## Compatibility graph

$G=(V,A,w)$  where:

- $V = \{1, \dots, n\}$  set of vertices, consisting of all patient-donor pairs.
- $A$ , the set of arcs, designating compatibilities between the vertices. Two vertices  $i$  and  $j$  are connected by arc  $(i, j)$  if the donor in pair  $i$  is compatible with the patient in pair  $j$ .

We denote by  $\mathcal{C}(G)$  be the set of feasible cycles of length at most  $K$  for  $G = (V, A)$ .

For each vertex  $i \in V$ , a preference order is given on the set of incoming arcs  $\{(j, i) \in A\}$ .

A preference  $p$  associated to arc  $(j, i)$  means that the recipient of the pair  $i$  ranks the donor of pair  $j$  at position  $p$  in its preferences list of acceptable donors.

Given a cycle  $c$  we define two sets:

- $\mathcal{A}(c)$

## Definition

For a given cycle  $c$ ,  $\mathcal{A}(c)$  be the set of cycles that are not disjoint with  $c$  but they are not potentially blocking  $c$  and  $c$  does not potentially block them neither.

If two cycles  $c_u$  and  $c_v$  are not vertex disjoint then three situations can occur:

- $c_u \in PBC(c_v)$
- $c_v \in PBC(c_u)$
- $c_u \in \mathcal{A}(c_v)$  and  $c_v \in \mathcal{A}(c_u)$

# Result

For an exchange  $\mathcal{M}$ , the following conditions are equivalent:

(a)  $\mathcal{M}$  is L-stable;

(b) for each cycle  $v \notin \mathcal{M}$ , if  $v$  is not disjoint from  $\mathcal{M}$ , then there exists  $w \in \mathcal{M}$  such that  $w \in PBC(v) \cup \mathcal{A}(v)$ .

- $PBC(A) = \{D\}$
- $PBC(D) = \{B\}$
- $PBC(B) = \emptyset$
- $PBC(C) = \emptyset$
- $PBC(E) = \{C\}$
- $\mathcal{A}(c) = \emptyset$  for all cycles

# Result

For an exchange  $\mathcal{M}$ , the following conditions are equivalent:

(a)  $\mathcal{M}$  is L-stable;

(b) for each cycle  $v \notin \mathcal{M}$ , if  $v$  is not disjoint from  $\mathcal{M}$ , then there exists  $w \in \mathcal{M}$  such that  $w \in PBC(v) \cup \mathcal{A}(v)$ .

- $PBC(A) = \{D\}$
- $PBC(D) = \{B\}$
- $PBC(B) = \emptyset$
- $PBC(C) = \{F\}$
- $PBC(E) = \{C\}$
- $PBC(F) = \emptyset$
- $\mathcal{A}(c) = \emptyset$  for all cycles

## IP formulation

we introduce the natural variables  $y_v$  for all  $v \in \mathcal{C}(G)$  and the following set of constraints:

$$y_u + y_v \leq 1 \quad \forall u \in \mathcal{C}(G), \forall v \in PBC(u) \cup \mathcal{A}(u) \quad (1)$$

$$y_u \leq \sum_{w \in PBC(v) \cup \mathcal{A}(v)} y_w \quad \forall u \in \mathcal{C}(G), \forall v \in PBC(u) \quad (2)$$

$$y_v \in \{0, 1\} \quad \forall v \in \mathcal{C}(G) \quad (3)$$

- 1 Constraints (1) ensure the independence of the cycles selected
- 2 Constraints (2) ensure the stability of the exchange

## Definition

Given a directed graph  $G = (V, A)$ , subset  $S \subseteq V$  is a **kernel** of  $G$  if it is independent and absorbing. That is:

- for all  $(u, v) \in A$  either  $u \notin S$  or  $v \notin S$
- for every  $v \notin S$  there exists a vertex  $u \in S$  such that  $(v, u) \in A$

## Definition

A **local kernel** of  $G$  is an independent subset  $S$  of vertices such that every neighbor (or out-neighbor) of  $S$  is absorbed by  $S$ . In other words:

- for all  $(u, v) \in A$  either  $u \notin S$  or  $v \notin S$
- if there exist  $u \in S$  and  $v \notin S$  such that  $(u, v) \in A$ , then there must exist  $w \in S$  such that  $(v, w) \in A$ .

