KEYWORDS. Non-isocyanate polyurethanes, poly(hydroxy urethane)s, hot-melt, adhesives, sustainability, green chemistry.

Titration of the cyclic carbonate by ${ }^{1} \mathrm{H}$ NMR.
A specified amount of cyclic carbonate (PPGdiCC or RdiCC) (around 50 mg ) and standard solution of DMSO with toluene (around 30 mg of toluene dissolved in 5 mL of DMSO- $\mathrm{d}_{6}$ ) were weighed into an NMR tube. The characteristic peaks of carbonate a , b and c (4.51, 4.29 and 4.92 ppm respectively) and $\mathrm{CH}_{3}(2.32 \mathrm{ppm})$ of toluene were integrated. The integration of $\mathrm{CH}_{3}$ of toluene was fixed to 300. Carbonate equivalent weight (CEW) of the carbonates was calculated according to eq S 1 , where $\mathrm{m}_{\mathrm{C} 5}-$ mass of cyclic carbonate introduced into the NMR tube, $\mathrm{n}_{\text {function of carbonate }}$ - molar amount of function carbonate in cyclic carbonate, $\mathrm{I}_{\mathrm{a}}, \mathrm{I}_{\mathrm{b}}, \mathrm{I}_{\mathrm{c}}$ - integrations of characteristics peaks $\mathrm{a}, \mathrm{b}$ and c of carbonate, $\mathrm{n}_{\text {toluene }}$ - molar amount of toluene introduced in standard solution, $\mathrm{I}_{\mathrm{CH} 3}$ - integration of peak $\mathrm{CH}_{3}$ of toluene. The CEW values for each cyclic carbonate were obtained in triplicate and are presented in Table S1.

$$
C E W=\frac{m_{C 5}}{n_{\text {function of carbonate }}}=\frac{m_{C 5} \times I_{\text {CH3 }}}{\left(I_{a}+I_{b}+I_{c}\right) x n_{\text {toluene }}}(\mathrm{S} 1)
$$

Typical procedure for PHU homopolymer synthesis.
Homopolymerization of 100/0-MXDA was carried out by adding PPGdiCC ( $2.0196 \mathrm{~g}, 6.110^{-3}$ equiv) and MXDA ( $0.5160 \mathrm{~g}, 7.6$ $10^{-3}$ equiv) to a 25 mL round bottom flask. The mixture was placed into an oil bath at $80^{\circ} \mathrm{C}$ and was left for 24 h under magnetic stirring. Afterwards, the reaction was cooled down and a viscous polymer was obtained. For the homopolymerization of $0 / 100-$ MXDA, RdiCC ( $1.1554 \mathrm{~g}, 6.110^{-3}$ equiv) and MXDA ( $0.5160 \mathrm{~g}, 7.610^{-3}$ equiv) were added to a 25 mL round bottom flask. The mixture was placed into an oil bath at $80^{\circ} \mathrm{C}$ and was left for 24 h under magnetic stirring. After cooling down the reaction a yellowish hard homopolymer was obtained. Polymers were used without further purification.

Typical procedure for PHU copolymer synthesis.
PPGdiCC ( $11.1458 \mathrm{~g}, 33.510^{-3}$ equiv) and $\operatorname{RdiCC}\left(4.2520 \mathrm{~g}, 22.310^{-3}\right.$ equiv) were added to a 100 mL jacketed glass reactor. The mixture was heated to $80^{\circ} \mathrm{C}$ before adding MXDA ( $4.7472 \mathrm{~g}, 69.710^{-3}$ equiv). The reaction was left for 24 hours under continuous mechanical stirring at 200 rpm without using any catalyst. Afterwards, the reaction was cooled down and the polymer stored. Polymers were used without further purification.

