#### Abstract

A proof of a conjecture advanced in [1] is presented.

In [1], a system of equations similar to the following was looked at

$$
\begin{gather*}
\frac{\partial C}{\partial t}=-\gamma C-\boldsymbol{\nabla} \cdot(\boldsymbol{u} C-\boldsymbol{K} \cdot \boldsymbol{\nabla} C)  \tag{1}\\
\frac{\partial \alpha}{\partial t}=-\gamma \alpha+C-\boldsymbol{\nabla} \cdot(\boldsymbol{u} \alpha-\boldsymbol{K} \cdot \boldsymbol{\nabla} \alpha) \tag{2}
\end{gather*}
$$

Equation (1) can be written in compact notation as

$$
\begin{equation*}
\mathcal{L}[C]=0 \tag{3}
\end{equation*}
$$

with the linear operator [ $L$ ] being

$$
\begin{equation*}
\mathcal{L}[\cdot]=\frac{\partial \cdot}{\partial t}+\gamma \cdot+\boldsymbol{\nabla} \cdot(\boldsymbol{u} \cdot-\boldsymbol{K} \cdot \boldsymbol{\nabla} \cdot) \tag{4}
\end{equation*}
$$

Equation (1) describe thus how a tracer concentration $C$ is transported in a domain $\Omega$ by a divergence-free velocity field $\boldsymbol{u}$ over time $t$ with a diffusion modelled using a positive-defined symmetric
diffusivity tensor $\boldsymbol{K}$. A linear decay term with decay rate $\gamma \geq 0$ is also included. All parameters might change with time $t$ and position $\mathbf{x}$ as long as the governing equations remain linear for $C$ and $\alpha$.

Usual boundary conditions are prescribed with zero fluxes in the normal direction $\boldsymbol{n}$ to impermeable boundaries $\Gamma^{i}$ :

$$
\begin{array}{ll}
{[\boldsymbol{K} \cdot \boldsymbol{\nabla} C] \cdot \boldsymbol{n}=0} & \mathrm{x} \text { on } \Gamma^{i} \\
{[\boldsymbol{K} \cdot \boldsymbol{\nabla} \alpha] \cdot \boldsymbol{n}=0} & \mathrm{x} \text { on } \Gamma^{i} \tag{6}
\end{array}
$$

At the departure boundary $\Gamma^{\text {dep }}$, zero values for $\alpha$ and unit values for concentration $C$ where used in the original problem, but we replace it by using a Robin condition with a piston velocity $\chi^{d e p}$ assumed to be a constant here:

$$
\begin{gather*}
{[\boldsymbol{K} \cdot \boldsymbol{\nabla} C] \cdot \boldsymbol{n}=\chi^{d e p}\left(C^{d e p}-C\right) \quad \text { on } \Gamma^{d e p}}  \tag{7}\\
{[\boldsymbol{K} \cdot \boldsymbol{\nabla} \alpha] \cdot \boldsymbol{n}=\chi^{d e p}(0-\alpha) \quad \text { on } \Gamma^{d e p}} \tag{8}
\end{gather*}
$$

We can recover the original case by using $\chi^{d e p} \rightarrow \infty$ and $C^{d e p}=1$.
At the arrival boundary $\Gamma^{a r r}$ we also use a general Robin condition but nudging the concentration and age concentration towards zero with constant piston velocity $\chi^{\text {arr }}$

$$
\begin{array}{ll}
{[\boldsymbol{K} \cdot \boldsymbol{\nabla} C] \cdot \boldsymbol{n}=\chi^{a r r}(0-C)} & \text { on } \Gamma^{a r r} \\
{[\boldsymbol{K} \cdot \boldsymbol{\nabla} \alpha] \cdot \boldsymbol{n}=\chi^{\operatorname{arr}}(0-\alpha)} & \text { on } \Gamma^{a r r} \tag{10}
\end{array}
$$

The present set of equations is a slight generalization of the problem posed in [1] in the sense that a linear decay term was added (so we can retrieve the original set by letting $\gamma=0$ ) and that the Dirichlet conditions or Neumann conditions are replaced by a Robin condition. We recover the Dirichlet condition if $\chi^{\text {arr }} \rightarrow \infty$. For a zero gradient condition $\chi^{\text {arr }}=0$. As in [1], zero initial conditions on $C$ and $\alpha$ are applied.

We take the usual definitions of age $a$, concentration $C$ and age concentration $\alpha$ as presented in the CART framework (www.climate. be/cart) such that $\alpha=a C$.

