

# An interactive activation model of verbal working memory:

## Simulating psycholinguistic effects

Benjamin Kowialiewski<sup>1,2</sup>, Steve Majerus<sup>2</sup>

<sup>1</sup>Université Grenoble Alpes, <sup>2</sup>University of Liège, Belgium

Linguistic knowledge impacts Working Memory (WM) performance

## **Psycholinguistic effects:**

**Phonological similarity effect.** Phonologically similar vs. dissimilar words

**Lexicality.** Words vs. nonwords

Lexical frequency. High vs. low frequency words

**Neighborhood density.** Words drawn from dense vs. sparse lexical neighborhood

**Semantic relatedness.** Semantically related vs. unrelated words

**Imageability.** High vs. low imageability words

These effects are robust **but**:

There currently exists no integrative architecture that explains all these effects at once.

Interactive activation models of language processing.

Dell & et al. (1997)

McClelland & Elman (1981)

Semantic

Lexical

Low imageability

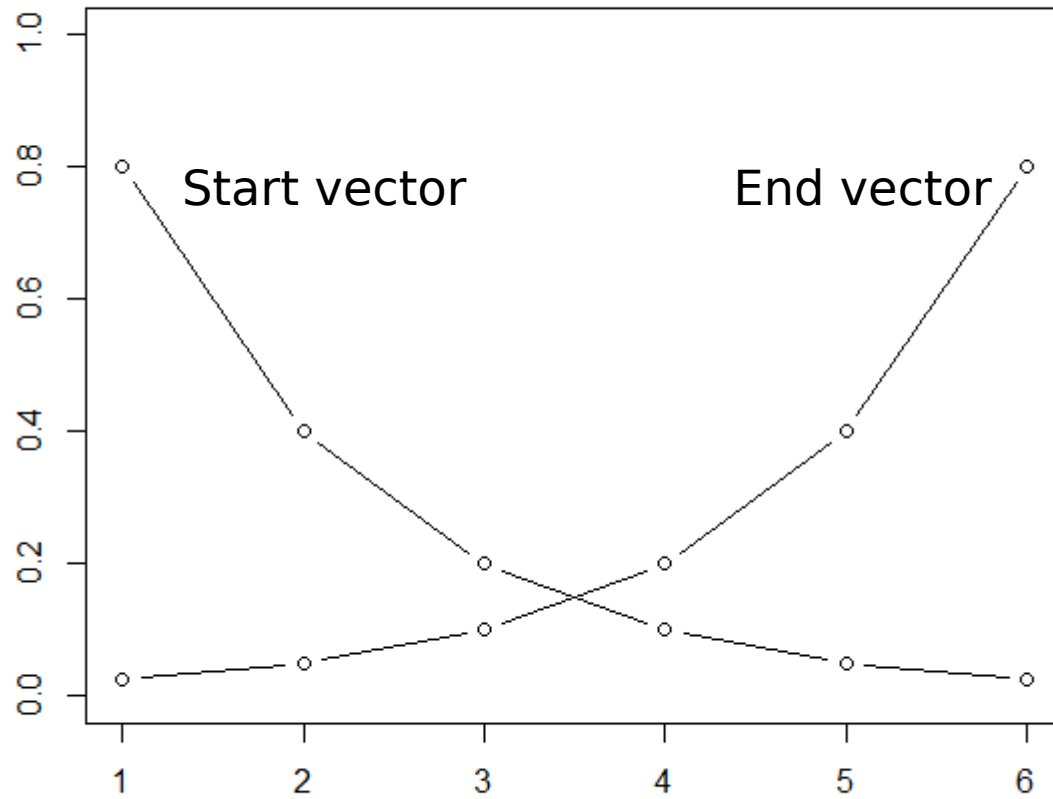

Semantic

Lexical

High imageability

## The Stard-End Model (SEM)

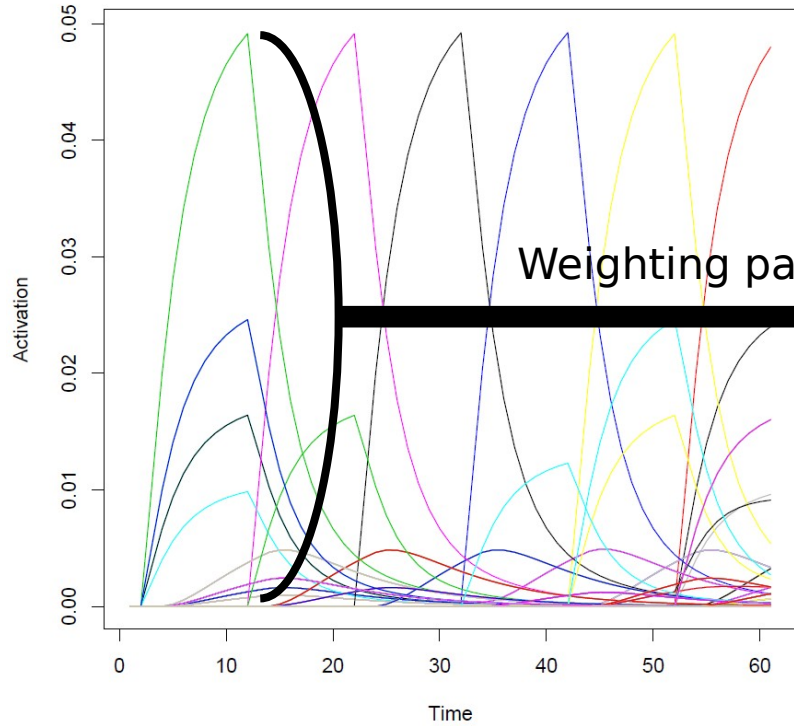

Henson (1998)

