANAL INCONTINENCE

D. Amaral¹, S. Moreira¹, F. Parada¹

¹Centro Hospitalar de São João, Physical Rehabilitation and Medicine Department, Porto, Portugal

Introduction/Background

Anal incontinence (AI) is a prevalent problem that drastically affects quality of life (QoL). Pelvic floor rehabilitation (PFR) is an important first-line treatment. When conservative (and surgical) measures fail, other options should be considered. Sacral neuromodulation (SNM) is a recognized treatment due to its less invasive approach, low associated morbidity and good results in AI.

The aim of this work was to perform a review about the role of SNM in the treatment of AI, exposing a clinical case. Material and Method

Data about the patient was extracted from the clinical process and in the consultations of PFR of our Department. A review of literature of the last 10 years was conducted in Pubmed-Medline and Cochrane databases using the keywords SNM and AI.

Results

Female, 49 years old, with a medical history of perianal abscess and transsphincteric fistula submitted to abscess drainage and fistullectomy in 2007. After surgery, she started AI. She underwent sphincteroplasty in 2008 and 2015 followed by PFR program (5 months) and peripheral neuromodulation (PTNS) without significant clinical improvement. Anorectal manometry showed hypotonia of both anal sphincters with minor improvement of squeeze pressures.

She maintained incontinence for gas (daily), liquid and solid feces (> 3 times/month), with important affectation of QoL (Wexner score:13/20).

Was referred for SNM, performed in January 2018 after a temporary stimulation period of 1 month. Since then, she had improvement of AI, maintained incontinence for gas but only 1-2 episodes/month of incontinence for solid feces and minor affectation of QoL (Wexner score:8/20).
Conclusion

Currently, we found a considerable number of studies about SNM and its application in the Al. Is a safe and efficacious procedure in properly selected patients, contributing for increase in anal canal resting pressure, improvement of squeeze pressures, rectal sensation to distention and continence.

THE EFFECT OF HYPERBARIC OXYGEN THERAPY ON HEALING OF CHRONIC LEG ULCERS
A. Shrivastava¹, N. purohit¹
¹kokilaben dhirubhai ambani hospital and research institute, centre for rehabilitation, mumbai, India

Introduction/Background

Chronic leg ulcers affect 0.6–3% of those aged over 60 years and are a common cause of morbidity; prevalence ranging from 1.9% to 13.1%. The aim was to assess the effect of hyperbaric oxygen therapy on healing of chronic leg ulcers as an adjuvant to standard wound care when compared to standard wound care alone in ulcer healing.

Material and Method

Prospective observational comparative study with followed up of 12 weeks. Patients are divided into two Arms, Arm (1) received HBOT+ Standard wound care and Arm (2) received Standard wound care. Arm (1) receives 100% oxygen at 2 ATA for 90 min in a mono-place chamber (HBOT) 4 times a week for a period of 3 weeks in a mono-place chamber along with standard wound care. In Arm 2, patients receive standard wound care alone. Based on the characteristics of the wound, dressings were changed as required. Both groups assessed at 3 and 12 week for change in size of the Index ulcer . Rate of healing is assessed by reduction in size of index ulcer i.e., ulcer area covered with epithelial regeneration.

Results

35 patients were enrolled in each arm. The mean percentage regression in size of Index ulcer was 39.9% (39.9% +/- 10.9%) in arm 1 and 20.0% (20.0% +/- 10.4%) in arm 2 at 3rd week. and 72.4% (72.4% +/- 17.5%) in arm 1 and 57.5% (57.5% +/- 21.2%) in arm 2 at 12 weeks which is significant

Conclusion

HBOT has a definitive adjunctive role in management of chronic non healing leg ulcers. Large scale randomized controlled studies are required.

Pressure ulcers develop in-patients who endure long periods of immobilization due to musculoskeletal and/or neurological diseases for example. This adversely affects the patient, increases caregiver burden and healthcare costs. Usual sites for development of pressure ulcers are the sacrum, troCHANTERS and heels. However, they can also manifest in unusual sites such as the nape of the neck, on the penis, nostrils, helix of the ear, and the upper back.

Material and Method

Compression stockings, commonly used globally, assist in prevention and further progression of, venous disorders including deep vein thrombosis. The authors describe three case reports of pressure ulcer development due to prolonged application of compression stockings.

Results

Following investigation, it was found that the stockings were applied continuously without any intermittent relief. The nursing staff are primarily responsible for the prevention of pressure ulcers, and unfortunately failed to take this factor into account. Moreover, the stockings did not come with any manufacturer instructions such as length of time used in continuum before relief is necessary. We were unable to find any other cause for these unusual and rare pressure ulcers except for prolonged application of compression stockings without any formal monitoring.

Conclusion

The authors recommend that nursing staff are trained in pressure relief and prevention of pressure ulcers, including such rare occurrences, and that manufacturer give detailed guidance regarding safe use of compression stockings.

A RETROSPECTIVE ANALYSIS OF TREATMENT OF WOUNDS CAUSED BY CALCIPHYLAXIS: HYPERBARIC OXYGEN THERAPY WITH AND WITHOUT SODIUM THIOSULFATE

Y. Tailor¹, D. Armour², E. Preston-Hsu¹
¹Emory University Hospital Midtown, Rehabilitation Medicine, Atlanta, USA
²Emory University Hospital, Rehabilitation Medicine, Atlanta, USA

Introduction/Background

Calciphylaxis, or calcific uremic arteriolopathy, is a rare, but devastating condition with a mortality approaching 80% in the United States, often seen in patients with chronic kidney disease. It is characterized by calcification and intimal fibrosis with arteriolar stenosis and subsequent thrombosis. Skin changes such as livedo reticularis, tender papules, and violaceous plaques result and progress to necrotic ulceration. Management of calciphylaxis includes maintenance of normal levels of calcium, phosphorus and parathyroid hormone, and optimization of hemodialysis and nutritional status. In our cohort, aggressive wound management coupled with sodium thiosulfate and hyperbaric oxygen therapy (HBOT) has achieved improvement in rates of healing for recalcitrant wounds associated with calciphylaxis but limited evidence for the efficacy of either treatment exists.

Material and Method

We conducted a retrospective analysis of 94 patients treated for calciphylaxis at a Wound and Hyperbaric Center at an academic institution between 2000 and 2017 who were considered for HBOT. We assessed whether response to therapy as measured by wound healing varied among patients who received sodium thiosulfate, hyperbaric oxygen treatment, both therapies, or neither therapy.

Results

We found HBOT to be beneficial in healing compared to no therapy – 81.7% or 36 of 44 patients with complete or substantial resolution of their wounds vs neither therapy – 11.4% or 3 of 26 patients. We found sodium thiosulfate to be beneficial in healing compared to neither therapy – 66.6% or 2 of 3 patients with complete or substantial resolution of their wounds vs no therapy. We found combined HBOT & sodium thiosulfate to be more beneficial in healing compared to either therapy alone and to neither therapy – 86.3% or 19 of 22 patients with complete or substantial resolution of wounds.

Conclusion
Given the dramatic clinical improvement, HBOT in combination with sodium thiosulfate has an important adjunctive role in the treatment of calciphylaxis.

AN INNOVATIVE IN WOUND MANAGEMENT TECHNOLOGY

S. Ezra¹, M. Topaz¹, O. Barzel¹
¹Haim Sheba Medical Center- Ramat Gan- Israel, Rehabilitation Center, Ramat Gan, Israel

Introduction/Background

“Difficult to heal wounds” are a common and complex medical problem. It causes suffer to the patient and adds medical, social and economic burden to the health system.

The medical definition of a difficult to heal wound is: a wound showing no signs of healing between 4-6 weeks from the beginning of treatment. Part of these wounds are colonized by anaerobic bacteria.

Material and Method

We applied a novel method for treatment of difficult to heal wounds the - Regulated Oxygen - Enriched & Irrigation Negative Pressure -Assisted Wound Therapy (ROI-RNPT). This method creates a negative pressure in the wound, in combination with oxygen administration and antibiotics, applied directly into the wound bed. The negative pressure is generated by a computer controlled pump connected to an open cell sponge, located over the wound, applying a sub-atmospheric pressure scattered evenly over the wound. As part of the care and wound closure process we use the “external tissue expansion” method which is implemented by the unique TopClosure® tension relief system (TRS). The TopClosure® applies two main mechanisms: Mechanical Creep in which tension is applied to the skin slowly, and over time, skin, and stress-relaxation - stretching the skin under high tension to a fixed distance followed by waiting for the skin to relax, then repeating this action for several cycles.

Results

These principles lead to a reduction in tension enabling early and immediate closure of big wounds.

Conclusion

This study aims to investigate the efficacy and safety of the combined treatment of ROI-NPT and TopClosure®, in treatment of difficult to heal wounds, compared with the previously used methods. Our findings demonstrate that this method aids in early closure of diabetic wounds,
shortens the length of time required for treatment and hospitalization, prevents re-hospitalization and leads to increase in patients’ quality of life in the long term.

EVALUATION OF THE IMPACT OF A THERAPEUTIC EDUCATIONAL PROGRAM CONCERNING THE PREVENTION OF RISK OF PRESSURE ULCERS FOR PERSONS WITH A SPINAL CORD LESION
A. Duruflé¹, L. Mathieu¹, S. Robineau¹, B. Nicolas¹, E. Leblong¹, B. Fraudet¹, A. Gelis², P. Gallien¹
¹Pôle MPR Saint Hélier, Ille et Vilaine, Rennes, France
²Centre Mutualiste neurologique PROPARA, Herault, Montpellier, France

Introduction/Background
We conducted a study measuring the impact of a program of therapeutic education concerning the prevention of risk of pressure ulcers for persons with a medullar lesion, during the chronic phase.

Material and Method
This study concerns each person older than 18 with a medullar lesion, no matter the cause, having had pressure ulcer or not. The participants benefited from 2 collective workshops with for educational objective the prevention of the risk of pressure ulcer.

Data are collected during an initial individual interview and after 3, 6 and 12 months. They are demographical and clinical and the results of different scales among which the Skin Management need assessment checklist revised (revised SMnac). The main evaluation criterion is the score of the revised SMnac.

Results
The results concern 20 middle-aged people 52 years. 19 have a traumatic spinal cord injury with median aged of lesion at 234 months (14-684). The last one has a congenital myelomeningocele. The results demonstrate a benefit shown by the very significant increase of the global score on SMnac revised after 3 months with stability at 6 and 12 months. Furthermore, the annual rate incidence of pressure ulcer went from 75 % the year before the study to 55 % during the study.

Conclusion
In literature, there is no evidence about the place of the therapeutic education in the management of the risk of pressure ulcer for the persons with medullar lesion and numerous questions remain unsettled including the timing moment to realize these educational programs, evaluation tools, type and duration of intervention. This study enables us to bring some answers
on the impact of the therapeutic education during the chronic phase for persons with a medullar lesion on their knowledge and their practices in terms of prevention of the risk of pressure ulcer.

PRESSURE ULCERS IN A TUNISIAN REHABILITATION CENTER: A CLINICAL AND EPIDEMIOLOGICAL STUDY ABOUT 148 CASES
K. Ben Jeddou¹, S. Frioui¹, S. Jemni², F. Khachnaoui¹
¹Hopital Sahloul, service de médecine physique rééducation et réadaptation fonctionnelle, Sousse, Tunisia

Introduction/Background

The pressure ulcer, a wound of ischemic origin, constitutes a real public health problem. It is often the consequence of a poorly evaluated risk or poor management. It is a pathology that alters the quality of life of the patient. The occurrence of a pressure ulcer leads to a considerable increase in the workload for the medical and the nursing staff and the length of hospital stay. The objectives of our study were to analyze the epidemiological, etiological and clinical aspects of patients managed in the Physiotherapy and Rehabilitation Medicine department of Sahloul University Hospital in Sousse.

Material and Method

This is a descriptive retrospective study of a series of 148 patients managed in the Rehabilitation Department of Sahloul University Hospital in Sousse between January 2002 and December 2017, who presented at admission or during their hospitalization one or more pressure ulcers.

Results

All of the analysable results include 148 patients with pressure ulcers, with an average age of 38.1 years and 69.5% of whom were male. The majority of the patients (50%) were transferred from the intensive care unit, their immobilization had exceeded 30 days in 53.4% of the cases. Paraplegia was the most common reason for hospitalization (30%) followed by tetraplegia (22.7%). The other reasons for hospitalization were traumatic brain injury (16.4%), polytrauma (10.9%), and hemiplegia (8.6%). The heel and sacred locations were largely predominant (61% and 48.4% respectively). Stages II and III together accounted for 75.2%.

Conclusion

There is currently no data available in Tunisia, but despite the efforts made, pressure ulcers remain widespread. Our study has allowed us to collect figures specific to our service, which, moreover, coincide on several points with those of studies carried out in other countries.

RISK FACTORS FOR PRESSURE ULCERS IN PATIENTS ADMITTED TO A REHABILITATION SERVICE

K. Ben Jeddou1, S. Frioui1, S. Jemni1, F. Khachnaoui1
1Hopital Sahloul, service de médecine physique rééducation et réadaptation fonctionnelle, Sousse, Tunisia

Introduction/Background

A pressure ulcer is an ischaemic skin lesion related to compression of soft tissue between a hard surface and a bony prominence. According to the National Agency for Accreditation and Evaluation in Health (ANAES 2001) the factors considered today as risk factors for pressure ulcer come from a clinical experience. Their relevance and relative weight are not defined and would require studies.

The objectives of our study were to determine which risk factors for pressure ulcer are found in patients managed in the Rehabilitation department of Sahloul University Hospital in Sousse.

Material and Method

This is a descriptive retrospective study of a series of 148 patients managed in the Rehabilitation Department of Sousse between January 2002 and December 2017, who presented at admission or during their hospitalization one or more pressure ulcers.

Results

All of the analysable results include 148 patients with pressure ulcers, with an average age of 38.1 years and 69.5% of whom were male. The majority of the patients (50%) were transferred from the intensive care unit. The risk factors incriminated in the formation of pressure ulcers found in the population of our study were distributed as follows: motor deficit (98.4%), use of diapers (87.5%) sensory disorders (68.8%), urinary and faecal incontinence (68%), spasticity (37.5%), poor nutritional status (31.3%), anemia (28.1%), depression (28.1%), age> 65 years (15.6%).

Conclusion

Our study has allowed us to determine risk factors for pressure ulcer found in rehabilitation patients. The motor deficit was the most implicated risk factor in pressure ulcer formation with 98.4%. We lack information supported by an adequate level of evidence to assess, prevent and manage pressure ulcers. Studies and research on these subjects need to be encouraged.

SUCCESSFUL TREATMENT OF DIGITAL ISCHEMIC ULCER WITH STELLATE GANGLION BLOCKADE

J.H. Kim1
1Catholic Kwandong University International St.Mary’s Hospital, Rehabilitation Medicine, Incheon, Republic of Korea

Introduction/Background

Stellate ganglion blockade (SGB) could be used for the treatment of sympathetic dependent circulatory insufficiency in the upper limb. The sympathetic blockade produces relaxation of the upper extremity arteries, which increases blood flow of capillary and helps to relieve ischemia then facilitate peripheral wound healing. We report a patient with refractory ischemic ulcer in distal phalanges, who was successfully treated with SGB.

Material and Method

A 36-year-old female patient admitted in department of plastic surgery for contact burn wound in the right hand. There were 2nd degree burn in the right 2nd through 5th fingertips (fig 1). Despite of 2 months of dressing, digital burn wound was not healed and seems to be refractory. Suspecting vascular insufficiency, upper extremity angiography was done. It revealed decreased perfusion in 2nd through 5th fingers (fig 2) and digital fingertip wounds were diagnosed as ischemic ulcer.
Results

For the improvement of circulation in her vulnerable fingers, physical modalities were applied and 100mg of aspirin was prescribed daily. The sympathetic skin response was conducted for the evaluation of sympathetic nerve system. It showed no response in right hand and foot. We planned SGB to increase blood flow at the fingers and SGB was done under ultrasonography, twice per week for 3 weeks. The follow-up angiography showed significant improvement of fingertip perfusion (fig 3). Consequently fingertip wounds were completely healed (fig 1). Finally,
she could achieved independent ADL with her hand.

Fig 3. The follow-up arteriography shows improved perfusions in 2nd- 5th fingertips

Conclusion

The SGB can be effective on improving blood flow for healing of ischemic ulcer in the fingertips. We suggest the SGB could be an alternative option to overcome intractable condition.

HOW ARE THE SURFACES AND SHAPE IMPORTANT TO PREVENT PRESSURE SORES?

M. Avellis¹

¹Ormesa srl, research and development, Foligno, Italy

Introduction/Background

The contact surfaces shape and the material type which they are made of, are very crucial issues to figure out better the consequences on the skin integrity of the users sitting on a wheelchair. More, we have to consider how a contact surfaces can grant breathability and moisture absence, in order to avoy the increasing skin temperature and local humidity. In this study, we demonstrated that a particular backrest shape (a V-shape) and a innovative material used for the backrest as well as for the seat, can work decreasing significantly the interface pressure on the user’s skin, even without using a specific antidecubitus cushion (for those patients with no so high level of risk, according to Braden and Waterlow Scale). We evaluated two patients: one with severe outcome of Sub Aracnoid Haemorragie by Brain Aneurism followed by a non response period, with high pressure sore risk (weight 45 kg), and another with an outcome of a Stroke Ischemic and Haemorragic followed by a non response period (weight 78 kg).

Material and Method

They used a tilt-in-space wheelchair with a specific V-shape backrest and with a particular surfaces material, totally breathable and with a visco-elastic effect. We tried to put them in different position according with the items of the study (no tilt-20° of tilting-max tilting-max tilting and backrest reclination-max tilting and backrest reclination plus rised legrest), with and without the upholstery. The acquisition with Pressure Mapping Sensor were done immediately after positioning, after 10 minutes and after 1 hour of sitting.

Results

The data obtained show in both of the patients a good distribution of the pressures, bearing in mind that there weren’t any interface cushion between the seat and the user’s bottom.

Conclusion

The records without upholstery showed that the back in the middle was completely unloaded and the pressure spread effectively.

Keywords
ergonomic sitting; better pressure distribution; alternative to bedridden

Introduction/Background

Pressure ulcers are frequent complications in PMR wards. A lot of patients arrive from intensive care units. French national society for Pressure Ulcer conduct several national studies in France and a study in intensive care units in 2017. We analyse PU prevalence and Acquired PU prevalence, for patients with neurological diseases and without.

Material and Method

A national study was conducted with French society of intensive care and French society for pressure ulcer. 1221 patients are screened, in 85 intensive care units in whole France. Patients have surgical disease in 28% and medical disease in 72% with 23% neurological disease (282 patients). 67% are men. Mean age is 61.7 y.o with 30% under 55. Mean IGS2 is 42. Prevalence was analyzed one day during same week in all units by auto delivered survey. Comparison was organized between pathologies and patients in logistic regression.

Results

Global PU Prevalence is 18.7% and acquired PU prevalence is 12.7%. As Acquired PU prevalence for neurological patients is 27% significatively higher than global (p <0.0001). 50.5% (47) of severe PU arrive with neurological disease. (p <0.0001). Neurological disease is an explicative variable for PU : odds ratio is 3.128 (IC 1.972- 4.961).

Conclusion

In intensive care units, Acquired PU is higher for patients with neurological diseases (27% against 12.7%). Neurological disease increase PU risk in intensive care units.

Keywords
pressure ulcer; neurological diseases; intensive care units

No conflict of interest
Introduction/Background

Pressure ulcers are frequent complications in PMR wards. Some patients arrive with PU, prevalence is 12% in national survey conducted by French society for PU (PERSE - prevention, education, research, care of PU). Some patients are Spinal cord injured (SCI) and require surgery.

French society for PU provide guidelines : in 2012 general guidelines according with international guidelines and in 2016 guidelines for surgical PU in SCI.

Material and Method

As PU is a general disease and some recommendation are contradictory, PERSE organized 2 conferences. The first updated previous guidelines from 2001 and the second provided first guidelines for surgical PU in SCI. During the conferences, all the references are reviewed to remove EBM recommandations. In a second time, for questions without EBM guidelines, professional agreement is searched out.

Results

Guidelines for prevention and care is written. First is : assess risk level as soon as possible. Second is organize prevention in relation to the issue and always with effort on nutrition and mobilization. Third is care is not only local dressings.

Then, the first guidelines for surgical PU SCI was written. The result is : to improve good results for patients, multidisciplinary work and patient compliance assessment is necessary. Second is progressive recovery of sitting is essential
Conclusion

Elaborate and disseminate guidelines is necessary and bring more consistent between all care
givers

THE EFFECTS OF HIGH-DENSITY HIGH-RESILIENCE MATTRESS ON INTERFACE PRESSURE IN BED-RIDDEN PATIENTS

K.H. Cho¹, K. Lee¹

¹Chungnam National University Hospital, Rehabilitation, Daejeon, Republic of Korea

Introduction/Background

Many bed ridden patients are suffering from complications like pressure-ulcer, even though mattress is applied to reduce pressure, and more effective methods are being studied. The aim of this study was to investigate the effects of high-density high-resilience (HDHR) foam mattress (ROTA mattress) on interface pressure compared with air mattress in bed-ridden patients.

Material and Method

Fifteen bed-ridden patients were included and their body mass composition measured. Interface pressure was measured by applying a pressure sensor(CONFORMat pressure sensor) from the lumbar spine to the area containing the pelvis in the patient's supine position on the bed. We measure the pressure in three ways as follow: 1) with hospital mattress 2) with air mattress 3) with HDHR mattress. The maximal peak pressure when used mattress was selected. For data analysis, we used SPSS version 22.0 (SPSS Inc., Chicago, IL, USA) for Windows. An post-hoc comparisons between groups on calculating Kruskal–Wallis ANOVA statistic

Results

There was no significantly difference in pressure reduction according to body mass composition. All types of air mattress showed a reduced in pressure compared with hospital mattress. Compared with all air mattress, the HDHR mattress showed a significantly reduced in pressure.

Conclusion

The HDHR foam is made of cell opener containing ester linkage in molecule have improved values of tensile strength, tear strength and elongation. The HDHR mattress is consist of central base of high-density high-resilience foam, which provides imprint of the body shape, follows its contour and maintains a floating state. So the distribution of pressure is optimized on the entire surface and the shearing areas are reduced. There are 4 specific discharge zones at the ends of the mattress to relieve pressure on the heels and head. The use of a more effective pressure reducing mattress may have a more positive effect on patient management and decreased complications.

TEMPORAL EVOLUTION OF BACTERIAL ECOLOGY OF PRESSURE ULCERS IN PEOPLE WITH SPINAL CORD INJURY

C. Dunyach-Remy¹, A. Gelis², M. Brunaud¹, J.P. Lavigne¹, A. Sotto³
¹CHU de Nîmes, Laboratoire de Microbiologie, Nîmes, France
²Propara Neurological Rehabilitation Center, Hérault, Montpellier, France
³CHU de Nîmes, Service des Maladies Infectieuses et Tropicales, Nîmes, France

Introduction/Background

Bacterial species and their role in delaying the healing of pressure ulcers (PU) in spinal cord injury (SCI) patients have not been well described. The aim of this study was to characterize temporal evolution of superficial and deep microbiota of PU in SCI population.

Material and Method

Patients treated for PU between 05/2015 and 12/2016 at the Propara Neurological Rehabilitation Center in Montpellier (France) were included. After wound debridement, samples for bacterial cultures were obtained by swabs (superficial) and tissue biopsies (deep) at the day of inclusion (D0) and 28 after (D28).

Results

Fourty-nine patients were included (median age: 56 years; 79.6% men). At deep level, coagulase-negative staphylococci (33.8% at D0; 20% at D28), S. aureus (17% at D0; 21% at D28), Enterococcus sp. (12.3% at D0; 16% at D28) and Corynebacterium sp. (13.8% at D0; 16% at D28) were the most frequent bacterial species isolated. After 28 days, percentage of Enterobacteriaceae had significantly increased (0% at D0; 10.5% at D28; p<0.05) and percentage of anaerobic bacteria had significantly decreased (10.7% at J0; 5.3% at J28; p<0.05). During the follow-up, at the intra-individual level, the bacterial species isolated were significantly different between D0 and D28, especially at the deep level. This great variability was also described between the deep and the superficial levels.

Conclusion

This study highlights for the first time the evolution of the ecology of PU during one month. The low proportion of Gram-negative bacilli suggests that these bacteria are often colonizing bacteria that could be eliminated by an efficient surgical or mechanical debridement. Moreover, this work demonstrates the uselessness of superficial swabs that do not reflect the bacterial ecology present in depth of the wound.

USE OF ABSOLUTE ETHANOL SCLEROTHERAPY FOR ISCHIAL PRESSURE SORES IN 4 SPINAL CORD INJURY PATIENTS.
A. Julien¹, M. Prud’homme¹, C. Montaut¹, M. Belle¹, C. Terracol¹, E. Ciucur², O. Mornet²,
E. Castel-Lacanal¹, P. Marque¹, J.L. Grolleau², X. de Boisexon¹
¹CHU Toulouse, Physical Medicine & Rehabilitation, Toulouse, France
²CHU Toulouse, Plastic Surgery Department, Toulouse, France

Introduction/Background

The ischial region is a common site of pressure sore in Spinal Cord Injury (SCI) patients. Ischial pressure sore with a large subcutaneous bursa and small surface fistula is usually resistant to conservative treatment and tends to require radical flap surgical treatment. A new alternative is to scar the bursa and to close it up by sterilizing, fixing, and denaturing by the pharmacologic effect of absolute ethanol.

Material and Method

Patients selected had a small defect of the cutaneous portion, and a large subcutaneous bursa. The surgical method is: irrigation and washing the inside of the bursa, insertion of a suction drain tube into the bursa, suture of the trimmed edges of the cutaneous wound together, and then 6 inflations of the bursa for a 90-seconds period with absolute ethanol.

Results

We report the use of absolute ethanol sclerotherapy in 4 SCI patients (4 males, 23 to 53yo) with an ischial pressure sore bursa for 9 months in average. Two of them had undergone a musculocutaneous flap surgery before. After sclerotherapy, they spent 6 to 13 days in the plastic surgery department and then 2.5 to 6 months in a spinal cord injury rehabilitation department for 3 of them before to go back home. They were cicatrized and sited from 7 to 26 weeks post-surgery for 3 of them with no recurrence for a 3 to 18-months follow-up. One patient did not cicatrized after a 10 weeks discharge and went back home with still an ischial sore.

Conclusion

This surgical procedure was efficient for 3 of the 4 patients. Sclerotherapy appears as an alternative to fasciocutaneous or musculocutaneous flap for ischial pressure sore in patients with a small surface fistula but large subcutaneous bursa. There is a need of a larger group of patients to better study the delay of full-cicatrizing and the recurrence risk.

ISPR8-2158
EFFECTS OF LOW-LEVEL LASER THERAPY ON THE PROGRESS OF WOUND HEALING IN HUMANS.  
G.R. Fortes¹, E. Neto², G.J. Luvizutto³, C. Witzel¹, R. Berto¹  
¹Faculty Southwest Paulista, Physical Therapy, Avaré, Brazil  
²Faculty of Human Talents, Physical Therapy, Uberaba, Brazil  
³Federal University of Triângulo Mineiro, Physical Therapy, Uberaba, Brazil

Introduction/Background

Pressure sores also identified as pressure ulcers, decubitus ulcers and bedsore, occur in structures supporting the body on bony prominences as a consequence of external skin compression, shear force and friction that generate ischemic necrosis on the tissue. The laser acts on the cellular level, increasing the metabolism, being able to accelerate the healing process with the decrease of the release of inflammatory mediators. It also promotes increased proliferation, fibrin reabsorption and fibroblast development. The aim of this study was to evaluate the physiotherapeutic performance in the application of laser therapy on the healing process through a retrospective analysis of medical records.

Material and Method

Medical records were analyzed from 02/2014 to 06/2017, collecting data relevant to the research including aspects such as: patient identification, age, sex, pathology, treatment period, number of applications, thus evaluating the evolutionary process and the healing process as well with the use of low intensity laser.

Results

A total of 45 medical records were analyzed from 02/2014 to 06/2017, 17 women and 28 men, with an age average of 65.1 years old, all with open wounds, with an average number of 40 applications per patient with diabetes mellitus and 25 applications in trauma. The used dose of the Hellium-Neon (632.8 nm) and Gallium Arsenide (904nm) lasers were respectively 5 J/cm² and 4 J/cm² with a frequency of 16Hz and using scanning and punctual mode.

Conclusion

It can be verified in this study that the application of low intensity laser was effective in the healing of wounds with both the application methods, punctual and scanning mode, therefore showing its reliability in the auxiliary work in the treatment of pressure sores, promoting tissue proliferation accelerating the healing process.

TREATMENT OF PRESSURE ULCERS WITH THE COMBINATION OF AUTOLOGOUS PLATELET RICH PLASMA AND PLATELET RICH FIBRIN: A CASE SERIES STUDY

X. yu¹, H. He¹
¹West China hospital, Rehabilitation Medicine Center, Chengdu, China

Introduction/Background

Platelet rich plasma (PRP) and platelet rich fibrin (PRF) are both autologous blood products and their high concentrated platelets, cytokines and numerous growth factors have drawn a worldwide attention for enhancement of tissue repair and regeneration. Pressure ulcer (PU) remains a severe challenge for clinical and rehabilitation professionals. The purpose of this case series was to study the safety and efficiency of applying both PRP and PRF for treating PUs.

Material and Method

The PRP and PRF were prepared from the whole blood with different centrifugation tubes under the same centrifugation protocol (RCF 117.7g). 3 patients with PUs in sacrococcygeal region were included. Each PU were treated with 4 pieces of PRF as tissue matrix plugs and 5ml of PRP as subcutaneous injections every 3 days. The baseline information of enrolled patients, platelet count of whole blood and PRP, sizes of PU and healing time of PU were record for analysis.

Results

The mean age of enrolled patients was 49.33±29.54 years. Two patients had diagnosis of spinal cord injury and the other had pelvic fractures. 4 PUs with different size ranging from 7.06cm² to 36.72cm² were treated with PRP and PRF. All patients demonstrated significant reduction of PU size and average follow-up time was 15.5 weeks. Our preparation protocol produce PRP with 3.52 times platelets compared with un-centrifuged whole blood.
Conclusion
PRP and PRF have shown their prosperity in tissue repair and regeneration in many aspects. Our case series have testified that the combination utility of PRP and PRF can be benefit for PU patients and may be useful for other chronic wound treatment.

CHARACTERIZATION OF KNEE EXTENSOR MUSCLES FATIGABILITY DURING ISOKINETIC CONCENTRIC CONTRACTIONS IN PATIENTS WITH MULTIPLE SCLEROSIS

S. Hameau¹, D. Bensmail², N. Roche³, R. Zory⁴
¹Hopital R Poincaré, Department of Physical Medicine and Rehabilitation. Inserm Unit 1179- Team 3: Technology and Innovative Therapies Applied to Neuromuscular diseases, Garches, France
²R. Poincaré hospital AP-HP, Department of Physical Medicine and Rehabilitation. Inserm Unit 1179- Team 3: Technology and Innovative Therapies Applied to Neuromuscular diseases, Garches, France
³University of Versailles Saint Quentin en Yvelines, Inserm Unit 1179- Team 3: Technology and Innovative Therapies Applied to Neuromuscular diseases, Garches, France
⁴University of Nice Sophia Antipolis, Laboratory of Human Motricity- Sport- Education and Health EA 6312, Nice, France

Introduction/Background

Increased muscle fatigability has been reported in patients with multiple sclerosis (MS) assessed during sustained isometric contractions however rehabilitation programs and daily life activities often involve concentric contractions. The aim of this study was to characterize knee extensor muscles fatigability in patients with MS during concentric contractions.

Material and Method

38 patients with MS and 14 healthy persons were included in this study. An isokinetic assessment of knee extensor muscles fatigability was carried out during a fatiguing task of 50 concentric contractions, associated with an electromyographic activity analysis of the rectus femoris, vastus lateralis, biceps femoris and semitendinosus muscles.

Results

Patients with MS experienced lower knee extensor muscles fatigability than healthy subjects. When torque was normalized to maximal isometric peak torque, patients with MS and healthy persons had the same level of relative strength at the end of the fatigue protocol (50% of the maximal isometric peak torque). During the fatiguing task neuromuscular efficiency decreased but coactivations of knee flexor muscles remained unchanged.

Conclusion
Fatigability is a common complaint in patients with MS but they experienced lower muscle fatigability than healthy persons during maximal concentric contractions, nevertheless they finished fatigue protocol at the same level of relative strength.

A7.06 Rehabilitation Addressing to Specific Issues - Management of Fatigue and Sleep Disorders

ISPR8-0766
THE EFFECTIVENESS OF A SLEEP CLINICAL PATHWAY IN AN INPATIENT MUSCULOSKELETAL REHABILITATION COHORT: A RANDOMISED CONTROLLED TRIAL
L. Ng¹, J. Hsu², K. Kee³, A. Gorelik⁴
¹The Royal Melbourne Hospital and University of Melbourne, Rehabilitation Medicine, Parkville, Australia
²The Royal Melbourne Hospital, Medicine, Parkville- Victoria, Australia
³The Royal Melbourne Hospital, Respiratory and Sleep, Parkville- Victoria, Australia
⁴The University of Melbourne, Medicine, Parkville- Victoria, Australia

Introduction/Background

Background: Sleep is important for health, quality of life and general well-being. Poor sleep in hospitalized patients is common and can affect recovery, engagement, and prolong hospital stay. The assessment and management of sleep in hospitalised patients is poorly understood. The inpatient rehabilitation setting may present an opportunity for better management of sleep disorders. Clinical pathways may be useful for the management of sleep disorders in a rehabilitation setting.

Aim: To assess the effectiveness of a sleep clinical pathway compared to standard care in improving sleep quality, patient engagement in therapy and length of stay in an inpatient rehabilitation setting.

Material and Method

Rehabilitation inpatients with a musculoskeletal diagnosis (N=51) were randomized to standard care (“control” N=29) and sleep clinical pathway (“intervention” N=22). Outcome measures included: Pittsburgh Sleep Quality Index (PSQI), Hopkins Rehabilitation Engagement Rating Scale (HRERS), Fatigue Severity Scale (FSS), Patient Satisfaction with Sleep Scale, and Actigraphy. Assessment time-points were at admission and upon discharge from rehabilitation.

Results

There were no significant differences between groups for any outcome measures. As a cohort (N=51), there were significant improvements from admission to discharge in sleep quality [PSQI (-2.31; 95% CI -3.33 to -1.30 P=<0.001)], fatigue [FSS (-8.75; 95% CI -13.15 to -4.34; P=<0.001)], engagement with therapy [HRERS-Physiotherapists (+1.37; 95% CI 0.51-3.17; P=0.037), HRERS-Occupational Therapists (+1.84; 95% CI 0.089-2.65; P=0.008)], and Satisfaction with sleep (+0.824; 95% CI 0.35-1.30; P=0.001). Actigraphy results showed that all patients reported more sleep than what was measured.
Conclusion

A sleep clinical pathway did not improve sleep quality compared with standard care. Larger studies and studies with alternate methodology such as “cluster randomization” are needed.

Obstructive Sleep Apnea (OSA) syndrome affects 5% of the adult population and its prevalence is 13 times higher in coronary patients. However, OSA in coronary patients is less suggestive, leading to under diagnosis and lower adherence to continuous positive airway pressure (CPAP) treatment. While oropharyngeal exercises showed significant decrease in apnea hypopnea index (AHI) in patients with moderate OSA, there were no studies on specific inspiratory muscle training (IMT).

The aim of our study was to assess the effectiveness of IMT on AHI reduction in coronary patients with moderate OSA and already engaged in a cardiac rehabilitation program post-infarction.

**Material and Method**

We included coronary patients involving in a cardiac rehabilitation program after infarction, presenting an AHI between 15 and 30, and without clinical symptoms requiring CPAP. Patients were randomized in a 1:1 allocation in a control group (CTL - classic training) or in an IMT group (classic training + IMT). IMT consisted in a prolonged inspiration into a device allowing the air to pass during the inspiration only according to the force developed. The resistance applied was 70% of the maximum inspiratory pressure (Pi\textsubscript{max}). Patients in the IMT group perform 2 sets of 30 breaths per day, 6 days a week for 2 months.

**Results**

We included 19 patients (59±10 years; BMI=27±3 kg/m\textsuperscript{2}). All the patients showed a significant decrease in AHI after rehabilitation (21.5±5.1 to 16.3±7.8, p<0.009). The IMT group (n=10) significantly improved Pi\textsubscript{max} (p<0.05) and had a significant decrease of AHI by 25% (-8.7, p=0.02). In the CTL group (n=9), the AHI decreased by 23% (-5.2; p=0.1). No significant differences were observed in anthropometric data.

**Conclusion**
A specific IMT during a cardiac rehabilitation contributes to reduce significantly AHI in coronary patients with moderate OSA. Further research is needed to determine which patients benefit more of this alternative therapy.

Introduction/Background

In literature Cancer-Related Fatigue (CRF) is the main symptom reported by onco-haematological patients, but a lot of them need information on its management. It is known that Physical Activity (PA) could help to deal with CRF, but the modalities to do it are not already definite.

For this reason multidimensional programs combining PA and Therapeutic Patient Education (TPE) are offered to onco-haematological patients, but their effectiveness is not clear yet.

Aims of the project:

- To Investigate the feasibility of TPE program associated to PA in onco-haematological patients.
- To assess the intervention’s effect on CRF, QoL, physical performances and psychological distress of this subgroup of cancer patients.

Material and Method

The study will be conducted in Arcispedale Santa Maria Nuova in Reggio Emilia (Italy) from November 2017.

It’s a pilot RCT, with blinded assessment, 18 months duration, addressed to adults onco-haematological patients newly diagnosed that received medical approval to do PA.

It's composed by 2 Phases:

1. Baseline: before starting intervention, at least 10 patients;
2. RCT: at least 40 patients.

Assessment with evaluation scales:
T0: Enrollment + Randomization in two groups
T1: 1 month after T0
T2: 2 months after T1  
T3: 6 months after T1

Interventions, acted between T1 and T2:  
Control Group (CG): Standard care + 2 group sessions of TPE  
Intervention Group (IG): as CG + 6 weekly individual sessions focused on planning a tailored PA program.

**Results**

Baseline early data collection showed that after 1 month of medical treatment (T1) CRF and psychological distress increase, meanwhile QoL decreases and physical performances remains stable.

**Conclusion**

Our program offered between T1 and T2 could help onco-haematological patients to prevent the further decrease of their conditions due to therapies. At the time of the congress we will describe all baseline data collection and early intervention data.

*No conflict of interest*
Fatigue and walking impairments are often reported in patients with neurological and non-neurological conditions. Fatigue during the performance of physical activities, can be defined as ‘fatigability’. Questionnaires, BORG and VAS-scores based on the subjective feeling that indicates more effort to perform a walking task, are currently used to assess fatigability. However, objective measures of fatigability during walking are still sparse.

Material and Method

The aim of this systematic review is to provide an overview of objective measurement systems assessing walking related performance fatigability in different pathologies and healthy subjects. Two databases were used for obtaining articles: Pubmed and Web Of Science. Articles were excluded according to title and abstract or by screening on full texts, if indistinctness occurred from the abstract. Extra articles were added through hand searching.

Results

In total, 711 articles were found, from which 32 were included in this review. Across different study populations performance related fatigability was most frequently measured during longer walking test such as; 6 minute walking test and 500 or 400-m walking test, by comparing the first and last minute/lap for spatiotemporal or other kinematic changes.

Conclusion

Longer walking test seem to be consistent methods for assessing walking-related performance fatigability, when comparing the changes over the last and first part of the test. However, due to differences in study population, terminology and definition of fatigability or variance in the walking task (e.g. speed, distance, protocol), there is no golden standard in the objective measurement of walking-related performance fatigability. Normative data based on performance of healthy individuals and psychometric properties are scarce or non-existing.

HE LIMITATION OF REHABILITATION IN A PATIENT WITH HETEROTOPIC OSSIFICATIONS AND SEVERE CRANIOCEREBRAL TRAUMA.

M. NITU¹, I. Stamate², G. Mologhianu³, V. Serban⁴, A.S. Nica⁵

¹NATIONAL INSTITUTE OF REHABILITATION MEDICINE BUCHAREST, REHABILITATION, BUCHAREST, Romania
²National Institute of Rehabilitation and Physical Medicine, Physical Medicine, Bucuresti, Romania
³Carol Davila University of Medicine, Physical Medicine, Bucharest, Romania
⁴National Institute Of Rehabilitation and Physical Medicine, Physical Medicine, Bucharest, Romania
⁵Carol Davila University of Medicine, Physical medicine, Bucharest, Romania

Introduction/Background

Heterotopic ossification represents the formation of bone tissue in abnormal anatomic sites, usually in soft tissue, due to mesenchymal cell metaplasia in osteoblasts leading to the presence of mature lamellar bone tissue in non-osseous tissue.

There are two forms: acquired - caused by muscular-skeletal trauma (fracture), termic trauma or total hip arthroplasty; neurogenic - determined by spinal cord injury, stroke, and traumatic cerebral lesions.

Material and Method

We present the case of 32-year-old patient with medical history of traffic accident polytrauma and severe craniocerebral trauma (Feb. 2012), with supratentorial, subtentorial and subarachnoidal hemorrhage, drained hemothorax, spastic, tetraparetic, motor deficit, splenectomy, hepatic lesions, fracture of the left 3-5 ribs arch, fracture of the right ilioischipubia and left ilioischipubian flexum (extension deficiency) 70 degrees irreducible, heterotopic right elbow ossification, coxofemoral volume expositions, percutaneous tenectomy, coodration synchines.

For the initial evaluation we used a number of scales; like muscles streight (Right superior limb 2/5, left-3/5, Inferior limb3/5), VAS because the movements were painful at the begining, VAS=7/10, the pasive flexural balace of the hip was 40m degree before operation, and 25 active.

The patient followed a staged rehabilitation program and drug therapy.
Results

After the drug treatment, rehabilitation program but especially the operator for heterotopic osteoporosis (Dec 2017), the pains at the level of the hips decreased, the mobility was better, the passive flexural balance was 60 degrees, 40 active Kinetec who was recommended post operator reaching after 2 weeks at 90 degrees flexion, keeps sitting seated in wheelchair without pain, maintains coordination synchines.

Conclusion

The parcellarity of the case; 32-year-old patient with polytraumatism and TCC severe post-trafic accident (2012) with multiple post-traumatic marks with bilateral coxofemural ossification and pain at this level, painful mobilizations that slowed the recovery program.

EFFECT OF MIND-BODY REGULATION TECHNIQUES ON HUMAN BLOOD FUNCTIONAL PROPERTIES
O. Aliskerova\(^1\)
\(^1\)Institute of Biosensory Psychology, Department of international cooperation, Saint-Petersburg- Zverinskaya street 42- 197198, Russia

Introduction/Background

Mind-body regulation techniques have many positive effects on human health, benefitting many different physiological systems of the body. Here, we show the effect of mind-body regulation techniques on several different functional properties of human blood.

Material and Method

The study was conducted on 45 subjects ages 20 to 50 years old. At the beginning of each experimental session, a blood sample was first obtained from a subject. Then the subject performed a series of mind-body regulation techniques, including specific breathing and articular exercises, for 10 to 20 minutes, after which a second blood sample was immediately obtained. Our results are based on a comparison of the two blood samples as well as a personal questionnaire. Microscopic examination revealed a reduction in red blood cell aggregation following the exercises.

Results

Thirty subjects had marked aggregation of red blood cells before the exercise period while only 15 subjects had marked aggregation following the exercises. Reduced aggregation indicates healthy red blood cells, including increased blood oxygenation. Changes in red blood cell color were also observed. Before the exercises, blood samples from 25 subjects exhibited uneven erythrocyte color, indicating low haemoglobin saturation, while after the exercises uneven erythrocyte color was observed in only 5 subjects. Additionally, motility analysis revealed leukocytes with low activity in 42 subjects before the exercise period, while only 12 subjects exhibited low leukocyte activity following the exercises. The exercises also had a marked beneficial effect upon the psychological state of the subjects. Before the exercises, 71% of subjects felt stressed and emotionally overloaded, 17% somewhat emotionally loaded, and 12% emotionally balanced. After the exercises 91% of subjects felt emotionally balanced.

Conclusion

Our results indicate a beneficial effect of mind-body regulation techniques upon several functional properties of human blood, which likely contribute to the overall health and psychological benefits of these exercises.

THE EFFECTIVENESS OF ADAPTIVE BEHAVIOR SKILLS FOR PEOPLE WITH MODERATE MENTAL DISABILITIES DURING THE MODIFIED PHYSICAL EDUCATION LESSON

N. Ibrahim¹
¹Faculty of Physical Education for girls,
Curriculum and Teaching Methods of Physical Education, Alexandria, Egypt

Introduction/Background

People with moderate mental disabilities suffer from inadequate adaptive behavior skills which have a negative impact on their daily tasks and interaction with their environment, especially the learning environment which turns this suffering into an acceptable integration with the teacher or colleagues. These skills are essential in the process of diagnosis and classification based on the levels of adoption of the educational plan and teaching strategies, content, goals of mobility and cognitive and behavioral. The aim of the research work is to assess the effectiveness of adaptive behavior skills during the modified physical education lesson for the mentally disabled.

Material and Method

A standardized scale designed during the physical education lesson for the mentally handicapped with the degree of intermediate disability (those who can receive training), who are between 40 and 54 degrees above 12 years of age and require special training programs appropriate to their age. Fitness scale includes, simple motor skills, moving to and from physical education classes, teacher response, peer and equipment handling, effort and self-acceptance, cognitive abilities.

Results

An accurate description of the levels the behavioral skills of the child during the physical education lesson, which was adapted to the mathematical learning environment, was identified and described in a certain lack of skills that can guarantee him and the teacher the maximum benefit during the lesson.

Conclusion

The need to design modified or integrated physical education classes to develop adaptive skills for the mentally handicapped in a specialized manner and to train physical education teachers working with that group on how to improve those skills

ISPR8-2414
CLINICAL RELEVANCE OF DIFFERENT OBESITY INDICES AND DEPRESSIVE SYMPTOMS IN THE ELDERLY ADULTS
C. Xiaoyu
1International Cardiovascular Hospital, Department of Rehabilitation Medicine, Tianjin, China

Introduction/Background

To identify optimal obesity indices and cutoff to identify depressive symptoms in suburb-dwelling older Chinese.

Material and Method

Data are from 576 men and 753 women aged 60 years and older recruited in the Hangu area of Tianjin, China. Depressive symptoms were examined using the 30-item Geriatric Depression Scale. A Geriatric Depression Scale score of ≥11 was used to indicate depressive symptoms. Receiver operating characteristic curve analyses were used with calculation of the area under the curve (AUC) to evaluate the performance of body mass index (BMI), body fat percentage (BF%), waist circumference (WC), waist-hip ratio (WHR), and waist-height ratio (WHTR) for the identification of depressive symptoms.

Results

The prevalence of depressive symptoms was 14.6% in women and 8.5% in men. The AUC for body fat percentage (BF%) was 0.686 (95% confidence interval [CI] = 0.602–0.770) in men and 0.614(95% CI = 0.557–0.670) in women, respectively. These values were indicated higher levels of depressive symptoms compared with other relative obesity indices. The cutoffs of the most relevant index in men and women that effectively identified individuals at risk of depressive symptoms were 19.20% and 32.35%, respectively.

Conclusion

Overall adiposity measures generally performed better than abdominal obesity indices, and BF% performed best in both men and women. Optimal cutoffs for clinically relevant index have the potential to identify elderly adults at risk of depressive symptoms.

ENHANCED EXTERNAL COUNTERPULSATION (EECP) IN REHABILITATION OF ERECTILE DYSFUNCTION: A NARRATIVE LITERATURE REVIEW

S.A. Raeis-sadat¹, F. Allameh², A. Javadi¹
¹Shahid Beheshti University of Medical Sciences- Tehran- Iran,
Physical Medicine and Rehabilitation, Tehran, Iran
²Shahid Beheshti University of Medical Sciences- Tehran- Iran, Urology, Tehran, Iran

Introduction/Background

BACKGROUND and AIMS: Enhanced external counterpulsation (EECP) is a noninvasive treatment option which has been recently applied in patients with erectile dysfunction (ED). The aim of this study was to review the efficacy of EECP in patients suffering from ED.

Material and Method

METHODS: PubMed, MEDLINE, Google Scholar, Tripdatabase, Scopus and Cochrane library databases were searched for articles with the following search terms: Enhanced external counterpulsation, erectile dysfunction. No restrictions with respect to study setting, date of publication or language were imposed.

Results

RESULTS: From an initial set of 208 records, four studies were selected after final review. Total number of 177 patients were included in these studies with the treatment duration with EECP ranging from 20 to 35 hours weekly. Peak systolic flow, quality of erection, International index of erectile function (IIEF) and overall satisfaction were all significantly increased after EECP treatment.

Conclusion

CONCLUSION: To the best of our knowledge, this is the first study reviewing the clinical effectiveness of EECP in patients with ED. According to the articles mentioned in this study, an enhancement in erectile function after EECP treatment courses has been observed in patients both with and without coronary artery disease without any significant adverse effects.

Keywords

coronary artery disease; enhanced external counterpulsation; erectile dysfunction

Introduction/Background

Patients admitted to hospital with prolonged hospital stay and those who had to stay in ICU particularly elderly age group are likely to get deconditioned quickly. They have postural hypotension, pain and stiffness and or functional decline. They may need a period of in-patient rehabilitation to get back their functional status and or coordinate care prior to discharge back to community.

Material and Method

Aim of our study was to look into the de-conditioned patients admitted to our rehabilitation wards

- To look at FIM (Functional Independent measures) gains, the functional improvements, length of stay and final discharge destination of these group of patients
- To streamline the de-conditioned patients admission to our wards and make more effective use of the available resources

Results

We collected 100 consecutive patients admitted to our rehabilitation wards from January 2017 to May 2017; patients included in the study were admitted for deconditioning, patients with stroke, fractures, spinal cord injury, amputees, Pulmonary rehabilitation and or any other neurological condition were excluded from the study. Age, sex, ethnicity, underlying diagnosis for deconditioning, length of stay in acute and rehab wards, FIM gains, discharge destination, medical issues during rehab stay and whether they returned to premorbid situation were analyzed.

Conclusion

Nearly 75% of patients returned to premorbid living situation with 85% returning to independent to minimal assist with activities of daily living. Including weekend therapy, newer equipment and regular education and closer involvement of family will help improve the FIM outcomes and reduce length of stay further.

SYSTEMATIC REVIEW ON THE EFFECTS OF DIFFERENT REHABILITATION THERAPIES IN ELDERLY POST-STROKE PATIENTS
A. Carmona Espejo¹, R. Gonzalez Villen², M.A. Carmona Espejo³, I. Garcia Montes⁴
¹Andalucia Health Service Spain, Physical And Rehabilitation Medicine, Maracena Granada, Spain
²Andalucia Health Service Spain, Pediatrics Service, Maracena, Spain
³Andalucia Health Service Spain, Nurse, Maracena Granada, Spain
⁴Andalucia Health Service Spain, Physical And Rehabilitation Medicine, Granada, Spain

Introduction/Background

Background:

It is right to review this topic, since currently one of the most prevalent pathologies in the elderly population is cerebrovascular accident, which is why it is necessary to know the rehabilitation therapies available for this pathology.

Aims:

Among the main objectives of this review are:

- List the different existing rehabilitation therapies for elderly patients who have suffered strokes.
- Clarify the results of the different therapies in these patients.
- Specify the most beneficial techniques in the treatment of these patients.
- Define the evolution of the elderly post-stroke patient after therapy.

Material and Method

A search was carried out through the main medical databases, specifically Pubmed, Cochrane and Medline.

The keywords used were: "rehabilitation", "stroke", "patients", "elderly" and "management"

Approximately 350 results were obtained, which were subjected to the following inclusion criteria:

- Publication in the last 3 years.
- Experimental studies.
- Inclusion of at least 2 key words in the title of the text.
- Do not be duplicated.

Results
Transcranial low frequency therapy seems to be a promising therapy to recover cognitive and motor function in patients with chronic cerebral ischaemia.

Body vibration therapy improves recovery in patients with subacute strokes.

Technique of repetitive facilitation exercises (RFE) showed improvement in elderly post-stroke patients.

Botulinum toxin appears to be useful in post-stroke patients and have shoulder pain and hemiplegia.

Valecular balloon application is useful in post-stroke patients with dysphagia, improving it and avoiding the risk of aspiration.

Conclusion

Currently, cerebrovascular accidents represent one of the most serious health problems in the Western world.

Numerous aspects / therapies that seem to be useful in the rehabilitation of elderly post-stroke patients have been described throughout this review. With proven results through experimental studies and with a promising future.

In my opinion, there should be greater efforts in the creation and research of rehabilitative therapies that try to improve step by step the future recovery of these patients.

DANCE THERAPY IN PATIENTS WITH PARKINSON’S DISEASE: A REVIEW

M. Mota Freitas¹, A. Silveira¹, S. Almeida¹
¹Hospital Garcia de Orta - EPE, Physical and Rehabilitation Medicine, Almada, Portugal

Introduction/Background

Parkinson’s disease (PD) is a chronic, progressive and disabling neurodegenerative disorder. It affects physical, psychological and emotional functions and consequently has a profound effect on quality of life. Emerging evidence suggests that rehabilitative exercise interventions can have a neuroprotective effect and promote neuroplasticity. Dance techniques are designed to encourage postural extension, head and trunk rotation with repetitive turning, ankle movements, stepping strategies, enhanced balance mechanisms and increased exercise capacity, all shown to be of deficit in people with PD. The aims of this study are to assess and synthesize the literature on dance interventions in patients with Parkinson disease and to provide information regarding the frequency, intensity and type of dance used in these programs.

Material and Method

Systematic literature searches were performed to select randomized controlled trials and observational studies. PubMed, Cochrane Library and Medline databases were searched from 2014 to 2018 using the following terms “Parkinson’s disease” AND “dance.” A total of 15 studies were eligible for this research after exclusion criteria were applied.

Results

Multidimensional benefits are sometimes achieved through dance in people with mild to moderately severe PD. The findings of this review have found that improvements in balance, motor impairment, and endurance were reported after participation in dance. Dance significantly improved motor scores, berg balance and gait speed when compared with no intervention. The mean duration of each session of dance-therapy was 1.25 hours. The frequency was once or twice per week for at least 3 months. Various dance styles were tested including modern dance, creative dance, tango and samba.

Conclusion

Dance-therapy significantly improved motor and cognitive tests in PD patients. All types of dance techniques showed positive results. This work shows evidence that dance-therapy may be included in rehabilitation programs for patients with PD.

Introduction/Background

Individuals with cervical spinal cord injury (ICSCI) have difficulty accessing computers through conventional methods. The purpose of this paper was to provide a critical narrative review on types of computer access devices and word prediction software for ICSCI.

Material and Method

A search was conducted in several electronic databases.

Results

There is limited data about Test Input Speed (TIS) in ICSCI. One study showed that TIS in ICSCI was significantly lower (mean = 11 words per minute (wpm)) (p=0.001) than TIS of abled-bodied individuals (19 wpm). In a sample of ICSCI, there was a significant difference between voice recognition system (mean = 18 wpm), a standard keyboard (mean = 8 wpm) and an onscreen keyboard (mean = 3 wpm) (p<0.001). However, the literature suggested that the impact of Word Prediction Software (WPS) for increasing TIS remains questionable. Indeed, there is limited scientific documentation of the influence of the parameters of WPS on TIS. Regarding the number of words displayed in the prediction list, this parameter did not increase TIS. For the parameter “frequency of use”, use of WPS with the activation of frequency of use increased TIS in participants with high-level tetraplegia. For participants with low-level tetraplegia, the use of WPS with frequency of use activated only decreased the number of errors.
Conclusion

Each professional could provide clear and accurate information on the benefits of WPS for people with cervical SCI. WPS must be set regarding the needs of people with cervical SCI. If not, the use of these software's may go against the expected benefits.

TRAINING PROGRAMS ON TEXT INPUT SPEED IN PERSONS WITH CERVICAL SPINAL CORD INJURY

S. Pouplin¹, D. Bensmaï², N. Roche³
¹Hôpital Raymond Poincaré / Université Versailles Saint Quentin., Plate - Forme Nouvelles Technologies / UNité INSERM U1179- Equipe TITAN / CIC 1429, Garches, France
²Hôpital Raymond Poincaré / Université Versailles Saint Quentin., Service de Médecine Physique et de Réadaptation/ Unité INSERM U1179 - Equipe TITAN, Garches, France
³Hôpital Raymond Poincaré / Université Versailles Saint Quentin., Service d'Explorations Fonctionnelles / UNité INSERM U1179- Equipe TITAN / CIC 1429, Garches, France

Introduction/Background

Computer access is important for social participation for people with cervical spinal cord injury (SCI). Different devices have been developed to enable them to use a computer but text input speed (TIS) with them is low. Several methods (eg, word prediction software (WPS)) have been developed to increase TIS. In the literature, the effect of WPS on TIS were debatable. One hypothesis to explain the disparity is the lack of specific WPS-training programs for people with cervical SCI.

Material and Method

The aim of this study was to compare the influence of three WPS-training programs on TIS in people with cervical SCI, and to determine which was the most effective. Participants were randomized to one of three different groups: a group with training with an occupational therapist (REHAB), a group with a standardized home self-training with a written training guide (SELF), and a third group that had no training (CONTROL).

Results

Forty-two participants were included and 38 completed the study. TIS improved significantly more in the REHAB group (with and without WPS) than in the CONTROL (p<0.001) and SELF groups (p<0.001) between D0 and D30.

Conclusion

The results of this study showed that OT-supervised training improved TIS but did not provide any specific improvements in the use of WPS on TIS, although the number of recorded errors decreased when using WPS after training and the improvement of the rate of word prediction
use. These results suggest that supervised training should be developed when providing patients with word prediction software, in order to increase their TIS.

HYDROTHERAPY AS A NON-PHARMACOLOGICAL ALTERNATIVE FOR THE TREATMENT OF CONGESTIVE HEART FAILURE

J. Viana

Introduction/Background

The World Health Organization stated that Cardiovascular diseases represent one third of the deaths in the world. Heart Failure is the main reason of hospitalization on the elderly population and a non-pharmacological treatment is necessary in order to promote, prevent and preserve general health among the population.

The purpose of this study is to determine whether Hydrotherapy can be classified as an effective means of treating elderly patients with heart failure.

Material and Method

Throughout Scientific research using worldwide data, the Hemodynamic and Respiratory effects were analyzed during water immersion and how this would impact the population suffering of Congestive Heart Failure, establishing safety parameters for the treatment of this disorder.

Results

During this research it was observed that Water Temperature is one key element, along with Hydrostatic Pressure, affecting Cardiac and Respiratory physiology. It was analyzed that individuals submitted to immersion in cold water (22°C) had significant increase in Systolic Blood Pressure (101 ± 31 to 118 ± 20 mmHg), opposed to warm temperatures (32°C) which remained on similar values.

In regards the Hydrostatic pressure, it was analyzed that, in average, 700 ml of blood move from the extremities to the chest, increasing 60% of the central volume and significant increase in the Intrathoracic Pressure (0.4 mmHg to 3.4 mmHg) and Pulmonary Blood Pressure (5 mmHg to 22 mmHg). These values promote increase of 65% on Respiratory Workload and decrease 66% of Expiratory Reserve Volume. Besides shocking changes, studies demonstrate that Hemodynamic and Respiratory values return to baseline immediately after getting out of water.

Conclusion

As conclusion, in spite of several changes, individuals did not reach concerning levels and researches demonstrated that physical activity in water using Scales of Perceived Exertion
demonstrate a proper monitoring strategy for the treatment of Heart Failure with patients having Hydrotherapy an important supporter as a non-pharmacological treatment.

⁵Faculty of Sport Sciences- University of Isfahan- Isfahan- Iran,
Department of Exercise Physiology-, Isfahan, Iran

Introduction/Background

Cycling with or without functional electrical stimulation (FES) is an effective way to rehabilitate patients with lower limb disability. The purpose of this systematic review and meta-analysis was to quantify the effectiveness of different protocols of cycling with/without FES on lower limbs after stroke.

Material and Method

The following databases were searched: PubMed, Cochrane Central Register of Controlled Trials, Ovid Medline, EBSCO Cumulative Index of Nursing and Allied Health Literature, Ovid EMBASE, Physiotherapy Evidence Database (PEDro), and Occupational Therapy Systematic Evaluation of Effectiveness, by means of words relevant to randomized and stroke, cycling and lower limbs disability. Randomized controlled trials from 1990 to July 2017 were included following predetermined search and selection criteria. Data extraction was performed using a pre-determined data collection form.

Results

A total of 15 trials satisfied eligibility criteria for this review. Cycling had a positive effect on 6 meter walking test performance (30.4 s; -1.9 – 62.6 (standardized mean difference; 95% confidence interval) compared with no or placebo intervention (control). Cycling had a positive effect on walking speed (0.10m/s; 0.1 - 0.2), based on the results of 10 meter walking test, compared with control. Cycling had a positive effect on balance based on Berg score (0.25; -0.44 - 0.94) compared with control. Cycling with FES had a positive effect on balance (1.95; 1.33 – 2.52) compared with cycling alone.
Conclusion

Although cycling alone has a positive effect on walking ability, walking speed, and balance the effects are small and variable. In terms of balance, positive effects substantially smaller when compared with concurrent effect of FES with cycling with low evidence. It appears that cycling with or without functional electrical stimulation has positive effects on walking ability walking speed and balance, but further research is needed to confirm the clinical utility of these modalities for stroke patients.

⁴Dr, Department of Rehabilitation Medicine- Faculty of Medicine- University of Malaya, Kuala Lumpur, Malaysia
⁵Associate Professor, Department of Otorhinolaryngology - Faculty of Medicine- University of Malaya, Kuala Lumpur, Malaysia

Introduction/Background

Benign paroxysmal positional vertigo (BPPV) is the most common vestibular disorder in adults and the treatment of choice is by particle repositioning manoeuvres (PRM). This study compares the effects of two home-based exercises, self-Epley manoeuvre (SEM) and Brandt-Daroff exercise (BDE) in patients with posterior canal BPPV.

Material and Method

This is a single-blinded prospective randomized controlled trial on 50 patients suffering from unilateral posterior canal BPPV with a documented positive Dix-Hallpike test and symptoms of vertigo for at least 1 week. Both groups (25 in SEM and 25 in BDE) performed the home-based exercise for a total of 2-weeks duration. The primary outcome was vertigo resolution at 1 month and 6 months. Secondary outcomes were conversion of a positive to a negative Dix-Hallpike test at 1 month, reduction of vertigo intensity and the Dizziness Handicap Inventory (DHI) scores at 1 month and 6 months.

Results

Vertigo resolution was achieved in 40% of patients at 1 month and 48% of patients at 6 months for both groups. Conversion rate from positive to negative Dix-Hallpike test at 1 month was 92% in the SEM group and 84% in the BDE group (p=0.38). From repeated assessments at 1 and 6 months, significant reduction in vertigo intensity, \( F(1.6, 78.4) = 84.6, p <.001 \) and improvement in the mean DHI scores, \( F(1.7, 85.1) = 74.3, p <.001 \) was seen within groups. There were no significant differences in vertigo intensity and mean DHI scores between the two groups. Both
SEM and BDE were well tolerated with few minor complications reported, such as transient dizziness and nausea.

**Conclusion**

Both the SEM and BDE are effective in treating posterior canal BPPV. Although there was no significant vertigo resolution, there was a reduction in vertigo intensity, and perceived negative impact on daily life from the improvement in the mean DHI scores

IMPLEMENTATION OF A FALL SCREENING PROGRAM FOR OUTPATIENTS IN PMR DEPARTMENT
E. Skikic¹, M.A. AlSwaini¹, C.G. Philip¹
¹Dubai Health Authority, PMR Department, DUBAI, United Arab Emirates

Introduction/Background

In PMR Outpatient department, within General Hospital and Trauma center, we developed and implemented a fall screening program as a part of routine assessment for patients at risk of fall coming for the treatment. With the main goal to promote patient's safety, we wanted to establish consistency in process of fall risk assessment in PMR department and to develop plan of care for the patients in risk.

Material and Method

The program was developed for outpatients, with clear inclusion criteria and it was applicable for all geriatric patients above 70 years of age, patients on neuro-rehabilitation, patients using walking device or support and patients with history of fall.

We selected Fall risk Assessment tool that is comprehensive, quick and easy and incorporate algorithm for interventions and management plan to the format. We used Madison State Hospital Falls Risk Assessment Form and modified scoring system, considering score above 10 as high risk for falls.

Results

Physiotherapists and Occupational Therapists are responsible for assessing the patients on the admission to the treatment, integrating the screening program into the usual clinic workflow.

To assure continuity of care for all patients at risk, in coordination with Quality department, we developed departmental Policy for fall risk assessment in PMR outpatient setup.

Conclusion

Implementation of a fall risk-screening program in an outpatient PMR department appears feasible with development of appropriate screening tool and integrated departmental policy in order to detect all patients in risk of fall and deliver proper management.

EFFECTIVE ELECTRICAL STIMULATION PLACEMENT COMBINED WITH EFFORTFUL SWALLOWING MANEUVER FOR POST-STROKE DYSPHAGIA THERAPY

J.W. Huh¹, T.D. Jung²

¹Kyungpook national university hospital, Department of Rehabilitation Medicine, Daegu, Republic of Korea
²Kyungpook National University Chilgok Hospital, Department of Rehabilitation Medicine, Daegu, Republic of Korea

Introduction/Background

The objective of this study is to evaluate which type of neuromuscular electrical stimulation (NMES) electrode placement is more effective for post-stroke dysphagia therapy.

Material and Method

Thirty-one post-stroke dysphagic patients were randomly divided into the three groups according to NMES electrode placement types; in group A (n=10), both pair of electrodes were horizontally attached on the suprahyoid muscles above the hyoid bone and on the infrahyoid muscles below it, in group B (n=11), each pair of electrodes was horizontally and vertically attached on the suprahyoid muscles above the hyoid bone and on the infrahyoid muscles below it, and in group C (n=10), both pair of electrodes were vertically attached across the hyoid bone above the thyroid notch and across the cricoid cartilage below the thyroid cartilage. All patients received NMES combined with effortful swallowing maneuver five times a week for a 4-week period as rehabilitation treatment. The effect of NMES electrode placement was assessed by comparing functional dysphagia scale (FDS) and dysphagia outcome and severity scale (DOSS) scores about thin liquid swallowing at the initial videofluoroscopic swallowing study (VFSS) and the follow-up VFSS after intervention. Additionally, FDS scores were categorized into oral phase (FDS-O) and pharyngeal phase (FDS-P).

Results

Significant improvement of FDS and DOSS scores was observed in all three types of electrode placements. However, only group A electrode placement showed significant difference in FDS and FDS-P scores compared to group B and group C after the intervention.

Conclusion

The group A electrode placement was significantly more effective than other electrode placements in NMES therapy for post-stroke dysphagia patients.

³Pamukkale University, School of Physical Therapy and Rehabilitation, Denizli, Turkey

Introduction/Background

The aim of this case report is to contribute to the literature about the physiotherapy treatment methods after poliomyelitis sequelae with patellar bone fracture and to report the results of the treatment programme.

Material and Method

Our patient was a 43-year old man with a poliomyelitis sequelae who had left patellar bone fracture occurring after traffic accident. Then a plaster cast was applied and worn for 2 months. After removal of the plaster cast, the subject was included physiotherapy and rehabilitation programme for 4 weeks (5 days/week) by physiotherapist. He had pes cavovarus deformity, 2 cm limb-length discrepancy, muscle weaknesses and atrophies, flaccidity, limitations of joint mobility and inadequate patellar mobilization in the left extremity. Pain intensity was assessed by Visual Analogue Scale (VAS), life quality was investigated by Nottingham Health Profile (NHP) and Beck Depression Inventory (BDI) was used to evaluate depression level. Also WOMAC scores were reviewed for knee status. He had never received any medication or surgery for poliomyelitis sequelae. Conservative management (i.e. hotpack, ultrasound, TENS, patellar mobilization, regular passive range of motion, strength, resistive, balance and proprioceptive exercises) was applied. Resistive exercises were added after the 2nd week of the programme. Also, balance and proprioception exercises were gradually complicated.

Results

After the 4-weeks physiotherapy, range of motion of knee (40° in flexion and extension) and life quality [before treatment (B.T.) 514.11, after treatment (A.T.) 504.13] were increased. Pain during activity, rest and asleep (B.F. 9.2, 6, 6.7; A.T. 6.9, 5.6, 4.1, respectively) and WOMAC scores (B.T. 61, A.T. 54) were decreased favour of recovery. Depression level was decreased from extreme to moderate.

Conclusion

It is recommended that physiotherapists would contribute to the patient’s functional recovery by performing a patient-tailored treatment programme.

Introduction/Background

Respiratory muscle weakness is well known in Chronic obstructive pulmonary disease (COPD), and it is an argument to the rational of respiratory muscle training. The aim of this review is to identify the most appropriate training modality of respiratory muscle and to investigate the effects of this training.

Material and Method

we performed a narrative review, bases on Pubmed database, with the key word « respiratory muscle training » AND « COPD » from 2011 to 2018.

Results

Twenty-two studies were selected in this research. Most of them expose an inspiratory work. No study compare different frequency, intensity, or duration. The work in endurance or in strength is not compare. A meta-analysis [1] promotes the inspiratory strengthening when the maximal inspiratory pressure (PIMax) is under 60cmH2O but other study show an interest of this work in patients with better PIMax. The use of threshold device seems to be more effective than resistive device. The inspiratory work in COPD patient in these studies show an impact in PIMax, six minutes walk test and dyspnea. Its impact is possible on quality of life. The effects on pulmonary volume are divergent.

Conclusion

Although the modality of respiratory muscle training is not clearly determinate, it is well tolerate and provide analytic and functional benefit. If further studies are needed, inspiratory muscle training should be included in a pulmonary rehabilitation program.

ROLE OF O-C2 ANGLE IN THE DEVELOPMENT OF DYSPHAGIA IN PATIENTS WITH HALO-VEST FIXATION

M. Miyagi¹, H. Takahashi², K. Tsuchiya², H. Sekiya³, S. Ebihara¹
¹Toho University Graduate School of Medicine, Department of Rehabilitation Medicine, Tokyo, Japan
²Toho University Omori Medical Center, Department of Orthopaedic Surgery, Tokyo, Japan
³Toho University Omori Medical Center, Department of Oral Surgery, Tokyo, Japan

Introduction/Background

The halo-vest brace has been a common mode for immobilization of the cervical spine. The incidence of complications such as pin looseing and infection are known in patients with halo-vest fixation. Dysphagia is one of the most serious complications seen with the use of a halo-vest brace. The aim of this study was to elucidate factors associated with the incidence of dysphagia in patients treated using a halo-vest brace in terms of not only demographic data, but also radiological findings of the cervical spine.

Material and Method

We retrospectively reviewed medical records and radiological measurements using lateral plain X-rays of the cervical spine in patients who had undergone halo-vest fixation in our institute between January 2006 and August 2016. Severity of dysphagia was assessed using the Food Intake Level Scale (FILS) from medical records. Patients were classified into non-dysphagia (FILS level: 10) and dysphagia (FILS level: 1-9) groups.

Results

Forty-three patients were attributed for analysis. Twenty-eight patients were classified into non-dysphagia group, 15 patients were classified into dysphagia group. Mean age was grater ($P=0.041$), length of ICU stay was longer ($P=0.002$), and frequency of tracheostomy was larger ($P=0.043$) in the dysphagia group. Mean O-C2 angle was smaller in the dysphagia group ($P=0.027$). Body mass index (odds ratio (OR)=0.522, 95% confidence interval (CI)=0.377-0.934, $P=0.024$), ICU stay (OR=1.302, 95%CI=1.272-10.624, $P=0.016$), and O-C2 angle (OR=0.911, 95%CI=0.833-0.996, $P=0.041$) remained independent risk factors related to incidence of dysphagia. Spearman rank correlation showed a negative linear correlation between ICU stay and FILS level ($r=0.476, P=0.001$) and a positive linear correlation between O-C2 angle and FILS level ($r=0.385, P=0.011$).

Conclusion

This study suggested the significance of O-C2 angle as well as ICU stay for incidence and severity of dysphagia in patients with halo-vest fixation.

USEFULNESS OF ICE STICK® IN SWALLOWING TRAINING
M. Tazawa¹, M. Kurosaki¹, N. Wada¹
¹Gunma University Graduate School of Medicine, rehabilitation medicine, Maebashi- Gunma, Japan

Introduction/Background

In Japan, ice massage is widely used as the prefeeding technique to facilitate dry swallowing. However, there was no device for ice massage, and it was handmade by nurse and therapist. We have developed Ice Stick® and evaluated the effect of ice massage using Ice Stick®.

Material and Method

The subjects were 30 dysphagia patients. Subjects were randomly divided into a group that performs ice massage with a conventional syringe (conventional group) and a group using a newly developed ice stick® (Ice Stick® group), indirect swallowing training was conducted, repeated saliva swallowing for 30 seconds (Repetitive saliva swallowing test: RSST) before and after training. The number of RSSTs was compared in both groups and tested by Wilcoxon’s signed rank test.

Results

The median RSST before and after ice massage increased from 3 to 4 in the conventional group and a significant difference was observed at r = 0.038. In the Ice Stick® group, it was 2.5 to 3 times, and a significant difference was observed at r = 0.041. There was no difference in the increase in both groups.

Conclusion

Both the conventional type and the Ice Stick® increased the number of RSSTs after training, so ice massage is considered to be effective against dysphagia. The Ice stick® reduces the work burden of creating staff’s ice massage device, which is considered to be effective in reducing the risk of infection because it is individual packaging.

HOW CAN BIOMECHANICAL FOOT ORTHOSIS AFFECT GAIT IN ARTHRITIS WITH HALLUX VALGUS?

D. Hwang, S. Ahn, B.O. Kim, S.K. Bok

1Chungnam National University Hospital, Rehabilitation, Daejeon, Republic of Korea

Introduction/Background

Hallux valgus (HV) deformity is the most commonly observed forefoot deformity in elderly women patients with arthritis. We investigated the effects of customized biomechanical foot orthosis (BFO) on kinematic data during gait in arthritis with HV deformities compared with normal control group.

Material and Method

Ten arthritis patients with HV deformities and 10 normal women were enrolled in this study. All patients were diagnosed with foot deformities by biomechanical and radiologic studies, and they received the customized BFOs manufactured at a commercial orthosis laboratory (Biomechanics, Goyang, South Korea) according to the strictly defined procedure by a single experienced technician. The kinematic data by the Vicon 3D motion capture system (Oxford Metrics, Oxford, England) were compared in with and without application of the BFO (Figure 1).

Results

Patients with application of the BFO showed increased gait cadence, walking speed and decreased stride, step time in temporal parameters (Table 1). Total mean range of motion (ROM) of hallux respect to forefoot was 52.67 degree (dorsiflexion (DF) 34.41; plantar-flexion (PF) 18.26) without BFO, and was increased to 73.12 degree (DF 24.75; PF 48.37) after application of the BFO. During specific gait events, a different range of motion was found at several inter-segment angles (Table 2). Particularly, the range of motion of the hallux (sagittal plane) and hindfoot (frontal-transverse planes) during stance were significantly different (Table 3). The averaged position of forefoot during whole gait cycle was persistently abducted in with application of the BFO (Figure 2).

Conclusion

The application of BFO will be considered to be useful effects for improvement of gait pattern in arthritis with HV deformities by increased ROM of hallux and change of foot position. Our results suggest that it is very important to find out pathophysiology of HV and the effectiveness of BFO on gait pattern in arthritis with HV.

SCREENING WATER TEST FOR ASPERSION.
P. Kittipanya-ngam¹, P. Wattanapan¹
¹Khon Kaen University, Physical Medicine and Rehabilitation, Muang, Thailand

Introduction/Background

One of the basic needs in life is eating. Swallowing problem is caused by a lot of diseases whose common complication is aspiration pneumonia. Physical examination, such as modified water swallowing test(MWST), can detect aspiration but not silent aspiration. The videoendoscope(VE)/ videofluoroscope(VF) are able to find out all aspirations but it is more complicated. Therefore this paper aims to study the capability of MWST to detect all aspirations.

Material and Method

The demographic data, swallowing physical examination, MWST and videoendoscope(VE)/ videofluoroscope(VF) test were recorded. Normal MWST scores 4 and 5. Abnormal MWST scores between 1 to 3. Aspiration with chocking or wet voice and silent aspiration were reported in percentage. Chi-square test was used to detect the different between normal and abnormal MWST.

Results

There were 60 patients who accessed the dysphagia clinic, MWST was used in 55 patients and VE/VF were done in 40 patients. There were only 36 patients who had done both MWST and VE/VF. From 22 abnormal MWST patients, 6 patients (27%) had aspiration with chocking or wet voice and 2 patients (9%) had silent aspiration from VE/VF. From 14 normal MWST patients, 3 patients (21%) had silent aspiration. Therefore, the MWST can detect aspiration 36%. Moreover, the MWST showed no significantly different between normal and abnormal group (p value 0.34).

Conclusion

The MWST detected aspiration at 36% which was quite low. Further study with a large number of patients or other screening tests should be done.

INCREASE OF SURVIVAL AND IMPROVEMENT OF THE PROGNOSIS WITH NEW THERAPIES FOR THE TREATMENT OF CYSTIC FIBROSIS

M.J. Buzzetta Devis¹, M.E. Martinez Rodriguez², A. Lamas Ferrero³, J.C. Estupiñan², D. Pozo Crespo⁴, D. Torres Noriega²

¹Hospital Ramon y Cajal, Medicina física y rehabilitación, Madrid, Spain
²Hospital Universitario Ramon y Cajal, Medicina Física y Rehabilitación, Madrid, Spain
³Hospital Universitario Ramon y Cajal, Neumología Pediatrica, Madrid, Spain
⁴Hospital Universitario Ramon y Cajal, Medicina Física y Rehabilitación, Madrid, Spain

Introduction/Background

Cystic Fibrosis (CF) is the most prevalent autosomal recessive disease in Caucasians, resulting from a mutation of the gene located on the long arm of chromosome 7, which encodes the production of cystic fibrosis transmembrane conductance regulator (CFTR) protein, present in epithelia, which functions as a channel for the passage of chlorine and other ions. Clinically it presents multi-organ involvement; being more serious the pulmonary manifestation and prognostic determinant.

Despite scientific advances, it remains an incurable disease, only with treatment to prevent and treat symptoms, until the appearance of therapies (genotype-dependent) such as the combined lumacaftor/ivacaftor, indicated in F508del homozygote patients above 12 years; aimed to correct the defect in CFTR, which could improve quality of life, prognosis and survival.

Material and Method

7-year-old patient with CF diagnosis through positive neonatal screening: genotype F508del/F508del. During the perinatal period, she presented: intestinal perforation, meconium peritonitis, jejunal atresia: Appel-Peel, intervened (resection of jejunum and ileum), as well as malnutrition. At 7 years of age, presented recurrent pulmonary exacerbations despite the symptomatic treatment of inflammation, infection and fluidification of secretions of the respiratory system and pulmonary rehabilitation. In addition, she required nutrition by gastrotomy with a low weight gain due to malabsorption. In view of the poor clinical evolution, treatment with lumacaftor/ivacaftor is introduced, for compassionate use, being less than 12 years old.

Results

One year after treatment, it was observed an important decrease in the number of pulmonary exacerbations (from having 3 to 1 exacerbations/year), weight gain (BMI from 12.98kg/m2 to 14.52kg/m2), improvement in FEV₁ (from 54% to 65%) and quality of life.

Conclusion
The new physiopathological treatments suppose a great hope in CF; in our patient they have decreased: the number of pulmonary exacerbations, improved lung function and quality of life. Even so, pulmonary rehabilitation remains one of the pillars of treatment for these patients.

Introduction/Background
Cervical osteophytes are often accidentally discovered on cervical spine X-rays. Usually, they have low impact on swallowing.

We report one case of surgical treatment for dysphagia secondary to cervical hyperostosis.

Material and Method
With the patient's consent, we retrospectively reviewed his medical record.

Results
A 77 years old man, diagnosed with hypertension and type 2 diabetes mellitus, was treated surgically for cervical spinal cord compression due to atlantoaxial subluxation. After an ineffective transorally procedure, he benefitted to a surgical decompression and stabilization by occipital-C2 arthrodesis

Dysphagia was complicated by one aspiration pneumonia and malnutrition requiring enteral nutrition by gastrostomy.

Thus, the patient was referred to the consultation of swallowing disorders. Although the larynx vision was limited by a posterior hypopharyngeal wall protuberance, the FEES exam reveals salivary stasis and left laryngeal immobility. In videofluoroscopy, the wall protuberance appears to be prevertebral osteophytes of cervical spine that limited the rise of the larynx, epiglottis tilt and induced inhalation.

Additionally, surgical treatment has been proposed because of the severe symptomatology and compromising of patient’s quality of life. An osteophytectomy via the anterolateral cervical access was performed without intercurrences, and the patient showed expressive improvement.
FEES and VFS show the improvement but swallowing disorders persist because of the propulsive deficit. The immobility of left larynx has been confirmed. The mechanism is still unknown.

**Conclusion**

The radiologic findings were consistent with diffuse idiopathic skeletal hyperostosis (DISH) or Forestier disease of the cervical spine causing dysphagia, which is an uncommon cause of myelopathy and dysphagia.

We must be aware that these anterior cervical osteophytes can affect laryngeal function, not only on swallowing, but also on airway management (ie during tracheal intubation).

THE ASSESSMENT OF RELATION OF MOVABILITY OF THE CERVICAL SPINE AFTER THE ODONTOID VERTEBRA DENS FRACTURE SINCE THE TIME OF WEARING THE ORTHOPEDIC COLLAR

A. Wolan - Nieroods, A. Guzik, A. Maciejczak, M. Drużbicki, G. Przysada, E. Szeli

Introduction/Background

The aim of the article is to evaluate kinetic efficiency of a cervical spine taking into consideration the range of active motion as well as to assess the relation of movability range of the cervical spine since the day of wearing the Philadelphia collar, as well as the level of the strength of pain, and age.

Material and Method

41 individuals surgically or conservatively treated at the Neurosurgery Ward and subjected to a post-hospital observation at the Neurosurgery Outpatient Clinic of Provincial Hospital in Tarnów participated in the study. The control group consisted of 41 individuals without a clinically diagnosed cervical spine disease. The study of the range of motion of the spine in the cervical section was performed by means of MCU (Multi Cervical Unit) appliance. The strength of the pain was evaluated by means of VAS - the visual analogue pain scale.

Results

The individuals after the odontoid vertebra fracture are characterised by a limited motion range in case of all types of motion, except for bending and extension. In the study extremely significant differences of the range of motion of the study group in comparison with the control group were discovered. In case of the time of wearing the orthopedic collar, statistically significant negative correlations related to entire motion apart from side bending. The strongest correlation was obtained for rotation (r=-0,36).

Conclusion

The patients after the odontoid vertebra fractures have statistically significant limitations of the range of active motion of the cervical spine. Age, strength of the spine ache as well as the time of wearing the Philadelphia collar are negatively correlated in a significant manner with the movability range of the cervical section of the spine of individuals after the odontoid vertebra fracture.

THE EFFECT OF EXERCISE IN THE TREATMENT OF OBESITY

E. Laskowski\textsuperscript{1}

\textsuperscript{1}Mayo Clinic, Physical Medicine and Rehabilitation, Rochester, MN, USA

Introduction/Background

The world continues in the midst of a significant public health problem related to obesity and inactivity. This epidemic has far-ranging consequences on the workforce of the world and on our children, and shows no signs of slowing down in the near future.

Material and Method

A significant amount of research has been performed on the effects of exercise for the reduction of body weight. A literature review was performed to address the effects of aerobic exercise, strength training, and high intensity interval training (HIIT) on obesity and weight loss.

Results

Most studies indicate that exercise alone has a small effect on body weight reduction independent of caloric restriction. When combined with dietary restriction, exercise has a synergistic effect and enhances weight loss beyond the effect of diet alone. Exercise also has been shown to have significant beneficial effects on cardiovascular and metabolic risk factors independent of actual weight loss, and losing just a small amount of weight can have a significant beneficial effect. Genetic factors related to obesity have been found to be positively modified when individuals incorporate physical activity into their lifestyle. Sitting time also appears to be an independent risk factor for the development of metabolic risk factors; individuals who spend more time sitting and watching television have worse metabolic profiles, even if they achieve the recommended amount of physical activity per week. High intensity interval training has been shown to be a safe, effective, and well tolerated mode of exercise in the obese population, and compliance may be better than continuous moderate duration exercise.

Conclusion

Continuous moderate intensity aerobic exercise has a synergistic effect with diet to enhance weight loss. Resistance training has significant cardiovascular and metabolic effects independent of weight loss. High intensity interval training is effective, time efficient, and well tolerated in the obese population.

EXAMINATION OF POSTURAL CHANGE ACCORDING TO THE STATE OF EXERCISE IN PREGNANCY IN BACKHACHE, DISABILITY AND DAILY LIFE ACTIVITIES

N. Öztürk¹, A. Çoban², F. Ünver³
¹Lecturer, Adnan Menderes University, Söke Health Services Vocational School, Aydın, Turkey
²Prof. Ph.D. Adnan Menderes University, Faculty of Health Science, Midwifery Department, Aydın Turkey
³Assoc. Prof. Pamukkale University, Physical Therapy and Rehabilitation Department, Denizli, Turkey

Introduction/Background

Aim of this study is to examine postural change according to the state of exercise in pregnancy in backhache and daily life activities.

Material and Method

This research is in analytical cross-sectional type and conducted in Aydın Obstetrics and Gynecology hospital polyclinics between 1st of September 2017 and 28th of February 2018. 160 pregnancy women have been included in the story. Survey form prepared by researches has included questions related to sociodemographic characteristics, questions about exercises, Visuel Analog Scale to evaluate backhache and Ostwestry Scale for disability and Katz Daily Life Activities form to evaluate life activities. New York Postural Analysis form also been used to evaluate postural change of pregnants prepared by researcher physiotherapist.

SPSS 20.0 programme has been used in coding of data, transferring to the computer environment and analysis. Descriptive statics of individuals participating in the study have been given in minimum average, maximum average and standart deviation. Depending on the exercise condition of the individuals participating in the study difference between their daily life activities, pain, disability situations and postural changes have been evaluated by t-test analysis in independent groups.

Results

Average age of pregnants participating in the survey has been identified as 26.43± 3.96. Daily average standing time of pregnants has been detected as 5.7 ± 1.58 her and average sitting time of them has been detected as 6.40 ± 1.59 hours. Pre-pregnancy body weights have been detected as 60.35± 8.15 kg. body weights in pregnancy have been detected as 71.41± 7.94 kg. In this research, pregnant who are doing exercise have more daily life activity. Scores, less backhache scores, have better postures and pain has less effected their daily life activities(p< 0.005).

Conclusion
As a result of our research, it is detected that exercising in pregnancy has effected positively in postural changes, backache and daily life activities.

Factors Affecting Location After Discharge in Patients of Hip Fractures.

E. Sho\textsuperscript{1}, T. Kameoka\textsuperscript{2}, K. Miyakoshi\textsuperscript{1}  
\textsuperscript{1}Kameda Medical Center, rehabilitation, Kamogawa city-Chiba, Japan  
\textsuperscript{2}Kameda Medical Center, Orthopedics, Kamogawa city-Chiba, Japan

Introduction/Background

Patients of hip fracture are increasing in Japan. The purpose of this study is disclosing the factor influence location after discharge in patients of hip fracture.

Material and Method

56 patients of hip fracture treated at our hospital since June 2015 and January 2017, who were living at home before the injury. 12 males and 44 females, mean age was 79.6 years. Patients were divided into those who were discharged to home and nursing homes or recuperation hospital. Predictor variables were functional level before fracture, Functional Independence Measure (FIM) total score at discharge, motor FIM score at discharge and family caregiver score. Statistical analysis was performed using Mann - Whitney U analysis. (p<0.05)

Results

In the Group of discharge to home, functional level before fracture (p=0.013) and motor FIM score at discharge (p= 0.049) were significantly high.

Conclusion

Various factors have been reported to affect location after discharge of patients of hip fracture. In this study, no significant differences were observed in caregiving ability and FIM total score at discharge which is considered to be related to the prognosis before. However, significant differences were observed in motor FIM score at discharge and functional level before fracture. This suggests that not only the presence or absence of caregivers but also independence in activities of daily living and less amount of care will increase the possibility of home discharge.

ACCURACY OF ULTRASOUND-GUIDED AND NON-US-GUIDED BOTULINUM TOXIN INJECTION INTO CADAVER SALIVARY GLANDS

D.H. Song¹, M.E. Chung¹
¹The Catholic University of Korea- College of Medicine- St. Paul's Hospital, Rehabilitation Medicine, Seoul, Republic of Korea

Introduction/Background

Recent investigations have reported the increased efficacy and safety of BTX injection under US guidance, there have not been any studies comparing the injection accuracy between blind and US-guided approaches. This study was designed to evaluate the injection accuracy of blind and US-guided botulinum injections into the parotid and submandibular glands of fresh cadavers.

Material and Method

Two rehabilitation physician injected dye into three sites in the salivary glands (two sites in the parotid gland, and one site in the submandibular gland) on one side of each cadaver (one was injected on the right side, while the other was injected on the left side), using either a non-US guided injection procedure based on superficial landmarks or a US-guided procedure. Orange dye was used for the US-guided procedure, and green dye was used for the blind procedure. Two physicians uninvolved with the injection procedures and who were blinded to the method of injection dissected the cadavers to identify whether the dye was accurately injected into each target site.

Results

The accuracies of the blind and US-guided injections into the parotid gland were 79.17% and 95.83%, respectively. In the submandibular gland, the accuracies of the blind and US-guided injections were 50.00% and 91.67%, respectively. The difference in accuracy between the two procedures was statistically significant only in the submandibular gland (p=0.025). There were no significant differences in the accuracy of US-guided and non-US-guided injections between the two physicians for the two sites in the parotid gland (p=0.278 and p=0.146, respectively).

Conclusion

US-guided BTX injection into the submandibular gland offers significantly greater accuracy over blind injection. For the treatment of drooling by injecting BTX into the submandibular gland, clinicians should consider using US guidance for improved accuracy.

REHABILITATION TEAM APPROACH FOR THE TREATMENT IN FACIAL PALSY IN A MULTICENTRIC CLINICAL PRACTICE. CONSENSUS GUIDE.
D. Issa-Benitez¹, M.L.T.B. Dr.¹, M.G. Dr², J.J. Dr², N. Montesinos³, R. Oller², G. Artasona⁴, M. Gomez⁴
¹Physical Medicine and Rehabilitation Service Vall d’Hebron Hospital, Facial Palsy Unit, Barcelona, Spain
²Physical Medicine and Rehabilitation Service Bellvitge Hospital, Facial Palsy Unit, Barcelona, Spain
³PT- Bellvitge Hospital, Facial Palsy Unit, Barcelona, Spain
⁴PT- Vall d’Hebron Hospital, Facial Palsy Unit, Barcelona, Spain

Introduction/Background

The treatment for facial palsy is complex and requires specialized units as well as a multidisciplinary team to assess the patient globally and respond to the problems of each phase.

To unify criteria and define the best treatment for each phase of the facial palsy, to improve facial function and quality of life.

Material and Method

Both doctors and physical therapists from the Facial Palsy Units from the Rehabilitation Services of two university hospitals in Barcelona, Spain, got together to revise scientific articles, share clinical experiences and introduce new technique for facial palsy management. Afterwards, a consensus document was created as a protocol for both medical centers.

Results

Consensus on best treatment for each phase was achieved, as follows:

- Hypotonic phase: neurosensory stimulation through Perfetti method, proprioceptive and cognositive activities with neurosensory feedback, and movement induction by neuromuscular training (ill side). Treatment with botulinum toxin helps diminish hypercontractility of the sound side.

- Initiation of movement: neuromuscular training and Perfetti’s neuromuscular stimulation.

- Synkinetic Phase: neuromuscular retraining with dissociated movements of the synkinetic muscles. Relaxation treatment of the maintained muscle contractures. Treatment with botulinum toxin helps control aberrant movements and induces facial symmetry.
Myofascial techniques (dry needling and mesotherapy) may help diminish maintained muscular contraction.

After dynamic surgery, treatment must be based on the physiology of the reconstruction implemented, inducing movement according to the given nervous stimuli.

In congenital/obstetric palsies, treatment will be similar to that of adults’ Bell’s palsy, adjusting treatment to patient’s age.

**Conclusion**

We believe this consensus will allow for a better clinical practice, to offer the patient the best treatment to improve functionally, mentally and socially, thus improving quality of life.

¹faculty of medicine of monastir-universiy of monast(4,168),(998,991)(1,2),(997,996)ar, Rhumatology, - Monastir, Tunisia
²Taher Star Hospital- Mahdia, Rhumatology, - Monastir, Tunisia
³Taher Star Hospital- Mahdia- Tunisia, Physical medecine and rehabilitation, Mahdia, Tunisia

Introduction/Background

Vitamin B12 deficiency could have a significant clinical impact. It could be manifested by neurological disorders or muscle weakness. The causes of deficiency are dominated by Biermer's disease. The aim of this study is to describe rheumatologic revelations due to vitamin B12 deficiency.

Material and Method

We reported a retrospective study, from 2003 to 2017, conducted in the Rheumatology department of Fattouma Bourguiba Hospital, Monastir, Tunisia dealing with patients who presented vitamin B12 deficiency.

Results

Five cases were analyzed (3 women and 2 men). Mean age was 55.2 years [49-70]. The clinical presentations were polymorphic. Neurological symptoms included paresthesia, tingling and limb heaviness in all cases, inferior limb pyramidal syndrome in 2 cases, gait disorder with muscle weakness in 3 cases and ataxia in 2 cases while memory disorder was documented in only one case. Biological explorations revealed macrocytic anemia in all cases. Mean hemoglobin rate was 10.76 g / dl, mean MCV was 109.16 fl. The sternal puncture, practiced in 3 cases, revealed a granular lineage gigantism with large myelocytes and metamyelocytes. In 3 cases, Medullar MRI revealed a cordonal demyelination of medulla. Vitamin B12 deficiency is noted in all cases. Mean vitamin B12 level was 130.63 pg / ml with a minimum level of 50pg/ml. Treatment with parenteral vitamin B12 regressed neurological and muscular symptoms in all cases. Memory disorders persisted with the patient who had the lowest rate of vitamin B12 (50 pg / ml).

Conclusion

Neurological and psychiatric symptoms are the mostly noted in our study. Their association with macrocytic anemia may suggest the diagnosis of vitamin B12 deficiency which will be easily treated with good prognosis.

OCCUPATIONAL THERAPY ADDRESSING SELF-CARE NEEDS WITH LOW TECHNOLOGY AND LOW-COST ASSISTIVE TECHNOLOGY IN BANGLADESH

H. Shakhawath¹, M. Afroze¹

¹Bangladesh Health Professions Institute BHPI, Occupational Therapy, Dhaka, Bangladesh

Introduction/Background

Understand the role of Occupational Therapy in the creation of assistive technology.
Learn about four low tech examples implemented by OTs in Bangladesh.
Be able to reproduce low tech assistive technology in other settings based upon information shared here.

Material and Method

There were some articles and review the literature, all qualitative and quantitative which are included in this review. All studies were mixed methods in design. All but one study was not conducted with participants. The literature search here, OT Seeker, Google search, Google Scholar, PubMed, and Hinari searched for literature related to the contribution to and involvement low technology and low cost assistive device for person with SCI.

Results

Scope of practice in Occupational Therapy for persons with SCI used self-care needs with low cost assistive technology in Bangladesh. Adapted Toilet/Shower Chair A plastic (resin) outdoor chair with handles has a hole cut in the seat create an over the toilet handled commode and shower chair. Toilets in many Bangladeshi homes, especially in rural areas, are “Squat toilets” which are difficult for people with SCI and mobility issues to safety use. Buttoning tool A lightweight eating utensil, a paperclip, a short piece of duct tape makes for a easy to hold buttoning tool for people with tetraplegia SCI and hand dexterity issues. Universal cuff A piece of elastic sown onto a small leather sleeve to hold eating utensils, toothbrushes, writing implements. A local leather (belt and purses) merchant created this to custom fit a woman with a SCI to feed herself and lessen caregiver burden of hand feeding her every meal. Shoe lift Extra sole attached to shoe of a foot with a shortened leg discrepancy.

Conclusion

Occupational Therapists working with SCI in Bangladesh use low assistive technology for effective rehabilitation. Low assistive technologies are appropriate for developing countries.

WHICH TREATMENTS FOR THE HYPERVENTILATION SYNDROME IN ADULTS?

A. Rapin1, J.B. Ferte1, A. Gerard1, F.C. Boyer1

1Reims Champagne Ardenne University Hospital, Physical Medicine and Rehabilitation, Reims, France

Introduction/Background

The hyperventilation syndrome is a complex entity whose management is poorly codified. A cochrane review in 2013 [1] highlighted the lack of proof in the treatment of this disease. The aim of this presentation is to expose the different options used in hyperventilation syndrome and to discuss their efficacy.

Material and Method

We performed a narrative review in Pubmed, Science direct and clinical trials, with the key word « hyperventilation syndrome », « Dysfunctional breathing », « breathing exercise », « physical therapy », « rehabilitation », « treatment », without limitation of date.

Results

Fifteen articles were selected. Among them, three studies about drug treatment and the others about non-pharmacological approaches. Among the last ones, a re-educational approach based on abdominal ventilation and regulation of the ventilatory rate, and an educative approach seems to be the most effective. Methodological biases did not permit a conclusion on the efficacy of these treatments. No study was done to explore the efficacy of pulmonary rehabilitation. A recent study was proposed on clinical trials to explore the nasal ventilation as a therapeutic modality.

Conclusion

Teaching abdominal ventilation and respiratory rate regulation, associated with a personalized therapeutic education, seems to be a pertinent management approach. Other clinical studies should explore this issue.

PATIENTS WITH BLEEDING OF UNKNOWN CAUSE AND JOINT HYPERMOBILITY: CLINICAL ASSESSMENT AND GENETIC SCREENING

J. Sanchez-Raya1, C. Altisent2, M. Martorell2, I. Corrales3, F. Vidal4, A. Crespo4

1Vall d’ Hebron Hospital, Musculoskeletal Rehabilitation Unit, Barcelona, Spain
2Vall d’ Hebron Hospital, Haemophilia Unit, Barcelona, Spain
3Banco de Sangre y Tejidos de Cataluña, ciber, Barcelona, Spain
4Vall d ’Hebron Hospital, Rehabilitation Haemophilia Unit, Barcelona, Spain

Introduction/Background

Symptomatic joint hypermobility has been associated with bleeding tendency, suggesting that collagen disorders could be the cause in some cases of bleeding. The aim of this study was to examine the clinical characteristics of patients with bleeding tendency of unknown cause and joint hypermobility and to perform a genetic study based on Next-Generation Sequencing (NGS).

Material and Method

This was a single-centre, prospective, observational study. Patients included were a Haemophilia Centre (HC) for bleeding symptoms of unknown cause (normal or abnormal haemostatic tests not explaining the bleeding phenotype) and having joint laxity and Musculoskeletal Rehabilitation Unit (RHB) for joint laxity and reporting bleeding symptoms. Bleeding severity was assessed by the haematologist using the ISTH Bleeding assessment tool (ISTH-BAT) and joint hyperlaxity by the physiatrist by the Beighton score. Molecular analysis was performed using TruSight One Sequencing Panel Kit (Illumina). Quality and population frequency filters were applied and the search was limited to 78 genes related with Heritable Disorders of Connective Tissue (HDCT).

Results

43 patients were included between June 2016 and January 2017. All were females; median age was 38.6 years (range 17-62 years). Median ISTH-BAT score was 8 (range 3-17) and Beighton score 7 to 9 (range 3-9). ISTH-BAT score was abnormal in 77% and Beighton score in 80%. In 25 patients, both scores were abnormal. A total of 175 potential mutations were identified in HDCT related genes for all except one patient. In 46.5% a direct correlation between the identified mutation and the clinical phenotype could be established. In 10 patients, mutations in COL5A1, COL5A2, COL1A1 and COL1A2 genes were identified and validated by Sanger sequencing.

Conclusion
Clinical assessment for symptomatic joint hypermobility should be considered in patients with significant bleeding history of unknown cause. NGS could be a useful tool for the study of the responsible genes and the classification of patients.

THE EFFECTIVENESS OF INTERVENTIONS TO INCREASE PHYSICAL ACTIVITY OF CHILDREN WITH PHYSICAL DISABILITIES: A SYSTEMATIC REVIEW.

F. Ganz¹, S. Armijo², S. Bajpai³, S. Amjad²

¹University of Alberta, Physical Therapist, Edmonton, Alberta, Canada
²University of Alberta, Public Health, Edmonton, Alberta, Canada
³University of Alberta, Physical Therapist, Edmonton, Canada

Introduction/Background

Increased sedentary behaviour (SB) and decreased physical activity (PA) is a concern in pediatric health care because of rising obesity rates and long-term adverse health effects. Since children with physical disabilities are even more sedentary than their peers without disabilities, there is growing concern over how to increase PA and decrease SB in this group of children. The purpose of this systematic review was to review the evidence related to the effectiveness of interventions aimed to increase objectively measured physical activity in children with physical disabilities.

Material and Method

Randomized controlled trials (RCTs) were obtained through a search of bibliographic databases conducted searching in six databases up to October 21, 2017. Articles were considered for inclusion if participants were aged 0–18 years, had physical disabilities, and the outcomes of interest were either PA and/or sedentary behavior. Two independent reviewers screened the abstracts found in the databases. Risk of bias was assessed using the Cochrane collaboration tool. Data were pooled considering mean differences with 95% confidence intervals.

Results

Nine articles were selected for inclusion. Of these articles, the majority of the studies implemented interventions in children with CP (n=5). The remaining studies included children with other physical disabilities. Accelerometry was the most common objective measure of PA and SB. Overall, the efficacy of interventions on increasing PA and decreasing SB was not significantly better than absence of interventions in children with physical disabilities. Most of the studies were considered to be of unclear risk of bias.

Conclusion

More research to evaluate interventions related to increase PA and decreased SB in children with physical disabilities is needed. Future research should also consider interventions that target behaviour change in a specific age range. In addition, interventions that addressed participation and increase PA in different environmental setting is necessary.

ISOKINETIC MUSCLE ASSESSMENT AND STRENGTHENING IN CENTRAL NEUROLOGY: STROKE PATIENTS

S. Mesure¹, N. Abdelnour², R. Briolotta¹

¹Institut of mouvement science, Aix Marseille Université UMR- FSS 7287, Marseille, France
²Université Francophone St Joseph, Institut de Physiotherapie, Beyrouth, Lebanon

Introduction/Background

It is important to solicit the brain in many ways, through very different exercises, to support the rehabilitation of people with stroke. The training and the repetition of the physical exercise is a major factor in secondary prevention after stroke. However, our main goal is to strengthen a hemiparetic patient muscularly through eccentric muscular work to increase his strength to transfer to his autonomy.

Material and Method

23 adults hospitalized with single episode of supra-tentorial stroke (less than eight months), with normal evaluation (spasticity, syncinesia, sensitivity, Functional Independence Measure), be able to perform the exercise requested on the horizontal press, and be voluntary. 3 sets of 5 repetitions each of eccentric contraction (Second leg for control) according to the maximum resistance (MR) evaluated. Two series at 40% of the MR and 1 series at 60% during 4 weeks. We test, the 10-meter test, the isokinetic test, the International Muscular Testing and the 6 minutes walking test.

Results

We observe a significant increase in the performance of these patients on all parameters analyzed between before and after the various rehabilitation sessions. This means that the progression in terms of strength and muscle power has impacted the functional component of the patients. We observed no change in spasticity. Our exercises did not modify a physiological component that could negatively affect the standard therapeutic management proposed to these patients.

Conclusion

This study provides additional information on the current trend in the use of muscle strengthening versus resistance. Moreover, this study shows that apart from the positive effects on muscular power, there is also a tendency to increase the functional capacities of the non-spastic hemiparetic patient in the subacute phase. At the central level, deficiencies in motor control have been identified, but no study has undertaken to evaluate the effect of specific training on the functioning of the predictive system.

PRACTICAL STRENGTH TRAINING FOR POPULATION HEALTH AND WELLNESS
E. Laskowski

1Mayo Clinic, Physical Medicine and Rehabilitation, Rochester- MN, USA

Introduction/Background

Strength training is universally recognized as an essential component of fitness and injury rehabilitation, and is a core component of the United States Department of Health and Human Services Physical Activity Guidelines for Americans. The multiple health benefits of resistance training, including physical, metabolic, and psychologic benefits, make it imperative to prescribe for public health, yet many people are intimidated by the emphasis placed on number of sets and repetitions, the amount of resistance, and complex periodization protocols.

Material and Method

This session will review multiple meta-analyses and research studies that compare a wide variety of combinations of resistance, repetitions, and sets. Outcomes of each of these methods and programs will be analyzed.

Results

Multiple combinations of applied resistance, repetitions, and sets produce similar outcomes, and heavier load does not produce a universally superior result. Subtle differences that may be gained from complex programs are less relevant to public health and injury rehabilitation. The degree of effort is a more accurate gauge of true intensity than the 1 RM resistance, and data are unclear as to whether more volume results in greater strength gains. Studies indicate that the external load is not the absolute muscle stimulus to induce muscle protein synthesis, but effort to fatigue is; a wide range of repetitions and time can be used.

Conclusion

Resistance training has documented benefits for injury rehabilitation as well as performance training and population health. Traditional training usually focuses on multiple set exercise with heavy loads and sometimes complex periodization protocols, which hinders participation by many. Multiple studies show that a variety of combinations of applied resistance, repetitions, and sets produce similar outcomes, and heavier load is not superior. Compliance and injury reduction could be enhanced with the prescription of practical programs of strength exercise that would provide overall benefit to public health.

THE AFFECT OF SERUM 25 (OH) D3 LEVEL OF THE BREAST CANCER-RELATED LYMPHEDEMA

P. Doruk Analan¹, E. Kaya¹
¹Baskent University, Physical Medicine and Rehabilitation, Adana, Turkey

Introduction/Background

In this study, it was evaluate whether there was a correlation between the serum 25 (OH) D3 level and severity of lymphedema in patients with breast cancer.

Material and Method

The study population was categorized two groups. Inclusion criteria of the first group was diagnosis with breast cancer-related lymphedema (BCRL) in unilateral upper extremity (n:31). Also, second group was consist of diagnosis with unilateral breast cancer without lymphedema (n: 34). The patients in the second group were accepted as control group. The patients in the second group were not described any pain, weakness or limitation of their upper extremity secondary to breast carcinoma.

Age, duration of malignancy diagnosis, side and type of malignancy, serum levels of the 25 (OH)Vit D3, calcium and phosphorus, the history of chemotherapy, radiotherapy, lymph node dissection, grade of breast carcinoma were recorded for both groups.

In BCRL group, it was recorded education level, dominant extremity, side of lymphedema (right /left), duration of BCRL, lymphedema stage, body mass index (BMI) (body weight [kg] / height² [cm²]), visual analog scale (VAS), the quick disabilities of the arm, shoulder, and hand questionnaire (Q-DASH) score, the diametric and volumetric differences between affected and unaffected extremities.

Firstly, the serum levels of the 25 (OH)Vit D3 were compared between two groups. After this analysis, it was evaluated the correlations between the measurements in the BCRL group.

Results

Demographic data were similar between groups (p>0.05).
In statistical analysis, it was found that the serum levels of the 25 (OH)Vit D3 were similar between groups (p:0.188).
Also, 25 (OH)Vit D3 levels were not correlated with VAS, Q-DASH, BMI, the diametric and volumetric differences in BCRL group (r<0.3; p >0.05).

Conclusion
25 (OH) D3 vitamin level seems to be not affect BCRL. In routine clinical practice, this vitamin may not important in BCRL patients.

ISPR8-2349
TREATMENT OF POST-POLOMYELITIS SYNDROME BY INTRAVENOUS IMMUNOGLOBULIN: A RETROSPECTIVE STUDY OF CLINICAL CRITERIA.

V. MOIZIARD¹, I. Laffont¹
¹CHU MONTPELLIER, Physical and rehabilitation medecine, MONTPELLIER, France

Introduction/Background

We investigated the efficacy of intravenous immunoglobulin therapy in the treatment of post-poliomyelitis syndrome (PPS) of clinical criteria.

Material and Method

We realised an unicentric retrospective descriptive study at the CHU of Montpellier, involving patients with PPS treated with intravenous immunoglobulin (IG), between 2009 and 2017. The doses administered were 0.4 mg / kg / day for 5 days, once a month for 3 consecutive months. Patients were evaluated on pre- and post-therapy on clinical and functional aspects using validated scales: pain Visual Analog Scale, 6 minutes walking test, walking speed.

Results

17 patients, 9 men and 8 women were included, some patients receiving multiple courses. All patients had lower limb involvement. The walking perimeter was improved in 67% of the patients studied (p = 0.320), the walking speed increased in 71% (p = 0.541) of the patients and the progression of the pain was favorable in 71% (p = 0.586) cases studied. 1 patient experienced a deterioration of functional abilities during walking after treatment. We will graphically represent the evolution of variables, before and after IG IV treatment.

Conclusion

Our analysis seems to show a favorable evolution of the PPS after treatment with IG on clinical data related to the pain and function of walking. This treatment could thus represent an effective therapeutic strategy in the management of PPS.

RECOVERY OF ORAL INTAKE AFTER INITIATION OF TUBE FEEDING: CLINICAL EXPERIENCE FROM A JAPANESE REHABILITATION WARD

Y. Mikami¹, T.Y. Ezekiel Wong², K. Nakao², M. Yoshikawa¹, C. Mihara²
¹Hiroshima Kyouritsu Hospital, Rehabilitation Department, Hiroshima, Japan
²Hiroshima Kyouritsu Hospital, Nutrition Support Team, Hiroshima, Japan

Introduction/Background

Tube feeding plays an important role in managing their nutritional needs of dysphagic patients. Although nasogastric feeding (NG) can be useful for the short term, percutaneous endoscopic gastrostomy (PEG) is usually the route of choice for long term tube feeding. In this study, we analyzed the current situation of tube feeding and the recovery of oral intake after dysphagia therapy in our rehabilitation ward.

Material and Method

Patients admitted into our rehabilitation ward between January 2012 and December 2016 were screened. Patients who were intubated (NG or PEG tube) when warded and patients who required intubation after admission due to insufficient oral intake were included in our analysis.

Results

A total of 1129 patients were admitted into our rehabilitation ward during the five year period. At admission, 1036 (92%) patients were fed orally, 63 (5%) patients received PEG tube feeding and 30 (3%) patients received NG feeding. Out of the 30 patients receiving NG feeding, 11 patients improved to full oral feeding whereas 19 patients required PEG tube placements after admission. Out of the 63 patients who receive PEG tube feeding, 22 patients recovered to full oral feeding at discharge. 7 patients from the 1036 patients who were fed orally at admission eventually required PEG tube placements, with 6 of them recovering partial oral feeding upon discharge. More than two thirds of tube feeding patients recovered at least partial oral intake upon discharge from our rehabilitation ward. More than half of patients who received PEG tube placement recovered full oral intake upon discharge.

Conclusion

The majority of tube-fed patients resumed at least partial oral intake after dysphagia therapy. Tube feeding plays an integral role in providing the nutritional needs of patients with dysphagia, and along with rehabilitation therapy, may contribute to the recovery of swallowing function.

ISPR8-0171
SPORTS MEDICINE ISSUES IN WOMEN
F. Torkan

Iranian Cardio Vascular Pulmonary rehabilitation society,
Cardiac Rehabilitation of Milad superficiality hospital, Tehran, Iran

Introduction/Background

Women and men have different anatomical and physiologic characteristics. Adult female is 6 inches shorter than her male counterpart. Men have stronger bones, muscles, and weigh more than women. Women's arms and legs are shorter than men's. Women have narrower shoulders and a smaller thoracic cage. Women have greater knee valgus and Q angle. Also female athletes have lower hemoglobin levels. While leisure sport rarely produces dramatic body changes, demanding physical activity, as may occur when participating in sports at a high competitive level, can produce alterations in some physiological parameters at very pathological levels. Some medical considerations should be addressed in female athletes. One of the most important issues is oligomenorrhea or amenorrhea in highly trained or low body weight athletes.

Material and Method

There are conflicting reports on the influence of menstrual status on the level of physical performance, and often amenorrhea is more common in female athletes with a history of menstrual disturbances preceding commencement of training activity, in those younger than 30, in those who run more than 40 miles per week, and in porous athletes.

Results

Exercise stimulates growth hormone production and enhances statural growth. Melatonin increases during exercise and is unresponsive to either dopaminergic or opioidergic blockade. Increased opioid production during exercise can stimulate prolactin release, which can stimulate adrenal release of androgens and interfere with the ovarian aromatization of androgen precursors to estrogens. Cortisol levels increase during exercise, particularly in amenorrhoeic athletes.

Conclusion

Best way for promoting health in women is considering scientific principle in exercise prescription.

THE ANALYSIS OF FORCE AND SURFACE ELECTROMYOGRAM OF AGONIST AND ANTAGONIST DURING ISOMETRIC ELBOW FLEXION AT DIFFERENT JOINT ANGLES

R. He¹, F. Jianzhong¹
¹Nanfang Hospital, Southern Medical University, Rehabilitation Medicine, Guangzhou, China

Introduction/Background

Kinematic and electrophysiological performance can effectively elaborate the characteristic of muscle contraction which can provide beneficial proof of rehabilitation program to treat motor dysfunction. In this study, we aimed to analyze the difference and regularity of force and surface electromyogram (sEMG) of agonist and antagonist during isometric elbow flexion at different joint angles.

Material and Method

Twenty-one young volunteers were recruited and then performed maximum voluntary isometric contraction (MVIC) of elbow flexion continuously until exhaustion at four different elbow flexion angles (i.e., 30°, 60°, 90° and 120°). Isokinetic dynamometer was used to assess the torque during MVIC and synchronous sEMG signal recorded from biceps brachii (BB) and triceps brachii (TB).

Results

The corresponding experimental results showed that PT at elbow flexion 60° was the highest among four angles. BB-RMS and BB-AEMG at flexion 30° and 60° were both significantly higher than those at flexion 90° and 120°, while no difference was found in TB-RMS among different angles. The MF and MPF of BB and TB increased with increasing in elbow flexion angle. It was found that both PT and Av-T correlated positively with BB-RMS and BB-AEMG and there is stronger correlation with smaller elbow flexion angle. Extensive analysis displayed that the torque under 0~70% MVIC at four elbow flexion angles had a good linear relationship with corresponding rectified EMG-amplitude but not rectilinear relationship.

Conclusion

It can be concluded that the joint angle can affect the force and sEMG signal and elbow flexion around 60° may produce the maximum force. Joint angle should be introduced to interpret the muscle force with the EMG-amplitude. Furthermore, an important conclusion is made in this study that muscle strength under 0~70% MVIC may be interpreted accurately by sEMG.

ISPR8-0451
CASE REPORT: CENTRAL SLEEP APNEA IN A PATIENT WITH PRESUMED CHRONIC TRAUMATIC ENCEPHALOPATHY
D. Krasna¹, E. Costanzo², A. Mendelson³
¹Schwab Rehabilitation Hospital, 1401 South California Avenue, Chicago, USA
²Jersey Shore University Medical Center, ICU Pulmonologist, Neptune, USA
³Jefferson University Hospital, Anesthesia, Philadelphia, USA

Introduction/Background

Chronic Traumatic Encephalopathy (CTE) is seen with repetitive head trauma, particularly in boxers and football players. Diagnosis can only definitively be made post mortem, though imaging, history and presentation can be used to make a presumptive diagnosis. We discuss a patient with history and clinical presentation consistent with CTE who required intubation on multiple occasions for hypercapnic respiratory failure. Despite a healthy body habitus and normal airway, the patient developed hypercapnia whenever he slept without bilevel positive airway pressure. The patient was noted to have Cheyne Stokes breathing pattern during sleep, consistent with Central Sleep Apnea (CSA). This appears to be a novel case of Central Sleep Apnea secondary to Chronic Traumatic Encephalopathy

Material and Method

Review of patient stay

Results

72 year old male with history notable for long career in football, culminating in an eight year NFL career as a wide receiver. According to family, he developed symptoms of memory loss starting at age 69 that progressively worsened. He required intubation three times in two months for hypercapnic respiratory failure. Physical Exam: Pulse Ox 100% on 40% FiO2 on ventilator. Lungs: CTA bilaterally. Pt was moving all extremities spontaneously. Initial ABG on ventilator showed pH 7.345, pCO2 of 66, pO2 of 171, O2 sat 98.9His initial neurologic examination after extubation revealed decreases in short-term memory and executive function but scored a 24/30 on his MMSE. He was stabilized and discharged with theophylline and trilogy ventilator.

Conclusion

Although there is an association of sleep disorders with TBI, even central sleep apnea, there have been no documented cases of CSA associated with CTE. We propose that patients with a history of hypercapnic respiratory failure and a history of repeated head trauma should be considered for workup of CTE. In addition the converse is of importance to physiatrists, that patients with CTE should be monitored for CSA.

THE EFFECTS OF KINESIO TAPING ON BALANCE REACTION IN HEALTHY YOUNG ADULTS AT DIFFERENT TIMELINE

Y. Tsai\textsuperscript{1}, W.L. Liu\textsuperscript{1}, T.W. Chen\textsuperscript{1}, P.Y. Yen\textsuperscript{1}, J. Chen\textsuperscript{1}
\textsuperscript{1}Kaohsiung Municipal Ta-Tung Hospital, Rehabilitation Dept, Kaohsiung City, Taiwan R.O.C.

Introduction/Background

Kinesio tape (KT) is used in sport injury prevention, rehabilitation and sports performance enhancement. KT does improve proprioception and decreasing pain. But KT will affect the balance or lower limb function, is still a controversial issue. At present, most studies are more focused on immediately effect on KT, while ignoring the correlation between taping time and its effects. Purpose of this study is to understand KT immediate, short-term and long-term effects on static and dynamic balance in healthy subjects.

Material and Method

17 healthy untrained young participants aged 18-30 years were allocated with KT on quadriceps with 25% tension to the dominant leg. All measurements would be done before and after taping 15 minutes, 1 day and 3 days respectively with Biodex Stability System for postural stability, fall risk and limits of stability (LOS). Repeated measurement ANOVA had been used to compare the balance measurements prior to application, 15 mins, 1 day and 3 days after.

Results

A significant increase of dynamic balance (fall risk and LOS) appeared, especially after the KT application 1 day and 3 days (P<0.05), however there were no significant differences between groups for three time periods (15 mins-post-tape, 1 day-post-tape, and 3 days-post-tape). In addition, there was no difference on static balance (postural stability) whenever tape was applied (P>0.05).

Conclusion

From this research, we demonstrated that the different taping time of KT affected differently, KT significantly improved dynamic standing balance after 1 day application in general. Further investigation can base on the varied effects of Kinesio tape, different intervention time will be suggested for specific purpose for injury prevention, rehabilitations and enhancement of sport performance.

PERSONAL EXERCISE TRAINING IN PATIENTS WITH GLIOMAS: PRELIMINARY RESULTS OF FEASIBILITY AND EFFECTIVENESS.

G. Moreau¹, N. Khalil¹, M. Blonski², M. Pousse³, B. Chenuel², L. Taillandier², J. Paysant¹

¹IRR, Centre de MPR de Lay-Saint-Christophe, Lay Saint Christophe, France
²CHRU Nancy, Neuro-Oncology, Nancy, France
³CHRU Nancy, Department of Pulmonary Function Testing and Exercise Physiology, Nancy, France

Introduction/Background

Gliomas are the most common primary brain tumors in adults. Physical activity is proposed as an associated care in multiple cancers with proven benefits but has not been often and specifically evaluated for gliomas. The main objective of our study was to assess the feasibility and the potential effectiveness of exercise training in patients with high and low grade gliomas.

Material and Method

28 patients (mean age 49 years, 16 high grades and 12 low grades, minimal Karnofsky Performance Status at 70%) were addressed by the neuro-oncology for fatigue complaint. They were first screened by a physiatrist and then included a program of individual exercise training. A six-minute-walking-test was realized before and after the training.

Results

On the 17 patients included, 14 finished the program (7 high grade and 7 low-grade gliomas). Only 2 patients were excluded for a clinical degradation and only 1 patient did not finish it for a reason linked to his tumor. Mean number of sessions was 8; no major sides effects were reported. After the program, a statistically significant increase of the 6-minute-test was found (p=0.0007).

Conclusion

In this population, this kind of program seems to be feasible and efficient. However our results cannot be extended to all gliomas patients due to the good general state of our population and the inner limits of the six-minute-walking-test. Further studies are needed to assess the possible benefits in larger sample.

INFLUENCE OF PULMONARY FUNCTION ON SPRINT ABILITY AND AGILITY IN AMATEUR FOOTBALL PLAYERS AGED BETWEEN 14-15 YEARS
H. Aksu¹, O. Bingol¹, M. Zeren², E. Safran², H.N. Gurses²
¹Bezmialem Vakif University, Faculty of Health Science - Department of Physiotherapy and Rehabilitation - Final-year student, Istanbul, Turkey
²Bezmialem Vakif University, Faculty of Health Science - Department of Physiotherapy and Rehabilitation, Istanbul, Turkey

Introduction/Background

Physical fitness in football consists of several factors including aerobic capacity, anaerobic power, strength, speed, flexibility, agility, balance and coordination. Importance of the pulmonary function for aerobic capacity is well documented but the relationship of pulmonary function with other components of physical fitness is not extensively investigated. Our aim was to investigate the influence of spirometric parameters on sprint ability and agility in amateur football players.

Material and Method

Forty football players aged between 14-15 years who play in an amateur club were included. Pulmonary function was assessed using a portable spirometer. Sprint ability was assessed using 30-m sprint test and agility using T-test. Tests were conducted on an open football field and photocells were used for precise measurement. Correlations of spirometric parameters with sprint and agility test results were analyzed. Also, subjects were grouped into either above or below average according to sprint and agility test performances, then the spirometric parameters were compared between groups.

Results

Average completion time was 4.39±0.22 seconds for sprint test and 10.59±0.41 seconds for agility test. None of the spirometric parameters correlated with sprint or agility test results (Table 1). There were no significant differences between below average and above average subjects in terms of spirometric parameters according to sprint (Table 2) or agility (Table 3) test performances.

Independent samples t-test

FEV1: forced expiratory volume in 1 second, FVC: forced vital capacity, PEF: peak expiratory flow

Cut-off data for the average performance in agility test is from “PAUOLE, K et al. (2000) Reliability and Validity of the T-Test as a Measure of Agility, Leg Power, and Leg Speed in College-Aged Men and Women. The Journal of Strength and Conditioning Research 14 (4), 443–450.”

Conclusion
Our results suggest that the pulmonary function of the subjects does not have an influence on the sprint ability or agility in amateur football players. It may be due to the fact that both sprint and agility tests are completed in a short time thus the respiratory system is not becoming a limiting factor for these tests. Nevertheless, the importance of the respiratory system could not be ignored in the performance of the players since it is one of the key determinants of aerobic capacity.

TRANSLATION AND VALIDATION IN CLASSICAL ARABIC LANGUAGE OF THE QUESTIONNAIRE OF FATIGUE FOR SPORT CHILD

S. Mahersi, S. Ltaief, M. Sguir, H. Azzabi, W. Kessomtn

1Regional hospital of Gabes, Physical Medicine and rehabilitation, Gabes, Tunisia
2University Hospital Taher Star Mahdia Tunisia, Physical Medecine and rehabilitation, Mahdia, Tunisia

Introduction/Background

Translate and validate linguistically in classical Arabic; the French version of the questionnaire of fatigue for sport child (QFES).

Material and Method

The Arabic translation of the questionnaire of fatigue was obtained by the method of "direct translation / backword translation".

We have included 28 children aged between 12 and 15 years old practicing an intensive sport or competition sport and training more than 12 hours per week. The questionnaire was self-administered and completed twice at two-week intervals.

We studied feasibility, acceptability, internal consistency using Cronbach’s alpha and test-retest repeatability by non-parametric Spearman correlation.

Results

Twenty-eight children were included. The average age was 14.07 years. The questionnaire was feasible and acceptable, no element was excluded. The Spearman correlation was 0.836. Internal consistency was rated good with Cronbach’s alpha 0.874.

Conclusion

The Arabic version of QFES was reproducible and the validity of the construction was satisfactory.

The study of its responsiveness to change with a larger number of patients will be subject to further work.

ASSESSMENT OF ARTERIAL OCCLUSION PRESSURE USING PULSE OXIMETRY: A VALIDATION STUDY

Z. Zeng, C. Centner, A. Gollhofer, D. König

University of Freiburg, Department of Sport and Sport Science, Freiburg, Germany
Chengdu Sport University, School of Sport Medicine and Health, Chengdu, China

Introduction/Background

Blood-flow-restriction (BFR) training is recently progressively applied in functional training settings. The optimal cuff pressure during BFR exercise, current literature recommends using percentages of each individual’s arterial occlusion pressure (AOP). Most frequently, blood flow is determined by Doppler ultrasound (DU) techniques. Despite its high accuracy, the practicability of this gold standard is limited and time-consuming. An alternative solution to assess blood volume changes and pulse is pulse oximetry (PO). It was hypothesized that measurement of AOP could simplify the determination of cuff pressure during BFR training. Therefore, the main purpose of this study was to evaluate the accuracy of the PO for measuring the AOP compared to the current gold standard DU.

Material and Method

Thirty-five subjects (27.7 ± 2.9 years) were enrolled in the study. Participants were positioned in a supine position and a 12-cm-wide cuff was applied in a counterbalanced order at the most proximal portion of the right upper and lower limb. The cuff pressure was then successively increased until the systolic pulse wave was no longer detected by DU and PO, respectively.

Results

The results show that the mean values of AOP were 145.7±19.1 mmHg and 144.0±26.4 mmHg for the upper limbs, 191.5±24.1 mmHg and 174.5±28.3 mmHg for the lower limbs tested by DU and PO respectively (Fig. 1). Significant differences (paired t-test) between the two methods
were revealed for the lower limbs \((p = .000)\) but not for the upper limbs \((p = .621)\).

**Conclusion**

Our results indicate that, compared with the gold standard DU, the PO method has statistically acceptable accuracy when measuring AOP in upper limbs. However, in lower extremities the PO significantly underestimates the actual AOP. This must be considered when implementing PO as a method for determining cuff pressure for BFR exercise.

Introduction/Background

This study clarified differences in players’ contributions to the team’s score in male wheelchair basketball at the 2016 Rio Paralympics by physical capacity classification, and examined the roles required in the team.

Material and Method

This study used stats (record of play contents) for players who played for more than 20 minutes from the official box scores of all 42 games at the 2016 Paralympics. Players were divided into three groups by physical capacity classification: low, middle, and high. The average stats for each group were compared and the covariance structure was analyzed to determine the role of each group during the game.

Results

Comparisons showed that the higher the class, the higher the value of many stats items. In the low group, important elements were field goal made, steal, and turnover. Steel leads to increased assist and successful shoot. In addition, players with many field goal attempts had a common point that there are many assistants. In the high group, important elements were field goal made, field goal attempts, assist, and turnover in the high group. In addition, players with many field goal attempts had a common point that there are many assistants.

Conclusion

Players in the high group have more plays related to the ball. Those in the low group should increase the numbers of field goal made and steals and reduce turnover. High group players are required to have scoring ability and reduce turnover.

ISPR8-0805
EFFECTS OF KINETIC CHAIN EXERCISE INTERVENTION ON PAIN AND MOTOR PERFORMANCE IN VOLLEYBALL PLAYERS WITH SCAPULAR DYSKINESIA:
PRELIMINARY RESULTS
C.C. Chang¹, Y.F. Shih¹
¹National Yang-Ming University, Department of Physical Therapy and Assistive Technology, Taipei, Taiwan R.O.C.

Introduction/Background

Shoulder is the 3rd-most commonly injured segment in volleyball players, with the majority resulting from chronic overuse. Scapular abnormal position and movement could lead to dyskinesia (SICK scapula), causing further shoulder girdle injuries. For treating scapular dyskinesia, conventional training focus on retraining of shoulder girdle, while some researchers consider that kinetic chain rehabilitation would be more beneficial. However, there was no study comparing different effects between these two interventions. Therefore, the aim of this study is to compare the effects of 4-week kinetic chain exercise intervention (KC) and conventional training (CT) on pain and motor performance in volleyball players with scapular dyskinesia.

Material and Method

40 volleyball players mainly from universities in Taipei would be enrolled in this study after PT’s evaluation. So far, ten subjects were enrolled and finished the pre-test, than randomly allocated into KC group (3M 2F, age: 22.17±1.32) and CT group (3M 2F, age: 21.50±1.05). All subjects would execute a 30-spikes task followed by warm-up and maximal voluntary isometric contraction (MVIC) test before and after intervention. Visual Analogue Scale (VAS) was used to measure self-reported pain. The electromagnetic wireless tracking system (LIBETY™) and the wireless surface electromyographic (sEMG) system (TELEmyo 2400T G2) were used to collect kinematics and muscle' activation data respectively. The proprioceptive feedback magnitude (PFM) was calculated for measuring scapular movement consistency in 30-spikes task. The data at timing of maximal shoulder flexion and ball contact during spikes was analyzed.

Results

The ten enrolled subjects was still undergoing the 4-week interventions. No significant between groups difference in baseline demographic data (p>0.35) and pre-test data, which including self-reported pain (p>0.25), kinematics (scapula and trunk movement) (p>0.35), and scapular muscle’s activation (serratus anterior, upper and lower trapezius) (p>0.22).

Conclusion

The study is still on-going, we anticipated all primary data would be collected and analyzed completely before June of this year.

Paralympic sports athletes are classified according to functional level and not diagnosis. Amputees can use mechanical prosthesis to compete, without changing their classification. A facilitator in sport participation for amputees is using optimal prosthetic components. Multiple studies have analyzed sprint in lower limb amputees and the impact of running prosthesis (RP). We found no articles for upper limb (UL) amputees and RP, but the role of UL in running has been described. We present the case report of an UL amputee athlete, that felt restrain when running with her regular body-powered prosthesis and share the process of creating and evaluating a new kind of RP, specially design for competition. To achieve this, we analyzed videos of pass years paralympics competitions in UL amputees and the role of UL during sprinting.

Material and Method

Study Type: Case Report. Population: 17 years old female athlete with congenital left transradial amputation. Variables: RP design description (materials, socket design, suspension system, terminal devise), timing of running test in 200 m (with no prosthesis, old prosthesis and RP), patient satisfaction with RP (Goal Attainment Scale (GAS)).

Results

RP design: Socket was made in carbon fiber, with aerodynamic shape to facilitate brace. Terminal devise was a rubber bumper, to lean on it without sliding, and suspension was with a silicone liner with Velcro straps. Timing in running test: 29.7 sec without prosthesis, 28.9 sec with old prosthesis, and 28.36 sec with RP. GAS: +2 (high satisfaction).

Conclusion

We share the design of an innovating RP for UL that had a positive contribution in a patient’s professional performance. She still uses her RP and has improved her competitive level.

DANCE THERAPY FOR CHILDREN WITH CEREBRAL VISUAL IMPAIRMENT: A SCOPING REVIEW TO ASSIST CLINICAL DECISION-MAKING
F. Poncet1,2, A. Rajadurai3, G. Sanchez1, D. Jean4, C. Proulx Goulet6,5, S. Fortin6, S. Bonnie2,7
1Université Concordia, Psychologie, Montréal, Canada
2Centre de recherche interdisciplinaire en réadaptation du Montréal métropolitain CRIR, Recherche, Montréal, Canada
3Centre de recherche interdisciplinaire en réadaptation du Montréal métropolitain CRIR, Recherche, Montréal, Canada
4CISSS Montérégie Centre – Institut Nazareth et Louis Braille, Réadaptation, Longueuil, Canada
5CIUSS du Centre Sud de l’Île de Montréal, Centre de Réadaptation Lucie Bruneau, Montréal, Canada
6Université du Québec, Danse, Montréal, Canada
7Université de Montréal, Réadaptation, Montréal, Canada

Introduction/Background

Dance Therapy (DT) seems to show promising effects on physical and cognitive function in children. The Institut Nazareth et Louis Braille, a Rehabilitation Center, is interested in exploring the effects of DT in children with Cerebral Visual Impairment (CVI) who may also have cognitive (e.g. executive dysfunction) or motor impairments. However, there are few studies on the effects of DT in children, and none for the population with CVI. Moreover, there is no consensus on the parameters of DT (e.g. duration and frequency of sessions). It is thus challenging to propose innovative, global therapeutic interventions to enable these children improve their activities and participation. DT is an innovative group intervention that could broaden the child’s motor experiences, help them explore the surrounding space, and interact with others.

