

## Report

## The Leiden-Turin Archaeological Expedition to Saqqara: Preliminary Results of the 2019 Fieldwork Season

Paolo Del Vesco, Christian Greco, Daniel Soliman, Nico Staring, and Lara Weiss

*With contributions by Valentina Gasperini, Alessandro Mandelli, Luca Perfetti, Corinna Rossi, Alice Salvador, Ali Jelene Scheers, Huw Twiston Davies, and Nicholas Warner*

In the 2019 season, the joint Leiden-Turin Expedition to Saqqara continued work in the area north of the tomb of Maya with the aim of lowering the terrain above the new tomb discovered during the 2018 season (V82.1) and to prepare the area for further exploration in 2020. Many layers of deposit situated immediately to the north of the new tomb were removed, and – although they mostly originated from previous excavations in the 1980s and 1990s – systematically investigated. Several dumps of organic material such as linen and wood as well as numerous small finds and relief fragments were identified and recorded. In addition, existing storage facilities on site were renovated and upgraded. In this process, part of the underground structures of the tombs of Horemheb and Meryneith were surveyed by the 3D Survey Group (Politecnico di Milano). Thanks to the cooperation with the same Milanese team, a new documentation method was tested during the ongoing excavation work. Within a 3D model the different stages of excavation were recorded, allowing the digital reconstruction of the stratigraphy of the whole area and the documentation of all finds in their original contexts. A Digital Surface Model of the entire concession area was also produced, and 3D models of some of the previously excavated monumental tombs were created. Lastly, since heavy rainfalls had damaged many of the earlier excavated monumental tombs open to the public, they were consolidated and where necessary rebuilt.

### ملخص

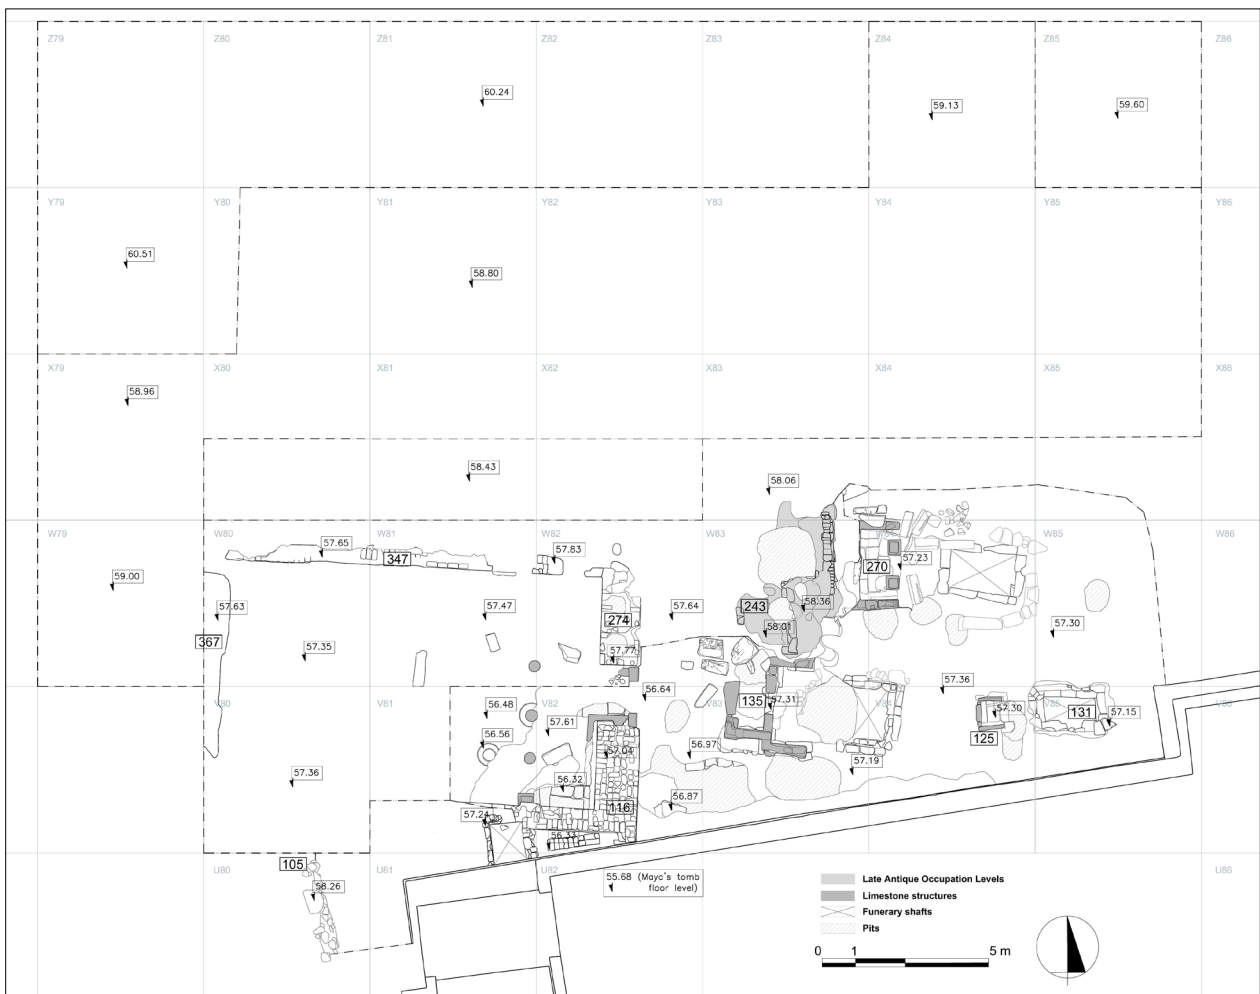

في موسم 2019، واصلت البعثة ليدن-تورينو والمشتركة عمله في سقارة في المنطقة شمال قبر ماي، بهدف إزالة الأتربة التي تراكمت فوق القبر الجديد الذي اكتشف خلال موسم 2018 (V82.1) وإعداد المنطقة لموسم التنقيب لعام 2020. تمت إزالة العديد من طبقات الأتربة التي تغطي المنطقة الشمالية من القبر الجديد، بالرغم من أن هذه الرواسب تراكمت في الغالب بموجبه الحفريات السابقة في التمانينيات والتسعينيات، فقد تمت دراستها بشكل منهجي. قامت البعثة بالتنقيب وبتسجيل العديد من المواد العضوية مثل الكتان والخشب وغيره من الشظايا واكتشافات أخرى صغيرة. كما أنه تم الكشف وتسجيل مرافق التخزين الموجودة في الموقع. من خلال هذه العملية، قام فريق الباحثين من الفرع التقني لجامعة ميلانو بمسح جزء من الهيكل تحت الأرض لمقابر حورمحب و مرينيث باستخدام الماسح ثلاثي الأبعاد. بفضل تعاون هذا الفريق، تم أثناء أعمال التنقيب اختبار طريقة جديدة في التوثيق. استناداً على النموذج ثلاثي الأبعاد، تم تسجيل مراحل التنقيب المختلفة مما سمح بإعادة البناء الرقمي للمنطقة بأكملها وتوثيق جميع الاكتشافات في أماكنها الأصلية. تم تنفيذ نموذج رقمي لكامل سطح المنطقة بالإضافة إلى إنشاء نماذج ثلاثية الأبعاد لبعض المقابر الأثرية التي نُقبت عنها سابقاً. وأخيراً، بما أن الأمطار الغزيرة ألحقت الضرر بالعديد من المقابر الأثرية المكتشفة سابقاً والمفتوحة لزيارة الجمهور، فقد تم تدعيمها وإعادة بناء الأقسام الضرورية.

