

Dear Author

Here are the proofs of your article.

- You can submit your corrections **online**, via **e-mail** or by **fax**.
- For **online** submission please insert your corrections in the online correction form. Always indicate the line number to which the correction refers.
- You can also insert your corrections in the proof PDF and **email** the annotated PDF.
- For **fax** submission, please ensure that your corrections are clearly legible. Use a fine black pen and write the correction in the margin, not too close to the edge of the page.
- Remember to note the **journal title**, **article number**, and **your name** when sending your response via e-mail or fax.
- **Check** the metadata sheet to make sure that the header information, especially author names and the corresponding affiliations are correctly shown.
- **Check** the questions that may have arisen during copy editing and insert your answers/corrections.
- **Check** that the text is complete and that all figures, tables and their legends are included. Also check the accuracy of special characters, equations, and electronic supplementary material if applicable. If necessary refer to the *Edited manuscript*.
- The publication of inaccurate data such as dosages and units can have serious consequences. Please take particular care that all such details are correct.
- Please **do not** make changes that involve only matters of style. We have generally introduced forms that follow the journal's style.
- Substantial changes in content, e.g., new results, corrected values, title and authorship are not allowed without the approval of the responsible editor. In such a case, please contact the Editorial Office and return his/her consent together with the proof.
- If we do not receive your corrections **within 48 hours**, we will send you a reminder.
- Your article will be published **Online First** approximately one week after receipt of your corrected proofs. This is the **official first publication** citable with the DOI. **Further changes are, therefore, not possible.**
- The **printed version** will follow in a forthcoming issue.

Please note

After online publication, subscribers (personal/institutional) to this journal will have access to the complete article via the DOI using the URL:

<http://dx.doi.org/10.1007/s11947-019-02341-8>

If you would like to know when your article has been published online, take advantage of our free alert service. For registration and further information, go to:

<http://www.link.springer.com>.

Due to the electronic nature of the procedure, the manuscript and the original figures will only be returned to you on special request. When you return your corrections, please inform us, if you would like to have these documents returned.

Abstract

The aim of this study was to evaluate the replacement aspects of conventional methods (petroleum-based solvent and Folch assay) by alternative methods (bio-based and biodegradable solvent 2-methyltetrahydrofuran (MeTHF) and supercritical CO₂ (SC-CO₂)) for seed oil extraction from anise (*Pimpinella anisum* L.) and fennel (*Foeniculum vulgare* Mill.). Results showed that the highest oil yield of aniseeds was obtained by using Folch (24.07%) and MeTHF (23.65%) extraction methods whereas fennel seeds had 20.02% and 18.72%, respectively. Fatty acid composition of both seed oils obtained by the two green extraction methods was similar to the conventional ones with the predominance of petroselinic acid (54.22–61.25% in fennel and 42.39–48.97% in anise). Besides, SC-CO₂ method allowed to obtain the maximum of sterol content in anise (3.85 mg/g of oil) and fennel (4.64 mg/g of oil) seed oils. Furthermore, anise and fennel seed oils extracted with MeTHF method significantly showed higher total phenolic content (2.43 and 1.32 mg GA/g oil, respectively), stronger antioxidant activity (9.23 and 5.04 μmol TEAC/g oil, respectively), and oxidative stability (8.23 and 10.15 h, respectively) than the other methods ($p < 0.05$). In conclusion, MeTHF appeared to be a good substitute to petroleum solvents for recovery of high oil quality from *Pimpinella anisum* and *Foeniculum vulgare* seeds.

Introduction

Oil seeds are crucial for the nutritional security of the global population (Abert Vian et al. 2013). They are a source of nutritious human and animal food. Oil is recovered from plant either by mechanical expression or by chemical extraction processes (Akinoso and Adeyanju 2012). The first is often associated with low yields, and the latter uses solvents. Such solvents are dangerous to handle and are harmful to human

health (Nyam et al. 2011). Frequently, hexane is widely used for oil extraction because of easy oil recovery, narrow boiling point (63–69 °C), and excellent solubilizing ability (Abert Vian et al. 2013). However, it is a noxious waste since it is released into the environment and reacts with pollutants to form ozone and photo. Moreover, several studies revealed that hexane is toxic both in short- and long-term expositions and affects the neural system when inhaled by humans (Misirli et al. 2008). In addition, the environmental contamination associated with its use has placed new demands on the food, cosmetic, and pharmaceutical industries to invest in clean technologies that could provide high-quality products for the highly competitive global market (Nyam et al. 2011). Hence, greener technologies are viable alternatives for oil extraction and are aimed to develop an environment friendly process with the elimination of the use of toxic solvents, the improvement of process efficiency and enhancement of extraction yields in a shorter time with less thermal degradation, and high quality of the oil (Virot et al. 2008). Greener solvents like

