Hence, the objective of this paper is to evaluate the aesthetics of streetscapes characterized by buildings with different heights and front setbacks, and distinct levels of order and visual stimulus, by three groups of people with different levels and types of educational background, and to strengthen the importance of the results generated by studies involving empirical aesthetics and their consideration in architectural and urban design projects and so, for a pleasant aesthetic experience for users of public open spaces.

2. METHODOLOGY

Questionnaires available in the LimeSurvey software via the Internet were used for data collection, being answered by 250 people as follows: 62 architects, 169 non-architects college graduates and 19 non-college graduates. These respondents were invited by e-mail sent to the unions of employees, Deans and Departments of many federal educational institutions, including the Federal University of Rio Grande do Sul, and to educational institutions in charge of preparing for the university entrance examination, in the city of Porto Alegre.

Simple-choice questions about the aesthetic evaluations of each of the nine streetscapes scenes and multiple-choice about the order of preference for the appearance of the three scenes in each of the three sets and multiple-choice questions about the justifications for the preferred and least preferred scene in each of the three sets were used, such as: "Do you think the appearance of the scene A is: [] Very beautiful, [] Beautiful, [] Neither beautiful nor ugly, [] Ugly, [] Very ugly"; "Rank scenes from the most (1) to the least (3) preferred in appearance: [] Scene A, [] Scene B, [] Scene C"; "Nominate the main reasons that justify the most preferred scene's appearance: [] Adequate height of buildings, [] Adequate amount of visible sky, [] Others:"; "Nominate the main reasons that justify the least preferred scene's appearance: [] Inadequate height of buildings, [] Inadequate amount of visible sky, [] Others:"

Nine streetscapes scenes with little or no solar incidence, in order to avoid high contrasts and shadows on buildings, were included in the questionnaire in three sets as follows: set 1 – three streetscapes scenes characterized by buildings of different heights inside the blocks, with no direct relationship with the street (Figure 1); set 2 – three streetscapes scenes characterized by buildings of different heights on the block perimeter, with doors and windows facing the street (Figure 2); set 3 – three streetscapes characterized by order and low visual stimulus, by order and visual stimulus, and by disorder (Figure 3). Due to the difficulty of properly representing these characteristics in just one photo with both street sides, each of the nine streetscapes results from the combination of two edited color photographs taken from the two sides of streets in Porto Alegre. The color photographs are adequate to simulate a real setting in aesthetic evaluations [16]. Those in this study have different viewing angles in order to eliminate or greatly reduce different types of elements, including visual barriers, that interfere with the aesthetic evaluations of streetscapes, which were further removed or

Proceedings

ISBN: 978-618-5765-02-6

greatly reduced in the color photo editing process, such as: trees and other vegetation, distinct skies, light poles and wires, dustbins, and cars. These variations among the scenes' perspectives do not have a noteworthy effect on the aesthetic evaluations of streetscapes, since the determinants for such evaluations are the existing architectural elements [17], as also evidenced by the fact that such variations did not affect preferences for streetscapes' appearance in the pilot studies carried out to test the suitability of the questions and figures.

Figure 1. Streetscapes scenes set 1 – A1, B1 and C1 (A. F. Panzenhagen, 2016)

Figure 2. Streetscapes scenes set 2 – A2, B2 and C2 (A. F. Panzenhagen, 2016)

Figure 3. Streetscapes scenes set 3 – A3, B3 and C3 (A. F. Panzenhagen, 2016)

In order to facilitate understanding of the meaning of the numbers obtained, the aesthetic evaluations of the nine streetscapes scenes in sets 1, 2 and 3 were categorized according to the categories in Table 1.

Table 1. Categorization of aesthetic evaluations of streetscapes scenes in sets 1, 2 and 3

EVALUATION	main condition % of positive evaluations	secondary condition % of negative evaluations
very positive ++	more than 80%	up to 10%
positive +	more than 65% up to 80%	up to 20%
average 0	more than 50% up to 65%	up to 30%
negative -	more than 35% up to 50%	up to 40%
very negative --	up to 35%	any %

Note: The main condition indicates the categorization of evaluations once the secondary condition is met.

Non parametric statistical tests were used to analyze the data transferred from the LimeSurvey to PASW Statistics 18 software, such as: Kruskal-Wallis - analyzes the existence of a statistically significant difference (sig. ≤ 0.05) between the evaluations carried out for each of the three scenes in each set by the three groups of respondents; Kendall W - shows the existence of a statistically significant difference between the evaluations of the three scenes in each of the three sets by each group of respondents.

3. RESULTS

The statistical significant differences (Kruskal-Wallis test) found among the aesthetic evaluations of scene A1 (test statistic = 27.037, sig. = .000), B1 (test statistic = 28.384, sig. = .000) and C1 (test statistic = 13.127, sig. = .001) by the three groups evidences that these three scenes in set 1 (buildings inside city blocks with no direct relationship with the street; Figure 1) were better evaluated by those without a college degree and worst evaluated by architects (Table 2). All the three scenes in set 1 were evaluated very negatively by the architects, either very negatively (A1) or negatively (B1 and C1) by the non-architects college graduates. Even so, there are statistically significant differences (Kendall's W test) between these assessments of these three scenes by the architects (test statistic = 12.885, sig. = .002) and by the non-architects college graduates (test statistic = 14.463, sig. = .001). The scenes best rated by architects is the lower buildings scene (C1 - 5 storey) and by non-architects college graduates are the lower buildings scenes (B1 - 10 storey; C1 - 5 storey), with the taller buildings scene (A1 - 18 storey) been the worst rated by these two groups. All the three scenes in set 1 were averagely rated by those without a college education; although no statistically significant difference (Kendall's W test) was found, the scene with taller buildings (A1 - 18 storey), as in the two previous groups of respondents, was the worst evaluated (Table 2; Figure 1).

Note: ++ = very positive; + = positive; 0 = average; - = negative; -- = very negative; N beautiful nor ugly = neither beautiful nor ugly; mrv Kendall = mean rank values obtained through Kendall W Test (values should be compared for each of the three respondent groups; higher value indicates prettier looking scene); mrv K-W = mean rank values obtained through Kruskal-Wallis Test (values should be compared for each of the three scene types; higher value indicates prettier looking scene); values between brackets represent percentages in relation to the total number of respondents in each scene; the number of respondents may vary in relation to the evaluation of each scene, since some questions were not answered by everyone in each of the three groups.

Comparing preferences for the three scenes appearance in set 1 (Figure 1) between the three groups of respondents no statistical significant difference (Kruskal-Wallis test; Table 3) was found. Nonetheless, regarding the existence of statistical significant difference (Kendall's W test; Table 3) between preferences for these three scenes by architects and by non-architects college graduates it was found that:

- the scene with 5 storey buildings (C1) is the most preferred due to (% of 35 architects; % of 102 non-architects college graduates): adequate buildings height (77.1%; 45.1%); adequate amount of visible sky (62.9%; 70.6%).
- the scene with 18 storey buildings (A1) is the least preferred due to (% of 45 architects; % of 100 non-architects college graduates): inadequate buildings height (80%; 59%); inadequate amount of visible sky (31.1%; 61%).

These preferences are in line with the individual evaluations of scenes in set 1 by these two groups, showing that greater sky visibility indicates greater preference for a scene appearance.

Synthesizing, the relationship between different levels and types of educational background and aesthetic evaluations and preferences of scenes with different building heights inside city blocks with no direct relationship with the street (set 1; Figure 1) shows that:

- the aesthetic evaluations of streetscapes (A1, B1 and C1) have been affected, with best evaluations by non college graduates and worst by architects; nonetheless, none of the three groups did evaluate these urban features as positive.
- preferences for the appearance of streetscapes have not been affected.
- lower buildings (5 floors) generated the best aesthetic evaluations and is the most preferred streetscape regarding its appearance by the two groups with college education, due to adequate buildings height and adequate amount of visible sky.
- taller buildings (18 floors) provoked the worst ratings and is the least preferred streetscape regarding its appearance by the two groups with college education due to inadequate buildings height and inadequate amount of visible sky.

K - test statistic = 47.306, sig. = .000			K - test statistic = 83.453, sig. = .000			no sig.			

Note: mrsv K = mean rank values obtained through Kendall W Test; these values should be compared in the column, considering the lowest value as an indicator of the highest preference; mrsv K-W = mean rank values obtained through Kruskal-Wallis Test; these values should be compared in the line of each scene, considering the lowest value as an indicator of the highest preference; the values in parentheses represent the sum of the points received by each scene in each of the three groups of respondents, each of them assigning values from 1 (for the preferred scene) to 3 (for the least preferred scene); thus, the smaller the value in parenthesis, the greater the preference for the scene.

Concerning set 2 (buildings on the block perimeter with doors and windows facing the street; Figure 2), statistical significant differences (Kruskal-Wallis test) were found among the evaluations of scene A2 (test statistic = 10.172, sig. = .006), B2 (test statistic = 15.753, sig. = .000) and C2 (test statistic = 16.120, sig. = .000) by the three groups, evidencing that these three scenes were better evaluated by those without a college degree (very negatively - A2 and B2; averagely - C2) and worst evaluated by non-architects college graduates (very negatively) (Table 2). These three scenes in set 2 were evaluated either very negatively (A2 and B2) or negatively (C2) by the architects. Nonetheless, statistically significant differences (Kendall's W test) were found between the assessments of scenes in set 2 by the architects (test statistic = 37.839, sig. = .000), by the non-architects college graduates (test statistic = 84.762, sig. = .000) and by the non college graduates (test statistic = 14.333, sig. = .001): the lower buildings scene (C2 - 6 floors) was the best rated and the taller buildings scene (A2 - 18 floors) the worst rated by any of these three groups (Table 2; Figure 2). Comparing the evaluations of streetscapes with the same (A1 and A2) or similar (B1 and B2; C1 and C2) building height in set 1 with those in set 2, clearly, the architects best evaluated the streetscapes with buildings on the block perimeter with doors and windows facing the street (set 2; Figure 2) than those in set 1 (Figure 1). On the other hand, the opposite happened with non-architects college graduates and non college graduates, which rated best streetscapes with buildings inside city blocks with no direct relationship with the street.

Looking at preferences for each of the three scenes appearance in set 2 (Figure 2) by the three groups of respondents, no statistical significant difference (Kruskal-Wallis test; Table 3) was found. However, considering the existing statistical significant difference (Kendall's W test; Table 3) between preferences for these three scenes by each group, the scene with 6 storey buildings (C2) is the most preferred while the scene with 18 storey buildings (A2) is the least preferred by architects and by non-architects college graduates. As in the analysis of preferences for scenes appearance in set 1, the main reasons are basically related to sky visibility, as follows: scene C2 (% of 32 architects;

Proceedings

% of 106 non-architects college graduates) - adequate buildings height (59.4%; 48.1%); adequate amount of visible sky (53.1%; 63.2%); scene A2 (% of 35 architects; % of 109 non-architects college graduates) - inadequate buildings height (68.6%; 65.1%); inadequate amount of visible sky (42.9%; 50.5%). These preferences are also in line with the individual evaluations of scenes in set 2 by these two groups, confirming that greater sky visibility indicates greater preference for a scene appearance. Summarizing, the relationship between different levels and types of educational background and aesthetic evaluations and preferences of scenes with different building heights on the city block perimeter with doors and windows facing the street (set 2; Figure 2) reveals that:

- the aesthetic evaluations of streetscapes (A2, B2 and C2) have been affected, with best evaluations by non college graduates and worst by non-architects college graduates, though none of the three groups did evaluate these urban features as positive.
- preferences for the appearance of streetscapes have not been affected.
- lower buildings (6 floors) generated the best aesthetic evaluations by any group and is the most preferred streetscape regarding its appearance by the two groups with college education, due to adequate buildings height and adequate amount of visible sky.
- taller buildings (18 floors) provoked the worst ratings by any group and is the least preferred streetscape regarding its appearance by the two groups with college education due to inadequate buildings height and inadequate amount of visible sky.

In relation to set 3 (buildings with order and low visual stimulus, buildings with order and visual stimulus and buildings characterizing disorderly street interfaces; Figure 3), statistical significant differences (Kruskal-Wallis test) was found only among the evaluations of scene C3 (test statistic = 13.425, sig. = .001), which was better evaluated by those without a college degree (negatively) and worst evaluated by the architects (very negatively) (Table 2). Nevertheless, statistically significant differences (Kendall's W test) were found between the assessments of scenes in set 3 by the architects (test statistic = 57.773, sig. = .000), by the non-architects college graduates (test statistic = 107.175, sig. = .000), and by the non college graduates (test statistic = 7.760, sig. = .021): the scene with buildings with order and visual stimulus (B3) was the best rated by any of the three groups, while the scene with buildings characterizing disorderly street interfaces (C3) was the worst rated by any of these three groups (Table 2; Figure 3). Among the nine streetscapes in sets 1, 2 and 3, streetscape scene B3 is the best evaluated, regardless of the respondent's level and type of college education, while streetscape scene C3 is the worst evaluated by architects and streetscape A2 is the worst evaluated by the other two groups.

On the other hand, no statistical significant difference (Kruskal-Wallis test; Table 3) was found between preferences for these scenes (A3, B3 and C3) appearance by the three groups of respondents. Nonetheless, the existing statistical significant differences (Kendall's W test; Table 3) between preferences for these three scenes appearance by architects and by non-architects college graduates reveals that the scene with buildings with order and visual stimulus (B3) is the most preferred, mainly due to (% of 38 architects; % of 91 non-architects college graduates): similarity between building heights (55.3%; 28.6%); similarity between the shapes of buildings (52.6%; 50.5%); presence of clear visual stimulus (44.7%; 60.4%); similarity between the colours of buildings (28.9%; 17.6%). On the other hand the scene with buildings characterizing disorderly street interfaces (C3) is the least preferred by these two groups of respondents, basically due to (% of 37 architects; % of 87 non-architects college graduates): difference between the shapes of buildings (78.4%; 60.9%); difference between building heights (67.6%; 36.8%); absence of clear visual stimulus (40.5%; 42.5%); difference between the colours of buildings (32.4%; 16.1%). Therefore, these results are similar to the individual evaluations of these three scenes and clearly reveal that the presence of order and visual stimulus tends to explain a greater preference while the existence of disorder and lack of clear visual stimulus tends to explain a lesser preference for the appearance of the scene, mainly for those with college education.

Proceedings

of the International Conference on **Changing Cities VI:**
Spatial, Design, Landscape, Heritage & Socio-economic Dimensions
Rhodes Island, Greece ● June 24-28, 2024
ISSN: 2654-0460
ISBN: 978-618-5765-02-6

Synthesizing, the relationship between different levels and types of educational background and aesthetic evaluations and preferences of scenes with buildings with different levels of order and visual stimulus (set 3; Figure 3) shows that:

- only the aesthetic evaluations of streetscape scene with buildings characterizing disorderly street interfaces (C3) have been affected, which was better evaluated by those without a college degree (negatively) and worst evaluated by the architects (very negatively).
- the scene with buildings with order and visual stimulus (B4) was the best rated by any of the three groups.
- the scene with buildings characterizing disorderly street interfaces (C3) was the worst rated by any of these three groups.
- preferences for the appearance of streetscapes have not been affected.
- the scene with buildings with order and visual stimulus (B3) clearly is the most preferred by those with college education, mainly due to similarity between the shapes of buildings, building heights and between the colours of buildings, and presence of clear visual stimulus.
- the scene with buildings characterizing disorderly street interfaces (C3) is the least preferred by those with college education, basically due to difference between the shapes of buildings, building heights, and between the colours of buildings, and absence of clear visual stimulus.

4. CONCLUSION

Results evidence the importance of building's height in affecting the aesthetics of streetscapes, particularly for those with college education, as evidenced by the best aesthetic responses for the streetscape scene with lower buildings (5 and 6 floors) and the worst for scene with taller buildings (18 floors), mainly due to differences in sky visibility, corroborating results from other studies [9]. Hence, these evidences do not corroborate the continuous proliferation of tall or very tall buildings in different urban areas in many cities around the world.

This paper also adds to the existing knowledge by reinforcing the fact that aesthetics of streetscapes is clearly influenced by distinct levels of order and visual stimulus. Contrary to the reality in many streets of different cities, the results of this research highlight the relevance of a streetscape characterized by the existence of order (similarity between buildings' heights, colours and forms) and clear visual stimulus for satisfactory aesthetic experiences, regardless of level and type of educational background of city users, corroborating results of previous studies [8].

On the other hand, this study add to the existing knowledge by emphasizing that streetscapes characterized by disorder (differences between buildings' heights, shapes and colours) tend provoke unsatisfactory aesthetic experiences, mainly by those with college education. These results are in line with those from other studies [8], reinforcing the fact that aesthetic quality is lost or drastically reduced when the streetscape is characterized by disorder.

Moreover, the results of this research also reinforce the fact, shown in previous studies about aesthetic evaluations and preferences [18; 19], that a formal education in architecture and urban design, which includes aesthetics, tends to generates stricter aesthetic evaluation criteria while the opposite tends to occur with lack of formal education, and so, what is well evaluated by the former would also tend to be so by the latter. The education in architecture and urban design may also explain the fact that architects, unlike those without such training, best evaluated the streetscapes with buildings on the block perimeter with doors and windows facing the street than the streetscapes with buildings inside city blocks with no direct relationship with the street. These evaluations by architects are in tune with the importance of the relationship between the ground floor and the street, as already emphasized [10; 11; 13]. This relationship tends to generate more pleasant urban experiences than buildings without a direct relationship with the street, as normally happens in modernist site layouts. In addition, the fact the streetscapes with buildings on the block perimeter present a more ordered set of buildings than the streetscapes with buildings inside city blocks helps to explain why the first scenes were better

Proceedings

evaluated by architects, corroborating findings from other studies [8] about a greater appreciation of the idea of order by architects and a greater appreciation of visual stimulus by non-architects.

Yet, the fact that those with no college education tend to be less severe in aesthetic evaluations and presented some inconsistency in their responses, in addition to be characterized by small samples in several studies on urban aesthetics, at least in Brazil [18], including this one, and the fact that no striking and constant differences between the aesthetic responses by those with no college education and those with college education were found, suggest that new research on the subject might include only this last group.

Concluding, these research findings, based on people's perception, contribute to deepen the understanding of streetscapes aesthetics, specifically, by emphasizing the relevance of lower buildings, on the front limit of the lot or very close, and with order and visual stimulus. It is also emphasized the relevance of such findings being considered in the undergraduate and postgraduate courses in architecture and urbanism, in the practice of professionals in the field and in urban legislation, having in mind that the urban aesthetics is an important aspect of urban experience and so, of a city formal characteristics.

Abstract

The purpose of this paper is to analyze, based on literature review, the uses of open spaces in housing estates with modernist site layout and the uses in the adjacent public open spaces. There are assertions in favour of modernist site layout, without evidence based on user attitudes and behaviour being presented. On the other hand, research results have shown that the uses in the open spaces of many housing estates with modernist site layout, as well as in the adjacent public open spaces, are not satisfactory for their users. However, these site layouts have been adopted even in the most recent housing estates designs in Brazil. Therefore, it is necessary to deepen the understanding about the implications of adopting modernist site layouts in such designs. This analysis highlights the inadequacy of uses in the open spaces in many housing estates with modernist site layouts, as well as in adjacent public open spaces, and reinforces the importance of considering research results in housing design.

Keywords: *modernist site layout; uses of open spaces; public open spaces; housing estates.*

1. INTRODUCTION

As mentioned in the Athens Charter (formulated in 1933 at the 4th CIAM - International Congresses of Modern Architecture) "... the house will never again be fused to the street by a sidewalk. It will rise in its own surroundings, in which it will enjoy sunshine, clear air, and silence." [1: 57], making clear the modernist idea of disconnecting the buildings from the streets. Years later, after the World War II, the "Unité d'Habitation" by Le Corbusier, built in Marseilles between 1947 and 1952 (Figure 1), incorporated the modernist ideas on a large scale, namely, a horizontal block 140 meters long, 56 meters high, and 19 floors (including the terrace), disconnected from the adjacent street due to setback, misalignment, and the empty space generated by the pilotis [2, 3]. Hence, the "Unité d'Habitation" clearly broke with traditional urbanism, generally characterized by buildings on the perimeter of the block, and became a reference for subsequent social housing projects in different countries [4].

Even so, the strong influence of modernist ideas was already present in Brazil, as revealed by the design of Várzea do Carmo Housing Estate (1938; Figure 4) by Atílio Correa Lima, built in São Paulo in 1942 [5], and the Prefeito Mendes de Moraes Housing Estate (1947), known as Pedregulho, by Affonso Eduardo Reidy, completed in 1952 in Rio de Janeiro [6]. Although these ideas have generated positive mentions in Brazil, for example, in relation to large open spaces [7, 8], the accessibility and collective use of open spaces in housing estates with modernist site layout [6, 9, 10], no evidence is presented for these mentions. On the other hand, results of research carried out in different housing estates [22; 25; 30] have shown the existence of problems related to the use of open spaces in the housing estates as well as in the adjacent public open spaces, such as the disregard of the visual and physical connections between the blocks and the streets as well as the definitions of use and access control to open spaces in the housing estates. In some cases, these problems provoked demolition, as happened with several blocks of the Puitt-Igoe Housing Estate, referred to by Charles

Jencks as such: 'Modern Architecture died in St. Louis, Missouri, United States, on July 15, 1972' [11: 9].

Figure 1. “Unité d’Habitation” by Le Corbusier, Marseilles (Google Earth, 2014; Fabiano Scherer, 2000)

Yet, in many cities in Brazil, the practice of architecture and urban design, including recent projects of housing estates [12], continues to incorporate modernist ideas, as a likely reflection of the teaching in architecture and urban planning courses. Nonetheless, this tends to happen in many countries, as reflected in this interview with Nikos Salingaros [13: 161]:

- “Almantas Samalavičius (A. S.): The urban trends of the second half of the last century were strongly affected by the Athens Charter of 1933 drafted by Le Corbusier and his ideological allies ... the mentality of several generations of urban planners, designers and architects worldwide, and especially in Eastern Europe, remains somewhat under the spell of Corbusian doctrines that are not so easy to abandon. Do you see any shifts in the ideological background of present urban theories and urban practices?”

- “Nikos Salingaros (N. S.): I’m afraid that I see no hope for improvement as long as the present ideological/pseudo-religious system retains its hegemony of power and controls both city planning and architectural academia. Because Corbusianism is a religious movement, much like other fanatical cults, it will not change just because it is unreasonable... We have overwhelming evidence revealing the type of living urban structure that is responsible for a higher quality of life, and it is the opposite of the Corbusian model... Schools continue to teach the same modernist city destroying typologies to their students...”

Furthermore, respecting the urban legislation, many modernist site layouts in several Brazilian cities are walled and/or have apartment blocks with blind walls facing the street [14], as in the case of São Paulo [15] where the front walls in residential buildings can reach 4 meters in height.

Thus, the disregard of existing knowledge about the negative effects, for example, of lack of definition of use and access control to open spaces in housing estates, as well as physical and visual barriers to the uses of public open spaces, is evident. Therefore, there is a need to deepen the analysis of such problems in order to highlight and make known their relevance, mainly for architecture and urban design students and professionals and for those involved with urban legislation and housing policies. Furthermore, the need for this examination is reinforced by the fact that the extensive review carried out of the relevant literature on the topic does not include any specific publication on the use of open spaces adjacent to and in housing estates with modernist site layout. Hence, the objective of this paper is to analyze, based on literature review, the uses in open spaces in housing estates with

modernist site layout and in adjacent public open spaces, and highlight the importance of this information for housing design and for the quality of public open spaces.

2. USE IN THE OPEN SPACES OF HOUSING ESTATES WITH MODERNIST SITE LAYOUT.

Some authors mention that open spaces in housing estates with modernist site layout in Brazil are true squares [7] and that they allow the installation of communal facilities [7, 16], enabling different uses [6, 17], and stimulating social interaction among residents [8, 9, 10, 16]. However, these mentions are not accompanied by evidence based on user behaviours and attitudes and are in tune with the use of open spaces in many housing estates with modernist site layout. For example, the partial demolition of the Pruitt-Igoe Housing Estate, 20 years after its occupation in the mid-1950s, due to the existence of a series of problems with different causes, including those enhanced by the modernist site layout of 33 horizontal blocks with 11 floors, totalling 2,870 apartments, spread over a large open area of 23 hectares without access control. Its open spaces do not seem to have been characterized as true squares with communal facilities and diverse uses that would have stimulated social interaction among residents [18, 19], with a clear majority of former residents speaking negatively about open spaces during the 1960s [19].

Additionally, the statement that increase in height of buildings in modernist site layout allows the creation of larger semi-public open spaces with varied uses, including the semi-public use of pilotis [8] is not supported by research results and ignores the fact that such increase in height can occur even with buildings along the front limits of the block (with residential, commercial and service use on the ground floors) and that semi-public and/or semi-private open spaces can exist inside the block, as in the Karl-Marx-Hof housing estate, designed by Karl Ehn and built in Vienna between 1926 and 1930 (Figure 2).

Figure 2. Karl-Marx-Hof housing estate by Karl Ehn, Viena (Author, 2004)

Furthermore, in her master's dissertation, Antocheviz [20] highlights the possibility of having buildings with 10 floors on the block perimeter, maintaining the same number of apartments and built areas as an existing modernist site layout with five 18-story towers inside a block in Porto Alegre, Rio Grande do Sul, Brazil, in addition to revealing the preference of research participants for living in buildings on the block perimeter.

Site layouts with loose and isolated buildings on the block, with no direct connection between the facades and the street [6, 10], the possibility of having setbacks with gardens [17] and buildings surrounded by extensive open grassy spaces have also been mentioned as positive [21]. However, research, such as those carried out in the metropolitan region of Porto Alegre and in Santa Maria, in

Proceedings

ISSN: 2654-0460
ISBN: 978-618-5765-02-6

Rio Grande do Sul, Brazil [22, 23], reveal that many housing estates with modernist site layout lack garden/lawn spaces and communal facilities and/or facilities that are not vandalized.

In turn, unlike traditional apartment block site layout, in which buildings tend to have a front and back relationship with public roads, enabling the existence of front and back open areas [24, 25], in modernist site layout this relationship is eliminated and, consequently, the elimination of open spaces for uses that require a higher level of privacy, such as domestic activities, repairs, cultivation of vegetable gardens, the importance of which had already been highlighted [26].

Studies have also shown that open spaces in housing estates with modernist site layout tend to lack access control, a clear definition of use, an evident relationship with the buildings and to be perceived as residual spaces by residents [22, 27], who do not feel responsible for maintaining these spaces [28, 29]. Although, generally, these open spaces can be understood as for community, collective or semi-private use (for use by the estate's residents) in the original projects, studies tend to reveal that the spatial characteristics of modernist site layout make communal uses difficult and facilitate illegal occupations for private uses [27, 30, 31], with the consequent reduction in the amount of open spaces. Specifically, in the study carried out in the five housing complexes in the metropolitan region of Porto Alegre (for example, Sapucaia Housing Estate, Figure 3), communal open spaces, originally intended for semi-private use such as leisure, recreation, parking and circulation, but without clear definitions of use and spatial hierarchy and without access control, were occupied by irregular (illegal) constructions for uses such as garages, barbecue areas, deposits, commerce, services and new housing [30]. These irregular occupations generated significant increases in the constructed ground floor areas (or occupancy rates) of the estates, ranging from a 36.9% (439.7 m²) increase in Angico to a 131.7% (8919.7 m²) increase in Guajuviras, eliminating spaces intended for communal use, reducing the possibilities for social interaction among residents and recreation for younger children in suitable areas close to flats [30].

Figure 3. Sapucaia Housing Estate, Sapucaia/ RS (Author, 2000)

However, the spatial characteristics of modernist site layout that facilitate illegal occupations and alterations are generally ignored, as well as the fact that these tend to indicate that residents' needs were not met. It has not been uncommon to find manifestations in favour of modernist site layout (and the visions of modernist architects) in providing open spaces considered suitable for their users, without presenting evidence for such manifestations, as can be exemplified in the following texts relating to the Housing Estate Várzea do Carmo (Figure 4): "The analysis of the IAP project demonstrated that the success of such projects was directly related to the quality of public spaces..." [5: 13]; "This is a project marked by... rationality of site layout and, on the other hand, richness in public spaces. Unfortunately, only the four-story blocks were built." [7: 184]. Furthermore, existing problems in this housing estate were attributed to changes caused by residents and not to the original characteristics of its site layout.

Figure 4. Housing Estate Várzea do Carmo (Google Earth, 2023)

The importance of site layouts providing open spaces suitable for use by residents is also evidenced by the existence of a relationship between these uses and the type of relationship between residents, there being better relationships between those who use communal open spaces. The inadequacy and/or insufficiency of spaces intended for socializing and recreation in modernist site layout, as exemplified by the existence of illegal constructions, tends to reduce social interaction between residents [30, 31] and provoke conflicts, for example, due to excessive noise, lack of privacy or material damage in places unsuitable for use [23, 31]. In turn, the fact that accesses to apartment blocks are generally far from public roads tends to cause spatial orientation problems and, therefore, make access to the blocks difficult, which is normally aggravated by illegal occupations of open spaces of the estates and the consequent proliferation of physical and visual barriers, and reduced legibility of the access paths to the blocks, as evidenced in a study carried out with four housing estates with apartment blocks in the metropolitan region of Porto Alegre [32].

3. USE IN PUBLIC OPEN SPACES ADJACENT TO HOUSING ESTATES WITH MODERNIST SITE LAYOUT.

Although generally disregarded in housing estates with modernist site layout, the importance of visual and physical connections for the intensity and type of street use has been highlighted [24]. The blocks with doors and windows facing the street, in predominantly residential buildings with apartments or shops and services on the ground floor, are the most used by residents and vacationers during the day in the coastal city of Capão da Canoa, Rio Grande do Sul, Brazil [33]. Positive correlations were found between the density of doors and windows (also on the upper floors) on streets in Rio de Janeiro and the amount of moving and stationary pedestrians, as well as between this density and the existence of buildings in continuous strip (or ribbon) and commerce and services [34], characteristics of architecture and urban design that tend to be present in traditional urban fabrics [35] and absent in modernist site layouts.

The fact that apartment blocks in housing estates with modernist site layout are normally physically and visually disconnected from adjacent public open spaces [25, 36] tends to reduce the uses in these spaces [37]. Many condominiums with apartment buildings (or houses) arranged in the interior of a city block are also walled, which tends to further reduce the intensity and types of uses on adjacent streets, basically limited to the passage of people, as per evidenced in a study carried out with two walled condominiums in Porto Alegre [38]. In this study, the behavioural maps reveal that the streets most used by adults and children (circulation, socialization/leisure and work activities) are those with greater physical and visual permeability, while the least used street is the one that does not have any physical and visual connection.

Proceedings

Considering the behavioural observations carried out in 15 blocks in Porto Alegre, characterized by the predominance of traditional buildings or walls of gated condominiums on both sides and by combinations of these interfaces with the existence of a square on one side of the block, the three blocks with gated condominium walls on both sides are those with the lowest rates of daytime use (six days a week and two weekends), rates that are very low and significantly lower than those in blocks with traditional buildings (with doors and windows facing the street) on one side of the block and the square on the other [39]. The importance of visual and physical connections for the uses of public open spaces is also corroborated in this research by the increases in daytime uses in these blocks as the rates of visual and physical connection increase [39].

Negative correlations were also found between the existence of walls and the presence of people on streets in Rio de Janeiro, both in movement and in stationary activities [34]. Furthermore, public open spaces, when adjacent to buildings with garage doors and/or blind walls, tend to have their uses reduced, as evidenced by the decrease in pedestrian movement rates in blocks with a predominance of residential buildings with these characteristics in Capão da Canoa [33].

The uses on the ground floor of buildings, added to the visual and physical permeability, can also affect the uses in adjacent public open spaces, and enhance the presence of people and the rapprochement between residents and users of the surrounding area, and thus, favour social interaction and urban vitality [40, 41]. In a study carried out in Porto Alegre, positive correlations were found between the quantities of commercial and service uses on the ground floor of buildings and the quantities of moving and stationary daytime and nighttime activities on the blocks, with the block having the highest number of optional stationary activities being the one with the greatest diversity of commercial use and services (such as restaurants, bars, cafes, stores and small markets) [42]. Likewise, positive correlations were revealed between the existence of buildings with shops or services on the ground floor and pedestrian movement on streets in Rio de Janeiro [34]. The city blocks with a predominance of these uses on the ground floor also have the highest rates of pedestrian movement during the morning, afternoon and night in Capão da Canoa [33].

Modernist site layout, in addition to making it difficult and/or preventing such uses on the ground floor, reduce or make it impossible for the ground floor interfaces to have storefronts that act as pedestrian attractors and for their uses to extend to the sidewalks, such as tables in restaurants, bars and cafes [36, 43]. The lack of commercial activities and services on the ground floors can be exemplified in the Killingworth Housing Estate, where the apartment blocks are far from the streets (Figure 5), as well as in the Pruitt-Igoe Housing Estate, where pilotis and significant distances of blocks from public roads predominate. Moreover, Gehl [36] already highlighted the positive effect of the continuity of ground floors in Vancouver, Canada, on urban dynamics. Corroborating this, in research carried out in Rio de Janeiro, positive correlations were found between the existence of continuous buildings and shops or services on the ground floor, and the movement of pedestrians, contrary to the negative correlations found for isolated buildings [34].

Figure 5. Killingworth Housing Estate (North Tyneside Borough Council, 1987; Author, 1987)

4. CONCLUSION

The reflection carried out fills an existing gap in the literature on the subject by synthesizing in a single paper, based on evidence generated by research carried out in different cities and countries, problems heightened by modernist site layout related to uses in the open spaces of housing estates, as well as well as in adjacent public open spaces [30].

The lack of definition of use and control of access to community open spaces in the housing estates stands out, which allows the occupation of these spaces in several estates in Brazil by illegal constructions for private purposes, and the consequent reduction of open areas and worsening of problems related to their uses, including spatial orientation and social interaction in these spaces.

Problems related to uses in adjacent public open spaces tend to be related to the lack of relationship between these spaces and the apartment blocks (far apart, visually and physically disconnected, and without uses on the ground floor), reproducing the disregard/denial of the importance of street by the modern movement [44] and so, of urban design characteristics that enhance these problems, as already highlighted: “The drop in the presence of pedestrians and microeconomic activities appears consistently associated with architectures that present discontinuity of facades, distancing, wider lots and walls.” [34: 277-278].

The contribution of this paper is also in the presentation of evidence that contradicts favourable mentions of uses in the open spaces of housing estates with modernist site layout, as well as in adjacent public open spaces. In addition to emphasizing the importance of considering this evidence in housing projects, which has been largely disregarded, the analysis carried out brings clear support to the teaching and practice of architecture and urban design by reinforcing that the physical-spatial characteristics of modernist site layout tend to explain the problems of use in the open spaces of the estates and surrounding areas, contradicting the fact that these characteristics have often been valued, and that existing problems are due to the “... distorted modernist paradigm of housing estates.” [6: 248].

This paper also adds to existing knowledge by addressing aspects of social housing design based on research results that deal with the relationships between people and the built environment, since these results have been disregarded in many publications on the subject such as those in Brazil, as well as in many housing projects.

The evidence presented also allows us to propose and justify site layouts with buildings in a continuous strip on the perimeters of the city blocks, physically and visually permeable, with shops/services and/or housing on the ground floors, and with access control to semi-private residential areas, enhancing more suitable use of community and public open spaces, as well as generating job

and income opportunities for the residents themselves. In this in this regard, keeping the same built area and number of apartments, a site layout with continuous blocks with 10 floors on the perimeter of a city block was preferred for living by research participants [20] to the detriment of a modernist site layout with five towers with 18 floors inside the same city block in Porto Alegre. Additionally, site layouts with continuous buildings along the front limits of lots, with doors and windows facing public streets, have been adopted in contemporary urban design, such as in the Västra Hamnen Neighborhood, Malmo, Sweden [45], and in Vancouver, Canada [36].

In conclusion, this paper adds to existing knowledge by emphasizing the importance of considering research results, especially those related to users' attitudes and behaviours, for the design of housing that enhance appropriate uses in its open spaces and surroundings. These results also highlight the importance of the uses of urban spaces for the qualification of cities, considering the fact that people are attracted to spaces where there are people [46], and can contribute to the teaching and practice of architecture, urban design and planning, and to housing policies and urban legislation.

Coexistence on the Mediterranean coastal territories: between protection and usability

E. Kasselouri^{1*}, K. Pica²

Abstract

The Mediterranean coast, seen as a multilayered porous boundary between land and sea, forms a fragile territory where different landscapes and ecosystems meet and interact: coastal areas of great ecological value neighbor with human settlements, archaeological sites, tourist facilities, agricultural fields, and production units. This coexistence is usually accompanied by conflicted relationships as the protection of an area collides with its usability. Both in marine and terrestrial contexts, intensive human appropriation of the territory becomes a threat to the local habitats. In parallel, climate change is accelerating the territorial transformations of this transitional area, further influencing its inhabitation patterns. Coasts are the areas most vulnerable to environmental impacts and most exposed to increasingly frequent and intense extreme events. While it seems opportune to reconcile environmental protection with the public interest, climate change relates to the need to protect natural areas of great ecological value or areas with cultural significance by introducing new urgent management forms. How do these new forms of coastal management reflect on the way we perceive the relationship between man and nature? What is changing in the definition and use of protected areas and their relation to their surroundings? Are the current conservation efforts corresponding to both the emerging societal and environmental needs?

Starting with these questions, this paper focuses on the Mediterranean coastal territories by exploring the notion of coexistence in two case studies: the Gaiola Underwater Park (IT) and the Axios River Delta (GR). Comparing the two case studies mentioned above, the contribution sheds light on the Mediterranean coast as a context characterized by contrasts and conflicting interests. The case of the Marine Protected Area of Gaiola in Naples specifically explores the intricate coexistence between environmental conservation and the public's actual enjoyment of the coastal resources, thereby exploring the theme of conflicts. More precisely, that of Gaiola is a tangled and delicate story of a marine protected area, of a particular form of management, of the many actors involved, but mainly of a community that feels increasingly excluded. In the case of Axios River Delta, the area is protected under three different protection protocols (Ramsar 1975, Natura 2000 & National Park), and yet it is a highly productive area, with rice culture and mussel aquaculture being the dominant production and of national importance. How do conservation and coexistence relate in these cases and where is their balance? By discussing these two case studies, the contribution reflects on the socio-ecological transition along the Mediterranean coasts. As fragile hybrids, the coasts host the collective interests associated with the public's access to and utilization of the coastal resources along with the ecological importance of marine and terrestrial ecosystems.

Keywords: *coast; ecology; conviviality; Mediterranean; public interest*

1. INTRODUCTION

As we live in an era where the emergencies of the new climate regime [1] along the coastal territories are gradually intensified, the scarcity of resources and the conflicts over their exploitation are growing bigger in parallel to the loss of biodiversity and the appearance of more intense climate risks. Urban planning and design need to contribute by investigating the new territorial ecologies of coexistence, sustainably and equitably. In particular, the Mediterranean - a sea between lands - is configured as a laboratory to deepen the challenges that characterize contemporaneity. Its coasts, similar to other coastal regions across the world, frame a common basin and are now considered vulnerability hotspots. The transitional zone between water and land, the coastal zone, is a vital interface [2] on the frontline of the climate battle. The importance of coastal adaptation to climate change is evident as “it is estimated that approximately one-third of the Mediterranean population is concentrated in its coastal regions, whereas more than half of the population resides in the coastal hydrological basins” [2].

The altering climatic conditions are putting the coastal areas in a more vulnerable frame and the coastal line is being compromised. Considering the “coastal areas as terminal parts – the extremities – of larger environmental regions” [3] is critical in envisioning their transitional character towards a sustainable future. “Evidence from other regions suggests that protection and restoration of coastal ecosystems is vital for building resilience in the face of climate change” [4]. The coasts, as porous land-sea interfaces, constitute spatial expressions of a land-sea gradient. These liminal places are fragile territories in which different ecosystems and urban systems meet and sometimes collide, and whose coexistence is often accompanied by conflicting relationships between the protection of a specific coastal territory and its usability as productive land or as a common public good. Instead of considering coastal protection as a static condition (a state which according to its mutable character cannot exist), it can be considered as an opportunity to adapt to its inherent dynamism.