The conjecture to be proven is that the age for Dirichlet conditions at the arrival boundary $\Gamma^{a r r}$ is lower than the one for zero gradient conditions, a conjecture which is generalized here to

$$
\begin{equation*}
\frac{\partial a}{\partial \chi^{a r r}} \leq 0 \tag{11}
\end{equation*}
$$

## 1 Green-function approach

$\mathcal{G}\left(t, \mathbf{x} ; t^{\prime}, \mathbf{x}^{\prime}\right)$ is Green function defined by the solution of the following problem:

$$
\begin{gather*}
\mathcal{L}\left[\mathcal{G}\left(t, \mathbf{x} ; t^{\prime}, \mathbf{x}^{\prime}\right)\right]=\delta\left(t-t^{\prime}\right) \delta\left(\mathbf{x}-\mathbf{x}^{\prime}\right)  \tag{12}\\
{\left[\boldsymbol{K} \cdot \boldsymbol{\nabla} \mathcal{G}\left(t, \mathbf{x} ; t^{\prime}, \mathbf{x}^{\prime}\right)\right] \cdot \boldsymbol{n}=0 \quad \mathbf{x} \text { on } \Gamma^{i}} \tag{13}
\end{gather*}
$$

$$
\begin{array}{cc}
{\left[\boldsymbol{K} \cdot \boldsymbol{\nabla} \mathcal{G}\left(t, \mathbf{x} ; t^{\prime}, \mathbf{x}^{\prime}\right)\right] \cdot \boldsymbol{n}=-\chi^{a r r} \mathcal{G}\left(t, \mathbf{x} ; t^{\prime}, \mathbf{x}^{\prime}\right)} & \mathbf{x} \text { on } \Gamma^{a r r} \\
{\left[\boldsymbol{K} \cdot \boldsymbol{\nabla} \mathcal{G}\left(t, \mathbf{x} ; t^{\prime}, \mathbf{x}^{\prime}\right)\right] \cdot \boldsymbol{n}=-\chi^{d e p} \mathcal{G}\left(t, \mathbf{x} ; t^{\prime}, \mathbf{x}^{\prime}\right)} & \mathbf{x} \text { on } \Gamma^{d e p} \\
\mathcal{G}\left(0, \mathbf{x} ; t^{\prime}, \mathbf{x}^{\prime}\right)=0 & \tag{16}
\end{array}
$$

where the Dirac function is noted $\delta()$. It can be shown that (for a positive-defined diffusivity tensor as we assumed in the problem definition) $\mathcal{G}\left(t, \mathbf{x} ; t^{\prime}, \mathbf{x}^{\prime}\right) \geq 0$ and that for zero initial concentration $C$ we have

$$
\begin{equation*}
C(t, \mathbf{x})=\int_{0}^{t} \int_{\Gamma^{d e p}} \mathcal{G}\left(t, \mathbf{x} ; t^{\prime}, \mathbf{x}_{\mathbf{s}}^{\prime}\right) \chi^{d e p} C^{d e p}\left(t^{\prime}, \mathbf{x}_{\mathbf{s}}^{\prime}\right) \mathrm{d} \mathbf{x}_{\mathbf{s}}^{\prime} \mathrm{d} t^{\prime} \tag{17}
\end{equation*}
$$

Note that the Green's function defined also allows for contributions from inside the domain and therefore allows to calculate age concentration $\alpha$. The latter indeed satisfies the same equation as $C$, except that it has no non-homogeneous part in the boundary condition but has a "source" term $C$ in the domain $\Omega$. Hence the solution is simply the superposition of all contributions of these "sources" propagated by the Green's function and reads

$$
\begin{align*}
\alpha(t, \mathbf{x}) & =\int_{0}^{t} \int_{\Omega} \mathcal{G}\left(t, \mathbf{x} ; t^{\prime}, \mathbf{x}^{\prime}\right) C\left(t^{\prime}, \mathbf{x}^{\prime}\right) \mathrm{d} \mathbf{x}^{\prime} \mathrm{d} t^{\prime}  \tag{18}\\
& =\int_{0}^{t} \int_{0}^{t^{\prime}} \int_{\Omega} \int_{\Gamma^{d e p}} \mathcal{G}\left(t, \mathbf{x} ; t^{\prime}, \mathbf{x}^{\prime}\right) \mathcal{G}\left(t^{\prime}, \mathbf{x}^{\prime} ; t^{\prime \prime}, \mathbf{x}_{\mathbf{s}}^{\prime \prime}\right) \chi^{d e p} C^{d e p}\left(t^{\prime \prime}, \mathbf{x}_{\mathbf{s}}^{\prime \prime}\right) \mathrm{d} \mathbf{x}_{\mathbf{s}}^{\prime \prime} \mathrm{d} \mathbf{x}^{\prime} \mathrm{d} t^{\prime \prime} \mathrm{d} t^{\prime} \tag{19}
\end{align*}
$$