# 1. Introduction

(Lara Weiss and Daniel Soliman)

During the 2019 season, between 16 March and 24 April, the Leiden-Turin Joint Expedition to Saqqara continued work in the northern sector of its concession area. In addition, the shaft and underground chambers of the tomb of Meryneith were surveyed. The staff consisted of Christian Greco and Lara Weiss (field directors), Paolo Del Vesco (archaeologist and deputy director), Miriam Müller (archaeologist), Daniel Soliman (epigrapher), Nico Staring (archaeologist), Corinna Rossi, Alessandro Mandelli and Luca Perfetti (surveyors), Barbara Aston and Valentina Gasperini (ceramicists), Stefanie Papenheim and Islam Taha (conservators), Nicola Dell'Aquila (photographer), Alice Salvador (illustrator), Lyla Pinch-Brock (artist), Nicholas Warner (architect), Ali Jelene Scheers (physical anthropologist), and Huw Twiston Davies (Egyptologist). The fieldwork benefited significantly from the kind collaboration of Dr Sabri

Farag (General Director of Saqqara) and Dr Hany el-Tayeb (Director of Saqqara) and the supervision of Dr Aiman Gamal (Chief Inspector), Dr Samir Shaheen (Director of Foreign Missions at Saqqara) and field inspector Mr Yousri Ali Abdel Azeem. The restoration of various limestone relief blocks found during the previous seasons as well as of those uncovered during the 2019 season was carefully completed under the supervision of the Head of Restoration, Ashraf Ashour Shaaban, and Ragab Turki of the Central Magazine. The joint expedition is very grateful to Prof Dr Khaled el-Anany (Minister of State of Antiquities), to Dr Nashwa Gaber (General Director of Foreign Missions) and to the Members of the Permanent Committee of the MSA for granting permissions, advice and assistance. As always, we are grateful to the mission's local agent Salah el-Deen Hasabalaa, the housekeepers and chefs of the Saqqara rest house, Atef Sayed Ramadan and Mahmoud Abu el Hassan Ahmed, and the more than thirty workmen, wa-

ter-carriers and pottery assistants,<sup>1</sup> without whose hard work the season would not have been possible. The excavations were generously sponsored by the Dutch Research Council (NWO).<sup>2</sup>

## 2. Preliminary report on the excavation

(Paolo Del Vesco and Nico Staring)

The excavated area lies in the northernmost sector of the concession, immediately to the north of the well-known Eighteenth Dynasty tomb of Maya (Fig. 1). This area, which has been the focus of the mission's fieldwork since 2017, was used by the former EES-Leiden archaeological expeditions during the late 1980s and early 1990s to dispose of sand and debris excavated from the tomb of Maya and its vicinity. As a result, a considerable spoil heap was formed. This mound of loose sand, several metres high, did not allow work to be continued on tomb V82.1<sup>3</sup>, the new structure found and partly excavated in 2018. Therefore, most of the 2019 season was spent gradually removing the spoil heaps and

preparing the area for exploration of the new tomb. The 2019 excavation extended over 26 grid squares (V80-82; W79-82; X79-83; Y-Z79-85, approx. 650 m<sup>2</sup>).

### 2.1 The modern spoil heaps

In order to better understand the formation of the high spoil heaps and relate it to the stratigraphic sequence recorded previously in the area stretching along the outer wall of the tomb of Maya, the decision was made to excavate the artificial mound as systematically and carefully as the timeframe of the fieldwork season allowed. A mixed system of regular arbitrary cuts, creating steps progressively sloping southward, and individual context recording was deemed to be the most cost- and time-effective approach. A number of horizontal terraces were gradually created, lowering the mound to the level of the highest preserved remains of the new tomb, at an average elevation of about 57.70 m ASL in squares W80-82. The highest part of the mound (60.90 m

ASL) was situated along the northern edge of the investigated area, in square Z85.

The upper deposits consisted of loose sand, mixed with conspicuous quantities of potsherds, bones, small to medium-sized limestone chips, fragments of mud-bricks, and modern materials, including pieces of rope and fabric, stamped red bricks, newspaper scraps, plastic packaging, and cigarette packets. Cigarettes (Figs. 2a-b) and newspapers, in particular, could be used to date the formation of the deposits. Thanks to them we were able, for instance, to assign the first arbitrary layer of 30-40 cm (immediately beneath the topsoil) to a timespan ranging between 1988 and 1994. Within this first artificial step, two well delimited contexts (321 and 323, Fig. 3) were identified and recorded in square Z85: they included concentrations of ancient materials (palm ribs, textile fragments, bone fragments, and pieces of painted wood coffins) mixed with fragments of plastic bags and palm leaf baskets. These contexts are clearly modern dumps of specific materials, most likely from the excavation of funerary deposits in the subterranean complex of the tomb of Maya, where the former EES-Leiden archaeological mission worked in 1988 (6 January–23 March).<sup>4</sup> The large, mostly sandy deposits of the first artificial layer within which the two dumps were found yielded numerous other objects, including Late Period shabti fragments and faience amulets, slipper-coffin pieces, and chips of relief-decorated limestone blocks.

In squares Y82-83 – at an elevation of 59.9 m ASL – newspaper scraps from 1987 were found (Fig. 4), suggesting that the associated deposits were formed during the corresponding fieldwork season of the EES-Leiden mission. This mission worked between 6 January and 16 March of that year in an area north of the tomb of Ramose in order to locate the aperture of the tomb shaft of Maya. During that season, most of Maya's tomb superstructure was unearthed, and this might explain the larger quantity of limestone and mud-brick fragments encountered at this level of the dump deposits. Carrying on the cutting of the arbitrary steps on the mound slope towards the south, in square Y84 (context 324) a newspaper scrap from 1986 was found. In that year (from

8 January to mid-March), the EES-Leiden mission excavated three tombs, investigating both their superstructures and their subterranean burial chambers: those of Khay, Pabes, and Ramose.<sup>5</sup> In these very loose deposits of sand and limestone flakes, a reed basket, comparable to those used by the workforce of the mission at the time, and another well delimited dump of funerary material were found. The modern dump pit included palm ribs and leaves, reed stems – some of which were still bound together by a rope and interwoven with palm leaves – textile fragments (incl. burnt ones), bones, Dutch-language newspaper scraps, pieces of plastered wood, a few potsherds, and some cotton wool. Although the main dumping area during the 1986 season lay west of the tomb of Ramose,<sup>6</sup> it is possible that part of the excavation debris was also carried further away to the north of that area, which was to be dug the following season in search of the superstructure of the tomb of Maya.

As became evident from the stratigraphic sequence visible in the east section of square Z85, the loose deposits encountered during the cutting of the higher artificial steps had gradually built up on top of a very compact mud surface (context 325), which is probably the topmost level of a mound of debris which already existed in the 1980s and is possibly visible in one of the plates of the final publication of the tomb of Ramose (Figs. 5a-b).

A second small mound (context 341), made of sand mixed with small limestone flakes and covered by a thick compacted surface sloping down from a maximum elevation of 59.60 m to a minimum of 58.90 m ASL, was identified in square X82. The absence of fragments of plastic bags and objects from the deposits sealed by the compact surface of these low mounds suggests that they belong among the humps that still characterise the landscape of Saqqara today. Such mounds were formed by indiscriminate ransacking of the necropolis, especially during the nineteenth century. The complex overlapping of these deposits and those deriving from more recent archaeological research has significantly altered the ancient funerary landscape and calls for more careful evaluations of the impact that present-day activities (such as archaeology and tourism) have on these often very vulnerable ancient sites. One way

to assess their effects, or to record new landscape modifications, is 3D photogrammetry, which allows the production of Digital Surface Models (Fig. 13) on which to plot, for instance, the exact location and progressive three-dimensional accretion of archaeological spoil heaps in the various dumping areas of a site.

