ICPLA 2021 Poster session Thursday 9.00 & 17.30

Morgane Warnier<sup>1</sup>, Andrea MacLeod<sup>2</sup>, Christelle Maillart<sup>1</sup>

## DISCUSSION

PCC is very inferior compared to current data for French children between 36-41 months : 63,85% vs 87,8% (MacLeod et al., 2011). This could be explained by :

- -The inclusion of 5 children of inferior age (35 months), but when we removed them, PCC is only increased by 1,41%
- <u>Biais</u> due to clinical sensibility to lisp as the main experimentator is an Orofacial Myofunctional Therapist **but** when we were less severe for transcriptions, PCC only increased by less than 1%
- <u>Specificities of Belgian</u> speech like devoiced fricatives in final position **but** assumed to have relatively minimal impact

- The differences between **target words used in picture naming tasks** is likely to be the most plausible explanation. Differences express in terms of **complexity of words (clusters) and number of syllables**. There are more words listed in the MB-CDIs (global database of young children's word production, <u>https://mb-cdi.stanford.edu/</u>) for ESPP, suggesting that items are more often produced by children of this age and therefore more **frequent**.

		•
	Evaluation Sommaire de la Phonologie ESPP	EULALIE adapted for young children (Meloni et al., n.d.)
Number of Words	40	43
Number of Clusters	7	16
4 syllables	0	6
3 syllables	3	11
2 syllables	20	13
1 syllable	17	13
% of word listed in MB-CDIs	51%	60%
(word usage by children)		

- PCC is originally meant to measure conversational speech (Shriberg et al., 1997) and seems to be influenced by speech material
- EULALIE seems to be more representative of real complexity of speech as young children produce more structure errors (Rvachew et al., 2013) whereas ESSP appears to suffer from ceiling effect
- It seems necessary to update the current French-speaking normative data, taking into account the speech material and the metric analysis employed : this data can be a starting point