With the goal of creating a DT intervention for children with CVI, this study aims to systematically map the current state of the literature describing different group physical activity interventions and their outcomes for children with CVI.

Material and Method

Our scoping review follows a 6-step framework (Levac, 2010; Arskey and O’Maley, 2005). The electronic search strategy, conducted and including 11 electronic databases such as MEDLINE, Embase, and CINAHL, resulted in 1535 references. Documents reporting any type of physical or leisure activities group for individuals with CVI or children with low vision are included. Data extraction, analysis, and synthesis are ongoing. An expert stakeholder group from the rehabilitation center will validate and enhance the results thereby constituting the consultation phase of the review.

Results
Preliminary results indicate a large variability of interventions that include different physical activities (judo, aerobic training), setting, duration and population.

**Conclusion**

This review will contribute to the creation of DT for children with CVI (guideline) and to help clinician to choose appropriate assessment tools.

HIP MOTOR CONTROL TRAINING DID NOT IMPROVE MUSCLE PERFORMANCE DURING JUMP LANDING IN YOUNG DANCERS WITH RECENT ANKLE-FOOT INJURY

Y.F. Shih1, C.T. Liu1
1National Yang-Ming University, Department of Physical Therapy and Assistive Technology, Taipei, Taiwan R.O.C.

Introduction/Background

Dance is a unique combination of athleticism and artistry which exposes dancers to extreme physical demands and risks of injuries. Previous studies showed that hip muscle training improved lower extremity neuromuscular control in patients with ankle instability. However, few studies investigated the effectiveness of hip control training in dancers with ankle-foot injury. Therefore, aim of this study was to determine whether hip control training could improve muscle performance in dancers with ankle-foot injury.

Material and Method

Thirty three young dancers with ankle-foot injury within 6 months were recruited. Participants were randomized to the hip motor control training group (3 males and 13 females, 19.24±3.03 years old, n=16) or the control group (4 males and 13 females, 19.45±1.41 years old, n=17) and received hip motor control training or regular training for 4 weeks. The outcome measurement included compensated turnout, muscle activation (gluteus maximus, gluteus medius, biceps femoris, femoris rectus, tibialis anterior, peroneal longus and soleus) during jump landing, and lower extremity muscle length and muscle strength. Two-way repeated measures ANOVA was used to examine the intervention effect. A statistical significance was set at P < 0.05

Results

After four weeks of training, the hip motor control training group did not show significant improvement in the compensated turnout angle or muscle activation during jump landing except the affected side rectus femoris (50.13±14.88 vs. 51.52±10.16, p=0.026) as compared to the control group. The 4-week hip training program however improved lower extremity muscle strength including both affected and non-affected side hip muscle strength and ankle dorsiflexion strength, and non-affected side knee flexion and ankle eversion and inversion strength.

Conclusion

Hip motor control training improved lower extremity muscle strength, but its effect on lower extremity muscle activation or turn-out angle requires further research to clarify.

ISPR8-1153
CORE BODY TEMPERATURE OF ABLE-BODIED INDIVIDUAL VERSUS AMPUTEE DURING WHEELCHAIR FIELD RUNNING: CASE REPORT
K. Fukuhara¹, D. Nakashima¹, Y. Mikami¹, H. Kimura², N. Adachi¹
¹Hiroshima University Hospital, Sports Medical Center, Hiroshima, Japan
²Hiroshima University Hospital, Department of Rehabilitation, Hiroshima, Japan

Introduction/Background

Heat dissipation in the thermoregulatory responses is important for sweating. However, it seems that an amputee has a decreased heat dissipation capacity due to decreased body surface area (BSA). Therefore, there is a possibility that amputees are more likely to experience an increase in core body temperature than able-bodied individuals. The lower limb amputees often execute field wheelchair sports; however, no report has yet measured their core body temperatures during wheelchair running.

Material and Method

An able-bodied individual (AB) and an above-the-knee amputee (AKA) performed wheelchair running on a field-track for 1 hour. Their core body temperatures were continuously measured during wheelchair running. In addition, running speeds, heart rates, and body weights before and after running were measured. The change in body weight was determined as the sweat loss. BSA was calculated using the Dubois equation. Thermal sensation was also recorded after running. The ambient temperature was recorded as the wet-bulb globe temperature (WBGT).

Results

WBGTs were 27.8° C and 27.5° C; changes in core body temperature were 1.11° C and 1.06° C; heart rates were 161 bpm and 127 bpm; running speeds were 8.6 km/h and 9.16 km/h; sweat losses were 0.95 kg and 0.75 kg; BSAs were 1.69 m² and 1.40 m²; and thermal sensations after running were hot and neutral in AB and AKA, respectively.

Conclusion

There was no significant difference in the core body temperatures of AB and AKA while wheelchair field running for 1 hour. Although AKA had a recognized decrease in BSA, his body temperature was within the range of core body temperature control due to sweating in an ambient temperature with WBGT at 27.5° C. AKA had a faster wheelchair running speed than AB; thus, convection might have assisted him with heat dissipation. Case studies are necessary for thermoregulatory responses of amputees in the future.

THE IMPACT OF THE LOCAL EXHAUSTION ON THE PROPRIOCEPTION OF THE SHOULDER IN YOUNG TUNISIAN VOLLEYBALL PLAYERS

I. Megdiche¹, K. Maaref², I. Ksibi², R. Maoui², H. Rahali²

¹Military Tunis Hospital. Tunis, Department of Physical and Rehabilitation Medicine, Sousse, Tunisia
²Military Tunis Hospital. Tunis, Department of Physical and Rehabilitation Medicine, Tunis, Tunisia

Introduction/Background

Proprioceptive afferents from the different structures of the particular complex of the volleyball players’ shoulder have an important role in the coordination and the control of the different technical gestures of this sport. The impact of local exhaustion on shoulder proprioception has been studied only for external and internal rotations and the results are controversial. The effect of local on the proprioception of the shoulder in all areas of mobility among young volleyball players is poorly known.

Objective: To study the impact of local on shoulder proprioception in all mobility sectors.

Material and Method

It was a prospective analytical study conducted on a population of eleven young Tunisian volleyball players in the Physiology and Functional Exploration Laboratory of the Faculty of Medicine of Sousse. The experimental equipment consists of a MONARK ergo meter bicycle and a digital camera. The measurement of the different joint angles was performed using the "GIMP2" software.

Results

Our results showed a significant effect of local on shoulder proprioception in active (p <0.03) and passive (p <0.003) repositioning mode for external rotation as well as for internal rotation, in two modes of active (p <0.01) and passive (p <0.003) repositioning.

We observed a significant difference (p <0.005) between active and passive repositioning in anterior elevation after local exhaustion, as well as posterior elevation in both active (p <0.009) and passive (p <0.003) repositioning modes.

Conclusion

Shoulder proprioception is impaired by local exhaustion, which is a major risk factor for injury.

Introduction/Background

Wheelchair racing is one of the disability the most recognized by the public. Obtaining the correct seating position is very important for an optimum power on the push rim.

Material and Method

The three keys for the best chair set-up are the horizontal position in relation with the rear axle, the seat and knee height.

Results

The position of the legs, the level of the impairement and the physical size determine two racing position: the conventional seating position and the kneeling position, the most popular among the top athletes. It exists two pushing techniques: the parabackhand and the T51 technique concerning the racer with a lack of triceps. The gloves used manufactured or made by the racer. The last generation of gloves, the solid gloves allow a third technique: the thumb catch technique. The injury prevention is in relation with a perfect chair set up, the best pushing technique and a good balance and flexibility between the different muscular of the shoulder.

Conclusion

The knowledge about biomechanics and technical improvements in wheelchairs have permitted a better injury prevention and significant racing progresses.
Keywords
wheelchair racing; injury prevention

Introduction/Background

In France, breast-cancer currently affects one woman in eight – 54,000 new cases were detected in 2015. Among them, some women with motor disabilities as almost 100,000 women aged under 65 have to use wheelchairs. Numerous scientific studies have highlighted the positive effects of well-adapted physical activity after breast-cancer surgery - it is shown to reduce fatigability, posture problems and the risk of recurrence, hence to foster a better quality of life. Several federations have adapted their sport to cancer patients; yet most of those adaptations take no account of the possible presence of pre-existing motor problems.

Material and Method

Solution RIPOSTE offers women with breast-cancer an adapted practice of fencing, devoid of hits, which improves shoulder mobility thanks to the reflexive gesture of high parry commonly made in sabre fencing, and also corrects posture anomalies thanks to the shoulder opening required by the en garde position. Besides, the elegance of the sport helps to restore a feminine self-image which has been severely impaired.

Results

All the fencing masters and instructors in charge of those special fencers have been specifically trained, and they are regularly re-trained. To further our action, a fencing instructor who is a member of the French National team of wheelchair athletes has just completed that course, and
she has started to run fencing sessions open to every single woman who has had breast cancer – debarring none.

**Conclusion**

With their oncologists’ backing, wheelchair fencing could also be proposed to women with lumbar or sacrum metastases, for whom any sport involving stamping is strictly contraindicated. Thus the French Federation of Disability Sports meets the French National Olympics and Sports Committee’s wish to develop a ‘sport for health’ policy.

**Keywords**

wheelchair fencing; breast-cancer; physical activity

*No conflict of interest*
Introduction/Background

Physical activity is often associated with increased bone mineral density and decreased osteoporosis. Low impact sports, have been described as having a neutral or negative effect on bone mass. However, the literature is not consensual in this practice. The objective is to identify the effects of high and low impact physical exercises on bone remodeling.

Material and Method

Research and selection of the most relevant bibliography, published in the electronic database Pubmed (from January 1990 to January 2018), using as keywords: "sport", "bone mass" and "osteoporosis."

Results

Were included 24 articles in this review. In all studies, bone mineral density was calculated by bone densitometry (whole-body, femoral neck and lumbar spine) in individuals between 18 and 30 years of age. The review demonstrates that high-impact exercises appear to be important for the prevention of osteoporosis by increasing bone mass. Studies also suggest that regular practitioners of low-impact exercise, particularly swimming, have bone mineral density similar to those who do not exercise, and values lower than those who practice high-impact sports.

Conclusion

These data suggest that physicians and other professionals accompanying swimming athletes should implement high-impact exercises before or after training in aquatic environments in order to improve swimmers bone mineral density. The effects described should not discourage the practice of the modality, which undoubtedly also provides positive body effects, but rather encourage a close look of the doctor who recommends regular practice of this modality, given the increased risk of osteoporosis development. Considering that the increase in latitude, with a consequent decrease in the sun exposure of the practitioners of out-door modalities, has reduced the differences found in bone mass among swimmers (in-door) and those with high impact modalities, it seems fundamental to do more studies in this area to evaluate possible bias and using new evaluation methods as biochemical markers of bone metabolism.

ISOLATED HOOK OF HAMATE FRACTURE IN PEOPLE WHO PLAY RACQUET SPORTS
B. Kwon¹, K. Nam¹
¹College of Medicine - Dongguk University, Departments of Physical Medicine & Rehabilitation, Goyang-si, Republic of Korea

Introduction/Background

To report characteristics of isolated hook of hamate fractures related to racquet sports and to identify factors affecting early diagnosis and recovery period.

Material and Method

A comprehensive literature search was conducted using MEDLINE, EMBASE, SCOPUS, Web Of Science, the Cochrane Central Register of Controlled Trials, ClinicalTrials.gov, International Clinical Trials Registry Platform, and the EU Clinical Trials Register. This article included case reports, literature reviews for patients with isolated hook of hamate fractures related to racquet sports from 1977 to 2016.

Results

A total of 21 case reports and literature reviews with 120 patients were satisfied with our criteria. Fifty-two patients (43%) had been injured playing golf, and 65 injuries (76.5%) were in the nondominant hand. The most common subjective symptom or physical examination finding were pain (38%) or tenderness (56%) over the ulno-palmar area. CT and/or MRI (magnetic resonance imaging) were most frequently used to confirmed diagnosis (41.6%). There was no significant difference in the time to diagnosis between the times before and after CT was widely used. There was a statistically significant correlation between time from injury to diagnosis or surgery and recovery period after surgery (correlation coefficient= 0.206). The coefficient of determination(r²) of time from injury to diagnosis or surgery was 0.042 for recovery period after surgery in the simple linear regression analysis.

Conclusion

Carefully hearing the patient’s history and symptoms and strong clinical suspicion of disease are important for optimal decision making and patient management in the hook of hamate fracture. Early diagnosis can prevent delayed complications and leads to an early return to sports activity and daily life.

Keywords

Introduction/Background

The Functional Movement Screen (FMS) has been utilized as a screening tool for detecting such as asymmetries and compensations on movement patterns. Previous study has reported that 14 points and under of the FMS composite score showed a higher risk of severe sports injury. To improve the FMS score is considered to be important for injury prevention. While the FMS has been considered to be a useful prediction tool for sports injury, it is still unknown whether active mobilization exercise (MEx) influences the FMS score. The aim of this study was to determine the effects of MEx on the FMS score.

Material and Method

Thirty-eight collegiate American football players participated in this study. The inclusion criteria were as follows; no orthopaedic injury history in latest 3 months, 2 points and under of the FMS mobility score (Shoulder Mobility Reaching; SMR and Active Straight Leg Raise; SLR) in baseline test. Written informed consent was taken from all players before the test. The FMS was measured at preseason as a baseline test and was retested after 12 weeks. Players performed MEx that focused on improving active mobility of shoulder, trunk and hip for 12 weeks (3 times per week). Wilcoxon signed-rank test was used to determine changes from baseline score.

Results

The median value (inter-quartile range) of the FMS composite score was 14 (13-14.25) at baseline, 15 (15-16) at 12 weeks, respectively. As the results of Wilcoxon signed rank test, composite score was significantly increased at 12 weeks.

Conclusion

12 weeks’ MEx focused on active mobility improved the FMS composite score. the SMR and SLR mainly require active mobility. This results means the significance of doing MEx based on the FMS, and the MEx may be useful as one of the injury prevention tools in sports field.

RELATIONS OF TOE GRIP STRENGTH AND PHYSICAL FITNESS TEST AT 10-14 YEAR OLD
T. Fukumoto
Kio University, Department of Physical Therapy- Faculty of Health Science, Nara, Japan

Introduction/Background

In our local government, physical therapists participate in the physical fitness test of the elementary and junior high schools and helps with subsequent data entry, the close inspection of data from enforcement.

The purpose of this study were to measure a toe grip to 10-14 years old, and to investigate the relations with each evaluation items of the physical fitness test.

Material and Method

We intended for five elementary schools and two junior high schools students (girls: 578, boys: 645) asked for intervention from the Board of Education to physical fitness test.

The measurement of the physical fitness test obeyed fate of Ministry of Education, Culture, Sports, Science and Technology.

The toe grip used toe muscular strength measuring instrument 2 (T.K.K.3364, Takei instrument industry Co., Ltd.).

We conducted this study with approval (H28-06) of the Ethical Review Board of the regional organization.

Results

When age rose, the toe grip significantly increased.

Only at 12 years old, the mean of girls exceeded the mean of boys (girls: 12.2±3.9kg, boys: 11.5±4.8kg). However, there was not the significant difference.

A finger grip (muscle strength) (r=0.66, p<0.01), standing broad jump (instantaneous force) (r=0.58, p<0.01), side step (agility) (r=0.65, p<0.01), and the relations with each item of the physical fitness test were a significant correlation to a toe grip.

Conclusion
It is very interesting that the muscular strength of girls is in the generation more than boys.

As for other results, a correlation was found in other according to report, a toe grip and muscular strength, a power, agility.

RELATIONS OF FOOT ALIGNMENT AND PHYSICAL FITNESS OF THE CHILDREN

K. Kano

Kio University, Graduate school of Health Science, Nara, Japan

Introduction/Background

It is reported that the physical fitness decreases when we have an abnormality in the alignment of the adult foot part, but the relations with the change of the foot part alignment of children are not reported.

The purpose of this study conducted the foot alignment investigation of children and decided to investigate the relations with the item of the physical fitness test.

Material and Method

We intended for the children (girls: 280, boys: 305) of five elementary schools asked for intervention from the Board of Education to the physical fitness test.

The measurement of the physical fitness test obeyed fate of Ministry of Education, Culture, Sports, Science and Technology.

The foot part alignment measured a navicular high, a valgus thumb angle, the flat feet with the footprint and the presence or absence of floating digit.

We conducted this study with approval of the Ethical Review Board of the regional organization (H28-06).

Results

By the measurement of the foot part alignment, there was flat feet 77(13.2%), and there was a floating digit 326 (55.7%). There was a thing with 15 degrees or more valgus angle of the thumb 94(16.0%).

The significant difference was not found in physical strength between a normal group with the group with the change in an above-mentioned foot part alignment.

Conclusion

Because there are a lot of children of an abnormal foot part alignment as we are reported so far, it is more likely to be with reason of a decrease and the locomotorium disorder of some kind of performances in future.
The person with the change had a report that there was the decrease of the motor function in a foot part alignment, but the significant change was not found in this subject age.

EXAMINATION OF THE EFFECT OF WHOLE BODY VIBRATION EXERCISES ON TRUNK ENDURANCE AND DYNAMIC BALANCE IN HEALTHY YOUNG PEOPLE: RANDOMIZED CONTROLLED STUDY

E. Gur Kabul¹, B. Basakci Calik¹, U. Bas Aslan¹
¹Pamukkale University, School of Physical Therapy and Rehabilitation, Denizli, Turkey

Introduction/Background

Whole body vibration exercises, defined as exercise applied to the body in contact with a vibrating platform, stimulate reflex muscle contractions and synchronize motor unit activation. This study was planned to investigate the effects of Whole Body Vibration Exercises on trunk endurance and dynamic balance in healthy young people.

Material and Method

The study included forty-six healthy subjects (mean age=22.93±1.04 years, 26 female, 20 male). Participants were randomly assigned to an exercise group (n=26) or a control group (n=20). Trunk endurance was evaluated using curl-up and Biering Sorensen tests, and dynamic balance was assessed using Y balance test. All assessments were performed at baseline and end of 3 weeks. Whole body vibration exercises lasted 3 weeks (3 sessions/week). No intervention was made to control group. Mann Whitney U tests were used to analyze the data.

Results

When the groups are compared; significance were obtained in right anterior (p=0.000), left anterior (p=0.000) and left posteromedial (p=0.048) directions of Y balance test in favour of exercise group, the difference in the results of other evaluations was not significant (p>0.05).

Conclusion

Whole body vibration exercises has had positive effects on dynamic balance in healthy young people. We recommend that the effect of long-term whole body vibration exercises on muscular endurance of the trunk is examined.

¹Hôpital Fernand Widal, Médecine physique de réadaptation, Paris, France
²Hôpital Lariboisière, Cardiologie, Paris, France
³Hôpital Lariboisière, Rhumatologie, Paris, France

Introduction/Background

Patients’ endurance capacities are decreased after stroke. Due to their motor impairment the feasibility of an exercise stress test is compromised. To date there are no guidelines regarding the cardiovascular evaluation before entering an endurance training program (ETP). We selected cardiologic parameters (cardiovascular history, blood pressure – BP, heart rate – HR, ECG) and aimed to evaluate their use before and during an ETP.

Material and Method

This is a preliminary prospective study. Patients performed an individualized ETP of 3 training sessions per week during 10 weeks on an arm or leg motor driven device, or walking treadmill. The predefined cardiovascular criteria were collected all along the session. The HR throughout the exercise had to be lower than defined by Karvonen’s formula [trainingHR=restingHR + 0.6(220-age-restingHR)] and systolic BP ≤190mmHg.

Based on these criteria, exercise’s duration and power were adjusted to obtain, in the first session, an exercise duration of 20 minutes with a perceived exertion ≤11/20 on the Borg scale. The duration and the power were gradually increased, with respect of a perceived exertion ≤12/20, to reach, at the fifth session an exercise duration of 30 minutes.

For next sessions, duration was 30 minutes and the power gradually increased and adjusted to maintain a perceived exertion ≤14/20.

Results

Twenty-eight patients (age 52.9±11.1, sex-ratio15/13, ischemic strokes 19 (68%)) underwent the first session of ETP (5 on an arm motor driven device, 12 on a leg-driven one and 14 on a treadmill.) Throughout the session, the perceived exertion was 12±2, only 2 patients reached the training HR and the blood pressure remained ≤180mmHg for all patients. None of the patients experienced adverse events. Based on this feasibility analysis, 8 patients are currently undergoing the entire ETP.
Conclusion

Simple cardiovascular parameters appear to be safe and sufficient to assess post-stroke patients for endurance training programs.

OVERTRAINING SYNDROME AMONG FOOTBALLERS

M. Sghir¹, K. Bessem¹, A. Haj Salah¹, W. Haj Ahmed¹, W. Lahmer¹, W. Kessomtini¹
¹Hopital Tahar Sfar Mahdia, service de Medecine physique, Mahdia, Tunisia

Introduction/Background

Primarily observed in athletes, the overtraining syndrome is characterized by metabolic changes, reduction in the athletic performance, and the response to the training in healthy individuals, incidence of bruises and viral and bacterial infections due to the fall in the immunological resistance, alterations in the mood, constant fatigue, etc. Although it has already been the subject of several studies, the syndrome of overtraining remains a complex and relatively unknown pathology.

One of the methods for early detection of overtraining syndrome using a questionnaire Assembly French Sports Medicine is (SFMS): a simple questionnaire, low-cost and accessible. The aim of this study is to detect early stage of overtraining with the (SFMS) questionnaire.

Material and Method

It is a transversal study which included thirty footballers (professional and amateur). We used the Assembly French Sports Medicine questionnaire (SFMS), It includes 54 items which the subjects have to answer by (yes) or (no) : 20 questions related to psychological symptoms, 17 questions related to physiological signs and 17 questions were related to fatigue. A score is then established by summing the answers by (yes) and a final score equal to or higher than 20 is the overtraining threshold.

Results

Thirty men were included in our study with a mean age of 24.65 years. The mean score obtained by all participants in this study was 11.84 with a minimum score of zero and a maximum score of 28. From 30 footballers five were given a score of 20 or more. The mean score of fatigue was 7.45, psychological score was 8.63 and physiological score was 2.18.

Conclusion

The overtraining syndrome is a condition of chronic fatigue, underperformance. psychological, endocrinological, physiological, and immunological factors all play a role in the failure to recover from exercise. Careful monitoring of athletes and their response to training will help to prevent overtraining syndrome.

13Teletón Atacama, Unidad de Ejercicio y Deporte Adaptado, Copiapo, Chile
14Teletón Puerto Montt, Unidad de Ejercicio y Deporte Adaptado, Puerto Montt, Chile

Introduction/Background

Teletón is a private non-profit institution whose mission is the integral rehabilitation of children and youth with neuromusculoskeletal diseases. Throughout Chile there are 14 Teletón Institutes, which rehabilitate more than 90% of the national population with motor disabilities in childhood and adolescence.

Material and Method

In each Teletón Institute, the Adapted Exercise and Sport Unit involves the physical education teacher (PET) within the rehabilitation team, who use sports tools with a playful nature to execute therapeutic programs that optimize some physical qualities with a functional objective defined by the Physiatrist.

During the execution of the therapeutic program, the PET objectifies if the patient is actively participating in the physical education class of his / her school. If a problem is detected, the teacher makes reports and visits to the school to promote school inclusion. If necessary, conduct training sessions for physical education teachers of the school community.

On the other hand, the PET carry out and coordinates community sports schools for people with motor disabilities. The economic resources of these sports schools are managed with public and private resources.
Results

Athletes with competitive potential are referred to the Paralympic Committee of Chile to continue the sport in a professional manner. The rest of the athletes are encouraged to continue practicing physical activity as a habit of healthy living.

Conclusion

This model of work has been implemented for four years, being a reference center for national and international training within South America for rehabilitation team who wish to use exercise and adapted sports as a tool for rehabilitation and social inclusion.

7IRMS2, Médecine du sport, Bois Guillaume, France
8Fédération Française Handisport / Centre Jacques Arnaud, Commission Médicale / Médecine Physique et de réadaptation, Paris, France

Introduction/Background

The benefits of physical activity on physical and mental wellness are recognised and Handisport is no exception. Physical activity is a key tool for the physical and social rehabilitation of disabled persons and has been increasingly used in recent years, as indicated in studies. Our objective was to review all published data on sports activities involving disabled persons and to summarize the requisite skills for physicians involved in Handisport.

Material and Method

First, we review the existing literature on medical management in Handisport. Second, we report the «Jeux de l’avenir» 2017 from an epidemiological perspective, and then give feedback and make proposals to improve medical management. Finally, based on our findings, we provide a summary of the medical skills and knowledge required for physicians involved in Handisport.

Results

We analysed 37 articles with the key words «sport medicine» and «disabled person»/«sports for persons with disabilities». These articles discussed medical check-ups, medical organisation for international events, «dangerous sports» and predominating injuries, psychological aspects, overtraining, illnesses induced by disability and overuse injuries, classification and doping issues. The «jeux de l’avenir» included 551 youths aged 8 to 21 years old in 14 sporting disciplines. Impairments were: cerebral palsy (45%), visual impairment (8%) and genetic
pathology (8%). The major sport activity was athletics (26%). There were 46 medical procedures, including 5 which required emergency room transfer.

**Conclusion**

Disabled athletes require multidisciplinary care and specific knowledge, close to physical and rehabilitation medicine. The aim is not to replace the specialist but to improve the athlete’s preparation with better knowledge of his/her impairment and better injury prevention. We propose a 12-point summary of the specific skills required in Handisport medicine. Our study may be a first database and a working tool to build the medical management of Handisport for tomorrow.

THE EFFECTS OF COMBINED STRENGTH AND ENDURANCE TRAINING COUPLED WITH WALNUT SUPPLEMENTATION ON COGNITIVE PERFORMANCE AND SLEEP PARAMETERS IN ELDERLY PEOPLE

A. Yahia¹, A. Kamoun², R. Fakhfekh², H. Eleuch²
¹Hôpital Habib Bourguiba-Médecine Physique- Sfax- Tunisia,
Unité de Recherche de l’Évaluation des Pathologies de l’Appareil Locomoteur UR12ES18- ine, sfax, Tunisia
²Hôpital Habib Bourguiba- Médecine Physique- Sfax- Tunisia,
Unité de Recherche de l’Évaluation des Pathologies de l’Appareil Locomoteur UR12ES18- ine, sfax, Tunisia

Introduction/Background

Aging is characterized by an alteration of cognitive function and accompanied by a sleep disorders. The present study aimed to investigate the effect of combined strength and endurance training coupled with walnut supplementation on cognitive performance and sleep parameters in elderly people.

Material and Method

Twenty elderly participants were divided into two groups in a randomized controlled trial: Training + walnuts diet (GTW, n = 10); Training + control diet (GT, n = 10). The experimental protocol consisted of two evaluation sessions (pre and post-training) and combined strength and endurance training (three sessions / week) for six weeks coupled with a walnuts supplementation (15 g per day). For each assessment session, cognitive test (Montreal Cognitive Assessment: Moca) and sleep quality tests (Spiegel's Sleep Questionnaire, Sleep Diary) were conducted.

Results

Age, body mass and height of the participants were 66.7 ± 2.8 years, 169.0 ± 3.8 cm, 73.7 ± 5.2 kg, respectively. In the present study, cognitive performance and sleep parameters were increased significantly for GTW compared to GT. For cognitive performance, the results of this study showed a significant increase in the Moca test score (F = 55.14, P <0.001). Concerning sleep parameters, statistical analysis showed a significant increase for sleep efficiency and Spiegel's Sleep Questionnaire (F= 16.36, P< 0.001, F=7.8, P= 0.01respectively).

Conclusion

In the present study, combined strength and endurance training coupled with walnut supplementation improves cognitive performance and sleep parameters. This improvement
could be explained by the beneficial effect of walnuts supplementation since walnuts contains significant amounts of ω3 fatty acids, vitamin E, and melatonin.

ISPR8-2074
EFFECTS OF SHORT AND LONG TERM PERIOD OF KINESIOTAPE APPLICATION IN BALANCE AND FUNCTIONAL STATUS OF CHRONIC ANKLE INSTABILITY
S.J. suhastika¹, F. Arisanti¹, T. Prabowo¹
¹Faculty of Medicine - Universitas Padjadjaran, Physical Medicine and Rehabilitation, Bandung, Indonesia

Introduction/Background

Ankle sprain can developed into chronic ankle instability which characterized by "giving way". Injury to the ligaments causes impaired of proprioception function due to joint mechanic alteration of the joints. This can cause disruption to the balance function. Application of kinesiotape aims to stimulate the cutaneous mechanoreceptor to provide information input to the brain. It is expected to improve the function of static balance, dynamic, and functional status of patients with chronic ankle instability. The purpose of this study is to determine the effect of kinesiotape application on static balance, dynamic balance, and functional status in the short and long term period.

Material and Method

The study was conducted on fifteen male futsal athletes who experienced chronic ankle instability. Short-term assessment was performed after 30 minutes of kinesiotape and long-term effects were performed after 2 weeks. Static balance measurements using Single Leg Stance Test (SLST), dynamic balance measurement with Normalized Star Excursion Balance Test (NSEBT), and functional status measurement using Foot and Ankle Ability Measure (FAAM).

Results

There was a significant increase ($p=0.001$) in the SLST between before and 30 minutes after kinesiotape application, as well as after 2 weeks. The SLST value for 2 weeks was not found to be increased compared to 30 minutes ($p=0.648$). NSEBT values increased significantly between before and after kinesiotape application for either 30 minutes or 2 weeks ($p<0.05$). A significant increase was also found in the NSEBT score between kinesiotape application for 30 minutes and 2 weeks ($p<0.05$). The value of FAAM was found to increase significantly between before and after kinesiotape ($p<0.05$).

Conclusion

Application of kinesiotape has both immediate and long-term effects on static balance, dynamic balance in patients with chronic ankle instability. Application of kinesiotape has effect on improving functional status in patients with chronic ankle instability.

NON-UNIFORM DEFORMATION IN ACHILLES TENDON IS NOT INFLUENCED BY A CHANGE IN KNEE ANGLE OR LEVEL OF FORCE PRODUCTION DURING ISOMETRIC CONTRACTIONS

S. Bogaerts\textsuperscript{1,2}, C. De Brito Carvalho\textsuperscript{3,4}, A. De Groef\textsuperscript{2,5}, P. Suetens\textsuperscript{3}, K. Peers\textsuperscript{2}

\textsuperscript{1}KU Leuven, Department of Development and Regeneration, Leuven, Belgium
\textsuperscript{2}University Hospitals Leuven, Physical Medicine and Rehabilitation, Leuven, Belgium
\textsuperscript{3}KU Leuven, Department of Electrical Engineering- ESAT/PSI, Leuven, Belgium
\textsuperscript{4}Institute for Systems and Computer Engineering- Technology and Science INESC TEC, Networked Intelligent Systems, Porto, Portugal
\textsuperscript{5}KU Leuven, Rehabilitation Sciences, Leuven, Belgium

Introduction/Background

Mechanical loading has become the golden standard in managing achilles tendinopathy. The goal of this study was to evaluate the impact of different levels of force production and knee angle on the non-uniform behaviour in the achilles tendon during an isometric contraction. It was hypothesized that a flexed knee position would lead to a more non-uniform behaviour, due to greater differential loading of soleus versus gastrocnemius in this position, but that this effect would be attenuated by higher levels of force production.

Material and Method

Nineteen healthy subjects participated in this study. A high-spatial and high-temporal resolution ultrasound system was used to acquire 2D + time ultrasound images during an isometric contraction at 25%, 50% and 75% MVC in the extended and flexed knee position. Local tendon tissue displacement and normalized displacement ratio of the different tendon layers were calculated.

Results

Contrary to the hypotheses, it was found that the non-uniform deformation, i.e. superficial-to-deep variation in displacement with highest displacement in the deep layer, is consistently present, irrespective of the level of force production and knee angle.

Conclusion

From clinical perspective, this might indicate the absence of a mechanical rationale for a change in knee angle during eccentric heel drops. Additionally, it was found that despite reaching high levels of force, the contribution of the achilles tendon might sometimes be relatively smaller, potentially due to compensatory actions. This is relevant for rehabilitation as the goal is to reach specific local tendon loading. Therefore, the tool used in this study might be ideally placed to
monitor local achilles tendon loading during rehabilitation and individually tailor exercises to reach that goal.

THE EFFECTS OF ACUTE SLING EXERCISE PROGRAM ON PAIN INDEX, PRESSURE INDEX, RANGE OF MOTION, GRIP STRENGTH OF EPICONDYLITIS PATIENTS
G.E. park1, G.B. Lim1, H.J. Hyun1, T.K. Han1
1Andong National University, Physical Education, Gyeongsangbuk-do- Andong, Republic of Korea

Introduction/Background

The purpose of this study was effects of acute sling exercise program on pain index (VAS), pressure index, range of motion (ROM), grip strength of epicondylitis patients

Material and Method

This study was acute sling exercise program examine changes in pain index (VAS; visual analog scale), pressure index (Upper trapezius muscle, Wrist flexor muscles, Wrist extensor muscles), range of motion (Wrist Flexion, Wrist Extension), grip strength compared analysis. Participants was randomized sling group and vibration sling group for 60 patient

Results

The result of this study is First, The pain index significant changes in both the experimental group(p<.001) and the control group(p<.001).Second, pressure index significant changes experimental group in Rt.URA(p<.001), Lt.URA(p<.001), Rt.WE(p<.001), Lt.WE(p<.001), Rt.WF(p<.01), Lt.WF(p<.001), and control group in Rt.URA(p<.01), Lt.URA(p<.01), Rt.WE(p<.001), Lt.WE(p<.001), Rt.WF(p<.05), Lt.WF(p<.001). Third, range of motion significant changes experimental group in Lt.flexion(p<.05), Lt.Extension(p<.01), and control group in Lt.Extension(p<.05).Fouth, grip strength is significant changes control group in Left strength(p<.05), Right strength(p<.01).

Conclusion

In conclusion, there were significant changes in the VAS, pressure pain, and ROM between the two groups, and control group saw a significant increase in grip strength, and further studies said that the two groups need to study each other continuously by extending the duration of their interventions.

ISPR8-2494
EVALUATION OF MUSCULAR IMPAIRMENT OF PLANTAR FLEXORS AND ANKLE DORSIFLEXORS IN AMATEUR AND PROFESSIONAL SOCCER PLAYERS BY ISOKINETIC DYNAMOMETRY
L. Manoel¹, M. Xixirry¹, T. Soeira¹, M. Riberto¹
¹University of São Paulo - USP,
Department of Biomechanics- Physical Medicine and Rehabilitation, Ribeirão Preto, Brazil

Introduction/Background

The ankle is the anatomical segment most prone to injury during soccer practice. Stability of the ankle joint is maintained by intrinsic controlling mechanisms such as muscle strength. The isokinetic dynamometry evaluates muscle performance dynamically, providing quantitative peak torque, work and power values, as well as relative values such as the agonist/antagonist ratio. The objective was to compare the performance of ankle muscle groups using the isokinetic evaluation in amateur and professional soccer players.

Material and Method

In this cross-sectional study, sample consisted of 107 athletes, age between 18-30 years old, being 36 amateurs and 81 professionals. Isokinetic evaluation of the dorsiflexors and plantar flexors muscles was performed with the isokinetic dynamometer Biodek System 4 Pro. Test consisted of five repetitions at 30°/s and fifteen repetitions at 120°/s, with 30 seconds period of rest between each test. Isokinetic parameters were qualitatively classified as symmetric and asymmetric and distributed according to the frequency of asymmetries. Comparison between the frequency of imbalances between legs according to the isokinetic parameters was performed by the chi-square test. Level of significance was 5%.

Results

No significant differences in isokinetic parameters found between the frequency of asymmetries for both professional and amateur groups regarding peak torque (plantar flexors 30°/s: p=0,28; 120°/s: p=0,05; dorsiflexors 30°/s: p=0,78; 120°/s: p=0,64), total work (plantar flexors 30°/s: p=0,83; dorsiflexors 30°/s: p=0,28; 120°/s: p=0,25), and average power (plantar flexors 30°/s: p=0,98; 120°/s: p=0,16; dorsiflexors 30°/s: p=0,37; 120°/s: p=0,37), in both speeds at 30°/s and 120°/s. Significant difference found in the frequency of asymmetries for the dorsiflexors / plantar flexors ratio (dominant 120°/s: p=0,00; non dominant 30°/s: p=0,03; 120°/s: p=0,02), with greater weakness of the ankle dorsiflexors muscles.

Conclusion
Both amateur and professional athletes presented high asymmetries of ankle strength, with no difference between groups. Dorsiflexors/ plantar flexors ratio asymmetries were higher in professional athletes.

Introduction/Background

To compare the effort perception on different physical activities, according to age.

Material and Method

29 young adults (from 20 to 33 years) and 27 elderly (from 65 to 83 years) volunteered. The effort perception was assessed by the Borg's scale (6-20) at the end of each activity. The metabolic equivalent of task (MET) was evaluated continuously by a gas analyzer (Metamax 3B). The participants realized successively: 3 minutes sitting at rest, 3 minutes computer-based word processing, 5 minutes biking (70 watts), 5 minutes walking (4.6km/h corresponding to a moderate intensity activity (≥3 METs)) and 5 minutes running (6.4km/h for young adults and 5.8km/h for elderly, corresponding to an intensive intensity activity (≥6 METs)).

Results

Table 1: Comparison of effort perception and oxygen consumption for each activity according to age

p= *<0.05; **<0.01; ***<0.001
Values are expressed in mean ± standard deviation

Conclusion
This study showed a difference of effort perception between young adults and elderly, for a same physical activity and a same intensity. Our results are not consistent with the literature (Groslambert and Mahon, 2006) that mentions that age does not influence the effort perception. Further works are necessary to show the age effect on the effort perception according activity type and intensity level.

VITALIZING PARTNERSHIP FOR ENHANCING ACTIVE AGING: THE JOINT EFFORT OF ARCHITECTURE AND NURSING IN YIN TUNG COMMUNITY, TAINAN
C.M. Chen¹, C.P. Lu², N.Y. Chen¹
¹National Cheng Kung University, Department of Nursing, tainan, Taiwan R.O.C.
²National Cheng Kung University, Research Center for Humanities and Social Sciences, tainan, Taiwan R.O.C.

Introduction/Background

An increasingly aging population has become an urgent and important global issue. Taiwan has no exception. Yin Tung Community, a deprived old neighborhood located in urban Tainan, Taiwan. During the urban renewal process, elderly has been suffering from social exclusion because of tourism business development and environmental interference of community public activities. Referenced the experience of Japan, this demonstration project is to evaluate the effect of scholarly collaboration between architecture and nursing to enhance the World Health Organization’s Active Ageing framework naming, health, participation and security, through setting up an Integrated Community Center (ICC) in Yin Tung community.

Material and Method

Through this single entry approach, community elderly needed continuous services from health promotion to palliative care through the integration of health care, housing facilities and living support services could be interdisciplinary provided. In our demonstration project, we formed an ‘active aging coalition’ and engaged community elderly in the first phase of our study. Through this interactive platform, some accomplishments such as renunciation unused community building and spaces, mobile kitchen, and elderly schools have been implemented in the community. As most of the community older residents revealing the need for health and social care, the second phase of this project aims to implement the ICC using Participatory Action Research approach.

Results

The main research foci for the following includes: a) to demonstrate the operation of ICC in Yin Tung, b) to identify and empower potential community health workers responsible for each neighborhood in the community, and c) to promote interdisciplinary collaboration and facilitate innovative community health programs.

Conclusion

Through this intersectoral action, this project demonstrates the effectiveness of the various proposed course of action on health, participation and security, it offers a platform for
consensus building that addresses the concerns of multiple sectors. Testing of the program is in process.

ANALYSIS OF SOCIAL DETERMINANTS IN CARDIOVASCULAR REHABILITATION: SOCIAL INEQUALITIES IN HEALTH?
M. Racodon¹, P. Masson², T. Peze³
¹Clinique Mitterie, Cardiac Rehabilitation, LILLE, France
²Université Lille 2, Staps, Lille, France
³Université Côte d'Opale, Staps, Dunkerque, France

Introduction/Background
Retraining and cardiac rehabilitation are looking to increase cardiorespiratory and functional capacity but also to master some risk factors like, smoking, high cholesterol and physical inactivity. It is therefore a suitable transition in changing health behaviors and engages the shift to healthier lifestyles. These behaviors are influenced by a multitude of social determinants that condition and shape patients and may lead to differences in care.

Material and Method
This study aims to analyze and understand the interactions between certain social factors and physical practice after cardiovascular rehabilitation in order to better understand the management and follow-up of patients.

Follow-up was conducted with 100 patients (23 women, 77 men) with a mean age of 59.8 years (± 10.4), who underwent a year ago of a rehabilitation program for cardiac rehabilitation. We determined the level of physical spending of these patients by a physical activity log and the International Physical Activity Questionnaire (IPAQ). We also determined the level of knowledge on physical activities by a pre-test/post-test style questionnaire.

Results
We observed that the level of physical activity depends to socioprofessional category and academic level of the patients, 73.7% of the patients with higher professions continue to be active, 89.5% of these patients follow the recommendations of physical practice. 70.6% of the patients with a higher academic level follow the recommendations and finally 66.7% of the patients with a culture of physical practice remain sufficiently active.

Conclusion

The pursuit of physical activities after cardiac rehabilitation is conditioned by the determinants of health. It becomes necessary to understand and learn about the social and cultural determinants of patients to improve our medical practices and reduce some social inequalities in health.

THE EFFECTIVENESS OF DANCE THERAPY AS AN ADJUNCT TO REHABILITATION OF PERSONS WITH A PHYSICAL DISABILITY
B. Swaine¹, F. Poncet², P. McKinley³, B. Lachance⁴, C. Proulx-Goulet⁵, É. Brousse⁶
¹Université de Montréal - CRIR, École de réadaptation, Montréal, Canada
²Concordia University - CRIR, Psychology, Montréal, Canada
³McGill University - CRIR, Rehabilitation, Montréal, Canada
⁴Université de Montréal, École de réadaptation, Montréal, Canada
⁵CIUSSS Centre-sud de l’île de Montréal, Érgothérapie, Montréal, Canada
⁶CRIR, Recherche, Montréal, Canada

Introduction/Background

Alternative treatment modalities have been gaining popularity in rehabilitation for the past decade. Among these modalities, Dance Therapy seems to be particularly interesting since it is an enjoyable physical activity that combines improvisation, music and social interaction. A 12-week dance therapy program (DTP) offered to rehabilitation out-patients aims to promote community participation and mobility. Its effectiveness has never been studied. The objective was thus to determine the effect of DTP on participants’ mobility and participation compared to that of persons only receiving rehabilitation.

Material and Method

A pre-post intervention repeated measures design with a comparison group was used (2 evaluations each pre and post intervention). Participants were receiving outpatient rehabilitation at the Lucie-Bruneau Rehabilitation Centre (Montréal, Québec). Outcomes measures included Timed up and go (TUG), Assessment of life habits (LIFE-H) relating to community mobility and community life, and number of leisure activities performed. Generalized Estimating Equations over repeated measures determined if groups evolved differently over time; paired t-tests assessed change among DTP participants in Flow state scale (FSS-2) scores pre-post intervention.

Results

Forty-three DTP and 50 control subjects participated (half were male, average age of 49.1±14.2 years). Subjects in both groups significantly (p<0.05) improved across pre and post intervention periods for the TUG and LIFE-H leisure and number of leisure activities. Interactions between group and time were not significant; groups did not evolve differently over time for any outcome
measure, nor were differences found between genders or between those with and without degenerative conditions. FSS scores significantly improved (p=0.008 to 0.01) for 5/9 dimensions of flow experience (e.g. clear goals, sense of control) indicating DTP participants were immersed in the program and enjoyed it.

Conclusion

Rehabilitation clients enjoy DTP however DTP appears to have limited added value beyond the provision of usual rehabilitation. Non-significant results are likely due to the choice of outcome measures.

Introduction/Background

Stroke has a negative effect on participation. The impairments and disability caused by a stroke raise the need for continuous management of the medical, emotional and functional consequences to achieve better quality of life. However, in rehabilitation settings the focus is mostly on the short-to-medium term recovery, and less on preparing the stroke survivors to manage the long-term disability, in order to improve their participation.

Self-Management (SM) approach is aimed at improving wellbeing and quality of life of people with chronic conditions. Over the past years SM programs have been implemented in diverse populations including stroke survivors, and were found effective in improving self-efficacy, health status and reducing health care utilization. Nevertheless, only a few interventions were aimed at improving participation. The 'Improving Participation after Stroke Self-Management Program (IPASS)', is one of the first SM group-based programs which aims to improve post-stroke participation, in addition to improving health-behaviors and symptom management. The program was found effective for stroke survivors in the United States.

The main aim of our research is to evaluate the feasibility and effectiveness of the IPASS, implemented for stroke survivors in the sub-acute phase, in a community setting in Israel.

Material and Method

Participants include adults aged 18 years and older, diagnosed with stroke, who were admitted to a day-rehabilitation center. The effectiveness of the SM intervention is compared to the regular 'one-on-one' treatment, which is the standard care given in this setting.

Results

Initial results from the first three IPASS groups show that the program is feasible. Outcomes of most participation measures show a clear trend for more improvement or less deterioration between T0 and T1 in the intervention group, compared to control.
Conclusion

The IPASS seems to have potential to prevent deterioration for a longer term post-stroke, compared to standard individual care.

A CASE STUDY EXPLORING THE SATISFACTION OF PSYCHOLOGICAL NEEDS FOR PHYSICAL ACTIVITY A FEMALE WHO COMPLETED A SMARTPHONE-DELIVERED PEER PHYSICAL ACTIVITY COUNSELLING (SPPAC) PROGRAM.

K. Best1, F. Routhier2, S. Sweet3
1Université Laval- CIRRIS, Rehabilitation, Quebec, Canada
2Université Laval, Rehabilitation, Québec, Canada
3McGill, Kinesiology, Montreal, Canada

Introduction/Background

A Smartphone-delivered Peer Physical Activity Counselling (SPPAC) program attempts to increase physical activity (PA) for manual wheelchair users. Given the importance of understanding real-life complexities, the purpose of this case study was to explore how the SPPAC may have satisfied one individual’s perceived autonomy, relatedness, and competence for PA.

Material and Method

One participant was followed through the SPPAC program (14, 30-minute sessions). This presentation reports findings from the Psychological Need Satisfaction in Exercise Scale (subscales for autonomy, relatedness, and competence) that were observed at baseline and three months follow-up. Findings from a post-study interview were also explored.

Results

At baseline, a 65-year old female ranked in the 45th, 10th and 25th percentile (compared to 303 females) for competence, autonomy and relatedness respectively. Three months after completing the SPPAC program, her percentile ranking improved to the 70th, 55th and 55th percentile for competence, autonomy and relatedness respectively. Preliminary deductive qualitative analysis revealed insights about the potential mechanisms of change. She expressed perceived competence: “Moving more made me feel good […] I realized that just moving my arms more made it [easier] to get out of my lazy-boy”. Perceived autonomy was reflected in statements about making choices: “It was me who decided what I was doing, and it was me who decided how to do it, and it was me who decided when I stopped […] I took control”. She conveyed feelings of relatedness with her peer trainer: “the feeling of being alone with your disease subsides when you can share stories with somebody who is facing a similar situation […] someone who’s not in a wheelchair, I have a hard time believing that he understands what we live on a daily basis”.

Conclusion
Preliminary findings provide some qualification of how the SPPAC program may influence an individual’s satisfaction of autonomy, relatedness, and competence for PA.

THE EFFECTS OF REGULARLY EXERCISE IN TERM OF SELF-EFFICACY, SELF-ESTEEM, FATIGUE AND BODY AWARENESS ON HEALTHY ADULTS

G. Tıkaç¹, A. Ünafl, A. Ahmed Hamood Al Sakka¹, F. Altuğ², E. Kavlak²

¹Pamukkale University, School of Physical Therapy and Rehabilitation, Denizli, Turkey
²Pamukkale University., School of Physical Therapy and Rehabilitation, Denizli, Turkey

Introduction/Background

This study was planned to examine the effect of regularly exercising on self-efficacy, self-esteem, chronic fatigue and body awareness on healthy adults.

Material and Method

In the study, 115 participants (47 F, 68 M) aged 20 to 40, who do regularly exercise at least two days a week for last 6 months (Group 1), and 115 sedentary individuals (69 F, 46 M; Group 2) were assessed. Demographics of participants and the type, duration, and frequency of the exercise were recorded. Participants were used General Self-Efficacy (GSE) for self-efficacy, Rosenberg Self-Esteem for self-esteem, Checklist Individual Strength (CIS) for the level of fatigue and Body Awareness Questionnaire.

Results

The mean age of Group 1 was 22.86 ± 3.07 years and Group 2 was 22.96 ± 3.20 years. It was found statistically significant differences in terms of self-efficacy, self-esteem, body awareness and fatigue between groups and the results of participants who were doing exercise regularly were much better than sedentary ones (p<0.001).

Conclusion

In our study shows positive effects of regularly exercising on personal and psychological parameters. Exercise is a preferred method to increase self-efficacy, self-esteem and body awareness and decrease chronic fatigue.

USING TELE-REHABILITATION TO PROVIDE METACOGNITIVE THERAPY FOLLOWING TRAUMATIC BRAIN INJURY: ONE WOMAN’S EXPERIENCE
D. SPERRY¹
¹McMaster University, Speech Language Pathology, Hamilton, Canada

Introduction/Background

Each year hospitals across North America are inundated with patient visits related to Traumatic Brain Injuries including concussion. In Canada, approximately 1.5 million people are living with a brain injury. The impact brain injury has on public health is considerable. A TBI can adversely affect a person’s ability to independently carry out many functional everyday activities. This population often requires a lifetime of ongoing support to help them navigate everyday life. However, for many this help is unavailable, very expensive, geographically unrealistic or not focused on the everyday support they require.

Tele-Rehabilitation is the delivery of rehabilitation services over the internet. Metacognitive therapy is well suited to this type of service delivery.

Material and Method

The subject of this case study is a 54 year old woman who sustained a brain injury in a motor vehicle collision and as a result had many neuro-cognitive impairments and a myriad of functional sequelae. Initially, she engaged in traditional community based rehabilitation, but still could not participate in many of her everyday life activities. She was introduced to a Meta-Cognitive program provided over the internet.

This case presentation will describe the Tele-Rehabilitation Program program and will demonstrate how the implementation of tele-rehabilitation contributed to the functional and meaningful changes seen in the one woman’s life.

Results

The subject participated in the Tele-Rehabilitation program with an eCoach three times weekly to implement compensatory and meta-cognitive strategies. She began to experience greater success in the participation of her life roles and experienced subsequent improved quality of life.

Conclusion

Tele-Rehabilitation is a cost effective way to deliver meta-cognitive therapy. Given the geographical realities of a country such as Canada, this service delivery model also makes it
possible to provide services to more people and helping to improve the quality of life for many people living with the effects of brain injury

Introduction/Background

Excess dietary salt intake consumption is a risk factor for high blood pressure, stroke and cardiovascular disease. Currently, dietary salt intake consumption in almost every country is too high. Excess salt intake is associated with high blood pressure, which is common and costly and accounts for significant burden of disease. The aim of this study was to assess the impact of population-level interventions for dietary salt intake reduction in Japan. And the second aim of this study was to assess the differential impact of those initiatives by social and economic indicators.

Material and Method

The subjects were 3904 people from 2007 to 2017 in Miyagi state of Japan. Daily salt intake measured dietary food records.

Results

The salt intake changed 12.5g (2007), 11.1g (2010), 10.4g (2012), and 10.3g (2017). Male of salt intake changed 14.7g (2007), 11.9g (2010), 11.5g (2012), and 11.4g (2017). Female of salt intake changed 13.0g (2007), 10.4g (2010), 9.5g (2012), and 9.5g (2017).

2013 year in December; since "Japanese traditional food culture of the Japanese people" has been registered in the UNESCO intangible cultural heritage, our will, with the cooperation of other relevant ministries and agencies of the Ministry of Agriculture. Registration application to the UNESCO intangible cultural heritage of Japanese culture in opportunity, in order to inherit the Japanese culture to the next generation, will continue to develop activities to share its value in the entire nation.

Conclusion

In order to protect reportedly healthy development of the Japanese culture, academic point of view to understand the significance of the tradition of food and ingredients will be supported. The Washoku Japan campaign of future initiatives should embed more effective means of evaluation to help salt reduction better the variation.

Introduction/Background

All over the World we are living a difficult moment about low resources in developing but also in so called developed countries, for this reasons the access to health systems is a lot difficult for many people and so we need to think about new activities nearer the needs of disable and old people who need for rehabilitation. We think that CBR may be a good way to bring rehabilitation to all people who need it.

Material and Method

We start in 1999 to teach CBR in Albania, Shkodra District, for volunteers of the Northern districts and we start to give rehabilitation in the mountais’ villages and in the towns of PuKe and Skhodra. After 5 years, through the job of italians NGOs and with the collaboration of University of Florence and Shkodra, started a regular course of Fisiotherapy in the University of Shkoder. In the years between 2004 and 2017 we did CBR course in Moldova, Montenegro, Etiopia, Guatemala, Giordania, Djbuti Ghana. In 2013 we start to teach CBR also in Italy in Forli and others districts and now people with disability in difficulty to frequent, for various reasons, regular rehabilitation activities in National Health service can do rehabilitation in the place in which CBR is active.

Results

The quality of life and the respect of human rights of disabled people, the integration in the communities. To do actions for something that can be really usefull for disable and poor people.

Conclusion

The gol will be to make rehabilitation available for all who need. We think CBR can be a good activity to listen and resolve integration requests of disable people.

Background and aims: Social participation in older adults is associated with several health components such as increased functional independence, but can be restricted by a visual impairment. The Personalized citizen assistance for social participation (APIC) involves stimulation with a non-professional attendant and has been shown to be feasible in people with acquired brain injuries and older people with disabilities. Recently adapted for visually impaired older adults and implemented in a rehabilitation centre, little is known about the effects of this APIC. Thus the aim of this project is to document the APIC experience adapted to visual impairment and implemented in a rehabilitation centre.

Methods: A qualitative clinical research design is used with 13 visually impaired aged adults. Trained community volunteers assist the participants weekly, over 6 to 9 months, under the supervision of the rehabilitation centre professionals. Standardized questionnaires, diaries and semi-structured interviews explore the effects of APIC.

Preliminary results: Aged from 70 to 92 years [median=76.0; semi-interquartile interval (Q)=3.5], participants suffer from moderate visual impairment through to blindness, acquired at ages 1 to 67 (median=3; Q=4). Following an accompaniment of less than 19 weeks (median=12, Q=5.5), a trust relationship was established between participants and volunteers, fostering the identification of significant social activities (e.g., walking with someone). The barriers to the APIC are related more to difficulties in socializing or disabilities other than visual impairment (e.g., gait disorder). However, support from professionals allowed volunteers to overcome most of these barriers and help participants to initiate social activities.

Conclusions: By providing gradual stimulation, the APIC should improve social integration of visually impaired older adults, and, ultimately, their functional independence. The support of community volunteers should enhance the ability of the health services to meet the needs of this population.

CROSS-CULTURAL ADAPTATION, RELIABILITY, INTERNAL CONSISTENCY AND VALIDATION OF A FRENCH VERSION OF READINESS FOR RETURN TO WORK SCALE (RRTWS)
M. Fédou¹, P. Vustinier², F. Luthi¹, B. Leger²
¹Clinique Romande de Readaptation, vocational rehabilitation, SION, Switzerland
²Clinique Romande de Readaptation, research, Sion, Switzerland

Introduction/Background

The Readiness for Return-to-work scale (RRTWs) is a Patient-reported Outcome Measure (PROM) developed to assess in a motivational perspective the individual stages during the process of return to work after injuries or illnesses. The aim of this study was to translate and to make a cross-cultural adaptation of this questionnaire into French (RRTWs-F) for patients who have not yet returned to work. Internal consistency, reliability, and criterion validity were also assessed.

Material and Method

International recommendations for the translation and cross-cultural validation of PROM were followed. Ninety subjects with chronic musculoskeletal pain (74 men, 16 women; mean age: 43±11) participating in a vocational rehabilitation program were included. Internal consistency was assessed with the Cronbach’s alpha, and reliability with the Intra Class Correlation (ICC) in 20 subjects who completed the questionnaire twice in a 7-day interval. Criterion validity was measured with Pearson correlation between the RRTWs and other constructs: the Brief Pain inventory, the Hospital Anxiety and Depression Scale, the Pain Catastrophizing Scale, and the Tampa scale for Kinesiophobia.

Results

According to the small number of items (from 3 to five items) for each dimensions, Cronbach’s alphas were satisfactory (0.62-0.88) in four dimensions with the exception of the Prepared for action-self evaluative stage (0.58). Reliability was also quite good (0.71-0.85) with the exception of the Contemplation scale (0.59). Small to moderate correlations (0.24-0.60) were found between the RRTWS and all the others constructs, with the exception of the Prepared to action-self evaluative stage only related with pain, depression, and kinesiophobia. No correlation was found with the Contemplation stage.

Conclusion
The RRTWs-F has good psychometric properties similar to those of the original questionnaire. This scale may be used to evaluate the patients’ motivation of return to work during vocational rehabilitation and may be helpful to tailor interventions for French-speaking patients.

HOW CAN WE ANTICIPATE FAILURE IN RESUMING VOCATIONAL TRAINING FOLLOWING BRAIN INJURY? A RETROSPECTIVE STUDY

R. Manoli, L. Chartaux-Danjou, H. Delecroix, W. Daveluy, F. Torre, C. Moroni

1University of Lille, PSITEC Lab - EA 4072, Villeneuve d'Ascq, France
2UEROS Lille, UGECAM Nord Pas de Calais Picardie, Lille, France
3University of Lille & INRIA Lille, GRAppA and Magnet CRIStAL- CNRS UMR 9189, Lille, France

Introduction/Background

Seventy-five percent of people with an acquired brain injury are of working age, most of them are young adults who want to return to work or need to resume a vocational training. However, a failure in returning to work / vocational training is associated with depression and isolation. Our aim was to identify objective measures to allow clinicians to anticipate failure in resuming vocational training following a brain injury.

Material and Method

Neuropsychological data from 343 patients with brain injury, who benefited from a vocational rehabilitation program (UEROS Lille, France) between 2002 and 2017, were retrospectively analyzed. After completing this program, 28 patients resumed a vocational training and we identified, through Machine Learning algorithms, the neuropsychological measures predicting vocational outcome.

Results

Success in resuming vocational training after brain injury was predicted by mnemonic scores (verbal forgetting and visual retrieval). The scores obtained on the Tower of London test predicted both success and failure.

Conclusion

Our study highlighted that neuropsychological measures underlying planning abilities could help clinicians to anticipate a failure in resuming vocational training in patients with brain injury. Planning and memory abilities would predict an effective vocational outcome. These initial results, that need to be confirmed with larger samples of patients with brain injury who resumed vocational training, may have a relevant implication for neuropsychological practice, allowing a better vocational guidance of these patients.

TOWARDS A BETTER PARTNERSHIP WITH EMPLOYERS AND OTHER STAKEHOLDERS DURING THE WORK REHABILITATION OF MILD TRAUMATIC BRAIN INJURY WORKERS

C. Sylvain¹, M.J. Durand¹, M.A. Paquette¹, P. Maillette¹

¹Université de Sherbrooke, CAPRIT- Centre de recherche Hôpital Charles-Le Moyne, Longueuil, Canada

Introduction/Background

Developing an effective partnership with employers and other stakeholders is now considered a key intervention for supporting the return to work (RTW) of workers following a long-term absence. However, how this applies to workers recovering from a mild traumatic brain injury (mTBI) remains unknown. The aim of this project was to describe strategies used by practitioners to develop this partnership during post-mTBI work rehabilitation and to explore how these strategies were perceived by workers.

Material and Method

Two viewpoints were documented: that of the practitioners (n=30) in a rehabilitation centre in Quebec (Canada), through four focus groups; and that of the workers (n=10), through semi-structured individual interviews. The data were transcribed verbatim and analyzed according to thematic analysis principles.

Results

The results indicate that seven different strategies are commonly used during work rehabilitation to develop a partnership with the various stakeholders (employer, insurer, attending physician and family). All are designed to bring these partners’ messages and interventions in line with those of the rehabilitation team. The mechanisms underlying these strategies are mainly discursive (e.g. validation, explanation, or persuasion). While the workers corroborate the strategies’ relevance, they consider some inadequate for attaining the goal, notably as regards the employer.

Conclusion

Though it appears desirable to use a range of strategies to ensure consistency among the different stakeholders’ messages and interventions during post-mTBI work rehabilitation, it alone does not guarantee success, particularly with the employer. It may also be necessary to use non-discursive mechanisms to achieve greater consistency.

⁵University of Applied Sciences and Arts Western Switzerland Valais, School of Health Sciences- HES-SO Valais-Wallis, Sion, Switzerland
⁶Lausanne University Hospital, Division of Physical Medicine and Rehabilitation, Lausanne, Switzerland

Introduction/Background

The Hand Function Sort (HFS) is a pictorial self-questionnaire with 62 items measuring task self-efficacy in working population. It is a valid and a reliable scale that focuses on upper limb physical function. [1] It is frequently used in order to assess the ability to resume work. [1, 2] Our goal was to develop a short version of the HFS with less than 30 items to improve its feasibility.

Material and Method

Inclusion criteria were as follows: patients aged between 18 and 65 years with chronic pain and various orthopaedic conditions of the upper limb in the aftermath of an accident, who were hospitalized for a vocational rehabilitation. Items were selected using various methods: interviews with patients, experts’ opinions, the Rasch analysis model, detection of the floor/ceiling effect, and measurement of unidimensionality (principal component analysis). In addition, the final version had to include the different levels of effort assessed by the original version.

Results

Six experts with over 10 years of clinical experience were consulted (2 physiatrists, 2 physiotherapists, and 2 occupational therapists), 34 patients were interviewed and the questionnaires of 629 patients were analyzed. Of the top-rated items, 25 were selected following a final round with the experts (items: 1,5-8,10-14,23-25,27,29,37,41,43,45,50-51,55,57,60-61). The internal consistency of the short version was satisfactory (Cronbach’s alpha = 0.959)
Conclusion

A short version of the HFS was developed. Further studies are needed to verify the reproducibility of the short version, its concurrent validity with the original version and its criterion validity with other clinical scales of the upper limb such as the Disabilities of the Arm, Shoulder and Hand (DASH score)

ASSESSING THE FEASIBILITY OF DELIVERING A COMBINED COGNITIVE AND VOCATIONAL INTERVENTION TO INDIVIDUALS WITH TRAUMATIC BRAIN INJURY IN THE SOUTH-EASTERN REGION OF NORWAY

E.I. Howe¹, K.P.S. Langlo¹, M. Løvstad², T. Hellstrøm¹, K. Sagstad³, H. Enehaug⁴, E.W. Twamley⁵, N. Andelic¹

³Norwegian Labour and Welfare Administration, Department of Vocational Rehabilitation, Oslo, Norway
⁴Oslo Metropolitan University, The Work Research Institute, Oslo, Norway
⁵University of California San Diego, Department of Psychiatry, San Diego, USA

Introduction/Background

Few studies have examined the effect of cross-sectorial collaboration on vocational outcomes, symptom burden, and quality of life following traumatic brain injury (TBI). In preparation for a larger scale randomized controlled trial (RCT), we assessed the feasibility of delivering a combined cognitive and vocational intervention to individuals with mild-to-moderate TBI in the South-Eastern region of Norway. The feasibility of the cognitive intervention is reported in this abstract.

Material and Method

Six patients received a manualized, group-based intervention targeting post-concussive and cognitive symptoms management (Compensatory Cognitive Training, CCT) in ten weekly sessions. In addition, all patients received individualized support at the work place (supported employment) for six months. Feasibility was assessed by exploring whether the CCT procedures were satisfactory in terms of recruitment and retention, satisfaction with the intervention, and treatment engagement (i.e. attendance, level of participation, ability to learn and apply strategies). The Therapist Checklist assessed level of participation and the CCT evaluation form assessed perceived helpfulness of the intervention.

Results

Gender distribution was 1:1, mean age was 40 years, and mean years of education was 16 years. All participants had a diagnosis of concussion, were enrolled on average 4 months post-injury, and were sick-listed at range 70-100%. Attendance across CCT sessions was 97%. Eight out of nine topics in the CCT-intervention received a rating above 3.5 on a 5-point scale (i.e., towards very helpful). The topics receiving the highest ratings were information about TBI, post-concussive symptoms and fatigue, memory, learning, and prospective memory. All participants
were rated as participating fully (3/6) or moderately (3/6), and most participants (5/6) attempted to apply skills to real-life situations.

**Conclusion**

The results indicate that the CCT procedures were feasible, and no major adjustments were made to the protocol. Recruitment of participants to the full-scale RCT began in July 2017.

³Reha Rheinfelden, Co-Leiter Physiotherapie.stationär, Rheinfelden, Switzerland
⁴Reha Rheinfelden, Physiotherapie - Ergonomie, Rheinfelden, Switzerland
⁵Reha Rheinfelden, Chefarzt/ Medizinischer Direktor, Rheinfelden, Switzerland

Introduction/Background

One of the main objectives of rehabilitation is the restoration of working capacity. In some cases, physical and mental performance cannot be achieved to the degree that was possible before the onset of illness or accident. Conventional medical examination alone often leads to a deficit-oriented assessment of work-related contents and limitations on work ability. Alternative employment opportunities are rarely recommended.

Material and Method

For this reason, a modular assessment tool was developed in cooperation with a regional Swiss disability insurance. The results of the reintegration assessment tool reflect not only medical but also performance as well as motivation-related aspects of individual vocational rehabilitation ability and lead to immediate occupational recommendations within the conclusions. Several modules are combined to achieve a case-related, task-oriented review with solutions for reintegration. The assessment of occupational reintegration capacity consists of 1. Clinical Examination, 2. Performance Tests and Questionnaires, 3. Roundtable with patient and insurer.

Results

Optionally, additional modules for psychiatric or specific medical questions can be integrated as needed. In addition to the examinations, validated assessments of general and disease-related function as well as quality of life and standardized physical tests including assessment of willpower, motivation and test consistency are used. The concluding round table discussion represents the novel key feature of this reintegration assessment tool. By explaining all the results to the patient in an understandable way, together, the remaining physical and mental resources can be worked out and further steps can be defined that take the individual situation into account. Consequences to the patient can be directly matched with the possibilities of the insurer.

Conclusion
The final assessment report, approximately 12 plus 12 pages, is largely standardized but highly individualized in terms of conclusions and recommendations, which makes it applicable by the insurer to further activities. More than 100 cases were completed - examples are given.

Introduction/Background

In Germany, work-related medical rehabilitation programs were developed for patients with musculoskeletal disorders to improve work participation outcomes. Randomized controlled trials have shown that return to work rates can be increased by about 20 points compared to common medical rehabilitation programs. Since 2014, the Federal German Pension Insurance has approved several work-related rehabilitation departments to implement these new rehabilitation programs. Our study was launched to assess the effects of work-related medical rehabilitation under real-life conditions.

Material and Method

Participants received either a common or a work-related medical rehabilitation program. Propensity score matching was used to identify controls that were comparable to work-related medical rehabilitation patients. Effects were assessed by patient-reported outcome measures 10 months after completing the rehabilitation program.

Results

We included 1282 patients (mean age: 52.4 years; 75.3% women). Work-related medical rehabilitation increased stable return to work (OR = 1.42; 95% CI: 1.02 to 1.96) and self-rated work ability (b = 0.38; 95% CI: 0.05 to 0.72) compared to common medical rehabilitation. Participants of work-related medical rehabilitation had also less depressive symptoms and fear of movement, and they reported better self-management skills. Subgroup analyses showed that the effect on stable return to work depended on the prior risk of not returning to work and the dose received as rated by the participants. Only persons with a high initial risk of not returning to work and a high dose received benefited from work-related medical rehabilitation. In this subgroup, i.e. high risk and high dose received, the absolute risk difference was about 20 points in favor of work-related medical rehabilitation.

Conclusion
Implementation of work-related medical rehabilitation in German rehabilitation centers affected work participation outcomes. Our effectiveness study showed that the results from randomized controlled trials can be also achieved under real-life conditions. However, effectiveness is moderated by the population reached and the dose received.

CROSS-CULTURAL TRANSLATION TO FRENCH AND PSYCHOMETRIC EVALUATION OF THE SELF-ADMINISTERED VERSION OF THE WORK REHABILITATION QUESTIONNAIRE (WORQ)

M. Finger¹, V. Roten-Wick², R. Escorpizo³

¹Swiss Paraplegic Research, Empowerment- Participation and social Integration Unit, Nottwil, Switzerland
²Clinique Romande de Réadaptation, Department of Research and Clinical Quality Control, Sion, Switzerland
³University of Vermont, Department of Rehabilitation and Movement Science, Burlington - VT, USA

Introduction/Background

The WOrk Rehabilitation Questionnaire (WORQ) is a generic instrument to examine work-related functioning, based on the ICF core set for vocational rehabilitation (VR). Comprehensive identification of functioning problems is crucial for developing specific return-to-work strategies. We cross-culturally adapted WORQ into French and evaluated its psychometrics.

Material and Method

We followed a dual-panel cross-cultural adaptation process to translate WORQ. A forward-translation into French was done by a bilingual panel including, two experts in questionnaire development, three bilingual experts, one VR-specialist and two of the developers. This first version of WORQ-French was then evaluated by two lay persons and three patients followed by a review by the panel. The resulting second version was pilot tested and cognitively tested. After a final evaluation, the panel finalized WORQ-French.

In connection with the cross-cultural adaptation, psychometrics were evaluated including internal consistency (Cronbach’s α), test-retest reliability (ICC₂,₁), and construct validity (Pearson correlation). The validity of the WORQ sumscore was analyzed based on Rasch analysis. Usability was evaluated in ten patients for comprehension, completeness and questionnaire length.

Results

Basic psychometrics were tested in a convenient sample of 89 patients in VR with various musculoskeletal conditions. Internal consistency (Cronbach’s α: 0.968) and test-retest reliability (ICC: 0.935) were high. WORQ correlated positively with HADS (r= 0.564 / 0.570) and self-rated general functioning (r=0.662). The WORQ sumscore was confirmed based on a Rasch analysis performed in a sample of 221 patients in VR with musculoskeletal conditions. Usability was rated as “good” to “very good.”
Conclusion

WORQ-French is a valid, reliable and easy to administer questionnaire with a valid sumscore to assess the concept of work-related functioning that can be used to identify functioning problems, plan interventions and measure and document change in the study population. Studies to evaluate its usability and psychometric characteristics in other populations and settings are ongoing.

MODEL FOR THE HUMAN AND OCCUPATIONAL DEVELOPMENT OF PERSONS WITH INTELLECTUAL DISABILITY. MIXED METHODS
V. Seijas¹, C. Quintero², D.A. Ramírez³, D. Pereira⁴, L.H. Lugo¹, M. Giraldo³, M.T. Rugeles³
¹Professor University of Antioquia- physician Clinica las Américas, Physical Medicine and Rehabilitation, Medellín, Colombia
²Professor University of Antioquia- Comité de rehabilitación de Antioquia, Physical Medicine and Rehabilitation, Medellín, Colombia
³Professor University of Antioquia, Physical Medicine and Rehabilitation, Medellín, Colombia
⁴Comité de Rehabilitación de Antioquia, Occupational therapy, Medellin, Colombia

Introduction/Background

The prevalence of intellectual disability (ID) in the world is 1 to 4%, in Latin America it is estimated to be four times higher. In Colombia it corresponds to 22.47% of all types of disability. Young people and adults with ID experience more inequality and social exclusion than the rest of the population. The objective of the project was to design and validate a model for the human and occupational development of people with intellectual disabilities with an ecological and interdisciplinary approach.

Material and Method

Quasi-experimental design that includes an experimental group and the application of pretest and post-test tests, with a deliberate control of the variables of interest, mixed methodological perspective with qualitative and quantitative data. Four stages, first the design, second the validation of the model and the third and fourth stages the construction of general recommendations for a higher education program and for the integral attention of the population in an ID situation, which help to reduce the barriers for family, social and occupational inclusion in Colombia.

Results

Until now, a 2-stage model has been designed, the first called "ESCALAR", pre-university with a duration of 6 months and the second one called "UIncluye", a university program with a duration of 1 year. A comprehensive evaluation model has been developed and the entry of 20 young people who met the inclusion criteria have been completed, they have completed the ESCALAR phase and the first semester of UIncluye. Outcomes: determinants of health, individual quality of life, quality of family life, anxiety, depression, practical, conceptual and social skills.

Conclusion
Inclusion in higher education of young people with ID requires a multidisciplinary team capable of constructing a model for the inclusion of people with intellectual disabilities in higher education adapted to the contextual characteristics of each country.

UPDATING THE EVIDENCE ON FUNCTIONAL CAPACITY EVALUATION METHODS: A SYSTEMATIC REVIEW
S. De Baets¹, N. Schalley¹, P. Calders², K. Vermeulen³, S. Vertriest³, L. Van Peteghem³, M. Coussens¹, F. Malfait⁴, G. Vanderstraeten³, G. Van Hove⁵, D. Van De Velde¹
¹Ghent University, Faculty of medicine and health care sciences - Department of rehabilitation sciences and physiotherapy - occupational therapy program, Ghent, Belgium
²Ghent University, Faculty of medicine and health care sciences - Department of rehabilitation sciences and physiotherapy, Ghent, Belgium
³Ghent University Hospital, Department of physical rehabilitation, Ghent, Belgium
⁴Ghent University Hospital, Centre for Medical Genetics, Ghent, Belgium
⁵Ghent University, Disability Studies, Ghent, Belgium

Introduction/Background

To synthesize the evidence on the psychometrics functional capacity evaluation (FCE) methods.

Material and Method

A systematic literature search in nine databases. The resulting articles were screened based on predefined in- and exclusion criteria. Two reviewers independently performed this screening. Included studies were appraised based on their methodological quality.

Results

The search resulted in 20 eligible studies about nine different FCE methods. The Baltimore Therapeutic Equipment work simulator showed a moderate predictive validity. The Ergo-Kit (EK) showed moderate variability and high inter- and intra-rater reliability. Low discriminative abilities and high convergent validity were found for the EK. Concurrent validity of the EK and the ERGOS Work Simulator was low to moderate. Moderate to high test–retest, inter- and intra-rater reliability was found in the Isenhagen Work-Systems (IWS) FCE. The predictive validity of the IWS was low. The physical work performance evaluation (PWPE) showed moderate test–retest reliability and moderate to high inter-rater reliability. Low internal and external responsiveness were found for the PWPE, predictive validity was high. The predictive validity of the short-form FCE was also high but need to be further examined on several psychometric properties. Low discriminative and convergent validity were found for the work disability functional assessment battery. The WorkHab showed moderate to high test–retest, inter- and intra-rater reliability.

Conclusion
Well-known FCE methods have been rigorously studied, but some of the research indicates weaknesses in their reliability and validity. Future research should address how these weaknesses can be overcome.

THE RELATIONSHIP BETWEEN EHLERS-DANLOS SYNDROME AND LABOR PARTICIPATION. AN INDUCTIVE THEMATIC ANALYSIS.

S. De Baets¹, P. Calders², L. Verhoost¹, M. Coussens¹, I. Dewandelet², F. Malfait³, G. Vanderstraeten⁴, G. Vanhove⁴, D. Van de Velde¹

¹Ghent University, 
Faculty of medicine and health care sciences - Department of rehabilitation sciences and physiotherapy - occupational therapy program, Ghent, Belgium

²Ghent University, 
Faculty of medicine and health care sciences - Department of rehabilitation sciences and physiotherapy, Ghent, Belgium

³Ghent University, Faculty of medicine and health care sciences, Ghent, Belgium

⁴Ghent University, disability studies, Ghent, Belgium

Introduction/Background

Ehlers-Danlos syndrome (EDS) is a heritable disorder influencing multiple aspects of daily life. As the disorder is still quite unknown, little knowledge about treatment and psychosocial effects has been collected yet. Participation in employment is an aspect influencing the Quality of Life of patients with EDS-HT. This study aims to find a deeper connection between EDS-HT and the difficulties in labor-participation through exploring lived experiences.

Material and Method

A inductive thematic analysis, using semi-structured interviews was used. Nine patients, selected by a purposive sampling strategy, were included. Interviews were audio-recorded and transcribed verbatim.

Results

The health complaints can, on the one hand, make labor-participation difficult, but on the other hand, the practice of a job can positively affect well-being. There are factors that can promote employment. The data analysis results in three main themes. (1) Elements assisting participation in employment, (2) limitations in labor-participation and (3) unemployment due to the EDS.

Conclusion

There are specific reasons either a person with EDS participates, or does not participate in labor. The reasons are individual and different for each and every person and may even vary in time.

RELIABILITY OF THE LATVIAN TRANSLATION OF THE ROTTERDAM TRANSITION PROFILE (RTP)
A. Vetra¹, Z. Rozkalne¹
¹Riga Stradins University, Rehabilitation department, Riga, Latvia

Introduction/Background

Transition process from childhood to adulthood is a crucial period for young adults with cerebral palsy. The Rotterdam Transition Profile (RTP) is a valid tool to gain more insight into the transition process (M Donkervoort et al. Dev Med Child Neurol 2008, 51: 53–62).

The aim of this study was to test the reliability of the Latvian translation of the RTP and to gain the first insight of the transition process of young adults with cerebral palsy.

Material and Method

The transition process of RTP included the following steps: forward translation, expert panel (10 physiotherapists and an English language specialist), back-translation, pre-testing and cognitive interviewing (young adults with cerebral palsy, aged 16-21y), and the admission of the final version. Reliability was tested in classes of inter-rater, test-retest and internal consistency reliability.

Results

Sixty-three participants (32 males, 31 females, Me 18, IQR=20-17) were included. The levels of Gross Motor Function Classification System (GMFCS) were: first- n=28, 44.4%, second- n=20, 31.7%, third- n=9, 14.3%, fourth- n=6, 9.5%, fifth- n=0, 0.0%. Reliability values of RTP were the following: good internal consistency- Cronbach’s Alpha 0.86, high test-retest reliability- rs 0.99 (p<0.01) and high inter-rater reliability- rs 0.91 (p<0.01). There was found a medium correlation between the level of GMFCS and the total score of RTP- rs -0.44 (p<0.01) and between the age of participants and the total score of RTP- rs 0.47 (p<0.01).

Conclusion

The Latvian version of RTP is a reliable tool to be used in assessment of transition process of young adults with cerebral palsy. It was found that the older and the more physically functional the person is, the more independent. Thus the correlation was only in a medium level. Validity testing should be advisable for stronger psychometric qualities of the Latvian version of RTP.

ISPR8-0427
A PRACTICAL EXPLORATION OF THE SERVICE MODE - COMBINATION OF REHABILITATION MEDICAL SERVICE AND EDUCATION FOR CHILDREN WITH SPECIAL NEEDS ON THE BASIS OF ICF

B. Liang¹, J. Li²

¹Suzhou Industrial Park Boai School & Boai Clinic, Rehabilitation Medical Service, Suzhou, China
²1st Affiliated Hospital of Nanjing Medical University, Dept. of Rehabilitation Medicine, Nanjing, China

Introduction/Background

To solve the social problem of children with special needs receiving either medical rehabilitation or just special education and explore the service mode of “rehabilitation medical service combined with education” provided in an integrated way in China.

Material and Method

To integrate the resources of rehabilitation medical service and education and establish a comprehensive intervention system suitable for the physical and mental development of children with special needs based upon ICF-CY and applying the theory of translational medicine, as well as build a multiple interactive service system of “rehabilitation medical service combined with education” and improve the services for the education and rehabilitation of children with special needs by means of experience summary and case study.

Results

The service system of “rehabilitation medical service combined with education” is an innovative setup of integrated courses in a multilayer and interactive way of rehabilitation medical service, education and life practice, realizing the functional rehabilitation course with activities and participation as its aim, laying a basis for them to be engaged in social life, and guaranteeing the equal access to rehabilitation medical service and education of children with special needs.

Conclusion

Exploring the pattern of rehabilitation medical service combined with education is of special significance in terms of mechanism innovation, which has facilitated the implementation of the government policy to purchase services and optimized the service function of the organization, thus playing an active role in helping underprivileged families, decreasing the abandonment of children with special needs, improving the employment of the people with disabilities and promoting the stability and harmony of society.

THE CHALLENGES FOR PSYCHOLOGICAL SUPPORT IN CHRONIC SPINAL CORD INJURY
E. Novak¹, T. Korobova¹, V. Daminov¹
¹National Medical Surgery Center named by N.I.Pirogov, Neurorehabilitation, Moscow, Russia

Introduction/Background

Spinal cord injury (SCI) is a tremendous psychophysical trauma. While most recourses and time has been spent to recover functional deficits, the importance of psychological support is often underestimated by patients. The aim of this study was to investigate the psychological status and make proposes for more effective psychological interventions.

Material and Method

The study was performed in the neurorehabilitation department and included 63 patients with chronic SCI (3-18 months) at different segments of the spinal cord. The following tools were used: psychological interview, Luscher color test, test “The non-existent animal”, Beck’s depression inventory (BDI) and Beck’s anxiety scale (BAS).

Results

All patients were psychologically closed and avoided sharing their feelings and 11 of them refused any contacts with a psychologist. At the beginning, most patients expressed affection and kindness which had been transformed to irritation and aggression during the conversation. The self-scored tests revealed the lowest possible scores: 0-4 via BAS and 0-6 via BDI. Oppositely, the projective tests demonstrated the high level of tension, anxiety and depression. Nine patients had unspoken suicidal ideations. The main issues were alterations in the body image with the rejection of objective facts. Patients were immersed on negative aspects of the life and ignoring or minimizing any positive changes.

Conclusion

The psychological support is an undisputed part of rehabilitation after SCI. It seems psychological interventions for emotional discharge and relaxation could be more accepted by patients even in the chronic phase. Rational psychotherapy ought to be also considered but it would take probably more time and resistance to reach any complacence.

ACCESS TO DENTAL CARE FOR PEOPLE WITH DISABILITIES IN BRITANNY

P. Gallien¹, A. Colin², B. Nicolas³, A. Durufle³, A. Brion⁴, S. Achille-Fauveau²

¹Pole MPR Saint Hélér, MPR, Rennes, France
²Health network BreizhPC, Handicap, Rennes, France
³Pole MPR Saint Hélér, Physical Medecine Rehabilitation, Rennes, France
⁴SDS bretagne, health network, Rennes, France

Introduction/Background

Oral health care is an important element in the care of people with disabilities. We conducted a survey among users of two french health networks: the BreizhPC network and the specific dental network to measure the impact of these on access to dental care.

Material and Method

A survey of dental care in terms of prevention and treatment was sent to 1500 users of the two networks.

Results

323 users answered the questionnaire, equally divided between the two networks, with a mean age of 38.8 +/- 16 years. 54.4% live in institutions, 45.6% at home most often with their parents. 86.8% are single. 91.4% of the population benefits from a dental follow-up, most often in town offices. An accompanying person is most often necessary for the care. Sedation was necessary for 14.9% of users and general anesthesia for 14.2%, in majority for behavioral handicap. The most common treatments are conservative and preventive care.

Users are very satisfied with their care, particularly with regard to pain. At the level of oral hygiene, brushing is performed at least once a day for 87.4% of users and remains the most frequent prevention treatment. Prevention messages are essentially delivered by the practitioner.

Conclusion

This study found a satisfactory access to dental care of the users. For comparison, the survey carried out by the UDAPEI on the same territory in 2015 on 185 establishments found a rate of 68.4% of dental follow-up in their population. This highlights the importance of health care networks in the access to care for people with disabilities.

ISPR8-1507
CASE ILLUSTRATION OF HOLISTIC FUNCTIONAL AND COGNITIVE REHABILITATION IN ECOLOGICAL SETTING FOR INDIVIDUALS WITH ACQUIRED BRAIN INJURY
G. Nguyen

Introduction/Background

Acquired Brain Injury often results in a range of impairments and leads a combination of physical disabilities, cognitive deficits, communication difficulties, and emotional and behavioural disturbances. Multi-disciplinary rehabilitation has been shown to be highly effective in improving the functional outcome, modifying and alleviating the problems associated with cognitive and behavioural issues. Supporting these individuals and providing therapy in naturalistic environment is highly conducive, enhancing their participation compliance and psychological motivation.

Material and Method

This case illustration asserts how a planned group excursion to a community venue creates an opportunity for participants to respond verbally and emotionally to the displayed visual installation, and provides interactions with the general public, with guidance from rehabilitation clinicians. In addition, with the terrain of the venue purposefully made to be uneven, the participants also exercised precautions with their mobility, as trained by their physical therapists.

Results

Participants responded very positively to the experience. Afterwards, individual participant was then assisted to recount his or her impression and appreciation, both verbally and facilitated with photos taken during the visit, with a rehabilitation clinician. Once having refined the details, the individual was then encouraged to again repeat the story with family and friends.

Conclusion

Through this excursion, the participants appeared to gain more confidence, and their motivation enhanced, having been given the exposure and chance to practise physical, cognitive, and communication skills in naturalistic setting. It also underlines the importance of designing an activity of rehabilitation treatment to have equally relevant and entertaining aspects, to be optimally successful, and fully embraced by participants.

Introduction/Background

With Japan’s population rapidly aging, the number of elderly households was estimated to be more than 12 million, which was approx. 23% of the entire households in 2015. In order to help elderly people to live longer independently in their own homes, we started the project to develop an assistive home environment called Robotic Smart Home (RSH), which integrates robotics and devices that support elderly’s mobility, operation, and information. Mobility support robots are aimed to assist walking and transfer movement, while an operation support robot communicates with users and help with small chores. Information support devices include tele-exercise and IoT connected home automation system.

In 2017, we established RSH’s experimental facility, and conducted an assessment by an elderly couple to preliminarily evaluate the effectiveness of RSH and its components.

Material and Method

An elderly couple aged over 70 years old were admitted for this assessment to stay at RSH and try assistive robots for walking and operation, tele-exercise and home automation system. After researchers gave the subjects thorough instruction to handle robots and devices, they were allowed to spend freely inside RSH on their own for several hours. After that, researchers conducted surveys to collect their feedbacks.

Results

The subjects showed mostly favorable responses to the robots and devices presented, and found the walking support robot highly effective to reduce the risk of falls, while they found more value in the communication function for the operation support robot rather than physical support it provides.

Conclusion

Although the result for this preliminary trial was favorable, further assessment is needed for evaluating the effectiveness of robotic devices and RSH itself. This trial also helped us
modifying the development goals for devices, and we will continue to collect feedbacks from subjects in order to improve RSH and its devices for sooner social implementation.

**Keywords**

Assistive technology; Elderly care; Home automation

**Conflict of interest**

*Disclosure statement:*

*We declare a potential conflict of interest as follows: Dr. Saitoh got collaborative research fund from Toyota Motor Corporation which developed the robot discussed in this study.*
The number of people in need of care is rapidly increasing in Japan. To continue life at their own home in elderly households requires not only social systems such as community comprehensive care but also home environment support. In order to provide a safe, secure and comfortable home life for everyone, we propose Robotic Smart Home (RSH) which is a living space designed for the use of activity assistive devices/robots and is used as a facility for conducting development and assessment of these assistive devices. This report is a literature review on smart home and activity assistive robots for the elderly, and introduction of our RSH project.

**Material and Method**

The database of PubMed was searched for articles published between inception and January 29, 2018 by using a term "smart home robot". This search and careful reading were conducted by one independent evaluator.

**Results**

Twenty-five papers were retrieved, among which 22 were concerned with living support for elderly and people with disabilities. Many of them were occupied by introduction of a concept, technical evaluation, and their reviews. Clinical trial was conducted in only five papers.

**Conclusion**

Several reports pointed out an insufficiency of clinical trials as a barrier to social implementation. This survey suggests that further objective reports in the living space such as demonstration tests and effectiveness verification on activity assistive devices for elderly will be needed. In order to challenge these problems, our university established RSH which is an empirical research facility introducing robots of mobility, operation and information support to the smart home system with IoT connection implemented. We would like to propose a new way of life in
an aging society by carrying out the demonstration experiment conducted at this facility, developing the robot to be used at home and validating its usefulness.

⁷University of Toronto, Toronto Rehab Institute, Toronto, Canada
⁸Centre intégré universitaire de santé et de services sociaux du Centre-Sud-de-l'Île-de-Montréal, Centre de recherche de l'Institut universitaire de gériatrie de Montréal, Montreal, Canada

Introduction/Background

Caregivers are critical to the health and support of older people with disabilities. Canada’s technology and aging network, AGE-WELL (agewell-nce.ca), is dedicated to the creation of technologies and services that benefit older adults and caregivers. One important research theme within this network focuses on the development of novel technological solutions to address caregivers’ needs. This presentation reports on AGEWELL activities that seek to gain insight as to how to support care providers of older adults with disabilities.

Material and Method

We use a mixed-methods approach to contribute to a growing body of knowledge about the complexity and diversity of caregivers’ lives and needs. Our inclusive research approach captures, and integrates a breadth of stakeholders and disciplines.

Results

An overview of 10 ongoing and completed projects with a balance between discovery and application-based research is provided. These range from surveying caregivers to better understand their needs and challenges, to developing online assistive technology rating and recommendation systems for caregivers. The projects consider different care recipient conditions (cognitive and physical limitations), caregiver needs (physical, social, emotional, and financial) and caregiver groups (paid work roles and family caregivers). The results also highlight shared tools and strategies used by the researchers all focusing on the needs of
caregivers, to optimize resources and increase visibility; these include a repository of scientific paper citations and promotional videos.

**Conclusion**

This presentation offers an example of collaborative research that seeks to develop a wide range of innovative technological solutions that can benefit both the lives of disabled older adults and their caregivers.

Visual impairment has been shown to influence the safe use of motor vehicles in fast traffic, such as motorcycles and cars. Motorized mobility scooters (MMS) are assistive products for personal mobility that can increase community participation and independent living of users. However, MMS are misused as vehicle in Taiwan. It is widely accepted that visually impaired people can't drive MMS safely. The objective of this study was to investigate driving performance of MMS of a visually impaired individual.

Material and Method

This was a case report study to preliminarily investigate driving ability of visually impaired people. Inclusion criteria of subject were Mini-Mental State Examination score ≥ 24, and Power Mobility Screening Tool score ≥ 13. A 4-wheeled MMS with a maximum speed of 10 km/h was used. The MMS driving performance was evaluated with Power Mobility Clinical Driving Assessment (PMCDA) which consisted of 13 indoor tasks and 10 outdoor tasks.

Results

The subject was a 51-year-old man who had blurred vision since 2013. He was diagnosed as polycythemia, hypertension and diabetes mellitus in 2014. He had 25 years car driving history, but no MMS driving experience. The last time he drove the car was 3 years ago. The binocular visual acuity was <0.1, the left and right visual fields were 85˚ and 90˚ outside central respectively. The passing rate of indoor tasks of PMCDA was 69.2%, and 90.0% of outdoor tasks.

Conclusion

The results of the driving assessment revealed that the visually impaired individual had partial ability to drive MMS. It's worth noting that this was the first time the subject drove MMS. This study indicated that visual functions were not the determining factors since there were no legal standards of vision for MMS driving. Visually impaired individuals might compensate poor vision from intact cognition and previous experience about car driving.

Background and aims: Clothing is important in everyday life. The act of dressing, among other clothing-related activities, can be challenging for persons living with a physical disability (PWD). As such, clothing can have an altering effect on their participation (everyday activities and fulfillment of social roles). Clothing design and wearable technologies are growing industries, however, their potential impact on participation of PWD is understudied. The aim of this scoping review is to map the state of the literature of the role of clothing on participation of PWD. Methods: A scoping review of literature (peer-reviewed and grey) published since 1990 is being conducted using Levac's updated six-step approach (2010). Six databases (MEDLINE, Embase, Cinahl, Eric, PsycInfo, Sociological Abstracts) have been searched, resulting in 2100 references. Three authors have reviewed references in iterative stages (abstract and full-text analyses) and inter-rater agreements were monitored to ensure an excellent kappa statistic (>0.75). Accepted articles (n=164) were retained for data extraction using the International Classification of Functioning, Disability and Health as a guiding framework. Grey literature will be added and experts (n=12) from different relevant fields (e.g., rehabilitation, technology, fashion) are validating the extracted data and synthesis. Results: Findings are being synthesized quantitatively and qualitatively for a complete picture of the existing literature. Preliminary results indicate a variety in study populations, types of apparel (e.g. shoes, coats, undergarments), and certain facilitators and barriers that exist when considering adapted clothing. This review will contribute towards recommendations for future innovations (e.g.
clothing design) and practice (e.g. information clinicians give to patients or their caregivers). Ultimately, supporting the development of an inclusive society. **Conclusions:** This scoping review protocol outlines a rigorous method integrating a multidisciplinary consultation team at many intervals, to best synthesize the literature related to the role of clothing on participation of PWD.

PHYSICAL MEDICINE AND REHABILITATION: INSIGHTS FROM 10TH GRADE STUDENTS OF A FRENCH SCHOOL IN BRAZIL

C.A.R.P. Abicalaf¹, C.P. Abicalaf², P.H. Toletti², L. Chatelet², L.R. Layet², L.U.D.C. Pinto², C. Le Franc², M. Imamura³, M.H. Miyazaki¹, L.R. Battistella³

¹Instituto de Medicina Fisica e Reabilitacao, Hospital das Clinicas HCFMUSP- Faculdade de Medicina- Universidade de Sao Paulo- Sao Paulo- SP- BR., Sao Paulo, Brazil
²Lycée Pasteur de Sao Paulo, Unité Vergueiro, Sao Paulo, Brazil
³Discipline of Physiatry, Faculdade de Medicina FMUSP- Universidade de Sao Paulo- Sao Paulo- SP- BR., Sao Paulo, Brazil

Introduction/Background

This study started with a five-student group of tenth grade (“Classe de Seconde” in the French system) which wanted to justify their choice to belong to the Science Class in High School. We applied for an internship in the Lucy Montoro Rehabilitation Center (HC-FMUSP). As the Institution accepted us, within our original objective, we established as a goal to correlate the technological advances in this area and its performance in the treatment.

Material and Method

We had the privilege to observe not only physical therapy and conditioning, gait training and movement of the limbs (robotics), but also to visit the Brazilian Paralympic Center and found the same patients met previously during their training in the various sport activities. Furthermore, we joined several therapeutic workshops with the patients: for instance, music, weaving and drama classes. In addition to observing the patients’ daily routine, we also analyzed clinical and diagnostic radiological tests. Moreover, engaging in the Physiatry League was an enriching experience since it gave us the will to know more and to focus our studies on this field. What we realized was striking: medical methods and treatments cannot reach their full potential without activities that motivate the patient and allow his social inclusion.

Results

On providing the opportunity to develop new interests and skills and to exchange experiences, the Institution has a highly satisfactory medical outcome.

Conclusion
Last but not least, this internship changed our lives as we realized that the motor improvement of the patients depends on their emotional well-being and social inclusion. We are extremely interested in the field of physical and rehabilitation medicine. We all learned that those patients had no deficiencies, but limitations, as we all have; and they can still perform flabbergasting tasks.

EXPERIENCE IN DISASTER RELIEF REHABILITATION ASSISTANCE IN THE AFTERMATH OF THE KUMAMOTO EARTHQUAKE

J. Fukuda¹, J. Hasada¹, M. Kawamura¹, M. Hldeki², Y. Mikami³, H. Kimura³
¹Amano Rehabilitation Hospital, rehabilitation, Hatsukaichi, Japan

Introduction/Background

Introduction: On March 11, 2011, The Great East Japan Earthquake struck. At the time of this unprecedented disaster, 10 groups involved in Rehabilitation started activities for evacuees. Thereafter, new groups joined, 15 groups involved in rehabilitation formed the Japan Rehabilitation Assistance Team (JRAT). On April 14, 2016 the Kumamoto Earthquake struck. This is a report on the assistance the Hiroshima JRAT provided as Unit 3 after the Kumamoto Earthquake with a focus on livelihood time of evacuees.

Material and Method

Report Description: Unit 3 (five people comprising one doctor, two physical therapists, one occupational therapist, and one speech-language-hearing therapist) carried out activities for four days in the Kashima Town civic gymnasium in Kumamoto Prefecture about one month after the earthquake (subacute rehabilitation phase). Kashima had 524 evacuees with 404 living in the gymnasium. Assistance focused on instruction about the prevention of disuse syndrome and preparation for living in temporary housing or at home, and activities such as weeding using regional characteristics and cleaning living spaces were incorporated into the lives of evacuees at the shelter.

Results

Results: About 30% of evacuees actively participated in cleaning living spaces, while only eight participated in weeding. Later teams continued carrying out these activities.

Conclusion

Discussion and Conclusion: The groups in the JRAT maintain communication at regular intervals and, after a large-scale disaster occurs, carry out activities to help citizens overcome the disaster and rebuild their independent lives and to reconstruct the area. When assistance was provided in the subacute rehabilitation phase, evacuees needed to prepare to move back home or into temporary housing. However, evacuees tended to become passive due to relief supplies and intervention by various volunteers. The ultimate goal of reconstruction is to rebuild the lives of evacuees so that they can live independently in their region. Our assistance gave them the chance to take the initiative.

SYSTEMATIC REVIEW OF PEER-BASED REHABILITATION INTERVENTIONS FOR IMPROVING MOBILITY AND PARTICIPATION AMONG ADULTS WITH MOBILITY IMPAIRMENTS
M. Beaudoin\textsuperscript{1,2}, K.L. Best\textsuperscript{1,2}, F. Routhier\textsuperscript{1,2}
\textsuperscript{1}Université Laval, Département de réadaptation, Québec, Canada
\textsuperscript{2}Centre intégré universitaire de santé et de services sociaux de la Capitale-Nationale, Centre interdisciplinaire de recherche en réadaptation et intégration sociale, Québec, Canada

Introduction/Background

Mobility is a key factor of participation. Many existing interventions aim to improve mobility and participation, some of which involve peers. The involvement of peers in the delivery of interventions is proliferating in healthcare. However, evidence surrounding involvement of peers for enhancing mobility and participation outcomes in rehabilitation is unclear. This study aims to identify existing peer-based rehabilitation interventions and summarize their effects on mobility and participation among individuals with mobility impairments.

Material and Method

A systematic review was conducted in CINALH, EMBASE, MEDLINE, PsycINFO. Guided by definitions in the International Classification of Functioning, Disability and Health (ICF), articles that applied a peer support model and at least one endpoint assessing mobility or participation were included. Study quality was assessed using the Physical Therapy Evidence Database (for RCTs) or the Quality Assessment Tool for Pre-Post Studies With No Control Group. Effects of the interventions on mobility and participation were documented and summarized.

Results

Thirteen studies were identified: six were peer-led (three RCTs, three pre-posts) and seven professional-led (five RCTs, two pre-posts). Two peer-led studies evaluated mobility and six evaluated participation. Six professional-led studies evaluated mobility and seven evaluated participation. Pre-post studies’ quality varied from poor to good and RCTs quality was either fair or high. Fewer studies have been conducted with a peer-led model and there were proportionally more peer-led RCTs presenting positive effects (3/3) than professional-led (2/5).

Conclusion

Peer-led interventions are of interest for improving mobility and participation among adults with mobility impairments because of the effectiveness they have demonstrated with different populations. The small number of studies, their current results as well as the lack of causal evidence of pre-post designs highlight the need for further research before going forward with any implementation in the clinical rehabilitation practice.

Introduction/Background

Evidence showed that pulsed electromagnetic fields (PEMFs) can ameliorate bone deterioration in streptozotocin (STZ)-induced diabetic rats. However, the underlying mechanism of its favorable effects has not yet been fully studied. This study aimed to investigate the effects of PEMFs on Wnt/β-catenin signaling in STZ rats.

Material and Method

Thirty 3-month-old Sprague Dawley rats were randomly divided to the following three groups: control group (injection of saline vehicle), DM group (injection of STZ), and PEMFs group (injection of STZ + PEMFs exposure). After 12-week PEMFs intervention, serum bone formation markers, bone mineral density (BMD), bone architecture, bone strength, and gene expression of Wnt/β-catenin signaling were investigated.

Results

Serum BALP in DM group was statistically lower than that in control group. While serum BALP statistically increased compared to DM group. The femur BMD in DM group was significantly lower than that in control group. The femur BMD in the PEMFs group was significantly higher than that in DM group. Histopathological examination showed markedly diminished trabecular area and trabecular number, and apparent expanded marrow cavity in DM group compared to control group. However, these changes of DM rats were partially reversed after 12-week PEMFs exposure. Maximum load and energy to failure in DM group was significantly lower than that in control group. However, maximum load and energy to failure in PEMFs-treated DM rats significantly increased compared to DM group. The mRNA expressions of β-catenin and Runx2 in DM group significantly decreased, and DKK1 significantly increased compared to control group. However, the mRNA expressions of LRP5, β-catenin and Runx2 were significantly increased, and DKK1 significantly decreased in PEMFs group compared to DM group.
Conclusion

Pulsed electromagnetic fields can ameliorate bone deterioration through regulating Wnt/β-catenin signaling in streptozotocin-induced diabetic rats.

Introduction/Background

We previously reported the development of a new acquired neurogenic HO (NHO) mouse model, combining spinal cord transection (SCI) and chemical muscle injury. Pathological mechanisms responsible for ectopic osteogenesis after central neurological damage are still to be elucidated. In this study, we first hypothesized that peripheral nervous system (PNS) might convey pathological signals from injured spinal cord to muscles. Secondly, we sought to determine whether SCI could lead to intramuscular modifications of BMP2 signalling pathways.

Material and Method

Twenty one C57Bl6 mice were included in this protocol. Bilateral cardiotoxin (CTX) injection in hamstring muscles was associated with a two-stage surgical procedure, combining thoracic SCI with unilateral peripheral denervation. Volumes of HO (Bone Volume, BV) were measured 28 days after surgery using micro-computed tomography imaging techniques and histological analyses were made to confirm intramuscular osteogenesis. Volume comparisons were conducted between right and left hind limb of each animal, using a Wilcoxon signed rank test. Quantitative polymerase chain reaction (qPCR) was performed to explore intra muscular expression of BMP2, Alk3 and Id1.

Results

Nineteen mice survive the complete SCI and peripheral denervation procedure. When CTX injections were done right after surgery (n=7), bilateral HO were detected in all animals after 28 days. Micro-CT measurements showed significantly increased BV in denervated paws (1, 47 mm3 +/- 0, 5) compared to contralateral sides (0, 56 mm3 +/-0, 4), p=0.03. When peripheral
denervation and CTX injections were performed after sham SCI surgery (n=6), bilateral HO were present in three mice at day 28. qPCR analyses showed no changes in intra muscular BMP2 expression after SCI as compared to control mice.

Conclusion

Peripheral denervation can be reliably added to spinal cord transection in NHO mouse model. This new experimental design confirms that neuro inflammatory mechanisms induced by central or peripheral nervous system injury plays a key role in triggering ectopic osteogenesis.

³Graduate Institute of Sports Science, National Taiwan Sport University, Taoyuan City, Taiwan R.O.C.

Introduction/Background

The current treatment options for muscle injury remain suboptimal and often result in delayed/incomplete recovery of damaged muscle. In this study, the effects of dextrose prolotherapy on inflammation and regeneration in skeletal muscle after contusion injury were investigated.

Material and Method

Mice were grouped into five groups, including groups of normal control (NC), post injury without any treatment (mass-drop injury, MDI), post-injury with 10% dextrose (MDI+10% dextrose), post-injury with 20% dextrose (MDI+ 20% Dextrose), and post-injury with 30% dextrose (MDI+ 30% Dextrose). The gastrocnemius muscles of mice were subjected to MDI and muscle samples were collected after 7 days post-injury.

Results

These results showed serum CK, BUN, CREA, and LDH of MDI-alone group were significantly higher than those in the normal control group (p<0.05). However, the levels of serum CK, BUN, CREA, and LDH were significantly decreased in different concentrations of dextrose. In addition, dextrose could suppress the macrophages response (F4/80 protein decreased) and promote the muscle satellite cell regeneration (desmin protein increased).

Conclusion

In conclusion, dextrose prolotherapy can effectively help the repair of muscle, thereby it may be one of the methods in clinical treatment of muscle injury.

Introduction/Background

Cells communicate with extracellular matrix (ECM) through the some essential components of mechano-biological factors. Integrin and Fibronectin are known as a connecting organizer between ECM and the cells. Moreover, these are also known as a sensor of mechanical cues. In this study, we focus the function of this sensor of mechanical cue to elucidate the mechanism of anterior cruciate ligaments.

Material and Method

All experiment used 10-week-old male Wistar rats after more than 2 weeks of acclimatization. Initially, 4 rats had their ACL transected, which were divided into 2 groups: ACL transection (ACL-T) groups and ACL transection and controlled abnormal tibial translation (CATT) groups. These rats were then used for a microarray analysis. Next, 40 rats were distributed across the 4 groups based on two factors for comparing controlled abnormal tibial translation and treadmill exercise (sedentary and exercise): ACL-transsection sedentary or exercise groups (ACLT-Sed or ACLT-Ex), or the controlled abnormal tibia translation sedentary or exercise groups (CATT-Sed or CATT-Ex). Contralateral knees (intact ACL [IN]) of ACLT-Sed rats were used as controls. These rats were used in RT-qPCR.

Results

The relative expression of ACL remnants had no remarkable changes between groups. However, the relative mRNA expression of infra-patellar fat pad in the both CATT groups had an increasing trend compared to the both non-exercise group.
**Conclusion**

Integrin and Fibronectin have a key role in ACL spontaneous healing as a sensor of mechanical cues. These protein works at the infra-patellar fad pad, not at ACL remnants. These results suggest that infra-patellar fad pad works mechanosensor in knee joint, and in detail, these function may support by the Integrin and Fibronectin.

NEURAL CORRELATES OF COGNITIVE AND EMOTIONAL MALADAPTATIVE BEHAVIOUR IN CHRONIC LOW BACK PAIN: A SYSTEMATIC REVIEW

A. Homs1, A. Dupeyron1

1CHU de Nîmes, Service de Médecine Physique et de Réadaptation, Nîmes, France

Introduction/Background

Non-specific chronic low back pain (ns-cLBP) is a leading cause of disability and loss of quality of life worldwide. Clinical and theoretical models explaining pain chronicization (such as the fear-avoidance model) emphasize the key role of maladaptive cognitive and emotional factors in the development of chronic pain. Modern neuroimaging techniques have demonstrated that pain chronicization leads to functional and structural brain changes, in various areas and networks. These changes seem to be specific to a given clinical condition. Our purpose was to study the association between maladaptive cognitive and emotional behavioural changes and structural or functional brain modifications in patients with ns-CLBP.

Material and Method

We performed a systematic scoping review of the literature, according to the PRISMA guidelines. Pubmed, Web of Science, OpenGrey and Cochrane databases were searched for original research reports. Methodological quality of included studies was assessed by two independent individuals. Risk of bias in included studies was investigated using a modified ROBINS tool.

Results

Sixteen studies met the inclusion criteria. We found significant modifications within emotional limbic network (including cingulate cortex, hippocampus and amygdala), and inconclusive evidence regarding other areas implied in attention to pain and pain perception.

Conclusion

More similar study designs and better defined groups may help to an increased understanding of these brain modifications, potentially leading to a better treatment of cLBP patients.

ISPR8-2283
PREDICTION OF THE PATHOLOGICAL FRACTURE RISK DURING STANCE AND FALL-LOADING CONFIGURATIONS FOR METASTASES IN THE PROXIMAL FEMUR, USING A COMPUTED TOMOGRAPHY-BASED FINITE ELEMENT METHOD.
Y. Shinoda¹, R. Sawada¹, S. Fujiwara¹, H. Inokuchi¹, Y. Karasawa¹, N. Haga¹
¹The University of Tokyo Hospital, Rehabilitation Medicine, Tokyo, Japan

Introduction/Background

It is important to assess the fracture risk associated with metastasis in the proximal femur. The study aimed to assess the effect of tumor location on the risk of pathological fracture of the proximal femur and investigate the fracture risk not only in the stance-loading configuration (SC), but also in the fall-loading configuration (FC) using a computed tomography (CT)-based finite element (FE) method based on a simulated metastatic model.

Material and Method

The axial CT scans of the proximal femora of healthy men (n=4; age range, 42-48 years) and post-menopausal women (n=4; age range, 69-78 years) were obtained with a calibration phantom, from which the three-dimensional FE models were constructed. A single 15-mm-diameter spherical void simulating a tumor was created at various locations from the neck to subtrochanter level. Nonlinear FE analyses were performed.

Results

The mean predicted fracture loads without spherical voids in the SC were 7700 N in men and 4370 N in women. With the void at the medial femoral neck and in the region anteromedial to lesser trochanter, the mean predicted load significantly reduced to 51.3% and 59.4% in men and 34.1% and 64.5% in women, respectively. The mean predicted fracture loads without a spherical void in the FC were 2500 N in men and 1862 N in women. With the void at the medial and posterior femoral neck, the predicted fracture load was significantly reduced to 65.7% and 79.7% in men and 48.3% and 65.4% in women, respectively.

Conclusion

These results showed that the risk of pathologic fracture was quite high in both the SC and FC when the lytic lesion existed along the principal compressive trabecular trajectory or posterior neck. Prophylactic intervention should be considered for metastases at these locations.

MECHANICAL ENVIRONMENT IN EDEMATOUS TISSUE PROMOTES MYOFIBROBLAST ACTIVATION

P.L. Kuo

1National Taiwan University, Department of Electrical Engineering, Taipei, Taiwan R.O.C.

Introduction/Background

Myofibroblast activation is essential to numerous physiological and pathological states, including wound healing, chronic inflammation, tissue and organ fibrosis, and tumor progression. Increased interstitial hydrostatic pressure (IHP) is a mechanical hallmark in edematous tissues resulting from damage or inflammation. We hypothesized that the increased IHP condition has a role in myofibroblast activation.

Material and Method

3T3 fibroblasts embedded in collagen matrix were cultured in a custom-made bioreactor that allows for culturing the matrix in various IHP conditions and dynamic measurement of the matrix elasticity using shear-wave elasticity imaging. Western blotting and immunostaining were applied to analyze the expression of myofibroblast specific proteins.

Results

We found that an increase of the IHP to 20 cmH₂O significantly increased expression of alpha smooth muscle actin, the molecular signature of myofibroblast, as well as the transforming growth factor beta-1, in the cultured cells. The activated myofibroblasts were highly contractile and stiffened the cell-populated matrix roughly two times than that in zero IHP condition.

Conclusion

Our results indicate that increased IHP promotes the transformation of fibroblasts into myofibroblasts and the stiffening the cell-populated matrix. These findings support our hypothesis that the mechanical characteristic associated with an edematous tissue promotes wound healing and tissue stiffening.

THE EFFECT OF PHYSICAL EXERCISE ON NEUROGENESIS FACTOR PRODUCTION IN GLIAL CELLS

J.E. Moreno Collazos¹, E. Segura Ort²
¹Universidad Manuela Beltrán - Colombia, Cundinamarca, BOGOTA, Colombia
²Universidad Cardenal Herrera - Valencia, Valencia, Valencia, Spain

Introduction/Background

The effects of physical exercise on cerebral function have been reported in various research studies, thereby leading to better understanding of the brain’s cellular mechanisms related to adaptations concerning physical exercise and the different cell responses which become compromised regarding chronic mechanisms. Relearning patterns of movement may thus be an alternative clinical approach affecting cognition and brain plasticity. Recent evidence has shown that neurogenesis can become increased by exercise; nevertheless, moderation mechanisms and the times involved in this process are not at all clear.

Material and Method

This review thus provides an update for understanding physical exercise-induced neurogenesis, covering mediating mechanisms and maturation. Results

The astrocytes, microglia and oligodendrocytes have dynamic situations which can substantially affect neuron function and activities; thus the astrocytes, more than being a simple support for nervous tissue structure, develop a very important function during the homeostasis of various ions in the CNS [50,51]; it is worth highlighting K⁺ capture from extracellular fluid [52, 53, 54]. The oligodendrocytes’ main function is to produce myelin bands in the CNS [55]; these bands’ structure was demonstrated almost simultaneously by Peters [56] and Maturana [57]. Nevertheless, since these first studies, research has focused on this area, especially work by Ochalski et al., who demonstrated the relationship between astrocytes and other types of stem cells in the grey substance from the neurohistochemical point of view in a rat model [58].

Conclusion

Research involving animal models and humans has provided an approach to the possible mechanisms which could be the basis for physical activity’s effects on cognition [43]. The main hypothesis is that exercise directly affects the brain’s structures and functions. Increased aerobic capacity increases cerebral blood flow (CBF), thereby improving the brain’s oxygen and glucose use, as well as increasing insulin, stimulating neurogenesis and increasing synaptic interconnections [44].

HISTOLIGICAL AND FUNCTIONAL RECOVERY IN PREVIOUSLY CHRONIC DENERVATED MUSCLES AFTER AUTOLOGOUS STEM CELLS INTRAMUSCULAR IMPLANT IN SCI PATIENTS

M.T. Moviglia Brandolino1, D. Couto1, S. Picone1, G. Albanese1, G. Moviglia1

1 Universidad Maimónides, Centro de Investigacion en Ingenieria de Tejidos y Terapia Celular, Buenos Aires, Argentina

Introduction/Background

In between January 2013 and January 2015, three chronic and complete SCI patients (thoracic level, flaccid paralysis) received 2 neural progenitor cells spinal cord implant and underwent intensive rehabilitation. During the evolution they showed recovery of electrical activity in muscles bellow the lesion level. Despite they continued the rehabilitation, muscular sings of severe atrophy persisted. In February 2016 and each 2 month they received intramuscular implant of muscular progenitor and neural progenitor cells looking forward to improve muscular trophism conditions in the muscles that had recovered the electrical activity.

Material and Method

Three previously flaccid paraplegic patients received 6-8 intramuscular implants with autologous stem cells previously in vitro differentiated to muscular and neural progenitor cells. The implanted muscles had severe sings of denervation atrophy but had recovered electrical activity after spinal cord cell therapy. The muscular cell therapy was complemented with an intensive rehabilitation program.

Results

All implants were well tolerated, no signs of muscular damage were observed. 3/3 patients showed ultrasound and histological changes in the implanted muscles. 2/3 patients also recovered visible and palpable muscular contraction. 1/3 recovered reflex activity.

Conclusion

Although this is a preliminary study with a small population. The results show that intramuscular cell therapy combined with rehabilitation, may be a therapeutic option for histological and functional improvement in chronic denervated muscles that had previously recovered electrical activity.

PHYSIOLOGICAL ISCHEMIA TRAINING IMPROVES ENDOGENOUS EPCS HOMING TO INFARCTED HEART
C. Wan¹, J. Li²
¹General Hospital of Tianjin Medical University, Rehabilitation Medicine, Tianjin, China
²The First Affiliated Hospital of Nanjing Medical University, Rehabilitation Medicine, Jiangsu, China

Introduction/Background

It was demonstrated that Physiological Ischemia Training increased EPCs in the ischemic limb. However, what about the EPCs levels in the rabbits with myocardial ischemia under physiological ischemia training? We checked and traced endogenous endothelial progenitor cells (EPCs) during physiological ischemia training.

Material and Method

Rabbits were randomly divided into 4 groups: a myocardial ischemia group (subjected to myocardial ischemia only); a physiological ischemia training group (subjected to physiological ischemia training only); a physiological ischemia training-myocardial ischemia group (subjected to both myocardial ischemia and physiological ischemia training); and a sham-operated group. Myocardial ischemia was induced experimentally by a 2-min ischemia, followed by a 1-h reperfusion. Physiological ischemia training involved a 4-min isometric contraction elicited by electrical stimulation (biphasic square wave, 40 Hz, 1 ms), which generated a contraction force at 40% of the maximal isometric contraction force. Myocardial ischemia and/or physiological ischemia training were performed twice a day, 5 days a week for 4 weeks. EPCs were counted by FACS and traced by double-labelling with super paramagnetic iron oxide and chloromethylbenzamidodialkylcarbocyanine.

Results

EPC levels in the blood and the ischemic heart region both improved significantly in the physiological ischemia training-myocardial ischemia group (mean 0.046% (standard deviation (SD) 0.007), 0.013% (SD 0.005)) and group myocardial ischemia (mean 0.038% (SD 0.016), 0.008% (SD 0.004)). The dual-labelled EPCs in the ischemic heart region were confirmed. Pearson’s analysis demonstrated that there is a positive correlation between EPC levels in the blood and the heart region (p < 0.05) in the physiological ischemia training-myocardial ischemia group.

Conclusion
Physiological ischemia training can effectively improve endogenous EPCs. Their homing process from the circulating blood to the ischemic myocardium was clearly traced in this study. This homing process is of great importance for remote neovascularization.

Introduction/Background

Introduction: Cilostazol is a selective phosphodiesterase III inhibitor that was prescribed as an anti-platelet agent, and increases cerebral blood flows in the cerebral infarction. Additionally, it acted as a neuroprotective agent by increasing cyclic adenosine monophosphate levels. Mood and emotional disturbance are common in stroke patients. Post-stroke emotional disturbance, depression, anxiety, apathy, fatigue are frequent and important symptoms. These symptoms are distressing for both the patients and their caregivers, and negatively influence the patient's quality of life. Monoamine transporters including the norepinephrine transporters (NET), the serotonin transporter (SERT) are located in the plasma membrane of the presynaptic nerve terminals. Most inhibitors of the monoamine transporters, especially of the NET and SERT, are clinically important antidepressants. Those antidepressants increase extracellular monoamine concentration by inhibiting the neuronal re-uptake of monoamines through the monoamine transporters. Most antidepressants act through inhibition of either the NET or the SERT or both transporters. The antidepressive effects of cilostazol on post-stroke depression have been reported, but the exact mechanism of this action is unknown.

Aims: The aim of this study was to investigate the direct effects of cilostazol on NET and SERT function.

Material and Method

Methods: SK-N-SH and SERT-transfected COS-7 cells were incubated with [3H]norepinephrine (NE) or [3H]serotonin (5-HT) in the presence or absence of cilostazol to assess the monoamine uptake.

Results

Results: Cilostazol decreased the [3H]NE uptake by SK-N-SH cells and the [3H]5-HT uptake by SERT-transfected COS-7 cells in a concentration-dependent manner.
Conclusion

Conclusions: The blood concentration of cilostazol in treating patients with cerebrovascular disease has been reported to be 13.8 mM after a single oral dose of 100 mg. These results indicate that cilostazol inhibit NET and SERT function at clinically relevant concentration, which is likely to show the antidepressant effect on post-stroke depression.

Source of findings: This study is supported by JSPS KAKENHI Grant Number 16K16456.

LOW POWER LASER IRRADIATION AND HUMAN ADIPOSE-DERIVED STEM CELL TREATMENTS PROMOTE BONE REGENERATION OF CRITICAL-SIZED CALVARIAL DEFECTS IN RATS
C.H. Chen¹, Y.H. Wang², M.L. Ho³
¹Kaohsiung Medical University, Physical Medicine and Rehabilitation, Kaohsiung, Taiwan R.O.C.
²Kaohsiung Medical University, School of Dentistry, Kaohsiung, Taiwan R.O.C.
³Kaohsiung Medical University, Orthopaedic Research Center, Kaohsiung, Taiwan R.O.C.

Introduction/Background

The treatments of large bone defects are often accompanied by various limitations and complications. Stem cell therapy and physical treatments have both been shown to be beneficial in accelerating bone healing. However, the efficacy of combined treatment with stem cells and physical stimuli on large bone defects remains uncertain. The aim of this study was to evaluate the bone regeneration effects of low power laser irradiation (LPLI) and human ADSC treatments during fracture repair using a comparative rat calvarial defect model.

Material and Method

The viability of human ADSCs was cultured on a porous PLGA scaffold using an MTS assay. The critical-sized (7 mm) calvarial bone defect Sprague-Dawley (SD) rats were divided into 4 groups: a control group, an LPLI group, an ADSC group, and an ADSC+LPLI group. Bone formation was evaluated using micro-CT at 4, 8, 12, and 16 weeks after surgery. New bone formation areas and osteogenic factor expression levels were then examined by histomorphological analysis and immunohistochemical staining.

Results

PLGA had no cytotoxic effect on human ADSCs. Micro-CT analyses showed that both the LPLI and ADSC groups improved calvarial bone defect healing compared to the control group. In addition, the ADSC+LPLI group showed significantly increased bone volume at 16 weeks after surgery. The area of new bone formation ranked as follows: control group < LPLI group < ADSC group < ADSC+LPLI group. There were significant differences between the groups. The ADSC and ADSC+LPLI groups showed strong signals of vWF expression in week 16.

Conclusion

ADSC and LPLI treatments improve fracture repair in critical-sized calvarial defects in rats. Importantly, the combined treatment of ADSCs and further enhances the bone healing process.

Introduction/Background

Knee osteoarthritis (OA) has an incidence rate of 25% per year and its responses to treatment are variable. The analgesic effect of intraarticular injection of botulinum toxin type A (BTX-A) has been observed in patients with knee OA. BTX-A might inhibit Rho GTPase by ADP-ribosylation of amino acid asparagine-41. Rho activity has a role in mediation of chondrocyte catabolic signaling pathways, and Rho/ROCK (Rho-associated coiled-coil containing kinase) activation induces articular cartilage degradation. In our unpublished data, chondroprotection of BTX-A was observed based on pathological findings in rat knee OA. ROCK I & II were found to be altered in chondrocytes treated with BTXA, with dose-dependent effect. This study aimed to compare the effect on chondrocyte of BTX-A and Rho-inhibitor.

Material and Method

ATDC5 chondrocytes were compared based on cell phenotype and markers for chondrocyte differentiation and growth after administration of BTX-A, Rho-inhibitor (Y27632), and normal saline (control) to clarify the downstream signaling pathway.

Results

Reverse transcription-PCR (RT-PCR) showed that in ATDC5 chondrocyte cell culture, Y27632 and BTX-A elevated aggrecan on culture day 4 and day 7. On day 21, the level of collagen type X and MMP13 were lowered in Y27632 and BTX-A. ROCK I and II level were decreased on day 4 and 7 in all three groups, but were remarkably higher on day 14 and 21 in Y27632. On day 8, in ATDC5 cells not pretreated with insulin, decreased cell density, small and flat chondrocyte morphology were observed after addition of Y27632 and BTX-A, in comparison to control.

Conclusion
BTX-A and Rho-inhibitor decreased ROCK I & II and increased aggregan level during early stage, and decreased collagen type X and MMP13 during late stage. Potential dedifferentiation effect in BTX-A and Rho-inhibitor were observed as well. Rho- signaling pathway might play different roles during early and late stage in chondrocyte growth.

ANGIOGENETIC EFFECT AND MECHANISM OF LPA ON THE PATHOLOGICAL HUMAN SYNOVIOCYTE FROM OSTEOARTHRITIS AND RHEUMATOID ARTHRITIS

H.C. Hsu1, Y.W. Chuang1, K.H. Chen1, W.C. Hsieh1, C.H. Lin1
1Chang Gung Memorial Hospital, Physical Medicine and Rehabilitation, Putz, Taiwan R.O.C.

Introduction/Background

Lysophosphatidic acid (LPA) is a natural form of phospholipids contained in platelet rich plasma (PRP), which is often used in treating osteoarthritis. Abnormal synovial fluid production is related to osteoarthritis which may due to dysregulated vascular permeability mediated by synoviocytes related angiogenesis factors expression. In this study, we investigated the effect of LPA on the angiogenic factors expression in synoviocytes from normal and osteoarthritis tissue.

Material and Method

Primary culture of human fibroblast-like synoviocytes (HFLS) from normal (N) and osteoarthritis (OA) tissue and human umbilical vein endothelial cells (HUVEC) were used in this study. The expression patterns of LPA receptors on HFLS-N and HFLS-OA were determined by qRT-PCR. The effect of LPA on the angiogenetic capability was evaluated by determining the effect of conditioned medium from LPA treated HFLS-N and HFLS-OA on HUVEC endothelial cell permeability and tube formation assays. Specific LPA modulated angiogenetic factors were screened by angiogenesis protein array and confirmed by ELISA. The role of specific angiogenesis protein was confirmed by recombinant protein.

Results

The expression levels of LPA specific receptors between HFLS-N and HFLS-OA are different. LPA may enhance the angiogenesis effect of HFLS-N but not in HFLS-OA on endothelial cell permeability and tube formation on the matrix gel. Meanwhile, the LPA activated angiogenesis related factors MMP-9, IGFBP-1 and Prolactin are at least partly involved in promoting the angiogenetic capability of HFLS-N.

Conclusion

HFLS-OA may lose the ability to express MMP-9, IGFBP-1 and Prolactin. The clinical significances of MMP-9, IGFBP-1 and Prolactin need further investigations.

Microscopic Observation of a Rat Spontaneous Anterior Cruciate Ligament Healing

Y. Morishita¹, N. Kanemura², T. Kokubun², K. Murata¹, K. Takayanagi²
¹Saitama Prefectural University, Doctoral course- Department of Health and Social Service- Graduate course of Health and Social Service, Saitama, Japan
²Saitama Prefectural University, Department of Physical therapy- School of health and Social Services, Saitama, Japan

Introduction/Background

Controlling abnormal joint movement immediately after anterior cruciate ligament (ACL) injury could prevent destruction of intra-articular tissues and lead to spontaneous ACL healing. In a previous study, healing tissue was observed between the remnant gaps in the process of spontaneous ACL healing. The purpose of this study was to evaluate the healing tissue as observed in the process of spontaneous ACL healing by histological analysis.

Material and Method

A total of 30 adult male Wistar rats were randomly assigned to three groups: Sham, ACL transection (ACLT), and Controlled abnormal movement (CAM). The ACLT group and the CAM group underwent an ACL transection procedure, and the CAM group underwent extra-articular braking to control for abnormal tibial translation. Samples of the knee joints were harvested at 1 and 2 weeks postoperatively, and stained by Hematoxylin-Eosin (HE), Aldehyde Fuchsin-Masson Goldner (AF-MG), and anti-CD68 antibody.

Results

HE staining showed that ACL healing was not observed in the ACLT group, while spontaneous ACL healing was observed at 2 weeks postoperatively in the CAM group. AF-MG stains showed that the healing area consists of collagen. CD68 positive cells were mainly located at the superficial layer and the fibrous layer in all groups. Furthermore, in the CAM group, CD68 positive cells were located at the remnant at 1 week postoperatively and at the healing area at 2 weeks postoperatively.

Conclusion

This study indicates that correcting abnormal kinetics during the early stages of ACL injury is critical for spontaneous ACL healing, and the healing tissue observed in the healing area contains collagen and type A synoviocytes.

SUPRASPINATUS TENDON TEAR REPAIR WITH PLASMA RICH IN PLATELET GROWTH FACTORS
F.J. De León García¹, A.M. García Bravo¹, M.A. Ruiz Fernández¹, R. Saavedra San Miguel¹, R. Zamora Rodríguez¹
¹Hospital Universitario Nuestra Señora de Candelaria, Servicio de Medicina Física y Rehabilitación, Santa Cruz de Tenerife, Spain

Introduction/Background

Supraspinatus tendon tears (STT) represent one of the most frequent causes of benign skeletal muscle pain. At present, conservative treatment doesn't achieve the regeneration of breaks. Recently, the use of Plasma rich in growth factors (PRGF) is proposed to repair of various tissue lesions.

Material and Method

Prospective Analytical Observational Study of 25 clinical cases "prevalent over six months" of STT diagnosed by ultrasound, which has been applied a treatment by ultrasound-guided infiltration of 4 ml of PRGF and the number of three at weekly intervals. Size of rupture, joint balance, pain using the visual analogical scale, global functionality using the Constant Scale, both at the basal moment and at 6 months after the infiltrations are over, were recorded.

Statistical analysis: Descriptive statistics are shown in mean ± ds, median (P25-P75) or in percentage according to the nature of the numerical or qualitative variable. The effectiveness of the treatment was estimated: decrease in the size of the break, Pain Improvement, Internal Rotation and Shoulder Abduction. The hypothesis contrasts were paired (before-after) using Chi-Square, T- Student and Linear Factorial Model for Repeated Measures (GLIM). The analyzes were carried out using the statistical program SPSS / PC (version 24.0.)

Results

Reduction of Size of rupture was observed in 86%, observing statistically significant improvements in the length (p = 0.018) and width of the lesions (p = 0.013). Regarding joint balance, 53% improved in abduction, and 50% in internal rotation; 42% of patients reduced initial pain. Constant scale shows an improvement in 50% of patients.
Conclusion

Although the treatment has been shown to be effective in reducing the size of tear, clinical improvement at six months is less evident. This could be due to the small size of the sample or to the fact that there could be clinical-sonographic dissociation six months after the end of PRFP treatment.

Ischrin and Early Exercise on NF-κB Signaling Pathway During Lung Injury Induced by Focal Cerebral Ischemia-Reperfusion in Rats

Introduction/Background

Inflammation and oxidative stress play an integral role in the pathogenesis of cerebral ischemia. Chrysin exhibits anti-inflammatory and neuroprotective effects. Early exercise is an effective strategy for stroke treatment. However, the signaling pathways that link these events are not fully understood. We investigated the effects signaling pathways of chrysin treatment with early exercise in a rat model of lung injury induced by transient focal cerebral ischemia.

Material and Method

Forty female healthy SD rats were divided into four groups randomly (n=10): sham operation (A), lung injury induced by ischemia-reperfusion (B), chrysin treatment (C), and chrysin + early exercise (D). In C, rats were treated intragastrically with chrysin every day at a dose of 20mg/kg while rats were treated intragastrically with the same volume of NS in A and B. In D, rats received forced treadmill training and were treated intragastrically with chrysin (20mg/kg). Fourteen days later, all rats were sacrificed. Brain and lung tissues were obtained for pathological analysis, lung water content and lung function were assessed. Meanwhile, qRT-PCR and western blotting were employed to detect the expression of NF-κB and TNF-α in lung.

Results

Neurobehavioral deficits and lung injury could be seen in B. Compared with B, chrysin (C and D) successfully decreased the infarct size, relieved pulmonary edema and improves lung function, while downregulated expression of NF-κB and TNF-α. Notably, neurobehavioral deficits and lung injury were significantly improved in D, as well as the decreased expression of NF-κB and TNF-α.

Conclusion

Chrysin treatment with early exercise improved functional outcomes and abrogated the lung injury induced by focal cerebral ischemia-reperfusion on rats, which might be associated with inhibition of NF-κB-mediated neuroinflammation. Chrysin combined with early exercise may be used as a potential treatment in patients at high risk of lung injury induced by ischemic stroke.

EXPERIMENTAL STUDY OF EXPRESSION OF HYPOXIA-INDUCIBLE FACTOR-1A AND ITS ROLE IN TRAUMATIC BRAIN INJURY

P. Huaping1
1The Affiliated Jiangning Hospital of Nanjing Medical University, Rehabilitation Medicine, nanjing, China

Introduction/Background

Decades of traumatic brain injury (TBI) research have not led to the development of novel drugs that successfully improve the outcome of injured patients. Thus, new research approaches or medicine are required. Vascular injury is the primary key event that can cause a range of secondary injury, and become a key part of TBI repairmen. Reduced blood flow is one pathophysiological symptom of TBI. Regenerative mechanisms are then initiated to reduce cellular damage, including the activation of hypoxia-inducible transcription factor 1 (HIF-1). Successful revascularization can provide critical neurovascular microenvironment, which produces effective perfusion to promote nerve repair and growth by clearing Toxic factors, providing nutrition, and making it a critical treatment for TBI.