ethanol, limonene, and 2-methyltetrahydrofuran (MeTHF) are mostly produced from agricultural sources and are greener processing fluids for bioactive compounds extraction and oil separation from oil seeds (Liu and Mamidipally 2005; Breil et al. 2016). In addition, supercritical carbon dioxide extraction is an eco-friendly technique that has been demonstrated to be useful in extracting edible oils from numerous sources (Kulkarni et al. 2017). Recent developments in supercritical carbon dioxide extraction technology have demonstrated that it can be a promising alternative to conventional extraction methods. Hence, supercritical CO₂ has been shown to produce extracts with a natural aroma free from chemical alterations induced by heat and water, and without solvent residues and undesirable compounds such as organic and inorganic salt, sugars, amino acids, and tannins (Danh et al. 2013).

Fennel (*Foeniculum vulgare* Mill.) and anise (*Pimpinella anisum* L.) are important members of the Apiaceae family. Recently, much attention has been focused on these species due to the nutritional and health protective value of their seeds. They are a source of healthy promoting compounds as minerals, vitamins, phenolic compounds, and volatile oils (Bettaieb Rebey et al. 2018; Miguel et al. 2010). Moreover, they contain a noticeable yield of oils ranging from 11% in anise (Kozłowska et al. 2016; Bettaieb Rebey et al. 2018) to 13% in fennel, which are rich on monounsaturated fatty acids including oleic and petroselinic ones. Publications in the literature had reported oil extraction from anise and fennel seeds by organic solvent n-hexane (Bettaieb Rebey et al. 2016, 2018) and by SC-CO₂ (Simándi et al. 1999; Moura et al. 2005; Shokri et al. 2011). However, there are no data about oil extraction from these two seeds using an agro-solvent as MeTHF.

Thus, the aim of the study was to obtain anise and fennel oil using MeTHF and supercritical carbon dioxide technique. The Soxhlet technique using n-hexane as the solvent and the Folch method were applied to obtain oils that were used for comparison purposes. In addition, the oil samples obtained were analyzed for their oil yield, fatty acid composition, sterol composition, antioxidant activity, and oxidative stability.

Materials and Methods

Plant Material

Fennel (*Foeniculum vulgare* Mill) and anise (*Pimpinella anisum* L.) seeds were harvested in June 2016, from Korba region in the northeastern part of Tunisia; latitude 36340 38.22" (N); longitude 10510 29.63" (E) and the altitude is 637 m. The precipitation average was 400–500 mm/year and the monthly average temperature was 17.7 ± 2 °C. Plants were identified by the botanist of the Biotechnology Center of Borj-Cedria (CBBC). A voucher specimen was deposited at the

herbarium of the Laboratory of Bioactive Substances at CBBC under the “BC2011-2000” and “BC2011-2002” numbers, respectively, for fennel and anise seeds. Both seeds were air-dried at room temperature until constant weight. After drying, seeds were placed in dark glass bottles and stored in a refrigerator (Fisher Isotemp brand, USA) at 4 °C until use for further analysis.

Seed Oil Extraction

Soxhlet Extraction

Harvested seeds were finely grounded with a type A10 blade-carbide grinding (Ika-Werk, Staufen, Germany) and 30 g of a powdered sample were weighted in a 30 mm × 100 mm cellulose thimble (Schleicher and Schuele) and were placed in the extraction chamber of a 125-mL Soxhlet apparatus (type Gerhardt) fitted with a condenser, which was placed on a 500-mL distillation flask containing 250 mL of the solvent. Samples were extracted under reflux with n-hexane and MeTHF during 8 h at 85 °C. After extraction, solvents were evaporated under reduced pressure, using a rotary evaporator (Labobase/Laborota 4000 Heidolph WB/G4-intensive condenser) at 45 °C. The dried residues were weighed and oils were aliquoted in vials and stored at 4 °C until analysis. Oil content was determined as a percentage of the mass of lipids (g) obtained after extraction relative to the weight of dry sample (g) used for extraction.

Folch Method

Thirty grams of ground powdered plant seeds were extracted with 300 mL of a chloroform/methanol (2/1, (v/v)) solution at room temperature under shaking for 2 h (Folch et al. 1957). Then, the mixture was filtered through Whatman No. 1 paper filter into a separatory funnel and a 1 M KCl solution (70 mL) was added. After gentle manual shaking, the mixture was left overnight for separation into two phases. The lower phase was collected and solvents were evaporated under reduced pressure at 40 °C (Rotavapor R-215, Büchi Labortechnik, Switzerland). The extracted oil was weighed and flushed with nitrogen, and stored in a freezer (Thermo Fisher Scientific brand, USA) at –20 °C until further analysis.

