

FRAC → WECO

A regional flux-based risk assessment approach of contaminated sites on surface water and groundwater bodies

Contaminated Site Management in Europe

Gent, October 27th 2009

Context of the FRAC-WECO project

Context of the FRAC-WECO project

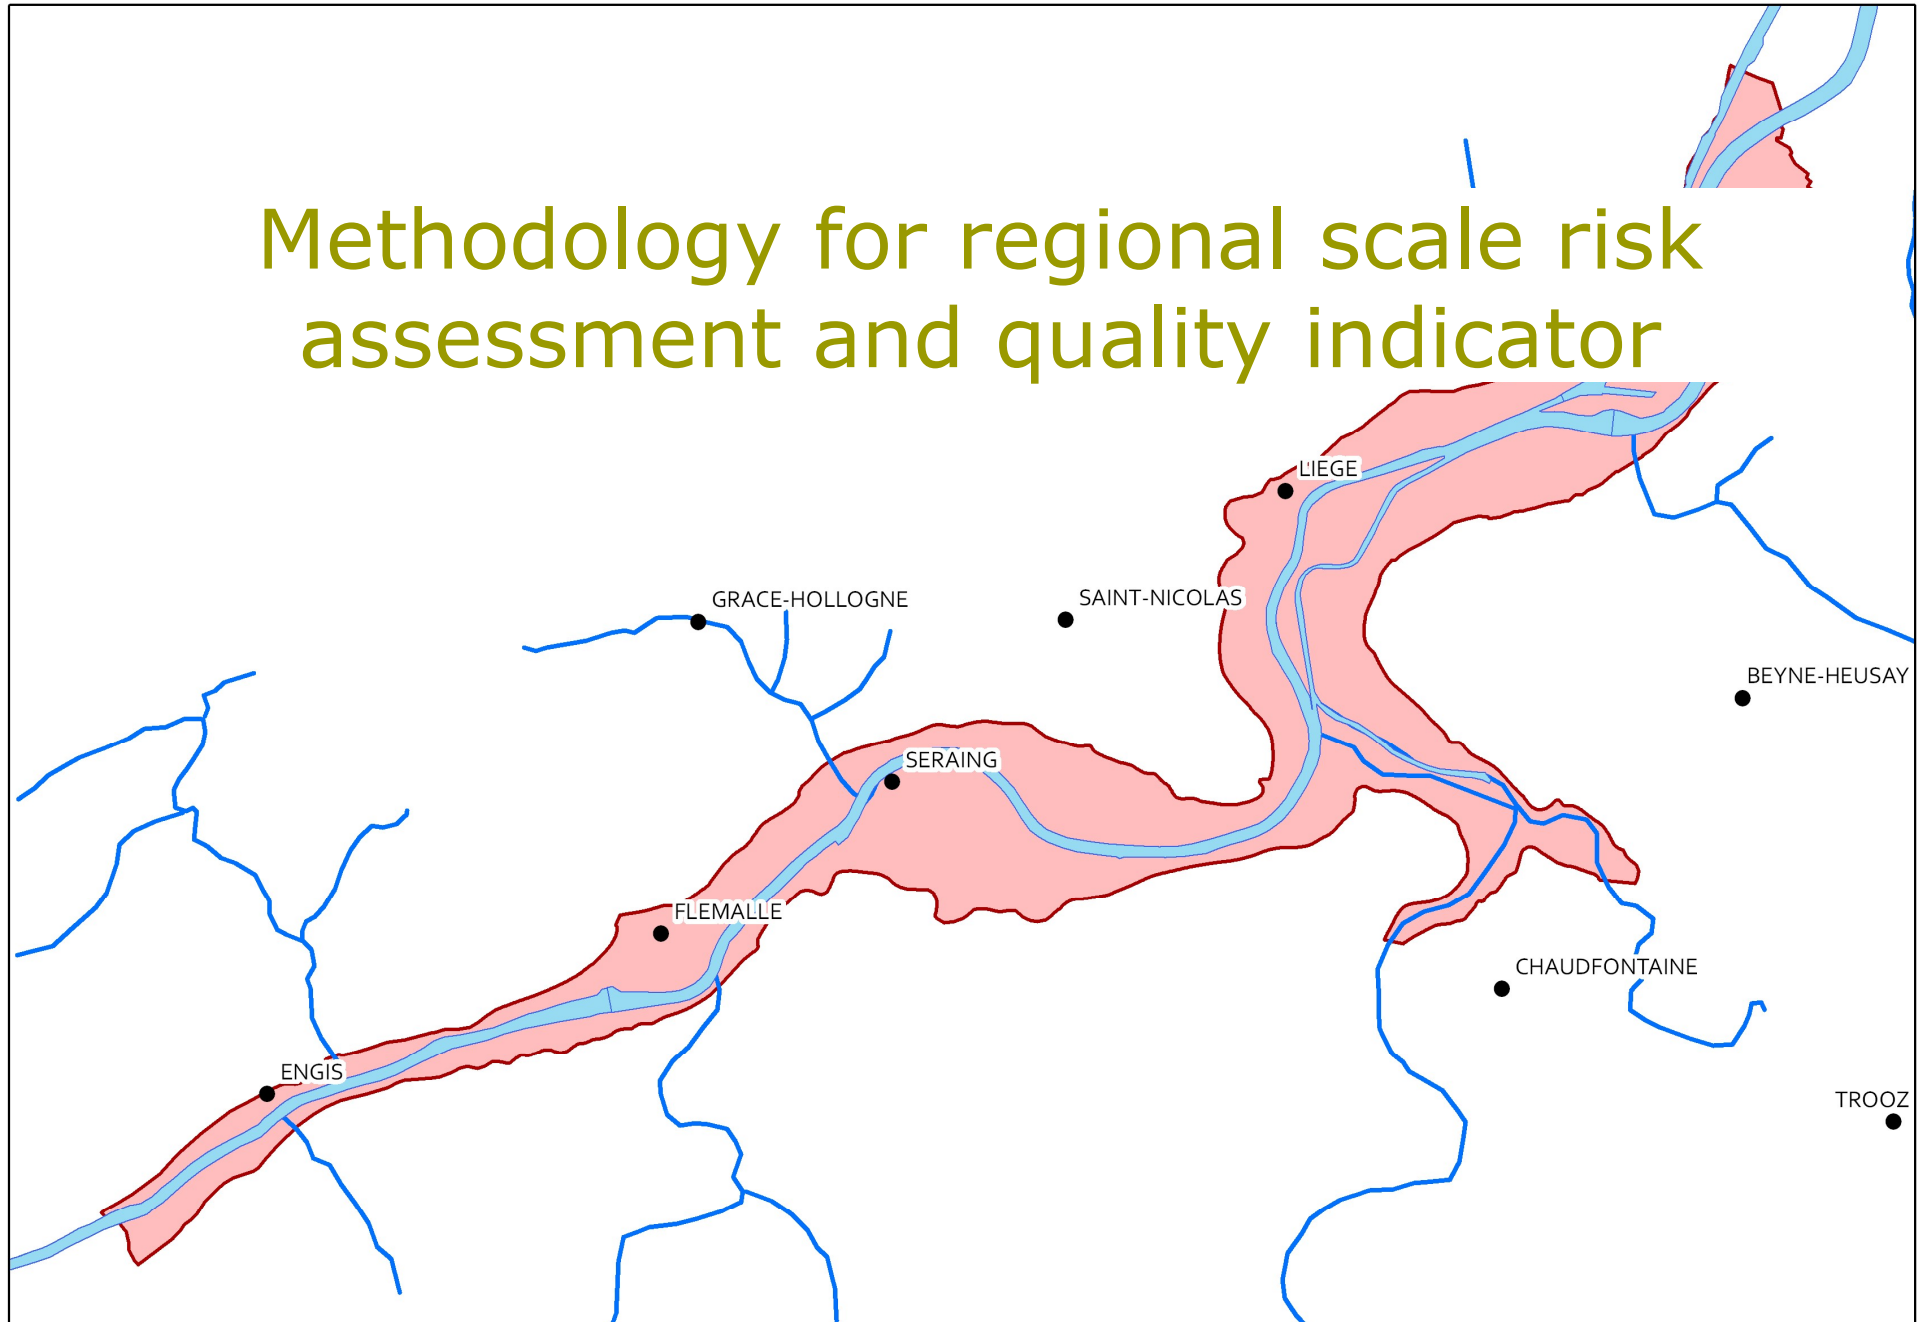

- Context: EU Water Framework Directive
- Relevance: management of heavily industrialized area with numerous contaminated sites
- Main objectives: risk assessment of contaminated site using mega-site approaches based on criteria able to reflect the risk of water quality degradation
 - In a cumulative way
 - At the water body scale

Context of the FRAC-WECO project

- ❑ Flux-based Risk Assessment of Contaminants on Water resources and ECOsystems
- ❑ Financed by the Belgian Science Policy 2006-2010, gathering 5 scientific partners from Belgium and France
 - ULg–Aquapôle: Coordinator, hydrogeology
 - ULg–LEAE: Ecotoxicity, TRIAD like approach
 - VUB: Spatially distributed ground water recharge from remote sensing
 - VITO: Behaviour of contaminants
 - BRGM: Socio economical aspects
- ❑ Today's presentation focuses on risk assessment methodology and application on groundwater body RWM073