Later in the analysis we would like to check how the age-concentration changes when the piston velocity $\chi^{\text {arr }}$ is changed. Therefore, following the idea of [2], it is interesting to calculate the changes in the Green's function $\frac{\partial \mathcal{G}}{\partial \chi^{a r r}}$ noted $\mathcal{G}_{\chi}\left(t, \mathbf{x} ; t^{\prime}, \mathbf{x}^{\prime}\right)$. Deriving all equations for the Green's function with respect to this piston velocity, we see that it must obey

$$
\begin{gather*}
\mathcal{L}\left[\mathcal{G}_{\chi}\left(t, \mathbf{x} ; t^{\prime}, \mathbf{x}^{\prime}\right)\right]=\delta\left(t-t^{\prime}\right) \delta\left(\mathbf{x}-\mathbf{x}^{\prime}\right)  \tag{20}\\
{\left[\boldsymbol{K} \cdot \boldsymbol{\nabla} \mathcal{G}_{\chi}\left(t, \mathbf{x} ; t^{\prime}, \mathbf{x}^{\prime}\right)\right] \cdot \boldsymbol{n}=0 \quad \mathbf{x} \text { on } \Gamma^{i}}  \tag{21}\\
{\left[\boldsymbol{K} \cdot \boldsymbol{\nabla} \mathcal{G}_{\chi}\left(t, \mathbf{x} ; t^{\prime}, \mathbf{x}^{\prime}\right)\right] \cdot \boldsymbol{n}=-\chi^{d e p} \mathcal{G}_{\chi}\left(t, \mathbf{x} ; t^{\prime}, \mathbf{x}^{\prime}\right) \quad \mathbf{x} \text { on } \Gamma^{d e p}}  \tag{22}\\
{\left[\boldsymbol{K} \cdot \boldsymbol{\nabla} \mathcal{G}_{\chi}\left(t, \mathbf{x} ; t^{\prime}, \mathbf{x}^{\prime}\right)\right] \cdot \boldsymbol{n}=-\chi^{a r r} \mathcal{G}_{\chi}\left(t, \mathbf{x} ; t^{\prime}, \mathbf{x}^{\prime}\right)-\mathcal{G}\left(t, \mathbf{x} ; t^{\prime}, \mathbf{x}^{\prime}\right) \quad \mathbf{x} \text { on } \Gamma^{a r r}}  \tag{23}\\
\mathcal{G}_{\chi}\left(t, \mathbf{x} ; t^{\prime}, \mathbf{x}^{\prime}\right)=0 \tag{24}
\end{gather*}
$$

i.e. again the same set of equations as the problem on $C$, except for a "source" term $-\mathcal{G}\left(t, \mathbf{x} ; t^{\prime}, \mathbf{x}^{\prime}\right)$ on the boundary $\Gamma^{a r r}$ instead of the departure boundary. Hence the solution has the same structure as (17) but where $\chi^{\text {dep }} C^{d e p}$ is replaced by $-\mathcal{G}\left(t, \mathbf{x} ; t^{\prime}, \mathbf{x}^{\prime}\right)$ and integration is done on the arrival boundary

$$
\begin{equation*}
\frac{\partial \mathcal{G}}{\partial \chi}=\mathcal{G}_{\chi}\left(t, \mathrm{x} ; t^{\prime}, \mathbf{x}^{\prime}\right)=-\int_{0}^{t} \int_{\Gamma^{a r r}} \mathcal{G}\left(t, \mathbf{x} ; t^{\prime \prime}, \mathbf{x}_{\mathbf{s}}^{\prime \prime}\right) \mathcal{G}\left(t^{\prime \prime}, \mathbf{x}_{\mathbf{s}}^{\prime \prime} ; t^{\prime}, \mathbf{x}^{\prime}\right) \mathrm{d} \mathbf{x}_{\mathbf{s}}^{\prime \prime} \mathrm{d} t^{\prime \prime} \quad \leq 0 \tag{25}
\end{equation*}
$$