Under this view, this contribution is structured as follows. After the introduction, it describes the overall framework within which the coast theme is placed, about its transition between the land and the sea condition that recalls the themes of broad-spectrum conviviality and coexistence. Secondly, the article delves into the coastal territories around Naples and Thessaloniki, describing the cases of the Gaiola Underwater Park and the Axios River Delta respectively. The cases, investigated with different methodologies (the first with direct and participant observation, the second with fieldwork and mapping), explore the notion of conviviality along the Mediterranean coasts, highlighting possible conflicts under the topic of coexistence. The main issues that have emerged will then be discussed, proposing a view that opens up new perspectives in response to the socio-spatial injustice and the protection of coastal ecosystems. Finally, the concluding reflections of the work will be discussed, emphasizing the need to adopt a multilayered approach in equilibrium with the various forms of life.

2. COEXISTENCE IN TRANSITION

Within the field of urban planning, the theme of socio-ecological transition has taken on an ever-increasing role over the years. If the transition is a process of mutation of a territorial system from point A (in a crisis situation) to point B (towards a new equilibrium), it seems more appropriate than ever to reflect on the spatial repercussions of this process [5]. Pellizzoni [6] underlines how the ecological transition, understood as a response to the environmental crises that cities face, calls for a radical mutation beyond socioeconomic configurations or mere modernization processes. It is rather a change in life models, cultural references, and ways of land use but, above all, a fair distribution of the costs that this process implies on the different social groups, the territories involved and the relationship of human-not human conviviality. Recently, scientists such as urbanists, sociologists, and biologists, who start from different points of view, have expanded their field of study by looking into the spatial relationships between different species and their environments. From the architect's

Proceedings

and urbanist's point of view, how is a multispecies coexistence conceived, and what type of public spaces it produces? Further and most importantly, how are the conflicting relationships and bordering conditions formed into boundaries of different landscapes and habitats in the design process? Within the discussion on coastal inhabitation and coexistence in the Mediterranean territories, tourism is an important aspect to consider, as it has been among the strongest drivers of change through time. Coastal tourism in the Mediterranean is complex because of the diverse range of sizes and types of tourist facilities and developments, as well as its significance as an economic sector. Even though it is a topic on its own, the time and intensity of human touristic activity along the coast seem to have a notable impact on the spatial relations of different landscapes and the balance of different species living together. The effects are mostly negative, but are they reversible? Which other parameters exist when thinking about coexistence?

The protection of the multilayered coastal system, under the pressure of a changing climate, relates more to the effort of inventing and establishing new balances, rather than imposing measures to maintain the existing balance. Unexpected extreme events, increasingly intense and frequent, are threats that create hostile conditions for all inhabitants, altering the balance of the coastal ecosystem. Seeing them as actors who participate in the establishment of new balances on the dynamic land-sea border is adding another perspective to the design process. According to Morf, «it is widely acknowledged that effective problem solving across the land-sea boundary, and the sustainable management of coastal and marine social-ecological systems, requires terrestrial and marine spatial planning to be linked» [7]. Ingold (p. 173) argues that «...what is needed is a completely new way of thinking about organisms and about their relations with their environments; in short, a new ecology» [8]. Spatial planning and design play a crucial role in this process and «it is important to highlight that most of the literature shows that no universal solution exists, and that robust planning and implementation is a prerequisite for any successful intervention» [9] (p. 562). Hence, the essential reimagining of how people live along the coast is crucial and is intertwined with the conversation about humans' connection to the natural world and to the territorial palimpsest [10] of signs and traces that over time accumulate on it. What is the added value that a multilayered approach provides for the modern reinterpretation of inhabiting the coast?

3. THE GAIOLA: A MARINE PROTECTED AREA, FROM WHOM?

On 7 August 2002, the Marine Protected Area of the Gaiola Underwater Park (Area Marina Protetta del Parco Sommerso della Gaiola) was established, a vast territory of approximately 42 hectares which extends from the Borgo Marechiaro to the Bay of Trentaremi, west coast of Naples. The Park is divided into two parts (fig. 1): a complete reserve (zone A) and a general one (zone B)¹. For each of the two areas, the decree provides for some restrictive limitations to safeguard the characteristics of the marine environment and submerged archaeological finds.

In 2005, the memorandum of understanding was signed between the CSI (Interdisciplinary Study Centre) Gaiola onlus association and the managing authority of the A.M.P.² for the study and enhancement of the coastal heritage of the Underwater Park, in collaboration with university and research centers. In 2010, the Center for Research and Dissemination of the Gaiola MPA was opened for studying naturalistic-archaeological resources, hosting numerous operational, educational, and research activities. In 2019, the management of the Gaiola submerged park was entrusted, by private negotiation, to the CSI association Gaiola Onlus for nine years.

¹ In zone A, bathing, scuba diving, mooring, fishing and navigation (except rescue vessels, those with a draft of less than 2.50 meters or those authorized by the managing body) are prohibited. In zone B, however, bathing, diving and some types of navigation are permitted.

² The Special Superintendency for Archaeological and Environmental Heritage of Naples and Caserta.

Proceedings

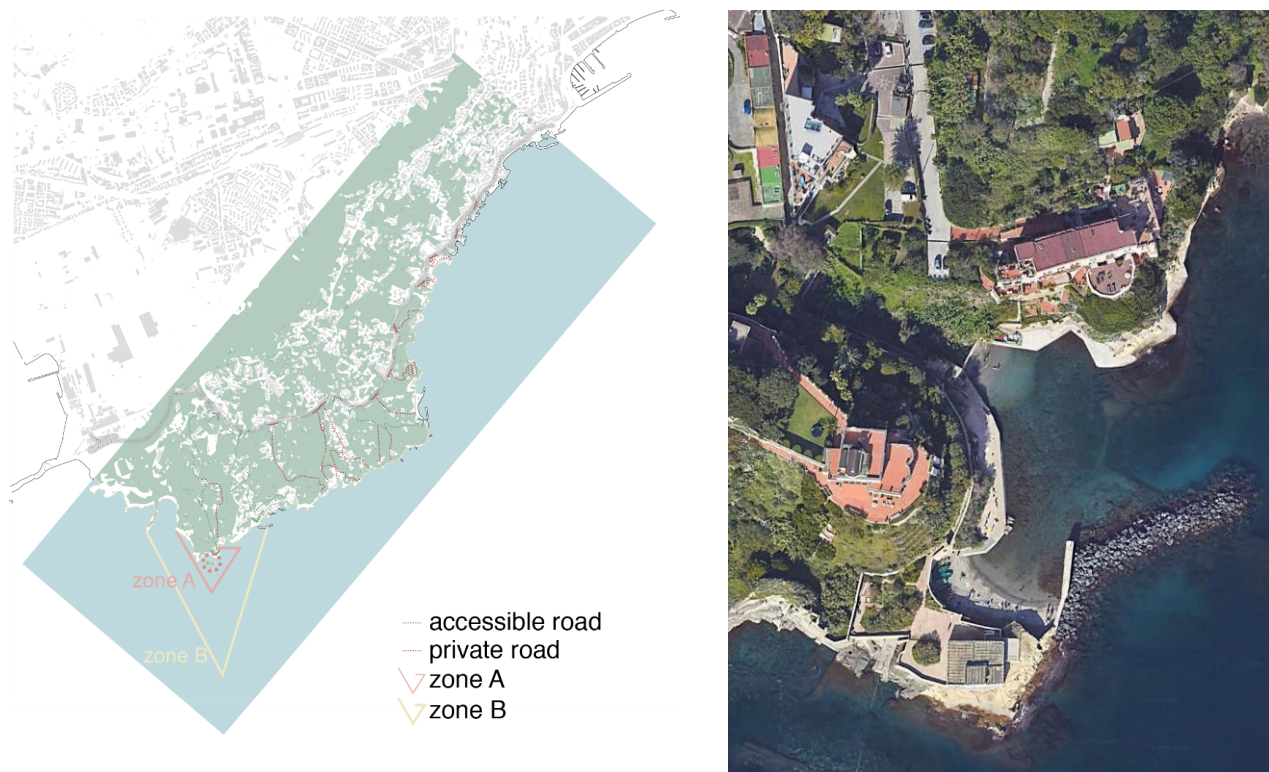

Figure 1. On the left, the highly inaccessible context in which the area is located and the two zones into which it is divided. Elaborated by K. Pica. On the right a satellite image from Google earth.

At a national level, the management of this protected marine area is unique [11]. These areas are usually managed by public institutions while, in the specific case of Gaiola, we are witnessing an assignment to a private entity without any competitive procedure or tender. The CSI aims to create a center for the dissemination of sustainable development through the promotion of research activities, training initiatives with schools and educational laboratories, carrying out control, beach cleaning and monitoring activities [12]. In addition it offers different types of guided tours. Through the work of the non-profit organization, the area has faced some problems that had characterized it for years, linked to exasperated overcrowding, wild parking, securing access to the sea, poaching and the accumulation of solid waste on beaches¹ [13].

In 2020, on the occasion of the opening of the Park following the closure imposed by the measures to contain the COVID-19 contagion, a technical safety protocol was developed, and an agreement stipulated, on an experimental basis, for the use of the Park and the public bathing area present in it. The agreement provides for contingent and differentiated access depending on the seasons and periods of the year². In 2021 the agreement was renewed, adapting it to conditions of ordinary use, considering being able to resolve “the atavistic problems of public safety, decorum, environmental impact and liveability of the area”. Furthermore, a two-year agreement was stipulated regarding zone B - located in an area that the Municipality considers “a free beach equipped in the City's bathing system” - to facilitate its usability. The direct assignment to the non-profit organization and the choice

¹ The area has been zero waste for some years and does not allow the introduction of disposable empties and objects.

² During high season, access takes place via online booking via the Park's institutional website, involving two shifts (morning/afternoon) of a maximum of 100 people each.

to extend the quota measures even at the end of the pandemic and the management model have sparked a reaction from citizens, aimed at questioning various legislative violations (fig. 2).

Figure 2. “This marine protected area is a free stolen beach”. On 22 April 2023, activists of Mare Libero committee put up banners near the access to the Gaiola beach. “Free Gaiola” and “The Sea Does Not Reach Naples” are messages placed right at the point where two guards had the task of verifying the necessary reservation for those who wanted to reach the area. Photo by Mario Avoletto

In May 2023, has been renewed the institutional agreement (signed in June 2021), aimed at guaranteeing the eco-sustainable use of the public bathing area present in zone B of the park, whose beach, according to the Municipality, “constitutes a site of great importance for citizens, considering its bathing and amenities”. The renewal of the agreement, without any public tender or transparent process, prevented the activation of participatory mechanisms¹ and alternative management models from being presented by other subjects [14]. This affair led the Euplea collective, with the support of the Coordinamento Nazionale Mare Libero and the Mare Libero, Gratuito e Pulito Napoli Committee, to present an appeal to the Campania Regional Administrative Court. The appeal is aimed at the annulment of the Resolution² of the Port System Authority, with which the collaboration agreement for the public use of the area approved bathing facilities present in zone B.

From the study of the current legal regime in force in the Park, according to the proponents of the appeal, numerous critical issues emerge in the management model, deriving from the direct

¹ Concerning the theme of participation, the Park, unlike other marine protected areas, does not provide for the presence of the Reserve Commission, i.e. the body - indicated by national legislation - made up of environmentalist associations and some local entities, aimed at comparing and support in the management of the marine protected area. The commission has the task of expressing opinions and formulating proposals, rebalancing the interests at stake. This lack has made, and still makes, dialogue with citizens difficult.

assignment procedures, from a poor involvement of active citizens and from a system of protection of the environment still based on a static vision of nature. Specifically, about the attribution of the management of the Park to the CSI Gaiola, it was underlined how this choice was in contrast with the regulations, also of a Euro-community nature, which instead impose that the selection - even in the field of the third sector - takes place through procedures that allow all interested parties to propose themselves. However, as regards the issue of limiting access to Cala San Basilio, the appeal criticizes the choice to sacrifice citizens' rights by placing obstacles in the way of using the beach and the limited number used with online booking damages the public nature of the property.

The Gaiola is a context of contrasts characterized by the presence of a protected marine area, an important archaeological heritage and marine biological system, vulnerable geological and meteorological-marine conditions, human pressure, and an active citizenship that is mobile for the reappropriation of the asset. What causes a problem in the city-sea relationship seems to be the issue of accessibility (too much/too little), conviviality (man/nature) and coexistence (conservation/use). The accessibility of this area makes coexistence between different interests, and between human and non-human, very difficult: if its limitation is linked to the need to protect and preserve it, it is perceived as an impediment to public enjoyment of the sea. So who should Gaiola be protected from? From the citizens who, by claiming their right of access to the sea and the beach, risk "impoverishing its peculiarities"; or from the CSI Gaiola onlus that, by using certain management methods on the marine protected area, is increasingly excluding citizens from a public space of collective importance? Is there an equilibrium and where does this line of balance lie?

4. AXIOS RIVER DELTA

The Cross chapter 4 of the IPCC 2022 assessment points out the Mediterranean region as "a hotspot for highly interconnected climate risks" [15], while the low-lying areas are identified as being the most vulnerable (p. 2235). Particularly susceptible to sea level rise are river deltas, which provide ideal habitat for a variety of species [16]. The delta of the Axios River is located in the north of Greece, adjacent to Thessaloniki, the second biggest urban agglomeration of the country. It is the biggest wetland in the country, with in total 4 main waterways forming the deltaic territory: Gallikos, Axios, Loudias, Aliakmon (from east to west). The greatest extent of the area lies in less than 2m above mean sea level, constituting a fluvially-dominated delta, in the inner Thermaikos Gulf [15]. Due to its location along one of Europe's primary bird migration routes, the area is well-known for its seasonal avifauna. The region's position and geomorphology make it a significant destination for bird nesting and resting, in addition to being home to significant populations of fish, mammals, and reptiles. This complex deltaic area is made up of many ecosystems, including riparian, agricultural, coastal, and inland, providing a home to a diverse and significant associated flora and fauna while «all these habitats and species are targets of the Europe-wide conservation efforts» [17]. In fact, the region is protected by multiple protocols; it is a National Park, a Ramsar Site 1975, and a component of the Natura 2000 network. The perimeters of the various protection regimes include vast areas with natural habitats, fields for agriculture, mussel aquaculture, and infrastructure. It is important to observe how these potentially incompatible land uses interact, particularly when enclosed by regulations to conserve habitat. How is the relationship developing between the coexistence of multiple species and what is the role of protection protocols?

Nevertheless, the current landscape, a significant wetland on many levels (national, European, global), is the result of several human appropriations. The image of the delta has been changing radically during the past century, mainly due to anthropogenic interventions such as drainage of the floodplains, sand quarrying, canalization, land reclamation, and construction of levees and weirs.

Figure 4. The Intermingle of agricultural fields, natural and man-made areas: this aerial image shows the Axios – Loudias – Aliakmonas Delta National Park (ALAD) in Greece, acquired by one of the Copernicus Sentinel-2 satellites on 31 August 2022. Source: <https://www.copernicus.eu/sk/node/12185> (accessed on 27/12/2023)

Figure 5. The appropriation of Axios Delta, Greece, is expressed as a fragile balance between human activities and the natural landscape. Photo by Eleni Samara © 2023

«Major changes took place in the twentieth century resulting in heavy losses of the original size and wilderness of this complex wetland area» [17]. As a result of the multiple land modifications, in the course of the 20th century, 70% of the original wetland was destroyed [18]. Even though a vast part of this «area has been reclaimed, drained by an extensive channel network» [16], it still holds an essential role as a biodiversity reservoir critically challenged by the overall human pressures. «The complex wetland system formed by the Axios, Aliakmon, Gallikos, and Loudias rivers, and their streams and irrigation channels, provides many services; prominent among these are water supply, rice, and mussel production» [17].

A variety of land uses and landscape characteristics compose the whole area. Perennial and intermittent marshes and swamps are covering the wetter parts, while intensive agriculture (mainly rice) is dominant on the majority of the fields. In parallel, the Axios complex delta has 12 different habitat types of Annex I of the EU Habitats Directive and multiple efforts have been made lately on «changing the way that people understand, value, and use the natural resources of the protected area» [17]. Besides human pressure, Sea Level Rise (SLR) and droughts are recognized as the main climate change related threats that will influence the hydrology of the area, its species and habitat types [17]. «Low-lying coastal urban centers, populated deltas, and coastal protected areas are key societal hotspots of coastal vulnerability in terms of relative sea level change» [18]. Poulos et al. in their study [16] declare that «in the event of a sea-level rise, significant parts of the deltaic coasts investigated will be inundated and the shoreline will retreat».

Coastal retreat is an inevitable effect of SLR in the area, as shown in the study of Elias et al. [18]. The examination of the relative SLR in 50 years in Chalastra for example (a village of an altitude of approximately 5m), revealed a max rate of 90cm and a min rate of 44cm. This rise results in a significant loss of land. «The substantial loss of deltaic land will also cause damage to the agricultural economy of the area, which may be worsened further by the process of salinization of the groundwater and, especially, of the phreatic horizon» [16]. Even though the future sea level projections include a level of uncertainty, they are important in creating local scenarios and dealing with minor or major alterations. Mediterranean delta ecosystems are undergoing substantial changes, requiring species to adapt, migrate, or face extinction due to the faster pace of the changes compared to adaptation. Changing climatic conditions are altering ecosystems and livelihoods, as they are transforming the productive territories. The rice production in the area equals about 80% of total rice production of Greece [19] while the mussel production reaches 80-90% of the domestic production. Both domains are highly influencing the neighboring ecosystems and will be influenced by climate change. A new productive landscape that embraces alternating crops will emerge as a need to the local societies. It remains a challenge for architects and urbanists to imagine the relation and coexistence between natural and productive areas within this frame of a transitional landscape.

5. CONCLUSION

Coastal inhabitation is seen as a fragile, multilayered inhabitation, where adopting the notion of conviviality is essential. To guarantee the long-term survival of coastal ecosystems, human activities should be in equilibrium with the needs of all coexisting species. Embracing coexistence in coastal inhabitation practices enhances the endeavor to preserve resilient ecosystems that can adjust to changing climatic conditions. Encouraging a balanced coexistence among these neighboring habitats means protecting these ecosystems and the ties that bind them. Benefits and turbulence occur simultaneously when multispecies landscapes come together and form [20] (p. 294). In this interaction, the practice of urbanism negotiates the relationships between the various components and has the advanced position to direct new systemic balances. In summary, by acknowledging and respecting the complex web of life in these settings, we can foster a sustainable coexistence of

different species and spaces. It necessitates that we consider ourselves to be “inhabitants not just of a human lifetime or generation, but also of deep time” (Macfarlane 2016)» [20] (p. 295).

The two cases bring into tension different declensions and aspects of coexistence. The case of Gaiola explores the intricate coexistence between environmental conservation and the public's actual enjoyment of the coastal resources, making clear the multitude of interests that can permeate around coastal territories, showing how sometimes, despite declaring the same goals, a meeting point seems far away. It also highlights how the current governance model creates difficulties in ensuring efficient management of marine protected areas, capable of reconciling the environmental protection needs with the public interests. From the case, it emerges that a regulatory realignment is necessary that is compared with environmental protection and safeguarding, with the objectives undertaken at European and international levels, as well as with the collective interests connected to the use of a public good. It would seem rather useful to strengthen participation, which in the case of Gaiola has been completely lacking, involving citizens in initiatives for the conservation of coastal resources, and promoting uses compatible with the need to protect areas at risk of impoverishment. In the case of Axios River Delta, the exploration of coexistence focuses on the relationship between the protection of the local habitats and productive landscape. The idea of nature protection has found certain expressions that enhance the man-nature dichotomies, while a new approach is necessary [21]. And this is where the notion of conviviality emerges as an alternative. The case study of Axios River Delta is an example of how conflicted uses overlap on a sensitive territory. The coexistence between the multiple ecologies of the area and the intense human activities is fragile and most of the times the regulatory protection boundaries are inadequate in bringing balance .

To enrich the efforts of safeguarding coastal ecosystems, spatial planning, and design at all scales must restore the relationship between humans and the natural world under a multilayered inhabitation strategy for the coastal landscape. The perception of nature in design and planning is transitioning along with the socio-ecological transition, giving new meanings to the notion of protection. This contribution presents itself as an opportunity for discussion on new ways of living together, through the recognition of bonds of interdependence between humans and non-humans, possible alliances, and renewed inhabitation proximity. From this perspective, the public accessibility of the protected landscape can act as a pillar for an innovative design scenario that respects or even enhances the coastal identity. The urban planning project in the socio-ecological transition will have to reconstruct conditions for living together in diversity, capable of reconciling the variety of forms of life and the need to share rules of coexistence.

Abstract

Burial grounds are an integral part of every social formation and social ritual. They reflect the peculiarity of cities over time and narrate the evolution of society's attitudes towards death, since they in turn constitute 'cities' of limited size. Over the centuries from scattered burial grounds to modern organized cemeteries, burial grounds constitute vital urban cells of multiple properties. These are important free urban spaces, open to the public of the city that go beyond religious rituals and can be treated as monumental 'gaps' in which its past is inscribed. From the medieval spaces that were social and crowded spaces, a displacement of the cemeteries from the core of the city is established, with the result that they function as 'organized spaces' on its borders, leaving behind the monumental burials as 'urban fragments'. Therefore, the purpose of the paper is to explore philosophical and cultural views on death from the Middle Ages to the modern era and the influence they have had on the design of modern burial grounds. The paper will focus on the emergent urban dynamics of cemeteries, studying issues of urban integration and spatial composition in the context of a climate of gentrification and a lack of open public spaces. The above problem can be understood in the light of 'Landscape Urbanism'. According to 'Landscape Urbanism', the landscape is defined as the prism through which the modern city is interpreted and at the same time the mean through which it is shaped. It is essentially an attempt to decode the urban situation in landscape terms and manage it as an ecosystem, which is studied and planned on the basis of a spatio-temporal ecology. Through the contemporary production processes of the space, the vanguard of landscape architecture design expresses the view of a 'new urban nature' which can be identified in the modern burial grounds. In addition, both incineration and conventional burial have some adverse environmental effects, with the result that some cities are already implementing innovative design strategies aimed at urban resilience. Therefore, the re-personification of the spatial issue of death projects the future form of specific spaces through their change, shrinking and even disappearance. In general, innovative design approaches to burial sites are emerging through modern technology and architecture under the gaze of the continuous ecological needs of the space. Beyond the theoretical part, the presentation focuses on two personal design research projects that examine the above issues. The first project focuses on the ways in which the question of burial is reintegrated into the urban fabric and the daily life of the inhabitants, while the second on the process by which the dead body ceases to cause disgust and returns to the city in a 'new form', identifying public space with memory

Keywords: *burial sites, urban voids, death, integration, landscape*

1. Introduction

The nature of death is a fact of human existence and can regulate life itself and the behavior of man towards others, since it is not something that comes to an end but is always potentially present. Thus, life turns into a perpetual conflict with the 'hereafter'. Thinking and living the experience of death takes place through the loss of the other, which marks the foreshadowing of our own death. Death was never accepted without fear and awe, as it remained in human consciousness an undefined and inconceivable event. The dead body also contributes to this logic, occupying an intermediate position

between 'here' and 'there', as it is considered vulnerable due to its perishability. Therefore, the purpose of the presentation is to investigate philosophical and cultural views on death, from the Middle Ages to the modern era. The issue of death is glossed over in the modern context, as it is inconsistent with current issues of happiness and image. In addition, the influence of the above considerations on the design of contemporary burial grounds and their looming urban dynamics through questions of urban integration and regional composition will be examined. Therefore, the re-personification of the spatial issue of death highlights the emerging urban dynamics of specific spaces through their change, shrinking and even disappearance. More generally, innovative design approaches to burial sites are emerging through modern technology and architecture under the gaze of the continuous ecological needs of the space.

2. Methodology

2.1 Death as a matter of theoretical thought

2.1.1 Death and mourning as the beginning of civilization

As Bronislaw Malinowski states, "*The question of death has been a central concern for various religious beliefs of human civilization. Both the places and the practices of the burial acquired a key and symbolic character, as they were the focus of urban formations and habitation until today*" (Walter, 1993:273). Historically, the cemetery is for most peoples the place to deposit the body, while burial traditions date back thousands of years and reflect social structures, habits and popular preferences. As Lewis Mumford records, "*The dead was the first to have a fixed abode, a place, where the living could often visit their ancestors*" (Mumford 1961). The above reference substantiates the claim that the first cities were the 'cities of the dead', i.e. that the core of every spatial organization was the Necropolis. Based on various archaeological findings, the burials within the urban environment and specifically within houses are able to support eventual considerations of the burial as centers of urban concentrations. "In primitive peoples there is no 'natural death', every death is social, public, collective, it is always the result of an opposing will that must be absorbed by the group, which takes place through celebrations and ceremonies related to mourning" (Makrynioti, 2008 :115). Thus one can talk about a symbolic and spatial continuity but also a gradual domestication of man with the issue of death with mourning and burial as the main mediator.

2.1.2 The tamed death

The studies of Phillipe Aries constitute the most important sources for the study of the attitude of Western civilization towards this specific issue. The specific studies cover a wide period of time from the Middle Ages to the modern era and aim to give meaning to human mortality. By reference to the study of Aries, one can identify critical stages in the meaning-making of human mortality. The first is described as the stage of 'tamed death' or otherwise 'common death' and is chronologically placed during the early Middle Ages. In this particular period, death is projected in the form of punishment to people. Through this terrifying image the church of the time sought to instill fear in order to manipulate the popular and middle class. The above raises the conclusion that in no other era is so much importance attached to the idea of death as an event before which all are equal, defying the unequal order of birth, wealth and power. In general, Medieval burial grounds were social and crowded places, where commerce and other activities flourished. Essentially, Medieval cemeteries were urban spaces that transcended religious ritual and included a multitude of commercial functions.

2.1.3 The romantic death

"At the beginning of the 16th century, a new model appeared, that of the 'beautiful' and 'ethicoplastic' death. This standard prevails until the 18th century and refers to a just and dignified death" (Aries, 1999:41). Therefore, the Medieval model where life is dominated by the agony of salvation at the last

moment succeeds the model of the 'beautiful' and 'romantic death', in which the coming of the end is surrounded by a new romantic view. Also, the burial grounds begin to consist of a multitude of representative monuments and acquire an autonomous and supervisory position within the city after a long period of discreet coexistence with the society of the living. In the same period of time, in European cities such as France and Italy mainly, the trend of visitable 'garden cemeteries' emerged, which are characterized as essential spaces for the city's monumental stock.

2.1.4 The beginning of concealment

At the end of the 18th century, a period that coincides with the end of the 'beautiful' and 'romantic death', an important change takes place which is a turning point in Western thought and in the urban culture of Europe. The spread of anatomy reached its peak during the 19th century and was not only due to scientific purposes but also to the effort to investigate things that were not clearly defined until then. Regarding burial grounds in the 19th century, the cemetery is considered a place of philosophical contemplation as it indicates that death is not a catastrophic event, but part of a perpetual cycle of reproduction. This results in it being directly connected to nature, while at the same time attempting to give a sense of historical continuity. The cemetery is not only a memorial site, as in the 18th century, but becomes an organized place of visitation and pilgrimage and therefore an element of preserving the city.

2.1.5 Forbidden - clinicalized death and the modern condition

From the Middle Ages to the middle of the 19th century, perceptions of death show slow but steady changes. However, in the period of industrialized Europe of the 20th century, a new perception towards the issue of death is recognized, that of the 'invisible' or 'forbidden'. "Moving into the 20th century, rapid advances in personal comforts, personal hygiene and the idea of antisepsis made people more sensitive and therefore contact with the dead body more abhorrent. This results in people banishing death from everyday life and focusing on a new uncontaminated world in which hygiene, medicine and morality are based" (Aries, 1999:411). So the banishment of death from everyday life, in which the uncontaminated world of hygiene and medicine is based, brings to the surface a new 'macabre', the 'macabre' of science. This development takes place in the early 1960s. Affluent societies marginalize death and, at the same time, promote a model of life without suffering. Furthermore, they favor the spread of an extreme cult of physical health, forgetting that it is something precarious, fragile and not permanent. Illness is presented as an exception, a misfortune, a derivative of non-observance of hygiene rules, but never as inherent to human fragility. In modern Western societies, the question of death is revived and returns to the public discourse through the politicization of biological life. Power takes the form of social and political intervention against the body of the population, there is a generalized tendency to naturalize the conditions of death, which now takes the form of state violence through visible and invisible death practices. At the same time, the burial grounds lose their dynamics and are trapped in the continuous and unstoppable construction of the cities. They thus turn into 'terrain vagues' within the urban fabric since they cannot defend themselves against the nature that has now been tamed by technical progress.

2.1.6 Forbidden - clinicalized death and the modern condition

From the Middle Ages to the middle of the 19th century, perceptions of death show slow but steady changes. However, in the period of industrialized Europe of the 20th century, a new perception towards the issue of death is recognized, that of the 'invisible' or 'forbidden'. "Moving into the 20th century, rapid advances in personal comforts, personal hygiene and the idea of antisepsis made people more sensitive and therefore contact with the dead body more abhorrent. This results in people banishing death from everyday life and focusing on a new uncontaminated world in which hygiene, medicine and morality are based" (Aries, 1999:411). So the banishment of death from everyday life,

Proceedings

in which the uncontaminated world of hygiene and medicine is based, brings to the surface a new 'macabre', the 'macabre' of science. This development takes place in the early 1960s. Affluent societies marginalize death and, at the same time, promote a model of life without suffering. Furthermore, they favor the spread of an extreme cult of physical health, forgetting that it is something precarious, fragile and not permanent. Illness is presented as an exception, a misfortune, a derivative of non-observance of hygiene rules, but never as inherent to human fragility. In modern Western societies, the question of death is revived and returns to the public discourse through the politicization of biological life. Power takes the form of social and political intervention against the body of the population, there is a generalized tendency to naturalize the conditions of death, which now takes the form of state violence through visible and invisible death practices. At the same time, the burial grounds lose their dynamics and are trapped in the continuous and unstoppable construction of the cities. They thus turn into 'terrain vagues' within the urban fabric since they cannot defend themselves against the nature that has now been tamed by technical progress.

2.2 Contemporary cemeteries as multidimensional urban spaces

Cemeteries function as spaces of coexistence of the real and the imaginary. In addition to their functional dimension, as spaces suitable for disposing of the dead, they are also public spaces where the bereaved come face to face with their loss. Therefore, in this proposal, an attempt is made to investigate the design of burial grounds as a special category of urban space. In particular, the presentation focuses on the spatial evolution of the topography of burial sites as urban monumental complexes and their emergence as points of reference in the fabric of the city and their relationship with the environment. Death is always marked and covered under the veil of architecture, whether it is a simple stone slab in the ground, or an organized burial ground. Based on the above position, the modern urban dynamic of the burial grounds is highlighted through the growing needs of the space. The mutations recorded in burial sites over time, from the late Middle Ages to modern times, are mainly based on historical, social and cultural spatial changes. An important contribution to the investigation of the spatial evolution of the topography of cemeteries is Maria Koumarianou's study on the Fantasy of Death. The above study records the spatial dependencies and mutations of the cemeteries in relation to the urban fabric of the city. The above mutations go hand in hand with historical changes in the question of response to death, as mentioned above based on the work of Phillipe Aries. It is a sequence of spatial determinations of the cemetery in relation to the urban environment. Four phases of change are briefly recorded, namely the 'closure' of the burial grounds in the urban environment, their 'visual isolation' from the city, their subsequent 'displacement' to the outskirts of the cities and finally their 'disguise'.

As has been recorded, during the Middle Ages the burial ground was an open public space, a reference point for the city, without defined boundaries within the urban fabric. This is how the first phase of 'closure' and the coexistence of the cemetery area with the city of the living can be distinguished. However, from the end of the 19th century, a morphological and not so topographical change took place, through the construction of walls, which led to their 'visual isolation'. The cemetery space maintains its central position, but is visually isolated from the space of the living, that is, from the space that surrounds it. The above practice of 'visual isolation' is directly linked to the period of 'personification' and ultimately 'romantic beautification' of death. This significant change in perceptions of the human response to death resulted in cemeteries gradually being displaced from the inner city. The intense building development of cities led to the incorporation of historical cemeteries into the urban fabric as 'urban fragments of memory', while in a second phase it displaced them outside their boundaries, thus turning them into ambiguous places. The gradual 'isolation' of burial sites on the outskirts of cities leads to their 'disguising', in the sense that the cemetery loses its specific spatial qualities and turns into either green spaces or undefined spatial units, a kind of 'topographical implication' in general space without a necessary urban function. The above practice raised issues

Proceedings

concerning the museological management of historical cemeteries, where they are places of memory and remain visible in the spatial reserve of the city without traces of particular disguise. In contrast, many of the cemeteries on the outskirts of cities function as unorganized 'urban voids'. The specific burial grounds do not have a clear function due to their location, i.e. they are places without specific meaning. Despite their ostracized position in the urban fabric due to the ecstasy of the city, they have a special spatial and symbolic value as they gather elements and qualities of 'transition'. For example, "Ignasi de Sola-Morales speaks of 'terrains vagues' referring to the empty places in the urban space that lack both meaning and use. The fact that they have been 'frozen' at some point in their history, automatically makes them places that are waiting to 'wake up' in order to narrate what they have lived through.

They are areas that are not used or have been abandoned for a long time, but whose deterioration and marginalization are so evident that they are classified as residual places" (Doron, 2008:204,205). More generally, the evolution of the topography of burial sites is a symbolic practice defined as the transition from 'being' and 'appearing' to 'not appearing'. Thus, cemeteries can be studied as multidimensional spaces in the changing urban periphery since their conditions of urban integration and their topographical particularities are constantly changing. Through these transformations emerges the need and desire of the people to restore the specific spaces into everyday and familiar spaces.

2.2.1 The urban dynamic of burial grounds

From the analysis recorded so far, it appears that the symbolic and spatial role of the burial grounds yield multifaceted approaches to their emerging urban dynamics in the contemporary condition. According to the architect Katrina Spade as recorded in her work *Urban Death*, the rationalization of the burial is deemed necessary in relation to the positive effect it can have on the environment and also on climate change. Her research is based on the issue of renewing people's relationship with the question of death and not on the location of cemeteries on the periphery of cities (Eveleth 2014). Therefore, through the rapid growth of the population, in the context of a climate of urbanization, and through the lack of open public spaces, the questioning of the character and role of modern cemeteries emerges. Spade's problematic can be understood in the light of '*Landscape Urbanism*'. "According to '*landscape urbanism*' the landscape is defined as the prism through which the contemporary city is interpreted and at the same time the medium through which it is shaped. It is essentially an attempt to decode the urban situation in terms of landscape and manage it as an ecosystem, which is studied and planned on the basis of a spatiotemporal ecology" (Corner, 2006:29). Through contemporary processes of space production, the vanguard of landscape architecture design expresses the view of a '*new urban nature*' (Giro 2005) which can be identified in contemporary burial grounds.

According to David Schreiner, it is necessary for city dwellers to think about conventional burials because it can become a luxury only available to the rich as urban congestion can reduce the space available for cemeteries. Cities and burial grounds are forced to adapt their relationship with each other along with emerging innovations in the handling of dead bodies so that everyone has access to a dignified burial. Therefore, the re-personification of the spatial issue of death highlights the emerging urban dynamics of specific spaces through their change, shrinking and even disappearance. The above condition is mainly detected in countries where cremation is not supported since residents pay for a burial place in cemeteries as if it were real property. So instead of growing, cemeteries simply expand. In addition, both incineration and conventional burial have some adverse environmental impacts, with the result that some cities are already implementing innovative landfill management strategies aimed at urban resilience (Schreiner 2014). More generally, innovative design approaches to burial sites are emerging through modern technology and architecture under the gaze of the continuous ecological needs of the space.

Proceedings

For example, in 2004 the architectural team Naja & de Ostos designed a fantasy scenario that investigates issues of extreme burial conditions. Their proposal refers to the design of a cemetery space, which hovers over the city of Baghdad and was shaped as a clash between the 'aggressive West' and 'stereotypes of the East' (Jackowski 2007). The cemetery in question is clearly influenced by Takis Zeneto's *Electronic Urbanism and Utopia* and features a flying city with multiple levels and locations for various civic functions suspended by a system of cables. The '*hanging cemetery of Baghdad*' is a utopian challenge and not an actual cemetery with a specific spatial articulation as it projects multiple spiritual symbolisms. The example of student Steve Baumann's *New London Necropolis*, which deals with the interdependence between the natural and the artificial, follows a similar logic. He proposes a hybrid necropolis which, beyond the burial ground, includes the city's power station and a market in the form of a garden through a romantic, functional and rationalist logic (Baumann 2011). A different approach to changing the shape of burial spaces is the vertical cemeteries that respond to the continuous urbanization of the space. Notable implemented examples are the *Yarkon Cemetery* on the outskirts of Tel Aviv in Israel and the *Memorial Necrópole Ecumênica in Santos*, Brazil. An innovative example of a vertical cemetery is the *Moksha Tower* in Mumbai, India designed by architects Yalin Fu and Ishuan Lin. It is a burial skyscraper that serves the needs of different religions with the aim of freeing up space for the creation of green oases in the city. The tower above has been designed with bioclimatic criteria such as its green facade.

Also, a proposal that caused multiple discussions on the emerging issues of urban burial is the proposal of architect Chan Joong Kim named *The Last House*. Its design is rendered as a floating vertical organic tower that through modern technology and ecology produces clean energy for the city of Seoul. A similar approach that responds to urban sprawl is the undergrounding of burial grounds. The proposal by architects López Balan, Elsa Mendoza Andrés and Moisés Adrián Hernández García called '*Tower for the dead*' aims to address the increased construction of Mexico City by designing an underground burial site. It is designed with curved walls and ramps while natural light diffuses into the space through a large opening (Schreiner 2014). Another example that responds to urban overpopulation and the loss of green land is the *Inverse Void* by architects Alison Huo, Ben Chang and Shengjie Qiu. '*Inverse Void*' composes an existential journey through a ramp into an underground space leaving the agricultural space untouched on the surface. In the logic of changing the location of the burial grounds, one also comes across some examples that go beyond the above locations. The innovative '*Light after life*' proposal treats human bodies as temporary forms but also as sources of biomass in a continuous energy cycle. Therefore, a park-like riverway consisting of burial properties that can be reused through aerobic biotransformation is proposed. The decomposition of the bodies produces biogas which takes the form of light on the river public road. A similar approach is recommended by '*Constellation Park*' from the DeathLab 8 team. This particular ecological proposal uses biomass management in an identical way by composing a hanging cemetery park with multiple levels under the Manhattan Bridge (Distasio 2016). The above examples respond to the change of position and form of cemeteries in an attempt to find new spatial solutions. Also responding to the search for new spatial solutions are proposals for floating and underwater cemeteries such as Fabián Leiva's '*Floating cemetery*', David Mutschlechner's '*Circle*', Coen van Bergeijk's '*Sunken Bodies*' and Espacio Cero's '*Columbarium in a pond*'.

In terms of Schreiner's view of shrinking future cemeteries there are numerous examples designed with urban resilience and ecology in mind. The international ideas competition entitled *Studies in Death* organized by the Lien Foundation and Designboom highlighted hundreds of contemporary approaches to conventional burials. The above approaches are related to the ecological management of human remains and new mortality enclosures as the competition committee called them. A number of proposals have emerged such as biodegradable capsules and special cast molds which help transform dead bodies through natural processes. In the same problematic, the *Dying* competition from the organization NON ARCHITECTURE COMPETITIONS highlighted interesting proposals

for the dematerialization of burial grounds within a wider framework of ecological management. Notable proposals are 'We are the nature' by Jakub Kozaczenco, Apolonia Slesarow and Konrad Zaborski and 'The story of atoms' by Manuel Alejandro Suárez Hernández and Haruka Tonegawa. The above proposals are aimed at the development of green spaces in the urban fabric of the city through the composting of dead bodies. Nevertheless, the scenario of the disappearance of burial grounds from the urban periphery is related to utopian digital solutions. Through the above competition, ideas were submitted for digital cemeteries through applications and even proposals for space cemeteries outside the earth. From the above examples, the effort to find new handling strategies for cemeteries under the gaze of new possibilities of destigmatizing mourning in modern societies can be understood. In this context, the emerging urban dynamics of the cemetery may shift to scientific fields that go beyond their functional dimension.