Eq S2 was employed for the calculation of the amine mass. The molar ratio between PPGdiCC and RdiCC was fixed according to the different compositions and the molar ratio of amine to cyclic carbonates was fixed to $1.25(r=1.25)$. The number of active hydrogens of amine was fixed at 1 for one amine function reacting with one cyclic carbonate. The active hydrogen equivalent weight (AHEW) was calculated from eq S3.

$$
\begin{align*}
& m_{\text {amine }}=r A H E W_{\text {amine }}\left(\frac{m_{\text {PPGdicC }}}{C E W_{P P G d i C C}}+\frac{m_{\text {RdicC }}}{C E W_{\text {RdicC }}}\right)  \tag{S2}\\
& A H E W=\frac{A E W}{\text { number of active hydrogen }}(\mathrm{S} 3)
\end{align*}
$$

Typical procedure for enhanced hot-melt adhesive preparation.
Around 4 g of 50/50-MXDA or 50/50-PXDA composition were heated up to $90^{\circ} \mathrm{C}$ and mixed with D.E.R. ${ }^{\mathrm{TM}} 671(0.6 \mathrm{~g}, 15 \mathrm{wt} \%)$ for 20 minutes. Afterwards, the sample was kept in an oven at $55^{\circ} \mathrm{C}$ for 3 days to assure complete reaction of the amine with epoxy groups.

Table S1. Carbonate equivalent weight (CEW), amine equivalent weight (AEW), epoxy equivalent weight (EEW) and thiol equivalent weight (TEW) values.

| Reactant | CEW $\left(\mathrm{g}\right.$ equiv $\left.{ }^{-1}\right)$ | AEW $\left(\mathrm{g}\right.$ equiv $\left.{ }^{-1}\right)$ | EEW $\left(\mathrm{g}\right.$ equiv $\left.{ }^{-1}\right)$ |

## Synthesis of PHU homopolymers from RdiCC and MXDA

The completion of the reaction was followed by FTIR-ATR through the disappearance of the carbonyl stretching vibration of the carbonate at $1782 \mathrm{~cm}^{-1}$ and the appearance of the carbonyl stretching vibration band of the urethane at $1694 \mathrm{~cm}^{-1}$ (Figure S1). Additionally, common signals at $3320 \mathrm{~cm}^{-1}\left(-\mathrm{OH},-\mathrm{NH}_{2}\right.$ stretching), 2930-2970 $\mathrm{cm}^{-1}\left(-\mathrm{CH}_{2},-\mathrm{CH}_{3}\right.$ stretching $)$, at 1592,1491 and 1450 $\mathrm{cm}^{-1}\left(\mathrm{C}=\mathrm{C}\right.$ stretching of the aromatic rings), at $1531 \mathrm{~cm}^{-1}$ ( $\mathrm{N}-\mathrm{H}$ bending), at $1240 \mathrm{~cm}^{-1}$ (C-O-C stretching), at $1038 \mathrm{~cm}^{-1}$ ( $\mathrm{C}-\mathrm{O}$ stretching) and at 775 and $700 \mathrm{~cm}^{-1}$ (C-H out of plane bending vibrations of the aromatic rings) confirmed the structure of the homopolymer. ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectrum of the MXDA-RdiCC PHU is shown in (Figure S2). The disappearance of the signals of the cyclic carbonate ( $5.02,4.62-4.53$ and $4.23-4.13 \mathrm{ppm}$ ) and the appearance of the signals at 7.72 ( $-\mathrm{NH}-\mathrm{C}(\mathrm{O}) \mathrm{O}-$, urethane) and at 4.16 ppm (methylene group of the amine), further confirmed the formation of the RdiCC-based homopolymer.

## Synthesis of copolymer based on PPGdiCC, BdiCC and MXDA (50/50-BdiCC-MXDA

After 24 h , the completion of the reaction was confirmed by the total disappearance of the $\mathrm{C}=\mathrm{O}$ stretching band of the cyclic carbonates ( $1790 \mathrm{~cm}-1$, PPGdiCC and $1780 \mathrm{~cm}-1$, BdiCC) in the FTIR-ATR spectrum (Figure S11). Further analysis by 1H NMR characterization showed the signals at $7.6-7.8 \mathrm{ppm}$ of the $-\mathrm{NH}-\mathrm{C}(\mathrm{O}) \mathrm{O}$ and the signal of $-\mathrm{CH} 2 \mathrm{NH}-$ at 4.15 and 4.17 ppm , verifying the formation of the urethane linkage (Figure S12).