We are now ready to proceed to the demonstration. First we rewrite the age $a$ as

$$
\begin{equation*}
a=\frac{\alpha}{C}=\frac{\alpha / \chi^{d e p}}{C / \chi^{d e p}}=\frac{\tilde{\alpha}}{\tilde{C}} \tag{26}
\end{equation*}
$$

with

$$
\begin{gather*}
\tilde{C}(t, \mathbf{x})=\int_{0}^{t} \int_{\Gamma^{d e p}} \mathcal{G}\left(t, \mathbf{x} ; t^{\prime}, \mathbf{x}_{\mathbf{s}}^{\prime}\right) C^{d e p}\left(t^{\prime}, \mathbf{x}_{\mathbf{s}}^{\prime}\right) \mathrm{d} \mathbf{x}_{\mathbf{s}}^{\prime} \mathrm{d} t^{\prime}  \tag{27}\\
\tilde{\alpha}(t, \mathbf{x})=\int_{0}^{t} \int_{\Omega} \mathcal{G}\left(t, \mathbf{x} ; t^{\prime}, \mathbf{x}^{\prime}\right) \tilde{C}\left(t^{\prime}, \mathbf{x}^{\prime}\right) \mathrm{d} \mathbf{x}^{\prime} \mathrm{d} t^{\prime}  \tag{28}\\
=\int_{0}^{t} \int_{0}^{t^{\prime}} \int_{\Omega} \int_{\Gamma^{d e p}} \mathcal{G}\left(t, \mathbf{x} ; t^{\prime}, \mathbf{x}^{\prime}\right) \mathcal{G}\left(t^{\prime}, \mathbf{x}^{\prime} ; t^{\prime \prime}, \mathbf{x}_{\mathbf{s}}^{\prime \prime}\right) C^{d e p}\left(t^{\prime \prime}, \mathbf{x}_{\mathbf{s}}^{\prime \prime}\right) \mathrm{d} \mathbf{x}_{\mathbf{s}}^{\prime \prime} \mathrm{d} \mathbf{x}^{\prime} \mathrm{d} t^{\prime \prime} \mathrm{d} t^{\prime} \tag{29}
\end{gather*}
$$

The conjecture $\frac{\partial a}{\partial \chi^{a r r}} \leq 0$ is true if

$$
\begin{equation*}
\tilde{C} \frac{\partial \tilde{\alpha}}{\partial \chi^{a r r}}-\tilde{\alpha} \frac{\partial \tilde{C}}{\partial \chi^{a r r}} \leq 0 \tag{30}
\end{equation*}
$$

or

$$
\begin{align*}
\int_{0}^{t} \int_{\Omega} \tilde{C}(t, \mathbf{x}) \mathcal{G}_{\chi}\left(t, \mathbf{x} ; t^{\prime}, \mathbf{x}^{\prime}\right) \tilde{C}\left(t^{\prime}, \mathbf{x}^{\prime}\right) \mathrm{d} \mathbf{x}^{\prime} \mathrm{d} t^{\prime} & +\int_{0}^{t} \int_{\Omega} \tilde{C}(t, \mathbf{x}) \mathcal{G}\left(t, \mathbf{x} ; t^{\prime}, \mathbf{x}^{\prime}\right) \frac{\partial \tilde{C}\left(t^{\prime}, \mathbf{x}^{\prime}\right)}{\partial \chi} \mathrm{d} \mathbf{x}^{\prime} \mathrm{d} t^{\prime} \\
& \leq \int_{0}^{t} \int_{\Omega} \frac{\partial \tilde{C}(t, \mathbf{x})}{\partial \chi} \mathcal{G}\left(t, \mathbf{x} ; t^{\prime}, \mathbf{x}^{\prime}\right) \tilde{C}\left(t^{\prime}, \mathbf{x}^{\prime}\right) \mathrm{d} \mathbf{x}^{\prime} \mathrm{d} t^{\prime} \tag{31}
\end{align*}
$$