## Definition

A **local kernel** of  $G$  is an independent subset  $S$  of vertices such that every neighbor (or out-neighbor) of  $S$  is absorbed by  $S$ . In other words:

- for all  $(u, v) \in A$  either  $u \notin S$  or  $v \notin S$
- if there exist  $u \in S$  and  $v \notin S$  such that  $(u, v) \in A$ , then there must exist  $w \in S$  such that  $(v, w) \in A$ .

## Result

The empty set  $S = \emptyset$  is an L-kernel. So, every directed graph has an L-kernel (but not necessarily a not empty one).

## Result

Given a directed graph  $G = (V, A)$ , deciding whether  $G$  has a nonempty local kernel is NP-complete.

*Reduction from SAT*

## Blocking digraph

Starting from the initial directed graph  $G = (V, A)$ , let's construct a directed graph  $G' = (V', A')$  such that:

- For each  $c_v \in \mathcal{C}(G)$  there is a vertex  $c_v$  in  $V'$  representing that cycle.
- An arc  $(c_u, c_v) \in A'$  if  $c_v \in PBC(c_u)$  or if  $c_v \in \mathcal{A}(c_u)$ .

$G'$  is the **blocking directed graph** associated to  $G$ .

## Result

A L-kernel in  $G'$  defines a L-stable exchange in  $G$ .

and a kernel in  $G'$  defines a stable exchange in  $G$

## 2 Formulation 2:

$$y_u + y_v \leq 1 \quad \forall (u, v) \in A' \quad (4)$$

$$y_u \leq \sum_{w \in N^+(v)} y_w \quad \forall (u, v) \in A' \quad (5)$$

$$y_v \in \{0, 1\} \quad \forall v \in V' \quad (6)$$

- **Independence** constraint (4) can be replaced by

$$\sum_{c \in C: i \in V(c)} x_c \leq 1 \quad \forall i \in V \quad (7)$$

- **Stability/Absorbing** constraint (5) can be replaced by fixing  $v$  and adding each constraint above for all  $(u, v) \in A'$ :

$$\sum_{w \in N^-(v)} y_w \leq |N^-(v)| \sum_{w \in N^+(v)} y_w \quad \forall v \in V' \quad (8)$$

where  $N^-(v) = |\{w : (w, v) \in A'\}|$ .

Comparison between 3 formulations:

- ① Initial formulation for L-stable exchange (Form-LS)
- ② Form-LS with independence constraints modified
- ③ Form-LS with independence constraints and stability constraints modified

Best IP formulation for L-stable exchanges in terms of computation time:

$$\sum_{v \in C(\bar{G}): i \in V(c)} y_v \leq 1 \quad \forall i \in V$$

$$\sum_{w \in N^-(v)} y_w \leq |N^-(v)| \sum_{w \in N^+(v)} y_w \quad \forall v \in V'$$

$$y_v \in \{0, 1\} \quad \forall v \in V'$$

# Stability vs *Local* stability

## Stability vs *Local* stability

- Problem of maximum stable exchange (SE) and problem of maximum L-stable exchange (LSE) are not the same problems (not the same set of feasible solutions) **BUT** when the objective function of both problems is to maximize the total length of the cycles selected, the two formulations have the same objective.
- **SE** problem: Some instances do not have a solution
- **LSE** problem: All instances tested have a solution of cardinality greater than zero
  - for  $N=300$ ,
    - 1 5 out of 50 instances do not have a stable exchange
    - 2 5: average optimal value is 74
    - 3 45: average optimal value is 150, 08
  - for  $N=400$ ,
    - 1 11 out of 50 instances do not have a stable exchange
    - 2 11: average optimal value is 141, 45
    - 3 39: average optimal value is 205, 94