# Architecture

## Simulated Annealing

Fitting the SEM model on the “weakest”  
condition  
(e.g. low imageability)

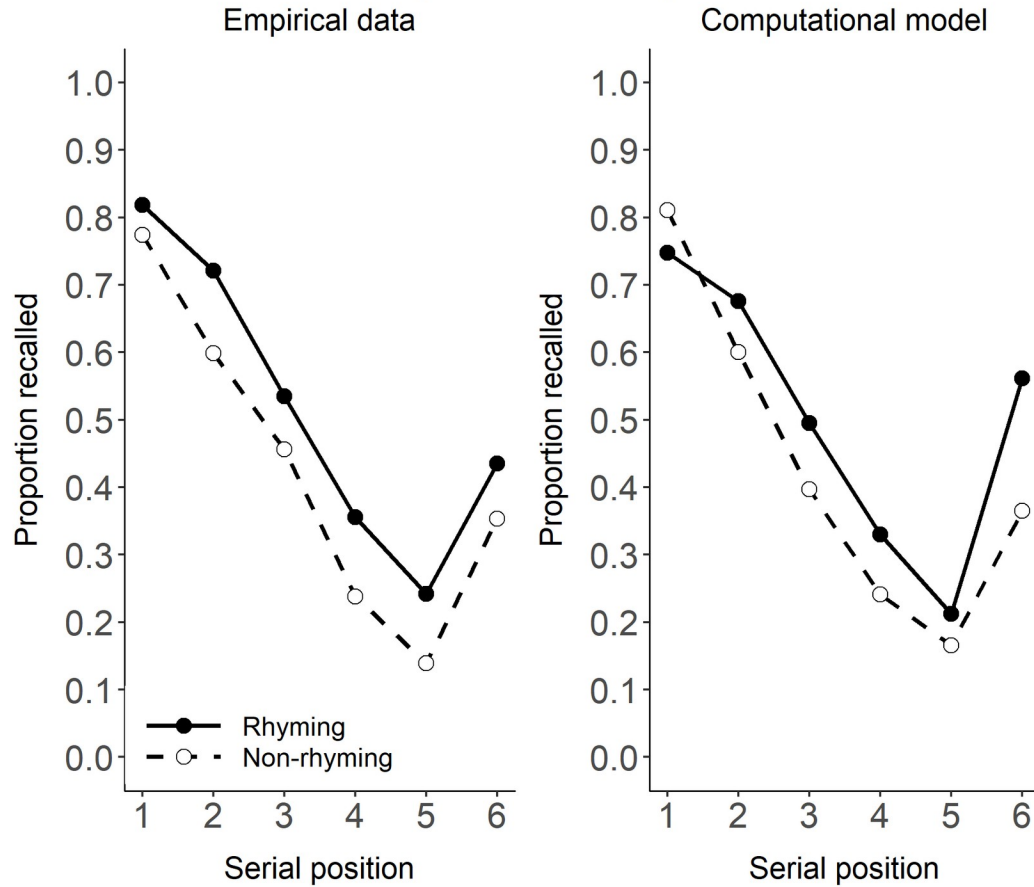

Modulating item’s linguistic properties  
(e.g. number of semantic features)

Prediction

## Phonological similarity effect

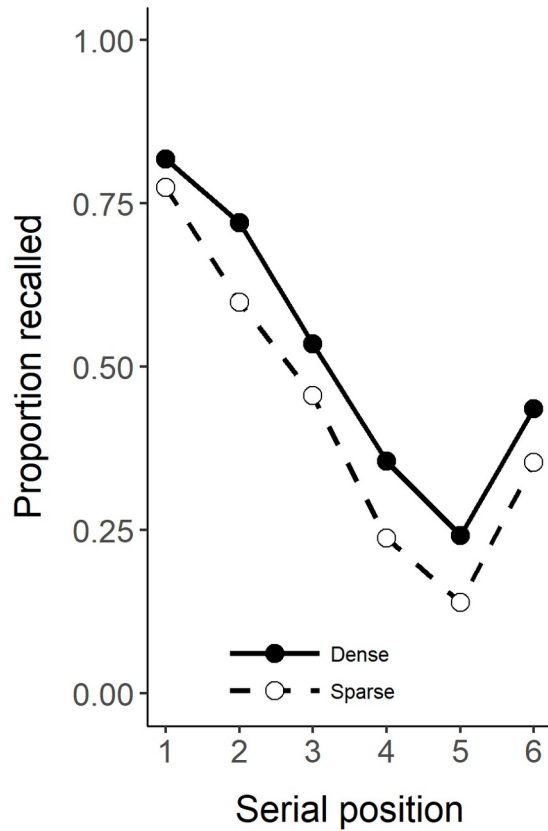

## Lexical frequency effect

## Neighborhood density effect

Empirical data

Computational model

## Semantic relatedness effect: Shared features

# Results

## Imageability effect

## **Lexicality effect?**

Requires strong assumptions as regards the way items are represented at the sub-lexical level. This remains unknown.

**Interactive activation** principles provide a **natural account** to explain the influence of linguistic knowledge on WM performance.

This using the same linguistic architecture.
