#### Introduction

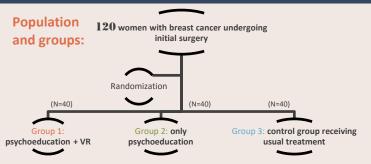

- · Many women with **breast cancer** who are scheduled for surgery suffer from **preoperative anxiety** (Majumdar et al., 2019).
- · Unmanaged preoperative anxiety can have a negative impact on the intra- and postoperative periods (e.g., pain, increased use of analgesics and anesthetics) (Kulkarni et al., 2017; Stamenkovic et al., 2018).

This study aims to examine the benefit of the combination of two psychological tools during the preoperative phase:

psychoeducation on relaxation and relaxing environments through virtual reality (VR).

### **Methods**

#### **Primary and secondary outcomes:**

- Preoperative anxiety, worries, and relaxation's indicators measured by visual analog scales.
- Perioperative experience (e.g., pain, comfort), heart rate, anesthesic and surgical data (e.g., anesthesia and analgesia requirement).

#### Data collection:

□ Baseline

☐ 21 days before surgery □ 14 days before surgery <sup>™</sup> 7 days before surgery

<sup>™</sup> The day o surgery

口 The day after surgery ° ∼1 month after surgery

## **Expected results and discussion**

- Repeated measures ANOVAs including within and between-subjects factors will be performed to compare the addition of RV to psychoeducation and treatment as usual.

**Figure 1**. Hypothetical graph of average anxiety scores.

- The combined action of psychoeducation and VR could become a real alternative to reduce anxiety in women awaiting for breast cancer surgery.
- · This new proactive approach may provide a much-needed, easy-to-use, nonpharmacological relaxation intervention to improve the health of surgical patients.