SC-CO₂

Oil was extracted from fennel and anise seeds with pilot-scale equipment (Separex, France), using SC-CO₂, as previously described by Koubaa et al. (2015) with slight modifications. The extracted oil was maintained at 200 bars pressure and 40 °C temperature. The extraction time was fixed to 180 min under a continuous flux of CO₂ (14 mL/min), for all experiments. After finishing the extraction processes, total

151 extraction yields (Y) were measured. Obtained extracts were
152 transferred into the glass bottles, sealed and stored in a freezer
153 (Thermo Fisher Scientific brand, USA) at $-20\text{ }^{\circ}\text{C}$ to prevent
154 any possible degradation of extract components until analysis.

155 Fatty Acid Analysis

156 Fatty acid composition was analyzed by gas chromatog-
157 raphy (GC) after derivatization to fatty acid methyl est-
158 ters (FAMES) with a 2 M methanolic solution of potas-
159 sium hydroxide (Cecchi et al. 1985). FAMES were ana-
160 lyzed by gas chromatography using a Hewlett-Packard
161 6890 chromatograph (Agilent Technologies, Palo Alto,
162 CA, USA) equipped with a flame-ionization detector
163 (FID) and an electronic pressure control (EPC) injector.
164 They were separated on a RT-2560 capillary column
165 (100 m length, 0.25 mm i.d., 0.20 mm film thickness).
166 The oven temperature was kept at $170\text{ }^{\circ}\text{C}$ for 2 min,
167 followed by a $3\text{ }^{\circ}\text{C min}^{-1}$ ramp to $240\text{ }^{\circ}\text{C}$ and finally
168 held there for an additional 15 min period. Nitrogen (U)
169 was used as a carrier gas at a flow rate of
170 1.2 mL min^{-1} . The injector and detector temperatures
171 were maintained at $225\text{ }^{\circ}\text{C}$. Individual fatty acids were
172 identified by comparing their retention times with a cer-
173 tified fatty acid methyl esters (FAME) mix and
174 quantified as a percentage of the total fatty acids.

175 Sterol Analysis

176 The content and composition of the sterols were deter-
177 mined by GC following the procedure described by
178 AOCS (1997) Official Method. Each seed oil (50 mg)
179 was saponified with 1 M KOH in methanol for 18 h at
180 room temperature, then water was added and the
181 unsaponifiables were extracted six times with n-hex-
182 ane/methyl tert-butyl ether (1:1, v/v). The solvent was
183 evaporated at ambient temperature under a stream of
184 nitrogen. Dry residues were dissolved in 0.2 mL pyri-
185 dine and silylated with 0.8 mL of Sylon BTZ (Supelco,
186 Bellefonte, PA, USA). Sterol derivatives were separated
187 on a Trace GC Ultra equipped with DB-35MS capillary
188 column. A sample of $1.0\text{ }\mu\text{L}$ was injected in a splitless
189 mode with an injection time of 5 min. The column
190 temperature was held at $100\text{ }^{\circ}\text{C}$ for 5 min, then in-
191 creased to $250\text{ }^{\circ}\text{C}$ at a rate of $25\text{ }^{\circ}\text{C/min}$, held for
192 1 min, then further increased to $290\text{ }^{\circ}\text{C}$ at a rate of
193 $3\text{ }^{\circ}\text{C/min}$ and held for 20 min. The detector temperature
194 was set at $300\text{ }^{\circ}\text{C}$. Hydrogen was used as a carrier gas
195 at a flow rate of 1.5 mL/min . Sterols were identified by
196 comparing their retention times with those of commer-
197 cially available standards and results were expressed as
198 milligram per gram (mg/g) of oil.

Total Phenolic Content Determination

199

Phenolic compounds of seeds were extracted by 200
methanol-water solution and determined by Folin- 201
Ciocalteu method described by Liu et al. (2012). In 202
5 mL hexane, 2.5 g of oil was dissolved and extraction 203
was carried out by methanol-water solution (80:20% 204
v/v). The aqueous phase was collected by centrifugation 205
(Heraeus Labofuge 200 Centrifuge) at 3500 rpm for 206
5 min, followed by rotary vacuum drying (RE-2000 207
Model, China) at least than $40\text{ }^{\circ}\text{C}$ and reduced pressure 208
to dryness. Dried sample was dehydrated in 5 mL of 209
methanol solution and was mixed with 2.5 mL of Folin 210
reagent and 10 mL of sodium carbonate solution in 211
50 mL volumetric flask and was adjusted to volume 212
with deionized water. The absorbance was evaluated at 213
 765 nm after 30 min (Ultrospec 7000 Spectrophotometer 214
UV-Vis). Gallic acid was used for calibration and the 215
results were expressed as milligram (mg) gallic acid 216
equivalent per 100 g of oil samples. Six replicate tests 217
were performed for each sample. 218