## 2.2 A New Kingdom tomb north of Maya

In the 2018 fieldwork season, the remains of the entrance pylon of a new tomb, provisionally numbered V82.1, had been found north of the tomb of Maya.<sup>7</sup> During the current season, after gradual lowering of the loose deposits north of the tomb, we removed the dry-stone retaining wall which we had built in 2017 and extended in 2018. The upper part of the north mud-brick wall (context 347) of the new tomb, running east-west almost exactly along the edge of the W80-82 squares and preserved up to an elevation of 57.83 m ASL, could thus be exposed for its whole length of about 11.60 m. A loose sand deposit covered the top of this wall in square W80 (context 345), which contained mud-bricks (average dimensions: 26 x 14 x 8 cm) and small flakes

of limestone. Under it, a sequence of thin layers of sand, with limestone dust alternating with darker layers of sand mixed with mud-brick particles, was identified; it sloped down towards the south, right into what should have been the tomb courtyard. These layers very likely constitute the filling of one of the numerous large looting pits that were dug in this area during the nineteenth century. One should not forget that the centre of the courtyard of the new tomb lies less than 10 m away from the innermost porticoed courtyard of the tomb of Maya, which had already attracted a great deal of attention from antiquity-seekers before Lepsius partially cleared it in 1843.<sup>8</sup> The dispersal, over an area of 3 x 2.3 m, of limestone blocks mixed with mud-bricks (complete specimens measuring 26.5 x 13 x 7 cm), and pottery sherds in square V80 (context 348, ca. 57.95 m ASL, Fig. 6) almost certainly originated from one of these looting activities. One of the limestone fragments is inscribed on two sides, one of which mentions the god Re-Horakhty (find no. R66). Among the other objects recovered from this context, four fragments of a stone canopic jar (find no. F387) stand out. Under a somewhat compact deposit of wind-blown

**Fig. 7:** A compact deposit of wind-blown sand (context 353) covers the west wall of the new tomb. Photo by Nico Staring/ Leiden-Turin Expedition to Saqqara.

sand (context 353) extending from the west edge of squares V-W80 across the central part of the new tomb, the west outer wall (context 367) of the tomb was found (Fig. 7). It is preserved to an elevation of 57.60 m ASL, extends north-south for more than 6 m, and is at least 70 cm thick (its full dimensions could not be established due to the deposits still covering its western edge). Having defined the perimeter of the new tomb (at least on three sides) a test trench of approximately 4 x 4 m was opened in the southeast quadrant of the structure in order to collect preliminary data on its general layout and on the deposits filling it (Fig. 8). The area enclosed by the outer wall measures 11 x 7 m, which is comparable, for instance, to tombs like that of Paser or that attributed to Sethnakht. The mud-brick wall of the pylon entrance is 1.20 m thick, and the main passageway is lined with limestone blocks and is 1.04 m wide at the door jambs and 1.20 m at the door reveals. The tomb courtyard has a portico and the remains of three columns (ca. 36 cm in diameter), a column base (68 cm in diameter) and part of a pillar jutting out of the south wall have been identified so

far (Figs. 9, 10). Originally, this porticoed court very likely featured four columns on each side, regularly spaced about 1 m apart.

Unfortunately, preliminary investigation revealed no decorated limestone slabs still *in situ* along the tomb walls, at least in this area, which showed clear traces of looting, probably by nineteenth-century diggers. One of the most exciting insights gained from the excavation of the test trench was the identification of the same thick layer of rubble, marl and pottery sherds that had been found during the previous seasons in the area surrounding the tomb and which seemingly constituted the walking level of this part of the necropolis during the Ramesside period (Fig. 11). This may suggest that the tomb was still accessible and used somehow, although already partly ruined, when the later Ramesside chapels unearthed in the 2017 and 2018 seasons were built and used. Finally, the looting pits dug along the walls in order to extract the decorated limestone slabs conveniently offered the opportunity to see, under this supposedly Ramesside layer, the original floor of the tomb, and to ascertain that the floor is

made of well-laid thick limestone slabs (see Figs. 8, 9, 10) and lies at an elevation of about 56.30 m ASL, some 60 cm above the floor level of the adjacent tomb of Maya.

### **3. Brief report on the work of the 3D Survey Group of the Politecnico di Milano**

(Alessandro Mandelli and Corinna Rossi)

In 2018, the Leiden-Turin Expedition to Saqqara, in collaboration with the Politecnico di Milano, started using digital imaging to document both the site and the excavation activities being carried out at it.<sup>9</sup> In 2019, the survey team carried on the two lines of work and research that had been started in 2018: the 3D survey and modelling of the ongoing excavation, on the one hand, and that of the “completed” part of the concession, that is, the already excavated tombs and their immediate surroundings, on the other.<sup>10</sup> These two lines of work merged into a third one, namely, the construction of an overall model of the entire concession.

### **3.1 Surveying and modelling the ongoing excavation and the concession area**

In recording the ongoing excavation, both the method and the workflow were improved on the basis of experience gained during the previous season. During the post-fieldwork processing of the data, it had become clear that overall surveys of the entire area under excavation were particularly useful, both to record the changing ground morphology and to correctly identify the position of all the smaller contexts, which needed to be surveyed repeatedly as they were gradually dismantled. For this reason, during the 2019 season, the team regularly performed two general surveys every week, on Mondays and Thursdays. The daily excavation work was recorded in 3D as the operations unravelled. Every morning the operators set up their topographic instruments in order to link all the ensuing surveys to the same reference system. The accuracy of topographic measurements was always kept below 1 cm. A Canon 5D Mark III camera, with alternating Canon 20-mm and SIG-

MA 8-mm fisheye lenses, was used to survey the contexts. The overall surveys were carried out by means of a photographic pole that lifted the camera to a height of 3 m above ground level. The geometry of acquisition, the overlap of the images, and the distance between the camera and the ground allowed for a resolution of about 2 mm at the end of the photogrammetric workflow. This means that the three-dimensional meshes could be computed using triangles of 2 mm on the side; consequently, each pixel in the final orthophotos corresponds to an area of 2 mm<sup>2</sup> (Fig. 12).

As regards work on the already excavated tombs, the survey team performed a 3D survey of the subterranean portion of the tomb of Meryneith (see below), which is therefore the first tomb of the concession to be fully documented in 3D both above and below ground. The survey of the first section of the subterranean portion of the tomb of Horemheb was also started, and will be continued during the next season. The overall survey of the entire concession was

completed with a series of images acquired with the same camera, using the SIGMA 8-mm fisheye lens. The result of the photogrammetric process is a Digital Surface Model (DSM) that describes the different elevations of the ground.<sup>11</sup> During the post-processing of the data, the DSM was enriched with high-resolution dense clouds of the tombs of Maya, Tia, Horemheb, and Meryneith (Fig. 13).