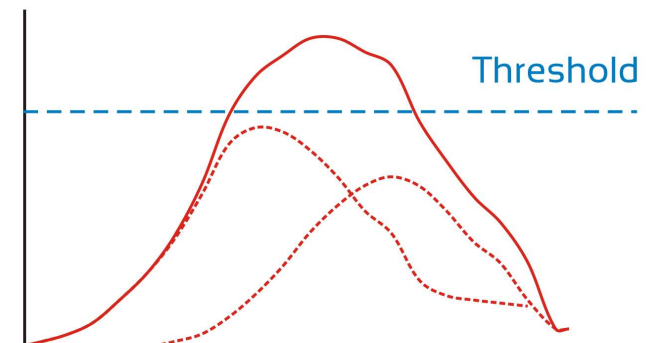

Methodology for regional scale risk assessment and quality indicator

□ Risk assessment of contaminated site

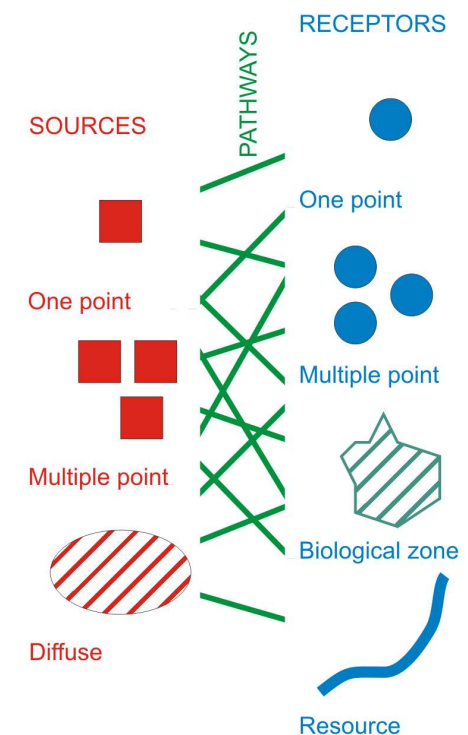

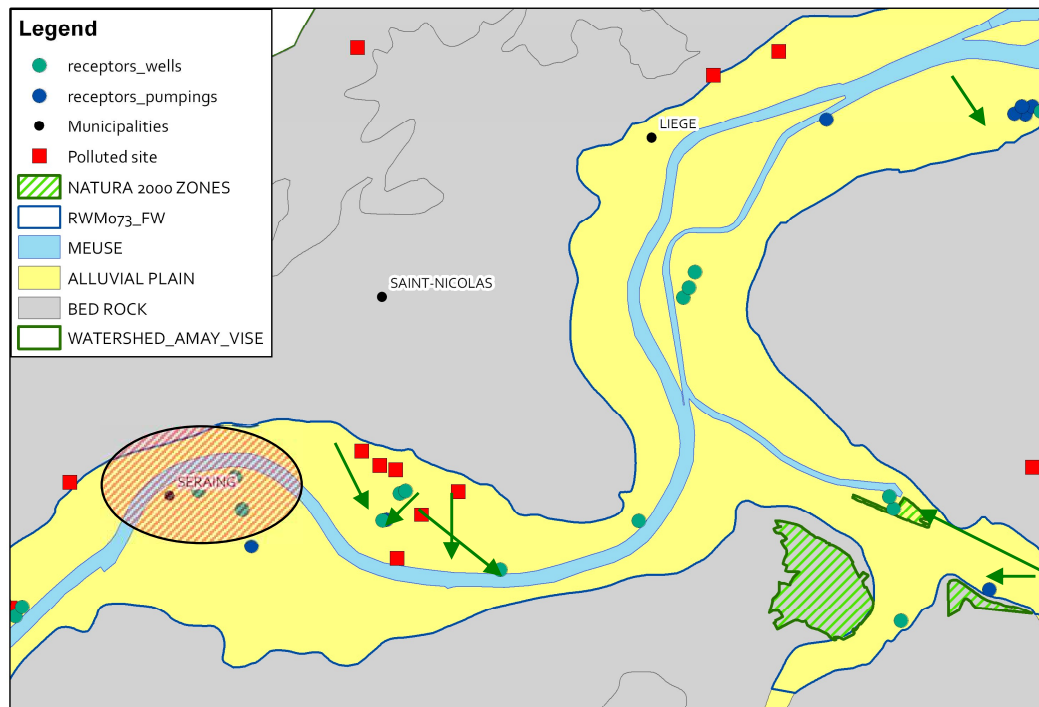

- Classical schema: simple S-P-R

□ 1 site means

- 1 or few sources
- 1 or few contaminants
- 1 or few pathways
- 1 or few well identified receptors
- Good characterization of context

- ❑ Risk assessment of multiple contaminations on multiple receptors at regional scale
 - FRAC→WECO: more than point sources and point receptors
 - Need for a lot of information about S, P and R

→ Flux based risk assessment in order to consider the additive effect of various sources

→ GIS data base to manage SPR information (Development in progress at ULg)

Local Risk Assessment Criteria

- 1S → 1R_{point}: OK with usual concentration-based criteria (referential is a function of the type of receptor)

- f_M = mass flux
- Q = amount of contaminated water × t⁻¹

$$C = f_M / Q$$

- nS → 1R_{point}: cumulative approach (flux-based) and still usual concentration-based referentials

- f_M^{cum} = cumulative mass flux
- Q = amount of contaminated water × t⁻¹

$$C = f_M^{cum} / Q$$

Regional Risk Assessment Criteria

- $nS \rightarrow 1 R_{RGW/SW}$: cumulative approach (flux based) but what referential to use?
- Contaminant to GW
 - f_M^{cum} = cumulative mass flux
 - $Q = ?$