Measurement of Antioxidant Activity (DPPH Assay)

219

The antioxidant activity of the methanolic extracts of 220
seed oils and seed oil samples was determined using 221
DPPH radicals as described by Kiralan et al. (2009), 222
with some modifications. Of each methanolic extract 223
of seed oils, 0.5 mL was diluted with 3.25 mL of meth- 224
anol, and then 0.25 mL of 1 mM methanolic solution of 225
DPPH was added. The mixture was vigorously mixed 226
for 10 s in a vortex apparatus and left in darkness for 227
10 min. The absorbance was measured at 515 nm 228
against pure methanol using a UV/Vis spectrophotome- 229
ter. The radical scavenging activity was expressed as 230
Trolox equivalent antioxidant capacity (TEAC) using a 231
Trolox calibration curve (1mol TEAC/g of oil). 232

Oxidative Stability

233

Oxidative stability of anise and fennel seed oils was measured 234
by Rancimat (Metrohm Rancimat; Metrohm, Riverview, FL, 235
USA), based on the method of Tabee et al. (2008). 236

Statistical Analysis

237

All results were reported as means \pm standard deviation (SD) 238
of six replicates. Duncan's test ($p < 0.05$) was performed to 239
determine significant differences among means of six inde- 240
pendent experiments. 241

242 **Results and Discussion**

243 **Seed Oil Extraction**

244 The seed oil yield mainly depends on which method and sol- 277
 245 vent were used to recover oil. As can be seen in Fig. 1, Soxhlet 278
 246 with n-hexane and Folch methods have been substituted by 279
 247 alternative solvent (MeTHF) and SC-CO₂ method in order to 280
 248 compare their oil recovery performances. Indeed, aniseeds 281
 249 yielded the highest amount of oil using Folch (24.07%) and 282
 250 MeTHF (23.65%) extraction methods whereas fennel seeds 283
 251 had 20.02% and 18.72%, respectively. The result obtained 284
 252 for aniseed oil yield extracted by n-hexane (16.87%) was 285
 253 higher than that reported by Kozłowska et al. (2016) in the 286
 254 case of Poland aniseeds (9.03%) and Bettaieb Rebey et al. 287
 255 (2018) for Tunisian (11.60%) and Egyptian (9.82%) aniseeds. 288
 256 These dissimilarities may be mainly attributed to the geo- 289
 257 graphic origin and the genera of seeds (Kozłowska et al. 290
 258 2016). On the other hand, our results were in line with those 291
 259 obtained by Sayed Ahmad et al. (2018) who reported a vege- 292
 260 table oil content of 19.80% in fennel seeds after cyclohexane 293
 261 extraction. 294

262 Comparing the extraction methods, in our study, there were 295
 263 significant differences regarding their extraction yields 296
 264 ($p < 0.05$). Thus, conventional Folch and Soxhlet methods 297
 265 using MeTHF as a solvent deliver significantly higher yields 298
 266 than the other two methods ($p < 0.05$). Hence, Soxhlet method 299
 267 using MeTHF as solvent, proposed in this work as a preferable 300
 268 method, besides of being an environmentally friendly alterna- 301
 269 tive, allowed to obtain one of the better oil yields in anise and 302
 270 fennel seeds. This was in good agreement with Breil et al. 303
 271 (2016) who stated that bio-based solvents could be an alterna- 304
 272 tive to petrochemical solvents. 305

273 What's more, the oil yield of these two seeds found by n- 306
 274 hexane was compared with that obtained by SC-CO₂. Thus, 307
 275 even though obtaining almost the same oil yield, SC-CO₂ 308
 276 extraction has offered many privileges compared with 309