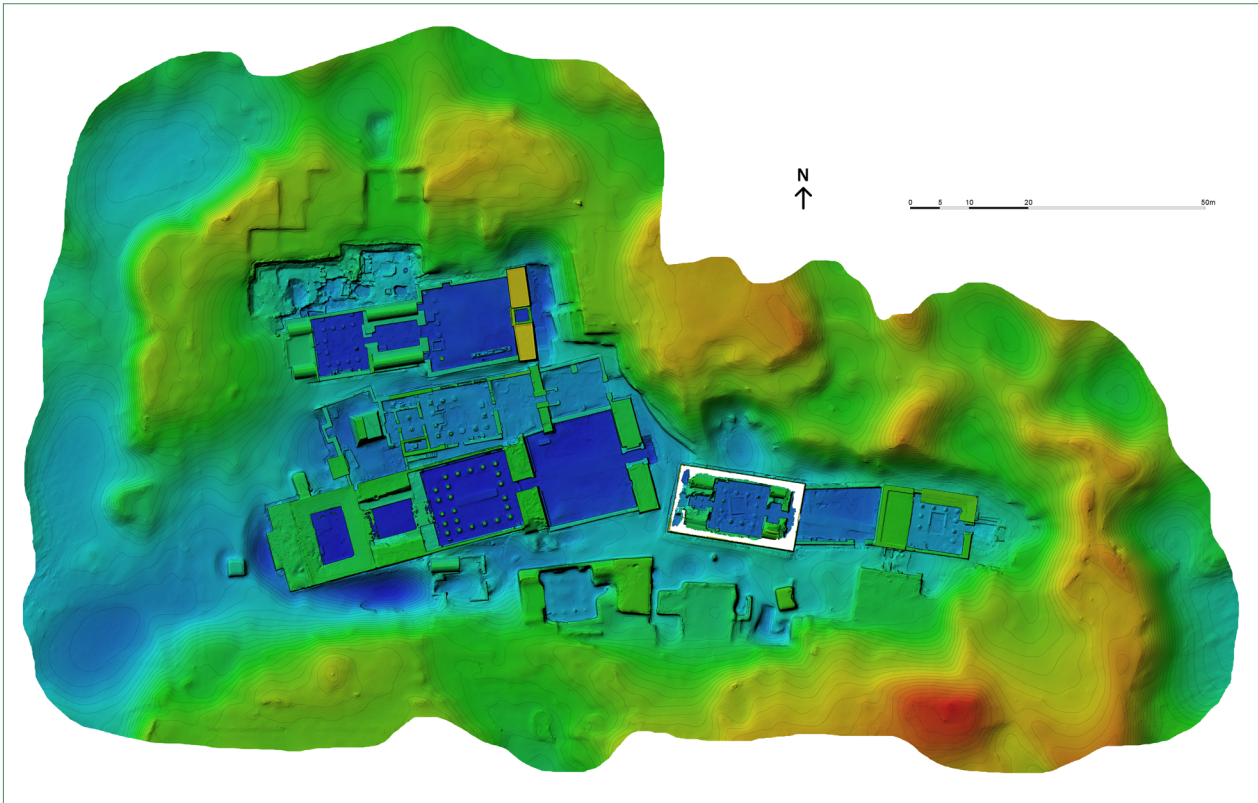

### 3.2 Three-dimensional survey of the underground structures of the tomb of Meryneith

(Luca Perfetti)

The underground portion of the tomb of Meryneith was 3D surveyed by means of the time-tested method of using fisheye lenses.<sup>12</sup> The data for the vertical shaft were acquired by lowering the camera using the same method already adopted in 2018 in another shaft.<sup>13</sup> The ensuing 3D model (Fig. 14) has an accuracy of ~1 cm. It was later georeferenced and merged with the 3D survey of the upper part of the

**Fig. 12:** Orthophoto of the current excavation area, at the northern limit of the Leiden-Turin Expedition concession area. Image by 3D Survey Group, Politecnico di Milano/Leiden-Turin Expedition to Saqqara.

**Fig. 13:** Digital Surface Model of the whole concession area of the Leiden-Turin Expedition to Saqqara. Image by 3D Survey Group, Politecnico di Milano/Leiden-Turin Expedition to Saqqara.

tomb as well as with the overall model of the entire concession.

Once the reliability of the survey data had been ascertained, the team moved on to test the acquisition of the same spatial data by means of videogrammetry. As part of his PhD thesis,<sup>14</sup> Luca Perfetti carried out a series of experiments using six different geometric configurations of a multi-camera system used to acquire and compare the same 3D data. The multi-camera system is made up of four low-cost action cameras mounted rigidly on an aluminium frame; different configurations were tested in the field (Fig. 15). The device is hand-held and acquires a continuous video sequence while the operator walks along the passages and rooms to be surveyed. Spaced still frames can be later sampled from the video streams and used to achieve the video-based 3D model of the area.

The main advantages of this method are affordability and speed: the survey of the entire subterranean tomb was completed in 30 minutes. These tests were carried out within a broader frame of activities aimed at defining the best geometric hardware configuration to record tunnel-like environments.

The preliminary results suggest that, in comparison with the photogrammetric survey achieved by a fisheye lens, the videogrammetric method shows a maximum deviation in the range of ~40 cm, as well as a lack of data in some areas (Fig. 16). These tests proved to be extremely useful in establishing how to develop this method into a reliable survey technique.

## 4. Recording graffiti in the tomb of Horemheb

(Nico Staring and Luca Perfetti)

### 4.1 Recording tomb graffiti

The tomb of Horemheb, the general who became king in the late Eighteenth Dynasty, dominates the necropolis in the Leiden-Turin concession area. The monumental, temple-like tomb superstructure was rediscovered in 1975<sup>15</sup> and the archaeological investigation of the forecourt was concluded in 2006.<sup>16</sup> The structure proved to contain numerous graffiti scratched into or painted onto the walls and paving stones in ancient times. Martin<sup>17</sup> published a corpus of 34 graffiti and Raven and van Walsem<sup>18</sup> added to it with another 10 specimens scratched into

**Fig. 14:** 3D Model of the tomb of Meryneith and its underground complex, by 3D Survey Group, Politecnico di Milano/Leiden-Turin Expedition to Saqqara.

**Fig. 15:** Examples of four different configurations for the multi-camera acquisition system used in the test. 3D Survey Group, Politecnico di Milano/Leiden-Turin Expedition to Saqqara.

**Fig. 16:** Results of the videogrammetric survey of the underground portion of the tomb of Meryneith: acquisition of survey data on site (left), oriented image network (centre) and a comparison of deviation against ground-truth data (right). 3D Survey Group, Politecnico di Milano/Leiden-Turin Expedition to Saqqara.

**Fig. 17:** The entrance doorway in the tomb of Horemheb, looking west. The arrow indicates the location of the graffiti survey on the exterior of the pylon gateway. Image by Nico Staring/Leiden-Turin Expedition to Saqqara.

the stone elements of the pylon gateway. Yet, not all the graffiti were seen at the time. In 2013, a closer look at the exterior jambs of the entrance pylon revealed 15 additional graffiti.<sup>19</sup> In direct sunlight or full shade most were invisible, which explains why they were not seen before, despite the fact that some were situated in close proximity to the specimens that had been copied in the field. Moreover, the wall surface displays a marked patina, which made recovering and adequately documenting the graffiti a complicated exercise.

Recent developments in the domain of digital imaging (e.g. Reflectance Transformation Imaging) have proved to offer great advantages in the documentation of graffiti.<sup>20</sup> The 3D documentation techniques employed at Saqqara by the 3D Survey Group of the Politecnico di Milano could also offer a solution to the problem of graffiti-documentation. The Leiden-Turin expedition therefore started to experiment with the documentation of graffiti in the pylon gateway of Horemheb (Fig. 17). The integrated approach we adopted allows the graffiti to be studied in the built context and in relation to the other

graffiti nearby. It also paves the way for a material approach to the study of the graffiti, in the sense that their detailed recording reveals something about how they were produced. Finally, the documentation offers the possibility of producing digital facsimile drawings by importing the orthorectified image in Adobe Illustrator as a JPG file. The following should be regarded as a progress report on a method still in the making.<sup>21</sup> The proposed integrated approach to the study of graffiti takes into consideration the architectural and iconographic setting, the archaeological context, and the wider landscape in which the tomb structures are embedded.