Material and Method

96 Male SD rats were divided into four groups: Sham group(n=8), Control (sham operate ,n=8), traumatic brain injury group (TBI group, n = 40) and TBI treated with 2ME2 group(n=40). Feeney’s method was applied to establish TBI model. At the time point 6h, 24h, 3d, 7d, 14d after modeling, the expression of PHD2/HIF-1α/VEGF/Ang-1 were observed by RT-PCR

Results

Compared with sham-operated controls, the expression of HIF-1α in TBI group have been significantly (p < 0.05) enhanced, which related to the degradation of PHD2 following TBI induction. HIF-1α expression began to increase after 6h, within 24h to 3d reached peak and fall to common levels before 7d. Nevertheless, VEGF/Ang-1 expression was remarkably (p< 0.01) decreased after inhibition of HIF-1α by 2-ME-2.

Conclusion

The expression of HIF-1α increased after experimental TBI, which can induce its downstream target gene expression to promote the repairment of injured vascular and angiogenesis.

NON-INVASIVE REMOTE ISCHEMIC POSTCONDITIONING STIMULATES NEUROGENESIS DURING THE RECOVERY PHASE AFTER CEREBRAL ISCHEMIA

P. Wang¹
¹Ruijin Hospital- School of Medicine- Shanghai Jiao Tong University,
Department of Rehabilitation Medicine, Shanghai, China

Introduction/Background

Ischemic postconditioning (IPostC) has been reported to have neuroprotection against ischemic diseases, and one cycle of IPostC induces neurogenesis when treated nearby.

Material and Method

To expanding these effects, we explored the effects of repetitively remote IPostC (NRIPostC) on neurogenesis in the subgranular zone (SGZ) and subventricular zone (SVZ) during stroke recovery. Animals underwent transient cerebral ischemia were treated with vehicle or NRIPostC immediately after reperfusion. Neurological severity scores, infarct size, neurogenesis, and protein expression levels of nestin and GFAP were quantified at 3d, 7d, 14d, 21d and 28d post-ischemia.

Results

Results showed that NRIPostC significantly reduced acute infarction and improved neurological outcomes during the recovery phase. Meanwhile, NRIPostC significantly increased the number of BrdU+/nestin+cells in SGZ on day 14 and in the SVZ on days 3, 7 and 14 respectively, and the number of DCX+cells from days 3 to 14. There were significant increments in the number of BrdU+/NeuN+ and BrdU+/GFAP+ cells in the SGZ and SVZ during the stroke recovery. The changing tendency of the protein expression of nestin and GFAP in DG was consistent with the result mentioned above.

Conclusion

In conclusion, NRIPostC reduced acute infarction and improved functional outcomes up to 28d, and it induced neurogenesis both in the SGZ and SVZ.

Introduction/Background

Elbow epicondylar tendinitis is a common problem that usually resolves with nonoperative treatments. When these measures fail, there is a role of Platelet-rich plasma (PRP) for tissue repair.

Material and Method

The trial was conducted in Bangabandhu Sheikh Mujib Medical University Hospital during the period August 2016 to February 2017. One hundred patients with chronic lateral epicondylitis were randomly assigned to a leukocyte-enriched PRP group (n = 51) or the corticosteroid group (n = 49). Patients received either a corticosteroid injection or an autologous PRP injection through a peppering needling technique. Outcome was measured in terms of VAS (Visual analog scale) and DASH (Disabilities of the arm, shoulder and hand).

Results

Success was defined as a reduction of 25% on VAS or DASH scores without a re-intervention within 6 months. When baseline VAS and DASH scores were compared with the scores of 6 months follow-up, both groups significantly improving within this time (intention-to-treat principle). But the DASH scores of the corticosteroid group come back to baseline levels, while the PRP group is unchanged at the end of 6 months (as-treated principle). The PRP group shows better outcome than the corticosteroid group (P < .0001). There were no complications shown in the use of PRP.

Conclusion

Patients with chronic lateral epicondylitis treated with PRP reduces pain and increases function, exceeding the effect of corticosteroid injection.

ASPIRIN, AN ASIC3 INHIBITOR, BLOCKS THE ANALGESIC EFFECT OF THERAPEUTIC ULTRASOUND IN CHRONIC MUSCLE PAIN

D.S. Han¹, C.C. Chen²
¹National Taiwan University Hospital BeiHu Branch, Department of Physical Medicine and Rehabilitation, Taipei, Taiwan R.O.C.
²Academia Sinica, Institute of Biomedical Sciences, Taipei, Taiwan R.O.C.

Introduction/Background

Therapeutic ultrasound is widely used in pain control in physical medicine, and substance P (SubP) is the key pathway. However, the ion channels involving the analgesic process is still not clear. The objective of this study is to prove that the mechanism of the analgesic effects of ultrasound in a rodent model of chronic muscle pain is through acid sensing ion channel 3 (ASIC3).

Material and Method

We employed the chronic hyperalgesia mouse model proposed by Sluka et al. and applied therapeutic ultrasound at 3MHz, 100% duty cycle, 1W/cm2 for 3 min. Mice were co-injected with pH 4.0 saline and 100 uM RP-67580 on day 0. From days 4 to 8 after the first acid injection, mice were co-injected with pH 7.4 saline and Aspirin (ASP) 500uM, 5mM, or ibuprofen (IBU) 500uM. The withdrawal response of mouse hind paws was defined as foot lifting when a 0.2-mN von Frey filament was applied (Fig 1).

Results

ASP diminished the analgesia induced by ultrasound treatment in mouse chronic muscle pain model. However, IBU, inhibitor of ASIC1a, did not. SubP and pERK content increased after ultrasound in DRG. Two minutes after ultrasound, ipsilateral pERK, subP, and tracer were significantly increased and overlapped each other. However, subP increased to less extent.

Conclusion

Therapeutic ultrasound and acid injection could inhibit intramuscular nociceptor activation, and result an anti-nociceptive effect against chronic mechanical hyperalgesia through ASIC3 pathway. In the future, small molecule inducing SubP and ASIC3 can be new candidate to treat chronic diffuse muscle pain.

⁵Guizhou Provincial people’s hospital, Department of Using Qulity Management, Guiyang, China
⁶Guizhou Provincial people’s hospital, Department of Neuroelectrophysiology, Guiyang, China

Introduction/Background

Time related cognitive function refers to the capacity of the brain to store, extract, and process specific information during the process of learning and memorizing. A large number of previous studies have shown that the cerebellar cortex is involved in the brain’s advanced cognitive function. However, the role of the cerebellar cortex in cognitive function is not fully understood. Therefore, we established a behavioral model by using classicaleyeblink conditioning(EBC) to study the role of the cerebellar cortex in associative learning and memory as well as the related underlying mechanism.

Material and Method

We carried out an investigation to determine whether EBC could be established by placing the stimulating electrode in the middle cerebellar peduncle (MCP). By using microcurrent pulse as a conditioned stimulus (CS), to stimulate theMCP, and corneal blow as an unconditioned stimulus (US), the behavior training was performed. Animals were male guinea pigs aged 4–5 months and without obvious eye diseases were selected.

Results

After 10 consecutive days of training, conditioned response (CR) was successfully achieved in Delay, Trace-200ms and Trace-300ms groups of guinea pigs, and the CR acquisition rates were greater than 60%, meaning that EBC was established successfully in these groups. However, the Trace-400ms and control groups did not achieve a CS-related blink CR.

Conclusion

By using pulsed micro-electric current as the CS, the cerebellar cortex of guinea pig can successfully establish EBC. Establishment of the optogenetic platform showed that by taking the induced AP in the neurons of LPN, which stimulates MCP directly, as the CS, the cerebellar cortex can successfully establish TEBC independently.

AN EXPLORATION OF MECHANOSENSITIVE MOLECULES ON HYPERTROPHIC SCARS UPON PRESSURE THERAPY: A PRELIMINARY STUDY

Y. Zhang¹,², C.W.P. Li-Tsang³, P. Li²,³

¹West China Hospital of Sichuan University, Department of Rehabilitation Medicine, Chengdu, China
²The Hong Kong Polytechnic University, Department of Rehabilitation Sciences, Kowloon, Hong Kong S.A.R.
³Chengdu Second People’s Hospital, Department of Rehabilitation Medicine, Chengdu, China

Introduction/Background

Hypertrophic scar (HTS) is an aberrant yet common consequence of trauma. Pressure therapy has been regarded as first-line treatment for HTS, while its mechanism still remains unclear. External force is found to affect HTS formation via mechanotransduction during wound healing. Recently, researchers proposed that pressure therapy might control HTS through mechanotransduction. Therefore, an in-vivo human study was conducted to explore the change of mechanosensitive molecules on HTS upon pressure therapy.

Material and Method

Patients with hypertrophic scars were recruited between May 2013 and April 2016. Standardized pressure therapy (interface pressure of 15~25mmHg) was prescribed. Ultrasound was used to measure scar thickness. Immunohistochemical staining of Integrinβ1, Phospho-FAK(Y397), Phospho-Erk(1/2) was semi-quantified using imaging analysis. Paired Sample T-test was used to compare scar thickness before and after pressure therapy. One-way Repeated measure MANOVA was used to compare the intensity of mechanosensitive molecules.

Results

Forty patients with Forty-three hypertrophic scars were recruited in the study. Post injury days ranged from 28 to 277 days. After pressure therapy, difference in scar thickness was not statistically significant (t=-1.41, p=.167), and staining intensity of integrinβ1 (F(1,39)=15.54, p<0.001), pFAK(Y397)(F(1,39)=7.51, p=.009), and pErk(1/2) (F(1,39)=.636, p=.016) was significant.

Conclusion

The study found integrinβ1, Phospho-FAK(Y397), Phospho-Erk(1/2) significantly decreased in dermis after pressure therapy. The study established a basis for exploring the mechanism of scar management from mechanotransduction aspect. A well-designed controlled group is needed in the future to examine the effect pressure therapy on HTS.

INTERLEUKIN-6 PLAYS AN ESSENTIAL ROLE IN PULSED ELECTROMAGNETIC FIELD IMPROVING CARTILAGE AND SUBCHONDRAL BONE IN MICE WITH OSTEOARTHRITIS

X. Yang¹, H. He¹, S. Zhu¹, C. He¹
¹West China Hospital of Sichuan University, Rehabilitation Medicine, Chengdu, China

Introduction/Background

Pulsed electromagnetic field (PEMF) has been investigated as a noninvasive alternative method to protect cartilage and subchondral bone from osteoarthritis (OA), and have anti-inflammatory and pro-regenerative effects. Interleukin-6 (IL-6) is a major cytokine in the pathogenesis of OA. Inhibition of IL-6 can alleviate cartilage degradation in mice with OA. This study aimed to investigate whether IL-6 is crucially involved in PEMF preserving cartilage degeneration and improving subchondral bone microstructure.

Material and Method

Forty 10-week-old male wild type (WT) C57BL/6 and IL-6 knockout (IL-6/-) mice were randomly divided into four groups (n=10): IL-6/-, WT, IL-6/-+PEMF, WT+PEMF. OA was induced by the destabilization of the medial meniscus (DMM) of the right knee. The PEMF groups were exposed to 75 Hz, 3.8 mT PEMF for 1 h/day, 7 days/week, 4 weeks. Cartilage destruction was investigated by Safranin O staining. Bone microstructure was evaluated by micro-computed tomography. Gene expressions were assayed with real-time quantitative polymerase chain reaction. Protein expressions were observed by the immunohistochemistry staining.

Results

The WT+PEMF group increased bone volume fraction (BV/TV), trabecular thickness (Tb.Th), trabecular number (Tb.N), and suppressed bone surface/bone volume (BS/BV) and trabecular separation (Tb.Sp) levels in the micro-computed tomography analysis. Real-time PCR analysis showed that PEMF decreased cartilage and subchondral bone’s IL-6, Stat3, MMP-13, Adamts4 and Adamts5 mRNA levels. Similar results were observed in the immunohistochemistry staining. No significant differences were found between IL-6/- and IL-6/-+PEMF group.

Conclusion

PEMF preserved cartilage and subchondral bone in knee OA mice by inhibiting IL-6/Stat3 signaling.

THE DEVELOPMENT OF CONTROLLED RELEASE REGIMEN FOR THE TREATMENT OF TENDINOPATHY USING ANTIOXIDANT AND HYALURONATE-BASED HYDROGEL
M.Y. Hsiao¹, W.S. Chen², T.G. Wang², F.H. Lin³
¹National Taiwan University- National Taiwan University Hospital, Institute of Biomedical Engineering- Department of Physical Medicine and Rehabilitation, Taipei, Taiwan R.O.C.
²National Taiwan University Hospital, Department of Physical Medicine and Rehabilitation, Taipei, Taiwan R.O.C.
³National Taiwan University, Institute of Biomedical Engineering, Taipei, Taiwan R.O.C.

Introduction/Background
For decades, tendinopathy therapy has seen limited progress because of incompletely understood pathogenesis, which includes repetitive microtrauma, impaired healing, and oxidative stress. Current treatment of tendinopathy is largely of limited efficacy and required a protracted treatment course. This study aims to develop a controlled release regimen using antioxidative medication and hyaluronic-based hydrogel as drug carrier for the treatment of tendinopathy.

Material and Method
In in-vitro model, tendon-derived cells (TDCs) were isolated from the Achilles tendons of Sprague-Dawley rats and cultured in a novel bioreactor capable of applying differential cyclic tensile strains (4% or 8%). The 8% strain TDCs were treated with/without epigallocatechin gallate (EGCG)-loaded hydrogel. Genes representing adipogenic, chondrogenic, and osteogenic lineages (PPARγ, Sox-9, and Runx2, respectively) and type I/type III collagen were analyzed by quantitative polymerase chain reaction (qPCR).

In in-vivo model, type I collagenase was injected to Achilles tendons of Sprague-Dawley rats in two successive days to induce tendinopathy. EGCG-loaded hydrogel was injected at day 3. At day 14, the tendons were harvested for histology and qPCR analysis.

Results
The 8% strain cells showed increased expression of non-tenocyte lineage genes and type III/type I collagen ratios compared with the control and 4% strain groups. Addition of EGCG ameliorated the expression of genes representing non-tenocyte differentiation.

Conclusion
EGCG diminished the expression of non-tenocyte lineage genes in *in-vitro* model. The injection regimen using EGCG-loaded hydrogel effectively ameliorated tendinopathy process in *in-vivo* model. The platform could be applied to future research on the pathophysiology of tendinopathy and development of treatment options.

ADAPTATION TO THE ABSENCE OF TACTILE AND PROPRIOCEPTIVE FEEDBACK IN OBJECT HANDLING

R. Parry¹, N. Jarrasse¹, F. Sarlegna², A. Roby-Brami¹
¹Institut des Systèmes Intelligents et de Robotique, Université Pierre et Marie Curie, Paris, France
²Institut des Sciences du Mouvement, CNRS- Aix-Marseille Université, Marseille, France

Introduction/Background

Dextrous manipulation necessitates efficient sensorimotor feedback mechanisms to orientate handheld objects, adjust for movement dynamics and respond to perturbations. In particular, cutaneous receptors and proprioception are paramount in the regulation of hand-object interactions (Johansson, 1991; Nowak et al., 2004). This study further examined the object handling skills of a person with massive peripheral deafferentation (consequent to sensory neuropathy) in order to improve knowledge of how people adapt/compensate for the loss of tactile/proprioceptive feedback.

Material and Method

Object handling abilities of a deafferented woman (GL) were compared to eight age-matched control subjects using three experimental tasks: 1) discrete vertical movements; 2) functional grasp and place and; 3) static holding with perturbations (taps) applied to the top of the object—firstly by the person themselves and secondly by the experimenter. Tasks 1 and 3 were performed under full vision and blinded conditions. Grip force and object acceleration/orientation were recorded using a portable, instrumented object.

Results

When compared to control subjects, GL demonstrated a global increase in grip force with diminished temporal coupling to changes in object acceleration and limited ability to maintain orientation of the handheld object in the absence of visual feedback. All phases of the grasp and place task were of greater duration for GL and a qualitatively distinct acceleration profile was observed. In the hold perturbation tasks, GL exhibited greater time delays between perturbation and grip force response but proved efficient at gauging grip force response with respect to the magnitude of the perturbation.

Conclusion

Whilst proprioceptive deficits limit temporal precision of grip force adjustments in object handling, visuomotor strategies and auditory feedback may assist in regulating object orientation during functional tasks and grip force scaling during perturbations. Future studies
might investigate the feasibility of augmented visual/auditory feedback devices to optimise object handling for people with somatosensory deficits.

LEFT UNILATERAL NEGLECT IS GREATER FOR NON-NAMABLE THAN FOR NAMABLE OBJECTS IN RECOGNITION MEMORY

E. Moreh¹, T. Orlov², E. Zohary²

¹Hadassah Hebrew University Medical Center, Physical Medicine and Rehabilitation, Jerusalem, Israel
²Hebrew University, Neurobiology, Jerusalem, Israel

Introduction/Background

Patients with right hemisphere damage often fail to notice, respond to, and report on left sided stimuli, a condition termed unilateral spatial neglect (USN). In a previous study, we found that USN patients showed a significant contralateral disadvantage both in immediate recall and in delayed recognition of presented visual objects. However, successful verbal recall of an object immediately after its presentation eliminated to a large extent the effect of the spatial position on delayed recognition. Our aim in the present study was to assess whether the formation of a verbal memory trace is responsible for the attenuation of the lateralized bias in recognition of objects that have been verbally recalled.

Material and Method

To this end, we compared the immediate recognition performance of 16 USN patients and 16 control subjects for two categories of pictures: namable objects (fruits, furniture, etc...) vs. abstract colorful non namable pictures.

Results

Both healthy controls and USN patients showed a better mean general performance for objects than for abstract pictures (controls: discrimination rate d'namable objects: mean± standard deviation 3.20±0.86, d'non-namable 2.05±0.73; USN patients d'namable 1.61±0.68; d'non-namable 0.98±0.58). Laterality index (LI = (d'Left- d'Right)/(d'Left+ d'Right)) revealed a greater lateralized bias for abstract pictures than for object pictures in USN patients (USN patients: mean LI namable: -0.14 ± 0.15, ; mean LI non-namable: -0.42 ± .27; Controls: mean LI namable: -0.01 ± 0.06; mean LI non-namable: 0.06 ± 0.11).

Conclusion

Semantic processing modulates the spatial biases exhibited by USN patients in recognition memory, even in the lack of an explicit verbal recall task; left-sided information is partially perceived and might be more accessible when coded dually - both verbally and visually. The use of verbalization as a rehabilitation technique in USN deserves further investigation.

STUDY ON EFFECTS BOTULINUM TOXIN TYPE A INJECTION FOR PATHOLOGICAL OF GASTROCNEMIUS IN RATS WITH SPINAL CORD INJURY
L. jiang1, X. wei2, D. xie1, Q. wang3, M. daï1, Z. dou1
1The Third Affiliated Hospital- Sun Yat-sen University, Department of Rehabilitation Medicine, Guangzhou, China
2The Third Affiliated Hospital- Sun Yat-sen University, Department of Rehabilitation Medicine, Guangzhou, China
3the 3rd Affiliated Hospital of Sun Yet-sen University, Department of Ultrasonic, Guangzhou, China

Introduction/Background
To explore pathological characteristic of gastrocnemius (GM) and BBB motor assessment and MAS of ankle dorsiflexors in SCI model rats which were injected with BoNT-A in different time points. To make sure the proper time for BoNT-A injection

Material and Method
48 SD male rats (weight 260-280g) were allocated normal control group and 12w-control group, NS- injection group and BT- injection group in this study. NS/BT-therapy groups were divided into three subgroups separately (2w-NS, 2w-BT, 4w-NS, 4w-BT, 8w-NS, 8w-BT). No injection was applied in normal control group or 12w-control group. Saline / BoNT-A was injected in right GM in NS/BT-therapy group at different time points. MAS was used to assess the ankle dorsiflexors spasticity; BBB was used to assess the movement ability of lower limb. GM at right side of rats would be forwarded for pathological examinations, such as muscle weight, myosin heavy chain electrophoretic analysis.

Results
To compared with 12W-Contrl group, GM muscle weight decreased significantly in rats from BT injection group (P≤0.05). Comparison with 12W-Contrl group, MAS and BBB values were showed no significant difference in the two injection groups (P> 0.05). The differences in MyHC type ratio of GM between BT injection group and Nor-Contrl group and 12W-Contrl group were statistically significant (P≤0.05); and following the injection happened in the different time points, the changes in MyHC type ratio of GM were different in each BT injection subgroup

Conclusion
BoNT-A injection results in some changes in GM, such as decreased muscle weight, decreased GM/total weight. No obvious changes were happened in the ankle dorsiflexors spasticity level and the movement ability of lower limb in rats of BT/NS-injection groups. Earlier BoNT-A
intervention will cause significant changes on MyHC types characterize than later intervention in GM.

RESEARCH PROGRESSES AND PROSPECTS OF INTELLIGENT SENSING EQUIPMENT IN SPORTS REHABILITATION
L. Zhang¹, X. Wang²
¹Renmin University of China, Sports Department, Beijing, China
²Shaanxi University of Science and Technology-, College of Electrical and Information Engineering-, Shaanxi, China

Introduction/Background

Sports rehabilitation is a combination of physical education and medical treatment. As a subdivision of rehabilitation medicine, the target group of the sports rehabilitation is patients who have skeletal muscle injuries and orthopedic surgeries but is gradually extending to people with chronic diseases and sub-health. There is a huge difference between the rehabilitative medicine and traditional one. The former regards the restoration and improvement of physical functions as its main task, and on the basis of recognizing the dialectical unity of structure and function, more attention is paid to the cure of functions, which provides an important supplement for many medical disciplines that are difficult to play a role.

Material and Method

In order to provide new ideas for the application of modern intelligent sensing technology in the field of sports rehabilitation medicine and human-machine integration, the paper analyzes international research literature on intelligent sensing equipment in the field of sports rehabilitation training.

Results

Through literature review, we find that smart sensor devices, especially those based on new materials or available to implant subcutaneously, have a significant influence on acquiring data efficiently, monitoring vital signs and body changes, guiding the training of body movements and recovering body functions rapidly.

Conclusion
With the idea of human-machine integration, the new intelligent sensing technology has exact, curative and obvious effects on body function improvements and quick recovery, showing an immeasurable application value and a broad application prospect in the field of sports medicine rehabilitation.

STUDY ON THE PROPERTY CAMK II IN TREADMILL EXERCISE ON MEMORY FUNCTION OF PARKINSON’S DISEASE
J. Xiang
The Hospital of Xuzhou Medical University, Department of Rehabilitation, Xuzhou, China

Introduction/Background

To investigate the molecular mechanism of calcine kinase II (CaMKII) in improving the memory function of mice with Parkinson's disease, and to explore the possible mechanism of Treadmill Training to improve the memory function of PD and to provide a new idea for rehabilitation of patients with Parkinson's disease.

Material and Method

Frozen sections of healthy adult male C57BL / 6 mice were perfused and the expression of CaMKII and TH in hippocampus were detected by immunofluorescence double labeling method.

Results

The results of immunofluorescence showed that CaMKII and TH were expressed in all regions of hippocampus, and CaMKII and TH were expressed in the same nerve cell.

Conclusion

CaMKII / TH expression in the same neurons of hippocampus in normal physiological conditions may provide the possibility of regulating the activity of TH by CaMKII.2, Treadmill training by raising the level of CaMKII / TH in the hippocampus to increase the release of DA in the hippocampus, and ultimately improve the memory function of PD+no-Ex mice.

Introduction/Background

Impaired manual dexterity is frequently reported after stroke and thought to result from corticospinal tract (CST) damage. However, how CST function contributes to functional recovery remains unclear. In this prospective longitudinal study we investigated recovery of dexterity and CST injury and excitability in six patients undergoing conventional rehabilitation.

Material and Method

The Finger Force Manipulandum was used to measure dexterity components like force control, finger tapping and independence of finger movements. Transcranial magnetic stimulation was used to measure CST excitability, and structural MRI to calculate weighted-CST lesion load.

Results

Clinical tests showed complete recovery of gross motor hand movements in three patients by six months (maximal Fugl-Meyer Upper Extremity assessment score for hand). At six months, four patients had fully recovered in their ability to accurately control finger force. However, tapping speed and independence of finger movements remained affected in all patients at six months when compared to healthy subjects. Recovery in gross motor hand movements and finger force control occurred in those patients with smallest CST lesion load and recovery of CST excitability on TMS, although motor evoked potentials (MEPs) remained of smaller amplitude compared to those evoked from the contralesional side. The two patients with poorest recovery in manual dexterity showed persistent absence of MEPs and greatest structural injury to CST.

Conclusion
Although in a small patient sample, the findings show persistent deficits in manual dexterity after stroke despite good recovery of gross motor hand function and partial recovery of CST excitability, suggesting that CST integrity may be necessary but not sufficient for post-stroke recovery of dexterity.

Introduction/Background

Osteoarthritis (OA) involves degradation of articular cartilage, subchondral bone and changes in periarticular soft tissues. It generates a local inflammatory process with increased pro-inflammatory cytokines (IL-1β, IL-6, TNF-a and IL-17) in synovial fluid and activation of catabolic enzymes (MMP-2,3 and 13 and ADAMT-4) that lead to cartilage destruction and failure of its renovation. There is a great need of biomarkers to define subsets of OA patients and to evaluate treatment outcome. Botulinum Toxin Type A (BoNT-A) has been identified as a potential novel analgesic. Inhibition of glutamate secretion by this treatment inhibits hyper-excitation secondary to nociceptive stimuli. The aim of this study was to correlate cytokine levels, demographics and clinical scores. Additionally, we evaluated clinical and biological effects of intra-articular BoNT-A treatment.

Material and Method

Experimental, longitudinal clinical trial. Diagnosis was confirmed using American College of Rheumatology criteria. Therapeutic approach: Knee Intra-articular incobotulinumtoxin A (100U) diluted in 1 mL of saline solution at days 0 and 90. Subjective assessment was evaluated using WOMAC and VAS scales. Cytokine levels (IL-2, IL-4, IL-6, IL-10, TNF-a, IFN-g and IL-17) were measured in serum and synovial fluid using Cytometric Bead Array. Association between clinical data and cytokines was analyzed using Spearman correlation, differences between groups using Mann Whitney-U test and basal and post-treatment changes in clinical scores and cytokines applying Wilcoxon signed-rank test.

Results
Kellgren-Lawrence score showed a negative correlation with TNF-a (R=-0.363, p<0.05) and IFN-g (R=-0.325, p<0.05). TNF-a and IFN-g could represent early knee degeneration markers in OA.

Schizophrenia (SCZ) is a neurodevelopmental psychiatric disorder, in which cognitive function becomes disrupted at early stages of the disease. Although the mechanisms underlying cognitive impairments remain unclear, N-methyl-D-aspartate receptors (NMDAR) hypofunctioning in the prefrontal cortex (PFC) has been implicated. Moreover, cognitive symptoms in SCZ are usually unresponsive to treatment with current antipsychotics and by onset, disruption of the dopamine system, not NMDAR hypofunctioning, dominates the symptoms. Therefore, treating cognitive deficits at an early stage is a realistic approach.

Material and Method

In this study, we tested whether an early treatment targeting mGluR2 would be effective in ameliorating cognitive impairments in the methylazoxymethanol acetate (MAM) model of SCZ. We investigated the effects of an mGluR2 agonist/mGluR3 antagonist, LY395756 (LY39), on the NMDAR expression with Western blot and function with electrophysiological recording in juveniles, as well as cognitive deficits in adult rats after juvenile treatment with cross-maze behavioral test.

Results

We found that gestational MAM exposure induced a significant decrease in total protein levels of the NMDAR subunit, NR2B, and a significant increase of pNR2BTyr1472 in the juvenile rat PFC. Treatment with LY39 in juvenile MAM-exposed rats effectively recovered the disrupted NMDAR expression. Furthermore, a subchronic LY39 treatment in juvenile MAM-exposed rats also alleviated the learning deficits and cognitive flexibility impairments when tested with a cross-maze based set-shifting task in adults.

Conclusion

Therefore, our study demonstrates that targeting dysfunctional NMDARs with an mGluR2 agonist during the early stage of SCZ could be an effective strategy in preventing the development and progression in addition to ameliorating cognitive impairments of SCZ.

⁵University of Haifa,
Edmond J. Safra Brain Research Center for the Study of Learning Disabilities, Haifa, Israel
⁶Sheba Medical Center, Acquired Brain Injury Rehabilitation Department, Ramat Gan, Israel

Introduction/Background

Using the finger-to-thumb opposition sequence (FOS) learning task several stages of procedural learning have been defined in healthy subjects, nevertheless, in patients with traumatic brain injury (TBI) they remain obscure. Given the importance of skill acquisition in the rehabilitation of TBI patients, optimization of theory-based training protocols is vital to fulfill their potential for long-term plasticity.

The aim of this study was to characterize motor skill acquisition in TBI patients using the FOS paradigm in comparison with healthy subjects.

Material and Method

10 TBI patients (Trained TBI), 11 healthy participants were trained using a multi-session protocol: a single session was afforded in the first week of the study, and 4 daily sessions during the second. Performance speed and accuracy were tested before and after each session. Retention was tested one month later. 10 TBI patients (Control TBI) had no FOS training and were tested only at the beginning and after 6 weeks.

Results

The phases of skill learning found in healthy adults (acquisition, between-session consolidation gains and long-term retention) were identified in TBI patients. However, their time-course of learning was atypical. The Trained TBI demonstrated significantly larger speed increase compared with the TBI controls with no speed-accuracy tradeoff. During the second week, while training daily, the rate of improvement of the Trained TBI group was significantly slower compared with the Healthy controls, due to within-sessions losses in speed found only in this group.
Conclusion

The data presented allows for improved characterization of neuro-behavioral constraints on motor learning after TBI and enable caregivers to optimize treatment protocols.

³The University of Tokyo, Department of Medical Research and Management for Musculoskeletal Pain- 22nd Century Medical & Research Center- Faculty of Medicine, Tokyo, Japan

Introduction/Background

Upright bipedalism is one of the distinctive features that differentiates humans from quadrupedal mammals. Imaging studies using single photon emission computed tomography and functional near infrared spectroscopy have demonstrated that, in the frontal lobe, the primary sensorimotor area and the supplementary motor area were activated during walking. To understand cortical mechanisms related to truncal posture control during human locomotion, we investigated hemodynamic responses in the supplementary motor area with and without trunk orthosis. If the supplementary motor area is related to truncal control, we assume that the activation of supplemental motor area would decrease during gait with trunk orthosis because human need less control for truncal posture.

Material and Method

Twelve healthy human adults participated in this study. All participants provided their written informed consent prior to the study. We used functional near infrared spectroscopy to measure the activity of supplementary motor area while participants walked on a treadmill. All participants walked in two conditions: walk independently and walk wearing trunk orthosis. In each condition, task comprised five repetitions of walking for 40 sec each followed by 40 sec of rest as a block. We used oxy-Hb concentrations rather than deoxy-Hb concentrations because the former are reportedly related to brain activity.

Results

Compared with the baseline, the oxy-Hb level increased from the beginning of the trial but subsequently decreased and remained below the baseline before a trough in the rest phase. The peak value of the independent condition was higher than that of the trunk orthosis condition.

Conclusion
From our results, the supplementary motor area is related to truncal control during walking.

REAL-TIME CEREBRAL BLOOD FLOW MONITORING BY LASER SPECKLE CONTRAST IMAGING AFTER CARDIAC ARREST WITH TARGETED TEMPERATURE MANAGEMENT
X. Jia¹, J. He², H. Lu³, L. Young², S. Tong³
¹University of Maryland School of Medicine, Neurosurgery- Orthopaedics- Anatomy Neurobiology, Baltimore, USA
²University of Maryland School of Medicine, Neurosurgery, Baltimore, USA
³Shanghai Jiaotong University, School of Biomedical Engineering, Shanghai, China

Introduction/Background

Brain injury is the main cause of mortality and morbidity after cardiac arrest (CA). Changes in cerebral blood flow (CBF) after reperfusion are associated with brain injury and recovery. Target temperature management (TTM) is the most effective treatment of CA patient. Despite of the advancement in detecting techniques, a real time CBF monitoring technique after CA and TTM, with a wide field of view and high spatiotemporal resolution, has not been established yet.

Material and Method

Fourteen rats underwent 7 min asphyxia-CA and were randomly treated with 6h post-resuscitation normothermic (36.5-37.5°C) or hypothermic (32-34°C) targeted temperature management (TTM) (N=7). rCBF was monitored by a laser speckle contrast imaging (LSCI) technique. Brain recovery was evaluated by neurologic deficit score (NDS) and quantitative EEG-information quantity (qEEG-IQ).

Results

There were regional differences in rCBF among veins of distinct cerebral areas. The rostral vein had a higher rCBF at the hyperemia phase (3-12 min after return of spontaneous circulation (ROSC)) and a lower rCBF at the hypoperfusion phase (40-90 min after ROSC) compared with both the middle and caudal veins. There were heterogeneous responses among the three components of the vascular system. The rCBF of capillaries increased more than that of veins and arteries in the hyperemia phase but decreased more in the hypoperfusion phase. Hypothermia immediately following ROSC led to a longer hyperemia duration, a lower rCBF at the hypoperfusion phase, a better NDS and a higher qEEG-IQ compared with normothermic TTM.

Conclusion

This is the first report on continuous CBF monitoring at the level of individualized vessels with high spatial and temporal resolutions in the setting of CA. The quantified rCBF response may help uncover the mechanism of injury and recovery after global brain ischemia and TTM.

PROPER METHODS FOR COLLAGENASE-INDUCED TENDINOPATHY ANIMAL MODEL
S. Kwon¹, H.S. Yang², W. Kim¹, K.H. Choi¹, M. Jung¹
¹Asan Medical Center - University of Ulsan College of Medicine, Department of Rehabilitation Medicine, Seoul, Republic of Korea
²University of Ulsan College of Medicine, Department of Rehabilitation Medicine, Seoul, Republic of Korea

Introduction/Background

The therapeutic advancements are limited for tendinopathy even though it is a common and might lead to disability. Collagenase injury model has been used for tendinopathy model. However, most of studies did not describe the precise protocols. We established proper injection volume and technique for collagenase induced tendinopathy model.

Material and Method

We injected type I collagenase to Achilles tendon of Eight-week old male Sprague-Dawley rats. We compared gross morphology and histologic findings according to injection volume, concentration, and injection technique.

Results

Injection of 62.5 units/ 10ul for each strip of two Achilles tendon strips, total 125 unit demonstrated homogeneous and adequate tendon injury. The homogeneity of tendinopathy was not improved with injection of > 125 unit. More than 10ul injection or blind injection without skin incision was not appropriate due to profuse leakage of injection materials. Injection of both strip in Achilles tendon made more homogeneous tendon damage than injection of one strip.
Fig 1. Control group. H&E staining of rat achilles tendon. Normal tendon fibrils are aligned.
Fig 2. H&E staining of single injection of 62.5UI for one strip. Injured one strip lost direction and tendon get thicker. Another strip was slightly affected and kept directional.
Fig 3. H&E staining of double injection of 62.5UI for each strip. Most of tendon area was damaged evenly and lost direction.

Conclusion
The injection with 10ul of 62.5UI collagenase type I for each strips of rat Achilles tendon under direct vision is effective way to make tendinopathy animal model. These precise techniques will be helpful in research fields of tendon injury and regenerative medicine.

THE EFFECT OF NEW ARTICULATED SPLINT IN PINCH STRENGTH IN DE QUERVAIN SYNDROME: A COMPARATIVE STUDY
Z. Nemati¹, M.A. Javanshir¹, H. Saeedi¹, F. Farmani², F. Ghorbani¹
¹Iran University of Medical Sciences, orthotics and prosthetics, Tehran, Iran
²Hamadan University of Medical Sciences, orthotics and prosthetics, Hamadan, Iran

Introduction/Background

For patients with De Quervain syndrome using thumb spica orthosis prescribing in acute stage of syndrome, is restricting. Many patients are dissatisfied with using the static hard design and find it difficult to perform their daily activities. The aim of this study is to compare the effect of modified articulated and conventional static orthoses on pinch power and functional abilities of hand in De Quervain syndrome.

Material and Method

In this quasi-experimental study, palmar and lateral pinch strength of the thumb, pain and functional abilities of hand, patient’s satisfaction of orthoses, were evaluated after using modified articulated and conventional static orthosis in two groups. 24 women between 18 and 60 years with De quervain syndrome were randomly allocated in two groups of treatment. The first group used conventional static orthoses and the second one utilized modified articulated design. During the period of treatment, patients were encouraged to do their daily activities just like before.
Results

Both orthoses improved palmar and lateral pinch strength of the thumb, pain level and functional abilities. In comparison of mentioned variables, there was no significant difference between two groups regarding to pain recovery and abilities improvement (p>0.05). However, the satisfaction level of the patients who had used the articulated orthosis was higher (p<0.05).

Conclusion

It seems, adding a joint to the static thumb spica leads to patient’s relief and consequently to their satisfaction. This study shows that static and modified articulated thumb spica orthoses were similar regarding to the effect on pain and functional abilities of the patients with De Quervain syndrome. However, according to the higher rate of satisfaction of the patients utilizing articulated orthosis, the use of new articulated design of orthosis is recommended instead of the conventional static model.

PSYCHOMETRIC QUALITIES CHANGES WHEN UPDATING A TEST: COMPARISON OF D2 AND D2-R NORMALIZATIONS IN A CLINICAL FRENCH POPULATION
F. Radiguer¹, C. Franconie²
¹Bicetre Hospital, ICU, Kremlin Bicetre, France
²CHU Nîmes, Réanimations Chirurgicale et Médicale, Nîmes, France

Introduction/Background

Updating psychometric tests is essential for neuropsychologists to correctly detect cognitive disorders in clinical practice. However, data concerning the usefulness of this update is often incomplete, and there is a lack of knowledge on the changes of psychometric qualities, especially with clinical populations.

The publication of the d2-R (Brickenkamp, 2015) by Hogrefe LTD incited us to compare this new normalization with the first standardization, still widely used, of this attention test (Brickenkamp, 1998).

Material and Method

We performed this comparison on a clinical population of 64 adult patients (median age 60.5 years [IQR: 49.5-69]) 4 months post ICU discharge, to whom we administered the d2 attention test.

We converted the results in standard scores according to both rating systems and normalizations. We then performed statistical analyzes with the R software, and compared the difference of scores distributions on two rating criteria, namely a quantitative criterion (GZ and CCT) and a criterion also taking into account the quality of answers (KL and CC).

Results

We found good correlations for both criteria, confirming data provided by the publisher. But the Wilcoxon test shows a significant difference between GZ and CCT percentiles distributions (w = 1256, p < 0.001), not for KL and CC percentiles (w = 1851, p = 0.35).

The results analysis shows a divergence in the pathological zone of the curves: 51.4% of patients who are classified as “significantly slow” in the former norms, are now considered having a normal speed using the new norms (figure 1), thus showing great disagreement for slow processing diagnosis.
Conclusion

Test publishers should provide more information on the clinical implications of their updates of psychometric tests, correlations cannot be sufficient to discuss sensibility and specificity changes.

AGE AND GENDER DIFFERENCES IN MOTOR IMAGERY

L. Subirats¹, G. Allali²,³, J.Y. Salle⁴,⁵, A. Perrochon⁴

¹ILFOMER-, Institut Limousin de Formation aux métiers de la réadaptation, Limoges, France
²Geneva University Hospitals and University of Geneva, Division of Neurology- Department of Clinical Neurosciences, Geneva, Switzerland
³Yeshiva University, Department of Neurology- Albert Einstein College of Medicine-, New Yord, USA
⁴University of Limoges, Laboratory HAVAЕ, Limoges, France
⁵Hôpital J. Rebeyrol- Limoges University Hospital, 3Physical and Readaptation Medicine, Limoges, France

Introduction/Background

This study aimed 1) to investigate the age- and gender-related effect on motor imagery (MI) in vividness and chronometry capabilities, and 2) to examine the relationship between these two dimensions of MI.

Material and Method

Seventy-two (47% of men) good imagers including 41 young subjects (mean±standard deviation (M±SD): 22.1 ± 3.1 years) and 31 older subjects (M±SD: 72.6 ± 5.4 years) were assessed on MI vividness using the revised version of the Vividness of Movement Imagery Questionnaire (VMIQ-2) and on the performances on the real Timed Up and Go (rTUG) test and its imagined version (iTUG). The main outcome variables were the VMIQ-2 score (each modality) and the delta-TUG (difference between realized rTUG and iTUG).

Results

Mental vividness was affected by aging with a loss of visual dominance in favor of kinesthetic imagery in older subjects compared to younger ones (p<0.05). rTUG and iTUG were performed faster in young than in old subjects, but no difference between the groups were found in chronometry measured by delta-TUG (p>0.05). Vividness capabilities were similar between men and women, but chronometry was better in women than men (i.e. shorter delta-TUG; p<0.05). VMIQ-2 scores were not associated with delta-TUG in the adjusted model, while only gender was significantly associated with delta-TUG.

Conclusion
This study was revealed 1) an age-related transfer from a visual to a kinesthetic MI ability, but no impact on mental chronometry; 2) a gender effect on mental chronometry without any impact on mental vividness; 3) no association between vividness and chronometry capabilities.

Introduction/Background

Verification of motor and cognitive load in DTI can show the cognitive or motor impact separately on the DT to consist the coping strategies for the daily performances.

Material and Method

Computerized 3 experiments of cognitive (CT), motor (MT) and dual tasks (DT) were randomly tested in participants. All participants (n=46) were educated to press the button 1 (BT1) during preparing period. In CT, participants should release the BT1 as fast as possible if congruent letters in meaning and color of letter (Go), or they should press the BT1 consistently if incongruent. In MT, participants should release the BT1 and then tap the BT2 10 times as fast as possible if intuitive “○” was presented (Go), or press the BT1 consistently if “×” was presented. In DT, the Go trials of MT were changed with those of CT. The reaction time (RT) of correct releases of BT1 in all tasks, the button shifting time between BT1 release and BT2 press, and finger tapping rate in MT and DT were also measured. Then the ratio of RT of CR in CT and MT over DT were calculated to represent the DTI.

Results

The ratio of RT of CR in CT (78.6±13.0%, \(P < 0.001\)), and MT (74.2±10.1%, \(P < 0.001\)) were significantly decreased compared to those of DT (100%). The button shifting time of MT was 92.0±23.7% of that of DT (\(P = 0.027\)), and the finger tapping rate of MT was increased up to 106.1±19.1% of that of DT (\(P = 0.036\)).

Conclusion

Significant decreases in ratio of RT of CR in CT and MT show the both residual cognitive load and preceding motor load. The ratio of button shifting time and finger tapping rate in MT shows the superimposed tapering residual cognitive load on motor task.

Introduction/Background

The neglect syndrome is frequently associated with neglect dyslexia (ND). ND is characterized by omissions or misread initial letters of words. In clinical settings, ND is usually assessed with “paper and pencil” tests. However, without controlling exposure time of items and patients’ response time, ND could be unnoticed.

Material and Method

Our computerized procedure consists of four tasks: a single word reading task, a lexical and a semantic decision task and a text reading task. In each task, the time exposure of the items is controlled and we measured both the errors and the participants’ response time. Twenty-eight brain-damaged patients, including 12 neglect patients, and 30 healthy neurological participants carried out this procedure.

Results

As expected, neglect patients produced more errors and are slower than brain-damaged patients and healthy volunteers and this especially during the single word reading task. This task shows 256 items: pseudo-words mixed with words (frequent or not, long or short) displaying in different ways (horizontal, vertical without anisometry or with a left or a right anisometry) with or without a spatial index. All this materiel permits error patterns to emerge according to the clinical state (neglect patients, brain-damaged patients or neurological healthy volunteers).

Conclusion

Our study aimed at proposing computerized tasks to help the diagnostic of neglect dyslexia. The neglect dyslexia could be observed with or without a severe neglect syndrome. In the case of a light neglect syndrome, having a computerized assessment is important in the ND diagnostic process especially as specific pattern have been observed based on the analyses of the error and the response time in the single word reading task.

VALIDATION IN HEALTHY SUBJECTS OF A CLINICAL PROTOCOL FOR THE EVALUATION OF FACIAL MICRO-EXPRESSIONS IN SEVERELY BRAIN INJURED PATIENTS AWAKENING FROM COMA

A. Bertholon\textsuperscript{1,2}, C. Arango Duque\textsuperscript{3}, O. Alata\textsuperscript{3}, R. Emonet\textsuperscript{3}, A.C. Legrand\textsuperscript{8}, H. Konik\textsuperscript{3}, P. Giraux\textsuperscript{1,2}

\textsuperscript{1}University Hospital of Saint-Etienne, Physical Medicine and Rehabilitation, Saint-Etienne, France
\textsuperscript{2}Univ Lyon- UJM-Saint-Etienne, Laboratoire interuniversitaire de biologie de la motricité- EA 7424, Saint-Etienne, France
\textsuperscript{3}Univ Lyon- UJM-Saint-Etienne- CNRS, IOGS- Laboratoire Hubert Curien, Saint-Etienne, France

Introduction/Background

Brain injured patients awakening from coma have a severe impairment of emotional facial expressions. Despite this impairment, very weak and brief facial expressions, called facial micro-expressions (FME), may persist whereas complete facial expressions are imperceptible. To test this hypothesis, we developed a complete system (device and method) to stimulate and analyze FME. We report here the validation of this system in an acute care unit environment with healthy subjects.

Material and Method

Eight healthy subjects were recorded in an intensive care unit. The multimodal stimulation paradigm consisted in 4 conditions acquired in distinct runs: no stimulation (control of spontaneous expressions), visual (PI), auditory (SO) and tactile (TA) stimulations. Each run lasted about 5 min, made of 6 random blocks of stimuli. To elicit FME, healthy subjects were asked to suppress their facial movements. Video were recorded with a high speed high resolution optical camera. Motion magnification was performed using Riesz pyramid algorithms. Native video (NV) and Magnified video (MV) were separately analyzed.

Results

On average, more than 9 FME per block of stimulation (intrablock FME rate) were detected in NV and MV. There was no statistical difference between NV and PV. The average duration of FME was 251,32 ± 87,24 ms. FME were also detected at a lower rate during the no stimulation run or the interblock periods (p=0,026 for intrablock versus interblock comparison). The intrablock FME rate was higher for PI (11,2) and SO (13,8) than for TA condition (5,3).

Conclusion
This study validate in healthy subjects the feasibility of this system to elicit and detect FME in a noisy (intensive care unit) environment. Following this validation, severely brain injured patients in coma condition will be repetitively recorded during their awakening period.

EXAMINATION OF VALIDITY AND RELIABILITY FOR PROTOTYPE SCALE TO ASSESS ACHIEVEMENT MOTIVE IN COMMUNITY-DWELLING HEALTHY OLDER ADULTS
N. Sano
1International University of Health and Welfare, School of Rehabilitation Sciences at Fukuoka, Okawa City, Japan

Introduction/Background

Long-term care prevention is an important issue, particularly given the rapidly growing aging society. For rehabilitation, an achievement motive defined as “the intention to achieve one’s goals while maintaining a standard of excellence” has been used as a means of assessment and intervention. The purpose of this study was to examine the validity and the reliability for a prototype scale for achievement motive in geriatric (P-SAMG) based on a scale for achievement motive in rehabilitation.

Material and Method

A cross-sectional study was conducted to measure the P-SAMG, which has been accepted content validity by 8 experts, classification and assessment of occupational dysfunction (CAOD) and comprehensive environmental questionnaire for the elderly (CEQ) in 238 older adults (average age: 76.1 ± 7.2) who participated in senior clubs. The factorial validity of P-SAMG was examined using exploratory structural equation modeling (ESEM) and a confirmatory factor analysis (CFA), the concurrent validity was assessed using correlative analysis, and the internal consistency reliability was assessed by calculating Cronbach’s alpha coefficient. This study was approved by the Ethical Review Board of Kibi International University and written consent was obtained from all the participants. This research was supported by JSPS KAKENHI Grant Number JP17H07288.

Results

ESEM presented good factor loadings (first factor of item 1–5: 0.93–0.56, the second factor of item 6–10:0.95–0.54) and the CFA presented adequate fit indices. Moreover, P-SAMG indicated a moderate or low correlation with CEQ (0.42–0.20) and a partially low correlation with CAOD (−0.20 to −0.29). Cronbach’s alpha coefficient demonstrated a sufficient value for two factors and the whole scale (0.89–0.94).

Conclusion

These results demonstrated that P-SAMG is useful in the assessment of achievement motives for older adults without rehabilitation service. Management of material or personal environment
and appropriate occupational engagements was suggested as a valid strategy to improve motivation in this population.

EFFECTS OF UNSTABLE FOOTWEAR ON GAIT CHARACTERISTIC: A SYSTEMATIC REVIEW

Z. Nemati¹, M. farzadi¹, R. Sheikhy doulagh¹, M. Jalali¹, M. Kamali²
¹Iran University of Medical Sciences, orthotics and prosthetics, Tehran, Iran
²Iran University of Medical Sciences, Management, Tehran, Iran

Introduction/Background

Over the last three decades, several designs of unstable footwear have been developed in the forms of shoes, sandals and boots. There are marketing claims related to the positive effects of these shoes on the training of lower limb muscles and improving gait. Many studies have been performed on the effects of unstable footwear on muscle activity, balance, posture, energy expenditure, lower extremity disorders, and bio-mechanical changes. The objectives of this study is to systematically review available evidence on the use of unstable footwear on kinetic and kinematic parameters to make specific recommendation for practice and future studies.

Material and Method

A computer-based search was undertaken through PubMed, Cochrane Library, Embase, PEDro, Web of Science and Google Scholar from 2005 to 2015. The included studies were appraised using McMaster Critical Review Form for Quantitative Studies.

Results

Ten studies (quasi-experimental design) were included (Table 1). A summary of the McMaster scores for each paper can be found in Table 2. All included articles scored moderate to high on McMaster critical appraisal tool. Statistically significant changes from wearing unstable footwear in chosen studies are available in (Table 3). Seven studies compared MBT with regular or running shoes and two investigated differences between unstable and stable sandals. Just one study collected barefoot variables and compared it with stable/unstable shoes. Two studies set a consistent gait speed of 5 km/h and in seven studies the participants were allowed to self-select their gait velocity. One study did not report any details about test condition.

PRELIMINARY DATA OF A NEUROSELECTIVE STUDY OF SENSORY PATHWAYS IN SPINAL CORD INJURED (SCI) PATIENTS

M. Zarbo¹, M. Spinelli¹, A. Leo¹, M.G. Ricchiuti¹, L. Frediani¹
¹ASST Grande Ospedale Metropolitano Niguarda, Unità Spinale Unipolare, Milan, Italy

Introduction/Background

Analyze the integrity of sacral area sensory pathways in all its components (Aβ, Aδ and C fibers). We evaluated the relative activation state of each single fiber and correlated these data with the clinical conditions, especially the AIS (American spinal cord injury association Injury Score), to define the grade of SCI completeness.

Material and Method

We examined 25 patients affected by acute post-traumatic SCI and admitted between June 2015 and 2016. Lesion level: 10 quadriplegic (all incomplete) and 15 paraplegic patients (8 complete, 7 incomplete); average age 36.2y (12-71); time between traumatic event and evaluation <1y. Examination: AIS grading; evaluation of sensory fibres with the technological device Neurometer®; we analysed the pudendal nerve (Penis Dorsal nerve in male and Superficial Perineal nerve in female).

Results

In 3 of the 8 AIS A patients we found out a residual activity of sensory fibres (normal activity of C fibres and inactivity of Aβ fibres) showing a discrepancy in AIS score between clinical and instrumental findings (discomplete lesions). Accidentally we found out that this typical sensory fibres activation pattern (observed in 13 of 25 patients) was also associated with non-responder, high-grade neuropathic pain (NRS 8-10/10).

Conclusion

The presence of a discomplete lesion could lead to a different rehabilitation programme; early identification of patients presenting a typical fibers activation pattern associated with neuropathic pain could give us the opportunity to design a tailored therapy before the onset of chronic pain and overactivities; could the neuromodulation of inactive Aβ fibers be a new therapeutic target?

Quantitative Ultrasound of Trapezius Muscle Involvement in Myofascial Pain: Comparison of Clinical and Healthy Populations Using Texture Analysis

D. Kumbhare¹, S. Shaw², S. Ahmed², M. Noseworthy³
¹University of Toronto/ Toronto Rehabilitation Institute, Department of Medicine, Toronto, Canada
²McMaster University, Psychology, Hamilton, Canada
³McMaster University, Biomedical Engineering, Hamilton, Canada

Introduction/Background

Myofascial pain syndrome (MPS) diagnosis is currently a source of contention amongst clinicians. Physicians, chiropractors, and registered massage therapists do not agree on the criteria they deem diagnostic of MPS. Ultrasound imaging is widely used in medicine to qualitatively identify anatomical structures and lesions. Quantitative ultrasound methods such as texture features have been used to characterize normal and pathological tissue in muscular disorders. We propose that quantitative ultrasound imaging techniques can be used to differentiate muscle with myofascial pain diagnosis from healthy controls. Therefore, we assessed whether texture features could differentiate upper trapezius muscle in patients with MPS relative to healthy participants.

Material and Method

We collected B-mode ultrasound images of the upper trapezius muscle in 15 healthy participants and 17 patients with MPS. The following texture features were extracted from the images: blob area, blob count, and 10 local binary patterns (LBP) (Figure 1). A principal components analysis (PCA) was performed to reduce the features to those that accounted for the most variability in the images (Table 1). A MANOVA was then performed to determine whether healthy or MPS group membership could be differentiated by the reduced features (Table 2).
Figure 1: The B-mode Ultrasound grayscale image of the upper trapezius muscle (panel a). Panel (b) shows the selected region-of-interest for the blob analysis. The first round of identified blobs that have echo intensities outside the specified range is given by panel (c). These blobs are filtered on the basis of their size using the specified area threshold. Those residual blobs (shown in panel (d)), are counted and measured.

</tr>
<tr>
<td>Cumulative variance</td>
<td></td>
<td>92.55%</td>
</tr>
</tbody>
</table>

Table 1: Rotated Component Solutions
Results

The PCA identified two components that accounted for 93% of the variability. Features with the highest loading factors included: LBP2, LBP6, LBP10, blob area, and blob count. All features but blob area could statistically differentiate healthy from myofascial pain groups (p<0.001).

Conclusion

Texture features are capable of differentiating muscle tissue in patients with MPS relative to healthy individuals. These findings may be used to develop an accurate diagnostic tool for clinicians to diagnose patients with MPS.

ASSESSMENT OF THE BLOB AREA AND ECHOINTENSITY RELATIVE TO SUBCUTANEOUS ADIPOSE THICKNESS IN ULTRASOUND IMAGES OF THE UPPER TRAPEZIUS IN PATIENTS WITH MYOFASCIAL PAIN

D. Kumbhare¹, S. Ahmed², M. Behr¹, S. Sikdar³
¹University of Toronto/ Toronto Rehabilitation Institute, Department of Medicine, Toronto, Canada
²McMaster University, Psychology, Hamilton, Canada
³George Mason University, Electrical and Computer Engineering, Fairfax, USA

Introduction/Background

Myofascial pain is a chronic pain disorder that affects 85% of the general population at least once in their lifetime. Individuals with myofascial pain show patterns of deconditioning, which is associated with weight gain, loss of muscle strength, and increased intramuscular adipose. The area of regions with homogenous echointensity (blob area) in ultrasound images has been previously used to characterize proportions of contractile and non-contractile tissue within muscle. Therefore, the objective of this study was to assess the association between subcutaneous adipose thickness and the echointensity within the blob and size of the blob areas.

Material and Method

Blob echointensity, blob area, and subcutaneous adipose thickness were extracted from twenty-nine ultrasound images of the upper trapezius from healthy participants, nineteen from patients with latent myofascial pain, and twenty-one from active patients. Linear regressions between echointensity and blob area were computed, controlling for adipose thickness within each group. A k-means cluster analysis was performed on blob echointensity, blob area, and adipose thickness within each group to assess for patterns.

Results

There was a significant association between echointensity and blob area while controlling for fat thickness in healthy, latent, and active participants (table 1 & visual representation figure 1). The association between fat thickness and echointensity or blob area was significant but very small (r <0.055). The k-means cluster revealed 3 clusters within each participant group that differed at the third cluster between groups.

</tbody>
</table>

Table 1. Correlations between blob echointensity and blob area controlling for subcutaneous adipose thickness

Figure 1: Visual representation of blob area and mean echo intensity in A) healthy B) latent C) active groups
Conclusion

There seems to be a pattern of larger blob areas with lower echointensity in the muscle images as they progress between healthy to latent to active, that is not associated with fat deposition. This enlarging region may represent non-contractile regions with the muscle associated with the pathophysiology of myofascial pain such as inflammatory exudate.

Keywords

musculoskeletal conditions; diagnosis of neurological; musculoskeletal and movement related functions

No conflict of interest
Introduction/Background

Chronic widespread pain affects almost 11.4-24% of the general population. Central sensitization (CS) is thought to be the mechanism underlying chronic pain. The goal of this study was to determine whether ultrasound texture features (statistical measure of echointensity patterns) can differentiate chronic pain patients with varying degrees of CS, as our previous work has shown that texture features can differentiate patients with myofascial pain.

Material and Method

Thirty patients with chronic widespread pain that fulfilled the 2016 fibromyalgia diagnostic criteria were included in the study. Patients completed the CS inventory, a questionnaire that indicates the degree of CS—mild, moderate, severe, and extreme. Patients’ upper trapezius muscle was then imaged using B-mode ultrasound. Ninety-one texture features were extracted from the acquired images, and a principal components analysis (PCA) was performed to reduce the features into components that accounted for a large proportion of the variability among the images. A MANOVA and post hoc analyses were then performed on the features with the top three loading factors to determine whether they could differentiate patients with mild, moderate, severe, or extreme central sensitization.

Results

The PCA identified eight components that account for 95% of the variability among the images. The MANOVA and post hoc analyses revealed that all extracted features could differentiate between two or more of the groups, and twelve variables could specify group membership (table 1 & a visual representation in figure 1).
### Table 1: MANOVA results that differentiate between the groups.

QUANTITATIVE ULTRASOUND USING TEXTURE ANALYSIS OF MYOFASCIAL PAIN SYNDROME IN THE TRAPEZIUS
S. Ahmed¹, M. Behr¹, M. Noseworthy², D. Kumbhare³
¹University Health Network, Toronto Rehabilitation Institute, Toronto, Canada
²McMaster University, Biomedical Engineering, Hamilton, Canada
³University of Toronto, Medicine, Toronto, Canada

Introduction/Background

Myofascial pain syndrome (MPS) is a prevalent pain disorder characterized by myofascial trigger points (MTrP), which are stiff contracted regions within a taut band of muscle. Clinically MTrPs can be differentiated in two groups, latent and active. Active MTrPs induce spontaneous pain whereas latent MTrPs do not. Clinicians disagree on the criteria that differentiate active and latent MTrPs, necessitating an objective method for their differentiation. Our previous work has shown that ultrasound texture features can differentiate between patients with MPS and healthy individuals in the upper trapezius muscle. The objective of this study was to determine whether ultrasound texture features can differentiate between active MTrPs, latent MTrPs, and healthy individuals in the upper trapezius muscle.

Material and Method

We collected B-mode ultrasound images of the upper trapezius muscle from 18 latent, 19 active, and 24 healthy participants. Ninety-two Haralick, Galloway, and histogram related texture features were extracted from the images. A principal components analysis (PCA) was performed to reduce the features into components that accounted for the most variability among the images (Table 1). A MANOVA and post hoc analyses were then performed to determine whether healthy, latent, or active group membership could be differentiated by the reduced factors (Table 2).

Table 1: A summary of the components and the highest ranked three features.
Results

The PCA identified eight components that explain 95% of the variability in the images. The features with the three highest loading factors in each component were included in the MANOVA, for a total of 23 features. All features could differentiate between at least two of the latent, active, or healthy groups.

Conclusion

Ultrasound texture features can differentiate between upper trapezius tissue in patients with active and latent MTrPs, and can differentiate these clinical groups from healthy tissue. Ultrasound should be further explored as a clinical diagnostic modality for differentiating MPS patients.

³ULPGC, Ciencias Básicas, Las Palmas de GC, Spain

Introduction/Background

Neck pain is one of the most common reason of consultation in Rehabilitation, especially after traffic accidents. Apart from pain, there are a number of symptoms that usually accompany the pain, like restricted of mobility, headache and dizziness. Of these, the only objectivize factor is restriction of mobility.

Werium dispositive is an evaluation system to capture patient movements. It can quantify the range of movement in all axes. Moreover, it also can quantify the variability of movements, providing valuable input about veracity and patient’s cooperation. It is not a diagnostic test, it is a tool to support the patients diagnosis.

The aim of this work is to demonstrate that WeriumÒ dispositive can provide useful information for designing the most effective method of intervention in patients with neck pain.

Material and Method

A prospective, analytical and observational study. All patients with neck pain diagnosed in any of Medical Rehabilitation Centre of ICOT group were selected.

All patients were evaluated by the doctor and physiotherapist and divided into two groups. Control groups received the common treatment, based on trigger point treatment. Intervention group received a specific treatment routed to improve range of motion.
Results

A group of patients were discarded because they were uncooperative. All patients of both groups improved the measurement in the range of movement from the first ten physiotherapy sessions. The intervention group obtained more improvement in the specific range that was individually treated, but we did not have enough patients to draw statistically significant results, we must to increase the sample size. A calibration problem was founded in one dispositive and it was solved on the go.

Conclusion

Werium dispositive could be a successful tool for designing more effective intervention’s methods in patients with neck pain, further studies are needed to follow up theses promising results.

There can be several reasons for the lack of communication or delayed speech development: damage in the CNS, autism, social or audiological or psychological problems. After finding out about the causes - during the rehabilitation - with the use of music therapy I promote and create the environment, where non-verbal and verbal communication begins and is achieved. It is of vital importance to enable the child to express themselves, to get in touch with others and understand others, irrespective of the causes hindering these activities. By using music one can express ideas without the limitations of speech, and this is how music becomes the tool of communication.

As for the therapy, it gives the opportunity for us to start working in a pre-speech or without-speech environment. Communication can take place without the active participation of the communication partner or without their intention to participate, e.g. seriously injured people: by musically reflecting and following their movements, mimics and body postures. The symbolism of musical instruments and sounds enable music to improve communication and following pre-verbal communication, speech can start to develop.

Another vital field of the application of music therapy is forwarding emotional contents and messages, actualising feelings.

All these can be the starting points and the beginnings of healing processes of overcoming conflicts and traumas: it reduces anxiety and releases hindrance. Music crosses boundaries by acting as a medium between two players, creating a mutual third party. An important feature of music in therapy is activity, emotional participation, joint experience and going through catharsis. It is not seeking after definite results; technical perfection is neither a condition, nor an objection.

DOES THERAPEUTIC EDUCATION OPTIMIZE THE REHABILITATIVE MANAGEMENT OF HEMOPHILIAC PATIENTS?
H. Aboura¹, S. Dr Ammor¹, A. Dr Sehimi¹, K. Dr Tayebi²
¹Centre Hospitalo-Universitaire Dr HASSANI Abdelkader, Service de Médecine Physique et de Réadaptation, Sidi-Bel-Abbes, Algeria
²Centre hospitalo-Universitaire Dr HASSANI Abdelkader, Service d'Hématologie, Sidi-Bel-Abbes, Algeria

Introduction/Background

Hemophilia is a hemostatic disorder that causes hemorrhages in the joints and muscles. Physical exercise is often put in place to facilitate convalescence after bleeding, and to improve joint function in the presence of arthropathy.

An Implementation of a personalized therapeutic education program (TEP) for the hemophiliac patient to help them acquire and maintain skills to improve their quality of life and prevent the complications inherent in the disease. Sensitization, information and learning sessions concerning illness, treatment, physiotherapy and self-education were planned and organized in collaboration with fellow hematologists.

Objective: To assess the contribution of TEP in improving hemophilia patient’s knowledge about disease management and prevention of comorbidities.

Material and Method

12 hemophilia patients participated in TEP sessions. Sessions were individual or collective provided by a multidisciplinary team. The educational tool is represented by slides, videos containing information (Arabic and French), diagrams and images.

A summary booklet of the main simplified self-exercises to be performed at home and the frequency of their achievement was provided to each patient in order to improve observance and adherence to the program.

Results

12 adult hemophiliacs: - 11 patients with hemophilia A (10 cases of severe hemophilia and 01 case of minor hemophilia), - 01 case of severe hemophilia B; the average age of patients is 30.67 years with extremes of 17 and 40 years. 100% of patients were unaware of the importance of self-rehabilitation exercises. 80% were unaware of the risk of the disease’s complication. 60% did not know the importance of rehabilitation in improving life quality. 50% were unaware of the precautions to take in case of acute bleeding.
Conclusion

The TEP is considered as an essential element in the management of hemophilic patients, but currently remains a very marginal approach in the care process, hence the interest of integrating it into our therapeutic arsenal.

⁴Chi Mei Medical Center- Tainan- Taiwan, Department of Physical Medicine and Rehabilitation, Tainan, Taiwan R.O.C.

Introduction/Background

Thyroid storm is a medical emergency characterized by decomposition of one or more organ systems. Associated cardiac involvement carries poor prognosis. Patients with thyroid storm complicated by decompensated heart failure have higher overall morbidity and mortality rates. Cardiopulmonary rehabilitation can enhance lung ventilation and activity endurance.

Material and Method

We collected his history, physical assessment, nursing care with physical activity, and performed literatures review.

Results

This paper described the nursing experiences of caring for a 33 y/o male patient with thyroid storm complicated by decompensated heart failure during ventilator weaning at our intensive care unit. The caring period was from May 8, 2017 to July 1, 2017. During the hospitalization, nursing records, medication, fluid intake, vital signs and peripheral edema were used as indicators to assess the improvement of heart failure symptoms. Systematic execution of cardiopulmonary rehabilitation in conjunction with dietary and medical therapy was given to progressively enhance the patient’s cardiopulmonary functions. During this period of hospitalization, we provided physical activities, with individualized rehabilitation program and maintaining support system to help him wean off the ventilator. The patient had successfully wean off the ventilator and was extubated on June 23, 2017. He was later transfer to the
general ward on July 1, 2017. After education of next phase cardiopulmonary rehabilitation and cardiologist follow-up, he was discharged home on August 4, 2017.

Conclusion

Hyperthyroidism and thyroid storm affect cardiac circulation. Cardiopulmonary rehabilitation, especially exercise-based rehabilitation, is a crucial strategy to improve activity tolerance in heart failure patients. Exercise-based rehabilitation can be applied to increase functional capacity, delay the progression of disease and reduce re-admission rate or mortality rate. We wish to share our nursing experience as a reference for peers when facing similar cases.

³TEI of Central Greece, Physiotherapy, Lamia, Greece

Introduction/Background

Impedance tomography is a modern method for real time monitoring of the air distribution during lung ventilation, as it can record the changes of lung impedance during breathing and via a mathematical processing creates a visual image representing the changes of lung ventilation. The aim of this study is to record the percentage distribution of lung ventilation in healthy subjects, in several positions. The results of this study can be used for explaining the fluctuations of oxygenation in cases such as bronchial drainage or for the interpretation of pulmonary ventilation in pathological cases such as scoliosis.

Material and Method

Eight young, non-smoking, healthy volunteers, without a previous respiratory disease, were monitored by impedance tomography. They were placed in the following positions: Sitting, Supine, Trendelenburg, Right Side Lying, Left Side Lying, Prone, Semi-Fowler's position 30°, Semi-Fowler's position 45°, Right Trunk Rotation and Left Trunk Rotation. The recorded data were used to compare the percentage of the air distribution between the anterior and posterior thoracic segment and between same lung (right or left) of each object in each position.

Results

The anterior-posterior percentage of the air distribution during lung ventilation did not show any remarkable changes in any position and in any angle of head elevation of the bed, while statistically significant differences were detected comparing the percentage of the air distribution in each lung on the lateral decubitus positions and on the trunk rotations (Mean±SD: 9 ±3.85 p=<0.001, 9.25±4.73 p=0.001 respectively)
Conclusion

In normal healthy young individuals, head elevation of the bed does not have any impact on the regional lung ventilation. On the contrary the side lying positions seems to favor the dependent lung and the trunk rotation appears to compress the same to the rotation side lung, with a significant impact on its ventilation.

THE INFLUENCE OF COOLING DOWN EXERCISE AFTER STEADY LOADING EXERCISE AT THE ANAEROBIC METABOLIC THRESHOLD INTENSITY ON AUTONOMIC NERVOUS ACTIVITY

T. Ujikawa¹, T. Koga¹
¹Kawasaki University of Medical Welfare, Department of Rehabilitation, Kurashiki, Japan

Introduction/Background

Cooling down exercise is known to promote the recovery of the internal homeostatic condition, and the exercise intensity of 50–75% of the anaerobic metabolic threshold (AT) is reportedly effective in removing lactic acid from the blood. This study aimed to determine the suitable intensity of cooling down exercises after steady loading exercise at the AT for recovering autonomic nervous activity using heart rate variability analysis.

Material and Method

A cardiopulmonary exercise test using a cycle ergometer was conducted to calculate the AT using the V-slope method in 10 healthy adult men (age, 22.0 ± 5.1 years). At least 2 days after the test, subjects performed exercises using the ergometer for 20 min at the AT intensity. Then, they were asked to perform cooling down exercises at 50% (50CD) or 75% (75CD) of the AT level for 10 min. Wireless electrocardiograms were continuously recorded during the exercise, and autonomic nervous activities were assessed based on heart rate variability. High-frequency components (HF) were used as an indicator of parasympathetic nervous activity.

Results

The average value of HF before exercise was 704 ± 161 ms², and the value during exercise significantly decreased to 123 ± 30 ms². These values, just after 50CD and 75CD, were 571 ± 207 ms² and 223 ± 75 ms², respectively. Significant differences were not observed between HF values before exercise and after 50CD, however, the HF value after 75CD was significantly lower compared to the HF value before exercise (p < 0.001).

Conclusion

Cooling down exercises at 50% of the AT level for 10 min was shown to be effective for the recovery of the parasympathetic nervous activity. Moreover, it was suggested that cooling down exercises at 75% of the AT level involved excessive movement for autonomic nervous activity recovery.

Cough strength is important for airway clearance. Some studies have shown that poor cough strength is a risk factor for extubation failure in patients receiving mechanical ventilation. Cough peak flow (CPF) is often measured for evaluation of voluntary cough strength. It has been reported that CPF is higher in the sitting position than in the supine position. However, it is unclear whether the difference of position on the bed such as supine position and prone position would influence CPF. Therefore, the purpose of the present study was to investigate the difference of voluntary cough strength in some positions on the bed in the healthy subject.

**Material and Method**

We measured CPF, chest circumference at maximal inspiratory level, chest circumference at maximal expiratory level, blood pressure and pulse rate in three positions, that is, supine position, prone position and prone position with a pillow under abdomen. We calculated the difference between chest circumference at maximal inspiratory level and that at maximal expiratory level, and defined it as the thoracic expansion difference.

**Results**

The subjects of this study were 50 normal adults. The CPF, chest circumference at maximal inspiratory level and chest circumference at maximal expiratory level were significantly higher in prone position with a pillow under abdomen than in supine position. There were no differences in the thoracic expansion difference and blood pressure among three positions. Pulse rate was significantly higher in prone position and prone position with a pillow under abdomen than in supine position.

**Conclusion**

This study suggests that voluntary cough strength would increase in prone position with a pillow under abdomen.

IS SUBCLINICAL HYPOTHYROIDISM LINKED TO LOWER FUNCTIONAL OUTCOMES MEASURED BY FUNCTIONAL INDEPENDENT MEASURES (FIM)?

L. Lan¹, Y.A. Chou²
¹The Prince Charles Hospital, Geriatric and Rehabilitation Dept., Brisbane, Australia
²The Royal Brisbane Hospital, Internal Medicine, Brisbane, Australia

Introduction/Background

Subclinical hypothyroidism (SCH) is a common finding in the cohort of rehabilitation patients. However, there is no reported study on how this population performs in the rehabilitation setting. We hypothesized that patients with SCH may have lower level of rehabilitation gains. The aims of this study are to: (1) quantify the incidence of subclinical hypothyroidism in rehabilitation patients; (2) review functional outcomes of patients with subclinical hypothyroidism; (3) seek correlation between the level of thyroid function and rehabilitation outcomes.

Material and Method

This was an observational retrospective cohort study of all patients receiving rehabilitation over 2 years from Jan 2015 till Dec 2016. Quantitative data were based on thyroid function tests at admission, Chart audits, and Functional Independent Measures (FIM). Data analysis involved an unpaired t-test and logistic linear regression.

Results

Overall, 653 patients (306 M and 347 F) were included in the study with a mean age of 74 (±12.8). While 553 patients had a Thyroid Stimulation Hormone (TSH) within normal limits, 100 patients were found to have an abnormal TSH, of which 81 presented with SCH (TSH 4.6~19.9), 5 with profound hypothyroids (TSH ≥ 20) and 14 with hyperthyroidism (TSH ≤ 0.2). The incidence of SCH was 12.4%. All patients with SCH had improvement in function with an FIM gain 26.9 (±19.6), compared to 23.8 (±18.9) of those patients with normal TSH. The efficiency of rehabilitation was similar in both groups. An interesting finding of note was that those with hyperthyroidism had low FIM scores at both admission and discharge however there was no significant difference in rehabilitation efficiency from other groups. There was no significant difference in length of stay across all groups.

Conclusion

All patients with SCH have obtained functional gains following rehabilitation treatment. Those with hyperthyroidism have lower FIM scores with the efficiency of rehabilitation being similar in all groups.

Introduction/Background

Body Mass Index (BMI) is the one method to determine cardiovascular risk which is the common cause of death in spinal cord injury. Previous study reported that patient with spinal cord injury had lower total lean mass and higher total fat mass than the normal person with the same body mass index. Therefore, this study aimed to develop and validate equation for predicting percentage body fat in spinal cord injured patient.

Material and Method

Cross-sectional descriptive study was conducted among sixty paraplegic patients for development group and 31 paraplegic patients for validation group. Demographic data including body weight, height and body mass index (BMI) were retrieved. All patients were evaluated percentage of body fat (%BF) using Dual Energy X-ray Absorptiometry (DXA). Regression equation for %BF was created from the data in development group. After that, the equation was evaluated for accuracy in the validation group.

Results

Only BMI showed significantly correlated with %BF (p<0.001). The suggested equation by stepwise multiple regression analysis was: %BF = (1.477 x BMI) – 0.091 (R² = 0.396, p< 0.001).

When the equation was validated in the validated data group, the correlation coefficient of the predicted and DXA-measured %BF was r=0.704 (p=0.003). Bland and Altman analysis showed mean differences -1.49% with the limits of agreement ranged from -18.6% to 15.6%.

Conclusion

This study suggested the simple equation which might be helpful for evaluation of percentage of body fat in spinal cord injured patients.

KINEMATIC ANALYSIS OF THE MOVEMENT OF THYROID CARTILAGE AND HYOID BONE DURING SWALLOWING
Y.J. Ra¹, S.H. Han¹, K.H. Lee¹, T.K. Kim², M.S. Chung³, J.S. Jang⁴
¹Hanyang University Medical Center, Department of Rehabilitation Medicine, Seoul, Republic of Korea
²Chungdam Hospital, Department of Rehabilitation Medicine, Seoul, Republic of Korea
³Hanyang University Medical Center, Department of Surgery, Seoul, Republic of Korea
⁴Kyushu University,
Center for Integration of Advanced Medicine Life Science Innovative Technologies, Kyushu, Japan

Introduction/Background

The movement of hyoid bone has been reported to be related in diagnosing dysphagia. In clinical setting, it could be evaluated by video fluoroscopic swallowing study (VFSS) that induces radiation exposure. In contrast with hyoid bone, the thyroid cartilage is easily seen through anterior neck. We hypothesize that the movement of thyroid cartilage correlates with that of hyoid bone and can be used as a parameter for swallowing evaluation. The purpose of this study is to investigate if the movement of thyroid cartilage and hyoid bone is correlated and to collect basic data for using thyroid cartilage as a parameter for swallowing evaluation.

Material and Method

Total 25 subjects' VFSS images with normal swallowing function were analyzed by specially developed software. Positions of laryngeal prominence and margin of the hyoid were automatically extracted. Two sets of the loci were obtained in all frames of VFSS. X- and Y-coordinates showed anterior-posterior axis and superior-inferior axis. Pearson correlation coefficients for X- and Y-coordinate components were computed respectively.

Results

X- and Y-coordinates of thyroid cartilage and hyoid bone moved in a similar pattern. Pearson correlation coefficient of X- and Y-coordinate components was from 0.611 to 0.981 which meant movement of thyroid cartilage and that of hyoid bone was strongly correlated.

Conclusion

We could analyze the movement of thyroid cartilage and hyoid bone by specially developed software and concluded that the movement of thyroid cartilage and hyoid bone was strongly
correlated. This study implies that analysis of thyroid cartilage can be used as a parameter for swallowing evaluation.

ISPR8-1774
PREVALENCE AND MANAGEMENT OF URINARY TRACT INFECTION IN AN INPATIENT REHABILITATION UNIT
C. Shippen¹, H. Osman¹
¹The Walton Centre NHS Trust, Rehabilitation Medicine, Liverpool, United Kingdom

Introduction/Background

Urinary tract infections (UTIs) are a regular complication in rehabilitation units due to impaired mobility, neurological conditions, catheters and constipation. National Institute of Clinical Excellence (NICE) released guidelines for management urinary tract infection in 2015; key aspects include treatment for UTIs, indications for investigation and requirement for urology referral.

Aim is to review prevalence of UTIs in a rehabilitation unit, compare management with national and local guidelines and to compare with data from 2015 to establish if there has been improvement.

Material and Method

Retrospective study of admissions Jan 2017-Dec 2017 identifying patients treated for UTI or urosepsis during inpatient stay. Data compared with previous audit in 2015.

Results

54 admitted in 2017, 26% (14/54) were treated for UTI. This is an improvement from 35% in 2015.

64% (9/14) female

Most common organism e.coli (7/14), other organisms’ isolated pseudomonas, coliform and klebseilla.

21% (3/14) recurrent UTIs, 2 had ultrasound of renal tract and referral to urology as recommended. One had a neurogenic bladder with urinary retention. Another had renal calculi. The third with recurrent UTIs did not receive further investigation.

28% (4/14) had persistent bacteriuria, only 1 was referred to urology, although this is recommended by NICE.
21% (3/14) had catheters and were treated for urosepsis. In 2015, 40% patients with UTI had a catheter.

2 were immunosuppressed; all were on laxatives for constipation.

42% (6/14) were treated in accordance with local protocol: nitrofurantoin or trimethoprim. Other were treated as per sensitivities or in discussion with microbiology.

Conclusion

A reduction from 35% to 26% of patients treated for UTI during inpatient rehabilitation. Also a reduction in those with a catheter associated UTI, and supports our strategy of early removal. Indications for further investigation and urology referral need to be considered, including persistent bacteriuria. Most patients as expected had risk factors for UTI. All were treated appropriately.

³Hôpital d' Instruction des Armées Clermont Tonnerre Hia, Department of Radiology, Brest, France
⁴CHRU Brest, Pediatric Physical Medicine & Rehabilitation, Brest, France

Introduction/Background
Assessment of muscle sizes, shapes and changes over time have significant clinical and research implications in rehabilitation. The aim of this study was to report the evidence of metrological properties for methods quantifying skeletal muscle volumes and 3D shapes using MRI.

Material and Method
A systematic review was conducted. Pubmed, web of science, Cochrane, Scopus databases were searched using relevant keywords and inclusion/exclusion criteria. A customized scale was used to evaluate the articles quality.

Results
Thirty articles were included. Six involved pathological subjects. Manual, and partially or completely automatic methods were respectively assessed in 24 and 10 articles. Manual slice-by-slice segmentation reliability was good to excellent (8 articles), its validity against dissection was good (1 article). It was used as a gold standard in the other articles. Reduction of the number of manually segmented slices increased the volume error (6 articles). With methods using one slice with or without muscle length, volume errors were between 4.8% and more than 20% (11 articles). Depending on the slice(s) chosen for these techniques, the error varied. Regarding partially or completely automatic methods, use of a method based on the deformation of a parametric specific object with manual segmentation (DPSO) (5 articles) decreased the number of manually segmented slices for a chosen error. Other automatic methods associated different techniques (statistical shape, atlas/images based) (4 articles), with validity evaluated in one article for each. Reliability data were lacking for all the techniques except manual slice by slice segmentation.

Conclusion
In healthy populations, errors in volumes and shape estimations increased with the simplification and shortening of the methods for manual segmentation. Automatic segmentation techniques were promising but metrological evidence was lacking except for DPSO. These data will help in choosing the appropriate segmentation techniques for measuring muscle properties for treatments responses and diseases progression evaluation in rehabilitation.

DIAGNOSIS AND REHABILITATION OF LOCOMOTOR FUNCTION OF CHILDREN WITH CEREBRAL PALSY BASED ON BIOMECHANICAL CONTROL
K. Davletyarova1, L. Kapilevich1
1Tomsk Polytechnic University, Division for Physical Education, Tomsk, Russia

Introduction/Background

Nowadays cerebral palsy (CP) takes one of the leading places in the structure of child disability.

Material and Method

Methods:
1. Computer tensodynamography
2. Rheovasography
The study involved 90 children aged between 8 and 12 years. The main group consisted of 60 children with special needs. The control group consisted of 30 children without any special needs.

Results

It has been proved that, during the jump of children of the main group there was an increase in pressure on the support to the lateral direction during the repulsion phase, they required more time to perform the initial phase of the jump due to the involvement of additional compensatory mechanisms to ensure the stability when landing. Thus, special attention should be given to the improvement of their coordination abilities and removal of muscle hypertonus. During physical exercises, it is recommended to focus on stretching and to enhance power quality of lower extremities. This approach will improve their motor adaptation. Moreover, regional hemodynamics reaction on locomotor load among children with special needs has been assessed. It has been shown, that children of the main group have a specific functional reserve of regional blood flow in proximal lower extremities. After locomotor load in the main group, there was an increase of pulse blood filling and blood flow velocity in hips, whereas the vegetative maintenance of distal extremities was decreased, which caused venous outflow.

Conclusion

Thus, children with special needs have a decreased vegetative maintenance mostly in distal extremities; in proximal extremities, there exists a specific functional reserve. It enables to recommend loading hip muscles and unloading shin muscles while forming locomotion adaptive stereotypes.
This research was conducted owing to grant, issued by Russian Science Fund (Project No. 16-18-00016).

GENDER AND LATERALITY DIFFERENCES ON MEASUREMENTS OF ACROMIOHUMERAL DISTANCE (AHD) AT REST AND AT SHOULDER ABDUCTION USING MUSCULOSKELETAL ULTRASOUND IN ASYMPTOMATIC FILIPINO ADULTS

M.N. Gelvosa¹, A. Azarcon¹
¹Veterans Memorial Medical Center, Department of Rehabilitation Medicine, Quezon City, Philippines

Introduction/Background

Musculoskeletal ultrasound is increasingly becoming a popular tool in the diagnosis of musculoskeletal disorders with the shoulder as one of the most routinely scanned joints. Common causes of shoulder pain, such as subacromial impingement syndrome and rotator cuff tendinopathy, have been shown to be associated with reduced acromiohumeral distance. This study aimed to determine mean ultrasonographic acromiohumeral distance and compare measurements between male and female Filipino adults, dominant and non-dominant side, at neutral shoulder position and at 60° abduction. Secondarily, it aimed to determine interrater reliability of ultrasonographic measurements.

Material and Method

This study employed a cross-sectional observational study design. AHD was measured on both shoulders of forty one volunteers, 15 males and 26 females with mean age 22.1 and 22.3 respectively, at neutral shoulder position and at 60° of passive abduction by two different raters.

Results

For the dominant side, mean AHD at neutral was 11.40 mm (SD 1.16 mm) for males and 10.65 mm (SD 1.22 mm) for females (p-value < 0.05). At 60° passive abduction, AHD decreased to 9.96 mm (SD 1.10 mm) for males and 9.49 mm (SD 1.43 mm) for females. For the non-dominant side, the mean AHD at neutral was 11.15 mm (SD 1.13 mm) for males and 10.70 mm (1.20 mm) for females. At 60° abduction, mean AHD was 9.86 mm (1.13 mm) for males and 9.36 mm (1.54 mm) for females (p-value > 0.05). Comparison of the dominant and non-dominant sides showed no significant difference at both shoulder positions. ICC values for the all the measurements ranged from 0.848 to 0.913.

Conclusion

Results of this study suggest that measurement of AHD may have gender differences, but is similar between the dominant and non-dominant side. Musculoskeletal ultrasound was found to
have excellent interrater reliability to measure AHD at both neutral position and at 60° of passive abduction.

Introduction/Background

Lumbar central canal stenosis (CCS) is one of the common diseases which increases by aging. We used quantitative image processing program to assess fat infiltration in paraspinal muscles especially multifidus as a diagnostic tool and its correlation with severity of CCS.

Material and Method

About 59 women with focal L4-L5 CCS as case group and 64 women as control group were enrolled. The bilateral multifidus innervated by L5 was assessed by image processing program. Moreover, Oswestry disability index (ODI) questionnaire was filled out by individuals.

Results

The mean ± Standard deviation (SD) of fat tissue deposition percentile in multifidus muscle of case and control group were 45.87% ± 23.42 and 36.48% ± 13.05, respectively. (P value<0.05). Besides, it correlated with severity of canal stenosis. A cut-off value of 46.7% fat percentile were measured for clinical diagnosis of canal stenosis severity. The fat infiltration did not correlated with weight of the participants in both case and control groups. We showed that age had effect on the fat degeneration totally, however it did not correlate with fat deposition in case and control group separately (Pearson correlation coefficient r=0.19 for case and r=0.18 for control group and P value>0.05).

Conclusion

It has been suggested that percentile of fat infiltration by our image processing program is a good diagnostic tool of CCS besides clinical symptoms of the patients. 46.7% cut-off value can be used in clinical setting for diagnosis critical stage of CCS.

IMAGING MUSCLE STIFFNESS POST STROKE

P. Raghavan¹, R. Menon², R. Regatte²

¹New York University School of Medicine, Rusk Rehabilitation, New York, USA
²New York University School of Medicine, Center for Biomedical Imaging, New York, USA

Introduction/Background

Post-stroke spasticity develops as a result of CNS injury, but secondary non-neural changes can contribute to upper limb muscle stiffness. The hyaluronan hypothesis postulates that an increase in the concentration of hyaluronan, a glycosaminoglycan (GAG) in the extra-cellular matrix (ECM) of muscles, may contribute to muscle stiffness in spastic patients. This study sought to provide imaging evidence of the hyaluronan hypothesis.

Material and Method

Five post-stroke patients (3 males, 2 females, age= 46 ± 15) and five healthy control subjects (3 males, 2 females, age = 27 ± 2) underwent Dixon based water-fat imaging and 3D-T1rho relaxation mapping of upper arm muscles were used to determine intramuscular GAG content. The MRI was study was conducted on a 3T clinical scanner (Prisma, Siemens Healthcare, Germany). Following the MRI, the patients underwent off-label intramuscular hyaluronidase injections (Hylenex, Halozyme Therapeutics, Inc.) for clinical treatment. Post-injection MRIs were conducted approximately two weeks after the treatment. Two tailed student t-tests were used for comparing the groups. A paired t-test was used for the pre- and post-injection comparison.

Results

Following the hyaluronidase injections patients reported significant relief from muscle stiffness and showed increased arm movement. Figure 1 shows a representative T1ρ map in a control subject and stroke patient pre- and post-injection respectively. The hyaluronan concentration in the biceps and triceps was significantly higher in patients pre-injection, and was reduced post-injection. Note the change in muscle shape from triangular to more circular as in controls post-injection in the patient.

Conclusion

3D T1ρ mapping of the muscle can be used to detect intramuscular GAG content (hyaluronan) non-invasively. The muscle micro-environment can contribute to muscle stiffness, and injections
of the enzyme hyaluronidase can be used to restore normal muscle microenvironment and reduce muscle stiffness post stroke.

RELATIONSHIPS BETWEEN COEFFICIENTS OF IMPAIRMENTS AT LOWER LIMB MUSCLES IN CHRONIC SPASTIC PARESIS – COULD THE MUSCLE DISEASE IMPACT ON THE NEUROLOGICAL DISEASE?
M. Pradines, M. Ghédira, E. Hutin, J.M. Gracies

1EA7377 BIONT- Hôpitaux Universitaires Henri Mondor- Université Paris-Est Créteil, Laboratoire d’Analyse et Restauration du Mouvement- service de Rééducation Neurolocomotrice, Créteil, France

Introduction/Background
At the onset of hemiparesis, muscle tissue is normal and spastic overactivity is nil. Later, motor function becomes gradually hindered by: spastic myopathy (part of soft tissue contracture) and co-contracture, in addition to paresis. Relationships between these remain unclear. This retrospective study explores correlations between muscle shortening on one hand, and, spastic co-contracture and agonist paresis on the other hand.

Material and Method
Eighty participants with chronic hemiparesis (29W, 51 (±13) years (mean (±SD)), time since lesion, 6.4 (±3.2) years)) were assessed through the Five Step Assessment, at least three months after any botulinum toxin injection, in six key lower limb antagonists: soleus (SO), gastrocnemius (GN), gluteus maximus (GM), hamstrings (HS), vastus (VA), rectus femoris (RF). Coefficients of impairment were calculated as: coefficient of shortening ($C_{SH}=(X_N-X_{V1})/X_N$; $X_N$, normally expected amplitude; $X_{V1}$, angle of arrest upon slow stretch), coefficient of weakness ($C_W=(X_{V1}-X_A)/X_{V1}$; $X_A$, maximal active range of motion). For each muscle and for the mean of the six muscles, bivariate correlations between $C_{SH}$ and $C_W$ were explored, using Pearson’s coefficients.

Results
The mean $C_{SH}$ are as follows: $C_{SH-SO}$, 0.15±0.05; $C_{SH-GN}$, 0.17±0.04; $C_{SH-GM}$, 0.14±0.08; $C_{SH-HS}$, 0.06±0.05; $C_{SH-VA}$, 0.09±0.05; $C_{SH-RF}$, 0.13±0.07. $C_W$ strongly correlated with $C_{SH}$ across the six muscles ($r=0.30$, $p=0.006$). This correlation was also found individually for GN ($r=0.43$, $p<0.0001$), GM ($r=0.22$, $p=0.04$) and HS ($r=0.21$, $p=0.052$).

Conclusion
While causality is not explored in this study, one may speculate that spastic myopathy (assessed through coefficient of shortening) may play a role in neurologic impairments, potentially by chronic modifications of afferent volleys to the spinal cord.

SUPPLEMENTAL THERAPEUTIC ROBOTIC BALANCE EXERCISE IN ACUTE ACQUIRED BRAIN INJURY REHABILITATION A RANDOMIZED, BLINDED STUDY
A. Esquenazi¹
¹MossRehab, PMR, Elkins Park, USA

Introduction/Background

Acquired brain injury (ABI) affects balance and may interfere with ambulation. A new robot that allows balance training while standing or setting is now available (Hunova®) and in clinical trials. Hunova® consists of a programmable mobile platform and seat to exercise standing or seated using passive or active mode for balance and proprioceptive exercises.

Material and Method

40 subjects with ABI participating in inpatient rehabilitation, ≥ 18 years of age with a MAS ≤3. Intervention - Patients participated in conventional therapy compliant with IRF mandates of 3 hours of one-to-one therapy. Participants were randomized to 30 minutes therapy of static (control) or 30 minutes of active training (intervention) aimed at balance and proprioception up to 5 days per week.

Tolerability; length of stay; FIM; FAC; MAS; 10 meter walk test; 5 times sit-to-stand and trunk control test were measured. Stabilometry using Hunova was performed before and the end of the treatment.

Results

In this ongoing study, we have enrolled 7 subjects. 5 male, average age 56. Average FIM gain total was 27.9 points and FIM efficiency was 1.3.

Conclusion

Findings in this ongoing study provide a proof-of-concept that an additional balance exercise in combination with mandated multi-disciplinary therapies in acute stroke population is feasible and may result in improved outcomes. The interventions can be provided with a single therapist hence may reduce costs.

ABSOLUTE RELIABILITY OF ULTRASOUND ASSESSMENT IN MEASURING TIBIOFIBULAR SEPARATION

K. Aoki¹, M. Shinoda², Y. Oda¹, K. Yamashita¹, J. Matsu³, M. Nishio³
¹Matsui Orthopedics department Ansyokai medical corporation, Department of Rehabilitation, Anjo, Japan
²Yoshida Orthpaedic Hospital, Department of Rehabilitation, Toyota, Japan
³Matsui Orthopedics department Anshokai medical corporation, Department of Orthopedic surgery, Aojo, Japan

Introduction/Background

We developed a method for measuring the tibiofibular separation space using ultrasound (US). However, the absolute reliability is unclear. The purpose of this study was to clarify the reproducibility and error range of the measurement of tibiofibular separation by US.

Material and Method

Two physiotherapists measured both the feet of 10 healthy participants [5 males and 5 females with a mean age of 25.9 ± 4.8 years (SD)], with no history of ankle problems. Participants slightly flexed their knee in supine position with the ankle was fixed at 35° plantar flexion (PF) and 20° dorsiflexion (DF). Imaging and measurement were randomly performed twice by each examiner using an US (F37, Hitachi Co, Tokyo, Japan). During US scanning, the probe was vertically aligned with the axis of the lower thigh, and the outer side of the tibia was the most protruding part on the side of the fibula. The fibula was aligned horizontally. The recorded image was analyzed only by examiner A using image analysis software (Image J). The interclass correlation (ICC) (1.1), ICC (2.1), Bland–Altman analysis, and minimal detectable (MDC) 95 were applied to determine statistical significance. ICC statistical analyses were performed with PASW Statistics 18.

Results

For examiner A, ICC (1.1) was > 0.9 in all image analyses. Both ICC (1.1) and ICC (2.1) in PF and DF conditions were > 0.9. As a result of Bland–Altman analysis, there was no addition / proportional error. MDC95 was 0.62 mm and 0.64 mm in interclass reliability and interclass examiner, respectively.

Conclusion
As a result of performing absolute reliability (Bland–Altman analysis and MDC95) in addition to ICC, showed high inter-examiner reliability, with no addition / proportional error. It was found that the error range was ≤0.64 mm. The method used in this study was considered to be a reliable method for evaluating tibiofibular separation.

POSTURAL CHANGES IN CANOE SPRINT ATHLETES: THE IMPACT OF TWO DIFFERENT ACTIVE RECOVERY METHODS
N. Silva¹, F. Silva², A. Santos³, B. Gomes³, J. Pinheiro⁴
¹University of Coimbra - Faculty of Medicine, Coimbra, Portugal
²Military Health Center of Coimbra, Coimbra, Portugal
³University of Coimbra, Faculty of Sport Sciences, Coimbra, Portugal
⁴Coimbra Hospital and University Center, Coimbra, Portugal

Introduction/Background

Canoe paddling technique requires an asymmetric and cyclic muscular work, as athletes paddle on the right or left side of a canoe, that predispose athletes to muscle imbalance and injuries. The purpose of the present study was to analyze the postural profile of 10 elite sprint canoeists and evaluate two different active recovery methods using a biophotogrammetry technique and a physical test protocol.

Material and Method

Ten males (22.30 ± 3.68 years old, 177.30 ± 3.62 cm stature, 77.36 ± 5.06 kg body mass) were evaluated using a postural assessment software (SAPO), that quantified the anthropometric imbalances, and performed two times an intermittent training protocol on a dansprint canoe ergometer followed by an active recovery method and a maximal 500m test to evaluate the effectiveness of the recovery. The athletes performed two randomized moments that differed in the active recovery method: paddling on the usual side or paddling on the paradoxical (opposite) side.

Results

There were significant imbalance findings in the measured corporal distances between relative heights of contralateral anatomical points: tragus (3.26 ± 1.52cm), acromion (2.43 ± 1.55cm), middle knee joint (5.67 ± 3.25cm) and lower angle of the scapula (3.86 ± 3.16cm). The half-body corresponding to the side of the stroke was always the highest. There were no significant differences in the performance in terms of time, mean power and blood lactate concentration in the maximal 500m test regardless of the type of active recovery performed after the training session.

Conclusion

Canoe practice leads to postural changes and, since there were no significant differences in the performance using the two different active recovery methods, it would be useful to implement
the paradoxical active recovery as a practice of the canoeists daily training, making a symbiosis between recovery and postural compensation at sportive and medical level.

³hospital Julio Díaz, departamento de docencia, La Habana, Cuba

Introduction/Background

Background: The Cobs Biofeedback Platform is an information and training response team that can be used in the early diagnosis, evaluation and rehabilitation of balance disorders; very frequent in children with Cerebral Palsy (CP). Objective: To evaluate the therapeutic response of the COBS Biofeedback platform in the rehabilitation of the balance of children with CP.

Material and Method

Explanatory, experimental, longitudinal and prospective study; with Experimental Group, Intervention (n = 35), application of 20 training sessions in COBS platform simultaneous to the program of action of the service; Control group, Control (n = 35), application of the service action program. Ashworth Scales and Gross Motor Function were applied at the beginning and end of the treatment. The results obtained before and after in each group were compared by Wilcoxon Signal Range Test, declaring as a significant difference a value of p≤0.05.

Results

Results: Average age 7.71 (± 2.2) years, 51% of the sample was female, spastic diparesia and genusa flexus predominated as the most frequent deformity with 62.9% and 38.6% respectively, standing and the evolution of the patients in the experimental group were evaluated as satisfactory with great statistical significance.

Conclusion

Conclusions: Patients with spastic CP using the COBS platform evolve better than patients with conventional therapy.

\textsuperscript{4}Department of Functional Physiological Explorations, University Hospital of Toulouse- Hôpital de Rangueil, Toulouse, France

Introduction/Background

Muscle overactivity, including spasticity and spastic cocontraction, is an involuntary motor unit recruitment participating in the spastic paresis syndrome after cerebral injury. Spasticity is defined as velocity-dependent increase in tonic stretch reflexes. Spastic cocontraction refers to increased antagonist muscles recruitment triggered by the volitional command of agonist muscles. This study aimed to clarify the association between spasticity and spastic cocontraction of elbow flexors and to study their contribution to the limitation of active elbow extension in hemiparetic adults.

Material and Method

Ten adults with acquired hemiparesis and ten healthy participants were included. Surface EMG recorded from elbow muscles during elbow isometric extension contractions was used to compute the index of cocontraction (ICC) for each participant, while spasticity, limitation of active elbow extension, and upper extremity Fugl-Meyer Assessment (FMA-UE) score were obtained in hemiparetic participants. Non-parametric Spearman correlations were performed to investigate the relationship between ICC and i) limitation of active elbow extension, ii) elbow flexors spasticity and iii) FMA-UE.

Results

Our results showed significant ICC in three hemiparetic participants compared with healthy participants, and significant associations between cocontraction and i) active elbow extension limitation ($rs = 0.81$, p $< 0.001$) and iii) Fugl-Meyer Assessment score ($rs = -0.53$, p=0.017) in hemiparetic participants. No significant correlation was found between spasticity and active elbow extension limitation.
Conclusion

Our results are the first to show that spastic cocontraction directly contributes to elbow extension deficit in adults with acquired hemiparesis, and further confirm that spasticity and spastic cocontraction have different functional repercussions with regards to impaired motor function. Our findings support the conclusion that spastic cocontraction, rather than spasticity, has significant functional repercussions on impaired active motor function in hemiparetic adults. Therapeutic innovations should be directed toward reduction of spastic cocontraction to improve motor function in acquired hemiparesis.

Introduction/Background
Loss of the longitudinal arch and progressive hindfoot valgus are common clinical observations in the foot deformities of patients with posterior tibial tendon dysfunction (PTTD). The biomechanical abnormalities in patients with PTTD have been described, but few studies have investigated biomechanical chains of adjacent joints. Therefore, we examined the abnormalities of hip and knee joints through the gait analysis in subjects with PTTD.

Material and Method
We compared 19 PTTD patients (average age: 67.1) with 30 age-matched control subjects (average age: 65.1). Subjects’ demographics was showed in Table1. Gait analysis was performed with a nine-camera motion-capture system and four force plates, using the VICON Plug-In-Gait and VICON Nexus software. Temporal-spatial parameters were compared between PTTD and control subjects, and joint angle and joint moment data were compared between the affected limb, the contralateral limb, and the right limb in control subjects.

PTTD: posterior tibial tendon dysfunction, BMI: body mass index, Numbers express the mean value (SD).

Results
Subjects with PTTD had increased stance phase ratio and decreased stride length, cadence, and gait speed. The limbs of subjects with PTTD showed increased knee internal rotation at lording response, which was biased to abduction in the knee joint during the gait cycle, and irregular hip flexion and knee extension moment in the terminal stance, especially in the contralateral limb.

Conclusion

We believe that the subjects with PTTD have an increased risk of knee osteoarthritis in both the affected and contralateral limbs.

ISPR8-0573
VALIDITY OF SMARTPHONE-BASED POSTURAL CONTROL ASSESSMENT FOR CHRONIC ANKLE INSTABILITY
Y.L. Chiu¹, Y.R. Hou¹, Y.J. Tsai², W.H. Sung¹
¹National Yang-Ming University, Physical Therapy and Assistive Technology, Taipei, Taiwan R.O.C.
²National Cheng-Kung University, Physical Therapy, Tainan, Taiwan R.O.C.

Introduction/Background

Decreased postural control ability are commonly found in who suffer from chronic ankle instability. Identifying decreased postural control ability could help to make an appropriate rehabilitation plan and reduce the possibility of recurrent ankle sprain. With newly emerging technologies, utilizing the inherent sensors in smartphones may provide a method of easy-access and portable alternative for postural control assessment. The purpose of this study is to establish the level of validity of smartphone-based postural control assessment.

Material and Method

Thirty-eight participants, with at least one ankle instable, were assessed using the smartphone application developed for recording built-in accelerometer data. Zenfone 3 smartphone was positioned at the middle of the shin. Participants completed 4 trails of single leg stance balance test each in eyes opened and eyes closed conditions, while simultaneously recording data from force platform, which was considered as the golden standard of postural sway assessment tool. Correlation between smartphone and force platform was evaluate using SPSS 20.0, and statistical significance was set as alpha < 0.05.

Results

Pearson’s correlation coefficient of eyes opened condition in medial-lateral direction between smartphone-based assessment and force platform was 0.700 (p<0.005), and 0.759 (p<0.005) in anterior-posterior direction. Pearson’s correlation coefficient of eyes closed condition in medial-lateral direction between smartphone-based assessment and force platform was 0.734 (p<0.005), and 0.803 (p<0.005) in anterior-posterior direction.

Conclusion

Our results show that the smartphone assessment has good correlation compared to the force platform when recording the performance of single leg stance balance test. The smartphone-based assessment shows potential as an easy-use and accessible tool to assess postural control ability.

THE EFFECTIVENESS OF A NEW NON-DRUG METHOD OF WALK REHABILITATION IN PATIENTS WITH PARKINSON'S DISEASE.

S. Ismailova¹, V. Ondar², M. Abroskina², S. Prokopenko²

¹Krasnoyarsk State Medical University named after Professor V.F. Voino-Yasenetsky, of Nervous System Diseases with a Course in Medical Rehabilitation and Post-Diploma Education, Krasnoyarsk, Russia

²Krasnoyarsk State Medical University named after Professor V.F. Voino-Yasenetsky, Department of Nervous System Diseases with a Course in Medical Rehabilitation and Post-Diploma Education, Krasnoyarsk, Russia

Introduction/Background

Gait disorders in PD manifest as disorders of walk initiation, speed of walking, length and height of the step. As PD progresses the phenomenon of freezing joins and often leads to falls. The phenomenon of freezing often occurs while switching from one movement program to another (when turning, the overcoming of a threshold, passing through a door). The article presents the results of the research of the effectiveness of the new non-drug method of walk rehabilitation, based on strengthening the back push of the foot. The idea of the method is mechanical activation of the moment of foot lifting from the surface. This device is fixed to the legs of patient and due to the mechanism providing adjustment of force and speed of push of the legs, it helps to lift foot from the floor in the early phase of movement, thus increasing the length and speed of step.

Material and Method

The study included 10 patients with PD, 2-3 stage by Hoehn-Yahr, akinetic-rigid form. The median age was 65 [51:75] years. Each patient had 14 sessions of 20-30’ for 2.5 weeks using the method under discussion. Before and after the course of rehabilitation, research methods were: neurological examination, objective assessment of balance function using the Computer Stabilometry (CS), objective assessment of gait using «laser analyzer of kinematic gait parameters» (LA-1), Unified Parkinson's Disease Rating Scale (UPDRS) and Dynamic Gait Index.

Results

Statistically significant changes were determined before and after the course. After the course the time of step increased (LA-1): before the course of rehabilitation it was 0.52 [0.47:0.53] seconds, after - 0.67 [0.6:to 0.78], p=0.01. Positive dynamics was in accordance with UPDRS. Before rehabilitation it was 14.0 [12.4:16.2], after - 18.6 [17.1:19.8], p=0.01.
Conclusion

The original method showed the effectiveness in restoring gait disorders in patients with PD.

THE USE OF STANDARDIZED MODULAR MULTIFUNCTION COMPLEX FOR REHABILITATION OF PATIENTS WITH DISEASES AND INJURIES OF THE CENTRAL AND PERIPHERAL NERVOUS SYSTEM
V. Luchenkov¹, D. Davydov¹
¹Main Military Hospital nm. after N.N. Burdenko, Ministry of Defence, Moscow, Russia

Introduction/Background
The purpose of the study was to explore the possibility and effectiveness of rehabilitation trainer
Material and Method

The study involved 1,700 people aged 55 to 65 with ischemic stroke in the area of blood supply of the left middle cerebral artery. Lessons began after 18 days after the stroke. To assess the results of rehabilitation we used scales and questionnaires. Trainer "Captain" consists of seven functional blocks. Patients performed ten exercises on the simulator. Classes were held 3 times a week for 60 minutes with the instructor and independently. The findings were assessed before the first train, and on the sixtieth day.

Results

All patients noted positive dynamics in the rehabilitation process. Injuries weren't recorded.

3-4 points during the initial examination fell to 2-3 points when re-examined by the modified Rankin scale. NIHSS: 7-8 points dropped to 4-5 points. MMSE: 26-27 points increased to 27-28 points. The Barthel index: 20-25 points increased to 50-60 points. Visual Analog Scale, VAS: 10-35 points increased to 60-85 points. The duration of rehabilitation was reduced by 30%. Disability patients decreased to 25-30%, motor function in hands improved to 45-80%, in the legs – by 70-85%, statelocomotor function increased by 45%.

Conclusion

The use of multifunctional rehabilitation trainer "Captain" is effective for complex rehabilitation of patients with stroke. The efficiency of the simulator is confirmed by objective data. Training on the simulator helps restore movements of the upper and lower extremities. The simulator is available to patients and does not require constant monitoring by experts during training. Use of the simulator "Captain" allows you to cut costs, continue rehabilitation at home, increase the motivation of the patient to quickly return to the social environment and proceed with the previously performed labour activities.

³Politecnico di Milano, MBMC Lab – DEIB, Milano, Italy

Introduction/Background

We compared muscle activation during in- and out-of-water gait of SCI patients to understand the influence of the aquatic ambient on rehabilitation programme.

Material and Method

20 healthy subjects and 20 SCI patients were enrolled. All patients had retained walking ability (AIS C and D, lesion level C4-L2, age 18-70 years) and could ambulate independently for a minimum of 5m with or without walking aids. We analyzed, with an surface 8 channel wireless EMG, the following muscles of the right leg: rectus femoris, vastus medialis, vastus lateralis, gluteus maximus, gluteus medius, biceps femoris, tibialis anterior, gastrocnemius medialis.

Results

In both healthy and affected subjects in water the walking speed decreases whereas the duration of gait cycle increases. Furthermore in SCI patients we found out an increase of the swing phase. Comparing in- and out-of-water results for SCI subjects the maximum muscle activation peak in water occured before than on dry land; at the opposite in healthy subjects we registered that the maximum muscle activation peak occured earlier out of the pool.

Conclusion

The in-water gait cycle is much more similar between SCI and healthy subjects than the out-of-water one. These results suggest that aquatic ambient could positively influence muscle recruitment in SCI patient. Moreover these data give us the opportunity to design water-based exercises that can enrich the tailored rehabilitation programme for every patient.

**ELECTRICAL IMPEDANCE MYOGRAPHY ALTERNATION AFTER NEUROMUSCULAR ELECTRICAL STIMULATION COMBINED CYCLING TRAINING IN CHRONIC STROKE**

C. Hu\(^1\), X. Wang\(^2\), K.W. Lueng\(^2\), R.K. Tong\(^2\), L. Li\(^1\)

\(^1\)The First Affiliated Hospital of Sun Yat-sen University, Rehabilitation medicine, Guangzhou, China

\(^2\)The Chinese University of Hong Kong, Department of Biomedical Engineering, Hong Kong, China

**Introduction/Background**

Electrical impedance myography (EIM) considered as a sensitive diagnostic tool for neuromuscular diseases with no invasive operation and little patients’ cooperation was increasingly studied. However, the application of EIM in stroke is relevantly few. The aim of this study is to detect muscle inherit properties changes in affected side compared with unaffected side as well as the immediate alternation after neuromuscular electrical stimulation combined cycling training in chronic stroke.

**Material and Method**

Eleven chronic stroke survivors are recruited for cycling training combined with neuromuscular electrical stimulation at the most tolerated stimulation intensity simultaneously on rectus femoris (RF), tibialis anterior (TA), hamstrings (HS) and medial head of gastrocnemius (MG) for one hour per day and three training days a week. All the survivors received EIM assessment before and immediately after the training. EIM estimates the main impedance parameters at 50 kHz, which consists of resistance (R), reactance (X) and phase angle (θ).

**Results**

Statistical analysis demonstrated the EIM parameters changed as follows, compared with unaffected side, R has significant increase only in TA (p=0.02), X significantly increased in RF (p=0.001), TA (p=0.03), MG (p=0.02), θ increased in RF (p=0.007), TA (p=0.031), HS (p=0.005), MG (p=0.005). And right after the training there is significant X elevation in affected TA (p=0.01),and MG (p=0.007), and θ elevated significantly in affected TA (p=0.02), and MG (p=0.013). No significant EIM parameters alternation has found in RF and MG.

**Conclusion**

Findings of this study revealed significant changes in the muscle intrinsic electrical properties after stroke, probably related to structural modifications caused by fat and connective tissue infiltration damage to the cell membrane integrity. Besides, there is immediate effects of training...
on muscle inherit properties alternation, which might because of metabolites accumulation, such as lactic acid right after muscle contraction training and electrical stimulation.

ISPR8-0685
SMARTPHONE APPLICATIONS FOR RANGE OF MOTION MEASUREMENT IN CLINICAL PRACTICE: A LITERATURE REVIEW OF INCLINOMETER AND GONIOMETRIC TOOLS.
A.V. Bruyneel
1University of Applied Sciences of Western Switzerland, physiotherapy, Carouge, Switzerland

Introduction/Background

Many smartphone applications have emerged in recent years for patient management, as range of motion tools. In order to use these tools under good conditions, it is necessary for the clinician to know the psychometric qualities.

The aim of this study was to provide a systematic review about validity and reliability (intra and inter-raters) of range of motion angle tests with goniometer or inclinometer smartphone applications.

Material and Method

The research was conducted, in english and french, using keywords “healthy subjects”, “phone”, “range of motion”, validity, “reliability” et “repeatability” on the databases: PubMed, ScienceDirect, Pedro and Kinedoc. A synthesis was carried out and the qualities of each study was evaluated by the Qarel score.

Results

512 articles were identified. Following the selection criteria, 18 articles were included, with 5 for cervical and lumbar motions, 6 for lower limb and 7 for upper limb. These studies included 601 healthy subjects. The mean Qarel score for all studies was 7.61/12 (min:6/max:9). The mean validity (ICC:0.86[min:0.40, max:0.99]), intra-rater reliability (ICC:0.86[min:0.05, max:1]), and inter-raters reliability (ICC:0.83[min:0.07, max:0.99] were good.

Conclusion

This review highlights the existence of numerous studies on the validity and reliability of smartphone applications to measure angles in clinical practice. All studies presented a consistent methodology with the stated objective and tested validity prior to reliability. The two most studied joints are the knees and shoulders. No studies at the time of the review were found on ankle and finger movements. In clinical practice, goniometric and inclinometric smartphone applications can be used to measure range of motion. However, these applications should be used with caution for cervical and hip rotations, for hallux movements and on the shoulder.

ISPR8-0696
DOES FUNCTIONAL MOBILITY VARY AMONG INDIVIDUALS WITH UP TO ONE YEAR AFTER STROKE? AN ANALYSIS USING THE TUG-ABS
T. Ribeiro¹, E. Silva¹, I. Silva¹, M. Costa¹, R. Lindquist¹
¹Universidade Federal do Rio Grande do Norte, Departamento de Fisioterapia, Natal, Brazil

Introduction/Background

The Timed “Up and Go” Assessment of Biomechanical Strategies (TUG-ABS) analyses functional mobility activities of Timed “Up and Go” (TUG) test, showing to be valid and reliable for individuals with stroke. The aim of this study was to evaluate if the performance of functional mobility activities varies between subjects within the first year poststroke.

Material and Method

Thirty-eight stroke subjects (mean age 56.5 years) of both genders and with up to one year of first stroke that caused gait deficits (gait speed<0.8m/s) participated in the study. Participants were instructed to perform the following activities: standing up from a chair without armrests, walking and circling (180° turns) a cone placed at the 1.35-m mark, walking back and sitting down. The performance of this activities was registered by the Qualisys Motion Capture System. By analyzing the images, TUG-ABS was applied to evaluate: sit-to-stand – STSt, walking – W, turn – T and stand-to-sit – STSi. For statistical analysis, participants were divided into: one group with up to 3 months poststroke (n=21), and another group with 4 to 12 months poststroke (n=17). Study groups were compared with Mann Whitney test for TUG-ABS activities and total TUG-ABS score (TS).

Results

The groups were homogeneous with regard to middle age, cognitive level (Mini-Mental State Examination), neurological status (National Institute of Health Stroke Scale) and walking ability (Functional Ambulatory Category). For TUG-ABS, there was also no difference between groups for the activities: STSt: $P=0.161$; W: $P=0.383$; T: $P=0.052$; STSi: $P=0.542$, and for TS: $P=0.144$.

Conclusion

Although motor recovery can be influenced by lesion time, the performance of functional mobility activities did not appear to be different among subjects in the first year poststroke. This suggests that biomechanical strategies for performing these activities are developed within the
first three months following stroke, indicating the importance of early intervention for rehabilitation.

DYNAMIC MOTION AND PRINCIPAL COMPONENT ANALYSIS OF STEP-OVER IN PATIENTS WITH MUSCULOSKELETAL AMBULATION DISABILITY SYMPTOM COMPLEX (MADS)
M. Maeda¹, H. Maeda², H. Iwase³, A. Kanda³, I. Morohashi³, O. Obayashi³, K. Kaneko², T. Sato⁴, Y. Arai⁵
¹Yamamoto and Maeda memorial Maeda Hospital
²Department of Orthopaedic Surgery, School of Medicine, Juntendo University
³Department of Orthopaedic Surgery, Shizuoka Medical Research Center for Disaster, Juntendo Shizuoka Hospital
⁴Department of Mechanical Engineering, School of Engineering, Tokyo Denki University
⁵Tokyo metropolitan rehabilitation hospital

Introduction/Background

The functional evaluation criteria of musculoskeletal ambulation disability symptom (MADS) complex include the one-leg standing duration with eyes open and 3-m timed up and go test, but actual measurement is physically difficult for many patients. Thus, it is necessary to investigate a new, safe, and simple evaluation method. Considering that falls are likely to occur when one is stepping over an obstacle, we investigated the association between the musculoskeletal ambulation disability symptom complex and dynamic motions by dynamic motion analysis of “step-over” in healthy subjects and patients with the complex.

Material and Method

This study examined the association between the musculoskeletal ambulation disability symptom complex (MADS) and dynamic motions by performing dynamic motion analysis of “stepping over obstacles”, involving 11 MADS patients (group-M) compared to 10 young (Y) and 11 elderly (E) individuals with no health-related problems. All participants stepped over an obstacle with a height of 9 cm by adopting 2 patterns: watching or not watching the obstacle on measurement of each joint angle and toe-obstacle clearance. The obtained values were examined through principal component analysis.

Results

The age, experience of falls, and hip and knee joint angles showed higher absolute values representing factor loading on the first principal component, and this was consistent with the subsequent result of dynamic motion analysis focusing on joint angles: elderly group-E or M members showed greater hip and knee flexion to improve their toe-obstacle clearance. Therefore, the first principal component was considered to accurately represent the
characteristics of the elderly, while the second principle component was likely to represent the characteristics of physical factors and clearance level.

Conclusion

It was clarified that items can be selected by dynamic motion analysis and principle component analysis, which may lead early evaluation of the musculoskeletal ambulation disability symptom complex.

Immediate Effect of Restricted Ankle Dorsiflexion on Ground Reaction Force and Trunk Acceleration During Walking

H. Osaka¹, K. Hanayama², D. Fujita¹, K. Kobara¹, Y. Yoshimura¹, T. Suehiro¹, Y.C. Asada³
¹Kawasaki University of Medical Welfare, Department of Rehabilitation, Kurashiki, Japan
²Kawasaki Medical School, Department of Rehabilitation Medicine, Kurashiki, Japan
³Sumitomo Electric Industries LTD., Life Science Business Development Division, Osaka, Japan

Introduction/Background

Accelerometer is widely used for gait analysis. The gait parameters calculated from trunk acceleration describes the features of gait patterns and represents the whole body motion in walking. However, they cannot evaluate the gait pattern corresponding to gait cycle. The aim of this study was to investigate the validity of an accelerometer for gait analysis corresponding to the gait cycle in healthy subjects on restricted ankle joints, which simulated the characteristic motion of the elderly.

Material and Method

Eight healthy volunteers walked with custom-made ankle braces under the following two conditions: walking without restricted ankle joint (free), and walking with restricted ankle dorsiflexion at 0° (restricted). The walking speed between two conditions was fixed on the same cadence, and tri-axis trunk acceleration on the third lumbar vertebrae and GRF from 4 force plates were measured. The peak of GRF (GRFmax) and its appearance time (GRFmax-t) at mid stance to terminal stance were extracted from the vertical component of GRF on the right foot, the peak of acceleration during the identical phase in GRF (ACCmax), and the amplitude ratio of the autocorrelation function (ACF) were calculated from the vertical component of trunk acceleration. These kinematic parameters were compared between two conditions though the paired t-test (p<0.05). This study was approved by the Ethical Committee of Kawasaki University of Medical Welfare.

Results

GRFmax and the ACF were significantly smaller in the restricted condition compared to the free. GRFmax-t was significant earlier in restricted condition compared to the free. There was no significant difference between the ACCmax for the two conditions.

Conclusion
This immediate effect shows that the restriction to ankle dorsiflexion changes the gait pattern represented in vertical GRF and trunk acceleration. This may suggest that these gait parameters can be used in the evaluation clinical risk such as frailty.

ISPR8-0735
IMPACT OF DIFFERENT EMG NORMALISATION METHODS ON MUSCLE ACTIVATIONS AND COCONTRACTION INDEX IN ADULTS WITH CHRONIC POST-STROKE HEMIPARESIS

A. Chalard, D. Amarantini, M. Belle, E. Montane, D. Gasq

1Inserm- UPS, UMR 1214 TOulouse NeuroImaging Center, Toulouse, France
2Ipsen, Ipsen Innovation, Les Ulis, France
3University Hospital of Toulouse, Department of Functional Physiological Explorations, Toulouse, France

Introduction/Background

EMG normalisation is a key step to draw definite conclusions on physiologically standardized data. In the absence of a consensus in scientific literature, recommendations would be useful for the choice of EMG normalisation method in patients, such as hemiparetics, who present atypical EMG patterns during motor behavior. The aim of this work was to compare muscle activations and cocontraction index (CCI) using different EMG normalisation methods during active elbow extension in healthy participants and patients with chronic post-stroke hemiparesis.

Material and Method

Four adults with chronic post-stroke hemiparesis (Hemi) and five healthy participants (Co) were included. Elbow kinematics and EMG activity of elbow flexors and triceps brachii were recorded during active elbow extensions performed at spontaneous speed. EMG signal was normalised in reference to EMG activity recorded during isometric or isokinetic MVC. Normalised EMG during elbow extension was used to compute muscle activations and CCI, during the acceleration and deceleration phases. Friedman tests were performed with two factors (group and normalisation).

Results

No differences were found between normalisation methods neither for muscle activations and for the cocontraction index in Co and Hemi groups. Greater muscle activations were found in Hemi vs Co (24.2±13.4% vs 4.3±3% and 52.4±33.2% vs 6.2±4.3% during acceleration and deceleration phase, respectively). Cocontraction index in acceleration phase was greater in Hemi vs Co (p<0.05), and in Co between acceleration and deceleration phases (p<0.05) (Fig.1).
Conclusion

Even if isokinetic MVC-based EMG normalisation accounts for the influence of angle- and velocity-torque relationships, our results on EMG activations and cocontraction index support the use of isometric instead of isokinetic MVC normalisation, and further suggest the need to take into account individual muscle activations to better understand differences in cocontraction between groups and phases.

**Introduction/Background**

Patients with cerebellar and brain stem lesions present symptoms of vestibular dysfunction, due to involvement of vestibular pathways. To investigate the relationship and availability of the VEMP and blink reflex study with vestibular pathways, we evaluated patients with cerebellar and brain stem lesion, analyzed the results of VEMP and blink reflex studies, which reflects vestibular dysfunction and vestibular nerve pathways.

**Material and Method**

16 Patients with cerebellar or brain stem stroke diagnosed by MRI were enrolled. VEMP and blink reflex study was performed using Nicolet.Viking IV D® and DantecKeypointMedtronic®. Clinical evaluation to check vestibular function and Berg balance scale was conducted. Participants were divided into normal and abnormal groups by comparing P13, N13 latency and amplitude of VEMP and latency difference of R1 and R2 of blink reflex, of the affected side against the sound side. McNemar and Wilcoxon rank sum test was done to confirm the correlation of abnormal VEMP, blink reflex studies and Berg balance test scores. (P<0.05)

**Results**

Participants with abnormal blink reflex, 37.5%(3/8) revealed abnormal VEMP results. 50% (3/6) of participants with abnormal VEMP, also revealed abnormal blink reflex results. Among the patients with brain stem lesion, 53.8% (7/13) showed abnormal blink reflex, while 46.2% (6/13) showed abnormal VEMP. There was no statistical correlation with the results of abnormal VEMP and abnormal blink reflex, but tendency of positive correlation was present. Brainstem stroke patients with abnormal blink reflex showed average of 6 in berg balance score, indicating very severe balance impairment, respectively.

**Conclusion**

The tendency of positive correlation of abnormal blink reflex and VEMP suggests the overlap of vestibular pathway and brainstem pathway. This infers the possibility of utilizing VEMP instead of blink reflex as an evaluation tool for brain stem lesion, since the VEMP is more painless and simply conducted than blink reflex. Further study with more participants is needed.

⁴Asahikawa Rehabilitation Hospital, Department of Rehabilitation Medicine, Asahikawa, Japan

Introduction/Background

Long-term immobilization of skeletal muscle results in a loss of muscle force. Previous research has revealed that one week of immobilization affects maximum voluntary contraction (MVC), MVC potential, low-level force modulation, and corticospinal excitation. Corticomotor excitability is reduced by short-term immobilization, even over days or hours. However, the effect of 12-hour immobilization period on muscle output function is unclear. Therefore, the aim of the present study was to investigate the change in motor function after immobilization of the upper limb for 12 hours.

Material and Method

Twenty subjects were assigned to the following two groups: immobilization, control (n = 10 in each group). The left hand of the subjects in the immobilization group were wrapped with an elastic bandage and further limited the arm movement using an arm sling to the upper extremity for 12-hours. MVC during isometric abduction of the index finger, fluctuation of force (force-fluctuation) during a force modulation task, and twitch force evoked by supramaximal electrical stimulation at rest were measured before (pre-test) and after the immobilization period (post-test). The control group performed these tests, but were not immobilized. The data were analyzed using two-way (time × group) repeated measures analysis of variance.

Results

MVC decreased significantly in the immobilization group in the post-test compared with the pre-test. Force-fluctuation increased significantly in the immobilization group in the post-test compared with the pre-test. Twitch force revealed that a significant main effect for time.

Conclusion

The results of the study demonstrate that MVC and force-fluctuation were affected by 12-hour immobilization period, but twitch force was not affected. These findings have significant
implications for preventing declines in muscle output function with time (for example, during cast immobilization).

4Institute of Higher Nervous Activity and Neuropsychology RAS, Moscow, Moscow, Russia

Introduction/Background

Currently, neurobiological feedback technologies based on neurocomputer interfaces are used in the rehabilitation of patients after a stroke (Yekutieli M, 2000). The ability to actively implement the capabilities of interface-brain-computer technology (IMC) remains limited for most patients (Cloutier S. et al., 2015).

Material and Method

Methods. The IMC was used, based on the analysis of EEG patterns and recognition of the synchronization / desynchronization reaction of the sensoro-motor (mu-rhythm) in imagining the movements of the hands of patients. The data of 15 patients (7 men, 8 women), at the age of 64 (62.0, 69.0) years, the duration of the stroke of 8 (5, 19) months, with right hemispheric localization in 7 patients (46%), mild to plegia (MRCWS); with a focus of stroke etiology (ischemic / hemorrhagic), supratentorial localization (CT, MRI); received therapy IMK-an exoskeleton brush with kinesthetic feedback, 9.5 (8; 10) procedures (ClinicalTrials.gov identifier: NCT02325947)).

Results

Results: only 6 (40%) patients solved the mental motor problem with accuracy of the EEG data (presence of the mu-rhythm) above 70%, 4 (26%) failed to solve the problem. The accuracy of their representations according to EEG data was no more than 20%. The accuracy of the representations of the remaining 5 (33%) patients was in the range of 45-55%. What is consistent with the literature (Ahn & Chan, 2015; Hammer EM, et al., 2014).

Conclusion
The absolute majority of patients with stroke have motor disregard for the affected side. Even with a minimal motor deficit, patients unconsciously prefer to use a healthy hand in everyday life. Such patients need to restore the functional system of formation of target motility by training the lost or altered links of this functional system. The combination of neurocomputer technologies (IMC) and physical training in a certain sequence will facilitate their more successful interaction and will improve the efficiency of rehabilitation.

ISPR8-1183
ULTRASOUND ASSESSMENT OF MORPHOLOGICAL MUSCLE AND TENDON PROPERTIES OF THE LOWER LIMB RELATED TO SPASTICITY POST STROKE: A SYSTEMATIC REVIEW AND META-ANALYSIS
F. Schillebeeckx¹, A. Degroef¹, G. Verheyden², K. Desloovere³, K. Peers¹
¹University Hospitals Leuven, Physical Medicine and Rehabilitation, Leuven, Belgium
²KU Leuven – University of Leuven- Belgium, Department of Rehabilitation Sciences-, Leuven, Belgium
³University Hospitals Leuven, Physical Medicine and Rehabilitation- Clinical Motion Laboratory, Leuven, Belgium

Introduction/Background

Stroke causes neural symptoms such as changes in muscle tone and secondary changes in skeletal muscle properties. The aim of this review was to summarize the evidence related to morphological muscle and tendon [MMT] properties of the lower limb defined by ultrasound in stroke patients with spasticity.

Material and Method

Following databases were searched for observational case control or cohort studies; PubMed, Embase, Scopus, Cinahl, and Cochrane Library. Search terms were (1) stroke or cerebrovascular diseases (and variations) and (2) ultrasound, echography, diagnostic imaging or elasticity imaging techniques (and variations) of the lower limb. Outcomes included (1) muscle thickness, (2) pennation angle, (3) fascicle length, (4) echo intensity, (5) elasticity index or ratio, and (6) tendon length. Inclusion criteria were first-ever stroke adult population (>18y) without musculoskeletal or other neurological pathology affecting the lower limb or peripheral spastic medication. Quality was assessed by the Newcastle-Ottawa scale (NOS). Meta-analysis was performed if possible.

Results

In total 7 studies were included. All studies investigated patients beyond one month post stroke. The investigated outcome parameters showed significant difference for the hemiparetic leg of patients with spasticity compared with the non-hemiparetic leg and healthy people in all seven studies. Due to heterogeneous methodology, the results of only 4 studies could be used for meta-analysis of the outcome parameter muscle thickness. See figure:
Conclusion

Our review shows evidence for changes in MMT properties of the lower limb measured by ultrasound in the hemiparetic leg of patients with spasticity compared with the non-hemiparetic leg and healthy people. Our search demonstrates a lack of studies investigating MMT properties and its evolution longitudinally, early after stroke. Unravelling the evolution of MMT changes after stroke may lead to new spasticity treatment opportunities.

**PREDICTIVE DIABETIC FOOT ULCER RISK FACTORS CORRELATED WITH ELEVATED FOREFOOT PEAK PLANTAR PRESSURE**

M.A. Assucena¹, M.D. Sanchez², R. Navarro³

¹Hospital of Requena, Rehabilitation, Requena, Spain
²Hospital La Fe, Rehabilitation, Valencia, Spain
³Hospital Clinical, Rehabilitation, Valencia, Spain

**Introduction/Background**

Polyneuropathy and foot deformity, such as Claw and hammer-toes (CHT), together with hyperkeratosis, are predictive diabetic foot ulcer (DFU) factors. These factors are correlated with increased forefoot peak plantar pressure (PPP). Increased PPP at metatarsal heads is correlated with forefoot DFU development. The aim of this study was to observe that the presence of CHT, hyperkeratosis and polyneuropathy is correlated with high forefoot PPP (FPPP).

**Material and Method**

An observational transversal survey with 103 diabetic patients, with or without CHT, hyperkeratosis and polyneuropathy, and without peripheral arterial disease, previous or current DFU and lower limb amputation was conducted. Mean age was 74 years old, 41 male and 62 women. Variables were CHT, hyperkeratosis, polyneuropathy and FPPP of each foot. PPP was obtained through the BIOFOOT/IBV baropodometric system. An analysis of difference between means of two samples was performed.

**Results**

“Hyperkeratosis” is correlated with higher FPPP than “CHT and hyperkeratosis”, and both with higher FPPP than those who had none of these features.

**Table 1**

</tbody>
</table>

**Conclusion**

Hyperkeratosis is correlated with higher FPPP, independently of polyneuropathy. The mean FPPP of up to 840 KpPa may be considered as indicative of a lower risk of DFU, in this sample and with this baropodometric system.
Keywords

diabetic foot; foot ulcer; plantar pressure

Introduction/Background

High peak plantar pressure (PPP) under metatarsal heads has been correlated with risk of first and recurrent neuropathic foot ulcer. Polyneuropathy and foot deformity (FD), especially, claw and hammer toes deformity are main risk factors of foot ulcer among persons with diabetes mellitus (PwD). It has been reported a 20 % of PPP reduction using orthosis to be effective. The aim of this study was to show the offloading effect of custom-made in-shoe orthoses in this sample.

Material and Method

An observational transversal survey with a 33 PwDM – 66 feet - sample with FD with or without polyneuropathy, without neither previous nor current foot ulcer, was conducted. Every patient received viscoelastic insoles with corrective modifications. Forefoot PPP in both feet was measured with a baropodometric IBV/BIOFOOT system, without and with insoles. The difference between them and its reduction rate was analysed.

Results

Table 1 shows forefoot PPP in each foot without and with insoles and the PPP ratio without/with insoles.

<table>
<thead>
<tr>
<th>PPP (Kpa)</th>
<th>Without insoles</th>
<th>With insoles</th>

<td>2.43</td>
</tr>
<tr>
<td>Left forefoot</td>
<td>1264.51</td>
<td>627.85</td>
<td>3.46</td>
</tr>
</tbody>
</table>

Table 2 shows ratio forefoot/rearfoot PPP in each foot without and with insoles.
The forefoot PPP reduction in both feet, whenever applying an insole, was statistically significant, according to ANOVA model (right foot p value 0.008; left foot, 0.000).

**Conclusion**

There was a 50% forefoot PPP reduction applying custom-made in-shoe orthoses, which is considered effective.

These insoles did not transfer pressure from forefoot to rearfoot, in this sample.

Quantifying an offloading effect is worthy to contribute to the preventive foot ulcer measures among PwDM.