conventional hexane extraction. As a matter of fact, with hex- 277
 ane, a mixture of oil–hexane was achieved. Hexane should 278
 then be evaporated which presented a risk of alteration of oil 279
 quality by oxidation (Mhemdi et al. 2011). In spite of, SC-CO₂ 280
 extraction permitted us to attain pure oil without residual or- 281
 ganic solvent traces, and thus any chemical changes due to the 282
 processing technique, which gave extract of outstanding qual- 283
 ity which is of large importance (Boutin and Badens 2009). In 284
 our study, the oil yield of anise and fennel seeds was procured 285
 when SC-CO₂ was carried out at 40 °C temperature, 200 bars+ 286
 pressure, and 180 min extraction time. According to our study, 287
 high pressures (200–300 bar) and low temperatures (30– 288
 40 °C) were used for oil extraction with SC-CO₂ from anise 289
 (Shokri et al. 2011) and fennel (Simándi et al. 1999; Moura 290
 et al. 2005) seeds. Similar findings were also observed in the 291
 case of SC-CO₂ oil extraction from borage (Molero Gómez 292
 and Martínez de la Ossa 2002) and rosehip (Salgin et al. 2016) 293
 seeds. So, high pressures were generally recommended to in- 294
 crease the solubility of oil in CO₂. However, the increase of 295
 the temperature generally resulted in the decrease of the ex- 296
 traction yield, due to the decrease of the solvents density, 297
 whose effect seemed to have dominated over the increase of 298
 the solute vapor pressure (Sovilj 2010; Shokri et al. 2011). 299
 Under these pressure and temperature conditions, extraction 300
 time was predicted to be 180 min as reported by Shokri et al. 301
 (2011). 302

303 **Fatty Acid Composition**

Vegetable oils are a mixture of mono-, di-, and triglycerides 304
 (97%) and other minor compounds with functional impor- 305
 tance, such as vitamins, sterols, pigments, carotenoids, to- 306
 copherols, free fatty acids, hydrocarbons, and others (Pereira 307
 et al. 2010). The fatty acid composition of oil is its most useful 308
 chemical property. In this context, fatty acid composition of 309
 the seed oils obtained using conventional and alternative 310
 methods is summarized in Table 1. Anise and fennel seed oils 311
 were characterized by the highest contribution of unsaturated 312
 fatty acid, whereas the saturated fatty acid content was the 313
 lowest in the two studied oil samples. 314

Regardless of the extraction method, petroselinic acid 315
 (C18:1Δ6) was the most prevalent fatty acid, 54.22–61.25% 316
 and 42.39–48.97%, respectively for fennel and anise seed oils. 317
 Hence, our results prove also that anise and fennel vegetable 318
 oils were mainly a source of petroselinic acid followed by 319
 oleic and linoleic acids, whereas the levels of other compo- 320
 nents were present with lower concentrations as reported by 321
 previous studies (Kozłowska et al. 2016; Bettaieb Rebey et al. 322
 2018; Sayed Ahmad et al. 2018). Typically, the major fatty 323Q4
 acid component in Apiaceae plant seed oils is petroselinic 324
 acid. 325

Pimpinella anisum L. and *Foeniculum vulgare* Mill. seed 326
 oils, belonging to the Apiaceae family, are considered among 327

Fig. 1 Oil yield of anise and fennel seeds obtained by different extraction methods. Values are means of six replications ($N = \pm 6$ SD). The data marked with different superscript letters (a–c) indicate significance at $p < 0.05$ (Duncan's test)

Table 1 Fatty acid composition (%) of anise and fennel seed oils obtained by different extraction methods

Fatty acids (%)		n-hexane	Folch	SC-CO ₂	MeTHF
C14:0	Fennel	0.09 ± 0.01 ^a	0.19 ± 0.02 ^a	–	–
	Anise	0.12 ± 0.01 ^a	0.22 ± 0.02 ^a	–	–

Myristic acid (C14:0), palmitic acid (C16:0), stearic acid (C18:0), petroselinic acid (C18:1 Δ6), oleic acid (C18:1 Δ9), linoleic acid (C18:2), linolenic acid (C18:3). MUFA, monounsaturated fatty acid; PUFA, polyunsaturated fatty acid; SFA, saturated fatty acid. Values are means of six replications (N = ± 6 SD). The data marked with different superscript letters in a row indicate significance at p < 0.05 (Duncan's test)

328 the highest natural source of petroselinic acid by several au-
 329 thors (Bettaieb Rebey et al. 2018; Sayed Ahmad et al. 2018)
 330 and has awakened a great interest as a natural source of this
 331 fatty acid. Thus, one of the main goals of this study was to
 332 evaluate if fennel and anise seed oils produced with alternative
 333 extraction methods have the same petroselinic acid composi-
 334 tion than traditionally extracted oils. As can be observed from
 335 Table 1, anise and fennel fatty acid profiles obtained from the
 336 different extraction methods were similar, nevertheless the
 337 statistical analysis showed few differences between them
 338 (p < 0.05). Comparable trends were also observed in the fatty
 339 acid composition of *Corylus avellana* (Bernardo-Gil et al.
 340 2002) and *Opuntia stricta* (Koubaa et al. 2016) seed oils as
 341 extracted by organic solvent (hexane) and SC-CO₂. Similarity
 342 in the fatty acid profile of SC-CO₂ and Soxhlet-extracted oils
 343 had been observed in *Sargassum hemiphyllum*, although the
 344 fatty acid composition of SC-CO₂-extracted oil had been re-
 345 ported to vary slightly with temperature and pressure (Cheung
 346 et al. 1998). However, Mariod et al. (2011) reported that the

fatty acid profiles of *Hibiscus cannabinus* seed oil did not
 change with pressure and temperature of SC-CO₂.