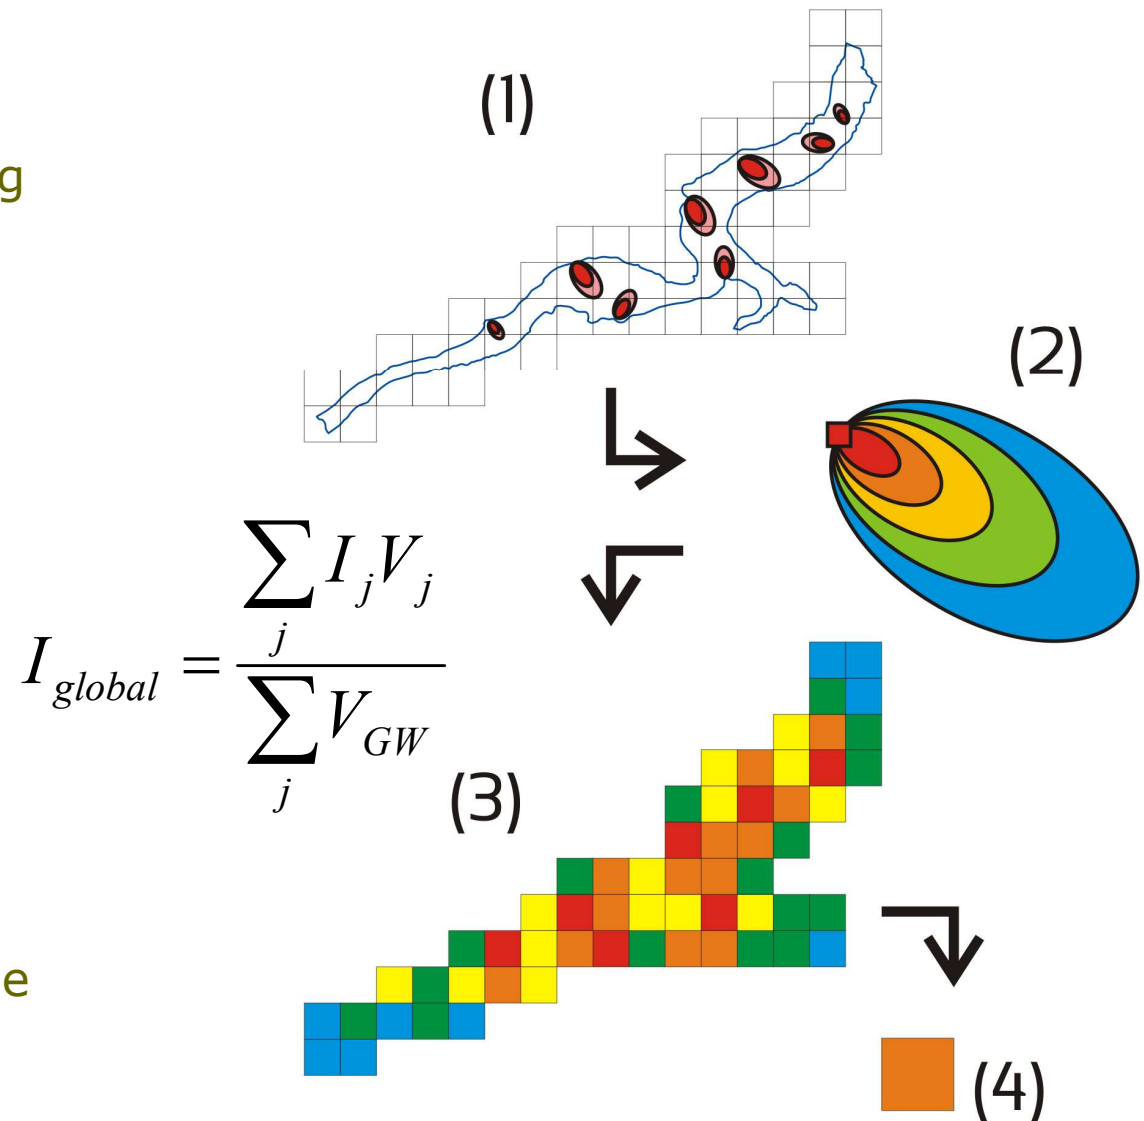

$$C = \frac{f_M^{cum}}{Q}$$

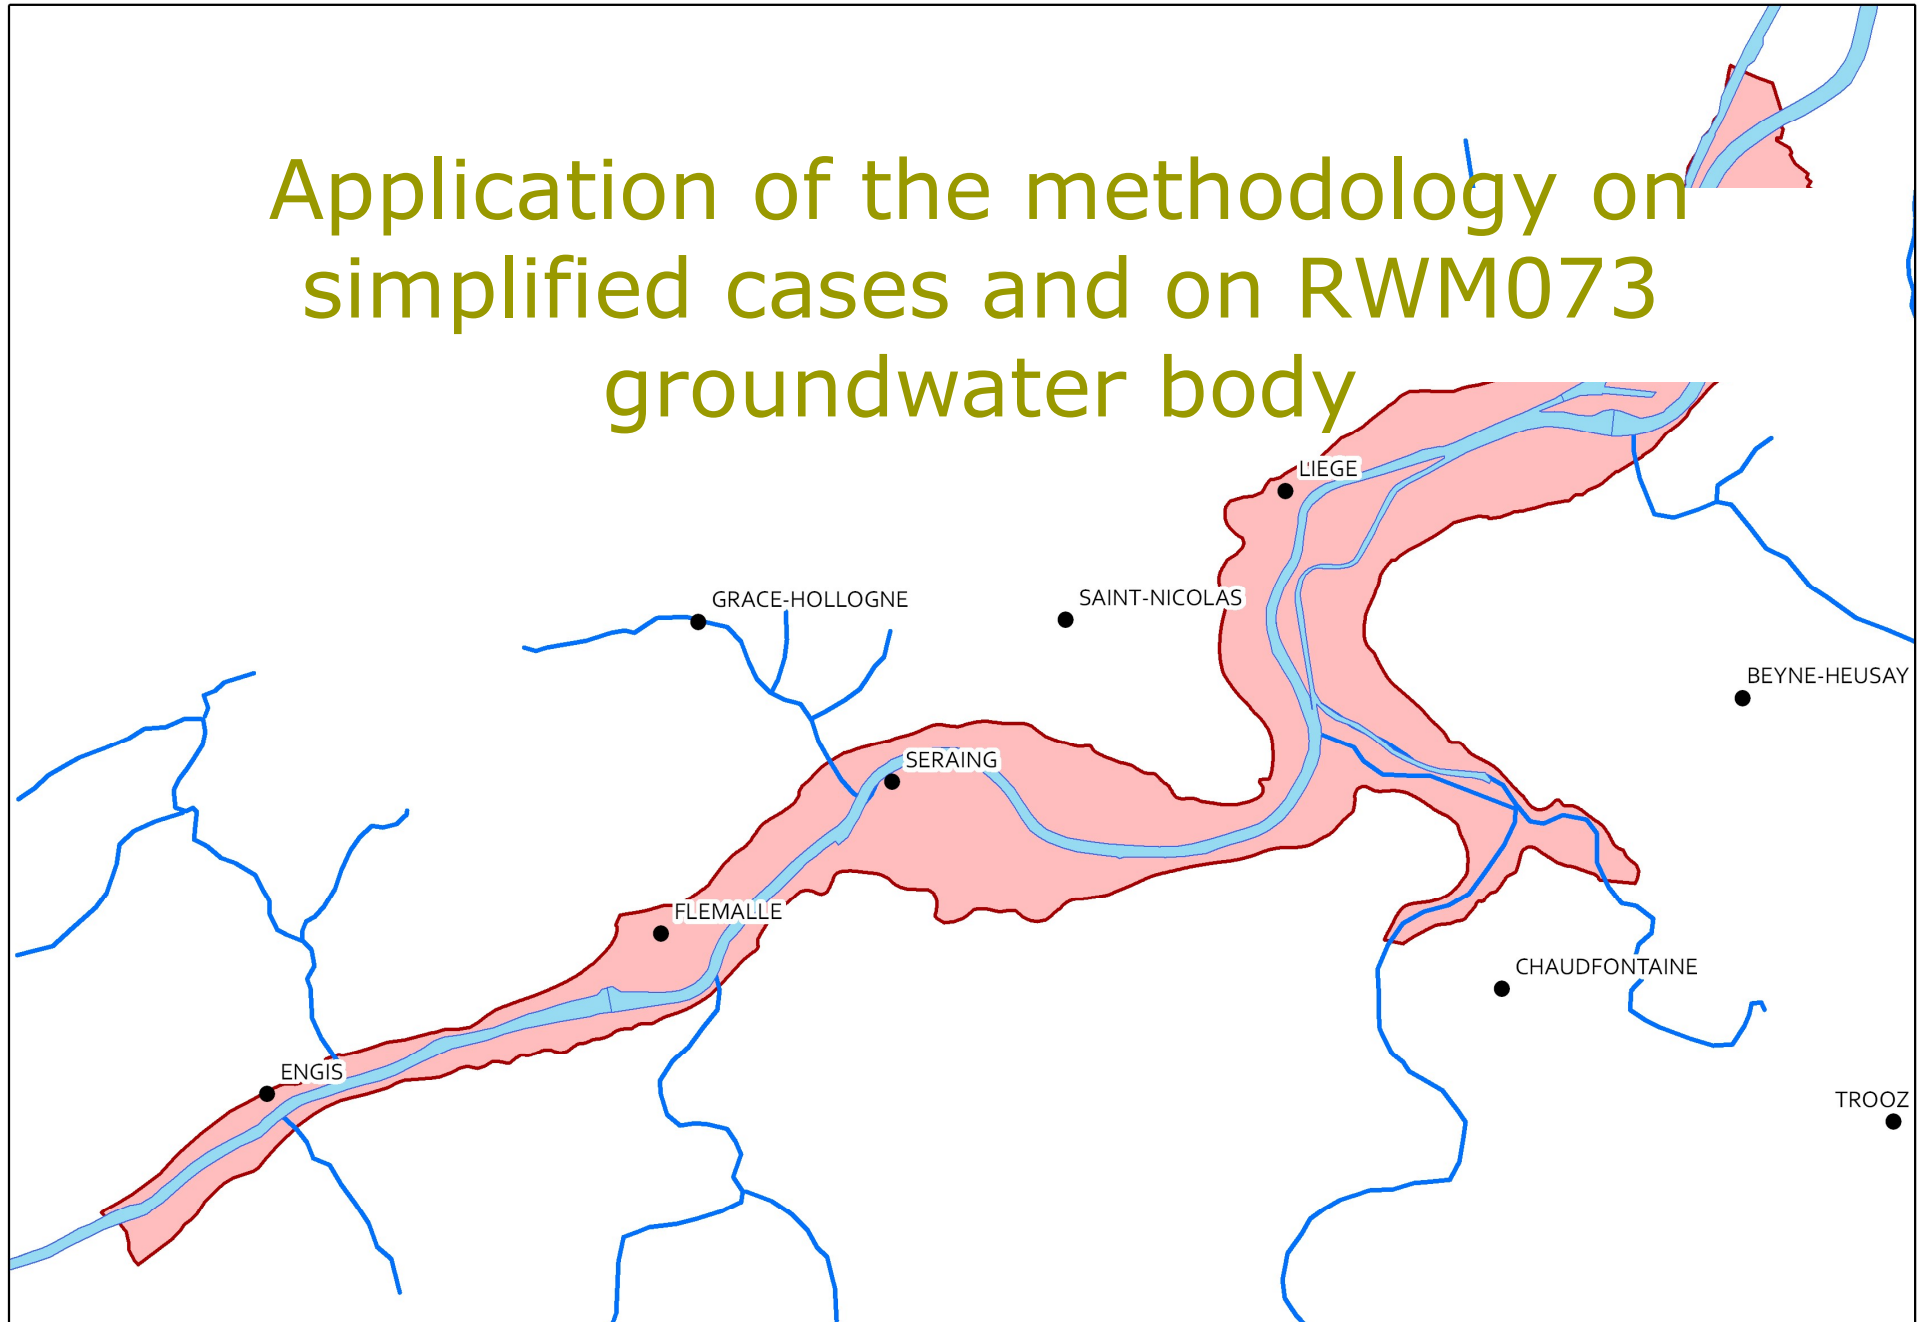

Contaminant through GW

1. GWB discretization and modelling of contaminant leaching + plume dispersion
2. For each plume, classification of concentrations according to threshold values of the Walloon region SEQ-ESO
3. In each grid cell: SEQ-ESO indicator taking into account the various contaminants and possible flux cumulative effects
4. Aggregation into a limited number of global SEQ-ESO indicators

C. Rentier et al., 2006 : A framework for an optimized Groundwater monitoring network and aggregated indicators. Environmental Geology, vol. 50/2, p194-201.