C1.07 Physical and Rehabilitation Medicine Diagnostics as Related to Organ Systems and Body Functions - Diagnosis and Assessment of Neurological, Musculoskeletal and Movement Related Functions (including Gait Analysis, Posturography)

ISPR8-1304
CLINICAL MARKERS OF CEREBELLAR TREMOR OF THE UPPER LIMB
J. VIELLOTTE¹, J.L. Barnay¹, E. Hutin², J.M. Gracies²
¹CHU de la Martinique, Service de Médecine Physique et de Réadaptation, FORT-DE-FRANCE, Martinique
²CHU Henri Mondor, Service de rééducation neurolocomotrice, Créteil, France

Introduction/Background

Hypermetric tremor, from cerebellar origin, directly relate to iterative hypermetria by delayed antagonist correction at each movement, is a frequent neurological disorder, which can cause significant functional and social disability.

Nowadays, the clinical evaluation of tremors relies mainly on subjective rating tools.

The purpose of the study was to develop quantitative markers of hypermetric tremor of the upper limb to help clinicians with diagnosis, follow-up and assessment of treatment effects.

Material and Method

We prospectively analyzed data from two volumetric tests (30 seconds and 5 table-to-mouth tests), a device for evaluating rapid alternating pronosupination movements “the Hand Tapper” (large/small movements ratios) and spiralography (number of spikes per turn and symmetry coefficient). We compared these parameters in three populations: 18 patients (age: 63±16 years) with upper limb cerebellar tremor, 15 patients with Parkinson's disease with predominant tremor (67±7 years) and 18 healthy subjects (age: 63±15 years).

Results

At the volumetric tests, the height of remaining water is measured in the polystyrene cup (90 mm height) after each test. For the 30 seconds posture test (H30) : cerebellar=41,2±8,5 mm, parkinson=82,9±4,5 mm, healthy subjects=90,0±0,0 mm, (p cérébelleux vs parkinson=2.10⁻⁵) and for the 5 table-to-mouth back and forth movements test (HX5) : cerebellar=27,3±7,6 mm, parkinson=88,7±0,3 mm, healthy subjects=89,9±0,1 mm (p cerebellar vs parkinson=10⁻¹¹).

At the “Hand Tapper”, the large/small pronosupination movements ratios (L/S) were : cerebellar=65,0±4,6%, parkinson=50,2±2,2%, healthy subjects=47,9±3,0% (p cerebellar vs parkinson=0.01).
At the spiralography, the number of spikes per turn were: cerebellar = 10.7 ± 1.7; parkinson 6.1 ± 1.3; healthy subjects = 2.0 ± 0.3 (p cerebellar vs parkinson = 0.03).

**Conclusion**

The height of remaining water on volumetric tests, L/S ratios with Hand Tapper, and the number of spicules on spiralography seem to be representative markers of cerebellar hypermetry, compared to "parkinsonism". Explorations of diagnostic performances of these parameters and correlations with the severity of the tremor will be the subject of a future analysis.

A NEW METHODOLOGY TO RE-EDUCATE MUSCLE SYNERGIES OBSERVED DURING GAIT

D. Bourbonnais¹, C. Villeneuve², C. Bellavance², M. Lalumière Boucher², M. Goyette¹

¹Institut Gingras Lindsay de réadaptation de Montréal, Centre de recherche interdisciplinaire en réadaptation, Montréal, Canada
²Université de Montréal, École de réadaptation, Montréal, Canada

Introduction/Background

Analysis of multiple electromyographic activities suggests that central and peripheral neurological structures modulate the relative amplitude and time course of specific muscle groups during gait. Following neurological insult such as stroke, spatiotemporal characteristics of the four muscular modules or synergies identified during gait (C1, C2, C3 and C4) are impaired. The objective of the present work is to develop a new methodology to recruit synergies involved in gait.

Material and Method

The subject is seated with his trunk leaning back and his foot fixed on a multidirectional force transducer, interfaced to a laboratory computer. The centers of rotation of the hip, knee and ankle joints are determined to estimate the lengths of the different segments of the lower limb. In addition, the relative angles between these segments are measured using a goniometer. In order to recruit different muscle synergies during progressive effort, a visual feedback was provided to the subject allowing him to control the direction and magnitude of the static force vector exerted in the sagittal plane of the foot. By measuring the location of the center of pressure exerted and the direction of the force vector applied at the extremity of the lower limb, it is possible to calculate the different moments of force exerted at the hip, knee and ankle using morphometric values of the subject.

Results

Seven healthy subjects were asked to exert progressive static efforts in eight sagittal directions while the activities of eight muscles of the lower extremity were recorded using surface electrodes. The muscle synergies elicited in specific directions during these efforts were highly similar to three of the four modules previously identified during gait (C1, C2 and C4).

Conclusion

It is suggested that this methodology can provide a basis to establish a training program re-educating muscle synergies of the lower limb that are specifically recruited during gait.

EFFECTIVENESS OF FUNCTIONAL ELECTRICAL STIMULATION OF GAIT. EVALUATING OF MODIFICATIONS TO THE CENTER OF PRESSURE FOR A HEMIPARETIC PATIENT.
E. Aleton¹, Y. Sagawa², F. Droz-Bartholet¹, F. Michel¹, P. Decavel¹
¹CHU Jean Minjoz, Physical medicine and rehabilitation, Besancon, France
²CHU Jean Minjoz, Laboratory of Clinical Functional Exploration of Movement, Besancon, France

Introduction/Background

Drop foot is the principal ambulatory anomaly impacting hemiplegic patients. The effectiveness of Functional Electric Stimulation (FES) on gait parameters in hemiplegics has been demonstrated over the medium and long term. Clinical evaluation of this setup and its' effectiveness is not always easy; changes in gait parameters being difficult to measure solely by observation. Ideally, the application of FES should be done along with a 3-D analysis of the patient's gait, which can be a time-consuming procedure. The goal of this study is to evaluate dynamic changes in the center of pressure (COP), measured using an instrumented walkway, when applying FES.

Material and Method

A mono-paretic patient, stable after frontal tumor surgery, was treated with FES of the fibularis communis nerve. The evaluation of gait, at a comfortable walking pace, was realized using an analysis of both spatio-temporal parameters and COP, obtained using the GAITRite walkway. The evaluation was conducted, immediately before and after application of FES.

Results

Spatio-temporal gait parameters (walking speed, stride length, cadence) were not modified by FES. Our analysis confirms an immediate ‘posteriorization’ of the COP upon initial application of FES. Net postero-anterior displacement of the COP was increased by FES.

Conclusion

This study confirms the findings in the referenced literature, where during same-day evaluation, FES is shown to not modify spatio-temporal parameters. These modifications only being manifest during prolonged use. We observed changes in the net displacement of the COP on initial application of FES. This corroborates a recent study which suggests that FES could have an immediate effect on weight transfer and thus increase gait stability. The evaluation of the displacement in the COP could represent a readily observable parameter in gauging the
effectiveness of FES when applied to patients with drop-foot. This parameter could be easily and objectively measured with available tools such as an instrumented walkway.

COGNITIVE LOAD DURING A WALKING TASK: A PILOT STUDY
I. Hoang¹, M. Ranchet¹, L. Paire-Ficout¹
¹IFSTTAR, Health and security transport, Bron Cedex, France

Introduction/Background
Evidence suggests that gait in complex situation is influenced by executive function in normal ageing. But to our knowledge, no study revealed what measurement is the most appropriate to assess impaired walking in older adults. The objective is to (1) test the feasibility of our protocol and (2) to explore the cognitive load during a simple vs. dual walking task in younger and older adults.

Material and Method
To date, 6 young adults (mean = 26.7 years old; SD = 4.1) were included in this study. Fifteen young adults and 25 older adults will be included by May 2018. Participants are asked to achieve a walking task including four conditions: (1) normal pace walking, (2) subtracting while standing, (3) walking while subtracting and (4) walking while counting forward. Cognitive load is measured by changes in oxygenated and deoxygenated hemoglobin in dorsolateral prefrontal cortex (fNIRS device) and the NASA-TLX questionnaire completed after each condition.

Results
fNIRS analyses are in progress. Preliminary results showed that younger adults felt higher cognitive effort in both conditions 2 and 3 compared to condition 1 (NASAscore condition2 (mean SD): 66.18.7 vs NASAscore condition1: 9.5 6.3, W = -2.2, P = 0.03 ; NASAscore condition3: 78 14.6 vs NASAscore condition1, W = -2.2, P = 0.03). No significant differences in speed, cadence and stride length were found between conditions 1, 3 and 4 (p > 0.05). No significant differences in subtraction performances were observed between conditions 2 and 3 (p > 0.05).

Conclusion
Higher cognitive load in condition 3 in younger adults confirm that our dual task walking is the most cognitively demanding condition. We expect that our fNIRS results in younger adults will be similar to those observed with NASA-TLX questionnaire. However, discrepancies between those two measures are expected in older adults.

ISPR8-1513
INTER-RATER RELIABILITY OF INERTIAL MEASUREMENT UNIT GAIT ANALYSIS IN PATIENTS WITH TOTAL HIP OR TOTAL KNEE ARTHROPLASTY.
M. Bravi¹, S. Milighetti¹, F. Santacaterina¹, R. Toglia¹, A. Marzolla¹, M. Morrone¹, S. Miccinilli¹, F. Bressi¹
¹Campus Bio-Medico University, Physical And Rehabilitation Medicine, Roma, Italy

Introduction/Background

Individuals undergoing surgery for total hip arthroplasty (THA) or total knee arthroplasty (TKA) often show gait abnormalities. Visual observation is shown to be inadequate for the accurate assessment of gait, pointing out the need for some form of quantitative measurement. (Saleh e Murdoch 1985).

Inertial Measurement Units (IMUs) combine accelerometers, gyroscopes and magnetometers into an algorithm; IMUs are wearable sensors, relatively inexpensive, able to carry out spatiotemporal and kinematic assessment in a quicker and easier way than the gold standard three-dimensional (3-D) motion capture systems and force plates (Gonzalez, et al. 2010). At the present, no study has investigated inter-rater reliability of IMUs on patient with THA or TKA.

Therefore, the primary purpose of this study is to determine inter-rater reliability of spatial-temporal metrics recorded by IMU in patients with recent surgery of THA or TKA.

Material and Method

Fifty people with THA (N=15) or TKA (N=35) were recruited. The mean time distance from surgery was 12.66 ± 3.69 days. Three different operators evaluated all the patients in three different times on the same day. Enrolled patients performed a total of nine timed 10-meter walk tests (10 MWT) while wearing G-SENSOR 2 IMU (BTS Bioengineering, Milan, Italy). The sensor was positioned on the skin projection of vertebrae S1 and S2.

Results

We found no difference among the evaluations performed by three operators. We found excellent correlation regarding cadence (ICC3.k = 0.923, 95%CI = 0.898 to 0.942) speed (ICC3.k = 0.955, 95%CI = 0.940 to 0.966) and step length (ICC3.k = 0.917, 95%CI = 0.891 to 0.937). All the other recorded parameters show good reliability with an ICC3.k > 0.82.

Conclusion

Data reported confirm the feasibility of using inertial systems to perform gait analysis as a routinely tool in clinical field on patients with TKA and THA.

Introduction/Background

The prevalence of dysphagia in the elderly is high and dysphagia increases the risks of low nutritional status and onset of pneumonia. We have developed the ward rounds to check the swallowing function by using videendoscopic evaluation of swallowing (VE) for suspected patients with dysphagia (swallowing rounds). The aim of this study was to investigate the effect of swallowing rounds.

Material and Method

Upon requests from ward nurses or clinical departments in our hospital, a full-time certified nurse specialist in dysphagia examined the general condition of patients and performed screening for dysphagia. For patients who required detailed investigations, a transdisciplinary dysphagia care team conducted the swallowing rounds. We reviewed the medical records of 158 patients (mean age 79 years) in whom swallowing rounds were conducted between February and May 2017. The etiology, recommended food and liquid, severity of dysphagia, and onset of pneumonia during intervention were analyzed.

Results

The median duration from admission to the first swallowing round was 13 days (range 2 - 112 days). Stroke (17%) and pneumonia (14%) were common in our series. After the swallowing rounds, mechanical soft and thickened food was recommended in 26% of the patients, while paste food in 21%, mechanical soft food in 11%, and nothing by mouth in 11%. Thin liquid was suggested in 23%, honey thick in 16%, and no liquid is allowed in 4%. Eight patients (5.1%) developed pneumonia during hospitalization.

Conclusion

The swallowing rounds was effective to check the swallowing function and to decide the appropriate food and liquid.

VALIDATION OF JOINT ANGLE MEASUREMENTS: COMPARISON OF A NOVEL LOW COST MARKER-LESS SYSTEM WITH AN INDUSTRY STANDARD THREE-DIMENSIONAL MARKER-BASED SYSTEM

S. Bahadori\(^1\), P. Davenport\(^2\), T. Immins\(^1\), T. Wainwright\(^1\)

\(^1\)Orthopaedic Research Institute, Health and Social Sciences, Bournemouth, United Kingdom
\(^2\)Bournemouth University, Faculty of Science and Technology, Bournemouth, United Kingdom

Introduction/Background

Human motion tracking is widely used for assessment of movement dysfunction in orthopaedic patients. Currently, most clinical motion analysis centres use marker based three-dimensional systems as they are deemed to be the most accurate method. However, due to space, costs and logistics they are not available in many clinical settings. This study compared joint angles measured in functional tests using the novel low-cost Microsoft Kinect Perfect-Phorm marker-less system with the established marker based Nexus VICON system.

Material and Method

Ten unimpaired volunteers were fitted with 16 retroreflective markers in the positions specified by the Plug-in-Gait (PiG) lower limb marker set. Participants were asked to make three movements: standing, a squat action and a hip abduction action. The two measurement systems were used simultaneously to measure changes in joint angle. The collection of data from each participant was synchronised manually between each system. Average values for left and right knee flexion (for the squat task) and left hip abduction (for the hip abduction task) were obtained from each system as the average across the steady state, and the relative change between the standing and task sections used as the basis of comparisons of system performance.

Results

When measuring right and left knee flexion, the average difference between the VICON and Perfect-Phorm measurement was 13.2\%, with a SD of 19.6. Both overestimation and underestimation of the joint angle was recorded in different participants. Although the average percentage difference during hip abduction tests was lower at 3.9\%, the range of error was far greater (SD=75).

Conclusion

From this, it can be concluded that the level of accuracy presented in the new low cost Perfect-Phorm marker-less system is not yet suitable for clinical assessments. However, for general
tests of performance, and for tracking cases where absolute accuracy is less critical, future versions of this software may have a place.

NEW BALANCING ABILITY TEST METHOD USING DIGITAL EQUIPMENT

M.J. Shin¹, P. Tae Sung², L. Je-Sang¹, L. Eun², L. Byeong Ju¹, K. Sang Hun¹, S. Yong Beom¹
¹Pusan National University School of Medicine & Pusan National University Hospital, Rehabilitation Medicine, Busan, Republic of Korea
²Pusan National University Hospital, Biomedical Research Institute, Busan, Republic of Korea

Introduction/Background

There have been many attempts to measure balance ability for a long time. However, most of the clinical tools are not digitized, and there are many discontinuous ordinal variables that make it difficult to analyze. Therefore, we will test a new balance ability test that can solve these problems simply and quickly.

Material and Method

A total of 60 healthy people (men; 30) in their 20-30s were recruited to perform a balance test using a new test method and analyzed gender differences between men and women. The new test method was able to evaluate such things as standing still, standing with eyes closed, standing on a mat, standing with eyes closed, standing on a mat, and evaluating static and dynamic balance ability.

<table>

<td>standing with eyes closed for 30 seconds using Balance Pad(19.7” × 16.1” × 2.4”, AIREX®, Switzerland)</td>
</tr>
</tbody>
</table>

Results

In healthy men, regardless of whether they have mat or not, their balance ability is lower than that of women when they open their eyes. However, when the eyes were closed, the balance of women was observed to fall at a higher rate than men.

<table>

<td>13.89±5.32</td>
<td>8.22±2.83</td>
<td>22.95±9.08</td>
</tr>
</tbody>
</table>
Conclusion

In this experiment, we found that women were more affected by postural balance than men when the eyes were closed. It is also expected that it will be possible to use it in schools or welfare centers because it is helpful to evaluate the balance ability by being close to the eyes and digital measurement in a short time.

Introduction/Background

Trunk muscular function has been identified as an early predictor of health-related outcomes post-stroke, revealing unbalance on both sides changing muscular response in the axis of the body. Then, we aimed to compare the isokinetic measures of strength and endurance for trunk movement in antagonistic actions (flexion and extension), starting from the two different methods of assessment (seated compressed [SC] and semi-standing [SS]) for groups of able-bodied (control) and post-stroke hemiparesis (hemiparesis) people.

Material and Method

A cross-sectional case-control study design was performed to compare strength (peak toque and normalized peak torque) and endurance (muscular power and total work) variables took at 60° and 120°/seconds, respectively, from the four observed conditions for a convenience sample composed by 26 volunteers (13 participants by group). The Functional Independence Measurement (FIM), the modified Ashworth Scale (mAS) and Mini Mental State Examination (MMSE) were the secondary variables to characterize the sample. Significant differences were detected by the two-way ANOVA followe by the Bonferroni post-test (p<0,05).

Results

For both groups and in all conditions, the extensor muscles performed around the doubled value recorded from all variables when compared to flexor muscles. Hemiparesis group revealed the expected weakness in comparison with control group, manifesting significant more strength and endurance when assessed by SS method, what was not observed in the control group.

Conclusion
In conclusion, our results suggested that trunk extensor muscles are naturally stronger than flexor and post-stroke hemiparesis people are favored by SS method during isokinetic assessment.

THE EFFECT OF THE USE OF A PRESSURE BIOFEEDBACK UNIT ON RECTUS ABDOMINIS ACTIVATION DURING A ‘MOTOR CONTROL’ STABILITY EXERCISE.
F. Cyrillo¹, V. Reis², R. Maretto³, F. Costa³
¹USP, IOT HC, sao paulo, Brazil
²FisioLogic Institute, Physical Therapy, Santo André, Brazil
³FisioLogic Institute, Physical Therapy, Santo Andre, Brazil

Introduction/Background

Normally the superficial muscles have the function to work on high load activities to help local and global stabilizers on joint control as they have predominantly fast/fatiguing fibers. But even those muscles have some tonic fibers and sometimes fascial attachments. PBU have been used by physiotherapists as a resource to get better recruitment of muscles during ‘motor control’ stability training. To study the effect of a pressure biofeedback unit (PBU) on rectus abdominis activation during a ‘motor control’ stability exercise.

Material and Method

Electrodes were placed on rectus abdominis. 25 females with low back pain between 42 and 55 years old performed five repetitions of a motor control stability exercise on crooked lying. A pressure biofeedback unit (PBU) from Chattanooga brand was used on lumbar spine to control it during the exercise. Subjects were asked to keep it on 40 mmhg. To get EMG data, a Miotool 400 from Miotec brand was used and the rectus abdominals signals were obtained by bipolar surface electrodes according to SENIAM. The mean activation of RMS signal was considered and the significance level adopted were 0.05. The data from this work has to be linked with other evidences as only one muscle could be studied. A one-way repeated measures ANOVA and post hoc of Bonferroni (p < 0.05) was used.

Results

The muscle activation were 122,32µV and 142,43 µV on right and left sides respectively without PBU. With PBU activation were 214,76 µV and 223,02 µV. There were a statistically relevance with p=0,002.

Conclusion

PBU seems to help getting a higher activation of rectus abdominis during this motor control stability exercise. We suggest for future works to collect data from other muscles together for a better interpretation.

CRITERION VALIDITY OF WEARABLE SENSORS IN LOWER LIMB JOINT ANGLE ESTIMATION: A SYSTEMATIC REVIEW

I. Poitras†, M. Bielmann†, C. Mercier†, L.J. Bouyer†, J.S. Roy†
†Laval University, Rehabilitation, Quebec, Canada

Introduction/Background

Motion capture systems are extensively used to measure human joint kinematics. These systems, however, lack portability and can only be used in laboratory settings. Recently, portable and wireless systems, such as inertial measurement units (IMU), have been developed and are seen as an alternative to quantify human movement outside of the laboratory. Several studies have established their psychometric properties. However, the variety of systems used and joints evaluated make it difficult to conclude on the validity of the different systems available. The aim of this systematic review is to determine the criterion validity of IMUs for the evaluation of lower limb kinematics when compared to motion capture systems.

Material and Method

Five different databases were screened (Pubmed, Cinhal, Embase, Ergonomic abstract and Compendex). Included articles had to report on criterion validity of IMUs (vs. motion capture systems) of at least one joint in healthy adults. Only articles published after 2005 were considered. Pairs of raters conducted data extraction and critical appraisal using structured tools, and consensus had to be reached.

Results

A total of ten articles was included. Quality ratings of 30% of the studies reviewed were characterized as high, and 70% as moderated (intrarater reliability: ICC=0.7). Knee and trunk movements showed moderate to good criterion validity, while hip and ankle movements were characterized as having poor to good validity.

Conclusion

IMU systems are valid to evaluate knee and trunk kinematics. For the hip and ankle, however, the validity varies according to movement studied. The measurement of hip flexion/extension, abduction/adduction and ankle plantar flexion/dorsiflexion with IMU can be considered as valid. For ankle inversion/eversion and hip internal/external rotation, the validity is poor. More studies are therefore needed to optimize the use of IMU for these movements (e.g. different calibration or biomechanical models).

VESTIBULAR EVOCKED MYOGENIC POTENTIALS IN HEALTHY PEOPLE IN BOGOTA, COLOMBIA.
D. Orozco¹, A. Castaneda², J. Diaz³
¹Universidad Nacional de Colombia, Physical Medicine and Rehabilitation, Bogotá DC, Colombia
²National University of Colombia, Medicine, Bogotá DC, Colombia
³National University of Colombia, Physical Medicine and Rehabilitation, Bogotá DC, Colombia

Introduction/Background

The vestibular evoked myogenic potentials (VEMP) enable evaluate the vestibular system besides the medial vestibulospinal tract, the medial longitudinal fasciculus and the activation of the cervical musculature, so they could be used for the study of different pathologies that affect the mentioned areas. Currently does not exist reference values for Colombian population and that test is not performed routinely. The aim of this study was evaluated a newfangled diagnostic tool and determine the feasibility of its application and possible normal values for Colombian population.

Material and Method

Prospective longitudinal descriptive study preceded by a pilot test in a group of 100 healthy individuals without comorbidities, in which VEMP were performed by auditory stimulation at 97db and recording in sternocleidomastoid muscle during its voluntary activation quantifying latency for P1 and N1 in addition to the amplitude of the potential and differences of latencies P1 and N1 left/right, statistical analysis was performed using SPSS 24.

Results

The values observed for the electrophysiological variables are correlated with those reported on international literature. The mean for the latency of P1 was 12.54 (SD 1.58), N1 19.49 (SD 2.56), P1 latency difference left/right 0.013 (SD 1.23), N1 latency difference left /right 0.1 (SD 1.91) and the median for amplitude 10.43 (IQR 6.77- 15.08). Weak correlation was observed between age and latency of P1 (R=0.242, P<0.01) and N1 (R=0.144, P<0.05).

Conclusion

VEMP can be used reliably, safely and consistently using conventional electrodiagnostic equipment that allows auditory evoked potentials recording using a 97dB click stimulus. Amplitude value is highly variable but there is a correlation between the latency of P1, N1 and age.

Lightly touching a stable surface with the forefinger strongly reduces postural sway. Interestingly, bilateral light touch with both forefingers reinforces the postural stabilization. If the touched surface moves periodically, the Center-of-Pressure (CoP) oscillates in coherence with the finger movement. Based on this coupling, we presented in a previous study a closed loop control of the CoP position in the Anterior-Posterior (AP) direction. We were able to drive the CoP around an arbitrary predefined path only by using finger movements. The current objective was to study the influence on this coupling of reinforcing the light touch by asking the participants to put both forefingers on the platform.

### Material and Method

Participants stand on a force platform and touch lightly with the index a 1-degree-of-freedom robot, which performs linear displacements in the AP direction. Robot velocity, and thus the finger velocity, is driven proportionally to the error between an arbitrary predefined path and the current CoP position, measured by the force platform and fed back to the robot. The finger-movements/CoP coupling is assessed through the efficiency of the closed loop to drive the CoP. 14 participants repeated 3 times in a random way two closed-loop conditions: one with dominant hand forefinger and the other with both forefingers. The finger and the CoP positions are recorded and used to compute the tracking error between CoP and a predefined path.

### Results

The efficiency of the closed loop is significantly increased (almost halved mean tracking error) with both forefingers compared to one.

### Conclusion

This observation extends results with bilateral light touch on a stable surface i.e. bilateral contact increases light touch effect on postural control. Giving more weight to the light touch
leads to a better integration of this reference and thus to a more consistent coupling between finger movements and CoP.

Introduction/Background

Parkinson Disease (PD) is the second most spread disease worldwide after Alzheimer. It is a neurological disorder affects the function of basal ganglia, producing serious motor and non-motor impairments. Methodologies are employed to diagnose, monitor treatment, and have an early detection of PD constrained with few know symptoms at early stages. Merely, Artificial Intelligence algorithms experienced great improvement reaching around 93% success rate in PD detection throughout literature. This abstract presents neural network-based algorithm for PD detection.

Material and Method

Data collected from 47 subjects in whom 29 are affected with PD. 16 ultraflex sensors distributed on both feet (see figure 1) to collect Vertical Ground Reactional Forces (VGRF) in newton over 2 minutes (see figure 2).

Figure 1: Sensors Distribution Underneath Both Feet

Figure 2: VGRF of Normal and Parkinson Subject

Total VGRF from each foot segmented and turning points a subject encounters at the end of corridor are omitted based on synchrosqueezing technique. Then set of features are extracted including: Forces aggregate sum average-weight ratio, number of peaks attained in step, average duration of step, the slope during heel strike and toe-off, first and last peak-stable zone drop, median value-to-weight Ratio and standard deviation. One hidden layer used in ANN for less time consumption. The number of internal hidden neurons is fifty five based on trial-and-error until contentment result is attained.

Results

100% in both training (70% of subjects) and validation accuracy (15% of subjects) is accomplished. The testing results display 85.7% accuracy in classification in which all normal subjects are classified correctly (see figure 3).
Conclusion

Classifying some Parkinson gait as normal gait indicates high variation within subjects which can be correlated to Hoehn-Yahr scale of PD progress. The overall accuracy is 97.9% making VGRF good element in PD assessment.

Introduction/Background

Our research highlight the utility of specific devices to enhance the performances of orthostatism and walking in patients with stroke.

Material and Method

The configuration of the orthosis skeleton, based on composite glass fiber, allows the adjustment of the dimensions and anatomical fit of the patient's lower limb by a telescopic system to make it as ergonomic as possible. The control is achieved by three hydraulic distributors powered by a miniature pump. Feedback from the level of the orthosis joints corresponding to human ones is ensured by three resistive potentiometric transducers. We corrected the posture of the foot, the equine and the muscular imbalance caused by the spasticity. The prototype testing will follow the bioethics rules in volunteer patients by analyzing the following parameters: modified Ashworth scale for spasticity, Tinetti balance and walking scales.

Results

The orthosis achieved the maximum compaction of the available components for the best functionality. For this purpose the support frame is made of composite material based on glass fiber, and the actuators are hydraulic, providing maximum force at the proposed gauge. The power supply of the system in this phase is made from the 220V AC with a power about of 100 W for normal walking on flat ground. An autonomy of several hours is expected. Although the movement is made on a flat ground, but orthosis allows the assisting for climbing and down stairs.
Conclusion

This prototype of orthosis could be the future in rehabilitation of walking in the stroke patient, and it has the capacity to be extend to the other lower limb for paraparetic patients.

SETUP OF THE FIRST GAIT ANALYSIS LAB IN MOROCCO: EXPERIENCE OF THE MARRAKECH UNIVERSITY HOSPITAL
Y. abdelfettah\textsuperscript{1}, H. Said\textsuperscript{2}
\textsuperscript{1}university hospital Mohammed VI, PMR, Marrakech, Morocco
\textsuperscript{2}university hospital Mohammed VI, Orthopedic and trauma surgery, Marrakech, Morocco

Introduction/Background
A gait analysis laboratory (GAL) must perform within a rigorous clinical governance.

Material and Method
The aim of this work is to describe the experience of the University Hospital of Marrakech in the setup of the first GAL in Morocco and the first patients who benefited from this analysis.

Results
The need to have a GAL is part of the fact that Morocco does not yet have a platform for analyzing movement and walking. It is managed by a multidisciplinary team. Currently about twenty patients, with multiple conditions: neurological and musculoskeletal, have benefited from this analysis.

Conclusion
A GAL is a tool for measurement, quantification, an understanding and functional assessment tool. For a successful GAL, it is necessary to have a multidisciplinary and homogeneous team, and an optimal organization.

FORCED USE OF THE PARETIC LEG INDUCED BY REPEATED EXPOSURE TO CONSTRAINT FORCE APPLIED TO THE NON-PARETIC LEG OF INDIVIDUALS POST-STROKE DURING WALKING.

M. Wu¹, C.J. Hsu¹, J. Kim¹
¹Shirley Ryan Abilitylab, Legs and Walking Lab 23rd floor, Chicago, USA

Introduction/Background

Locomotor training has been used to improve walking function of individuals post-stroke. However, the functional gains are relatively small, which may be due to the compensatory movements of the non-paretic leg during locomotor training. Our previous study indicated that applying a constraint force to the non-paretic leg could increase muscle activations of the paretic leg during treadmill walking. It is still unclear whether muscle responses in the paretic leg are acquired through feedback correction mechanisms or feedforward control mechanisms. The goal of this study was to examine electromyography (EMG) responses in the paretic leg to a repeated constraint force applied to the non-paretic leg during treadmill walking.

Material and Method

Fifteen individuals with chronic stroke participated in this study. Subjects walked on a treadmill with no force for 1 minute, i.e., baseline. A controlled resistance force was then applied to the non-paretic leg starting from toe-off to mid-swing through a custom designed cable-driven robotic system for 7 minutes, i.e., adaptation period. The force was released and subjects continued walking on the treadmill for another 1 minute, i.e., post-adaptation period. The magnitude of resistance force was ~18% of MVC of the hip flexion. EMG from 8 muscles of the paretic leg were recorded using electrodes and ankle movement of both legs were measured using position sensors.

Results

Integrated EMGs of ankle plantarflexors and hip extensors during stance phase significantly increased (33-50% increase, p < 0.01) during the early and late adaptation periods, and partially retained (17-22%) during the post adaptation period.

Conclusion

Our results suggest that both feedback correction and feedforward control mechanisms may be involved in response to the constraint force applied to the non-paretic leg. Results from this
study may be used to develop a long-term training paradigm to induce a forced use of the paretic leg and improve walking function of individuals post-stroke.

FUNCTIONAL IMPACT OF A NEW PROSTHETIC FOOT DESIGN IN TRANSTIBIAL AMPUTATION, A COMPARATIVE STUDY
A. Esquenazi
1MossRehab, PMR, Elkins Park, USA

Introduction/Background

Prosthetic feet designs are complex with energy storage and shock absorption characteristics. These feet store energy in the heel and the mid-foot during loading and release energy at push off. Device selection is based on subjective criteria because of a lack of quantitative methods. Studies have compared different prosthetic feet however, did not include functional outcome and rating for comfort. This study evaluated a new prosthetic foot (Pro-Flex XC TS and Pro-Flex LP TS) from Ossur.

Material and Method

Prospective, comparative study that included 10 trans-tibial prosthetic users walking with current foot design vs. the Pro-Flex XC/LP TS. Outcomes included the Prostheses Evaluation Questionnaire, Socket Comfort Scale, 6 MWT Performance, L-Test, Activities-specific Balance Confidence Scale and temporal spatial parameters of gait measured with original prosthetic device and the test devices used for 4 weeks.

Results

With the Pro-Flex XC TS and Pro-Flex LP TS, most subjects demonstrated average 10% increase in walking velocity, improved scores in the PEQ and 15% increase walking capacity. Improved L test time and swing/stance ratio. Most had improvement in the ABC, with small non significant decrease was reported in 4 subjects.

Conclusion

The newly designed Pro-Flex XC TS and Pro-Flex LP TS foot produce improvement in walking and functional rating as well as benefits in self rated performance and stability. This new foot design should be considered as an excellent choice for patients with functional ambulatory category 2 - 4. Tests of function and satisfaction should be used in future prosthetic foot trials and included in foot prescription.

APPS FOR SMARTPHONE AVAILABLE THROUGH DISTRIBUTION PLATFORMS AND VALIDATED FOR GONIOMETRIC MEASUREMENT: A SYSTEMATIC REVIEW
G. Ferriero¹, L. Longoni², R. Brunati²
¹Scientific Institute of Lissone- IRCCS- Istituti Clinici Scientifici Maugeri, Department of Physical Medicine and Rehabilitation, Lissone, Italy
²Scientific Institute of Lissone- Istituti Clinici Scientifici Maugeri- IRCCS, Department of Physical Medicine and Rehabilitation, Lissone, Italy

Introduction/Background

The use of smartphones for medical purposes is increasing due to the steadily growing number of downloadable applications (apps) that transform the mobile phone into a medical device. Apps make use of the inbuilt smartphone to obtain fast measurements useful for clinical practice, in particular for goniometry. Medical apps are an emerging technology that need to be appropriately validated to ensure their safe and effective operation.

The objective of this review was to provide a systematic review of apps validated for goniometry available through distribution platforms, relevant to physical medicine and rehabilitation (PMR) practitioners.

Material and Method

A literature search was conducted by two independent reviewers on relevant articles indexed by PubMed before April, 2017. We selected only research papers published in English. Papers dealing with apps not relevant to PMR or unavailable on the market were excluded. We analyzed the following information for all apps: target population, object of the measure, body segment evaluated, modality of use, operating platform system, and validation results.

Results

The literature search produced 91 papers, 39 of which met the inclusion criteria. The included papers featured 20 different apps: 13 exclusively for upper/lower limb joint angles, 4 for spine, and 3 for both limbs and spine measurement. The 20 apps used the inbuilt smartphone magnetometer, accelerometer or camera to produce angle measurements. The overwhelming majority of the selected apps are available in the App Store for iOS. No goniometric app has been validated in dynamic conditions.

Conclusion
Our report highlights the availability –for angle measurement of diverse body segments– of a large body of validated goniometer apps that physiatrists and other healthcare practitioners can use with confidence in research and clinical practice. There is a need for validation studies on apps focused on goniometric measurement in dynamic conditions, such as during gait or during performance of therapeutic exercises.

AN ANALYSIS OF MOVEMENT PATTERNS DURING REACH AND GRASP IN STROKE PATIENTS: A KINEMATIC APPROACH

D.Y. Kim¹, H.S. Choi², J.S. Kim¹, Y.J. Jo³, H.S. Nam⁴, D.W. Rha¹
¹Yonsei University College of Medicine, Dept. and Research Institute of Rehabilitation Medicine, Seoul, Republic of Korea
²Eulji University School of Medicine, Dept. of Rehabilitation Medicine, Seoul, Republic of Korea
³Yonsei University College of Medicine, Research Institute of Rehabilitation Medicine, Seoul, Republic of Korea
⁴Yonsei University College of Medicine, Dept. of Neurology, Seoul, Republic of Korea

Introduction/Background

This study aimed to evaluate spatiotemporal and kinematic movement patterns during reach and grasp task performance in post-stroke hemiplegic patients and compare the movement pattern according to upper extremity impairment severity.

Material and Method

46 subacute post-stroke patients and 20 healthy participants were enrolled in this study. Spatiotemporal and kinematic data were obtained through 3D motion analysis (VICON) during reach and grasp task performance. The reach and grasp task consisted of four sub-phases: reaching, forward transporting, backward transporting, and return. Movement time, peak velocity, number of movement units, joint angles, range of motion, and sum of the deviation angles from normative data were compared between groups, which were classified by the upper-Fugl-Meyer Assessment (FMA) performance-based impairment scale.

Results

The severe group showed significant longer movement time, lower peak velocity, and a higher number of movement units than the mild group during the reach and grasp task performance (p<0.05). The characteristic compensatory movement patterns, such as shoulder abduction, thoracic posterior tilting, and upward and external rotation motion were significantly larger during forward transporting in the severe group compared to the mild group (p<0.05). The FMA-UE score was significantly associated with the movement time during the forward transporting phase, the number of movement units during the reaching phase, range of shoulder abduction-adduction motion during the reaching and backward transporting phase, range of thoracic upward-downward movement during the forward transporting phase, thoracic internal-external rotation motion during the backward transporting phase, and elbow flexion-extension motion during the return phase in the multivariate analysis (p<0.05).
Conclusion

This study suggests that post-stroke hemiplegic patients have unique spatiotemporal and kinematic movement patterns during reach and grasp task performance according to upper extremity impairment severity. The results of this study may be helpful for interpreting upper extremity motions in post-stroke patients.

ISPR8-2288
QUANTITATIVE ASSESSMENT ON FOUR MOVEMENTS TO REPRESENT THE HAND FUNCTION IN STROKE
S. Chen¹, J. Jia¹, X. Lu²
¹Huashan Hospital- Fudan University, Rehabilitation Medicine, Shanghai, China
²Shanghai University, College of communication and information engineering, Shanghai, China

Introduction/Background
As the hand motor function rehabilitation after stroke has attracted more and more attention, the treatment and assessment of hand function become increasingly important. A more precise assessment of hand function is of great significance for the stroke patients. Methods of assessment include qualitative, semiquantitative and quantitative modalities. It is more meaningful to have quantitative assessment to evaluate the situation, which can produce suitable treatment.

Material and Method
A multi-dimensional visual hand function rehabilitation quantitative assessment system was invented by our team. It used advanced cameras to catch movements of the hand. Both hands of the patients were recorded with their active range of motion(AROM). The AROM was considered to be a symbol of functional movement of the hands. For stroke patients, we chose four typical actions, which were forearm supination, wrist dorsiflexion, thumb adduction and abduction and the four-finger(except for the thumb) adduction and abduction, to represent the hand function of the patients. At the same time, the Fugl-Meyer assessment(FMA) of upper extremity was evaluated to these patients.
Results

For stroke patients with unilateral cerebral injury, AROM of the four typical movements of both the affected and the unaffected hand were recorded through the quantitative system. Normally, we take the unaffected hand as a standard. Percentage from the affected to the unaffected one was also calculated. For each patient, he had a set of quantitative assessment and a result of FMA.
Conclusion

Quantitative assessment in hand function of stroke patients is valuable because a good assessment is the foundation of an effective treatment. The AROM data from the system is found compared to the FMA. The four functional movements can be used to stand for the hand function of the stroke patient. Quantitative assessment on these four movements will be of great value during the rehabilitation process.

EEG EVALUATION OF STROKE PATIENTS WITH HAND DYSFUNCTION

S. Chen¹, J. Jia¹, X. Shu²
¹Huashan Hospital- Fudan University, Rehabilitation Medicine, Shanghai, China
²Shanghai Jiaotong University, College of mechanical and power engineering, Shanghai, China

Introduction/Background

EEG-based BCI evaluation was a non-invasive way to assess the brain function of stroke patients. With higher temporal resolution, it can be used to see the brain activation change when patients were asked to perform a specific task like motor imagery(MI). For patients with hand dysfunction after stroke, specific task-based EEG evaluation can not only be used to assess brain function but also be a reference in BCI rehabilitation system improvement suitable for stroke patients.

Material and Method

The research recruited 31 stroke patients with hand and upper extremity motor dysfunction. Patients were asked to perform motor imagery task according to the tips on the screen. EEG signals of stroke patients were recorded. BCI performances of this system were evaluated. We chose 12 and 14 channels to respectively calculate the BCI performances. They total 12 are C3, FC1, FC5, CP1, CP5, P3 in the left hemisphere and C4, FC2, FC6, CP2, CP6, P4 in the right hemisphere. In addition, we add F3 and F4 to a total 14 channels.
Results

We found that in the lower alpha-α, the BCI performance of ischemia was significant higher than that of hemorrhage (P<0.05) both in the 12 and 14 channels. We also found that the higher the BCI accuracy, the higher FMA score the patient will get (P<0.05). And there was no statistical significance in other EEG frequencies related to motor imagery task.

Conclusion

The brain activation and BCI accuracy can be used as monitor and assessment for stroke patients. The difference in BCI accuracy between ischemia and hemorrhage may be an improvement reference in BCI system. For hemorrhagic patients, the BCI feedback threshold may be lower in other to get a better interaction. And the correlative result between FMA scores and BCI accuracies suggests that the person with higher hand function, the higher BCI accuracy he may get.

ASSESSMENT OF ELBOW SPASTICITY WITH SURFACE ELECTROMYOGRAPHY AND MECHANOMYOGRAPHY BASED ON SUPPORT VECTOR MACHINE

Y. Xiang¹, H. Wang²

¹Nanshan District Hospital, Rehabilitation Medicine Dept., Shenzhen, China
²Shenzhen Institutes of Advanced Technology- Chinese Academy of Sciences, Key Lab of Human-Machine Intelligence-Synergy Systems, Shenzhen, China

Introduction/Background

The Modified Ashworth Scale (MAS) is the gold standard in clinical for grading spasticity. However, its results greatly depend on the physician evaluations and are subjective.

Material and Method

In this study, we investigated the feasibility of using support vector machine (SVM) to objectively assess elbow spasticity based on both surface electromyography (sEMG) and mechanomyography (MMG). sEMG signals and tri-axial accelerometer mechanomyography (ACC-MMG) signals were recorded simultaneously on patients' biceps and triceps when they extended or bended elbow passively. 39 post-stroke patients participated in the study, and were divided into four groups regarding MAS level (MAS=0, 1, 1+ or 2). The three types of features, root mean square (RMS), mean power frequency (MPF), and median frequency (MF), were calculated from sEMG and MMG signal recordings. Spearman correlation analysis was used to investigate the relationship between the features and spasticity grades.

Results

The results showed that the correlation between MAS and each of the five features (MMG-RMS of the biceps, MMG-RMS of the triceps, the EMG-RMS of the biceps, EMG-RMS of the triceps, EMG-MPF of the triceps) was significant (p<0.05). The four spasticity grades were identified with SVM, and the classification accuracy of SVM with sEMG, MMG, sEMG-MMG were 70.9%, 83.3%, 91.7%, respectively.

Conclusion

Our results suggest that using the SVM-based method with sEMG and MMG to assess elbow spasticity would be suitable for clinical management of spasticity.

VALIDITY AND DIAGNOSTIC ACCURACY OF THE FILIPINO VERSION OF THE BOSTON CARPAL TUNNEL QUESTIONNAIRE IN THE DIAGNOSIS OF CARPAL TUNNEL SYNDROME
F. Dela Cruz¹,², C. Gonzalez-Suarez³, M.L. Buenavente¹, M.A. Ledesma³, R.C. Cua¹, D.D. Feliciano¹, J.M. Lleva³, M.V. Gesmundo¹

³University of Santo Tomas, Faculty of Medicine and Surgery, Manila, Philippines

Introduction/Background

The Boston Carpal Tunnel Questionnaire (BCTQ) is the most utilized, reliable and valid condition-specific questionnaire for carpal tunnel syndrome (CTS). Recently, its Filipino version (BCTQ-Fil) was developed. The aim of this study was to evaluate its validity and diagnostic accuracy in the diagnosis of CTS using two reference standards: nerve conduction studies (NCS) alone, and physical examination (PE) and NCS combined.

Material and Method

One hundred sixty-six participants were recruited in offices in Manila, Makati, Pasig and San Juan City from September 2015 to September 2016. History and physical examination were done. 117 participants were qualified which included those with clinical diagnosis of CTS based on symptoms of wrist or hand pain, tingling sensation and numbness of hand and/or fingers, and healthy volunteers. Excluded were participants less than 18 years old, women known to be pregnant, presence of history or clinical evidence of an accompanying condition that mimics CTS or interferes with its evaluation, history of underlying disorders associated with CTS, and previous upper extremity surgery. All completed the BCTQ-Fil and underwent NCS.

Results

There was a significant correlation found between the BCTQ-Fil scores and the two reference standards.
Using NCS alone, the sensitivities of the Symptom Severity Scale (SSS), Functional Status Scale (FSS) and total scores of BCTQ-Fil were 60.00%, 47.37% and 60.00%, respectively, while specificities were 66.91%, 75.54% and 64.03%, respectively, shown in table 2.

THE CHARACTERISTICS OF CORTICAL ACTIVATION DURING HAND LATERALITY TASK AFTER ISCHEMIC STROKE

J. Jia¹, L. Ding¹, X. Wang², X. Guo²

¹Huashan Hospital Fudan University, Rehabilitation Medicine, Shanghai, China
²Shanghai Jiaotong University, School of Biomedical Engineering, Shanghai, China

Introduction/Background

Motor imagery (MI) has shown its effects as a neuro-rehabilitation strategy. But limited literature emphasized the neural mechanisms during MI in stroke patients. The purpose of this study is to investigate the features of cortical activation during the hand laterality task (HLT) using electroencephalogram (EEG) in stroke patients.

Material and Method

Nine ischemic stroke patients and five age-matched control were recruited. EEG and behavior performances of subjects were recorded in the left/right hand judgement (HLT) which involves visual processing and mental rotation, and provides a good paradigm to study motor imagery and visual perception of hands. Reaction time (RT) and accuracy were used to evaluate the behavior performances; moreover, event-related potential (ERP) with the frequency from 0.5 to 40 Hz was analyzed to investigate the cortical activation. EEG and T1-weighted structural MRI (TR=7.42 ms, TE=3.26ms) were incorporated to reveal the source activity of the cortex during the task.

Results

The RT is significantly longer in patient group than control, while the accuracy has no statistical difference between two groups (Figure 1). The ERP analysis showed that P200 (in parietal zone) and P300 (in central zone) amplitudes were significantly lower in stroke patients (Figure 2). Besides, source analysis shows the inactivation of the frontal lobe during P200 and bias activation during P300 when patients underwent this task.
Conclusion

The manifestations of EEG signals during HLT in stroke patients indicated the impairments of visual perception and mental rotation related cognitive processes. It suggested that the underlying neural mechanisms of MI in time course and helped to optimize rehabilitation strategy.

CHANGES IN LOWER EXTREMITY BIOMECHANICS AND MUSCLE ACTIVITY AFTER SIX-MINUTE FAST-WALK IN INDIVIDUALS WITH FLATFOOT

C.Y. Chiang¹, K.W. Lin¹, W.W. Yang¹, Y.C. Chang¹, L.W. Chou¹
¹National Yang-Ming University, Physical Therapy and Assistive Technology, Taipei, Taiwan R.O.C.

Introduction/Background

Flatfoot is a common disorder which is caused by dysfunction of medial longitudinal arch. Individuals with flatfoot usually exhibit symptoms such as fatigue and discomfort after fast walking, and association syndromes to other lower extremity joints. Therefore, it is important to understand how flatfoot affects the biomechanics and muscle activities of the lower extremity, especially after a challenging walking activity.

Material and Method

Fourteen individuals with flatfoot (8M6F, age: 24.5±2.47) participated in this study. All subjects performed maximal voluntary isometric contraction (MVIC) and functional tasks including walking, single-leg standing and sit-to-stand before and immediately after a 6-minute fast-walking protocol. The motion capture (Vicon Motion Systems Ltd, Oxford, UK) system, force plate and the surface electromyography (sEMG) system (MP150, BIOPAC Systems Inc., CA, USA) were used to collect kinematics and muscle activation data respectively. Median frequency and RMS amplitude of EMG, as well as joint angles and moments were calculated and compared using paired t-tests.

Results

Most of subjects showed decrease in median frequency (fatigue) in tibialis anterior, but increase in abductor hallucis after 6-minute fast-walking. Also, during stance phase of gait, ankle joint showed more adduction and hip joint showed more flexion at heel contact, decreased knee extension moments at 30% to 50% of stance phase, and decreased hip internal rotation moments at 30% of stance phase.

Conclusion

Our study found that tibialis anterior became fatigue after 6-minute fast walking, and as a result abductor hallucis increased muscle recruitment to compensate and provide support to the foot arch. Along with the altered biomechanics of the proximal joints, this challenging fast walking protocol could help explain the mechanism of overuse injury and associated syndromes in individuals with flat foot.

ISPR8-2437
SUPPRESSING INVOLUNTARY MOVEMENTS BY MECHANICAL COMpressing STIMULATION WITH HARNess
S. Inaguma¹, Y. Murou¹, A. Yodu², S. Yamada¹
¹JCHO Tokyo Shinjuku Medical Center, Department of Rehabilitation, Shinjuku, Japan
²Department of Rehabilitation medicine, Center for Medical Sciences, Ibaraki Prefectural University of Health Sciences, Inashiki, Ibaraki

Background and Aim.
Muscle tone depends on voluntary movement, but there is a condition that voluntary movement becomes dystonic and exercise does not go well. We developed a harness device to suppress dystonia with compression from the body surface to improve the performance.

Case. The patient is a 20-year-old Japanese woman with a recent history of Miller Fisher syndrome undergoing occupational therapy. After intravenous immunoglobulin therapy, she started to show dystonia during voluntary movements disturbing her motion, which made her daily activity difficult. The dystonia made her shoulders adduct, elbows flex and forearm externally rotated. When she walked, her hips were externally rotated with ankle dorsally flexed and externally rotated. We found that pressure on lower inside area of the shoulder blades, and on the planter side of the fourth to fifth metatarsal bones inhibited dystonic movements of the upper and lower extremities, respectively.

Discussion. The aquaplast splint material (APM) resembling a thumb on the harness was an effective device made upper limb movements free from dystonia. A similar device on the foot sole suppressed dystonia of the legs during when she walked. Thus these simple devices made her over-all ADL performance. No similar case has been reported to date. This case suggests that the use of APM on a harness can help managing dystonia during ADL performance. There are a key points to suppress muscle tones by pressing body surface. There may be other points that can control muscle tones by pressure on body surface with a harness device.

Conclusion. We think that a similar device can be widely used to control troublesome muscle tone abnormalities including spasticity to make patient’s ADL better.

INVESTIGATING CHANGES IN GLOBAL CONDUCTION VELOCITY ESTIMATES FROM BICEPS BRACHII MUSCLES OF STROKE SURVIVORS

T. Pinto¹, A. Turolla², M. Gazzoni¹, M. Agostini², T. Vieira¹
¹Politecnico di Torino, DET - LISiN, Turin, Italy
²IRCCS Fondazione Ospedale San Camillo, Laboratory of Kinematics and Robotics, Venice, Italy

Introduction/Background

It has been inferred that stroke-induced alterations of the lower motor neurons and their muscle fibres may contribute to muscle weakness and thus to motor impairment. Although previous accounts have investigated the mechanisms underpinning muscle weakness from muscle fiber conduction velocity estimates, reports about how the global conduction velocity (CV) differ between healthy and paretic muscles post-stroke are uncommon. Thus, in this study we examined side-differences in global CV estimates from biceps brachii muscles of stroke survivors, and their relation with differences between muscles’ functions.

Material and Method

Seven chronic post-stroke patients participated in this study. Surface electromyograms were sampled with a grid of 32 electrodes (8x4; 10 mm inter-electrode distance) from biceps brachii. Stimulation electrodes were placed in bipolar configuration as proximally as possible over the muscle. CV values were estimated from differential M waves elicited by supramaximal current pulses. Impairment of biceps brachii functions was assessed with the Fugl-Meyer Assessment scale. Spearman’s rank-order correlation was applied to verify the relationship of the healthy/paretic ratio values for CV and Fugl-Meyer values.

Results

There was a significant negative correlation ($\rho=-0.96; P=0.003; N=7$: Figure) between side-differences in CV values and the functional scores.
Conclusion

Marked differences in CV values estimated for the healthy and paretic limbs were associated with highly impaired, biceps brachii function. Conversely, patients with either preserved or recovered motor function exhibited similar CV values for both limbs. Whether these side-differences in CV may be explained by structural adaptations remains an open issue. Current results reveal however the CV values may constitute a relevant index to assess the degree of motor function in biceps brachii motor units.

**WHAT IS THE BEST SET OF MARKERS FOR FACIAL MOVEMENTS RECOGNITION?**

N. Dagnes¹,², K. Ben-Mansour², F. Marcolin¹, F. Marin², F.R. Sarhan³,⁴, S. Dakpé³,⁵, E. Vezzetti¹

³Centre Hospitalier Universitaire d’Amiens, Service de Chirurgie Maxillo-faciale, Amiens, France
⁴Université Picardie Jules Verne, EA Chimere, Amiens, France
⁵Institut Faire Faces, Institut Faire Faces, Amiens, France

**Introduction/Background**

Nowadays, motion capture with light and markers is a valid tool for medical applications. However, in the face analysis domain, a framework for defining the optimal marker set layout does not exist yet.

Therefore, the objective of this study is to propose an automatic approach to compute the optimized layout with the minimum number of facial marker.

**Material and Method**

124 distinct face motion captures, acquired through 18 optoelectronic cameras T160 and two Bonita video cameras at a frequency of 100Hz, have been analyzed. Every capture contains the 3D coordinates of 109 markers (Ø 1.5mm) fixed by a trained physiotherapist on the facial skin surface.

The six facial movements acquired are the closure of the eyes, the forced closure of the eyes, the pronunciation of the sounds [o] and [pµ], a smile, and a spontaneous smile. These movements have been chosen due to their great importance in analysis of facial expression in healthy, pathological or rehabilitative subject. They take place in different zones of the face involving both the frontal and orbicular zones, and the zones of the lips and the chin.

Then, the distances between each marker and its nearest neighbours are computed and used as input of a recursively two-step KNN classification process, performed on a subset of the previous computed features, selected through a Feature Selection Procedure. The subset that best of all allows an automatic identification of the types of the performed movement is recorded and the marker set layout is extracted from it.

**Results**
This systematic study has identified a set of 19 markers, shown in Figure 1.

*Figure 1* The position of the 109 facial marker during the acquisition. In red the minimum optimum marker layout found by our automated procedure.

**Conclusion**

The recognition rate obtained is 95%. Hence, the solution accurately records the motion information necessary to discriminate the six facial expressions.

THE ANALYSIS OF TISSUE COMPRESSIBILITY PATTERN USING ULTRASONOGRAPHY IN LYMPHEDEMA PATIENTS AFTER BREAST CANCER SURGERY

C. Kwon¹, K.S. Dr.²

¹Sheikh Khalifa Specialty Hospital, Physical Medicine and rehabilitation, Ras Al Khaimah, United Arab Emirates
²Seoul, Seoul National University College of Medicine, Seoul, Republic of Korea

Introduction/Background

To investigate the subcutaneous tissue elasticity by using ultrasonography in lymphedema patients after breast cancer surgery.

Material and Method

Lymphedema patients who took breast cancer operation were included. Thickness of subcutaneous tissue was assessed at two spots; 10cm below elbow (forearm) and 10cm above elbow (upper arm), not only in affected side but also in sound side. By using probe attached to real-time pressure sensor, we could obtain stress-strain (subcutaneous) curves. We defined tissue elasticity as slope of that curve at range of 7.5~15% of strain to avoid toe region. By comparing the elasticity of normal side and that of affected side, lymphedema tissues were classified into ‘softer’ and ‘harder’ tissues.

Results

Overall 30 cases of lymphedema tissues and 30 cases of sound tissues were checked. The difference of the elasticity between normal and affected side ranged from -3.98 N/m² to 1.40 N/m². The lymphedema tissues were classified into 17 softer tissues and 13 harder tissues. No demographic and clinical values, including clinical stage of lymphedema, showed statistically meaningful differences between two groups.

Conclusion

Evaluation of subcutaneous tissue elasticity with ultrasonography and real-time pressure sensor could be one of the useful tools for investigation of lymphedema tissue characteristics.

QUALITY OF LIFE AND PHYSICAL FUNCTIONING IN PATIENTS WITH MYOPATHY
A. Rohmer-Cohen¹, C. Bungener², D. Delorme¹, J. Rangel Escribano¹, M. Mane¹, P. Thoumie¹
¹Hopital Rothschild APHP, Bâtiment Jardin, Paris, France
²Université Sorbonne Paris Cité - Paris Descartes, Psychologie, Boulogne-Billancourt, France

Introduction/Background

The aim of this research was to investigate the physical functioning of patients with myopathy and to measure its influence on quality of life (QoL). Previous studies have observed a lower QoL in myopathy than in control patients but its relationship with physical functioning as not yet been evaluated. We hypothesized that motor abilities evolution would predict a lower physical and psychological QoL.

Material and Method

25 patients with adult-form myopathy were included: 14 patients with myotonic dystrophy type 1, 6 with facioscapulohumeral dystrophy, 2 with limb girdle muscular dystrophy, 1 with mitochondrial myopathy, 1 with Central Cores myopathy, 1 with Ullrich muscular dystrophy (population description in table, n=25)
They all answered two questionnaires of QoL: Medical Outcomes Short-Form 36 (SF-36) which gives a physical and a mental score and the Quality of Life of genetics neuromuscular diseases (QoL-gNMD) which gives three under-scores: Body symptom, Self-perception, Activity and participation. The physical functioning was evaluated with two measures by physiotherapists: balance with the Berg Scale and walking range with the 6 Minute Walk Test.
Results

Linear regression analysis showed the 6 Minute Walk Test was significantly predictor of the three scores of QoL-gNMD and the physical score of SF-36. The under-score “Activity and Participation” was also predicted by a balance trouble (Table: regression analysis recapitulative,
**p-value < 0.01). None independent variable was linked with the mental score of SF-36.

### Conclusion

Results reveal the negative influence of the physical function lost on QoL, especially the walking range. Effects are observed in body aspects like symptom or social relationship as well as deeper psychological aspects as the self-perception. So, it appears very important to take into account the motor abilities evolution of each patient in order to recommend an adapted rehabilitation, and if necessary, a psychological support to optimally preserve their quality of life.

THE NUMBER OF WALKING STEPS OF JAPANESE YOUNG PEOPLE ARE DECREASING

Y. Urabe¹, N. Maeda², N. Tonegawa², N. Moriyama³

¹Hiroshima University, Graduate School of Biomedical & Health Sciences, Hiroshima, Japan
²Hiroshima University, Graduate School of Biomedical & Health Sciences, Hiroshima, Japan
³Fukushima Medical University, Department of Public Health, Fukushima, Japan

Introduction/Background

Walking is the simplest exercises for ordinary person. The Ministry of Health, Labour and Welfare proposed the average number of steps increases 9,000 steps/day from 8,000 steps/day over a ten-year period in Health Japan 21 Project in 2012¹.

The Great East Japan Earthquake occurred on March 11, 2011. Because many citizens were forced to evacuate from their house, it was feared that they were lack of walking steps.

On the other hand, freshmen in university were checked how many steps they walked for the purpose of health education. This study aimed to compare the walking steps between elder residents in temporary housing and freshmen in university, and to clarify the present situation of Japanese walking steps.

Material and Method

The number of steps of 50 elder residents in temporary housing and 50 elder residents living in their own house were measured in December 2014 at Minami-soma City, Fukushima. In addition, walking steps of 350 freshmen in Hiroshima University were counted from May 2015 to May 2017.

Results

The number of steps were 4,200 steps/day with Minami-soma evacuees, 6,300 steps/day with residents living in their own house, 3,590 steps/day with freshmen in Hiroshima University (Table 1).

Conclusion

Ordinary Japanese people walked 7,360 steps/day in 2010¹. It documented that elder residents living in temporary housing are less physically active than those living in their house. Collapse of original community and lacking of motivation to go outside may cause this situation.
However, freshmen’s walking step was less than evacuees. Lack of walking steps is critical issue. They will walk less and less in the future, and spend their life depending on medical care. It is necessary to change this negative tendency.

Introduction/Background

In 1959, the poisoning with adulterated oils is one of the most tragic sanitary catastrophes in Morocco. More than 20,000 persons were affected and a larger number become disabled. 51 years after, many patients continue to report participation restriction and impaired quality of life (qol). This study aims to evaluate the outcome, qol and participation of this population, a half-century after the tragedy.

Material and Method

We conducted a cross-sectional study in 2010. Among 450 survivors, 111 people were included. A structured interview was carried out to investigate the socio-demographic and clinical aspects. The Functional Independence Measure (FIM) and Short Form Health Survey (SF-36) were used to assess activities limitations, participation restriction and qol. To study the relationship between quality of life and disability, a univariate analysis was carried out. The chi-square test was used for inter-group comparisons. A p-value of 0.05 was adopted as the limit for inclusion of a variable in the multivariate analysis.

Results

The average age of the study population is 68 +/- 99.9 years with a female predominance (56%). The average age at the time of intoxication is 17 +/- 9.97 years. The majority is married (68.5%), illiterate (58%), without any adhesion to the insurance system (79%) with similar cases in the family (63%). The overall average score for qol is 31.64. Women were significantly more impaired than men. The age of over 65 years, illiterate and the female sex are the 3 factors of participation restrictions and Impaired quality of life in this population.

Conclusion

The improvement of the physical, psychic and social care is an urgent and obligatory action in a "right" approach, to ensure an optimal social participation of this population that has suffered and continues to suffer half a century after the outbreak.

The use of scales to evaluate quality of life is common practice in clinical research, particularly in Physical Medicine and Rehabilitation (PMR). Among existing scales, the EuroQol-5D (EQ-5D) or Medical Outcome Study Short Form (MOS SF-12 or MOS SF-36) are often used, either to characterise a group of persons, or to evaluate their quality of life. Our aim is to highlight certain limitations in the scope of application of knowledge provided by these tools for PMR, among others.

Material and Method

The analysis of the scales was carried out in two stages. Firstly, a sociologist has reviewed the diversity of the sociocultural aspects present in the scales, to notice the missing aspects, which appear significant according to several sociological studies. Secondly, 32 interviews with patients presenting after-effects of a stroke were carried out to confirm and develop these reports.

Results

The problems which will be mentioned concern different aspects of the scales; the items and domains (lack of questions on autonomy and self-image), the list of possible responses (total or episodic lack of the response « I don’t know ») and the system of evaluation of quality of life (lack of a personal point of view on the impact on quality of life, and thus on possible improvements induced by treatment, whatever its nature). These faults and limitations are not confined to these four generalist scales, they can be found in other scales.

Conclusion

Our analysis invites future clinicians or researchers to improve existing tools and to develop new ones in order to cover a larger repertoire of important dimensions relating to the existence of persons. With this aim in mind, we will present a new tool for PMR which takes into account the problems outlined.

VALIDITY AND RELIABILITY OF THE LIFE BALANCE INVENTORY IN CHRONIC STROKE
A. Van Gils¹, S. Meyer¹, H. Beyens², F. Schillebeeckx², G. Verheyden¹, D. Kos¹
¹KU Leuven, Department of Rehabilitation Sciences, Leuven, Belgium
²University Hospitals Leuven, Department of Physical Medicine and Rehabilitation, Leuven, Belgium

Introduction/Background

The Life Balance Inventory is a questionnaire developed to assess congruence between how people want to spend their time in various activities and how they actually spend their time in those activities. Stroke has a major impact on daily activities and life balance might be compromised after stroke. The aim of this study was to validate the Flemish version of the Life Balance Inventory (LBI) in people in the chronic phase after stroke.

Material and Method

The LBI was translated according to the principles of translation and cultural adaptation process of patient-reported outcomes. We recruited 22 first-ever stroke survivors, aged 18 or older and at least 6 months post stroke. The LBI was administered twice, with a time interval of one week. Test-retest reliability of the LBI was examined using intraclass correlation coefficients (ICC) and Bland-Altman plots. Construct validity was assessed by calculating Spearman Rank correlation coefficients between LBI and Hospital Anxiety and Depression Scale (HADS) and Stroke Impact Scale (SIS).

Results

Mean age (+/- SD) of our sample was 60±11 years, mean time post stroke 655±139 days and 14/22 (64%) participants were male. Mean total LBI score was 2.41±0.42 out of 3 on the first occasion and 2.39±0.47 on the second occasion, demonstrating relatively good satisfaction with life balance after stroke. The ICC [95%] for total LBI score was 0.91 [0.77-0.97] indicating good test-retest reliability. Construct validity was supported by moderate association between LBI and HADS (rs=-0.46, p=0.011) and between LBI and SIS (rs=0.65, p=0.002), as hypothesized.

Conclusion

In stroke recovery and rehabilitation, more attention is warranted to evaluate life balance. LBI results may guide the rehabilitation approach. Psychometric properties for the Flemish version of the LBI are underpinned by the results of this study and support use of LBI in clinical practice and research.

⁴The Chinese University of Hong Kong, Department of Sports Science and Physical Education, N.T., Hong Kong S.A.R.
⁵Western Sydney University, School of Science and Health Occupational Therapy, NSW, Australia

Introduction/Background

Tai Chi (TC) is a mind-and-body exercise and may improve cognitive functions and cardiovascular outcomes in elderly people. This study aimed to confirm the acute effects of TC training on attention and meditation, perceived stress level, heart rate, oxygenation in blood, and palmar skin temperature in community-dwelling healthy older adults.

Material and Method

Twenty older TC practitioners and 20 age- and sex-matched non-practitioners volunteered to join the TC and control groups, respectively. After baseline measurements were taken for each group, the TC group performed a TC form for 10 minutes while their cognitive states and cardiovascular responses were concurrently monitored. The control group rested for the same duration in quite standing. Both groups were then reassessed. The participants’ attention and meditation levels were measured using a single-channel electroencephalographic device; stress levels using Perceived Stress Scale; blood oxygenation and heart rate using an oximeter; and palmar skin temperature using an infrared thermometer.

Results

Attention level tended to increase during TC and dropped immediately thereafter (p < 0.001). Perceived stress level decreased from baseline to posttest in the TC group (p = 0.005). Heart rate increased during TC (54.3% of maximum heart rate) (p < 0.001) and decreased thereafter (p = 0.001). No significant group, time, or group-by-time interaction effects were found in any other outcomes.

Conclusion
While TC training could temporarily improve attention and decrease perceived stress levels, it could not improve meditation, palmar skin temperature, or blood oxygenation among older adults.

COMPARISON OF RESPONSES TO TREADMILL EXERCISE LISTENING TO THAI CONTEMPORARY MUSIC AND NO MUSIC IN UNTRAINED ADULT
J. Champaiboon¹, S. Rangkla², P. Decharin¹
¹Chulalongkorn Hospital, Physical medicine and rehabilitation, BANGKOK, Thailand
²Faculty of Medicine- Chulalongkorn university, Physical medicine and rehabilitation, Bangkok, Thailand

Introduction/Background

Living an active lifestyle is important to stay healthy especially in the aging society. Present studies showed Listening to music while exercising can enhance work capacity and delay fatigue. However, most of the research were conducted in trained subjects and used western music such as classical music which were not familiar in Asian countries. This study aimed to investigate the effect of Thai contemporary music on response of treadmill exercise in untrained adults.

Material and Method

30 untrained healthy adults were equally allocated to one of the two sequence groups. The first group were listening to Thai contemporary music selected from four types of music while performing treadmill exercise at 60% of maximal heart rate for 20 minutes, washout 1 week then performed treadmill exercise again without listening to music. For the second group, the sequence of treatment was reversed. Rate of Perceived Exertion, SBP, maximum speed, total distant and enjoyment VAS were recorded for each exercise session.

Results

Mean RPE was significantly lower while listening to music (11.29) comparing with no music (12.37, p < 0.001). Mean enjoyment VAS was significantly greater while listening to music (6.92) comparing with no music (4.37, p<0.001). No statistically significant difference regarding SBP, speed and total distant.

Conclusion

Thai contemporary music can decrease RPE and increase enjoyment during treadmill exercise at fixed work load, therefore music may be useful as a tool to assist exercise adherence in healthy untrained adults.

THE USE OF PERIODIZED EXERCISE PRESCRIPTION IN PHYSICAL REHABILITATION: A SCOPING REVIEW OF LITERATURE

B. Boggenpoel*

University of the Western Cape, Physiotherapy, Cape Town, South Africa

Introduction/Background

The purpose of this review was to describe the use of periodized exercise prescription within the context of physical rehabilitation. This form of exercise prescription, seems to be a possible alternative to the current American College of Sport Medicine (ACSM) model of exercise prescription.

Material and Method

The following databases were searched: The Cochrane Central Register of Controlled Trials, Medline, Pubmed, Cinahl, Science direct, Pedro, Web of science, SPORTDiscus, SAGE and Google Scholar. Methodology used was based on Arksey and O’Malley’s five stage scoping review framework. A self-developed data extraction form was developed to gather the necessary information under the following headings: Author(s), year of publication, study location, study design, study population, intervention type (linear or nonlinear periodized programme); stage of rehabilitation; structure of the intervention (i.e. specific phases); dosage of the intervention (i.e. frequency, intensity, time); outcome measures; beneficial / adverse effects; primary result.

Results

Six studies were included in this review. Two studies were RCT’s; two were pair matched RCT’s; one was a repeated measures design; and one was a quasi-experimental case study. The included papers focused on the following population groups: cardiac; chronic non-specific lower back pain; chronic obstructive pulmonary disorder; and spinal cord injury. Methodological quality and internal validity of the included papers were lacking. Main outcome levels used in the included studies were related to physiological, impairment and quality of life. Programme structure relating to the use of a familiarisation phase; sequencing of exercises; and structuring of specific phases was present. The majority of the included studies failed to indicate in which phase rehabilitation had occurred.

Conclusion

Although there is a lack of consistency with regard to the structure and implementation of a periodized model of exercise prescription in the physical rehabilitation context, it nonetheless seems to be a novel way of prescribing exercise within the rehabilitation setting.

Cardiac Rehabilitation Programs (CRP) following an acute coronary syndrome have shown to be effective in reducing mortality. The aim of our study is to investigate the seasonal influence on adherence to physical activity after one year of CRP.

**Material and Method**

We prospectively collected data from all the patients that underwent CRP during one year and divided them in two groups: patients who finished phase II in cold months (October to March), and those who ended in hot months (April to September).

They completed an exercise-based CRP during 6-12 weeks and were evaluated by a stress test in 3 different moments: ST1 (before the CRP); ST2 (after phase II of CRP) and ST3 (12 months after ST1). We performed a two-sample t-test \((p\text{value} 0.05)\) between the results obtained in stress test (measured through METs achieved) in the two groups in the 3 moments.

**Results**

During 2016, 102 patients, aged <65 enrolled phase II after an acute coronary syndrome. There were 21 missing cases.

We found no statistically difference between the results of two groups, after one year.

However, all patients \((N=81)\) presented a positive evolution between ST1 and ST2 and also between ST1 and ST3, in this case with a statistically significance (two-sample t-test \((p\text{value} 0.05))\) corroborating the result.

On the other hand, the overall outcome between ST2 and ST3 was negative or null.

**Conclusion**
Although we found no difference in our sample, it’s still relevant to analyze the seasonal influence in a larger population.

The results also show the importance of the CRP after an acute coronary syndrome and demonstrate the need to implement a phase III or other forms of incentive physical activity after hospital discharge from phase II.

Stroke patients have shown expressive asymmetry between the paretic and non-paretic lower limb (NPLL). The aim of this study was to examine the effects of unilateral leg load used as a restraint for the NPLL during gait training on weight bearing asymmetry after stroke.

**Material and Method**

Thirty-eight stroke patients of both genders and with up to one year of first stroke that caused gait deficits (gait speed<0.8m/s) participated in the study. Participants were randomized into: treadmill training with load (equivalent to 5% of body weight) on the NPLL (experimental group) and treadmill training without load (control group). Interventions lasted 30 min per day, for 2 weeks (9 sessions). Kinetic data were collected with a force plate, during standing position (static) and during gait (dynamic). Limb loading was evaluated by the mean of vertical component of ground reaction force (GRF), for paretic and non-paretic limbs. Static and dynamic symmetry ratio (paretic GRF/non-paretic GRF) was calculated for both groups at baseline, post-training and after 40-day follow-up.

**Results**

At baseline, groups were homogeneous with regard to age, time since stroke, neurological status (according to National Institute of Health Stroke Scale) and walking ability (according to Functional Ambulatory Category). Repeated-measures analysis of variance showed no effects over time in static and dynamic symmetry ratio (static: F=0.985; P=0.364; dynamic: F=2.005; P=0.153). In addition, ANOVA showed no changes between experimental and control groups in static and dynamic symmetry ratio (static: F= 0.031; P= 0.862; dynamic: F= 0.063; P= 0.803).

Conclusion

Although load addition might favor the use of paretic limb by restraining NPLL, weight bearing asymmetry has not been changed over time in any group. Once this protocol is innovative,
future studies should investigate other parameters such as training duration and amount of load, to improve weight bearing asymmetry after stroke.

THE EFFECT OF NORDIC HAMSTRING EXERCISE ON PREVENTING HAMSTRINGS INJURY ON HAMSTRING INJURY RATE AND TIME-LOSS INJURY RATE IN HIGH SCHOOL SOCCER PLAYERS IN JAPAN

K. Akasaka¹, Y. Hasebe¹, T. Otsudo¹, H. Hattori¹, A. Tamura¹
¹Saitama Medical University, Graduate School of Medicine, Moroyama, Japan

Introduction/Background

The Nordic Hamstring Exercise (NHE) has been used for the prevention of hamstring injury among soccer players. Many studies have shown the effect of NHE among professional soccer players but there are a few studies for adolescent amateur soccer players. The purpose of this study was to clarify the effect of the NHE on preventing hamstrings injury by calculating hamstring injury rate and time-loss injury rate in adolescent amateur soccer players.

Material and Method

The subjects were high school soccer players in Japan. They were clustered as a team and randomly assigned into two groups; 156 in the NHE group and 103 in the control group. All of the subjects were measured by physical function, practice and game hour per day, injury detail if happened and time-loss hour for soccer. Hamstring injury rate and time-loss injury rate were calculated. Two groups were compared by unpaired t test at significant level of 5%.

Results

Hamstring injuries occurred in 7 cases; 4 in the NHE group and 3 in the control group. Hamstring injury rate was 0.09 per 1000 athlete-hours in the NHE group while 0.10 in the control group. The relative risk of hamstring injury rate was 1.14. Time-loss hamstring injury rate was 0.11 per 1000 athlete-hours in the NHE group while 0.52 in the control group. The relative risk of time-loss hamstring injury rate was 4.54.

Conclusion

As an effect of the NHE in high school soccer players, time-loss injury rate had stronger impact than the hamstring injury rate. These results indicated that the NHE in high school soccer players may had reduced the severity of hamstrings injury without changing injury rate. It is suggested that importance of investigating hamstrings injury prevention in adolescent amateur soccer players using time-loss injury rate in future.

ISPR8-0755
AEROBIC CAPACITY AND QUALITY OF LIFE OUTCOMES AFTER AN AEROBIC EXERCISE PROGRAM USING AN UPPER BODY ERGOMETER IN DIABETIC AMPUTEE TREATED AT MEXICAN REHABILITATION HOSPITAL.
C.E. Jiménez Pérez Campos

Introduction/Background

Background and aim: Amputation in diabetics comes from several complications and with deplored aerobic capacity, furthermore cardiac rehabilitation programs are usually in standing position, unsuitable for them. Aim: evaluate the diabetic amputee’s aerobic capacity and quality of life (QoL) after an aerobic exercise program, with upper limb ergometer.

Material and Method

Methods: The design is longitudinal, prospective, comparative and no randomized. It included 23 diabetic pelvic limb amputees. Subjects were separated in two groups: experimental (n=15) and control (n=8). All patients had an exercise testing, with the author’s designed protocol and replied SF36 questionnaire. The experimental group completed 24 exercise sessions with an intensity determined through the training heart rate. After, all patients had a final exercise testing and SF36 evaluation.

Results

Results: Both groups were homogeneous in age mean (years); (57.6±12.5) and (52.5±8.0), sex, occupation, education and economic features. (square chi) (p=0.28). Initial aerobic capacity assessed with the initial VO2peak mean (mL/O2/kg/min) was similar in both groups: experimental group (13.5±3.5), control group (11.5±2.5) p=0.17. The aerobic capacity reached after the program was statistically significant. Final VO2peak mean (mL/O2/kg/min) for the experimental group was (17.1±3.8), and for the control group was (10.5±3.8), p=0.001. (t student). Initial QoL was similar in both groups. Final QoL mean recorded after training program was (3110.6±384.7) for the experimental group, and (1363.1±770.4) for the control group, statistically significant p=0.0001 (t student), corresponding to 86.7% and 40% of optimal QoL respectively. We observed a significant Pearson’s correlation coefficient between initial-final VO2peak switch, and initial-final QoL switch, r = 0.724 (p = 0.0001).

Conclusion

Conclusion: Aerobic capacity and the QoL improved after arm ergometer training. Cardiac rehabilitation should embrace upper limb exercise testing and training for diabetic amputees.

LATERALITY OF CORTICAL OXYGENATION IN THE PREFRONTAL CORTEX DURING 20 MIN OF MODERATE-INTENSITY CYCLING EXERCISE: A NEAR-INFRARED SPECTROSCOPY STUDY

A. Tsubaki\textsuperscript{1}, S. Morishita\textsuperscript{1}, Y. Tokunaga\textsuperscript{2}, D. Sato\textsuperscript{1}, W. Qin\textsuperscript{1}, S. Kojima\textsuperscript{3}, H. Onishi\textsuperscript{1}

\textsuperscript{1}Niigata University of Health and Welfare, Institute for Human Movement and Medical Sciences, Niigata-city, Japan
\textsuperscript{2}Niigata Rehabilitation Hospital, Department of Rehabilitation, Niigata-city, Japan
\textsuperscript{3}Niigata University of Health and Welfare, Department of Physical Therapy, Niigata-city, Japan

Introduction/Background

Exercise therapy is a core component of rehabilitation for patients with cardiopulmonary disease and diabetes. A recent study showed that cognitive function improved after a single episode of moderate-intensity exercise. However, the laterality of cortical oxyhemoglobin (O\textsubscript{2}Hb) increases during exercise is unknown. We aimed to evaluate the laterality of O\textsubscript{2}Hb changes in the prefrontal cortex (PFC) during 20 min of moderate-intensity cycling exercise.

Material and Method

Twelve healthy volunteers (9 women) participated. After a 3 min of rest, 20 min of exercise was performed at a workload of 50% VO\textsubscript{2}peak, followed by 15 min of post-exercise rest. The O\textsubscript{2}Hb levels in the right (R-PFC) and left (L-PFC) prefrontal cortices were measured using a 34-channel, near-infrared spectrometry system. The O\textsubscript{2}Hb levels in each area were expressed as changes from the mean pre-exercise rest phase values. The O\textsubscript{2}Hb values in the last 5 min of the 20-min exercise period were averaged in both regions. The laterality index (LI) was calculated using the formula \((L-PFC \text{ O}_2\text{Hb} - R-PFC \text{ O}_2\text{Hb})/(L-PFC \text{ O}_2\text{Hb} + R-PFC \text{ O}_2\text{Hb})\). A positive LI indicated that the increase in O\textsubscript{2}Hb in the L-PFC was larger than in the R-PFC; a negative LI indicated the opposite.

Results

O\textsubscript{2}Hb levels increased during the first 10 min and were maintained over the latter half of the exercise period in both R-PFC and L-PFC. The average O\textsubscript{2}Hb values in the last 5 min were 0.066 ± 0.013 mM·cm in the R-PFC and 0.085 ± 0.015 mM·cm in the L-PFC. The average LI of the PFC was 0.16 ± 0.10.

Conclusion

L-PFC-dominant O\textsubscript{2}Hb increases were observed during 20 min of moderate-intensity cycling exercises. The L-PFC plays an important role in executive functions and verbal working memory, which might be promoted by 20 min of exercise.

Introduction/Background
People with high level of spinal cord injury feel a lot of discomfort in breathing ability. However, the rehabilitation exercise program to solve this problem is not activated. Also, the respiratory rehabilitation exercise program developed specifically for those is very scarce. Existing breathing exercises are uncomfortable because the method is tedious and cannot see the degree of improvement. Therefore, it is important to develop a variety of exercise programs that can effectively enhance the respiratory muscle.

The purpose of this study was to investigate the effect of respiratory rehabilitation exercise to improve pulmonary function.

Material and Method
The subject were 7 people with high level of spinal cord injury (C3-6, ASIA A, B). The exercise program developed was consist of 8 weeks of 1-h exercise session 2 days a week. Each session included warm up (stretching), respiratory rehabilitation exercise, and cool down (flexibility and relaxation). The pulmonary functions were measured with digital spirometry meter (Pony FX, Cosmed, Italy). The pulmonary function tests were conducted before and after the 16 sessions of respiratory rehabilitation exercise program.

Results
As a result of respiratory rehabilitation exercise during 8-week for subjects, pulmonary function showed significant changes in inspiratory capacity, vital capacity and inspiratory reserve volume.

Conclusion
We confirmed the positive effect of the respiratory rehabilitation exercise program developed for people with high level of spinal cord injury. The results of this study are expected to be used as basic data for the development of specialized programs for each degree of severity.

THE EFFECTS OF THE KINESIO TAPING ON THE BICEP MYOELECTRIC ACTIVITY: AN EXPERIMENTAL STUDY

B. Guimaraes\textsuperscript{1}, J. Barreto\textsuperscript{1}, S. Tomé\textsuperscript{1}, V.C. Pereira\textsuperscript{1}, R. Cardoso\textsuperscript{2}, F. Melo\textsuperscript{1}, C.A. Branco\textsuperscript{1}

\textsuperscript{1}Centro Hospitalar de Entre o Douro e o Vouga, Physical and Rehabilitation Medicine Department, Santa Maria Da Feira, Portugal
\textsuperscript{2}School-Hospital of Fernando Pessoa University, Department of Physical Medicine and Rehabilitation, Porto, Portugal

Introduction/Background

Kinesio Taping (KT), has become more popular in the last decade and is now used by several athletes in different sports. It was shown to be effective in pain control, muscle and joint re-education (through proprioceptive input), in the prevention of lesions or in the improvement of both blood and lymph circulation. Surface Electromyography (EMGs) is a noninvasive technique (surface electrodes are placed on the skin over the muscle or muscle group) that measures muscle activity. The aim of this study is to find the influence of different tensions of KT applications in the myoelectric activation of biceps brachii.

Material and Method

The study design consisted in the evaluation, through the EMGs, of the myoelectric activity of the biceps brachii, in different activity states (rest and Isometric Maximal Voluntary Contraction [MVC]). The assessment was conducted with a sample of 22 participants (11 women and 11 men), ages between 18 and 32 years (mean age 23.00 ± 2.93). Each participant was tested in three different KT application tensions (0% tension, 25% tension and 50% tension). Myoelectric activity was evaluated, at each KT tension, 24 hours after the application of the KT.

Results

Significant differences were not observed in the myoelectric activity regarding the different tensions applied on KT either during rest (0% tension: 0.74 mV vs 25% tension: 0.76 mV vs 50% tension: 0.74 mV; p = 0.873) or during MVC (0% tension: 74.08 mV vs 25% tension: 71.44 mV vs 50% tension: 76.84 mV; p = 0.664).

Conclusion

The application of KT, regardless of the tension used in its application, doesn’t appear to interfere with the in myoelectric activity of the muscle. Therefore, KT may be applied, at the ideal tension according to each clinical case, without interfering with the neuromuscular activity of the muscle.

ISPR8-1222
BLOOD SERUM HUMAN CARTILAGE OLIGOMERIC MATRIX PROTEIN (HCOMP) CONCENTRATION IN CLOSED KINEMATIC CHAIN EXERCISES AND PHYSIOLOGICAL CYCLIC LOADING USING ENZYME-LINKED IMMUNOSORBENT ASSAY (ELISA)

L. Adorable¹, J. Litang¹
¹Southwestern University, College of Rehabilitative Sciences, Cebu City, Philippines

Introduction/Background

Patients with high levels of human cartilage oligomeric matrix protein (hCOMP) in serum might indicate increased degradation of articular cartilage. Conflicting studies recommend both open kinematic chain exercises which imposes minimal shock load in joints of arthritic patients to prevent further cartilage degeneration, and close kinematic chain exercises among healthy individuals which can significantly increase serum hCOMP concentration. This study was conducted to establish a scientific basis in choosing between physiological cyclic loading (PCL) and closed kinematic chain exercises (CKCE) for individuals of varying body mass index having weight bearing joint conditions associated with diminishing cartilage turn over resulting from loss of hCOMP after cartilage degeneration.

Material and Method

Blood samples were drawn from 45 healthy male adults before and after intervention. All subjects were randomly distributed to 3 groups with 15 subjects each. Group A performed CKCE for 30 minutes as many repetition as possible, Group B executed (PCL) for 30 minutes at their own pace, while the remaining 15 subjects served as control. The blood samples were centrifuged to separate the serum. The hCOMP in the serum was measured using the ELISA kit at absorbance Optical Density 450 pg/ml.

Results
Conclusion

There is a significant difference in pre and post-intervention serum hCOMP concentration in CKCE, PCL, and the control group. There was also a significant difference in the post-intervention serum hCOMP concentration among the three groups. In contrast, the BMI and post-intervention serum hCOMP concentration within each group did not show any significant relationship but it was observed that BMI was inversely proportional to the hCOMP serum level 30-minutes post-exercise and resting.

ISPR8-1382
EFFECTS OF NEUROMUSCULAR TRAINING ON ANKLE SPRAIN IN JUNIOR HIGH SCHOOL BASKETBALL PLAYERS
K. Ono¹, K. Akasaka¹, T. Otsudo¹, Y. Mizoguchi¹, K. Suzuki¹, A. Tamura¹, H. Hatton¹, Y. Hasebe¹, K. Take², M. Yamamoto², T. Hall³
¹Saitama Medical University, Graduate School of Medicine, Moroyama, Japan
²Saitama Medical Center- Saitama Medical University, Rehabilitation, Kawagoe, Japan
³Curtin University, School of Physiotherapy and Exercise Science, Perth, Australia

Introduction/Background

In recent years, neuromuscular training (NMT) using a balance board has become a common form of exercise to prevent ankle sprain. Previous studies of effectiveness of this approach have focused on adults, and there are few studies investigating junior high school students. The purpose of this study was to clarify the effect of the NMT using a balance board upon ankle injury in junior high school basketball players.

Material and Method

106 junior high school basketball players without concurrent injuries were recruited. All players were randomly assigned with 40 allocated to a control group and 66 to a NME group. Subjects in the NME group completed an ankle injury prevention program including single calf rising, single leg squat, dribble with single leg, handling with single leg and pass with single leg on the floor for 2 weeks and those on the balance board for the following 6 weeks. Ankle injury rates were calculated and compared by occurrence of injury’s per 1000 practice hours in the control and NME groups.

Results

The number of ankle inversion injuries were 17 in the control group and 13 in the NME group. Ankle injury rate per 1,000 hours revealed 4.43 in the control and 1.99 in NME group, respectively. Serious injuries, judged by single calf raise, where time loss to sport exceeded 1-week were 4 in the control group and 1 in the NME group. Average time loss in days in the control group (1.98±0.59) was significantly greater than that in the NME group (1.37±0.17).

Conclusion

Our study showed that NMT using a balance board reduced the occurrence of ankle sprain in junior high school basketball players. In addition, NMT may have contributed to a reduction in the severity of ankle injury.

FUNCTIONAL MOVEMENT SCREEN SCORE AND BASEBALL PERFORMANCE IN JAPANESE HIGH SCHOOL BASEBALL PLAYERS AFTER CORRECTIVE EXERCISES

K. Suzuki¹, K. Akasaka¹, T. Otsudo¹, Y. Mizoguchi¹, K. Ono¹, A. Tamura¹, H. Hattori¹, Y. Hasebe¹, K. Takei², M. Yamamoto², T. Hall³

¹Saitama Medical University, Graduate School of Medicine, Moroyama, Japan
²Saitama Medical Center- Saitama Medical University, Rehabilitation, Kawagoe, Japan
³Curtin University, School of Physiotherapy and Exercise Science, Perth, Australia

Introduction/Background

In recent years, the Functional Movement Screen (FMS™) has been used for the prevention of disability. Some studies have reported that corrective exercise to improve FMS score is an effective method of preventing injuries (Bodden et al. 2015; Justin et al. 2017). However, measurement instrument to assess FMS™ are not available in high school's. The purpose of this research is to clarify the effectiveness of corrective exercises without specific FMS measurement instruments on FMS score, physical function, and throwing performance in high school baseball players.

Material and Method

High school baseball players were randomly assigned to two groups; 37 in the training group and 34 in the control group. All subjects were evaluated for FMS score, eyes closed single leg stance time, subjective fatigue, as well as pitching ball speed and control at the beginning of the intervention and at 2-months follow-up. Baseball players in training group conducted the corrective exercises 4 times per week for 2 months.

Results

When comparing the 2 groups group, pitching ball control significantly decreased in the training group compared to prior to the intervention. After 2 months, deep squat, hurdle step, inline lunge, active straight-leg raise, trunk stability pushup, rotary stability, total score of FMS, and pitching ball control showed significant better results in the training group compared to the control group.

Conclusion

Results of this study showed that corrective exercises improved asymmetries, trunk stability, movement pattern, proprioception, total FMS score, and pitching ball control without using special instruments following a 2-months training period. Corrective exercises to improve FMS are effective even in high school baseball players without using special measurement instruments.

Neurological disorders such as neuromuscular disease or cerebral palsy have impacts on motor functions but can also lead to cognitive and psychosocial impairments. Recent studies suggest that dance can be an effective approach to improve cognitive and psychosocial functions in different populations. Based on these evidence, we have developed and implemented three dance programs aiming at improving cognitive and psychosocial dimensions in children with neurological disorders.

**Material and Method**

The dance programs were 10 to 12 weeks long (60 minutes per session, two sessions a week) and included various types of dance. These programs were specifically adapted to the need of children with cerebral palsy (1 program, *pre/post-*test design, n=20) or neuromuscular diseases (2 programs, *controlled pre-post* design, n=19). Dance sessions were provided by physiotherapists, adapted dance teachers and a researcher specialized in dance therapy. Cognitive and psychosocial dimensions were evaluated before and after each dance program.

**Results**

Attention was improved in children participating in each of the three programs. Emotional aspects of quality of life and rhythmic abilities were improved in children with neuromuscular disease while specific aspects of memory improved in children with cerebral palsy.

**Conclusion**

Results from these three dance programs provides evidence of cognitive and psychosocial benefits for children with neuromuscular disease and cerebral palsy.

MOTION AND HEART RATE DURING HORSE RIDING THERAPY AND HORSE RIDING SIMULATOR IN CHILDREN WITH CEREBRAL PALSY

B. Hong¹, J.S. Kim², J.Y. Kwon³
¹St. Vincent's Hospital- College of Medicine- The Catholic University of Korea, Rehabilitation medicine, Suwon, Republic of Korea
²St. Vincent's Hospital- College of Medicine- The Catholic University of Korea, Department of Rehabilitation Medicine, Suwon, Republic of Korea
³Samsung Medical Center- Sungkyunkwan University School of Medicine, Department of Physical and Rehabilitation Medicine, Seoul, Republic of Korea

Introduction/Background

The evidence of efficacy of therapeutic horse riding in children with cerebral palsy is increasing. However, there are limitations in applying it because of scarce of experts for hippotherapy and hassle of going to the place for horse riding. Therefore, some people apply the horse riding simulator instead of horse riding for the therapeutic purpose. The study aimed to determine the difference between the movement and heart rate response on the actual horse and the device.

Material and Method

The participants were 12 children with cerebral palsy (GMFCS level I-III) aged 5-12 years. Five were boys, and eight were bilaterally involved. The body movement was monitored by accelerometer wearing at the waist during the beginner mode of the simulator and the horse riding. Heart rate was monitored by wireless heart rate monitor equipment. Movement of 3 axes, x, y, z, and monitored heart rate was analyzed.

Results

The movement of y-axis was significantly less during the horse riding simulator compared to real horse riding, 300.27 ± 277.22 and 210.71 ± 243.70, respectively (P < 0.05). However, movement of x- and z-axes significantly more during the simulator. The axis x movement were 649.89 ± 337.24 and 1050.44 ± 379.00, and axis z movement were 840.66 ± 406.85 and 1147.95 ± 414.10 during horse riding and simulator exercise, respectively (P < 0.05). The variability of heart rate on equipment was significantly less than the real horse riding (P = 0.001).

Conclusion

On a horse, there is a rhythmical up and down movement while the horse is walking. However, on the simulator equipment, the movement of the y-axis was less, but the movement of x- and z-axes was significantly more than the horse riding. Although total vector magnitude of
movement was more on the simulator, the variability of heart rate was significantly more during the real horse riding.

DEFINING PLAYER’S PROFILE IN WHEELCHAIR RUGBY: IMPACT OF CLASSIFICATION AND ON-COURT ROLE ON PHYSICAL ACTIVITY LEVEL DURING COMPETITION.

B. Borel¹, J. Lacroix¹, S. Mandigout¹

¹Université de Limoges, Laboratoire HAVAE, Limoges, France

Introduction/Background

During official competition, Wheelchair Rugby (WR) uses a classification system, defined with 7 levels (from 0.5 to 3.5 points) according to the level of disability. But 2 main roles can be observed on the court: defensive role (generally for player from 0.5 to 1.5 pts) and offensive role (players from 2 to 3.5 pts). Very few studies aimed at defining the on-court player role during competition, using various methods (Morgulec-Adamowicz et al. 2011; Rhodes et al. 2015). This kind of information could be of great interest in order to optimize training programs and players’ physical preparation. The aim of the study was to evaluate energy expenditure (EE) and intensity level of WR players during competition, according to the classification and the on-court role.

Material and Method

Fifty-two WR players, from 8 French elite teams and from France national team, were evaluated using a tri-axial accelerometer (SenseWear Armband) during national competition games. This device was previously validated for manual wheelchair users (Abel et al. 2008). Data from game times (4 periods of 8 min) were collected and analyzed, with EE, physical activity (PA) intensity and duration as main outcomes.

Results

Data from 24 defensive and 28 offensive players highlight that the mean intensity level was about 4 ± 1 METs, corresponding to a moderate intensity. Statistical analysis shows significant correlation between the player’s classification level and vigorous PA duration (P=0.04; r=0.285), higher classification level being associated with higher vigorous PA duration. Lastly, offensive players show higher vigorous PA duration, in comparison with defensive players (p<0.01).

Conclusion

This work provides supplementary data for the definition of the different WR player profiles. In the current context of an important development of this sport, this could be useful for the individualization of the training programs of WR players, according to player’s classification or on-court role.

Introduction/Background

General practitioners (GPs) have a key role to promote physical activity, especially in identifying and counseling persons with a sedentary lifestyle. However, many limitations exist to have a significant impact. “Pas à Pas” (“step by step”) is a pilot project initiated in 2015 by the Canton de Vaud (French-speaking part of Switzerland) to support physically underactive people towards a behaviour change.

Material and Method

“Pas à Pas” allows GPs to refer the PA evaluation, counselling and follow up to specialists in adapted physical activities (APA) through a specific prescription. APA sessions are free and consist in supervised, individualized and motivational primary prevention approach. They create a link between health professionals in contact with sedentary publics and PA offers organized in the regions. Consultant medical experts (internal medicine, public health, exercise and sports medicine) help the successful completion of the project. A « Plan, Do, Check, Act » method allowed to improve the PA referral scheme. Data collected by the specialists in APA have been analysed. Moreover, an external formative evaluation through focus groups and literature review has been realized.

Results

Between the 15.09.2015 and the 16.09.2017, 50 physicians referred 198 patients to the 3 specialists in APA of the project, with a total of 153 patients evaluated. Many interesting strengths and some limitations are highlighted. This project helps the local population to be more active with interesting motivational effects, in accordance with medical literature. Different recommendations have been established for the implementation of the project.

Conclusion

“Pas à Pas” is an innovative project permitting GPs to delegate PA counselling and follow up of their patients to specialists in APA, with well-appreciated results. This project proposes a
practical solution to promote PA, especially in people with noncommunicable diseases and could represent an interesting model to broadcast within Switzerland and others countries.

ISPR8-2056
EFFECT OF INTRADIALYTIC ISOMETRIC EXERCISE WITH OR WITHOUT NEUROMUSCULAR ELECTRICAL STIMULATION TO IL-15, TNF-α REGULATION, AND FUNCTIONAL CAPACITY IN CHRONIC KIDNEY DISEASE PATIENT

H. Laswati¹
¹Faculty of Medicine- Airlangga University- RSU Dr-Soetomo,
Physical Medicine and Rehabilitation, Surabaya, Indonesia

Introduction/Background

Background and aims: One of the etiology of limited functional capacity in chronic renal disease patient is muscle wasting. Increasing of Tumor Necrosis Factor Alpha (TNF-α) in chronic renal disease causes muscle wasting. Strengthening exercise is recommended by ACSM but it is hard to be done. Contraction of skeletal muscle will express interleukin-15 (IL-15) which is important for metabolism and skeletal muscle function. Isometric exercise and Neuromuscular electrical stimulation (NMES) are easy to be applied intradialytic and can fascilitate muscle contraction and has strengthening effect, but their effect in chronic kidney disease patient have not been largely reported yet. This study aimed to prove that intradialytic isometric exercise with or without NMES can modulate IL-15, TNF-α expression and improve functional capacity in chronic kidney disease patient.

Material and Method

Methods: Twenty five chronic kidney disease patient underwent hemodialysis was randomly divided into 3 groups, control group, isometric group, and isometric and NMES group, received treatment twice a week, for 6 weeks. The subject were examined for five times sit to stand test (FTSTS), IL-15 and TNF-α test by immunoassay before and after intervention.

Results

Results: There was increased of FTSTS in isometric group (p=0.007) and also combined isometric and NMES group (p=0.001). TNF-α in isometric group was increased (p=0.003) and also in combined isometric and NMES group (p=0.025). Compared to the control group, TNF-α was change significantly in isometric group (0.017) and also in combined isometric and NMES group (0.020). There was no significant difference in IL-15 levels pre and post experimental in all three groups (p>0.05).

Conclusion

Conclusions: Intradialytic isometric exercise with or without NMES for 6 weeks can improve functional capacity and also regulates TNF-α.

TAIJUAN FOR HYPERTENSION: A SYSTEMATIC REVIEW AND META-ANALYSIS

P. Huaping1

1The Affiliated Jiangning Hospital of Nanjing Medical University, Rehabilitation Medicine, Nanjing, China

Introduction/Background

Hypertension is the most common chronic disease and the most important risk factor for cardiovascular and cerebrovascular diseases. It not only causes high mortality and morbidity, but also seriously consumes medical treatment and social resources, posing a heavy burden to families and society. Research shows that hypertension is a disease that can be prevented and controlled. Reduce the blood pressure in patients with hypertension, can significantly reduce the occurrence of these complications, significantly improve the quality of life of patients. Originated in China, the ancient boxing taijiquan, due to its significant illnesses and fitness effect, currently, studies show that taijiquan is conducive to the recovery of cardiovascular system function, can reduce the risk of cardiovascular disease-related factors. However, it has not been evaluated according to the PRISMA systematic review standard. This study aims to assess the current clinical evidence of taijiquan for hypertension.

Material and Method

To evaluate the efficacy and safety of taijiquan for the treatment of hypertension. Methods: Randomized controlled trials (RCTs) regarding taijiquan for hypertension were comprehensively searched via PubMed, EMBASE, Cochrane Library (Central), Ovid and Wanfang databases. CNKI, VIP. Evaluating and researching the quality by Cochrane handbook 5.1.0 and data were analyzed by Review Manager (Rev Man) 5.2. Results: A total of 6 RCTs were included.

Results

The pooled results showed that taijiquan can significantly improve the SBP (SMD = -0.43, 95%CI(-0.62,-0.23), P<0.01), DBP (SMD = -0.48, 95%CI(-0.67,-0.30), P<0.01), P<0.00001), BMI (SMD = -0.11, 95%CI(-0.31,-0.09), P<0.01). However, there was no difference in quality of life between the two groups of lipids.

Conclusion

Taijiquan could improve the SBP, DBP and BMI in patients with hypertension effectively without any significant adverse effects. However due to the small sample size and lack of long-term follow-up, more RCTs with larger sample size and long-term follow-up were needed.

Exercise preconditioning (EP) induces ischemic tolerance and reduces inflammatory injury; however, the mechanism underlying these effects remains unclear. In this study, the influence of EP on the activity of the toll-like receptor (TLR) 4/nuclear factor (NF)-κB-signaling pathway was explored in a rat model of cerebral ischemia/reperfusion (I/R) inflammatory injury.

**Material and Method**

Ischemia was induced in rats using transient middle cerebral artery occlusion (tMCAO) after 3 weeks of EP. Male SD rats (n=54) were divided into sham, MCAO, and EP (EP+MCAO) groups. Following the induction of cerebral I/R injury, rats were scored for neurological deficits. Various techniques were used to evaluate ischemic infarct volume and explore pathological changes in tissue morphology after cerebral I/R injury, wherein the levels of TLR4 and NF-κB were analyzed. In addition, enzyme-linked immunosorbent assays were used to detect the levels of tumor necrosis factor (TNF)-α and interleukin (IL)-1β in peripheral serum.

**Results**

Twenty-four hours after cerebral I/R injury, the neurological deficit scores of animals in the EP+MCAO group were significantly lower than those in the MCAO group (P<0.05). A significant reduction in cerebral infarct volume was also observed (P<0.05). Pathological analysis demonstrated that ischemic cortical damage was alleviated in the EP+MCAO group, and the number of TLR4- and NF-κB-positive cells decreased in the infarct region (P<0.05). TLR4 and NF-κB expression was downregulated in the ischemic side (P<0.05), and the concentrations of TNF-α and IL-1β were significantly reduced in the peripheral serum (P<0.05).

**Conclusion**

The present study indicates that EP can improve cerebral I/R-induced neurological deficits in rats, reduce infarct volume, mitigate pathological damage in the ischemic cortex, and exert neuroprotective effects. The mechanism underlying these effects might involve the regulation of the TLR4/NF-κB signaling pathway and the inhibition of central and peripheral inflammatory cascades during cerebral I/R injury.

EFFECT OF EXERCISE PRECONDITIONING ON CELL APOPTOSIS AND EXPRESSION OF MITOKATP PASSAGE PROTEIN KIR6.2 AND SUR1 IN RATS WITH CEREBRAL ISCHEMIA-REPERFUSION

H. Li

1The second hospital affiliated to Heilongjiang university of Chinese medicine, Rehabilitation Centre, Harbin, China

Introduction/Background

To implore the effect and mechanism of exercise preconditioning on neurological deficits in rats with cerebral ischemia-reperfusion (MCAO/R).

Material and Method

Thirty-six healthy Sprague-Dawley rats were divided into model group, sham operation group and exercise preconditioning group according to the random number table. Each group consisted of 12 rats (n=12). A rat model of cerebral ischemia-reperfusion (MCAO/R) was established by modified suture method. After 2h, 12h, 24h of reperfusion, neurological impairment was evaluated by neurological deficit score. After 24h reperfusion, the expressions of mitoKATP channel protein Kir6.2 and SUR1 were detected by Western blot, the cerebral cell apoptosis was detected by TUNEL assay.

Results

Compared with model group, neurological deficit scores of rats in exercise preconditioning group were significantly decreased (P<0.05). Compared with model group, exercise preconditioning group Kir6.2, SUR1 protein level and TUNEL-positive cells decreased significantly (P<0.05).

Conclusion

Exercise preconditioning may improve neurological impairment after cerebral ischemia by regulating the expression of mitoKATP channel proteins Kir6.2, SUR1 and cell apoptosis.

EFFECTS OF STRENGTH TRAINING ON JUMP HEIGHT IN ELDERLY PEOPLE
S. Vuk
University of Zagreb, Faculty of Kinesiology, Zagreb, Croatia

Introduction/Background
The aim was to examine the effects of strength training program on jump height (JH) in elderly people. JH represents an important determinant of functional capacity such as walking upstairs or rising from a seated position.

Material and Method
40 participants were randomly assigned to either a training group (n = 20; 66.8 ± 1.97 years), or a control group (n = 20; 68.2 ± 2.91 years). Participants trained 3 times per week for 12 weeks. Each session consisted of 8 exercises with their own body weight. Pre- and post-intervention data were compared using Wilcoxon signed ranks test, with an alpha set at p < 0.05. The JH were assessed using the countermovement jump (CMJ), squat jump (SJ) and arm swing-countermovement jump (ACMJ) performed on a force plate.

Results
There were no significant differences in the pre-training JH (p = 0.405, p = 0.495 and p = 0.095 for CMJ, SJ and ACMJ respectively) between the training group and control group. There was a significant post-training effect only for the CMJ (6.53%; p = 0.032), but not for SJ and ACMJ (p = 0.653 and p = 0.115 for SJ and ACMJ, respectively) in the training group.

Conclusion
The study results showed that the 12-week strength training is a safe, suitable, and efficient strength-training method for elderly people. It may be helpful in preserving leg muscle strength with advancing age and suitable for increasing JH in the elderly people, which may be an important way to increase functional independence and decrease the prevalence of many age-associated chronic diseases.

Introduction/Background

Persons with low back pain (LBP) display delayed activity of the transversus abdominis (TrA). The abdominal drawing-in maneuver (ADIM) reduces delayed activity of TrA in individuals with LBP. Because performing accurate ADIM is difficult in persons with LBP, feedback methods such as real-time ultrasonographic imaging (RUSI) and the pressure biofeedback unit (PBU) are used. RUSI and PBU are expensive and therefore difficult to use as home exercises for ADIM. The TrA draws in the abdominal wall and narrows the waist. Therefore, we hypothesized that winding a tape measure (TM) on the waist and drawing in the lower abdominal to the spine was effective to measure and feel TrA contraction. We aimed to examine the most effective feedback method for TrA contraction using a PBU and TM during ADIM.

Material and Method

Twenty healthy male volunteers (24.2±6.6 years, 169.8±5.2 cm, 65.3±5.1 kg) performed ADIM under three conditions: (1) without feedback (control condition), (2) with feedback, using PBU (PBU condition), and (3) with feedback, using TM (TM condition). A B-mode ultrasound imaging system was used to determine the thickness of the lateral abdominal muscles. Percent changes from pre-ADIM were calculated in each condition. Repeated measure analysis of variance and post-hoc analyses were used to detect differences in thickness of the lateral abdominal muscles between the conditions.

Results

The thickness of TrA was significantly increased in the TM condition than in the control (TM condition: 92.4±43.9%, control condition: 74.1±43.3%, p<0.01). No difference in the thickness of TrA was found between the PBU (85.4±43.3%) and TM conditions and between the control and PBU conditions (p>0.05). No difference in the thickness of internal and external oblique were found between conditions (p>0.05).

Conclusion

The feedback method using TM may be more effective in thickening the TrA during ADIM than without feedback.

NEW EXERCISE INTERVENTION FOCUSING ON COMPENSATORY STRATEGY IS AN EFFECTIVE TREATMENT FOR PATIENTS WITH MASSIVE ROTATOR CUFF TEAR

W.R. Su¹
¹National Cheng Kung University, Orthopaedic Surgery, 台南市, Taiwan R.O.C.

Introduction/Background

To examine the effect of compensatory strategies training for patients with massive rotator cuff tear (MRCT).

Material and Method

Twenty-four subjects with MRCT were recruited to participate three times shoulder assessments and 12 weeks of intervention. After initial assessment, the subjects were assigned randomly into two groups (CS-TE and TE-CS). CS-TE group was provided compensatory strategies (CS) training followed by 6 weeks of traditional exercise (TE) training. In comparison, TE-CS group took 6 weeks TE training followed by CS. All the participants were arranged to attend the second assessments after completing the first 6 weeks of intervention, and the third assessment at the end of 12 weeks of intervention, including measurements of visual analogue scale (VAS), range of motion (ROM) of shoulder, shoulder pain and disability index (SPADI) questionnaire, shoulder and scapular muscle strength (Table 1). In addition, scapular kinematics analysis were performed at initial and 2nd assessments.

Results

After the first 6 weeks training, CS-TE group showed significant important in motion pain measurement, SPADI score, AROM and strength of local muscles at 6th week; however, TE-CS group only showed significant improvement in SPADI score and flexion of shoulder. Moreover, after 6 weeks of the CS training, TE-CS group showed significant improvement in VAS and strength of compensatory muscles and scapular muscles (Table 2). Furthermore, significant improvements in scapular control strategies were only found in CS-TE group after completing 6 weeks of intervention (Table 3), showing significantly increasing scapular external rotation (ER) and posterior tipping (PT).

Conclusion

Our results have supported that CS training is an effective treatment for establishing the compensatory strategies after MRCT and regaining the shoulder function by strengthening the humeral head depressors and scapular stabilizers.

Introduction/Background

Interactive computer play (ICP), or serious games, can provide motivational and flexible rehabilitation environments. This is useful for the 1 in 400 children born with Cerebral Palsy (CP) each year, whose daily activities are impacted by impaired motor control. Improvement through traditional rehabilitation is often hindered by low adherence and limited repetitions. This study aims to build an ICP game which offers a motivational and effective environment to supplement reaching and grasping rehabilitation in youth with CP.

Material and Method

Through a user-centered design process, we first met with five youth with CP and four occupational therapists to establish reach and grasp movement priorities. Then, seven youth, age 16-23 years with hemiplegic CP, participated in 1-3 game design sessions. During each design session, participants extended and relaxed their hand to control an ICP game using a forearm muscle activity sensor (Myo Armband). Participants played games with different types of feedback and control mechanisms (detailed in Figure 1). Game versions were iterated.
between design sessions.
Figure 1. Two examples of the ICP game with different feedback. Top version includes ‘power bar’ (left) of user muscle activity and user choice panel (right). Player insert at bottom left. Bottom version includes upcoming reward achievements bar (right) based on performance.
Results

The top priority identified by youth and therapists was increasing amplitude and endurance of wrist extension while fingers open. Thus, this action was used as the primary game control. At each design session, participants played an average of 15 levels, each lasting 129±56 seconds and requiring 43±19 wrist extension repetitions. In total, during a typical session, participants practiced 645±285 repetitions through the ICP game. User input showed participants were most responsive when feedback directly followed wrist extension (e.g. increased power bar or bonus points).

Conclusion

The user-centered design process engages participants to build practice tools that they find motivating. The ICP game can offer youth with CP the high quantity of repetitions required to improve reach and grasp activities. Next, the game will be used in a home-based pilot study to demonstrate its efficacy for improving reach and grasp activities.

EFFECT OF A HEALTH PROMOTION SESSION ON THE KNOWLEDGE OF POSTURAL HYGIENE IN 1ST CYCLE OF PRIVATE SCHOOL
S. Lopes, A. Martins, L. Rocha, F. Monteiro, A. Simões, P. Chaves, A. Couto
1Escola Superior de Saúde de Vale do Sousa, Physiotherapy, Paredes, Portugal
2Escola Superior de Saúde de Vale do Ave, Physiotherapy, Famalicão, Portugal

Introduction/Background
School health is a very important area of intervention, considering the prevalence rates and incidence of postural changes in younger age groups. It is pertinent to promote knowledge in this area to prevent these postural changes. Verify the effect of a health promotion session on the knowledge in the 1st cycle students of private school and identify the determinants that influence the Knowledge.

Material and Method
The sample consisted of 46 students from the 1st cycle of private school. A questionnaire on knowledge determinants was delivered to parents / guardians and a questionnaire on postural knowledge was given to students. This questionnaire was applied on the knowledge about the posture of the students, in two moments. The first moment was before the health promotion session and the second was after two weeks of the session, to see if the health promotion session influenced children's knowledge about postural hygiene. Data analysis was performed using Statistical Package for the Social Sciences, version 24. The level of significance was $\alpha = 0.05$.

Results
After the health promotion session, the student’s knowledge increase and it was statistic significant ($p = 0.000$). It was also possible to analyse that gender ($p = 0.00$), the environment where they live ($p = 0.001$), pedagogical activities ($p = 0.000$) and sports activities ($p = 0.000$) are determinants that influence knowledge.

Conclusion
This study allowed us to conclude that the health promotion session increased the knowledge about posture in the children of the 1st cycle of private school. It is concluded that gender, environment, pedagogical activities and the sports activities are determinants that influence knowledge.

Influence of the Spinal Manipulation on Muscle Spasticity in Cerebral Palsy, Randomized Controlled Trial

O. Kachmar\(^1\), V. Kozyavkin\(^2\), A. Kushnir\(^1\), O. Matiushenko\(^1\), M. Hasiuk\(^1\)

\(^1\)International Clinic of Rehabilitation, Innovative Technologies Department, Truskavets, Ukraine
\(^2\)International Clinic of Rehabilitation, Rehabilitation department, Truskavets, Ukraine

Introduction/Background

Muscle spasticity is an important clinical syndrome of Cerebral Palsy (CP). Recent research indicates possible influence of spinal manipulation (SM), a therapeutic intervention in which a low-amplitude high-velocity impulse of force is applied to the spinal joints, on muscle spasticity. Studies on animal models, electrophysiological H-reflex studies and clinical observations of stroke and CP patients provide data supporting this hypothesis. The aim of our study was to investigate the short-term influence of SM on wrist muscle spasticity and manual dexterity in CP patients in a randomized controlled trial.

Material and Method

After baseline examination, 78 subjects with spastic CP (7-18 y) without contractures or hyperkinetic syndrome were randomly allocated into two groups. Experimental groups underwent SM, control group – imitation of the manipulation. Second evaluation was performed 5 min post intervention. Wrist muscle spasticity was gauged quantitatively with Neuroflexor, a device measuring resistance to passive movements of different velocities. Manual dexterity was evaluated by Box & Blocks test. Nonparametric statistics were used.

Results

In the experimental group muscle spasticity reduced by 2.18 newton: from median 5.53 with interquartile range (IR) 8.66 to 3.35 (IR=7.19), the difference was statistically significant \((p=0.002)\). In the control group reduction in spasticity was negligible. The between-group difference in change of muscle spasticity was statistically significant \((p=0.034)\). Improvement of manual dexterity was not statistically significant \((p=0.28)\).

Conclusion

Study indicates that SM causes reduction of spasticity in patients with CP. Long-term effects of spinal manipulation on muscle spasticity have to be studied.

HOW MUCH CERVICAL ORTHOSIS ARE APPLICABLE IN NONINVASIVE MANAGEMENT OF CERVICAL DISORDERS?
F. Ghorbani¹, S. Ganjehie¹, Z. Nemati¹
¹Iran university of medical sciences, Orthotics and Prosthetics, tehran, Iran

Introduction/Background

Neck pain is one of the most prevalent disorders in the world and became a major public health problem. Cervical collars have been approved to be effective on neck pain and disability as a one of conservative treatments. The purpose of this review was to describe the effectiveness of cervical collars in noninvasive protocols and explain the importance of describe a specific guidelines in prescription cervical collars.

Material and Method

The search was performed in Google scholar, Medline, Science Direct, PubMed, and ISI web of knowledge databases in August 2017 for the keywords, cervical, orthoses, collars, conservative management and pain. Twenty articles were selected for final evaluation.

Results

Five studies indicated that cervical collars have been helpful in the management of different cervical spine fractures in the case of being stable as odontoid, axis and vertebral body of C₂ cervical spine fractures. Four studies suggested cervical collars as a simple conservative treatment that efficiently decrease radiculopathy symptoms. Actually one of the evidence stated cervical collars is as effective in long run as surgical management. Specifically using soft cervical collars would relieve pain in whiplash injuries. Rigid cervical collars are the standard of care for supporting and stabilizing the cervical spine in acutely injured trauma patients. Although, there is an agreement that, plate fixation provides rigid internal fixation and would eliminate the need for a cervical collar postoperatively in the majority of patients.

Conclusion

A number of studies have demonstrated that cervical collars can reduce patient’s symptoms and prevent neck pain associated with cervical disorders, including degenerative conditions. Furthermore, they are effective in restricting cervical motion in acute injury, and can be used postoperatively to provide cervical stabilization. The choice of a particular collar should be determined by various factors, including restrictiveness, pressure-relieving capabilities, patient mobility, tissue tolerance, and the patient’s ability to communicate discomfort.

EVALUATING THE EFFECT OF A VIBRATING INSOLE ON VIBRATION PERCEPTION THRESHOLD IN A PATIENT WITH TYPE 2 DIABETES AND SENSORY PERIPHERAL NEUROPATHY: A CASE REPORT

L. Ennion¹

¹University of the Western Cape, Physiotherapy, Cape Town, South Africa

Introduction/Background

The prevalence of Diabetes mellitus (DM) is increasing globally and affects 8.27% of the South African population. South Africa hosts a very young diabetic population with 67% of all diabetics being under the age of 60 years. Sensory peripheral neuropathy (SPN) is a common complication of DM that affects 33% of all persons with DM. Sensory peripheral polyneuropathy is a major predisposing risk factor for developing foot ulcers which can become infected and in turn is the biggest risk factor for lower limb amputation in diabetic patients. An increased Vibration perception threshold (VPT) is indicative of SPN and an increased risk for diabetic foot ulcers. The aim of this case study was to determine if a vibrating insole intervention will effectively reduce VPT in a patient with Type 2 DM and SPN.

Material and Method

A pre-test post-test study design and a Biothesiometer was utilised to evaluate the effect of the intervention on the VPT over seven points on the feet of a single case with known sensory peripheral neuropathy secondary to type 2 DM.

Results

The use of the vibrating insole resulted in a statistically significant (p = 0.000) reduction in VPT over seven points of measurement on the foot from baseline to post-intervention. The VPT score increased slightly, but not statistically significantly (p = 0.051) during the washout period, but the overall positive effect of the intervention was maintained after a wash-out period of one month.

Conclusion

The significant change from pre-intervention to post-intervention scores might indicate that the intervention might be deemed effective in reducing VPT in this specific group of patients, thus reducing the risk for Diabetic foot ulcers. Further piloting with a bigger sample is however required.

ABSTRACT NEED TO BE EDITED - REPEATED INJECTIONS OF BOTULINUM TOXIN A IN RESIDUAL LIMB HYPERHIDROSIS: WHAT EFFECT?

V. Martins

Centre Hospitalier Nord Caraïbe, Physical and Rehabilitation Medicine, Le Carbet, France

Introduction/Background

Residual limb hyperhidrosis is a problem frequently encountered in amputations: 66% of the subjects in the Hansen et al. Study. In case of resistance to conventional treatments (appropriate hygiene measures, antiperspirants), it can be treated by botulinum toxin injections in intradermal or intraepidermal.

Material and Method

Objective: To evaluate long-term efficacy of botulinum toxin A in the treatment of residual limb hyperhidrosis.

Type of study and duration: case report, for more than 2 years

Participant: Afro-Caribbean man, 29-year-old, femoral amputee with disabling hypersudation of his residual limb, causing a sliding of his prosthesis.

Intervention: four sessions of superficial intradermal injections of botulinum toxin A in his residual limb, respectively spaced from 14, 9 and 4 months.

Results

Botulinum toxin A reduced residual limb sweat production by -70.5% on average. It reduces discomfort due to perspiration when this discomfort is important. It extends duration of wearing prosthesis when this delay is short on pre-toxin assessment.

On average, it reduces overall discomfort due to sweat by -38.25%, discomfort during work by -37%, and increases delays before removal (+1h39 during work and +3h22 during activities everyday).

Pain related to injection session decreases during the 4th session.

Finally, a progressive decrease in action duration of botulinum toxin A is observed.
Conclusion

This study suggests that botulinum toxin A injections at long-term effectively decrease amount of sweat of residual limb. Embarrassment due to sweat and short wearing time of prosthesis could be improved by botulinum toxin A. However, action duration would decrease over time.

ABSTRACT NEED TO BE EDITED - THE EFFECT OF USING 8-WEEK BACK BRACE ON ELECTROMYOGRAPHY ACTIVITY OF YOUNG WOMEN WITH CHRONIC BACK PAIN DURING WALKING

F. Farmani¹, H. Khodaveisi², S.D. Mohammadi³
¹Hamadan University of Medical Sciences, Orthotics & Prosthetics, Hamedan, Iran
²Islamic Azad University of Hamadan, 1. Department of Physical Education, Hamadan, Iran
³Qom University of Medical Sciences, Department of Medicine, Qom, Iran

Introduction/Background

Different braces are designed to stabilize the spinal column in terms of symptoms in spine. One of the common braces to treat back pains is lumbar supporting braces in design of which a support on erectus spine muscles is used to keep and support these muscles. This research aims to evaluate the effect of using 8-week back brace on electromyography activity of young women with chronic back pain during walking. Although some studies have evaluated the effect of back brace on muscle activities in patients with back pain, less have examined the EMG of the muscles during walking while using lumbosacral brace.

Material and Method

In this semi-experimental research, the activity of erector spine muscles, abdominal erectus, abdominal external oblique, abdominal internal oblique of 22 women with chronic back pain was evaluated. These women were randomly divided into experimental and control groups. The experimental group used back brace for eight weeks. Before and after using brace, the electromyography (EMG) activity was recorded in both groups. Independent t-test and correlated t-test were used to analyze the data.

Results

In experimental group, EMG activity of erector spine and abdominal erectus muscle in midstance of walking was significantly decreased after 8-week using brace (P<0.05). Also, there was a significant reduction in pain after using brace in experimental group (P<0.05) while in control group no significant change was observed (P>0.05).

Conclusion

It can be concluded that using brace can reduce the activity of erector spine and abdominal erectus muscles in midstance of walking, and decreasing in back pain may be achieved. Examining kinematic and kinetic characteristics may more reveal the cause of efficacy of back brace in these patients.

EVALUATION OF THE EFFECTS OF ADDING VIBROTACTILE FEEDBACK TO MYOELECTRIC PROSTHESIS USERS ON PERFORMANCE AND VISUAL ATTENTION IN A DUAL-TASK PARADIGM
S. Portnoy¹, J. Friedman², E. Raveh¹
¹Tel Aviv University, Occupational therapy Dept., Tel Aviv, Israel
²Tel Aviv University, Physiotherapy Dept., Tel Aviv, Israel

Introduction/Background

Myoelectric prostheses inherently lack tactile feedback. Therefore, users of these devices have to rely on their visual feedback. Since daily tasks are often performed in a dual-task paradigm, e.g. holding a coffee cup while reading a newspaper or folding clothes while watching the television, they pose a cognitive challenge to the prosthesis user. Our objective was therefore to evaluate the effects of adding vibrotactile feedback to myoelectric prosthesis users on the performance time and visual attention in a dual-task paradigm.

Material and Method

Twelve transradial amputees using a myoelectric prosthesis (age 65±13 years) performed five functional grasping tasks with their prosthetic hand, while controlling a virtual car on a road with their intact hand (see Figure 1). The dual-task was performed twice: with and without vibrotactile feedback. We measured the performance time of each of the grasping tasks and gaze behavior, measured by the number of times the subjects shifted their gaze towards their hand, the relative time they applied their attention to the screen, and the percentage of error in the virtual driving task.

Results

The mean performance time was significantly shorter (p=.024) when using vibrotactile feedback (93.2±9.6s) compared with the performance time measured when vibrotactile feedback was not available (107.8±20.3s). No significant differences were found between the two conditions in the number of times the gaze shifted from the screen to the myoelectric hand, in the time the subjects applied their visual attention to the screen, and in the total time that the virtual car was off-road with and without vibrotactile feedback, as a percentage of the total game time (51.4±15.7 and 50.2±19.5, respectively).

Conclusion

Tactile feedback can be an effective addition to myoelectric prosthesis users, improving performance time during grasping and manipulating objects in a dual-task paradigm.

Introduction/Background

Among health professionals, there is a high prevalence of musculoskeletal disorders. In our hospital, during a one-year period, 18% of the hospital staff was treated in the Rehabilitation Department, 50% because of pain in the neck and back. Therapeutic approach to cervical pain should include posture modification and exercise. A new garment, Posture Plus Force®, includes thoracic and abdominal tensitional bands for the postural realignment. The aim of this study was to investigate the effects of a postural garment versus exercises in nurses with non-specific cervical pain.

Material and Method

Randomised clinical trial. Nurses and allied health professionals with cervical pain aged 21 to 55 years are allocated at random in two groups for a 3 month period: P+ (postural garment to be worn 2- hours per day) or Ex (5 physiotherapy sessions to learn stretching and strengthening exercises and continue at home on a daily basis). Primary outcomes are pain intensity (visual analog scale) and posture measured with a digitalized scan (SpinalMouse®) by a blinded observer. All measures are conducted at T0 (pre-intervention), at 30 days, 60 days and 90 days follow-up. Secondary outcomes are cervical pain-related disability, catastrophizing, global perceived effect of treatment and evaluation of garment comfort. Pharmacological treatment and sick leaves are recorded. Physical activity is assessed with the International Physical Activity Questionnaire. Statistical analysis is conducted following intention-to-treat principles, and the treatment effects calculated using linear mixed models.

Results

29 nurses were recruited and 27 completed the study. Pain reductions are observed for both groups although P+ rated VAS lower and needed less drugs over 3 month period. Posture (kyphosis/ inclination) improves more in P+. Treatment perception is superior in P+ although not significant differences were found.

Conclusion
Positive effects are observed in all outcome measures in P+ group, although low in magnitude.

A SIMPLE MOVEMENT BASED CONTROL APPROACH TO EASE THE CONTROL OF A MYOELECTRIC ELBOW PROSTHETICS IN TRANSHUMERAL AMPUTEES

N. Jarrasse¹, D. Müller¹, E. De Montalivet¹, F. Richer¹, M. Merad¹, A. Touillet², N. Martinet³, J. Paysant³

¹Sorbonne Université, Institut des Systèmes Intelligents et de Robotique CNRS UMR 7222, Paris, France
²Regional Institute of Rehabilitation, Louis Pierquin Center, Nancy, France
³Regional Institute of Rehabilitation, Louis Pierquin Centre, Nancy, France

Introduction/Background

Common myoelectric control strategy remains complex to use and produce unnatural gestures since it does not allow simultaneous movements of several joints. This is especially an issue for the transhumeral amputees who can use an active elbow in addition to active prosthetic wrist and hand. Since most transhumeral amputees have a mobile residual limb, an interesting approach aims at utilizing this mobility to control the elbow. We thus developed a simple electronic device relying on an inertial measurement unit, that can be interfaced with existing commercial myoelectric elbows and which convert chosen displacements of the residual limb into control signals, offering an intuitive way of controlling an active elbow prosthesis whilst allowing a simultaneous myoelectric control of the wrist and hand.

Material and Method

We performed an experiment with one transhumeral amputee wearing his myoelectric prosthetic (active elbow, wrist and hand) who was asked to grasp and transfer different objects several times while being recorded with a motion capture system. Theses task were performed twice: with a conventional full myoelectric control and with the proposed movement based control. Several metrics (position error, time, smoothness, along with body compensatory strategies) were used to quantify the performances obtained with these two modes.

Results

Analyses showed that the participant was able to perform the tasks in both condition, but that the movement based control approach allowed a reduction in task time and in exhibited body compensatory strategies, by offering an easier access to adjustments of the elbow posture compared to the full myoelectric control approach.

Conclusion

This work illustrates the potential of using residual limb mobility in the control of prosthetics, to make it more natural and intuitive, and how this can have an indirect but positive impact on the whole body compensatory strategies exhibited by amputated subjects.

THE EFFECT OF DIFFERENT ANKLE BRACE ON GROUND REACTION FORCE PARAMETERS AND KINEMATIC PARAMETERS

S. Numano1, U. Yukio1, N. Maeda1, N. Moriyama2, N. Tonegawa1

1Biomedical & Health Sciences, Hiroshima University, Hiroshima city, Japan
2Department of Public Health, Fukushima Medical University, Fukushima, Japan

Introduction/Background

Previous study showed that use of ankle brace increased the risk of other lower extremities injuries in forward jump because of large ground reaction force (GRF) and decreased ankle dorsiflexion angle (AF). However, in lateral landing that was often used during the game or practice in many sports, the risk factor was still unknown. This study aimed clarify the effect of ankle brace on ground reaction force and kinematic parameters among forward and lateral landing.

Material and Method

Ten college female students without a history of knee or ankle injuries participated in this study. The subjects wore an ankle support brace on the non-dominant foot. They performed with three conditions that using soft brace (SB) (SA-1, Japan Sigmax Inc.), semi-rigid brace (SRB) (A-1, Japan Sigmax Inc.), and no ankle brace (NB). The Each participant jumped 50 cm to the forward and lateral direction, landing on one leg from a 20-cm-height box. Two-way analysis of variance was used to analysis the differences in peak GRF (pGRF), time to pGRF (TpGRF), Impulse (N/BW · s), AF, ankle inversion angle (AI), AF moment (AFM), and ankle inversion moment (AIM) among forward and lateral landing. The significance level was set at p < 0.05.

Results

pGRF, AF, AI and AIM were not significant difference among each condition. TpGRF were smaller SRB than NB (p<0.05). Impulse were larger SRB than NB and SB (p<0.05). AFM was smaller in SRB than NB (p<0.05).

Conclusion

Large Impulse was thought the higher risk of lower extremities. In this study, Impulse was smaller in SRB than other conditions. In addition, AFM and AIM were smaller in SRB than other conditions. This result showed using ankle brace such as rigid type is effective on return to sports.

Many children with neuromuscular disorders have limited motion of their upper limb. To sustain their little upper limb movement possibilities against gravity and offer them more autonomy, the objective of this study was to develop an exoskeleton that would be light, easy-to-make and costless. The application took the form of a case study: the first elected patient in our center to be equipped was a 4 year-old girl with congenital RYR-1 myopathy.

Material and Method

The patient growth and management of her scoliosis led to an under-utilization of her upper-limb. Her muscle weakness limited her prehension capacities. The modeling and drawings were developed thanks to a computer aided design software. The design process led to a 3D printed exoskeleton for the upper limb members (ExoMS), equipped with an anti-gravity mechanism composed of springs. The drawings were printed using a Delta-type printer. Assembly and tolerance of the printed pieces, add-on the existing CTLSO Garchois type brace was excellent. The functional mobility of the patient upper limb was assessed before and after equipment with 7 items of the Melbourne upper limb assessment scale: range of movement, accuracy of reach and placement, dexterity of grasp, fluency of movement.

Results

The assessment of functional mobility of the upper limb with the Melbourn assessment scale showed a significative enhancement for all designated items. The obtained 3D printed ExoMS is a simple, light weight and costless device to facilitate upper-limb motion with patient with neuromuscular weakness.

Conclusion

This clinical and technical multidisciplinary work with the great collaboration of the family motivates us to enhance new possibilities in giving back some precious mobility to patients with neuromuscular disorders.

CHARACTERISTICS OF 3015 USERS OF LOWER LIMB PROSTHESIS GRANTED BY CORPORACION MAHAVIR KMINA ARTIFICIAL LIMB CENTER IN COLOMBIA

A.Y. Matamoros-Villegas¹, J.A. Plata-Contreras¹
¹Universidad de Antioquia, Grupo de Rehabilitación en Salud, Medellin, Colombia

Introduction/Background

Objective: To describe the clinical, sociodemographic and functional characteristics in users of limb prostheses provided by Corporación Mahavir Kmina Artificial Limb Center (CMKALC) from 2007 to 2017, as well as the causes of amputation or absence of lower extremities in that population.

Material and Method

Methods: A retrospective description of patients who attended CMKALC during ten years, and who were adapted with prostheses for amputation of one or both lower extremities. Statistical methods were used to determine the proportion of patients by level and cause of amputation, as well as the prevalence of these conditions.

Results

Results: 3015 patients were included, 601 women and 2414 men with an average age of 45.5 and 46.7 years respectively. Above the knee was the most frequent level of amputation or limb absence (54.89%); of this group 546 were due to traffic accidents (32.99%), followed by diabetes mellitus with 225 (13.59%). Traffic accidents accounted for 28.95% of total causes of amputation, and diabetes accounted for 18.77%; in the case of landmines, a cause thought to be highly prevalent in Colombia, it accounted for 4.90% of amputations. The average age of amputees due to motorcycle traffic accidents was 35.43 years for women and 38.32 for men, 60.55 and 60.98 years for women and men with diabetes respectively. For landmines, the average age in women was 36.73 years and 34.65 in men. The amputations due to diabetes showed a male to female ratio of 4:1, similar to that reported in other case series. 32.45% of people included in this study had used some sort of prostheses formerly.

Conclusion

Conclusions: The results of this study describe the statistical data and the most important demographic features of the recipients of exoskeletal prostheses with the Jaipur foot and high-density polyethylene, granted by CMKALC during ten years of labour.

Keywords
Exoskeletal prostheses; Jaipur foot; Lower limb amputation

Objective: Identify the time of duration between the first and second low-cost prostheses, donated by an orthopedic equipment shop in Medellin, Colombia, from 2007 to 2017.

Material and Method

Methods: A retrospective description of lower limb amputee patients was performed during a 10 year period. Statistical methods were used to determine the proportion of patients by level and causes of amputation, as well as the prevalence of these conditions.