In our study, the proportion of the different fatty acids as
 well as the proportion of SFA, PUFA, or MUFA had not been
 changed by the new methods used in our experiment; in other
 words, the use of SC-CO₂ and MeTHF as solvents did not
 introduce extraneous effects in the composition of the extract-
 ed oils. As reported by Chemat et al. (2017), green extraction
 methods can be considered interesting alternative technologi-
 es for conventional methods.

In the main, fatty acid profiles obtained from anise and
 fennel seeds are considered ideal for edible oils, because of
 its high percentage of UFA and low percentage of SFA, indi-
 cating the possible use of these oils in food industry (Pereira
 et al. 2017). Besides, oils containing high amount of PUFA are
 generally used in cosmetics and pharmaceutical industries
 (Stupp et al. 2008). Moreover, a recent trend is the use of
 vegetable oils for biodiesel production, especially those de-
 rived from agro-industrial wastes (Malacrida and Jorge 2012).

366 **Sterol Content**

367 Phytosterol content of anise and fennel oils was investigated
 368 due to their roles in the reduction of blood LDL cholesterol
 369 content and hence, their potential to decrease the risk of car-
 370 diovascular diseases (Dong et al. 2016). Moreover, they can
 371 be considered valuable tools for oil ranking and primary in-
 372 dexes for identification of fraud in edible oils (Ribas et al.
 373 2017). As can be seen in Fig. 2, significant differences be-
 374 tween the total sterol content in fennel and anise oils extracted
 375 from seeds with conventional and alternative methods
 376 ($p < 0.05$). Indeed, the contribution of total sterols reached,
 377 interestingly, the highest amount in both fennel (4.64 mg/g
 378 of oil) and anise oil (3.85 mg/g of oil) extracted with SC-
 379 CO₂ method (Fig. 2). Besides, in fennel and anise oil extracted
 380 with the MeTHF, the total sterols content was about 1.5 times
 381 higher as compared with the Folch method. Eventually, sterol
 382 contents, of both seeds, obtained by MeTHF procedure were
 383 quite similar to those obtained by conventional extraction
 384 method using n-hexane as reference. Similarly, Sicaire et al.
 385 (2015) reported that rapeseed oil extracted with MeTHF was
 386 comparable with oil extracted with n-hexane in total sterol
 387 content. Mariod et al. (2011) showed that extraction of kenaf
 388 seed oil using SC-CO₂ at high temperature (80 °C) gave
 389 higher sterol amount when compared with hexane extraction.
 390 So, the content of sterol in oils could be affected by several
 391 experimental factors, namely temperature, pressure, time, type
 392 of solvent, and type of oil extraction method. In brief, SC-CO₂
 393 method, proposed in this work, besides being an environmen-
 394 tal friendly alternative, allowed to obtain the maximum sterol
 395 content in anise and fennel seed oils and there is a commer-
 396 cialization potential using this method.

397 The tested oil samples of our study were characterized by
 398 the presence of the following sterols: cholesterol, campesterol,
 399 stigmasterol, D⁷-campesterol, β-sitosterol, sitostanol, D⁵-
 400 avenasterol, and D⁷-avenasterol. The data is listed in
 401 Table 2. Cholesterol, an untypical sterol of plant lipids, was
 402 only detected in fennel oil at the level of 0.04–0.06 (mg/g oil).
 403 What's more, stigmasterol was present in the highest amount
 404 in fennel, regardless of extraction method. Therefore, oil ex-
 405 tracted from fennel seeds using SC-CO₂ method contained
 406 1.28 and 1.34 times higher amount of stigmasterol than that
 407 extracted with n-hexane and Folch method, respectively.
 408 Moreover, stigmasterol occurred in fennel seed oil obtained
 409 with MeTHF was 1.21 and 1.27 folds higher than that obtain-
 410 ed by the two conventional methods used in our study.
 411 Besides, the content of β-sitosterol, the most prevalent sterol
 412 in aniseed oil, ranged from 1.45 mg/g in oil extracted with
 413 Folch method to 2.38 and 1.97 mg/g in aniseed oil obtained
 414 by SC-CO₂ and MeTHF methods, respectively. The compa-
 415 rable amount of β-sitosterol in Polish anise seeds was
 416 reported by Kozłowska et al. (2016). They also found signif-
 417 icant content of stigmasterol in these seeds, which is in