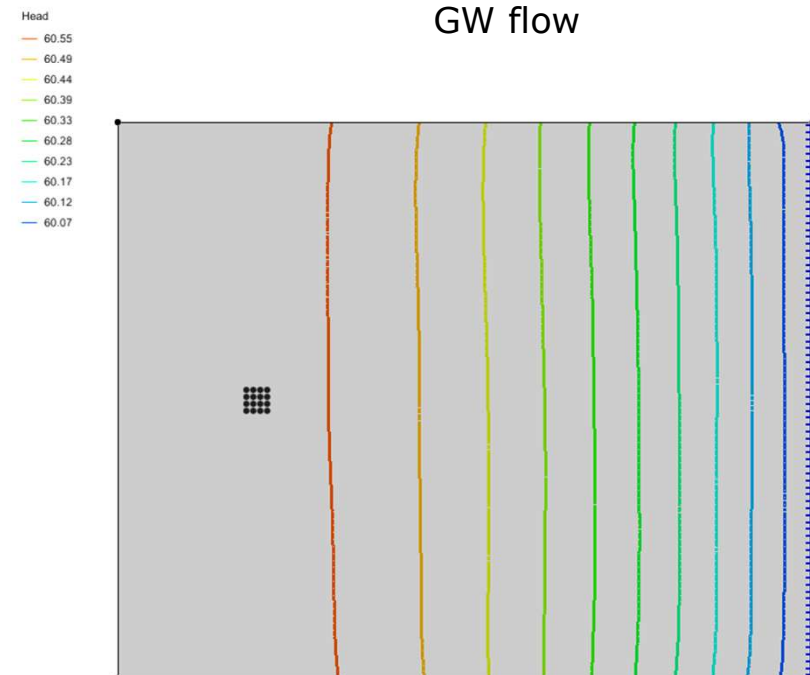

Application of the methodology on simplified cases and on RWM073 groundwater body

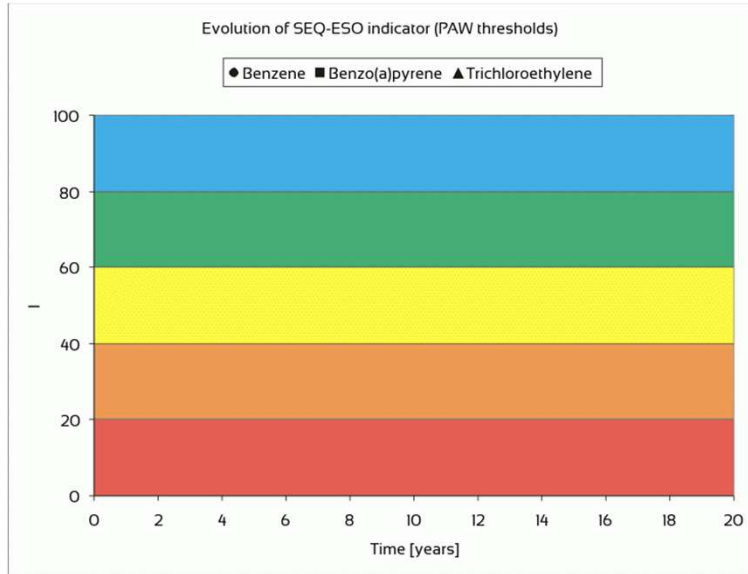

The regional risk assessment methodology using indexes from SEQ-ESO has been tested on simplified cases (in the same time than general model development).

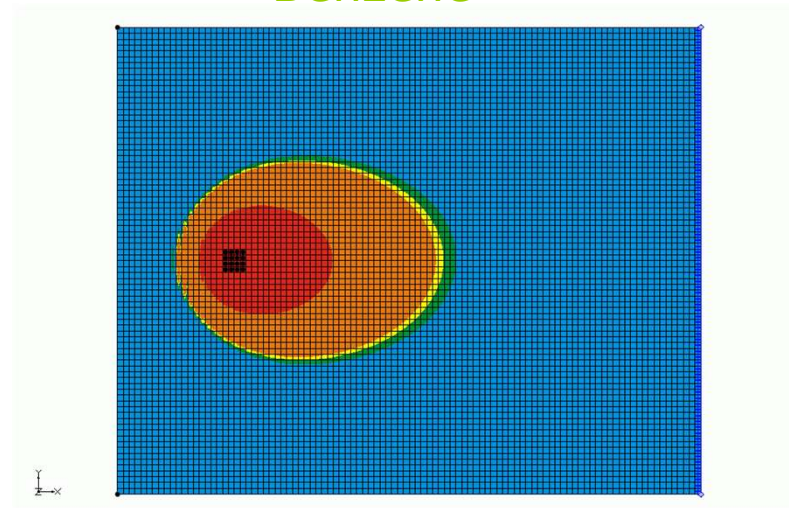

- Simplified model, 500 x 400 x 20 m, with no-fluxes boundary conditions N, S, W and river E.
- Flow and transport parameters coming from former studies on the Meuse alluvial plain.
- Chemical pollutant properties coming from literature.
- Tested for 3 species
 - Benzene: high mobility, high degradation, 1 g/l
 - Benzo(a)pyrene: low mobility, low degradation, 1 µg/l
 - Trichloroethylene: high mobility, low degradation, 1 g/l