Results

Results: A total of 3,449 amputees were included in the study, of whom 51.8% presented amputation above the knee and 48.1% presented amputation below the knee. The causes for amputation were classified as 54.82% medical and 45.17% traumatic. Of those with medical causes, 61.6% were neurovascular, followed by 11.8% congenital; in the traumatic ones the traffic accident occupied 65.7%, followed by violence 23.9% (landmines 4.8%). 30% of total patients were previously prosthesis users.

Patients who received a second prosthesis (249) met the following characteristics: 69.8% were between 18 to 60 years old, the level of absence of limb below the knee was the most frequent at 69.8%. The amputation causes: 49% medical and 51% traumatic. Among medical causes, the most frequent ones were 16.06% congenital, followed by neurovascular 20.48%. In those with traumatic causes, traffic accidents represented 34.54%, of which, 5% were on a motorcycle, while violence represented 8.8%, with a minority of 5% due to landmines. The average duration of the first prosthesis was 33.8 (SD +/- 23.1) months.

Conclusion

Conclusions: the results describe the durability of exoskeletal prostheses made with the Jaipur foot and high density polyethylene, and the main characteristics of patients with lower limb amputations, who have been awarded by Corporación Mahavir Kmina Artificial Limb Center in Medellin – Colombia, between 2007 and 2017.

ULTRASOUND SENSING-BASED INTUITIVE PROPORTIONAL CONTROL: AN EVALUATION STUDY WITH UPPER-EXTREMITY AMPUTEES
A. Dhawan¹, B. Mukherjee², S. Patwardhan², J. Majdi², R. Holley³, W. Joiner², M. Harris-Love², S. Sikdar²
¹George Mason University, Computer Science, Fairfax, USA
²George Mason University, Bioengineering, Fairfax, USA
³MedStar National Rehabilitation Hospital, Occupational therapy, Washington D.C, USA

Introduction/Background

Recent studies have shown that unintuitive control is a key factor leading to upper-extremity, myoelectric prostheses abandonment. We have developed a non-invasive modality to extract proportional control signals in the residuum using ultrasound imaging. In this study, we investigate the performance of this technology in upper-extremity amputees.

Material and Method

We recruited 4 amputee subjects (Table I) who currently use myoelectric prostheses. Subjects were instrumented with a portable ultrasound system connected to a low-profile transducer on the volar aspect of their residuum. Ultrasound images were processed in real-time to extract graded muscle activity signal in response to volitional user-intended motions (UIMs). Subjects were trained by iterating each UIM while being provided with visual feedback of ultrasound images and muscle activity signal. Participants were then given control of an on-screen cursor that responded proportionally to the level of muscle activity for a particular UIM and asked to reach and hold the cursor at predefined set-points. Control steadiness (standard deviation) and control error (difference between cursor and target) were computed.

Results

All subjects were able to complete the training phase within 15 minutes (25 iterations or less) for at least 4 degrees-of-freedom (DoF), while achieving motion prediction accuracies greater than 88% (Table I). 3 subjects participated in the motion control task. The congenital amputee subject performed 2 motions and the rest performed at least 4 motions with control errors between 2.1% and 9.36% (Table II). Our approach provides direct positional control based on muscle deformation, resulting in improved proprioceptive feedback, unlike myoelectric control. We believe that ultrasound images coupled with the muscle activity signals serve as an intuitive visual feedback mechanism, resulting in reduced training time and improved performance.
Conclusion

We demonstrated intuitive proportional control using ultrasound-based muscle activity sensing paradigm for multiple DoFs with traumatic and congenital amputees.

OPEN-DESIGN COLLAR VS. CONVENTIONAL PHILADELPHIA COLLAR REGARDING USER SATISFACTION AND CERVICAL RANGE OF MOTION IN ASYMPTOMATIC ADULTS

F. Ghorbani¹, M. Kamyab¹, F. Azadinia¹, B. Hajiaghaei²

¹ Iran university of medical sciences, Orthotics and Prosthetics, tehran, Iran

Introduction/Background

Cervical collars are often prescribed to minimize physiologic loads and movements between the head and thorax by limiting cervical motion; they are also used for supporting a patient’s head and reducing the risk of cervical injury resulting from additional spinal movements. One of the problems in orthotic treatment is the unpleasant appearance of the orthosis, which could impede the patient from continuing treatment. Currently, it is essential to consider the importance of the psychologic effect of rehabilitative treatment. The current study aimed to compare the Philadelphia collar and an open-design cervical collar with regard to user satisfaction and cervical range of motion in asymptomatic adults.

Material and Method

Seventy-two healthy subjects (36 women, 36 men) aged 18 to 29 years were recruited for this study. Neck movements, including active flexion, extension, right/left lateral flexion, and right/left axial rotation, were assessed in each subject under 3 conditions—without wearing a collar and while wearing 2 different cervical collars—using a dual digital inclinometer. Subject satisfaction was assessed using a 5-item self-administered questionnaire.

Results

Both Philadelphia and open-design collars significantly reduced cervical motions ($P < 0.05$). Compared with the Philadelphia collar, the open-design collar more greatly reduced cervical motions in three planes and the differences were statistically significant except for limiting flexion. Satisfaction scores for Philadelphia and open-design collars were $15.89 \pm 3.87$ and $19.94 \pm 3.11$, respectively.

Conclusion

This study demonstrated that the open-design collar is more cosmetically acceptable as a semirigid cervical collar compared with the Philadelphia collar, at least for subjects aged under forty years, while it also has optimal restriction potential. Further studies are needed to investigate its effectiveness in restricting cervical intervertebral motion and long-term compliance.

Growing rate of amputation (more than 1.6 million in U.S that will increase to 3.6 million in 2050)\(^1\) and the complications of using passive prostheses, as falling and more energy consumption, illustrates the relevance of improving more secure technology as microprocessor prosthesis\(^2, 3\).

C-leg is a variable damping, hydraulic stance and swing control, containing sensors, strain gauge, microprocessor and hydraulic components, which simulates eccentric muscles function during gait, aiming to resolve passive prostheses limitations as step length asymmetry, excessive swing phase knee flexion and intact limb overloading\(^4, 5\).

This study aimed to investigate kinematic and kinetic parameters of level walking in C-leg users.

**Material and Method**

A database search was made between the years 1997 and 2017 under “C-leg”, “microprocessor”, “semi-active prosthesis”, “gait kinematic”, “gait kinetic” and “gait biomechanics”. Database searched included: Cochrane database, PubMed and Medline. Five journal articles were selected.

**Results**

According to the result of literature, C-leg helped amputees cinematically by: providing loading response knee flexion which helps shock absorbing and decreases load on intact limb and prosthetic side hip joint\(^\text{6}\); placing GRF posterior to joint axis, which provides knee flexion in toe-off without delay and attempt\(^\text{6}\); and damping excessive swing phase knee flexion\(^\text{5}\).

Gait kinetic parameters were also improved, as C-leg increased peak knee flexion moment in loading response, and consequently reduced vertical ground reaction force, hip flexion moment and intact limb moment and power generation\(^\text{5-7}\). Due to easy of rotation, knee extension moment increased in preswing\(^\text{7}\). Gait smoothness increased because of lower jerk when transferring from stance to swing and vice versa\(^\text{7}\) and knee flexion moment decreased in swing phase\(^\text{5, 8}\).

**Conclusion**
Based on the limited evidence, C-leg improved gait symmetry and reduced metabolic rate, compared to passive prostheses, by improving kinematic and kinetic parameters of level walking(6, 9).

CHARACTERISTICS OF LOWER LIMB PROSTHESIS USERS GRANTED BY TWO CENTERS IN INDIA AND COLOMBIA

J.A. Plata Contreras¹, P. Mukul²

¹Universidad de Antioquia, Grupo Rehabilitacion en Salud and Corporacion Mahavir kmina artificial limb center, Medellin, Colombia
²Jaipur Foot Rehabilitation Center & Paul Hamlyn International Center-BMVSS, Jaipur Foot Rehabilitation Center & Paul Hamlyn International Center-BMVSS, Jaipur, India

Introduction/Background

To describe the clinical, sociodemographic and functional characteristics in users of limb prostheses provided two centers in India and Colombia (BMBSS and CMKALC) from 2007 to 2017, as well as the causes of amputation or absence of lower extremities in that population.

Material and Method

A retrospective description of patients who attended by BMVSS and CMKALC during ten years and who were adapted with prostheses for amputation of one or both lower extremities and upper limbs. Statistical methods were used to determine the proportion of patients by level and causes of amputation, as well as the prevalence of these conditions.

Results

19952 patients were included by BMVSS and 3015 patients by CMKALC, in the first center the male:female ratio of were 9:1 while in CMKALC were 4:1, at least the 75% of patients in BMVSS were between 20-50 years, at Colombia´s center the 66% were 30-70 years. Above the knee was the most frequent level of amputation or limb absence (40.75% and 50.85%); the most frequent cause at both centers were due to traffic accidents (45.31% and 28.65% respectively), followed by train accidents in India (12.5%) and in the second center were diabetes mellitus with 17.68% while in BVSSS were 1.72%; in the case of landmines, a cause thought to be highly prevalent in Colombia, it accounted for 4.90% of amputations. Satisfaction Level (with Prosthesis, Prosthetist, Training, Services of the organisation) were High (52% vs. 96.7%), moderate (47% vs. 2.7%) and low (1% vs. 0.6%) respectively. Functional Satisfaction High performance (45% and 57.1%), Moderate (46% and 32.71%) and Low (9% vs. 10.28%)

Conclusion

The results of this study describe the statistical data and the most important demographic features of the users of exoskeletal prostheses with the Jaipur foot and high density polyethylene, granted by BMVSS and CMKALC during ten years of labour.

INEFFECTIVENESS OF MUSCLE REACTION TIME AND TORQUE OF QUADRICEPS IN TREATING HAMSTRINGS USING DEEP TRANSVERSE FRICTION MASSAGE

R. Arai¹, H. kuruma²
¹Yashio Central General Hospital, Rehabilitation, Yashio, Japan
²Tokyo Metropolitan University, Tokyo, Japan

Introduction/Background

Deep transverse friction massage (DTFM) is used to treat pain and restricted range of motion. It is known to decrease nerve excitability and performance. However, few studies have focussed on the function of antagonist muscles. This study aimed to determine the effect of DTFM on the antagonist muscle in comparison with stretching.

Material and Method

Overall, 33 healthy male participants (mean age, 23.1 ± 4.2 years) were randomised into three groups: DTFM (n = 11), stretching (n = 11), and control (n = 11). DTFM was performed on the hamstrings for a duration of 10 minutes. Stretching of 10–40 seconds was statically applied to the hamstrings followed by 20-second rest. The control was provided 10-minutes of rest. Peak torque (PT) at a speed of 60°/s and 120°/s on quadriceps and hamstrings, respectively, were the outcome measures, and muscle reaction time, namely, pre-motor time (PMT) and electromechanical delay (EMD) on the rectus and biceps femoris. Two-way analysis of variance for repeated measures was used to evaluate statistical significance of all the measured variables.

Results
Therefore, no difference was found between the subjects and within groups in all measurements (p < 0.05). The result indicated that adding DTFM or stretching on the hamstrings did not affect PT, PMT, and EMD on the quadriceps.

</tbody>
</table>

Mean±SD *:p<0.05

Conclusion

A previous study described reaction time change only when the muscle tendon was treated using DTFM. It was also considered that the difference in treatment site could affect neural mechanisms. In conclusion, this study showed that using DTFM for the treatment of hamstrings improve neither PT nor muscle reaction time on the quadriceps.

\textsuperscript{6}University of Campania “Luigi Vanvitelli”, Department of Medical and Surgical Specialties and Dentistry, Naples, Italy

Introduction/Background

Upper limb volume assessment is the first step in lymphedema diagnosis and rehabilitative management. Circumferential method (CM), the most commonly used limb volumetric method, showed several limitations in common clinical rehabilitation practice and recently a new method using three-dimensional laser scanning (LS3D) has been proposed for limb volume measurement and validated by our group in healthy subjects. Aim of this study was to verify the reproducibility and reliability of LS3D compared to CM in upper limb volume measurement in women affected by breast cancer related lymphedema (BCRL).

Material and Method

We included young women (aged >18 and <45 years) affected by BCRL, with normal weight (BMI >18 and <25 kg/m\textsuperscript{2}). Two raters randomly performed both LS3D and CM upper limb volume evaluation twice in each subject (the mean value of the two CM and LS3D evaluations was used) at baseline and at the end of the rehabilitative lymphedema treatment. CM assessments were performed by two expert lymphotherapists with more than 20 years of experience in lymphedema treatment and blinded to other rater's assessments.

Results

Ten BCRL patients, mean aged 54.3±10.2 years have been enrolled. Both LS3D and CM showed a significant inter and intra-operator correlation in upper limb volume measurement (r\textsuperscript{2}=0.99; p<0.0001). LS3D showed a strong correlation with CM (r\textsuperscript{2}=0.99; p<0.0001); moreover LS3D was significantly quicker in upper limb volume measurement than CM (195±24 sec. vs 258±19 sec; p<0.0001).
Conclusion

Results of this small pilot study suggest that LS3D seems to be a highly reproducible, reliable and easy to use method to evaluate upper limb volume in BCRL patients, as previously evidenced in healthy subjects. Our results suggest a potential implementation of LS3D as a useful tool in lymphedema common clinical rehabilitation practice. Future investigations should address its reliability and reproducibility in different stages of lymphedema.

TEMPERATURE CHANGES IN BONE BY THERAPEUTIC ULTRASOUND: AN EXPERIMENTAL SETUP WITH PHANTOMS AND A BOVINE EX VIVO SAMPLE
D.B. Novaes¹, C.B. Santos¹, E.S. Lucena¹, E. Butterworth², W.C.A. Pereira³, C.B. Machado¹
¹Estácio de Sá University, Biomedical Ultrasound Laboratory, Niterói, Brazil
²Northumbria University, Biomedical Sciences, Newcastle, United Kingdom
³Federal University of Rio de Janeiro, Biomedical Engineering Program, Rio de Janeiro, Brazil

Introduction/Background

Heat distribution in multilayered tissues after therapeutic ultrasound (TUS) stimulation has been investigated in the last decades. However, there are still some concerns regarding wave parameters, dosage and physiological responses, leading to the need for further research. The aim of this study was to assess temperature changes in bone samples and phantoms (mimicking materials) caused by TUS.

Material and Method

It was used a sample of bovine ex vivo femur and two cortical bone phantoms (Sawbones®, USA): a 4-mm thick plate and a 5-mm thick cylinder put under a custom-made two-layered soft tissue phantom, and a TUS probe (1-MHz, intensity SATA of 1 W/cm², continuous or 50%-pulsed regimen) was used in contact with it, in a fixed or moving configuration, for a 5-minutes stimulation. A thermometer captured temperature values with two K-type thermocouples: one in the bone-soft tissue interface, and the other between the two soft tissue layers. Everything was inside a water bath at 36.5°C and experiments were repeated five times. Wilcoxon tests (p < 0.05) were used for statistical analysis.

Results
The figure depicts boxplots representing the difference between minimum and maximum temperatures for the five experiments concerning both pulsed regimens and interfaces, for fixed (fix) and moving (mov) transducers. It can be observed that fixed transducer leads to a higher increase in temperature compared to moving transducer, mainly for the continuous mode. The 50%-pulsed regimen raised maximum temperatures to more than 40ºC. Some significant differences were observed ($p < 0.05$).

**Conclusion**

Fixed transducer may be deleterious since it may lead to great temperature increases. Pulsed regimens seem to heat with less intensity compared with continuous applications. Heating by TUS on phantoms may differ from bone samples because of their different thermal constants and geometries.

THE OPTIMAL CONDITIONS OF THERAPEUTIC ULTRASOUND ON MUSCLE STIFFNESS OF MEDIAL GASTROCNEMIUS MUSCLE IN HUMAN: A SHEAR-WAVE ELASTOGRAPHY STUDY

K. Morishita¹,², S. Nishishita²,³,⁴, M. Nakamura⁵, J. Saeki², M. Yagi², T. Tsuboyama², N. Ichihashi²

¹Josai International University, Physical Therapy, Togane, Japan
²Kyoto University, Graduate School of Medicine, Kyoto, Japan
³Tokuyukai Medical Corporation, Institute of Rehabilitation Science, Osaka, Japan
⁴Tokuyukai Medical Corporation, Kansai Rehabilitation Hospital, Osaka, Japan
⁵Niigata University of Health and Welfare, Institute for Human Movement and Medical Sciences, Niigata, Japan

Introduction/Background

Therapeutic ultrasound (TU) is most widely used as biophysical agents to treat contracture in orthopedics rehabilitation. Its effect is to increase range of motion by increasing tissue extensibility. However, no studies have reported the effect of TU on human muscle stiffness (MS). Also, the optimal conditions including frequency, intensity, and duty cycle of TU remain unclear. This study aimed to clarify the optimal TU conditions on MS using ultrasonic shear-wave elastography (SWE).

Material and Method

This study was a randomized cross-over trial. All of the following TU conditions were applied on ten healthy males (mean ± SD, age 25 ± 2.9 y.o., height 171.2 ± 4.7 cm, weight 63.1 ± 5.1 kg); frequency (1 and 3 MHz), intensity (continued mode: spatial average-temporal average (SATA) intensity of 0.5, 1.0, 1.5, and 2.0 W/cm²; pulsed mode: 1.0, 2.0, and 3.0 W/cm² with 50% duty cycle (i.e., 0.5, 1.0, and 1.5 W/cm² SATA)) for 10 minutes. Outcome was the change rate of MS in medial gastrocnemius (MG) muscle by using SWE. Statistical analysis was performed using one-way analysis of variance followed by Bonferroni post hoc test.

Results

MS showed significant differences between the different frequency, intensity, and duty cycle. MS significantly decreased with 1.0, 1.5, and 2.0 W/cm² SATA than 0.5 W/cm² SATA at continued mode, and with 1.0, and 1.5 W/cm² SATA than 0.5 W/cm² SATA at pulsed mode at both 1 MHz and 3 MHz. There was no significant difference in MS between the above five SATA intensities, i.e., 1.0, 1.5, 2.0 W/cm² SATA at continued mode and 1.0, 1.5 W/cm² SATA at pulsed mode.

Conclusion
The optimal conditions of TU to decrease MS in MG were over 1.0 W/cm$^{2}$ SATA of intensity for both continued mode and pulsed mode at both 1 MHz and 3 MHz of frequency.

APPLICATION OF FUNCTIONAL HYDROTHERAPY IN THE REHABILITATION OF CHILDREN WITH SPECIAL NEEDS

B. Liang¹, J. Li²

¹ Suzhou Industrial Park Boai School & Boai Clinic, Rehabilitation Medical Service, Suzhou, China
² 1st Affiliated Hospital of Nanjing Medical University, Dept. of Rehabilitation Medicine, Nanjing, China

Introduction/Background

To move from the passive treatment of injuries to their functional active treatment by combining the functional rehabilitation theory with the rehabilitation technique of hydrotherapy.

Material and Method

To make use of the physical properties of water, take games as the carrier, and adopt the approaches of experimental intervention and experience summary to integrate the management of motion, sensory perception, consciousness and behaviors into the rehabilitation environment of hydrotherapy and develop the multi-sensory fun games as well as the motion and sensory perception training.

Results

By means of the functional hydrotherapy training, the interaction and cooperation between therapists and children with special needs are realized, the organization, time sequence and coordination of physical therapies are optimized, and the motion function is rebuilt with individual functions improved.

Conclusion

The functional hydrotherapy training is based upon the framework of ICF-CY “Individual – Task – Environment”, with the realization of various functions as the goal. It combines quite a few physical therapies, arouses the interest of children with special needs in motion and re-learning, and improves the individual function of motion, which conforms to the theory of the environment improving the neuroplasticity in neurophysiology and is regarded as one of the most important physical therapies in the comprehensive rehabilitation treatment in modern children rehabilitation medicine.

FEATURES AND UNIQUENESS OF THE MINERAL SPRINGS WATER OF TSKHALTUBO

T. Valishvili¹, I. Pkhakadze¹, A. Gochelashvili¹
¹Akaki Tsereteli State University, Faculty of Medicine-, Kutaisi, Georgia

Introduction/Background

Tskhaltubo is beautiful powerful resort in West Georgia. It is located near Kutaisi, where there is a great regional state university and the faculty of medicine, where we have planed comprehensive study of the spring waters of Tskhaltubo and their therapeutic effects. One of the objectives of our study is to conduct clinical trials and statistical processing of the results obtained for the purpose of further developing the methods of balneological treatment based on the unique waters of Tskhaltubo.

Material and Method

A literature review of all available literature is presented in this paper, starting from the time of the beginning of the study of the mineral waters of Tskhaltubo in the late 19th century. Physico-chemical properties of mineral waters were compared and their balneological therapeutic effect was studied.

Results

One of the main specific features of the Tskhaltubo mineral springs is the consistency of physical and chemical properties, as well as the uniformity of all mineral sources, both in physico-chemical and therapeutic properties. Tskhaltubo mineral springs do not contain potent, toxic substances, so they are very soft by action and easily transferred by patients, so they can be used for treatment at any stage of the disease, when the use of other mineral waters is contraindicated.

Conclusion

The chemical composition of the Tskhaltubo water is stable and does not change over time, as evidenced by the comparison of chemical analyzes performed in the last 70-80 years.

Some balneologists consider the Tskhaltub water to be radon, thanks to the natural temperature of the mineral water, which allows it to be used in flowing pools without preheating, which promotes the formation of an active deposit on the skin, even if a small amount of radon is present in the water.

⁴ASST Grande Ospedale Metropolitano Niguarda, Unità Spinale Unipolare, Milan, Italy

Introduction/Background

A good stability in sitting position is essential for people with spinal cord injury (SCI) for carrying out the activities of daily life, for autonomy, for social inclusion, to be able to make transfers, to ensure a good mobility and the ability to push a manual wheelchair. Rehabilitation in water offers many facilities and it can be an excellent tool to re-educate the trunk balance. The aim of the study is to evaluate the effectiveness of rehabilitation treatment in water using sequences of the protocol of the Sequential and Propedeutic Approach method (A.S.P.) on trunk control in SCI people without voluntary abdominal muscles control.

Material and Method

8 patients were recruited: 5 patients with cervical lesion, 3 with dorsal lesion. Evaluations were performed in three phases (T0, T1 and T2 over a maximum period of 4 months) through the Sitting Balance Assessment for Spinal Cord Injury (SBA-sci) and Spinal Cord Independence Measure (SCIM III) scales. The treatment, foreseen in 8 individual sessions of hydrotherapy with the A.S.P method, with frequency once a week, was added in the period T1-T2 in addition to the traditional re-education of the balance of the trunk proposed in a "dry setting" between T0 and T2.

Results

8 subjects completed the program. After the treatment in water (T1-T2) the subjects showed instead a significant increase (-2.02 ± 1.96, p <0.05). This does not occur with the SCIM III scale T1-T2 (-1.60 ± 1.96, p > 0.05).

Conclusion

The results collected seem to bring out the effective contribution in controlling the trunk of the treatment in water through the A.S.P. method on people with SCI with level upper than T7. This increase does not appear immediately related to an increase in autonomy.

EFFECT OF KNEE JOINT ANGLE-BASED, ADAPTIVE FUNCTIONAL ELECTRICAL STIMULATION OF THE PERONEAL NERVE IN SPASTIC PARESIS. A CASE REPORT
W. Huo¹, M. Ghédira², S. Mohammed¹, V. Arnez-Paniagua¹, E. Hutin², J.M. Gracies²
¹Université Paris-Est Créteil, Laboratoire Images- Signaux et Systèmes Intelligents LISSI- EA 3956, Vitry-sur-Seine, France
²Hôpitaux Universitaires Henri Mondor- AP-HP, Laboratoire Analyse et Restauration du Mouvement ARM- BIOTN- EA 7377- Service de Rééducation Neurolocomotrice, Créteil, France

Introduction/Background

Functional electrical stimulation (FES) of the peroneal nerve has long been proposed to improve ankle dorsiflexion during swing phase of gait in hemiparesis. The present study assesses the effect of a knee joint angle-based adaptive FES compared with classical FES and no use of FES on active ankle dorsiflexion during gait. The rationale behind aFES is to amplify dorsiflexor stimulation when it is most needed, to face increased plantar flexor cocontraction as gastrocnemius muscles are stretched by knee re-extension in late swing.

Material and Method

Three subjects with chronic hemiparesis (time since stroke, 4±3 years) underwent gait analysis at comfortable speed with shoes in three conditions: without stimulation (control), with classical FES (cFES) using trapezoidal stimulus intensity pattern and with an adaptive FES (aFES), in which stimulus intensity is indexed on the degree of knee flexion (the more re-extended the knee in swing, the higher the intensity). We compared cFES and aFES on the gain in active ankle dorsiflexion from control condition, during three periods of swing phase (T1 [0-42.5%], T2 [42.5-65%], T3 [65-100%], 10 gait cycles analyzed), and on the stimulation intensity delivered.

Results

For the three patients pooled, the gain in active dorsiflexion from control condition was +4±2° at T1, +3±1° at T2 and +5±5° at T3 with cFES; and +2±1° at T1, +3±1° at T2 and +5±3° at T3 with aFES. Stimulation intensity was 12±10% lower with aFES compared with cFES.

Conclusion

Both classical and adaptive FES increase ankle dorsiflexion during swing phase in hemiparesis. These first case studies suggest higher effect of classical FES compared with adaptive FES in early swing, and similar effects of both FES systems during mid and late swing, while aFES used lower stimulation intensity.

EFFECTS OF NEUROMUSCULAR ELECTRICAL STIMULATION COMBINED WITH CONVENTIONAL DYSPHAGIA THERAPY IN AN INCOMPLETE LOCKED-IN SYNDROME PATIENT, ONE YEAR AFTER STROKE: A CASE REPORT
P. Estevez¹, T. Ramos²
¹Clinique de Montévrain, 77144, Montévrain, France
²Clinique de Montévrain, Ile de France, Montévrain, France

Introduction/Background

The purpose of this study was to investigate the effects of the neuromuscular electrical stimulation (NMES) combined with conventional dysphagia therapy, in a patient with an Incomplete Locked-in Syndrome (ILIS) presenting with oropharyngeal dysphagia secondary to a bilateral pontine stroke (October 2015). The subject was a 67-year-old man with no history of dysphagia before the stroke. He completed 11 months of neurological rehabilitation, including conventional dysphagia therapy, with no improvement in the dysphagia. He was admitted to our clinic 14 months post-stroke. His Functional Oral Intake Scale (FOIS) score before treatment was 4. The Penetration-Aspiration scale (PA) score before treatment was 8 and the videofluoroscopic assessment (6 months after conventional dysphagia therapy) showed aspiration and pharyngeal residue¹.

Figure 1: Videofluoroscopic assessment 6 months after conventional dysphagia therapy
Material and Method

Intensive rehabilitation swallowing program, involving NMES combined with conventional dysphagia therapy (patient received NMES during lunch and functional exercises). We performed 4 sessions of 1h each week, over a period of 7 months. Swallowing function was assessed using videofluoroscopic evaluation, FOIS and PA scale.
Figure 2: Electrode placement

Results

After 7 months, videofluoroscopic assessment showed an improved swallowing reflex and reduced pharyngeal residue\textsuperscript{3}. The FOIS score increased to 7 and aspiration decreased from 8 to 5 on the PA scale.

Figure 3: Videofluoroscopic assessment after intensive rehabilitation swallowing program
Conclusion

Our results suggested that the NMES combined with conventional dysphagia therapy, can be effective in the rehabilitation of dysphagia, in ILIS patients, even one year post stroke.

SATISFACTION IN THE MANAGEMENT OF PAIN DURING LABOUR WITH THE USE OF TRANSCUTANEOUS NERVE STIMULATION
A. Báez Suárez, E. Martín Castillo, J. García Andujar, J.A. García Hernández, M.P. Quintana Montesdeoca, D. Álamo Arce, J.F. Loro Ferrer
1University of Las Palmas de Gran Canaria, Medical and Surgical Sciences, Las Palmas de Gran Canaria, Spain

Introduction/Background

There are many factors involved with satisfaction in women during labour. Pain relief is considered one of the weaknesses, in such a way that it could influence the rating of the rest of satisfaction items. The use of Transcutaneous Electrical Nerve Stimulation (TENS), like a non-pharmacologic approach, is an effective and safe technique used during childbirth. Measure for Testing Satisfaction (COMFORTS) scale is a specific questionnaire that includes the most important factors associated with the relation between mother satisfaction and the childbirth experience.

The aim of this work was to analyze factors that can influence satisfaction in pregnant women during labour and its relation with pain management.

Material and Method

A randomized and double-blind controlled trial was conducted. All participants completed the satisfaction scale immediately after childbirth. 63 participants were randomly assigned to one TENS device to relieve the pain, with different dose in each patients group. The primary outcome was to evaluate satisfaction in patients during childbirth and its relation with pain relief. This measurement was made with two scales, the satisfaction level was measured with COMFORTS scale and pain was measured with Visual Analogue Scale (VAS).

Results

The total COMFORTS scale mean score was 171.03 ± 19.69 with an individual item mean of 4.28. Women who have had more than one delivery presented the highest level of satisfaction, followed by nulliparous and those who have had a previous pregnancy. Women who expressed a low level of satisfaction had experienced severe pain. Lower degree of satisfaction was observed in women with severe pain 3.03 ± 1.1 than women with moderate pain, 4.53 ± 0.7.

Conclusion

Overall, high level of satisfaction during labour was obtained; we recommended the use of TENS for pain relief to improve general satisfaction.

CATHODAL TDCS OF THE PARIETAL CORTEX COMBINED WITH MIRROR THERAPY IMPROVED HAND DEXTERTY IN A CASE OF FOCAL DYSTONIA.

M. Pigliapoco¹, E. Andrenelli¹, E. Baldoni¹, R. Cima¹, M. Fabri¹, G. Polonara², M. Capecci¹, M.G. Ceravolo¹

¹Università Politecnica Marche, Department of Experimental and Clinical Medicine, Ancona, Italy
²Università Politecnica Marche, Dipartimento scienze cliniche specialistiche ed odontostomatologiche, Ancona, Italy

Introduction/Background

The role of not-invasive brain stimulation (NIBS) as an add-on treatment to motor training in children suffering from focal dystonia has described in the literature with contrasting results. The study is aimed at describing the clinical and functional outcome observed in a 13-years-old girl suffering from hand dystonia and undergone NIBS combined with mirror therapy.

Material and Method

We report the case of a 13-years-old girl suffering from hand dystonia following right hemisphere lesion in the basal ganglia area, due to cerebrovascular accident occurred in the infancy. At the basal assessment she showed a complete muscle strength recovery, a quite normal gait pattern, but a complete impairment in left hand dexterity due to hand muscle dystonia. She had already undergone several training protocols, including splint wearing and repeated botulinum toxin injections. These last induced a partial resolution of muscle contraction at rest, without any improvement in hand dexterity. We proposed the following treatment protocol: daily sessions (20 minute each) of cathodal tDCS on the right sensorimotor cortex (P4), 1 mA, followed, in the same morning, by 20minutes mirror therapy, for five consecutive days. Functional status was assessed using the Fugl-Meyer upper limb score at baseline (T0), after treatment end (T1) and one month later (T2). Moreover, a fMRI was performed at T0 and T1, in order to look what brain networks were activated during the left and right limb movements.

Results

The NIBS was well tolerated. No adverse events were complained for. The Fugl-Meyer score increased from 21/66 (T0) to 29/66 (T1) and up to 30/66 (T2). The fMRI showed a significant reduction of brain activation under active left limb movement after treatment.

Conclusion
Parietal cortex inhibition via cathodal tDCS at the lesioned hemisphere was effective at reducing dystonia, improving voluntary movement and inducing the reorganization of brain networks.

SHORT-TERM EFFECTS OF TRANSCUTANEOUS ELECTRICAL NERVE STIMULATION VERSUS ULTRASOUND THERAPY IN REHABILITATION OF LOW BACK PAIN
I.M. Borda1, I.S. Bulzan1, V.M. Ciortea1, L. Irsay1, I. Onac1, R.A. Ungur1
1University of Medicine and Pharmacy "Iuliu Hatieganu", Rehabilitation Department, Cluj-Napoca, Romania

Introduction/Background

Background and aims. Low back pain (LBP) is a very disabling musculoskeletal disorder, with high prevalence in the general population. Although electrical therapy is largely used, studies trying to prove its benefits are very few up to now and they often have contradictory results. The aim of this study is, therefore, to evaluate the short-term effectiveness on pain relief, mobility and functional improvement of transcutaneous electrical nerve stimulation (TENS) versus ultrasound (US) therapy in patients with LBP.

Material and Method

Methods. 60 patients with LBP (age between 30 and 75 years, 34 women and 26 men) participated in this prospective randomized clinical trial. Patients were assigned to TENS group (n=30) or to US group (n=30). Study participants received 10 sessions of TENS or US therapy, 5 days / week, for 2 weeks. All patients were assessed on the first and on the last day of treatment, by: visual analogue scale (VAS) for pain, Schoeber index for mobility, Roland-Morris Disability Questionnaire (RMDQ) for function.

Results

Results. There was no difference between groups in any of the parameters at baseline. At the end of treatment patients in both groups obtained significant improvement in all parameters: pain (VAS decreased from 7.8±1.7 to 4.9±1.2, p<0.001 in US group, and from 7.5±1.5 to 3.8±1.1, p<0.001 in TENS group), mobility (Schoeber index increased from 13.9±3.1 to 15.4±3.8, p<0.001 in US group, and from 14.2±1.7 to 15.6±2.7, p<0.001 in TENS group), function (RMDQ decreased from 14.8±6.2 to 3.3±1.2, improvement 70.9%, p<0.001 in US group, and from 13.5±7.1 to 3.6±1.2, improvement 76.4%, p<0.001 in TENS group). No significant difference was found between the final results of the 2 groups (p>0.05) in any parameter.

Conclusion
Conclusions. TENS and US therapy had similar effects in LBP. Both were effective in relieve pain, increase mobility and reduce disability, representing promising therapeutic options for rehabilitation of LBP.

CLINICAL OBSERVATION OF SELF-DEVELOPED SWALLOW THERAPEUTIC EQUIPMENT FOR STROKE PATIENTS WITH DYSPHAGIA
J. He¹, Q.C. Wei¹
¹West China Hospital- Sichuan University, Department of Rehabilitation Medicine, Chengdu, China

Introduction/Background

To observe the effects of self-developed swallow therapeutic equipment on swallowing function and safety for stroke patients with dysphagia.

Material and Method

50 stroke inpatients with dysphagia were randomly divided into two groups. The patients in intervention group received rehabilitation training on dysphagia and swallow therapeutic equipment treatment. The control group only received rehabilitation training on dysphagia. Both were given 5 times a week, and lasted for 4 weeks. Patients in both groups were followed up 2 months after the therapies ended. They were assessed by indirect swallowing test scores and water swallow test scores before and after treatment. The safety of the equipment was observed too.

Results

Either 2 weeks or 4 weeks of treatment, the total effective rate in intervention group is higher than those in the control group; follow-up after 2 months, the cure rate in the intervention group is higher than that in the control group. Comparison of the water swallow test scores between the 2 groups showed: Either 2 weeks and 4 weeks of treatment, the total effective rate in intervention group is higher than that in the control group; follow-up after 2 months, the total effective rate in intervention group is higher than that in the control group. No unpleasant effects of the swallow therapeutic equipment treatment have been found. Only one patient felt pain on the skin of the electrode pasted area.

Conclusion

The self-developed swallow therapeutic equipment treatment combined with rehabilitation training on dysphagia had better effects on improving swallowing function than single rehabilitation training on dysphagia. It is safe

EFFECTIVENESS OF COMBINED USE OF LEVODOPA AND AMANTADINE ON PROLONGED CONSCIOUSNESS DISTURBANCE DUE TO TRAUMATIC BRAIN INJURY IN CHILDREN -A CASE REPORT-
N. Kigawa

1Hannou-seiwa hospital, Department of rehabilitation, Tokyo, Japan

Introduction/Background

Prolonged consciousness disturbance associated with traumatic brain injury (TBI) in children is one of the most serious complications for rehabilitation in order to perform cognitive / behavioral therapy. We report two cases of young TBI who got the remarkable recover by combined use of Levodopa and Amantadine.

Material and Method

Case: TBI in two children. Case 1 was a 17-year-old man with diffuse brain injury following traffic accident showing prolonged consciousness disturbance and easy irritability due to damage of bilateral orbital part of inferior frontal gyrus. Case 2 exhibited similar symptoms at 14 years of age.
Method: After admission to our recovery rehabilitation ward, they had daily 6 hours of rehabilitation, and at the same time, and took Levodopa and Amantadine for 10 weeks.

Results

In case 1, the disorder of consciousness was changed from E1V2M4 to E4V5M6 Glasgow Coma Scale, WAIS - III also to VIQ 72 → 96, PIQ 48 → 80, FIQ 58 → 87, FIM improved from 40 to 93, he discharged to his home in 3 months after hospitalization, and then returned to high school. In addition, he succeeded in getting a driver's license. Case 2 also followed a similar course and succeeded in successful recovery.

Conclusion

It is said that deficiency of dopamine, a mediator in the brain, is involved in prolonged consciousness disturbance and easy irritability after TBI of children. It is thought that Levodopa
was converted into dopamine in the brain, and Amantadine was activated dopamine in the brain by enhancing the neurotransmission of dopamine in the brain. It suggests that this therapy will be recommended as one of treatment methods for TBI in children.

MULTI-PROFESSIONAL POST-STROKE CONSULTATION: WHAT ROLE FOR THE PHARMACIST?

C. Grézard¹, F. Bour¹, A. Janoly Dumenil², C. Rioutol¹, J. Luauté³, S. Courtois³, G. Rode³, E. Carré¹

¹Centre Hospitalier Lyon Sud - Hospices Civils de Lyon, Pharmacy, Pierre Bénite, France
²University of Pharmacy – ISPB Laennec, Pôle Management de la Qualité – Santé Publique- EA4129 P2S Parcours Santé systéémique, Lyon, France
³Hôpital Henry Gabrielle- Centre Hospitalier Lyon Sud- Hospices civils de Lyon, Physical and Rehabilitation Medicine, Saint Genis Laval, France

Introduction/Background

In France, following the instruction DGOS / R4 n° 2015-262 relating to the organization of multi-professional consultations after stroke, consultations involving a neuropsychologist, a specialist of physical and rehabilitation medicine and a pharmacist have been set up on our establishment. Is the choice of a pharmaceutical intervention justified? Its relevance was evaluated through the activity report at 22 months.

Material and Method

For each consultations, the pharmacist collects the treatments prescribed and their knowledge (names, indications, time of taking - (qualitative scale at 3 degrees)), the side effects and the adherence score (MORISKI to 4 items). Self-medication, use of tools to help compliance and knowledge of hygiene and dietary rules are also collected.

Results

111 patients were received in consultation (cancellation rate 22%) equating to 8 consultations per month of 30 minutes. The average age was 52 years old. The average time between stroke and consultation was 5±3 months. The patients had an average of 4.9 lines of medication; 80% had at least one platelet antiaggregant, 23% an oral anticoagulant, 66% a statin and 59% an antihypertensive drug. Associated treatments were prescribed in 92% of cases and 1/3 used self-medication. 44% of patients reported side effects. Mediocre or mean compliance was found in 24% of patients (MORISKI score ≤2) unrelated to patient treatment knowledge (at risk α = 0.05) - the latter were considered to be total in 69% of patients. Finally, 21% used a pillbox and 72% knew hygiene and dietary rules.

Conclusion

The role of the pharmacist is essential in view of the number of patients with low medication compliance or poor knowledge. A national multi-center study to measure the impact of
enhanced pharmaceutical support on adherence to treatment of stroke patients is underway (ADMED-AVC study) and will reinforce its position.

EFFECT OF BUPRENORPHINE TRANSDERMAL DELIVERY SYSTEM AND REHABILITATION ON ACTIVITIES OF DAILY LIVING AMONG PATIENTS WITH NON ONCOLOGIC CHRONIC PAIN
V. Matassa¹, M.D.L.A. Lemos²
¹SAMFYR - Rocca Hospital, Physical Medicine and Rehabilitation, Buenos Aires, Argentina
²Sur Center, Clinic, Buenos Aires, Argentina

Introduction/Background

THE BUPRENORPHINE TRANSDERMAL DELIVERY SYSTEM (BTDS) IS INDICATED FOR REDUCTION OF PAIN IN MODERATE TO SEVERE CHRONIC PAIN (CP), WHICH AFFECTS PATIENTS’ ABILITY TO PERFORM ROUTINE ACTIVITIES OF DAILY LIVING (ADLS). ADLS ARE FUNCTIONAL ACTIVITIES THAT ALLOW INDEPENDENT LIVING.

THE AIM OF THIS STUDY IS TO EVALUATE THE EFFECT OF BTDS 10µg/H ON PAIN AND FUNCTIONALITY IN PATIENTS IN REHABILITATION PROGRAM WITH MODERATE TO SEVERE CHRONIC PAIN.

WE USED THE VISUAL ANALOGUE SCALE (VAS) AND PAIN DISABILITY INDEX (PDI) AT THE BEGINNING (BASELINE) AND 2 MONTHS

Material and Method

TWENTY-FIVE ADULT PATIENTS, WITH MODERATE TO SEVERE PAIN, WITH VAS GREATER THAN OR EQUAL TO 8.

ALL PATIENTS WERE RECEIVING ONLY PHYSICAL THERAPY. ALL OF THEM WERE INDICATED BTDS 10 AND INTENSIVE REHABILITATION PLAN.

WE USED VAS AND PDI BEFORE STARTING (BASELINE) AND AFTER 8 WEEKS, AND 5-POINT TREATMENT SATISFACTION SCORE EVALUATING.

THE DATA WERE ANALYZED WITH EPIDAT 1.4, PERFORMING STUDENT’S TEST FOR COMPARISON OF RELATED SAMPLES.

Results
TWENTY PATIENTS COMPLETED THE STUDY. DIFFERENT ETHIOLOGIES OF CHRONIC PAIN OF THE PATIENTS WERE ADMITED.

AFTER 2 MONTH OF TREATMENT, WE OBSERVED IMPROVEMENT IN ALL PARAMETERS EVALUATED. THE STUDENT TEST WAS STATISTICALLY SIGNIFICANT (P<0.05), FOR PAIN AS WELL AS RELATED FUNCTIONALITY.

REGARDING THE ADVERSE EFFECTS, CONSTIPATION OCCURRED IN 4 PATIENTS WHO RESPONDED TO DIETARY AND LACTULON TREATMENT, AND TWO PATIENTS WERE REMOVED FOR PRESENTING DERMATITIS WITHOUT RESPONSE TO ANTIHISTAMINIC.
Conclusion

THESE RESULTS SUGGEST THAT FOR PATIENTS WITH MODERATE TO SEVERE CHRONIC PAIN, BTDS CAN BE USED SAFELY AND EFFECTIVELY.

RETROSPECTIVE STUDY OF PSYCHOTROPIC DRUGS USED IN NEUROLOGICAL REHABILITATION (2010-2016): IMPACT OF A COLLABORATION BETWEEN PRESCRIBERS AND PHARMACISTS
C. Grezard¹, F. Bour¹, F. Goyet¹, C. Rioufol¹, J. Luauté², S. Courtois², G. Rode², E. Carré¹
¹Centre Hospitalier Lyon Sud - Hospices Civils de Lyon, Pharmacy, Pierre Bénite, France
²Henry Gabrielle Hospital- Centre Hospitalier Lyon Sud - Hospices Civils de Lyon, Physical and Rehabilitation Medicine Department, Pierre Bénite, France

Introduction/Background

The prescription of psychotropic drugs is common in neuro-rehabilitation. In our establishment it represents 16% of prescriptions. Since 2010, a collaboration between pharmacists, psychiatrists and medical specialists has led to a policy of reducing and supervising their prescriptions. The retrospective study of the psychotropic drugs’ consumption compared to the evolution of the type of patients treated with makes possible to evaluate the undertaken measures.

Material and Method

From 2010 to 2016, in addition to its routine analysis, audits and awareness campaign of the psychotropic drugs’ prescriptions were regularly carried out by pharmacists to doctors and interns. Over the same period, the data of stays by psychological diagnostic code: psychotic disorders, anxiety, depressive disorders, other - were collected from the DIM (Medical informations department in France). Consumptions of psychotropic drugs (hypnotics, anxiolytics, antidepressants, antipsychotics) were extracted from pharmaceutical management software. For each drug the daily intake was calculated according to the SPC.

Results

The overall number of patients with psychological diagnosis code hospital stays increased by 321% in 6 years. +150% for depressive disorders, +287% for psychotic disorders, +443% for anxiety disorders and +488% for sleep disorders. The daily consumption of psychotropic drugs decreased by 19.9%; a decrease of 45.3% and 39.4% for hypnotics and anxiolytics respectively, antipsychotics remained stable (0.9%) and antidepressants increased by 21.1%. The Pearson correlation test shows a negative correlation with a phi coefficient -0.7 (p = 0.06) between the number of targeted stays and the psychotropic drugs’ consumption.

Conclusion

The collaboration between prescribers and pharmacists is successful: the use of psychotropic drugs is decreasing despite a number of ever-increasing stays of patients. The involvement of pharmacists must be continued. As a reinforcement of these results, drug-free therapeutic
alternatives are currently being examined such as relaxation techniques, RESC, psychiatric or psychological care.

ISPR8-1334
EFFECTIVENESS OF INTRAMUSCULAR INJECTIONS OF BOTULINUM TOXIN INTO AGONIST MUSCLES ONLY ON DISABLING CEREBELLAR TREMOR OF THE HAND
J. VIELOTTE1, J.L. Barnay1, E. Hutin2, J.M. Gracies2
1CHU de la Martinique, Service de Médecine Physique et de Réadaptation, FORT-DE-FRANCE, Martinique
2CHU Henri Mondor, Service de rééducation neurologomotrice, Créteil, France

Introduction/Background

Hypermetric tremors, from cerebellar origin (essential tremor, cerebellar stroke or tumor, multiple sclerosis), directly relate to iterative hypermetria by delayed antagonist correction at each movement and cause significant functional and social disability. Botulinum toxin injections (BoNT) can reduce the amplitude of any tremor, but at the expense of muscle weakening when the injection is performed on both agonists and antagonists contributing to tremor. We measured the functional effects one month after botulinum toxin injections into agonist muscles only (eg pronator injection sparing supinators) in patients with cerebellar tremor causing upper limb disability.

Material and Method

We prospectively analyzed, in 15 patients (age 62±17 years) with upper limb cerebellar tremor, data from two volumetric tests (30-seconds posture and 5-table-to-mouth tests) and Activities of Daily Living self-Questionnaire (ADLQ), before and one month after their last BoNT injection into selected agonist muscles. The volumetric tests consisted of measuring the amount of remaining water (in mm) in a polystyrene cup (90 mm height), after 30 seconds of posture with the arm outstretched (H30) and after 5 table-to-mouth back and forth movements (Hx5). The ADLQ's score reflects the degree of daily disability caused by the tremor.

Results

Injections were well tolerated based on an open-ended questioning. The amounts of water remaining in the cup on H30 and Hx5 tests were: pre BoNT injection H30=36,8 ± 8,9 mm and Hx5=24,7 ± 8,0 mm ; 1 month post injection H30=62,5 ± 6,5 mm (+70% ; p=0.005, t-test pre vs post) and Hx5=48,6 ± 8,3 mm (+97% ; p=0.004). The ADLQ's score were: pre injection 59 ± 4 ; post injection 54 ± 4 (p=0.002, Wilcoxon signed-rank test).

Conclusion
Our results suggest functional efficiency on upper limb cerebellar tremor of injecting botulinum toxin into one agonist only. Explorations of correlations with tremor electromyographic parameters will be the subject of a future analysis.

Introduction/Background

Botulinum toxin is frequently used for pain conditions, especially those associated with muscle spasm. We reviewed relevant literature for information on botulinum toxin injection techniques into the pelvic floor and describe our methodology for treating endometriosis-related pelvic pain after optimized hormonal/surgical treatment.

Material and Method

PubMed, Embase and Scopus databases were searched using the terms "botulinum toxin" "pelvic pain" and "vaginismus." Data were extracted on the type of report, condition being treated, toxin serotype/brand, dose, dilution, muscle selection, muscle guidance technique, anesthesia, and other methodologic information.

Results

Thirty-nine reports were identified with technical information on botulinum toxin injection for pelvic pain and/or vaginismus; many lacked complete information. Most were open-label prospective reports with only one randomized, double-blind, placebo-controlled study of efficacy; one randomized, double-blind comparison of 2 doses; and 4 technical reports. Cumulatively, these studies provide information for approximately 1300 patients. Pelvic floor muscles were approached transvaginally, transperineally, or transgluteally. Toxin brand, dose, and dilution varied widely. Of 35 protocols providing information on localization method to confirm needle position in muscle, 18 used anatomic landmarks/manual palpation only, 10 used electromyography (EMG), 2 EMG with ultrasound, 1 ultrasound only, and 4 fluoroscopy/CT scanning. Thirteen papers were silent on anesthesia/sedation; 4 studies used no anesthesia. Five papers utilized general anesthesia, 7 conscious sedation, and 5 local anesthesia, without or with conscious sedation/nerve block. Pudendal block was used in 6 studies, sometimes combined with conscious sedation or general anesthesia. One study used only diclofenac for analgesia. Our own approach uses conscious sedation, topical lidocaine, and EMG guidance for transvaginal injection.

Conclusion
There is little evidence to guide practitioners on optimal approaches to botulinum toxin injection for pelvic pain and, importantly, a critical lack of clinical trials addressing the efficacy and safety of this emerging treatment.

ISPR8-2075
NEURAL RECOVERY RESULTING FROM LOW DOSE CARBON MONOXIDE TREATMENT: ROLES OF ADULT NEUROGENESIS IN INJURED MAMMALIAN SPINAL CORD
Y. Teng¹, L. Wang¹, R. Zafonte¹
¹Harvard Medical School, Physical Medicine & Rehabilitation and Neurosurgery, Charlestown, USA

Introduction/Background

We recently reported that non-toxic low dose carbon monoxide (CO) inhalation dose-dependently protected epicenter neurons and white matter in a rat model of T9-10 moderate compression spinal cord injury (SCI). CO treatment significantly improved hindlimb function mainly through sparing neural tissue and antagonizing secondary inflammatory or oxidative damages.

Material and Method

In a subsequent replication study, 500 ppm CO, the most potent dose identified, was administered to SCI rats, starting 4 hours post injury (p.i.) and thereafter 1 h CO inhalation per day for 12 consecutive days. Besides reconfirming CO’s therapeutic benefits on locomotion, neuroprotection and neuroinflammation, the effect of CO on adult neurogenesis derived from the central canal ependymal cells was investigated, to test our hypothesis that CO could activate neural stem cells (NSCs) via HO1-p38 MAPK-VEGF and p-nNOS pathways.

Results

There were differentially manifested neurogenic outcomes around the lesion site and lumbar enlargement, respectively, in the CO-treated spinal cords that were discernibly different from the control group exposed to room air (RA). The impact was detectible at 5-6 weeks after CO treatment (i.e., 7-8 weeks p.i.), indicating a possible role of CO-induced neurogenesis in promoting long-term neural repair. Compared to the control epicenters where newborn neural progenitors contributed to augmenting glial scarring, the mean scale of reactive astrogliosis was significantly reduced in the CO-treated spinal cords. Importantly, we observed presence of developing neurons in Rexed laminae (RL) IV-VIII in the CO-ventilated groups only.

Conclusion

Since the quantities of CO-mediated preservation of cholinergic and GABAergic interneurons in the same RL zones were positively correlated with the levels of hindlimb locomotor improvement, our data suggested that in addition to its efficacy for acute SCI, low dose CO may also be devised into a pharmacological treatment to recover function and to ameliorate inflammatory complications (e.g., neuropathic pain and spasticity) for chronic SCI.

A BOLD, SAFE, AND NEARLY PAINLESS NEW APPROACH TO INJECTING OF BOTULINUM TOXIN A TO THE SUB-SCAPULARIS MUSCLE TO RELIEVE TIGHT PAINFUL SPASTIC SHOULDERS

H.M. Adahan

1Sheba Medical Center, Head of the Pain Rehabilitation Service, Ramat Gan, Israel

Introduction/Background

Many skilled Botulinum toxin injectors do not regularly offer injections to the sub-scapularis and prefer to inject the much more accessible internal rotator of the shoulder, the pectoralis.

The subscapularis muscle is the strongest of the internal rotator muscles in the shoulder. Spasticity of this muscle results in limited external rotation, abduction and flexion of the shoulder, and causes pain. Many studies report the effectiveness of botulinum toxin and phenol injections into the subscapularis muscle to relieve pain and to improve the ROM of the shoulder. Different injection techniques have been presented, including lateral, medial and inferior approaches. All existing techniques require uncomfortable painful forced scapular winging.

Material and Method

Our new anterior approach, uses a long 25cm needle inserted in the chest and traverses the largely insensate soft tissues under the axillary line. Direct fluoroscopic visualization of the thorax in real time during the injection minimizes the risk of damaging the lung or neurovascular bundle and it does not require an unpleasant positioning of the shoulder. We assure effective delivery to the Motor points crossing the middle of the scapulae which are missed by other techniques.
Results

Our experience on 15 patients has shown the technique to be nearly painless, safe, and effective as demonstrated by pre- and post injection Brief Pain Inventory and Shoulder Pain and Disability Index and videodocumentation of arm elevation.

Conclusion

We wish to pursue a crossover RCT where all subjects will get both Pectoralis + Subscapular muscle injection. One of the 2 will be placebo.

SILENCING PHANTOM LIMB PAIN BY SILENCING THE DRG
H.M. Adahan¹
¹Sheba Medical Center, Head of Pain Rehabilitation Centre, Ramat Gan, Israel

Introduction/Background

Nearly all amputees continue to feel their missing limb as if it still existed, and many experience chronic phantom limb pain (PLP) and non-painful phantom limb sensations (nPLS). What is the origin of these sensations?

Material and Method

We tested the hypothesis that PLP, (nPLS), is due not to the loss of input but rather to exaggerated input, generated ectopically in axotomized dorsal root ganglia (DRGs) that used to innervate the limb.

In 63 amputees with Phantom Pain and 32 non-amputee patients with various Neuropathic pain syndromes, the local anesthetic lidocaine (0.3%) was delivered to the DRG surface via intra-foraminal epidural block. This rapidly and reversibly extinguished PLP and also non-painful phantom limb sensation (npPLS).
Results

Almost all amputees with PNP and/or RLP had immediate complete or near complete disappearance of their PLP + RLP+ npPLS for the duration of the lidocaine and/or steroid block without any detectable anesthetic effect on their stump.

We believe that this work should encourage further investigation to confirm this idea and its therapeutic consequences.

Conclusion

We do not argue that the eventual pain experience ultimately lies in the consciousness of the amputees, but we are confident that we may yet find that effective treatment could be delivered to the periphery. The hope is to create a treatment that will persistently silence the DRG and let
the nerve cell somatosensory function persist and thus obtain profound lasting pain relief without creating deafferentation pain phenomena.

GIVE MUSIC THERAPY A CHANCE IN POST STROKE REHABILITATION
M. orantin¹, A. yelnik², M. jousse², L. tlil², M. guillemette², A. bernard², V. quintaine²
¹Sorbonne Paris Descartes university, Artistic Creation-Music therapy, Paris, France
²GH Lariboisière-Fernand Widal, Physical and Rehabilitation Medicine, Paris, France

Introduction/Background
Researching music in the field of stroke rehabilitation[i] is now encouraged and is becoming a field of increasing interest. This study aimed to investigate how patients and caregivers experience music therapy when it is included in routine stroke rehabilitation.

Material and Method
The study was performed among inpatients in a PRM department. Music therapy sessions were included in usual routine care from October 2015 to April 2016. Each patient received 40-min individual sessions of music therapy, twice a week, for at the most 2 months, consisted of listening to recorded music and practicing improvisation with an instrument. The perceptions of caregivers and patients were analysed by using questionnaires specifically designed for the study.

Results
Thirty-one caregivers returned the questionnaire. The feasibility of music therapy was considered good for 90%: sessions were simple to implement, easily integrated into the course of the day and did not disrupt the functioning of the department. All caregivers believed that the therapy may improve practices in stroke rehabilitation and be helpful to the patient. Fifty-three % of the caregivers noted positive improvement in patients, especially in mood, motivation, self-esteem, oral expression and behavior.

Eleven patients followed the program and completed 69 survey cards over 118 sessions. All said they had benefited from music therapy. To describe their feelings after a music therapy session, they often first chose the word “relaxed”, “quiet”, “alert”, “rested”, and “light”.

Furthermore, with the open question “What does music therapy bring to you?”, we observed 3 types of answers: "something else in the hospital care experience", "music discovery, hearing and expressing, playing", and "a kind of creativity with improvisation".

Conclusion
The reaction of the caregiver team was excellent and patient compliance was also excellent. We conclude on the feasibility of music therapy in a PRM department for post-stroke inpatients.

ELECTROACUPUNCTURE INHIBITS CARTILAGE DEGENERATION BY INHIBITING MITOGEN-ACTIVATED PROTEIN KINASES IN RATS WITH ACLT-INDUCED OSTEOARTHRITIS
Y. Liao¹, J. Liu¹, G. Sun¹, Y. Zeng¹, Q. Wu¹, G. Zhou¹, X. Li², J. Zhou¹
¹The First Affiliated Hospital of University of South China, Department of Rehabilitation, Hengyang, China
²Hunan Polytechnic of Environment and Biology, Rehabilitation, Hengyang, China

Introduction/Background

The therapeutic effects of electroacupuncture (EA) on osteoarthritis (OA) are well documented, however, the precise mechanisms of action have not yet been fully elucidated. The present study aimed to investigate the effect of EA on cartilage in an experimental animal model of OA induced by anterior cruciate ligament transection (ACLT) and to examine for concomitant changes in the expression of mitogen-activated protein kinases (MAPKs) in the articular cartilage.

Material and Method

Thirty 3-month-old male Sprague Dawley rats were randomly divided into the following three groups (n=10 each): sham operated group (Control group), ACLT without treatment (ACLT group), and ACLT with EA treatment (ACLT+EA group). One week after ACLT, rats in the ACLT+EA group received 12 weeks of EA treatment. Histological analysis and quantitative real-time polymerase chain reaction were used to investigate the effects of EA on cartilage morphology (quantified using modified Mankin scores) and expression of MAPKs (p38, c-Jun N-terminal kinase (c-Jun), and extracellular signal-regulated kinase (ERK)1), respectively.

Results

ACLT produced coarse cartilage surfaces, fibrous degeneration, and fissuring, all of which were suppressed by EA treatment. Although Mankin scores in the ACLT+EA group were significantly higher compared to the Control group (p<0.01), they were significantly lower than the (untreated) ACLT group (p<0.01). The increase in mRNA expression of p38, c-Jun, ERK1 and MMP-13 observed in cartilage after ACLT was significantly inhibited by EA.

Conclusion

EA appears to prevent the degeneration of articular cartilage, at least partly, through regulation of MMP-13 and inhibition of MAPKs in the cartilage of rats with ACLT-induced OA.

ACUPUNCTURE IN THE TREATMENT OF FOOT DROP AND SCAR TISSUE PAIN AFTER TRAUMATIC LEG INJURY

V. Abdovic Skrabalo¹, D. Bobek²

¹MD. PRM specialist and acupuncturist, Department of Physical Medicine & Rehabilitation with Rheumatology- University Hospital Dubrava- Zagreb- Croatia, ZAGREB, Croatia
²University Hospital Dubrava, Department of Physical Medicine with Rheumatology, Zagreb, Croatia

Introduction/Background

Objective: To report the clinical efficacy of acupuncture combined with rehabilitation for foot drop and scar tissue pain after the traumatic leg injury.

Material and Method

A 27-year-old male who suffered a traumatic injury of the right leg with common peroneal nerve transection was operatively treated by neurorrhaphy with the suture of the anterior tibial muscle. Rehabilitation treatment began after wound healing with the peroneal orthosis. Five months later he was referred to our center because of poor motor control while walking. On clinical examination, he suffered from numerous scars in the right anterolateral shin, had stoppage gait with right foot drop, and poor right foot dorsiflexion (manual muscle test (MMT) score 2). Scars were painful on palpation, and he had anterolateral shin hypoesthesia with the numbness of right thumb. Treatment started with electrostimulation of right peroneal nerve, sonotherapy, TENS, and kinesitherapy which were used during 6 months. After three cycles of therapy, he had a follow-up MMT of 2+. Because of insignificant response to the treatment and the persistence of scar pain, acupuncture was initiated. The Wei Qi technique around the scar tissue was used with the non-concomitant stimulation of points GB34, DM20, and Sp6. The patient received a treatment once a week, with total of 15 weeks.

Results

After the full acupuncture treatment, he is walking without the orthosis, has active right foot dorsiflexion (MMT 4) and feels the thumb better; each scar of the shin is paler with less pain.

Conclusion

In this case report, a combination of acupuncture and conventional rehabilitation resulted in the improved motoric function of right foot after traumatic common peroneal nerve lesion, reduced scar tissue pain, and improved sensibility. Case-control, prospective studies are needed to further investigate the possible beneficial role of acupuncture in this sample of patients.

Introduction/Background

Shoulder pain is the common complaint among patients with stroke. Bee venom acupuncture (BVA) has increasingly been used for shoulder pain treatment after stroke. The aim of the present study was to summarize and evaluate evidence on the effectiveness of BVA in alleviating the shoulder pain after stroke.

Material and Method

Seven databases were searched from inception through October 2017 without language restrictions. Randomized controlled trials (RCTs) were included if BVA was compared to placebo or other conventional therapy for treatment of shoulder pain after stroke. Assessments were performed primarily with Visual Analogue Scale (VAS).

Results

A total of 138 studies were identified; 4 RCTs met our inclusion criteria. Two of the included RCTs compared BVA with placebo; one compared BVA with acupuncture; and one compared BVA accompanied by standard therapy with standard therapy by itself. Meta-analysis showed that BVA appeared to be more effective than placebo in reducing the shoulder pain after stroke, as assessed by VAS (weighted mean difference, 1.46; 95% confidence interval [CI], 0.30–2.62; \(P=0.02\)).

Conclusion

Our results suggest that BVA could be effective for treating shoulder pain after stroke. However, further studies are needed to confirm the role of BVA in the treatment of this disorder.

THE RELATIONSHIP BETWEEN DIFFERENT STIMULUS OF NIEJI THERAPY AND ACTIVATED MAST CELLS SKIN IMMUNE SYSTEM

L. Lin

Fujian University of Traditional Chinese Medicine, Acupuncture College, Fuzhou, China

Introduction/Background

It's well known that the traditional Chinese medicine rehabilitation mainly stimulated the body surface skin. What is the relationship between intensity stimulation and local skin cell activation? In this study, different stimulation of Nieji therapy treated the rats on the Governor meridians points, observed the number of mast cells and degranulation rate.

Material and Method

Twenty four adult male Sprague-Dawley rats were randomized into blank group (BG), little stimulus nieji group (LG), moderate stimulus nieji group (MG) and heavy stimulus nieji group (HG) (n=6 for all groups). The BG had no treatment; however, the LG, MG, LG received the different stimulus with nieji on the spine (Governor pulse), 7 times, 14 times, 21 times. We treated the groups once per day for twenty-one days. After 21 days of treatment drawn we obtained DU14, DU9, DU4 points of Governor Vessel local skin tissue. By the toluidine blue staining of immunohistochemistry to observe the different nieji stimulations on the skin of three points. Observed the variety of mast cells pattern and calculate the total number of mast cells and degranulation rate.

Results

The different nieji stimulus groups compared with BG, the total number of mast cells in papillary layer of DU14 showed high increased expression, which have significant difference (P <0.05). The total number of mast cells in subcutaneous tissue layer of DU14, reticular layer of DU9 and papillary layer, reticular layer, subcutaneous tissue layer of DU4 were higher in the MG and HG than in the BG (P<0.05). With the increase in the amount of stimulation, the total number of mast cells had an increasing trend but had no statistical significance.

Conclusion

Nieji therapy stimulation can affect the mast cells aggregation on the partial skin. The MG and the HG have a significant influences on the total number of mast cells. The effect of Nieji treatment on Mast Cell in the skin mainly in the subcutaneous tissue layer.

THE USE OF KINESIOTAPING IN HYPOTONIC AND EARLIER REINNERVATION PHASE IN PERIPHERAL FACIAL PALSY. APPLICATION IN ORBICULARIS ZONE

D. Issa-Benitez¹, M. Gómez-Martinez², M.L. Torrent-Bertran³

¹MD- specialist at Facial Palsy Unit,
Physical Medicine and Rehabilitation Service Vall d’Hebron Hospital, BARCELONA, Spain
²Vall d’Hebron Hospital, PT Facial Palsy Unit- Physical Medicine and Rehabilitation Service, Barcelona, Spain
³Physical Medicine and Rehabilitation Service Vall d’Hebron Hospital,
MD- specialist at Facial Palsy Unit-, Barcelona, Spain

Introduction/Background

The kinesiology tape (kinesiotaping) is a therapeutic method based in the use of an elastic cotton bandage heat sensible with elasticity between 140–150%. The properties of the bandage simulate a “second skin” with a special design in order to promote the proprioceptive improvements and somatosensory perception in the sensitive receptors of the skin. In the current evidence few researches have been concluding in evaluating the kinesiotaping treatment for correcting the ectropion and/or lagophthalmos in patients with peripheral facial palsy.

The main objective of this technique is to improve proprioception of patients with diagnosis in ectropion and/or lagophthalmos secondary to facial nerve paresis or paralysis and therefore, improve the functionality of periocular muscles in case of reinervation.

Other important objectives are the neuromuscular facilitation, corneal protection and the subjective comfort of the patient improving eye closure from the early stage of the pathology.

Material and Method

This research consists of a prospective 5 cases study.

The patient received the proper instructions and kinesiology tape was applied.

Results

Up to the date we have compiled data of 3 out of 5 patients, the physical disability index improve 7.71 %.

The social disability index improves 7.9 %. Regarding the subjective perception of the ocular proprioception patients showed an important improvement.
Finally, according to the kinesiotaping results using picture analysis, the distance between the lower and upper eyelid improve.

**Conclusion**

With the kinesiotaping treatment patients showed an important improvement in their physical and social disability index as well as heir sensation of ocular movements and their overall wellbeing.

Proven positive outcomes with these patients, future investigations seem indicated to evaluate the kinesiotaping for low functioning facial muscles, insisting on ocular occlusal correction-

THE USE OF DRY NEEDLE FOR TREATMENT OF MAINTAINED MUSCLE CONTRACTION IN PERIPHERAL FACIAL PALSY. A FUNCTIONAL STUDY.
M.L. Torrent - Bertran¹, D. Issa-Benitez¹
¹MD, Physical Medicine and Rehabilitation Service Vall d'Hebron University Hospital, Barcelona, Spain

Introduction/Background

Based on the clinical and neurophysiologic similarities between the palpable taut band of the myofascial pain and the facial palsy’s maintained muscle contraction, we considered treating the latter with dry needling the trigger points found in the physical examination.

To assess the effect of dry needling as a method of treatment for the maintained muscle contraction in patients with peripheral facial palsy, to improve pain and tightness as well as to facilitate movement.

Material and Method

We performed dry needling techniques in the affected side of the face to 5 random patients with facial palsy with maintained muscle contraction and trigger painful points noticed in physical exam. The dry needling technique was applied one or two months after botulinum toxin injection. Generally, dry needling was done over zygomaticus major, zygomaticus minor, levator labii superioris, mentalis, procerus, buccinator, depressor labii inferioris, using a screw technique.

After one week, the patient answered the Patient Global Impression of Improvement Scale and the Clinical Global Impression of Improvement Scale, through which relief of pain and tightness were assessed and the question ‘Do you have better face movement after the dry needling?’, which was evaluated through a Likert Scale.

Results

The Patient Global Impression Improvement Scale results were “Much improved” in 4/5 patients and “Very much improved” in 1/5 patient. The Clinical Impression of Improvement Scale was “Improved” in all patients.

The assessment of improvement in movement through the Likert Scale was of 5 in all cases.

Conclusion
Patients refer significant improvement in both pain and movement after the dry needling technique.

We consider that the dry needling technique as a supplemental treatment after botulinum toxin may improve maintained muscle contraction and facilitate movement in the affected side of the face.

EFFECT COMPARISON OF DIFFERENT ACUPOINT STIMULATION WAYS IN IMPROVING CFA-INDUCED INFLAMMATORY PAIN IN RATS
M. sui1, T. yan2
1Shenzhen Nanshan Hospital, rehabilitation, Shenzhen, China
2Sun Yae-sen Memorial Hospital Sun Yat-sen University, Rehabilitation Medicine, guangzhou, China

Introduction/Background

This study was performed to compare the effects of different acupoint stimulation ways on CFA-induced inflammatory pain and to explore the possible mechanism.

Material and Method

SD male rats were divided into four groups (n=10): Vehicle+Sham Electroacupuncture (Veh+Sham EA), CFA+Sham EA(CFA + Sham EA), CFA+ EA(CFA+EA), CFA+ Transcutaneous Electrical Acupoint Stimulation (CFA+TEAS). At Day4 after Veh/CFA injection, we used Vonfrey and PWL to test the effect of acupoint stimulation on CFA-induced mechanical allodynia and thermal hyperalgesia before and after treatment in all the groups. At Day5, 1.5 hours before till to the end of the treatment, in the right tibialis anterior muscle of rats, use microdialysis to collect dialysate to analyse the level of adenosine with high performance liquid chromatography.

Results

At Day4 after injection of CFA, EA and TEAS treatment can obviously increase the pain threshold of CFA-induced inflammatory pain rat model. As the mechanical allodynia show, compared with the Veh+Sham EA group and CFA + Sham EA group, the Vonfrey result of CFA + EA group and CFA+TEAS group were significantly decreased (P < 0.05) after the treatment, PWL results also significantly prolonged (P < 0.05); But between CFA+EA group and CFA+TEAS group, both Vonfrey and PWL have no obvious difference (P > 0.05).At Day5, compare with Vehicle+Sham EA group and CFA+sham EA group, the adenosine of CFA+EA group and the CFA+TEAS group improved obviously (P<0.05), but there is no difference between CFA+EA group and CFA+TEAS group.also we found the duration of improving adenosine concentrations in CFA+TEAS group are longer than CFA+EA group.

Conclusion

There is no difference between EA and TEAS on alleviating CFA-induced inflammatory pain. The results also suggest that increasing adenosine in the micro dialysate is a possible
mechanical of EA and TEAS on CFA-induced inflammatory pain. but TEAS have a longer effect than EA.

EFFECT OF CLUSTER NEEDLING OF SCALP ACUPUNCTURE COMBINED WITH REHABILITATION ON DEPRESSION AFTER STROKE FOLLOWING MOTOR APHASIA

H. Zhang¹, Q. tang²

¹Beijing United Family Rehabilitation Hospitlal, Traditional Chinese Medicine Department, Beijing, China
²The Second Affiliated Hospital of Heilongjiang University Of Chinese Medicine, rehabilitation department, Harbin, China

Introduction/Background

Stroke is a common disease, and 21% ~38% stroke patients with aphasia in acute phase.

About 25% of patients with cerebrovascular disease are associated with speech disorders, China reported. It is difficulties for patients with aphasia when communicating with others.

Stroke patients with aphasia easy to lead to depression. In the past, the study of Post-stroke depression was more, but the study of depression in patients with exercise-related aphasia was relatively low.

To explore the effect of cluster needling of scalp acupuncture combined with rehabilitation (Acupuncture-rehab Approach) on depression of stroke patients with motor aphasia.

Material and Method

70 stroke patients were randomly divided into the acupuncture with rehabilitation group and the control group. The cluster needle of scalp point with speech rehabilitation training was used in the acupuncture with rehabilitation group, while speech rehabilitation training was used only in the control group. The degree of depression and aphasia were observed in the two groups 4 weeks after treatment.

Results

4 weeks after the treatment, the classification of aphasia was getting better in the acupuncture with rehabilitation group than in the control group (P<0.05), and the incidence of depression decreased significantly in the acupuncture with rehabilitation group compared with the control group (P<0.01). The score of Stroke Aphasic Depression Scale (SADQ) decreased significantly in the acupuncture with rehabilitation group compared with the control group (P<0.01).

Conclusion
Acupuncture-rehab Approach is an innovative method to treat stroke, and it may improve the depression of stroke patients with motor aphasia.

⁵Clinique Romande de Réadaptation, Service de réadaptation en neurologie et paraplégie, Sion, Switzerland
⁶Ecole Polytechnique Fédérale de Lausanne, Chair in Brain-Machine Interface, Lausanne, Switzerland

Introduction/Background

Virtual Reality (VR) based rehabilitation provides intensive, motivating and task-specific training to promote motor recovery of stroke survivors. We aim to show that kinematic analyses of movement data collected during VR-based training can be used to provide objective and continuous assessments of motor performance. This is highly valuable as objective measurements can be used to better quantify patients’ needs and adapt their therapy accordingly.

Material and Method

A chronic stroke patient (38 y.o. female, 6 months post-stroke) performed 10 sessions over 5 weeks of VR-based upper limb rehabilitation (MindMotion™ PRO). The VR-based training consisted of functional tasks, such as reaching virtual objects. The system recorded the patient’s upper limb movements via a 3D motion tracking camera. Clinical assessments including Fugl-Meyer assessment (FMA-UE) and active range of motion (AROM) were measured at baseline, post-treatment and 4-week follow-up.

Results

We observed an improvement in elbow extension during reaching exercises over the sessions, from a median flexion of 77° to 39° (Fig. 1). We also observed a trend of decreasing trunk forward flexion, suggesting a reduction in trunk compensation. These kinematic results are coherent with observed clinical improvements in FMA-UE (17 at baseline; 24 at post; 26 at follow-up) and elbow flexion AROM (30° at baseline; 20° at post; 0° at follow-up).
Figure 1: Evolution across sessions of elbow flexion angle recorded during reaching exercises in VR (0° = fully extended elbow).

Conclusion

Kinematic analyses of upper limb movement captured the changes in movement amplitude of elbow and trunk across VR-based therapy sessions. Quantitative measures like kinematics offer new insights into the objective evaluation of motor function during rehabilitation after stroke and other conditions with motor deficits. This could enable the implementation of personalized, and thus optimal, motor rehabilitation therapy.

AUGMENTED REALITY SYSTEM FOR MUSCLE ACTIVITY BIOFEEDBACK
M. Gazzoni, G.L. Cerone
Politecnico di Torino, Department of Electronics and Telecommunications, Torino, Italy

Introduction/Background

Augmented Reality (AR) has been proved successful in several applications from surgical training to balance rehabilitation. This work aims to develop an AR system for real-time visualization of an index of muscle activity superimposed to the investigated muscle.

Material and Method

The system includes: 1) a video camera, 2) one or more surface EMG (sEMG) detection/acquisition systems, 3) one processing and visualization unit (Figure 1).

The system integrates the information from the video camera and from the sEMG systems (the ARV of the sEMG signal epoch corresponding to the current video frame) and creates an “augmented video frame” by coloring the detection systems, identified within the video frame, with a color representative of the muscle activity (blue for low and red for high sEMG activity). The patient or the clinical operator can see the real-time augmented video on a display.
**Results**

The software can run 1) on a PC using a webcam for video capture and showing the augmented video on a monitor, 2) on a tablet using the integrated camera or 3) on the Epson Moverio BT-300 smartglasses using the see-through modality. Figure 2 shows the AR feedback during a leg extension exercise; vastus medialis, vastus lateralis and rectus femoralis muscles are monitored using a sEMG bipolar system (Due, OTBioelettronica and LISiN). Figure 3 shows the AR system used for the monitoring of sEMG activity distribution in the lumbar muscles using a multi-channel sEMG systems (32 channel amplifier by LISiN).
Figure 2. Visualization of muscle activity during a leg extension exercise.
Figure 3. Left: experimental setup for the monitoring of lumbar muscles. Right: AR feedback.

Conclusion

An AR system for the visualization of sEMG activity over the muscles has been developed. The system is currently under validation for augmented biofeedback in sport and rehabilitation in order to verify advantages with respect to standard biofeedback.

IMMEDIATE EFFECTS OF VIRTUAL REALITY MENTAL PRACTICE IN SUBJECTS WITH LOW BACK PAIN: A PILOT STUDY

Y.W. Tsai¹, H.H. Hsu¹, Y.R. Hou¹, Y.L. Chiu¹, W.H. Sung¹
¹National Yang-Ming University, Physical Therapy, Taipei, Taiwan R.O.C.

Introduction/Background

Low back pain (LBP) is one of major reasons that influence people’s life quality and lead to dysfunction. Modality therapy or manual therapy were usually used to reduce pain. Mental practice (MP) had been applied to intervene on pain on subject with spinal cord injury, and virtual reality (VR) also had been verify that could reduce chronic pain and kinesiophobia. The purpose of this study is to investigated the immediate effects of virtual reality mental practice (VRMP) for subjects with LBP.

Material and Method

Nine subjects suffered from LBP were recruited (2 males and 7 females, age=33.670±16.560). Each subject had two types of intervention while suffering from pain, one was using VR glasses (Cardboard®) to watch LBP therapeutic exercise video in sitting and asked them to imagine as if they were doing the exercise shown in the video (VRMP); another type asked subjects to rest in sitting as long as the video clip (Rest). Before and after intervention, Visual Analogue Scale (VAS), range of motion (ROM), Oswestry disability index (ODI) and Fear avoidance beliefs questionnaire (FABQ) were assessed. The sequence of two types of intervention was assigned randomly. The data was analyzed by paired t-test and statistical significance was set as alpha < 0.05.

Results

Before interventions, all assessments had no significant differences between VRMP and Rest. After VRMP intervention, VAS, FABQ, ODI and ROM (extension and side bending) showed significant improvements, but there were no significant differences found in Rest. However, in post assessments, only VAS (VRMP 1.330±1.414 vs Rest 2.670±1.581, p=0.042) and FABQ (VRMP 26.000±17.270 vs Rest 32.670±11.916, p=0.029) had significant differences between two types of intervention.

Conclusion

Our results showed that VRMP had immediate effects on pain relief and kinesiophobia in subjects with LBP.

IMPLICATION OF MEDICAL THERAPISTS IN THE INTRODUCTION OF INNOVATIVE TECHNOLOGIES: SPECIFICATION OF S'TIM, A REHABILITATION SERIOUS GAME ON A TOUCH TABLE CASE.
J. Golliot¹, T. Michèle¹, F. Elodie¹, H. Cathy¹, A. Alexandre², D. Michel²
¹Clinique Provence Bourboune Ramsay Générale de Santé, Bouches du rhône, Aubagne, France
²IMSIC Toulon, Var, Toulon, France

Introduction/Background

Patients with dysexecutive syndrome present cognitive, emotional and behavioural consequences. They are also unable to recognize their disorders which limits their implication in rehabilitation. Improvements are observed but the transfer in daily-life is very limited and patients don't recover their autonomy. In a context where innovation makes the difference, medical specialists found funds from Europe, and foundations to specify and develop an efficient technology to counteract this situation.

Material and Method

A working group constituted by rehabilitation doctors, neuropsychologists, occupational therapists, a PhD Human-Centred Engineer and researchers in Informatics and Information & Communication Science defined a common scope statement project. After observation of patients and therapists, a work on the choice and specification of the technology to use has been done, thanks to feedbacks from the users (Figure1).
Results

The multidisciplinary group specified and developed a persuasive serious-game to immerse patients in a virtual world with an elaborate scenario including various challenges (Figure2). The chosen device is a robotised 46-inch touch-table, easy-to-use by people of all age.

Each detail of the serious-game and its use was discussed with all the experts and take into account the various needs. Furthermore, this device is designed for patients and therapists.
Thus, their implication that started since the beginning of the process reinforces their adhesion and reduces objections or rejections.

**Conclusion**

This innovating and multidisciplinary program implicate various experts at each stage of the study with an iterative process to incorporate improvements following users’ feedbacks. Backed by a communication campaign, more funds were allocated, other rehabilitation centres show their interest to join the study and clinical studies should begin soon.

EFFECTIVENESS OF VIRTUAL REALITY TREATMENT AFTER FLEXOR TENDON SURGERY: PRELIMINARY RESULTS
G. Gula¹, A. Oral¹, E.I. Şen¹, D. Sindel¹
¹Istanbul University- Istanbul Faculty of Medicine, Physical Medicine and Rehabilitation, İstanbul, Turkey

Introduction/Background

Biofeedback can improve the effectiveness of an intervention as a helpful tool in the physiological process of rehabilitation. In our study, we aimed to investigate the efficacy of Virtual Reality (VR) in the rehabilitation of patients with flexor tendon repair.

Material and Method

Twenty patients with flexor digitorum superficialis (FDS) and/or flexor digitorum profundus (FDP) tendon repair were included in the study and randomized into two groups: VR and traditional treatment. VR was administered with the HandTutor™ device from postoperative 8th week for 3 weeks, 3 sessions per week. Both groups were given splinting and progressively increased exercise as a home program. Before and after treatment, patients were assessed using the Disabilities of the Arm, Shoulder and Hand (DASH) outcome measure and hand grip strength was measured using a Jamar dynamometer. The Wilcoxon signed rank test was used to compare dependent variables and the Mann-Whitney U test was used to compare independent groups.

Results

The mean age of the patients was 35.4 ± 13.8 years. 10% of the patients had FDS, 40% had FDP, 50% had FDS and FDP tendon injuries. There was a significant decrease in DASH scores and a significant increase in hand grip strength in both VR (p = 0.008) and traditional treatment groups (p = 0.003). In between-group comparisons, no significant difference was found in DASH scores (p = 0.110). However, the increase in hand grip strength was significantly greater in the VR treatment than that in the traditional treatment group (p = 0.030).

Conclusion

The results of this pilot study support the use of HandTutor™ with traditional therapy in hand rehabilitation after flexor tendon repair and warrant further studies with larger samples.

Introduction/Background

Tele-rehabilitation refers to the use of information and communication technologies to more efficiently provide rehabilitation services to people remotely in their homes or other community-based settings. The goal is to improve patient access to care by receiving therapy beyond the physical walls of a traditional healthcare facility as well as to increase self-practice thus expanding the continuity of rehabilitation care. The recent developments of advanced sensors, graphic and remote monitoring technologies have enabled development of an increasing number of Virtual Reality (VR)-based tele-rehabilitation applications. The inclusion of VR into tele-neurorehabilitation aims, similar to regular rehabilitation, to increase the physical fidelity of the treatment to enable better generalization to real life activities and to increase engagement and motivation by providing the “right” challenge to users by “immersing” them into the therapeutic task. In addition, it allows implementation of principles to increase neural plasticity by providing opportunities for intensive and goal oriented practice. When delivered remotely, this form of VR intervention is challenging, for example, due to the need of the user to learn complex activities without a therapist physically present. An additional challenge is the need to develop applications that will achieve a balance between physical fidelity, level of challenge to the user and immersion, to assure quality of movements when the therapist is not present. The purpose of this presentation is to show evidence-based examples gleaned from our database of more than 200 users (and 5000 on-line sessions) who have used the CogniMotion VR tele-neurorehabilitation services over the past four years. A discussion will focus on the lessons learned while providing this form of intervention remotely.

SERIES OF CASES ABOUT BRAIN ACTIVATION OF ELDERLY DURING BALANCE TESTS AFTER A VIRTUAL REALITY REHABILITATION PROGRAM: A DECISION TREE METHOD

T. Pacheco¹, M. Dantas Soares¹, D. Carvalho de Oliveira¹, K. Mansur Yano¹, T. Fernandes Campos¹, F. Azevedo da Costa Cavalcanti¹

¹Federal University of Rio Grande do Norte, Physiotherapy Department, Natal, Brazil

Introduction/Background

Virtual Reality based therapy (VR) is a therapeutic approach that has been applied in motor rehabilitation of elderly to restore postural control, since balance is generally impaired by aging. Aging causes a decline in central nervous system function related to information processing speed, which leads to a deficit in the motor performance of elderly. Such impairments reinforce the idea of a relationship between the activation of cortical areas and postural control, culminating in restrictions on the functional independence of elderly. Thus, this study investigates the behavior of cortical activation of elderly women during a static and dynamic balance test after a VR protocol, considering the EEG potential of theta (4Hz - 7.5Hz), alpha (8Hz - 12Hz), beta (13Hz - 30Hz) and gamma waves (above 30Hz).

Material and Method

It is a series of three cases carried out at the Physiotherapy Department of Federal University of Rio Grande do Norte, Natal, Brazil, in which the participants were submitted to a functional EEG assessment before and after 10 sessions of balance training with Nintendo Wii®. A mobile EEG device (Emotiv EPOC) was used to assess brain activity during a static and dynamic balance test. Decision trees were constructed to evaluate how VR could influence brain activation during these tasks.

Results

The decision trees showed that the VR training used increased alpha and gamma activation in both the static (p = 0.000; df = 3, chi-square= 228.5) and dynamic (p = 0, 000; df = 3; chi-square: 217.6) tests.
Conclusion

These findings may configure the task learning after VR training, since the greater potential of both are related to better motor performances.

BIMODAL EEG-FMRI NEUROFEEDBACK FOR STROKE REHABILITATION: A CASE REPORT
G. Lioi1, M. Fleury1, S. Butet2, A. Lécuyer3, C. Barillot1, I. Bonan2
1INRIA, VisAGeS Project Team, Rennes, France
2CHU Rennes, Médecine physique et de réadaptation, Rennes, France
3INRIA, Hybrid Project Team, Rennes, France

Introduction/Background
Neurofeedback (NF) consists on training self-regulation of brain activity by providing real-time information about the participant brain function. Few works have shown the potential of NF for stroke rehabilitation however its effectiveness has not been investigated yet. NF approaches are usually based on real-time monitoring of brain activity using a single imaging technique. Recent studies have revealed the potential of combining EEG and fMRI to achieve a more efficient and specific self-regulation, which may be critical in clinical applications. In this case report, we tested the feasibility of applying bimodal EEG-MRI NF on stroke patients.

Material and Method
Two chronic patients affected by left hemiplegia (subcortical lesion) participated. The protocol included a calibration step (motor imagery of hemiplegic hand) and two NF sessions (5 minutes each). The experiment was run using a NF platform performing real-time EEG-fMRI processing and NF presentation (Figure 1). The NF metaphor consisted of a ball moving on a gauge proportionally to the average BOLD and EEG activity in regions of interest (ROI) identified over the ipsilesional motor cortex during calibration.
Results

Both patients were able to self-regulate their brain activity during the NF sessions. The EEG activity was harder to modulate than the BOLD activity (Figures 2, 3). The correlation of the BOLD signal with the task varied depending on the ROI targeted and was particularly high for the supplementary motor area. The patients were highly motivated to engage and satisfied with the NF animation, as assessed with a qualitative questionnaire.
Conclusion

We performed two NF experiments involving chronic stroke patients: preliminary results showed the feasibility and the potential of applying EEG-fMRI NF for stroke rehabilitation.

THE EFFECT OF VIRTUAL REALITY ON LEFT AND RIGHT MIDDLE CEREBRAL ARTERY CHRONIC STROKE PATIENTS

M. Murie¹, S. Iturralde², A. Inausti²
¹Clinica San Miguel, Neurology Department, Pamplona, Spain
²Clinica Universidad de Navarra, Departamento de Anatomia, Pamplona, Spain

Introduction/Background

There is a considerable body of evidence around the use of non-immersive virtual reality as a therapeutic modality in stroke rehabilitation. Studies report its use in isolation, and as an adjunct to traditional physical therapy approaches.

Very little is known about what effect the location of lesion and the participants’ stage of recovery can have on the efficacy of VR interventions. We present a study using non-immersive VR in two groups consisting of right-middle or left-middle cerebral artery stroke survivors in the chronic stage.

Material and Method

Seventeen chronic stroke patients participated in this study. Participants performed 30 sessions of therapy with a Virtual Reality system supervised by a physiotherapist. A series of cognitive (MMSE), ADL (FIM and Barthel), motor (MAS, FMA upper and lower limb and MRC), gait (6MWT, Tinetti), spasticity (Asworth), balance (Berg and Tinetti EQ) and depression (GDS) scales were administered to each group of right middle cerebral artery or left middle cerebral artery stroke survivors.

Results

Participants with lesions in the left middle cerebral artery had significant improvements when compared with pre and post scores in the Barthel, FMA lower and upper, Berg and Tinetti. Participants with right cerebral artery lesions showed significant improvements on the Barthel Index and Fugl-Meyer (lower extremity).

Conclusion

We suggest that lateralization may be influencing the different outcomes reported between the right and left cerebral artery stroke groups in this study. We conclude that future VR motor rehabilitation strategies should consider the location of the lesion when designing interventions and call for additional research on this topic.

CORTICAL ACTIVATION OF HEALTHY ADULTS DURING A MOTOR TASK PERFORMED IN A REAL ENVIRONMENT AND IN VIRTUAL REALITY: A COHERENCE ANALYSIS OF ALPHA FREQUENCY

T. Pacheco1, K. Mansur Yano1, D. Carvalho de Oliveira1, F. Azevedo da Costa Cavalcanti

1Federal University of Rio Grande do Norte, Physiotherapy Department, Natal, Brazil

Introduction/Background

Virtual Reality (VR) contributes to neurorhabilitation due to its interactive and multisensory nature. In this sense, studies have been suggesting that brain activity may vary according to the environment – virtual or real. Given the use of mobile EEG devices, there is the possibility of investigating how VR or real tasks influence brain activity. By obtaining the EEG signal, it is possible to explore these variations through a study of coherence between pairs of electrodes. Thus, the aim of this study is to compare alpha coherence in healthy adults during a motor task performed in a virtual and real environment.

Material and Method

It is a crossover study in which 04 healthy adults were submitted to an EEG assessment during a one-minute task consisted of going up and down a step in a real environment. Then, the subjects underwent a virtual task composed by a Nintendo Wii game called “Basic step”. To perform coherence analysis, a MATLAB script was created considering intra and inter-hemispheric relation of all 14 EEG channels.

Results

The real task caused a more widespread pattern of coherence through the cortex, with low or moderate intensity. In contrast, the virtual task caused moderate to high coherence patterns between specific areas of the brain. In addition, the highest levels of coherence in the real task were observed in the left hemisphere, while in the virtual task, the highest coherence values...
were observed especially in the right.

**Conclusion**

Alpha coherence differs according to the environment that the task is performed - real or virtual. It is known that the greater the neuro-cognitive effort imposed by a task is, the lower the intensity of alpha. Thus, it is suggested that the virtual task required a greater neural effort than the real one.

VIRTUAL REHABILITATION FOR UPPER LIMB MOTOR RECOVERY IN STROKE PATIENTS: CASE STUDY.

M. Bayon Calatayud¹, M.D.P. Vazquez Muñoz², A. Gil Agudo³

¹Complejo hospitalario Toledo, Physical and Rehabilitation Medicine Department, Toledo, Spain
²Complejo hospitalario de Toledo, Department of Physical and Rehabilitation Medicine, Toledo, Spain
³Hospital Nacional de Parapléjicos, Department of Biomechanics and Technical Aids, Toledo, Spain

Introduction/Background

Virtual reality is a potential therapeutic tool for motor Rehabilitation in stroke patients. This is a case study which aim was to investigate functional recovery outcomes with TOyRA® virtual reality system in stroke patients.

Material and Method

TOyRA® uses information from Kinnect™ motion sensor and patient anthropometric measures to create a biomechanical model, providing upper limb kinematic data. Software consists on an interactive therapy system (STI) and a therapy management system (SGT), for managing patient’s data, planning therapy sessions, and creating follow-up reports. Study included 3 stroke patients with chronic hemiparesis 3/5. Exclusion criteria were age older than 75 years, unstable medical or psychiatric disease, prior upper limb orthopaedic injuries, and severe cognitive impairment. Study received approval from research and ethics committee. Intervention consisted on 15 therapy sessions, 30 minutes length, based on range of motion virtual exercises, with kinematic evaluation of wrist flexion, shoulder flexion and shoulder abduction. It was followed by an activities of daily living virtual training involving paretic upper limb. Functional independence measure, Fugl-Meyer scale, box and block test, stroke impact scale and adverse effects questionnaire, were used for patients’ assessment.

Results

Mean age was 63.3 + 11.6 years. Mean time passed since stroke was 42.6 + 14.7 months. Pre-posttreatment mean difference for shoulder abduction was +34.8º, for shoulder flexion +16.6º. Pre-posttreatment mean difference for upper limb Fugl-Meyer score was 7.7. Pre-posttreatment mean difference for box and block test was + 8.7 blocks/min.

Conclusion

Virtual Rehabilitation improved motor function among study patients with moderate upper limb paresis. No adverse effects derived from therapy were found. Further controlled studies should be addressed. with larger sample size.

1Université de Montréal, Ecole de réadaptation, Montréal, Canada

Introduction/Background

Patients with stroke have difficulty accessing external conventional rehabilitation services. Telerehabilitation combined with video games provides a new approach that may counter the accessibility problem and optimize motor recovery of the upper limbs, even in the chronic phase of the disease. Objectives: 1/Assess the primary effect of the technology on the motor and functional recovery of the upper limbs after a stroke in the chronic phase 2/Describe the experience of stakeholders in using the technology.

Material and Method

A mixed study: pilot randomized trial and a multiple case study. The intervention consists of the provision of remote rehabilitation services using the combination of REACTS as a telerehabilitation system and the Jintronix Inc exergame. We plan to recruit 24 patients, randomly assigned to control group (n= 12, a 2 months home exercise program described on paper) and experimental group (n= 12, a 2 months home program of the combined version of Jintronix and React system, 5 times of 30 minutes per week). In addition to the experimental group, 5 physiotherapists and 5 managers will be recruited by convenience to conduct the case study. The Fugl-Meyer and Motor Activity Log (MAL) Manual scales will be administered 3 times in both groups (before and after the intervention, 1 month after the end of the intervention). Qualitative data will be collected by focus groups and interviews with all the stakeholder groups, 1 month after the end of the intervention. The analysis will be done using Statistica and Nvivo.

Results

We expect to: 1/Collect primary data of the effect of the technology on the functional and motor recovery of the upper limbs, following a stroke 2/ Identify the obstacles and the facilitating factors of the use and the integration of the technology in clinical practice.

Conclusion

This study aims to improve external rehabilitation services offered in the context of stroke.

³Hopitaux Universitaires Henri Mondor, Fédération de rééducation neurolocomotrice, Créteil, France
⁴NaturalPad, Bâtiment EuroMov, Montpellier, France

Introduction/Background
Unilateral Spatial Neglect (USN) is a neurological syndrome usually observed after a right hemispheric stroke in which patients fail to explore the left contralateral space. USN is a factor of bad functional prognosis and is thus challenging more complete assessment and rehabilitation interventions. Virtual reality (VR) has emerged as a promising new tool in both the assessment and rehabilitation of USN. VR permits more ecological conditions, is more engaging and maybe more effective for patients.

In this study, we used the therapeutic serious game “Hammer and Planks” in which the patient should guide a boat for recovering gold coins without hitting rocks by moving his/her trunk laterally. Our aim was to evaluate the improvement of USN using VR in combination to conventional rehabilitation method.

Material and Method
Five neglect patients were included in this study. Neglect was assessed with BIT at 3 different times (baseline, 3 weeks, 6 weeks). Three patients were randomly assigned to the group who received VR rehabilitation in the first 3 weeks, 2 received conventional rehabilitation only in the first 3 weeks.

VR rehabilitation was performed 3 days per week, each session lasting 15-20 minutes. “Hammer and planks” was designed to allow continuous variation of 4 factors (luminance/size of coins, number of coins/rocks, game time) to increase the difficulty (see fig1).

Results
There was no group effect. In comparison to conventional rehabilitation method, a significant difference was found between before and after rehabilitation with VR (p < .044) for the conventional BIT score (see fig.2).

Conclusion
Our preliminary findings suggest that the combination of more ecological and more engaging tool such as VR with conventional rehabilitation method is promising for improving left neglect.

THE USE OF THE ROBOTIC DEVICE HUNOVA® AS A REHABILITATION TOOL FOR FUNCTIONAL BALANCE IN INDIVIDUALS WITH SPINAL CORD INJURY

A. Leo¹, M. Zarbo¹, A. Cassinis¹, D. Pometto¹, L. Re¹, T. Bianconi¹, C. Gambirasio¹, M. Spinelli¹
¹ASST Grande Ospedale Metropolitano Niguarda, Unità Spinale Unipolare, Milan, Italy

Introduction/Background

Postural control is a very important and basic requirement in daily human life. The robotic device Hunova® allows to evaluate and practice postural control using different exercises both in upright stance and in seated position. While most functional tasks are not isolated to the trunk, the ones that challenge balance and sitting postural control require a high level of trunk control. When trunk control is impaired the development of less effective compensatory strategies is required. Impaired trunk control functional implications are most evident in neurological conditions, such as spinal cord injury.

Material and Method

This is a preliminary study to explore the possibility of using Hunova® as a tool in Spinal Cord Injury rehabilitation. Thanks to the opportunity to grade exercises complexity we were able to use the device with subjects with different level of lesion and different functional abilities. We trained patients with acute/subacute lesion admitted to our Spinal Cord Unit as well as persons with a stabilized lesion and paralympic athletes.

Results

Preliminary data show that Hunova® is appreciated by users and, at the same time, can be a versatile instrument for balance rehabilitation in Spinal Cord Injury. In individuals affected by incomplete lesion it promotes the use of leg residual muscles activity. Moreover it is interesting to see how athletes show high level of functional balance even in presence of complete lesion.

Conclusion

Hunova® can be considered as a tool for rehabilitation in individuals with Spinal Cord Injury. The device allows to set up focused exercises performed in a pleasant way. The performance of paralympic athletes may lead to the design of sport associated training meant to introduce acute patients to sport activities.

The Lucy Montoro Rehabilitation Network in Sao Paulo, Brazil, used the WHO Wheelchairs Guidelines to standardize wheelchair service provision. 11 wheelchair clinics were established and 180 professionals were trained. This Network delivers comprehensive rehabilitation and provides assistive products to persons with physical disabilities through the universal Brazilian Public Healthcare System.

**Material and Method**

The study analyses 222 records of the first group of patients serviced according to WHO Wheelchair Guidelines’ 8 steps. Patients were seen from July to December, 2017.

**Results**

62% were male, 38% female, with an average age of 32.57 years; 48% were unemployed or on sick leave; 51% were retired or receiving disability benefits; 84% were not able to walk; 62% were assessed to change their wheelchair and 38% were serviced in order to receive their first wheelchair; 71% were at risk of developing pressure sores.

Among users who already had a wheelchair, previous models were manual (95%), inappropriate to the user (88%), inappropriate to their environment (58%), and unsafe (55%).

27.67% of users used their wheelchairs more than 5 hours/day and 61.48% propelled the wheelchair for less than 1km daily. Indoor and outdoor use was balanced (79.85% and 82.84%, respectively), with a predominance of paved (74.63%) and even (41.49%) terrains.
15.35% of users were able to sit upright without additional postural support. Among the remaining 84.65%, who needed additional support, the most frequent postural deviation was the posterior tilt of the pelvis (22.83%).

25.20% of the 220 wheelchairs prescribed were models for children and 74.80% for adults; 92.68% were manual and 7.32% powered wheelchairs; 27.12% had rigid and 72.88% had folding frames.

**Conclusion**

The sample shows young, men users, with a severe level of disability, at risk of developing pressure sores, and only travel short distances despite been seated in their wheelchairs for many hours. Their wheelchairs were unsafe and unappropriate for personal and environmental needs.

A process of capturing foot data using 2D images taken by a smartphone camera and converting it into a 3D model of insoles and 3D printing using fused deposition modelling technology is being developed and holds promise for simplifying the customised foot insole data acquisition and 3D modelling. This study elaborates on clinical and process related issues and outcomes of this developing technology. The main aim of this study was to document the clinical effectiveness of custom made 3D printed orthotics in patients with foot problems attending foot clinic of Department.

Material and Method

Clinical Validation of 3D printed insoles was done by taking patient’s feedback after 15 days and 3 months of wearing insole using foot Function Index and 50 feet walk test. Other variables were also analyzed and the iterations for manufacturing and refining of the process studied.

Results

A total of 46 subjects with various foot problems who were given 3D designed and printed insoles according to their prescription completed the study. On average 2-3 iterations were required to get the best outcome. Feedback of the patients was assessed after 15 days and 3 months duration. Paired T test was applied to find out the comparative values showing the differences between Pre-and Post-intervention data of each parameter. The VAS score, Foot Function Index and the 50 feet walk test improved and correlated with increase in duration of use of orthosis.

Conclusion

There were problems encountered during the process of 3D measurement and printing which were worked upon on case to case basis. This is an emerging technology and needs lot of iterations. The current need of the hour is to refine and automate the process and the materials so that it can be a cost effective alternative for fabrication of foot orthotics.

EVALUATION OF RANGE OF MOTION AND STRENGTH OF UPPER LIMBS IN TETRAPLEGIC PATIENTS TO PERFORM SELF-CATHETERIZATION
M. Zarbo¹, A. Leo¹, L. Frediani¹, M.G. Ricchiuti¹, M. Spinelli¹
¹ASST Grande Ospedale Metropolitano Niguarda, Unità Spinale Unipolare, Milan, Italy

Introduction/Background

A functional hand is fundamental for a patient affected by quadriplegia in order to get as independent as possible. We evaluated the ROM and strength of upper limbs in patients affected by tetraplegia, with stabilized lesion, able to regularly practice intermittent self-catheterization.

Material and Method

We used the device Pablo® Tyromotion, an electronic dynamometer and accelerometer; it allows to collect informations about strength and ROM of the body districts analysed. We tested 25 patients (23 males, 2 females); average age 37.5y (min 14 – max 66); average years passed by the injury 9.96 (min 1 – max 36); different lesional levels (C0 n. 1, C2 n. 1, C4 n. 2, C5 n. 13, C6 n. 6, C7 n. 2); different injury etiologies (C0 arteriovenous malformation, C2 spinal cord empyema, others traumatic). Inclusion Criteria: cervical SCI; traumatic and non-traumatic etiology; stabilized lesion; intermittent self-catheterization.

Results

We compared the average values of strength for these movements: Terminal pinch I-II fingers (dx 0,708; sx 0,844 Kg); Terminolateral pinch I-II fingers (dx 1,14; sx 1,276 Kg); Interdigital pinch II-III fingers (dx 1.4; sx 1.4 Kg).

Conclusion

We found out how districts and movements not routinely tested, used or trained can preserve a greater potential for what concerns the Spared Function than other mostly known and studied movements. These data should become a strong input to design devices, for rehabilitation and everyday life, based on a new concept of pinch and function of the hand underlining the importance of clinical experience in the projecting phase of devices.

Introduction/Background

Hemiparesis is the classic clinical condition of stroke and is related to important locomotor limitations. The treatment strategies traditionally chosen are limited by the monotony, boredom and repetitiveness of the exercises. Serious games (SG) combine specific physical training with a higher attentional and motivational level, increasing adherence to treatment. The aim of this study was to verify the therapeutic effects of exercise program using a SG developed for evaluation and rehabilitation of hemiparetic patients after stroke.

Material and Method

Non-Randomized Controlled Clinical Trial involving 24 patients (12 men) was conducted. Patients were divided into 2 groups. One group consisted in realize exercises with a SG mim-Pong (experimental, Figure 1) and the other group a conventional physical therapy (control). Both groups completed the 20-session treatment protocol. The following variables evaluated were: muscle strength, motor control, motor impairment, spasticity, functional mobility and gait speed. Data were analyzed with descriptive statistics, paired Student’s t-test and effect size calculation.
Figure 1: The objective of the mim-Pong is to bounce the ball by controlling the bars position with the patient's force applied in a load cell.

Results

Patients did not differ in terms of sociodemographic characteristics at baseline. In the experimental group, significant improvements were observed for all variables (Table 1). Large effect sizes were found for muscle strength of hamstrings, quadriceps femoris and hamstrings scores, Fugl-Meyer Assessment Scale and Modified Ashworth Scale. In the control group the improvements were lower than experimental group with small to moderate effect sizes. Significant differences were found only for game scores (QFS and HS) probably due to learning during the training phase conducted before assessment with the SG.

Conclusion

These results suggest that SG promote superior improvements to those obtained with conventional treatment of hemiparetic patients after stroke. This superiority is probably due to increased attention demand and motivation during interventions with SG.

Keywords

Serious Game ;Stroke;Hemiparesis

No conflict of interest
Introduction/Background

The use of Serious Games (SG) in post-stroke rehabilitation has been considered a promising therapeutic resource. Key elements in rehabilitation (intensity, repetitiveness and task orientation), are highlighted by using SG. Moreover, SG improve both patients' attention and motivation during rehabilitation sessions contributing to patients' adherence. However, existing commercial games have been crafted with no concern on clinical efficacy. SG conception orientated on clinical efficacy is fundamental for patients' rehabilitation. Therefore, the aim of this work is to present a conceptual model for SG design/development for post-stroke rehabilitation.

Material and Method

A systematic literature was performed to identify main limitations in games used in the rehabilitation of post-stroke patients. From 309 articles identified 31 respected all inclusion/exclusion criteria and were selected for further analysis. The fields investigated were methodology and multidisciplinarity of design, clinical evaluation with patients and game metric properties.

Results

No game design methodologies were observed. Almost half of the studies were conducted by joint authorship of the technology. No information was found about the development team. Only half of the studies evaluated therapeutic outcomes. The relationship between game score and clinical evaluation was not found. To overcome these drawbacks a conceptual model called STRONGER - SysTemS for Rehabilitation based on GamE scoRe - for SG design for post-stroke rehabilitation was proposed (Figure 1).
Conclusion

Regarding the inconsistency of studies in SG, a framework as STRONGER that establishes a relationship among the key stakeholders (experts and patient) and elements (biomedical device, SG and game score) should be used in SG design. The score aimed for clinical evaluation is an innovative aspect. The correlation between game score and clinical tests can lead the biomedical system to become an aid for treatment and evaluation. Although this study has been limited to post-stroke rehabilitation, the proposed model can be extended to other populations.

DEVELOPMENT OF RESPIRATORY REHABILITATION EXERCISE DEVICE FOR HIGH LEVEL OF CERVICAL SPINAL CORD INJURY
J. Park¹, D. Kang¹, P. Hyunju¹, E. Seon-Deok¹
¹National rehabilitation center, Dept. of Rehabilitation Policy and Standardization, Seoul, Republic of Korea

Introduction/Background

The high level of cervical spinal cord injury of the diaphragmatic nerve is impaired and the dysfunction of the respiratory muscles becomes severe. Also, respiratory complications associated with pneumonia account for the highest percentage of deaths (67%).

Material and Method

The purpose of this study is to develop a respiratory exercise device that can improve the lung function by making full use of the residual function of the high level of cervical spinal cord injury (C3-6, ASIA A-B). In order to develop a new respiratory exercise device as a research method, we conducted the 1:1 in-depth interviews on the disability experiences and requirements of disabled people to use directly. Through semi-structured interview questions, we investigated the reasons for not exercising at home, difficulties during respiratory exercises, and requirements for respiratory exercises to be developed in the future.

Results

As a result of the research, we developed 3 kind of a respiratory rehabilitation exercise device that can be used for the high level of cervical spinal cord injury.
We performed 16 exercises for 8 weeks using 3 developed devices for 10 high level of cervical spinal cord injury and then conducted 1:1 in-depth interviews.
The interview results showed that the device was very suitable respiratory exercises of high level of cervical spinal cord injury. They would like to recommend developed devices to high level of cervical spinal cord injury, as exercising with others increases their fun, morale, and vitality.

Conclusion

The respiratory exercise devices proposed in this study can be used by a single person or a group of people with a disability and can be used with non-disabled people. In addition, the developed respiratory exercise device can be used in various places other than the hospital.
based rehabilitation treatment activity, and it is expected that it will be able to perform continuous respiratory exercise.

OUTCOME OF WALKING SUPPORT MACHINE TRAINING IN GAIT REHABILITATION FOR
CHRONIC STROKE PATIENTS

T. Chotjumlong¹, P. Wattanapan², B. Sindhupakorn³

¹SURANAREE UNIVERSITY OF TECHNOLOGY, Suranaree University of Technology hospital, Nakhon Ratchasima, Thailand
²Khon Kaen University, Rehabilitation Medicine, Khon Kaen, Thailand
³Suranaree University of Technology, Orthopaedic surgery, Nakhon Ratchasima, Thailand

Introduction/Background

Chronic stroke patients had restriction in mobility and ambulation due to motor weakness, abnormal muscle tone and balance impairment. The locomotor training using partial weight supported treadmill has been shown benefit in stroke patients, but cost is too high. Therefore, innovative walking support machine(CoWalk) (as figure) has been invented by our staffs to improve gait and balance. This study aimed to determine the effect of using CoWalk in gait performance of chronic stroke patients.
Material and Method

Ten chronic stroke patients (≥ 6 months) with functional ambulation categories 1-3 participated in this study. The participants were received gait training using CoWalk for 15 minutes in addition with usual rehabilitation program twice a week, total 45 minutes for each session, for 8 weeks. The physical therapist adjusted percentage of body weight support according to patient’s ability. Berg Balance Scale (BBS) and 10 Meter Walk Test (10MWT) were used to measure gait performance by pre-training and after the end of 8-weeks training program.

Results

Most of participants were male (70%) with mean age 67.8 ± 9.3 years. The result showed significantly improved in BBS (BBSpre = 17.3 and post = 23.0; p=0.01) and 10MWT (pre =29.2 s and post = 22.9 s; p= 0.005). No adverse event was reported during training.

Conclusion
This study showed benefit of C0-Walk in addition with usual rehabilitation program. However, the further study should be considered to compare with the control group and investigate more gait parameters.

ISPR8-1188
ADAPTATION OF UPPER LIMB MOVEMENT USING EXOSKELETON-BASED TRAINING AND TRANSFER OF CINEMATIC PATTERNS TO UNCONSTRAINED MOVEMENT: A PRELIMINARY STUDY
T. Proietti¹, R. Parry¹, F. Lejeune¹, A. Roby-Brami¹, N. Jarrasse¹
¹Institut des Systèmes Intelligents et de Robotique, Assistance aux Gestes et Applications Therapeutiques, Paris, France

Introduction/Background

Robotic technologies offer the possibility for highly specific training of upper limb movements. How exactly the motor coordination imposed during an intervention carries over into unconstrained upper limb activity, however, remains poorly understood. This preliminary study sought to examine the after effects of robotic training on upper limb joint kinematics during reaching.

Material and Method

Using a four degree of freedom upper limb exoskeleton, healthy adult subjects trained on a series of reaching tasks. Shoulder and elbow joint coordination was modified using a viscous corrective force field. Kinematic variables during the different reaching tasks without the robotic device were evaluated using a motion capture system prior to and following the intervention. Movement adaptation was evaluated with respect to subject performance on reaching toward experimental targets as well as untrained targets.

Results

Shoulder abduction profiles and terminal elbow position appeared modified two hours following the training. These changes reflected the joint kinematics forced during the robotic intervention. Furthermore, distance metrics based upon principal components analysis indicated that exposure to the corrective force field had durable effects upon shared coordination between the shoulder and elbow. This shift in movement patterns was observed for both the experimental and untrained targets.

Conclusion

These preliminary results suggest that certain features of upper limb movement, trained using corrective force fields in an exoskeleton, may be retained following the intervention and potentially generalised to prehensile movements in the peripersonal workspace.

THE MANUAL WHEELCHAIR TILT-REST SKILL: A CROSS-SECTIONAL SURVEY OF AWARENESS AND CAPACITY AMONG WHEELCHAIR USERS

R.L. Kirby¹, A. Agur¹, A. Chen¹, C. Smith², C. Theriault³, K. Matheson³
¹Dalhousie University, Division of Physical Medicine and Rehabilitation, Halifax, Canada
²Nova Scotia Health Authority, Occupational Therapy, Halifax, Canada
³Nova Scotia Health Authority, Research Methods Unit, Halifax, Canada

Introduction/Background

The tilt-rest skill consists of tipping the wheelchair back and allowing it to rest against a solid object with the wheel locks applied (e.g. for pressure redistribution, neck comfort or hands-free activities). The objective of this study was to test the hypotheses that many wheelchair users are unaware of the skill and even fewer can perform it.

Material and Method

We conducted a cross-sectional survey following STROBE guidelines on 49 manual wheelchair users with a variety of diagnoses. The main outcome measures were a questionnaire regarding demographic, clinical, wheelchair and tilt-rest data, as well as skill demonstration by those who reported that they were capable of doing so.

Results

Participants’ mean (SD) age was 55.1 (18.2) years, 38 (77.6%) were male, their mean (SD) duration of wheelchair use was 7.0 (10.4) years and their mean (SD) daily time spent in the wheelchair was 9.5 (4.6) hours. Twenty-seven (55.1%) of participants were aware of the skill, 20 (40.8%) reported being able to perform the skill and 16 (33.3%) could demonstrate it.

Conclusion

Just over half of manual wheelchair users are aware of the tilt-rest skill and one-third of them can perform it. Older people are less likely to report being able to complete the skill. These findings have implications for wheelchair skills training.

THE EFFECTS OF LEG ELEVATION ASSIST BAND FOR GAIT DISTURBANCE IN STROKE PATIENTS
K.M. Lee¹
¹Chungbuk National University, department of rehabilitation, Cheongju, Republic of Korea

Introduction/Background

Patients with stroke often suffer from gait difficulties. Gait speed was often reduced and maintaining balance during gait was also affected. In swing phase of gait, maximal hip and knee flexion and ankle dorsiflexion are often reduced in sagittal plane. The leg elevation assist band was designed to assist elevation of lower extremity and foot clearing during swing phase. The purposes of this study were to evaluate the effects of leg elevation assist band in patients with hemiplegia due to stroke.

Material and Method

10 chronic hemiplegic patients after cerebral stroke at least 6 months after onset who can walk indoor were recruited. The leg elevation assist band is consisted of chest harness, two elastic band to assist leg elevation and foot part. The band helps to elevate involved foot and leg of the patients. All the patients wore leg elevation assist band and practiced walking indoor for 20 minutes 5 times a week for 2 weeks.

Results

After applying the band, 10 meter walking time improved to 32.6±17.6 seconds comparing 34.5±14.1 seconds without the band(p<0.05). After 1 week, 10 meter walking time improved to 30.9±17.5 seconds comparing 31.8±15.0 seconds without the band(p<0.05). After 2 weeks, 10 meter walking time was 31.9±17.5 seconds comparing 31.2±14.4 seconds without the band. Before the experiment, all 10 patients could not go up the stairs. 2 weeks after training with the band, 4 out of 10 patients could climb up the stairs. They did not show significant change in functional reach test after 2 week training.

Conclusion

The leg elevation assist band could improve the walking speed of hemiplegic patients and the band also had therapeutic effects on walking ability in the patients.

THE REHABILITATIVE VALUE OF PABLO® TYROMOTION FOR THE EVALUATION AND THE FUNCTIONAL RECOVERY OF THE UPPER LIMB AND THE HAND IN SCI PATIENTS

C. Bonfanti\textsuperscript{1}, M. Panico\textsuperscript{2}, P. Meazza\textsuperscript{2}, L. Re\textsuperscript{2}, A. Oggioni\textsuperscript{2}, M. Zarbo\textsuperscript{2}, M. Spinelli\textsuperscript{2}, T. Bianconi\textsuperscript{2}

\textsuperscript{1}University of Milan, Degree in Physiotherapy, Milan, Italy
\textsuperscript{2}ASST Grande Ospedale Metropolitano Niguarda, Unità Spinale Unipolare, Milan, Italy

Introduction/Background

The aim of this work is to verify the possibility to use Pablo® Tyromotion device for the evaluation and rehabilitation of the upper limb of the person with quadriplegia.

Material and Method

9 patients with quadriplegia, lesion level C4-C8, were included in the study. The protocol considered a T0 and T1 evaluation of the upper limb and the hand with the Pablo® device and the Grasp and Release Test modified (GRT mod) and Tetraplegic Functional Test (TFT) scales. At the T1, after 8 rehabilitative sessions performed with Pablo®, a second evaluation was performed with the same items of the first one. The Physical Therapy Patient Satisfaction Questionnaire mod (PTPSQ-1 mod) was also administered to evaluate the patients’ appreciation of the use of this kind of device to improve the rehabilitation program.

Results

7 of 9 subjects completed the study protocol. The correlation values were positive for all the grasps and very high especially for the palmar grasp and the termino-terminal pinch. A high statistical significance turns out for all the grasps. The correlation values for the palmar grasp and the termino-terminal pinch in the group with the functional hand set up were negative.

Conclusion

The correlation values obtained indicate that the variables force (Pablo®), number of grasps performed (GRT mod) and functional abilities (TFT) were correlated and if one increases, the others increase too according to the calculated values. On the basis of the PTPSQ-1 data the Pablo® device seems to be appreciated by the patients for what concerns acceptance and pleasantness in use. Pablo® can be considered an evaluative tool complementary to a scale like the GRT mod in subjects that do not take advantage of the functional hand for the grasps.

Introduction/Background

This paper studied the estimation of walking steps based on knee joint change of the unaffected side leg to estimate the walking environment of the intelligent transfemoral prosthesis in the future.

Material and Method

Knee joint change was estimated using an inertial sensor by considering the ease of attaching the sensor to the body. In general gait, there are four pole points in the change of the knee joint. These pole point change patterns show reproducibility in the same gait environment and different patterns in the gait environment of different situations. These pole point patterns appear with periodicity in the gait. If this is subdivided step by step, the current step is related to the former and latter steps.

Results

Therefore, this paper is to study the gait step estimation first to estimate the gait environment based on these characteristics in the future. The proposed method is a method of estimating the gait steps based on the pole point according to the angle change of the knee using the state machine.

Conclusion

The inertial sensor has the disadvantages that a delay is caused by a low-frequency filter for eliminating noise, and it is difficult to recognize when the pole point is not detected according to the step of the subject. This requires modification and supplementation of the algorithm. In addition, the gait step detection algorithm proposed in this paper requires comparison and evaluation with other algorithms and further research and experiments are needed.

EFFECTIVENESS OF WEARABLE UPPER LIMB ASSISTIVE DEVICES IN HEMIPARESIS FOR IMPROVEMENT OF FUNCTIONAL ABILITIES: A SYSTEMATIC REVIEW
C. Cormier¹, C. Villepinte², D. Gasp³
¹Hôpital Rangueil- CHU de Toulouse, Service des Explorations Fonctionnelles Physiologiques, Toulouse, France
²PREFMS- CHU de Toulouse, Institut de formation en ergothérapie, Toulouse, France
³INSERM - Université Paul Sabatier Toulouse 3, Toulouse NeuImaging Center UMR 1214, Toulouse, France

Introduction/Background

Assess short-term benefits of wearable devices in activities of daily living (ADLs) and functional tasks, for people suffering from upper-limb impairment due to acquired brain injuries (ABI).

Material and Method

Two independent reviewers conducted a systematic review across Cochrane Database of Clinical Trials, Medline, Web Of Science, PEDro, OT-Seeker and Open Grey databases until November 2017, identifying citations in included studies and systematic reviews. Inclusion criteria included: adults with hemiparesis due to all causes of ABI; wearable devices such as orthosis, prosthesis, exoskeleton, electrical stimulation devices, neuroprosthetics; use of functional outcome measures assessing ADLs and functional tasks with and without device. Methodological quality of articles was assessed according to the Joanna Briggs Institute (JBI) scale for case series.

Results

From 1452 titles initially selected, eleven studies were finally selected (n=95 participants), all focusing on post-stroke hemiparesis. Nine were self-controlled case-series and two were single-case reports. Six studies described functional electrical stimulation devices, three described use of exoskeletons and two passive devices. Command of the nine active devices included electromyography, kinematic data, push-button, inertial unit measurement and force sensors. Quality assessment using JBI Scale found low quality evidence of all studies with heterogeneity of outcomes. One of the two studies describing passive assistive devices demonstrated significant improvement in the size of block lifted during the box and block test (BBT). Only one of the three studies using exoskeleton found significant improvement in the BBT and various functional tasks. Four of the six neuroprosthetics studies found moderate to significant improvement across outcomes.

Conclusion
Considering high heterogeneity of studied assistive devices, small samples sizes and study designs implicating insufficient high quality evidence, it is not possible to either support or reject the use of assistive devices on the ABI population. Further research is needed to investigate the use of these devices on functional outcomes.

CASE OF PLANTAR ORTHOTICS IN A LOWER LIMB AMPUTEE
M. Timsit¹
¹Clinique de Provence Bourbonne, Bouches-du-Rhône 13, Aubagne, France

Introduction/Background

Many changes in balance and plantar support appear after amputation of a lower limb. The goal of this work is to provide of modifications using treadmill run times and possible improvements with the use of orthotics.

Material and Method

One measure of balance using the death test along with footprint analysing using static and dynamic treadmill run times. The same tests are administered after wearing plantar orthotics to redistribute loads for at least 15 days. The static position of the center of gravity was measured. Prosthetic plantar and heel supports and healthy were measured statically and dynamically. Statistical analysis of the various parameters is presented.

30 patients agreed to participate in the study.

Results

The characteristics of the population and test results were presented at the former meeting.

Conclusion

The treadmill run times allows the measurement of footprint static and dynamic but also the position of the center of gravity. After a lower limb amputation the plantar supports are modified. The plantar orthoses can help to find correct supports.

A REVIEW ABOUT THE ENHANCED REHABILITATION OF KNEE ARTHROPLASTY

J. Du¹
¹Xuan Wu Hospital- Capital Medical University, Department of Rehabilitation Medicine, Beijing, China

Introduction/Background

Background and aims: Knee arthroplasty is a common and effective intervention to deal with the highest incidence of osteoarthritis. It has increased fast, but its long recovery time and not very satisfactory effects are not in line with the concept of enhanced recovery. So rehabilitation is very important.

Material and Method

Methods A literature search was conducted using PubMed with the search terms “knee arthroplasty AND rehabilitation” published between 2007 and 2017.

Results

Results: (1) Preoperative rehabilitation has a certain effect, especially in early postoperative recovery. It can promote patients to resume functional activity as soon as possible. We should be hard to do preoperative rehabilitation. (2) Rehabilitation training should start as soon as possible. On the one hand, rehabilitation training could avoid disuse syndrome that will increase the training difficulty once appeared. On the other hand, early training can prevent or reduce complications such as deep venous thrombosis and the unnecessary treatment. Traditional rehabilitation methods are enough. The high intensity training mode can be used within the limits of patients. The total rehabilitation time is not very important. The training emphasis should be put on the muscle strength of quadriceps. (3) Cryotherapy could relief postoperative pain to some extent, but it is not clear about the reduction of edema.

Conclusion

Conclusions: Rehabilitation could promote the function recovery. It is suggested that rehabilitation training should be started before surgery and rehabilitation should be carried out as early as possible. The appropriate combination of cryotherapy is OK.

⁶Hyogo College of Medicine Sasayama Medical Center, Department of Rehabilitation, Sasayama, Japan
⁷Bando Chemical Industries Ltd., R & D Center, Kobe, Japan

Introduction/Background

Chronic obstructive pulmonary disease (COPD) patients often have shortened inspiration phase and experience breathlessness even during light exercise. The respiratory rate that reflects breathlessness during exercise is usually measured by a flow sensor with a face mask. Since many COPD patients use oxygen therapy with a nasal cannula and face mask that sometimes inhibit breathing, a less invasive wearable sensor for monitoring respiratory rate is required. This study investigated the characteristics of a new wearable respiratory sensor and its performance was compared with that of a standard flow sensor.

Material and Method

Twenty-four healthy volunteers wore wearable stretch sensors (STRs) while performing a treadmill walking test protocol that included standing and sitting, an incremental walking with and without a stick on treadmill (belt speed was increased from 2 to 6 km/h). Two STRs were symmetrically attached to a band placed around the participant’s trunk. Participants wore two sets of the STR bands at the 4th rib level and 10th rib level. Each respiratory cycle including respiration phase was determined by the stretching and shortening cycle of the STR signal. Based on the respiratory cycle, the number of breaths was counted every 1 min. We compared breath counts by the STR and flow sensor using Bland–Altman plot.

Results

Breath counts ranged from 8 to 45 bpm throughout the test protocol. STR signals showed positive correlation with flow signals (p < 0.05). In more than 90% of testing periods, the difference in breath counts between the STR and flow sensor was less than 10%. The limit of
the agreement between breath count differences was less than 3 bpm in all movement conditions.

**Conclusion**

The wearable respiratory monitoring system showed high accuracy and precision for breath counts even while the participants were walking. The results suggest high potential of the system for clinical applications.

Disclosure statement: The authors of this manuscript declare the following competing interests: this project was funded by a grant from Bando Chemical Industry Ltd. YB is an employee of Bando Chemical Industry Ltd. Bando Chemical Industry Ltd. provided the materials used for the experiment.
Ageing societies and the increase in chronic disabilities are irrevocable trends in the EU which usually result in a loss of autonomy and increased social isolation. Many people with complex disabilities face increased isolation due to loss of independent mobility because of difficulties of meeting the criteria for the provision of an Electric Powered Wheelchair (EPW) and the availability of an appropriate EPW. Several studies highlight the key role of innovative Assistive Technologies and smart EPW as effective tools to empower disabled people and improve social inclusion. Nevertheless, standardization, interoperability, limited involvement of users, lack of specialist training for health professionals and funding models are which impede the uptake of such innovations.

**Material and Method**

Within this framework, a transdisciplinary consortium of French and English partners formed the 4 year ADAPT project, starting in May 2017. The aim of ADAPT is to overcome the barriers to the uptake of assistive technology.

**Results**

The ADAPT project aims to:
- Develop two technologically mature innovative assistive technologies:
  * A smart EPW with driving assistance to compensate for user disabilities, to monitor and report changes users’ health through the internet.
  * A Virtual Reality EPW simulator platform. This will give the user an immersive experience of the smart EPW and train them to drive in everyday life. Professionals will assess the suitability of the EPW for particular patients and environments and gain understanding from the user perspective.
- Develop training programs for healthcare professionals about innovative assistive technologies.
- Formalize agreements between research institutions and companies ranging from local to international meetings, so as to boost R&D and facilitate the uptake of the ADAPT's results by the market.

**Conclusion**
This presentation will provide an opportunity to share an overview of the ADAPT project: context, objectives and results.

HYBRID ASSISTIVE LIMB (HAL) TREATMENT FOR PATIENTS WITH SEVERE THORACIC MYELOPATHY CAUSED BY OSSIFICATION OF THE POSTERIOR LONGITUDINAL LIGAMENT (OPLL) IN POSTOPERATIVE ACUTE PHASE
S. Kubota¹, Y. Shimizu², H. Kadone³, T. Abe¹, H. Mutsuzaki⁴, Y. Hada², M. Yamazaki¹
¹University of Tsukuba, Orthopaedic Surgery- Faculty of Medicine, Tsukuba- Ibaraki, Japan
²University of Tsukuba Hospital, Department of Rehabilitation Medicine, Tsukuba- Ibaraki, Japan
³University of Tsukuba Hospital, Center for Innovating Medicine and Engineering CIME, Tsukuba- Ibaraki, Japan
⁴Ibaraki Prefectural University of Health Sciences, Department of Orthopaedic Surgery- Centre for medical sciences, Ami, Japan

Introduction/Background
The purpose of this study was to clarify the safety and feasibility of rehabilitation using the robot suit hybrid assistive limb (HAL) for severe thoracic myelopathy due to ossification of the posterior longitudinal ligament (OPLL).

Material and Method
Eight patients (mean age, 60.9 years) in the postoperative acute or subacute phases who presented with severe gait disturbance before surgery and underwent posterior decompression with instrumented fusion for thoracic ossification of the posterior longitudinal ligament (T-OPLL) were included in this study. Treatment using HAL (about 60 min per session, 2-3 times a week, 10 sessions in total) was started on mean postoperative day 27.5. Gait speed, step length, and cadence for each session were measured with the 10-m walking test. The American Spinal Injury Association (ASIA) motor score (lower extremities) and Walking Index for Spinal Cord Injury (WISCI) II were also evaluated at baseline and after 10 sessions. In addition, the Japanese Orthopaedic Association (JOA) score was calculated over time after surgery.

Results
Ten sessions of HAL treatment were completed in all patients. No serious adverse events related to the locomotor treatment with HAL were noted. Gait speed, step length, and cadence improved over time. Compared with baseline values, WISCI-II and ASIA motor score (lower extremities) after 10 sessions improved. The JOA score improved over time after surgery.

Conclusion
Treatment using HAL can be performed in the early postoperative period without severe adverse events in patients with T-OPLL and severe gait disturbance.

⁵Approche Network, Assistive technology, Coubert, France
⁶Approche Network, Assistive technology, Kerpape, France

Introduction/Background

Facilitating home support of elderly and dependent people is one of the major challenges currently offered to assistive robots. Can a humanoid robot answer needs of persons with frailty and help them stay in their home longer? The objective of the study is to assess usability and perceived usefulness of the human-shaped robot Pepper®.

Material and Method

Fifteen in-patients lived with the robot seven days a week. After a learning phase, they were invited to interact with Peppers® through several implemented applications originally designed to unveil the potential field of use of Pepper. Satisfaction with use, attitudes and opinions were studied via open and closed-ended questions as well as film sequences. Data collection was performed daily from day 0 to 7.

Results

Pepper was mainly seen as a possible ambulatory assistive device, capable

-of following people with walking difficulties and/or cognitive disorders

-of reminding him to take medications and/or to drink and providing him with helpful information. Seven of 10 recall tasks were considered as priorities for 80 to 100% of the participants.

-of alerting in case of a fall, an illness or an emergency. These functions are claimed by at least 80% of the patients.

Comparison of base-line and end-line data has suggested that an emphatic and a reciprocal relationship with Pepper had been established. At the end of the experience, 80% stated that use of Pepper was perceived as logical in 2017 and all believed that the future will lie in robotics
while 47% acknowledged that it was a frightening prospect. The overall satisfaction with this experience was rated at least 6 on a 10-point scale by 12 of the 15 participants.

**Conclusion**

Living with a humanoid robot on a 24 hours/7 days basis was demonstrated to be viable and safe making possible experimentation at home providing that some technological issues are solved.

EFFECT OF A NOVEL DEVICE WITH LASER POINTER IN PRACTICING POSTURE CONTROL
K. Kobara¹, M. Tanetani², M. Hirota³, H. Osaka¹
¹Kawasaki University of Medical Welfare, Department of Rehabilitation, Kurashiki, Japan
²Osaka Saiseikai Nakatsu Hospital, Department of Rehabilitation, Osaka, Japan
³Kawasaki Medical School Hospital, Department of Rehabilitation, Kurashiki, Japan

Introduction/Background

A simple and efficient method for posture control and preventing falls during walking is needed. We developed a novel device for this purpose using a laser pointer. We should investigate the effect of this device in posture control.

Material and Method

Thirty-five healthy young women (20.2 ± 0.5 years) were recruited. The device was placed on their right knee with the laser pointing toward the wall surface in front of their patella. The participants could see the position of their patella by looking at the laser point on the wall in front of them. During posture control practice, the participants stood on one-leg on the balance pad for one minute. Posture control practice was performed three days a week for two weeks. The participants were randomized to one of the three following groups: those practicing posture control with the device, those practicing posture control without the device, and those who did not practice posture control (control group). The rectangular area of center of pressure during one-leg standing on the balance pad was measured using a Gravicorder before and after practice to determine the effect of posture control practice. The measurements from the rectangular areas after practice were normalized to before practice [%BP]. For statistical analysis, one-way ANOVA and Bonferroni’s multiple comparison tests were performed ($p < 0.05$). This study was conducted with the approval of the Research Ethics Committee of authors' affiliation facility (# 15-079).

Results

The rectangular areas were 64.4 ± 17.1 %BP in the group that practiced posture control with the device, 86.3 ± 23.1 %BP in the group practicing without the device, and 99.6 ± 24.8 %BP in the control group. Participants who practiced posture control with the device had a significantly lower %BP than the two other groups.

Conclusion

These results suggest that this novel device can improve posture control.

Introduction/Background

Manual propulsion wheelchair with handrail propulsion, always ends up generating musculoskeletal disorders. The objective is to study with numerical simulations, the benefits of using an alternative propulsion system powered by lever.

Material and Method

A numerical approach has been developed to modelize muscles contributions considering a lever propulsion with this new wheelchair prototype. Arm movement has been modeled with AnyBody™ software to visualize the participation of each muscle and proximal upper limb muscular groups. This numerical model has been experimentally validated for the upper limbs. It will be possible to compare muscular group activations for a lever pushing propulsion stage compared to a handrail propulsion.