3. Conclusions

In conclusion, at the root of every culture, from primitive social structures to modern reality, is the constant effort to give meaning to human mortality. Starting from the claim that the core of every spatial organization was the Necropolis, the beginning of civilization itself can be distinguished in the issue of death and mourning. In the first section of the presentation, an attempt was made to take a historical, cultural, social and political view of the issue of death from the Middle Ages to the modern era. Through this historical path, death is transformed from a visible social event to an invisible individual event, from a content of narratives to a taboo subject, from a community test to a personal drama unfolding in the modern hospital, to end up as a matter of managing the biological existence. The above changes towards the issue of death are reflected in the spatial evolution of burial grounds from the Middle Ages to the present day. Furthermore, the symbolic organization that governs the above spaces makes them the 'negative' of the city of the living, i.e. an 'other city'. Through the continuous evolution of the urban environment, the spatial dependence of the cemetery on the city and therefore its modern role is constantly changing. The need to redefine the character of the cemetery as part of the spatial stock of the city and not as an 'urban void' brings to the fore its emerging urban dynamics. Through modern technology and ecology, new possibilities for the management of dead bodies and the dematerialization of future burial sites can be discerned in accordance with the needs of the exasperated urban space. Despite the wide contrasts, the specific spaces are an integral part of the continuous and changing urban condition, since through their design they are able to function as multidimensional urban cells and as spatial carriers of meanings that raise multifaceted readings of the city and the place.

City and coastal interface: investigating planning as a research framework in the urban context of Patras

D. Giannisis

Associate Professor, Department of Architecture, University of Patras, Greece

E-mail: dgiannisis@upatras.gr, tel +30 6977652932

Abstract

Contemporary cities confront critical challenges stemming from climate change, public health issues and transportation, a network of interconnected problems with significant implications for urban life. Coastal cities in particular, confront heightened risks due to rising sea levels, a global phenomenon affecting numerous coastal areas and posing risks to infrastructure, communities, and ecosystems. Areas previously considered secure are now vulnerable to transformations. Proactive measures are imperative to address this crisis, including the implementation of strategic urban plans, the promotion of sustainable urban design, and the development of resilient infrastructure.

In examining the considerations outlined above in both a real-world context and the practical realm of architectural design, our focus turns to the case study of the city of Patras. Chosen as a design project within our architectural school, Patras presents a compelling case study due to its intricate relationship with the coastal front. This front characterized by its port promenades in the city center, heavy traffic along the coastline, and ultimately, disconnection of the city life from the coastal front. Efforts have been made to liberate the coastal front from the confines of the port facilities, attempting to restore this significant space to the city. However, before any solution is implemented and the coastal front is reclaimed by the city, Patras faces anew the threat of losing its coastal land due to the climate crisis and rising sea levels. The rise in sea level poses both a threat and an opportunity to investigate the problematic relation of the city with water because of the port facilities, but certainly endangers residential communities, public space, transportation networks and unique ecosystems. Part of the investigation is based on the relocation and replacement of the city's coastal transportation network onto the water. The climate crisis presents both a threat and an opportunity for the long-term revitalization of cities.

Through this exploration, our aim is not only to understand the theoretical concepts but also to apply them tangibly and in context -specific manner, unraveling the complexities of architectural design, urban planning, sustainable design, and resilient infrastructure in response to the distinct challenges faced by the city. The studio seeks to develop strategies for addressing the phenomenon, leading to design proposals and investigating innovative architectural solutions that go beyond mere visual upgrades. The focus is on a comprehensive design exploration to enhance the overall urban experience. The role of architecture is explored as a field of design research for improving urban conditions. By viewing architecture as a catalyst for positive change, the project aims to investigate specific spatial problems and propose sustainable and resilient design solutions. An interdisciplinary approach and the integration of architectural research aim to pave the way for a more resilient and sustainable urban future.

Keywords: *urban design; coastal cities; resilience; sustainability; transportation network*

1. INTRODUCTION

Modern cities are facing critical issues regarding energy, inequality, public health, economy and transportation. These problems are interconnected and largely exacerbated by the climate crisis, resulting in serious implications for urban life. Coastal cities face additional risks due to rising sea levels. This is a global phenomenon affecting many coastal areas, endangering infrastructure,

Proceedings

communities, and ecosystems. Areas once considered safe are now vulnerable to change. Addressing this crisis requires preventive measures such as strategic urban planning, sustainable urban design, and the development of resilient infrastructure.

Future climate predictions indicate rising temperatures in the Mediterranean with reduced rainfall and an increase in sea levels. These phenomena are expected to intensify in the future, enhancing the risk of severe droughts, soil erosion, and increasing demand for water and energy.

'As the temperature of the waters in the oceans rises and the seas become less dense, they expand and will spread, occupying more surface area on the planet causing inundation of low-lying areas. Increased temperature will accelerate the rate of sea level rise. Since the end of the last Ice Age, 18000 years ago, sea level has risen by over 120 m.' [1]

During the 20th century, the average annual increase in sea level doubled compared to the past 3000 years. Predictions for the global average sea level rise for the next 30 to 50 years are consistently increasing, particularly in recent years due to the unstable nature of average temperature rise. While sea levels are expected to elevate almost everywhere, the extent of coastline retreat depends on various factors such as geographic location, soil geomorphology, ocean currents, wave heights in the area, and the structure (materials and form) of the coastline. Even within the same area, the degree of water intrusion into the land and its impact on citizens' lives vary. The intrusion of salty seawater affects the aquifer horizon and river estuaries with significant consequences for drinking water and food production.

2. CITY OF PATRAS: A MODEL AREA FOR ARCHITECTURAL STUDY

We examine the above issues within a real-life context, focusing on the city of Patras and applying principles of architectural design. Patras is a coastal city in western Peloponnese, that faces challenges in its interaction with the seafront. This relationship is complex, characterized by the distinctive port promenades in the city center, heavy traffic along the coastline, and ultimately, the distancing and detachment from its coastal waterfront.

After the liberation from the Turks, the city developed mainly around its port, becoming renowned for its commercial activity and the raisins that supported Greece's economy for decades. In 1828, following the order of Governor Kapodistrias, Stamatis Voulgaris designed the city's expansion towards the sea, which was the center of the region's trade. The main principle of the urban plan was not only to support the old upper town but also to extend the city towards the sea and the port, where the economic, social, and cultural life of the new Patras would be organized. Since then and up to the present day, the city has expanded with the port facilities at its center, extending along the coastline to the north and south. However, despite the sea's significance for the city, Patras has not managed to inhabit its waterfront. The city's challenging relationship with the water has deep roots. *'In 1830, during the implementation of Voulgaris's plan, at the request of the residents, the coastal zone, which Voulgaris had intended for a park, was parceled out and later the railway line passed through it. In this way, Patras lost even this opening - breathing space towards the sea.'* [2] Due to the constantly expanding port and traffic infrastructures, the city never managed to relate to its waterfront. On the contrary, over the years, the city's relationship with its waterfront has become increasingly problematic. The recent relocation of the commercial port to the southern edge has freed up the coastal front and opened up new prospects for changes in the city's structure and public life. In 2018, the port facilities were transferred from the Greek State to the Municipality for management and exploitation. The already established situation requires drastic decisions and interventions for the reconstruction and improvement of the city's relationship with the water. With the release of the waterfront from the port facilities, efforts are being made to find solutions that will utilize this significant urban space. A significant step in this direction was the architectural competition announced by the Municipality of Patras in 2019 for the *'Redevelopment of the Coastal Front of Patras'* as an important project for the quality of life and the image of the city's public space. A key objective of the competition was *'the*

Proceedings

radical reorganization of the coastal front, the connection of the central part of the city with the water element, the aesthetic and functional upgrade of the coastal zone.' [3] Although the announcement sets the organizational principles of the plan as *'the functional and environmental upgrade of the area, the integration of developments into a unified spirit and style, the application of environmental protection techniques,'*[4] it does not account for future risks related to the threats of climate change, which in any case will alter the coastline once again. Any effort to integrate the coastal zone into the city's life must not ignore the anticipated changes in the natural environment. The problem appears to be twofold. On the one hand, the water element threatens to alter the coastline with the loss of coastal land and the city's infrastructures, and on the other, the necessary traffic network does not allow access to the sea. The looming threat of the climate crisis presents us with a unique opportunity to change and revitalize our city both in the short and long term within a rapidly changing environment.

3. ARCHITECTURAL STUDIO: CITY & WATER

These topics constitute the focus of study and research in Architectural Design 8 courses during the fourth year of the study program at the Department of Architecture, University of Patras. The initial idea is based on both the protection of the coastline and the relocation and replacement of the city's coastal traffic network with water-based transport. After preliminary research, we aim not only to understand the theoretical principles and issues but also to formulate architectural proposals adapted to the problem's framework, highlighting the complexities of architectural design, urban planning, sustainable design, and resilient infrastructure. The workshop aims to develop strategies to address the phenomenon, leading to design proposals and examining innovative architectural solutions that go beyond simple aesthetic upgrades. The studio includes a generalized design research to enhance the overall urban experience, examining the role of architecture as a field of research for improving urban conditions. Viewing architecture as a catalyst for positive change, the project aims to investigate specific spatial problems and propose sustainable and resilient design solutions. This multifaceted approach, which integrates architectural research into urban planning, aims at a resilient and sustainable urban future.

3.1 Design Process, From Concept to Creation

In the initial phase of formulating and developing design proposals, group research is conducted along two main axes of information and analysis. The first axis focuses on the location, the program, the unique characteristics of the site, and the climate systems. This includes an in-depth study of the site's geography, context and environmental conditions. The second axis examines flood mitigation techniques, natural resource management technologies such as water, wind, and tidal energy systems, as well as advanced construction technologies and materials that are not commonly available and influence the proposed architectural project.

Figure 1. Analysis of the Coastal Front

A detailed reading of the urban landscape provides a comprehensive understanding of various phenomena, allowing us to perceive both traces of the past and potential future scenarios. As a method of design research, we thoroughly analyze and outline every aspect of the city's waterfront, including piers, small ports, and beaches, along with the adjacent neighborhoods that either currently extend or could potentially extend towards the waterfront. All these locations serve as reference points which, with their diversity and interconnections, shape the whole city. They are like pieces of a collage of urban structure that encompass all necessary functions and programs. Each intervention site is treated as part of an evolving urban whole that can enhance the city's potential over time. The coexistence of different functions and characters in nearby and easily accessible areas leads to a sustainable city. The transportation network is responsible for connecting these areas. Traditionally, the central transportation network holds special significance in the city as it links different neighborhoods with centers of cultural, educational, social, institutional, and commercial activity. It facilitates social interaction, plays a crucial role in the quality of the urban experience, and imparts identity to the urban environment. For the goals of our proposals, we consider that a good public water transport network along the waterfront can contribute to reducing car usage, which has caused congestion in the city center.

3.2 City and Infrastructure

As Elizabeth Mossop states, *'Infrastructure increasing lyprovides the public spaces of our cities, and the infrastructure of movement is an essential presence in the developed world.'* [5] And referring to transportation networks, *'it is the connection of elements to one another that is the foundation of urban and suburban life. Are required to perform multiple functions: they must fulfill the requirements of public space and must be connected to other functioning urban systems of public transit, pedestrian movement, water management, economic development, public facilities, and ecological systems. Thesedemandsarethereforepropellingnewdesignapproaches'* [6]

In our case, central role in this matter is played by waterborne transportation as a sustainable option for reducing traffic congestion. By providing an alternative to traditional road traffic, water transport reduces the burden on coastal roads, which often act as barriers to water access. This mode of transportation not only alleviates congestion but also promotes economic and social activity along the waterfront by improving accessibility.

Additionally, waterborne transportation encourages a more dynamic and integrated coastal boundary. This is complemented by flood protection projects that safeguard the shoreline while enhancing its

usability. To further support sustainable mobility, we propose energy-efficient infrastructure that leverages natural resources and phenomena. This includes harnessing renewable energy sources such as solar, wind, and tidal power to create a more resilient and efficient transportation network. This approach not only enhances mobility but also contributes to a more vibrant and sustainable urban environment, where natural and built elements work in harmony to support the city's growth and resilience.

3.3 Overview of Design Projects

The experience of being near the water and the experience of moving on the water is central to the design. Implementing such a daily experience relies on a network of coastal hubs that extend along the city's waterfront. These network hubs integrate public water transport with urban infrastructure. After collectively studying the entire waterfront, each group of students selects a specific site for intervention. Each proposal articulates an urban scenario accompanied by functional programs, which are designed to enhance the character of each area, meet its needs, and ensure its smooth integration and participation in the overall functioning of the city.

Figure 2. Map from the course website showing intervention points on the city's waterfront

Regarding the management of the new coastline, there are various approaches to addressing future sea level rise and ensuring coastal resilience. One strategy involves preemptively transforming land to accommodate anticipated sea level rise, effectively bringing the water onto the land up to the expected future shoreline. This proactive approach allows for a gradual adaptation to changing conditions. Another strategy focuses on preservation and protection through technical works along the coastal front. These measures might include constructing seawalls, revetments, and other forms of coastal defense to shield the land from rising waters. Additionally, there are proposals for extending the city towards the water, integrating urban development with the coastal environment. These approaches aim to balance ecological sustainability with urban expansion, ensuring that coastal areas remain resilient, functional, and seamlessly integrated into the broader urban fabric. Here, we present six selected representative cases that exemplify these strategies and their implementation. Each case highlights different methods and techniques for managing the coastline while promoting ecological and urban harmony.

The first proposal [7] selects a location north of the city center, on the banks of the Melichos stream, in a sparsely built residential area. Until 2004, this vacant space housed a refugee camp. The memory of the violent eviction of the refugees in 2004 still lingers in the area, making it a significant landmark for the city. After this tragic event, the land remained undeveloped. The proposal symbolically and literally chooses to establish a transportation station on this site, bringing water into the area. Historically, this location was a marsh during the Ottoman period, which was drained after liberation. The topographical slope of the land allows for the influx of water to create a safe maritime station that will serve a large portion of the city's residents, enhancing its significance as a historical site. The proposal takes into account and implements the anticipated encroachment of water into the land area,

Proceedings

ensuring its resilience to future changes. The proposed structure, housing the suggested programs and the station, is a lightweight construction that allows the landscaped surroundings to dominate, creating an open public space - a park. The existing clusters of trees are preserved on small created and protected islands. These specific trees are resilient to the salty marine environment.

Figure 3. Aspects and sections of the proposal by student Alexopoulou, I.

Another proposal [8] brings water into the urban fabric, by creating a canal at the southern boundary of the city center. This area is characterized by a dense urban fabric separated from the sea by a zone of commercial buildings and a park. Nowadays, these commercial buildings host supra-local public functions such as shopping centers and cinemas. The canal aims to bring the aquatic element closer to the residents of this densely populated area while simultaneously enhancing the public character of the park, which currently acts as a barrier between the city and the sea, serving a protective function. The canal transforms the park space and the public buildings into island, providing autonomy to the city's functions. This creates a unique urban landscape where the network of floating transportation will serve both the residents of the area and park visitors. This integration of water transport will operate at both the neighborhood and city levels, blending urban development with the creation of a more sustainable and functional city. The entire architectural proposal is developed spatially within the existing topographical differences of the section. By utilizing the natural variations in elevation, the design ensures a seamless and harmonious integration of the canal into the urban environment, making the aquatic element a central and accessible feature of the city's daily life.

Figure 4. Topographic plan for canal excavation, by students Garefalaki, I. and Natsi, A

In the next case, front shielding measures are designed to preserve the existing shoreline. This proposal [9] suggests a new dynamic in the urban coastal area by placing the station at the former customs area. On the existing pier is located the former Port Authority building, an emblematic building of the city, representing public modernist architecture in Greece. Given projections of rising sea levels, this building is at risk of being underwater within the next 50 years. To preserve the

Proceedings

building, a coastal protection system is being designed specifically for this location. The proposal includes the construction of embankments in the form of artificial hills that will house water desalination facilities, providing the city with vital water resources. This creates a new urban landscape by combining public space with an essential production unit that meets the city's water needs. The already existing artificial boundary of the area evolves into a small ecosystem, an autonomous green space or park that independently satisfies its own water requirements. This transformation redefines our relationship with water and creates a sustainable, functional space that addresses present and future needs while preserving the existing coastline and emphasizing its importance. In this way, the proposal not only protects and preserves a significant historical building but also enhances the urban environment by integrating practical water management solutions with public space.

Figure 5.Topographic section, by student Moustaka, F.

In close proximity to the previous project, another case [10] aims to protect and enhance the city's fish market, which is the third largest in Greece. The fishing trade here serves needs beyond the borders of Patras. The fish market is located on the edge of the old port in a significant and vital part of the city, with the iconic lighthouse of Patras situated across from the church of Agios Andreas, the city's patron saint. The proposal involves creating low protective dykes at the land-sea boundary and expanding the fish market's activities with light constructions. These constructions will revive the once important outdoor market and enhance the circulation of fishing commodities. Additionally, a fishing shelter is planned for both professional and amateur fishermen. Furthermore, the creation of a water airport, previously proposed by the Municipal authorities for this area is included in the plan. All the new constructions mimic the industrial character of the area and are developed in the form of piers over the water, creating a protected environment for the land. This approach not only safeguards the fish market and its activities but also enriches the urban landscape, integrating the market more closely with the waterfront. By enhancing the functionality and resilience of the fish market area, the proposal supports both the local economy and the cultural heritage of Patras, ensuring that this vital part of the city remains active and vibrant for future generations.

Figure 6.Section of pier, by student Nikolakopoulou, M.

In another approach focusing on energy [11], the proposal harnesses the power of water with a floating structure capable of adapting to sea level changes while generating electricity from water currents. The proposal includes tidal hydroelectric turbines that channel the generated energy into the

station's parking lot for car charging. The proposal aims to minimize car usage in the city center and promote clean energy production, creating an energy self-sufficient system. The architectural intervention includes the design of a marine platform and an energy infrastructure that utilizes the region's climatic conditions, such as prevailing winds and coastal currents. Beyond the operation of the floating transportation station, the platform features a promenade, a café, waiting area and mooring infrastructure for small boats at the hydroelectric pillars. The platform's wavy form references water wave formations, embodying the concepts of fluidity, variability, and continuous change. Located on the northern edge of the city, it encourages visitors and residents to move to the city center by watercraft while simultaneously offering the opportunity for free car charging using environmentally friendly energy sources. The entire structure is anchored on land without being affected by the rising sea levels.

Figure 7. Research diagrams and 3D visualization, by student Patsioti, D.

In another proposal [12], a sea-based traffic hub is designed, to integrate various models of transportation, including a cable car that connects the hub to the hill at the diametrically opposite point from the sea border of the city. Centrally located along the city front, this construction opens new possibilities for traffic circulation, facilitating movements in two perpendicular directions. The hub serves as infrastructure where floating structures can be developed to accommodate city activities and future expansion needs. The concept draws inspiration from Constant Nieuwenhuys' New Babylon proposals, Archigram's Walking City, and the architectural developments in the Netherlands involving urban extensions onto the water. This proposal envisions a new dimension of the city on water, creating a sustainable urban space that connects people with the environment while enhancing the city's cohesion and social life. By extending the city onto the water, it aims to inhabit the aquatic surface while maintaining a close relationship with the existing structures on land. The design includes facilities for docking and transportation, recreational areas, and social spaces, all integrated into the floating hub. This setup not only provides practical transportation solutions but also creates a vibrant urban environment that promotes interaction and community engagement. The hub's floating nature ensures adaptability to changing sea levels, making it a resilient addition to the city's infrastructure. Overall, this proposal offers a visionary approach to urban development, merging

Proceedings

innovative transportation solutions with sustainable design principles. It transforms the city's relationship with its waterfront, making it an active and integral part of urban life.

Figure 8. Sectional and Perspective Drawings, by students Ziros, N. and Kaloudis, S.

4. EPILOGUE -FINAL THOUGHTS

Each proposal develops a strategy for the city and implements an architectural concept that meets the needs of today and tomorrow, while maintaining a strong connection with the environment. In each area, a new boundary with the water is carefully designed, utilizing both building and land installations to bridge the city's relationship with the sea. Just as urban configurations and development rely on detailed planning to create cohesive and wholes, our approach recognizes the close relationship between architectural scale and urban planning. The integration of architectural research into urban planning contributes to the creation of integrated environments that meet the needs of residents. This approach is a way of thinking and a methodology considers the complexity of urban development and prioritizes the quality of life for residents. Through this process of analysis, planning and design, we come to the conclusion that there is no one specific way for protecting the coastal front and integrating it into city life. Instead, a multitude of approaches can be combined, tailored to local characteristics and needs, even at a small scale. This diversity and variety of approaches results in a rich and varied coastal landscape that corresponds to the complexity of urban structure. It's important to recognize that the seafront is not uniform or homogeneous but rather responds to both natural and anthropogenic influences, leading to diverse characteristics at each point and area. By embracing this diversity and harnessing the potential of various strategies, we can create resilient and vibrant coastal environments that enhance the overall urban experience.

Public Space and Publicness: Between Center and Periphery

Z. Toloudi

Associate Professor of Architecture, Studio Art, Dartmouth College, USA

E-mail: zenovia@dartmouth.edu, Tel +1(312)404-4929

Extended abstract

This paper investigates public space through the concept of *publicness*, an approach that emphasizes what creates an inclusive, democratic, and socially driven public space in everyday life. It particularly examines how the small-scale design of the physical environment might affect the interaction among people towards the shaping of a more community-based spirit. It asks, is it possible for the architectural design or the physical environment to foster a civic identity? What structures and which elements within places can inspire a civic self among people? Using both theory and practice, the paper expands the idea through which architecture might influence the shift from an individualistic to collective society. Through fieldworks within central and peripheral regions of Southern Europe it records existing tendencies that mark the possibility of (and ways reinforcing) such transition.

Theoretically the paper discusses the relevance of: the artistic approach of installation/intervention within public space (Diller Scofidio+Renfro, Krzysztof Wodiczko); working through a civic vocabulary, a visual language as a set of verbs that respond to particular actions within public space (Zenovia Toloudi), emphasizing the social imaginary by linking the future, through the past (Cornelius Castoriadis); favoring rituals rather than events (Byung-Chul Han); working towards tangible futuristic ideas (The Japanese Metabolists); and the politics of cooperation (Richard Sennett) among other ideas. The fieldworks, which include architectural, photographic, and drawing studies in Italy, Spain, and Greece, and the proposals for public space from the architectural design studios constitute the examples which illustrate this vision linking public structures to public activities.

The examples of *publicness* include structures that host public moments (structure and activity); identifying public moments that happen (no structure, but there is activity); public structures that stay unused (structure, but no activity). These structures/ activities) may be found within traditional public spaces, such as street, plaza/square, park; office space (individual versus collective), private houses (open and inviting spaces). Some examples from the recent pandemic era (known for extreme lack of public interactions) explore the idea of “public space” within one’s private home (private car as well, such as the van-life). Such examples, all together create a spectrum of *publicness* through which public space can be reimaged. In this, the following three conditions exist: The creation of multiple centers for important actors (a process of de-centering to ensure an inclusive space for the marginalized and neglected); b) Structures that relate to (slow) time, towards a non-productive everyday life establishing rituals that emphasize empathy, courage, and interpersonal connectivity; and c) complex structures within a broken world, architecture structures that are neither complicated, nor simplistic to help rediscover a sort of public identity and to cultivate (within all) a more public-centric personality.

Heritage Conservation and the Triple Bottom Line: Findings from two recent North American Studies

D. Rypkema

President, Heritage Strategies International and Principal, Place Economics

Corresponding author: E-mail: DRypkema@HS-Intl.com Tel +1 202 290 9395

Extended abstract

Heritage advocates argue that the retention and reuse of the historic built environment is, in and of itself, a major contributor to sustainable development and an effective tool for resilience. While there has been some research on the role of heritage conservation and each of the three pillars of sustainable development – environmental, economic, and social – there are few examples of single studies or articles that demonstrate heritage conservation’s contribution to all three. This paper will consider two recent studies in North America that in one instance quantified the value of heritage resources at risk from sea level rise and the other monetizing the “triple bottom line” value of four commercial districts with a concentration of heritage buildings.

St Augustine, Florida, founded in 1565, is the oldest continuously occupied European settlement in the United States. It is home to 14,500 people, a small college, and a major tourism industry based on its collection of Spanish colonial architecture. It is also a waterfront community on Florida’s Atlantic coast and subject to regular weather events that seem to be getting stronger and more frequent with climate change. Much of the city lies in identified flood zones. As part of its climate mitigation efforts, the city commissioned an analysis that included: 1) quantification of the value of heritage properties located in flood zones; 2) how weather events impact the city’s tourism industry; 3) the value of its heritage resources using the travel cost method of valuation.

Calgary, Alberta is a city of 1.3 million in Western Canada. Founded in 1875 it is now the center of Canada’s largest petroleum producing area. But the economy has diversified with major economic sectors including aerospace, financial services, agribusiness, transportation, and technology. It also has four commercial districts with a concentration of heritage buildings. The city is committed to a comprehensive sustainable development strategy. City staff suspected but needed evidence that the commercial districts had quantifiable monetary value not only economically, but also socially and environmentally. A Calgary architectural practice and a US-based heritage research firm were commissioned to undertake the analysis. The social value was estimated using, in part, a willingness to pay study. Environmental values were estimated considering landfill costs avoided, embodied carbon, embodied energy, and other metrics. The economic portion of the analysis identified both a heritage premium (an additional value increment recognized by the marketplace) and a heritage halo effect – enhanced value of non-heritage buildings resulting from their proximity to historic structures.

Focusing on the generic city to transform Athens' urban landscapes

T. Roidis

Technical University Munich, Chair of Sustainable Urbanism, Germany

Extended abstract

Transforming and regenerating urban landscapes involves a wide range of disciplines and addresses several pressing issues: climate adaptation, stormwater management, mobility infrastructure, social inequalities, gentrification and the housing crisis. Many of these aspects are evident in the current urban situation of Athens, Greece. Since 2010, Athens has been recovering from, but continues to cope with, a series of crises including the economic crisis, pandemic, migration and climate change. At the Technical University of Munich, Chair of Sustainable Urbanism, we led a three-year research and teaching programme entitled Athens' Inner-Urban Landscapes, which addressed the multidimensional urban transformation of the city and the issues mentioned above. We worked with the National Technical School of Athens and an interdisciplinary group of experts from academia, local authorities and practitioners to gain valuable insights into the city's current urban issues.

With the aim of bringing together different fields into a condensed set of knowledge and action for the future of the city, the research project was built on three main pillars: Research - on the theme of urban transformation and regeneration; Teaching - in the form of interdisciplinary seminars, design studios and workshops; and Outcomes - in the form of a book, a symposium and others that will ensure creating a strong network and disseminating the project. The research project has succeeded in proposing a series of ideas, plans and actions for the metropolitan area, identifying current and future urban challenges, governance and climate adaptation issues. It is the generic city that, in order to improve the quality of daily life of its citizens, is in need of urban transformation on several levels, from the upgrading of its building stock to the defragmentation of its urban landscapes. Considering the natural elements of the city, such as green corridors, streams, topography, we must develop new climate-adaptation strategies that improve the quality of life in these areas, leading to a common agenda among stakeholders to improve the urban context we live in. Inner urban landscapes are therefore defined as landscapes of (urban) regeneration. They play a crucial role in climate adaptation in the city, but also provide social cohesion as spaces for public interaction.

The presentation will highlight the process of developing the project, from conception and structure, to identifying themes and taking action. It will also show examples of the teaching procedure, along with research findings which focus on these themes. Finally, it will explain the benefits of synergies and active collaboration between administration, academia and practice, contributing to the collective discussion on a sustainable future for the city.

Abstract

The devastating railway incident on February 28, 2023, in the area of Tempi (Thessaly region) caused intense discussions regarding the safety of the railway networks and particularly where they intersect with urban areas. In Thessaly region, there are three main railway lines: the primary national route Athens to Thessaloniki and two regional routes, one connecting Palaiofarsalos to Kalambaka and the other linking Larissa to Volos. These railway lines traverse through the cities of Larissa, Trikala, Karditsa and Volos. While Larissa and Trikala have the railway lines passing through their urban cores, in the cases of Karditsa and Volos, they run along the outskirts. The paper aims to statistically analyze railway accidents, comparing them against national statistics, and subsequently benchmarking the data against other countries, particularly those in Europe. As the jurisdiction of the regional department of the Technical Chamber of Greece only encompasses the three regional units of Larissa, Trikala, and Karditsa, the study will not incorporate data from the Magnesia regional unit. Raw data from 1995 until 2023 are collected, detailing accidents occurring in the railway networks in these three regional units. The analysis results reveal a notable upward trend in railway accidents occurrence across the three regional units in Thessaly. A comparative analysis between regional and national data illustrates a decline in national accident rates post-2018, contrary to the escalating trend observed regionally. This fact reinforces the conclusion that, on regional scale, the challenge is the railway passages through urban areas. Comparing the national data with the data from other countries, Greece exhibits a higher accident rate compared to EU27 level. In essence, these findings underscore the urgent imperative to address safety concerns within railway networks. Our study aims to delve deeper into potential solutions to mitigate risks and ensure the safety and well-being of the residents.

Keywords: *railway; accidents; Thessaly; urban environment; safety.*

1. INTRODUCTION

Railway systems serve as vital lines of transportation in cities, efficiently connecting people and goods across vast urban landscapes. However, the integration of railways within densely populated urban areas poses significant safety challenges. Railway safety and the prevention of accidents are paramount concerns for urban planners, policymakers, and citizens.

Railway accidents in cities can vary in nature and severity, involving collisions between trains, derailments, or accidents involving pedestrians and vehicles at railroad crossings. Identified common causes of railway accidents in urban areas include human error, track and equipment failures, collisions, trespassing, security threats, weather conditions, and other causes. Human errors by train operators, signal maintainers, or other personnel can lead to accidents. Defective tracks, broken rails, or issues with switches and crossings can cause derailments or other accidents. Other causes leading

Proceedings

ISSN: 2654-0460
ISBN: 978-618-5765-02-6

to accidents are malfunctions in train components such as brakes, engines, or signalling systems. Accidents can occur when trains collide with each other or with vehicles at railroad crossings. People trespassing on railway tracks or attempting to cross them illegally can be struck by trains, resulting in accidents and fatalities. Moreover, problems with infrastructure such as bridges, tunnels, or overhead wires can lead to accidents if not properly maintained. In some cases, adverse weather conditions like heavy rain, snow, or fog can affect visibility and track conditions, increasing the risk of accidents. Security issues such as acts of vandalism, terrorism, or sabotage can pose serious risks to railway safety in urban areas.

This paper aims at investigating railway accidents within the regional units of Larissa, Trikala, and Karditsa, in Greece. Specifically, the paper performs a statistical analysis of the railway accidents in order to stress out the need for measures in the region. The accidents were categorized based on their date and location of occurrence, the underlying cause, and the number of casualties. In order to investigate the trend of the railway accidents in the area compared to the national data, a comparative analysis was conducted illustrating a decline in national accident rates post-2018, contrary to the escalating trend observed regionally. Finally, the national data was compared to the data from other countries (both EU and non-EU). The study aims to delve deeper into potential solutions to mitigate risks and ensure the safety and well-being of the residents.

2. RAILWAY ACCIDENTS CAUSES: A LITERATURE REVIEW

Rail transport is recognized globally as a secure and environmentally friendly mode of travel. Although safety standards can fluctuate, even in highly developed regions like the European Union, the railway is considered as the safer mode of travel compared to other transport modes, except for commercial aviation. EU data [1] show that railway accidents resulting in fatalities in 2019 in EU-27 account for 0.09 deaths per billion train Km, compared to 0.24 deaths per billion Km by bus/coach. The related number of deaths in airlines is 0.08 per billion Km.

Based on the International Railway Safety Council [2] the common risks identified in railway are: (a) train collisions; (b) derailments; (c) level / grade crossings and trespass; (d) railway staff risks; (e) stations; (f) suicides; and (g) dangerous goods. Collisions between trains or between trains and infrastructure is one of the common risks identified in railway industry. Although collision between passenger trains travelling at high speed in opposite directions are rare, they can result in severe consequences (recent examples in Germany, Spain, and Greece). The causes of such accidents include drivers running signals, incorrect routing, speeding, train separation, poor wheel-rail adhesion, and both technical and human errors in the signalling system.

Another risk is derailments which is common, but the consequences are not extremely severe [2]. Derailment causes include technical issues such as poor track geometry, damaged or defective switches and crossings, and wear and fatigue in the wheel-rail interface. Vehicle suspension faults and operator errors, including incorrect setting of points, excessive speed, and poor driving behaviour, also contribute to derailments.

Globally, the predominant occurrences of rail-related injuries and fatalities (excluding suicides) are concentrated at railway level crossings. The study of Larue et al. [3] showed that in the United States 31% of such incidents were recorded in 2015; in the European Union the figure stood at 26% between 2012 and 2014; Australia reported 31% between 2002 and 2012; India documented 43.5% between 2009 and 2015; and South Korea witnessed a staggering 95% from 1998 to 2002. Despite a decline in the number of collisions, the latest available data indicate a stagnating level in fatalities and serious injuries at level crossings [3]. The main causes of these incidents include road users who are unaware of the level crossing, distraction / inattention, failure of level crossing equipment or a second train unexpectedly approaching the crossing and violations by road users ignoring the warning of approaching trains. Larue et al. [3] reported that investigations both internationally and in Australia consistently reveal that the primary cause of these collisions is the actions of vehicle drivers or

Proceedings

of the International Conference on **Changing Cities VI:**
Spatial, Design, Landscape, Heritage & Socio-economic Dimensions
Rhodes Island, Greece ● June 24-28, 2024
ISSN: 2654-0460
ISBN: 978-618-5765-02-6

pedestrians, characterized by lapses, errors, and violations. In the US as many as 60% of drivers disregard lowered gates and flashing lights and attempt to bypass warning infrastructure, even when an oncoming train is clearly visible [3]. In addition, in some cases the drivers are reluctant to stop because they perceive they have sufficient time to cross. Trespasses are common in densely populated regions resulting in severe injuries and fatalities.

Another common incident is suicides causing significant disruption and psychological trauma for railway staff and passengers [2]. Finally, as trains are also used to goods transportation, the railway often is used to carry dangerous goods such as chemicals, petrol, etc.

One of the major causes linked to train accidents is the human error. The study of Baysari et al. [4] in Australia reviewed Australian incident and accident reports and revealed that almost half of the cases were linked to equipment failures, primarily stemming from insufficient monitoring or checking procedures. The predominant causes were lapses in attention, characterized as skill-based errors, often tied to reduced alertness and physical fatigue. Organizational factors are identified as influencing factors of these incidents, highlighting the necessity to address issues related to resource management, organizational climate, and processes to effectively mitigate errors within the Australian railway system.

3. ANALYSIS OF RAILWAY ACCIDENTS

3.1 Railway in Greece

The Hellenic Railways Organization (HRO) was established in 1970 for the organization, operation, and development of rail transportation. The management of HRO is carried out by a board of directors. HRO legal form changed over the years from a public law legal entity to a public limited company with the separation of infrastructure management from transport activity with the establishment of subsidiary companies and their sale to individuals. HRO S.A. became the managing company of the railway infrastructure while the transport business was sold to the Italian company Ferrovie dello Stato Italiane in September 2017 [5].

The current railway network extends along 2552 Km of operational lines (Figure 1). In the study area there are three railway lines: the one from Athens to Thessaloniki, passing through the city of Larissa, with a total length of 87 Km (located in Larissa regional unit), the one from Paleofarsalos to Kalambaka, passing from the cities of Trikala and Karditsa with a total length of 80 Km and the one from Larissa to Volos with a length of 34Km within the limits of Larissa regional unit only. Within the limits of Larissa city the length of the railway lines is 9.5Km. The length of the railway lines pass through the city of Trikala is 5 Km and through the city of Karditsa is 3.8Km. In all cases the railway infrastructure is located in the ground level. In the city of Larissa there are two underground passages for the vehicles while all other crossings are guarded passages.

3.2 Railway accidents in Europe and in Greece

Railway incident data from EUROSTAT database [6] were drawn in order to assess the frequency and the impacts of the railway incidents in Greece compared to other countries. Railway incident data is recorded from 2004 to 2022 at country level (NUTS 1). Railway incidents in the EUROSTAT database are distinguished based on their causes as: (a) train collisions and collisions with track obstacles, (b) derailments, (c) railway crossings, (d) trains in motion, (e) fires. The total number of incidents and the average number of casualties (dead and injured persons) in the member states of the European Union except Cyprus and Malta for the period between 2004 and 2022 are shown in Figure 2. The highest number of railway incidents are met in Poland, Germany and Hungary, while the lowest number of incidents are met in Denmark, Norway and Slovenia. The highest number of fatalities and injured people are met in the countries with the highest number of incidents, that is Poland, Germany, Romania, Hungary, and Turkey.

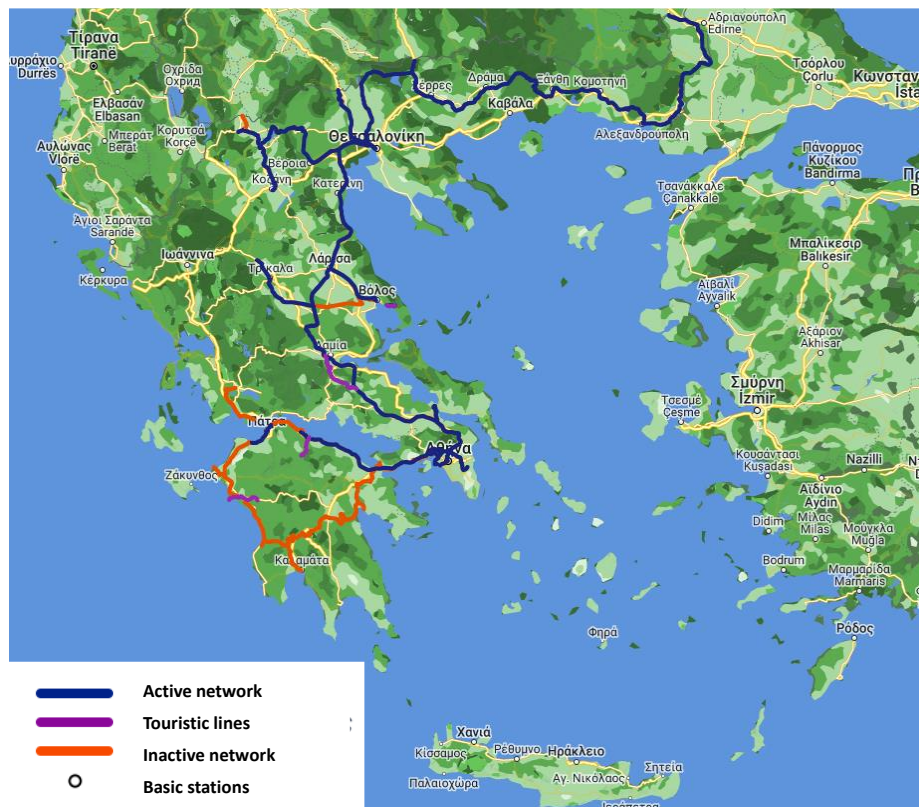

Figure 1. Map of railway network in Greece (<https://ose.gr/>) [5]

As the absolute figures among the different countries are not comparable, we have regressed the numbers of railway incidents, fatalities, and injuries per kilometer of railway line. Figure 3 presents the average numbers of railway incidents, fatalities, and injuries in the European Union Member States other than Cyprus and Malta for the period 2004-2020, per kilometer of railway line. The countries with the highest number of incidents per railway length are N. Macedonia, Montenegro, Hungary and Slovakia and the countries with the lowest number of incidents per Km of railway are Ireland, UK, and Sweden. The countries with the highest average number of fatalities per railway network length are Montenegro, N. Macedonia, and Poland while the countries with the lowest number of fatalities per railway network length are Norway, Ireland, and UK. The countries with the highest average number of injuries per railway network length are N. Macedonia, Turkey, and Hungary while the countries with the lowest number of injuries per railway network length are Ireland, Norway, and UK. Greece has 12.6 railway incidents per 1000Km of network which is higher than the EU average (8.8 per 1000Km). The fatalities in Greece are 7 people per 1000Km and the injuries are 7.1 people per 1000Km while the average EU fatalities are 5 people dead and 3.8 people injured respectively.

