Introduction

The supporting information materials are following.

1. We show the polar projection of bright spots and the SIII longitude position after extrapolation to location that can be mapped by Vogt's mapping model.

:

2. The color ratio plot shows bright spot detected during PJ1 in high color ratio region.

3. We also show the power variation for PJ4 which has quasiperiodic behaviors as same as the PJ16 power variation plot (Figure 7.)

4. Based on period analysis using Lomb-Scargle periodogram method for bright spots during PJ4 and PJ16, the Lomb Normalized Periodogram will be presented.

Figure S1. Polar projections (Left: Northern, right: Southern) show positions of bright spots and local times according to Vogt's magnetic flux equivalent mapping with JRM09 model. The grid represents meridians and parallels in the SIII jovi-centric system, spaced every 10°. The two dash contours are the statistical locations of the main emission for the compressed and expanded cases (Bonfond, Gladstone, et al., 2017). The yellow asterisk represents the magnetic pole of each hemisphere (Bonfond, Saur, et al., 2017; Connerney et al., 2018). The lines represent the tracing paths from the magnetic pole to the bright spots' peak positions in the directions toward system III longitudes and latitudes, which can be mapped by Vogt's mapping model.(Vogt et al., 2011, 2015)

January 28, 2021, 1:06pm

Figure S2. The color ratio map observed from PJ1 shows the bright spots positions (plus symbols) in high color ratio region. The asterisk represents the magnetic pole. The grid coordinates and two dashed contours are the same as in figure S1.

Table S1. The bright spot characteristics observed during PJ1 to PJ25 are presented. The power is calculated from the total brightness in bright spot's elliptical area. This power is different from the power variation plot (Figure 7 and Figure S3) which is the integrated area corresponding to all bright spots detected during a perijove. The last two columns are mapped positions in magnetosphere and the local times from Vogt's magnetic flux equivalent using JRM09 model.

Figure S3. The power variation as a function of time for the southern bright spots during PJ4. The black arrows indicate the times that bright spots appear in UVS view. The red arrow presents the peak at which no bright spot appears but there is the increase in the brightness in the region of interest. The grey areas indicate times when the region of interest is covered by UVS view less than 50%.

Figure S4. Fitted result from Lomb-Scargle periodogram for PJ4 (top) and PJ16 (bottom). The dashed lines represent significant levels. The lower significant level implies the high probability for the period to be important. The highest peak of normalized power for PJ4 corresponds to period 28.18 minutes. In addition, for PJ16, the clearest peak of normalized power in our period range is 22.68 minutes.