#### **4.2 Horemheb's entrance gateway: date of construction**

In total, 25 graffiti were recorded on the stone surfaces of the pylon gateway, a mud-brick structure with a limestone-lined doorway and a limestone-block floor. The mud-brick pylon gateway is part of the tomb's forecourt. This architectural feature was created after the construction of the tomb's core (here considered as construction phase 1), consisting of

**Fig. 18:** Orthomosaic of the southeast jamb of the pylon gateway. Image by Luca Perfetti and Nico Staring/Leiden-Turin Expedition to Saqqara.

the limestone pylon, outer peristyle courtyard, statue chamber, inner peristyle courtyard, and three cult chapels in the west. The north and south walls of the forecourt were built against the east façade of the stone pylon. The decoration of the limestone revetment blocks in all areas of the core building were executed in the reign of Tutankhamun. The forecourt was probably built in the reign of Horemheb,<sup>22</sup> likely in conjunction with the enlargement of the subterranean complex entered from the tomb shaft in the inner courtyard. The figural graffiti depicting the king (Gr. 36, striding king wearing the blue crown; Gr. 43, king's head wearing the white crown; Gr. 44, king's head wearing the blue crown; Figs. 18, 19) were possibly produced in relation to the cult of the deified king, which started in the Nineteenth Dynasty. The graffiti of boats (Figs. 18, 20) – often considered as metonyms representing both an identity and a journey<sup>23</sup> – were probably also left by people visiting the deceased king's memorial temple.

### 4.3 Horemheb's entrance gateway: the archaeological context

The published archaeological report states that the west half of the entrance gateway was filled with windblown sand up to 1 m above floor level.<sup>24</sup> The lower 30 cm of this sand deposit contained potsherds of Ramesside date. Thus, this part of the gateway was likely clear of sand to floor level well into the Nineteenth Dynasty. This suggests that the entrance gateway remained accessible despite increasing accumulation outside the tomb. In the east half of the gateway, the 10 cm thick deposit on top of the pavement flagstones consisted of a grey layer filled with small limestone chips and small weathered potsherds. The latter ranged in date from the early Eighteenth Dynasty to the Ramesside period. This fill likely slid into the gateway from the east. This is corroborated by the observation that in front of the gateway, to the east, a 10 cm thick mud layer sloped up away from the doorway to the north and east. Underneath this deposit, situated east of the north and south doorjambs at floor level, late Eighteenth Dynasty potsherds were found.

### 4.4 The 3D survey

The 3D survey of the graffiti of the tomb of Horemheb

was designed to fulfil a twofold purpose: i) to produce an orthomosaic of the wall carrying the graffiti, and ii) to construct a high-resolution 3D model of the stone surface with the aim of enhancing the engravings by means of simulated light. The first goal required control over light conditions and a 2D image resolution of 0.5 mm/pixel; the second goal, instead, required a 3D resolution of 0.5 mm, which commonly translates to a required 2D image resolution of 0.1 mm/pixel. To meet both requirements at the same time, a full-frame 24-megapixel camera (Canon 5D Mark III) equipped with a 35 mm lens was employed. The capturing distance was set equal to the minimum focusing distance of the lens so as to ensure the maximum possible resolution with the available instrumentation. The Ground Sampling Distance (GSD) of this configuration was 0.1 mm/pixel. A white cloth was placed in front of the graffiti to diffuse the natural sunlight when present and two speed lights were employed to illuminate the scene with a narrow-incidence angle to reveal the shallow engraving. The acquisition followed classical nadir capturing geometry and was carried out row-wise from top to bottom. The overlap between consecutive images and rows was set respectively to 80% and 60%. The acquisition ended with few additional images acquired from a distance, thus with a higher GSD, and tilted vertically to help further processing steps (structure from motion). In total, 404 photos were taken of the exterior wall surface (the limestone doorjambs) and 131 of the interior limestone doorjambs. These photos were processed at full resolution following a typical photogrammetric pipeline using Agisoft Metashape (Fig. 21). The two acquisitions were scaled using calibrated scale bars included in the data capture and the resulting scaling error was 0.003 mm.

The texturised OBJ models can be opened in the free and open-source processing software system MeshLab. The software offers the user a tool that simulates artificial light. The tool can illuminate the 3D object from different angles in a way similar to an RTI (Reflectance Transformation Imaging) application (Fig. 22).

### 4.5 Preliminary conclusion

The graffiti carved on the exterior wall surface, in particular those on the southeast doorjamb, cover

**Fig. 19:** Graffito of a striding king (Gr. 36) and hieratic visitor's inscription (Gr. 37). Orthoimage by Luca Perfetti/Leiden-Turin Expedition to Saqqara. Line drawing by Nico Staring/Leiden-Turin Expedition to Saqqara.

**Fig. 20:** Group of boat graffiti (nos. 46-51). Orthoimage by Luca Perfetti/Leiden-Turin Expedition to Saqqara. Line drawing by Nico Staring/Leiden-Turin Expedition to Saqqara.

the wall from bottom to top (as preserved). A group of six boats (Gr. nos. 46-51) was carved on the two lower courses of limestone blocks very close to the floor (12.3 cm above floor level). The boats' positions on the wall suggests that the graffitists assumed a sitting or crouching posture, and that the area in front of the entrance to the tomb was kept free of sand.

## 5. Preliminary report on pottery

(Valentina Gasperini and Alice Salvador)

The ceramic analysis of the 2019 season focused on the materials from the “embalmers’ caches” (from the 2017/2018 season), shaft 131 (from the 2018 season), and the newly excavated spoil heaps of the 1980s excavations.

### 5.1 The “embalmers’ caches”

The excavation of the “embalmers’ caches”, begun in 2017, was completed during the 2018 season. The study of the ceramics from these seasons had not been finished in the spring of 2018,<sup>25</sup> and its completion was hence the first task for 2019. During the first week of the 2019 season, the reconstruction and processing of the “goldfish” bowls and pot-stands were completed. In the second week, they were classified, inventoried, described, drawn, and photographed. The processing of the bottle types began in the third week. The results of the 2019 analysis confirmed the preliminary conclusions regarding the materials and forms found and processed in 2018: the newly studied pottery consisted of “goldfish” bowls, pot-stands, and bottles exhibiting the same features and characteristics as the types already studied during the previous campaigns, and no new forms were identified.

#### 5.1.1 “Goldfish” bowls

This very standardised form usually has a diameter between 14 to 16 cm, an inturned rim that thickens slightly towards its external edge, a convex wall, and a rounded, sometimes slightly pointed base. The poor manufacturing of some of the examples may result in quite an irregular and asymmetrical shape, in particular towards the base and rim. The surface treatment is characterised by a burnished red slip, and the fabric is usually quite fine J1 (Nile silt). Only

**Fig. 23:** “Goldfish” bowl C1184 with “charcoal docket”. Photo by Nicola Dell’Aquila/Leiden-Turin Expedition to Saqqara.

one example (Fig. 23) yielded a charcoal docket, possibly mentioning one of the four Sons of Horus. As stressed in the 2018 report, the charcoal docket were most probably written with black ink, resulting in a very faded, and often barely legible, inscription.<sup>26</sup> The study of the legible inscriptions, found to date on seven bowls, is ongoing.