Figure 2. Railway incidents, fatalities, and injuries in Europe 2004-2020 (based on [6])

Figure 3. Railway incidents, fatalities, and injuries per railway network length in Europe 2004-2020

From the analysis in the EU countries, it can be concluded that Greece has a higher average number of fatalities and injuries per railway lines length and per incident than the corresponding average of the EU during 2004-2020.

3.3 Railway accidents in Thessaly, Greece

In order to investigate the trend in railway accidents in the region of Thessaly and in particular in the regional units of Larissa, Trikala, and Karditsa, we have gathered the data of the railway incidents from April 1995 until February 2023. During this period 48 railway incidents occurred resulting to 86 fatalities, 201 injuries and 1 missing person. From these incidents, 22 took place on the Paleofarsalos – Kalambaka line, 15 took place on Athens – Thessaloniki line within the limits of the regional unit of Larissa and 11 took place on Larissa – Volos line within the limits of the regional unit of Larissa (Figure 4).

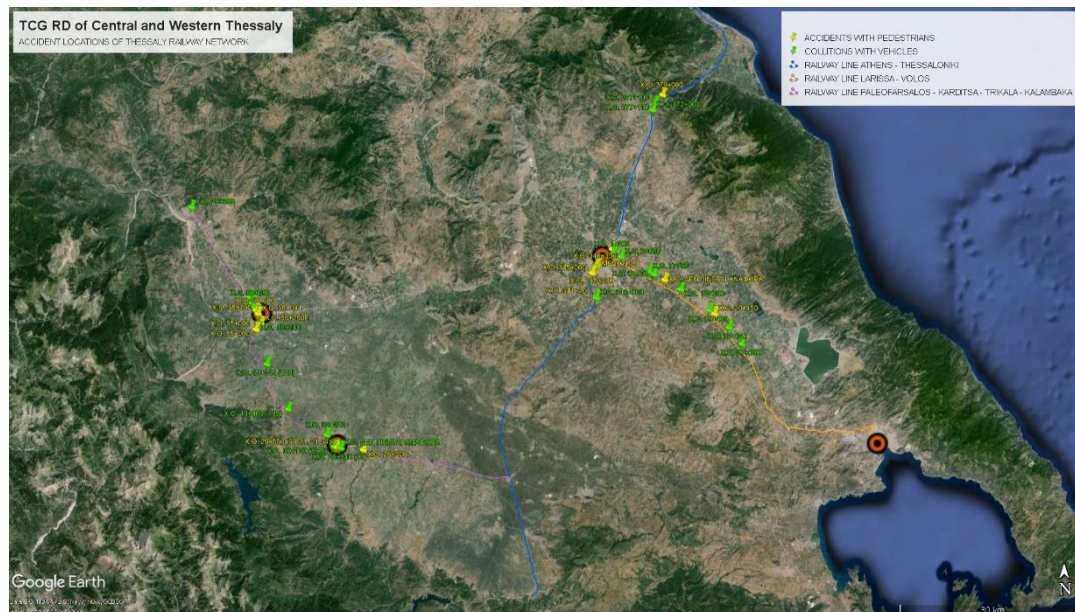

Figure 4. Locations of railway incidents in the regional units of Larissa, Trikala, and Karditsa

Figure 5. Number of railway incidents in the regional units of Larissa, Trikala, and Karditsa

From the total number of the 48 railway incidents, 6 were recorded as suicide attempts resulting in 4 fatalities and 1 injury. These incidents include 3 falls from a bridge and 3 suicide attempts on the railroad tracks. Three incidents were related to electric shock in the area of Mezourlo (in Larissa city) after a breach of the fence of the depot area and near the Athens-Thessaloniki line. The causes of the remaining incidents are: collision of train with vehicle (23 incidents), pedestrian encroachment (15 incidents), collision of trains (2 incidents) and derailment (1 incident). The railway incidents per year show an increasing trend with some fluctuations per year (Figure 5).

The causal analysis by event type showed that the dominant reason for the trains' collision is the violation of the priority of the train in unguarded crossings, while events of unspecified reasons are

also observed. For the "pedestrian encroachment" incident type, the dominant cause is the vertical crossing of a railway line from a point other than a guarded or non-level crossing (27% of similar incidents) and crossing a railway line (20% of similar incidents).

One of the railway incidents recorded is the devastating railway incident on February 28, 2023, in the area of Tempí which resulted in 57 fatalities and one missing person. As the number of fatalities of only one incident is high and in order to analyze the temporal trend of fatalities and injuries, this incident is excluded from Figure 6 showing the number of fatalities in railway incidents in the area from 1995 to 2022. The data show an increasing trend in fatalities caused by railway incidents in the area. Also, an average number of 2.29 incidents per year are observed, which is in line with the national average (2.4 incidents per year).

Figure 6. Number of fatalities in railway incidents in the regional units of Larissa, Trikala, and Karditsa (1995-2022)

Figure 7. Ratio of the number of railway incidents in the study area over the number of the railway incidents in the country 2004-2022

In order to investigate the incidents trend in the study area and at the national level, the number of incidents in the country are gathered from 2004-2022 (Figure 7). The comparison shows that the railway incidents number in the study area increases compared to the national data. This means that while the trend of railway incidents in the country between 2004 and 2022 is decreasing, the corresponding trend in the study area is increasing.

4. DISCUSSION AND SUGGESTIONS

In the study area of the regional units of Larissa, Trikala, and Karditsa, railway incidents and casualties are recorded from the year 1995 onwards, taking place on the railway lines Thessaloniki - Athens, Palaiofarsalos - Kalambaka and Larissa - Volos. The information was provided by the Police Departments of the regional units. The most common type of incident is the collision of a train with a wheeled vehicle followed by a pedestrian encroachment.

The analysis of the causes of the incidents showed that the majority is due to a violation of safety measures (fences, crossings, etc.) by pedestrians and vehicles. From the total of 48 incidents between the years 1995 and 2023, one derailment and three collisions between trains are recorded. The spatial distribution of railway incidents shows that the largest number of incidents take place in the residential areas, i.e. in the cities of Larissa, Trikala and Karditsa where railway lines pass (Figure 8). A significant number of incidents are also observed on the Larissa - Volos line. The data analysis also shows that there is an increasing trend of railway incidents in the study area, which is not the case for the rest of the country.

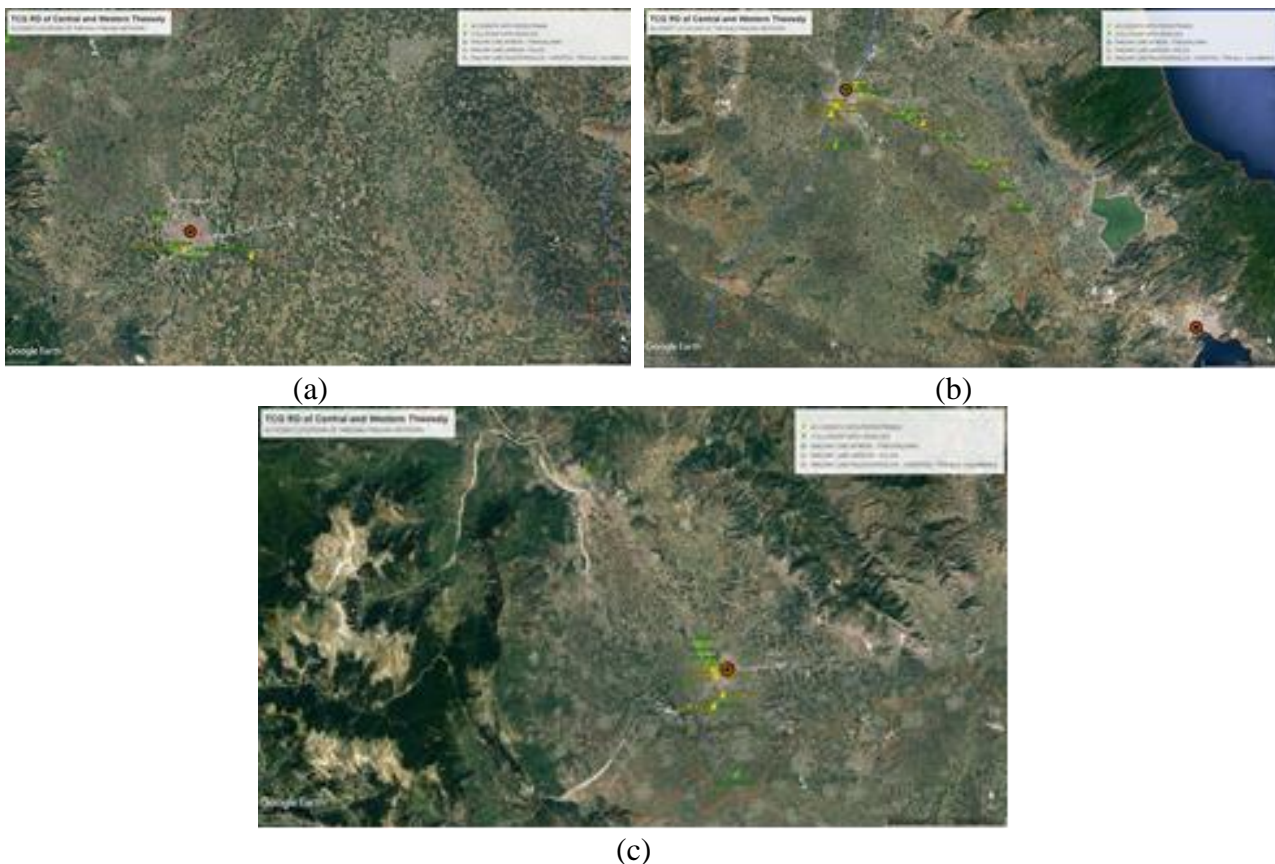

Figure 8. Incidents in railway lines (1995-2023) in (a) Karditsa city; (b) Larissa -Volos line; (c) Trikala city

At the European level, the Greek average of incidents, deaths and injuries per Km of lines in 2004-2022 is higher than the corresponding one of the EU-27, as formed after 2020. Compared to other countries, Greece ranks low in terms of average incidents, deaths, and injuries per number of traveling passengers. Regarding the severity of the incidents, our country presents relatively high averages of fatalities and injuries per incident.

The analysis revealed that measures are needed to reduce railway incidents. Recent advances such as the ETCS (European Train Control System) may enhance safety, especially in the case of collisions, but are technologically challenging [1]. The railway industry addresses derailment risks by implementing rigorous maintenance systems and ensuring high levels of staff competence through comprehensive training. Strategies such as erecting fences, issuing public announcements, conducting educational campaigns, and implementing police patrols are employed to reduce trespasses.

There are two categories of level crossings identified: active and passive ones [3]. Active crossings employ various mechanisms such as visual and auditory signals, including flashing lights, bells, and boom gates, to warn motorists and pedestrians about approaching trains. On the other hand, passive crossings rely on signage, expecting users to be vigilant and yield. The study of Larue et al. [3] mentioned that boom gates are the most effective in preventing collisions. Furthermore, crossings equipped with flashing lights show significantly better safety records compared to those with stop signs and yield indicators. According to Larue et al. [3] an analysis is needed to select the crossings that can be upgraded to active protection. However, some researchers indicate that upgrading may have unintended consequences, such as congestion issues, while complexity with which road users interact at active crossings, it may also introduce other unconsidered risks.

A more effective solution is to engineer out the hazard of rail-road interaction (i.e. grade separate) [3]. Although this solution is the most efficient one, it involves redesigning the road network, construct bridges and tunnels, thus involving high costs. Generally, there is growing interest in urban regeneration around the world [7]. Many advocate for incorporating transport infrastructure, such as railways or highways, underground as part of urban revitalization efforts. This approach involves redirecting or concealing transport routes to free up surface-level space for alternative uses. Notable examples include the Big Dig in Boston and the Rive Gauche redevelopment in Paris, focusing on road and rail realignment respectively [7]. Environmental concerns, like noise pollution and visual degradation, further underscore the need for change. Residents living nearby often advocate for the removal of unsightly concrete structures. Redirecting infrastructure typically involves refurbishing and rerouting major sections underground, necessitating significant financial investment. While such projects face challenges such as extensive excavation and encountering geological or archaeological obstacles, they yield diverse benefits. Redevelopment opportunities arise as former transport areas transform into green spaces, pedestrian walkways, bike paths, and new residential or commercial developments. Additionally, noise reduction, decreased vibrations, and improved safety near the facilities contribute positively to urban cohesion. Underground transportation systems can lead to increased safety for both pedestrians and motorists by minimizing the risk of accidents and collisions. Additionally, improved accessibility can foster greater connectivity within the city. On the other hand, except of the high cost involved, there are other disadvantages. Excavating tunnels and rerouting major transport arteries underground present significant technical challenges, including geological obstacles, utility relocations, and engineering complexities [7]. In addition, construction activities associated with tunneling projects can cause disruptions to local communities, businesses, and transportation networks. Traffic diversions, road closures, and noise disturbances may inconvenience residents and commuters during the construction phase. Finally, underground transport systems require ongoing maintenance and operational expenditures to ensure safety, reliability, and efficiency. Underground tunnels are susceptible to issues such as water infiltration, structural deterioration, and equipment malfunctions, necessitating regular inspections and repairs [7].

5. CONCLUSION

In conclusion, the analysis of the incidents in the study area and the comparison of the data with corresponding ones for the country and other European countries demonstrate that the upgrading of the railway at the country level has reduced the number of railway incidents and the severity of their effects. However, the railway accident of February 2023, for which a judicial investigation is being conducted, revealed that there are safety issues to be addressed. The purpose of this study is to investigate the causes of the railway accidents in the study area and propose solutions. The analysis of the data showed that while at the national level the number and effects of railway incidents have been limited, this is not the case in the study area. On the contrary, in the study area there is an increasing trend in the number of incidents with the main causes being collisions of trains with vehicles and pedestrians, especially in crossings. This conclusion is in agreement with the fact that at the EU level the predominant type of incidents with the highest number of fatalities are those occurring at level crossings and due to unauthorized persons on railway tracks (responsible for 98% of railway accident deaths). The spatial distribution of the incidents in the study area also shows that they are taking place within residential areas, which leads to the conclusion that these areas require immediate action for the safety of their residents and the safe passage of trains.

The measures to address these challenges include investing in modernizing infrastructure, implementing strict safety regulations, providing comprehensive training for personnel, and raising public awareness about the dangers of trespassing on railway tracks. Additionally, advanced technologies such as predictive maintenance systems and automated safety mechanisms can help mitigate the risk of accidents. Technological advancements offer promise for revolutionizing railway safety by enhancing operational capabilities, mitigating human error, and anticipating potential hazards. Such advancements include innovations such as predictive analytics, autonomous systems, and intelligent infrastructure, which hold potential to transform railway safety in urban environments through data-driven insights and advanced automation. Urban regeneration suggestions include the underground rerouting of transport infrastructure. While rerouting ground transport infrastructure into tunnels offers various benefits such as mitigating social costs, optimizing urban space, and enhancing safety, it also poses challenges related to cost, technical complexity, disruption, and ongoing maintenance. Effective planning, stakeholder engagement, and innovative design solutions are essential to maximize the advantages of underground transportation while mitigating potential drawbacks.

Abstract

The paper presents a multicriteria analysis method and its application to rank the 30 Informal Industrial Concentrations (IIC) in the Region of Central Macedonia, Greece. IICs are areas characterized by intense economic activity, inadequate infrastructure, deficient urban planning, and environmental challenges (article 41, paragraph 2 of Law 3982/2011). By using multi-criteria analysis, the Region's IICs are prioritized for transformation into Business Parks for Remediation. Overall, Business Parks (BP) are planned and developed by means of a street layout plan, with specific requirements and conditions for the orderly positioning of business activity within an urbanized status. They have contemporary and extensive technical infrastructure facilities to meet the needs of established businesses, promote entrepreneurship, and guarantee environmental preservation. A Business Park for Remediation (BPR), also known as *Epiheirimatiko Parko Exygiansis* in Greek, is a Business Park that has been created, delineated, urbanized, and structured specifically for the environmental remediation of areas with informal industrial clusters.

The criteria considered encompass factors that influence the feasibility analysis and act as either incentives or deterrents for the development of Business Parks. Structurally, the criteria are organized into distinct sets, each comprising specific sub-criteria. The three main categories of criteria are: Technical Environment (infrastructure/accessibility), Human-made Environment (socioeconomic characteristics), and Natural Environment. The process includes rating the criteria, determining the partial utility value of the alternatives, setting the criteria weighting factors and lastly evaluating feasible options.

Keywords: *informal industrial concentrations; multi-criteria analysis; Business Park for Remediation; spatial planning policy; urban planning; Greece*

1. INTRODUCTION

In the previous years, the lack of an integrated spatial consideration of industry location in Greece, combined with the absence of a national industrial policy, resulted in the formation of Informal Industrial Concentrations (IIC). These are frequently located on the outskirts of large urban areas, in strategic locations, near important transportation networks, and contribute significantly to the national and local economies. At the same time, they demonstrate urban planning and environmental problems in both their internal environment and their link to the wider area [1]. They are characterized by intense economic activity, inadequate infrastructure, deficient urban planning, and environmental challenges (article 41, paragraph 2 of Law 3982/2011); nonetheless they "support" industry, logistics, small and medium-sized craft facilities in various regions of the Greek territory [2].

The establishment of informal industrial concentrations (IICs) in the country was made mainly in two time periods [3]: a) between 1970 to 1990, when a substantial effort was made to enact legislation on industrial land use in Greece. During that period, special regulations were issued, aimed at moving industry away from the Greek capital, while measures to protect the environment were also promoted,

Proceedings

such as the classification of industrial activities based on the type of nuisance they caused. Despite relevant state policies at the time, the persistent effort to dissuade industrial businesses from launching new installations in the major urban agglomerations (Athens and Thessaloniki) led to the continuation of a well-known practice: the establishment of informal industrial concentrations (IICs) at a short distance from the country's major urban centers; b) from 1990 to 2020, when investments gradually declined, precipitating the 2009 economic crisis. New circumstances caused economic and other structural changes. Business Park institutional framework improvements allowed private firms to organize themselves in a business park or informal industrial concentration (ICC), promoting several institutional reforms.

“Business Parks” (BPs) are planned and developed by means of a street layout plan, with specific requirements and conditions for the orderly positioning of business activity within an urbanized status. They have contemporary and extensive technical infrastructure facilities to meet the needs of established businesses, promote entrepreneurship, and guarantee environmental preservation. Currently there are 26 Business Parks (i.e. organized receptors) operating in the country, which, compared to the needs of manufacturing, are unevenly distributed. Most Greek businesses continue to operate in IICs [2]. 185 IICs, with a total area of 307,733 sq.m., have been registered in the Greek territory. The largest concentration is found in the Regions of Attica and Central Macedonia, i.e. in the metropolitan regions of Athens and Thessaloniki [1]. Based on the Greek legislative framework, an appropriate solution for the remediation of IICs is their evolution into modern Organized Receptors of Manufacturing & Business Activities (*OYMED*), i.e. into Business Park for Remediation (BPR), also known as *Epiheirimatiko Parko Exygiansis* in Greek. BPR is a Business Park that has been created, delineated, urbanized, and structured specifically for the environmental remediation of areas with informal industrial clusters.

The paper presents a multicriteria analysis method and its application to rank the 30 Informal Industrial Concentrations (IIC) in the Region of Central Macedonia in Greece. By using multi-criteria analysis, the Region's IICs are prioritized for transformation into Business Parks for Remediation.

2. METHODOLOGY: DESIGN AND APPLICATION

The transformation of IICs into BPRs requires a detailed feasibility analysis based on a multicriteria approach. This method involves evaluating various factors that influence the viability and success of the transformation. The present study employs a spatial multicriteria analysis (MCA) through cartographic overlay modeling. This approach evaluates alternative options from a geographical and spatial perspective at a strategic level, integrating systematically critical factors to prioritize the areas for development.

1. Defining objective

The initial step is the definition of a clear objective. The overall goal of the MCA defines the problem scope, which is to prioritize and rank the 30 IICs for transformation into BPRs based on their need for remediation and development potential. The specific focus is the quantification of remediation needs, which guides the evaluation and ranking process. This involves:

- **Objective Clarification:** The primary objective is to systematically rank the IICs from the most to the least suitable for development into BPRs. This ranking reflects both the urgency of remediation needs and the feasibility of development.
- **Contextual Understanding:** The development of BPRs aims to address inadequate infrastructure, urban planning deficiencies, and environmental challenges in the IICs, taking into consideration the principles of sustainable development and economic growth in the region. This final method will facilitate the prioritization of IICs for conversion into BPRs.

The feasible solutions are examined using one of the four problem formulation (*problematique*) types, according to Roy's *Multicriteria Methodology for Decision Aiding* [4]. In this analysis, problem

formulation (problematique) “ γ ” is applied, which involves ranking the feasible solutions from best to worst based on their evaluation against the defined criteria. This approach is aligned with the project's goal of producing a hierarchical ranking of the IICs.

2. Defining the feasible solutions

In the first stage, the set A of feasible solutions is identified. This set consists of 30 identified IICs in the Region of Central Macedonia, which have been selected as potential sites for development into BPRs. Each IIC represents a unique alternative that will be evaluated in the next steps based on various key criteria to determine its suitability for transformation.

3. Data collection and GIS Analysis

Accurate and comprehensive data collection is fundamental to the success of the MCA. This involved collecting primary and secondary data relevant to each of the defined components. Geographic Information System (GIS) analysis is crucial in this step by providing spatial data that helps understanding the geographical distribution and characteristics of the IICs, by mapping infrastructure, environmental conditions, and accessibility, providing a visual and analytical basis for the evaluation [5]. The collected dataset consists of quantitative, qualitative, and spatial data, which include metrics and information from relevant authorities, services, websites, and reputable online open data platforms. Regarding data that constitute purely spatial parameters (e.g., required distances, areas, zone overlaps, etc.), these are either provided by the respective governmental services or digitized based on official backgrounds, to be processed through GIS. In this initial phase, all necessary information is recorded, and analog data are digitized to create their spatial representation, to create a geodatabase (a vector spatial model), which is necessary for the application of the multicriteria analysis.

4. Identifying the criteria

In this stage, the specific criteria within each component are identified. The criteria consist of factors and restrictions related to the problem under investigation and are derived from the objectives and encompass the factors that will influence the success of transforming IICs into BPRs. These typically include infrastructure quality, accessibility, socioeconomic characteristics, and environmental conditions. In the context of multicriteria analysis, a criterion is defined as any real function g that maps the behavior of each feasible solution to a real number. For any two feasible solutions x and y , the following holds:

$$g(x) > g(y) \Rightarrow x > y \quad g(x) > g(y) \Rightarrow x > y \quad (x \text{ is preferred over } y)$$

$$g(x) = g(y) \Rightarrow x \sim y \quad g(x) = g(y) \Rightarrow x \sim y \quad (x \text{ is indifferent to } y)$$

The set of criteria $G = \{g_1, g_2, \dots, g_n\}$ identified must form a consistent family of criteria with the following properties:

- **Monotonicity:** For any pair of feasible solutions x and y where there exists a criterion $g_i \in G$ such that $g_i(x) > g_i(y)$ and $g_j(x) = g_j(y)$ for every $j \neq i$, it is concluded that $x > y$.
- **Exhaustivity:** For any pair of feasible solutions x and y such that $g_i(x) = g_i(y)$ for every criterion $g_i \in G$, it is concluded that $x \sim y$.
- **Non-redundancy:** A set of criteria is non-redundant if removing any criterion violates the properties of monotonicity or exhaustivity [6, 7].

Specifically, the criteria to be introduced for the multicriteria analysis will constitute parameters related to the framework for the development of Business Parks in general, and widely for the Region of Central Macedonia, as these will emerge from the analysis of the institutional framework for the development of Business Parks, the broader developmental and institutional framework that affects the development of business activities, and the directions of spatial planning.

Regarding the structure, it is noted that the groups of criteria that were defined consist of individual sub-criteria. In this context, the criteria and sub-criteria selected are presented in Figure 7, which

encompass the data collected during the evaluation of the current state of the 30 examined IICs and the broader area in which they are located.

Criteria

Criteria	
g1	TECHNICAL ENVIRONMENT (INFRASTRUCTURE / ACCESSIBILITY)
g1.1	Proximity of the Informal Industrial Concentration (IIC) to transport networks (Road, Railway)
g1.1.1	Proximity of the IIC to the nearest junction of Egnatia Odos or PATHE
g1.1.2	Proximity of the IIC to the nearest railway station
g1.1.3	Proximity of the IIC to the port of Thessaloniki
g1.1.4	Proximity of the IIC to the nearest operational airport (Thessaloniki or Kozani)
g1.2	Proximity of the IIC to Thessaloniki's Central Railway Station (combined transport hub)
g1.3	Service of the IIC by integrated hydraulic networks (water supply, sewerage, stormwater)
g1.4	Service of the IIC by the natural gas network
g2	HUMANMADE ENVIRONMENT – SOCIOECONOMIC CHARACTERISTICS
g2.1	Total area of the IIC
g2.2	Directions of spatial/urban planning
g2.2.1	Inclusion of the IIC in an area of intensification, expansion, qualitative restructuring, or support of the industry
g2.2.2	Priority of spatial policy for manufacturing in the Regional Unit where the IIC is located
g2.2.3	Need for the creation of new organized industrial areas in the Regional Unit where the IIC is located
g2.2.4	Legally established land uses (from General Urban Plans/Spatial and Urban Planning Frameworks and Zoning Regulations) in the area of the IIC compatible with the industrial character
g2.3	Number of industrial units
g2.4	Availability of land for business activities (undeveloped plots)
g2.5	Estimated percentage of coverage of built plots over the total area of the IIC
g2.6	Proximity to developing/planned tourist areas
g2.7	Constraints due to the presence of archaeological sites
g2.8	SEVESO units
g2.9	Economic robustness
g2.10	Entrepreneurship index
g2.11	Availability of land in existing Organized Industrial Areas (OIAs)
g3	NATURAL ENVIRONMENT
g3.1	Environmental protection zones / Environmental restrictions
g3.1.1	Inclusion of the IIC in environmental protection zones where industrial organization is not permitted
g3.1.2	Inclusion of the IIC in a flood zone
g3.1.3	Presence of forest areas within the IIC

Figure 7. List of criteria used in the multicriteria analysis.

5. Defining the criteria alternatives

An alternative is defined as the potential outcome that will be given to a decision option based on the criteria being examined. The alternatives essentially represent the different values that the criteria, defined in the previous step, can take, reflecting the characteristics of the feasible solutions (IICs) being studied. These can be limited in number or there may be a large number of alternatives.

Proceedings

Geospatial data and collected information are entered into the attribute table of vector layers (shapefiles), with necessary vector spatial analysis conducted in a GIS environment (QGIS).

When numerous alternative options are present, multi-criteria analysis requires grouping these into classes. This grouping uses a spatial analysis model; the Jenks algorithm [8]. The Jenks algorithm identifies optimal "natural breaks" and is employed for this classification process. Generally, the Jenks algorithm is one of the data clustering methods designed to determine the best arrangement of values into different classes. This method minimizes the variance within each range so that the values in each class are as close to each other as possible. Essentially, the algorithm tries to find natural groupings of the data to create classes. The number of classes used for each criterion is predetermined based on its needs and characteristics. The aim is to have the resulting classes such that there is maximum variance between individual classes and minimum variance within each class. The purpose of this task is to identify natural groupings of values that are in proximity with each other while maximizing the value between the other groupings.

6. Determining the Partial Utility Value of alternatives

Partial utility values are used in multicriteria analysis (MCA) to represent the degree to which different options or alternatives satisfy individual criteria. This involves scoring each IIC against the identified criteria. The scores reflect the extent to which each IIC satisfies the criteria, providing a basis for comparing the feasible solutions. This method helps in breaking down the overall decision-making process into manageable parts, allowing for a more nuanced and detailed evaluation of each criterion. Partial utility values provide a way to quantify and compare the extent to which different feasible solutions meet specific criteria. This quantification is crucial for objective and consistent comparisons, especially when considering multiple criteria. Each criterion is evaluated separately, clarifying how each solution performs across different dimensions. Since alternatives are measured on various scales (e.g. km for distance, percentage for performance), partial utility values standardize these measurements into a common scale for meaningful comparisons. The process includes reclassifying data into up to five classes and transforming factors/variables into a unified scale and reference unit. Each partial utility function $U_i(G_i)$ determines the value/utility of the feasible solution based on their performance in criterion g_i , while each weighting coefficient w_i indicates the trade-off that the decision-maker is willing to make in a reference criterion to achieve an increase of one unit in criterion g_i [6]. The fundamental assumption underlying the use of the additive utility function concerns the mutual preferential independence of the evaluation criteria.

$$U(G) = \sum_{i=1}^n w_i u_i(g_i)$$

Standardization of criteria is required to allow for trade-off between criteria in the calculation of the final evaluation score. Regarding the proposed scoring of criteria/sub-criteria, which corresponds to the significance level of the evaluation criteria, this can be carried out on a scale from 0 to 10 with proportional weighting, considering the following calibration milestones:

0: No response to the criterion	1-9: Partial response to the criterion	10: Full response to the criterion
---------------------------------	--	------------------------------------

The score for each criterion and each IIC area will derive from the value or the class where the value falls, based on the data obtained from the analysis of each examined area. According to Russell and Norvig [9], this method is a value/utility function in which the user converts ranges of attribute values into a single utility score based on her choices. In this case, attribute categories or attribute intervals can be converted into utility scores using the value/utility function. The utility values across the set of studied criteria and their values (alternative options) are presented in the following figure.

Criterion	Alternative Options	Values	Utility Value / Weight (U _i)
g.1.1.1	E1	0-4 km	10
	E2	4-15 km	8
	E3	15-28 km	6
	E4	28-51 km	4
	E5	> 51 km	2

Figure 8. List of all alternative options, including values and weights.

7. Assigning criteria weights

In the multi-criteria analysis (MCA) process, assigning weighting factors to various criteria is a critical step. Recognizing that not all criteria are of equal importance, the determination of these weights significantly influences the final evaluation and ranking of feasible solutions. Assigning appropriate weights to each criterion ensures that their relative importance is accurately reflected in transforming Informal Industrial Concentrations (IICs) into Business Park for Remediation (BPRs). The delineation of weighting factors, or weights, represents a pivotal stage in the MCA process. At this stage, the team of analysts integrates their preferences regarding the significance of each criterion into the modelling framework. These preferences are quantitatively expressed as weighting coefficients (w_i) for each criterion. This step is essential because, with known weighting coefficients

Proceedings

for each criterion, along with homogenized criteria and clearly defined alternatives, the final evaluation of each alternative can be effectively derived. The preferences are quantified by assigning weights (w_i) to each criterion on a scale ranging from 1% to 100%, reflecting the criterion's importance. High weights are attributed to criteria of critical importance, medium weights to those of moderate importance, and low weights to criteria deemed less important.

The quantification process is rooted in a comprehensive evaluation of policy directions, which can either foster or hinder specific developments. This evaluation is augmented by the consultants' expert judgment, which is based on their extensive technical knowledge in spatial planning and regulatory frameworks. The determination of weights is guided by the directives found in regulatory documents and strategic plans. For instance, the weighting factors are influenced by the strategic directions outlined in the *Business Plan for the Development of Business Parks* issued by the General Secretariat of Industry, as specified in the Government Gazette 3437B/2013. This alignment ensures that the weighting process is consistent with broader policy objectives and regulatory mandates. Ultimately, the scoring process applies these weighting factors to each criterion within the evaluation scale, ensuring a robust and policy-aligned assessment.

The decision rule employed in this context is the Weighted Linear Combination (WLC) technique. This technique allows the user to specify a set of weights representing the relative importance of criteria according to the user's preferences and involves calculating a weighted sum of the criteria scores for each feasible solution. The weight of a criterion defines its impact on the compensatory aggregation. Mathematically, the score of feasible solution i is calculated as $s_i = \sum w_j x_{ij}$, where w_j is the weight of criterion j , and x_{ij} is the standardized attribute value of alternative i for criterion j [10]. The WLC method integrates the assigned weights and the criteria scores in a linear function, where each criterion's score is multiplied by its respective weight, and the results are summed to derive a final score for each alternative. The WLC technique is particularly advantageous in MCA as it allows for a straightforward and transparent aggregation of diverse criteria, facilitating a balanced consideration of all relevant factors in the decision-making process. Through the meticulous application of the WLC technique, the final evaluation reflects a comprehensive and balanced assessment, guiding informed decision-making in the transformation of IICs into BPRs.

8. *Ranking and evaluation of the feasible solutions*

With the partial utility values and criteria weights determined, the subsequent step involved aggregating these values to produce a composite score for each IIC. This process entailed combining the individual scores and weights to rank the IICs according to their suitability for transformation into Business Parks and Business Park for Remediation (BPRs). This ranking identifies the IICs that are the most viable candidates for development. The evaluation of the 30 IICs was conducted based on each of the established criteria, resulting in a hierarchical ranking derived from their accumulated scores. This evaluation highlights the IIC areas that should be prioritized for remediation. Utilizing the utility of the alternative options, as calculated through the utility function, the final overall utility (U) value is determined. Through necessary processes within the GIS environment, the (U) values for each IIC area under study are aggregated, yielding a total score from all criteria. This approach enables the ranking of feasible solutions. Consequently, an accompanying database is produced, presenting the hierarchical ranking of the examined areas for the development of Business Parks and BPRs.

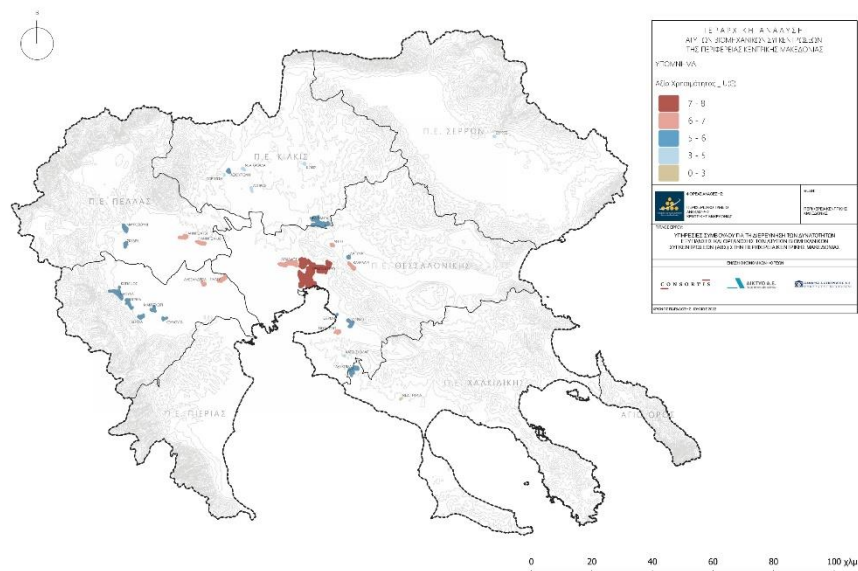

Figure 3. Map of the IIC areas involved in hierarchical ranking resulting from the multicriteria analysis.

3. RESULTS AND CONCLUSION

The study conducted a comprehensive evaluation of 30 Informal Industrial Concentrations (IICs) in the Region of Central Macedonia to determine their suitability for transformation into Business Parks for Remediation (BPRs). A multicriteria analysis (MCA) was utilized, integrating various criteria, including technical infrastructure, socio-economic characteristics, and environmental restrictions. The final ranking of the IICs is presented in Figure 4.

RANK	LOCATION	PARTIAL UTILITY	RANK	LOCATION	PARTIAL UTILITY
1	Oraiokastro	8.16	16	Lagyna	5.45
2	Anchialos	6.97	17	Lakkoma	5.41
3	Alexandria	6.69	18	Naousa	5.29
4	Kavalari	6.63	19	Makrochori	5.27
5	Neo Rysio	6.6	20	Patrida	5.17
6	Liti	6.33	21	Axioupoli	5.16
7	Giannitsa (A)	6.15	22	Mavrovouni	5.09
8	Giannitsa (B)	6.1	23	Kouloura	5.07
9	Platy	6.05	24	Serres	4.65
10	Nea Santa	5.85	25	Kato Scholari	4.59
11	Thermi	5.8	26	Kilkis	4.27
12	Thermi	5.8	27	Aspros	4.2
13	Veroia	5.73	28	Gorgopi	3.83
14	Skydra	5.67	29	Nea Kavala	3.81
15	Kopanos	5.55	30	Nea Triglia	3.09

Figure 4. Final ranking of the IICs.

The presented methodology provides a robust framework that is adaptable to different regions and contexts. The MCA approach, and especially the use of WLC, ensured a multi-part assessment of each IIC by taking into account all relevant factors in decision making process. Furthermore, these criteria were corroborated with other policy objectives, ensuring that such evaluation supports strategic development goals. The methodology can be potentially applied in cases of IICs beyond Central Macedonia Region, but also in various regional planning and development settings. During the process, certain gaps were identified in relation to data availability and criteria calibration. Overall, the study underscored the importance of a structured and balanced approach to evaluating industrial concentrations, contributing to the decision-making process of strategic planning and sustainable development.

Acknowledgements

The presented methodology was developed and implemented as part of a contract titled "Study to investigate the possibilities of remediation and organization of informal industrial concentrations in the Region of Central Macedonia" between the Region of Central Macedonia, Greece, and the participating companies Samaras and Partners S.A., CONSORTIS, and DIKTYO S.A. CONSORTIS was primarily responsible for developing the methodology provided here.

Abstract

The paper investigates the wheelchair accessibility of neighborhoods Cerak Vinogradi and Višnjička Banja in Belgrade, Serbia. Accessibility plays an important role in social sustainability as a part of sustainable urban development. In Serbia, during the last two decades, numerous laws and regulations have been adopted that oblige designers and contractors to build accessible spaces, but the lack of a control system for the implementation of these regulations leads to improper implementation. This paper researches the requirements that should be included in the design logic in order to ensure the accessibility of residential areas for wheelchair users. The focus is on the Cerak Vinogradi and Višnjička Banja neighborhoods, significant examples of late modernism. The goal of the paper is the proposition of design recommendations for the formation of new accessible settlements and assessment of the current situation with the formation of a map for orientation and problem-solving. The research method includes the analysis of the accessibility of public spaces and entrances to buildings through field research and accessibility mapping. The results show that Cerak Vinogradi has better entrance accessibility, while Višnjička Banja shows a clearer pattern of inaccessibility of public spaces. In the Cerak Vinogradi neighborhood, accessibility problems mainly arise from the low-grade materialization of paving and numerous "dead ends". In Višnjička Banja, accessibility problems are more pronounced due to inadequately designed cross passages and large height differences. Additionally, design logic to be applied in future projects to ensure accessibility is identified. This includes placing streets in the direction of isohypsis to minimize height differences, carefully planning building entrances to avoid internal obstacles such as stairs, ensuring continuity and legibility of space, as well as properly solving parking problems to ensure the smooth movement of people in wheelchairs.

Keywords: *accessibility, social sustainability, disability, wheelchair, heritage*

1. INTRODUCTION

Accessibility plays an important role in social sustainability as a part of sustainable urban development, and in the past two decades, several laws and regulations have been successfully implemented in Serbia that oblige designers and contractors to build accessible spaces. However, there is no system to control the implementation of regulations regarding accessibility, which is why newly built ramps are too steep or do not exist at all [1]. Due to the lack of a control system, it is necessary for us as architects to be one step ahead and to understand from the initial urban planning phase which of our decisions create barriers for people with disabilities. The paper researches the requirements that should be included in the design logic when considering the issues of the morphology of residential areas to ensure the technical requirements that enable the smooth communication of wheelchair users.