All terms are negative, but there is a strong symmetry in terms 2 and term 3 which will be shown to cancel each other. Exploiting the expression (17) and (25) we can rewrite the inequality to prove as

$$
\begin{equation*}
\int_{0}^{t} \int_{\Gamma^{d e p}} \int_{0}^{t} \int_{0}^{t^{\prime}} \int_{\Omega} \int_{\Gamma^{d e p}}\left(\mathcal{H}_{1}+\mathcal{H}_{2}-\mathcal{H}_{3}\right) C^{d e p}\left(t^{\prime \prime \prime}, \mathbf{x}_{\mathbf{s}}^{\prime \prime \prime}\right) C^{d e p}\left(t^{\prime \prime}, \mathbf{x}_{\mathbf{s}}^{\prime \prime}\right) \mathrm{d} \mathbf{x}_{\mathrm{s}}^{\prime \prime} \mathrm{d} \mathbf{x}^{\prime} \mathrm{d} t^{\prime \prime} \mathrm{d} t^{\prime} \mathrm{d} \mathbf{x}_{\mathrm{s}}^{\prime \prime \prime} \mathrm{d} t^{\prime \prime \prime} \leq 0 \tag{32}
\end{equation*}
$$

$$
\begin{align*}
& \mathcal{H}_{1}=\mathcal{G}\left(t, \mathbf{x} ; t^{\prime \prime \prime}, \mathbf{x}_{\mathbf{\prime \prime}}^{\prime \prime \prime}\right) \mathcal{G}_{\chi}\left(t, \mathbf{x} ; t^{\prime}, \mathbf{x}^{\prime}\right) \mathcal{G}\left(t^{\prime}, \mathbf{x}^{\prime} ; t^{\prime \prime}, \mathbf{x}_{\mathbf{s}}^{\prime \prime}\right)  \tag{33}\\
& \mathcal{H}_{2}=\mathcal{G}\left(t, \mathbf{x} ; t^{\prime \prime \prime}, \mathbf{x}_{\mathbf{s}}^{\prime \prime \prime}\right) \mathcal{G}\left(t, \mathbf{x} ; t^{\prime}, \mathbf{x}^{\prime}\right) \mathcal{G}_{\chi}\left(t^{\prime}, \mathbf{x}^{\prime} ; t^{\prime \prime}, \mathbf{x}_{\mathbf{s}}^{\prime \prime}\right)  \tag{34}\\
& \mathcal{H}_{3}=\mathcal{G}_{\chi}\left(t, \mathbf{x} ; t^{\prime \prime \prime}, \mathbf{x}_{\mathbf{s}}^{\prime \prime}\right) \mathcal{G}\left(t, \mathbf{x} ; t^{\prime}, \mathbf{x}^{\prime}\right) \mathcal{G}\left(t^{\prime}, \mathbf{x}^{\prime} ; t^{\prime \prime}, \mathbf{x}_{\mathbf{s}}^{\prime \prime}\right) \tag{35}
\end{align*}
$$

and finally
$\int_{0}^{t} \int_{\Gamma^{d e p}} \int_{0}^{t} \int_{0}^{t^{\prime}} \int_{\Omega} \int_{\Gamma^{d e p}} \int_{0}^{t} \int_{\Gamma^{a r r}}\left(\mathcal{F}_{1}+\mathcal{F}_{2}-\mathcal{F}_{3}\right) C^{d e p}\left(t^{\prime \prime \prime}, \mathbf{x}_{\mathbf{s}}^{\prime \prime \prime}\right) C^{d e p}\left(t^{\prime \prime}, \mathbf{x}_{\mathbf{s}}^{\prime \prime \prime}\right) \mathrm{d} \mathbf{x}_{\mathbf{s}}^{\prime \prime \prime \prime} \mathrm{d} t^{\prime \prime \prime \prime} \mathrm{d} \mathbf{x}_{\mathbf{s}}^{\prime \prime} \mathrm{d} \mathbf{x}^{\prime} \mathrm{d} t^{\prime \prime} \mathrm{d} t^{\prime} \mathrm{d} \mathbf{x}_{\mathbf{s}}^{\prime \prime \prime} \mathrm{d} t^{\prime \prime \prime} \geq 0$