Results

The results of AnyBody™ simulation, for the propulsion phase, highlight an important muscular activity at the shoulder, anterior and lateral deltoid group levels for lever propulsion. Muscle activity is also observed in the triceps brachial group, long lateral triceps and major pectoralis as well. For an equal resistant load, the muscular activity decreases with the lever system. In addition, overall maximal muscle activity is lower with lever propulsion (13% max activity compared to 24% for handrail).

Conclusion

This study allowed us to develop a upper limb kinematic model that quantifies the activity of the main muscular groups involved in the movement of wheelchair propulsion by lever.

STUDY ON THE STANDARDIZATION OF THE EVALUATION METHOD FOR REHABILITATION ROBOTS

K. Murata¹, T. Asami², Y. Nanri¹
¹Saga University, Department of Rehabilitation Medicine, Saga, Japan

Introduction/Background

These days, many rehabilitation robots are used in clinical practice. In order to prove the effectiveness and safety of rehabilitation robots, it is necessary to standardize the method used to evaluate rehabilitation using robots.

The purpose of this research is to create evaluation standards for rehabilitation using robots and to standardize them.

Material and Method

In preparing evaluation criteria for rehabilitation that uses robots, the candidate evaluation items were objectively collected from past articles and academic abstracts. These items were classified into clinical evaluation items, economic evaluation items, safety evaluation items, and evaluation items related to engineering development.

For the first questionnaire survey, we divided the evaluation items into "upper limbs", "trunk + lower limbs", and asked about "measurement experience", "usefulness", "difficulty of measurement" and so on. This questionnaire was carried out at 63 facilities in Japan which are using rehabilitation robots. Based on the results of the first questionnaire, we carried out a second questionnaire survey and selected what seemed to be useful from among the collected evaluation items. Furthermore, we used the selected evaluation items in clinical practice and verified their practicality.

Results

As a result of the questionnaire survey, 27 items of "upper limbs" and 34 items of "trunk + lower limbs" were selected. The validity of the selected evaluation items was also verified. However, there were some problems such as: expensive evaluation tools are required, a large amount of time and labor for evaluation is required, and the sensitivity to rehabilitation using robots is low.

Conclusion

We conducted a questionnaire survey to standardize the evaluation of rehabilitation using robots and selected evaluation items that seemed useful.

We would like to increase the number of cases, narrow down useful evaluation items, and aim for standardization of the evaluation items for rehabilitation robots.

⁴University College London, Aspire Centre of Rehabilitation and Assistive Technology, London, United Kingdom

Introduction/Background

People with motor impairments can benefit from the use of a power wheelchair (PWC). However accidents can occur while driving, particularly outdoors. In order to reduce the risk, research has been performed for several years on driving assistance. Here, we present a curb-following shared control method for PWC driving assistance preventing the user from falling down the curb. Drop-offs are detected with distance sensors. Then, a curb-following algorithm is computed and the result is blended with user control, providing a progressive correction of the wheelchair trajectory.

Material and Method

The curb-following method has been developed and tested on a 15cm height sidewalk. In order to test the method in simulation, linear and angular user commands were automatically set to the maximum value towards the curb. Wheelchair commands and wheelchair trajectory were recorded. In PAMELA, the method has been tested with a standard PWC equipped with curb detectors on a 15cm height sidewalk. For this test, an able-bodied participant was driving the PWC on the sidewalk, towards the curb or along the curb.

Results

The trajectory of the wheelchair is modified in order to avoid from falling from the curb. The desired trajectory is respected as long as no negative difference of elevation is detected. When such an obstacle is detected, wheelchair linear and rotational velocities decrease until the wheelchair is parallel to the curb. Then, only the rotational velocity is restrained and the wheelchair can go forward and follow the curb.

Conclusion

The behavior of the system in simulation as well as while embedded on real wheelchair leads to a proof of concept of our method. The shared control model is flexible, computationally inexpensive and independent of the range measurement sensor type. Moreover, this work
showed the versatility of our method of wheelchair navigation assistance and encourages us to go further in our research process.

FEASIBILITY AND USABILITY OF A NOVEL ROBOTIC WALKER FOR POSTSTROKE GAIT REHABILITATION: A CASE REPORT

H.J. Cheng¹, F. Anaya Reyes¹, H. Yu¹, P. Thangavel¹, S.K. Seetharamani²
¹National University of Singapore, Department of Biomedical Engineering, Singapore, Singapore
²National University of Singapore, Department of Medicine, Singapore, Singapore

Introduction/Background

Stroke survivors suffer from impaired walking abilities, limited activities of daily living and poor quality of life. Conventional body-weight supported treadmill training can only be administered in clinical settings and the walking pattern on a treadmill is different from overground walking. Therefore, a novel robotic walker was developed to provide body weight support during overground walking for poststroke gait rehabilitation. The purpose of this study was to clinically evaluate the feasibility and usability of the robotic walker in stroke survivors.

Material and Method

Participants underwent four testing conditions in one session: walking with barefoot and walking with the robotic walker with 0%, 10% and 20% of body weight supported at National University Hospital, Singapore. We collected gait parameters and kinematics data. Friedman Test was selected to examine the difference among conditions and Wilcoxon Signed Ranks Test was chosen for further analysis. All statistical analyses were performed by IBM SPSS Statistics for Windows, Version 22.0 (α = 0.05).

Results

Three participants (all males, mean age 70.86 ± 4.23 years, mean time poststroke 20.00 ± 3.61 months) provided signed informed consent form and completed the experiment. There was no significant difference regarding gait parameters, but a trend showed that providing body weight support could improve gait parameters. Regarding kinematics data, walking with the robotic walker with body weight support provided significantly improved the range of motion of hip, knee and ankle joints of the unaffected side (p = 0.029, 0.042 and 0.042, respectively) and knee joint of the affected side (p = 0.042) compared with no body weight support. The range of motion of knee and ankle joints of the affected side were also improved but not significant.

Conclusion

The robotic walker is feasible and usable for poststroke gait rehabilitation. Larger clinical trials are warranted for testing its treatment effect.

Introduction/Background

Balance Exercise Assist Robot is a training assist system which combines personal transport assistance robot (robot) ridden in standing position and computer games. The robot moves to reflect the movement of the rider’s center of gravity (COG). The purpose of this study is to clarify the kinematic characteristics of the rider required for the forward and backward movements of the robot.

Material and Method

Eleven healthy male subjects participated in this study. The task were forward and backward movement in two conditions; 1) maximum movement required the game using the robot (robot task), 2) maximum COG movement on a flat floor (floor task). Each task was conducted once in 2 seconds, and it was performed ten times. Kinematic data were collected using a 3D motion analysis system and electromyography(EMG). These data were to calculate the displacement of COG, angular displacements of hip, knee, ankle joints and the maximum EMG activities of gluteus medius(GM), rectus femoris(RF), biceps femoris(BF), anterior tibialis(TA), medial head of gastrocnemius(MG), peroneal longus(PL) in right lower extremity. To compare with tasks, we performed a repeated measures ANOVA using a mixed model. The significance level was set at P<0.05.

Results

Both movements, the robot task had a larger COG than the floor task, and the angular displacement of the hip and knee joints were smaller. In the forward movement for robot task, the angular displacements of ankle joint, maximum EMG activities of RF were larger, but MG and PL were smaller than floor task. In the backward movement, the angular displacements of ankle joint, the all the maximum EMG activities except for the GM for the robot were smaller than floor task.

Conclusion
The forward and backward movement on the robot was a large movement with a small physical activity compared with the flat floor.

Introduction/Background

Balance Exercise Assist Robot (BEAR) is a training assist system that combines personal transport assistance robot (robot) ridden in standing position and computer games. The robot moves to reflect the movement of the rider’s center of gravity (COG). The aim of this study was to clarify the kinematic characteristics of standing position on the robot.

Material and Method

Eleven healthy male subjects participated in this study. The subjects were requested to keep a standing for 30 sec on the robot (robot task) or the flat floor (flat floor task) each 10 times. Kinematic data were collected using a 3D motion analysis system, the robot’s foot pressure sensor or stabilometer and electromyograph. These data were used to calculate the total locus lengths of COG and center of pressure (COP), the total joint momentums of the hip, knee, and ankle, the average muscle activities (gluteus medius: GM, rectus femoris: RF, biceps femoris: BF, anterior tibialis: TA, medial head of gastrocnemius: MG, peroneal longus: PL) in the right lower extremity. To compare between tasks, we performed a repeated measures ANOVA using a mixed model. The significance level was set at P<0.05.

Results

In the robot task, the total locus lengths of COG and COP, total joint momentums of hip, knee, ankle joints and muscle activities of the GM, RF, and TA were larger than flat floor task, but muscle activities of the BF, MG and PL were smaller.

Conclusion

Since keeping the standing on the robot is unstable compared to the flat floor task, active postural control was necessary. From the results of the muscle activity it turned out to be a different postural strategy. Exercise using BEAR is useful as a rehabilitation program aimed at improving postural control.

INTRODUCTION/BACKGROUND

Recently, the robot-assisted rehabilitation has emerged as a promising new technology for patients with severe lower limb impairment. The effect of rehabilitation including the concepts of repetitive, intensive, task-orientated training, which has been shown to be effective for chronic stroke patients, may be facilitated by using robotics in improving physical functions of patients. The aim of the present study is to investigate whether gait training using a robot suit HAL® (Hybrid Assistive Limb: an exoskeleton robot that enhances the limb motion of the human body by detecting the weak bioelectrical nerve signals) would improve gait functions in chronic stroke patients.

MATERIAL AND METHOD

Fourteen patients with chronic stroke in Kyoto University Hospital were participated in the study. They received 8 gait training sessions (60 min/session) using HAL® of double leg type during 3 weeks. Before and after intervention, gait speed (m/s), stride length (m), cadence (step/min), and 2-minute walk distance (m) were measured. Paired t test was used to determine the differences in outcome measurements between before and after intervention. Spearman’s rank correlated coefficients were calculated between change percentage of gait speed and change percentage of gait parameter (stride length or cadence).

RESULTS

Gait speed (0.56±0.32 → 0.71±0.41 m/s), stride length (0.72±0.32 → 0.82±0.35 m), cadence (90.0±29.4 → 98.7±33.2 step/min), and 2-minute walk distance (62.2±34.7 → 77.9±45.2 m) increased significantly after the intervention. The change percentage of gait speed was significantly correlated with the change percentage of stride length (r = 0.75), but not with cadence.

CONCLUSION
The results of the present study demonstrated that gait training using HAL® was an effective intervention, especially in improving spatiotemporal gait parameters and gait distance in chronic stroke patients.

Introduction/Background

The traumatic and non-traumatic pathologies that cause hand and wrist disability, have high incidence and high treatment costs related to the loss of productive life; new technologies are needed to facilitate rehabilitation and assist patients at home.

Material and Method

This is a descriptive study of clinical cases where robotic rehabilitation is applied for hand and wrist passive and active mobilization. The first patient had a complex fracture in the fifth right metacarpal; the second patient had a base fracture in the fourth and fifth right metacarpals; the third patient had severe hand and wrist spasticity after stroke; and the fourth patient had disability caused by traumatic cervical spinal cord lesion on C6 level. The instruments used were medical record, robotic orthoses PRO-Dix and PRO-Wix, exoskeleton EMMRA-1 (figure 1), disability arm shoulder and hand scoring (DASH), visual analogue scale (VAS), ashworth scale, and goniometer. All the patients received physical therapy complemented with robotic orthosis therapy, electronic control of the angle, strength and speed of movement was carried out according to the pain tolerated by the patients.

Results

The first and second patients had gain in degrees of movement of the metacarpophalangeal (MP) and the proximal interphalangeal (IFP) joints. The third patient had gain in degrees of movement of the hand and wrist joints and decreased spasticity. The fourth patient had neuronal reeducation process improving quality of life. All patient had pain reduction and
functionality improvement according to table 1.

Development of Prototype and Phantom Study of a New Portable Automatic Urinary Catheterization Device

H. Choi¹, J.S. Yoon¹, J.M. Kwak¹, S. Kang¹, H. Choi², G.H. Kim³
¹Korea University Guro Hospital, Department of Rehabilitation Medicine, Seoul, Republic of Korea
²Korea University, Department of Medical Sciences, Seoul, Republic of Korea
³Eulji University, Department of Biomedical Engineering, Seoul, Republic of Korea

Introduction/Background

Neurogenic bladder dysfunction is one of the most important sequelae after spinal cord injury, stroke or multiple sclerosis. Intermittent catheterization (IC) is an effective bladder management strategy for incomplete bladder emptying. However, the patients with impaired hand function are difficult to perform self IC and dependent to caregivers. Thus, we developed a new small-sized portable device for self catheterization.

Material and Method

The new device is composed of two parts; disposable part and operating part. The disposable part would consist of a penis cap which would contact with glans of penis and contain lubricational system, and a sterilized catheter. The operating part would include a gear and motor which would advance the catheter, and a rechargeable battery. The penis cap of disposable part would be docked with operating part. Then the operating part would advance the catheter into the penis cap and orifice of the penis. This system would be composed of sponge containing distilled water. As the pre-lubricated hydrophilic catheter used in this system would contact with the sponge, the catheter could be lubricated and glide smoothly into the penis.

Results

In a dummy model phantom study, the catheter was lubricated well and inserted smoothly into the bladder without any complications. We filed a patent for a new device lubrication system.

Conclusion

We confirmed a possibility of the newly developed portable automatic urinary catheterization device that could assist performing the IC. Even a patient with impaired fine motor ability in upper extremity or a caregiver might perform the IC easily using this device.

USING REAL-TIME PHYSICAL ACTIVITY MONITOR TO DEFINE PATIENTS’ RECOVERY: THE SENSING IN AT-RISK POPULATIONS (SARP) STUDY
1UCLA- David Geffen School of Medicine, Medicine, Los Angeles, USA
2West Los Angeles- VA Hospital, Geriatric Medicine, Los Angeles, USA
3UCLA, Computer Science, Los Angeles, USA
4UCLA, Center of Smart Health, Los Angeles, USA
5Cedars-Sinai Medical Center, Physical Medicine and Rehabilitation, Los Angeles, USA

Introduction/Background

Accurate assessments of functional improvement play a significant role in rehabilitation success. This study uses a smartwatch based remote sensor system to monitor physical activity in real-time.

Objective: To examine whether longitudinal changes in SARP correlate to changes in physical therapy (PT)/occupational therapy (OT) evaluations; and whether early changes of SARP correlate with functional recovery status.

Material and Method

Design: A prospective cohort study

Setting and Participants: Skilled nursing facility, 174 subjects

Methods: SARP monitored and classified physical activities as Assisted/Non-Assisted Walking and Active/Non-Active Sitting, Standing, and Lying Down, and calculated Energy from motion signals. Activity Tolerance (minutes), Gait (functional independence measurement (FIM) score), and Transfers (FIM score), were extracted from PT/OT records. Changes in SARP were computed based on the second and last day vs. first day differences. Changes in PT/OT activities were computed based on the second and last visit vs. first visit differences. Spearman correlations were performed to determine the association between SARP and PT/OT evaluations. The false discovery rate (FDR) tests were used to correct multiple hypothesis testing with a FDR<0.2 considered significant.
**Results**

Subjects’ mean age was 80.6 years with mean length of skilled nursing stay 23.4 days. Assisted and Non-Assisted Walking functional improvement from SARP were significantly associated with the functional gain of Activity Tolerance (both p<0.001, rho=0.38 and 0.36 respectively). Real-time changes of Energy were significantly associated with discharge status of Transfers (p<0.001, rho=0.45). Active Standing and Total Active minutes of the first day from SARP were significantly associated with functional improvement of Gait on Level Surfaces (both p<0.001, rho=-0.44 and -0.42 respectively).

**Conclusion**

SARP monitors physical functions in real-time accurately and significantly correlates to in-person evaluations. The early changes in SARP significantly correlate to discharge functional status. Moreover, the first day SARP data could predict physical resilience. Future study is ongoing to use SARP in an acute rehabilitation hospital and home settings.

⁴University of Oradea- Faculty of Medicine and Pharmacy, Clinical Hospital of Medical Rehabilitation Felix Spa, Oradea, Romania
⁵University of Medicine and Pharmacy "Carol Davila"- Teaching Emergency Hospital, Physical neural-muscular and Rehabilitation Medicine Clinic Division, Bucharest, Romania

Introduction/Background

The increasing interest in mechatronic/robotic technologies, for medical rehabilitation, changes the upper and lower limb neurological impairments therapeutic approach and introduces in the medical repertoire of methods, beside the current physiotherapists interventions, robotic-assisted medical interventions. Our purpose was to verify in which Balneal Resorts, where can be found traditional balneal rehabilitation interventions, they are now combined with robotic assisted possibilities, revealing a modern and advanced technological development of the medical/clinical units from the Balneal Resorts. This can improve, including medical addressability and increase health tourism in the respective resorts.

Material and Method

Specialty articles (Google Academic/Scholar Database) was searched for robotic medical rehabilitation. dealing with robotic rehabilitation devices have been searched and analyzed, combined with on the ground quest for information regarding this situation in main balneal resorts in our country.

Results

The main pathology spectra, approachable by robotic devices, evoked in the literature, consists of: stroke, traumatic brain injury, spinal cord injury, Parkinson’s disease/tremor, muscular dystrophy, peripheral nerve lesions, Cerebral Palsy, Multiple Sclerosis, Spinal Muscular Atrophy.

Therapeutical natural factors used for neuro/locomotor rehabilitation:
- salty and iodine waters (Govora);
- thermo-mineral waters (Felix, 1 Mai, Geoagiu)
- iodurate salty waters (Bazna)
- sulphur salty waters (Calimanești, Govora)
- sulphur thermal waters (Herculane)
- sapropelic mud and salty waters (Techirghiol, Amara, Sovata, Slanic Prahova);

Techirghiol and Baile Felix are the main resorts with expertise in neurorehabilitation and in the recent years have been provided with such robotic devices. **Conclusion**

Balneotherapy is acting by three main ways: thermally, mechanically and chemically. We suggest that the joint use perspective of natural therapeutic factors and physiotherapy with new robotic assistive interventions might increase the clinical importance of balneal resorts, and also include the modern trend of availing robotic assistive equipment to the benefit of patients.

CAN A NOVEL REHABILITATION ROBOT DEVICE CHANGE THE MUSCLE SYNERGY PATTERNS DURING WALKING IN INDIVIDUALS AFTER STROKE?

K. Ohata1
1Kyoto University Graduate School of Medicine, Department of Human Health Sciences, Kyoto, Japan

Introduction/Background

Rehabilitation Robots for improvement of gait dysfunction with neurological deficits have been developed to regain the adequate gait control. Motor relearning with repetition of assisted motion by robotic devices is assumed to be able to make the efficient motor kinematics and kinetics. However, it is not clear what changes with the motor control via motor relearning process with using robot devices occur during walking in this population. In general, the nerve system was considered to control the motion using a low-dimensional modular organization of muscle activation. We aimed to clarify the effect of the robots for muscle synergy control using non-negative matrix factorization.

Material and Method

Robot Knee Ankle Foot Orthosis (RKAFO) that can control the knee motion during gait was used as robot device to assist to normalize gait kinematics. In 8 participants after stroke, EMG signals from ten leg muscles on both sides were measured before and after robot assist walking for 3 minutes at self-selected speed.

Results

The number of modules on paretic side was less than that on non-paretic side. Furthermore, fewer modules were needed to be account for muscle activation in walking before robot assist than after robot assist. The number of fractionated synergy from before to after assisted gait related to the increase of gait speed by using RKAFO.

Conclusion

Our results suggest the muscle synergy coordination during walking was changed with normal motion induced by using robot assist in post-stroke subjects. And also, increase in number of fractionated synergy was related with higher gait function.

\textsuperscript{4}Advanced Telecommunications Research Institute International, Department of Brain Robot Interface, Kyoto, Japan
\textsuperscript{5}Higashisaitama National Hospital, Department of Rehabilitation Medicine, Saitama, Japan

Introduction/Background

Genu recurvatum is one of the common problems in patients with hemiplegia after stroke. For its improvement, it may be important to manipulate the ankle movement in coordination with the knee during gait. However, no device is available yet that can achieve it. We are developing a new exoskeleton robot that can assist knee and ankle joints simultaneously. This study aimed to test the feasibility of the robot in healthy individuals and patients with stroke, and to investigate its effect on genu recurvatum during gait.

Material and Method

Two healthy individuals and two patients with chronic stroke participated in this study. Healthy individuals received the robot-assisted gait training for 60 min in total. We assessed the safety of the training and muscle activities during gait with or without the robot-assistance. Patients with stroke had moderate lower-limb paralysis and genu recurvatum during gait. They received the robot-assisted gait training for 30 min in total. The robot consisted of a knee ankle foot orthosis and an actuator with pneumatic artificial muscles (Figure. 1). We adjusted the assist parameters to prevent their knee hyper-extension during the stance phase. We evaluated the range of knee joint motion, temporal and spatial parameters during over-ground gait without the
Results

All participants safely completed the training. The robot decreased muscle activities during gait in healthy individuals. One of the patients showed a decrease in the maximum knee extension range during the stance phase, an increase in the maximum knee flexion range during the swing phase, and improvements in the temporal and spatial asymmetries.

Conclusion

The robot which can assist knee and ankle joints simultaneously has a potential to be a new therapeutic device for genu recurvatum in patients with hemiparetic stroke.

UPPER LIMB ROBOT-ASSISTED REHABILITATION IN SUB-ACUTE STROKE: SLACKING OR ENGAGEMENT PROMOTION? EVIDENCE FROM PATIENT-ROBOT INTERACTIONS ANALYSIS.
C. Duret\textsuperscript{1}, A.G. Grosmaire\textsuperscript{1}, T. Koeppel\textsuperscript{1}
\textsuperscript{1}CRF Les Trois Soleils, Neurorééducation, BOISSISE-LE-ROI, France

Introduction/Background

After stroke, interventions based on active repeated movements stimulate neuroplasticity and enhances upper limb motor outcomes. Robotic devices using interactive and adaptive programs offer the ability to perform a large number of movements, including in patients with severe paresis. However, some authors argued that assist-as-needed algorithms would not ensure optimal patient’s participation. This retrospective study analyzed robot-patient interactions by measuring motor performance and robotic assistance parameters during robotic sessions.

Material and Method

16 patients (age 51±15) with upper limb paresis due to stroke carried out a 16-session robot-assisted training combined with usual care during the sub-acute phase (time from stroke, 43±15 days). The robotic program (5 days a week) comprised at least 2 consecutive series (S1 and S2) of 320 assisted reaching movements performed in the horizontal plane. Time of series completion, active-assisted motor performance (range of motion, accuracy, smoothness) and robotic assistance parameters during movements’ execution were analysed between S1 and S2 every 4 sessions during the training program.

Results

Time of 320-movement series completion, robotic assistance and motor performance were not different between S1 and S2 over the training (table 1).
The results indicated that a highly repetitive robot-assisted training for the upper limb can be associated with both sustained active participation and motor performance during robotic sessions. Robotic algorithms might optimize patient’s active engagement and motor performance in spite of an unparalleled number of repetitions compared to usual care.

HYBRID BRAIN-MACHINE INTERFACE TO PALLIATE THE MOTOR HANDICAP CAUSED BY DUCHENNE MUSCULAR DYSTROPHY: A CASE REPORT

A. Duprès¹, F. Cabestaing², J. Rouillard², V. Tiffreau³, C. Pradeau³

¹ISAE-SUPAERO, DCAS, TOULOUSE, France
²Université Lille1, CRIStAL, Villeneuve d'Ascq, France
³University Hospital of Lille, Physical Medicine and Rehabilitation Unit, Lille, France

Introduction/Background

We describe a hybrid Brain-Machine Interface (hBMI), designed for improving DMD (Duchenne Muscular Dystrophy) patients' autonomy. We assess relevance of our hBMI with 2 DMD patients performing the virtual driving task shown in figure 1. To adapt our hBMI to patients' motricity, it allows hand movement (real or intentional) detection by processing signals from electroencephalography (EEG), electromyography (EMG), and joysticks. It allows using different applications, by controlling an object (real or virtual) trajectory through movements of right hand, left hand, or both hands simultaneously. Right and left hand movements result in respectively a left and right rotation, whereas both hands movements move the object forward.

Figure 1: Karting driving task
Material and Method

Patients (men, 20/28 years) realized home-based experiments, using a portable equipment, thanks to a collaboration with Lille University Hospital and Centre Hélène Borel (Lille, France). As shown in figure 2 (Left) patient is seating in front of a computer displaying the task and recording 12 EEG signals from the primary motor cortex. Figure 2 (Right) shows EMG electrodes location over each hand.

![Figure 2: (Left): Hybrid BMI experiment overview. (Right): EMG location](image)

Patients instruction was to make 2 laps, by making hands movements detected in real time by processing EMG signals in OpenVIBE software.

Results

Figure 3 compares patients performing times (in seconds) to those of 10 healthy subjects performing the same task. Patients performances look quite similar to those of healthy subjects, suggesting that our hBMI is relevant for DMD patients. Moreover, we observe a learning effect between the two laps, expecting improvement with training.
Conclusion

After this conclusive preliminary study, we plan further experiments including more DMD patients. Offline EEG processing enables to identify motor-related patterns, necessary to detect movements at the cerebral level, and to propose an interface adapting to patient motricity.

SIMPLE REAL-TIME CLOUD-CONNECTED ACTIGRAPHY SOLUTION FOR MONITORING PATIENT ACTIVITY USING MOBILE PHONES
H.C. Chang1, A. Vezeridis2
1Cheng Hsin General Hospital, Department of Rehabilitation, Taipei, Taiwan R.O.C.
2UC San Diego, Radiology, San Diego, USA

Introduction/Background

Rehabilitation patient activity is not typically monitored in real-time due to lack of suitable actigraphy devices. We present an open-source actigraphy system with integrated real-time cloud data storage based on mobile phones for potential use in patient activity monitoring and quantitation.

Material and Method

An iPhone program was created to stream an actigraphy score to a cloud data storage service, Adafruit IO, in real-time. The actigraphy score is calculated as vector magnitude from three-axis accelerometer data at 2.5 second epochs.

Results

Actigraphy data was successfully streamed to the cloud storage and visualization platform at up to 30 Hertz, with 60 Hertz possible at a higher cost tier. Data was represented as decimal with two significant digits of precision. No movement at all is normalized to 0. Maximum vector magnitude with moderate walking was 0.39. Maximum vector magnitude with jogging was 1.02. Maximum vector magnitude with the phone in the hand during a throwing motion was 5.47. iOS reported energy draw was low (level 1 out of 20).

Conclusion

In summary, we present an open-source design for a simple and inexpensive real-time cloud-connected actigraphy system for rehabilitation patients. Alternative platforms and devices are discussed, as are security and cost implications. The widespread use of mobile devices and the iOS platform, with optional integration of global positioning coordinates and other phone data, are advantageous compared to purpose-built existing actigraphy solutions.

Lower limb trauma can cause kinetic chains impairments that compromise quality of movement and postural stability. A pilot study is now being conducted in INAIL Rehabilitation Center of Volterra using Hunova, a robotic system for lower limbs and core stability training and evaluation, to examine whether robot-assisted therapy is effective in motor control and gait performance recovery when compared to conventional rehabilitation programs.

**Material and Method**

Hunova consists of two mobile platforms for exercising in both seated and upright mono and bipodalic conditions. The device can operate in passive, active and assistive mode, detecting compensatory trunk movements with an inertial sensor and giving sensory feedback during exercise.

The ongoing open randomized controlled trial foresees the enrolment of fifty-six patients with functional locomotor impairments following work-related injuries of the lower limbs. Patients are randomly allocated to experimental or control group and receive a 3 weeks rehabilitation program and a pre and post treatment assessment including robotic, clinical and instrumental non-robotic evaluations.

All participants undergo an individualized rehabilitation protocol, tailored to specific patient needs and injury characteristics; the experimental group perform instability and resistive training with Hunova; control subjects follow a training program using traditional non-robotic equipment.

**Results**

Robotic therapy was well tolerated and easy to manage. An interim analysis on 37 patients shows that both groups benefited the proposed training protocol and robotic therapy was not inferior to conventional rehabilitation; moreover, patients with distal lower extremity injury show a significantly greater improvement in statistic stability than patients with proximal lower extremity injury.

**Conclusion**
Hunova allows to measure significant parameters of static and dynamic stability and can centralize a complex progression of exercises to recover trunk control and reactive balance after traumatic injuries. Final results of the study will contribute to explore the rule of robotic therapy in orthopedic conditions.

PSYCHOSOCIAL IMPACT OF POWERED WHEELCHAIRS ON PARTICIPATION PROFILE OF THEIR USERS
1. Domingues1, J. Silveira1,2, J. Pinheiro1,2
1Faculty of Medicine of the University of Coimbra, Faculty of Medicine of the University of Coimbra, Coimbra, Portugal
2Coimbra Hospital and Universitary Centre, Department of Physical and Rehabilitation Medicine, Coimbra, Portugal

Introduction/Background

Disability is a worldwide health issue and demands for support with assistive technologies, like powered wheelchairs (PW). The purpose of this study is to assess the psychosocial impact of PW on social participation and quality of life of its users.

Material and Method

From May to October 2017, 30 PW users were interviewed using the Quebec User Evaluation of Satisfaction with Assistive Technology (QUEST), the Psychosocial Impact of Assistive Devices Scale (PIADS) and the Activities and Participation Profile related to Mobility (APPM), in addition to some demographic, clinical and powered wheelchair related questions. Descriptive and correlational statistics were performed.

Results

From the 30 participants sample, 18 were men (60%) and 12 women (40%). The mean age was 40.63, ranging from 23 to 65 years old. Cerebral palsy was the most prevalent diagnosis (37%). All the participant's current PW was being used for at least 1 year. According to the data obtained from APPM, there was an average moderate limitation in social participation, with a mean score of 1.72 (SD = 0.69). The APPM score was negatively correlated with all QUEST scores, meaning the most satisfied users were the ones with a better performance on social participation (with less limitations and, therefore, a lower APPM score). A worst participation profile was noted among the users who use wheelchairs for a longer period. There was no relation between the psychosocial impact of the PW and participation.

Conclusion

According to our findings, the user's social participation doesn't seem to be related with the psychosocial impact of the PW. Although, there was an overall positive psychosocial impact of the powered wheelchairs, and, therefore, an increase in the quality of life of the users. Also, higher levels of satisfaction with the PW characteristics and assistance resulted in better participation outcomes.

PSYCHOSOCIAL IMPACT OF THE MANUAL AND POWERED WHEELCHAIRS ON THE PARTICIPATION. WHAT HAVE AGE AND TIME SINCE DIAGNOSIS GOT TO DO WITH IT?
A. Correia Martins¹, J. Pinheiro²³, P. Francisco¹, I. Domingues², J. Silva²³
¹IPC ESTeSC Coimbra Health School, Physiotherapy Department, Coimbra, Portugal
²Faculty of Medicine of the University of Coimbra,
Faculty of Medicine of the University of Coimbra, Coimbra, Portugal
³Coimbra Hospital and Universitary Centre, Department of Physical and Rehabilitation Medicine, Coimbra, Portugal

Introduction/Background

Recognizing that assistive technology (AT) for mobility play an important role in their users’ participation, it will be useful to rehabilitation professionals and services to assess if perceived psychosocial impact of such devices and associated services, systems and policies contribute to enhance lifelong capacity and performance. To build comprehensive rehabilitation services, information on a person’s experience in every aspect of his/her life is essential, including the role of psychosocial impact of the wheelchair on functioning and, particularly, in participation. “What have time since diagnosis (years) and age got to do with it?” was the other question addressed in this survey.

Material and Method

From May 2017 to January 2018, 73 wheelchair’s users (35 powered and 38 manual wheelchairs), mean age 48.66 +/- 15.68 years, 53.4% female, with mix diagnosis, were interviewed using the Psychosocial Impact of Assistive Devices Scale (P-PIADS), the Activities and Participation Profile related to Mobility (PAPM) and demographics, clinical and questions about the wheelchair.

Results

The participation profiles revealed that 8.2% of the participants present no restrictions, 13.7% mild, 32.9% moderate and 45.23% severe restrictions in social participation. All –PIADS subscales (competence 1.36, adaptability 1.29, self-esteem 1.04) and P-PIADS total (1.25) were positive and moderately correlated to the activities and participation profile. Age and type of wheelchair do not influence statistically the participation, however, number of years on a wheelchair and medium time since diagnosis do.

Conclusion

These results encourage the authors to keep studying the impact of the manual and powered wheelchairs on participation to develop robust evidence for rehabilitation, particularly after finding that age and time since diagnosis do not determine participation of the wheelchair’s
users. A wheelchair (manual or powered) correctly prescribed and trained represents an opportunity for improving competency, adaptability and self-esteem of its user at any time since diagnosis and throughout the lifetime.

ROBOTIC TREATMENT OF THE HAND ACCORDING TO IMPAIRMENT SEVERITY IN PATIENTS AFFECTED BY CHRONIC STROKE: A MONOCENTRIC LONGITUDINAL STUDY

S. Miccinilli, M. Bravi, F. Santacaterina, M. Morrone, S. Milighetti, F. Bressi, S. Silvia

1Campus Bio-Medico University of Rome, Physical and Rehabilitation Medicine, Rome, Italy

Introduction/Background

In 35% of cases stroke results in a severe disability of the hand and few studies investigated the effects of a robotic treatment in motor recovery after stroke. The present study investigated the efficacy of a hand rehabilitative treatment by means of Gloreha® robotic glove in motor recovery in subjects affected by chronic stroke with different impairment.

Material and Method

Monocentric longitudinal study. Chronic stroke subjects were assigned to two groups according to their ability to actively extend or not wrist for at least 20 degrees and underwent respectively active-assisted and passive Gloreha® treatment of the hand. All subjects were evaluated before and after treatment with Modified Ashworth scale, Upper Extremity Fugl-Meyer Assessment (FM), Motricity Index (MI), Motor Power Scale (MP), wrist goniometric measurement, dynamometric measure of strength, Nine Hole Peg Test, Grip Test, Quick Dash Scale. Treatment was provided for 20 consecutive sessions, lasting 40 minutes each.

Results

Thirteen subjects were enrolled, 6 underwent active-assisted treatment and 7 passive treatment. Active-assisted group showed significant improvement in: MI (“pinch” item p=0.023); FM (“shoulder-elbow” section p=0.026 and total score p=0.027); MP (“hand closure” item p=0.020, “dorsal extension” p=0.014 and total score p=0.026); Ashworth (total score p=0.039); strength (dynamometer p=0.003). Passive group showed a significant improvement in: FM (“shoulder-elbow” score p=0.026, wrist score p=0.016 and total score p=0.017); MP (“hand opening” item p=0.011, “hand closure” item p=0.011), FM (total score p=0.016); Ashworth (fingers score p=0.011, supination score p=0.008 and total score p=0.017).

Conclusion

Gloreha® revealed to be well tolerated, able to target hand treatment on differently impaired subjects. Severely impaired subjects can benefit from robotic treatment in terms of spasticity, whereas less impaired in terms of strength and function. The combination of repetitive, intensive, task oriented exercises with the sensory-motor feedback results particularly appropriate, in accordance with action observation therapy.

SHOULDER MOTION ASSISTANCE USING HAL (HYBRID ASSISTIVE LIMB) SINGLE-JOINT TYPE FOR IMPROVEMENT OF SHOULDER EXTENSION-FLEXION MOTION IN PATIENTS WITH PARALYZED DELTOID MUSCLES

H. Kadone¹, T. Makihara², S. Kubota², Y. Shimizu³, S. Onishi², Y. Sankai⁴, Y. Hada², M. Yamazaki²

¹University of Tsukuba, Center for Innovative Medicine and Engineering, Tsukuba, Japan
²University of Tsukuba, Department of Orthopaedic Surgery, Tsukuba, Japan
³University of Tsukuba, Department of Rehabilitation Medicine, Tsukuba, Japan
⁴University of Tsukuba, Center for Cybernics Research, Tsukuba, Japan

Introduction/Background

Patients with paralyzed control of deltoid muscles after neurological disorders tend to have impaired shoulder flexion when raising arm, compensated by excessive activation of trapezius muscles leading to shrugged shoulders. We developed a device for shoulder motion assistance using single-joint type HAL for training of such patients, by extending the HAL’s original function of providing joint motion assistance in accordance with bioelectric activation of relevant muscles. We report the development and assessment of the assistance by the device with healthy participants.

Material and Method

The single-joint HAL was fixed to a custom-designed platform and upper arm attachment, and aligned 3 cm below the acromion process. The surface electrodes to induce flexion motion were attached on anterior deltoid. This cross-sectional feasibility study included six healthy adult men with no impairment in shoulder motion (Figure). During shoulder motion with and without the device, activity of selected muscles of the shoulder was recorded using a wireless superficial electromyography device. Shoulder movement was captured using a three-dimensional motion analysis system.

Results
The HAL supported smooth flexion-extension of the arm at the shoulder joint, with no negative effects on vital signs, shoulder fatigue, and shoulder pain. The HAL decreased muscle activity levels, with a 55% decrease in trapezius muscle activity. The upward rotation angle of the scapula was significantly lower with the HAL at 120 degrees of shoulder flexion.

Conclusion

The single-joint HAL provided safe and effective assistance to scapular plane shoulder flexion-extension among healthy adults. Activity of trapezius muscles was significantly reduced during the assisted motion, suggesting that the device might be able to provide an effective method for improvement of patients with reduced control of deltoid muscles accompanied with compensatory excessive activation of trapezius muscles.

⁴Kikkoman General Hospital, Department of Orthopaedic Surgery, Chiba, Japan

Introduction/Background

This study aimed to evaluate the effectiveness and safety of using the upper limb single-joint Hybrid Assistive Limb (upper limb HAL-SJ) during elbow flexion training following elbow flexion reconstruction for brachial plexus injury (BPI). We present cases of two patients in whom the upper limb HAL-SJ was implemented 5 and 7 months postoperatively following elbow flexion reconstruction for BPI.

Material and Method

They underwent elbow flexion reconstruction with intercostal nerve-to-musculocutaneous nerve transfer (ICN-MCN transfer) after BPI. Postoperative training using the upper limb HAL-SJ was started from the Manual Muscle Testing (MMT) [1] elbow flexion power to MMT [3] once every week or every 2 weeks. Clinical evaluation included the MMT and active flexion ROM of the elbow joint at the start of every session.

Results

No serious adverse events were observed during the upper limb HAL-SJ training in two patients. Both patients could implement elbow training using the upper limb HAL-SJ even in MMT [1] of their elbow flexion power. Improvement in elbow flexion power of MMT [3] was observed after 15 sessions using upper limb HAL-SJ at 10 months postoperatively in case 1. Remarkable improvements in elbow flexion power were observed, as indicated by improvements in MMT from [1] to [3], after 32 sessions using the upper limb HAL-SJ at 16 months postoperatively in case 2.

Conclusion

Training with the upper limb HAL-SJ was performed safely and effectively in two patients with elbow flexion reconstruction with intercostal nerve transfer after BPI.

⁵University of Tsukuba Hospital- Faculty of Medicine, Department of Neurosurgery, Ibaraki, Japan
⁶University of Tsukuba, Center for Cybernics Research, Ibaraki, Japan

Introduction/Background

Ossification of the Posterior Longitudinal Ligament (OPLL) of the spine may induce motor impairment due to compressive myelopathy. Despite surgical decompression, some patients have residual motor disturbances; after surgery, there is no available intervention for this population. We propose the use of Hybrid Assistive Limb (HAL) robot to promote gait recovery in OPLL patients after decompression surgery.

Material and Method

Five acute and 7 chronic patients underwent 10 sessions of HAL therapy. Before the first and after the last session, walking performance was evaluated using the 10 meters walk test. To record segmental kinematics, a motion capture system (VICON MX, 100Hz) was used. Data was analyzed regarding the elevation angles described for thigh, shank and foot. Kinematic data from 8 healthy volunteers was used for comparison.

Results

HAL therapy improved the walking performance by increasing the speed and stride length in acute and chronic groups (figure 1).
Kinematics evaluation showed improvement in plane fitting for acute group (PV3 mean; pre: 0.03±0.01, post: 0.02±0.007. P-value: 0.02) but not for chronic group after HAL therapy. When compared to healthy, tendency of PV3 recovery was observed for acute group only (PV3 mean; healthy: 0.009±0.002. P-values; pre-acute Vs healthy: <0.01; post-acute Vs healthy: <0.01).
Comparisons between chronic and healthy did not show significant difference (Figure 2).

**Conclusion**

HAL therapy improved the walking performance of acute and chronic patients. Interestingly, improvement of loop planarity was only found for acute patients suggesting gait coordination recovery. Chronic patients may have achieved a functional level of coordination through previous rehabilitation and daily life activities.

GAIT TRAINING WITH A POWERED EXOSKELETON IMPROVE GAIT COORDINATION IN ACUTE STROKE PATIENTS

S. Puentes¹, H. Kadone², H. Watanabe³, Y. Sankai³, K. Suzuki⁴, Y. Hada⁴, A. Marushima⁵
¹University of Tsukuba, Faculty of Engineering- Information and Systems, Ibaraki, Japan
²University of Tsukuba Hospital, Center for Innovative Medicine and Engineering, Ibaraki, Japan
³University of Tsukuba, Center for Cybernics Research, Ibaraki, Japan
⁴University of Tsukuba Hospital, Department of Rehabilitation Medicine, Ibaraki, Japan
⁵University of Tsukuba Hospital, Department of Neurosurgery, Ibaraki, Japan

Introduction/Background

Stroke is a leading cause of acquired disability in adults. Despite rehabilitation, some patients cannot achieve a functional motor recovery. The Hybrid Assistive Limb (HAL) robot is an exoskeleton able to support and enhance the lower extremities performance of patients using their own bioelectrical signals. We think HAL may help acute stroke patients achieve an adequate motor recovery.

Material and Method

Eight hemiparetic patients underwent 9 sessions of HAL. A motion capture system (VICON MX, 100Hz) was used to record segmental kinematics regarding the elevation angles described for the thigh, shank and foot before the first and after the last session. Data from 9 healthy volunteers was used for comparison.

Results

Reduction of the percentage of variance was observed for the paretic (par) side of patients reaching similar levels to healthy (h) volunteers (P-value: pre-par Vs post-par: 0.039, pre-par Vs h: 0.018, post-par Vs h: 0.49). Tendency of recovery for the non-paretic side also was observed but was still significantly different from healthy group after HAL (P-value <0.01).

Conclusion

HAL improved significantly the planarity of coordination in hemiparetic acute stroke patients. This novel intervention offers a new approach to improve motor recovery in this population.

³Ibaraki Prefectural University of Health Sciences Hospital, Department of Orthopaedic Surgery, Ibaraki, Japan
⁴Ibaraki Prefectural University of Health Sciences Hospital, Department of Neurology, Ibaraki, Japan

**Introduction/Background**

The birth palsy is a peripheral nerve palsy resulting in disturbance in activities of daily living (ADL), and it occurs the co-contracture due to nerve misdirection phenomenon, such as co-contracture of between the biceps and deltoid, biceps and triceps. This case study aimed to report the effectiveness and safety of using the newly developed upper limb single-joint Hybrid Assistive Limb (upper limb HAL-SJ) for an adult with birth palsy.

**Material and Method**

A 40-year-old man sustained the birth palsy when he was born. He has both brachial plexus palsy (upper type, C5, 6, 7) with co-contracture between the deltoid and biceps. He did not undergo any operations. The rehabilitation training with left elbow exercise using the upper limb HAL-SJ was implemented for 12 sessions 3 every week as an inpatient. At baseline and after the upper limb HAL-SJ training, active flexion ROM of the elbow joint, elbow flexion 10-second testing, and dynamometric testing using a hand-held dynamometer (HHD) for the elbow flexion were evaluated without use of the upper limb HAL-SJ.

**Results**

The patient completed all 12 sessions of training using the upper limb HAL-SJ. No serious adverse events were observed during the upper limb HAL-SJ training. Improvements in active flexion ROM of the elbow joint, elbow flexion 10-second testing, and HHD for the elbow flexion were observed after 12 sessions using the upper limb HAL-SJ.

**Conclusion**

The rehabilitation training with the upper limb HAL-SJ could be performed safely and effectively for an adult with birth palsy.

CLINICAL ASSESSMENT OF STAND-UP AND SIT-DOWN MOTION ASSIST BY PERSONAL STANDING MOBILITY QOLO IN PEOPLE WITH SPINAL CORD INJURY

H. Kadone¹, Y. Shimizu², S. Kubota³, D. Paez⁴, T. Ueno², Y. Hada², K. Suzuki⁵, M. Yamazaki³
¹University of Tsukuba, Center for Innovative Medicine and Engineering, Tsukuba, Japan
²University of Tsukuba, Department of Rehabilitation Medicine, Tsukuba, Japan
³University of Tsukuba, Department of Orthopaedic Surgery, Tsukuba, Japan
⁴University of Tsukuba, Faculty of Engineering, Tsukuba, Japan
⁵University of Tsukuba, Center for Cybernics Research, Tsukuba, Japan

Introduction/Background

We developed Qolo, a new personal mobility device for those with motor disability in their lower limbs. It assists sit-to-stand and stand-to-sit postural transitions, as well as navigation in standing posture with hands-free operation. Its mechanism to assist postural transition is implemented with passive gas springs without using electric actuators, making it compact, lightweight and low cost. The purpose of this study is to report a clinical assessment of the device with people with spinal cord injury (SCI), and investigate plausibility of the device and discuss further technical improvements.

Material and Method

Four participants with SCI (age: 31-52y, 3 males and one female, neurological level: T10-L3, AIS: A-C, MMT Hip Ext.: 0-1, Knee Ext.: 1-5) were asked to conduct stand-up and sit-down postural transitions using the device (Figure). Feasibility and duration of the assisted motions were evaluated.

Results

Two of the participants conducted stand-up motion by themselves using the device (duration: 14 and 16s). The other two needed external posture support. The main factor that differed in relation to the ability of performing stand-up motion using the device was MMT Knee Ext;
greater than 2 for the group that was able to perform, and 1 for the other. All participants conducted sit-down motion by themselves using the device without external support (10-15s).

**Conclusion**

Capability of the device to assist posture transition was shown for some SCI people through the experiment. At the same time, greater assistance on the knee joint was found to be necessary. Because the device utilizes voluntary control of the trunk to induce assisted motion of knee and ankle joints for posture transition, we considered that assistance for trunk motion would be helpful for them. For the next step, we plan to introduce a mechanism for lumbar posture stabilization that can support motion of hip in coordination with knee.

MUSCULAR ACTIVITY CHANGES DURING VOLUNTARY WALKING USING ROBOT SUIT HAL (HYBRID ASSISTIVE LIMB) IN A PATIENT WITH SEVERE SPINAL CORD DISORDER

H. Kadone¹, S. Kubota², Y. Shimizu³, T. Abe², Y. Hada², M. Yamazaki²

¹University of Tsukuba, Center for Innovative Medicine and Engineering, Tsukuba, Japan
²University of Tsukuba, Department of Orthopaedic Surgery, Tsukuba, Japan
³University of Tsukuba, Department of Rehabilitation Medicine, Tsukuba, Japan

Introduction/Background

There are several reports on gait improvement after clinical intervention using a wearable robot suit HAL (Hybrid Assistive Limb) in patients with gait impairment after spinal cord disorders. HAL assists motion of the bilateral hip and knee joints during walking in accordance with voluntary joint motion intension of the user, based on bio-electric activation of the relevant muscles. However, movement-physiological or biomechanical detail behind the functional improvement by using the robot has not been discussed enough as far as we know. In this study, gait and muscle activity during walking using the robot are recorded and analyzed in a patient with gait impairment after severe spinal cord disorder.

Material and Method

The participant was a 64 years old man who showed severe sensorimotor dysfunction in the lower limbs, diagnosed as compressive myelopathy after cervico-thoracic ossification of posterior longitudinal ligament. HAL intervention was started 43 days after a decompressive surgery and included 10 sessions in total (Figure). In all sessions, gait and lower limb muscle activity during walking were recorded using a motion capture (VICON MX) and a wireless EMG (Delsys Trigno Lab) measurement systems.
Results

Comparing gait with and without HAL through the sessions, the walking speed, the step length and the ratio of swing to stance duration were greater in gait with HAL than without HAL. For the EMGs, activation of quadriceps muscles during stance was smaller and that of gluteus maximus (GMAX) was greater in gait with HAL than that without HAL in later sessions. The amount of increment of GMAX activation using HAL increased throughout the sessions.

Conclusion

Gait and lower limbs muscle activity were recorded through the intervention and analyzed in a patient with severe spinal cord disorder. Walking using the robot provided chances to walk in larger and smoother gait, which might lead to the gait improvement after the intervention.

No conflict of interest
Spastic diplegic patients with cerebral palsy (CP) have difficulty in performing activities of daily lives (ADLs) using their upper arms, due to weakness and abnormal tonus of the relevant muscles. Hybrid Assistive limb (HAL) single joint type for upper limbs is a portable wearable robot developed for elbow motion support. The purpose of this study is to evaluate feasibility and efficacy of HAL for spastic diplegic CP patients.

Material and Method

Two patients enrolled in this study. Case 1 was a 19 year-old male, classified as the Gross Motor Function Classification System (GMFCS); level IV and the manual ability classification system (MACS); level III. Case 2 was a 17 year-old male, GMFCS; level III, MACS; level II. Both had difficulty in voluntary elbow extension in ADLs, such as changing clothes. HAL intervention included 8 sessions. Each session consisted voluntary elbow extension-flexion training using HAL and clinical evaluation. The intervention was done for both sides in Case 1 and for the right side in Case 2. Clinical assessments were conducted before, during and after the intervention. Surface electromyography was used to evaluate the muscle activities of the biceps and triceps brachii during elbow flexion and extension. The modified Ashworth scale (mAs) score was evaluated before and after each session.

Results

In case 1, co-contraction during elbow flexion decreased during and after HAL session, compared to before. In both cases, voluntary elbow extension and flexion angle increased after intervention. In addition, the mAs score decreased after each session.

Conclusion

In both cases, elbow voluntary extension-flexion training using HAL was safe and feasible. We considered that it contributed to improvement of elbow motion control by reducing co-
contraction of flexor and extensor muscles. It might be a feasible option for rehabilitation in CP patients.

EFFECT OF SUPERVISED IMPLEMENTATION OF THE INTERNATIONAL CLASSIFICATION OF FUNCTIONING, DISABILITY AND HEALTH ON PHYSIOTHERAPEUTIC ELECTRONIC PATIENT RECORDS: A RANDOMIZED CONTROLLED TRIAL
L. Lamsens¹, K. Peers¹, L. Janssens¹, K. Caluwé¹, C. Kiekens¹, J. Van Eldere², J. Vandersmissen², K. Vanhaecht², L. Bruyneel²

²UZ Leuven, Department of Quality Improvement, Leuven, Belgium

Introduction/Background

Documentation of the International Classification of Functioning, Disability and Health (ICF) components in physiotherapeutic electronic health records may improve interdisciplinary productivity and efficiency. We examine the effect of targeted teaching and personalized feedback on physiotherapists’ completion of physiotherapeutic patient records and description of these components.

Material and Method

A randomized controlled trial in a tertiary care hospital in Belgium. Ten physiotherapists were included in the intervention group and five physiotherapists were in the control group. The intervention (2015-2016) included targeted teaching and weekly personalized feedback for a period of four weeks regarding reporting of ICF components in electronic patient records. At baseline, after targeted training, after each round of personalized feedback, and at long-term follow-up, electronic patient records for 10 random patients per physiotherapist in the intervention group were reviewed for completion of a physiotherapeutic patient record and reporting of ICF components. Data for the control group were collected at baseline, after the third round of feedback, and at long term follow-up. 670 and 140 patient records from 729 unique patients were reviewed for the intervention and control group, respectively.

Results

In the intervention group, all outcomes improved (Table 1 and Figure 1). Although reporting declined for several components between personalized feedback and at long-term follow-up, at both occasions patient record completion and reporting of ICF components of activity, participation, and personal factors were significantly higher compared to the control group. For environmental factors, the significant effect after personalized feedback disappeared at long-term follow-up. Reporting of body functions and structures improved similarly across groups.
Conclusion

Targeted teaching and personalized feedback improved completion of physiotherapeutic patient records and reporting of ICF components. Intervention strategies should factor in regular reminders to ensure continued reporting of ICF components in the long term.

¹Shuang Ho Hospital, Department of Physical Medicine and Rehabilitation, Taipei, Taiwan R.O.C.

Introduction/Background

Extracorporeal shock-wave therapy (ESWT), including radial (RaSW) and focused (FoSW) shock-wave types, has been widely used in clinical practice for managing musculoskeletal disorders such as tendinopathy. The difference in therapeutic effects between two shock-wave characteristics with different dosage levels for lower extremity (LE) tendinopathy remains controversial. The purpose of this systematic review and meta-analysis was to determine the difference in effectiveness between RaSW and FoSW as well as between high-dosage (HD) and low-dosage (LD) applications for patients with LE tendinopathy.

Material and Method

A comprehensive search of online databases and search engines, namely Medline, PubMed, Excerpta Medica database, the Cochrane Library Database, the Physiotherapy Evidence Database (PEDro), and Google Scholar, was performed. We included randomized controlled trials (RCTs) and observational studies reporting the efficacy of ESWT in treating LE tendinopathy. The included articles were subjected to a meta-analysis and risk of bias assessment.

Results

We finally included 19 RCTs, all of which were of high or good methodological quality, with a PEDro score ≥ 7/10. Meta-analyses revealed significant effects favoring general ESWT at immediate follow-up [pain score: standardized mean difference (SMD) −1.41, 95% confidence interval (CI) −2.01 to −0.82, P < 0.00001; heterogeneity (I²) = 95%; function: SMD 2.59, 95% CI 1.54 to 3.64, P < 0.00001; I² = 97%] as well as at 3, 6, and ≥12 months. In sequence, HD-FoSW, HD-RaSW, and LD-RaSW have superior pooled effects on overall clinical outcomes.

Conclusion

ESWT exerts an overall effect on pain and function, particularly in patients with LE tendinopathy. Shock-wave types and dosage levels may have different contributions to treatment efficacy, which must be investigated further for optimizing clinical practice.

USE OF OPTOKINETIC CHART STIMULATION TO RESTORE MUSCLE STRENGTH AND MOBILITY IN BED BOUND PATIENTS WITH CRITICAL CARE POLYNEUROPATHY AND OR MYOPATHY: 3 CASE STUDIES
B. Chitambira \(^1\)
\(^1\)East Kent Hospitals University NHS Foundation Trust, Physiotherapy- Richard Stevens Stroke Ward, Ashford, United Kingdom

Introduction/Background

Optokinetic chart stimulation (OKCS) is evolving as a neuro-muscular rehabilitation intervention for non-ambulatory patients critical care polynueopath and or myopathy. The aim of the presentation is to show and discuss benefits of OKCS for patients with critical care polynueopath and or myopathy.

Material and Method

The optokinetic chart is made of laminated A4 paper and consists of repeated colours of the rainbow. From 20 centimetres in front of a patient’s face, the chart was moved from side to side at one cycle per second for 3 minutes. The chart was then moved up and down for 3 minutes and then forwards and backwards for another 3 minutes.

Results

With the OKCS based treatment protocol, recovery from quadripareis and loss of mobility occurred in an in-patient setting. Three post intensive care unit (ICU) patients with aggregate manual muscle weakness of 1/5 on the Oxford Scale remained bed bound after at between 9 to 12 weeks of conventional therapy. After at least 6 weeks of OKCS, aggregate muscle strength improved to at least 4/5 The Barthel index scores improved from 0/20 for each of the cases to 17/20, 75/100 and 20/20 respectively. All the case studies regained their mobility.

Conclusion

OKCS shows preliminary efficacy in quadriparetic patients with critical care polynueopath and or myopathy. Early use of OKCS may prevent the deterioration in muscle strength and function taking place in the first place. OKCS aids what therapists do but does not replace the therapist. Randomised controlled trials are needed to provide evidence for its wider uptake in clinical practice.

IMPLANTATION OF SILICONE TUBING IN POSTMASTECTOMY LYMPHEDEMA
C. De Miguel Benadiba¹, C. Gandarias Zuñiga², P. Sánchez Tarifa¹, J. Ocaña Guaita², A. Duque Santos², A. Teixeira Taborda³
¹Hospital Ramón y Cajal, Rehabilitation, Madrid, Spain
²Hospital Ramón y Cajal, Vascular Surgery, Madrid, Spain
³Fundación Jiménez Díaz, Rehabilitation, Madrid, Spain

Introduction/Background

Multiple surgical techniques have been described in lymphedema surgery. All of them have great complexity and doubtful efficacy. Rehabilitation and Vascular Surgery Departments have developed a new method which consists in implanting hydrophobic tubing in the affected limb to create an artificial system for draining lymph.

Material and Method

This prospective study involved five patients (January-October 2017) with postmastectomy lymphedema stage IIb (according to the International Society of Lymphology classification) in upper limb, who had no severe pathology associated and who were motivated to following the subsequent treatment. Preoperatively and postoperatively lymphoscintigraphy was performed. The rehabilitation treatment consisted of decongestant therapy (10 preoperative sessions and 15 immediate postoperative) followed by sleeve compression therapy. Surgery was performed under general anesthesia for implanting 2-3 hydrophobic silicone tubing, from the most distal area (radio-metacarpal joint) to the most proximal (scapular region) of the affected limb. Subcutaneous cellular tissue consistency (plicometer), volume (tape measure) cellulitis and upper limb lymphangitis were recorded before and after surgery. Satisfaction was measured by VAS.

Results

Every patient had previous axillary lymphadenectomy. Most affected side was right (80%). Median of age was 59 years (range:45-69). Median of postoperative following-up was 8 months (range:4-13). Median of preoperative cellulitis or lymphangitis episodes was 2 (range:0-4). No patient presented infectious events during postoperative following-up. We found only one postoperative complication: the distal tube implant was cut. Median postoperative volume reduction was 2 cm (range:1-3 cm). Four patients presented significant improvement in consistency (clip reduction: 3 cm) and all patients reported a subjective improvement in quality of life after the procedure (median of VAS=8 [range:7-9]).

Conclusion
This initial experience with this new surgical technique shows promising short-term results in function as well as in consistency and in cirometry of the affected limb. It is necessary to validate these results with long-term and randomized studies.

Clinical practice guidelines in various countries recommend various lifestyle-oriented interventions for the treatment of Fibromyalgia (FM), including patient education, aerobic or other physical exercise, cognitive-behavioral therapy (CBT), and multi-component interventions. These approaches to FM management can be delivered in various forms, and Information and Communication Technology (ICT) may effectively address some of the challenges faced by those dealing with FM. The purpose of this study was to review the evidence for the effectiveness of existing ICT interventions for FM.

Material and Method

A literature search was performed in PubMed and Google Scholar, with relevant abstracts reviewed for inclusion.

Results

There is high quality evidence to suggest that a number of online interventions, including WEBSM, “Living Well with Fibromyalgia”, MoodGYM, and SMARTLog improve self-management of FM and certain outcomes. Additional research suggests added value for ICT on quality of life in FM in the areas of gaming, smartphone data collection and monitoring by healthcare professionals, integration of electronic health records to improve patient care, and new wearable monitoring technologies.

Conclusion

Users of existing online platforms that deliver evidenced-based multi-component treatment modules for FM and/or of FM symptom tracking systems experience improved outcomes. Moreover, various innovative ICT interventions are being developed with promising preliminary results. A user-centered approach to application development that takes into account the needs of all individuals with FM, regardless of their technological ability, is one key factor resulting in a successful intervention.

ISPR8-2330
A FEASIBLE CUSTOMIZED CAMERA-BASED MIRROR VISUAL FEEDBACK APPARATUS IN STROKE PATIENTS

L. Ding¹, X. Wang², X. Guo², J. Jia¹
¹Huashan Hospital, Department of Rehabilitation Medicine, Shanghai, China
²Shanghai Jiaotong University, School of Biomedical Engineering, Shanghai, China

Introduction/Background

It has been reported that there were kinematic disadvantages, like weight shifting, and perceptive limitations like insufficient embodiment which hindered the effectiveness of a plain mirror based mirror visual feedback (MVF). Some novel MVF apparatuses have been the focus of much interest, but sparse literatures on this topic reported the effectiveness in patients with stroke. The purpose of the study was to investigate the clinical feasibility of a camera-based MVF apparatus in stroke patients.

Material and Method

Eleven sub-acute stroke patients (Age (y): 53.08 ± 11.11; Duration (m): 12.00 ± 15.25; Male (N): 10; Left paralysis (N): 5) were recruited and received the camera-based MVF intervention as an adjunct treatment among their routines for 60 minutes per day, 5 times per week, lasting for four weeks. The primary outcome was the upper-limb function based on Fugl-Meyer Assessment (FMA); the Brunnstrom stages, modified Barthel Index (mBI), and the Berg Balance Scale (BBS) were the second outcome measures. Moreover, electroencephalogram (EEG) and behavior performance were recorded in the left/right hand judgement. All data was collected before and after intervention.

Results

The Wilcoxon-signed ranks test was employed for the Brunntrom stages, and pair-t test was used for other measurements. All the patients showed dramatic improvements of upper limb function after the treatment, see Table 1. However, the reaction time and accuracy during left/right hand judgement and the EEG signal analysis emphasized on altered motor pattern have not been completed yet.
### Conclusion

The camera-based MVF might be a feasible apparatus as an adjunct treatment to improve the motor function, quality of life, balance control and mental reaction in stroke patients.

VISUAL REHABILITATION TRAINING REGIMEN PLUS BINAURAL FREQUENCY ENTRAINMENT WITH FREQUENCY FOLLOWING RESPONSE ATTENUATE THE SEVERITY OF MYOPIA
S.D. Lee

Introduction/Background

Myopia is the most common refractive vision disorder which causes the refractive image formed by the cornea and the lens to fall in front of the photoreceptors of the retina. There is no widely accepted means of prevention or cure. The study is to apply several possible physical agent modalities on subjects with myopia.

Material and Method

Ten female subjects with myopia (mean spherical equivalent, -5.0 +/- 4.0 D; age 40.5 +/- 15.5 years) participated in the study. A visual rehabilitation training regimen (computer-based eye exercise therapy modified from Bates, Periocular TENS application, Post-occipital Thermotherapy) plus Binaural Frequency Entrainment with Frequency Following Response were performed for 60 minutes for one time and after two weeks.

Results

After 60 min of visual rehabilitation training regimen plus Binaural Frequency Entrainment, participants showed an improvement of 0.15 Snellen VA (R) and 0.15 Snellen VA (L) in uncorrected Visual Acuity. After 2 weeks of visual rehabilitation training regimen plus Binaural Frequency Entrainment, participants showed an improvement of 0.31 Snellen VA (R) and 0.43 Snellen VA (L) in uncorrected Visual Acuity from baseline.

Conclusion

These results show that computer-based eye exercise therapy modified from Bates, Periocular TENS application, Post-occipital Thermotherapy and Binaural Frequency Entrainment acutely and chronically attenuate the severity of myopia. The findings suggest that the combination of visual rehabilitation training regimen and Binaural Frequency Entrainment can be a potential therapeutic approach in improving sight in individuals with myopia. Further studies are required to investigate the underlying mechanism why these physical agent modalities can improve myopia such as via eye muscular relaxation or visual melanopsin.

USING TWITTER TO IDENTIFY HEALTHCARE CONSUMER SENTIMENT
D. Burke¹, C. Ibekwe¹, M. Jerome¹, M. Tran²
¹Emory University School of Medicine, Physical Medicine and Rehabilitation, Atlanta, USA
²Emory University Healthcare, Department of Computational Statistics, Atlanta, USA

Introduction/Background

Twitter is a social networking service, founded in 2006, and now with over 400 million monthly active users. This study was designed to assess the utility of Twitter as a tool for the assessment and comparison of healthcare systems.

Material and Method

Java and R programs were used to capture, analyze, and compare Tweets posted about one academic university hospital system and two community hospital systems in a large metro area in the Southeastern United States throughout 2016. Natural language processing with sentimental analysis was used in conjunction with an object clustering algorithm to categorize and quantify positive versus negative posts regarding care received at these facilities. An analysis of the positive and negative tweets for the academic facility was completed.

Results

Among the 12,579 Tweets captured for 2016, 89.4% were associated with the academic medical center, 9.7% with community hospital #1, and 0.9% with community hospital #2. Relative to annual patient visits, the use of Twitter was 0.31% for the academic hospital, 0.34% for community hospital #1, and 0.03% for community hospital #2. A majority of Tweets were positive for all three hospital systems. Hospital system #2 received the highest percentage of positive and the lowest percentage of negative tweets (Table 1). The subject of positive comments concerning the academic facility were hospital staff, hospital facilities, and hospital services, while the negative comments focused on appointments, wait time, and emergency room visits.
Conclusion

This study demonstrates the utility of Twitter to determine the overall sentiment of a segment of users of competing healthcare systems. In our initial analysis, we were able to compare the largest competitors of our academic system and to assess the topics of the positive and negative comments made by our healthcare system users. Further study and development of computing techniques are needed to fully maximize the potential this tool offers.

SWOT MATRIX ANALYSIS OF PHYSICAL MEDICINE AND REHABILITATION SPECIALTY IN IRAN
S.M. Rayegani¹, S.A. Raeissadat¹
¹Shahid Beheshti University of Medical Sciences, Physical Medicine & Rehabilitation Research Center, Tehran, Iran

Introduction/Background

The SWOT investigates the external environment to discover opportunities and threats and the internal environment to understand the strengths and weaknesses. As far as we know, the use of this system to rebuild and improve physical medicine and rehabilitation field has not been considered yet. However, this study aims to: 1) review the results which are derived from SWOT analysis on physical medicine and rehabilitation services, 2) describe how SWOT analysis may provide a new model to improve rehabilitation services.

Material and Method

This was a descriptive-analytical applied research. The qualitative study and SWOT analysis were used as research methods. The participants included 24 academic experts and 9 executive planners. Using convenience and targeted sampling method, the participants were selected from among university professors, experts, and planners in research field. The experts were informed by experienced and trained interviewers and the planners were informed by Association of Physical Medicine and Rehabilitation about study objectives.

Results

After examining and identifying environmental factors (including internal environment factors, i.e. strengths and weaknesses) and (external environment factors, i.e. opportunities and threats), the final factors are provided in tables 1, 2, 3, and 4.
Conclusion

Using SWOT analysis method and comparing the factors, 5 development strategies (SO) were determined using opportunities and strengths; 2 conservative strategies (WO) were determined taking advantage of opportunities and eliminating weaknesses; 2 competitive strategies (ST) were determined using strengths to prevent external threats, and 2 defensive strategies (WT) were determined for development of physical medicine and rehabilitation.

PHYSICAL ACCESSIBILITY OF THE UNIVERSITY OF KWAZULU-NATAL (UKZN) ENVIRONMENT TO PERSONS USING WHEELCHAIRS: A CASE STUDY IN SOUTH AFRICA

T. Nadasan¹, D. Goetsch¹, J. Subramoney¹, B. Thabede¹, S. Tembe¹, A. Rambally¹

¹University of KwaZulu-Natal, Physiotherapy, Durban- KwaZulu-Natal, South Africa

Introduction/Background

There are an increasing number of wheelchair users in South Africa. Despite government efforts to promote equality for all without discrimination, there remain barriers to accessibility that limit full participation by people using wheelchairs at Higher Education Institutions. Modern approaches aligned to the Social Model of Disability and Rehabilitation aim to remove these barriers by including travel time, exertion and ability to complete a task as parameters to assessing accessibility. Furthermore, these new approaches are yet to be applied to UKZN. The aims of this study was to assess the accessibility compliance of buildings to the South African National Standards (SANS) guidelines, to explore whether the travel time between lectures were adequate and to understand the main challenges experienced by students using wheelchairs.

Material and Method

A mixed method, qualitative and quantitative design. Participants were students using wheelchairs registered at UKZN (N=13) in 2015.

Procedures: Part A: Quantitative component measured compliance of Westville and Howard campus facilities according to SANS 10400 Building Regulations. Part B: Qualitative component were a questionnaire and an interview was conducted with participants addressing sufficiency of time during the changeover between lectures and challenges faced on campus.

Results

A total of 89 measurements indicated high level of non-compliance to SANS (94.4%). The main reasons for non-compliance for doorways were doorway width, handle type and height at various buildings namely cafeterias, libraries, lecture and examination venues. Lifts did not meet the internal dimensions lacking audible and visual warnings. The allocated lecture changeover time was mostly inadequate. Accessibility to lecture venues was the main challenge indicated by all the students with majority expressing its negative impact on their academic performance.

Conclusion
Westville and Howard campus measured facilities are not up to current standards with accessibility to lecture venues and lecture changeover time being the main challenges faced by wheelchair users.

RETURN TO WORK AFTER STROKE IN JAPAN: THE COLLABORATION BETWEEN THE MEDICAL REHABILITATION TEAM AND OCCUPATIONAL HEALTH PHYSICIAN

S. Saeki\textsuperscript{1}, K. Sugimoto\textsuperscript{1}, A. Hachisuka\textsuperscript{1}, J. Shiraishi\textsuperscript{1}, H. Itoh\textsuperscript{1}, N. Kato\textsuperscript{1}, M. Ochi\textsuperscript{1}, Y. Matsushima\textsuperscript{1}

\textsuperscript{1}University of Occupational and Environmental Health, Department of Rehabilitation Medicine, Kitakyushu, Japan

**Introduction/Background**

Considering the declining working population in Japan, it's important to promote work style reforms (WSR) to help women, elderly and disabled workers play more active roles in society, as well as raise wages. Japanese Prime Minister Shinzo Abe's latest key policy is this WSR. Promotion of return to work (RTW) after suffering a stroke is one of the important policy of Ministry of Health, Labor and Welfare (MHLW) for the balance support of treatment and professional life associated with the WSR. Then, the MHLW is going to structure the collaboration system between the medical rehabilitation team and occupational health physician in the workplace for RTW after stroke as a medical treatment reward. We introduce and discuss this system on the merits and demerits for RTW after stroke.

**Material and Method**

We surveyed the guidelines and documents made by the committee of the MHLW.

**Results**

The process of RTW after stroke is unique to each patient. Employment support for patients who become disabled after stroke comprises two steps: RTW after stroke and resuming work after returning. Many of the stroke patients had returned to work directly from not vocational rehabilitation but medical rehabilitation in Japan. Therefore, the connecting system between a hospital and the workplace is necessary, and the system would be effective by adding a medical treatment reward.

**Conclusion**

The collaboration system could be effective for RTW after stroke.

IMPLEMENTATION OF THE MOROCCAN DISABILITY ACTION PLAN: ACHIEVEMENTS, CHALLENGES AND BARRIERS

A. Hajjioui¹, M.K. Diouri², C. Gutenbrunner³, M. Fourtassi⁴
¹University Sidi Mohammed Ben Abdellah- Fez, Department of Physical and Rehabilitation Medicine, Fez, Morocco
²Ministry of Health, Rehabilitation and Geriatrics, Rabat, Morocco
³Hannover Medical School, Department of Rehabilitation Medicine, Hannover, Germany
⁴Université Mohammed Premier, Oujda, Morocco

Introduction/Background

Following the adoption of the Global Action Plan for People with Disabilities 2014-2021 by the WHO, the National Health and Disability Action Plan (NHDAP) 2015-2021 was presented on the 21st of October 2015 by the Moroccan Ministry of Health with the support of WHO and UNICEF. Two years later, we will outline the achievements and the potential barriers and facilitators for the implementation of the NHDAP 2015-2021.

Material and Method

The qualitative evaluation process aimed to take stock of the implementation of NHDAP 2015-2021 by establishing direct contact with the main actors involved in its implementation. The exchanges with the consulted interlocutors were intended to collect their assessment of the various NHDAP 2015-2021 measures’ implementation.

Results

During the years 2016 and 2017, several actions were carried out, in particular in the field of initial training and continuing education, by the introduction of a module on disability in the curriculum of medical schools and the implementation of a curriculum and training program for occupational therapists. A framework law on the protection and promotion of the rights of people with disabilities has been adopted in Morocco in 2016. Also, a national innovation and disability research award was launched in 2016. The main barriers to the implementation of the NHDAP 2015-2021 are an underfunding and lack of knowledge of the policy makers about the place of rehabilitation in the health care system.

Conclusion

2 years after its adoption, the NHDAP 2015-2021 implementation assessment remains positive despite the barriers and obstacles. The synergic efforts of the different stakeholders and the implication of policy makers are the keys to a successful implementation of the NHDAP 2015-2021.

PREVALENCE OF DYSPHAGIA IN CHINA: AN EPIDEMIOLOGY SURVEY AMONG 6102 PARTICIPANTS

M. Zhang¹, Z. Dou¹, C. Li¹
¹Affiliated 3rd Hospital of Sun Yat-sen University, Rehabilitation, Guangzhou, China

Introduction/Background

Dysphagia is relatively common among older population and patients with stroke, head and neck cancer or neurodegenerative diseases and can have a negative impact on their quality of life. The aim of this study was to explore the prevalence of dysphagia among these people.

Material and Method

The survey used three-step approach consisting of questionnaire screening (Sydney or Ohkuma Swallowing Questionnaire) and clinical evaluation (Kubota's Water Swallow Test) and instrumental assessment (videofluoroscopic swallowing study). The subjects consisted of elderly persons 65 years and older living in the communities/nursing home and three relative phenotypes of patients (stroke, head and neck cancer, neurodegenerative diseases) in the hospitals. We studied these participants whose dysphagia could be assessed by the three-step approach and compared the prevalence of deglutition disorders with age, gender and three Chinese economic regions.

Results

A total of 6102 persons met inclusion criteria. Of all the participants, 2363 (38.7%) were identified as having swallowing abnormalities and showed increased risk of oropharyngeal dysphagia with age. Dysphagia was found 46.3% in stroke patients of acute phase, 56.9% in stroke patients of chronic phase, 40.8% in Alzheimer's disease, 46.2% in Parkinson's disease, 12.5% in Multiple Sclerosis, 50.0% in Amyotrophic Lateral Sclerosis, 35.5% in head/neck cancer. The prevalence of oropharyngeal dysphagia has also been calculated in older persons across different settings, with rates 26.4% in nursing home and 13.9% in community-dwelling older people. This study demonstrates that dysphagia of male is higher prevalent than female in these populations. Comparing three Chinese economic regions, the average prevalence rate of deglutition disorder in the midland (55.0%) was obviously higher than east coast (37.1%) and west (32.5%) of China.

Conclusion
This study demonstrates that dysphagia is highly prevalent among patients with stroke, head and neck cancer or neurodegenerative diseases and the elderly in China. The prevalence of dysphagia were significant correlations with age, gender and economic region.

NEGATIVE EFFECTS OF INACTIVITY IN YOUNG PEOPLE

P.-D. Mihailescu¹, A.-C. Catanescu², F. Nechita³

¹Respiro Pro Lotus- Costimar Ortopedic,
Physical Rehabilitation Medicine- Orthotic and Medical Devices, Mioveni, Romania
²Transilvania University- Faculty of Physical Education and Mountain Sports,
Physical Education and Special Motility, Brasov, Romania
³Transilvania University - Faculty of Physical Education and Mountain Sports,
Physical Education and Special Motility, Brasov, Romania

Introduction/Background

Practical experience over the past years (both medical and sports-related) has led us to look for repercussions with regard to the fact that the number of children with poor body posture, overweight/obese and age-specific mobility is increasing more and more.

A decrease in overall sports skills is noticed in students from the field of physical education and sports, directly influencing the specific ones, impacting general health status.

Material and Method

Our goal was, aware of physical exercise’s vital role, to research the actual state over the past years within specialized institutions and their involvement.

We also wanted to find solutions to support us with regard to the practical, applicable side.

Annual reports issued by Ministry of Health, National Health Assessment and Promotion Center, The National Public Health Institute and National Institute of Statistics etc. revealed the most frequent issues to be: refraction deficits, obesity and posture deficits. The conclusions of these studies aim primarily at bad habits in children and young people with regard to nutrition and physical exercise. Subsequently, public intervention programs were designed and funded by the Ministry of Health and by other public or privately-owned institutions.

Results

Our research showed that there is major preoccupation on national level of state institutions and that the problems we found are the same. However, data linking reveals the need for practical intervention programs, which would act as a prevention measure in children and an improvement or treatment measure in young people and adults.
Conclusion

Also, medical policies need to be correlated with sports ones, multilateral training of the teaching staff is necessary, the number of physical education and sports classes needs to be higher (from 2 to at least 3/week), more compulsory subjects in the curriculum planning need to be introduced, aiming at healthy diet and its benefits over health (physically, mentally and socially).

A SITUATION ANALYSIS OF REHABILITATION SERVICE IN INDONESIA
G.R. Setyono1, I.R. Defi2, C. Gutenbrunner1, B. Nugraha1
1Hannover Medical School, Rehabilitation Medicine, Hannover, Germany
2Universitas Padjadjaran, Physical Medicine and Rehabilitation- Faculty of Medicine, Bandung, Indonesia

Introduction/Background

People with disability (PWD) in Indonesia are one of vulnerable groups. They are often neglected in the society. They have also barriers to access many facilities to participate in their social life, including access to health services. Rehabilitation is a health services and strategy that can improve functioning, quality of life and participation of PWD in society. However, it seems rehabilitation services in Indonesia still need to be improved. Before taking any action for an improvement, a situation analysis on rehabilitation services and its provision in the country is a precondition. Thus, this study aimed to collect available data of the current situation related to disability and rehabilitation services in Indonesia.

Material and Method

Rehabilitation Services Assessment Tool (RSAT; Gutenbrunner and Nugraha, 2017) was used as a framework to collect the data systematically. From the collected data, gaps were analyzed. List of generic recommendation to improve rehabilitation services in the country was generated.

Results

Findings show that Indonesia faces enormous challenges in the field of rehabilitation services, including health workforce, service delivery, health information systems, and provision. Results from this situation analysis were used to generate generic recommendations that may be used to further discuss with relevant stakeholders to develop national strategy /action plan in strengthening rehabilitation services in the country.

Conclusion

In the health services, particularly rehabilitation, strengthening rehabilitation services is crucial, including in health workforces and their distributions, coordination among ministries, education, and information about disability and rehabilitation service provision.

DEVELOPMENT OF A CEREBRAL PALSY REGISTER IN A SMALL AREA.
M. Avellanet1, E. Aisa2, A. Mena3
1Hospital N Sra de Meritxell, Rehabilitation - Paediatric Developmental Unit, Escaldes-Engordany, Andorra
2Hospital N Sra de Meritxell, Paediatric Developmental Unit, Escaldes-Engordany, Andorra
3Complejo Hospitalario de Navarra, Rehabilitation, Pamplona, Spain

Introduction/Background

Population registries facilitate the identification of cerebral palsy (CP) cases within a specific geographic population. The aim of our study is to build up a CP register in Andorra. As a small area, data will help to describe all features of CP and to optimise management of resources and patients’ follow-up.

Material and Method

Based on the items described in the Survey of CP Registers and Surveillance Systems and on the Surveillance CP in Europe (SCPE) instructions, a population register has been set up. The registry consists of 118 items divided into seven sections: child affiliations, maternal history and parents’ information, pregnancy and neonatal period data, diagnoses and classification, neuroimaging tests, therapeutic interventions and others. In order to test its validity, we firstly enter data of patients attending Paediatric Rehabilitation consultations in Navarre and in the Child Development Unit of Andorra, two differentiated and geographically delimited health areas. Data were collected on a face-to-face interview basis. Written informed consent was obtained either from patients or their families. Secondly, information was also obtained from the electronic medical record system of the National Health System.

Results

53 patients (47.1% males, 52.8% females) were evaluated to test the register validity. Data were consistent with published epidemiological features in Europe, except for the incidence (1.2 / 1000 inhabitants) due to limited access to patients. With the Ministry of Health support, we have continued collecting data from patients aged fewer than 25 who contacted the National Health Service.

Conclusion

The use of population registers allows a better knowledge of CP as well as the evaluation and development of prevention strategies and optimisation of care resources with objective data. Our next step will be to obtain data from other sources such as social and educational services, according to recommendations established by the SCPE.

MUSIC AS AN ADJUVANT TO OPIOIDS?
S. Guétin¹, T. Jacques²
¹University Paris 5 - René Descartes - France,
Clinical Psychology and Psychopathology Laboratory EA4056, Paris, France
²CHU Montpellier, Neurology Department- INSERM U1061, Montpellier, France

Introduction/Background

International epidemiological studies on opioid use have highlighted the lack of effective complementary therapies capable of reducing the consumption of these dangerous medications. For example, opioids are currently killing an average of 123 people every day in the USA. A national emergency plan to deal with this issue was recently declared in October 2017.

Material and Method

There is therefore an urgent need to propose non-medicinal therapies as an alternative for patients who have to deal with pain on a daily basis. At present, the international literature clearly describes the neurophysiological actions and potential applications of using music for therapeutic purposes in order to manage acute and chronic pain. The impact of music on the localisation and intensity of dopaminergic activity has been demonstrated using neuro-imaging techniques (1).

Results

Both music and opioids stimulate reward circuits in the brain (2). For example, meta-analyses of the Cochrane Database have demonstrated a significant reduction in the preoperative use of opioids if patients can listen to music tailored to their tastes. The recent scientific literature has also described certain digital applications which include innovative algorithms in the field of music care. Use of these new digital applications would optimise the therapeutic efficacy of musical interventions designed to modulate pain and reduce opioid use.

Conclusion

Some digital applications in the music therapy field have demonstrated their efficacy and already enabled a large number of patients with acute and chronic pain to significantly reduce their consumption of medications without experiencing any adverse effects.

IMPORTANCE OF VEHICLE EMISSION CONTROL FOR VOCATIONAL AND ADL IMPROVEMENT IN MALE PATIENT WITH SEVERE CHRONIC OBSTRUCTIVE PULMONARY DISEASE (COPD): A CASE REPORT

D.M. Sari¹, M.A. Moeliono¹

¹Staff lecturer, Physical Medicine and Rehabilitation, Bandung, Indonesia

Introduction/Background

Prevalence of COPD in Indonesia had reached the number of 3.7% in 2013, most frequent in male and elderly. Since air pollutant is an important risk factors for COPD after smoking, local regulations such as vehicle emission test had been established but still need evaluation in the implementation. Herein we present a case of a male patient employed at outdoor parking lot with disturbed activity of daily living (ADL) due to severe COPD.

Material and Method

A 61-years old male patient was consulted after acute exacerbation of COPD. He had a history of smoking 1 cigarette pack per day for 18 years, stopped at 2010 after his first exacerbation. He had been working for about 20 years in outdoor parking lot with the consequence of daily exposure to vehicle emission. He was unable to change jobs due to socioeconomic factor. He had severe grade COPD (MMRC = 4, CAT = 14) and spirometry showed obstructive result (FEV1: 23%, FVC: 33%). Six minutes walking test was stopped after 4 minutes because of desaturation from 92-94% to 88%. Barthel index of 18 showed his disturbed ADL (bathing and dressing). Patient was encouraged to use face mask at workplace to reduce pollutant exposure, add ventilation, and plants around his house. Patient was also encouraged to routinely walk in the park to increase exposure of oxygenated environment. Routine symptom-limited training with monitoring of Borg scale and oxygen saturation was also implemented to optimize endurance and control breathing training for dyspnea.

Results

Disturbance in ADL still persisted in this patient despite of absence of exacerbations.

Conclusion

Rehabilitation strategy without completely avoiding vehicle emission exposure was not enough to improve the condition of patient with severe COPD. Socialization and implementation of vehicle emission laws still needed to be strongly encouraged by the stakeholders to promote healthy working environment.

Introduction/Background

The role of physiatrists with severe brain injured patients and intensive care unit (ICU) teams is often pointed out but remains still partly unknown. We aimed at evaluating, from ICU physicians and physiatrists' points of view, the characteristics of interventions of physiatrists in ICU (especially concerning end-of-life decisions) and their possibilities of development.

Material and Method

A national study using an online survey was performed between January and September 2017, sent to ICU physicians (n=181 answers) and physiatrists (n=35) dealing with severe brain injured patients.

Results

A large majority of ICU physicians (72%) collaborated with physiatrists in their practice, most often non-routinely (78%) on a weekly (30.5%) or monthly basis (36.6%). Physiatrists mainly helped ICU teams in post-ICU orientation of patients (85%), but also in clinical assessment (55%). Considering end-of-life decisions, solicitations of physiatrists were rare in the ICU physicians' point of view (47% on an annual basis), but more frequent in the physiatrists sample (monthly or bimonthly=48%), and was considered as beneficial or necessary for 70% of ICU physicians. Physiatrists and ICU physicians gave the same importance in the end-of-life decision process to clinical and paraclinical examinations, but not to patients socio-economic data. Physiatrists mainly conceived their interventions in end-of-life decisions in complex cases (56%), their legitimacy in this domain was rated as 6.5/10 (10=high legitimacy) by ICU physicians. Improving the collaboration between both specialties was a common desire (of 68% of physiatrists and 88% of ICU physicians).

Conclusion

Physiatrists have a specific and important role to play with severe brain injured patients in ICU, in various domains of action including particularly orientation, assessment or end-of-life decision process. This role should be promoted and better valorized.

BODY MASS INDEX AND PHYSICAL ACTIVITY DURING LEISURE TIME OF THE STUDENTS OF MEDICINE

S. Jandric

Faculty of Medicine of University of Banjaluka,
Department of Physical and Rehabilitation Medicine, Banjaluka- Republic of Srpska,
Bosnia - Herzegovina

Introduction/Background

There is evidence for the importance of promoting a healthy lifestyle and normal-weight in order to reduce health risk. The aim of this study was to examine the association of Body mass index (BMI) and various leisure time physical activities: frequency of playing sport during leisure time (FPSLT), frequency of television watching (FTW), frequency of walking during leisure time (FWLT), frequency of cycling during leisure time (FCLT) and minutes per day spent walking and cycling to get around (MDWC) of the students of Faculty of Medicine.

Material and Method

The study was designed as a cross sectional study that included 76 of students of medicine (60 female and 16 male), average age of 26.4 ± 3.3 years. Instrument used to measure a person's leisure time physical activity of the students was the questionnaire of Baecke et al. Pearson's test of correlation and Linear regression (ANOVA) were used to analyze numerical data. Differences were statistically significant on the level of p<0.05.

Results

Average value of BMI of the students was 22.2±2.5 kg/m2 (range of 18-28.3 kg/m2). Results of Linear regression with the BMI as dependent variable have shown that FCLT is significantly associated with BMI (t=2.254, p<0.05). Results of Pearson's test of correlation have shown that there was statistically significant association between age and frequency of FWLT (r=0.355, p<0.05), BMI and FCLT (r=0.395, p<0.05), and negative association between FTW and MDWC (r=-0.329, p<0.05), FTW and FPSLT (r=-0.418, p<0.001).

Conclusion

Results of our research show that average value of BMI of the students was in range of normal-weight and that BMI is significantly associated with frequency of cycling during leisure time. There was statistically significant association between age and frequency of walking during leisure time. These findings can be important for planning leisure time physical activity of medical students.

Introduction/Background

Clinical-quality registries have an important role to play in improving quality of care via monitoring and benchmarking of clinical care outcomes. The inclusion of process measures in the data collection enables exploration of variations in additional aspects of service provision, such as timeliness of access to care and clinical approaches. Additionally, registries which provide outcome reports for specific patient populations (“disease” registries) have been demonstrated to act as a catalyst for improving the quality of care provided, often at a lower cost.

Material and Method

AROC commenced operations on the first of July 2002, a joint initiative of the Australian rehabilitation sector and the Australasian Faculty of Rehabilitation Medicine. Now, 15 years later, AROC holds data describing more than a million episodes of inpatient rehabilitation care in its database, collected from 280 rehabilitation units across Australia and New Zealand. AROC provides regular benchmarking reports to all members, supported by annual quality benchmarking workshops.

Results

The use of benchmarking and decision support tools has improved the efficiency of care whilst introducing a common language and increasing standardisation in practice. In addition, the less direct aspects of registry operations such as the facilitation of networking across the sector, the facilitation of translation of benchmarking results into practice and process changes, the access to the registry data to underpin research in the sector, provide added value and extend the registry from a single dimension initiative to a powerful platform for improving the quality and value of rehabilitation.

Conclusion

The AROC clinical registry is a valuable resource for the rehabilitation sector, and provides an example of how clinical registries can function as powerful platforms for improving health outcomes, potentially lowering health care costs, and increasing health care value. In addition they can act as a data spine to facilitate more efficient, less expensive clinical research studies.

ADDITIVE MANUFACTURING FOR PROSTHETICS AND ORTHOTICS: FASHION OR TECHNOLOGICAL NECESSITY
G. Ponomarenko¹, M. Golovin², K. Shcherbina²
¹FSBI FSCRD named after G.A. Albrehta Ministry of Labor, Administration, Saint-Petersburg, Russia
²FSBI FSCRD named after G.A. Albrehta Ministry of Labor, Institute of prosthetics and orthotics, Saint-Petersburg, Russia

Introduction/Background

In technically developed countries, additive manufacturing is actively developing in production. In particular, it opens new opportunities in the manufacture of prostheses and orthoses.

Material and Method

Currently, the manufacturing process on CNC machines is widely used in the prosthetic and orthopedic industry and is well combined with the prosthesis and orthosis traditional manual manufacturing. There is a fundamental limitation: traditional technology, like its symbiosis with CNC technology, makes it possible to combine materials with different physical properties within a single product only by combining different parts. With additive manufacturing one detail can consist of a variety of materials, providing conflicting requirements for various areas at the design stage. The variety of materials available for the sockets requires the creation of 3D printers of in principle different technologies.

Results

3D-printing does not compete in cost with traditional manufacturing technology. In developing countries, the economic benefits of such technology are not obvious. However, the use of 3D-printing technology is necessary to accelerate the rehabilitation of a large number of victims as a result of wars, regional conflicts, and emergency situations - for a one-stage manufacturing of prostheses for a large number of patients. 3D-printing is justified in case of complicated stumps and atypical prosthetics, when the task of stump's comfort in the prosthesis socket can be solved by combining materials with different properties. At present, the speed of socket's additive manufacturing in the best practices is manufactured in 2,5-3 hours, which is comparable with the time by a qualified specialist.

Conclusion

Prospects for the development of 3D printing sockets of prostheses and orthoses are in the plane of development of artificial limbs's remote manufacturing, using 3D-scanning. Additive
manufacturing is part of the digital and "smart" factories of the future, which are parts of a virtual factory – it indicates a great potential of this technology.

Acute stroke care is extremely well organized in Czech republic, with high availability of thrombolysis and thrombectomy treatment and stroke unit care, but only 10-12% of stroke patients are transferred to acute rehabilitation beds. Comprehensive stroke center of our hospital treats up to 900 stroke patients a year. Only 3% of them are admitted to general rehabilitation ward. They represent only 4.6% of all admitted patients.

**Material and Method**

Retrospective analysis of stroke patients data from 2014 to 2017 was carried out. NIHSS, mRS and Barthel index, time from stroke to admission, from what type of care, days of hospitalisation, rate of complications interfering with rehabilitation and type of care discharged to were evaluated.

**Results**

Complete data were available for 90 of 115 patients, 60 males and 30 females, age 29 to 89, mean 67, average 63 years. 70% were transferred directly from neurology bed, 12% from nursing facility, 16% came from home and 2 % from another rehab facility. Time from stroke to admission was 8-135 days, mean 25 days. NIHSS reached 0-16, mean value 6 on admission and 4 at discharge. Barthel index spanned 5-100, mean 80 increased to mean 90. Average mRS of 3,3 decreased to 2,9. Length of stay reached 10-30 days, 19 days on average. Complications appeared in 11% of patients, resulting in preterm end of rehabilitation in half of them. 41% of patients were discharged home, 41% to another rehabilitation facility, 12% to acute hospital bed and 6% to nursing facility.

**Conclusion**

Patients admitted to our general rehabilitation ward belong to younger, more self sufficient population of stroke victims with moderate neurological deficit and good potential for recovery. Parameters analysed above do not explain low percentage of patients after stroke admitted. Retrieved data can incourage more frequent admission of stroke patients who benefit substantially from rehabilitation.

Introduction/Background

Clinical Care Pathways (CCP) optimize quality of care and resource allocation in health systems. They translate guidelines or evidence into local practice. This work aims to provide a methodological approach for drafting a CCP, referring to a model for the prevention, diagnosis and treatment of post-stroke disability.

Material and Method

The research method is based on a six-stages process: identification of health needs to priorities in the local care system; establish a multidisciplinary working group; selection of guidelines and evaluation of quality with the Grilli criteria, the AGREE and GRADE methodology; integration of gaps/updates among guidelines; adaptation to the local context; regular updating. The output is an integrated flow-chart. Indicators are identified for auditing.

Results

3 international guidelines were selected (NICE 2013, Canadian 2015, AHA/ASA 2016). The US one was excluded because of non-comparable health services in the two countries. Evidence for upper limb robotic rehabilitation was obtained with a narrative review by the authors. Outpatient rehabilitation is the most appropriate context for management of post-stroke disability. Access to outpatients is regulated by the rehabilitation physician, the GP or other specialists involved in stroke care. A clinical and instrumental assessment will provide indication to physical, medical and/or surgical treatments. Cognitive deficits will be already been identified and treated from the Stroke Unit. Follow-up entails clinical and/or instrumental re-evaluations, treatment modifications, or exit from the pathway. The “process” indicators include: number of first accesses; number of visits/year; time to access to service from prescription; number of control visits and retreatment. Among “outcome” indicators there are: complications; number of resolved cases; access within 6 months of the acute event.

Conclusion
This CCP was designed according to international standards for CCPs. Adaptation to the local context led to the development of a codified and univocal pathway with a specialized and personalized care for patients with post-stroke disability.

EXAMINATION OF DISASTER RESPONSES UTILIZING THE DISASTER IMAGINATION GAME (DIG) AT A REHABILITATION CENTER—A STUDY BASED ON PARTICIPANT EVALUATION—

A. Nasu¹, H. Satou², K. Hanayama³, K. Chinone², S. Miyahara², A. Washida², M. Kawasaki², H. Abe³, K. Watanabe¹

¹Kawasaki Medical School Hospital, Nursing, Kurashiki, Japan
²Kawasaki Medical School Hospital, Rehabilitation center, Kurashiki, Japan
³Kawasaki Medical School Hospital, Department of Rehabilitation Medicine, Kurashiki, Japan

Introduction/Background

In recent years, various approaches have been taken in order to improve and reinforce the medical system at the time of disasters, such as the development of manuals at the facilities at individual medical treatment locations and simulation trainings against disaster occurrences at various settings. Though the rehabilitation center at our hospital also implements evacuation drills, anticipating fire and earthquake in order to train staff on how to check on patients or transport them. We sensed the necessity to provide reinforcement regarding disaster response and decided to employ the Disaster Imagination Game (DIG) in disaster drills. This study is a report of the change of the disaster preparations enforcement for therapists consciousness after the DIG.

Material and Method

DIG was carried out in the rehabilitation center at our hospital. An anonymous questionnaire survey was conducted on the participants of DIG. We compared the data after enforcement if before DIG enforcement.

Results

For the total of 42 research participants, their self-evaluation score through VAS in self-efficiency regarding their capability to properly respond to disasters came out to be 44.4, which increased from the pre-DIG score. Self-efficiency in other items such as role sharing on the occurrence of disasters, information gathering as well as their response to the anticipated case of transporting patients also increased respectively, whereas their anxiety at the occurrence decreased.

Conclusion

The DIG implemented in this research has improved the participants’ self-evaluation in responding at the time of a disaster occurrence. In addition to the fact that the effectiveness of the preparatory training was verified by the nurses’ responses in the Great East Japan
Earthquake, the result of this research suggests the strong possibility that repeating DIG as disaster response preparation could lead to a reinforcement of their responding capability.

**Introduction/Background**

Most of patients with stroke and traumatic brain injury (TBI) suffer from lack of persistent and appropriate rehabilitation program after discharge. It is needed to develop the hospital and community-linked education program (HCLEP) for community reintegration of patients with brain injury after discharge. Thus, the aim of this study was to investigate perspectives of health professionals in rehabilitation field to decide appropriate items in HCLEP.

**Material and Method**

In this study, rehabilitation physician, nurse, physical therapist, occupational therapist, social worker, and others were participated (n = 204). An electronic survey was performed to decide education items for community reintegration of patients with stroke and TBI. To quantify the required degree of several items which can be included, Likert 5 point scale was used and a rating average for responses of each item was calculated.

**Results**

In this study, respondents strongly agreed safety management, functional maintenance and improvement, emergency management, and prevention of secondary disorders as appropriate items of education for community reintegration in patients with stroke and TBI. Personal counseling (n = 97) and small group learning with 3-5 individuals (n = 80) were selected as suitable teaching methods. Participants responded that education content type using video is appropriate (n = 94). Social worker was selected as an appropriate educator (n = 147).

**Conclusion**
The present results provides fundamental information which be needed to develop HCLEP for persistent rehabilitation in patients with stroke and TBI. Further studies are needed to reach a consensus of professionals or patients for specific items included in the education contents.

EVALUATING INTERDISCIPLINARY CARE COORDINATION AND TEAM FUNCTIONING IN INPATIENT REHABILITATION TO IMPROVE PATIENT OUTCOMES: RECENT FINDINGS FROM A MULTIYEAR QUALITY IMPROVEMENT PROJECT

D. Strasser¹, E. Preston-Hsu¹, A. Backscheider Burridge², S. Penna¹
¹Emory Rehabilitation Hospital, Rehabilitation Med - Emory University, Atlanta, USA
²Houston Community College, Research and Analytics, Houston- TX, USA

Introduction/Background

While the interdisciplinary team is an established and proven component of rehabilitation services, rehabilitation professionals often struggle to generalize findings from clinical research to make and sustain improvements in team processes and service delivery.

Material and Method

For three years a Working Group of rehabilitation faculty and hospital service directors in a 50 bed rehabilitation hospital in the U.S. have been meeting to evaluate and improve interdisciplinary care coordination and rehabilitation team functioning with the goal of improved patient outcomes. Here, we report the latest findings of this ongoing quality improvement initiative – a two part (quantitative, qualitative) survey (N= 110). The survey was modified from previously reported measures of team functioning to capture broader issues of interdisciplinary care coordination. In addition to core inpatient team members, (PT, OT, RN, SLP, AT, Neuro-psychology, MD), staff working in admission liaisons, nursing staff who do not routinely attend team conference, hospital administrators, residents, and weekend covering attending physicians participated.

Results

Analysis of the revised scales supported the previous data on the reliability and validity of the five scales of Teamness (cronbach's Alpha = .942); Team Effectiveness (.935); Supervisor Support (.905); Physician Engagement (.782) and Shared Leadership (.956). Qualitative examination revealed concerns of the integration of nursing service and admissions liaisons with overall care coordination, along with concerns on managing patients with high medical acuity and the administrative push for higher census. The Working Group is developing action plans based on this survey and specific findings will be discussed.

Conclusion

Results from the survey support prior quantitative domains of team functioning. Subgroup differences on the five scales will be discussed. Qualitative measures reveal tensions between
care coordination, staffing levels, needs for a higher census, and concerns of patient acuity. The action plans developed by the Working Group from the survey are presented.

INTEGRAL MANAGEMENT OROPHARYNGEAL DYSPHAGIA
M.J. Durà Mata1, M. Molleda1, J.M. Sánchez-Migallón2, C. Viña3, C. Pollán3, C. Calderón1
1Hospital Universitari Germans Trias i Pujol, Physical Medicine and Rehabilitation, Badalona. Barcelona, Spain
2Hospital Universitari Germans Trias i Pujol, Nutrition, Badalona. Barcelona, Spain
3Hospital Universitari Germans Trias i Pujol, Otorhinolaryngology, Badalona. Barcelona, Spain

Introduction/Background

Dysphagia is a symptom that indicates difficulty in swallowing. The etiology of dysphagia is multiple. Patients with dysphagia were referred to different hospital services (Otorhinolaryngology (ENT), Rehabilitation, Nutrition...). These referrals involved, multiple appointments. From October 2013 with the idea of providing accessible and comprehensive care to the patient, we have a unified dysphagia clinic creating a multidisciplinary practice in which after the joint assessment of the patient, we decide the optimal treatment for each case. In the case of hospitalized patients, a circuit has been generated to speed up the assessment and treatment of oropharyngeal dysphagia, which is occasionally performed bedside when the patient's condition so requires.

Material and Method

We analyze patients referred in 2017. Their diagnosis, etiology, treatments applied and number of medical visits needed.

Results

During 2017, 97 patients have been referred to dysphagia multidisciplinary practice. 57.3% of patients dysphagia was of Neurological etiology (Vascular 21%, Neuromuscular 18.3% Demyelinating diseases 5% Extrapyramidal 1% Others 12%; Otolaryngology pathology 18% (Oncological 15% and Non-oncological 4%)

424 in-hospital consultations have been carried out, 80% of those performed at the ENT department. Nutritional status assessment showed, 30% of moderate malnutrition. After the joint consultation, dietary recommendations were indicated in 44%, modification in the texture of the diet in 22%, prescription of speech therapy in 30% and gastrostomy in 4%. Following the consultation, In 55% of the cases, only one visit was necessary to diagnose and give a therapeutic orientation. The remaining 45% required follow-up.

Conclusion
We consider that multidisciplinary joint visits are high-resolutive, as they imply fewer visits per patient with lower health care costs and provide higher quality care.

POS-PROSTHETIC GAIT TRAINING AMONG UNILATERAL TRANSFEMORAL AMPUTEES. A SYSTEMATIC REVIEW
F. KUHN¹
¹Universidade de São Paulo- Faculdade de Medicina da Universidade de São Paulo, Departamento de Medicina Legal Ética Médica Medicina Social e do Trabalho., SAO PAULO, Brazil

Introduction/Background

The post-amputation rehabilitation of the lower limb is usually focused on the use of prosthesis to restore the ability to walk. Patients with transfemoral amputation (TFA) are mainly impaired due to lack of muscles that control the knees and depend on a prosthetic knee joint. Interventions to reduce gait deviations and improve the quality of life of lower limb amputees include proper prosthesis prescription and participation in physiotherapy for gait training and neuromuscular re-education. Specifically, gait training is capable of improving spatiotemporal parameters, joint kinematics and bioenergetic efficiency during gait of above knee amputees. However, to our knowledge, there is no established guideline based on evidence of better specific practices for gait training after transfemoral amputation. The aim of this study was to systematically evaluate the literature to determine the strength of evidence supporting gait training interventions to further guide practices and research related to therapeutic gait training for unilateral transfemoral amputees.

Material and Method

This systematic review accessed three databases and followed the Cochrane Collaboration protocol.

Results

We were unable to identify any randomized clinical trial that compare different kind of gait training specific for unilateral transfemoral amputees.

Conclusion

There are still only a few studies and researches endorsing therapeutic practices in the rehabilitation of amputees. Of the few randomized clinical trials, most are about below-knee amputees or they assess all lower limb amputees as one, not taking into consideration the specific bio-mechanical, etiological and psychosocial differences among transfemoral amputees. Lately, the investments in research have been commonly directed to pharmacological and technological interventions. However, it is of the utmost importance that
methodological studies are conducted in this field of rehabilitation, aiming the prevention of newer deficiencies and promoting gain in functionality and quality of life to the patients.

ROLE OF HEALTH INSURANCES IN MEDICAL COVERAGE OF PHYSIOTHERAPY AND REHABILITATION MEDICINE IN IVORY COAST

K.B. Manou¹, A.E. Konaté-Konan¹, A.D. Akadje¹, N.A. Ngandeu¹, D.J. Bombo¹, K.J. Kouakou¹, A.D. Alloh¹, M.B. Nandjui¹
¹University Félix Houphouët-Boigny, UFR Sciences Médicales, Abidjan, Ivory Coast

Introduction/Background

The medical coverage of rehabilitation and rehabilitation care of persons with disabilities is few times limited to a partial kinesitherapy acts management, despite the multitude of situations generating disability and handicap in our context.

Objectives: Determine the insurance and mutual health insurance role in the repayment of physiotherapy and rehabilitation medicine care expenses

Material and Method

It was a prospective study using questionnaires structured around physiotherapy and rehabilitation medicine activities submitted to twenty-five insurance companies and mutual health insurance companies from January to March 2016.

Results

Almost all insurance companies had a medical adviser, 80% of whom had notions about the PMR activities. Twenty percent of insurance and mutual insurance companies routinely rejected reimbursements for physiotherapy and the rejection reasons were dominated in most cases by the non-guarantee of rehabilitation in 89% of cases. The majority of insurers and mutual health insurers (76%) only reimbursed physiotherapy care, of which 35% had a reimbursement ceiling of 20 sessions depending on the disability.

Conclusion

Discussion: Our regularly insured patients in a situation of disability are confronted to a refusal of physiotherapy and rehabilitation acts, further aggravating their exclusion and their stigmatization in the Ivorian society.

Conclusion: Insurance companies and mutual health insurance companies, that are supposed to be essential supports for their clients in particular and the general population well-being, by contributing to alleviate the medical expenses, sometimes become obstacles to the improvement of their health quality of life by restricting reimbursements for physiotherapy and rehabilitation care.

ISPR8-2105
REVIEW OF COST-EFFECTIVENESS OF NON-OPERATIVE TREATMENT IN LATERAL EPICONDYLITIS

M. Saeedi¹, T. Babaee²
¹MSc. student in Orthotics & Prosthetics - School of Rehabilitation Sciences - Iran University of Medical Sciences, Dept. of Orthotics & Prosthetics, Tehran, Iran
²PhD. - Assistant professor - School of Rehabilitation Sciences - Iran University of Medical, Department of Orthotics and Prosthetics, Tehran, Iran

Introduction/Background

Lateral Epicondylitis (LE), often termed “tennis elbow” is defined as acute tenderness or strain of the wrist extensor muscles at or near their lateral epicondyle origin or directly over the epicondyle. It is associated with continued stretching of forearm extensor musculotendinous structures with an annual incidence between 1% and 3% in the general population.

The conservative treatments for this complaint are vary and this is the therapist who decides which one is the best by the situation of patient. Health care center and also the patient undergo to the huge amount of costs for each treatment, therefore it would be very economic to know the cost effectiveness of conservative interventions for LE.

Material and Method

A literature search was conducted in computerized bibliographic databases like: PubMed, Google Scholar, Science Direct, Medline, Cochrane Library. The search identified the cost efficacy of interventions for LE. The studies were inspected if the design was original and review articles and if the type of the interventions were conservative.

Results

Although the interventions are different in cost and benefit in patient, there is no relevant or statistically significant differences in effectiveness between the interventions. More than 40 treatments for the tennis elbow have been described in the literatures, but it is the wait and see policy recommended by them.

Conclusion

Physiotherapy showed more beneficial effects than the wait and see policy and brace, but the two last intervention are slightly less costly. With regards to cost effectiveness, none of the interventions was found to be superior.
As no treatment strategy has yet been shown to be superior, therefore cost may be a decisive factor in deciding which treatment is to be preferred for tennis elbow.

STUDY OF OCCUPATIONAL DYSFUNCTION AND DAILY ACTIVITIES USEFUL IN THE PREVENTION OF FRAILTY IN ELDERLY PATIENTS WITH ATRIAL FIBRILLATION
M. Sudo

Dokkyo Medical University Nikko Medical Center, Rehabilitation, Nikko, Japan

Introduction/Background

The prevalence of atrial fibrillation (AF) in people aged over 75 is 9%. People in this age-group are at a high risk of frailty, cerebral infarction and heart failure. A psychosocial perspective is needed for the prevention of frailty. Occupational dysfunction (OD) is a factor that directly affects psychological issues. We conducted a comparative study of OD and daily activities.

Material and Method

In terms of study design, this is a cross-sectional study conducted in a single facility. A total of 47 people with non-valvular atrial fibrillation aged over 75 were enrolled in this study (mean age: 81.3±4.9; 25 men). Frailty index scores were interpreted as follows: 0 (Healthy (H)); 1 – 2 (Pre-frailty (PF)); ≥3 (Frailty (F)). Information regarding daily activities (driving; frequency of going out; frequency of telephone use; exercise habits; hobbies) was collected using questionnaires and assessed using Classification and Assessment of Occupational Dysfunction (CAOD). Daily activities, CAOD total scores and secondary factors (occupational imbalance; occupational deprivation; occupational alienation; occupational marginalization) were compared among 3 groups using ANOVA.

Results

Significant differences among the 3 groups were observed in driving, exercise habits, CAOD score, occupational deprivation and occupational alienation. Differences in daily activates were observed between individuals in the H and F groups. Significant differences in OD were observed in individuals in the H group compared to those in the PF and F groups. Not significant differences were observed between individuals in the PF and F groups in terms of OD.

Conclusion

Daily activities tended to become more limited as the severity of frailty increased. On the other hand, marked OD is experienced in the pre-frailty group, and it is useful to treat OD early to prevent exacerbation.

HEALTH STATUS AND QUALITY OF LIFE IN PEOPLE WITH PHYSICAL DISABILITY

E. Song¹, J.H. Yang¹, J. Park¹, S.H. Ho¹

¹Department of Rehabilitation Standard and Policy,
Korea National Rehabilitation Research Institute, Seoul, Republic of Korea

Introduction/Background

Physical disabilities may either be congenital or caused by accidents or diseases later life, deteriorate the quality of life. The aim of this study was to investigate the factors based on three types of health definition (physical, mental and social) presented by World Health Organization (WHO) that affect quality of life on people with physical disabilities.

Material and Method

In total, two hundreds forty one subjects who were Seoul in South Korea residents and registered to the local government with physical disability aged from 40 to 69 were participated in this study. We performed face to face interview and self-administered questionnaire. The questionnaires consisted of socioeconomic status, physical function, participation, depression assessment and quality of life. We operationally defined activities of daily living (ADL), participation part of domain in WHO Disability Assessment Schedule 2.0 (WHODAS 2.0) and Center for Epidemiological Studies Depression (CES-D) as physical, social and mental health. Stepwise regression model were conducted to identify related factors of quality of life in people with physical disability. Socioeconomic status, ADL, score of participation and CES-D score entered into the regression model.

Results

For the 241 individuals with physical disability, 51.0% were female, 47.7% were aged 60 to 69, 71.0% were unemployed and 32.4% were graduated high school. ADL (β=0.025, p<0.001), participation in social activities (β=0.150, p<0.01) and CES-D (β=0.256, p<0.001) were significantly associated with quality of life. In addition, the employment status (β=0.167, p<0.01) affected quality of life in individuals with physical disabilities.

Conclusion

Our findings suggest that employment status associated with quality of life and positive correlation and association between physical, social, mental health and quality of life in people with physical disability. We expected to be a foundation for promoting of health policy for people with physical disability.

DEVELOPMENT AND APPLICATION OF INDIVIDUALLY CUSTOMIZED HEALTH PROMOTION PROGRAM USING CLASSIFICATION ALGORITHM BY THE RESULTS OF HEALTH ASSESSMENTS FOR PEOPLE WITH DISABILITIES

M. Lee¹, Y.J. Choi², E.Y. Lee², H.M. Oh², S.H. Ho²

¹Korea National Rehabilitation Center, Department of Clinical Research for Rehabilitation, Seoul, Republic of Korea
²Korea National Rehabilitation Center, Department of Rehabilitation Standard & Policy, Seoul, Republic of Korea

Introduction/Background

It is difficult to find specific guidelines in terms of what kinds of and to what extent health promotion services should be applied to individuals with disabilities for improving their health in community settings. Further the health promotion service has restrictively provided for a few individuals with disabilities, because of limited human resources. We developed individually customized health promotion program, according to the results of health assessments, to suggest necessary kinds of health promotion services and proper amount of it for improving health of the individuals with disabilities, and examined its feasibility.

Material and Method

Thirty-three participants aged 59.69 years enrolled the study. Blood pressure, fasting blood sugar, neutral fat, cholesterol, and BMI were administered as general health factors. Modified Barthel Index, Mini–Mental State Examination, and Patient Health Questionnaire-9 were administered as disability-specific health factors. Participants were classified into the three groups: intensive support group, motivation group, and education group by the classification algorithm using results of assessments related to general and disability-specific health factors. Intensive support group participated in group-based multi-component programs including exercise, psychology, and nutrition classes each for 50min/d, 1d/wk, for 8 weeks. Motivation group received three-time individual counseling. Education group received education only once regarding general health knowledge.

Results

For within group analysis, intensive support group showed improvement trends in all of the assessments, excluding bleed pressure, although not significantly. Motivation group showed greater improvement compared to education group in neutral fat (p = 0.015). Intensive support group showed greater improvement compared to motivation group in BMI (p = 0.028).

Conclusion
The newly developed individually customized health promotion program is feasible to apply the individuals with disabilities in community. Three classified groups according to health assessments may enable disabilities to receive necessary kinds of health promotion services at a proper amount for improving their health.

RESULTS OF OCCUPATIONAL THERAPY IN A NEW COMMUNITY SUPPORT PROJECT FOR FRAIL OLDER PEOPLE IN JAPAN

N. Kobayashi¹, Y. Ishibashi¹, R. Kobayashi¹, C. Mura², H. Nagayama³

¹Tokyo Metropolitan University, Faculty of Health Sciences, Tokyo, Japan
²Ishikawa Takamatsu prefectural hospital, Department of Rehabilitation, Takamatsu- Ishikawa, Japan
³Kanagawa University of Human Services, Department of occupational therapy, Yokosuka- Kanagawa, Japan

Introduction/Background

The total population in Japan was 126 million as of 2016. 27% of them (34 million) were over 65 years old persons. 6 million persons were certified by the municipal government as being in need of care. A new community support project (CSP) aimed at health promotion for the frail elderly people resident in community began. In that project, occupational therapists is expected to work in support of instrumental activity of daily living (IADL). We examine the result of occupational therapy in the CSP.

Material and Method

31 OTRs who has worked in the CSP participated in this survey. They were required to provide a client information, including Frenchay Activities Index (FAI, Holbrook, 1983) score, EQ-5D-5L score, a content of personal goals of IADL. This study design was pre-post design without a control group. Also, in order to clarify the results, the achievement rate of each personal goal was calculated. This survey was initiated after approval of the Ethics Review Committee.

Results

We collected 108 client information. Examples of personal goals of IADL include the following: “Visit the family grave on foot”, “hike on the mountain trail with my friend once a month”, “cook with a microwave”, “shop in a local store”, “go to a nearby hot spring by bus”, “make a friends”. 80% of these personal goals were achieved. There were significant improvements in FAI score.

Conclusion

This result proves that occupational therapists work effectively in the CSP.

A SURVEY ON SURVEYS: HOW A NATIONAL SCIENTIFIC SOCIETY OF PRM INVESTIGATED ITSELF TO IMPROVE ITS ACTIVITY

P. Boldrini¹, P. Fiore², G. Checchia³

¹Italian Society of Physical and Rehabilitation Medicine, Executive Committee, Roma, Italy
²Unità Operativa Complessa di MFR, Azienda Ospedaliera Universitaria "Consorziale Policlinico", Bari, Italy
³Medical Rehabilitation Unit, Rehabilitation Department - Azienda ULSS Euglena Regione Veneto, Monselice, Italy

Introduction/Background

One of the common objectives of the Scientific Societies is the collection and dissemination of information on the activities of its members, as well as on their needs in relation to the improvement of the quality services and the support they may expect from the Society itself.

Material and Method

In 2015, SIMFER launched a program of surveys to get information on the competencies and type of clinical activities carried out by its members in their usual practice, and of the characteristics of patients referred to the rehabilitation services in different settings. Some surveys were specifically addressed to the members of SIMFER, other were developed in cooperation with other scientific societies or academic or research institutions. Newsletters were sent to each "active" member, explaining the scope of the survey and asking to complete questionnaires using web-based applications. The surveys addressed clinical or organizational aspects, and were proposed by the Executive Committee or the Scientific Committees.

Results

Since 2015, 13 surveys have been carried out, 10 of them specifically addressed to its members, the other including other specialists or rehabilitation professionals. The number of respondents varied from 28 (1 survey addressed only to members of specific committee) to 798 (approx. 42% of the "active" members of SIMFER). The subject of the surveys were: clinical problems (10 of which: prevalence of conditions in rehab settings: 4; therapeutic approaches: 2; mixed: 3); research in PRM (1 survey); organization/methodology (2)

Conclusion

The surveys were found to be a valuable tool to get information on many aspects of the clinical practice, their differences in the various settings and in the different Regions of the Country, and in highlighting many critical aspects that could be improved with the intervention of the Scientific
Society.
They also provided relevant informations which would be useful in the communication with patients, other professionals, policy makers and the community at large.

FACTORS ASSOCIATED WITH ACTIVITY LIMITATIONS IN ELDERLY PEOPLE: A SYSTEMATIC REVIEW
S. Begum¹, R. Kobayashi¹
¹Tokyo Metropolitan University, Occupational therapy, Tokyo, Japan

Introduction/Background

Independence in performing activities of daily living (ADLs) is a central aspect of functioning. Elderly people often experience different kinds of impairments and limitations in their various life areas. So, the objective of this systematic review is to identify activity limitations and associated factors in elderly people.

Material and Method

We systematically searched four electronic databases (Scopus, EBSCOhost- CINAHL & MEDLINE, and PubMed) and bibliographies for relevant studies published between 2000 and 2017. Of the initial 629 identified articles, 37 met inclusion and exclusion criteria and were analyzed. The content analysis involved categorizing the factors into six domains representing factors associated with activity limitation.

Results

In multiple studies, elderly people exhibited significant activity limitations. Six domains were significantly associated with activity limitations in elderly people. These included socio-demographic factors, chronic health conditions, mental health status, health behaviors, psychosocial factors, and health-related factors. Older age (in 21 studies) and female gender (in 19 studies) were the most prevalent factor for activity limitation. In addition, stroke, arthritis, eye diseases, diabetes, anxiety, depression, cognition, physical inactivity, and poor mobility exhibited high evidential strength.

Conclusion

This review revealed various demographic, health conditions, mental status and behavioral factors associated with activity limitation among elderly people. Our findings may help to establish priorities for future research, and assist early detection and health and social program planning efforts for those at higher risk of activity limitation.

Key Word: Activity Limitation, Associated Factors, Elderly people

Introduction/Background

Appropriate physical activity can be a great help for a healthy life and increases work efficiency in the workplace. In this study, we tried to measure the amount of physical activity of workers in St. Vincent's hospital using the accelerometer (Actigraph wGT3XBT). The purpose of this study is to identify the relationship between physical activity and several factors such as a type of work, commuting method, marital status, and gender.

Material and Method

We enrolled doctors, nurses and other workers including medical staffs who work at the hospital. All participants wore the Actigraph for 7 days and consumed kcal per hour, numbers of steps and the intensity of physical activities were analyzed with a simple questionnaire including personal health status. Among them, 16 volunteers repeated the study to see if any improvements were made after counseling for activity enhancement.

Results

No significant difference was found in the amount of physical activities of the workers depending on gender, marital status, and commuting methods to work. However, subjects with kids showed higher average kcal per hour than those without a kid, and the steps counts were significantly higher in the other worker’s group than doctors and nurses. Interestingly, no single participant reporting vigorous intensity physical activity suggesting the general lack of physical activity in people working at the hospital. In the additional study for 16 volunteers, there was no significant enhancement from the previous results.

Conclusion

We found there was no significant difference in physical activities of the workers in the hospital according to sex, marital status, and commuting methods. So far increasing the physical activities we need constant attention for physical activities in daily life. Additionally, high intensity exercise was found to be insufficient for all subjects suggesting that workers in the hospital need to increase their physical activities.

¹¹University of Melbourne, Department of Medicine Royal Melbourne Hospital, Parkville, Australia

Introduction/Background

Despite the prevalence of disability in low-and-middle income countries (LMICs), the clinical skills of rehabilitation workforce are not well described. We report health professionals’ perspectives on clinical skills in austere settings and identify context-specific gaps for workforce capacity.

Material and Method

An exploratory-descriptive, cross-sectional, pilot survey of healthcare professionals working in rehabilitation in hospital and community settings conducted in Pakistan, Morocco, Nigeria and Malaysia. A situational-analysis survey-tool captured cross-sectional assessment of clinical skills required in various rehabilitation settings. Participant responses were coded in a line-by-line process, and clustered into common terms based on International Classification of Functioning, Disability and Health (ICF) framework to classify skill-categories in target domains.

Results
Survey respondents (n=532) from Pakistan 248, Nigeria 159, Morocco 93 and Malaysia 32 completed the survey. The participants were: physiotherapists (52.8%), nurses (8.8%), speech and occupational therapists (8.5%, 5.3%), other medical doctors (5.5%), rehabilitation physicians (3.8%), and prosthetist/orthotists (1.5%). The 10 most commonly used clinical skills reported were prescription of physical activity and medications, transfer-techniques, daily-living activities, allied health interventions, patient/carer education, comprehensive patient-care, diagnosis/screening, behaviour/cognitive interventions, referrals, assessments and collaboration. Most responses linked with ICF categories in activities/ participation, and personal factors.

**Conclusion**

The survey tool identified task shifting amongst healthcare professionals. The core skills and gaps reflected general rehabilitation practice, rather than discipline-specific skills.

D2.01 Comprehensive Rehabilitation Intervention Research - Rehabilitation Service Evaluation (including Acute, Post-Acute and Community Rehabilitation Services)

ISPR8-0130
ROLE OF NEUROPSYCHOLOGY IN LEVEL 2A REHABILITATION UNIT
F. Anwar\textsuperscript{1}, H. Liddiard\textsuperscript{1}, J. Nejand\textsuperscript{1}
\textsuperscript{1}Blackheath Brain Injury Rehabilitation Centre, Neurorehabilitation, London, United Kingdom

Introduction/Background

Neuropsychological assessment and evaluation is essential following acquired brain injury. The valuable clinical information obtained from the neuropsychological assessment can guide the rehabilitation team in goal setting and discharge planning. The neuropsychologist also plays a significant role in managing the challenging behaviour after any neurological insult to the brain.

Blackheath Brain Injury Rehabilitation Centre (BBIRC) consists of two wards, Heathside Neurodisability Unit (HNDU) with 18 beds and Thameside Brain Injury Rehabilitation Unit (TBIRU) with 16 beds. HNDU is a level 2a specialist rehabilitation service. These individuals typically present with greater physical needs. The aim of this study was to explore the role of neuropsychology in the level 2a specialist rehabilitation service.

Material and Method

All patients referred for neuropsychology assessment from September 2015 to July 2017 from HNDU were included in the study. To inform how psychology resources were allocated, further information was gathered about the number of TBIRU beds occupied during this period, as well as the number of psychologists each month.

Results

Our results showed that psychology resources provided to HNDU have consistently exceeded 20% since November 2015. Most frequent reason for referral to Psychology was for cognitive assessment (42%) followed by mood intervention (31%), and behaviour management (16%).

Conclusion

Our study concluded that there is range of reasons for referral and rate of referral per month. There is a regularly high demand for Psychology on Level 2a rehabilitation unit in a variety of areas.

QUALITY IN DEMENTIA CARE: A CROSS SECTIONAL STUDY ON THE BIO-Psycho-Social Competencies of Health Care Professionals.

D. Van De Velde¹, P. De Vriendt², E. Cornelis², V. Desmet², R. Vanbosseghem²

¹Ghent University, Rehabilitation sciences and physiotherapy, Ghent, Belgium
²Artevelde University College, Department of Occupational Therapy- Research group Innovation in Health Care-, Ghent, Belgium

Introduction/Background

Professionals in dementia-care ought to be able to work within a Bio-Psycho-Social model. The objectives were to examine whether dementia-care is delivered in a Bio-Psycho-Social way, to explore the influencing factors and to evaluate the factorial validity of the ‘Bio-Psycho-Social-Dementia-Care scale’.

Material and Method

413 healthcare-professionals completed the ‘Bio-Psycho-Social-Dementia-Care scale’. Differences between groups (settings, professions, years of experience) were calculated with a student’s t-test and one-way ANOVA. The facture structure of the scale was evaluated using a confirmatory factor analysis.

Results

The factor-analysis confirmed the 5 subscale-structure (1) networking, (2) using the client’s expertise, (3) assessment and reporting, (4) professional knowledge and skills and (5) using the environment. (No significant differences were found between professionals in residential care and community care for the subscales ‘networking’ and ‘using the client’s expertise’.

Professionals in residential care score higher than community care for ‘assessment and reporting’ (p<0.05) and ‘professional knowledge and skills’ (p<0.01) but lower for ‘using the environment’ (p<0.001). The juniors score higher for ‘professional knowledge’ compared to seniors (p<0.01) and the seniors score better for ‘professional experience’ (p<0.01). The Cure and Care disciplines and the Therapy disciplines had higher values in ‘assessment and reporting’ compared to the Social Support disciplines (p<0.001 and p<0.001). The Therapy disciplines scored higher in ‘using professional knowledge and skills’ compared to the Social Support group (p 0.021) and the Cure and Care disciplines (p<0.001). The Social Support disciplines scored higher in ‘using the environment’ compared to the Therapy disciplines (p<0.001) and the Cure and care disciplines (p<0.001).

Conclusion
The Bio-Psycho-Social-Dementia-scale is a valid tool and offers opportunities not only to rate, but also to improve Bio-Psycho-Social functioning in dementia-care: increase interdisciplinary collaboration, facilitate assessment, combine the strengths of the different professions and install a heterogeneous team with regard to age and experience.

HOLISTIC REHABILITATION SERVICES FOR WAR VICTIMS IN GEORGIA

Introduction/Background

War and related migration becomes more and more actual in worldwide. Georgia is war affected country with about 500 000 victims of war and 20 % of occupied territories by Russia, with ongoing aggression alongside of para – military villages. Aim of study was: assessment of rehabilitation services for elaboration of conception for comprehensive, multilateral system of rehabilitation in War affected Country.

Material and Method

Methods include assessment of effectiveness of multi-disciplinary rehabilitation services, including medical, psychological, social and legal assistance. Study was conducted among 120 war victims, including in – take and follow up assessment.

Results

Different target groups were identified: IDPs, civilians living in para military regions and population still living in occupied regions. In 84 % of 120 were identified physical disturbances, together with mental /psychological outcomes of trauma that mainly were revealed in PTSD symptoms with other stress – related disorders.

Conclusion

Assessment of effectiveness of services and interventions revealed necessity of complex – holistic approaches in buildup of national wide rehabilitation services for war affected population. At the same time a holistic rehabilitation should include not only multi-disciplinary attitude during rehabilitation, but also different levels of services, including crisis interventions, long term rehabilitation, community based follow up interventions, with client centered approaches, build up with key role of timely and territorial accessibility.

TRANSLATING EVIDENCE INTO ACTION: AN INTERVENTION FOR INCREASING VITAMIN D SUPPLEMENTATION IN A DEFICIENT REHABILITATION POPULATION

Y. Tailor¹, B. Abramoff², C. Krull³, M. Jerome⁴

¹Emory University Hospital Midtown, Rehabilitation Medicine, Atlanta, USA
²Rehabilitation Institute of Chicago, Physical Medicine and Rehabilitation, Chicago, USA
³Baylor, Physical Medicine and Rehabilitation, Houston, USA
⁴Emory University, Rehabilitation Medicine, Atlanta, USA

Introduction/Background

Inadequate vitamin D is highly prevalent, affecting approximately 42-77% of the general United States population. Vitamin D deficiency (VDD) increases the risk of osteoporosis, falls, and fractures. Acute inpatient rehabilitation patients have several risk factors for VDD, and the adverse effects of VDD may hinder long-term functional gain.

Material and Method

Prospective cohort study, evaluating patients admitted before and after a screening intervention as part of a quality improvement initiative at an academic, freestanding acute inpatient rehabilitation hospital. This study included a convenience sample of patients admitted two months pre-intervention (n=128), and patients admitted two months post-intervention (n=129). Providers obtained a routine serum vitamin D level on admission (universal screening), then utilized a standard supplementation protocol. Vitamin D insufficiency (VDI) was defined as a 25-hydroxyvitamin D (25(OH)D) level of 20-29.9 ng/mL, and VDD as <20 ng/mL. The prevalence of VDD and VDI in the post-intervention population was evaluated, as well as changes in vitamin D screening and supplementation rates pre- and post-intervention.

Results

Pre-intervention, 10.2% of patients were screened for VDD, with 23.1% found to be VDI and 46.2% VDD. Post-intervention, 89.9% of patients were screened, with 31.9% found to be VDI and 47.4% VDD. Pre-intervention, 88.9% of all screened patients were on vitamin D supplementation at discharge versus 75.0% post-intervention. In both uni- and multivariate analyses, we found increased risk of VDD was significantly associated with African American race (OR 7.3, 95% CI, 1.56-34.2, p=0.12) and age younger than 65 (OR 13.6, 95% CI, 2.5-73.8, p=0.002). Diagnoses in the “other neurologic” category were associated with decreased risk of VDD (OR 0.01, 95% CI, 0.001-0.193, p=0.002).

Conclusion
Given the high prevalence of VDD in an acute inpatient rehabilitation hospital, a routine screening and standardized supplementation protocol may be a good practice to improve quality of care.

A RETROSPECTIVE REVIEW OF OUTPATIENT CASES SEEN AT THE FIRST PHYSICAL MEDICINE AND REHABILITATION CLINIC IN A TERTIARY HOSPITAL IN GHANA

A. Tannor, A. Haig, A. Christian
1Komfo Anoye Teaching Hospital, Family Medicine, Kumasi, Ghana
2University of Michigan, Physical Medicine and Rehabilitation, Michigan, USA
3Good Shepherd Rehabilitation Hospital, Physical Medicine and Rehabilitation, Allentown- Pennsylvania, USA

Introduction/Background

There are an estimated 4.2 million persons with disabilities in Ghana. Physical Medicine and Rehabilitation services were however non-existent until 2016. The first outpatient PM&R clinic began at the Komfo Anoye Teaching Hospital, a tertiary hospital, with support from the International Rehabilitation Forum (IRF). It is run by a PM&R physician being trained by the IRF. Consultations are held at the clinic once a week. This study analyses comprehensively the cases seen at the clinic in the first year of its establishment.

Material and Method

Outpatient consultations that took place from June 2016 to May 2017 were identified from the clinic’s records. Demographic information and diagnoses made were recorded and analyzed.

Results

A total of 208 cases were seen with 108 (51.9%) females and 100 (48.1%) males. An average of 4 cases were seen on each clinic day. Ages ranged from 5 weeks to 88 years with an average age of 42 years. The most common diagnosis made was stroke with hemiparesis 63 (30.2%) followed by back pain 41 (19.7%), arthritis 30 (14.4%), cerebral palsy 18 (8.7%), talipes equinovarus 11 (5.3%) and complications of fracture management 17 (8.2%). The rest of the diagnoses included Bells palsy 9 (4.3%), Erbs palsy 4 (1.9%), spinal deformities 3 (1.4%) and others 12 (5.8%). All the cases seen were referrals from health professionals.

Conclusion

Though challenging, we have been able to start and sustain a PM&R outpatient service in a developing country. There is however the need to expand the clinic to care for patients with disabilities in other parts of the country with increased awareness creation on the existence of such services. More PM&R physicians need to be trained as the ratio of a PM&R physician to persons with disabilities is currently 1:2,100,000 in Ghana.

D2.01 Comprehensive Rehabilitation Intervention Research - Rehabilitation Service Evaluation (including Acute, Post-Acute and Community Rehabilitation Services)

ISPR8-1066
A LITERATURE REVIEW OF OCCUPATIONAL THERAPY IN POST-ACUTE HOSPITAL IN JAPAN - 43 CASE STUDIES FROM 2012 TO 2016 -
H. Nakamoto¹,², N. Ohshima³, M. P. Sy¹
¹Tokyo Metropolitan University, Department of Occupational Therapy- Graduate School of Human Health Sciences, Tokyo, Japan
²Teikyo Heisei University, Department of Occupational Therapy- Faculty of Health and Medical Science, Tokyo, Japan
³Tokyo Metropolitan University, Department of Occupational Therapy- Graduate School of Human Health Sciences, Tokyo, Japan

Introduction/Background

There are approximately 1300 rehabilitation hospitals in Japan where patients receive 3 to 4 months of intensive rehabilitation (post-acute care). A rehabilitation team is primarily involved in helping patients improve their function, skills for both activities of daily living (ADL) and instrumental activities of daily living (IADL). To ensure best quality in rehabilitative care, it is necessary for professionals to always base their actions on existing evidence. Fortunately, the Japanese Association of Occupational Therapy (JAOT) has a registry system for case studies which members can both access and use as a venue for sharing knowledge and practice. Herewith, this paper aims to examine the occupational therapy process in post-acute care in Japan.