Although some newly built buildings are accessible, there is no systemic solution for the adaptation of inherited buildings, interventions are carried out on the buildings when necessary, concerning residents' reports. Accessibility is possible only if urban structure consisting of old and new residential buildings, public institutions, and spaces are connected. The paper investigates the wheelchair

accessibility of neighborhoods Višnjička Banja (Figure 1.) and Cerak Vinogradi (Figure 2.). These settlements represent a significant part of the architectural heritage of late modernist architecture and urbanism. The connection between residential buildings and public spaces does not ensure accessibility, and people with disabilities do not have access to information on which buildings/roads are accessible, which creates additional problems in their daily communication. The complications and effort required to leave the house in an unregulated system further demotivate people with disabilities [2], so that they practically do not use the public spaces of Belgrade.

All the mentioned factors point to the importance of looking at accessibility at the system level, which is why it is necessary to conduct the research primarily in planned settlements. The problem of accessibility is especially evident in settlements located on steep terrain. The settlements of Cerak Vinogradi and Višnjička Banja were selected for analysis because they were planned in the same period and on a similar steep terrain morphology. The main research questions are which design decisions have influenced the accessibility quality of the analyzed settlements and which problems occur in the settlements independently of the designers. The goal of the research is to understand the origin of the problems that arose in the context in order to establish design recommendations for designing the new accessible settlements, and on the other hand, to assess the state of the selected settlements and to create a map that can be used for orientation and problem-solving. The paper provides an overview of accessibility in the historical and social context, and a brief description of the settlements Cerak Vinogradi and Višnjička Banja, after which the method of data analysis and systematization will be given. The paper ends with a discussion of the collected data with a focus on general design recommendations and problems in context and a general conclusion.

2. PHYSICAL AND SOCIAL CONTEXT OF RESEARCH

2.1. Accessibility in social, historical and architectural-urban context

The term "accessibility" has different meanings in different disciplines and contexts. Given that the concept of accessibility is defined by the relation between a person and the material and immaterial context that surrounds them, accessibility is relevant in social sciences and it is not possible to research it with quantitative methods, but it is necessary to conduct qualitative research. Accessibility has the greatest importance in the fields of economics, sociology, urban planning, and architecture, most often in the intertwining of these fields. In the literature, it is most often observed in the physical context, but in the broadest sense, it represents the individual's ability to satisfy physical and spiritual needs in the context in which they exist.

Every person encounters barriers that prevent them from satisfying their needs regarding their social status, the country they live in, physical health, etc. For example, countries that are poor in natural resources have limited access to necessities such as water and food, and religious minorities around the world may encounter a lack of religious infrastructure, which can act as a barrier to meeting religious needs. Nowadays, conversation about the accessibility of information due to digitization is active, because digital literacy is needed to function within society. Identical barriers are not equally limiting to all people; accessibility, therefore, consists of a complex scope that can only be researched from fragments, by selecting users and the barriers they face in order to remove them.

Space in conjunction with the social context plays a significant role in the creation of barriers, which is why the concept of accessibility is very important in architecture. Architects design barriers to achieve certain goals; stadiums and arenas have physical barriers, which are overcome by buying tickets for events, and in this case, the physical barrier is connected to the economic factor. School and kindergarten facilities are supervised, accessible only to children, parents, and staff, and designed with controlled barriers to ensure children's safety. In prison facilities, the design of barriers is the most significant, because they represent spaces where access to inclusion in society is limited for people who are not safe for it. This term most often implies the accessibility of physical space for people with disabilities and the removal of barriers by adapting the space to ramps and elevators. This fragment is the most researched and legally regulated, and it will be explored in the paper. In relation to the fact that limitations and barriers always exist in architectural work, we can conclude that the goal is not to create barrier-free architecture, but optimally regulated barriers that enable a normal life for people with disabilities.

Another thing that is important to understand is that the accessibility of architecture in the context of disabilities is understood as a problem that existed until the second half of the 20th century, after which the situation improved. However, society's attitude towards people with disabilities is part of a historical course with phases of improvement and deterioration. Since ancient times, people have been organized into social systems and alliances, and one of the greatest achievements of human civilization is the care of the weaker members of society and the development of a system of care for them. Religious buildings were initially used as places to care for the sick, such as in the temples of ancient Egypt, and Christian monasteries that took care of the sick. During the Industrial Revolution, the opportunity for mobility that never existed before occurred, and in this period, an ideological change occurred where caring for the weaker members of society lost importance [3]. After the First and Second World Wars, the situation worsened with a large number of injured people who were unable to work. During the 70s the conscience of the condition of people with disabilities was reawakened [4], and until today, the necessary parameters of an accessible space have been quite researched. The next step is the implementation of the observed necessary parameters at the system level, as well as the consideration of needs that are not only physical but also spiritual.

2.2. Cerak Vinogradi and Višnjička Banja

During the 70s of the 20th century, a sudden wave of industrialization and urbanization in the former Yugoslavia caused migration from the countryside to the city. There was a need for large cities, and by the end of 1980, the construction of 800,000 apartments was planned.

The concept of the Cerak Vinogradi (Figure 3.) neighborhood is a hierarchical organization of spatial sociological levels of the neighborhood to create favorable conditions for humane housing. Pedestrian residential streets are grouped into small neighborhoods that are encouraging residents to gather. The pedestrian paths of the three neighborhoods are directed towards the stretch of the neighborhood park, on which the center of the neighborhood, the school, the pre-school facility, and free spaces rest [5]. A series of buildings that were placed on the sloping terrain on one side of the park were selected for analysis, to research the communication between the buildings and the relationship with the park. Streets and traffic are separated from the park areas by buildings, with only narrow fire protection/integrated streets passing through. The Cerak Vinogradi neighborhood was recognized as a cultural heritage and was selected for display at the MoMA Museum of Modern Art in New York, as part of the "Concrete Utopia - Architecture of Yugoslavia 1948-1980" exhibition. After the exhibition was completed, it was selected for the Museum's permanent collection, as one of two works from Serbia, thus confirming its status as a national and international cultural heritage [6,7].

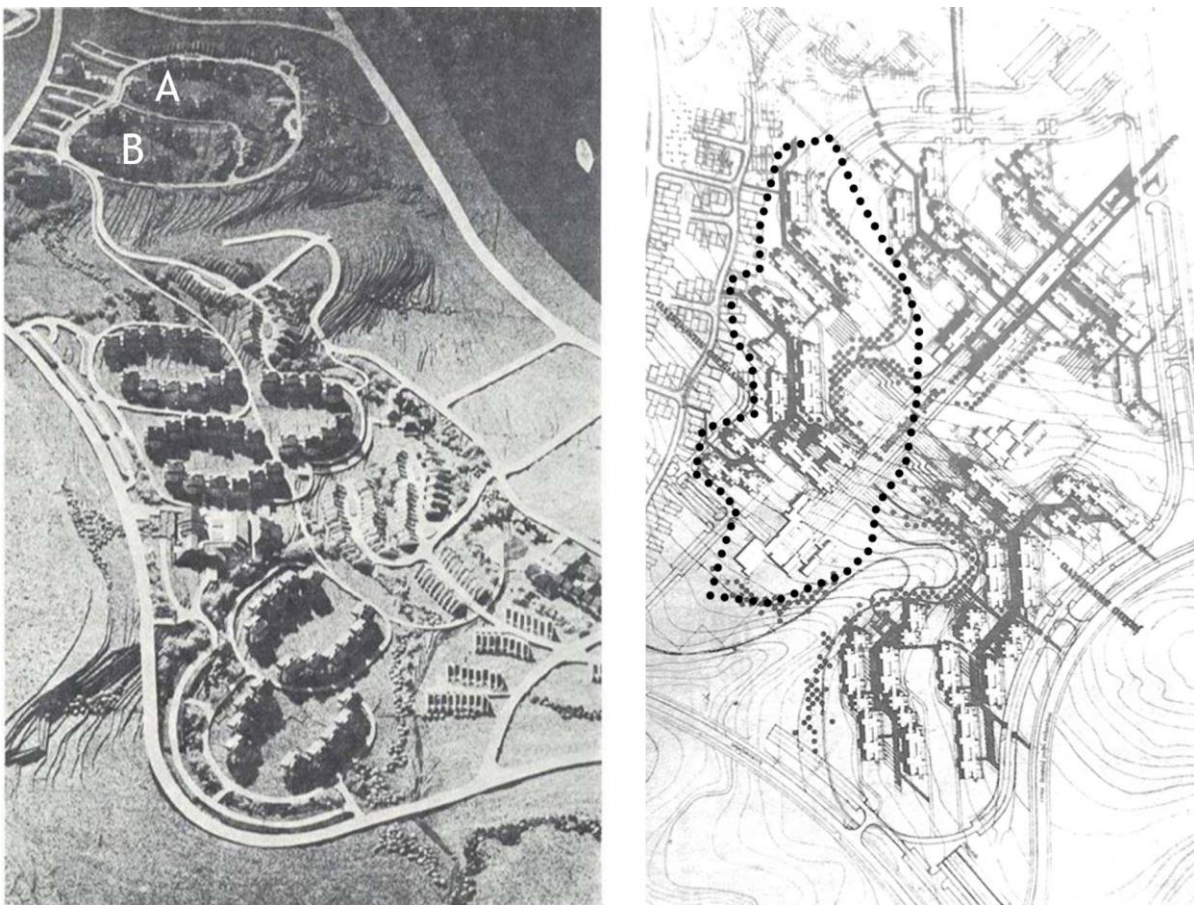

Figure 3. Višnjička Banja model (left) and Cerak Vinogradi plan (right)

(<https://www.facebook.com/photo/?fbid=2388036251273543&set=a.487321424678378>, Šobota, Đ., 1978., Model izgradnje stambenog naselja "Cerak Vinogradi" u Beogradu, Beograd: Arhitektonski fakultet, 1978)

The Višnjička Banja neighborhood is a residential neighborhood built as an investment by the Belgrade Housing Association, with planned high-density collective and individual housing zones. In addition to residential buildings, the urban project provides for an elementary school, two kindergartens, a local community center, and provides one parking spot per resident [8,9]. Višnjička Banja is made up of several rings of a similar organization that are connected by a common street in the south. Rings A and B from the urban setting were selected for the analysis (Figure 3), which consist of a common ring-shaped street, placed along the slope of the terrain. Within the individual rings, there are two rows of multi-family buildings of higher density that are symmetrically placed along the common park space located between them. The terrain slopes downward towards the north. The neighborhoods were selected concerning the characteristic that they were planned on hilly terrain and at a similar time. Relevant segments were selected based on the general analysis and through a more detailed observation of the context, the objects to be studied were selected. For the analysis, two segments were selected that represent the essence of the relationship between urban planning and architectural setting, i.e. relationship between public spaces and facilities. Segments measuring around 250x250m were selected (Figure 4.), and the selected buildings surround the public green area along the entire decline of the terrain. Public spaces on Cerak and in Višnjička Banja are formed similarly, the buildings separate the park area from the street, with the difference that there is one common park space on Cerak, while in Višnjička Banja each ring has its own smaller private park.

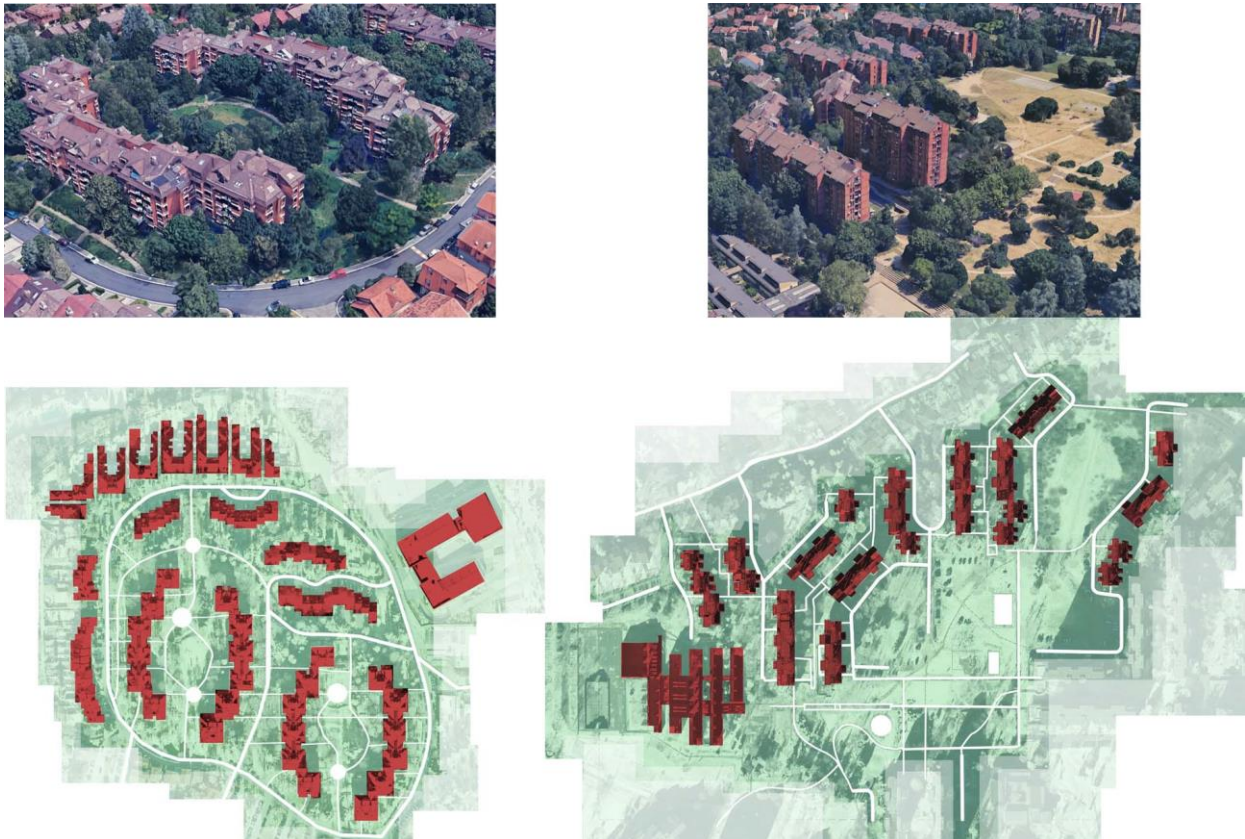

Figure 4. Selected segments in Višnjička Banja (left) and Cerak Vinogradi (right) (google earth and author illustration)

3. METHODOLOGY

Accessibility is analyzed regarding three aspects: public spaces, access to building entrances, and literature review of relevant regulations and documents. These three aspects were chosen, because the conclusions regarding accessibility as well as the design logic can be drawn by intertwining them. Three tools were used to research these aspects: a literature review, an analytical drawing, and a table (Figure 5.). The literature review is significant for all three analyzed aspects. The literature that generally studies the subject of accessibility is significant for analyzing aspects of public spaces and entrances, it provides input data on how the space should be organized, materialized, and connected. The Alliance for Accessibility of Serbia provides a useful overview of current regulations, inconsistencies, and unfulfilled conditions. Graphic and written documentation of the projects of the analyzed settlements gives an insight into the understanding of the wider picture and the observation of patterns (mostly the access to public facilities, and the urban layout of the settlement is similar). The analytical drawing indicates the flow of movement and its interruptions. The table in which the access to the entrances systematizes the data on the accessibility of the facilities and the level of necessary intervention. By synthesizing the data from the table and the drawing, a stance and conclusions are formed concerning the data that emerges as a result.

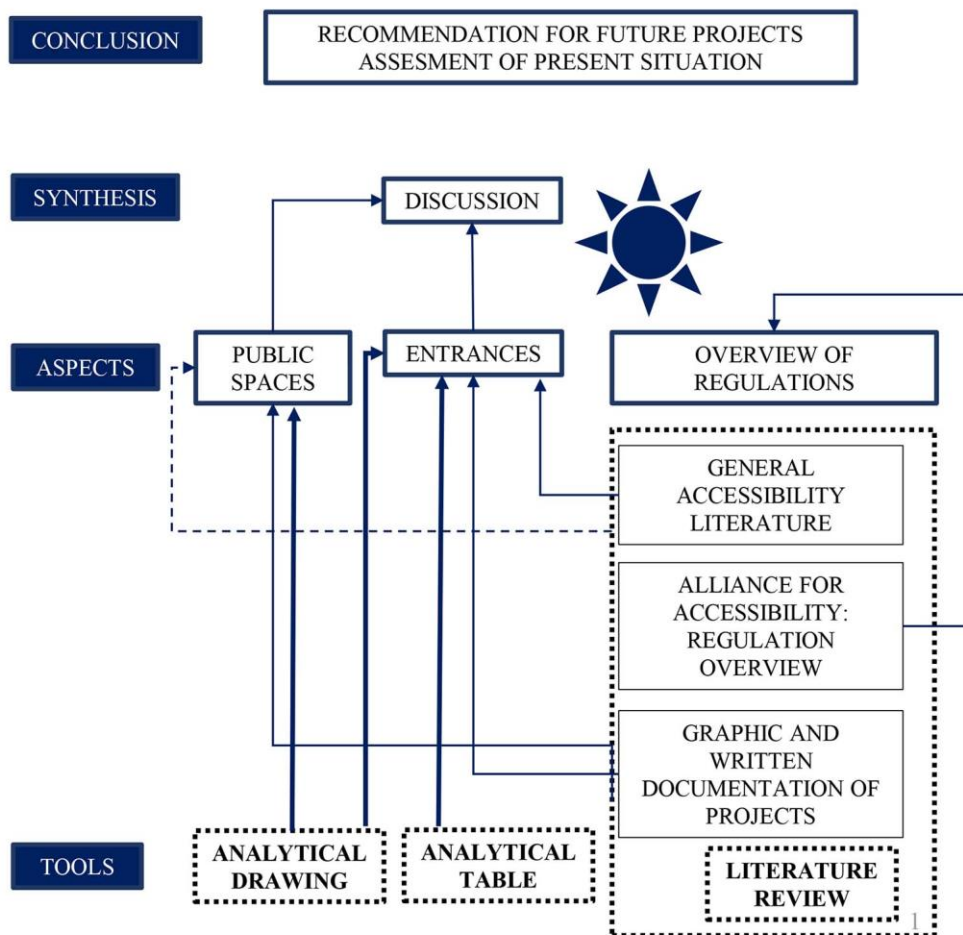

Figure 5. Methodology diagram

3.1. Analytical drawing

Analytical drawing was used to reveal the problems that occur in public spaces. Streets with sidewalks and footpaths are mapped in the drawing, different categories are formed concerning the conditions that interfere with accessibility. Streets represent an important communication flow that enables people with disabilities to connect with other parts of the city, public institutions, and facilities. Due to the aforementioned importance of streets in communication, they are mostly marked with a thick green solid line as passable.

The impossibility of using the sidewalk is a problem that puts people who don't have walking problems at risk, even though the streets represent a space that people in wheelchairs know for sure that they can use, this type of communication is not safe. Such situations of the relationship between the sidewalk and the street are marked in yellow as slightly problematic. Sidewalks and footpaths are important because they are the only surfaces that people in wheelchairs can use for safe movement. Pedestrian paths and sidewalks are marked in three categories: passable, slightly problematic, and extremely problematic.

Passable sidewalks and footpaths represent spaces that can be accessed from the entrance of buildings and the street. They are marked with a thin dashed green line. Mildly problematic segments are those that are easy to solve, while extremely problematic segments are those that require more energy to solve. The slightly problematic segments are separated by one low step, poor paving, poor materialization of the paving, and a sidewalk where cars are parked illegally. Such parts are marked with a thin dashed yellow line. Extremely problematic segments are those in which movement is not possible and they are marked in red, and arrows indicate places where there is a height difference. A red arrow indicates an altitude difference that cannot be overcome, a yellow one with difficulties, and a green one that is well overcome (Figure 6.).

Figure 6. Types of roads and sidewalks a) passable sidewalks b) problematic and unpassable sidewalks c) both sidewalks are unusable, people need to walk on the road d) types of ramps: problematic; passable, unpassable

3.2. Analytical table

To analyze the relation between buildings and public space, the buildings are labeled CV1-17 and VB1-19 and it is written how many entrances there are in which unit. Access to the entrances was analyzed through a table listing the entrances, the number of floors, the height of access to the entrance, and the number of steps. Concerning entrance accessibility, buildings are marked in three categories according to a similar system as pedestrian streets. Accessible entrances are entrances to buildings that are accessible from the street without steps or using a suitable ramp. Accessible entrances are marked in green color. It is estimated that the average step is about 15 cm, and in relation to that slightly problematic entrances are those that are not accessible from the street, but there are up to 6 steps (90 cm), which requires a ramp of 11 m length, with one break. Extremely problematic entrances are those whose access is prevented with more than 7 steps, because this requires a ramp longer than 11m, as well as entrances whose access is too narrow, that is, all accesses that require greater intervention. Online portals used to create the table are Beoland; GIS Geosrbija; google maps; Street View; google earth; Cadmapper.

4. RESULTS

4.1. Public space

By comparing the maps on which the accessibility of public spaces is documented, it is noted that a pattern of inaccessibility can be observed in the Višnjička Banja (VB) settlement (Figure 7.), while in the Cerak Vinogradi (CV) neighborhood there are no patterns, there is only one space within the block that is not accessible (Figure 8.). In relation to the slope of the terrain and the way the buildings are organized in the VB settlement, it was necessary to make transverse passages that would enable easier communication of public spaces that also serve as an entrance to the building. The entrances to the multi-story buildings in the VB neighborhood are not accessible, which is why inaccessible zones of public spaces appear inside the "rings". The "readability" of the space could be highlighted as a positive aspect of this settlement, it is very clear which parts are not accessible, which is why it is easy to bypass them and use the available space without interference.

In the CV neighborhood, the park space is represented by the spaces within the blocks, as well as the main park space between the blocks. In the CV neighborhood, it can be seen that most of the public space is physically accessible, but the problem that arises is the poor materialization of paving and a large number of "dead ends". Commonly several steps are placed in the public space without necessity, but contribute to the ambient value of the whole. In some situations it is necessary to go over 50m to access different levels that physically border each other, which leads to confusion and makes the public spaces of the CV inaccessible in terms of the readability of the space. The extremely inaccessible segment of the CV neighborhood represents the design culmination, where the public space is the most complex and takes place on several levels. A problem that can be observed in both neighborhoods is the parking of cars on the sidewalks. This behavior can be observed in a pattern on sidewalks that are not adjacent to houses.

4.2. Access to entrances

Considering that the selected neighborhoods were built at a similar time and have similar characteristics, the initial assumption was that the problems with the entrance accessibility would be similar. However, after a tabular review of the entrance accessibility data, it was found that this assumption is not correct. When looking at the accessibility map of the entrances in the neighborhoods VB and CV, it is noticed that the buildings in Višnjička Banja are mostly problematic in multi-family buildings, while in the neighborhood CV the entrances to the buildings are mostly slightly problematic or accessible (Table 1.). Also, in the CV neighborhood there is a pattern in the accessibility of entrances, while in VB the data varies. In situations where the slope of the terrain is less steep, the entrance is easy to access (eg grouping VB3), while in situations where the terrain is steeper, the height difference can be over 20 steps compared to the street (eg grouping VB1). Accessible entrances are mostly in family houses, which affects the smaller number of users and makes these data less relevant. One of the problems in the Cerak Vinogradi settlement is that the entrances are accessible, but inside the entrance, there are stairs that are difficult to overcome. In the category of slightly problematic entrances, there is a difference between Višnjička Banja and Cerak Vinogradi. In Cerak Vinogradi, the height difference is 2-4 steps, while in Višnjička Banja, the number of steps is 7-12, which requires ramps longer than 15 meters.

5. DISCUSSION

Although a higher percentage of public spaces is accessible in CV, the quality of accessibility of public spaces is more favorable in VB concerning the networking and readability of spaces and systemic problem-solving would be simpler. The first step in the creation of central accessible park spaces of the VB is the adjustment of the transverse passages where the entrances are located, and then the networking within the park space. Interventions in public space that would be necessary for the CV neighborhood are the implementation of ramps to eliminate "dead ends". "Desire paths" that exist on the site overcome the height differences and indicate the areas where the space should be paved to enable the flow and connection of the space. Parking on the sidewalk and poor paving often result in the necessity of using the roadway for people in wheelchairs, which is an unpleasant and demotivating phenomenon. In this context, the first step in establishing sidewalk accessibility is to systematically solve the parking problem and sanction illegal parking.

It was concluded that the Cerak Vinogradi neighborhood has better entrance accessibility characteristics compared to Višnjička Banja, where most of the residential areas are not accessible. Interventions in the CV neighborhood would involve adjusting the space inside the building's entrance where there are several steps, and these interventions are similar on all buildings and would not negatively affect the ambient value of the whole. In the VB settlement, the interventions would be ramps that would have unique dimensions for each entrance and would require the removal of handrails that represent part of the neighborhood's ambient value.

The design logic that has been observed is related to the urban layout of the streets and the reaction to the terrain. In CV, the streets are placed in the direction of the isohypsis, and the entrances are placed perpendicular to them. This design decision makes it easier to overcome height differences, making entrances more accessible. In Višnjička Banja neighborhood, the streets are placed steeply and along the slope of the terrain, which creates greater height differences and makes the entrance more difficult to access. The focus of the urban layout of the Višnjička Banja neighborhood was to provide a view of the river to as many apartments as possible, which conditioned the layout of the streets. In the CV, the focus was on the establishment of people-friendly spaces, away from car traffic, with integrated streets that contribute to the favorable features of accessibility to the entrances.

Accessible design logic should be applied in future projects concerning the following guidelines: it is desirable to place streets in the direction of isohypses to minimize height differences, careful planning of building entrances to avoid internal obstacles such as stairs, ensuring continuity and legibility of space, as well as proper solving parking problems, to ensure the undisturbed communication for people in wheelchairs. In case some factors require the steep placement of streets each entrance needs special attention, which represents a design challenge that can contribute to the quality of the entire project.

6. CONCLUSION

This paper researches the accessibility of Cerak Vinogradi and Višnjička Banja and highlights the importance of looking at accessibility in a wider social context. Accessibility is not only a technical, but also a social problem that affects the daily life of people with disabilities, it is important that accessibility is not only seen as a physical ability to move, but also as enabling equal chances for all citizens to meet their physical and spiritual needs. Analysed problems, such as inaccessible entrances, poor materialization of paving and improper parking, complicate the communication and use of public spaces, which leads to social isolation and demotivation of wheelchair users.

This research fits into the broader context of social sustainability by pointing to the necessity of a systemic approach to accessibility. The essence of improving accessibility lies in the creation of a system that will ensure the consistent application and improvement of legal regulations and standards. It is necessary to establish an effective system of control and maintenance of accessible spaces, as well as continuous education and sensitization of designers, contractors and the general public about the importance of accessibility. In this way, future neighborhoods can be designed to remove existing barriers and prevent the creation of new ones, enabling disabled people to be included in social life. Further research may focus on the application of artificial intelligence (AI) in the creation of these systems. AI can play a key role in analyzing existing structures, identifying problems and proposing optimal solutions to improve accessibility. By using AI technologies, such as machine learning and big data analysis, it is possible to create dynamic and adaptive models that will effectively contribute to the design and implementation of accessible urban spaces.

In conclusion, accessibility must become an inseparable part of design logic and urban planning, with the aim of forming inclusive, sustainable and socially responsible urban environments.

Exploring Blue-Green Infrastructures for Rainwater Management: the Case of Fethiye, Turkey

M. Yılmaz

PhD Candidate, Istanbul Technical University, Turkey

Corresponding author: E-mail: yilmazm17@itu.edu.tr, Tel +90 5380499092

Extended abstract

"Sustainable Cities and Communities" which is one of the United Nations' 17 Sustainable Development Goals, aims to make cities and human settlements inclusive, safe, resilient, and sustainable. One of the most important principles of a sustainable city is rainwater management especially considering the increasing frequency of extreme weather events due to climate change which can negatively affect the quality of life. For stormwater management; compared to traditional piping and storm ponds, Low Impact Development (LID) practices provide more sustainable solutions (Chen, Samuelson & Tong, 2016). Blue-green infrastructure, which is designed to achieve long-term sustainability, provides many benefits related to society, culture, business, and ecology. While not sufficient on its own to protect the threat of wildlife, it has been shown to increase habitat connectivity (Nguyen, Meurk, Benavidez, Jackson & Pahlow, 2021). The study focuses on the critical aspect of rainwater management within the context of sustainable urban development, particularly in a specific case study which is Fethiye, Turkey. The reason for choosing the case-study area is high rainfall, heavy rains, and floods affecting daily life, and infrastructure works including rainwater-related works. According to the precipitation normal report prepared by MGM, Fethiye received between 600 and 800 mm of precipitation in 2021 while the normal precipitation in Turkey is 573.4 mm. Heavy rains and floods occurred recently (2021,2022 and 2023); and various houses, workplaces, and greenhouses were damaged in these raids. In addition; infrastructure and superstructure works are done including the undergrounding of power lines by AYDEM in some regions, the renewal of drinking water and stormwater drainage lines by MUSKI, and the expansion of infrastructure lines by telecommunication companies. It was completed by pouring hot asphalt (BSK) with the motto of "modern Fethiye" in July 2022. In this framework, infrastructure works and preferred methods related to rainwater management in Fethiye were examined. To understand the general organization of the rainwater management system, a diagram supported with photographs, was created for the case-study area. After the current situation was fully examined, similarities and differences between the case-study area and blue-green street pilot projects from Hamburg and Copenhagen were analyzed. Finally, the study was completed with recommendations for the case-study area.

Deployment of mobility hubs and its impact in the urban context of Vienna and Munich

O. Roider^{1*}, R. Gkavra¹, Y.O. Susilo¹

Abstract

Due to climate change, cities are facing serious problems caused by rising temperatures. Converting street space into areas with high standards for a pleasant quality of life is a suitable strategy to mitigate the negative effects. For example, the city of Vienna recently published a climate roadmap as a guideline for designing a "climate-friendly" built environment. Tree planting should lead to shaded areas and low surface temperatures. However, these measures require space. Redistribution of the space allocated to car traffic could both provide the necessary space and decrease urban air pollution. In addition to limiting car traffic, improving public transport services and enhancing infrastructure for walking and cycling, several European cities are introducing new shared modes of transport as a missing link in the transport system. In this context, the concept of mobility hubs has been introduced to make the various mobility services more accessible by integrating the different transport options. As part of the European SmartHubs research project, a multidimensional typology for mobility hubs was developed, which includes three dimensions: physical, digital and democratic integration (SmartHubs integration ladder). Each dimension has 5 levels that allow the comparison of different hubs with different services to analyze potential impacts (Geurs, et al., 2022). However, the degree of impact on mobility behavior and the framework conditions to become a sustainable alternative to the private car is currently less known (e.g. Miramontes, et al., 2017; Miramontes, et al., 2019, Tsouros, et al., 2021, Gkavra et al. 2024). For this reason, a standardized survey was conducted in four urban areas in Europe.

The paper will focus on the comparison of the results gained in the cities of Vienna and Munich, as these cities have similar spatial characteristics, e.g. in terms of number of inhabitants or the availability of public transport, and shared modes of transport are already available in both cities. A total of 1022 people responded to the questionnaire. Almost 66% of respondents stated that they had already seen a mobility hub and are aware of it. Of these, around 40% had already used at least one of the sharing services offered at the hubs. The most popular shared modes of transport in Munich are shared e-scooters or shared cars, each with a proportion of around 37%, while in Vienna car sharing is used most frequently at 28% (multiple answers possible). The younger the people are, the higher their interest in shared modes of transport seems to be. The sample design enables the analysis of the socio-demographic characteristics and mobility behavior of certain population groups to form the basis for an impact analysis and further recommendations.

1. INTRODUCTION

Due to the climate change, cities are facing serious emerging problems caused by rising temperatures. Converting street space into areas with high standards for a pleasant quality of life is a suitable strategy to mitigate the negative effects. For example, the City of Vienna recently published a climate roadmap as a guideline for designing a "climate-friendly" built environment. Measures such as tree planting should lead to shaded areas and low surface temperatures. However, these measures require a lot of urban space allocation. On the contrary, redistribution of the existing space dedicated to car traffic could both provide the necessary space and decrease urban air pollution. In addition to limiting car traffic, improving public transport services and enhancing infrastructure for walking and cycling could contribute to a more sustainable mobility network. Several European cities are introducing shared modes of transport to fill in a missing link in the transport system. In this context, the concept of mobility hubs has been introduced. Mobility hubs aim to increase accessibility make the various mobility services more accessible by integrating the different transport options.

Ideally, both public transport and multiple shared modes, such as shared bikes and shared cars, should be present in a mobility hub. The hubs should have a dedicated space that also facilitates more mobility infrastructure e.g. parking of private vehicles. Additionally, non-mobility facilities such as repair, eating, shopping, and logistic pick-up points should be added to increase the attractiveness and efficiency hubs. In the course of the European SmartHubs project a multidimensional typology for mobility hubs was presented, the SmartHubs integration ladder, which includes three integration dimensions: physical, digital and democratic integration. These dimensions can be used to assess and compare different mobility hubs regarding the consideration of universal design principles [1].

With the abovementioned characteristics, mobility hubs have the potential of transforming both the mobility and urban space layers in the cities. Despite these assumptions, until today, there is limited research on specifying their (potential) impacts to both pillars. Past research, which focused on user profiles, found that public transport users are more likely to be early adopters of shared mobility [2] [3]. Users of public transport were also found to be more inclined to switch their mode of transport to shared e-mobility than car users [4]. Another study, comparing mobility hub user profiles in Manchester, Utrecht and Malmö, found user satisfaction and positive previous experiences with shared mobility to be an important factor in possible future uses of shared mobility services [5]. A study concentrating on shared e-scooter use in Munich found a high influence of temperature and precipitation on e-scooter use [6]. An attempt to describe the general interest and knowledge concerning shared mobility and characterize a user profile was made by Krämer and Bongaerts, using data from Switzerland, Germany and Austria. Their research found that while awareness of shared mobility services is relatively high in all three countries, only few people consider it to be relevant regarding their own mobility. Furthermore, they found that no coherent demand segment for shared mobility exists for these countries [7]. Research focusing on equity in transportation stressed the need to install infrastructure for electrical vehicles in areas with currently low demand, e.g. low income and rural areas, to increase accessibility and awareness and thereby increase shared mobility usage and usage of electrical vehicles overall [8].

The impacts of mobility hubs were discussed in a recent study conducted in Munich, where users of shared bikes and cars were found to increase their use of public transport after adopting shared mobility [9]. Another study focusing on shared car usage in Berlin and Munich showed, that a large share of car-sharing users doesn't own a private car, naming absence of need to own one as the main reason [10]. Nonetheless, to create a comprehensive understanding of the changes in mobility behaviour induced by mobility hubs and the circumstances under which mobility hubs pose a true alternative to private motorised mobility, more research is necessary.

Within the European SmartHubs research project a standardized survey was launched in four European regions in Belgium, the Netherlands, Germany, and Austria. The survey had multiple goals, including identifying the current level of awareness and usage of mobility hubs. Furthermore, the

Proceedings

survey collected data on the barriers that people face towards embracing mobility hubs. The present paper discusses the descriptive results of the data collected in two European cities, Vienna and Munich. The main research objective is to enrich our knowledge on mobility hubs' current usage, and corresponding impacts as well as determining the factors that restrict their potential.

2. URBAN CONTEXT OF VIENNA AND MUNICH

For a better understanding of the urban characteristics in the study areas, the present chapter describes both Vienna and Munich regarding their population, strategies on future transport development and shared mobility services. As of October 2023, Vienna had 2.002.821 inhabitants [11], up to the year 2048 the population is estimated to grow to 2,2 Million [12]. Munich had a population of 1.589.038 in January 2023 and an increase in population numbers to 1,81 Million is projected for the year 2040 [13].

In 2023, Vienna's modal split shows a strong emphasis on public transport and walking, each making up 32%. Motorized private transport comes in second place with 26% while the share of bicycle use makes up for 10% [14].

The most recent available data on Munich's modal split comes from data collected in 2017. The data

revealed that motorized private transport, public transport and walking each accounted for 24% of the modal split. The modal split for Munich also differentiates between actively driving and being a passenger in motorized private transport. As being a passenger constitutes 10% of the modal split in Munich, the total share of motorized private transport users sums up to 34% of the modal split. The bicycle as a mode of transport accounts for 18% of the modal split [15].

According to the City of Vienna reports, 240 mobility hubs are already installed across all districts of the city [16] [17]. Other sources state, that 185 permanent mobility hubs exist that can be expanded with 50 digital and mobile stations for major events taking place in the city [18]. The mobility hubs each consist of a bike sharing station and for around 50 of them, car sharing stations are added [19] (see Figure 2 for an example). Additionally, four companies (Lime, Bird, Link, Voi) provide shared e-scooters [19].

Munich implemented a new platform in the course of the development of their new mobility strategy called Münchenunterwegs over which information on mobility hubs, called Mobitatsstationen, are distributed (see Figure 3 for an example). Nonetheless, information on their number and available offers is scarce. By 2026, 200 mobility hubs are planned to be installed that should include car, bike and e-scooter sharing options. A consultation of the mapped stations shows around 50 already installed mobility hubs. The Munchner Verkehrsgesellschaft MGV provides the largest share of available shared bikes and works with a station-based model while all other providers use a free-floater system. [20]

Figure 1. Modal Split of Vienna and Munich

Figure 2. Mobility Hub “WienMobil” in front of the railway station “Westbahnhof”

Figure 3. Mobility Hub in Munich

Munich is in the process of developing its new mobility strategy with the target year 2035 and provides a comprehensive outline. The main focus is to ensure higher accessibility and quality of stay in public spaces. Furthermore, living without a car should be possible and the total share of walking, bikes, more sustainable cars, and public transport should be raised to 80% by 2025. More specifically, Munich aims to raise the share of public transport in the modal split to 30% until 2030. With all these advancements transport in Munich is supposed to be climate neutral by 2035. The new strategy also includes the centralization of all mobility offers and creating framework conditions for a comprehensive offer of shared mobility. Shared mobility should become more attractive than motorized private transport and the transition from one mode of transport to another should be as easy as possible. The specific goal for the already-implemented mobility hubs is to rise their number to 200 by 2026 [21].

The City of Vienna issued their mobility strategy STEP25 in 2014, defining fairness in the public space, health and active mobility, compactness and short ways respectively, ecological mobility, resilience and efficiency as the main goals. The strategy is complemented by a list of measures for each mode of transport to achieve said goals. In more detail, the spatial share of public spaces for walking, cycling and public transport should rise, 30% of the population should participate in active mobility, 45% of all trips for the daily demand should be done using a form of active mobility and emissions and energy demand should decrease by 20% by 2025 [22].

3. SURVEY SAMPLE

The goal of the joint SmartHubs survey was to get more (quantitative) understanding of the current and potential use of mobility hubs gaining an insight into the characteristics (socio-demographic, mobility) of current and potential users of mobility hubs as well as on people’s barriers and willingness to use mobility hubs under various circumstances. To enable the analysis data had to be representative for the population as well as allow in-depth analysis on particular groups of the population. Therefore, based on the sociodemographic characteristics of the population, groups of interest and the SmartHubs objective on equity analysis, minimum sample requirements were defined prior to the data collection [23].

The whole area of the City of Vienna was targeted for data collection by commissioning a panel company. In Munich, data were collected by a panel company as well, but most responses were collected in-person at the main campus of the Technical University. Finally, some individuals responded online via a public open survey link distributed on media channels (e.g. via LinkedIn).

A total of 1022 people responded to the questionnaire in Vienna and Munich. Compared to the proportions of age groups as presented in the census data, the survey data show a higher share of younger participants in Munich due to the selected data collection methods, and in both cities less people older than 65, a well known hard-to-reach group in surveys. However, the total number of persons reached is sufficient to serve as basis for in-depth analysis, but needs to be considered for a stratified analysis of the data (Figure 4).