$$
\begin{align*}
& \mathcal{F}_{1}=\mathcal{G}\left(t, \mathbf{x} ; t^{\prime \prime \prime}, \mathbf{x}_{\mathbf{\prime}}^{\prime \prime \prime}\right) \mathcal{G}\left(t, \mathbf{x} ; t^{\prime \prime \prime \prime}, \mathbf{x}_{\mathbf{s}}^{\prime \prime \prime \prime}\right) \mathcal{G}\left(t^{\prime \prime \prime \prime}, \mathbf{x}_{\mathbf{\prime \prime \prime}}^{\prime \prime \prime} ; t^{\prime}, \mathbf{x}^{\prime}\right) \mathcal{G}\left(t^{\prime}, \mathbf{x}^{\prime} ; t^{\prime \prime}, \mathbf{x}_{\mathbf{s}}^{\prime \prime}\right)  \tag{37}\\
& \mathcal{F}_{2}=\mathcal{G}\left(t, \mathbf{x} ; t^{\prime \prime \prime}, \mathbf{x}_{\mathbf{s}}^{\prime \prime \prime}\right) \mathcal{G}\left(t, \mathbf{x} ; t^{\prime}, \mathbf{x}^{\prime}\right) \mathcal{G}\left(t^{\prime}, \mathbf{x}^{\prime} ; t^{\prime \prime \prime}, \mathbf{x}_{\mathbf{s}}^{\prime \prime \prime}\right) \mathcal{G}\left(t^{\prime \prime \prime}, \mathbf{x}_{\mathbf{s} \prime \prime \prime} ; t^{\prime \prime}, \mathbf{x}_{\mathbf{s}}^{\prime \prime}\right)  \tag{38}\\
& \mathcal{F}_{3}=\mathcal{G}\left(t, \mathbf{x} ; t^{\prime \prime \prime \prime}, \mathbf{x}_{\mathbf{s}}^{\prime \prime \prime \prime}\right) \mathcal{G}\left(t^{\prime \prime \prime \prime}, \mathbf{x}_{\mathbf{s}}^{\prime \prime \prime} ; t^{\prime \prime \prime}, \mathbf{x}_{\mathbf{s}}^{\prime \prime \prime}\right) \mathcal{G}\left(t, \mathbf{x} ; t^{\prime}, \mathbf{x}^{\prime}\right) \mathcal{G}\left(t^{\prime}, \mathbf{x}^{\prime} ; t^{\prime \prime}, \mathbf{x}_{\mathbf{s}}^{\prime \prime}\right) \tag{39}
\end{align*}
$$

For the integration of $\mathcal{F}_{2}$ we can exploit

$$
\begin{equation*}
\int_{\Omega} \mathcal{G}\left(t, \mathbf{x} ; t^{\prime}, \mathbf{x}^{\prime}\right) \mathcal{G}\left(t^{\prime}, \mathbf{x}^{\prime} ; t^{\prime \prime \prime \prime}, \mathbf{x}_{\mathbf{s}}^{\prime \prime \prime \prime}\right) \mathrm{d} \mathbf{x}^{\prime}=\mathcal{G}\left(t, \mathbf{x} ; t^{\prime \prime \prime \prime}, \mathbf{x}_{\mathrm{s}}^{\prime \prime \prime \prime}\right) \tag{40}
\end{equation*}
$$

meaning that the distribution at time $t$ and position $\mathbf{x}$ due to a Dirac at moment $t^{\prime \prime \prime \prime} \mathbf{x}_{\mathbf{s}}^{\prime \prime \prime \prime}$ can be obtained by looking what looks the solution at a later moment $t^{\prime}$ in any place of the domain $\mathbf{x}^{\prime}$, i.e. $\mathcal{G}\left(t^{\prime}, \mathbf{x}^{\prime} ; t^{\prime \prime \prime \prime}, \mathbf{x}_{\mathbf{s}}^{\prime \prime \prime \prime}\right)$ and calculate how this new "initial condition" would propagate to time $t$. Similarly for integration of $\mathcal{F}_{3}$ we can use

$$
\begin{equation*}
\int_{\Omega} \mathcal{G}\left(t, \mathbf{x} ; t^{\prime}, \mathbf{x}^{\prime}\right) \mathcal{G}\left(t^{\prime}, \mathbf{x}^{\prime} ; t^{\prime \prime}, \mathbf{x}_{\mathbf{s}}^{\prime \prime}\right) \mathrm{d} \mathbf{x}^{\prime}=\mathcal{G}\left(t, \mathbf{x} ; t^{\prime \prime}, \mathbf{x}_{\mathbf{s}}^{\prime \prime}\right) \tag{41}
\end{equation*}
$$

But then the remaining integrals of $\mathcal{F}_{2}$ and $\mathcal{F}_{3}$ are the same as the running parameters $t^{\prime \prime}, \mathbf{x}_{\mathrm{s}}^{\prime \prime}$ and $t^{\prime \prime \prime}, \mathbf{x}_{\mathbf{s}}^{\prime \prime \prime}$ (over the same boundary $\Gamma^{d e p}$ ) can be interchanged in one of them, yielding then the same expression for the integrals of $\mathcal{F}_{2}$ and $\mathcal{F}_{3}$.
Q.E.D.