#### 5.1.2 Pot-stands

The examples occur in a very standardised form with a diameter between 13 and 16 cm. They have an everted rim that thickens slightly towards its external edge, a cylindrical wall, and a rounded, externally thickened base. The coarse clay fabric usually has a grey core. The pot-stands show no wear-marks, confirming the hypothesis formulated in the 2018 season that their usage was limited in time, possibly to the embalming procedure and consequent deposition (Figs. 24, 25).

#### 5.1.3 Bottles

Those identified in 2019 are of the same types as those identified in 2018: 68% have a vertical rim, with a shallow indentation just below it, a cylindrical neck, ovoid body, and convex, slightly pointed base (Figs. 26, 27); 21% (Figs. 28, 29) are characterised by two shallow ridges just below the rim; 11% (Fig. 30) have a slightly inturned rim, a short cylindrical neck, an ovoid body, and a rounded base. The first two types have a burnished red slip, while the third is plain. Though all are manufactured from Nile silt,

**Fig. 24:** Pot-stand C1192. Photo by Nicola Dell'Aquila/Leiden-Turin Expedition to Saqqara.

**Fig. 25:** Pot-stand C1194. Photo by Nicola Dell'Aquila/Leiden-Turin Expedition to Saqqara.

**Fig. 26:** Bottle C1201. Photo by Nicola Dell'Aquila/Leiden-Turin Expedition to Saqqara.

**Fig. 27:** Bottle C1195. Photo by Nicola Dell'Aquila/Leiden-Turin Expedition to Saqqara.

**Fig. 28:** Bottle C1217. Photo by Nicola Dell'Aquila/Leiden-Turin Expedition to Saqqara.

**Fig. 29:** Bottle C1274. Photo by Nicola Dell’Aquila/Leiden-Turin Expedition to Saqqara.

**Fig. 30:** Bottle C1272. Photo by Nicola Dell’Aquila/Leiden-Turin Expedition to Saqqara.

the first two types are of fine J1 fabric, whilst the third type is of a coarser fabric.

The “embalmers’ caches” include small percentages of New Kingdom (2%) and Late Antique (6%) materials. The majority (92%) of the pottery from these caches is consistent with a Late Period, fifth century BCE date.

## 5.2 Shaft 131

The pottery from this location<sup>27</sup> displays a very similar typological and chronological profile as the assemblage from the “embalmers’ cache”: “goldfish” bowls, bottles, and pot stands from the Late Period (62%), with occasional (10%) Late Roman/Late Antique amphorae and dishes, and New Kingdom (17%) beer and funnel-necked jars.<sup>28</sup> Additionally, four small plates with direct rims, oblique walls, and flat, string-cut bases, also made of J1 Nile silt and dated to the Late Period, were identified.

## 5.3 The spoil heaps

The vast majority of the pottery processed during the 2019 season was recovered from the spoil heaps. The investigation of the less disturbed, sealed contexts found immediately underneath these heaps was a priority. A rigorous statistical analysis was undertaken for the pottery from the contexts underlying the modern surface and therefore belonging to less jumbled contexts (see below). It included a detailed description of all diagnostic sherds and vessels, taking into account fabric, measurements, percentage of the preserved diameter (either rim or base), style, and surface treatment, including decoration. Parallels with the existing site typology were established. This analytical strategy will facilitate accurate counts of the amount of vessels originally present in each context and high-probability estimates of the minimum number of forms originally deposited in the assemblages. The identification of the type and frequency of vessels will help to

**Fig. 31:** Basin C1223 decorated with geometric motifs (external and internal surfaces). Photos by Nicola Dell’Aquila/Leiden-Turin Expedition to Saqqara.

shed light on the original usage and function of the assemblages.

The statistical analysis identified new forms not previously represented in the Saqqara assemblage, increasing the site typology by 157 new diagnostics. These were all registered with C-numbers, and their measurements, fabric, surface treatment, typological parallels, and dating were recorded in detail, with accompanying general analytical and interpretative comments. The vases have been drawn and photographed and will be integrated in the existing site typology from next year onwards. Such a statistical approach is an accurate method for the analysis of ceramics retrieved from secure contexts. For surface finds of pottery and finds from excavation spoil heaps, a general fabric and typological identification was given, along with a general description. Body and diagnostic sherds were counted and registered, and their relative percentages calculated.

The preliminary analysis of these materials confirms the preponderance of Late Period and Late Antique contexts. The Late Antique material mainly consists of Late Roman amphorae (LR1 and LR7), Aswan Ware (mainly open shapes) and locally produced cooking ware. A minor portion of the Late Antique materials consists of large dishes and basins, often with wavy rims, and having a polychrome decoration of ge-

ometric or stylised floral motifs, applied to the interior, the exterior, or the lip (see for example Fig. 31). Imported pottery appears to have been abundant during the Late Period and in Late Antiquity, confirming the observations made during the previous season. During both periods, the vast majority of imports appear to come from the Eastern Mediterranean. LR1 amphorae are, unsurprisingly, by far the most common type of imported transport containers excavated from the Late Antique layers (9% of the total number of sherds processed; 74% of all imported sherds). Additionally, during the same period there is a noticeable scarcity of imports from North Africa (Tunisia and Libya), as African sigillata occurs in very low percentages. The Late Period shows a prevalence of Greek and Phoenician imports, with a slight prevalence of Torpedo Jars.

Among the LR1 amphorae, three examples with *tituli picti* (see, for example, Fig. 32) are noteworthy. *Tituli picti*, written in cursive Greek and preferably with red instead of black ink (as in the case of the Saqqara examples), occur very often on Late Antique transport containers.<sup>29</sup> Related to commercial marks and added in extremely stylised writing, these signs are often difficult to read. Several different types of *tituli picti* may occur on LR1 amphorae.<sup>30</sup> They occur on the neck, shoulder, or in the proximity of the han-

**Fig. 32:** LR1 Amphora C1307 with *titulus pictus* and detail. Photos by Nicola Dell'Aquila/Leiden-Turin Expedition to Saqqara.

dles. A preliminary analysis of the marked transport containers from the spoil heaps was undertaken in 2019, but further investigation is required.

New Kingdom material is only represented by a small number of blue painted sherds, very occasional beer jars, funnel-necked jars, and sherds manufactured from both Marl D and F, indicating a privileged regional import from the Eastern Delta (Marl F), and Lower and Middle Egypt (Marl D). The almost complete absence of Marl A, on the other hand, indicates limited imports from the Theban area and prompts the question of network exchanges between Saqqara and Upper Egypt during the Ramesside period.

## 6. Preliminary analysis of human remains

(Ali Jelene Scheers)

Differently than in the previous excavation season, the skeletal material recovered during the 2019 season consisted solely of loose surface material that cannot be traced to a complete skeleton. As such, most of the season was spent reorganising and inventorying the skeletal material from previous seasons (see below).

The loose surface material that was studied during the 2019 season consisted of 3121 individual bones. However, due to time constraints not all recovered material could be studied; consequently, the numbers noted here are not a complete representation of everything that was found during the 2019 season. The remaining bones will be studied at the start of the next season.

Of the 3121 individual bones studied, 66 were of animals and 419 were found out of context. This leaves us with 2636 individual human bones that can be ascribed to a well-defined archaeological context. These can be used to determine the MNI (minimum number of individuals) for the area excavated in 2019.