Figure 4. Age distribution of the respondents

4. SURVEY RESULTS

4.1 Awareness and mobility behavior among survey participants

Substantially more respondents in Munich than in Vienna stated that they have seen a mobility hub already (73%), of which 41% have used the service provided there. A remarkable number of 20% are not sure about their recognition of a mobility hub in Vienna. These results indicate that the awareness strategy and the noticeable design of the mobility hubs in Munich could have been more successful. However, it has to be noted that many of the mobility hubs have been established around already existing public transport stations in Vienna. Thus, the concept might not to be fully clear for the respondents. Moreover, the sample, as described in Section 3, consisted of more young people in Munich than in Vienna, who seem more familiar with shared modes (Figure 5).

The most popular shared modes of transport in Munich are shared e-scooters and shared cars, each with a proportion of around 37%, while in Vienna car sharing is used most frequently (28%) (multiple answers possible).

The detailed analysis of the socio-demographic characteristics determines the hypothesis that the services offered at mobility hubs are attracting younger people in particular and interest in them is lower for older people. Only 4% (Vienna) and 8% (Munich) of the respondents older than 64 years stated that they have used a mobility hub at least once. However, it is remarkable that only 56% of the respondents aged 25 to 44 years in Munich have already used any shared service (Figure 6).

Have you ever seen a mobility hub in your city?

Have you ever used a mobility hub in your city?

Figure 5. Recognition and usage of mobility hubs

Figure 6. Age classes of hub users and non-hub users

A noticeable difference between Vienna and Munich is the share of hub users aged 25-44. While the age distribution of hub users in Vienna was as expected and agrees to previous findings [1][7], the share of hub users in Munich aged 25-44 surpasses the one of the youngest age group represented in this study (Figure 6). A possible explanation might be the higher prices for bike sharing in Munich compared to Vienna. The biggest provider in Munich, MVG, operates with a minute-based pricing system with 9 cent per minute for the standard tariff and 5 cents for students (no age limit) [24], whereas the pricing system of Vienna's provider, Wiener Linien, operates with a 30-minutes-based system and 0,75 cents per half hour for the standard tariff [25]. This means that students in Munich pay 1,50 Euros per half hour- double of the price in Vienna.

The main communality between Vienna and Munich regarding hub users and non-users is the age group of 64 years and over, showing an extremely small share of users in both cities (4% in Vienna, 8% in Munich). This could relate to the fact, that most sharing options, such as the bike sharing options mentioned earlier, require bookings and payment via either an app or online. Older people tend to be more reserved towards using new apps [26] and face greater accessibility issues (e.g. font size, navigation issues etc.) [27]. Thus, the need for accessible on-site information and payment options seems evident for attracting older people.

The survey also asked people for their modes used on a daily basis. It turned out that hub-users are using environmental-friendly modes more often in both cities. In particular, cars are used less frequent, but even more clearly bikes are used as a regular mode of transport. More than half of the hub users are taking their bike at least once a week, whereas this share drops to 39% among non-hub users (Figure 7).

Figure 7. Frequency of using a bike

4.2 Barriers to using shared modes at hubs and potential usage of mobility hubs

As there is a substantial number of people in our dataset who have never used a mobility hub before, the survey also examined the reasons for not using hub-based services and distinguished between different options of shared modes. About one third of the respondents preferred using their own car (Figure 8), which means car ownership matters. As a consequence, the success of mobility hub in terms of reducing car traffic in a city depends not only on an appropriate offer, but on including restrictive measures to private car usage as well. The high share of respondents preferring their own bike reflects the high share of bike ownership in both cities and the usage of private bikes as daily mode as revealed by the present modal split in Munich (see Figure 1).

The second most frequent concern of people who have never used any service offered at mobility hubs are the costs. Considering the fact that most of the users belong to the age class younger than 25 years old the pricing scheme of shared modes should be embedded in an inclusive and affordable mobility pass that will enable using all kind of hub modes, including public transport as well. A deeper analysis of the data in Munich determines that employed persons are using car sharing more than students do (compare chapter 4.1. above). E-scooters are fairly new means of transport and the analysis of our survey clearly indicates the concerns, e.g. not fulfilling particular travel needs like carrying a bag or people feeling unsafe when using a e-scooters. Thus, it needs to be considered that the current service design accommodates the needs and requirements of a particular population group, mainly younger people and early adopters (Figure 8).

Figure 8. Reasons for not using a shared mode (multiple answers possible)

Despite the given barriers mentioned, respondents who never used a mobility hub before reported how likely it is that they use any service at mobility hubs in the future. Not surprisingly, students could imagine the most to use the services in the future. However, it is remarkable that the share in Munich (34%) is by far higher than in Vienna (21%). This could be explained by the fact that cycling is more represented in the daily mobility of younger people, in particular in Munich (compare Figure 1). Moreover, it clearly indicates less accessibility for older and retired people (Figure 9).

Figure 9. Likelihood of using a mobility hub in the future

4.3 Evaluation of different mobility hub elements

Apart from the availability of different shared modes at mobility stations, other service facilities can contribute to making them more attractive. For this reason, the questionnaire asked the respondents to rate possible additional elements regarding their importance. As there are no remarkable differences between Munich and Vienna, the responses of survey participants are presented together for both cities. An “all-in-one-app” (for planning, booking and paying) is seen as the most important service. This can be seen as an indication that people are not satisfied with the current procedure (in case of a user) or the procedure how to use a mobility hub is unclear for non-hub users. However, this result can also be attributed to the high share of young people in the survey sample. The per group

Proceedings

detailed analysis shows that older people in particular are not as familiar with the use of apps and would like to have more information on site. The existence of additional services such as parcel boxes was rated as the least important, but there are only few examples of implementation in practice and respondents may lack experience or be unable to directly imagine and assess the added value (see e.g. [28] for further research on this matter).

Figure 10. Rating different services offered at mobility hubs

4. CONCLUSION

The sample design of the standardized survey launched in four European regions within the SmartHubs research project enabled the analysis of the socio-demographic characteristics and mobility behaviour of certain population groups to form the basis for an impact analysis and further recommendations. The findings on awareness level suggest mobility hub strategies in two European cities, Vienna and Munich, have managed to communicate the presence of mobility hubs. Nevertheless, there is an unequal distribution of awareness and usage across the population groups. For example, current design and communication strategies appear to better reach younger people. On the contrary, older people are less attracted. Overall, it seems that the majority of people do not experience the benefits of mobility hubs until today and many of them still prefer travelling by their modes. Nevertheless, despite existing barriers, such as physical and digital accessibility and affordability, most people would be willing to use hub-based modes in the future. Future research could focus on specifying under which circumstances people would use mobility hubs. Similarly, based on the findings of this study, mobility hubs could contribute to advancements in the urban landscape by providing attractive designs that facilitate not only mobility services but also serve other functions. However, ensuring sufficient information both on the spot and online via a user-friendly app is considered of high importance to make hubs more accessible and attractive.

Changes in the Connotation of Livability and China's Practice under Sustainable Development

Y. Wang^{1*}, C. Liu²

¹ PHD, Associate Professor, School of Architecture, Tsinghua University, China

Extended abstract

The concept of livability has been an important driving force for urban construction and development in both ancient and modern times, and this paper introduces the Chinese practice in the context of sustainable development based on combining and summarizing the connotation of the livability concept. In this paper, we first take the timeline as a clue to summarize the changes in the connotation of the concept of livability. In the West, the ideological origins of the concept of livability can be traced as far back as ancient Greece, and the problem of livability brought about by the rapid development of modern industrialization and urbanization has become an important incentive for urban change, Howard's theory of the Garden City is considered to be the origin of the modern concept of livability in the West. From the 1960s to the 1970s, along with the rethinking of modernist planning ideas, the pursuit of a comfortable pleasant, vibrant, and humane urban environment became the goal of livable development. From the 1970s to the 1990s, the connotation and practice of the livability concept was extended from the humanistic perspective to sustainable development, and since Habitat II in 1996, The concept of sustainable development continues to influence the concept of livability.

China's concept of livability also runs through ancient and modern times. Ancient China pursued "paradise" and "peach blossom garden", and the idea of "resembling heaven and earth, nurturing mountains and managing water" runs through the traditional concept of city camping in ancient China. The modern development of the concept of livability originated mainly from Wu Liangyong's research on human settlements in the 1990s. Since the 21st century, it has been widely discussed in academia and practices, and different cities have also incorporated the concept of livability into various aspects of urban planning and development.

In the context of sustainable development, the concept of livability has a richer connotation, emphasizing various aspects including, natural and ecological environments, communities and housing, urban functions and public spaces, infrastructure, and transportation. Based on this, this paper introduces two of China's "livability" practices in the context of sustainable development: the Nanjing Xiaoxihu Area Conservation and Renewal Project, and the Guangzhou Enning Road Yongqing Fang Renovation Project. In the light of the sustainable development goals, we analyze the initiatives and scientific systems of these cases in realizing a sustainable ecological environment, intensive and reasonable space, economic prosperity and development, social inclusion and equity, and cultural preservation and inheritance, to provide experience and reference for the future development of livability.

Abstract

The paper introduces the concept of sustainability in China's human settlements' construction: taking the timeline as a clue, it summarises the characteristics of China's human settlements construction from the pre-Qin period to the modern era and the concept of sustainability embodied in them, taking into account the elements of nature, the context of the time, culture, and the strategy of urban development. The origin and prototype of China's human settlements ideal can be traced back to the pre-Qin period, and in the cyclical change of dynasties, it has achieved inheritance and innovation, and embodied the concept of sustainability in the four dimensions of ecological resources, spatial order, social governance, and cultural aesthetics, displaying the characteristics of wholeness, hierarchy, order, inclusiveness and artistry.

Of the four dimensions that the sustainability concept focuses on - in terms of ecological resources, it focuses on creating harmony between humans and nature, paying attention to the carrying capacity of ecological resources, and realizing the integration and sustainability of humans, nature, and human settlements; in terms of spatial order, it builds the spatial order of "world-region-city-community", emphasizing the coordinated development of all levels, and focusing on the organization and balance of functions, to provide high quality and order in ecology, production, and life. In terms of social governance, based on the spatial foundation of human settlement creation, it relies on the synergistic governance of spatial units of different scales to realize the ideals of Chinese society; and in terms of cultural inheritance, it takes culture as the vein, integrating natural, social, regional and cultural aspects. From ancient times to the present, the construction of human settlements, which embodies the concept of sustainability, has shown vigorous vitality.

The new era of China's construction continues the concept of sustainability. In this paper, we take Fuzhou's urban construction as an example to introduce China's practices in the period of stock renewal. Through analyzing the background, design concept, construction initiatives and results, participating subjects, support and guarantee, and operation and governance of the cases, the paper explores the cases' initiatives in the protection of ecological resources, creation of spatial order, synergistic social governance, and preservation of cultural inheritance, to provide experience and reference for the future development of sustainable concepts and sustainable construction.

1. INTRODUCTION: THE IMPORTANCE OF SUSTAINABLE DEVELOPMENT AND CHINA'S INTERPRETATION

1.1 Sustainable development becomes a must for world development

The sustainable development of urban territories is key to the achievement of sustainable human development, and in the 21st century cities have become decisive drivers of economic growth and centers of opportunity, prosperity, innovation, and social and cultural interaction. Currently, 55 percent of the global population lives in urban areas, and the number and proportion of urban dwellers continue to grow. As a result of urbanization and global population growth, the share of the urban population is expected to reach 68 percent by 2050. As a result of rapid urbanization, cities are facing

increasingly severe social, economic, and environmental challenges in various aspects. The topic of sustainable urban development has become a widely discussed theme around the world [1]. Since 1989, under the advocacy of the United Nations and the support of governments and institutions around the world, a series of conferences and activities have been held to address the negative impacts of economic development on society resources, and the environment. In 2015, the United Nations Summit on Sustainable Development (UNSSD) adopted the "Transforming our World: the 2030 Agenda for Sustainable Development" to respond to the outstanding contradictions between economic development and society, resources, and the environment, with 17 goals of sustainable development, clarifies the global vision of development by 2030. The concept of sustainable development has become a global consensus for addressing challenges and guiding national and regional development.

1.2 The concept of sustainable development embedded in China's human settlements construction

China is an ancient civilization with a long tradition. During the five thousand years of its history, under the influence of ecological, economic, cultural, social, and technological factors, and at different levels of human settlements, such as the world, the region, the city, the gate of heaven, and the building, the five elements of nature, society, people, housing and support interacted with each other and influenced each other, thus forming a splendid and glorious culture of human settlements. No matter whether traditional or modern, the concept of sustainable development has always been embedded in the process of China's human settlements construction, which is specifically manifested in four aspects: ecological resources, spatial order, social governance, and cultural aesthetics. Taking the timeline as a clue, the article will introduce the characteristics of China's human settlements construction from the pre-Qin period to the modern era and the sustainable concepts embodied in it, taking into account the elements of nature, the context of the era, culture, and the strategy of urbanization. These concepts, aiming to realize the harmony and unity of environmental protection, social progress, and economic development, are not only the inheritance of traditional wisdom but also a response to modern challenges, contributing Chinese wisdom and solutions to global sustainable development.

1.3 The continuation and sublimation of the concept of sustainable construction in the new era

Since the reform and opening up, China has experienced the largest and fastest urbanization process in world history. Data from the Ministry of Housing and Construction show that by the end of 2022, China's urbanization rate had reached 65.22%, with 920 million people living in cities and towns, and the area of built-up urban areas had reached 63,000 square kilometers [2]. At this stage, China has stepped into the second half of new urbanization, urban development has entered an important period of urban renewal, urban development has shifted to solve the problem of "good or bad", and the importance of sustainable development has been highlighted. In urban development and construction, China has continued and innovated the concept of sustainable development, and adopted the White Paper on Population, Resources, Environment and Development in the 21st Century in 1994, which incorporates the sustainable development strategy into the long-term planning of economic and social development. Since 2000, China's Ministry of Housing and Urban-Rural Development has established the "China Habitat Environment Award" [3], reflecting the overall achievements of cities in improving the human environment [4]; adhering to the concept of better cities for a better life, further promoting China's urban governance experience, and jointly promoting the sustainable development of cities around the globe, China has pushed UN-Habitat to set up the *Global Sustainable Cities Award* [5], recognizing the efforts made in the field of urban environment and development and promoting the development of cities around the world. In practice, the concept of sustainable development has been upheld in everything from small community renewal and space

ISBN: 978-618-5765-02-6

remediation to large historical and cultural neighborhood preservation and urban system governance, and a large number of excellent projects and cases have emerged, providing the world with Chinese experience in sustainable development.

2. THE CONCEPT OF SUSTAINABILITY IN THE CONSTRUCTION OF TRADITIONAL CHINESE HUMAN SETTLEMENTS: FOUR DIMENSIONS

Taking the timeline as a clue, and taking into account the elements of nature, era background, culture, and urbanization strategy, we summarize the sustainable concepts embedded in China's traditional human settlements since the pre-Qin period. The origin and prototype of China's human settlements ideal can be traced back to the pre-Qin period, and in the cyclical change of dynasties, it has achieved inheritance and innovation, and embodied the concept of sustainability in the four dimensions of ecological resources, spatial order, social governance, and cultural aesthetics, displaying the characteristics of wholeness, hierarchy, order, inclusiveness and artistry.

2.1 Natural ecology: Harmony between human beings and nature is the priority in the construction of human settlements

The construction of a suitable relationship between human beings and nature is the first key to the construction of human settlements, and in the process of traditional Chinese human settlements construction, emphasis is placed on the creation of harmony between human beings and nature, and attention is paid to the carrying capacity of ecological resources. Nature is the basis for the development of human settlements, in the past process, it has been realized that the scale of human settlements construction can not exceed the carrying capacity of natural resources, the so-called "measure of the land to make a euphonium, the degree of the land to inhabitants" (*Zhou Li*). Thus, the measurement of land area and the determination of the degree of natural fecundity were used as a basis for harmonizing resources with the scale of land and population for human settlements.

Human settlements is gradually formed by people in the process of continuously utilizing and transforming nature, and the process of human settlements construction is a process of transforming the wilderness, building a disaster-resistant security support system, developing agriculture to cultivate suitable land, and forming a humanization of nature, which is how traditional Chinese human settlements construction utilizes and transforms nature. In all aspects of utilizing and transforming nature, traditional water conservancy technology and the accompanying water conservancy culture play a key role. Major water conservancy projects on a regional scale play a crucial role in the construction of regional settlements systems. For example, *the canal of Zheng* project created *Guanzhong Region*. *The Dujiangyan* project created Chengdu. And *the Tangpu dike system* created Suzhou. The construction of Dujiangyan, a traditional large-scale water conservancy project, honors the idea of "conforming to nature", closely integrates the construction of water conservancy projects with hydrological and topographical conditions, and successfully solves the problems of flood control and drought prevention, ensures the safety of the basic life, and builds an overall artificial natural system supporting the development of regional human settlements on a larger scale [6][7].

Figure 1. Sichuan Chengdu Water Conservancy Map (The History of China Human settlements, ISBN978-7-112-16785-2)

The establishment of an artificial canal system at the national scale promoted the overall prosperity of the habitat. The excavation of canals communicated the water transport routes of various regions, facilitated regional transportation, integrated the Chinese habitat on a larger scale, and promoted the prosperity and development of the regions along the routes. In addition, the ancients would culturally disseminate their experience of using the "artificial nature" system after it had been cultivated, for example, by accompanying it with a system of "annual repair" and maintenance of water conservancy projects, and by writing books on the management of artificial nature systems.

2.2 Spatial order: traditional oriental wisdom in the search for harmonized development of space at all levels

The construction of traditional Chinese human settlements embodies the wisdom of Oriental traditions, seeking to establish a harmonious spatial order at various scales. This approach aims to create a habitat that is ecologically sound, culturally rich, aesthetically pleasing, and conducive to a high quality of life. By adhering to the spatial hierarchy of world-region-city-community-architecture, these settlements are meticulously planned to ensure ecological balance, cultural vibrancy, and aesthetic harmony.

Throughout history, the design of human settlements in China has consistently focused on the overarching spatial order. This includes selecting the world's settlement centers through the principles of *Picturing Heaven and Law of the Earth*, which underscores the interconnectivity of the city's core with its surroundings. Monumental projects like *the Great Wall*, the repair of *the Chidao*, and the excavation of canals were undertaken to establish a robust support network, reflecting the societal ethos of *family-country-world*. Moreover, the development of administrative and urban systems, along with the refinement of *the Yuezhen and Haidu sacrificial systems*, contributed to the completion of the world's spatial habitat structure.

Ancient Chinese human settlement planning and design were guided by the philosophy of "settling people, benefiting them through skill, and touching them with beauty". This philosophy encompassed strategies like site selection, layout, construction, and landscaping, blending spiritual and material aspects. The goal was to harmonize with the natural environment, as seen in the reverence for the "Five Mountains", which symbolize the spatial order on a world scale. The process involved detailed environmental analysis to choose the best location, followed by careful planning of the spatial arrangement within the natural setting. This created a framework for the human settlements, prioritizing key areas for overall harmony. While physical structures were important, integrating cultural elements was crucial for adding depth and elevating the spirit of the place. This approach aimed to create enduring and inspiring landscapes that resonate with both beauty and cultural significance.

Proceedings

2.3 Social governance: realizing social ideals based on synergistic governance of different spatial units

Society is the nexus of the organization of human settlements, and the law of harmonious society formed by the Chinese nation unifies the spatial order of human settlements with the social order of the crowd, combines multi-scale spatial synergy in social governance, guarantees the solidity of the state, the continuity of the nation and the happiness of the people, and facilitates the nurturing, development, and maturation of the cultures and ideologies of traditional Chinese societies. In ancient China, people formed groups in forms of space, i.e., settlements, and developed from primitive settlements to capitals and even states, developing a set of social order structures from the family down to the state and even the world. The order not only conformed to the general pattern of heaven, earth, and man but also met the needs of people's production and life. This order was organized by the ritual and music system on a large scale, while on a small scale, it was mainly based on clans and geography, etc., and worked on the spatial organization of the human environment on different scales and levels, and was realized through the construction of human settlements, which ultimately led to the realization of harmony among the residents, education, and culture, and collaboration in production.

Agriculture is the foundation of Chinese civilization and the root of the vernacular nature of society[8]. Ancient Chinese human settlements pattern, based on agricultural production, shaped a vernacular society rich in the characteristics of agricultural civilization, giving rise to a system of grass-roots social organizations based on the land, *the Xiangli organization*, based on which township rules and regulations, *the Xiangli system* and *the Baojia system* were linked to each other to maintain the social order of the rural areas.

In ancient China, the design of human settlements was deeply intertwined with cultural values, emphasizing the nurturing of its inhabitants. The traditional living spaces were crafted to educate and instill a sense of social order rooted in ritual and propriety. The layout of cities, from the grand axes to the intimate courtyards, reflected a hierarchy that mirrored societal values. This spatial organization was not just about physical structures but also about fostering a sense of belonging and community, uniting families and the nation. The emphasis on ritual in both private and public life aimed to maintain harmony and stability. Moreover, the integration of social, festive, and spiritual spaces ensured that residents experienced both material comfort and spiritual fulfillment, contributing to a cohesive and inclusive society.

China's traditional human settlements construction has evolved a grassroots spatial governance system with the county as the core[9], which is still significant for today's sustainable development. This governance structure ensures security, improves livelihoods, establishes political power, and promotes education. It emphasizes creating a stable and safe home, a peaceful and prosperous community, and a strong educational and cultural foundation, using Confucianism and the imperial examination system to nurture a rich local culture. This approach underpins the stability of the nation and reflects a deep understanding of sustainable governance.

2.4 Cultural aesthetics: focusing on beauty and the pursuit of spiritual care with culture as a vein

Historically, the Chinese have cherished life and sought an aesthetic lifestyle. They crafted their settlements to blend natural beauty, societal harmony, and cultural diversity, with cultural aesthetics as the core. The concept of *settlements between heaven and earth* reflects the ancient belief in the unity of humanity with the cosmos. Differing from the Western buildings with rich variations of light and shadow, the traditional Chinese pays more attention to the broader outdoor space, organizing several single buildings around different sizes and numbers of patios, courtyards, and squares to form architectural clusters of different scales and functions, to meet the various spatial needs of social life.

This design philosophy extended to the city's integration with nature, creating a distinctive *mountain-water-city* rhythm.

China's historical human settlements are a human life-centered appreciation of beauty and artistic creation, life is all-encompassing, so the beauty of the settlements is also a comprehensive integration of various types of culture and art, such as calligraphy, literature, painting, sculpture, and so on, which can be summed up by the word *art and literature* in the Chinese tradition. The classical garden epitomizes this blend, featuring pavilions, streams, and plant arrangements that evoke poetry within a painting. Despite social stratification, these settlements fostered a shared aesthetic standard, allowing elegance and commonality to coexist harmoniously. The ancient theatre exemplifies this, serving both as a venue for popular entertainment and a space for cultural edification[9].

Based on material space shaping, the aesthetics of the traditional Chinese human settlements have been sublimated to the connotations contained in the material space. "The wise man enjoys the water, the benevolent man enjoys the mountains" shows that Confucius, while appreciating the natural beauty of mountains and waters, took the natural form of prosperity as a symbol of the moral attributes of human beings. Ancient people's appreciation of natural beauty implies the feeling and realization of the universe, history, and life, and the physical habitat and the virtual human spiritual emotion are interrelated and perceived.

Traditional Chinese human settlements aesthetics are deeply rooted in life, enhancing it through a fusion of various arts and cultures. These aesthetics serve not only to enrich life but also to elevate it, imparting moral and spiritual upliftment. In crafting these environments, the focus is on a higher state of being, where the beauty of the habitat is as diverse as the times, places, and people it encompasses.

2.5 Harmony and beauty in the construction of traditional Chinese human settlements

Behind the construction of the Chinese human settlements lies the philosophical concept of wholeness: the habitat is centered on human beings, with a diverse life as its core, stretching out in time and interconnected in space. Time, space, and the human world are constantly changing, and thus the human settlements as a whole are evolving and changing, with new wholes being formed at various stages based on the original. In the process of cyclical dynastic change, China's human settlements construction has been characterized by both inheritance and innovation, showing vigorous vitality.

The concept of sustainability is embedded in the construction of Chinese human settlements, although there is a big environmental constraint of feudal rites, the core emphasizes the harmony and unity between human beings and all kinds of elements in the construction of human settlements and pursues the harmony and unity between the artificial environment and the natural environment, the material environment and the spiritual home, and the spatial order and the order of the crowd. Based on shaping the material space, the construction is further oriented to the beauty, and the pursuit of the care for spirituality and heart, and the establishment of standards on the significance of the human existence and the value of the existence. The four dimensions of natural ecology, spatial order, social order, and cultural aesthetics concerned with the construction of traditional Chinese human settlements, take the shaping of space and establishment of the system of "human settlements in the world" as the goal and ideal, and lead the construction of human settlements as a whole, emphasize the appropriate order between human beings and nature, make use of nature and transform nature under the state of harmony and sustainability, and combine the construction of human settlements with the landscape and landscape scenery. The construction of the environment is combined with the landscape scenery. This process, presents the "Trinity" synergistic and balanced construction strategy, with rules and order as the means of construction control, reflecting the characteristics of self-organization and self-adaptation. Environmental construction relies on the integration of planning, architecture, gardening, art, and other fields, and is characterized by wholeness, hierarchy, order, inclusiveness, and artistry.

3. CONTEMPORARY PRACTICE OF CHINA'S SUSTAINABILITY PHILOSOPHY: THE FUZHOU PROGRAM FOR SUSTAINABLE CITIES

Fuzhou, the capital of Fujian Province, is located on the southeast coast of China and is one of the second batch of famous historical and cultural cities in China, with 340 kilometers of coastline three excellent deep-water harbors, and a forest coverage rate that ranks among the top of the provincial capitals. On October 28th, 2023, Fuzhou as the only city in China, was awarded the inaugural Global Sustainable Cities Award (Shanghai Prize)[10]. The award takes economic vitality and urban prosperity, ecological construction and green development, urban safety and resilient development, and capacity building for sustainable development as the four main selection dimensions. The winning city must have excelled and made great progress in all four areas, and the actions taken must be sustainable.

As a thousand-year-old banyan city among green hills and green water, Fuzhou's sustainable urban construction from its ancient founding to the modern era is embedded with the oriental ideas of traditional Chinese human settlements construction, and fused with the modern concepts of sustainable development. In the following section, the traditional and modern sustainable urban experiences of Fuzhou will be introduced.

3.1 Construction of a traditional human settlement environment integrating mountains and rivers into the city

Located in the hilly area of Fuzhou, mountains are an important element in its natural environment. The topography of Fuzhou is a basin, which is divided into three parts: plains, hills, and mountains, and is distributed in layers from the bottom of the basin to the outer edge. Hilly areas surround the center of the basin, forming a "left Qi, right Gu, before the Wu Hu after Gao Gai", towering around the Fuzhou Plain this unique landscape natural pattern [11].

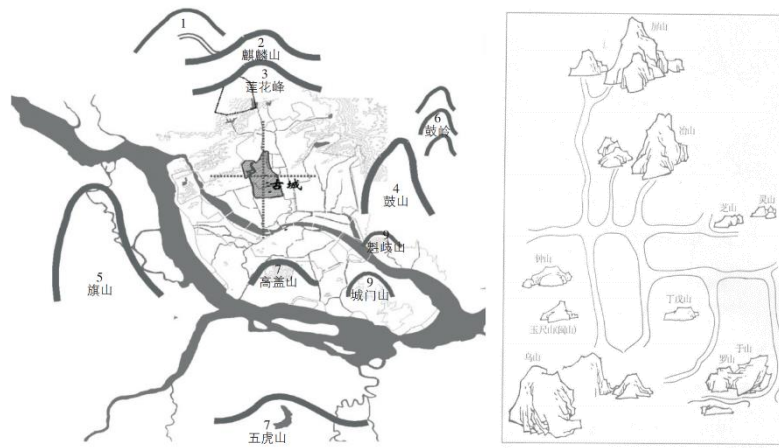

Figure 3. Fuzhou General Layout Map (left[12]), Map of the location of the mountains in Ancient City(right[11])

Fuzhou City not only has a very favorable environment outside the city but also has a very superior small environment inside the city, with small mountains such as Mount Luo and Mount Zhong in the city. The two-fold natural landscape skeleton inside and outside the city constitutes a unique landscape pattern of "city in the mountains, mountains in the city". Traditional Chinese landscape culture believes that there are Penglai, Yingzhou, and Fangzhang "three mountains" in the sea. In the ancient city of Fuzhou, there are three groups of "three mountains" known as "three mountains hidden, three mountains present, three mountains invisible". The three mountains hidden refer to the three famous mountains in the city, the north is Mount Ping, the east is Mount Yu, and the west is Mount Wu, into a *Pin*(品) tripod.

Fuzhou is also rich in water elements, and historically it is an important port city for foreign trade. Located in the south of the ancient city center, the Minjiang River, which runs from northwest to southeast across the Fuzhou Basin and into the East China Sea, is a long-flowing river. Historically, the Zicheng of the Jin Dynasty, the Luocheng of the Tang Dynasty, the Jiacheng of the Liang Dynasty, and the Outer City of the Song Dynasty all had moats, and the expansion of the city wall made these moats become the inner rivers of Fuzhou Ancient City so that merchant ships could directly enter Fuzhou Ancient City by following the rivers. Almost all of the river systems dug for the city of Fuzhou during the various dynasties have been preserved to this day.

Ancient urban planning and construction in Fuzhou was by the natural environment, realizing overall harmony within the city and harmony with nature. The construction of the city wall conformed to the mountainous terrain, and the internal layout of the city was also based on the topographical features. Ancient Fuzhou city construction has been centered on the three mountains, with Mount Ping as the main location, forming the north-south main axis, and Mount Yu and Mount Wu as the auxiliary mountains, confronting and defending the left and right. The main buildings and functional areas are distributed on both sides of the main axis, built in the Wu Tower on Mount Wu and built in the White Pagoda on the mountain, echoing each other, separated from the city axis on both sides of the avenue. The three hills in the city and the two towers facing each other have become the symbol of Fuzhou and a unique urban spatial art pattern.

Fuzhou's urban development has remained true to its original site, despite several expansions driven by military, political, and economic changes. The city's distinctive layout, featuring three mountains, has been preserved throughout history. This reflects Fuzhou's alignment with traditional Chinese principles of harmonizing with nature and making rational use of the environment, embodying the enduring concept of sustainable living. Key aspects of Fuzhou's planning include:

Proceedings

Ecological Harmony: The city's location is exceptional, nestled south of the Minjiang River and surrounded by mountains on three sides, embodying the traditional *Feng Shui philosophy*.

Landscape Integration: The city's layout follows the natural contours of the land, resulting in a harmonious *mountain-water-city* spatial order.

Cultural Landscape: Fuzhou combines its landscape and water conservation efforts, enhancing the city's beauty through projects like moat excavation and river dredging.

Cultural Aesthetics: The city's unique landscape culture, influenced by local Min traditions and Central Plains culture[13], has been celebrated by historical figures like Li Yangbing and Xin Qiji through their literary works.

3.2 Green and digital economy-oriented modern sustainable development

As early as the 1990s, Fuzhou became the first city in China to formulate a 20-year development plan after Comrade Xi Jinping personally drew and organized the implementation of the 20-year strategic vision for the economic and social development of Fuzhou City. Over the past 30 years, Fuzhou has continued to explore the path of sustainable development and has introduced several influential, innovative, and replicable comprehensive solutions in the economic, social, and environmental aspects, which have resulted in a fundamental change in the cityscape [14].

In terms of ecological construction and green development, Fuzhou is surrounded by mountains on three sides, and the urban area is embraced by 58 mountains, which makes Fuzhou's urban development once faced with the dilemma of "looking at the mountains but not into the mountains, and it is difficult to enjoy the green". With the "City of a Thousand Parks" construction action, the construction of *Fudao*, country parks, bead parks and pocket parks, the mountains, water, people, the city into one, for the public to open up the last meter of the pro-mountain water. At the same time, the implementation of the Minjiang River Basin ecological protection and restoration of mountains, water, forests, fields, lakes, and grasses, and to promote the protection of biodiversity. Nowadays, the air quality of Fuzhou composite index of 2.51, air quality excellence rate of 97.5%. An average of nearly 15 square meters per person with parks and green space, can breathe the oxygen provided by the 200 trees, every 10,000 people have a length of 3.64 kilometers of the greenway.

Figure 4. Ecological construction and green development in Fuzhou(pictures are)

In terms of urban safety and resilient development, Fuzhou is born with water, but also vulnerable to natural disasters. Facing urban flooding and the black odor of water bodies and other phenomena, Fuzhou implementation of urban water system management project, optimize the allocation of water resources, reduce water use and waste, through the widening of the river, the river landscape enhancement of the riverbanks and other means, so that the city's 139 rivers to regain a new lease of life, the water management of the city's more than 8 million residents to create a safe and resilient new home. The city's flood prevention and drainage capacity has been increased from one in five years to one in 20 years, and the efficiency of emergency disposal of drainage and flood prevention in urban areas has been increased by 50%. The storage efficiency of the urban water system has been increased by 30%, and the flood prevention and control capacity has been raised from one in five years to one in 20 to 30 years. The city has successfully withstood more than 10 typhoons and more than 300 short-duration heavy rainfalls.

In terms of economic vitality and urban prosperity, digital industries such as big data, Internet of Things, and new displays, forming chains and clusters, as well as the flourishing green and digital economies, constitute the underpinnings and driving force of Fuzhou's sustainable economic development. Fuzhou ranked 2nd in GDP growth rate of major cities in China in the past decade, with a digital economy scale of over 610 billion yuan, more than 50% of GDP, over 1,300 high-tech enterprises in the digital economy, and an increase of more than 18,000 yuan in the annual per capita disposable income of urban residents. In addition, the city has focused on combining culture and tourism, utilizing old urban areas to promote urban consumer tourism, creating 17 distinctive historical and cultural districts, and repairing more than 1,200 key cultural relics. Focusing on the renewal of urban communities so that citizens can enjoy more of the fruits of reform and development, more than 500 parent canteens have been built across the city, 35 major projects of child-friendly renovation have been launched, 18 sustainable community pilots have been built, special plans have

Proceedings

been compiled to improve the quality of accessibility facilities, and attention has been paid to the needs of all citizens to create a sustainable, all-age-friendly urban community.

In terms of sustainable development capacity building, the world's first 16 MW ultra-large capacity offshore wind turbine was connected to the grid and generated electricity in Fuzhou, the nation's first marine fisheries carbon sink transaction was completed in Fuzhou, and digital platforms such as "e Fuzhou" are used to enhance the efficiency and quality of urban public services and the sustainability of urban governance. In December 2023, the People's Government of Fuzhou issued the "Construction of Sustainable Development Communities in Fuzhou", a pilot project for the construction of sustainable development communities, actively responds to the United Nations' 2030 Agenda for Sustainable Development, focuses on the people-centered development ideology, creates a modernized international city, and promotes the work of building a sustainable city in Fuzhou. Fuzhou, a livable and happy city, has well demonstrated the city's practices of integrated planning, innovative development, and response to climate change, contributing to global sustainable development with the Fuzhou Program for Sustainable Urban Development.

1. SUSTAINABLE DEVELOPMENT IN THE PERIOD OF STOCK RENEWAL HAVE A LONG WAY TO GO

China has inherited and developed the concept of sustainable development in the construction of human settlements, from the traditional to the new era. The road to sustainable development is still a long one. Since the reform and opening up, China has experienced the largest and fastest urbanization process in the history of the world, and at the present stage, it has shifted from "incremental expansion" to "stock renewal". This is not only a concrete embodiment of proactively adapting to the transformation of the main contradiction in China's society, but also an inevitable requirement for realizing high-quality development. In the face of the ever-changing natural environment, social needs, and technological advances, we must continue to explore and innovate to ensure that the construction of human settlements can adapt to the challenges of the future and realize truly sustainable development. This requires the joint efforts and wisdom of Governments, enterprises, and all sectors of society, as well as the inheritance and development of traditional wisdom, to protect the Earth's homeland while promoting the harmony and progress of human society.

Smart and green regeneration for the creation of a theme park: the case of the Thermis dam

E. Pavlou

Department of Planning and Regional Development, of the School of Engineering, University of Thessaly, Greece

E-mail: eleannap98@gmail.com, *tel* +30 6936080579

Extended abstract

The park, as an open air public space, performs important functions to the urban living (or lifestyle); it facilitates the coexistence of humanity and environment; it boosts productivity, and physiological health; and it is directly linked leisure activities.

The present paper concerns the research carried out for the Diploma Thesis, University of Thessaly, Greece. As case study, the Park of Fragma, Municipality of Thermi, Thessaloniki, has been analysed and redesigned adopting a 'Green & Smart' approach. More specifically, analysing the park's potential, the redesign scheme contributes not only to the differentiation of daily life's boundaries, but also to tourism development, while adding dynamic stimulus to the place for intercity competition.

The proposed redesign scheme strengthens the ecological dimension, the leisure aspects and the human-centric approach to urban design.

Abstract

Inequalities are widening across the world and recent studies indicate that there is a clear relationship between urban growth and spatial inequalities. The shape of urban inequalities is influenced by the interplay of factors that range from socio-economic, land-use, environment and housing to transport and mobility aspects. Notwithstanding the relevance of the challenges relating to the field of transport inequalities for both academics and (on a few occasions) political bodies, in many cities from Southern Europe, there are still pressing levels of deprivation and marginality that are aggravated by the lack of appropriate knowledge and instruments to identify and tackle such unbalances. Simultaneously, in the last three decades, different urban planning paradigms studies and approaches like the Transit Oriented Development or 15 Minute-city concepts, have emerged and stressed the role of spatial accessibility as a relevant condition for reducing urban inequalities. On such a basis, the convergence between city and transport appears as a significant strand of urban planning studies that can support policymakers in addressing the urban development of cities that witness unequal access to transit networks. Taking as case studies Palermo and Naples, two of the largest cities of Southern Italy, this paper aims to understand the spatial interplay between the rail system and the urban system. In particular, the study focuses on key socio-demographic aspects, land-use features and accessibility, and relies on different spatial analysis elements. As part of a wider research project that seeks to understand spatial inequalities, the preliminary outcomes of this paper unfolded interesting insights regarding transport inequalities which can be useful to develop a more sustainable, and inclusive transportation system.

Keywords: *accessibility; transportation; inequalities; Palermo; Naples.*

1. INTRODUCTION

While European cities seek to foster social cohesion and sustainable development, they face the challenges posed by rising socio-spatial disparities [1]. Urban inequalities are the result of a wide array of thematic domains, including transport poverty [2], accessibility [3, 4], housing [5], spatial justice [6], energy poverty [7], digitalisation [8, 9], social segregation [10], among others. Concurrently, the distribution of resources and opportunities across urban territories [11] cannot be done independently from the geographies within the places where they occur [12]. This was made even clearer with the Covid-19 Pandemic especially in terms of equitable access to basic urban services and infrastructures, green spaces and mobility opportunities [13, 14].

Against this backdrop, the efforts to rethink urban planning paradigms by emphasising the creation of sustainable and liveable cities, can play a direct role in reducing the many faces of intra-urban inequalities. For instance, urban development concepts such as the Transit-Oriented Development (TOD) [15] (Calthorpe Associates, 1990) and 15-Minute City [16] advocate for enhanced accessibility, social inclusion, community building, and the integration of urban and transport planning. In the TOD concept, train stations take an important role as the main public transport modes that connect neighbourhoods and hubs and create highly dense development areas that offer more equal opportunities.

Proceedings

In this paper, we present the cases of Palermo and Naples, two of the largest urban conurbations in Southern Italy, which are also places of widespread territorial challenges translated into spatial inequalities and complex mobility and transport settings. The work is part of an ongoing study that seeks to promote a better understanding of the accessibility to urban mobility nodes as a key aspect to support design strategies that answer spatial inequalities by integrating land use and transport. In particular, the research question raised by this paper is how each city is interlinked, from a socio-spatial perspective, with their railway system.