Evolution of SEQ-ESO index during 20 years simulation

Benzene

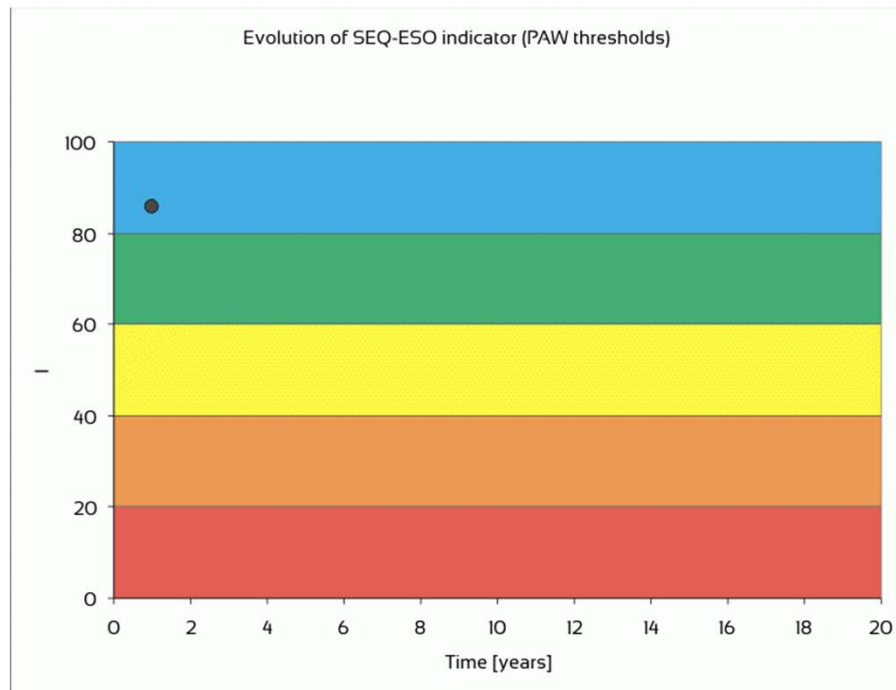

Benzo(a)pyrene

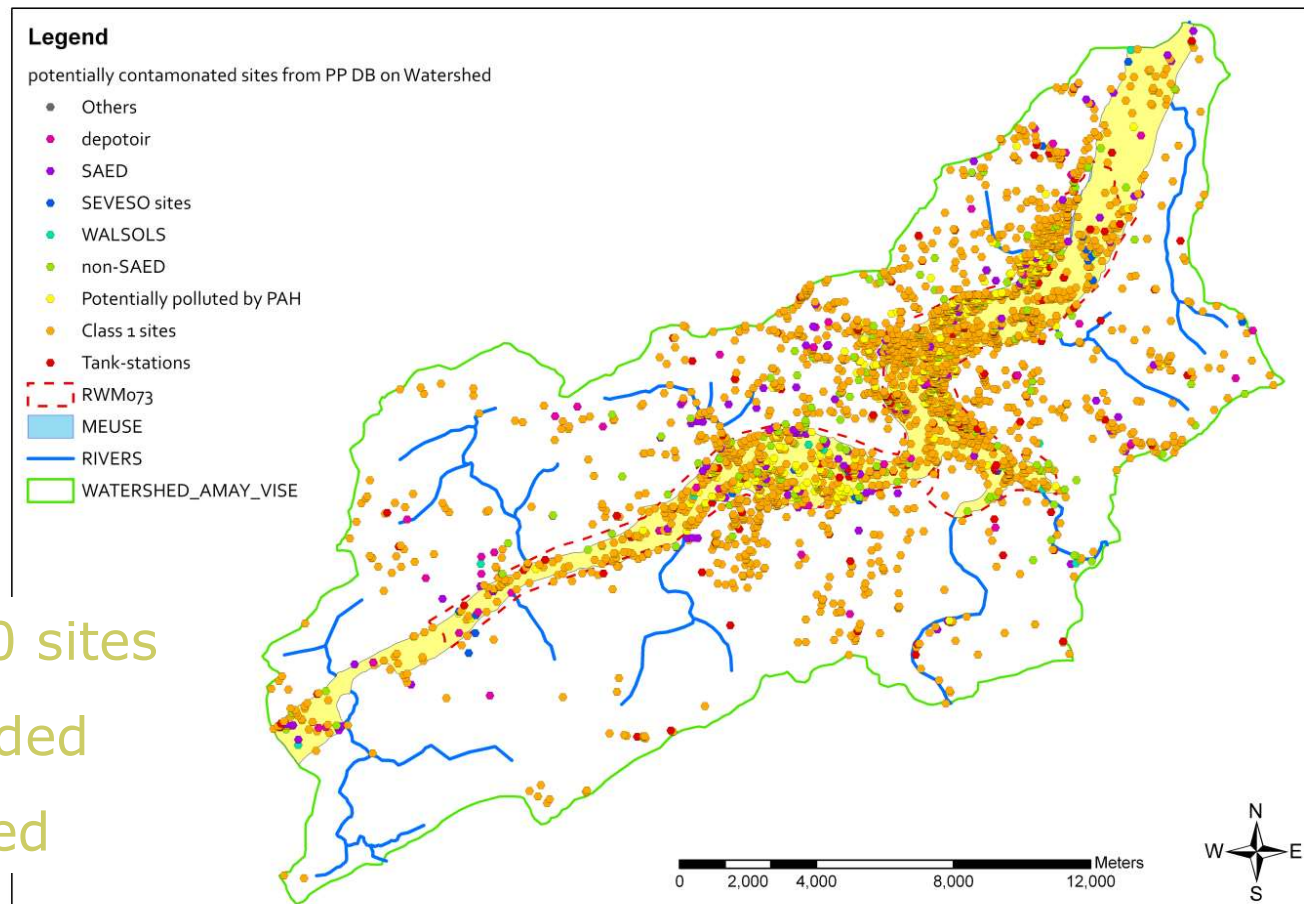

TCE

Evolution of SEQ-ESO index during 20 years simulation
Integrating several pollutant species

- ❑ RWM073: Alluvial plain of the Meuse River between town of Engis and Herstal
- ❑ Heavy industrial past: metallurgy, cokery, mining, urban areas,...