Fig. 2 Sterol content (mg/g oil) of anise and fennel seeds obtained by different extraction methods. Values are means of six replications ($N = \pm 6$ SD). The data marked with different superscript letters (a–d) indicate significance at $p < 0.05$ (Duncan's test)

418 harmony with our research. Moreover, the highest content of
 419 campesterol was found in aniseed oil. Thus, Soxhlet with
 420 MeTHF gave an oil with the highest proportion of
 421 campesterol (1.34 mg/g oil) followed by SC-CO₂ method
 422 (1.19 mg/g oil). Ben khedir et al. (2017) reported that β-sitosterol,
 423 campesterol, cholesterol, and stigmasterol have oxida-
 424 tive, anti-inflammatory, and antimutagenic activities.

425 **Total Phenolic Content**

426 Phenols constitute one of the major groups of compounds
 427 acting as antioxidants and having different therapeutic and
 428 protective effects on human health (Sayed Ahmad et al.
 429 2018). The phenolic fraction of anise and fennel seed oils
 430 was isolated with methanol/water (80:20 v/v) as the case of
 431 black cumin, cumin (Ramadan et al. 2012), and grape
 432 (Konuskan et al. 2019) seed oils. In fact, the use of
 433 methanol/water (80:20 v/v) was reported as an efficient ex-
 434 traction solvent and it has been used in the official method of
 435 phenol determination from olive oil (Montedoro et al. 1992;
 436 Tasioula-Margari and Tsabolatidou 2015). In this study, the
 437 effect of oil extraction method on total phenolic contents
 438 (TPC) of anise and fennel seed oils was determined by
 439 Folin–Ciocalteu assay.

440 As reported in Table 3, anise and fennel seed oils extracted
 441 using MeTHF showed significantly higher TPC (2.43 and
 442 1.32 mg GA/g oil, respectively) than those extracted with
 443 hexane (1.94 and 0.93 mg GA/g oil, respectively), Folch
 444 (1.11 and 0.67 mg GA/g oil, respectively), and SC-CO₂
 445 (0.89 and 0.54 mg GA/g oil, respectively) methods
 446 ($p < 0.05$). Our results revealed that MeTHF solvent had better
 447 selectivity and gave oil with higher TPC than hexane and
 448 chloroform methanol (Folch method). Different results were
 449 obtained by Kozłowska et al. (2016) concerning TPC of
 450 Polish aniseed oil extracted by chloroform/methanol and
 451 hexane methods having 2.52 and 0.42 mg GA/g oil, respec-
 452 tively. Such differences could be explained by the effect of

453 origin, environmental conditions, and/or genetic factors on
 454 TPC of seed oils. Additionally, TPC of seed oils can be also
 455 affected by several experimental factors, namely temperature,
 456 pressure, time, type of solvent, and type of oil extraction meth-
 457 od. To the best of our knowledge, this study is the first that
 458 reports the comparison of TPC of oils seeds and especially
 459 those of fennel and anise extracted using conventional and
 460 alternative methods.

461 **Antioxidant Activity**

462 At present, most of the preservatives used by the food industry
 463 are artificial additives such as nitrates, sulfur dioxide, and
 464 benzoates. However, there is an increasing public concern
 465 over the use of artificial food additives and a growing demand
 466 for natural alternatives. Consequently, there is a constant de-
 467 mand in the food industry for natural food preservatives and
 468 antioxidant agents (Danh et al. 2013). In addition, consump-
 469 tion of foods rich in natural antioxidants has been reported to
 470 give protection against certain types of cancer and may also
 471 reduce the risk of cardiovascular and cerebrovascular events
 472 (Liu et al. 2009). Hence, the antioxidant ingredients and their
 473 health-related functionality and mechanism in the oil deserve
 474 further study. In this work, the fennel and anise seed oils