Of the 48 contexts identified during the 2019 season, 31 contained human bone material. Of these, context 332 – a dump mound from earlier excavations – contained the most pieces, with 417 individual bones. Context 322, also a surface deposit from the excavation of nearby tombs, came in second with 242 individual bones. Three other contexts<sup>31</sup> contained between 200 and 230 individual bones each. Six contexts<sup>32</sup> fall in the 100-to-199-item range, while the remaining contexts<sup>33</sup> all contained less

than 76 individual bones, with eight contexts<sup>34</sup> containing less than ten fragments.

The MNI is determined by examining each of the bone fragments in a given context and estimating how many individuals they represent. Doing this for each context separately is problematic, as comingling and scattering between contexts (and over the whole site in general) has certainly happened through the years. The MNI should thus be calculated for the whole range of individual bones excavated during the 2019 season. This results in a MNI of 26 individuals, based on the presence of 21 adult left 5<sup>th</sup> metatarsals and 5 sub-adult right femora. As this is only the minimum number of individuals, the true number of individuals scattered throughout the area of this year's excavation is probably higher, but of course impossible to determine exactly.

## 7. Objects and reliefs

(Lara Weiss and Daniel Soliman)

As expected, the dumps of earlier excavations yielded many fragmentary objects whose original archaeological context was lost. Yet, a provenance can be proposed for some groups, such as twenty fragments of calcite stoneware, mostly dating to the Early Dynastic period, which probably derive from the Second Dynasty elite tomb underneath the tomb of Maya.<sup>35</sup> This tomb, as well as the one underneath the tomb of Meryneith,<sup>36</sup> are under investigation by Ilona Regulski.

Over 60 limestone fragments dating to the New Kingdom were recovered, the majority of which were small and non-diagnostic. Many were decorated in relief, some with traces of pigment. Still, it was often not possible to sufficiently interpret their decoration or to understand their provenance, although some may come from the new tomb discovered in 2018 or perhaps even from the tomb of Maya and Merit. A few reliefs, described below, are of particular interest.

Fragment R31 belonged to a fine raised relief. It shows the face of a woman wearing an elaborate wig. It is cut in a style that is similar to that of the decoration of the tomb of Maya, although no join could be established. The fragment may perhaps rather derive from another tomb of a similar date. Two smaller limestone fragments of funerary stela were found. R68 is the right upper part of a round-topped

stela showing Anubis in the shape of a recumbent jackal on a booth. R74 is stylistically datable to the Ramesside period. It shows a seated woman and an inscription that may identify her as a mistress of the house named Meryt.

The largest architectural fragments were found inside or immediately adjacent to the new tomb. One very damaged limestone block, F82, is worked in sunken relief in a style that is characteristic of the late Eighteenth Dynasty and early Nineteenth Dynasty. It is inscribed with titles, one of which is *hmnr* ('priest'). It remains to be seen if it originally belonged to the decoration of the new tomb. Block R78 (Fig. 33) is probably a door jamb from a not yet identified tomb chapel. It shows part of an offering formula carved in fine sunken relief, and reads "[...] Ptah-Sokar and Nefertem, lord of ka-souls,<sup>37</sup> may they give [...]".

The rectangular capital of a column, R66, is inscribed in sunken relief with an offering formula containing

**Fig. 33:** Block R78. Photo by Nicola Dell'Aquila/Leiden-Turin Expedition to Saqqara.

**Fig. 34:** F186. Photo by Nicola Dell'Aquila/Leiden-Turin Expedition to Saqqara.

the name of the god Re-Horakhty. Finally, the large limestone block R77 displays part of a tabular offering list. The lower parts of a row of items can be seen, indicated for each column by a sign of a kneeling man holding an offering bowl, and the top of a sec-

**Fig. 35:** F192. Photo by Nicola Dell'Aquila/Leiden-Turin Expedition to Saqqara.

ond row of items. A fragment of a similar offering list was found in the main shaft of the tomb of Ramose.<sup>38</sup> Various smaller objects also date to the New Kingdom, such as eight very fragile, fragmentary wooden shabtis of the Ramesside period, which were restored by Islam Taha. Unfortunately, their inscriptions are still largely illegible. The fragments of a delicate cosmetic jar, F389, and a brightly painted fragment of a wooden shabti box, F186, showing the arms of the deceased in adoration, should date from the same period (Fig. 34). The latter is inscribed with the male name Iuty, which is attested in Memphis in the Eighteenth Dynasty.<sup>39</sup> It is also tempting to link this fragment to the statue, now in Leiden, of the Nineteenth Dynasty physician Iuty, whose name is written in the exact same way.<sup>40</sup> A female candidate is the woman by the same name attested on a stela dedicated by an Amenmose, probably from Saqqara.<sup>41</sup> All other attestations of the name Iuty date to the Eighteenth Dynasty.<sup>42</sup> Two curious calcite objects attributed to the Ramesside period, F192 and F378 (Figs. 35, 36), have been tentatively identified as elements of the wheels of a chariot. Parallels excavated in Egypt<sup>43</sup> and from museum collections<sup>44</sup> suggest that at least F192 is probably a yoke-saddle finial.<sup>45</sup>

Ten shabti fragments date to the Third Intermediate Period. Substantial quantities of fragments of textile, rope, and matting, as well as wood and reed were recovered. This material likely originates from

**Fig. 36:** F378. Photo by Nicola Dell'Aquila/Leiden-Turin Expedition to Saqqara.

burials found during the seasons of 1987 and later, when the tomb of Maya was excavated. This is clear from surrounding finds of dated newspaper snippets and a blue-painted sherd matching the ceramic ware from the tomb of Maya and Merit, which Barbara Aston is preparing for publication. Although these deposits evidently originated from the old excavation spoil heaps from the then Anglo-Dutch mission, it was decided to study them in detail in the upcoming season. This decision is justified not only by the consideration that excavation methods and techniques, as well as research questions and aims, have changed since the late 1980s, but also because current archaeological approaches will hopefully allow new insights into materials that previously went unnoticed. The Late Period date of these materials is supported by associated finds such as faience amulets, shabtis, and ceramic coffin fragments. The number of Late Period shabtis and shabti fragments, predominantly uninscribed, totalled 86. In addition, 93 ceramic “slipper” coffin fragments of various sizes were found. They were typically broken all around and undecorated. The shape of three calcite canopic jar fragments suggests they date to roughly the same time.

Two fragments of inscribed papyrus were discovered among the material from the spoil heaps. One fragment, F95, was restored and consolidated by the Head of Restoration at Saqqara, Ashraf Ashour Shaaban. After restoration, the now legible passages suggested it contains a Coptic letter written in black ink.<sup>46</sup> The text, which is very fragmentary, mentions the month Pamenoth. The second papyrus fragment, F283, was folded when found, and may constitute the lower edge of a Book of the Dead papyrus, decorated with two red bands framed by thin black lines. Traces of columns with black hieroglyphs are visible, but too little is preserved to identify the content of the text. A similar fragment, dated to the New Kingdom, was found in the tomb of Horemheb.<sup>47</sup>

Excavations also recovered a group of tools made of reused pottery. This category of objects consists of recut ceramic sherds, and includes 12 rounded specimens and 22 scrapers.<sup>48</sup> The scrapers were probably used for the production of ceramics as well as the processing of wood, stone, fur, and skins.<sup>49</sup> The rounded pieces are relatively common, but their exact date and function remain subject to debate.<sup>50</sup>

they have been interpreted as tokens, lids, or game pieces. The interpretation of the objects as lids can probably be dismissed in the absence of a comparable number of receptacles with matching-shaped mouths.<sup>51</sup> Objects made of reused pottery have hitherto mostly been found in production areas.<sup>52</sup> The group found this season may also come from an occupation layer excavated in 2018 that showed signs of production activity.<sup>53</sup> The finds from this season, a flint stone knife blade (F351), a whetstone (F337), a possible biface (F400), and a few ceramic bowl fragments used as painters’ palettes (one for plaster) are comparable to those from last season. These tools are difficult to date but, based on the archaeological context as well as the fabric, a Late Period date is perhaps the most plausible.