Material and Method

Using the registry system, we searched case studies relating to post-acute care and occupational therapy within the years 2012 to 2016. The search parameter was “physical rehabilitation practice”. Moreover, a key word “post-acute practice” must be in the case’s title or main body.

Results

The search revealed 47 case studies, but 4 cases did not meet the set criteria. After tabulating and classifying the 43 case studies, it revealed that the case studies focused on cases of people with stroke, spinal cord injury, traumatic brain injury, and fracture. The occupational therapy evaluation used were ROM, sensory test, Br-Stage, or FIM, while the intervention methods were ROM exercise, Basic motion exercise or ADL exercises. A small percentage of the studies focused on IADL functions and training.

Conclusion
Occupational therapists need to engage in the occupations they want to, need to, or are expected to do (WFOT 2012). So we have to support life as well as patient function. But there were few studies. I think we need to identify the evidence of occupational focus practice in post-acute hospital.

Acute Coronary Syndromes (ACS) is a spectrum of conditions compatible with acute myocardial ischemia and or infarction due to abrupt reduction in coronary blood flow. It can manifest as ST-Elevation Myocardial Infarction (STEMI), Non ST-Elevation Myocardial Infarction (NSTEMI) or Unstable Angina Pectoris (UAP). It can cause decrease function of the left ventricle which can be measured by Ejection Fraction (EF) through Echocardiography. In CiptoMangunkusumo Hospital, phase I Cardiac Rehabilitation were given in Intensive Cardiac Care Unit (ICCU) and Six Minutes Walking Test (6MWT) were done before patients discharged to get 6 minutes walking distance (6MWD) that can be used as a prognostic tools. This study aims to find correlations between initial left ventricular function measured by ejection fraction and predischarged 6MWD in patients with ACS.

Material and Method

This is a retrospective study. Fourty three subjects were diagnosed with ACS, admitted at ICCU on January-May 2017 were divided into 3 groups (STEMI, NSTEMI and UAP). Echocardiography were done initially on the ICCU. All patients underwent phase I rehabilitation. The 6MWT were done on the last day of hospitalization, before discharged.

Results

Twenty one patients (49%) were diagnosed with STEMI, 8 patients (19%) with NSTEMI, and 14 patients (32%) with UAP. The mean age were 52 (± 9,6). All data were normally distributed. The mean EF were 48 (±2,0) % in STEMI, 43 (±3,7) in NSTEMI and 62 (±2,5) in UAP. The mean 6MWD were 290 (±19,4) meters in STEMI, 274 (±27,8) in NSTEMI and 330 (±23,0) in UAP. There were no correlations of EF and 6MWD.

Conclusion

There are no correlations between initial left ventricular function and predischarged 6MWD in patient with ACS in ICCU settings. The mean 6MWD in STEMI and NSTEMI group were lower than 300 meters indicating worse prognosis compare to UAP group.

COGNITIVE ASSESSMENT OF PATIENTS WITHOUT BRAIN INJURY AT ICU DISCHARGE, COMPARISON WITH MILD AND MODERATE TRAUMATIC BRAIN INJURY PATIENTS. PRELIMINARY RESULTS.

F. Radiguier¹, A. Rodrigues², H. Lenoir³, A.C. De Crouy², C. Ract², J. Duranteau², B. Vigué²
¹Bicetre Hospital, ICU, Kremlin Bicetre, France
²Bicetre Hospital, Intensive Care Unit, Kremlin Bicetre, France
³Paris Descartes, Neuropsychology, Boulogne Billancourt, France

Introduction/Background

Significant cognitive impairment after ICU stays in up to 40% of patients without any initial brain damage has been reported. This is a part of the Post Intensive Care Syndrome, alongside motor and psychiatric dysfunctions. In these studies, cognitive evaluation scores are found similar to scores for patients with moderate traumatic brain injury. However, the precise nature and magnitude of the cognitive disorders are not well described.

We decided to deepen analysis of cognitive disorders in non-brain injury patients at ICU discharge (No-BI) and develop a comparison with mild and moderate traumatic brain injury patients (TBI).

Material and Method

After ICU stay (≥48 hours), we administered outcome measures (GOSE, DRS) and neuropsychological tests to assess global cognitive functioning (MOCA), working memory (digit span), spatial neglect (line bisection), selective attention and speed processing (bells cancellation) to No-BI and TBI patients.

Patients with history of neurologic or psychiatric troubles were not included. For each patient, we noted age, gender, initial Glasgow Coma Score (GCS), type of disease, and intubation and sedation periods in ICU.

Results

We tested 16 No-BI and 32 TBI. GCS and intubation period were significantly lower for TBI compared to No-BI (respectively p=0.04 and p=0.01).

The median GOSE for both groups was 5 (lower moderate disability). Neuropsychological measures showed no significant difference between No-BI and TBI patients. Only MOCA (No-BI: 21±5 and TBI: 21±5) and digit span (No-BI: 7±2 and TBI: 7±2) are significantly lower than normality (p<0.001 for both, figure).
Conclusion

We found no neuropsychological difference between No-BI and TBI patients, confirming the hypothesis that these two populations have comparable global cognitive functioning and working memory impairment at ICU discharge. We need more patients to improve these results. A new evaluation at 12 months will allow to discuss a possible recovery.

Introduction/Background

The aim of the work was to evaluate a current condition upper extremity (UE) of stroke survivals after 6 months discharge from high intensity neurorehabilitation program at Rehabilitation Centre Kladruby.

Material and Method

The study included patients with a diagnosis of first stroke in the subacute phases, who were hospitalized in intensive comprehensive neurorehabilitation program at Rehabilitation center Kladruby. All stroke patients were screened for eligibility. Inclusion criterion were moderate to severe hand movements impairment equivalent to a score two or three of a possible six points on the Motor Assessment Scale (MAS) items 7, able to follow commands, either with verbal instructions, demonstration or other non-verbal cues. 15 patients were screened at a time T0 (admission), T1 (after 1 month) and T2 (after 6 months post discharge in home environment).

Results

Primary outcome measures showed up improvement in 53.33% patients and worsening in 13.33% for Box and Block Test (BBT), MAS in item 7 showed up improvement in 46.67% patients and worsening in 13.33%, MAS in item 8 showed up improvement in 40% patients and 60% patients remains same at a time T2.

Conclusion

During Home based functional evaluation of UE at a time T2 was taken as well dataset about accesss to local and community rehabilitation care. Data showed up none to minimum access for psychology and speech language pathology care. Occupational therapy was accessible for 27% stroke survivals and conventional physiotherapy and physical therapy for 91% stroke survivals. Despite this findings stroke survivals are improving after intensive inpatients neurorehabilitation in home settings with poor access to rehabilitation in long term evaluation. Our thought is that access to early intensive neurorehabilitation could contribute to continuous hand function improvement even in home environment.

Introduction/Background

Individuals with spinal cord injury (SCI) are at high risk of developing pressure ulcers and depression. The purpose of the study was to develop and evaluate the feasibility and cost of a community-based peer mentor program to prevent and manage pressure ulcers and untreated depression for individuals with SCI.

Material and Method

Design:

Mixed methods: Non-randomized feasibility study with randomized cost analysis

Setting: Safety-net rehabilitation center and participants' homes/communities in an urban metropolis

Participants: Forty ethnically/racially diverse patients from underrepresented backgrounds from a rehabilitation center in an urban metropolis

Inclusion criteria: 18 years or older; SCI; at high risk of developing a pressure ulcer and/or depression. Control group was matched by age, gender, and SCI level/severity to intervention group

Intervention: 6-month community-based peer program to reduce pressure ulcers and untreated depression

Outcomes:
1) Feasibility study: a) Pressure ulcer risk; b) Depression; c. Program adherence
2) Cost analysis: Cost of healthcare
3) Interview: Report of participants and mentors

Results
All outcomes exhibited a positive trend in favor of pressure ulcer prevention; management of pressure ulcers and depression; self-management; and community reintegration (t-test for pre-post scores; n=20 intervention participants). The intervention was cost effective as compared to traditional services. The healthcare services rendered by the control group cost $500,000 more than the intervention group during the study phase (cost analysis; n=40; included a randomized standard care control group). Most pressure ulcers were healed and prevented from surgeries. Factors/themes were identified for successful future programming (interviews; n=20 intervention participants).

**Conclusion**

The community-based peer mentoring program was feasible to administer and cost effective. Based on the cost analysis and use of the key factors/themes identified, this type of program could minimize the cost of burdensome health issues, maximize appropriate use of services, and improve the health and quality of life of individuals with SCI.

LIVE WELL AFTER STROKE: METHODS OF A COMMUNITY-BASED, OCCUPATIONAL THERAPIST-LED, LIFE MANAGEMENT INTERVENTION

V. Hill
University of Cincinnati, College of Allied Health Sciences, Cincinnati, USA

Introduction/Background

Stroke is one of the leading causes of disability across the world. Post-stroke disability results in physical, cognitive, and emotional deficits leading to activity limitations and participation restrictions for individuals with stroke. Suffering a second stroke further compounds the devastating impact of stroke related disability. Lifestyle programs have shown effectiveness in preventing stroke; however, few individuals with stroke are able to participate in such programs, especially if they are from disadvantaged populations. The purpose of this study was to develop a comprehensive and intensive life management intervention for stroke survivors from racially/ethnically diverse, underrepresented populations by inculcating sustainable health-promoting behaviors, improving health-related quality of life, and mitigating recurrent stroke risk factors.

Material and Method

Design: Formative Evaluation: Interviews

Setting: Safety-net rehabilitation hospital and participants' homes and community

Participants: Ten ethnically/racially diverse patients from underrepresented backgrounds from a rehabilitation center in an urban metropolis

Intervention: 6-month life management intervention with one-on-one sessions with an occupational therapist in the participants' home and monthly group sessions in the community. Intervention focused on changing lifestyle habits to reduce secondary stroke risk factors and improving health-related quality of life through knowledge acquisition, self-management skill practice, self-efficacy/confidence to change, motivation to change, and habit formation.

Main Outcome Measures: Interview narratives and content and narrative from session notes.

Results

Based on the information gleamed from the narratives, the intervention was revised in the following areas: manual outline and content, foundational components, and treatment theory structure revisions (active ingredients, mechanisms of change, target outcomes).

Conclusion
Based on the findings of the feasibility study narratives, the life management intervention was revised to capture more effective methods and content to assist individuals with stroke to make healthy lifestyle habit changes, mitigating secondary stroke risk factors and improving health-related quality of life. The program was feasible to administer in a US safety-net healthcare system.

ACTIVITY AND MOBILITY USING TECHNOLOGY (AMOUNT) REHABILITATION TRIAL: SUPPORT AND HEALTH COACHING DURING THE COMMUNITY PROGRAM

L. Hassett¹,², M. van den Berg³, H. Weber³, S. Chagpar¹, A. Rabie⁴, S. Wong⁴, K. Schurr⁵, A. McCluskey², R. Lindley⁶, M. Crotty³, C. Sherrington¹

¹The University of Sydney, Musculoskeletal Health Sydney, Sydney, Australia

³Flinders University, Rehabilitation- Aged & Extended Care, Adelaide, Australia
⁴South Western Sydney Local Health District, Liverpool Brain Injury Rehabilitation Unit, Sydney, Australia
⁵South Western Sydney Local Health District, Bankstown-Lidcombe Hospital, Sydney, Australia
⁶The University of Sydney, Westmead Clinical School, Sydney, Australia

Introduction/Background

The need for rehabilitation is growing although there are limited resources to meet this demand. Use of affordable technologies to enable health professionals to prescribe and monitor rehabilitation remotely may be one strategy to meet this demand. **Aim:** to describe physiotherapy support provided to participants using technology to improve mobility and physical activity in the post-hospital phase of the AMOUNT rehabilitation trial (n=300).

Material and Method

Process evaluation including participants (mean age 70 (SD 18); 52% male; 54% with neurological conditions limiting mobility) randomised to the intervention group (n=149). Intervention was additional to standard rehabilitation, prescribed using a protocol which matched games/exercises from eight technologies to the participant’s mobility limitations. Technologies included video and computer games/exercises, tablet applications and activity monitors. Participants were taught to use the technologies during inpatient rehabilitation and were then discharged home to use the technologies ≥ 5 days a week for the remainder of the 6-month trial. Trial protocol required the physiotherapist to provide support every 1–2 weeks using a health coaching approach. Intervention datasheets were audited to determine frequency, duration, mode and type of support provided.

Results

Participants used on average 2 (SD 1) technologies in the post-hospital phase, with 95% of participants using an activity monitor. Physiotherapists had contact with participants on average 15 (SD 5) times (approximately every 11 days), of which eight were phone calls (11min duration), six home-visits (46min duration) and one other. Contact primarily incorporated health coaching (68%) with 8% of contact specifically for technology support. Topics discussed during
health coaching included discussing data from prescribed technologies (79%), physical activity and mobility status (70%), adherence (64%) and goal setting (47%).

Conclusion

A health coaching model to support technology-based rehabilitation post hospitalisation is feasible. Some support can be provided remotely limiting the need for frequent home visits.

SIMILARITY STUDY OF THE AR-BASED MOTION ANALYSIS AND THERAPIST'S MANUAL ROM MEASUREMENT
J. Im¹, J. Yu¹
¹SunMoon University, Department of Physical Therapy, Asan, Republic of Korea

Introduction/Background

AR program is comfortable and easy to use medical evaluation. In medical evaluation, Range of motion is a methods to measure of patients joint motions and important tools in physical therapy. Nowadays, AR program is being used to measure patients ROM. The purpose of this study is to compared the results of ROM between AR program and electric goniometer.

Material and Method

Forty students participated in the study. This study used AR-based motion analysis and Electro goniometer to measure ROM of each joint[Figure 1,[Figure 2]. Each volunteer performed three different motion. At this time research measured each joint ROM used motion analysis and electro goniometer. For analysis methods, Measured ROM using motion analysis and lector goniometer used paried t-test. The significance level of all statistical analysis was set at p<0.05.

Results

Mean and standard deviation values of the motion M1, M2 and M3 is shown in [table 1]. According the result, the ROM significantly difference with the 90° shoulder abduction measured motion analysis and electro-goniometer(p<0.05). However, no significant difference were observed another motion at the M1, M2 and M3 position except the shoulder
Conclusion

ROM measurement of the used AR-based motion analysis and electro goniometer has similarly results. And both plane showed coefficient of reliability $p<0.5$. So in this study, upper extremity’s except 90° shoulder abduction and lower extremity’s measured ROM used each tools has no signification. However only 90° shoulder abduction has significant difference. In conclusion, motion analysis is easy to use and save the evaluation time.

FEASIBILITY STUDY OF A COMMUNITY-BASED INTERVENTION IN THE CHRONIC PHASE OF TRAUMATIC BRAIN INJURY

I.M.H. Borgen\textsuperscript{1,2}, S.L. Hauger\textsuperscript{1,3}, M.V. Forslund\textsuperscript{1}, I. Kleffelgård\textsuperscript{1}, N. Andelic\textsuperscript{1,4}, S. Sigurdardottir\textsuperscript{3}, M. Løvstad\textsuperscript{2,3}, C. Røe\textsuperscript{1,4}

\textsuperscript{1}Oslo Universitetssykehus HF, Department of Physical Medicine and Rehabilitation, Oslo, Norway
\textsuperscript{2}University of Oslo, Department of Psychology, Faculty of Social Sciences, Oslo, Norway
\textsuperscript{3}Sunnaas Rehabilitation Hospital, Department of Research, Nesoddtangen, Norway
\textsuperscript{4}University of Oslo, The Faculty of Medicine, Oslo, Norway

Introduction/Background

Few studies have investigated treatment needs and rehabilitation options in the chronic phase of traumatic brain injury (TBI). A Norwegian study showed unmet needs for rehabilitation services up to five years after TBI in the domains of emotional, cognitive and vocational functioning (Andelic et al., 2014). Patients highlighted the need for support to gain insight into emotional and cognitive problems and job skills, and the need to develop long-term efficient coping strategies. Hence, efficient interventions in the community setting are needed in the chronic phase of TBI. Winter et al. (2016) developed an individually fitted goal oriented in-home program guided by the person-environmental fit model. The aim of the present study is to evaluate the feasibility of this intervention adapted to a Norwegian setting. The goal setting process, as well as the achievability and acceptability of the intervention will be discussed. In preparation for a planned randomized control trial, the inclusion criteria, measurements and translated intervention manual will also be evaluated.

Material and Method

Persons that sustained a severe TBI in 2009-2010 in Oslo and Akershus, Norway, were invited to participate. Three main self-reported activity problems (target outcomes) were established at baseline assessment. During eight intervention sessions over a four-month period, therapists and participants together developed targeted SMART (Specific, Measurable, Achievable, Realistic/Relevant and Timed) goals with Goal Attainment Scaling (GAS) and created evidence-based compensatory strategies to mitigate the reported problems. Outcome measures will be evaluated 4 and 12 months after baseline.

Results

Eight subjects with persistent TBI-related symptoms were included. Preliminary target outcomes were related to memory, planning/organizing, emotional regulation, sleep, depression, communication and physical functioning. More detailed results of the target
outcomes, feasibility of the intervention and 4 months results with GAS will be presented at the Congress.

**Conclusion**

Conclusions will be presented at the Congress.

A REVIEW OF CURRENT WEARABLE TECHNOLOGY AND INNOVATIONS FOR REHABILITATION FOLLOWING HIP AND KNEE REPLACEMENT.

S. Bahadori\textsuperscript{1}, T. Immins\textsuperscript{1}, T. Wainwright\textsuperscript{1}

\textsuperscript{1}Orthopaedic Research Institute, Health and Social Sciences, Bournemouth, United Kingdom

Introduction/Background

Total knee replacement (TKR) and total hip replacement (THR) are highly successful operations for controlling pain, restoring function and enhancing quality of life for patients with hip and knee osteoarthritis. However, approaches to rehabilitation following surgery vary greatly and evidence is limited with regard to successful interventions. There is a wide variety of new technologies and wearable sensor devices currently being marketed, which are proposed to assist with rehabilitation following joint replacement. However, very little is known about how these technologies work, how they differ, and whether they are effective.

Material and Method

A search was conducted of the PubMed database of studies from January 2000 to October 2017. The Review was structured using the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) statement. Search terms included: hip arthroplasty, hip replacement, hip prosthesis, knee arthroplasty, knee replacement, knee prosthesis, rehabilitation, recovery, trackers, devices, wearables, and sensors. Studies included those that were published in English language and examined portable wearable technologies capable of providing feedback to the end user following hip or knee replacement surgery.

Results

Five studies met the eligibility criteria, and all used an accelerometer and a gyroscope for their technology. A review of the studies found very little evidence to support the efficacy of the technology, although they show that the use of the technology is feasible.

Conclusion

Wearable technology is being promoted by companies as a way of improving rehabilitation following THR and TKR surgery. However, this review finds very little evidence to support its efficacy. Future work should establish which wearable technology is most valuable to patients, which improves patient outcomes, and the most economical model for deploying the technology.

The objective of the rehabilitation of physical exercise should enhance the speed and efficiency of the return of motor functions affected after accident injuries, which affect the efficiency of the motor system. The hope is to reduce functional motor disabilities, allowing the person to return to the level of professional activities and sports to the previous life. The results of this study show the weakness of the outcomes of the injured after the rehabilitation of accident injuries. As such, the goal of the research is to determine the standards of physical recovery and indicators of verification between the stages of rehabilitation programs for functional disabilities resulting from accident injuries.

Material and Method

After completion of the review of the qualifying objectives and the exercise content for each stage of the physical and motor rehabilitation programs, a number of transitional criteria were assumed from a qualification stage to the next stage, and indicators were developed to measure the criterion. These criteria were presented to physical and medical rehabilitation experts and practitioners to express their views on these criteria.

Results

Three basic criteria were achieved in the initial rehabilitation phase. The second phase was achieved by five basic criteria; including improving the fixed strength of the muscles by 15-20%, improving the motor range of flexing the joints from 5-10 degrees, loading at least 50% of the body weight on the injured side, improving the fixed balance on the end injured, and improved walking with reduced auxiliary tools. The number of standards in the third phase was 8, the fourth phase was 10 and the fifth phase was 13 standards.

Conclusion
When designing rehabilitation exercises programs for functional disabilities resulting from accident injuries we should rely on the criteria of transition, and not to move from one stage to another only after meeting the standards and measurement indicators.

DIRECTED ACYCLIC GRAPH (DAG) TO ANALYSE THE IMPLEMENTATION OF A CLINICAL PRACTICE GUIDELINE WITH A TELE-REHABILITATION PROGRAM AFTER LOWER LIMB AMPUTATION: INSIGHTS FOR EPIDEMIOLOGIC RESEARCH

M. Giraldo-Prieto¹, J. Plata-Contreras¹, J. Donado-Gomez²
¹Universidad de Antioquia, Medicina Física y Rehabilitación, Medellín, Colombia
²Universidad de Antioquia, Epidemiology-Faculty of Medicine, Medellín, Colombia

Introduction/Background

The graphical and algebraic formulation of the Directed Acyclic Graph (DAG)(1) are useful tools to analyse how the combined effects of multiple variables affect rehabilitation outcomes. Based on systematic reviews, this lecture shows how multi causal interactions affect Odds Ratios/Risk Ratios in rehabilitation for the amputee.

Material and Method

To facilitate the understanding, the lecture takes the recommendations derived from The Clinical Practice Guideline (CPG) for the surgery and rehabilitation after lower limb amputation.(2) These analyses are a core step of the methodology of an ongoing randomized controlled trial (RCT) (Colciencias Research code 57229) that analyzes the effect of TeleRehabilitation as a Knowledge Translation strategy to implement the CPG -patients´ version-(3) and to evaluate the adherence of persons with recent amputations to such CPG recommendations and the change in their health status.

Results

A classical way to explore the effect of a treatment is to draft a linear path between an exposure (exercise) and the outcome (recovery of walking) (Figure 1). Therefore, the statistical analysis lacks an accurate detection of other multi-causal effects.(4) A real effect of an exposure (adherence to stump care) could be obscured by multiple variables (i.e. stump edema) on the final effect of the outcome (healed stump) (Figure 2)

Conclusion

To understand real impacts, clinicians and researchers face the challenge of the simultaneous effects of treatments (adherence to exercise) and their interaction with multiple comorbidities (cognition, deconditioning, diabetic polyneuropathy and stump quality), as it happens in real life. These comorbidities modify the relationship between the intervention (rehabilitation) and the outcome (walking). The DAG causal diagrams (confusion, interaction, collinearity or mediator variables) (5)(6) allows a landscape to analyse multi causal effects and facilitates the individualization of research results at the physician´s desk.

TELEREHABILITATION OF PATIENTS WITH INJURIES OF THE LOWER EXTREMITIES
A. Hospodarskyy1, A. Tsvyakh1
1Horbachevsky Ternopil Medical University, Traumatology and Orthopedic, Ternopil, Ukraine

Introduction/Background

Background. Orthopedic rehabilitation is a subspecialty that involves the care of patients who have complex musculoskeletal problems. After the injury in the body of the patients, physiological constants are temporarily violated, causing protective, restorative and compensatory reactions. Currently not sufficiently studied sequential algorithm of dosed loads on the injured extremity after immobilization and postoperative treatment of patients, not studied physiological and pathophysiological response for the sequence and dose of axial load on the limb.

Material and Method

All patients were undergo generally accepted methods of rehabilitation in hospital. Patients trained with the method of assessment of pain on a 10-point scale, the method of measuring the volume of soft tissue and compared it with healthy limb before and after each stage of the exercise.

Results

In a telerehabilitation program participated 27 patients with injuries of the lower extremities affected more than 2 months ago. The system of remote monitoring includes device with sensors (with 6-axis sensor, pulse-oximetry, temperature sensor), fixed to the injured limb and software. During the telemonitoring physician controls the adequacy of execution of exercises and has the ability to adjust the load depending on the functional state of the limb. Software allows monitoring the exercises time, the frequency of active movements of injured limb, pulse.

Conclusion

Telerehabilitation is good alternative for providing access to specialty care for the growing number of patients with traumatic injuries. Telerehabilitation system and dosed load algorithm can be used in a complex rehabilitation of patients with injuries of the lower extremities. This will improve the quality of life in this group of patients and significantly reduce the cost of the rehabilitation period.

TELEREHABILITATION OF PATIENTS WITH INJURIES OF THE ELBOW JOINT OF THE UPPER EXTREMITIES
A. Tsvyakh¹, A. Hospodarskyy¹
¹Horbachevskiy Ternopil Medical University, Traumatology and Orthopedic, Ternopil, Ukraine

Introduction/Background

The international orthopedic community aims to achieve the best possible outcome for patient care by modifying rehabilitation methods and using telemedicine technology. Therefore, the overarching theme of this paper is to acknowledge the gold standard in implementation of the telemedicine technology for rehabilitation of the patients with injuries of the elbow joint of the upper extremities. Currently not sufficiently studied sequential algorithm of movement activity on the injured upper extremity after immobilization, not studied physiological and pathophysiologica response during rehabilitation.

Material and Method

Consecutive patients were recruited over a two-year period. 67 subjects with upper extremity elbow joint injuries were enrolled in the study. Thirty-eight patients from the control group underwent traditional rehabilitation procedures for a 2-weeks period after completion of immobilization. 29 subjects were enrolled in the telerehabilitation group for a 2-weeks period after completion of immobilization and were trained with a set of exercises for home use. Home remote monitoring for the 29 test subjects included use of a device with 6-axis sensor, pulse-oximetry, temperature sensor, that was fixed to the injured forearm. During the execution of exercises data from device’s sensors goes to the doctor and displayed as digital data and graphs.

Results

During the telemonitoring physician controls the adequacy of execution of each stage of rehabilitation exercises and has the ability to adjust the amplitude of movements in real time depending on the functional state of the limb and pain syndrome. Software allows monitoring the exercises time, the frequency of active movements of limb, the number of active movements, pulse. The orthopedic during telerehabilitation took significantly less time to consult patients than the traditional rehabilitation. Patient satisfaction was higher for the telerehabilitation than for the orthopedic traditional rehabilitation.

Conclusion

Telerehabilitation is good alternative for providing access to specialty care for the growing number of patients with upper extremity elbow joint injuries.

EFFICIENCY OF LASER FOX III IN THE TREATMENT OF ONYCHOMYCOSIS, REHABILITATION HOSPITAL JULIO DIAZ, HAVANA, CUBA

V. Cisneros¹, S.Y. Gallego Pérez², Y. Coronados Valladares³, J.I. Pluma Jimenes², Y. Suárez Jardínez⁴, P.L. Pazo Mollineda⁴

¹hospital julio diaz, vicedireccion de rehabilitacion, La Havana, Cuba
²hospital Julio Diaz, Rehabilitacion, La Habana, Cuba
³hospital Julio Diaz, Docencia, La Habana, Cuba
⁴hospital Julio Diaz, Podología, La Habana, Cuba

Introduction/Background

Onychomycosis is a health problem, it is considered the most difficult to treat superficial mycosis, in Cuba it constitutes 10% of the superficial mycoses in patients who come to dermatological consultations. Podiatry care is part of rehabilitation services in our country, it is the government's interest to introduce new technologies, the Julio Díaz hospital is an excellent place to try new treatment modalities.

Objective: To evaluate the therapeutic efficacy of LASER FOX III in the treatment of onychomycosis.

Material and Method

Experimental study in 100 patients diagnosed with onychomycosis treated in the podiatry area of the Julio Díaz Hospital, between January 2016 and January 2018. Frequencies and percentages were used, mean, standard deviation, minimum and maximum value were calculated. A homogeneity test was applied (Chi-square), contrasts of parametric hypothesis were performed, unilateral with a student T statistic, Pearson's linear correlation was used to establish a relationship between variables of interest.

Results

The average age was 54.0 ± 11 years, the female sex predominated (77.4%), the mycological study showed as more frequent filamentous fungi (59.5% control group and 64.3% experimental group). In the inter-group analysis there were no differences in the evolution of the patients, both treatments were equally effective (p = 0.557), all patients started with positive mycological studies and the treatments ended with 59.5% of negative results. 58.3% of the sample obtained satisfactory results, by groups the highest percentage of positive results was from the control group (61.9%), against 54.8% of satisfactory results of the experimental, difference not significant (p = 0.389).

Conclusion
The treatment with LASER FOX III is as effective as the pharmacological treatment for symptomatic relief, decrease of the severity index of onychomycosis and elimination of the fungal agent.

Introduction/Background

This study aims to investigate the validity of a smartphone application for post-stroke ADL (activities of daily living) management based on an evaluation by users and experts.

Material and Method

The research design was done according to the ADDIE (Analysis-Design-Development-Implement-Evaluation) model. In the analysis phase, we researched and analyzed other applications and items to investigate stroke patients' disease-related knowledge and devise contents for the smartphone application to be developed. In the design phase, we wrote a list of ADL and created a database and scenarios based on expert meetings. In the development phase, we created and configured the contents. In the implementation phase, we downloaded the application on the smartphones of 33 users and 30 experts, taught them how to use it, and asked them to use the application for four weeks. In the evaluation phase, we investigated the content validity and reliability of the application and evaluated the usability of the application. Data were analyzed using the SPSS 21.0 software. Users’ and experts’ evaluation scores were analyzed using descriptive statistics. Content validity was tested with content validity index (CVI), and reliability was tested with Cronbach's alpha.

Results

The results were as follows. Users gave an average rating of 2.93 out of 4 for the application for managing ADL of stroke patients. Experts' evaluation was 3.14 out of a score of 4. The experts were more satisfied with the application than did the users. The overall CVI of the application was .93, and the overall Cronbach alpha was .85, indicating that both validity and reliability were high.
Conclusion

The STROKE CARE application confirmed that it is easy to use videos about the information needed for stroke patients and management of ADL without restriction of time and space. We speculate that the STROKE CARE application is usable and would be helpful for stroke patients to manage ADL.

EARLY REHABILITATION OF DISTAL RADIUS FRACTURE THROUGH REHAND: AN INNOVATIVE DIGITAL TOOL.
A. Suero Pineda¹, M. Rodríguez Piñero², P. Rodríguez Sánchez-Laulhe³, J. Blanquero Villar⁴, L. Gabriel Luque Romero³, M. Dolores Cortés Vega⁴
¹Health researcher, Andalusian Public Health System, Seville, Spain
²Head of Rehabilitation Service of Hospital Virgen Macarena
³Head of Reseach of Seville’s District North, Andalusian Public Health System
⁴Health Researcher, University of Seville

Introduction/Background
Distal radius fractures are very common and estimations point out an increase incidence of 50% by 2030. Home program exercises are predominantly used in clinical practice. Evidence shows that these programs need to be personalized, progressive, controlled and early implemented. There is a period of time patients have to suffer without treatment before be attended by rehabilitation services.

We propose the use of ReHand to accelerate rehabilitation treatments, provide patients with personalized exercises programs and allow rehabilitation services to monitorized this process. ReHand is an app tablet which implement exercises based in new paradigms of sensorimotor system and a dashboard that allows rehabilitation services to monitored patients.

Material and Method
Urgency and rehabilitation services of Hospital Virgen Macarena and Hospital Virgen del Rocio will select patients with diagnosis of distal radius fracture to be enrolled in a prospective clinical trial comparing those who received ReHand home exercise program with those enrolled in the rehabilitation services. When trauma services remove the splint one group will received ReHand and the other group will be send to rehabilitation service where will be provide with traditional home exercise program guided by paper sheet. Outcomes: dexterity (Nine Hole Peg Test), grip strength, sensorimotor assessment (Joint Position Sense), arc of motion for wrist flexion and extension and functionality (Patient Rate Wrist Evaluation Scale). Assessments take place at 3 weeks and at 3 month. This study is part of a multicenter study of Andalusian Public Health System.

Results
Currently we are in analysis data and evaluation results phase. According to our preliminary studies we expect have significant results time before the congress.

Conclusion
According to our preliminary outcomes we will be able to conclude that Rehand is an effective tool for to improve the functional status of the hand after a distal radius fracture with better outcomes than traditional method.

Introduction/Background

Androgen ablation therapy (ADP) in prostate cancer patients may cause complications such as cardiovascular disease, metabolic syndrome and fatigue. The study aimed to evaluate the effect of regular rehabilitation exercise using smart after care in improvement of exercise capacity in prostate cancer patients undergoing ADP.

Material and Method

The prostate cancer patients under ADT with age of or over 40 years were recruited and randomly allocated. The exercise group was provided with a smart aftercare program application and wearable device, providing general health information, nutritional and medication care and rehabilitation program which was adjusted in level according to the test results at 6 weeks follow up. The patients visited at time of enrollment, 6 weeks and 12 weeks and their physical performance status (2 minutes’ walk test, 30-second chair stand test, grip strength test, short physical performance battery) was tested. The quality of life and satisfaction
was evaluated with questionnaires (EORTC QLQ C30, PR 25) and body composition was additionally measured.

Results

After 12 weeks, the exercise group showed significant improvement in social functioning (P=0.016) as well as in appetite loss (P=0.048) (Table 1). Both groups showed significant improvement in urinary symptom, whereas the exercise group additionally showed significant improvement in sexual functioning (P=0.032). In the aspect of physical performance, both groups showed significant improvement in 30s chair stand test and 2 minutes' walk test after 12 weeks of smart aftercare program, whereas the exercise group had additional significant improvement in right hand grip strength (P=0.047) and reduction in body fat percentage (P=0.003)(Table 2).
Table 1. Change in quality of life of prostate cancer patients after smart after-care

Conclusion

The smart aftercare program is a safe, highly satisfied method that also helps increase compliance among participants. Therefore it is an effective method in prostate cancer patients under hormone therapy in improving exercise capacity and general health related quality of life.

Keywords

Smart after-care; Prostate cancer; Hormone therapy

THE EFFECTIVENESS OF TELEHEALTH FOR THE TREATMENT OF CHRONIC SHOULDER PAIN IN WHEELCHAIR USERS WITH SPINAL CORD INJURY: A PROTOCOL OF RANDOMISED CONTROLLED TRIAL

P.H. Barbosa¹, L. Harvey², E. Fachin Martins¹
¹University of Brasilia, Faculdade de Ceilandia, Brasilia, Brazil
²University of Sydney, Kolling Institute, Sydney, Australia

Introduction/Background

Shoulder pain is a debilitating and highly prevalent problem for people with spinal cord injury. Home exercise programmes are typically a compilation of exercises provided to patients on paper handouts. The objective of this study is determine the effect of advice and a home exercise programme delivered through an App, text messages and weekly telephone contact versus no intervention on chronic shoulder pain during performance of daily activities.

Material and Method

The trial will be a pragmatic single-centre, single-blinded between-participant randomised controlled trial. Eligible participants will be randomised to one of two groups (Intervention group or Control group). Intervention group will receive advice and a home exercise program along with encouragement, reassurance and support delivered through an App, text messages and weekly telephone contact for 6 weeks. At the initial face-to-face session (only that) the physiotherapist will provide advice and reassurance, and prescribe a home exercise program using freely available web-based software (www.physiotherapyexercises.com). The exercise program will be sent to participants' mobile device as an App. Participants will be encouraged to exercise six time a week and use the App to record their exercise adherence. Adherence will be remotely monitored and used as a reference for each weekly phone call and text message. Control group will receive no treatment. A sample size of 72 will be required to provide an 80% probability of detecting a between-group difference equivalent to 15 points on The Wheelchair Users Shoulder Pain Index.
Results

A Redcap database has been set up to capture the results. Recruitment will commence in May 2018 and finish in April 2018.

Conclusion

The results will provide precise estimates of the effects of a low cost way to manage shoulder pain in this population. If effective, this intervention could be rolled out in different countries.

TELECOMMUNICATION TECHNOLOGIES FOR DISTANT CONTROL OF THE PATIENTS AFTER STROKE.
P. Tkachenko¹, V. Daminov¹
¹National Medical Surgery Center named by N.I.Pirogov, medical rehabilitation, Moscow, Russia

Introduction/Background

Many patients after stroke can`t continue professional rehabilitation in the remote regions of Russia. Telerehabilitation via the telecommunication technologies will provide continuous rehabilitation for the patients at home in the most effective period of the impaired function`s recovery.

Material and Method

18 patients, 1 month ± 10 days after ischemic stroke. Released from the hospital patients had right-sided hemiparesis up to 3 points (Muscle Strength Grading Scale); walking was possible with bilateral support – 5 and 6 points (Hauser Walking Index); 3 and 4 points (modified Rankin scale); cognitive disorders ~ 21,2 (MMSE); dependence in activities of daily living ~ 68.7 points (Barthel scale). 9 patients continued to train by themselves at home (control group), 9 patients had distant sessions under physiotherapist and neuropsychologist control via protected video link during 3 months, 3 times/week. Assessment was done on the 30th – 45th - 90th days of treatment.

Results

After 3 months of treatment 5 patients of the main group had changes in Hauser walking index from 6 to 5 points, in 4 patients - from 5 to 4. Memory-intellectual functions increased at 5,5 points. 8 patients changed the MMSE grade to a slight cognitive impairment. Patients became more active in daily living at 24,2 points, the control group only at 13 points. Only 1 patient had changes from 5 to 4 points in control group. Cognitive functions of 7 patients were improved at 1,5 points, 2 patients had a positive shift by 3 points. Assessment in Rankin scale for both groups remained the same.

Conclusion

Continuous distant control by the medical specialists and positive results of treatment are good stimulating and motivating factors for rehabilitation. We can do preliminary conclusion on the efficacy of the telemedicine technologies in the Stroke patient`s rehabilitation at home. Expansion of the study to obtain reliable results is needed.

ISPR8-2088
BUILDING A GLOBAL TELEMEDICINE PLATFORM BASED ON BASIC ETHICAL PRINCIPLES OF BENEVOLENCE AND BENEFICENCE TO OVERCOME THE REGULATORY AND LEGAL BARRIERS
S. Vaidya¹
¹Burke Rehabilitation Hospital, Physical Medicine and Rehabilitation, White Plains, USA

Introduction/Background

Advances in telemedicine technology provides an opportunity for rehabilitation practitioners and clients with chronic illness and disabilities to interact, efficiently and cost-effectively. Existing telemedicine platforms are franchised to physicians with restrictive contracts thus limiting the choices to recipients and the scope of usage of telemedicine in general and tele-rehabilitation in particular. The internet is by its very nature, international and can enable the markets for cross border services to grow rapidly. Healthcare typically poses a greater risk to patient safety than other e-commerce services and underpinned by a complex set of regulations.

Material and Method

The main objective is to build a freestanding telemedicine application platform for global usage based on basic ethical principles of benevolence and beneficence to overcome regulatory and legal barriers. The aim is to connect clients with chronic illness and disabilities with their trusted rehabilitation practitioners through internet. The trusted practitioners could recruit global talent and globally available technologies to help their client. The second goal is to expand the use of innovative tele-rehab technology.

Results

The result of the extensive research and sample contracts drawn by global legal experts will be presented. The innovations in, globally compliant, encryption technology to protect client’s medical information, will also be presented.

Conclusion

Telemedicine developers need to venture into such innovations, to promote global health and use the available advances and affordable technology.

CLINICIAN PERSPECTIVES OF AN AVATAR-DIRECTED SCHEDULING AND MEMORY AID
C. Morris¹, C. Barr¹, M. van den Berg¹, S. George¹, M. Crotty¹
¹Flinders University, Rehabilitation- Aged and Extended Care, Bedford Park, Australia

Introduction/Background

An avatar-directed scheduling and memory aid app (Anna Cares™) was identified as a potential solution to scheduling difficulties in busy rehabilitation services. However, there are well documented difficulties with clinician acceptance and uptake of technology. This study investigated clinician perspectives of Anna Cares for use within two rehabilitation teams.

Material and Method

Two focus groups were conducted with sixteen clinicians from various disciplines working in two rehabilitation settings at a metropolitan hospital in Adelaide (SA, Australia). Focus groups aimed to explore, clinicians’ perceptions of acceptability and usefulness of the app, and their attitudes towards this type of technology in general. Clinicians also completed self-assessed technology proficiency, perceived usefulness, and perceived ease of use scales.

Results

Clinicians described time constraints and the reliable scheduling of therapy sessions to be of significant importance, and they welcomed technology that could assist with this. They liked the concept of the avatar and found the app novel and fun. However, the preparation of the app for use with patients was problematic and time consuming. The more experienced clinicians found the app more difficult to use (r=.586, p=.027) and did not see the app as beneficial to their patients nor did the technology add value to delivery of care. There was a significant relationship between age and mean value for ease of use (r=.540, p=.046) but no significant relationship between age or experience, and the mean score for usefulness. Nor did there appear to be a relationship between self-assessed level of technology proficiency and either perceived usefulness and perceived ease of use.

Conclusion

Although clinicians appreciated the concept of an avatar-directed scheduling and memory aid, they did not see it as a useful tool in the provision of scheduling assistance in short-term rehabilitation services.

Cervical range of motion evaluation as an integral part of the physical examination and functional evaluation of patients with musculoskeletal disorders, through which clinicians identify joint and muscle limitations to select the appropriate therapeutic plan. Currently, the use of smartphone applications has become increasingly popular since they are more convenient than other tools, are user friendly, do not require trained users, and are more cost effective than other tools. Thus, the purpose of this study was to compare the reproducibility and accuracy of clinometer and the compass applications on iPhone smartphone to those of the CROM device, as the gold standard for non-invasively evaluating cervical movements.

Material and Method

The CROM device and iPhone 6S were used for evaluations. Two examiners, who were PhD candidates in orthoses and prostheses, conducted the assessments. Cervical range of motions
in three planes were evaluated as the subject sat upright on an 18-inch chair with the knees at 90° of flexion, feet flat on the ground, arms relaxed at the sides, and head and neck in a neutral position.

Results

Based on data obtained of 24 healthy subjects, both instruments, the CROM device and applications of iPhone showed excellent intra-rater reliability for all three planes. For the CROM device and iPhone applications assessments, the inter-rater reliability in the all three planes were excellent except in flexion measurement by clinometer application, which was moderate. The validity analysis of the iPhone showed very high or high correlation for all movements, except for flexion. Comparison of the measurements taken using the iPhone, with the ROM measured obtained using the CROM device, as demonstrated on the Bland-Altman plots, revealed that the iPhone showed a higher ROM for extension and lower ROM for other movements.

Conclusion

The iPhone clinometer and compass applications had acceptable absolute and relative reliability for neck movements in all planes.

CURRENT PRACTICE PATTERNS IN THE MANAGEMENT OF BELL’S PALSY AMONGST PHYSIOTHERAPISTS IN NEPAL: A CROSS-SECTIONAL STUDY
T.K. Limbu¹, G. Nepal¹
¹Kathmandu University School of Science, physiotherapy, Dhulikhel, Nepal

Introduction/Background
Bell's palsy (BP) is an idiopathic, acute, unilateral paralysis of the face in a pattern consistent with peripheral facial nerve dysfunction, affecting 1 in 60 people. Evidence for physiotherapy management of BP is heterogeneous and limited. Current clinical practice guidelines recommend tailored facial exercises including mime therapy for patients with persistent weakness and recommend against the utilization of electrical stimulation in BP. No studies have looked at current physiotherapy treatment patterns for BP management. The aim of this study is to find out current physiotherapy practice patterns in the management of Bell's palsy in Nepal and to compare current practice with guidelines.

Material and Method
A questionnaire was distributed to registered physiotherapists throughout Nepal utilizing various internet platforms and in person. Information collected included demographics, level of education, years of experience, and management strategies utilized for treating BP. Descriptive data analysis was completed utilizing SPSS 16.0.

Results
Total number of participants was 116. The majority (78%) of physiotherapists prefer to use electrical stimulation for management of Bell's palsy. Only 34% of physiotherapists utilize mime therapy. Most (72%) physiotherapists believe that their management is in line with current evidence-based practice.

Conclusion
The majority of Nepali physiotherapists utilize electrical stimulation for the management of BP, and also believe their current management is in line with evidence-based practice for BP. These dichotomous findings suggest that further education and standardization of physiotherapy management of BP in Nepal is needed.

ACCESSIBLE TEMPORARY HOUSES, REHABILITATION PLANNING IN EARTHQUAKE AREAS IN UMBRIA: ASSESSING FUNCTIONING PROFILES IN PERSONS WITH DISABILITIES

M. Porzi¹, A. Bellanti², M. Zampolini²
¹Assistive Technology Center, Rehabilitation Department- USL Umbria 2, foligno, Italy
²Rehabilitation Department, USL Umbria 2, Foligno, Italy

Introduction/Background

This study comes from needs of people with disabilities after the earthquake in central Italy in 2016. People with disabilities that lose their house undergo changes in living conditions, housing, social life and health services. That leads to a reduction in activities, in assistance skills of families, in participation and in quality of life. We plan to project Accessible Emergency Housing Solutions (SAE) in accord with “design for all” criteria, to assessing people with disabilities, to provide and personalize Accessible SAE, to plan rehabilitative interventions solutions to improve participation, quality of life in the new life context post earthquake.

Material and Method

The project involves the Rehabilitation Department of USL Umbria 2, the Assistive Technology Products Centre, Health Districts, Municipalities, Umbria Region Civil Protection.
We defined appropriate tools based on ICF, adapted to the specific needs in earthquake emergency, to systematically assess disability related problems.
We used a direct semi-structured interview to collect informations about health, functioning, family context and assistance need.
We created functioning profiles to define the appropriateness of SAE’s assignment and house adaptation needs to improve accessibility.

Results

We included 194 people with disabilities candidate for Accessible SAE; 102 people had functional limitation or other conditions that required adapted temporary accessible houses, personalized and with appropriate size.
783 SAE will be realized in earthquake areas, 102 of them (13%) will be Accessible SAE. People will be checked after the entrance in the Accessible SAE to define the impact of them on quality of life and to plan eventual rehabilitation and assistance programs.

Conclusion
The application of ICF based assessment tools improved disability management, allowing the identification of accessible housing, technologies and rehabilitation needs to improve participation and social inclusion.

The study shows the importance of standardising the assessment of disability in a more complete biopsychosocial framework to support disability in disaster areas.

Introduction/Background

Background: The study will assess the acceptability, practicality, preliminary efficacy of an integrated model of rehabilitation and paediatric HIV services in order to improve diagnosis and interventions for disability among children living with HIV. The model will integrate data entry and management tools, improving identification, referral and linkage to care, with an intervention manual that can be used by trained lay health professionals. The study targets cognitive disabilities to improve school readiness and success.

Material and Method

Methods: Phase one will inform the design of an optimal integrated model of rehabilitation and paediatric HIV care. The study will first undertake a formative investigation of the factors relating to integrating rehabilitation with paediatric HIV services from the perspective of caregivers and health professionals. It will use qualitative methods, including in-depth interviews and focus group discussions. The knowledge from this phase will inform the design of the model in phase two and phase three will pilot the integrated rehabilitation and paediatric HIV model at the study site. The pilot intervention will be formally evaluated.

Results

Results: The results from this study will determine whether the model has potential for widespread application in South African paediatric HIV care and what further modifications are needed.

Conclusion

Conclusion: The study results will also inform South Africa’s current efforts to strengthen early interventions for children with disabilities and will be an important and critically needed step in the use of rehabilitation to strengthen paediatric HIV care in the region.

GLOBAL DISABILITY ACTION PLAN 2014–2021 (GDAP): THE WAY FORWARD
F. Khan¹, B. Amatya¹, A. Elmalik¹, M.P. Galea²
¹Royal Melbourne Hospital, Department of Rehabilitation Medicine, Parkville, Australia
²University of Melbourne, Department of Medicine Royal Melbourne Hospital, Parkville, Australia

Introduction/Background

An estimated 80% of persons with disability (PwD) live in low- and middle-income countries (LMICs), with significant burden of disease and subsequent disability. The WHO Global Disability Action Plan 2014–2021 (GDAP), provides a list of specific actions and metrics for the empowerment of PwD, including strengthening/extending rehabilitation, assistive-technology, support services, and community-based rehabilitation. The aim of this study was to identify potential barriers for implementation of the GDAP in LMICs.

Material and Method

The Flying Faculty rehabilitation team from the Royal Melbourne Hospital, Australia conducted intensive workshops at medical/academic institutions in LMICs for healthcare professionals from various local Physical Medicine and Rehabilitation (PM&R) facilities. A modified Delphi method identified challenges for future implementation to address gaps identified.

Results

Despite differences in the healthcare system and practices in LMICs, the challenges reported in four countries, at both macro (governmental/policy makers) and micro levels (community/social/individual) were similar. Common strategies were implemented to address challenges: limited knowledge of disability services, PM&R workforce, guidelines and accreditation standards; coordination amongst healthcare sectors; social issues; data and research; legislation and political commitment. Support of potential facilitators were: need for strong leadership; advocacy of disability-inclusive development; investment in infrastructure/human resources; coordination/partnerships in healthcare sector; and research.

Conclusion

Disability care and rehabilitation is an emerging priority in LMICs to address the needs of people with disability. The GDAP framework provides guidance to facilitate access and strengthen PM&R services.

ISPR8-0817
CAPACITY BUILDING FOR REHABILITATION PROFESSIONALS IN EASTERN UKRAINE: TOWARDS IMPROVED COMPREHENSIVE AND INCLUSIVE CARE FOR INJURED AND VULNERABLE PERSONS AFTER HOSPITALIZATION.
E. Weerts
Handicap International, Emergency and Rehabilitation, Brussels, Belgium

Introduction/Background

Eastern Ukraine is subject to a status of “frozen” armed conflict currently leading since a few years to increasing pressure on equitable access to Rehabilitation services for the population in need either displaced or not. The Health Cluster for Eastern Ukraine aims to improve the technical capacity of the health services delivered through upgrading the training of rehabilitation professionals throughout the trauma care pathway as well as addressing the needs of injured and disabled people through expansion of adapted services at regional and community level.

Material and Method

Training periods were conducted in general hospitals based on WHO guidelines, Minimum Standards for Rehabilitation and particular courses and topics for management of injured in complex settings. This was completed with practical demonstrations and bedside teaching putting emphasis on the need for patient education and psychosocial needs after discharge.

Results

The rehabilitation workforce targeted by the training is in demand for specific capacity building in post acute management of trauma care to allow an optimal recovery of the patient, preventing post operative complications, providing personalized patient education and psychosocial advise before discharge to the community. Early mobilisation and stimulation leads to shorter lengths of stay when needed trained workforce of PT, OT and special educators are available.

Conclusion

Ongoing Health and Rehabilitation Strategy Reforms in Ukraine should include early comprehensive physical rehabilitation in trauma centers, filling gaps at the level of community follow-up and be completed with psychosocial services for the beneficiaries of the health system. The particular ongoing strain that Eastern Ukraine is experiencing should be paid more attention too in regard to access to services in an adapted manner proper to the specific context.

Conflict of interest
Disclosure statement:
This activity was financed and made possible by WHO health Cluster support project for Eastern Ukraine and implemented by a staff from Humanity and Inclusion NGO.
Introduction/Background

This report characterizes traumatic rehabilitation injuries due to the 2017 Bangladesh landslides. Emergency care for rehabilitation conditions provided by field respondents, at receiving community treatment centers, district and at regional hospital(s) is described. Recommendations to improve rehabilitative care in future landslides are provided.

Landslides are triggered by external processes including earthquakes, rainstorms, and slope disturbance by humans. Humans are highly vulnerable to the high energy forces of sliding earth and debris which can result in severe traumatic physical injury and death. Landslides triggered by torrential seasonal monsoon rain began early June 2017 and severely affected 42,000 persons in several hilly and coastal districts of Bangladesh. Material and Method

An electronic literature search was performed to identify relevant articles on landslides in Bangladesh, Southeast Asia, and other developing countries. Reports from government and non-governmental sources including relevant hospital admissions data were obtained and analyzed. Information was also obtained through personal communications with local health and emergency management officials and from local and international media sources.

Results

The 2017 Bangladesh landslides resulted in 172 deaths and 11 missing persons. Thousands of persons received first aid from responding medical teams. Of the 194 persons admitted to district hospitals for severe injuries, 33.50% of injuries treated were musculoskeletal conditions. Twelve (12) persons with critical injuries including long bone fracture, spinal injury, and head injury were referred to a regional tertiary hospital for management by neurology, orthopedic
surgery, physical Rehabilitation medicine and psychiatry specialists

Conclusion

Landslides can result in severe traumatic injuries. Rehabilitative treatment with involvement of physiatrists should be provided at all levels of emergency care. Specialized rehabilitation
response teams should be employed in landslides and other severe natural disasters in Bangladesh

GLOBAL ADVOCACY FOR WOMEN WITH DISABILITIES: FORGING INTERNATIONAL RELATIONSHIPS
A. Akande¹
¹The Pennsylvania State University – Abington College, Rehabilitation and Human Services, Philadelphia, USA

Introduction/Background

The promotion of global advocacy, international research and service, multi-cultural education, and encouraging rehabilitation professionals to work and intern overseas are areas that our field would benefit from expanding on. Specifically, women and girls with disabilities around the world and the organizations that serve them are looking to collaborate and communicate internationally, for the sharing of ideas and resources, and to receive support. “Women and girls with disabilities represent more than 500 million people (the population of the European Union) and they face, on a daily basis, violations to their human rights; including, forced sterilization, forced abortions, violence and abuse, lack of access to sexual and reproductive health services, among many others” (Women Enabled International, 2016, p. 2).

Material and Method

The presenter hopes to engage in conversations with conference attendees about the ways that we as individual professionals/students and as a field can be more deliberate and organized in our efforts to reshape the idea of inclusiveness to promote ideas of global citizenship. The presenter is currently engaged in international research herself, as it relates to services and experiences of women with disabilities.

Results

This poster will feature findings from the Global Disabled Women’s Rights Advocacy Report (2016), which was the result of international surveys and interviews to gain information about current advocacy efforts and organizations for women and girls with disabilities around the world. This included an assessment of programmatic resources and needs.

Conclusion

Women with disabilities and their service providers want to work collaboratively, enhance their skills and demand their rights. This highlights a need to develop mechanisms for collaboration, strategies for organization capacity building and increased funding for these organizations. Across interviews, barriers to productive collaboration were found to be Capacity,
Communication, Competition, Funding, Language Barriers, Leadership, Qualified Staff, Time, and Willingness to Collaborate.

*No conflict of interest*
Introduction/Background

December 26, 2004 an earthquake with a magnitude of 8.9 SR US followed by tsunami has hit the west and north coast of Nangroe Aceh Darussalam (NAD) province and North Sumatra region in Indonesia. Hundreds of thousands has been dead, many more have been injured, it also caused damaged to almost every infrastructures including health services.

Health problem related to earthquake and tsunami other than respiratory problems are multiple bone fractures, peripheral nerve injuries, severe infected wounds, gangrenes which often lead to amputation of the injured limbs. The only rehabilitation centre in Aceh province at Zainoel Abidin hospital in Banda Aceh, have been damaged seriously including all equipments for mobility and the prosthesis-orthosis workshop. Many limb amputee persons, has great need for prosthesis so they can walk and do their daily living activity. Prosthesis manufacture need special skill and are individually design.

Material and Method

After early assessment, a special rehabilitation medicine team together with an international NGO, work for relief after disaster, made and distribute free prosthetic-orthotics.

Results

From april 24, 2005 till March 29, 2006 the rehabilitation medicine team and prosthetic-orthotic technicians has made seven visits to Banda Aceh and approximately for three to four days on each visit. The team made and give one hundred fifty (150) free prosthesis-orthosis appliances for 134 amputee. All these prosthetic-orthotic appliances was made at the orthotic-prosthetic laboratory. Departement of Rehabilitation Medicine, Cipto Mangunkusumo teaching hospitals in Jakarta.

Conclusion

There is a great need to rebuilt rehabilitation medicine services in Aceh with its infrastructures, equipments and specialized trained person such as rehabilitation medicine specialist and prosthetic-orthotic technician. Long term plan from rehabilitation medicine view are to develop a
mobile limb workshop for rehabilitation medicine services, so an outreach program can be done more effectively.

**REPORT ON 2016 EARTHQUAKE IN CENTRAL ITALY. THE JOB OF SIMFER FROM 2016 TO 2018.**  
G. Pestelli

SIMFER, Italian Society Of PM&Rehabilitation, Forli, Italy

**Introduction/Background**

A big earthquake Richter scale 6.0 hit central part of Italy 24 August 2016 and after a lot of less strong earthquakes again in October and November 2016 and January 2017. The regions were Lazio, Marche, Umbria and Abruzzo. Simfer began his job immediately in all the parts of EQ. Especially in the villages of Arquata and Pescara del Tronto (Marche), Amatrice (Lazio), Norcia e Cascia (Umbria). Who is speaking as responsible of SIMFER for the relief in natural disasters with the collaboration of MDs in Rehabilitation of the areas of EA, went after 3 days in the crater of EA and start to organize activities for the disable people.

**Material and Method**

All the chiefs of Rehabilitation departments of the EA areas were activated for maintain both therapists and MDs present for the needs of people, but they were active also in the place where the inhabitants went after disaster. We were operative in agreement with italian civil safeguard and other institutions.

**Results**

With the help of NGOs and associations we can built a compound for primary care and rehabilitation in the territories of Arquata del Tronto (Marche). The Simfer tent for rehabilitation was active in Cascia (Umbria), while we are again in construction of the compound in Amatrice because of in this part the aids have been more difficult for complete destruction of the village.

**Conclusion**

So as in earthquakes of Aquila (2009) and Modena (2012) SIMFER has been present and active also in this EA both with his MDs in rehabilitation to help local teams and also with advices of his experts.

³Universidad Central, Computer Engineering, Bogotá, Colombia

Introduction/Background

Technology transfer is a permanent challenge in rehabilitation. Academic and corporate initiatives are generating an increasing number of alternatives and therapeutic tools supported in technology which should be transferred to the market via the commercialization and real use of the product with a social impact.

Material and Method

For this purpose, it is necessary to pose an effective transfer strategy from the exploratory stage in academic contexts (R&D) to real clinical practice. This paper presents a case study of vertical technology transfer applied to low-cost computer vision devices for the assessment and rehabilitation of balance and movement in people with multiple sclerosis.

Results

This work defines, from simulation, the potential commercialization of the technology in the market, the economic impact for the developers and the potential beneficiaries and interested parties in the offer of physical rehabilitation services based on computer vision and virtual reality, considering the technology developing costs, potential revenues for the service provider, size of the target population, growth projection and costs of patent registration. To do so, the service providers future income is estimated by exploring a representative set of scenarios, according to a predefined distribution of parameters.

Conclusion
This analysis is carried out through an approach based on Monte Carlo method, which shows a range between 828,085.28 and 5,924,181.37 USD for the commercialization of the technology developed in the world market (Figure 1).

THE EFFECT OF HEALTH EDUCATIONAL APP ON IMPROVING STROKE RELATED KNOWLEDGE AND QUALITY OF LIFE IN PATIENTS WITH STROKE: A RANDOMIZED CONTROLLED TRIAL
C.Y. Lin¹, T.F. Wu², W.H. Hou¹
¹Taipei Medical University Hospital, Physical Medicine and Rehabilitation, Taipei, Taiwan R.O.C.
²Taipei Medical University, College of Nursing- Master Program in Long-Term Care, Taipei, Taiwan R.O.C.

Introduction/Background

Background: Up to date, the stroke knowledge of Taiwanese people is insufficient leading to lots of cost wasted. Furthermore, there are more and more stroke patients with poor health and quality of life. Therefore, in order to prevent stroke patient from stroke again, allowing stroke patients understand the risk factors of stroke is an important issue in the practical field of long-term care.

Purpose: This study had developed an APP that provides health education about preventing stroke patients from stroke again. That can improve stroke knowledge and quality of life in stroke patients.

Material and Method

Method: This study employed a single-blind, randomized controlled trial design. Seventy-six stroke patients were randomly assigned to the health educational APP intervention experimental group (n=38) and traditional paper control group (n=38). Subjects of this study had all been diagnosed a stroke and been tested with Mini-Mental Status Examination scoring more than 24. After 10-30 days of the health educational APP intervention, the Stroke Knowledge Questionnaire and EuroQOL Instrument will be filled. Participants: 76 individuals (30 in experimental group; 33 in control group) were diagnosed stroke and MMSE scores >24

Intervention: 10-30 days of the health educational APP were intervened to improve the stroke knowledge and quality of life. Measurements: The primary outcome was the stroke knowledge, assessing by the Stroke Knowledge Questionnaire. The secondary outcomes were quality of life, assessing by the EuroQOL five dimensions questionnaire (EQ-5D).

Results

Results: Our results supported that the health education APP produced significant improvement in stroke knowledge between groups but the EQ-5D has no significant improvement.
Conclusion

**Conclusion**: The findings supported the clinical efficacy of the health educational APP in stroke patients to improve knowledge and quality of life.

“NOTHING ABOUT ME, WITHOUT ME”. USING USER-CENTRED DESIGN TO DEVELOP EVIDENCE-BASED SOLUTIONS TO COMMON PROBLEMS IN MOTOR NEURONE DISEASE

E. Hobson¹, S. Baxter², E. Pryde³, H. Reed⁴, L. Spronson³, C. Soreny⁵, S. White⁶, C. McDermott¹

¹Sheffield Institute for Translational Neuroscience, Neuroscience, Sheffield, United Kingdom
²University of Sheffield, School of Health and Related Research, Sheffield, United Kingdom
³Sheffield Teaching Hospitals NHS Foundation Trust, Devices4Dignity, Sheffield, United Kingdom
⁴Sheffield Hallam University, Lab4Living, Sheffield, United Kingdom
⁵Optical Jukebox, Optical Jukebox, Manchester, United Kingdom
⁶Sheffield Teaching Hospitals NHS Foundation Trust, Dietetics, Sheffield, United Kingdom

Introduction/Background

Supportive care in motor neurone disease (MND)/amyotrophic lateral sclerosis aims to promote independence and sustain life using assistive devices and interventions such as non-invasive ventilation. Success of these solutions depends on patient and carer acceptance and self-management but this is often hindered by the solutions’ failure to fulfil patients’ expectations or meet the complex and changing needs of those with MND. One reason for this problem is that they are not designed with the end-user in mind.

Material and Method

Patients and carers highlighted the lack of a suitable collar for those with neck weakness. They also concurred with recent evidence that identified the need to provide better, evidenced based information to facilitate decision making, acceptance and self-management of gastrostomy feeding and non-invasive ventilation. Collaborations with patients, carers, clinicians and technology developers adopted iterative, user-centred design methods to develop and evaluate potential solutions based on research evidence and technology expertise and the lived experience of MND.

Results

The Sheffield Head-Up collar was developed and evaluated in a total of 126 patients with MND and other diseases. This affordable and adaptable collar was demonstrated to provide increased support while providing a greater range of movement, flexibility of use, and improved appearance and comfort and was preferred to traditional collars in 80% of users.

MyTube (www.mytube.mymnd.org.uk) and MyNIV (www.myniv.mymnd.org.uk) websites use patient, carer and clinician stories to deliver evidence-based information about considering,
starting and living with a gastrostomy and non-invasive ventilation. These websites are freely available and are now used by clinicians, patients and carers to support decision making.

**Conclusion**

Involving end-users, clinicians and designers in all stages of development of new solutions is key to ensuring that solutions will be acceptable, effective and evidence-based. We recommend ways in which the experiences of these experts can be harnessed in product design.

THE EFFECT OF SINGLE TEACHING SESSION ON PHYSICAL ACTIVITY IN PEOPLE WITH INTELLECTUAL IMPAIRMENT

J. Kesiene¹, K. Luzina², A. Adomaviciene³

¹Vilnius University MF- Vilnius University Hospital Santariskiu Clinics,
Rehabilitation- Physical and Sports Medicine, Vilnius, Lithuania
²Vilnius University, Rehabilitation- physical and sports medicine, Vilnius, Lithuania
³Vilnius University Hospital Santariskiu Clinics, Rehabilitation- Physical and Sports Medicine,
Vilnius, Lithuania

Introduction/Background

Physical activity, health and quality of life are interrelated. A lot of scientific researches declares that people with intellectual impairment have lack of physical activity. Teaching shows to be effective to improve physical activity in different groups. The aim of study was to evaluate effect of single teaching session on physical activity and physical capacity of people with intellectual impairment.

Material and Method

The study was accomplished at daily activity and employment center for disabled people in Trakai. 50 adult people with mild and moderate intellectual impairment were included in this study. Quality parameters of physical activity, physical capacity were evaluated. The subjects were assigned to two groups: experimental (n=25) and control (n=25). The experimental group received single teaching session and printed recommendations of physical activity, while control group have got only printed recommendations of physical activity. Quality parameters of physical activity, physical capacity were evaluated after one month.

Results

Physical capacity by Harvard step test results showed that both groups were of average fitness. Single teaching session have improved physical activity, physical capacity in experimental group statistically significantly (p<0,05). Improvement of physical activity and physical capacity was observed also in control group, but without statistical significance (p>0,05). No statistically significant difference between experimental and control group results of physical activity and physical capacity was found (p>0,05).

Conclusion

Even single teaching session had positive effect on improvement of physical activity in persons with intellectual impairment. Further investigations are needed to determine optimal educational program for this vulnerable group.

IMPORTANCE OF PATIENT EDUCATION THE MANAGEMENT OF LOW BACK PAIN

D. Matanovic¹

¹Medical Faculty University of Belgrade, Clinic of Physical medicine and rehabilitation, Belgrade, Serbia

Introduction/Background

Interdiction identify the information’s needs of people with low back pain (LBP) is very important. LBP is very common and information’s of disease is very important for patients and management of LBP. Available online LBP resources are limited.

The aim of this study is to identify knowledge of patients with LBP

Material and Method

42 patients did questioner about LBP, what is acute, chronic pain, how to recognize disease, how to manage with LBP choosing a answer.

Results

Results 20% of patients chose answers I don’t know, about 50% give correct answer

Conclusion

Education for patients with LBP is necessary. This research suggests that patients with LBP do not have relevant information’s about LBP and do not know how to manage, and reduce sick level. Patient education appears to reduce the negative consequences of fear-avoidance behaviour and thus promote treatment compliance in LBP patients

Keywords

low back pain

IMPLEMENTATION AND EVALUATION OF A REHABILITATION SPECIFIC PATIENT EXPERIENCE SURVEY

F. Simmonds1, J. Capell1, J. Pryor2, M. Fisher2
1University of Wollongong, AHSRI, Wollongong, Australia
2University of Sydney, Nursing, Sydney, Australia

Introduction/Background

Rehabilitation specific patient experience surveys could enhance opportunities for sub-acute facilities to identify factors critical to the provision of optimal rehabilitation care. However, currently in Australia there is no commonly utilised rehabilitation specific patient experience survey. A literature review identified only one relevant instrument, the Client-Centred Rehabilitation Questionnaire (CCRQ)1. The project aimed to evaluate the CCRQ for use in the Australian context and modify it if indicated; assess the validity and reliability of a modified CCRQ; explore the relationship between self-reported patient experiences of rehabilitation and rehabilitation outcomes, such as functional improvement and length of stay as measured by the Australasian Rehabilitation Outcomes Centre; and survey senior rehabilitation staff at each participating facility regarding the utility of reports provided to them based on the survey data.

Material and Method

Data was collected using:
- Focus groups
- Multi-site patient survey
- Senior rehabilitation staff telephone interviews

Results

The CCRQ demonstrated good face validity with some minor modifications to item wording indicated for the Australian context.

A total of 408 completed surveys were returned. Based on analysis of the responses the modified CCRQ demonstrated good construct validity and internal consistency reliability. Analysis provided support for a number of modifications to further improve reliability. The validity of the survey was further supported by survey item responses being independent of patient demographics, facility sector and patient outcomes.

Senior rehabilitation staff feedback from all participating units (20) was very positive regarding the facility reports provided. The rehabilitation specific focus and level of detail was regarded as a point of difference compared with their usual patient experience surveys.

Conclusion
A modified CCRQ is a reliable and valid instrument providing actionable data that organisations could use to support and inform their commitment to person-centred rehabilitation care.

WHAT WORKS FOR WHICH RIDERS, AND TO WHAT EXTENT? EVALUATING THE EFFECTIVENESS OF A NEW ZEALAND THERAPEUTIC RIDING INTERVENTION USING A SINGLE-CASE EXPERIMENTAL DESIGN

R. Martin¹, W. Taylor¹, F. Graham¹, L. Surgenor², W. Levack¹
¹University of Otago- Wellington, Rehabilitation Teaching and Research Unit, Wellington, New Zealand
²University of Otago- Christchurch, Department of Psychological Medicine, Christchurch, New Zealand

Introduction/Background

Therapeutic horse riding (THR) is a complex intervention using horses and horse-related activities to positively influence health in people who experience disability. It is difficult to meaningfully evaluate the effectiveness of complex rehabilitation interventions with parallel randomised controlled trial methods when used in isolation. Reducing intervention complexities to simple variables for the purposes of minimising bias can enhance claims regarding causal associations between variables, but can result in difficulties translating the findings from these studies to ‘real world’ clinical practice where complexity is a certainty. This study aimed to evaluate the effectiveness of a therapeutic horse riding (THR) intervention using a single-case experimental design (SCED).

Material and Method

A randomised, multiple-baseline SCED replicated across 12 participants, was used to quantitatively evaluate in which riders, and to what extent, changes in balance, functional performance, social responsiveness, quality of life and participation outcomes occurred as a result of the 20-week THR intervention. Analysis of data included analysis of individual participant responses (i.e., visual analysis, descriptive nonparametric approaches, analyses considering baseline stability evaluated with Mean Phase Difference and Slope and Level Change procedures) and between participant responses (i.e., Modified Brinley plots, estimation of effect sizes).

Results

An inconsistent intervention response to THR was seen across participants in the SCED. Participation outcomes measured using the Canadian Occupation Performance Measure (COPM) demonstrated the most consistent positive between-phase difference (performance score ES = 1.23; satisfaction score ES = 1.11). However, when taking baseline data stability into account these improvements only reached clinical significance for two of the participants.

Conclusion
Being involved in THR may improve participation outcomes for some children who live with the experience of disability. SCED’s provide a rigorous but clinically meaningful way to evaluate the effectiveness of complex rehabilitation interventions in real world.

DEVELOPMENT OF A MODEL OF CLINICAL EDUCATION: A PROPOSAL FOR PHYSIOTHERAPY UNDERGRADUATE STUDENTS AT THE UNIVERSITY OF KWAZULU-NATAL (UKZN), SOUTH AFRICA

N. Chemane¹, V. Chetty¹, S. Cobbing¹

¹University of KwaZulu-Natal, Physiotherapy, Durban- KwaZulu-Natal, South Africa

Introduction/Background

This project is aligned to a current need for healthcare within a South African (SA) context to address resource poor climates in rural and Peri-urban settings, shifting focus from an over served urban region. Traditionally, clinical education for undergraduate physiotherapy students has been centered on acute services in large teaching urban hospitals closer to the university (McMahon S., et al 2013).

Aim: To develop a model of clinical education for undergraduate physiotherapy students at the UKZN in order to prepare graduates who are socially responsible and responsive to the unique health care needs of SA.

Material and Method

Phase one will inform the design of an optimal integrated model of clinical education. A cross sectional analytical study which will follow qualitative methods, including in-depth interviews and focus group discussions. The participants will involve clinicians, clinical educators and physiotherapy students from the University of Kwa-Zulu Natal. The knowledge from this phase will inform the design of the model in phase two.

Results

The results from this study will determine whether a model of clinical education can be developed and implemented in the School of Health Science in the Physiotherapy discipline. This model will be embracing a call to develop healthcare professionals who are competent and prepared for the changing dynamics of healthcare in a developing world.

Conclusion

It is envisaged that this study, the first to develop the model of clinical education for physiotherapy students in Kwa-Zulu Natal in a decentralised clinical training platform at UKZN, would not only contribute to effective service delivery but may also serve to inform an inter-professional programme within the SHS and tertiary institutions in similar settings.
Keywords

Introduction/Background

The general practitioner (GP) is the first-line interlocutor of people with disabilities (PwD), and his involvement in the care process is necessary to optimize the care of PwD. This work aims to assess the knowledge, attitudes and practices of GPs on disability in Morocco and to measure their degree of involvement in the management of disability.

Material and Method

This is a cross-sectional study with a descriptive aim, which was carried out throughout Morocco and has targeted GPs both in the public and private sectors, as well as 7th year medical students. The assessment of the knowledge, attitudes and practices of GPs concerning disability was carried out using a questionnaire of 26 closed and semi-open questions.

Results

457 GPs were included, 65.6% were female, 41.4% were in the public sector. The average age of participants is 34.6+/-11 years. The average years of experience is 11.4+/-9. 41.2% had PwD in their entourage. 92.3% of GPs had no idea about the prevalence of disability in Morocco, 91% never received training on disability. 17.9% of GPs have never heard about physical medicine and rehabilitation (PRM), and 56.7% do not know any PRM. 6.5% of participants believed that the GP had an important role in the medical care of PwDs. 54.5% of GPs find contact with PwD rather difficult, and 32.6% feel discomfort with them. 72% of doctors complained about the lack of means and training. 51% had issues with communication. 66.3% of physicians refer PwD to physiotherapists for a specialized medical care, while only 24.2% refer them to RPM.

Conclusion

This study clearly highlight the need to integrate specific modules on disability into the curriculum of medical studies. It is crucial to train more GPs to be able to attend to PwD and to make them aware of the existence of PRM and knowledge in the field.

In the 1950s, problem based learning-based learning (PBL) has been used in medical education. PBL is student-centered and teachers help students guide them to ask questions. However, few studies have been reported on clinical teaching of aphasia by PBL. In this study, we have explored the effect of PBL in the motor aphasia teaching about clinical theory and practice.

**Material and Method**

One hundred students were enrolled in this study and were divided into 2 groups based on teaching methods. Group A included students who had theory combined with practice with a PBL teaching method, whereas group B included those with a traditional teaching method. The teaching time of the two groups was 4 weeks. Items for evaluation included written examination, skill assessment and questionnaire survey at the end of teaching.

**Results**

There were significant differences in the written examination and skill assessment between the two groups before and after teaching. When compared with the traditional teaching, a PBL teaching method had a higher working sense of responsibility and doctor-patient communication based on the questionnaire survey by the patient's assessment, and a higher satisfaction about clinical theory and practice teaching from the student.

**Conclusion**

We found PBL teaching had a significant advantage over the traditional teaching method in the motor aphasia of stroke teaching about clinical theory and practice.

REHABILITATION IN THE CORE GRADUATE MEDICAL CURRICULA AT UNIVERSITY OF SÃO PAULO SCHOOL OF MEDICINE: THE STUDENT’S PERCEPTION

E.T.S. Guiotoku¹, A.T. Sugawara¹, M.C.L. Carvalho¹, M. Imamura², F. Fregni³, R.B. Linamara²
¹Instituto de Medicina Física e Reabilitação- Hospital das Clínicas HCFMUSP- Faculdade de Medicina- Universidade de São Paulo- São Paulo- SP- BR., Departamento de Medicina Legal- Ética Médica e Medicina Social e do Trabalho- Faculdade de Medicina FMUSP- Universidade de São Paulo- São Paulo- SP- BR., São Paulo, Brazil
²Discipline of Physiatry, Departamento de Medicina Legal- Ética Médica e Medicina Social e do Trabalho- Faculdade de Medicina FMUSP- Universidade de São Paulo- São Paulo- SP- BR., São Paulo, Brazil
³Spaulding Neuromodulation Center, Department of Physical Medicine & Rehabilitation- Spaulding Rehabilitation Hospital and Massachusetts General Hospital, Boston, USA

Introduction/Background

Rehabilitation is a key health strategy for the 21st century. Increase the number of medical graduates aware of rehabilitation competencies and skills is a success indicator of strengthening and extending the provision of rehabilitation services. Our objective was to evaluate a novel teaching method to third year medical students based mostly in student-centered techniques. This course was offered at Faculdade de Medicina da Universidade de São Paulo, Brazil.

Material and Method

One hundred sixty-eight third year medical students responded an anonymous survey evaluating their perception of a 12-hour discipline on Rehabilitation. The Discipline was developed collaboratively in the 2017 Medical Teaching and Learning Innovation Program. Teaching materials were available to students at an educational platform to promote interaction and collaboration. The didactic curriculum was presented in the case-method format. Students performed the anamnesis and physical examination, with emphasis on the functional semiology, developing a treatment plan with functional goals, under the supervision of physical and rehabilitation medicine specialists, who mentored the activities. Members of the multidisciplinary team participated in the discussions. Rehabilitation interventions were performed as needed. Students were requested to produce and to present a mental map of the evaluated cases.

Results

95.3% of the students responded the anonymous survey. 88.2% of the responding students considered rehabilitation as an important discipline in medical training. For 90.8% of the students, the overall assessment for the course was "very good" or "good" and 59.6% requested the increase in its duration.
Conclusion

Third year medical students perceive rehabilitation as an important discipline in medical education. The overall assessment for the course was "very good" or "good", and there is a request for the increase in its duration from more than half of the students. Improvement of course methodology in rehabilitation may improve to attract more medical students to rehabilitation specialty.

Introduction/Background

Over a billion people are estimated to live with disabilities (15% of the world's population). In 2011, WHO produced the World Report on Disability that recommended improve human resource capacity through effective training of health professional staff including medical undergraduated students. Beside this, gamification has been used as a educational strategy for medical education. Gamification is the use of games to promote engagement and enjoyment of problem-solving in non-game situations. So, in line with these ideas, we have implemented an active learning strategy based on games construction by medical students to improve their knowledge about three important disable conditions: Duchenne’s muscular dystrophy, Dyslipidemia and Osteoporosis.

Material and Method

An interdisciplinary team of faculty mentored student game developers to design educational game prototypes. It included the phases of analysis, design, development, and evaluation. A 10-question survey was coupled with group discussions and literature review addressing key points about health conditions. Hundred medical students of first semestre of medical course divided into groups of five students each were engaged to create and produce games based on science data collected from the survey. Rounds of playtesting and feedback supported the process.

Results

At the end of a semestre a formal evaluation test about the 3 clinical conditions was applied. The degree of student retention of knowledge and skills in this subject varied from 80 to 95%, showing that this active learning technique was efficient.

Conclusion

Students find them engaging and enjoyable. This coordinated model is feasible and could improve the disability education into undergraduate medical education. Build, play and create a game with your peers is an example of educational gaming as an innovative active teaching strategy in medicine. Thus, the teacher does not work with only 1 type of teaching methodology, but with a combination of different methodologies. It does not replace curricular practice, but helps.

INTRODUCING COMPETENCE IN CARING FOR PATIENTS WITH DISABILITIES IN THE MEDICAL SCHOOL CURRICULUM

T. Verghese

Burke Rehabilitation Hospital, Neuroresearch Department, Pound Ridge, USA

Introduction/Background

According to the World Health Survey (2004), around 785 million (15.6%) of people 15 years and older live with a disability, of whom 110 million people (2.2%) have very significant difficulties in functioning. Without training, healthcare providers tend to underestimate the abilities and quality of life of patients with disability, as well as minimize their autonomy and capacity for self-care. In a survey of medical schools, 50% of deans reported that disability training is not a high priority, and 61% reported that their graduates were competent to treat. However, 81% of medical students reported no clinical training in disability, and a majority of seniors and graduates expressed inadequate competency in the care of patients with disabilities. In a study by O'Fallon and Hilson (2005), it was found that physicians rated performing disability assessment to be the most daunting task out of 12 common clinical procedures.

Material and Method

N/A

Results

Several recommendations have been put forward to improve health of people with disabilities. Two surgeon general reports (2002, 2005), IOM, and the WHO World Report on Disability (2011), has recommended improving the knowledge, skills, and attitudes of healthcare providers towards patients with disabilities. Healthcare providers need to understand the nature and prevalence of disability; health and health-care disparities; and the role of the physician in preventing secondary conditions and improving quality of life. This should include didactic instruction of knowledge and etiquette, patient panels, use of standardized patients with disabilities, clinical experience, and formative exams in transfer and communication. Home visits and community service are an important tool in increasing familiarity and sensitivity.

Conclusion

By increasing the prioritization of disability in the medical school curriculum, the hope is that people with disabilities will move towards a greater parity of care as their non-disabled counterparts.

PHYSICAL MEDICINE AND REHABILITATION LEAGUE OF FACULDADE DE MEDICINA DA UNIVERSIDADE DE SAO PAULO: AN INNOVATIVE MODEL OF UNDERGRADUATE TEACHING AND LEARNING

L. Iuamoto¹, G. Numakura¹, T. Guedes¹, A. Sugawara¹, M. Imamura¹, L.R. Battistella¹

¹Instituto de Medicina Fisica e Reabilitacao- Hospital das Clinicas HCFMUSP, Physical Medicine and Rehabilitation, São Paulo, Brazil

Introduction/Background

Current medical education strategies are based on OSCE, self-assessment, clinical teaching, lectures and textbooks. The predominant method of learning anatomy, for example, consists primarily of reading textbooks and attending classes. Recently a new model of complementary education to graduation has become popular in Brazil: the Academic Leagues of Medicine. The Physical Medicine and Rehabilitation League of the University of São Paulo Medical School (PMR League of FMUSP) aims to complement this traditional method and also provide students with practical activities to improve their knowledge in clinical practice in physical medicine and rehabilitation. We aim to describe the educational, evidence-based assistance, community extension and research experiences gained through PRM League and the rate of medical student’s exposure to the field after its implementation.

Material and Method

PMR League of FMUSP counts on teaching activities, research projects and university extension to the community. The PMR League of FMUSP promotes the development of educational materials to the population, such as the “Postures’ Manual” adopted in the social project of districts’ revitalization in São Paulo; it also promotes theoretical classes correlating anatomical data with clinical cases and patient care activities. PMR League of FMUSP students and physicians are responsible for the preparation of classes, patient care, research and innovation projects at the Institute of Physical Medicine and Rehabilitation (IMREA).

Results

Medical students from the second to fourth grade take part of the PMR League mentored by attending physicians and residents. There was a 150% (from 10 to 35 medical students) increase in the number of members during the first year of activities, with growth prospects still higher in the coming years.

Conclusion

PMR League of FMUSP with its activities, introductory course and classes, had a positive influence on student’s interest and learning. It may represent a successful initiative for enhancing physical and rehabilitation medicine teaching.

THE NEUROUROLOGY MULTIDISCIPLINARY TEAM MEETING AS A POTENTIAL TEACHING TOOL DURING THE THIRD CYCLE OF MEDICAL STUDY

E. Castel-lacanal¹, P. Marque¹, X. Game², X. De Boissezon¹, F. Muscar1, N. Nasr⁴
¹CHU Toulouse Rangueil, Medecine Physique et Réadaptation, TOULOUSE, France
²CHU Toulouse Rangueil, Urologie-Andrologie-Transplantation rénale, Toulouse, France
³CHU Toulouse Rangueil, Chirurgie générale et digestive, Toulouse, France
⁴CHU Purpan, Neurologie, Toulouse, France

Introduction/Background

The Neuro-urology is a medical speciality, practiced by numerous urologists and doctors in physical medicine and rehabilitation (PMR), and corresponds to a need in terms of medical formation. In our hospital, during their studies, the interns in the Urology and PMR departments participate in weekly Neuro-Urology Multidisciplinary Team Meetings (MTM). This meeting could be a teaching place of this speciality. Our objective was to restructure MTM so that interns acquire skills to take in charge neurological urinary disorders, and also to evaluate the interest of the MTM as a teaching tool.

Material and Method

Inter alia, to restructure MTM, we taught a specific lesson at the beginning of the semester, distributed a booklet on neuro-urology and the meetings were more livened up. The assessment consisted of an anonymous evaluation by the interns of their perception of their knowledge, results expressed in median, and an assessment by the teacher of their knowledge from 2 clinical cases, results expressed in number of objectives acquired. It concerned 2 groups of interns: those before the intention of transforming the MTM (G1), with an evaluation only at the end of the semester (E1); and those who benefited on the restuctured MTM (G2), with evaluations at the beginning and the end of the semester (E2 and E3).

Results

The G1 interns perceived themselves at ease (median at 4.5) but their knowledge was not so good (6 objectives acquired / 17). The G2 interns progressed, they significantly improved their own evaluation (median which went from 2 to 5/7, p=0.018) and their knowledge, the number of objectives acquired passing from 6 to 14/17.

Conclusion

This work has shown the feasibility of transforming MTM as a teaching tool in the field of neuro-urology for interns.

THE RELATIONSHIP BETWEEN STUTTERING SEVERITY AND TYPES OF INFLECTIONAL MORPHEMES STUTTERED IN 15-35 YEAR-OLD STUTTERERS WITH MILD TO MODERATE SEVERITY

H.ghaemi

Hamide ghaemi- school of paramedical sciences- Mashhad university of medical sciences- Mashhad- Iran, speech therapy, Mashhad, Iran

Introduction/Background

Stuttering is considered as one of the most important speech disorders and general cognition among speech and language disorders (1). Persian-speakers with a stuttering problem demonstrate a different degree of prolongation, silence or block at the beginning and remedial review in different ages based on stuttering severity with stuttering changes from sentence and types; namely, the length, meaning and complexity of the word influences fluency deficit intensity.[H1] The purpose of this study was to investigate the relationship between stuttering severity and type of inflectional morphemes stuttered in 15-35 year-old stutterers with mild to moderate severity.

Material and Method

20 stutter participated in this study. 10 stutter with a mild stuttering problem and 10 stutter with a moderate one. Participants’ speech was recorded while they narrate a story (about 400 syllables) in a natural setting for 3-5 minutes. Then the speech was analyzed and the types of inflectional morphemes which stuttered were identified. Stuttering severity was also measured utilizing the SSI4 scale. Statistical analysis data was done by SPSS software and Spearman correlation test.

Results

Data analyses indicated that there is a direct and significant relationship between moderate stuttering severity and inflectional morphemes in particular types of verb prefixes (p=.024), and there is a direct and linear relationship between mild stuttering severity and inflectional morphemes in type of verb prefixes ( p=.008), whereas this relationship was not statistically meaningful (p<.05). Additionally, there is no significant statistical relationship between mild to moderate stuttering severity and inflectional morphemes) plural, indefinite, comparative and superlative, transient maker and identity verbs) (p<.05).
Conclusion

Results demonstrated the severity of stuttering was related to length, meaning and consonant complexity of morphemes. As stuttering severity reduced (mild and moderate), the effect of inflectional morpheme’s type on stuttering, reduced.

Introduction/Background

The implementation of best practices in cognitive rehabilitation after acquired brain injury is challenging, as it involves complex and individualized interventions. This project aims 1) to develop a tailored and multifaceted intervention to support the implementation of best practices in rehabilitation and 2) to evaluate participants’ perception of this intervention.

Material and Method

Case studies were conducted within two teams (n=11 and 14 clinicians) including occupational therapists, neuropsychologists, speech and language pathologists and educators from two rehabilitation centers. Each team prioritized one evidence-based practice to implement. Learning tools, including videos, pocket cards and summary sheets for caregivers, patients and staff, were created based on the results of two rapid reviews. Interactive workshop was also developed for each team with high level activities based on Bloom’s taxonomy. Participants’ perception of the material developed and their satisfaction with the intervention were documented using focus group discussions and questionnaires.

Results

The overall mean level of satisfaction regarding the intervention was high (i.e. 88%). Interactive activities fostering exchanges between colleagues were seen as important strengths. Participants also had a positive view of the material. Videos were appreciated for their short duration (20 minutes), clarity and practical demonstrations. As time constraints emerged as an important barrier for evidence-based practice, participants underlined the importance that the print-based material (i.e. pocket cards and summary sheets) be concise and concrete in order to see its use being maximized.

Conclusion
This work suggests that interventions relying on interactive activities and social opportunities along with short, clear, and concrete material have the potential to support the implementation of an evidence-based practice.

EVIDENCE BASED PRACTICE: WHAT THERAPISTS SAY ABOUT IT?
K. Mu1, A. Bahle-Lampe1, Y. Qi1
1Creighton University, Occupational Therapy, omaha, USA

Introduction/Background

The significance of evidence based practice (EBP) can not be overstated. However, literature on the perception of occupational therapists and physical therapists toward EBP, is scarce. The purpose of this survey study was to examine occupational and physical therapists's attitudes toward evidence based practice.

Material and Method

A total of 47 among 261 practicing occupational and physical therapists in a health care system in the Midwest responded to the questionnaire previously developed by Rubin and Parrish, 2011. Follow up reminders were implemented to achieve a higher response rate.

Results

The results of the study showed that therapists maintained an overall positive attitude toward EBP, reported familiarity with the EBP process and an overall positive attitude toward EBP. In addition, therapists reported intend to engage in the EBP process but their current engagement was a little less than “some of the time.” However, therapists reported slightly lean unfeasible to engage in the EBP process. Barriers to engaging in EBP included time, access, and the constraints of the responders’ practice setting.

Conclusion

Overall, the findings of this study showed that therapists hold positive perception on evidence based practice and such findings are consistent with previous research. The current study suggests practicing occupational therapists and physical therapists in general have positive perception on evidence based practice, particularly in the area of familiarity with EBP, the intend to and current engagement of EBP. Therapists, however, identified many factors that contribute to their negative perception on feasibility of the EBP in their day to day practice.

Administrative support, decreased productivity pressure, adequate education and training are essential in ensuring and promoting EBP, a key ingredient in help achieve triple aims of health care services.

ISPR8-0870
PREPARATORY COURSE TO HAPTIC SENSORY DISCRIMINATION SKILLS
C. Dr Winkelmann¹, M. Dr Grunwald²
¹DHBW, Studienzentrum Gesundheit, Heidenheim, Germany
²Universität Leipzig, Haptik-Forschungslabor, 04103 Leipzig, Germany

Introduction/Background

Due to considerable interindividually variability in terms of haptic threshold, the use of valid, practicable test and training systems is particularly relevant before and during manual therapy training and further training. The active sensory discrimination skills of participants need to be continuously assessed and, where necessary, appropriately trained.

The implementation of reliable haptic test and training systems in curricula contributes to assuring the quality of training standards and ultimately to optimizing patient care.

Material and Method

Based on literature review a special preparatory course to the haptic sensory discrimination skills is introduced.

Results

Crossings of the competence areas are fluent partly and the main focus lies for the haptic sensory discrimination skills on the method competence.

The number of the training sessions compares to the individual learning progress. Per single training a temporal extent of from 60 to 90 minutes should be kept because of the decrease of the attention and concentration achievements and by consideration of work everyday conditions. Under certain circumstances, they can also be used in the self-study context. Learning evaluation must be constructively for positive results. Instead of teaching commenting of the performance, success must be aware.

Conclusion

This test and training systems offer the option of measuring and training the haptic sensory discrimination skills of healthy individuals under objective and reproducible conditions. As part of this, the systems are oriented as far as possible to explorative occupational situations, while at the same time guaranteeing the scientific merit of a reproducible test situation. However, the consolidation of skills and knowledge requires adequate timetabling by lecturers, a clear
definition of tasks, and reflection on performance, whereby simulation in the skills laboratory should be integrated in the curriculum.

⁵Ipsen Pharma, Global Medical Affairs, Boulogne-Billancourt, France
⁶Santa Maria University Hospital, Department of Neurology, Terni, Italy

Introduction/Background

Botulinum neurotoxin-A (BoNT-A) is commonly used as first line treatment for Cervical Dystonia (CD) and Spastic Paresis (SP). The Ixcellence Network® (IN) international survey aims to describe the current situation of training and practices among physicians performing BoNT-A injections.

Material and Method

A self-completion questionnaire, written by a multidisciplinary steering committee, was completed by experts managing patients with SP and CD, selected from the IN faculty, regarding their experience, training and confidence in different BoNT-A injection techniques and rehabilitation methods. Here we present a partial analysis of the 17 first respondents’ answers. Additional results from a database of more than 700 practitioners (IN attendees) will be available for the congress.

Results

Seventeen physicians specialized in physical medicine and rehabilitation (9/17), neurology (7/17) and neuropsychiatrics (1/17) completed the questionnaire. They reported a mean experience of 22 years in their field (from 14 to 30 years) and 18 years in BoNT-A injection (from 5 to 25 years).

All received training prior to first injection, complete with dedicated sessions on guidance techniques: 15 on ultrasound, 11 on anatomical landmarks, 6 on electrostimulation (ES) and 7 on electromyography (EMG). In their current practice, BoNT-A injection was mostly performed without guidance or using ultrasound (16/17 respondents vs 11/17 for ES or EMG).
Fifteen physicians also attended specific training on rehabilitation methods for SP (11), CD (1) or both (3).

Overall, physicians who followed specific training in injection techniques or in rehabilitation reported greater self-confidence in using them.

Conclusion

Training on injection technique and rehabilitation for SP and CD management is variable. Nevertheless, attending specific courses was associated with greater self-confidence. Moreover, physicians mainly used the techniques and methods for which they were trained. These first results highlight the relevance of training in this field.

5Ipsen Pharma, Global Medical Affairs, Boulogne-Billancourt, France
6Chulalongkorn University and King Chulalongkorn Memorial Hospital- Thai Red Cross Society, Chulalongkorn Center of Excellence on Parkinson’s Disease and Related Disorders- Department of Medicine, Bangkok, Thailand

Introduction/Background

Botulinum neurotoxin-A (BoNT-A) is a well-established treatment for cervical dystonia (CD) and spastic paresis (SP). However, proper BoNT-A administration requires specific training. The Ixcellence® Network is a high-level training program developed for physicians using BoNT-A to improve patient care. Here, we describe the impact of the program on the attendees’ practice.

Material and Method

A Steering Committee composed of 6 experts in the management of CD and SP was convened to design the network, choose the centres and trainers, and validate the contents of the 9 training courses. Training courses were designed in order to encourage innovative methods and approaches to patients’ management, including diagnosis, tailored treatment and rehabilitation.

To assess the program quality and impact, attendees received a first questionnaire at the end of each course (T0), and a second one by email six months later (T6).

Results

Since the program launch in 2012, 728 physicians have been trained. Of the 615 physicians who answered the T0 questionnaire, 77% reported an excellent general level of satisfaction, 93% stated that they were provided with new information and 95% reported that the training achieved their personal objectives.

Regarding the long-term impact of the program, of the 211 physicians who provided feedback 6-months after attendance, 92% confirmed that the training had changed their daily practice and
helped improve their self-confidence. Of the 105 respondents who attended courses between January 2015 and December 2016, 83% reported having shared some of the information learned during the training with their colleagues (45% through daily practice, 24% by sharing documents, 8% by organizing a meeting, 6% by another way).

Conclusion

By attending Ixcellence Network® training courses, physicians are able to further develop their specialised skills, and are provided with the expertise to train their peers at a local level.

Introduction/Background

Cochrane Rehabilitation Field (CR) is a worldwide network aiming to act as a bridge between Cochrane and Rehabilitation community and stakeholders. CR specific goals are to undertake Knowledge Translation and to progress the methods for evidence synthesis in order to make them appropriate with the needs of people with disabilities and daily clinical rehabilitation practice. The aim of this paper is to describe the Organization and Functioning of the Field.

Material and Method

Currently, 294 people from 52 different countries are part of CR. The organization includes: Director (responsible for the Knowledge Translation strategy); Coordinator (responsible of the Networking Strategy); Executive Committee; Advisory Board.

Results

The Communication Committee created the website (www.rehabilitation.cochrane.org) and is in charge of constantly updating it. It set up a YouTube channel, a Facebook page and a Twitter account. It is also responsible for the preparation of the Newsletter and of the production and dissemination of blogshots, a concise synthesis of the main message of Cochrane Evidence in Rehabilitation.
The Publication Committee has been working on the creation of Cochrane Corners in rehabilitation National and International scientific journals.

The Education Committee is responsible for the preparation of Cochrane sessions and workshops at Rehabilitation Meetings, 4 Workshops and 10 sessions at National and International Meetings have been realized so far.

The Reviews Committee has been selecting all Cochrane Reviews relevant for rehabilitation, it has been developed and tested a systematic search strategy which is providing material for the other Committees.

The Methodology Committee has been working for the improvement of the methods to synthesize evidence.

**Conclusion**

Cochrane Rehabilitation is growing fast and more and more people are joining the different committees with the aim to obtain the same results of disseminating evidences.

FACE SCALE RATING OF PERCEIVED EXERTION DURING CARDIOPULMONARY EXERCISE TEST

S. Morishita¹, A. Tsubaki¹, S. Nashimoto², J. Fu³, H. Onishi³
¹Niigata University of Health and Welfare, Institute for Human Movement and Medical Sciences, Niigata City, Japan
²Niigata Medical Centre, Department of Rehabilitation-, Niigata, Japan
³University of Texas MD Anderson Cancer Center, Department of Palliative- Rehabilitation & Integrative Medicine-, Houston, USA

Introduction/Background

This study aimed to investigate the correlation between the face scale and the heart rate (HR), exercise load, and oxygen uptake (VO₂) during cardiopulmonary exercise testing.

Material and Method

This was a prospective, observational study of face scale rating of perceived exertion (RPE) and HR, exercise load, VO₂ during cardiopulmonary exercise testing. A total of 30 healthy college men and 21 healthy college women were included. Subjects performed a cardiopulmonary exercise test with ramps and an increment increase in workload of 20 watts/minute using a stationary bicycle. We recorded the responses of subjects using a face scale for RPE, HR, exercise load, and VO₂ every minute during the cardiopulmonary exercise test.

Results

In men, there was a significant positive correlation between the face scale RPE and HR (p=0.856, p <0.01), exercise load (p=0.888, p <0.01), and VO₂ (p=0.878, p < 0.01) during the cardiopulmonary exercise test. Similarly, in women, there was a significant positive correlation between the face scale RPE and HR (p=0.885, p <0.01), exercise load (p=0.908, p <0.01), and VO₂ (p=0.895, p <0.01) during the cardiopulmonary exercise tests.

Conclusion

This study showed that there was a significant positive correlation between the face scale RPE and HR, exercise load, and VO₂. The face scale proposed in this study was related to physiological parameters, which suggests that it may be used to determine the intensity of exercise in healthy adults.

SIMULATED E-LEARNING APPROACHES IN UNDERGRAD PHYSIOTHERAPY TRAINING FOR BOTH KNOWLEDGE AND SKILLS. A CASE REPORT.
C.N. Lo¹, M.B.N. Ariffin², L. Chan², S.Y. Tan², Z.H. Teo², Y.L. Leong², C.H. Low², H.R. Sze²
¹Singapore Institute of Technology, Cluster of Health and Social Sciences, Singapore, Singapore
²Singapore Institute of Technology, Cluster of Infocommon Technology, Singapore, Singapore

Introduction/Background

Traditionally, physiotherapy training is highly skill-based. Intensive tangible supervision is expected in undergrad physiotherapy training. The training of physiotherapy profession is experiencing unprecedented pressures with a significant growth in demand for training and shortage of clinical instructors in universities. The problem will affect the quality of healthcare graduates as well as the healthcare service.

The application of simulated training technology is getting more recognition in healthcare education; it is suggested to be a possible alternative to the traditional clinical training. Not only the scientific knowledge but also skill-based training can be facilitated by the technique.

Material and Method

This presentation is going to share and demonstrate several computer-based simulating approaches used in undergrad physiotherapy training including the 180-simulating video for skills training, electronic scoring system and computer-based scenario-mock-up exam. The interventions are cost-effective and well available as common resources. In additional, quantifiable data can be collected through the systems for the analysis of the students’ progress.

Results

Instructors and students feedback of the e-learning week have been recorded. The data reflects the cost-effectiveness of the simulated e-learning approaches for undergrad physiotherapy students.

Conclusion

The use of computer-based simulated teaching can be an alternative to improve the quality of training in large classes of students in healthcare programmes.

DEVELOPMENT OF ESSENTIAL STANDARDS FOR THE TRAINING OF COMMUNITY REHABILITATION WORKERS IN LOW RESOURCE SETTINGS

W. De Groote¹

¹St Jozef Belgium, Physical and Rehabilitation Medicine, Bornem-Willebroek, Belgium

Introduction/Background

One of the objectives of the WHO Global Disability Action Plan 2014-2021 is to strengthen rehabilitation and Community Based Rehabilitation (CBR). In order to achieve this goal, the training of Community Rehabilitation Workers (CRW) is crucial. However, results of the last World CBR Congress show a lack of recognition of this professional group, looking at accountability and training with certificates. This is partially related to their wide range of skills and duties.

Material and Method

In September 2017 a research protocol was conducted at community rehabilitation programmes in 6 low and middle income countries. It consisted of workshops with the management team (31 members) and CRW (78), field visits and Focus Group Discussions with the beneficiaries (182). The protocol looks at the needs of the beneficiaries, training received and activities carried out by CRW, and their support system. It uses an open question method, categorising and stratifying the responses according to their relative importance along the process.

Results

Training of CRW is inconsistent with the variety of interventions needed in the field, which leaves the users insecure. The needs of the beneficiaries are multifaceted, and activities carried out by CRW only partially reflect a needs-based approach. Competencies regarding economic empowerment, disability specific issues, psychosocial support and inclusion are underaddressed. Also, a mismatch was found between activities carried out most often and activities determined as most important.

Conclusion

This research protocol identified gaps and priorities for the development of a standardised training content for CRW. We describe minimal standards that answer the needs of a person with a disability living in the community of a low resource country.

PHYSICAL ACTIVITY AND CANCER: THE VIEWS AND KNOWLEDGE OF PHYSIOTHERAPISTS IN MOROCCO.

Y. Azemmour¹, A. Hajjoui²

¹High institute of nurses’ careers and health technics ISPITS, Rehabilitation, Rabat, Morocco
²University Sidi Mohammed Ben Abdellah- Fez, Department of Physical and Rehabilitation Medicine, Fez, Morocco

Introduction/Background

As part of cancer care, physical activity (PA) increases the chances of healing and survival, and improves the quality of life of patients. The practice of PA must be done by a trained and experienced professional. This study aims to identify Moroccan physiotherapists’ current knowledge and practice in recommend PA for cancer care and barriers to such prescription and to investigate their views on PA for cancer patients.

Material and Method

An online cross-sectional survey was distributed to the Moroccan physiotherapists in December 2017. An instrument was created, which included dichotomous question with multiple responses according to the Likert scale. The questionnaire explored physiotherapists’ views on the role of PA for patients with cancer and physiotherapists’ prescription of PA for cancer patients.

Results

A total of 49 physiotherapists, including 23 (47%) women, completed the study. 57% (n=28) of physiotherapists have less than 5 years of professional experience and 49% (n=24) practice in the public hospital. 71% (n=35) of physiotherapists have never or rarely prescribing PA for cancer care. In all, 90% (n=44) of physiotherapists agreed with the statement «PA increases the chances of healing and survival, decreases the complications and side effects of cancer and its treatment and improves the quality of life of patients », while 84% (n=41) of physiotherapists agree with the statement «Cancer patients must remain physically active». 34(70%) agree that physicians are convinced of the importance of PA in the cancer care. However, 82% (n=40) of physiotherapists are unable to recommend physical activity because they did not have training in PA and oncology rehabilitation.

Conclusion

The majority of physiotherapists perceived PA to be of benefit for cancer patients. Physiotherapists’ knowledge seems to be insufficient to inform, and encourage cancer patients to use PA. There is a need for a specific module on PA and cancer rehabilitation in education and training of physiotherapists.

N95 MASK FITTING TEST ON THE REHABILITATION THERAPISTS

I. Saotome¹, T. Muramatsu¹, M. Fujimoto¹, J. Fujitani¹
¹National Center for Global Health and Medicine Hospital,
Department of Rehabilitation Medicine, 1-21-1 Toyama-Shinjuku ward, Japan

Introduction/Background

N95 masks offer protections from airborne diseases like Tuberculosis (TB). Our hospital has a specialized ward for TB patients, and from the context of preventing inpatients disuse syndrome, we receive quite a number of rehabilitational consultations on these patients. On the other hand, we were pointed out by the doctor from other institutions that there was concern about the increased risk of TB infection by rehabilitation therapists even with the N95 mask on. From this, we thought that there was a need to consider countermeasures and guidance to prevent possible leakage due to misalignment in N95 mask wearing during rehabilitation work. To set up simulated training scenes among rehabilitation staff, and to consider appropriate mask use and personal protection measures during rehabilitation work.

Material and Method

We assessed 23 staff in total, including 14 PTs, 4 OTs and 5 STs. Under the cooperation of our hospital ICN, we measured the mask leakage rate (%) before and after the simulated training using laboratory mask fitting tester MT-03 (manufactured by Shibata Science). Leak rate of 5% or more was judged as "leaked". The content of the training activity was established, and when the mask adhesion was in doubt, a corrective measure was given during the training.

Results

In the mask fit test before simulated training, 15 out of 23 (65%) were able to fit N95 mask without leakage. Eight people had insufficient mask adhesion at the nose and/or jaw. In the fit test after the simulated training, 12 people (52%) had mask leaks. In the ST group, who were performing the swallowing training operation, 4 out of 5 (80%) had mask leaks.

Conclusion

Since this mask fitting test was experience based training, and the examinee gets immediate feedback, it was an opportunity to reconfirm the correct wearing of the N95 mask.

ISPR8-1266
EFFECTIVENESS OF THE WHEELCHAIR SKILLS TRAINING PROGRAM: A SYSTEMATIC REVIEW AND META-ANALYSIS
L. Keeler², R.L. Kirby¹, K. Parker³, K. McLean⁴, J. Hayden²
¹Dalhousie University, Division of Physical Medicine and Rehabilitation, Halifax, Canada
²Dalhousie University, Community Health and Epidemiology, Halifax, Canada
³Nova Scotia Health Authority, Assistive Technology Program, Halifax, Canada
⁴Nova Scotia Health Authority, Library Services, Halifax, Canada

Introduction/Background

The Wheelchair Skills Program (www.wheelchairskillsprogram.ca) is a set of assessment and training protocols – the Wheelchair Skills Test (WST), the questionnaire version of the WST (WST-Q) and the Wheelchair Skills Training Program (WSTP). Evidence has been accumulating about the important role that wheelchair skills training has in the wheelchair-provision process recommended by the World Health Organization. The objective of this study was to conduct a systematic review synthesizing the evidence for the effectiveness of the WSTP.

Material and Method

We searched PubMed, the Cochrane Library, CINAHL and Embase databases, as well as grey literature, up to October 10, 2017. We selected studies that were randomized controlled trials (RCTs) assessing the effectiveness of the WSTP. Two independent reviewers screened articles and extracted data. Methodological quality was assessed using Cochrane’s Risk of Bias Tool. Meta-analyses (including sub-group analyses) were conducted for the WST and WST-Q total capacity scores. We qualitatively assessed retention, WST/WST-Q subtotal and individual-skill capacity scores and other identified outcomes. The quality of evidence was determined using the Grades of Recommendation, Assessment, Development and Evaluation (GRADE) approach.

Results

Thirteen RCTs (581 participants) were included for analysis. The level of evidence was of moderate quality. The WSTP increased the post-training WST/WST-Q total capacity scores by 14.0% (95% CI: 7.4, 20.8; p < 0.0001) compared to no treatment, standard care or educational controls, a relative increase of 21.2%. Subgroup analyses showed that training was more effective for new wheelchair users. Retention of training effects was suggested by the absence of significant declines between tests post-training and at follow-up. The WSTP was found to have positive effects on some other outcomes. No serious adverse events were reported.

Conclusion
There is moderate quality evidence that the WSTP is a safe intervention that has a clinically meaningful effect on WST/WST-Q capacity scores and some other outcomes.

EFFECT OF PATIENT SUPPORT ON PSYCHOLOGICAL AND ACTIVITY OF DAILY LIVING IN PATIENTS WITH EARLY SPINAL CORD INJURY
H.Z. Yang¹, L. Rao¹, J. Cui¹, G. Yuan²
¹Xiangya Boai rehabilitation hospital, Rehabilitation Department, Changsha, China
²Ningxiang Renming Hospital, Rehabilitation Medicine Department, Ningxiang, China

Introduction/Background

To observe the effect of adding the patient support on the psychological and activity of daily living of patients with early spinal cord injury on the basis of conventional rehabilitation intervention and psychological therapy.

Material and Method

60 patients with early spinal cord injury were randomly divided into group A (conventional physical therapy), group B (conventional physical therapy + psychotherapy), group C (conventional physical therapy + psychotherapy + patient support). Each group has 20 patients. The Hamilton Anxiety Scale (HAMA), the Hamilton Depression Rating Scale (HAMD), the Modified Barthel Index (MBI), Spinal Cord Independence Measure III (SCIM III) were used for evaluation of the three groups before and 6 weeks after treatment. Using PRO-KIN Computer-based Proprioception Test and Training System to measure sitting peripheral area.

Results

After 6 weeks of treatment, HAMA score, HAMD score, MBI score and SCIM III score of group A and B are both have statistically significant than before (P <0.05). The HAMA score, HAMD score, MBI score and SCIM III score in group C were significantly better than those before treatment (P <0.01). There was statistical significance between the fourth week and the initial test results (P <0.05). There was significant statistical difference between the sixth week and the initial test results (P <0.05). The peripheral area score of the group B was better than that of the group A after 6 weeks treatment (P <0.05). The peripheral area score of group C was significantly higher than that of group A (P <0.01).

Conclusion

Patient support combined with conventional rehabilitation intervention and psychological therapy of early spinal cord injury patients is a worthy promotion as better effect on mental health, the ability of activity of daily living, functional independence and sitting position balance.

ISPR8-2735
THE OPPORTUNITIES AND GAPS IN REHABILITATION EDUCATION IN LOW INCOME COUNTRIES
L. Chandler
1Carolinas Rehabilitation, Physical Medicine and Rehabilitation, Charlotte, USA

Introduction/Background

There is an increasing prevalence of disability worldwide. This is associated with a concomitant increase in the need for rehabilitative service globally. This is particularly true for low and middle-income countries. In some parts of the world such as the continent of Africa, the imbalance between available services and the needs of the population can be viewed as a crisis. As such there have been efforts to optimize the formulation and delivery of educational content in these parts of the world. This literature review aimed at identifying current models of education delivery to rehabilitation professionals in low income countries and possible future directions in this arena.

Material and Method

A literature review was performed using Medline, Cinahl, and PreMedline databases, with filters for English language from 1996 – week 3 of December 2017. The search terms were PT/OT/PM&R (physical therapy, occupational therapy, physical medicine and rehabilitation) Education/Training in Developing Countries and Educational Models in Medical Education in Developing Countries. This was performed with the aid of a medical librarian. Additional search terms were used to identify educational models / efforts for prosthetists and orthotists in low income countries.

Results

The literature regarding PT and OT in low income countries far exceeds, the amount of articles on educating / training physiatrists in these settings. Similarly, there is a relative paucity of articles on educating / training prosthetists / orthotists in this setting.

Conclusion

There is significant opportunity for improvement in the absolute amount of physiatric and prosthetist / orthotist training in low income countries but also the incorporation of technological advances such as additive technology (3-D printing), telemedicine / telehealth, quality improvement techniques, simulation training, and local as well as international partnerships.

IMPLEMENTATION OF THE OCCUPATIONAL THERAPY IN MOROCCO: FROM THE NEEDS ANALYSIS TO CURRICULUM DESIGN DEVELOPMENT

C. Leroy¹, A. Hajjioui²
¹Handicap International, Occupational therapy, Rabat, Morocco
²University Sidi Mohammed Ben Abdellah- Fez, Department of Physical and Rehabilitation Medicine, Fez, Morocco

Introduction/Background

The creation of Occupational Therapy Curriculum Design in Morocco is one of the priorities of the 2015-2021 National Health and Disability Action Plan. This study aims to describe the main steps of the first year of the project of the Implementation of the occupational Therapy in Morocco which began in 2016, and which aims to strengthen human resources for health and rehabilitation and physical rehabilitation workforce.

Material and Method

We conducted a study of the mapping of the supply of care and the need for occupational therapy as well as reflection workshops with the experts and stakeholders involved in this project.

Results

An occupational therapy curriculum program of 3 years training has been designed, adapted to the Moroccan context and based to the international standard. This occupational therapy curriculum program has been accredited by the WFOT and the first year starts in September 2017.

Conclusion

The creation of the occupational therapy education is a first and a big step in the implementation of occupational therapy in Morocco. The success of this project requires the collaboration of stakeholders and policy makers to overcome all the barriers.

EFFECT OF INTERNATIONAL REHABILITATION VISITING STUDENT PROGRAM ON STUDENTS’ PROFESSIONAL DEVELOPMENT

K. Mu\textsuperscript{1}, A. Patterson\textsuperscript{1}, A. Bahle-Lampe\textsuperscript{1}, H. Lohman\textsuperscript{1}, B. Greiner\textsuperscript{1}, Y. Qi\textsuperscript{1}

\textsuperscript{1}Creighton University, Occupational Therapy, Omaha, USA

Introduction/Background

One of the important and enduring strategies that developing countries take in advancing education and training of rehabilitation students and professionals is fostering international partnerships, improving the quality of international education provision, and encouraging partnerships with foreign education institutions. The purpose of this presentation is to describe and examine the effect of an international visiting student program in a university of USA on students’ professional development. A total of seventy students in rehabilitation from China participated in the three month summer visiting student program that included a combination of didactic coursework, clinical observation, and cultural immersion in the past three summers.

Material and Method

The outcomes of the program were evaluated annually through a mixed methods approach incorporating a single group pre/posttest analysis and focus group discussions. The quantitative portion of the study incorporated the use of two instruments: the Team Skills Scale (TSS) (Hepburn, Tsukuda, & Fasser, 2002), and one subscale of the Cultural Competence Health Practitioner Assessment (CCHPA) (National Center for Cultural Competency, 2014). Qualitative data collection included videotaped interviews with participants at the end of the CRISP prior to the participants returning to China. The participants were asked open-ended reflection questions by a CRISP staff moderator.

Results

The results of quantitative data analyses revealed significant differences between pre and post tests suggesting the summer program had significant impact on students’ team work skills and cultural competence. The results of qualitative data analysis echoed the findings of the quantitative data.

Conclusion

Findings of the program evaluation revealed that international immersion programs is one of the effective stepping stones to help prepare and develop rehabilitation professionals for countries in which rehabilitation is less developed. The willingness of educational institutions to commit to working with partners in another country is vital to initiate the collaboration.

No conflict of interest
Material and Method

Based on WHO’s WSTP modules (basic, intermediate and manager’s), a cascade strategy was used to train 7 core teams of trainers from different rehabilitation facilities and expand it to 180 rehabilitation professionals in 11 facilities. The analysis of the educational process used a structured satisfaction questionnaire and a knowledge evaluation.

Results

The project trained 180 professionals and created 11 wheelchair clinics abiding by the WHO Wheelchair Guidelines. 97% professionals were approved. 98.48% trainees acknowledged the training offered new knowledge (even though they were all experienced health and rehabilitation
professionals) and 89.39% rated it as very good or excellent. Trainees indicated it would result in changes to their daily practice (64%) and behaviour (18%).

Table 1. Course trainees according to their professional background.

Conclusion

The cascade strategy based on WSTP was successful at building the capacity of rehabilitation professionals about the WHO Wheelchair Guidelines and decentralizing wheelchair service provision.

THE USE OF TOTAL CONTACT ORTHOSES IN PATIENTS WITH FOOT PROBLEMS IN FOOT CLINIC, SIRIRAJ HOSPITAL

N. Kanjanapanang¹, N. Chadchavalpanichaya¹

¹Faculty of Medicine Siriraj Hospital- Mahidol University, Rehabilitation Medicine, Bangkok, Thailand

Introduction/Background

To study the use rate, result and concomitant factors of the use of total contact orthoses in Foot Clinic, Siriraj Hospital which has not been studied before.

Material and Method

Studying from patient records and interviews with patients who had foot problems without impairment of foot sensation and received TCO from Foot Clinic between July, 2015 and April, 2016. First interview, patients were asked information before use and latter about the latest TCO after use in first 1 month.

Results

One hundred and fifteen participants were recruited but eight lost to follow up. The majority had chronic plantar fasciitis (26.2%), posterior tibial tendon dysfunction (25.2%), hallux valgus (21.5%) and metatarsalgia (21.5%). The use of TCO defined as the participants had to use for more than 3 days/week and for more or equal to 50% of daily walking and standing duration was 67.3%. Using TCO can provide walking stability (p-value=0.008). For patients with metatarsalgia, using TCO can significantly reduce pain (p-value=0.002). Many factors found associated with the use of TCO including receiving TCO for more than first pair (Odds ratio=4.09, 95% CI 1.51-11.05), ability to find proper shoes that fit with TCO (Odds ratio=0.36, 95% CI 0.15-0.89), level of convenience of putting on/taking off shoes with TCO≥9 (Odds ratio=2.66, 95% CI 1.16-6.12), level of comfort satisfaction during TCO use≥9 (Odds ratio=3.61, 95% CI 1.55-8.40). The latter two factors are found to be associated with the use of TCO from stepwise logistic regression analysis (adjusted Odds ratio=3.39, 95% CI 1.18-9.71, 3.02, 95% CI 1.07-8.47 respectively).

Conclusion

The use of TCO in Foot Clinic was 67.3%. Using TCO could result in walking stability. Patients who received more than first pair of TCO and had comfort satisfaction level≥9, were more likely to use TCO.

FEASIBILITY AND EFFECTIVENESS OF DIABETES PEER COACHES

P. McGowan¹, F. Hensen², S. Lynch³
¹School of Public Health and Social Policy, Human and Social Development, Victoria, Canada
²Fraser Health Authority, Primary Care and Chronic Disease, Surrey, Canada
³Institute on Aging & Lifelong Health, Health and Human Services, Victoria, Canada

Introduction/Background

This was a two-year project funded by a grant from the Lawson Foundation involving a university and 11 Diabetes Centres. One hundred nine persons with type 2 diabetes or who were familiar with type 2 diabetes (e.g., family member) were trained to use Self-Management behavioural change strategies and to navigate the healthcare system. Diabetes educators recruited 115 adults with type 2 diabetes who were experiencing difficulty.

Material and Method

Coaches and subjects were paired and over a 6-month period coaches telephoned subjects once each week and engaged in a 30 minute conversation. Both the coaches and subjects completed questionnaires at baseline, and at 6 and 12 months. A one-way repeated-measures analysis of variance was used to investigate change with 14 measures. To investigate process, a grounded theory qualitative analysis was conducted to obtain information on how the coaching process worked.

Results

The analysis showed statistically significant improvements in A1C, patient activation, depression, self-efficacy, communication with health care professionals, and diabetes empowerment. Improvement levels were sustained at 12 months and these results were not influenced by covariates of age, gender, number of chronic health conditions and education level. The study also obtained information on recruiting coaches and participants, training coaches, pairing coaches with participants, length and intensity of the intervention, liaising with diabetes health professionals and monitoring and supporting coaching integrity.

Conclusion

This pilot “pragmatic” study demonstrated that peer coaches are acceptable to clinicians and clients and have an important role in the continuity of care for persons experiencing chronic conditions. At study completion the program protocol was modified slightly and is currently being
implemented on a permanent basis to persons experiencing various types of chronic condition, and the program is currently being evaluated in a randomized controlled trial.

REVIEW OF CURRENT LEGISLATIVE DOCUMENTS ON REHABILITATION SERVICES IN MONGOLA
D. Tsendjav¹, B. Oidov², O. Ragchaa³
¹Implementing Agency Of The Capital City Governor, Health Department, Ulaanbaatar, Mongolia
²Shastin Central Hospital, Deputy Chief Of Research And Training And Cooperation, Ulaanbaatar, Mongolia
³Ministry Of Health Mongolia, Department Of Policy And Planning, Ulaanbaatar, Mongolia

Introduction/Background

As technical advancement increases efficiency of acute medical care and survival rate, the demand for evidence-based, accessible and comprehensive rehabilitation in health systems grows. For the progress in rehabilitation service in Mongolia the established legislative policy is required. It was considered that the review of all currently effective legislative policy documents is essential for practicing medical professionals.

Material and Method

To review all currently effective legislative policy documents, including laws, acts, decrees, guidelines and any regulation documents on rehabilitation service

Results

Rehabilitation service was stated in one provision in the State Policy on Health, in ten provisions in the Law on Health, in ten provisions in the Law on Medical Care Services, in three provisions in the Law on Health Insurance, in six provisions in the Law on Social Welfare. Classification of activities of specialists, general and qualified competency indexes of physician and other professionals in rehabilitation were approved by the Order of the Minister of Health. There are five currently effective regulation documents on rehabilitation services.

Conclusion

The provision in the Law on Medical Care Services, as an independent field of medical service, indicates the biggest achievement in the policy and further development of our field.

Keywords
Conflict of interest
Disclosure statement:
For the progress in rehabilitation service in Mongolia the established legislative policy is required
Introduction/Background

The assessment of the quality of rehabilitation at different levels (individual, specialist, department, institution, territory, etc.) is a complex process. There are several methods that allow assessing at a certain level. However, the end-to-end assessment does not exist in a unified manner.

Material and Method

The system for assessment of the quality of rehabilitation services has been elaborated. It allows at an individual level to compare the average rates of the categorical profile regarding to the International Classification of Functioning, Disability and Health and to assign a weight characteristic to the result. It makes possible to conclude: good, satisfactory, no results; at the level of the department based on the average weight index of the individual assessment the efficiency of the department activity is calculated; at the level of the organization it is calculated on the index of the departments, etc. Starting from the second level, it is necessary to take into account the variance of the rates, which shows the presence / absence of significant deviations in the process of the rehabilitation and to assess the stability of the results that were obtained.

Results

Testing of the developed approach was started in 2017 in the pilot regions of the Russian Federation (Sverdlovskaya Oblast and Permksiy Kray) in the framework of improving the rehabilitation system in the country and will be completed in 2018.

Conclusion

The results indicate the high effectiveness of the proposed approach from the point of view of monitoring and management of the rehabilitation services and systems at the macro level.

DEVELOPMENT OF SCI SERVICES IN MADAGASCAR

R. Jean Jacques Renaud¹, R. Hariharan², A. chamberlain³

¹Association De Medecine Physique Et De Readaptation De Madagascar Ampr Mada, CHU/JRA, Antananarivo, Madagascar
²Consultant in Spinal Injuries, Sheffield Teaching hospital NHS, UK
³Academic Departement of Rehabilitation Medicine, Faculty of Medicine and Health, University of Leeds, UK

Introduction/Background

Madagascar, a country of 24 million people, until 2013 did not have any SCI services. For the only two neurosurgery services, one in the capital in Antananarivo and one in the province in Fianarantsoa, the management of spinal cord injury was limited to initial surgical fixation of the fractured vertebrae for those who could afford it. 8 doctors gained the Diploma in Rehabilitation Medicine in 2013 through a joint collaboration between the University in Antananarivo and Leeds University, UK with the support of the charity Optin.

Material and Method

Retrospective method by situation analysis of SCI services before 2013.

Results

Data from two years suggests that the service is beginning to have a positive impact. The rates of secondary complications are comparable to other reports from the region. A 2015 study in Ethiopia found 22.5% of patients with SCI developed pressure ulcers, compared to 11.5% in Madagascar in 2016 (9).

The other notable developments are the multidisciplinary team in collaboration with neurosurgical team.

Challenges:

- Lack of SCI Rehab services in Madagascar
- Poor access to online resources.

Future:

- Centre of excellence for SCI rehab in Antananarivo
- Develop SCI services in Fianarantsoa.

Conclusion
SCI services in Madagascar are continuing to develop, with an emphasis on clinical knowledge and systematic management rather than advanced technology. These developments are a source of considerable pride, in spite of poor transport infrastructure and the low level of healthcare funding. Other countries now acknowledge the positive advancements in Madagascar, which is leading the way for rehabilitation services across Africa (1).

Background and aims: Critical in promoting older adults’ health and preventing disabilities, social participation includes social and leisure activities, e.g., doing physical exercises, visiting friends and volunteering. To support the development of social participation, the Personalized citizen assistance for social participation (APIC) is an intervention that involves stimulation with a non-professional volunteer fostering the establishment of an egalitarian relationship. Although it can complement and extend professional healthcare services, little is known about the strengths and challenges of involving volunteers in the APIC and, more broadly, in the rehabilitation process. This presentation aims to explore the experience of involving volunteers in the APIC.

Methods: In six studies among adults with acquired brain injuries (mixed-method; n=9), older adults with loss of autonomy (mixed-method, multiple case & pragmatic multicentre randomised controlled trial designs; n=19+5+25), and aging adults with visual impairment (mixed-method; n=13) or psychosocial and mental health issues (multiple case; n=5), APIC has been experienced in a research context, and implemented in community organizations and one rehabilitation centre. Semi-structured individual or group interviews were conducted with volunteers who also kept a diary.

Results: Volunteers provided weekly three-hour personalized stimulation sessions over at least six months, targeting significant social and leisure activities. The strengths and challenges of involving volunteers in the APIC depended on their interest and helpfulness. Main issues concerned reaching, engaging and supporting volunteers throughout the APIC. Volunteer training and supervision once a month, through a group meeting that included a rehabilitation professional, were essential.

Conclusions: While social participation should be fostered, it is important to have a better understanding of the impacts of the involvement of volunteers in the APIC and other similar rehabilitation contexts. Strategies to properly reach, train, involve and support volunteers are important to ensure a positive experience for the patient and everyone involved in the rehabilitation process.

UTILIZATION OF HIGH-TECH VERTICALIZATION EQUIPMENT FOR WHEELCHAIR DEPENDENT SCI PATIENTS DURING INPATIENT REHABILITATION AT HAAPSA LU NRC BETWEEN 2016 - 2017

P. Eelmae1,2, M. Pakkanen3, A. Tõnutare3, O. Vanem2,3, M. Riina2,3, K. Englas1,2, M.L. Ööpik-Loks2,3

1Haapsalu Neurological Rehabilitation Centre, Administration, Haapsalu, Estonia
2Centre of Excellence in Health Promotion and Rehabilitation, Clinical Laboratory of Rehabilitation Robotics, Haapsalu, Estonia
3Haapsalu Neurological Rehabilitation Centre, Department of Spinal Rehabilitation, Haapsalu, Estonia
4Haapsalu Neurological Rehabilitation Centre, Department of Neurorehabilitation, Haapsalu, Estonia

Introduction/Background

Since 2012 Lokomat Pro, Erigo and tilt-beds have been used at Haapsalu Neurological Rehabilitation Centre (HNRC) for verticalization of spinal cord injured (SCI) patients. In 2017 HNRC underwent a structural reform during which the former profession-based departments were turned into diagnose-based units, aiming to provide more efficient and patient-centered services and to increase the use of expensive high-tech equipment by at least 10%. The goal of this retrospective study is to assess the effect of the reform on the use of high-tech instruments and to clarify the motivation of patients and hospital staff in providing these services.

Material and Method

HNRC’s medical software Medisoft Liisa and standard statistical methods were used for data collection and analysis. Qualitative interviews of staff and patients were used to obtain information on motivation. All SCI patients treated in HNRC between 2016-2017 irrespective of the cause of injury and financing conditions were included in the present study. All patients eligible for verticalization were wheelchair dependent. Eight tilt beds were used in 2016 and twelve in 2017 in spinal rehabilitation unit for verticalization.

Results

In 2016 and in 2017 the number of SCI patients in spinal rehabilitation unit was 422 and 474 respectively. Erigo was used 33840 minutes in total for 115 patients in 2016 and 50220 minutes for 178 patients in 2017. In 2016 Lokomat Pro was used 6846 minutes for 44 patients and 11745 minutes for 56 patients in 2017. Tilt-beds were used 16140 minutes for 51 patients and 33630 minutes for 101 patients in 2016 and 2017. From 1535 scheduled tilt-bed standing sessions 1121 were performed in 2017 due to the low motivation of patients.
Conclusion

The use of high-tech equipment for verticalization increased by 52,3% between 2016 and 2017. The utilization of tilt-beds increased by 108,3%, but patient empowerment remains a challenging task for the staff.

EFFECT OF HORSE RIDING THERAPY ON QUALITY OF LIFE AND GROSS MOTOR FUNCTION IN CHILDREN WITH CEREBRAL PALSY

B. Hong1, J.Y. Kwon2, J.S. Kim3, S. Jun3
1St.Vincent's Hospital- College of Medicine- The Catholic University of Korea, Rehabilitation medicine, Suwon, Republic of Korea
2Samsung Medical Center- Sungkyunkwan University School of Medicine, Department of Physical and Rehabilitation Medicine, Seoul, Republic of Korea
3St. Vincent’s Hospital- College of Medicine- The Catholic University of Korea, Department of Rehabilitation Medicine, Suwon, Republic of Korea

Introduction/Background

Therapeutic horse riding is one of the popular alternative therapy other than physical therapy for improvement of posture and gross motor function. There are increasing references about the benefit of hippotherapy on motor function. However, their evidence on quality of life is not sufficient. The study aimed to find the effect of horse riding therapy (HRT) on both gross motor function and quality of life in children with cerebral palsy.

Material and Method

The participants were 12 children with cerebral palsy (GMFCS level I-III), and their mean age was 6.5±1.9 (ranged 5-12) years recruited from university rehabilitation hospital. Five were boys, and eight were bilaterally involved (Table 1). The gross motor function measure(GMFM) test, pediatric berg balance test (PBS), and Child Health Questionnaire – parent form 50 (CHQ-PF50) were evaluated before and after the 8 weeks of HRT schedule (30minutes/session, total 16 sessions).

Results

Total score of GMFM-88, GMFM-66, and PBS did not show significant change after 16 sessions of HRT (P > 0.05). However, GMFM-D dimension which deals with various aspects of standing showed significant improvement after 8 weeks of horse riding therapy, the mean score (SD) from 27.9 (11.1) to 29.8 (10.7) (P = 0.006) (Table 2). And various score dimensions of CHQ-PF50 showed no significant difference during and without HRT; Physical functioning, Role/Social Emotional/Behavioral, Role/Social Physical, Bodily Pain and Discomfort Scale, Behavior Scale, Mental Health Scale, Self Esteem Scale, General Health Perception Scale, Emotional Impact on Parent Scale, Parent Impact Time Scale, Family Cohesion, Family Activities, Physical Summary Score, Psychosocial Summary Score (P > 0.05).

Conclusion
After 8 weeks of HRT, the standing function was significantly improved in children with CP. However, balance and walking score and quality of life score did not improve significantly.

The Pace Centre is an early intervention and educational facility for children aged 0 – 14 years with motor disorders. A transdisciplinary team of teachers, therapists, conductors and learning support assistants enables the provision of a bespoke therapy and learning environment to meet the individual needs of the child within the classroom.

Having a motor disorder can lead to deprivation of typical sensory experiences that are necessary for children to develop emotionally, physically and academically (Ayres 2005). Therefore, incorporating individualised sensory based interventions (SBI) into our daily programmes are integral to facilitate the child’s learning.

Material and Method

Skilled observation and where appropriate, structured assessments of sensory processing are utilised alongside liaison with parents and other professionals to inform which SBI may be of benefit and whether individualised Ayres Sensory Integration (ASI) may also be suitable.

SBI may take the form of whole group but differentiated accordingly, programmes that include the considered use of vestibular, proprioception and tactile sensory input to support arousal, attention, engagement and muscle tone/ postural stability. During the school day SBI are also incorporated by having a variety of seating and movement opportunities available to support the sensory needs of the child to facilitate their learning; ranging from sitting on a platform swing during a lesson to pushing oneself on a scooter board to move throughout the school.

Results

See below

Conclusion

Data collected from termly reviews of Individual Educational Profiles which measure physical and academic attainment support the beneficial use of SBI to enable and facilitate accelerated emotional, physical and academic learning attainment.

“TREATING A PATIENT SHOULD BE APPROACHED IN A HOLISTIC MANNER”: COLLABORATION OF DOCTORS AND PHYSIOTHERAPISTS IN THE REHABILITATION OF PEOPLE LIVING WITH HIV

V. Chetty1, S. Maddocks1, L. Chetty1
1University of KwaZulu-Natal, College of Health Sciences, Durban- KwaZulu-Natal, South Africa

Introduction/Background

A team based approach to medical management of people living with HIV is imperative to promote coordinated, comprehensive and continued care in order to facilitate reintegration into daily life and community living. Doctors and physiotherapists are key role players involved in the management of the impairments and disability related to the HI-virus and its treatment. The paper explores the collaboration of doctors and physiotherapists in the rehabilitation of people living with HIV in a semi-rural healthcare setting in KwaZulu-Natal, South Africa.

Material and Method

A qualitative approach using a semi-structured interview guide was employed to interview six doctors and two physiotherapists.

