In order to investigate the role of coastal seas in the global carbon cycle, an intense field campaign has been carried out in the North Sea located at the NW European shelf. The partial pressure of CO₂ (pCO₂) and related parameters have been measured in the surface waters of the North Sea with high spatial and temporal resolution in all 4 seasons consecutively. The variability of the pCO₂ and the corresponding CO₂ air-sea fluxes will be investigated. Two biogeochemical regions can be identified in the North Sea, and the different control mechanisms such as biology, temperature, terrestrial inputs of the pCO₂ will be unraveled. The effects of climate change processes on the CO₂ air-sea fluxes will be assessed employing an ecosystem model for three different scenarios: increased temperature, increased CO₂ and increased temperature and CO₂.