## 8. A Late Period offering table

(Huw Twiston Davis and Daniel Soliman)

One half of a double-sided offering table from the Late Period, F92 (Fig. 37), was found in context 320.

**Fig. 37:** F92. Photo by Nicola Dell’Aquila/Leiden-Turin Expedition to Saqqara.

The rectangular offering table shows a spout protruding from the short edge. A band of incised hieroglyphs runs along a raised outer edge with an elevated central column. A close parallel was reused in the rim of a shaft lying just north of the northern wall of the tomb chapel of Meryneith.<sup>54</sup> As the fragment found in 2019 is similar in shape, it may have been reused as well. The recessed centre of F92 depicts two round bread loaves on an offering mat in the shape of a *hṭp*-sign. Below the mat, offerings are depicted between two *kbh*-jars. The central column has a dedicatory inscription, parts of which are legible. The first sign group is disturbed and may be a title.<sup>55</sup> It is followed by a name with filiation, read as Paenpahesemmaakheru, son of Pasheriese,<sup>56</sup> born of Nefer- [...]. The reading of the first name Paenpahesemmaakheru (“son of the one praised in justification”) is tentative, as it is seemingly not attested elsewhere. The block-stature hieroglyph (Gardiner extended library sign A 313) appears very clearly on the table, and is here taken as a cryptographic writing of *hṣi*, “praise”.<sup>57</sup> Names ending in *m-mꜣꜥ-hrw* are rare, but they are attested in theophoric names. A Khonsuemmaakheru is attested during the Third Intermediate Period at Thebes,<sup>58</sup> while the names Raemmaakheru<sup>59</sup> and Horemmaakheru<sup>60</sup> are attested in the Late Period. The text along the edge of the offering stone starts at the spout, where it is damaged. It reads “... these [libations of yours (?)] which come forth before your son, which come forth before Horus, [...] the liquid which comes forth with you, without wea[rying your heart ab]out [it...]”. These phrases are part of a standard text on offering tables from the Late Period, adapted from Pyramid Text utterance 32.<sup>61</sup>

## 9. Reorganisation of storage rooms

(Lara Weiss, Daniel Soliman, Alice Salvador, and Ali Jelene Scheers)

A reorganisation of the on-site storerooms was undertaken to make better use of the existing space and create additional storage space in order to preserve excavated materials as best as possible and make them more readily accessible in the future. With kind support from architect Nicholas Warner, new timber shelving was installed in the north storage vault and the first subterranean chamber of the tomb shaft of

Horemheb, and in two chapels. Material excavated in previous seasons was repacked where necessary to be stored more efficiently. Specifically, Horemheb B was inventoried, and broken crates were replaced. The materials of seasons 2002, 2003, 2004, 2009, 2010 and 2013, and the materials from shaft 99/I, Maya, the Tia deposit and Ramose were moved to gallery M in the subterranean complex of Horemheb. The materials stored in the subterranean complex of Meryneith were re-crated and inventoried as well. The new pottery materials have been stored on new wooden shelves, guaranteeing easier access to, and an improved preservation of, the whole assemblage.

## 10. Tomb conservation

(Nicholas Warner)

In this season, conservation work at the site was carried out between 18 March and 20 April. Following the serious damage to mud-brick structures caused by heavy rainfall in the winter of 2018-2019, the focus of the work was on remedial conservation of the worst affected tombs, most particularly the tomb of Horemheb. The mud-brick entrance pylon of the tomb of Horemheb, previously consolidated in February 2010, was badly affected by rains over subsequent years. Severely eroded sections of brickwork were cut out and replaced, and all wall faces were re-pointed with mud mortar. The upper surfaces of each pylon block were given a plastic isolation layer below the upper two courses of brickwork, and a layer of stone chips was used to strengthen the top layer of mud render above. This render contained a small percentage (1 part to 10 parts of water) of Addibond adhesive, a non-migratory plasticiser. It is hoped that this will improve the adhesion and wear of the plaster over time, but the treatment will be monitored to evaluate its success, both at this location and in other areas where it was employed this season. The two storeroom roofs between the second and third courtyards of the tomb were consolidated with new mud-bricks over a plastic isolation sheet. The new brickwork was stepped in order to reduce the load on the vaults below, and a layer of stone chips and pottery sherds was used to strengthen the top layer of mud render above the consolidated brickwork. This render also contained a small percentage of Addibond plasticiser. The original inner

wall faces of the two storerooms, north and south of the entrance passage to the third courtyard of the tomb, were entirely re-pointed to prevent continuing erosion. On the southwest external face of the tomb, two reconstructed mud-brick wall faces showing serious erosion due to wind and rain were re-plastered with a mud plaster containing a small percentage of Addibond plasticiser. This area will be monitored to assess the effectiveness of this treatment.

In addition to the conservation work in the tomb of Horemheb, work was carried out elsewhere in the necropolis. At the small chapel of Paser, wind

and rain erosion had damaged its west and north walls, consolidated over a decade ago, to the point where a structural collapse was feared. The base of the west wall and the entire north wall of this chapel were therefore faced with limestone rubble set in lime mortar. The roofs of Maya's chapels were also re-plastered to inhibit rainwater infiltration. At the tomb of Meryneith, it was found that the concrete plank covering the shaft of the tomb was causing severe condensation. The plank was therefore replaced with a new painted steel open grille cover to increase air circulation in the subterranean chambers.

## Notes

- <sup>1</sup>The 2019 season was made possible by the participation of: Mohamed Abdel Tawab Fawzy, Assam Rashed, Abbas Moussa, Rafat Kis, Sami Ashour, Mohamed el Aseli, Adel Mohamed Othman, Guda Abd el Khaled, Saber Hussein, Mohamed Abd el Zayr, Emad Bayoumi, Mohamed Ramadan el Hady, Abd el Mohsen Ali, Emad Abd el Minan, Mohamed Hamed, Salama Ramadan Fekri, Mahdy Abd el Nabi, Mohamed Ibrahim Shahed, Sameh Rageb Farag, Mohamed Samir Hassan, Mahmoud Samir Hassan, Said Imam, Karam Gomaa Abdel Razek, Gomaa Salama Gomaa, Gamal Abdel Gamaal el Eswed, Gamal Kilani, Assam Saad, Assam Mundy Afrah, Eid Said Imam Salem, Fahmy Ahmed Mohamed, Abu el Hassan Ahmed, Walid Sayed, Faris Sayed, Mohsen Awad, Ahmed Gamal, Hagag Ibrahim, Ibrahim Naser, Hussein Abdul, Sadiq Ahmed, Abd el Rahman Samir, Tareq Guda, Mahmoud Abu Sareya, Yahya Rabia Nefs, Abd el Tawab Shaeab, Nabil Adawy, Assam Azmy Ali, Gaballa Abu el Ghayeb, Islam Gamal Abd el Alam, Mohamed Gerwesh, Ahmed Sami Azem, Omar Abd el Gawab, Ahmed Mohamed Fekri, Fahmy Mohamed Shaaban, and Taha Mohamed Hany.