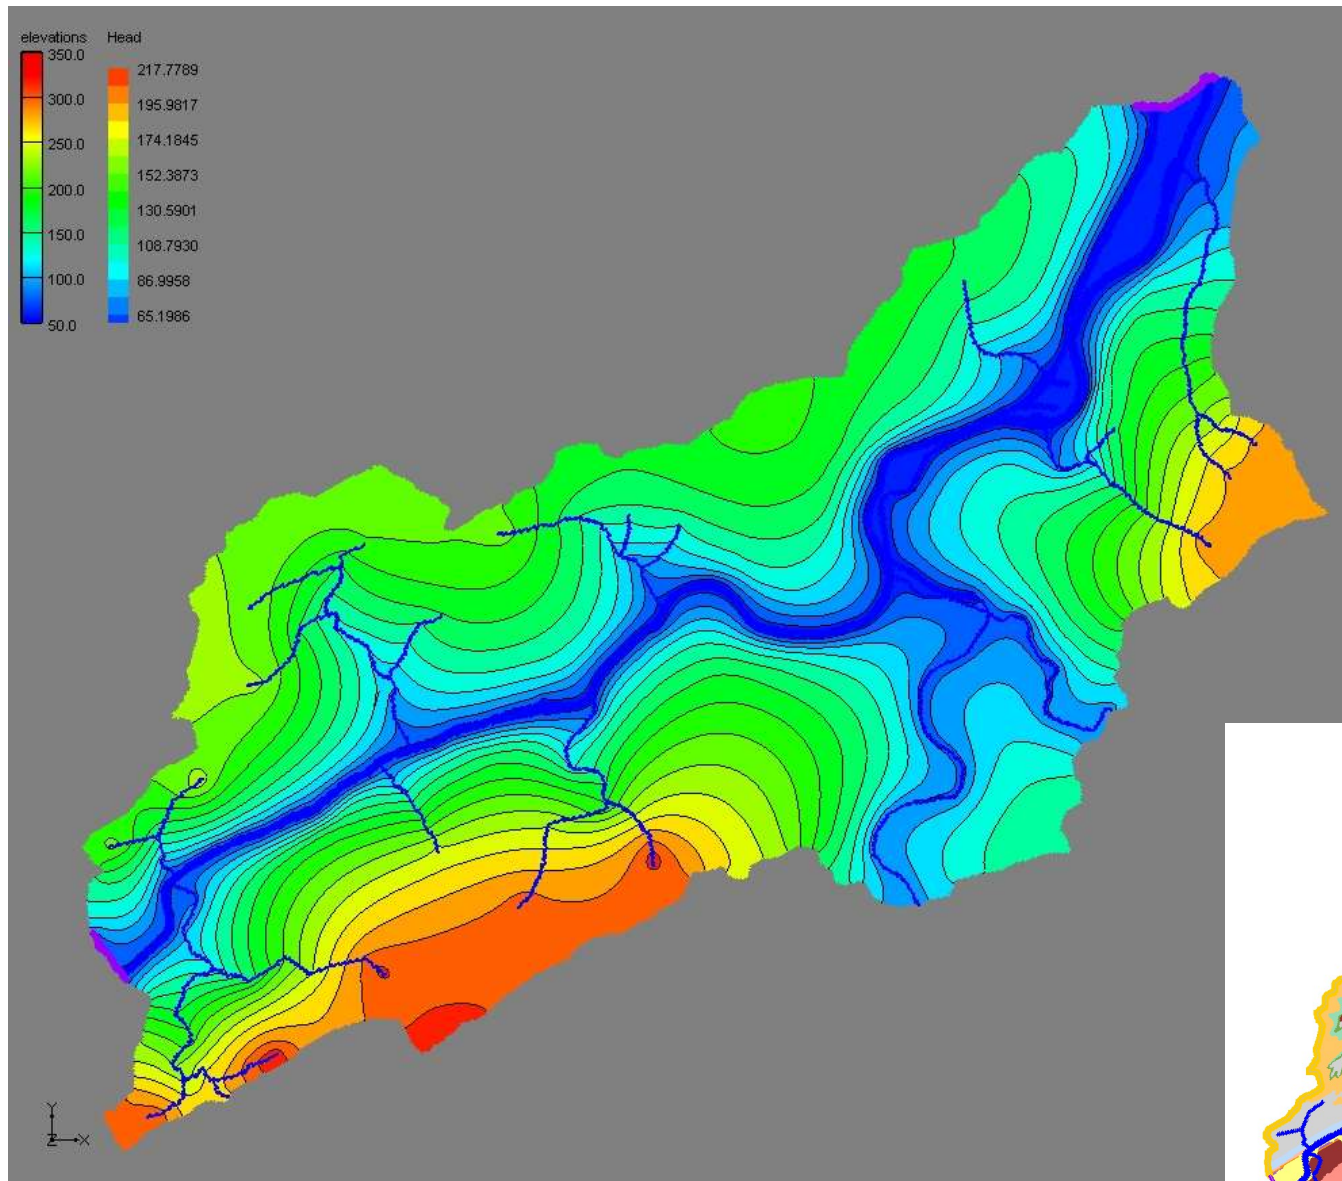

On watershed: 3600 sites
Some can be discarded
Only 13 characterized

RWM073 modelling

- ❑ Local alluvial aquifer fed by rainfall and runoff water from the slop of the watershed, and drained by the Meuse
- ❑ Watershed mainly composed by low permeable deposits but a groundwater flow occurs in the shallow altered fringe of those sediments from crest to alluvial plain
- ❑ Modelling Steps:
 - Run GW flow model on the watershed
 - Extract the results about GW flow and apply them on the alluvial plain boundaries
 - Run GW transport model on the alluvial plain

Conclusions and perspectives

Conclusions and perspectives

- Main outcome if the research:
 - An efficient and flexible methodology of risk assessment for groundwater (or surface water) at the regional scale of the megasite (or groundwater body)
 - A physically based cumulative flux approach giving a global indicator of water quality/degradation
 - The easy usability of this indicator for costs and benefits analyse of management plans
 - The ability to test scenarios and model trends what is Water Framework Directive compliant

- First encouraging results that have to be push further:
 - Complete regional real application on RWM073
 - Complete the development and feed the GIS SPR data base
 - Integrate uncertainties/probabilistic scenarios of pollution sources, pollutants properties, GW flow,...
 - Perform socio-economical analysis (BRGM)
 - Integrate the ecotoxicological indicator of LEAE

Thank you for your attention