extracted by conventional and alternative methods were inves- 475
 476 tigated for their antioxidant activity through reduction of the
 477 DPPH free radicals. From Table 3, anise and fennel seed oils
 478 extracted with MeTHF exhibited the highest DPPH activity
 479 (5.04 and 9.23 μmol TEAC/g oil, respectively) followed by
 480 hexane (5.32 and 14.02 μmol TEAC/g oil, respectively),
 481 Folch (8.82 and 18.56 μmol TEAC/g oil, respectively), and
 482 SC-CO₂ (5.04 and 19.58 μmol TEAC/g oil, respectively).
 483 Such differential scavenging activities can be explained
 484 through the strongest ability of MeTHF solvent to extract
 485 the adequate bioactive compounds responsible of this potent
 486 antiradical activity. In fact, solvents may influence the antiox-
 487 idant activity of samples because they may affect the
 488 hydrogen-donating ability of antioxidants. Moreover, accord-
 489 ing to the “polar paradox” theory, polar antioxidants are more
 490 effective in the lipophilic media, while nonpolar antioxidants
 491 are more active in the polar media (Ramadan and Moersel
 492 2006). Additionally, our findings pointed out a linear and pos-
 493 itive correlation between phenol content and antioxidant ac-
 494 tivity of both seed oils, which supported the hypothesis that
 495 phenolics could be the major contributors to efficient DPPH
 496 radical scavenging capacity of both seed oils especially ex-
 497 tracted by MeTHF solvent. In fact, anise and fennel seed oils,
 498 extracted by the green solvent MeTHF, were found to

499 represent eventually a strong electron donor and could react
500 with free radicals to convert them to more stable products and
501 terminate the radical chain reaction (Koubaa et al. 2017).

502 **Oxidative Stability**

503 Oxidative stability (OS) is a very important parameter
504 once it gives a good perception and estimation of the
505 susceptibility to oxidation process (Malheiro et al.
506 2013). In our study, OS of fennel and aniseed oils
507 was analyzed by Rancimat, where the ability of oil to
508 resist peroxidation was measured as the induction period
509 (Holser 2003). OS can be considered a valuable tool for
510 oil ranking and a primary index for identification of
511 fraud in edible oils. The values of induction period in
512 aniseed oils were 10.15, 7.45, 5.26, and 3.02 h, respec-
513 tively, for MeTHF, n-hexane, Folch, and SC-CO₂ ex-
514 tracted oils. A similar trend was observed in fennel seed
515 oil that was extracted by these four extraction processes.
516 For both seed oils, the oxidative stability of MeTHF-
517 extracted oil was higher than three other samples and
518 indicated significant differences with them ($p < 0.05$).
519 The higher oil stability may be attributed to the higher
520 value of TPC and antioxidant activity of MeTHF-
521 extracted oil. Enhancement of oil oxidative stability
522 due to MeTHF extraction was reported for the first time
523 in Apiaceae seeds.

524 **Conclusion**

525 In the course of time, green solvents and technologies
526 are in great demand because of environmental, health,
527 and energy issues. It is inevitable to develop a novel
528 green technology for the oil extraction from various
529 seed oils. As each seed oil comprises of different archi-
530 tecture, the process needs to look for suitability of tech-
531 nology in economic and technical ways. In this study,
532 the production of anise and fennel seed oils was pro-
533 nounced by using Folch (24.07% and 20.02%, respec-
534 tively) and MeTHF (23.65% and 18.72%, respectively)
535 extraction techniques. Fatty acid profiles of both seed
536 oils obtained by the four extraction methods were com-
537 parable with the predominance of petroselinic acid
538 (42.39–61.25%). SC-CO₂ method allowed to obtain the
539 maximum of sterol content in anise (3.85 mg/g of oil)
540 and fennel (4.64 mg/g of oil) seed oils. Concerning
541 MeTHF solvent, it recovered more bioactive compounds
542 as phenolics (2.43 mg GA/g oil in anise and 1.32 mg
543 GA/g oil in fennel) as well as enhanced the antioxidant
544 activity (9.23 μmol TEAC/g oil in anise and 5.04 μmol
545 TEAC/g oil in fennel) and the oxidative stability (8.23 h
546 in anise and 10.15 h in fennel). Additionally, this bio-

based MeTHF solvent derived from a renewable source 547
has lower toxicity allowing it to be selected as a poten- 548
tial alternative of conventional solvents to practice in 549
our further experimental studies and in pharmaceutical 550
chemical processes. 551

AUTHOR QUERIES

AUTHOR PLEASE ANSWER ALL QUERIES.

- Q1. Please confirm if the author names are presented accurately and in the correct sequence (given name, middle name/initial, family name).
- Q2. Please check if the affiliations are presented correctly.
- Q3. Ref. "Moura et al. 2005" is cited in the body but its bibliographic information is missing. Kindly provide its bibliographic information in the list.
- Q4. "Typical of the Apiaceae plant is that the major fatty acid component...." was modified. Please check if appropriate.
- Q5. Reference [Chatterjee et al, 2012] was provided in the reference list; however, this was not mentioned or cited in the manuscript. As a rule, all references given in the list of references should be cited in the main body. Please provide its citation in the body text.
- Q6. Please provide complete bibliographic details of this reference: AOCS, Official Method Ch 6–91 (1997).