Results

Five themes emerged from the analysis- namely biomedical versus biopsychosocial approach; scope of practice challenge; multidisciplinary team enigma; institutional structure limitations and recommendations from healthcare professionals.

Conclusion

Both groups of professionals believed that a lack of understanding into scope of practice and role of the associate profession in the multidisciplinary team led to poor referrals and lack of collaboration. Furthermore, shortage of personnel and resource limitations posed barriers to effective team interaction. Timely, appropriate referrals, good communication and understanding of roles were suggested as endorsements to improved collaboration for future practice.

REINTEGRATION IN NORMAL LIFE, IMPACT ON LIFE SATISFACTION AND MODERATE ROLE OF SELF-CONCEPT AND COPING STRATEGIES

D. Duric¹, D. Cekrlja², B. Majstorovic³
¹psychology, ZFMR "Dr Miroslav Zotovic", Banja Luka, Bosnia - Herzegovina
²Faculty of Psychology, Department for Psychology, Banja Luka, Bosnia - Herzegovina
³ZFMR "Dr Miroslav Zotović", Department for prosthetic rehabilitation and post traumatic conditions, Banja Luka, Bosnia - Herzegovina

Introduction/Background

Recent studies confirm relationship between reintegration in normal life and life satisfaction at persons with limb amputation. In this study, within the illumination of reintegration in normal life and life satisfaction relationship, mediation role of self-concept, coping strategies, and optimism were considered.

Material and Method

Sample consisted of 80 males with leg amputation, between 31 and 57 years old.

For the purpose of the study were used tests: Reintegration in Normal Life Questionnaire Scale, Life Satisfaction Scale, SC-4 was used in estimation of self-concept primary domains, Coping Inventory of Stressful Situations and optimisms scale.

In order to examine complex relationship between considered constructs mediation analysis were performed. At the first step impact on RNL index on general self-concept, coping strategies and optimism were mediator variables. In the second step life satisfaction was dependent variable, while self-concept, and coping strategies and optimism were varied in position of mediator variables.

Results

Results show significant direct effect of RNL index on general SC, while direct effect is not significant. Coping strategies and optimism dimensions does not contribute in establishing significant total effect on general self-concept. There is no direct RNL index impact on Life satisfaction, but total impact when moderate variables are included (Self-concept primary domains) is significant. Physical, Emotional and Competence self-concept significantly moderate both life satisfaction aspect. With coping strategies and optimism in moderate variables position, direct and total effect of RNL index on general SC are both significant. Emotion oriented coping styles, and pessimism show significant impact on both, general and situational life satisfaction.
Conclusion

Findings suggest that reintegration of people with leg amputation in normal life does not just directly effect life satisfaction. Moderate role of self-concept, coping and coping strategies is confirmed. Specific role of primary self-concept domains, coping strategies and optimism dimensions are to be discussed.

THE POST-RETIREMENT WORK SUPPORT FROM AN OCCUPATIONAL PERSPECTIVE: A LITERATURE REVIEW OF ISSUES WITHIN THE SILVER HUMAN RESOURCES CENTER IN JAPAN

K. Funakoshi¹, Y. Ishii²
¹Tokyo Metropolitan University Graduate School of Human Health Sciences, Department of Occupational Therapy Master Course, Tokyo, Japan
²Tokyo Metropolitan University Graduate School of Human Health Sciences, Department of Occupational Therapy, Tokyo, Japan

Introduction/Background

The number of working elderly in Japan has been increasing, and one-fifth of workers in 2016 were older than 60 years. Silver Human Resources Center (SHRC) is a Japanese organization providing post-retirement work. SHRC has a purpose resembles the philosophy of occupational therapy: to support retirees improve their well-being. The aim of this research is getting suggestions from an occupational perspective for post-retirement work support through a literature review of issues within the SHRC.

Material and Method

The research was conducted in Cinii Articles with a keyword: "Silver Human Resources Center". 31 Japanese studies were extracted from 211 results based on "aims" and "methods" description and 55 labels refer to issues of SHRC were extracted from them. The labels were analyzed based on a categorizing method to reveal the relation each other.

Results

5 categories occurred. <A better matching of jobs with human resources> was a systematic issue of SHRC, and taking on this issue was important for <increasing active working>. In addition, a difficulty of proactive management by members and gathering new members were also identified as issues, and it was needed <to be matured as an organization>. This maturing was related to the propulsion of community-based efforts and being a place enables local residents to spend time with others. It means <to be a part of every day>, and efforts <to be a part of every day> and for <increasing active working> were expected to expand to support <not only member's working but also their lives>.

Conclusion

Analyzed issues of SHRC seem to include an occupational perspective: to support one's occupation from personal history and environments. Therefore, occupational therapy may be able to contribute preventing from occupational crisis due to change ways of spending life after
retirement. One of the important tasks is revealing the subjective experience process of life changing with retirement.

INFLUENCE OF ENVIRONMENTAL FACTORS ON WELL-BEING AND CARE BURDEN OF ELDERLY FAMILY CAREGIVERS: A BAYESIAN STRUCTURAL EQUATION MODELING APPROACH
K. Yabuwaki1, M. Iwata1, K. Ono2
1Kibi International University, Department of Occupational Therapy, Takahashi-shi, Japan
2Kawasaki University of Medical Welfare, Department of Rehabilitation, Kurashiki-shi, Japan

Introduction/Background

In Japan, the magnitude of the care burden and difficulties with continuity of in-home care among elderly caregivers have been reported, but support systems for elderly family caregivers remain insufficient. This study aimed to test a hypothetic model holding that environmental factors influence elderly family caregivers’ well-being and care burden.

Material and Method

Participants were 60 family caregivers of elderly people with care needs who were aged ≥60 years (24 men and 36 women; mean age, 75.7 ± 8.9 years). The study was approved by the Kibi International University Ethical Review Board (No. 17-16). Participants underwent a demographic survey, the Comprehensive Environmental Questionnaire (CEQ), a short version of the Japanese version of the Zarit Caregiver Burden Interview, and the Visual Analogue Scale of Happiness, and the generated hypothetical model was assessed by means of Bayesian Structural Equation Modeling (BSEM).

Results

When the hypothetical model was assessed using BSEM, environmental factors were found to influence the well-being more strongly (standardized coefficient [sc] = .406) than the care burden (sc = -.377). Factor loading of environmental factors was largest in family environment, followed by secure living environment, and interactive environment. In addition, the gender of the caregiver also influenced the care burden (sc = -.324) and well-being (sc = -.275). The posterior predictive p-value of the final model was 0.170.

Conclusion

This study assessed a hypothetic model holding that environmental factors influence elderly family caregivers' well-being and care burden, and that the gender of the caregiver is a covariate. Women’s care burden was strong, while men’s well-being was low. Accordingly, by supporting an interactive environment, a secure living environment, and a family environment as mapped by the CEQ, it may be possible to improve the well-being and mitigate the care burden of elderly family caregivers.

RELEVANCE OF ENVIRONMENTAL FACTORS TO FACILITATE PARTICIPATION OF PATIENTS IN REHABILITATION

T. Meyer¹, V. Kleineke², A. Menzel-Begemann²
¹University of Bielefeld, School of Public Health, Bielefeld, Germany
²University of Applied Sciences Muenster, Department of Health, Muenster, Germany

Introduction/Background

The introduction of the ICF model as a basis for rehabilitation provides new perspectives on rehabilitation practices. According to the ICF, participation can be enhanced via different pathways, including interventions on environmental factors. Aim of the presented project was to systematically compile present knowledge on environmental factors that could be a target for interventions in inpatient rehabilitation to improve patient participation.

Material and Method

First, we have conducted a document analysis comprising icf core sets, clinical rehabilitation guidelines or standards, and health classifications on interventions to identify the array of rehabilitation interventions related to environmental factors. Second, these interventions were linked to the ICF environmental factor codes resulting in a linking table that can be used to identify commonalities and potential blind spots of possible intervention targets. Third, after the conduction of an expert workshop eight focus groups with rehabilitation professionals from different fields of inpatient medical rehabilitation were conducted. Fourth, another two expert workshops were conducted to develop a list of possible targets for the development of interventions and recommended course of action for future projects.

Results

The project resulted in a substantial number of different recommendations. They relate to the fields of new technologies, to measures that help to sustain rehabilitation effects in daily living, to the work place, to the reference to language and cultural diversity, to the home environment of the patients, to matters of de-acceleration, to individualisation of rehabilitation, to the way patients deal with their own resources and roles, to explicit environmental strains, and to the specific use of products and technologies.

Conclusion

This project used a theoretical perspective on rehabilitation to inspire new approaches to rehabilitation interventions that target environmental factors with the aim to improve participation of patients. A substantial number of proposals have been developed that could be used as a starting points for further projects.

Developmental disorder is widely recognized as communication and learning disabilities. However, motor development should also be meticulously evaluated. Some reports have indicated that children with motor developmental disabilities show lack of skill and stiffness. In particular, there are numerous reports on awkwardness of motor imagery. However, the maturity process of motor imagery has not been fully clarified. The present study was designed to comprehend factors influencing motor imagery in children.

Approval for this study was granted by the Ethics Committee of Tokyo Metropolitan University.

Material and Method

The subjects were 96 healthy elementary school students (male:58, female:38, mean age:8.7, SD=1.9) without any specific diagnosis. They were asked for their age, and the average time spent on a sport every day. The motor imagery of these children was estimated by the following methods. The motor imagery was evaluated by expected walking time. First, the children indicated their expected time to walk 8m. Next, their actual walking time is measured. The difference between these times was assigned as a dependent variable. The age and the average time spent on a sport were assigned independent variables. The relations between the dependent variable and independent variables were analyzed using the Pearson's methods. The significance level was set at 10%.

Results

The children’s expected time was as follows. Expected time: mean 6.9sec, SD= 2.3. Actual walking time: mean 7.3sec, SD= 1.8. The difference between these times (prediction error): mean 1.6sec, SD= 1.3. The correlative analysis showed that the correlation coefficient between age and prediction error was -0.3 (p<0.1); the correlation coefficient between the average time spent on a sport and prediction error was -0.2 (p<0.1).

Conclusion

The results of the present study suggested that motor image maturity correlates with the children’s age. In addition, daily experience in sport influences motor image maturity.

THE RELATIONSHIP BETWEEN ANTICIPATORY POSTURAL ADJUSTMENT AND STEPPING DIRECTION IN HEALTHY ADULTS

K. Kikuchi1, N. Osamu1, F. Natsuki1

1Tokyo Metropolitan University, Department of Physical Therapy, Tokyo, Japan

Introduction/Background

The anticipatory postural adjustment (APA), one of postural controls, has two functional significance: to control posture in advance and prepare activity for main motion. The aim of this study was to clarify the relationship between anticipatory postural adjustment and stepping directions in healthy adults by focusing on the reverse response phenomenon. This study was approved by the Ethics Committee of Tokyo Metropolitan University.

Material and Method

The subjects, eight healthy adults (male: 3, female: 5, mean age: 21.8, SD= 0.7, right-footed: 7, left footed: 1), initiated stepping on a force plate. The step directions were straight ahead; 0, 30, 60 and 90° in both feet, and the step length were 20% of body height. The maximum moving distance of center of posture (COP) which was established by the right and left composition of COP at rest and APA was calculated by using the Pythagorean. The kinetic variables during APA phase (from the initiation of COP displacement to heel-off of the swing limb) were measured using a 3D motion capture system and the floor-reaction-force measuring device. The comparisons were analyzed using a two-way repeated measures ANOVA. The significant level was set at 5%.

Results

The result of two-way repeated measures ANOVA showed a main effect between the dominant foot and non-dominant foot (p<0.05), and stepping directions (p<0.01). In addition, the result of multiple comparison showed a significant difference between dominant and non-dominant foot at 0°.

Conclusion

These results showed stepping direction relates with the maximum moving distance of COP, and the maximum moving distance of COP of the non-dominant foot step is shorter than that of the dominant foot. Therefore, it is suggested that stepping on non-dominant foot is likely to be unstable in forward gait.

ADDUCTOR MAGNUS IS JUST AS MUCH AN ANTIGRAVITY MUSCLE AROUND HIP JOINT AS GLUTEUS MAXIMUS

M. Takizawa¹, Y. Suzuki², Y. Kobayashi³

¹Ibaraki Prefectural University of Health Sciences, Physical Therapy, Ami- Inashiki, Japan
²Osaka City University, Research Center for Urban Health and Sports, Osaka, Japan
³Sakushin Gakuin University, Faculty of Business and Public Administration, Tochigi, Japan

Introduction/Background

The adductor magnus (AM) is the third largest muscles, and also monoarticular muscle in the lower limb. The purpose of this study was to compare the AM with the gluteus maximus (GM) and the hamstrings (semimembranosus SM, semitendinosus ST, and long head of the biceps femoris BF) in terms of how these muscles generate extension torque during antigravity movement and to assess whether or not the AM plays a role as a primary antigravity muscle.

Material and Method

Ten healthy young men took part in this study, approved by the ethics committee. Squatting activities were selected for an anti-gravity movement. Each subject performed unloaded squats maintaining the trunk as upright as possible with either the hips in neutral rotation or the feet shoulder width apart, or letting the trunk flex naturally with either the hips in neutral rotation or the feet shoulder width apart. Kinematic data were taken with a motion capture system (VICON) and floor reactions were recorded with force plates (Kistler). We determined muscle torques by optimization calculation. The skeletal model used was SIMM.

Results

In task1 and task2, lacking trunk flexion, GM and AM exerted much greater hip extension torques than did hamstrings. In task3 and task4, with the trunk naturally flexed, SM and BF were much more contributory, whereas ST exhibited relatively little torque in either task.
Conclusion

Given that the antigravity function of the AM is more like that of the GM than of the hamstrings, the AM might more appropriately be considered a primary antigravity muscle than an ancillary one.

CONCEPTUAL UNDERSTANDING OF HUMAN BEING TO REDEFINE REHABILITATION MEDICINE

Y.K. Kang¹, S.B. Pyun¹, W.J. Meng¹, H.J. Han²
¹Korea University College of Medicine, Rehabilitation Medicine, Seoul, Republic of Korea
²Korea University College of Medicine, Medical Humanities, Seoul, Republic of Korea

Introduction/Background

What is rehabilitation medicine? What is its aims and goals? These fundamental questions were rarely asked in rehabilitation medicine, although it has been practiced every day for decades. Since the practice of rehabilitation medicine affects physical, mental, and social aspect of patient at the same time, an interdisciplinary research of human being is required to understand what practitioners of rehabilitation medicine really do and should do. As a preliminary result of such research, this article focuses on philosophical understandings of human being, functioning, and disability with regard to ICF and also endeavor to establish a theoretical framework for rehabilitation medicine.

Material and Method

Pairs of concepts defining human being, living, life in general, and their relationships with rehabilitation medicine are discussed on the basis of French philosophy of medicine from the 18th century to the present, in particular that of Pierre-Jean-Georges Cabanis (1757-1808) and Georges Canguilhem (1904-1995).

Results

From the theoretical consideration of French philosophy of medicine and rehabilitation medicine, an analogical framework between philosophical concepts and ICF is found. Furthermore, new aims and goals of rehabilitation medicine can be established under the name of ‘REHAB SMART’ (Sustaining Movement And Restorative Thinking) as shown in the following. [Table attached]

According to the chart, living human being consists of not only functioning, but also disability. Disability should thus be understood as diversity and not as criteria of discrimination. Eventually, rehabilitation medicine should aim to recover self-identity of patient by restoring patient’s neural and social network.

Conclusion

In order to ensure more successful practice of rehabilitation medicine, it’s basic concepts, underlying aims and goals should be examined with the help of philosophical understandings of
patient as a holistic human being. Such broad and fundamental considerations will enforce the integrity of theory and practice in rehabilitation medicine.

E1 Theory and Models of Functioning (e.g. Disability Creation Process)

ISPR8-2345
EXPANDING PANJABI’S STABILITY MODEL TO EXPRESS MOVEMENT: A THEORETICAL MODEL
J. Hoffman¹
¹Private Practice, Physiotherapy, Tel Aviv, Israel

Introduction/Background

The expanded model of Panjabi’s stability model views functional movement as a synergy between the body-wide systems of stability and mobility; thus adhering to fundamental movement philosophies of holistic mind-body disciplines such as yoga, Pilates, Feldenkreiz and Alexander.

Material and Method

The justification to regard full-body functional movement as a combined stability/mobility effort is derived from the observable clinical environment. It is clinically recognised that the stability and mobility systems are present and identifiable throughout the body in different joints and muscles and their synergistic interactions. The literature has reported that the neural system manages harmonious movements by accurately sequencing the activation timing between these two systems. Since movement requires both stability and mobility forces, the Panjabi model requires a generalization to express movement through a matching of mobility system with the same subsystems as the original stability model created.

Results

The expanded model suggests that the quality of a functional movement is determined by the ability of both the stability and mobility systems and their subsystems to work harmoniously. Conversely, malfunction of either system, or their subsystems, will deleteriously affect all other subsystems and consequently overall movement quality.

Conclusion

This expanded model ensures that clinical focus is placed on the body-wide synergy between the stability and mobility systems. Consequently, relevant exercises can be prescribed accordingly as specific intervention techniques. In physical therapy settings this may initially be in parallel with non-functional methods, including passive manual interventions or modalities. However, basic level training of full-body, pain-free functional movements should commence as soon as physically possible. As symptoms decrease, the exercises progress to be more complex and challenging in the direction of the relevant impaired full-body functional movements as diagnosed in the clinical examination.

INTENSIVE MULTIFACTORIAL NEUROREHABILITATION SYSTEM. 29 YEARS OF EXPERIENCE IN CUBA. INTERNATIONAL CENTER FOR NEUROLOGICAL RESTORATION.
A.E. Pérez Pérez¹, A.S.L. Dra.¹, D.D.C.G.F. Dra.¹, B.Y.N.P. Dra.¹, A.V.L. Dra.¹
¹Centro Internacional de Restauración Neurologica, Centro de Neurehabilitación, La Habana, Cuba

Introduction/Background

With the introduction of neurotransplants in Cuba in 1987, and the inauguration of the Ibero-Latin American Center for Transplantation and Regeneration of the Nervous System in 1989, a new modality of rehabilitation with variants of continuous and intensive stimulation was needed to accelerate the process of neuroplasticity in the cells transplanted to the brain of patients with Parkinson’s disease. From the attempts of a group of professionals in Neurosurgery, Neurology, and Nursing, and with the gradual introduction of specialists from different branches of rehabilitation, through the use of repetitive and intense physical exercise, what we know today as System of Intensive Multifactor Neurorehabilitation (SNMI). The purpose of this exhibition is to show how, over the last 29 years, the SNMI was organized and developed under the principles of neuroplasticity, the basic principles of international rehabilitation, and sports training applied to therapeutics, combining with different physiotherapeutic procedures, with the use of advanced technologies. It has been applied to hundreds of patients, with different neurological diseases, from more than 90 countries. It also shows the scientific evolution, national expansion, and current situation, concluding with its future perspectives and possibilities of exchange with other institutions.

Material and Method

Description of the casuistry of patients treated in these 29 years, according to clinics

Results

The most significant sample is in the patients of the Neuropediatric, Raquimedular and Movement Disorders clinics.

Conclusion

In 29 years of work in neurorehabilitation, CIREN has treated more than 1000 patients, in different pathologies and neurological sequelae. An integral intervention is carried out, with the application of novel technologies, and the realization of specific programs

E2 Classification of Functioning (e.g. ICF Core Sets; ICF Up-Date and Revision)

ISPR8-2630

D. Van De Velde¹, P. De Vriendt², T. Satink³, C. Kiekens⁴
¹Ghent University, Rehabilitation sciences and physiotherapy, Ghent, Belgium
²Vrije Universiteit Brussel, Department of Gerontology and Frailty in Ageing Research Group, Brussels, Belgium
³HAN University of Applied Sciences, 4 Research Group Neurorehabilitation, Nijmegen, The Netherlands
⁴University Hospitals Leuven, Physical and Rehabilitation Medicine, Leuven, Belgium

Introduction/Background

The ICF is considered as a tool to enhance the quality of rehabilitation delivery. Though its use can be further enhanced by developing tools that are feasible in practice, not increasing the administrative burden, but adhere to the quality-standards. As part of the international study, this project aimed to develop simple and intuitive descriptions of the ICF Generic and Rehabilitation set for use in The Netherlands and Belgium.

Material and Method

A two-stage consensus process was conducted with experts from the Netherlands and the Dutch speaking part of Belgium. Firstly, the English simple and intuitive descriptions of each ICF category were translated into Dutch by 4 rehabilitation and ICF experts. Secondly a consensus conference comprised three voting rounds and three working groups. Participants first voted on whether they agreed with the initially translated descriptions; a consensus of 75% was aimed for (Vote A). Descriptions that were considered ambiguous were divided among the three groups who were asked to propose alternative descriptions for the allocated categories. Subsequently, the alternatives were voted in a plenary session aiming for 75% consensus (Vote B). When categories were still considered ambiguous, every group was asked to develop alternative descriptions for all categories. Participants then voted in plenum which of the three proposed descriptions they preferred (Vote C).

Results

Twenty-Four clinicians, comprising PRM-physicians, physiotherapists, occupational therapists, nurses, speech/language therapists and psychologists (from various regions in Flanders and The Netherlands experienced in acute, post-acute and/or community rehabilitation) participated in the consensus process in Breda in September 2017. One ICF category achieved consensus in vote A, sixteen ICF categories were accepted in vote B. Thirteen descriptions were decided in the third round.
Conclusion

This translation process leaded to a Flemish-Dutch version of the simple intuitive descriptions and is now ready for implementation in rehabilitation practice.

MOVING FORWARD TOWARDS PARTICIPATION: KEY-ISSUES TO BE CONSIDERED FOR APPLICATION IN CLINICAL PRACTICE.

D. Van De Velde, M. Coussens, S. De Baets, L. Sabbe, G. Vanderstraeten, P. Vlerick, P. De Vriendt

1Ghent University, Rehabilitation sciences and physiotherapy, Ghent, Belgium
2University Hospital Ghent, Department of Physical and Rehabilitation Medicine, Ghent, Belgium
3Ghent University, Department of Personnel Management Work and Organizational Psychology, Ghent, Belgium
4Vrije Universiteit Brussel, Department Gerontology and Frailty in Ageing FRIA Research Group, Brussels, Belgium

Introduction/Background

Rehabilitation services are increasingly targeting involvement in daily life. Within the ICF this is referred to as participation. Questions regarding its conceptualization have been raised and a consensus is lacking.

Material and Method

In a first phase a critical review of the literature was performed to detect recurring conceptual problems in applying participation and to detect how researchers deal with these. This leaded in the second phase to a systematic review to identify how participation measures are operationalized.

Results

Phase 1 resulted in possible solutions to overcome 4 recurring key-limitations: (1) how to deal with ambiguity and vagueness about the term itself, (2) how to differentiate between activity and participation (3) what is the current empirical knowledge about the subjective aspects of participation (4) what are the different ways to measure participation. Phase 2 resulted in 18 instruments operationalising participation in different ways: (a) unidimensional; the frequency of performing activities (b) unidimensional; the limitations in experiencing participation when performing activities (c) multidimensional; multiple subjective dimensions when performing activities and (d) multidimensional: objective and subjective dimensions.

Conclusion

Notwithstanding an increasing body-of-knowledge some issues still remain blurred and specifically how participation is measured is subject to debate. This leads to difficulties to use participation in clinical practice. However: insight in current body-of-knowledge and awareness of shortcomings might inspire professionals aiming it’s application.

ON THE PRESENT USE OF ICF IN MEDICAL PUBLICATION

G. Grimby

Introduction/Background

The aim of the study is to record the present use of ICF with respect to publications, types of reports and diagnostic groups.

Material and Method

Search was performed using PubMed for International Classification of Functioning, Disability and Health or ICF for 2011 and 2016. The areas for journals were grouped using Web of Science. Type of studies and diagnostic groups were recorded.

Results

280 and 274 papers were found for 2011 and 2016 respectively. Most common areas for publications were Rehabilitation (46.1%, 43.4%), Public, environmental and occupational health (8.6%, 6.6%), Paediatrics (5.0%, 6.6%), Clinical neurology (5.0%, 5.9%). Most common journals were Disability and Rehabilitation (10.4%, 16.1%), Journal of Rehabilitation Medicine (10.0%, 5.5%), BMC Public Health (5.4%, 0%). Most common diagnostic groups were Neurological (20.4%, 28.5%), Paediatric (13.9%, 13.1%) and Musculoskeletal (13.6%, 13.1%) and general use of ICF (26.8%, 22.6%). Around 60% of the papers were original reports, the rest being reviews, special reports or editorials. ICF was used as a conceptual background in original reports (22.9%, 29.6%), in reviews etc. (25.4%, 21.9%) and to describe instruments or subjects with codes in original reports (39.6%, 35.0%) and reviews etc. (10.7%, 11.3%). ICF was in original reports used for outcome assessments (1.8% and 2.2%), but no such reports were found among reviews.

Conclusion

The use of ICF and journals for publication has been rather constant between 2011 and 2016. Variations in use of publication journals may to some extent depend on topic issues. Few papers have yet appeared where ICF is used for outcome assessment.

Introduction/Background

We aimed to develop a comprehensive International Classification of Functioning, Disability and Health (ICF) core set for systemic sclerosis (SSc) and to conceive an original ICF core set-derived questionnaire assessing activities and participation in patients with SSc.

Material and Method

The development of the ICF comprehensive core set followed 2 steps. In the first step, meaningful concepts related to SSc were collected from 3 sources: focus groups of patients (N=13), experts (N=10), and literature (200 articles selected). In the second step, concepts were linked to the relevant ICF categories by 2 independent reviewers according to prespecified linking rules. Finally, understandable questions related to activities and participation were derived from the corresponding categories of the comprehensive ICF core set by a sociologist of the French ICF Research Branch.

Results

146 ICF categories were collected from focus groups, 22 from experts and 48 from literature. After fusion of the sources and removal of duplicates, the comprehensive ICF core set included 169 ICF categories at the second level with 43 categories on body functions, 15 on body structures, 52 on activities and participation and 48 on environmental factors. A 65-item questionnaire was derived from the categories on activities and participation.

Conclusion
We developed a comprehensive ICF core set that offers a relevant conceptual framework for SSc patients’ care and health policy. Using an original approach, we conceived an ICF core set-derived questionnaire assessing activities and participation. A brief version of the questionnaire is in development, and may enhance the usability of the ICF in clinical research and in patient’s care.

INTRODUCTION/BACKGROUND

Globally physiotherapists are required to be on par with the latest in evidence based research and treatment techniques in order to provide the best practices and quality healthcare to their clients. As such, is the implementation of International Classification of Function (ICF) in daily physiotherapy practice, endorsed by the World Confederation for Physiotherapy (WCPT), since 2003. However, little is known about the extent of ICF use in daily South African and international physiotherapy practice in order to maintain international standards.

This research was aimed at exploring the level of understanding, attitudes, perceptions and extent of use of the ICF framework by Physiotherapists in the private and public sector in Gert Sibande District. Barriers and opportunities for using ICF framework, were also investigated.

MATERIAL AND METHOD

A prospective, explorative study, utilizing a mixed method (qualitative and quantitative) design. The objectives were accomplished by employing a semi-structured self-administered questionnaire, supported by a focus group discussion.

RESULTS

Gert Sibande physiotherapists (n=32) possessed some knowledge of ICF, whilst maintaining negative perceptions and attitudes towards ICF, resulting in minimal to no use of ICF. The only significant difference between the public and private health sectors, was perceptions (p < 0.05), which revealed public service physiotherapists to perceive ICF as favourable. Significant barriers to ICF use were, high patient loads resulting in time constraints during patient assessments, lack of knowledge, information, and comprehension of the framework.

CONCLUSION

ICF has not yet reached full maturity, however its benefits and many uses in health care and the profession of physiotherapy are continually expanding. It would be negligent of South African physiotherapists to ignore the recommendations of WHO and WCPT, therefore further education in ICF knowledge and improved application skills, is deemed the first step in promoting the frameworks use and indefinite benefits to South African physiotherapy and quality health care.

\textsuperscript{3}Hospitak del Salvador, Kinesiologia, Santiago, Chile
\textsuperscript{4}Hospital del SA lvador, Medicina Fisica y Raehabilitacion, Santiago, Chile

Introduction/Background

The biopsychosocial model of the ICF comprises more than 1400 categories. These categories need to be operationalized, to guarantee clinical applicability, through the development of instruments that describe the functioning and disability of patients in different contexts or health conditions. **Aim:** To describe the process of operationalization and subsequent verification of the inter-rater reliability of a set of ICF categories for adult patients treated for cancer at hospital discharge

Material and Method

Corresponds to an observational validation study. A previous process of systematic review and expert consensus selected 24 ICF categories, which were operationalized in a formal decision-making consulting different experts in the subject - health professionals with experience in the clinical management of patients with cancer. Subsequently, these operationalized categories were exposed to verification of inter-rater reliability by two trained raters in a sample of 31 patients with different types of cancer in two public Hospitals in Santiago, Chile. This study was approved by the Ethics Committee.

Results

24 CIF categories were operationalized using a scale of 0 to 4 corresponding to the CIF scale. The average age of the participants was 54.2 (of = 19) years. In relation to inter-rater reliability, the only item that did not present a correlation between both evaluations was d240 regarding stress management. In this way, this item was excluded from the instrument because it was very ambiguous. The other items obtained significant correlations that varied from $r = .916$ to $r = 1.0$ (perfect correlation).

Conclusion

This process resulted in the operationalization of 23 CIF categories relevant to the context of patients hospitalized for cancer, which obtained good inter-rater reliability. More research is suggested investigating other psychometric properties of this set of operationalized categories.

ARABIC TRANSLATION AND VALIDATION OF THE DASH INDEX

S. Ghorbal1, G. Mohamed2, K. Moez3, E. M. Habib4

1 Faculty of Medicine, Tunis, Tunisia, Faculty of Medicine, Tunis, Tunisia, Jeddah, Saudi Arabia
2 Unité de recherche de l'évaluation des pathologies de l'appareil locomoteur 04/UR/08-07, Université de Sfax, Sfax, Tunisia
3 d Service de neurochirurgie, CHU Habib Bourguiba, 3029 Sfax, Tunisia
4 Service de médecine physique et réadaptation fonctionnelle, CHU Habib Bourguiba, route El Ain, n° 3000 Sfax, Tunisia

Introduction/Background

Objective.– To translate and validate an Arabic version of the "Disabilities of the Arm, Shoulder and Hand scale" (DASH) for use in a Tunisian population with periarticular pathologies of the shoulder.

Material and Method

Patients and methods.– The method of "forward/backward translation" was performed for translation. Have been included in this study patients with periarticular pathologies of the shoulder. Clinical measures included the assessment of pain and functional disability by the functional visual analogue scale (VAS). Adaptations were carried out after a preliminary test including 15 patients. The interrater concordance was evaluated by intraclass correlation coefficient (ICC) and Bland and Altman method; the validity of construct was assessed using the Spearman correlation coefficient and the factorial analysis followed by orthogonal rotation. The internal consistency of each factor was graded by the study of Cronbach alpha coefficient.

Results

Results.– This study has included eighty people. The interrater agreement was good (ICC = 0.80) confirmed by Bland and Altman Method. The validity of convergence studied on the analysis of Cronbach alpha coefficient assessed on all item was 0.701.

Conclusion
Conclusion.-- The Arabic version of the DASH index for Tunisian population has good methodological qualities. Further studies with other Arabic-speaking populations will assess its applicability.

Introduction/Background

Patient reported outcomes are frequently used in clinical practice, epidemiologic studies and researches.

Cross–cultural adaptation of existing questionnaires to arabic is important for a number of reasons as exploring the impact and prevalence of low back pain in Arabic societies..

Objectives

To identify the available cross cultural adaptations to Arabic of questionnaires for low back pain and describe the psychometric properties of these adaptated questionnaire

Material and Method

Methods

A search on Medline and Google scholar for the terms back pain and lowback pain combined with the terms questionnaire, index, scale and outcome measures and Arabic

The data of the psychometric properties was extracted.

Results

Five questionnaires adapted to Arabic were identified: the Oswestry Disability Index (ODI), the Roland Morris Disability Questionnaire (RMDQ), the Fear Avoidance Beliefs Questionnaire (FABQ), the Japanese Orthopedic Association Back Pain Evaluation Questionnaire (JOABPEQ) and the Back Beliefs Questionnaire (BBQ)

The crosscultural adaptations were performed using the "forward/backward " translation method.
All the adaptation have been evaluated for the test-retest reliability, internal consistency and construct validity with adequate acceptance.

**Conclusion**

The Arabic version of these questionnaires are reliable tools that enables clinicians and researchers to assess and compare consequences, functional disabilities, and clinical outcomes of different interventions for LBP.

ACTIVITY LIMITATION OF CLINICALLY SLOW ELDERLY INDIVIDUALS

A. Miciano MD, C. Cross PhD, PStat R

Nevada Rehab Institute, PMR, Las Vegas, USA

Introduction/Background

Objectives: quantify the activity limitation (AL) of clinically slow elderly individuals (CSE); and, investigate the inter-relationship of AL status with body function and participation restriction.

Material and Method

In a retrospective study at a PMR clinic, 28 community dwelling elderly individuals participated (age range 65-85 years old) labeled as clinically slow (defined as < 2.2 miles per hour by 6-Minute Walk Test).

The PROMIS-57 v1.0 physical function sub-scale (PROMIS-PF) from the National of Institute (NIH) toolbox was designated as the patient-reported outcome (PRO) to describe activity limitation (AL). The clinician-derived Performance-based Assessments (PBA) also were used to describe AL and included the Dynamic Gait Index (DGI) and Berg Balance Scale (BBS). The PROMIS-57 v1.0 fatigue (PROMIS-FA) and sleep disturbance (PROMIS-SD) sub-scales assessed body function, and the satisfaction with social role sub-scale (PROMIS-SSR) quantified participation restriction.

Results

Data met normality assumptions; mean differences were examined among variables using ANOVA with age as a covariate. Age did not differ significantly among participants. Descriptive statistics and significance tests are provided for each variable, followed by a Pearson Correlation analysis split by gender (significant p <= 0.05). The mean (SD) score were as follows (female, male): PROMIS-PF T-scores 34.10 (5.70), 40.14 (8.82); DGI 13.76 (3.91), 22.10 (3.60); BBS 39.88 (8.28), 48.8 (7.06); PROMIS-FA 55.71 (12.30), 56.10 (3.97); PROMIS-SSR 51.53 (9.15), 46.50 (9.68). In females, PROMIS-PF correlated with PROMIS-FA (r=-.474, p=.04). In males, DGI correlated with PROMIS-FA (r=-.771, p=.042).

Conclusion

CSE tend to have moderate to severe AL and moderate PR, while their body function tend to be within population mean. The AL of CSE had a statistically significant correlation with the body function (specifically fatigue) in both genders. These findings support the importance of
assessing AL in these individuals, along with the BF and PR. Further research should be conducted on the inter-relationship relationships of BF, AL, and PR in other geriatric syndromes.

VALIDITY STUDY OF ALBERTA INFANT MOTOR SCALE
C. Wang⁷, Z. Huang⁸
⁷Peking university First Hospital, Rehabilitation Medicine, Beijing, China
⁸Peking University First Hospital, Rehabilitation Medicine, Beijing, China

Introduction/Background
Alberta Infant Motor Scale is an assessment tool to evaluate the gross motor development of the infant between birth until independent walking. It is a clinical practical assessment tool to be used and has been used broadly. The aim of this study was to examine the concurrent validity of Alberta Infant Motor Scale (AIMS) in Chinese with gross motor scale of Peabody Developmental Motor Scale II (PDMS-II) when used in high-risk infants.

Material and Method
One hundred and eighteen high-risk infants with the average age of 7.76±3.93 months (from 2 to 17 months) were recruited to this study. Three investigators experienced in AIMS and PDMS-II participated in this study. Each investigator administered the AIMS and PDMS-II to the infants within one week and recorded the assessment results. The raw scores of AIMS and PDMS-II-GM for each infant were analyzed for the concurrent validity.

Results
The Pearson correlation coefficient of AIMS with PDMS-II was 0.97. For the 0~4 month group, the Pearson correlation coefficient was 0.94. For the 4~8 month group, Pearson correlation coefficient was 0.95. For the 8~12 month group, Pearson correlation coefficient was 0.94. For the >12 month group, Pearson correlation coefficient was 0.91.

Conclusion
The AIMS in Chinese had high concurrent validity with PDMS-II when used in high-risk infants at very early age.

E3 Measurement of Functioning (e.g. Psychometrics of Assessment Tools; Operationalisation of ICF Categories)

ISPR8-0246
RATER RELIABILITY OF THE EXTENDED INTERNATIONAL CLASSIFICATION OF FUNCTIONING, DISABILITY AND HEALTH CORE SET FOR STROKE
N. Nualnetr¹, S. Kamalasing²
¹Faculty of Associated Medical Sciences, Division of Physical Therapy, Khon Kaen, Thailand
²Kabchoeng Hospital, Department of Physical Therapy, Surin, Thailand

Introduction/Background

The extended International Classification of Functioning, Disability and Health core set for stroke (eICFCS-stroke) is an assessment tool for describing stroke-related health. However, there were no reports of its use in Thailand. Before this core set could be applied to Thai population, there was a need to investigate its quality of measurement. This study aimed to evaluate rater reliability of the eICFCS-stroke in Thai population.

Material and Method

Participants were 43 community-dwellers with stroke (27 males and 16 females, mean age ± SD 65.6±10.6 years). Raters were 2 physical therapists who independently assessed the participants and filled in the eICFCS-stroke with a qualifying scale ranging from 0 (no problem/facilitator/barrier) to 4 (complete problem/facilitator/barrier) or the qualifiers 8 (not specified) and 9 (not applicable). The ratings were based on information obtained through interviews with the participants and their caregivers, observations and physical therapy examinations. Rater reliability was analyzed by using the percent observed agreement and the weighted kappa for each category.

Results

Based on the kappa coefficients and respective confidence intervals, the results revealed that of 166 categories of the eICFCS-stroke, 123 (74.1%) and 119 (71.7%) had intra- and inter-rater reliability, respectively.

Conclusion

Most categories of the eICFCS-stroke had rater reliability when assessing within the context of Thai community. However, reduction of some categories which were difficult to make a judgment in the community as well as reduction the number of qualifiers and simplification of the “environmental factors” categories should be considered to improve the efficient use of this core set.

PSYCHOMETRICS STUDY OF ALBERTA INFANT MOTOR SCALE AND PEABODY DEVELOPMENTAL MOTOR SCALE IN HIGH RISK INFANTS
C. Wang¹, H. Zhen², Y. Xi²
¹Peking university First Hospital, Rehabilitation Medicine, Bei jing, China
²Peking University First Hospital, Rehabilitation Medicine Department, Beijing, China

Introduction/Background

The aim of this study was to compare the psychometric properties of Alberta Infant Motor Scale (AIMS) with gross motor scale of Peabody Developmental Motor Scale II (PDMS-II) when they were used in high-risk infants.

Material and Method

Fifty-eight high-risk infants with the average age 4.46±0.97 months (from 2 to 6 months) were recruited to this study. Three investigators experienced in AIMS and PDMS-II participated in this study. Each investigator administered the AIMS and PDMS-II to the infants and recorded the assessment results. Forty-seven high-risk infants were followed-up till two years old. The diagnosis at two years old and the first scale assessment result were used to investigate the sensitivity, specificity, positive predictive value and negative predictive value of AIMS and PDMS-II.

Results

When used in high-risk infants in an early age, the AIMS’s sensitivity was 0.857, specificity was 0.731, positive predictive value was 0.720, and negative predictive value was 0.864. For the PDMS-II, the sensitivity was 0.524, specificity was 1.000, positive predictive value was 1.000, and negative predictive value was 0.722.

Conclusion

The AIMS is a sensitive monitor tool to evaluate the motor development of high-risk infants at very early age compared with PDMS-II. It needs to dynamic monitor for the high-risk infants.

ISPR8-0421
SYSTEMWIDE ROUTINE CLINICAL ASSESSMENT OF FUNCTIONING BASED ON THE ICF IN CHINA: INTERRATER RELIABILITY, CONVERGENT, KNOWN GROUP, AND PREDICTIVE VALIDITY OF THE ICF GENERIC
S. Liu1
1Jiangsu Province Hospital, Rehabilitation department, Nanjing, China

Introduction/Background

Based on WHO's International Classification of Functioning, Disability and Health (ICF), the ICF Generic-6 is a minimum set of information on functioning to be routinely collected across health conditions and settings. This study aimed to validate the ICF Generic in daily routine clinical practice in Mainland China. Specific objectives were to a) analyse the interrater reliability, b) convergent validity, c) known group validity and d) predictive validity of the ICF Generic.

Material and Method

Data from 4,510 patients with various diagnoses from 50 hospitals located in 20 provinces of Mainland China were collected by nurses who applied a 0 (no problem) to 10 (complete problem) numeric rating scale to each of six ICF categories of the ICF Generic at admission and study endpoint. 703 patients were rated independently by two investigators. Interrater reliability was evaluated with intraclass correlation coefficients (ICC). Convergent validity was evaluated with Spearman correlation coefficients between ICF Generic and SF-12 items. Known group-validity was examined by comparing discharge scores between different discharge destinations. Predictive validity was determined by employing ICF Generic baseline scores for estimating length of hospital stay and cost of in-hospital treatment.

Results

The interrater reliability of items and score of ICF Generic was good with ICCs ranging from 0.67 to 0.87. Spearman correlation coefficient analysis showed that ICF Generic items were correlated with respective SF-12 items. Discharge scores of patients differed significantly by discharge destination. ICF Generic admission score was a significant predictor of length of stay and treatment cost.

Conclusion

The ICF Generic administered in combination with a 0 to 10 numeric rating scale is a reliable and valid tool for the collection of minimal information on functioning across various clinical settings.

QOL-gNMD AND PATIENT REPORTED FUNCTIONING IN GENETIC NEUROMUSCULAR DISEASES: A NEW RASCH TOOL
F.C. Boyer1, A. Rapin2, A. Dany3, J.L. Novella4
1Reims Champagne Ardenne University Hospital, Physical Medicine and Rehabilitation, Reims, France
2Reims Champagne Ardenne University Hospital, Physical Medicine and Rehabilitation Department, Reims, France
3Brest University, Medicine and Health Sciences Faculty, Brest, France
4Reims Champagne Ardenne University Hospital, Geriatric Medicine Department, Reims, France

Introduction/Background

The “Quality of Life in genetic Neuromuscular Disease” questionnaire (QoL-gNMD) is a new patient reported outcome (PRO) measure tool specifically designed for patients with a slowly-progressive neuromuscular disease with genetic predominant muscular damage. The QoL-gNMD has been developed in 3 domains: “Impact of Physical Symptoms”, “Self-perception” and “Activities and Social Participation”. The objective was to construct and develop a PRO tool, easy to use in clinical settings, and validated by rasch model theories.

Material and Method

QoL-gNMD was developed using focus groups consisting of expert patients meeting (5 focus group, n = 41, item bank) and then a quantitative construction phase (n = 150, principal component and RMT analysis). The French version of the QOL-gNMD (26 items) was administered to patients recruited in 9 tertiary hospitals dedicated to genetic neuromuscular diseases. Each QoL-gNMD domain is measured on a T score metric i.e. a normal distribution with a mean of 50 and a standard deviation of 10. High values represent good quality of life. Standard errors of measurement were estimated and adjusted using rasch model theories (RMT). For each QoL-gNMD domain we estimated, face validity, test retest reproducibility, concordant validity and the conditional minimum detectable changes.

Results

315 patients were recruited for psychometric assessment. Each domain showed good psychometric properties (person separation index > 0.7, test-retest ICC>0.7) and fitted the partial credit model (RMT). Concurrent validity was assessed using the WHOQOL-BREF. Estimated conditional MDC were calculated for each possible measure change.

Conclusion
QoL-gNND is an rasch operational validated measure. QoL-gNMD English version is available but needs psychometric validation.

ISPR8-0681
THE EFFECT OF EDUCATIONAL LEVEL IN THE COMPARISON OF PRE-INJURY HEALTH-RELATED QUALITY OF LIFE (HRQOL) WITH HRQOL OF A DUTCH REFERENCE POPULATION

N. Kruithof1, J. Haagsma2, L. de Munter1, S. Polinder2, M. de Jongh3
1ETZ Tilburg, Trauma TopCare, Tilburg, The Netherlands
2Erasmus Medical Center, Public Health, Rotterdam, The Netherlands
3Brabant Trauma Registry, Network Emergency Care Brabant, Tilburg, The Netherlands

Introduction/Background

Differences between retrospectively collected pre-injury Health-related Quality of Life (HRQoL) data and population norms might be partly explained by differences in the distribution of educational level between cohorts. The first aim of this study was to examine whether retrospectively collected pre-injury HRQoL of the Dutch general hospitalized trauma population, is identical to HRQoL of a representative sample of Dutch individuals stratified by age, gender and educational level. Second, we examined the role of educational level in this comparison.

Material and Method

This study was part of a longitudinal survey among trauma patients admitted to the hospital between August 2015 and November 2016. Pre-injury HRQoL was collected by using the EuroQol-5D-3L (EQ-5D-3L) questionnaire. The reference cohort compromises a representative sample of the Dutch population. HRQoL was compared between the injury cohort (n=3032), reference cohort (n=1839) and general population norms by using descriptive statistics. The effect of educational level in the comparison between the injury cohort and reference cohort was investigated by entering educational level in the multiple regression model after age and gender. Outcome measures were EQ-5D-3L tariff, EQ-VAS and the five domains of the EQ-5D-3L.

Results

In general, the injury cohort reported better recalled pre-injury HRQoL compared to the HRQoL of the reference cohort and compared to the general norm population after adjustment. The ≥10% increment of the Beta after the addition of educational level in the multiple regression analysis suggested that educational level is a confounder for HRQoL.

Conclusion

Even after adjustment for age, gender and educational level trauma patients report a better pre-injury HRQoL score compared with the HRQoL of the reference cohort. To make a reliable
comparison between an injured cohort and a reference group it is strongly advisable to adjust for educational level besides age and gender.

COMPATIBILITY TEST BETWEEN THE SIX MINUTES WALKING TEST AND FOUR METER WALKING TEST

N. Nusdwinuringtyas¹, T. Fransiska UT¹
¹Faculty of Medicine- Universitas Indonesia, Physical Medicine and Rehabilitation, Jakarta, Indonesia

Introduction/Background

Functional capacity is an important parameter in Physical and Rehabilitation Medicine to be assessed, it represents general function of a patient in living their daily activity, and it can be rate with a walking test. Six-minute walking test (6MWT), using fifteen to thirty meter track is the most common test to be used world wide, but the limitation in working space makes this test difficult to be executed. Aside from 6MWT, distance based test such as four-meter walking test is more practical and therefore used. Hence, a research is needed in order to do a compatibility test between four-meter walking test and the 6MWT in healthy adult patients in Indonesia.

Material and Method

This descriptive study is done by examining 61 healthy and sedentary Indonesians age 18-50 years old. Subjects are then examined for a full general check-up. After fulfilling the inclusion criteria, subjects will then perform three tests, 6MWT and four-meter walking test in six and eight meter track. Results will then compared to assess the compatibility between each tests.

Results

Mean results for the 6MWT is 1.602 m/s for male and 1.462 m/s for female. Mean results for the four-meter walking test with six meter track is 2.114 m/s for male and 1.908 m/s for female. For the four-meter walking test with eight meter track is 2.108 m/s for male and 1.986 m/s for female. Compatibility test result using Bland Altman method between the 6MWT and four-meter walking test shows scatter dots with the limit of agreement closed together which shows a compatibility between the 6MWT and four-meter walking test with both track.

Conclusion

The four-meter walking test with both six meter and eight meter track can be use to assess functional capacity as well as 6MWT.

EVALUATION OF THE FUNCTIONALITY OF OBESE GRADE III USING THE BRAZILIAN FUNCTIONALITY ÍNDICE-IF-BR

P. Hipólito¹, E. Vega¹, D. Xerez¹, A.C. Franzoi¹, L. Hipólito², P. Rocha¹, L. Ribeiro¹
¹Universidade Federal do Rio de Janeiro, Serviço de Medicina Física e Reabilitação, Rio de Janeiro, Brazil
²Graduação, Campos dos Goytacazes, Brazil

Introduction/Background

The IF-Br is a tool designed to classify the human functionality, pointing out the possible external factors that may act as barriers to the performance of their daily activities and their social participation. IF-Br is a generic instrument and can be applied to all kind of disabilities. It is considered 41 activities and participations, extracted from The International Classification of Functioning (ICF), that describe the way which the individual carries out his daily activity (functionality) being divided into 7 domains: sensory; communication; mobility; personal care; domestic life; education; work; economic life: socialization and community life. The goal of this study was to evaluate the functionality of a group of Grade III obese person using The Brazilian Functionality Índice-IF-BR.

Material and Method

Twenty-three people accepted to participate in the interview to complete the IF-Br form. The inclusion criterion of was the diagnosis of Grade III obesity. The exclusion criterion was to oppose the application of the instrument. The questionnaires were applied in 3 distinct days, two of them at the Clementino Fraga Filho Universitary Hospital and one day at Self-esteem Rescue Group and Citizenship of the Obese (GRACO), a non-profit organization to support the obese. The data were analyzed through the SPSS program.

Results

The average functionality of the studied population was 86.59%. Comparing the domains, we observed that the most affected were mobility (average functionality value of 78.26%) and education (78.47%).

Conclusion

According to the data analyzed in this small sample we can conclude that people diagnosed with grade 3 obesity have a negative impact on their functionality. The domain of greatest loss of functionality was mobility.

A suitable screening to assess self-efficacy in clinical routine and studies? Psychometric properties of the short-form generalized self-efficacy scale (GSE-6) in rehabilitation

M. Brünger¹, K. Spyra¹

¹Charité - Universitätsmedizin Berlin, Institute of Medical Sociology and Rehabilitation Science, Berlin, Germany

Introduction/Background

Self-efficacy plays a key role in explaining and predicting health behavior (e.g. physical activity, nutrition, substance consumption) which are addressed in multimodal rehabilitation. The 10 item General Self-Efficacy Scale (GSE) is a widely used instrument to assess self-efficacy (Schwarzer, 1995). For economic reasons, it is not always possible to apply the GSE. Therefore, this work aims to determine psychometric properties of the recently introduced short form GSE-6 (Romppel, 2013) in rehabilitation patients.

Material and Method

GSE and other relevant impairments and resources were assessed by postal mail in a nationwide study in Germany in 2,530 patients aged 20 to 65 years prior to rehabilitation (Brünger, 2017). Psychometric properties were calculated by comparing the short and original version (GSE-6/GSE). The concurrent validity is reported with Spearman correlations to other impairments and resources. Confirmatory factor analyses (CFA) demonstrate the factorial validity.

Results

Distribution and mean sum scores of both scales were comparable. Soil and ceiling effects were low (Fig. 1). The mean discriminatory power \(r_{xx}=0.70/r_{xy}=0.74\) and internal consistency were similar (\(\alpha=0.89/\alpha=0.93\)). GSE-6/GSE were correlated with \(r_s=0.98\) (Fig. 2). The correlations of GSE-6/GSE to other impairments and resources were almost identical (Fig. 3). Stratified analyzes by gender and diagnosis groups provided analogous results. Multigroup CFA confirmed the one-dimensional structure of both scales independently of gender, age and diagnosis group.
Spearman's rho = 0.98
Conclusion

Psychometric properties of GSE-6 and GSE were comparably good. Thus, an application of the short version in rehabilitation across all major diagnosis groups seems possible without relevant losses compared to the original version. It allows for a significant reduction in time and may facilitate the assessment of self-efficacy for screening purposes in clinical routine and studies.

CHANGES IN THE HEALTH STATUS AND PATIENT REPORTED DISABILITY AFTER MULTIMODAL LOW BACK PAIN REHABILITATION
T. Kienbacher¹, K. Tuechler², A. Friedl³, P. Prof Mair³, G. Prof Ebenbichler⁴
¹Karl Landsteiner Institute of outpatient rehabilitation research, PMR, Vienna, Austria
²Karl Landsteiner Institute of outpatient rehabilitation research, Physical Medicine and Rehabilitation, Vienna, Austria
³Harvard University, Department of Psychology, Boston, USA
⁴Vienna Medical University, Department of Physical Medicine and Rehabilitation, Vienna, Austria

Introduction/Background

Multimodal rehabilitation concepts based on the biopsychosocial model significantly improve patient reported outcomes in chronic low back pain (cLBP) but so far there is no study investigating the health status before and after such intervention.

Material and Method

1463 patients (65% females) aged 18 to 90 years [mean 50.8 (SD 6.8) years] suffering from nonspecific chronic low back pain performed six months of therapy comprising muscle strength and proprioceptive training, psychological interventions, and education in a referral outpatient rehabilitation center twice weekly. They answered the Roland Morris Disability Questionnaire (RMDQ), the Pain Disability Index (PDI), and rated their pain on a visual analog scale (1-100) prior to (t1) and at the end of rehabilitation (t2). A preliminary study revealed that the most relevant activity and participation categories of the brief International Classification of Functioning, Disability and Health (ICF) core set for low back pain can be predicted from the RMDQ and the PDI with good performance.

Results

314 patients (21.5%) dropped out from rehabilitation. RMDQ improved from 9.27 to 5.85, the PDI from 20.3 to 17.0, and the pain score from 49.7 to 25.2. D530 `toileting` was reported with low frequencies and was thus excluded from recording. The percentage of patients reporting impairment in the various activity and participation categories differed when 85% of the patients had difficulty with d415 `maintaining a body position` and 34% with walking `d450`. All categories improved from t1 to t2.

Conclusion

Multimodal rehabilitation improves patient reported disability measurement scores beyond minimal clinically important differences. Assessment of the activity and participation ICF
categories helps to track the aspects of the individual functional status enabling specific goal setting and treatment guidance and it shades light to the effects of the rehab community’s therapeutic doing to the overall health state of cLBP patients.

Introduction/Background

The ACTIVLIM questionnaire was developed to measure global activity performance of neuromuscular patients (NMPs). It also has the potential to assess real life improvement resulting from new coming therapies. For this purpose, long term follow-up data are mandatory. Such data are currently absent from the literature. The aim of the present study is to compare ACTIVLIM measures of NMPs from the Belgian Neuromuscular Disease Registry (BNMDR) between years 2011 and 2015.

Material and Method

Data from 1064 NMPs who completed the ACTIVLIM questionnaire in 2011 and 2015 were extracted from the BNMDR. RUMM 2030™ was used to obtain their global activity performance level on a unidimensional and linear measurement scale. The Wilcoxon signed rank tests and paired t-tests were used to compare ACTIVLIM measures obtained in 2011 and 2015 for the whole sample and for the 9 most prevalent diseases in BNMDR.

Results
In the whole sample, 64% of NMPs showed a deterioration of their activity (p≤0.012; effect size (ES) =-0.32). The magnitude of deterioration was the most important for Duchenne muscular dystrophy (74% of them deteriorated; p<0.001; ES=-0.46), limb-girdle muscular dystrophy (74% deteriorated; p<0.001; ES=-0.44), hereditary spastic paraplegia (66% deteriorated; p<0.001, ES=-0.41), and amyotrophic lateral sclerosis (69% deteriorated; p<0.001; ES=-0.40). Deterioration was significant but less important for myotonic dystrophy type 1 (63% deteriorated; p<0.001; ES=-0.32), spinocerebellar ataxias (67% deteriorated; p<0.001; ES=-0.31), facioscapulohumeral dystrophy (59% deteriorated; p=0.016; ES=-0.23), and hereditary motor and sensory neuropathy (60% deteriorated; p<0.001; ES=-0.22). For patients with chronic inflammatory demyelinating polyneuropathy (CIDP), no deterioration was observed (p=0.939; ES=-0.01).

**Conclusion**

This is the first study focusing on activity level of NMPs using ACTIVLIM across a 5-year period. As expected, most patients showed deterioration in their activity. Among the most prevalent neuromuscular diseases, CIDP patients showed a different evolution of their global activity performance.

E3 Measurement of Functioning (e.g. Psychometrics of Assessment Tools; Operationalisation of ICF Categories)

ISPR8-1144
TOWARDS AN ICF-BASED ASSESSMENT OF PHYSICAL AND MENTAL FUNCTIONS IN PATIENTS WITH INTELLECTUAL DISABILITY
A. Palomba¹, A. de Sire¹, T. Caporaso², D. Perez³, R. Gimigliano¹, G. Iolascon¹, F. Gimigliano⁴
¹University of Campania "Luigi Vanvitelli", Department of Medical and Surgical Specialties and Dentistry, Naples, Italy
²University of Naples Federico II, Department of Industrial Engineering – Fraunhofer JL IDEAS, Naples, Italy
³Don Orione Rehabilitation Center, Sport Science, Ercolano, Italy
⁴University of Campania "Luigi Vanvitelli", Department of Mental and Physical Health and Preventive Medicine, Naples, Italy

Introduction/Background

The DSM V emphasizes the need of using standard clinical methodologies to classify the functioning of patients with intellectual disability (ID) rather than just their Intelligence Quotient (IQ). It was underlined the influences of step length over height ratio (ρ) and smoothness (μ) on motor performance in patients with ID during running. The International Classification of Functioning, Disability and Health (ICF) provides an international language for describing human functioning. Our aim was to characterize in term of ICF the kinematics and intellectual indices of patients with ID.

Material and Method

We included young adults with ID (with at least IQ≥20) referring to a residential or semi-residential care facility. We collected data on the IQ from the psychiatric evaluation. Moreover, we asked all patients to perform 30m linear sprint test and 30m two change-of-direction sprint test, wearing an inertial sensor placed on L5/S1 vertebrae, in order to assess on agility (α), and running kinematics (β). In order to obtain data on these two parameters (derived from specific formulae), we compared the results of subjects with ID to control subjects, matched per age, gender, and physical activity. We evaluated these three outcomes (IQ, α, and β) in all participants, according to the qualifiers of three specific ICF codes: b117: intellectual functions, d4503: walking around obstacles, d4552: running.

Results

Eight patients with ID, mean aged 39.75 years, 7 males and 1 female, were evaluated in terms of ICF (see Table 1).
## Conclusion

The ICF in concert with the use of wearable tools might better evaluate and quantify physical and mental functions patients with ID, even because the only IQ does not give a complete description of ID functioning.

FUNCTIONAL EVALUATION OF APHASIC PATIENTS USING THE BRAZILIAN FUNCTIONALITY INDEX - IF-BR, IN SMFR- UFRJ
L. Ribeiro¹, D. Xerez¹, P. Hipólito¹, E. Vega¹, A.C. Franzoi¹, P. Rocha¹
¹Universidade Federal do Rio de Janeiro, Serviço de Medicina Física e Reabilitação, Rio de Janeiro, Brazil

Introduction/Background

The IF-Br is a tool created to describe the functionality of a person, pointing out the possible external factors that can act as barriers to the performance of their daily activities and their social participation. IF-Br is a generic instrument and can be applied to all types of deficiencies. The instrument is composed by 41 activities and participations, extracted from the ICF, that describe the way in which the individual carries out his daily activities and his social activity (functionality), being divided into 7 domains: Sensorial, Communication, Mobility, Personal Care, Domestic Life, Education / Labor / Economic Life, Socialization and Community Life. Aphasia is a language disorder that happens when you have brain damage, affecting the production or comprehension of speech and the ability to read or write. The goal of this study is describe the functional index impact in the aphasic patients group in a university hospital rehabilitation service and to characterize their performance in daily activities and their social participation.

Material and Method

Application IF Br between 7 aphasic patients from the neurological rehabilitation area. The inclusion criterion: patients with significant language change and comprehension.

Results

The average functionality in all domains was 68%. The most affected domains were communication with value 60% and mobility 70%, followed by socialization 68%.

Conclusion

Aphasic patients, from this sample, in addition to presenting deficits in the communication domain, have their functionality compromised in the domains of mobility and socialization.

Keywords

Aphasic; Functionality; Communication

Introduction/Background

The Duke Activity Status Index (DASI) is a self-administered questionnaire that measures functional capacity in an economical and simple way; allows follow-up and is useful in clinical practice. 
Objectives: to make validation for Colombia of the questionnaire Duke status index in patients with heart failure.

Material and Method

The translation and cultural adaptation of the Duke Activity Index (DASI) into Spanish was done. A total of 135 patients were included, with which the content validation was done with a confirmatory factor analysis. The validity of the convergent and divergent construct and the criterion validity were assessed by comparing groups of the New York Heart Association (NYHA) and correlations with the quality of life questionnaire "Minnesota Living with Heart Failure Questionnaire", the generic scale of quality of life SF-36, and a disability assessment questionnaire from the World Health Organization (WHO-DAS II). Internal consistency and interobserver and intraobserver reliability were evaluated. Sensitivity to change was assessed at 1.3 and 6 months.

Results

In the content validity the scale was adjusted to two domains, in the convergent and divergent validity it was verified with significant correlations of the DASI with the scales which it was compared. The criterion validity of the DASI with the NYHA classification showed adequate relation, although it is not statistically significant. In internal consistency the Cronbach’s alpha
coefficient was 0.69, the intraclass correlation coefficients for inter-evaluator and intra-evaluator reliability were 0.81 and 0.90, respectively.

**Conclusion**

This Spanish version of the Duke Activity Index (DASI) is valid and reliable for patients with heart failure in Colombia. There is a good correlation between DASI and WHODAS II.

E3 Measurement of Functioning (e.g. Psychometrics of Assessment Tools; Operationalisation of ICF Categories)

ISPR8-1524
DEVELOPING A COMMON METRIC OF GENERIC AND CONDITION-SPECIFIC DISABILITY SCALES IN PEOPLE WITH RHEUMATOID ARTHRITIS AND STROKE
A.A. Küçükdeveci¹, B. Prodinger², C.S. Fellinghauer², Ş. Kutlay¹, A.H. Elhan⁴, A. Tennant³
¹Ankara University- Faculty of Medicine, Department of Physical Medicine and Rehabilitation, Ankara, Turkey
²University of Applied Sciences Rosenheim, Faculty of Applied Health and Social Sciences, Rosenheim, Germany
³Swiss Paraplegic Research, ICF Unit, Nottwil, Switzerland
⁴Ankara University- Faculty of Medicine, Department of Biostatistics, Ankara, Turkey

Introduction/Background

Aim is to develop a common reference metric of functioning incorporating generic and health condition-specific disability instruments and to test whether this common metric is invariant across two health conditions belonging to a musculoskeletal (rheumatoid arthritis=RA) and a neurological (stroke) disorder.

Material and Method

A psychometric study using secondary data analysis of 487 people; 61.4% with RA and 38.6% with stroke was performed. In RA sample 25.4% were male, and in stroke sample 53.7%. Generic instrument, included in the analysis was World Health Organization Disability Assessment Schedule (WHODAS 2.0) whereas condition-specific instruments were Health Assessment Questionnaire (HAQ) in RA, and Functional Independence Measure (FIM⁷) motor scale in stroke. The International Classification of Functioning, Disability and Health (ICF) Linking Rules were used to examine the concept equivalence between the included instruments, and a scale-banking approach based on the Rasch measurement model was applied to examine score equivalence between these instruments. Only scales (or domains) that resulted in content and score equivalence were included in the reference metric.

Results

Three sub-domains of WHODAS 2.0 and all items of HAQ and FIM⁷ motor scale were linked to the ICF chapters d4-Mobility, d5-Self-care and d6-Domestic life. The scale banking of these items resulted in good model fit ($\chi^2 (df=21)=22.755; p=0.357$) with good reliability (PSI=0.891), indicating that a reference metric across these three instruments was available. Operational range of each scale in reference to the common metric is shown in Figure which supports that
co-calibration of 3 scales resulted in an improved coverage of the measurement continuum.

**Conclusion**

This study provides evidence for, and the transformation table to enable direct comparisons among instruments measuring physical functioning commonly used in RA (HAQ) and stroke (FIM™ motor), as well as in people with disability in general (WHODAS 2.0).

Introduction/Background

The International Classification of Functioning, Disability and Health (ICF) proposes an organization that is based on coded and qualified information distinguishing functioning and disability codes. The aim of this study was to develop a tool able to use information converted into qualified codes proposed by the ICF to establish a measure of the health-related states for individuals and populations, and that represents reliable and valid indices for investment in health information systems.

Material and Method

We outlined a cross-sectional study with descriptive and exploratory aims for technological development, including quantitative and qualitative approaches to collective speech content analysis, and modelling of data of in a single case report. We perform three stages: (1) modelling of data coming from the information reported in the case to identify codes and qualify them; (2) survey of the requirements and face validation through focus group, which was heard the demands of future users of the software, beyond to establish a list of useful requirements for
Results

The sequence of events followed the simulation model, producing theoretical results, conceptual, graphics and numeric components. The simulation revealed that the measure may be better represented by a three-dimensional model which considers the events over time, the ratio between functioning and disability codes and discrete events representing health condition hallmarks.
Conclusion

The model was validated by the focus group (face validation), resulting in a list of requirements that contributed to development of the preliminary version of the desired product: the DataCIF.

CORRELATION BETWEEN FUNCTIONAL MOVEMENT OF LOWER EXTREMITY AND ANKLE MOVEMENT AND WALKING
C. Ji¹, S. Kim¹, J. Baik¹
¹Korea University, Sport Science, Sejong, Republic of Korea

Introduction/Background

The purpose of this study is to investigate the factors related to ankle movements when functional unstable movements of the lower limb are repeated. In addition, we want to find out the difference in the muscle activity when the motor control changes during the gait.

Material and Method

In this study, Y-Balance Test (YBT) was performed. Anterior categorization of functional disturbances in 25 patients with a difference of more than 4 cm between the left and right of the Anterior reach distance (ARD) or a composite reach distance (CRD) of 89% or less. For the ankle movement, the items of Isometric Contraction (IC), Weight-bearing ankle lunge test (WBLT) and One leg stand (OLS) were measured. The Electromyography (EMG) test was performed by walking on the treadmill for 10 seconds and then using the mean value of the EMG data obtained from three consecutive strides in the middle.

Results

First, Correlation between lower extremity functional instability and ankle functional movement element. The correlation coefficient of ARD with IC was .477, and the correlation coefficient of ARD with WBLT in the ankle was .754, which showed a statistically significant correlation(p<.05), (p<.001).

Second, we investigated the muscle activity of the lower limb during functional walking instability group (Anterior reach distance (ARD), Composite reach distance unilateral (CRDU), and Composite reach distance bilateral (CRDB)). Statistical significance was found only in Right Medial Gastrocnemius (RMG) (Mann-Whitney U = 24, p <.05) in the ARD group (difference of more than 4 cm, difference less than 4 cm).

Conclusion

It is important that the rehabilitation program for functional movement improvement focus on improvement of control mobility through IC and WBLT in the Inner and Outer range. In particular, ARD and CRDU are essential to reduce instability of lower extremity muscles through motor relearning of three muscles (Left lateral gastrocnemius, Left Medial Gastrocnemius, Right Medial Gastrocnemius).

E3 Measurement of Functioning (e.g. Psychometrics of Assessment Tools; Operationalisation of ICF Categories)

ISPR8-1685
DEGREE OF DISABILITY ANALYSIS IN 21 HEMIPLEGICS AFTER STROKE BY IF-BR (BRAZILIAN Funcionaliry INDEX), AT SMFR-UFRJ
P. Rocha¹, D. Xerez¹, A.C. Franzoi¹, P. Hipólito¹, L. Ribeiro¹, E. Vega¹
¹Universidade Federal do Rio de Janeiro, Serviço de Medicina Física e Reabilitação, Rio de Janeiro, Brazil

Introduction/Background

The IF-BR is a tool created to classify the degree of disability in brazilian citizens. Being generic, it evaluates external factors that act as barriers and analyses the patient's performance in daily tasks. It contains 41 activities taken from The International Classification of Functioning (ICF), divided in 7 major domains: Sensorial, Communication, Mobility, Self-care, Domestic Life, Education/ Work/ Economic Life, Socialization and Community Life. Stroke is the neurological syndrome most prevalent in adults and elders and the main cause of death in the world, according to WHO. It is also the leading cause of disability in Brazil, with an annual incidence of 108/100 thousand inhabitants. The objective of the present study is to compare the disability degree measured by IF-BR to other validated instruments of analysis.

Material and Method

Instruments used: Motor Domain from the Functional Independence Measure (FIM) and Rivermead Assessment; Population: 21 stroke patients with hemiplegia; Inclusion Criteria: stroke > 6 months; Statistical package used: SPSS 2.0 version. All patients signed the informed consent term.

Results

There was significant correlation between FIM and mobility and Self-care domains from IF-BR, (p0,01), Domestic Life and communication (p0,05); and between Rivermead and Mobility, Socialization, Self-care and Domestic Life (p0,01) and Communication (p0,05) domains.

Conclusion

There was significant correlation between FIM's and Rivermead motor domains and some IF-BR domains, particularly associated to motor activity.

Introduction/Background

The National Institute of Rehabilitation in Mexico has an electronic clinical record system in which health conditions are classified with ICD-10, in 2013 the functioning / disability registry is started according to Mexican regulations, where it is indicated that for the generation of statistics on the level of health and disability must meet the guidelines established by the WHO in the ICF in the overall functioning of people. The objective of this work is to make known the implementation of the registry of the diagnosis of functioning / disability (DFD) in an electronic clinical record (ECR).

Material and Method

The DFD is recorded in the following notes of the ECR: initial note of external consultation, note of admission and hospital discharge. Characteristics of DFD: 1) Diagnosis of the four components. 2) Possibility of a wide range of number of codes for each component. 3) Inclusion of the ICF catalog up to a second level. 4) Text writing is predictive. 5) Use of the raters from 0 to 4. 6) Mandatory use, without filling this section cannot record the medical note.

Results

Different analyzes have been carried out with different objectives: the functioning of the people served according to their health condition, their functioning during the time of their treatment, quality in the registry of functioning by the health person, among others.

Conclusion

The main conclusions are: a) Continuation in the training of the ICF among the health personnel, since it is observed that some registered codes are not "congruent" with the health condition, as well as codes with terminations 8 and 9 ("other specified" and "unspecified") that indicate the quality of health information. b) Development of the methodology to assess and
qualify disability, since the registration does not conclude the degree of disability of the person served.

Introduction/Background

Proper walking and running forms are important to improve speed and efficiency while reducing the risk of injury. Good walking and running conditions are characterized by a series of biomechanical and neurophysiological variables (posture, coordination, flexibility, respiratory rhythm). That said, everyone has a different perceptivo-motor style and therefore the question is to what extent these differences are idiosyncratic and/or detrimental and at what point they should be readjusted.

Material and Method

In order to investigate these questions, we quantified the body movements of 18 subjects during walking at three different velocities (comfortable walking, imposed walking velocity of 4 km/h and maximum speed) and running (maximum speed) on a treadmill. The Cartesian Optoelectronic Dynamic Anthropometer (CODA) motion analysis system was used to capture the vertical, horizontal and rotational movements by tracking 24 markers' position in real-time at rest and during these three conditions. The markers were positioned on the head, shoulders, sternon, lower back, tibias, ankles and feet.

Results

We calculated the skeletal configurations of the subjects at rest and when the body mass reached its highest point, which coincided with the period of unipodal support. These configuration were not correlated with velocity, sex, age, height or weight while some correlation was observed with the expertise of running in the population. We also studied on the dynamics of each marker and their intra and inter-individual variability during walking and running.

Conclusion

Our data showed that the skeletal configuration was distinct at rest, during walking and running but differed amongst subject. Our result showed that the dynamics were very variable both at the intra and inter-individual level in the frontal, sagittal and horizontal plane and tend to
decrease from the lower extremities to the head. These differences could be used to characterize the perceptive-motor style of each investigated subject.

E3 Measurement of Functioning (e.g. Psychometrics of Assessment Tools; Operationalisation of ICF Categories)

ISPR8-2352
IMPLEMENTATION OF CLINICAL QUALITY MANAGEMENT INCLUDING STANDARDIZED REPORTING AND INDIVIDUALIZED MANAGEMENT DURING FIRST REHABILITATION OF PATIENTS WITH SPINAL CORD
A. Scheel-Sailer1, I. Bersch1, J. Pannek1, K. Schmitt1, J. Schneider1, D. Sigrist-Nix1, M. Baumberger1
1Swiss Paraplegic Centre, Acute Care and Rehabilitation, Nottwil, Switzerland

Introduction/Background

Clinical quality management (QM) during acute and post-acute rehabilitation after newly acquired spinal cord injury (SCI) remains challenging due to complex impaired functioning including bio-psycho-social aspects. International societies developed recommendation for standardized reporting with respect to the international classification of functioning (ICF). However, there is still a lack of implementation of these recommendations. Therefore, this study aims to analyze reasons and create strategies to implement these guidelines in daily practice.

Material and Method

Situation analyses, consensus process and requirement analyses of clinical QM in a specialized SCI rehabilitation centre.

Results

SCI specific and validated assessments were applied consequentially after newly acquired SCI when a controlling system existed (e.g., Spinal Cord Injury independence Measure III: SCIM III) and partly with recommendation (e.g., International Standards for the Neurological Classification of Spinal Cord Injury (ISNCSCI)). The individual management appeared complex and could not be easily reported in a standardized and comparable way. The leadership decided to use a consensus process to develop an assessment standard according to national and international requirements (Common Data Elements, EMSCI, SwiSCI, ICF Core Sets, association of national quality (ANQ)). For data and process based management the information technology (IT) had to fulfil different requirements (reminder system, clear visibility, connectivity of information). Education tools in specific health professional groups concerning the goal-orientated use of assessments were needed to increase knowledge and to use the assessments. Improvement in patient-centred communication and interdisciplinary team culture optimized the individualized rehabilitation management.

Conclusion

Implementation of QM during acute and post-acute care after SCI succeeds when respecting national and international standards, when clinical IT systems are integrated in the decision
making, when health professionals are aware of patient-centred communication and continuous education covering these aspects takes place. Change management may happen when representatives of all intended groups are engaged and adequate resources available.

VARIATION OF THE PHYSICAL CONDITION IN SOLDIERS DURING A 4-MONTH OPERATION IN MALI

L. Have, L.M. Pessey, A. Schmitt, Y. Plouzennec, A. Malgoyre

HIA Desgenettes, service de MPR, Lyon CEDEX 03, France
French Military Health Service, French Military Health Service, Valence, France
French Military Health Service, French Military Health Service, Avord, France
institut de recherche biomédicale des armées, département des environnements opérationnels, Brétigny sur Orge, France

Introduction/Background

The aim was to assess the variation of the physical condition in French soldiers during a 4-month operation in Mali.

Material and Method

48 soldiers from two operational units were subjected to a series of physical tests before leaving for Mali, then just before their return to France 4 months later. The different studied parameters included: weight, fat mass, extensibility of spine and lower limbs, duration of Shirado’s test and chair position with a ballast of 20 kg, number of push-ups and squats in 2 minutes, prehension strength. In addition, subjects were asked to fill out 5 questionnaires: overtraining screening questionnaire of the French Sports Medicine Society, Hospital Anxiety and Depression Scale (HAD), Pittsburgh Sleep Quality Index (PSQI), numeric scale for motivation and state of form.

Results

Number of squats in 2 minutes, PSQI and prevalence of sleep troubles were observed increasing in a significative way, while duration in chair position and Shirado’s test, prehension strength, weight, fat mass, motivation and self perception of state of form were observed decreasing in a significative way. No modification were observed in number of push-ups, extensibility, HAD and overtraining screening.

Conclusion

Hardiness of life condition during operations, quality of food and hydration, climate, modifications in sport training, physical constraints, family remoteness, psychological stress related to combat and insecurity constitute some of hypothetical parameters likely to influence the variation of the physical condition in soldiers during an operation. This study appears like the first having succeeded in carrying out tests on a operation field. This involved choosing tests which could be performed in insecurity and heat conditions. For example, endurance in running were consequently excluded. These first results offer a reflection tool to adapt the physical
training of soldiers and to determine point of vigilance, in order to maintain the physical and psychological capabilities of soldiers.

E3 Measurement of Functioning (e.g. Psychometrics of Assessment Tools; Operationalisation of ICF Categories)

ISPR8-2402
RESEARCH ON EARLY INTERVENTION FOR 3-6 YEARS OLD CHILDREN WITH DISABILITIES BY FUNCTIONAL ASSESSMENT SCALES UNDER ICF THEORY AND PRACTICE
K. He¹, J. Wang¹, Y. Xu¹, L. Zhang¹, J. He¹
¹Nanjing Normal University of Special Education, School of Rehabilitation Sciences, Nanjing, China

Introduction/Background

Abstract: (Objective) To assessment handicapped children’s physical and mental function in the early rehabilitation as well as the effect of rehabilitation.

Material and Method

(Method) The assessment tools and ICF were matched through content analysis, questionnaire investigation, group interview, action research basing on the ICF and ICF-CY classification systems. Then Functional assessment scales were developed. 251 three-six years old children with disabilities were investigated by functional assessment scales and the applicability of the scale were examined for three-six years old children with disabilities

Results

(Results) Basing on the clinical research, this paper constructs the functional assessment scales for 0-6 year old children with disabilities which can apply to the early rehabilitation. Full scale contains seven subscales: sensory perception, motor abilities, communication, cognition, emotion and social adaptation. Every subscale includes several items. The assessor can set down the goals for children with disabilities according to their physical and mental functions. Meanwhile, the effect of rehabilitation can be text regular by using this assessment scale with three graded score from unable to completely will. The full scale can assess the every domain’s function of child with disabilities.

Conclusion

(Conclusion) The scale can not only evaluate 3-6 years old disable children’s physical and mental function and the effects of rehabilitation but also apply to develop individualized rehabilitation programs and early intervention program.

A STUDY ON THE BALANCE ABILITY OF THE ARCHERS

G.E. Park¹, T.K. Han¹
¹Andong National University, Department of Physical Education, Gyeongsangbuk-do- Andong, Republic of Korea

Introduction/Background

Stability must be the basis for good performance. The purpose of this study is to provide an athletic program by measuring and evaluating the balance of archers’ athletes from 24(yrs:22.38±4.28) eligible to compete in the Olympics.

Material and Method

Participants grouped 12 qualified athletes for the second national selective match in 2018 and general in 12 athletes, used the MFT3 check(Booyteamwork, German) to analysis balance.

Results

The results of this study second national selective match athletes better then general athletes on left-right stability(p<.05). And then, there was no statistically significant difference between left-right sensorimotor system, front-back sensorimotor system and stability.

Conclusion

In conclusion, this study shows that the participants in the second round of the national team competition have shown better results stability, and that they continue to supply a relationship between athletic performance, core-stability and strength program.

E3 Measurement of Functioning (e.g. Psychometrics of Assessment Tools; Operationalisation of ICF Categories)

ISPR8-2505
A STUDY ON CHILDREN’S DEVELOPMENT OF AUDITORY CONCEPTS
C.K. Lin¹, C.H. Li², H.M. n Wu³, B.C. Kuo²
¹National Taichung University of Education, Department of Early Childhood Education, Taichung, Taiwan R.O.C.
²National Taichung University of Education, Graduate Institute of Educational Information and Measurement, Taichung, Taiwan R.O.C.
³National Academy for Education Research, Research Center for Testing and Assessment, Taipei, Taiwan R.O.C.

Introduction/Background

The concept of auditory sound is the function of the temporal cortex of human brain. The main function is to identify what the voice is and discriminate the volume, distance, length, and sequence of voice. The auditory concept is the basis of auditory comprehension and social communication. Many children with developmental delay have difficulty on perceiving the sound. In the past studies, many studies focused on the language comprehension or expression, however, in the research of Auditory Concepts is very lacking, so this study is mainly to explore the development of Auditory Concepts, with the important factors of Auditory Concepts.

Material and Method

The participants were 4 to 6 years old in kindergarten, and the non-random sampling method was used to select 8 schools. A tool of “the computerized assessment for Auditory Concepts” was used as a research tool for this study. There were 6 subtests including the concept of Activity of Daily Living (6 items), Mechanical Sound (12), Human Sound (12), Transportation Sound (7), Animal Sound (11), and Auditory Perception (27). A total of 615 valid samples were collected, aged between 4 and 6 years (M = 49.45 months, SD = 9.6). The descriptive, t test, one way ANOVA were used to analyze the research data.

Results

Results showed that there was no difference of children’s gender on the 6 subtests for Auditory Concepts. For the effect of age, the performance of the 6-year-old children is significant greater than 5-year-old children, the performance of the 5-year-old children is significant greater than 4-year-old children for 6 subtests and the total of the Auditory Concepts. The average total score of auditory concept for the children with 4, 5, and 6 years old was 42.86 (SD=12.81), 52.36(SD=12.64), 57.51 (SD=9.77) respectively.
Conclusion

The conclusion is that children's Auditory Concepts has a developmental effect.

THE IMPACT OF ENVIRONMENTAL FACTORS ON ACTIVITY AND PARTICIPATIONS OF PERSONS WITH SPINAL CORD INJURY IN KOREA

B. Lee

1National Rehabilitation Center, Public Health and Rehabilitation, Kangbukgu, Republic of Korea

Introduction/Background

There is lack of data on the lived experiences of persons with spinal cord injury (SCI) which may lead to lack of proper health policy and service provision for optimal functioning in their everyday lives. To resolve this issue, International spinal cord injury (InSCI) survey was launched in 28 countries in 2017. In this study, we aim to describe the impact of environmental factors on the activity and participation in persons with SCI based on the InSCI survey conducted in Korea.

Material and Method

Korean version of InSCI survey questionnaire was used for data collection which consists of 125 items that cover relevant information on all aspects of lived experience according to the ICF categories. Community dwelling adults who have sustained traumatic or non-traumatic SCI were recruited using the databases of National Rehabilitation Center and Korean Spinal cord injury Association. For the data analysis, items on ‘environmental factors’ were grouped into three categories of ‘accessibility’, ‘service provision’, and ‘attitudes of others’ by using factor and reliability analysis. Items on activity and participation were grouped into four categories – ‘coping issues’, ‘health management’, ‘physical activity’, and ‘transportation’ by using the same analysis. Multivariate regression was used for the analysis of the impact of the environmental factors on the four categories of activity and participation.

Results

A total of 892 out of 6047 eligible people participated in the survey through online and paper-pencil version questionnaires. Multivariate regression analysis showed that environmental categories (p<0.05) except ‘attitudes of others’ (p=0.755) had statistically significant impact on activity and participation of persons with SCI.

Conclusion

As the first community survey for persons with SCI in Korea, InSCI study may reveal many aspects of the lives of persons with SCI. It has shown that indeed accessibility and proper service provision is important in activity and participation of persons with SCI in Korea.

²Instituto de Medicina Fisica e Reabilitacao- Hospital das Clinicas HCFMUSP- Facu, Disciplina de Fisiatria. Faculdade de Medicina FMUSP- Universidade de Sao Paulo, Sao Paulo, Brazil

Introduction/Background

The loss of a limb causes decrease of function and independence. Rehabilitation is necessary to reintegrate patients into their communities. The aim of this study was to describe the demographic profile of patients from the amputee in-patient rehabilitation program at the Instituto de Medicina Fisica e Reabilitacao (IMREA) HCFMUSP. The results of the study will be used to improve the program.

Material and Method

This study included patients from the amputee in-patient rehabilitation program during the period of November 2014 to December 2017. A descriptive analysis was done on the profile of the patients. Data was obtained from a review of medical records.

Results

A total of 116 patients were analyzed. The average age was 43 years and the initial Functional Independence Measure (FIM) of 112.6. Forty percent of the population was from the capital of São Paulo, 40% from the other cities of the state of São Paulo and 20% from the metropolitan area of São Paulo and other states. Regarding gender: 80% were male and 20% were female.

Considering only the traumatic amputations, a total of 68 patients (59% of the study population), the gender proportion changed to 90% male and 10% female. Sixty two percent of the traumatic amputations were caused by motorcycle accidents. Amputations related to vascular diseases, infections and tumors were 26 (22%), 16 (14%) and 6 (5%), respectively.

³Health rehabilitation research group, Physical medicine and rehabilitation, Medellín, Colombia
⁴University of Antioquia-Health rehabilitation research group, Physical medicine and rehabilitation, Medellín, Colombia
⁵University of Antioquia, Clinical epidemiology, Medellín, Colombia

Introduction/Background

Each day 3,400 people die in the world in a Traffic Accident (TA) and tens of thousands suffer injuries or acquire a disability every year(1). Ninety percent of the deaths associated with TA occur in developing countries, even though they only have 54% of the vehicles in the world(2). In Colombia, in 2016, 45,256 non-fatal injuries and 7,280 fatal injured were recorded by a TA. With a rate of 92.84 injured and 14.93 deaths per 100,000 inhabitants(3). Children, pedestrians, cyclists and older adults are the most vulnerable public roads users and represent almost half of the deaths on the roads of the world(1). The aim of the study was to describe the conditions of the persons with moderate or serious injuries happened in traffic accidents in Medellin, Colombia and his metropolitan area in 2015-2016.

Material and Method

Descriptive study according to the severity of the injury, the sociodemographic characteristics, the characteristics of the TA, pain, disability (WHO-DASII) and quality of life (SF-36) of the people injured, in the first month after accident.

Results

247 patients were included, 93.1% with moderate injuries. 94.1% of the serious injuries happened when a pedestrian was knocked down. 73.6% of the injuries happened for trampling, 71.2% were pedestrians and in the 60.7% of the cases a motorcycle was involved. The most affected corporal regions were the extremities, the most affected domains of the WHO-DASII were the domestic activities, the activities out of the house and the mobility. The physical function, physical performance and change in health were the most affected domains of the SF-36.

NISS: New Injury Severity Score

Conclusion

The majority of patients suffered moderate and severe injuries when being run over as pedestrians, in most cases by a motorcyclist. There is a significant decrease of in the quality of life and functioning.

Introduction/Background

We know depression comes out after any neurological conditions even as a normal way in all human being at any age and further may give hurdle for the life span of the people; but there is a dearth of literature which identifies the factors most strongly associated with depression in neurological conditions. Here we try to identify the correlation between depression and various associated factors such as cognitive, functional, social status and quality of life in neurologically disabled and to find out the factor which affects depression most.

Material and Method

We included 42 participants diagnosed with stroke, head injury, spinal cord injury and Parkinson’s disease of least had 6 month of duration, aged between 20-79 year of both genders and used to assess depression, cognitive function, activities of daily living, social support and quality of life were Beck Depression Inventory(BDI), MMSE, BARTHEL INDEX(BI), Multidimensional Scale of Perceived Social Support (MSPSS), WHOQOL-BREF respectively; then divided the participants accordingly to the individual condition in four groups. We did an overall correlation between the above variables for all subjects and then according to individual neurological condition.

Results

Data was analyzed using SPSS 17.0 version shows that are clinically depressed with very less cognitive impairments, mild functionally disabled with poor social support and have poor quality of life. Our study showed significant (p <0.05) correlation between depression and other factors with all neurological conditions except head injury. The correlation between BDI with BI, MSPSS and WHOQOL-BREF showed significant results except MMSE.

Conclusion
From the results it can be concluded that the majority of the patients have depression related to reduced QOL, poor social support and functional status in the same order. So intervention should emphasize the importance of the patient's QOL and social support also. The future researches are required to done with large sample size and homogeneous subjects to validate current hypothesis.

LOWER EXTREMITY BIOMECHANIC ASYMMETRY IN FEMALE ATHLETES PERFORMING DROP-LANDING TASKS

D. Xie1, X. Shi1, X. Ma1, H. Wang1, J. Zhang1, X. Li1, H. Liu1, Y. Zhang1, S. Chen1, P. Mao1, X. Liu1, Y. Liu1
1Taishan Medical University, Institute of Sports Medicine, Taian, China

Introduction/Background

Anterior cruciate ligament (ACL) injury occurs frequently in sports such as skiing and basketball. To analyze the differences in causes of ACL injuries between both legs is essential to elucidate mechanism. The purpose of this study is to compare the differences in knee joint biomechanics during drop landing maneuver between left and right legs.

Material and Method

Sixteen healthy female college recreational athletes (age 21.1±1.6 years; height 163.8±3.8 cm; mass 54.8±5.6kg) were asked to perform drop landing; the knee flexion and valgus angles as well as the electromyographic activity of the vastus lateral, vastus medial, biceps femoris, and semimembranosus muscles of left and right legs were analyzed during the maneuver. The results were averaged for three successful maneuvers. Paired t tests were conducted to assess differences in the kinematics, kinetics, and EMG data between left and right exercise.

Results

There were significantly reduced in maximum knee valgus angle, maximum knee valgus torque and vastus medial muscle activity during drop landing of the left leg compared with right (P < 0.05). However, the muscle activity of the long head of biceps femoris in the left leg is greater during drop landing compared with right (P < 0.05). There are no difference on knee flexion angle at initial contact, knee extension torque at initial contact, vastus lateral and semimembranosus muscle activity.

Conclusion

ACL injury may be occur more frequently on right leg compared to left leg.

2Universidad de Antioquia- Grupo de Epidemiología Clínica, Physical Medicine and Rehabilitation, Medellín, Colombia
3Universidad de Antioquia, Physical Medicine and Rehabilitation, Medellín, Colombia
4Universidad de Antioquia. Grupo de Rehabilitación en Salud, Physical Medicine and Rehabilitation, Medellín, Colombia

Introduction/Background

In Colombia, the mortality rate per 100,000 inhabitants due to road accidents was 19.98 between 18 and 39 years and 33.11 over 65 and non-fatal injuries was 142.08 (18-39 y) and 80 over 65. In the world 23% of injuries involve a motorcycle and in Colombia more than 50% of deaths and injuries are related to motorcycles. Rates in Colombia increased between 2010 and 2016. The aim was to compare the epidemiological and clinical characteristics, the quality of life and functioning outcomes in Medellín from patients under and over 60 years.

Material and Method

Prospective, descriptive, cross-sectional study from 1081 patients form two cohorts, 834 under and 247 over 60 years old, in which they were described the sociodemographic characteristics, TA characteristics Including severity with the New Injury Severity Score (NISS), pain, disability (WHO-DASII) and quality of life (SF-36).

Results

Comparison cohort of 18 to 60 years Vs over 60 years. Men were 75.8% vs. 51%, studied more than 6 years 86.1% Vs 55.8%, collision as cause 54.9% Vs 9.3%, runover as cause 25.1% Vs 73.6%, motorcycle driver 58.4% Vs 8.0%, pedestrian 17.5% Vs 71.2%. In both cohorts the most affected domains of quality of life were physical performance and function, in the group of young people the emotional performance was more affected. In both cohorts, the most affected domains in functioning were activities outside the home, housework, and moving in one’s environment. See table1. and fig 1.2.
Conclusion

In Medellin most of the young adults have traffic accidents when they drive a motorcycle and collide with a vehicle, on the contrary, older adults suffer accidents when they are runover by motorcycles as pedestrians. All suffer important consequences in their quality of life and functioning. Colombia is losing the battle against road insecurity. It is a tragedy and a challenge for public health.

Introduction/Background

The aim of the first rehabilitation of persons with Spinal Cord Injury (SCI) is the optimization of functioning. Thus, a comprehensive understanding of the interaction between impairments in body functions, including impairments in mental functions, and limitations in daily activities is fundamental for an informed decision making amongst health professionals and patients throughout the rehabilitation process. Functioning has been scarcely studied in the context of SCI. This project aims to examine the associations between the health condition, functioning, and personal factors in persons with SCI attending first rehabilitation.

Material and Method

Data from the national clinical Swiss Spinal Cord Injury Inception Cohort Study were used. Functioning was operationalized through impairments in body functions and daily activity limitations. Items from existing instruments, including ISCoS International SCI Data Set, the Hospital Anxiety and Depression Scale, Brief Pain Inventory, and SCI Independence Measure III were used to collect the respective data. As personal factors, age and sex were considered. Structural equation models were used to estimate the relation between impairments in body functions and limitations in daily activities and to test the moderation effect of personal factors. The models were controlled for etiology and lesion level as measured by the American Spinal Injury Association Impairment Scale.

Results

The preliminary results show the expected negative effect of impairments in body functions on limitations in daily activities. Nevertheless, this effect relies mainly on the impairments in body functions than on the impairments in mental functions. Therefore, the role of impairments in mental functions as moderators of the described effect requires further analysis. A moderation effect of personal factors is analysed.
Conclusion

The analysis is currently ongoing but results will be available for presentation in July. This study will provide evidence for understanding the complexity of functioning in first rehabilitation of persons with SCI so to inform the rehabilitation process.

IMPLEMENTATION OF THE MODEL DISABILITY SURVEY IN PEOPLE FROM VARIOUS CULTURAL BACKGROUNDS IN A DEVELOPED COUNTRY; THEIR ACCESS TO WORK, AND HEALTHCARE; FACILITATORS AND BARRIERS

A. Elmalik1, B. Amatya1, M. Breese1, F. Khan1

1Royal Melbourne Hospital, Rehabilitation Medicine, Melbourne, Australia

Introduction/Background

Various studies were completed in the developing countries however this is the first one to be carried out in a developed country with a universal healthcare system.

Material and Method

Study design: community based descriptive study

Settings: community dwelling in the greater Melbourne region, catchment area of Royal Melbourne Hospital

Participants: 100 consecutive recruited community residents has been interviewed

Procedure:

After an informed consent was obtained, participants will be required to fill and answer the standard MDS questionnaire.

The Alpha version of the MDS comprises two questionnaires:

- Household questionnaire (answered by the head of the household) with two modules: household roster: targeting a short description of the household and all household members and, the children module: targeting disability and health conditions in children.
- Individual questionnaire (answered by a randomly-selected adult member of the household) with eight sections: socio-demographic characteristics, work history and benefits, environmental factors, functioning, health conditions and capacity, health-care utilisation, and satisfaction, personality and well-being.

The WHO coding system for the individual questionnaires of the MDS will be used to quantitatively measure each participant’s response.

Results
Many people with disability have less access to healthcare system, improved access to transport means and recreation facilities. Vocational opportunities are presented to individual with disabilities less than expected. Household with a person with a disability have greater difficulties and less freedom because of the caring responsibilities.

**Conclusion**

Although Australia has an equitable universal healthcare system, people with disability were still disadvantaged and inferior to the persons without disability in their access to work, education and healthcare system. Household with a person with a disability have a negative impact on the other family members in their educational and vocational interest.

STATE OF HEALTH AND UNDESIRABLE OUTCOMES OF PEOPLE PRACTICING PARALYMPIC SPORTS: A PROSPECTIVE COHORT STUDY

S.R.D.P. Coelho¹, E.F. Martins¹
¹University of Brasília, Faculdade de Ceilândia, Brasília, Brazil

Introduction/Background

In a general context, a health condition of people dealing with chronic diseases or injuries are better represented by a biopsychosocial model. As a result, they face the impact of these health conditions in their daily lives, experiencing impaired functions and structures of the body, limited activity, and restricted participation. It is believed that adapted sport contributes positively for the presented context. However, participation in sports not only promotes favorable outcomes to health-related states, but also increases the exposure to risk factors that may predict undesirable situations. From this, we aimed to identify the health-related state parameters from people facing disabilities who practice Paralympic sports, exploring disabilities in biopsychosocial domains that could be predictors of undesirable outcomes in sports.

Material and Method

We carried out a prospective longitudinal observational design by qualitative and quantitative approach, through interviews and questionnaires, respectively, applied for the coaches and athletes of Paralympic sports linked to a Special Physical Education Training Center, from June to September 2017.

Results

Sixty-nine athletes performing 12 sports pointed out causal relations between the self-care and the reported undesirable outcomes, producing theoretical, graphical and numerical results.

Conclusion

Our analysis showed that there are causal relationships between one of the explored domains of the health-related states and reported undesirable outcomes, evidencing that good scores reported in self-care by people with disabilities practicing sports may predict undesirable outcomes.

³Professor University of Antioquia- Physician Clinica las Américas, Physical Medicine and Rehabilitation, Medellin, Colombia

Introduction/Background

Traffic accidents (TA) are increasing problem worldwide, affecting this population’s health, disability, quality of life and the health care system’s budget, being this population the most vulnerable regarding frequency, severity and mortality. In 71.2% of the cases the injured were pedestrians. Aim: evaluate the quality of Life and disability in adults over 60 years of age injured in TA with moderate and serious injuries happened in traffic accidents in Medellin, Colombia and its metropolitan area in the years 2015-2016 with a 3 months follow up.

Material and Method

It is a prospective cohort study according to the severity of the injury, measured by the NISS (New Injury Severity Score), to evaluate disability (WHO-DAS II), and quality of life (SF-36), by interviews at 1 and a 3 months follow up. The patients were treated with surgical, medical and rehabilitation interventions according to the protocols of each institution.

Results

Of 247 patients, 241 of them (97.6%) fulfilled the 3 month follow up. The functioning improved with significant changes (p<0.05). The differences in means were; daily life activities [-36.28 (49.99)], self-care [-30.12 (29.64)], mobility [-20.28 (31.72)], social participation [-11.65 (28.95)]. The domains; understanding and communicating and interpersonal interactions showed small changes. Table 1.

Regarding quality of life, the SF-36 domains that improved with significant changes (p<0.05) were: physical functioning, differences in means [25.02 (26.15)], role-physical [13.80 (36.46)], bodily pain [13.73 (33.82)], and social function [13 (41.09)]. Role emotional, general health,
mental health and vitality did not show significant clinical changes. Table 2.

THE RELATIONSHIP BETWEEN MENTAL HEALTH AND QUALITY OF LIFE IN CHILDREN WITH TRAUMATIC BRAIN INJURY THREE MONTHS AFTER THE INJURY

**Objective:** To explore the relationship between mental health and quality of life (QoL) in children with traumatic brain injury (TBI) from Guadalajara, Mexico three months after the injury.

**Material and Method**

**Methods:** Forty six children with mild to severe TBI from Guadalajara, Mexico completed measures of mental health (anxiety and depression) and QoL 3 months after TBI. Anxiety and depressive symptoms were measured with the Anxiety Scale for Children Revised (CMAS-R) and Children’s Depression Inventory (CDI). QoL was measured using the Pediatric Quality of Life Inventory (PedsQL), which is composed by four subscales: physical, emotional, social and school functioning. For this analysis emotional functioning subscale was remove to avoid conflicts with mental health scales. The majority of the sample was men (67%) and the average age was 10.48 (SD=2.7).

**Results**

**Results:** A canonical correlation analysis between the mental health variables and QoL variables revealed that the two sets of constructs were significantly related, $r = .50$ (24.8% overlapping variance), $\lambda = .62$, $\chi^2 (6) = 19.81$, $p < .005$. The standardized canonical coefficients for the mental health variables showed that anxiety loaded most highly (-.687) followed by depression (-.499). The standardized canonical coefficients for the QoL variables showed that social functioning (.774) loaded above the cutoff of .40. This pattern of shared variance suggests that children with TBI who had high anxiety and depression also tended to have lower social QoL.

**Conclusion**
Conclusions: Intervention programs for children with TBI in Mexico should include techniques to reduce anxiety and depression symptoms which could improve children’ social quality of life.

Introduction/Background

According to the World Health Organization, over a billion people are estimated to live with some form of disability. A good quality data on disability are essential to policy makers in order to establish tailored programs for persons with disabilities (PWDs) based on the specific needs of each category. In low- and middle-income countries, data on disability are very scarce. The aim of this study is to determine the prevalence of disability and participation in Adult Moroccan population, and its distribution according to socio-demographic characteristics and geographical regions.

Material and Method

A national Survey was conducted in 2014, including a sample of 47,275 adult participants drawn from 16,044 households from urban and rural areas proportioned to population size. The sample’s socio-demographic characteristics were collected in a face-to-face interview. Then it was screened for disability using the Washington Group Short Set of Questions on Disability.

Results

Overall disability prevalence among Moroccan adult population was 9.5%, with important geographical disparities. Older age, lower education rates, unemployment, being single, and living in rural areas, were associated with higher disability prevalence rates. Visual and motor deficiencies were the most common disability modalities, and the prevalence of moderate to extreme disability, that is associated with more significant functioning limitations, was 2.6%.

Conclusion

The study was conducted and funded by the Moroccan government as part of a National action plan on Disability.

Introduction/Background

Traumatic brain injury (TBI) can be a debilitating injury at any age, with significant morbidity and mortality attached. The rehabilitation needs are complex especially in the elderly population, when complex multiple co-morbidities are often present, resulting in difficult initial management and on-going rehabilitation decisions. We sought to investigate the epidemiology of traumatic brain haemorrhage in patients aged 75 and over who were referred to a regional neurosurgical unit over a 6-year period.

Material and Method

Patients aged 75 or over referred with an acute or chronic subdural haemorrhage, extradural or subarachnoid haemorrhage between November 2010 and November 2016 were identified from the neurosurgical on-call database of a single tertiary centre. Data was correlated to show severity of TBI based on initial GCS score; GCS 13-15 mild TBI, 9-12 moderate TBI and <8 severe TBI. Outcome measures to include transfer to the neurosurgical unit; locally managed and follow up were recorded.

Results

A total of 4182 patients over 75 were referred, of which 3354 (80%) were referred with a traumatic brain haemorrhage. These made up 10% of all neurosurgical referrals of any age (n=34850). Severity of TBI at referral: mild 81% (2715), moderate 8% (277) and severe 11% (362). Acute subdural haematoma accounted for 39% (1295) of referrals; chronic subdural haematoma 49% (1659); extradural haematoma 1.5% (50) and traumatic subarachnoid haemorrhage 10% (322). 21% (690 patients) were transferred to the major trauma centre from the referring hospital. The majority of neurosurgical transfers (608; 88%) were for management of chronic subdural haematoma – 580 (95%) of which were for urgent transfer to the neurosurgical ward for consideration of operative management.

Conclusion
Traumatic brain haemorrhages account for the majority of elderly trauma neurosurgical referrals. Most are managed locally with potentially unknown and unmet physical or cognitive rehabilitation needs.

E5 Functioning Impact Assessment (e.g. Prediction of the Implications of Policy and Legislation on Functioning)

ISPR8-0152
DESCRIPTIVE ANALYSIS OF COMMUNITY DWELLING ELDERLY INDIVIDUALS WITH LOW FALLS RISK: UTILIZATION OF THE STEADI TOOLKIT FROM THE CENTER FOR DISEASE CONTROL AND PREVENTION (CDC)
A. Miciano Md¹, C. Cross Phd- Pstatr²
¹Nevada Rehab Institute, PMR, Las Vegas, USA
²University of Nevada- Las Vegas, Biostatistics, Las Vegas, USA

Introduction/Background

The study objectives were: to investigate the fall risk and physical performance of community dwelling elderly individuals with low falls risk using the CDC’s STEADI (Stopping Elderly Accidents, Deaths, & Injuries) toolkit: STEADI screening measure and recommended Clinical Observation Assessments (COA); and, to describe the multi-morbidity burden and physical function of such individuals.

Material and Method

In a retrospective study at a PMR clinic 17 elderly community-dwelling subjects (age range 60-79 years old) participated. The outcome measures were: the patient-reported STEADI measure assessed falls risk factors (low fall risk defined as STEADI score <4). The COAs consisted of the Timed-Up-and Go (TUG) and 30-Second Chair Stand Test (CST). The Self-Administered Co-Morbidity Questionnaire (SCQ) described the multi-morbidity burden, and the PROMIS-57 v1.0-Physical Function (PROMIS-PF) quantified the activity limitation.

Results

Data met normality assumptions. Mean differences were examined among variables using ANOVA with age as a covariate; age did not differ significantly among participants. Descriptive statistics and significant tests are provided for each variable. No variables demonstrated a gender effect (perhaps because of small n for females). A Pearson Correlation analysis (p<.05) among variables was also conducted. The mean (SD) scores were as follows: STEADI 0.944 (1.21); TUG 16.0 (6.79); CST 10.07 (2.73); SCQ 6.47 (3.28); and, PROMIS-PF 41.48 (9.15). No significant correlations were found, specifically the STEADI score did not correlate with COA, SCQ, and PROMIS-PF.

Conclusion

Community dwelling elderly individuals with low falls risk tend to have low multi-morbidity burden, mild activity limitation, slow gait speed, and fair lower extremity power – independent of age and gender factors. The study showed the limited use of CDC-recommended COAs in individuals with low falls risk. Future studies should address the appropriate performance-
based assessments (PBA) in these individuals with low falls risk as categorized by the CDC’s STEADI measure and contrast these PBA with those current CDC-recommended COAs.

ISPR8-2688
EVALUATION OF ATTITUDES TO DISABILITIES IN THE PERSPECTIVE OF PEOPLE WITH PHYSICAL DISABILITIES: A CROSS-SECTIONAL STUDY IN A TERTIARY REHABILITATION INSTITUTE

F. Canale Cabral¹, A.T. Sugawara¹, M. Imamura¹, L. Rizzo Battistella¹
¹Instituto de Medicina Fisica e Reabilitacao- Hospital das Clinicas HCFMUSP- Faculdade de Medicina- Universidade de Sao Paulo- Brazil,
Departamento de Medicina Legal - Etica Medica e Medicina Social e do Trabalho, Sao Paulo, Brazil

Introduction/Background

People with disabilities, estimated at one billion worldwide, deal with a wide variety of facilitators or barriers that improve or limit their functionality and quality of life, narrowing or widening the difference between their performance (real) and their capacity (ideal). Attitudes, positive or negative reactions towards disability, influenced by culture, media, concepts and beliefs, impact directly their social inclusion. The aim of this study was to better understand and to measure attitudes toward disabilities, reported by people with disabilities followed at the Instituto de Medicina Fisica e Reabilitacao, Hospital das Clinicas HCFMUSP, Faculdade de Medicina, Universidade de Sao Paulo, Brazil.

Material and Method

68 patients, aged between 18-65 years, without cognitive impairments, with one of the following diagnosis: amputee, paraplegia, tetraplegia or hemiplegia, were exposed to the following evaluations: sociodemographic, Attitudes to Disabilities Scale for physical disabilities (ADS-D) and the Hospital Anxiety and Depression Scale (HADS). The collected data was associated with data from medical records, such as time since disability and Functional Independence Measure (FIM).

Results

The average and standard deviation of the total ADS-D score was 61.294 (8.74), statistically higher than previous studies in developing countries (Brazil p = 0.0067 and China p < 0.0001). Correlation was found between ADS-D and: depression (HADS) and self-reported income. No correlation was found between ADS-D and time since disability or FIM.

Conclusion

In spite of having a more positive perception than previous studies, the population of the study reported attitudinal barriers. Lower incomes and depression were associated with lower ADS-D scores.

PAIN MANAGEMENT AND THE BURDEN OF PAIN AMONG ASYLUM SEEKERS IN DETENTION

S. Faux¹, C. Shiner¹

¹St Vincent's Hospital Sydney, Department of Rehabilitation and Pain Medicine, Sydney, Australia

Introduction/Background

Prolonged detention of refugees and asylum seekers is known to have negative effects on individual’s physical and mental health. There is growing evidence that the management of health complaints and common health conditions is much poorer among detained and community-dwelling refugee populations. In the wider community, chronic pain is a common and debilitating condition that can impact on emotional well-being, physical functioning and overall quality of life. To date no formal research has been conducted examining the incidence, burden and management of persistent pain among those in detention.

Material and Method

Throughout 2015-2017, voluntary humanitarian visits to an immigration detention centre in Sydney, Australia were conducted. Informal interviews were conducted verbally with detainees who wished to discuss medical issues, including pain and pain management.

Results

Interviews were conducted with 22 male detainees (aged 19-61). 19 reported to be suffering from persistent pain (86%), resulting from a variety of afflictions including gunshot wounds, trauma such as motor vehicle or boating accidents, assault, inflammatory arthropathies, dental problems and undiagnosed visceral pain. Described pain patterns largely mirrored those commonly seen in trauma settings including the military setting, with a high incidence of chest and pelvic pain. Of those with pain, 31% reported they had no access to any medication or treatment for their pain, including simple paracetamol. Many individuals reported associated psychiatric symptoms including depression, anxiety, post-traumatic stress disorder (PTSD) and sleep disturbances, which they believed were exacerbated by their ongoing pain.

Conclusion

Anecdotal evidence uncovered a considerable and debilitating chronic pain burden among detainees that is currently being inadequately managed and is compounding the traumatic experience of being in detention. There is a notable social and moral imperative to further investigate and address this issue.

THREE-DIMENSIONAL MOTION ANALYSIS OF THE 2ND CERVICAL SPINOUS PROCESS AT END RANGE CERVICAL ROTATION IN DIFFERENT SCAPULAR POSITIONS USING 3D DIGITIZER

T. Otsudo¹, K. Akasaka¹, H. Hattori², Y. Hasebe³, A. Tamura⁴
¹Saitama Medical University, Health and Medical care, Iruma-gun- Saitama, Japan
²Kawagoe clinic- Saitama Medical University, Department of rehabilitation, Kawagoe, Japan
³Saitama Medical Center- Saitama Medical University, Department of Rehabilitation-, Kawagoe, Japan
⁴Saitama Medical University, Graduate School of Medicine, Iruma-gun- Saitama, Japan

Introduction/Background

It has been reported that passive elevation of the scapulae significantly decreases neck pain and increases cervical range of motion. However, it is unknown whether upper cervical rotation is influenced by different scapula positions or not. The study used a 3D digitizer to determine three-dimensional motion analysis of the 2nd cervical (C2) spinous process at end range cervical rotation with the scapula in different positions.

Material and Method

30 healthy adults (21.2±0.8 years) participated in this study. Different scapula positions were adopted bilaterally and passively placed at (1) normal resting position, (2) depression, (3) adduction (4) abduction, with a neutral gleno-humeral joint in sitting. Under each scapula position, bilateral end range cervical rotation (degree) and displacement of the C2 spinous process [mm] were analyzed by a 3D digitizer device. End range rotation was analyzed by the vector from the left to right mastoid of the occipital bone related to the vector from the left to right acromial angle. Displacement of the C2 spinous process was calculated as the change in distance between the mastoid process and the point of intersection from perpendicular line from the C2 spinous process to the line between both mastoids at neutral and end range of cervical rotation.

Results

The results of our study indicate that there were no significant differences between end range cervical rotation and displacement of the C2 spinous process relative to the occiput in any scapular position. However, displacement of the C2 spinous process relative to the occiput was significantly correlated with range of cervical rotation under all scapular positions (p<0.05).

Conclusion

Flexibility of upper cervical rotation would be influenced on end range cervical rotation regardless of scapular positions.

ISPR8-0233
EVALUATION OF PULMONARY FUNCTION BEFORE, DURING AND AFTER WATER IMMERSION
J. Viana
Self applicant, Self applicant, Dothan, USA

Introduction/Background

Water has been used for the treatment of Diseases since Ancient times and Hydrotherapy has been presenting a great development due the number of researches and attention of scientific community and because of its capacity to restore and maintain health.

The purpose of this project is analyze the effects of water immersion on the pulmonary function of healthy young adults and assess the variables before, during and after immersion.

Material and Method

The experiment used 16 individuals with age of 21,4 ± 1,6 years immersed until the Xiphoid process. In order to provide an objective measure, Spirometry test was performed pre-immersion, 5 and 60 minutes during and 5 minutes post-immersion.

Results

During research major alterations were observed, like the reduction of the Expiratory Reserve Volume and Functional Residual Capacity, possibly caused by hydrostatic pressure acting on the Diaphragm and limiting Chest expansion. It was observed significant decrease on the Forced Vital Capacity (4,17 ± 0,9 to 3,69 ± 0,7) and Forced Expiratory Volume during First second ( 3,83 ± 07 to 3,27 ± 05) after water immersion. It is also concluded that the time of immersion does not have an influence on the pulmonary function, with pulmonary values returning to its normal levels after getting out of water.

<table>

</tbody>
</table>

Conclusion

It is concluded that water properties such as Hydrostatic Pressure and Temperature have an effect in the respiratory and hemodynamic system. However, the explanations for the immediate return of pulmonary function levels after water immersion is not yet seen in the literature.

THE EFFECT OF ANTICIPATION OF AN ONGOING CONNECTION WITH OTHERS ON BRAIN ACTIVITY OF NEUTRAL FACE RECOGNITION

R. Miyamoto¹, M. Kurusu²

¹Tokyo Metropolitan University, Faculty of Health Sciences, 7-2-10 Higashiogu- Arakawa-ku, Japan

Introduction/Background

In humans, information about the face is very important for first impression formation and establishing interpersonal relationships. We investigated the effect of anticipation of an ongoing connection with others on brain activity and neutral face recognition using functional magnetic resonance imaging (fMRI).

Material and Method

Sixteen young, right-handed females participated in this study (mean age ± standard deviation: 21.7 ± 3.2 years, range 20–34 years. They were healthy undergraduate or graduate students with no history of significant medical, psychiatric, or neurological disorders. All gave written informed consent to participate, and Tokyo Metropolitan University Research Ethics Committee (No. 17048) approved the study. During fMRI scanning, subjects were shown photographs of people with neutral facial expressions (72 neutral photographs from the face database that made by the university of FEI). Subjects were asked to consider each photograph under the following conditions: Condition 1, “I will meet the person in this photo only once.”; Condition 2, “I will meet the person in this photo multiple times.” Each photo was presented for 8 s. The total fMRI duration was 408 s. All functional imaging data were preprocessed and analyzed using SPM8 implemented in MATLAB (significance set at an uncorrected p < 0.001). We estimated brain activity differences between the 2 conditions.

Results

The left caudate nucleus was significantly activated in Condition 2 compared with Condition 1. The right substantia nigra had a significantly different blood-oxygen-level dependent response in Condition 1 compared with Condition 2.

Conclusion

The anticipation of an ongoing connection could affect the first impression formation process in the human brain.

RELEVANCE OF METACOGNITION AND BRAIN ACTIVITY TO DECISION-MAKING TASKS RELATED TO SELF-REFLECTION

R. Miyamoto¹, A. Senoo¹
¹Tokyo Metropolitan University, Faculty of Health Sciences, 7-2-10 Higashiogu- Arakawa-ku, Japan

Introduction/Background

Daily life requires many decisions. People with high metacognition may effectively and quickly make decisions. We used functional magnetic resonance imaging (fMRI) to examine the neural basis of the relationship between metacognition and self-related decision-making.

Material and Method

Tokyo Metropolitan University Research Ethics Committee (No. 14072) approved this study. Participants included 13 young, healthy, right-handed people (mean age ± standard deviation: 21.38 ± 1.12 years, range 20–24 years). Before fMRI scanning, explicit self-esteem and metacognition were assessed using the Rosenberg Self-esteem Scale (RSES) and Metacognitive Awareness Inventory (MAI), respectively. Using a computer mouse, subjects answered decision-making task questions, which were randomly presented during scanning. Condition 1 (self-related decision-making) asked, “If given these 2 types of work, which would you do first?” Condition 2 (word decision-making) asked, “Which of the 2 words is longer?” The 2 presented words were randomized and the same for each condition. We analyzed differences between these conditions using SPM12 implemented in MATLAB R2017a. We also analyzed the correlation between the MAI scores (Factor 1: monitoring; Factor 2: control; Factor 3: metacognitive knowledge) and RSES scores and the averaged parameter estimates in the spherical region of interest.

Results

The left orbitofrontal cortex, left superior frontal gyrus, left inferior frontal gyrus, left angular gyrus, left temporal pole, bilateral middle temporal gyrus (MTG), and left hippocampus were activated in self-related compared with word decision-making. MAI Factor 1 and 3 scores were negatively correlated with the MTG (r = −0.84 and r = −0.71, respectively; p < 0.05). MAI Factor 2 was not significantly correlated with any activity.

Conclusion

The negative correlation between MAI Factor 1 and 3 scores and MTG activity disagrees with previous reports that MTG is involved in higher subjective confidence ratings. Moreover, metacognitive control may be regulated by other brain areas.

CHANGES IN THE MOTOR FUNCTION IN CHILDREN WITH TYPICAL DEVELOPMENT OF DIFFERENT AGE GROUPS
X. Zheng¹, C.L. Chen², C.J. Chang³, C.Y. Chung², L.T. Chou³
¹Chang Gung University, Graduate Institute of Early Intervention, Taipei, Taiwan R.O.C.
²Chang Gung Memorial Hospital-Linkou, Department of Physical Medicine and Rehabilitation, Taoyuan, Taiwan R.O.C.
³National Taiwan Normal University, Department of Human Development and Family Studies, Taipei, Taiwan R.O.C.

Introduction/Background

Early intervention is effective for children with developmental delay. However, there are few longitudinal follow-up studies on the motor development in infant and toddler. This study aims to explore the changes in the motor function in children with typical development of different age groups.

Material and Method

This study was a follow-up study. Participants were from Kids in Taiwan: National Longitudinal Study of Child Development & Care (KIT). Children with typical development were classified into infant (6 months old, n=500) and toddler (3 years old, n=500) groups. Motor outcomes were measured by Developmental Motor Screening Scale for Preschool Children (DMSSPC) at baseline and follow-up (six months for infant and twelve months for toddler). DMSSPC includes gross motor (stability and locomotion, body coordination) and fine motor (grasp and manipulation, visual motor integration) domains. Analysis of covariance (ANCOVA) was used to compare the differences in the changes of motor outcomes between the infant and toddler groups. A p <0.05 is considered as statistically significant difference.

Results

ANCOVA showed infant group had greater changes in gross motor, fine motor, and total scores than toddler group (η²=0.919-0.942, p<0.001). Furthermore, infant group had greater changes in stability and locomotion, body coordination, grasp and manipulation, visual motor integration than toddler group. (η²=0.545-0.908, p<0.001).

Conclusion

These findings suggest infants have a greater potential of motor changes than toddlers. Therefore, infants may have greater brain plasticity in motor development than toddlers.

ISPR8-0877
EFFECTS OF HOME ENVIRONMENT ON CHANGES IN THE MOTOR DEVELOPMENT FOR TYPICAL-DEVELOPMENT INFANTS AND TODDLERS
C.Y. Liang¹, C.L. Chen², L.T. Chou³, C.J. Chang³, C.Y. Chung²
¹Chang Gung University, Graduate Institute of Early Intervention, Taoyuan, Taiwan R.O.C.
²Chang Gung Memorial Hospital, Physical Medicine and Rehabilitation, Taoyuan, Taiwan R.O.C.
³National Taiwan Normal University, Human Development and Family Studies, Taipei, Taiwan R.O.C.

Introduction/Background

Motor functions are affected by the home environment in childhood. This study aims to identify the home environment factors in the motor development of infants and toddlers.

Material and Method

This follow-up study had involved 1000 typical-development children, classifying children into infant group (6 months old, n=500) and toddler group (3 years old, n=500). Participants were from Kids in Taiwan: National Longitudinal Study of Child Development & Care (KIT). Developmental Motor Screening Scale for Preschool Children (DMSSPC), including body coordination (BC), stability and locomotion (S&L), visual motor integration (VMI), and grasp and manipulation (G&M) domains, was used to assess motor development at baseline and follow up (infants: 6-months follow up and toddlers: 12-months follow up). Home Environment Scale (HES), including parent response (PR), parent participation/learning stimulation (PP/LS), physical environment (PE), child acceptance (CA), speech stimulation (SS), learning material (LM), and environmental diversity (ED), was measured at baseline. Pearson correlation was used to analyze the correlation between HES and DMSSPC at baseline and change scores of DMSSPC (DMSSPC score at follow-up - DMSSPC score at baseline).

Results

Nearly all HES domains had significantly positive correlations with DMSSPC domains at baseline in infant group. In toddler group, HES domains had significantly positive correlations with DMSSPC domains, except PE with VMI and S&L, and CA with VMI and S&L. Additionally, HES domains except PE and CA had significantly negative correlations with change scores of G&M in infant group. While only PP/LS and ED had significantly negative correlations with change scores of G&M in toddler group.

Conclusion

A better home environment is associated with greater motor development in most domains. However, a better home environment is linked to lesser changes in G&M development,
especially infant groups. These findings may suggest providing a good home environment is important for motor development, especially infant groups.

ISPR8-0893
EFFECT OF POSTURAL CONFIGURATION ON UPPER LIMB FUNCTION
M. Ben David Bauch¹, D. Libermann², J. Friedman²
¹Tel Aviv University- The Stanley Steyer School of Health Professions, Department of Physiotherapy, Shoham, Israel
²Tel Aviv University, Physiotherapy, Tel Aviv, Israel

Introduction/Background

Whole body configuration is thought to affect upper limb (UL) performance based on the assumption that posture precedes movement, whereas the forthcoming task goal determines postural configuration. However, it is not well documented how different postural modalities benefit UL motion. The aim of the current study was to examine the effect of postural configuration – sitting versus standing – on a fast and accurate (i.e., under Fitts' law constraints) point-to-point hand movement, and to compare performance results in different conditions. We hypothesize that standing and sitting will not differ neither in terms of temporal or spatial UL kinematics

Material and Method

Twenty-three healthy adults performed an UL Donders-type task in sitting and standing positions and data were collected for off-line analysis of the following performance variables describing the hand movement: movement time, peak velocity, straight-line deviation, response time, and number of no-go errors. In addition, center of pressure (CoP) displacement was collected in four conditions: sitting and standing, with and without arousal manipulation. Galvanic skin response (GSR) was measured to assess the possibility of arousal changes that may interact with posture and underlie differences in hand performance

Results

No statistically significant difference was obtained between sitting and standing in regard to any of the UL performance variables. Yet, different arousal level was found among the two grouping conditions; however, no difference in arousal was found between sitting and standing (F=19.39; p<0.001). Finally, CoP displacement onset was found to be earlier in the two standing conditions compared to the two seated ones (F=41.67; p=0.044)

Conclusion

Postural configuration does not affect the UL task. Rather, the underlying control variables as reflected by the early onset of CoP displacement in standing compared to sitting

INFLUENCE ON POSTURAL CONTROL AND AUTOMATIC NERVE ACTIVITY USING SIMPLE VIRTUAL REALITY SYSTEM

Y. Otani\(^1\)
\(^1\)Kobe International University, Rehabilitation, Kobe, Japan

Introduction/Background

Virtual reality (VR) environments can be used to stimulate movement, motor imagery, and affect. We developed visual stimuli to generate fear under a simple VR environment using a smartphone. This study aimed to evaluate the influence of automatic nerve activity and standing postural sway within this VR environment.

Material and Method

Seventeen healthy adults were instructed to stand on a stabilometer with an outward-facing camera mounted to the VR headset. The subjects were evaluated with or without VR stimuli for each of the following conditions: (1) control (no VR), (2) gazing a human in front of oneself on VR, and (3) gazing a ball coming toward oneself on VR. Body sway while standing upright was recorded for 60 seconds with 200 Hz sampling. Heart rate variability was measured by a wearable heart rate sensor, and the low-to-high frequency (LH/HF) ratio was calculated for sympathetic nerve activity during each condition. At the end of each condition, we evaluated “surprises” and “fears” subjectively felt under each condition using a visual analog scale (VAS). We compared the results from each of these conditions with Kruskal–Wallis and Steel–Dwass test. The level of significance was set at p < 0.05.

Results

The results revealed that fear-VAS was significantly higher under condition 3 (p < 0.05). Additionally, the LF/HF tended to higher, and total length of the body sway tended to smaller than other conditions.

Conclusion

Using a simple VR system, we observed that fear stimuli induced motor inhibition, such as “freezing” by activating the limbic system.

Keywords

postural control; automatic nerve activity; virtual reality

Introduction/Background
Anatomical and biomechanical studies showed that total maximal arm flexion was limited to 150°, nevertheless an asymptomatic subject is able to raise his arm up to the vertical. Some studies highlighted that arm flexion involved trunk 3D rotations, but no study has yet assessed with accuracy the kinematics of the cervical spine during arm flexion. The aim of the present study is thus to evaluate the 3D head rotations during arm flexion in asymptomatic subjects.

Material and Method
Observational study: 3D head and trunk rotations were assessed in ten healthy, right handed subjects during maximal unilateral left arm flexion using a Polhemus Fastrak electromagnetic device. The 3D rotations were measured at 30°, 90°, 140° of maximal active and passive arm flexion, respectively. 3D rotations at the different levels of arm flexion and for active and passive conditions were compared using Bayesian ANOVA.

Results
Head and trunk rotations increased with active and passive arm flexion. Head and trunk kinematic patterns were opposite at maximal arm flexion: relative to the trunk, the head 3D rotations showed flexion, ipsilateral bending and contralateral axial rotation whereas trunk was in extension, contralateral lateral bending and ipsilateral axial rotation. Compared to passive condition, active maximal arm flexion involved significant less head and trunk lateral bending and axial rotation, consequently, the head orientation was better stabilized in space.
Conclusion

Maximal arm flexion involves a kinematic pattern of 3D head rotations opposite to the kinematic pattern of 3D trunk rotations. The rotations in the cervical spine could either be a way to compensate trunk rotations in order to maintain the orientation of the head supporting horizontal gaze and/or the result of the synergic organization of movement by the central nervous system.

Introduction/Background

Alzheimer’s disease (AD) often causes severe social and psychological burden to the patients' caregivers. In this study we examined the inter-relationships between caregivers' burden, stress related growth (SRG), resilience and the cognitive and emotional status of AD patients receiving cholinomimetic treatment.

Material and Method

A prospective study in which 17 caregivers of patients with AD treated in a memory clinic were recruited. Evaluations of the patients' cognitive and behavioral state were performed using the MMSE, Alzheimer's disease assessment scale-cognitive (ADAS-Cog) and Mindstream computerized program and Neuropsychiatric inventory questionnaires, respectively. Caregivers' characteristics were evaluated using the stress related growth, resilience, and burden of disease questionnaires. Evaluations were performed at baseline, 6 months after and at 1 year of cholinomimetic therapy.

Results

The mean age of the caregivers was 68 ±13 years, 59% of them were women. During the year of treatment, a decline was noted in the cognitive and behavioral state of most patients. Among caregivers, a trend towards increased SRG, resilience and disease' burden was observed. Also, among caregivers, greater disease burden was associated with greater levels of SRG and resilience in the second and first evaluation but not at baseline. Lower levels of SRG among caregivers were associated with greater decline in cognitive abilities of patients, as measured by a reduction in ADAS-cog. No correlation was found between any of the cognitive measurements of patients and resilience or disease burden among caregivers.

Conclusion

Similar to our findings in medical personnel treating survivors of political violence, also in caregivers of Alzheimer’s patients, greater levels of traumatic stress were related to greater stress related growth. This trend became more evident during the year of follow up. We also found that the decline of cognitive abilities of patients was related to lower levels of SRG of caregivers. These findings need to be further authenticated in future studies.

Developmental Motor Screening Scale for Preschool Children (DMSSPC) exhibits high reliability and validity. This study aims to analyze this tool by Item Response Theory (IRT).

Material and Method

Data of this study were collected from Kids In Taiwan: National Longitudinal Study of Child Development & Care (KIT). Four hundred and fifty children’s parents (216 boys and 234 girls) from New Taipei City were recruited. DMSSPC includes gross motor (stability and locomotion, body coordination) and fine motor (grasp and manipulation, visual motor integration) domains. The ConQuest software was used to perform the IRT analysis, including difficulty estimates and mean square error (MNSQ).

Results

After IRT analysis, the difficulty estimates of DMSSPC were -3.33 - 1.85, and the MNSQ values were 0.53 - 1.76. The difficulty estimates for the DMSSPC ranged from -2.08 - 1.99 for the fine motor and from -3.43 - 2.33 for the gross motor. The MNSQ values of fine motor and gross motor were 0.52 - 1.83 and 0.50 - 1.59, respectively.

Conclusion

According to the IRT analysis, the difficulty estimates and MNSQ values of DMSSPC were within reasonable limits. Future studies will develop the Computerized Adaptive Testing (CAT) of DMSSPC based on the IRT results.

INSPIRATORY MUSCLE RESISTANCE IN OBESE AND EUTROPHIC INDIVIDUALS
C. Callegaro1, A.D. Hoffmeister2, K.S. Lima3, V. Binotto4
1Universidade Federal de Santa Maria,
Department of Physical Therapy and Rehabilitation. Physiology and Rehabilitation Laboratory, Santa Maria, Brazil
2Postgraduate Program in Comprehensive Health Care,
University of Cruz Alta and Regional State University of Northwestern Rio Grande do Sul UNIJU
I, Cruz Alta, Brazil
3University of Cruz Alta, Physical Therapy, Cruz Alta, Brazil
4University of Cruz Alta, Nursing, Cruz Alta, Brazil

Introduction/Background

Obesity seems to be related to reductions in the inspiratory muscle strength. However, the effects of obesity on inspiratory muscle resistance have not been studied yet. The objective of this study was to compare the inspiratory muscle resistance between obese and eutrophic individuals.

Material and Method

Participated 20 obese (31 ± 6 years old, 10 men, 37.5 ± 4.7 kg/m²) and 20 healthy subjects (29 ± 8 years old, 10 men, 23.2 ± 1.5 kg/m²). Inspiratory muscle strength was measured by a manovacuometry through the determination of the maximum inspiratory pressure (MIP). Inspiratory muscle endurance was determined by an incremental test with an initial load of 50% MIP and increments of 10% MIP every 3 minutes until the individual was unable to continue the test.

Results

Obese (470 ± 326 sec) showed a reduction in inspiratory muscle resistance compared to eutrophic individuals (651 ± 215 sec, P = 0.04). Inspiratory muscle strength did not differ between groups (Obese = 120 ± 45 cmH₂O; Eutrophic = 118 ± 31cmH₂O, P = 0.81). Inspiratory muscle endurance test induced a similar increase in systolic, diastolic and mean arterial
pressure, as well as in heart rate in obese and eutrophic individuals (Table 1).

**Conclusion**

Obeses show reduction in inspiratory muscle resistance compared to eutrophic individuals, but the hemodynamic responses did not differ between groups.

**Keywords**

obesity; inspiratory muscle resistance; arterial blood pressure

INTRODUCTION/BACKGROUND

Over recent decades holistic mind-body exercise methods have gained international popularity and importance in the management of musculoskeletal disorders. The scope of this historical research paper was to investigate from the last two centuries: the origins of Western mind-body methods, their philosophies, exercises and relationship with mainstream healthcare.

MATERIAL AND METHOD

Research was limited to readily available published documents from internet sources. The search engines used were: Medline, Google, Google Books, Google Scholar, YouTube, Kindle and AbeBooks.

RESULTS

Within a several decades at the turn of the Twentieth century a cluster of mind-body exercise methods emerged and flourished from at least six pioneering founders: Edwin Checkley, Jørgen Peter Müller, Frederick Matthias Alexander, Minnie Randell, Joseph Pilates and Margaret Morris. Each method was based upon similar philosophies and exercises. This renaissance of independent mind-body schools cooperated in part with mainstream medicine and physiotherapy and mirrored the science and art renaissance of the period. Though mostly forgotten today, these methods enjoyed celebrated success by medical and health practitioners and millions of followers.

CONCLUSION

This research revealed a forgotten chapter in the recent history of physical rehabilitation. Rediscovering the grand existence of the Western mind-body exercise movement may, after due scientific validation, facilitate current official healthcare establishment recognition of this training as an integral entity. This could widen research opportunities and consolidate approaches towards: optimal musculoskeletal rehabilitation, injury prevention, promotion of healthy active lifestyle environments in the modern world and enhancement of natural pain-free human athletic appearance, feel and performance.

Introduction/Background

Individuals with chronic heart failure (CHF) and inspiratory muscle weakness exhibit exacerbated peripheral chemoreflex sensitivity (PCS) in relation to patients with preserved inspiratory muscle strength. However, it remains unclear whether patients with CHF patients with preserved inspiratory muscle strength show PCS similar to healthy individuals. The objective of this study was to compare PCS between patients with CHF and preserved inspiratory muscle strength and healthy individuals.

Material and Method

Ten subjects with CHF (55 ± 8 years old) and 10 healthy subjects (54 ± 7 years old) matched for sex and age participated in this study. All subjects showed preserved inspiratory muscle strength, which was measured through a pressure transducer. PCS was obtained through the technique of transient hypoxia induced by the inhalation of pure nitrogen, which was repeated for 10 times. PCS was calculated by linear regression analysis between maximal ventilation and lower oxygen saturation.

Results

PCS in patients with CHF and preserved inspiratory muscle strength (1.09 ± 0.95 L.min⁻¹.% SaO₂⁻¹) did not differ from healthy subjects (0.70 ± 0.73 L.min⁻¹.% SpO₂⁻¹; P = 0.31). There was a significant association between PCS and inspiratory muscle strength (r = 0.58, P = 0.006), however only 19% of variance in PCS may be explained by inspiratory muscle strength.

Conclusion
Patients with CHF and preserved inspiratory muscle strength show PCS similar to healthy individuals.