To answer such question, after setting the theoretical framework, the paper delves into a brief contextualisation of the two cities that illustrates some key socio-economic aspects, and the main features of the railway systems. Subsequently, is presented an initial set of maps that highlight the geographic distribution of urban features in relation to the rail network, followed by a discussion on the elements resulting from the spatial analysis. In the conclusion, the paper offers a critical view regarding the observations made and the potential of this type of analysis, followed by the limitations of the study and the following steps of the research.

2. TRANSPORT INEQUALITIES AND ACCESS TO RAILWAY SYSTEM

Transportation is essential for accessing opportunities and exercising our rights as citizens, and as advocated by different theories of justice, it is vital to ensure inclusive mobility policies and strategies. These policies can shape the distribution of resources, prioritise disadvantaged groups, or reduce inequalities [17]. In addition, the fair design, management and operation of transport systems can enhance accessibility for all individuals.

While transport inequality is not a new concept within the transportation field, traditionally the key interrelated aspects of transport poverty have been categorised as [2]: (a) lack of access to transport or mobility as a consequence of limited public transport infrastructure, unreliable services, or lack of personal car ownership due to financial constraints [18]; (b) the difficulty of reaching certain key activities, such as employment, education, healthcare services, shops at reasonable time, ease and cost [19]; and (c) the financial capacity (affordability) due to high ticket prices, fuel cost and maintenance expenses that create financial burden [20].

There is an ever-increasing relationship between the share of population most socially and economically disadvantaged and those mostly affected by transport disadvantages. For instance, a European study has highlighted how the disproportioned spread of public transportation networks limits the access of low-income groups to essential daily activities, such as commuting for work, education, healthcare, grocery shopping, and other critical trips [21]. However, it is also crucial to underline that transport disadvantage and transport-related social exclusion are not inherently equivalent [22]. One can experience social exclusion while having adequate access to a transport system, although one can face transport challenges while being socially well-integrated [23].

To address urban inequalities and grasp the complexity of sustainability issues, it is crucial to strengthen the integration between the city, its transportation and land use planning [24, 25]. For instance, this strand of urban planning studies can support policy makers in addressing the urban development of cities that witness unequal access to transit networks.

The challenge for urban planning and policy lies in balancing the essential role of mobility in enhancing cities' welfare and well-being with the unsustainable nature of current transportation practices. Equity and accessibility are related concepts that change depending on the context and frame of reference [26]. Accessibility represents the interaction between the transportation system, the spatial distribution of social groups and services, individual characteristics, and time constraints [11]. It underscores transport's role in facilitating opportunities vital for well-being, including employment, education, social interactions, and human capital development.

Alongside, there are urban development concepts, such as TOD or x-Minute City, that combine planning, sustainable mobility and well-being. These models advocate, among other things, for

Proceedings

enhanced accessibility to relevant urban functions, social inclusion, community building, and the integration of urban and transport planning. For instance, by densifying populations and activities around transit nodes it may be possible to achieve better accessibility and increase the efficiency of public transportation [27, 28]. In such cases, the importance of public transport, particularly the railway system, comes from the fact that providing efficient and integrated transport alternatives to car ownership is crucial for overcoming social isolation and car dependency while also contributing to a more sustainable development.

3. TWO SOUTHERN ITALY CASES

This section briefly introduces the two cities that are the object of this study, giving readers an outline of the factors that may have affected the development of the rail system and, in turn, its capacity to respond to the mobility need of people. While both cities have a prominent role in their regions, it is worth noting some relevant differences related to their role within their respective metropolitan systems.

The city of Palermo is the capital of Sicily and the second largest urban area of Southern Italy by population, with 628.894 inhabitants in January 2024. It is the core city of a metropolitan area with a population of 1.198.594 inhabitants, 52% of which reside within Palermo's municipal boundaries. The conurbation process outside these boundaries has been rather limited due to geographical reasons and the urban area of Palermo concentrates most functions, including health, education, culture, tourism, and government.

Differently, the metropolitan area of Naples has more than twice the population of that of Palermo, concentrated in a rather narrow land area, which makes it the first Italian metropolitan area for demographic density. Although the city of Naples is the place of the main strategic functions of the region, relevant production and service activities are located outside its municipal boundaries and the city itself hosts only 31% of the metropolitan area population. Moving our focus on the socio-demographic trends, land-use features and characteristics of the railway system, other analogies and differences can be outlined among the two cities.

Palermo has experienced a continuous demographic decline in the last three decades (-7%), only partially compensated by the rise of foreign population (+13% between 2013 and 2023). The development of Palermo's urban fabric followed different expansion periods associated with several historical events. Most of the current urban area is primarily the result of the great expansion taking place in the second half of the 20th century, motivated by different drivers, including the dereliction of the historic centre, the lack of effective planning regulations, and the influence of the mafia on the real estate sector. At the same time, due to the morphology of its land area – surrounded by mountains –, the urban fabric is still limited by relevant environmental resources, including nature reserves such as 'Monte Pellegrino' and 'Capo Gallo' or the Orto River valley (see Figure 1, left).

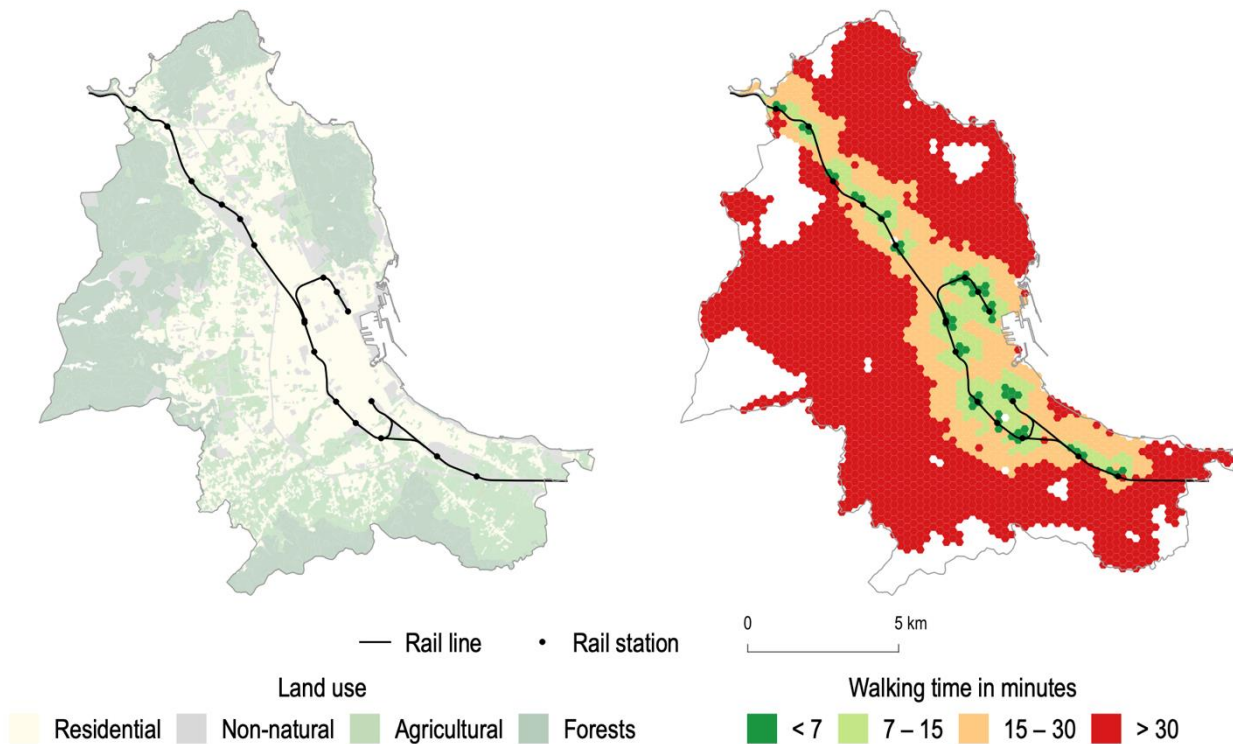

Figure 1. Palermo: land use coverage (left) and walking time to the rail system (right).

Despite the city being the daily destination for thousands of commuters (268.802 from the city itself and 52.789 from neighbouring towns in 2011), the public transportation system has been long underdeveloped, and the city is still known for its ‘car-dependency’ status [29].

Currently, the city is not equipped with a proper underground network and the transit system relies on two train lines (see Figure 1), managed by the Italian Railway Authority. In recent years, however, different mobility strategies (see the ‘Integrated Plan for Mass Public Transport’ of 2013 and the ‘Sustainable Mobility Plan’ of 2019) have stressed the need to expand and improve the rail network, creating ground for a better integration with different transport modes (including the three existing tram lines).

The specific strategy for the rail system includes the redevelopment of the two existing rail lines, namely: the construction of four new stations and 3 km of underground line on the ring line (full completion is expected in 2029); and the construction of three new stations on the bypass line, that upon completion will be among the largest projects ever funded by EU’s structural funds in Italy.

Similarly to Palermo, Naples has experienced a constant population decline over the past thirty years (-8%) against a population movement towards cities of the metropolitan area. For the high density of population (7.772 inhabitants per square kilometres) and urban functions, Naples is the target of more than one million daily commuters that reach the city for work and study reasons (379.383 from the city itself and 912.124 from neighbouring towns in 2011).

Naples’ highly urbanised layout spreads from the organic and highly dense network of narrow alleys of the historic centre towards the residential outskirts. The latter resulted from multiple expansion periods including the post-1980 earthquake construction boom. The city’s hilly terrain results from the complex Vulcanic system (‘Campi Flegrei’ at the West and ‘Somma-Vesuvio’ on the East) and despite being urbanised it encompasses several green areas (such as the ‘Parco dei Camaldoli’ and Bosco di Capodimonte’ towards the West and North of the city centre correspondingly, see Figure 2, left).

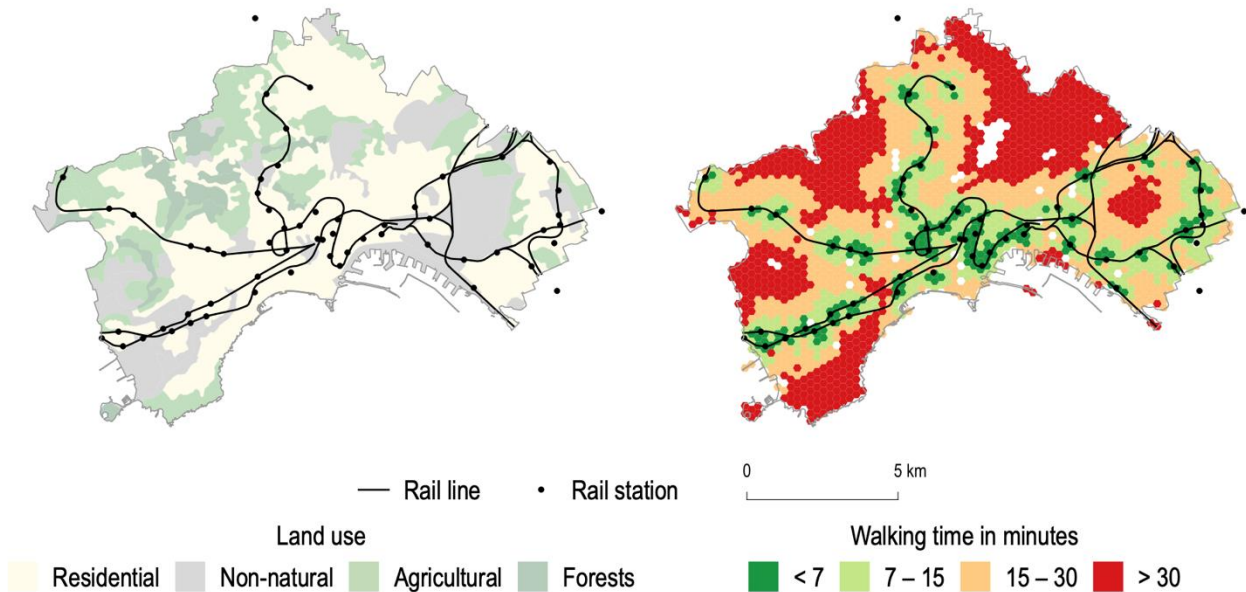

Figure 2. Naples: land use coverage (left) and walking time to the rail system (right).

Thanks to its rich historical background (Europe's second-largest city in the 17th century), Naples boasts a longstanding public transportation system, with a notable emphasis on rail network (see Figure 2). The system is a vital component of the city's transportation network, offering extensive coverage and accessibility to various neighbourhoods. It connects residential, commercial, and peripheral areas, with a strong focus on intermodal connectivity (see Figure 2, right).

Ongoing developments and expansions wish to further enhance its reach and service quality, making it an integral part of urban life. Stations are distributed to cover major residential, commercial, and tourist areas, ensuring that most of the Naples' population is within reasonable walking distance of a metro or train station. Today the city has three rapid transit system lines in use and nine sub-urban lines, and despite being operated by different providers (e.g., The Italian Railway Authority or the Metropolitan Mobility Company), the rail network (particularly Line 1 of the underground), provides a good accessibility to/from the historic center and peripheral areas such as 'Piscinola' or 'Scampia'. On the other hand, other sub-urban lines ensure that even the more distant neighbourhoods (including neighbouring municipalities) are served and have a reliable access to the city centre.

4. METHODOLOGY AND ANALYSIS

The scientific community has come up with a vast array of approaches to explore the dynamics of spatial development around transportation nodes [28, 30, 31, 32]. Given the purpose of this study we focused on accessibility by walking to rail stations. The reasoning behind this choice relates directly to the critical role that the rail system can play in highly congested urban contexts; the impact that public transportation can have as a driver of social equity; and the intrinsic transportation benefits of walking.

As part of an ongoing research project that will develop more advanced spatial analysis tools to identify intra-urban inequalities, our approach, in the current moment, mixes a descriptive analysis with quantitative data analysis. The methodology followed was based on a spatial analysis of publicly available data (Public Open Data portals, ISTAT, OpenStreetMaps, Corine Land Cover), developed with QGIS software.

The first step was to establish a hexagonal grid (250m height, 5,4ha area) over the municipal boundaries, followed by mapping all active rail stations (points). Thereafter, the walking time around the stations was estimated using the “OD-Matrix from Points” algorithm (QNEAT3 plug-in). Due to the experimental nature of the approach, and with the goal of reaching a better understanding of the relationship between the city and the rail system, a particular set of features related to transport demand was selected (see Table 1) to test the method.

Travel demand			Walking time to rail station
FEATURE	GRADING	SCORE	GRADING
Population density (units: people)	0	0,00	> 7 minutes
	< 200	0,25	
	200 – 500	0,50	
	500 – 800	0,75	
	> 800	1,00	
Commuters for work or study (units: people)	0	0,00	7 – 15 minutes
	< 250	0,25	15 – 30 minutes
	250 – 1000	0,50	> 30 minutes
	1000 – 2000	0,75	
	> 2000	1,00	
Local services and urban functions (units: absolute value)	0	0,00	
	< 5	0,25	
	5 – 10	0,50	
	10 – 15	0,75	
	> 15	1,00	

Table 1. The travel demand criteria and normalisation, and the accessibility to the rail system.

For the spatial analysis, we considered as starting point the smallest scale available by ISTAT: census tracts (polygons) for statistical data, and points for local urban services. In a second step, data was reaggregated over the hexagonal grid where the different features were projected. An areal interpolation with weighed areas was used in the case of statistical data (population and commuters), and a direct count of overlaying features was done in the case of points.

Due to the different grading scales (see Table 1), the final step encompassed normalising each feature on a 0 to 1 scale and calculate a final score (by summing partial scores) for each hexagon (the closest to 3, higher the transport demand). By applying a filter to highlight hexagons with a high transportation demand score, it was possible to represent the accessibility conditions in both cities (see Figure 3).

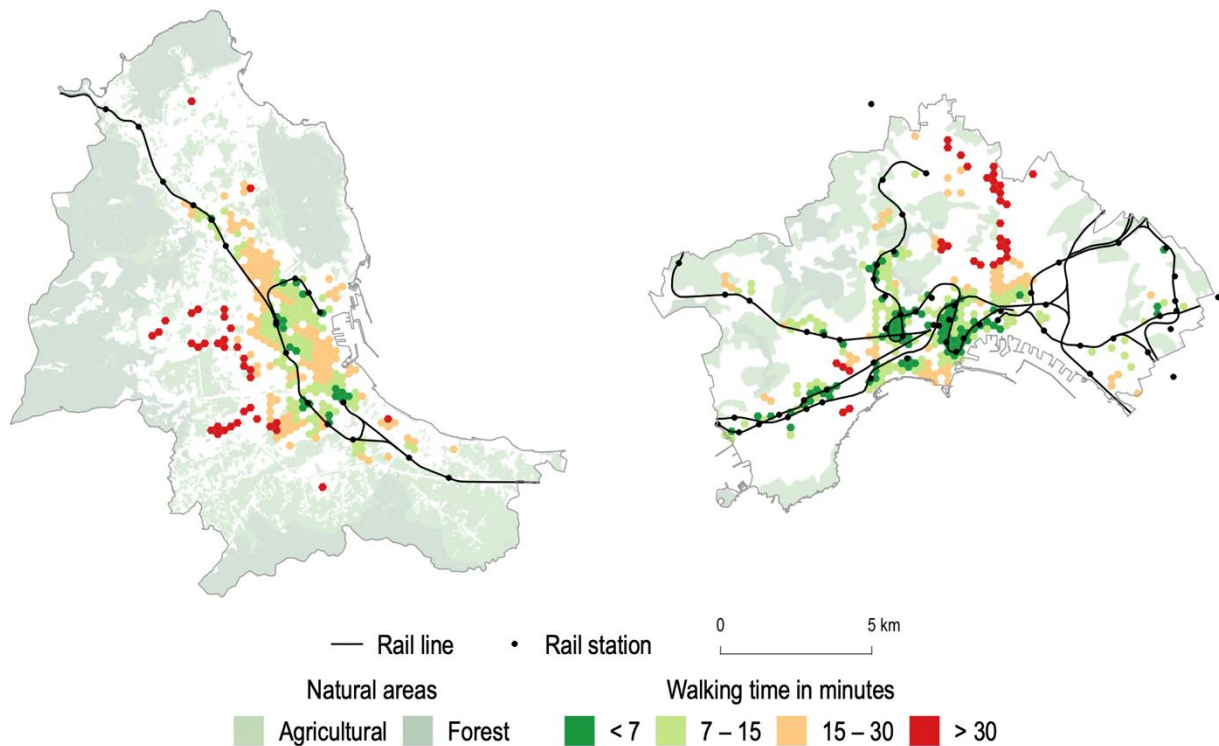

Figure 3. Walking time to the rail system of high demand areas in Palermo (left) and Naples (right).

In a general way, the presence of green patches can be seen as an effective implementation of the rail system within the city. In other words, there is good walking accessibility in areas with great transport demand. Light green areas show potential in terms of match between demand and the rail service and they can be the target of ‘chirurgical’ interventions to improve walkability and reduce the access/egress times to the rail nodes. Orange and red areas can open space for different reflections as they represent areas with considerable long walking times to the rail system, despite the presence of high density of residents, commuters and points of interest.

As Figure 3 reveals, regardless of Naples having a more extensive network than Palermo, both cities have relevant red patches that shall be investigated (in West of Palermo, and in the North of Naples). At a first glance, these areas seem to match highly populated neighbourhoods where a proper access to rail system could improve social equity. From a policy maker point of view, these red spots can be taken as neighbourhoods that request prioritised interventions.

In contrast, there are relevant green patches on both cases. Palermo presents areas with good accessibility around two biggest transit hubs and a few areas that concentrate important public infrastructures such as the University or the Hospital. Naples has a relevant number of green patches that overlay the rapid transit system on great part of the centre and along the line that spreads towards the West. A great portion of the city is therefore accessible to the rail system within 15 minutes by walking. Finally, one difference that stands out concerns the orange patches in the two cities, which are more noticeable in Palermo. Some of these areas will become more accessible with some of future developments of the rail ring, a fact that opens space for a successive research step that shall take into consideration the effects of planned interventions.

Yet another aspect that shall be looked after in a future analysis is the presence of the tram and bus system, as well as bike lines. This can help illustrating the complementary, potential role of other mobility options in feeding the rail system like in other remarkable cases (e.g., Helsinki). Further stages of the analysis shall also cover additional features of what we called “demand”, such as socio-

demographics, housing or work. This will be of key importance as we want to accommodate more aspects of urban inequalities.

In short, looking at the specific cases under analysis, some preliminary considerations could be taken such as the apparent poor accessibility of some residential areas, but more interestingly, the method has proved to work when trying to identify hotspots that are worth focusing further research.

5. CONCLUSION

This paper offers an evaluation of the city-rail interplay within two of the largest Italian cities, under the lens of planning concepts (TOD, 15mC) that look at the transportation hubs as key places for the quality of life in urban areas, and a focus on proximity to the transit network as a condition to reduce mobility inequalities. Naples and Palermo appear to be interesting targets for this type of analysis, as they are urban areas historically affected by an overall inefficiency of public transport, the relevance of car dependency, and poor attention to transport and land use integration.

Even from the limited perspective of this study, the analysis suggests that in places with longer attention to the development of urban railways – as in Naples – the interaction between the transport network and the built environment has led to a polycentric urban structure. In contrast, as only recent investments in Palermo are turning the rail network into a metropolitan service, wider portions of the built area have no coverage by the system. This is the case of several highly populated peripheral districts where no rapid transit service is yet available, and parts of the city centre that await the completion of the rail ring expansion.

The main limitations of this work are twofold. The first one lies in the consideration of only few socio-demographic variables to measure attractiveness of the rail stations. Furthermore, there is only an approximate evaluation of the attractiveness of each urban areas due to the presence of local services. In a further step of the research, a more accurate location of urban functions able to generate significant mobility flows will be implemented, as well as of a temporal perspective to consider trips outside the home-work range. The second limitation lies in the scale of observation, which here is limited to the municipal areas. As it is well known in literature – and particularly relevant to the Naples case – a large amount of the home-work trips is generated within the metropolitan areas, creating additional demand for transportation to the core city and, conversely, wider areas of marginality due to transport poverty in the periphery.

This type of analysis can help policy makers to acquire a better understanding of the mechanism regulating mobility flows within urban areas, to which extent the transport system has a spatial pattern that helps meeting the demand for transportation of different kind of users while reducing the marginality of other groups. At the same time, this kind of multilayered transportation geography can give urban planners recommendations in addressing future development within the city, in which districts (around the rail nodes) densification strategies are suggested by low density of population and activities and, by contrast, which missing links could be realised to lower the pressure over the most congested station areas.

Extended abstract

The concomitant of rapid population growth and urban development has confronted the delicate balance of the ecosystem and the natural environment. It unveils a complex interplay between the quest for increased spatial efficiency and the imperative to create sustainable and liveable urban environments. As a result, the majority of the voting population of Switzerland agreed that densification needs to be established as a legally binding policy objective, requiring cities to develop inwardly within their existing boundaries in order to create more housing and job positions. The challenge is evident as a projected around 23% resident population increase upon the existing urban area in Zurich without compromising the high quality of living. An urban planning strategy for densifying the city is imminent.

The study collaborates with the City of Zurich and searches for strategies and approaches to urban densification and transformation in the context of Zurich. It generates densification scenarios based on a real case of Altstetten-Albisrieden, Zurich, a district that very well represents the social and geographic situation of the city. The district has comparatively low population density and indicates excellent potential for accommodating future population growth.

The study has created eight scenarios to identify influential factors and their impact on social and environmental perspectives. These scenarios cover the situations of complete rebuilding, partial redevelopment, and building retrofits. The feasibility of each scenario is evaluated in accordance with the baseline of building densification requirements, the latest Building and Zoning Plan of Zurich (BZO 2016), and building features, such as development year and structure types, and further indicates possible challenges and strategies.

The scenario analysis results propose the pivotal role of green spaces near buildings, as they impact the microclimate of the whole area and the availability of community green spaces. To maintain the current resident-share ratio of these green spaces, new developments must be built in a compact manner. Therefore, building typology designs with more green surfaces are crucial, and the inclusion of greenery elements like rooftop gardens and green facades should be encouraged. In addition, the main concern is to increase the green surface plot ratio (GsPR) for each redevelopment. The specified minimum open space for each parcel is not enough; there should be clear limitations on the green surface plot ratio to promote the growth of green spaces around buildings in the zoning and building regulations.

The design dimension of the student social housing: New approaches for the changing European city

Abstract

The university residence as a design theme is today in the centre of a renewed scenario of reflections due to a change not only in the architectural paradigms (increasingly integrated with the urban context) but also with reference to the users' ways of use, no longer limited to the student population but extended to other more and more different categories. In this context, the design of furnishing elements (relating to both accommodation and common spaces), after a long period of undoubted marginality, is now experiencing renewed interest as a result of both the need to increase the quality levels of university residences in their complex, and of the awareness of the contribution that design can provide with respect to the needs of modifiability, adaptability and flexibility which have now become essential.

If the now consolidated trend (also implemented by the regulatory system with very culturally advanced laws and decrees) is to overcome models that respond to merely demanding and quantitative requests, the approach to design strategies not only recognizes design's ability to contribute to improve the quality standards of university residences, but also borrows themes and issues that have always characterized the discipline itself; among these: sustainable production, recovery of material culture, process innovation, attention to materials and components' life cycle, cost-effectiveness, social relationship between individual dimension and collective dimension of the solutions. Thus, the reconstruction of a continuity with the great design masters' experiences of the past century appears possible today, just as the reconstruction of the relationship between user, object, space and architecture becomes possible and necessary.

Keywords: *student housing; furniture design; public city; sustainability; social architecture.*

1. INTRODUCTION

The design for contemporary university housing, although still not entirely organic, today shows an interesting panorama of projects and creations; the trend of new design schemes is to relate architectural construction and the functional dimension of space to more specific requests deriving from new economic conditions, cultural interests and social sensitivities. Among these, at least three can be identified: the reuse of existing buildings, energy sustainability, social participation.

The reuse of existing buildings refers to design-schemes for university housing created in buildings of high historical-architectural value. In this case, interior and furniture design takes on an important central role in reuse strategies because it has to offer solutions for contained and non-modifiable spaces. Spaces in reused buildings are at the same time multifunctional, transformable, adaptable and customizable, and modular. Even the relationship itself with architecture no longer appears univocal: Given that is impossible to work on the typo-morphological configuration of the accommodation and common spaces, it is only interior and furniture design that implements design strategies suited to the quality of the historic building providing a quicker solution to accommodate the new needs of the students (increasingly differentiated and dynamic), transforming building constraints into new spatial opportunities.

Proceedings

of the International Conference on **Changing Cities VI:**
Spatial, Design, Landscape, Heritage & Socio-economic Dimensions
Rhodes Island, Greece • June 24-28, 2024
ISSN: 2654-0460
ISBN: 978-618-5765-02-6

Energy sustainability constitutes a new specific trend in design-schemes for creating university residence; it expresses a renewed environmental sensitivity and a new form of dialogue between construction technology and architecture.

Finally, social participation constitutes a new characteristic of the design-schemes for university residence. Design strategies aiming at composition and configuration scenarios are always new and transversal with respect to the official functions of the environments (whether private or public) and through self-construction experiences.

In a future scenario - not too distant -, it is clear that the design furnishings for university residences can no longer ignore their centrality in the design process taking on the responsibility of being the driving force in the development strategies aiming at the quality of people's life, the environment and buildings, precisely by virtue of the significant characteristics of flexibility, modifiability and configurability - always with respect to different and changing needs of socialization, to the integration of the public and private dimension (understood both as co-living and co-working), in total harmony with the most innovative approaches to the students' new social housing models.

2. THE RESEARCH FRAMEWORK

The reflections contained in this article are part of a wider multidisciplinary research called "RUSH. Responsive University Housing: Innovative Solutions for Socio-economic and Urban Regeneration of Neighbourhoods in Southern Italy", under development since 2023 between Polytechnic of Bari, Polytechnic of Milan and University of Florence. The research is aimed at combining technical and scientific skills to implement the student housing within an urban ecosystem made of a new vision for the temporary support to hospitality and with new strategies of urban contexts' regeneration in the Mediterranean areas.

Through the definition of facilities and opportunities of co-living, co-learning and co-working, the research objective refers to the definition of responsive support models to create innovative urban ecosystems through an inter-scalar approach and a virtuous process of economic, social and environmental recovery and resilience. As regards design, a specific objective is the definition of new morpho-techno-typological models of student housing in terms of adaptability, environmental sustainability and building rehabilitation.

In this framework, the role of design goes beyond architecture and construction because when the building already exists and no modification is permitted, it's the object/product which is asked to give a contribution to the promotion of virtuous processes of regeneration, creating interconnected communities, activating services and promoting principles of sharing economy, ecological digital transition and sustainability, working in terms of physical and social flexibility and adaptability.

Under an economic point of view, the role of design is strongly compatible with the more general sustainable economic urban development strategies because innovative design solutions, aimed at creating innovative university residences in new urban ecosystems, can help to improve the students' social dimension and enhance their attractiveness and their integration to the city and its neighbourhood.

Under a social point of view, this innovative character of design is the starting point for the creation of micro-communities intended as social groups linked to collective living places in which people can enhance the existing relationships and create new ones.

In this phase of the research, the activities are addressed to detect study cases in which the contribution of design comes out as a recognizable and measurable element within all the parameters of intervention.

3. THE DESIGN DIMENSION OF STUDENT HOUSING

3.1 General framework

Within the aim of strengthening the quality of the university residences, both in terms of architectural construction and individual/collective space for users, the problems related to students' hospitality now take into account the role of furniture design, currently in a phase of renewed attribution of cultural value by users, by national and local public administrations as well as by productive companies' marketing strategies [1, 2].

The big increase in the number of graduate students which appears to have tripled in the last three generations and the radical change in the new university students' needs and requirements, with their rituals, habits, lifestyle, study methods and tools, make the actual university spaces not adequate anymore owing to their difficulty to be flexible, able to accommodate different functions and changes according to the rapid social transformations [3].

If in general the new economic, social and political conditions at a European level tend to promote new visions of urban planning and architectural interventions for university residences made of reuse of traditional building typologies, settlement methods' renewal, definition of new relationships with the urban context, application of innovative-sustainable strategies and new technological-constructive solutions, in the field of design the research seems to take on the contours of an almost autonomous path [4].

This path, on the one hand shows an interest for the valorisation of symbolic and figurative aspects, for the creation of situations of customizable domesticity in contrast with the homologation of standardized solutions, on the other it supports conditions of 'nomadism', recognizes a value in 'movement' and transience of the daily life rituals.

The criteria of modifiability, adaptability and flexibility, as well as the increasingly articulated ways in which university spaces and structures are used by the student population, today become extended to furnishing objects, artefacts and product-services for students, which increasingly start offering significant contributions in changing the student housing paradigms towards social, open and participatory models [5]: this affects the traditional typology of student housing (where individual spaces are rigidly separated from the common areas, these rationally distinguish according to their specific functions), whose models seem to have been definitively overcome in favor of systems made up of integrated nuclei in which common spaces, leisure areas, spaces for socialization are now fluid and interconnected [6,7].

3.2 Study cases

There are many university residences built in Europe since the 1990s, but few are completed with innovative reflections on furniture design (see, citing only the best known, the Studentenwohnhaus WIST in Graz by Klaus Kada (1987), the Antipodes I student residential building in Dijon by Herzog&De Meuron (1990), the residences for the Parma university campus by Massimo Carmassi (1996), the Residenza Caponnetto Novoli in Florence by C+S Associati (2002), the DUWO Student Housing in Delft by Mecanoo (2007), the student residences for the University of Limerick by Grafton Architects (2012), the 98 student accommodation in Paris by Lacaton&Vassal (2013), the Villa Val di Rose University Residence in Sesto Fiorentino by Ipostudio (2013), the Woodie Student Housing in Hamburg by Sauerbruch Hutton (2016), the expansion of the Milan College by Piuarch (2020), the Grand Morillon Student Residence in Geneva by Kengo Kuma (2021), the ESMA student accommodation in Montpellier by Mateo Arquitectura (2021), the Hainbase student residence in Hainholz-Hannover by Max Dudler (2021), etc.).

Although outside Europe, among the recent experiences which represent the wish to rebuild a union between design and student housing is the Simmons Hall at MIT in Boston by Steven Holl (2002), a university residence that stands right in front of the Alvar Aalto's Baker House across the Briggs Field. Inside, 350 beds are distributed in rooms of various types and sizes, articulated along a linear

Proceedings

ISSN: 2654-0460
ISBN: 978-618-5765-02-6

corridor reminiscent of Le Corbusier, which contain modular wooden furnishings (wardrobe, stool, bookcase, desk, bed, drawers) which can be customized in their configurations according to the students' needs through autonomous actions of assembly, movement, interlocking: paradigmatic in this sense is the bed which can be raised on two pillars which are then set up as a bookcase or wardrobe in order to get the desk in the space below. All the furnishings are also characterized by perforations with variable circumference, an aesthetic motif that unites them and aesthetically integrates them with the idea of porosity that characterizes the entire construction, subverting the traditional relationship between architecture and design, becoming itself a great design object.

Simmons Hall also inherits the idea of integrating private and common spaces as well as the conception of shared areas as places of socialization where activities strictly related to study are extended to hobbies (reading rooms, meeting rooms, multipurpose rooms) and leisure (game rooms, cafes, etc.) [8].

More measured and introspective is the residence of the Disentis Monastery Boarding School (Switzerland) by Gion Caminada, a building born from a 2001 competition project and built in 2004, conceived as a place of study and relationships and not as a mere dormitory (Figure 1).

Figure 1. Gion Caminada, Disentis Monastery Building School (www.reddit.com)

The residence, located in the city center between the main square and the Monastery, contains 31 accommodations (5 accommodations on the first floor + services, 8 accommodations on the second floor and 9 on the third and fourth floors) organized in three blocks of rooms on three sides of a square plan, with the fourth side left free to accommodate collective spaces facing outwards but each floor in a different direction.

Proceedings

In this case, architecture is the protagonist: rigidly respectful of the functional program and of the responsibility of its influence on the students' education, it's based on the balance between coexistence and privacy in which the rooms are conceived as small refuges while the spaces municipalities, marked by the presence of a central nucleus which, almost as if it were a large domestic hearth, is plastically articulated in such a way that it acts as a hinge between all the collective spaces on the various floors, these intended as domestic places of socialization.

The furnishing elements are integrated into the morphological plastic of architecture but still remain perfectly recognizable: the change of material, both in the accommodation and in the common spaces, underlines their presence compared to the adjacent structures but at the same time checks their adherence to the principle's formalities of the building and the idea of unity of the construction.

In more recent years, particularly interesting in terms of contribution to contemporary furniture design are the BaseCamp university residences whose interiors and furnishings are designed by the Berlin designer Werner Aisslinger in the Sølvgade (2016), Potsdam (2017), Lodz (2018), Lingby (2021) and Copenhagen-South Campus (2021) and whose furniture is produced in collaboration with companies such as Rolf Benz (tables), Cappellini (seats and armchairs), Wästberg (lamps), Kvadrat (curtains), B.Lux, Produx (furniture), Muuto (lamps) and Conmoto (stools), in addition to Thonet which produces and catalogs mod. n. 1140, an oak table with solid wood structure and veneered blockboard top.

Lingby BaseCamp is a new building designed by Lars Gitz, located within a large natural park, having an integrated structure which contains 639 student studios, 48 senior studios, 99 corporate apartments with interconnected multifunctional common spaces and shared, in which the architectural project is accompanied by a significant contribution of design both in terms of interior design and furnishing products, with an apparently radical aesthetic but in reality strongly linked to Scandinavian culture and design and with a notable typological multiplicity and variety of figurative languages (Figure 2). BaseCamp South Campus in Copenhagen is located in the old site of the Royal School of Library and Information Science of Copenhagen University; on the ground floor there are reception and access to the vertical distribution, in the basement the common areas (cinema, gym, laundry, study area and relaxation area) and on the first floor the rooms and study areas: all spaces which in the common areas present a large morphological and chromatic richness (although controlled by geometric patterns) and in the accommodation a greater sobriety and a more explicit relationship with the tradition of Danish design, especially referring to the figure of Arne Jacobsen (Figure 3).

An experience similar to that of BaseCamp, which in fact commissions designers to design the aesthetic line of all university residences, is the San Mamés University Residence in Bilbao by Greystar-Resa group, which in 2020 commissions the creative agency Masquespacio (Ana Milena Hernández Palacios and Christophe Penasse) to set up accommodation and common spaces.

In this case, the design interpretation is to create a community of spaces, enhancing the connective relationships and the environments' functional flexibility, maintaining a visual identity with a strong identifying character (through the use of materials and colors) and respecting the low-cost requirements of the furnishing elements' production (Figure 4).

4. DESIGN FOR STUDENT HOUSING AND REUSE OF EXISTING BUILDINGS

Within the more general issue of design of (and for) university residences, the specificity of interventions in existing buildings acquires a peculiar perspective in the interdisciplinary dialogue between urban planning, architectural construction and design, with all its trans-scalar connections. Much more than in the cases of new constructions, furniture design here takes on a renewed role of centrality, increasing its potential in reusing existing buildings and enhancing student spaces: small and non-modifiable spaces together with new instances linked to customization and integration are now opportunities to work with multifunctionality, transformability, adaptability and modularity so to overcome official and traditional functions and ways of use [9].

New compositions and configurations become necessary in private spaces but mainly in the collective spaces that, from being areas containing shared functions and then meeting spaces between students, they become now places of interaction between new kind of complex and heterogeneous groups of users (including people from the urban community) and between different uses no longer merely linked to university life: in relation to this, it's clear that the furnishings must necessarily acquire characteristics of flexibility, modification and configurability respecting the different socialization needs which can also change over time, as well as with respect to the opportunity of integrating the public dimension (intended as co-living, co-learning and co-working) with the private one [10].

This renewed sensibility and convergence between the issues related to the general topic of university student housing and those referring to the reuse of existing building (sometimes belonging to our historical-architectural heritage) has started producing some interesting design experiences on the international scene.

Among these, significant episodes are represented by the transformation of the former district prison of Aversa (Italy) into a student housing by Davide Vargas (2001) and the reuse of the Caserma Bligny in Savona (Italy), transformed between 2007 and 2011 into a university campus: inside of the latter,

specifically in the space of the former military canteen, the university residence for students and young researchers designed by Alfonso Femia is a case of reconversion of a pre-existing building with high historical-architectural value within which 42 beds have been created, recreational and service spaces, all equipped with economical and easy-to-maintain furnishing elements (Figure 5).

Figure 5. Alfonso Femia, Student Housing in Caserma Bligny, Savona (Italy), 2001 (www.atelierfemia.com)

A paradigmatic example within this design field of action is represented by the student housing at the Convento dei Crociferi in Venice: designed in 2010 by RMA Studio and built in 2013, the building has a capacity of 255 beds organized in single and double rooms in two main typologies (hotel and integrated nucleus) and common spaces partly for exclusive use and partly open to the external public. The furnishings, both in the accommodation and in the common areas, are all custom-made and constitute the true protagonists of the dialogue with the pre-existing structures, in a condition of balance, harmony and aesthetic quality (Figure 5).

Another experience is the intervention called Palestro 3 in Turin (2019), designed by DAP studio, in which a historical building from the mid-century XIX located in the center of the city is converted into a university residence: the project is interesting because it represents an attempt at integration both between architecture and design and between privacy and the public dimension; the seven floors of the building (including the attic and the basement) contain 19 apartments (4 units per floor plus 3 in the attic) for 82 students and common spaces connected together by an open and flexible connective system, made up of social spaces, gyms, study rooms, relaxation areas and various service areas.

Figure 4. RMA Studio, Student Housing at Convento dei Crociferi, Venice, 2010. Common spaces (www.rmastudio.it)

5. CONCLUSIONS

Looking at the general tendencies of the contemporary approaches in designing university housing complexes, both in new constructions and already existing building, considering the characteristics of the most recent experiences in the field, we can say that the role of the furniture, whose design can no longer be borrowed from hospital or school equipment, in general shows three main important aspects: first of all, the ability to respond to various and changing needs, behaviors and rituals of students by "qualitatively" reviewing consolidated regulatory models; secondly, the capacity to recognize a value to the symbolic and figurative dimension of the spaces, as well as the character of "domesticity" in contrast with the anonymity of the standardized solutions; thirdly, the acceptance of the conditions of nomadism, people's movement and temporariness in contrast with the traditional tendencies to sedentary living [11].

More specifically, and transversally with respect to the models cited and the thematic categories identified, furnishing elements today seem to be called upon to take on common specific characteristics which mainly concern: for design and production, the processes of formal and productive simplification and cost-effectiveness; for use, reversibility, lightness, flexibility, autonomy in assembly and disassembly actions; for the life-cycle management, the easy maintainability and recyclability of materials and components [12].

But as anticipated in the introduction, there are two other dimensions which can be now considered fundamental in the new design practices: energy sustainability and social participation.

Energy sustainability expresses a renewed environmental sensibility and a new form of dialogue with construction technology, architecture and furniture: in the student housing this can be translated into a new integrated relationship between containment of construction costs and needs of energy efficiency according to the students' daily needs, balancing sociality and privacy. In the furniture, it means processes of formal and productive simplification, reversibility, lightness and flexibility of use, autonomy in assembly and disassembly actions, cost-effectiveness, easy maintainability and recyclability of materials and components.

Social participation constitutes a new aspect of the university residences, intercepted through design strategies aimed at defining composition and configuration scenarios that are always new and

transversal with respect to the official functions of the environments (whether private or public) and through self-construction experiences. Participation, social interaction, creative discussion, sharing of knowledge are elements of a new awareness of the potential of the student housing as a place of opportunity for the urban regeneration strategies, especially in a geographic context such as Italy or any other Mediterranean country where the university system still acts as a 'social lift' and where the presence of the students in the urban contexts is always the starting point for the promotion of social development, especially in peripheral and marginal neighborhoods.

Extended abstract

Cohesion Policy contributes to strengthening economic, social and territorial cohesion in the European Union and it is oriented towards sectoral thematic areas and administrative borders (articles 174 to 178 of the Treaty on the Functioning of the European Union). It aims to correct imbalances between countries, regions and cities. The current paper focuses on the implementation of integrated sustainable strategies in European territories during the programming period 2014-2020. The available new mechanisms named the Integrated Territorial Investment (ITI) and the Community-Led Local Development (CLLD) for the urban, peri-urban, rural areas have been implemented also in Greek territories during the programming period 2014-2020. Selected territories used these tools in designing and implementing community-led local development strategies to meet their own needs and be implemented the selected interventions by using one Fund or by combining several funds. The proposed bottom up approach should be combined with a multilevel approach in order to gain the city the necessary technical assistance for attracting relevant funds. A multi-level governance model for the implementation of the proposed actions and local actors' involvement are essential parts of an integrated strategy and create an added value in the implemented actions. The multi-funded objective of the strategies also emphasizes the integrated value of the mechanism.

Adding to the literature overview we have conducted, we followed semi-structured interviews (n = 15) with the involved responders to be part in the designing and/or in the implementation of an ITI in the Greek territory. The involved persons are executives from local authorities, executives from managing authorities, experts. All interviews were guided by a set of questions related to themes identified through an extensive literature review. The participants contribute with their knowledge and their expertise to draw valuable conclusions about the research question we have set about the ability of Greek cities to implement integrated development plans and the possibilities for integrated planning in the future. The conclusions of this qualitative research assist us to combine its finding with the literature research we have made and to compose our findings but also our research proposals.

Extended abstract

The role of universities in local growth and development is undeniable. In addition to being a beacon of research and education, universities contribute to the economic and social development of a city and the wider region. Moreover, universities are agents of innovation and change. It is widely accepted that universities are actors that can contribute to all the pillars of sustainable development (social, economic, environmental) and develop actions to achieve almost all the Sustainable Development Goals of the 2030 Agenda (not only Goal 4/Quality Education).

This paper examines the relationship and interconnection between a sustainable city and a sustainable university. It investigates whether a university's commitment to sustainable development and the implementation of a strategy to achieve sustainable development goals affect the sustainable development of the city.

However, the interplay between universities and cities raises complex questions: How do the sustainability strategies of universities interact with those of the surrounding urban environment? Under what conditions do collaborative efforts between universities and cities flourish, and how does the scale of the city impact this dynamic? Can universities function as catalysts for accelerating the transition towards urban sustainability?

This paper deals with the interaction between the city and the university. More specifically, it examines European cities with large percentage of student population, which in terms of population correspond to small-medium sized urban areas (e.g. Bologna, Cork, Elche). In framework, the research investigates the existence of such a dipole in Greece.

The paper offers a comprehensive exploration of the symbiotic relationship between universities and cities, shedding light on the opportunities and challenges inherent in the collaborative sustainability pathways for a more resilient and inclusive urban future.

Exploring Sustainability at the Nexus of Architectural Design Education, Campus Life, and Artificial Intelligence: A Case Study of Atılım University

S. Çınar

Ph.D., Department of Architecture, Atılım University, Türkiye

E-mail: sinem.cinar@atilim.edu.tr, Tel: +90 532 646 1383

Extended abstract

This study delves into the intersection of architectural design education, university campus life, and artificial intelligence within the sustainability framework. The importance of university campuses in terms of sustainability is increasingly recognized as they can serve as exemplary models and contribute to the sustainability of cities and communities. In this context, the campus of Atılım University shares many characteristics and common problems with the overall urban fabric of Ankara. Issues such as transportation to and within the campus being predominantly by private vehicles, prioritization of vehicle transportation and parking over pedestrian circulation and usage, limited social interaction spaces, restricted use of open areas, and inadequacies in the design of indoor-outdoor spatial relationships reflect the general structural challenges of Ankara. Therefore, the transformation of campuses in terms of sustainability presents not only an opportunity for campuses themselves but also for cities at large. Another focal point of this study is the analysis of university campuses by students enrolled in architectural design education from the perspective of sustainability principles. This analysis provides students with an opportunity to observe spaces with a more critical eye, thereby deepening their understanding of architectural design. To achieve this goal, an examination of a project assigned in the 3rd-year architectural studio at Atılım University will be presented. Another characteristic of this project is that students conduct their work and design processes within an artificial intelligence environment. The employment of artificial intelligence within architectural education is emerging as a significant research and discussion topic in both academic and professional spheres. Questions such as how the use of artificial intelligence can influence students' creative thinking abilities, and how design processes can evolve are central to these discussions. In architectural education, students should be equipped with the abilities to understand, utilize, and effectively integrate these new technologies into their designs, while also considering the intellectual and ethical dimensions of this field. In this project, it was important for students to endeavor to enhance sustainability in their campuses within an artificial intelligence environment, as it prompted them to begin considering the design and thinking tools of this environment. The dialogue fostered by student proposals at the nexus of architectural education, artificial intelligence, and urban design fosters innovative sustainability solutions. This exploration aims to catalyze sustainable practices in architectural design education and contribute to the shaping of the profession.

Extended abstract

This paper presents a comprehensive examination of Carrying Capacity (CC) as a vital instrument in spatial planning and sustainability assessments. It explores the evolution of the CC concept, emphasizing its crucial role in linking sustainable development with climate neutrality. Central to this study is the development of an innovative quantitative methodology that employs weighted indicators to accurately assess CC, highlighting its significance in mitigating human impacts on vulnerable island ecosystems.

The application of CC, particularly in diverse spatial systems such as regions, cities, and settlements, faces significant challenges. These include difficulties in quantitatively defining CC, the need for data often unavailable at localized spatial levels, and the reliance on statistical estimates due to the lack of comprehensive environmental data. Moreover, determining a spatial system's sustainability level requires integrating complex indicators and data across environmental, social, and economic categories. The introduced methodology advances a forward-weighted approach to indicators, facilitating the calculation of overall deviation from CC through a nuanced combination of weighted deviation percentages. This approach is complemented by the Factor Hierarchy Process, which acknowledges the structural levels of factors, enhancing the assessment's accuracy. Acknowledging that each spatial system possesses unique characteristics, the paper outlines a methodological approach structured into five stages: defining the spatial system for CC assessment, identifying critical parameters and determining necessary data, calculating weighted deviation percentages, diagnosing sustainability levels and proposing restoration actions, and prioritizing projects for sustainability transition and monitoring implementation. For effective CC assessment, the paper advocates using recent data, sourced from certified providers or based on secondary processing, ensuring that methodologies for estimating indicators and their thresholds adhere to scientifically accepted methods and relevant legislation. This ensures the reliability of the sustainability assessment process.

By integrating environmental and socio-economic dimensions, this paper proposes a holistic approach to urban planning that incorporates CC into planning and development policies. It aims to redefine the integration of sustainability and climate neutrality into spatial planning, setting a new standard for future research and policy development. This contribution significantly advances the discourse on sustainable and climate-neutral development in urban planning, offering a pragmatic framework for assessing and enhancing the sustainability of spatial systems.

Coastal cities and marine natural and technological disasters: the role of spatial planning and the Greek experience and practice

T. Kostopoulou¹, M. Papageorgiou²

Abstract

Over the last decades, there has been an increased concern about the disasters caused by both natural phenomena and technological accidents occurring both in the land and in the marine space. Undoubtedly, these disasters are becoming more frequent and intense nowadays, also because of climate change, which is accelerated by the constant human pressure on the environment, implicating a higher risk for humans and especially those residing in the coastal zone.

Spatial planning is thought to be crucial to prevention management, acting as a way against uncertainty in handling dangers. The discussion of risk analysis and management integration in terrestrial spatial planning started relatively recently and has slowly been more and more considered in spatial planning processes over the years. However, it is still not consistent. This inconsistency is even more intense regarding the way that terrestrial spatial planning integrates the impacts of marine natural and technological disasters, especially affecting the coastal zone and urbanized areas. In Greece, integration of risk management and impacts deriving from marine natural and technological disasters is of major importance, given the intense coastal and insular nature of the country and extensive urbanization taking place along the coastal zone.

The research conducted for this paper, regards a literature review about the integration of prevention and management of natural/technological disasters in terrestrial spatial planning, with an emphasis on work addressing interactions from the sea and especially from marine natural and technological disasters on the land. The research includes extensive research in scientific search engines, using relevant keywords in a combined way, for more targeted results. In the second part, the paper focuses on the case of Greece and on how the Greek spatial planning system integrates risk analysis, especially for risk deriving from the sea, affecting the land and more specifically the coastal zone and cities.

The literature review reveals limited research specifically on coastal hazards and shows that spatial planning is also not extensively researched as a tool for dealing with coastal hazards. The paper further concludes that Greece's spatial planning system has significantly improved risk integration over the years and presents some proposals about its enhancement in the planning process.

Keywords: spatial planning; natural disasters; technological disasters; coastal cities; Greece

1. INTRODUCTION: THE COASTAL ZONE AND CITIES VAULNERABILITY TO HAZARDS

In the past years, the concern about disasters caused by either natural phenomena or technological accidents has been growing. In addition, climate change, being also the result of constant human pressures to the environment, implicates a higher risk of those phenomena occurring.

Natural phenomena such as earthquakes, floods, hurricanes etc. are classified as natural hazards and occur because nature tries to restore the balance. A balance that is lost not only by natural endogenous and exogenous forces but also by the increased anthropogenic pressures to the environment [1].

ISSN: 2654-0460

ISBN: 978-618-5765-02-6

Simultaneously, technological disasters are also a point of concern, especially nowadays with the accelerating advancement of technology. These disasters happen when an accident occurs in human activities and there is poor management of the technology involved (e.g. nuclear accidents, explosions etc.) [1].

The coastal zone is prone to several hazards that can trigger a disaster, mainly due to the interactions between the sea and the land and the degree of interrelation between them. Therefore, there is a very high level of influence from hazards coming from the sea alongside the coastal interface. Natural hazards events such as flooding and erosion coming from extreme weather events or sea level rise can pose a significant threat to not only the coasts but also the infrastructure and communities that have been developed along the shore. According to the United Nations [2] about half of the number of cities having a population above 1 million (513 cities in 2015), were located on or near the coast and with the expectancy of population density growth by 25% by 2050 [3]. Cities consist of complex interactions between multiple systems (e.g. housing and business infrastructures, water and energy networks and supply chains and transportation networks), agents (e.g. businesses, households and individuals) and institutes that influence the agents and systems [4, 5]. Thus, a disruption caused by the occurrence of these events imposes a significant pressure on all the aspects of the cities. Consequently, major coastal cities worldwide are emphasizing the need to make their essential infrastructure systems more resilient to disasters [6].

Coastal cities are frequently impacted by natural disasters and climate change, including storms, floods, landslides, and riverbank erosion. Urban areas, particularly those in sensitive locations, are very vulnerable, with their impact and risk varying based on their geographical location and landscape [7]. For this paper an essential note to make is about the distinction between the term “coastal hazards” and “hazards in the coastal zone”. The former refers to hazards happening at sea that affect the coast due to their interaction and the latter includes all the hazards that can affect the coastal zone regardless if they occur from its interaction with the sea (e.g. landslide, heatwave etc.) [4]. Coastal hazards can include either natural (e.g. coastal flooding, erosion, sea level rise) or technological ones (e.g. oil spill risk). As Tonmoy et al. [4] describes coastal hazards like flooding, erosion, and sea level rise have varying impacts on coastal systems. Flooding during storms or cyclones is immediate, while sea level rise has a slow onset and longer-term effects. Erosion can be rapid or moderate-term, depending on long-shore sediment transport. Seasonal erosion occurs due to sediment deficit and erosion, while long-term erosion increases with rising sea levels. These hazards propagate and have varying time scales, affecting coastal systems in different ways.

For this reason, prevention before the occurrence of a disaster as well as reaction and mitigation measures after the event is key. Spatial planning is a diverse process that: a. contains vision and as such can be used as a tool to plan for future trends and b. can mitigate effects of a disaster after the event.

Considering the above, this paper regards a literature review about the integration of prevention and management of natural/technological disasters in terrestrial spatial planning, with an emphasis on work addressing interactions from the sea and especially from marine natural and technological disasters on the land. The research includes extensive research in scientific search engines, using relevant keywords in a combined way, for more targeted results. In the second part, the paper focuses on the case of Greece and on how the Greek spatial planning system integrates risk analysis, especially for risk deriving from the sea, affecting the land and more specifically the coastal zone and cities. The paper aims to contribute to the discussion of disaster prevention and management in spatial planning, focusing in coastal cities and their protection against the impacts deriving from marine natural and technological disasters.

2. COASTAL ZONE AND CITIES VULNERABILITY TO NATURAL AND TECHNOLOGICAL DISASTERS: THE ROLE OF SPATIAL PLANNING

The discussion of risk analysis and management integration in spatial planning started relatively recently and has slowly been more and more considered in planning processes over the years. But despite extensive discussions on multi-hazard assessment and risk analysis, their inclusion in spatial planning is still inconsistent. Nevertheless, spatial planning is thought to be crucial to risk prevention/management, acting as a way against uncertainty in handling dangers.

From its nature (contains decision-making about if and how certain areas will be used and developed), spatial planning can influence the vulnerability of spaces in natural and technological hazards [8], therefore continuing efforts in integrating hazard related topics into the planning process have been discussed.

Natural hazard mitigation started being incorporated in spatial planning of developed countries from the 1980's, which led to a worldwide approach [9]. But the integration of hazards and risk mitigation in planning became more actively implemented in the mid-1990's. Around the same time, these considerations were starting to appear in several EU bodies (ESDP 1999, CEMAT 2003, SUD 2003) and the European Commission stressed that an integrated approach on risk management is required at the EU level [9, 10, 11]. Today there are several funds and policies that support the EU member-states through the EU Civil Protection Mechanism by providing knowledge and information about disaster risks (Disaster Risk Management Knowledge Centre, Union Civil Protection Knowledge Network).

With climate change affecting the frequency and magnitude of a range of climate-related hazards [12] more efforts are being made to prevent and/or mitigate their consequences. Climate change effects and the probability of different natural and technological hazards happening in an area can be predicted based on scenarios which can help the planning process [13]. But even though multi-hazard assessment and risk analysis have been broadly discussed, their presence in spatial planning is still not sufficiently considered [14, 15]. Nonetheless, spatial planning can play an important role in emergency management acting as a medium for the uncertainty in dealing with hazards or even mitigating past mistakes [16].

It is evident that it is essential for the coastal communities to become hazard-resilient by being prepared for the occurrence of these threats as well as developing the ability to withstand the impacts and recover. Spatial planning can play an important role to this and especially to the protection of coastal cities from hazards. An example of how spatial planning can contribute to the protection of coastal cities comes from a study from World Bank [17] titled "Climate change adaptation and natural disasters preparedness in the coastal cities of North Africa". This study indicates that adequate urban planning and land-use policies will be crucial in lowering Alexandria's vulnerability to risks, damages, and losses. The 2030 Greater Alexandria Master Plan, which is presently being developed, provides a great chance to incorporate the study's urban risk assessment findings and refocus the city's future expansion away from the regions identified as most at danger. The Master Plan should also guide future urban growth, set city boundaries, and provide a land-use program with standards for densities, building heights, and open space ratios that take into account future climate possibilities.

In the following section, the paper further examines the relationship between spatial planning and natural and technological disasters occurring from the sea, by performing a literature review.

3. LITERATURE REVIEW: METHODOLOGY AND RESULTS

A literature review with the goal to highlight the connection and evolution of the integration of natural and technological disasters in spatial planning was performed. The search included all literature up to April 2023 and the methodology included the search of a string that each time included the term "spatial planning" in combination with one of the terms "natural disaster", "technological disaster",

“risk management” and “risk analysis”. The search engines selected for the research were Web of Science, JSTOR, Scopus and IEEE in order for the results to be peer reviewed.

The search was done in three consecutive steps that included the identification of the literature, the screening of the results and the final selection of the literature that was eligible for the bibliometric analysis. The identification stage began with the search of the key words in the aforementioned search engines. The remaining records were screened with the intention of retaining only records that were explicitly relevant to spatial planning. In order to achieve this the literature that was kept had to fall into one of the three categories:

- Spatial planning and natural/technological disaster: records that link spatial planning with a specific disaster either in its prevention or management.
- Spatial planning and risk management/analysis tools: records that describe risk management/analysis tools that can be used in the spatial planning process.
- Spatial planning and climate change: records that link spatial planning and climate change effects were considered relevant as several disasters (e.g. flooding) could be the aftermath of the effects of climate change.

The final and total number of records that were relevant was 392. In order to uncover the connection and further data about the “coastal hazards” and spatial planning a further screening of these results was performed by keeping only the records that were referring specifically to a form of “coastal hazard”. Out of the total records, 39 of them (10% of the findings) were examining disasters that are related to the sea. Tsunamis were the most repetitive one, with sea level rise coming to a close second. There were also records about flooding and erosion as well as one about oil spill and sand extraction. The geographical scope, even though diverse, revealed a recurring country as a study case and that was Indonesia. That can be linked to the most recurring disaster (tsunami) as Indonesia, because of its place and geomorphological characteristics, is an area that has a very high risk of the specific disaster occurring.

Furthermore, the literature that was analyzed had two main themes: a. records that were focusing on risk management and prediction tools (e.g. modelling, GIS tools, quantitative vulnerability assessment) that can be used by spatial planning and b. records that presented how spatial planning was or could be used in the case of an emergency. The mass amount of records fell into the first category showing that the way that spatial planning can be used as a tool in this kind of emergencies is not fully explored.

To further examine the way disasters are being handled and incorporated into the spatial planning system of a specific country, Greece which is a highly insular and coastal country was selected.

4. THE GREEK SPATIAL PLANNING SYSTEM AND DISASTERS

4.1 The vulnerability of Greece in disasters and the existing Risk management and policy framework

The Mediterranean is affected by a number of natural hazards with the most common including forest fires, volcanic eruptions, earthquakes and landslides [8, 18]. At the same time the Mediterranean Sea is one of the busiest marine spaces (Plan Bleu), making it very susceptible to technological accidents. Greece being a part of the Mediterranean and being a highly insular and coastal country, with a strong and growing marine economy is very vulnerable to such events.

Risk management in Greece is under the authority of the Ministry of Climate Crisis and Civil Protection. The Ministry has developed a number of policy frameworks that correspond to the management of different natural and technological disasters. These frameworks are extensive documents with detailed information on how to react in each disaster in order to protect the general population in the occurrence of such events. More specifically they include guidelines that must be

followed which the Regions and the Municipalities should take into account when producing their local risk policy documents. Furthermore, they specify the role and actions of each public body (e.g. Ministries) during or after the event.

These risk policy frameworks, corresponding to either level (national, regional or local) are referring and focusing on a disaster. Specific guidelines for coastal hazards do not exist but are rather mentioned and included in one of the other categories of risks (e.g. tsunami guidelines are included in the earthquake risk policy document).

4.2 Risk management integration in the Greek local spatial plans

The extensive coastline of Greece which is more than 15,000 kilometers and makes up for over 25% of the Mediterranean's total is home to more than 70% of the country's inhabitants with an intense residential development with nine of the country's biggest cities having been built on the coast [19]. Therefore, urban development and especially alongside the coast when planned should take into consideration the appropriate measures for risk prevention/management from potential hazards.

Considering the structure of the spatial planning system of Greece, the proper planning scale to address risk prevention/management of the coastal cities from potential hazards, is the local one. At the local scale, local spatial plans constitute land-use plans. These plans are responsible for the determination of the development profile, the residential characteristics and the elements of the natural and built environment of each area. The drafting of a land-use plan is based on technical Specifications, i.e. a guiding document describing how to develop the Local Spatial Plan, (e.g. the chapters and their contents, specific elements that should be taken into account when planning etc.). The drafting is also based on another document, defining the planning standards at the urban district level.

Going back to the importance of risk prevention/management integration in spatial planning below is presented how and if this element (risk prevention/management) is incorporated in the Greek Local Spatial Plans and more specifically on the technical specifications and the planning standard documents.

Risk prevention/management reference in the technical specifications of the land use-plans

Until 2021, land use plans were drafted following the technical specifications described in the National Gazette 209/Δ/09-04-2000. In this document there are only a few and very abstract remarks about civil protection and risk management that are only referring to “data collection about potential floods, landslides and fires for the protection of the planning area”, a “geological research for earthquake prevention” and to “develop infrastructure of safety and protection”. The new technical specifications introduced in 2021 (by National Gazette 3545/B/03-08-2021) designate a specific chapter that is dedicated to “Risks and Civil Protection” as is its title. The subchapters cover a great number of hazards that need to be described and recorded depending on the risk that they bestow to the area. This also includes the designation of zones of vulnerability and zones of safety. A risk assessment for the planning of the correct designation of land uses as well as regulations for the traffic network in the event of a disaster and the protection of critical infrastructure. All the above should be accompanied by the corresponding maps and are being recorded during the analysis phase of the plan.

Risk prevention/management reference in the planning standards for the urban district units included in the land use-plans

Up to now, the urban planning standards to be adopted at the urban district level, were described in the National Gazette 285/Δ/05-03-2004. This document did not provide many guidelines in the inclusion of risk in the planning process with the only mention being about the suitability of the land (regarding its mechanical strength) for potential seismic activity. This document and standards were very recently replaced by National Gazette 200/Δ/01-04-2024.

The new document on the urban planning standards is more comprehensive and contains a chapter dedicated to civil protection. In this chapter guidelines are being given about the standards that should be followed regarding: places of refuge (their capacity and their optimal placement), traffic regulations in case of an emergency, protection of critical infrastructure of local and European level. It is evident that the evolution of the policy documents that accompany the Local Spatial Plans in Greece is remarkable as the documents currently in place that guide the creation of these plans have an extensive reference to the potential risks and the protection of the areas that are being planned. And even though the older guidelines had some abstract references in risks like earthquakes, floods and fires, the current ones take one step further and include other types of hazards like salination, coastal erosion, sea level rise and technological accidents.

5. CONCLUSIONS

Natural hazards and technological accidents can cause a number of disasters and are occurring more frequently adding in the factor of climate change. Coastal cities are at the forefront of these risks and they need a targeted management for their protection and enhancement of their resilience.

Dealing with the immediate/rapid management of the consequences of the risks is linked to spatial predictions and adaptations. In that light spatial planning, can be used in the prevention of risks as well as means of restoration after the event.

The literature review revealed that the research being done about dealing with disasters coming directly from the sea is rather limited as it corresponds to a small percentage (10%) of the literature. Furthermore, the literature review also showed that spatial planning is not yet extensively researched as a tool in dealing with hazards coming directly from the sea. As such proposals about future research include both to turn the focus on coastal hazards (as most of the population is living alongside the coast) and how to further utilize spatial planning as a tool for the enhancement of protection and resilience of the coast and especially the coastal cities.

Regarding the case of Greece, as of now the Greek spatial planning system took a huge leap in the way that integrates risk in the planning process. The new guidelines for the development of the Local Spatial Plans take into consideration a number of disasters that include coastal hazards (e.g. salination, erosion, sea level rise) but there is still little to no mention about technological disasters coming from accidents occurring at sea.

Considering the above, it is evident that spatial planning in Greece has margins to further integrate and assist in the risk management of coastal cities. This could be achieved by:

1. Incorporating further coastal hazards, including technological ones, in both the planning standards and the technical specifications of the land-use plans.
2. Creating specifics in the planning standards when the plan is about a coastal urban district, so its special characteristics are taken into account during the process.
3. Connecting more efficiently the civil protection guidelines with the spatial planning process in order to have a more organized and cohesive approach.
4. Updating frequently the hazard studies, as well as their standards, incorporated in the land-use plans, as the rapid changes happening at the environment could make them outdated fast. This could help to ensure that the knowledge about these hazards is relevant and the planning for these areas can be adjusted accordingly and timely.

In conclusion, even though most disasters (natural or technological) are impossible to avoid and predict, it is natural that the efforts are and should be focused on the minimization of impacts and consequences especially in the coastal cities, with the adding hazards coming from the sea and the fact that the majority of the population calls them home.

Quantifying and Visualizing Rebalancing Activity in Mobility on Demand Systems from Publicly Available Trip and Accumulation Data: The Case of Boston's Bike Sharing System

D. Papanikolaou

Assistant Professor, School of Architecture,
National University of Athens, Greece

Extended abstract

Widely considered as emerging modes of sustainable transport, bike sharing systems (BSS) utilize shared bikes, parking docks, and advanced information technology, allowing users to move from point to point on demand while cities to gain back urban land. With a global fleet of 9M bikes in more than 2K cities and a \$9B industry (2023) doubling biannually, BSS remain one of the most rapidly growing sectors of urban mobility. Despite their popularity, opinions on BSS performance, environmental impact, and costs are controversial, with some studies claiming that sharing reduces congestion and parking requirements and improves air quality while other studies showing that motorized VKT (vehicle-kilometres travelled) and carbon emissions increase due to rebalancing operations in combination with low mode substitution from private automobiles.

Quantifying rebalancing costs of BSS is essential to properly assess costs, benefits and potential of shared mobility. According to the Institute for Transportation and Development Policy (ITDP) Bikeshare Planning Guide, rebalancing costs in the BSS industry range between \$0.86-\$4.80 per bike trip while capital costs range between \$1,810-\$5,000 per infrastructure unit (one bike and two docks). While reported costs give a gross estimate of the scale of costs in BSS, they depend on context-specific factors like local labour cost, accounting practices, travel patterns, rebalancing strategies, system infrastructure, and, importantly, they include variable sunk costs of excessive unused infrastructure capacity that, collectively, make these figures lacking a common basis for comparative analysis. In order to compare cost of service between BSS objectively, rebalancing work must be computed from trip data, costs must be expressed as resources requirements rather than monetarily and normalized by the same unit of output rather than expressed as whole sums. Unfortunately, computing rebalancing costs from data has methodological challenges as operators do not publicly share rebalancing data but only user trip and station accumulation data.

In this paper, I introduce a novel method to accurately compute rebalancing work in BSS from publicly available trip and station accumulation data. The method computes departure-arrival time series data from user trip data, then it computes user accumulation data from the departure-arrival time series data, and, finally, it subtracts the resulting accumulation data from the reported accumulation data to obtain the rebalancing work from operators. The method accurately identifies concurrent arrivals and departures that often occur in the same timestep that appear as zero changes in the reported accumulation dataset. I evaluate the method with a synthetic trip dataset and demonstrate the approach in a case study of Boston's bike sharing system. I conclude with the significance of the approach, application areas for urban planners and researchers of smart urban mobility systems and future steps.

Abstract

Climate change indiscriminately damages both tangible and intangible heritage. The global lack of adequate protection for cultural heritage exacerbates this issue due to the absence of long-term strategies. This research advocates for actionable research to inform policymakers on cultural heritage management issues. The paper presents the 'Luxor Living Lab' a live project on sustainable heritage preservation in Luxor a partnership between the University of Lincoln (UK) and Ain Shams University (Egypt), funded by the British Council, offers insights into cultural heritage preservation and digital management in Luxor, Egypt. Despite Luxor's diverse and layered heritage, including Pharaonic, Roman, Coptic Christian, and early Islamic sites, the focus on Pharaonic heritage neglects other narratives, echoing international concerns. To address this, Luxor Living Lab prioritises digital preservation and community-centric policy development in multi-layered cultural heritage management. Through site analysis and qualitative surveys with the local community, this paper offers recommendations which will inform sustainable cultural heritage management and policy development. These recommendations transcend Luxor's context, offering globally relevant strategies aligned with UN Sustainable Development Goals, particularly SDG3, SDG4, SDG5, SDG 11, SDG 16, and SDG 17.

Keywords: *sustainable heritage; multi-layered heritage; digital heritage documentation; heritage preservation; living history*

1. INTRODUCTION

Within Luxor's heritage exist multiple layers of historical narratives, including Pharaonic, Coptic, Islamic, Roman, Greek, and living histories (1). Globally, there is a consensus that cultural heritage management plans should be developed using community-centric methodologies to exhibit the layered truths of the local heritage (2-4). In doing so, the cultural heritage management plans will be resilient, sustainable, and well-suited to their local context, as they consider the needs, concerns, and ideas of the local population (5). The Comprehensive Development Plan for the City of Luxor, implemented in 1996 (6), should be revised to reflect the layered heritage narratives, as currently the plans and policies are not inclusive of multi-layered heritage. This paper employs primary research through a community-centric participatory action methodology utilising a questionnaire with the local community, to collect their concerns and ideas, and an interdisciplinary co-creative workshop, to mould the community's ideas into actionable recommendations. Thus, this paper contributes to international ideas of the interconnectedness between cultural heritage management, community engagement, and sustainability (3-5), to produce transformative recommendations which are relevant not only within Luxor's specific context, but which are also adaptable to global heritage contexts.

2. LUXOR'S LAYERED HERITAGE

Luxor is home to multiple layers of heritage, including Pharaonic, Coptic, Islamic, Roman, Greek, and living histories. This layered heritage is evident in the built heritage of Luxor, as well as the cultural practices. For example, Luxor Temple, originally a place of Pharaonic worship, is also home to an Islamic Mosque, thus emphasising its enduring significance as a place of worship in multiple heritage contexts. In the Pharaonic Valley of the Kings, marks on the wall indicate Qurnawi occupation (7), highlighting the location as not only a place of rest but a place of residence.

Often, these narratives come into conflict, with some being nearly erased, as cultural heritage management systems are not reflective of the layered context in Luxor. Centrally, Pharaonic heritage is preserved above all other layers due to the associated increase in heritage tourism in Egypt nationally, as well as Luxor on a local scale. However, this cultural heritage management approach does not reflect the heritage of the community and creates a false sense of unique closeness to Pharaonic heritage by erasing other layers of heritage through targeted preservation. Pellini, Marconetto, and Ghenco (8) describe targeted preservation in the Valley of the Kings, wherein non-Pharaonic layers of heritage are

erased as if dirty, as an “illusion, a trick, that leads us to think that such a space has always been and still is exclusively a Pharaonic tomb” (8), despite evidence of use of residence for Qurnawi (7) and Jinns (9) populations, and use as a monastery (11). Hence, scholars (7-10) call for heritage professionals in Luxor, and globally, to consider heritage more critically as a social and cultural construct, and to “understand that our choices of how to approach and treat this space determine what this space will be” (8). This paper critically engages with their discussions, to provide transformative recommendations, developed through community-centric research design, to encourage critical employment of multi-layered heritage in Luxor and globally.

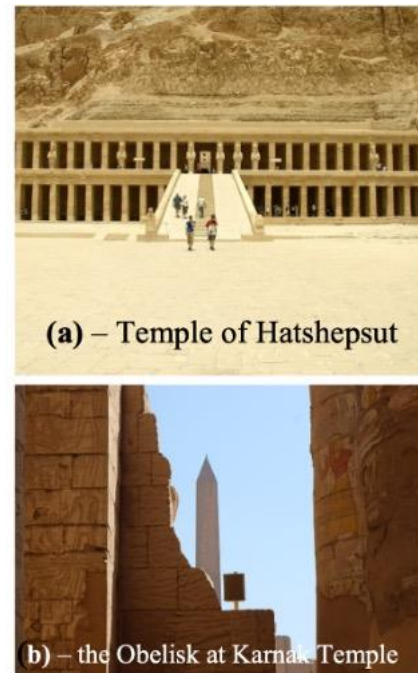

Figure 1 – Heritage sites in Luxor, source: www.luxorlivinglab.com

2.2. Sustainable Cultural Heritage: A Comprehensive Development Plan for the City of Luxor (CDCL)

Cultural heritage is widely discussed as a facilitator of sustainability (11-18). It is recognised for its ability to “shape a different future for all” (19) through emphasising unity, compassion, and understanding (15). Whilst safeguarding ‘heritage’ is emphasised as an end goal itself (20), cultural heritage’s potential contribution to all Sustainable Development Goals (16) has been noted in literature as “the only way to ensure a human-centred, inclusive and equitable development” (21).

To holistically integrate culture into sustainable development, the cultural heritage framework must be community centric (22, 23), to ensure plans fit the specific cultural context of the community to provide sustainable longevity (24). Researchers have critiqued current cultural heritage strategies in Luxor for prioritising the demands of heritage tourism over the needs of the local populace (22, 24, 25). Specifically, the Comprehensive Development Plan for the City of Luxor (CDCL), implemented in 1996 (6), has been highlighted for its failure to incorporate the perspectives and interests of the local community, instead centring on heritage tourism (22, 25). This is reflected in the market developments focusing on El Souq, the tourist market, and neglecting the Local Market where the community spend their time. Furthermore, the restoration of the Avenue of the Sphinx required the demolishing of a large

residential and commercial area, including religious buildings (25). This has resulted in practical issues for the local community who can no longer easily pass through, which negatively impacts their daily lives (25). This raises the question to ask whether the transformation to a larger 'open museum' displaying the life of the people and the community would have made a better approach for the regeneration undertaken. This exemplifies broader issues within the cultural heritage management systems in Luxor, wherein plans revolve around Pharaonic heritage narratives to meet the demands of heritage tourism, neglecting the diverse layers of heritage valued by the local community, such as Coptic, Roman, Greek, and Islamic (8). Additionally, the plans fail to capture the dynamic living histories and movements of the local community (22).

In response to these contextual challenges, and to invite critical engagement with Luxor's layered heritage, the research presented in this paper proposes a framework for community-centric cultural heritage management systems to ensure resilience and sustainability (1), as has been identified as suitable for Luxor by Amara (22). Hence, this paper aligns with literature which highlights the centrality of an integrated framework bridging sustainability and cultural heritage (26-29).

3. METHODOLOGY

This study employed an inductive mixed-methods research framework (30, 31), featuring an intensive case study analysis of Luxor's layered heritage (32), a semi-structured questionnaire (33, 34), and two co-creative workshops to gather original community-centric data. The questionnaire developed by the authors of this paper, which was distributed by a team of researchers from Ain Shams University who collected questionnaire responses at the Luxor Heritage Day and the Local Market in Arabic. There were 100 questionnaires distributed, 84 returned and 73 responses were completed, with all being valid to use in analysis, resulting in a sample of 73. The questionnaire was tailored for participatory action research, which facilitated community input on focused themes, echoing the principles of citizen science (35, 36). From the collection of these concerns and ideas of the community in Luxor, the international workshops served as platforms for co-creation of regeneration plans to develop community-centric recommendations, aligning with the methodologies employed in similar cultural heritage studies aiming to address power imbalances (37-39).

Aligned with the primary objective of developing sustainable community-centric cultural heritage management systems in Luxor, Egypt (25), the methodology facilitated community articulation of concerns and ideas and fostered solution-oriented discussions. Additionally, the Luxor case study provided contextual understanding, informing comprehensive community-centric recommendations. Grounded in the transformative research paradigm (40, 41), the methodology aimed to address power imbalances, employing a dynamic mixed methods approach responsive to community needs. The research design was guided by the United Nations' Sustainable Development Goals (SDGs) (42) specifically SDG 3 Good Health and Well-being, SDG 4 Quality Education, SDG 5 Gender Equality, SDG 11 Sustainable Cities and Communities, SDG 16 Peace, Justice and Strong Institutions, SDG 17 Partnerships for the Goals (42). This ensures the recommendations remain relevant to both local and global cultural heritage contexts. From this, the Integrated Capitals and Goals Framework for Holistic Sustainable Development (ICGF) emerged (Figure 2), which positions culture at the centre of sustainable development.

Figure 2 – the Integrated Capitals and Goals Framework for Holistic Sustainable Development (ICGF), developed by the Luxor Living Lab team (1)

The semi-structured questionnaire enabled dynamic engagement through open-ended questions, structured around key themes, and disseminated in community gathering places. Data analysis employed line-by-line coding to identify emerging themes and develop recommendations collaboratively with stakeholders. From this, the international interdisciplinary workshops generated solution-based action points.

Thus, the methodology facilitated continuous reflection on community concerns, generating actionable solutions which support sustainable cultural heritage management in line with the UN SDGs.

4. RESULTS, DISCUSSIONS, AND IMPLICATIONS

From the results of the questionnaire and case study, themes centring on the importance of involving the local community in heritage projects emerged. The results are discussed alongside relevant literature, to develop holistic recommendations which are adaptable and adoptable in global heritage contexts.

4.1. Involvement in Cultural Heritage Projects

The majority of respondents acknowledge the significant role of heritage tourism in shaping Luxor's identity and economy, citing benefits like job opportunities, economic growth, and a unified cultural identity (Figure 3a). Some of the comments of the respondents are below:

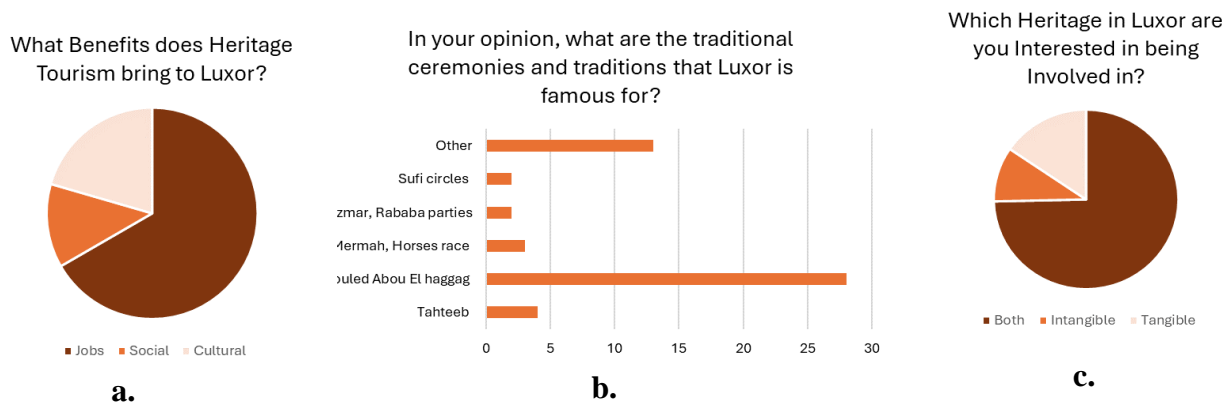

Figure 3. Questionnaire responses

“Provides them with an identity, character, and job opportunities”.

“The profession of most of the Luxor population depends mainly on the cultural heritage”.

“Economic and cultural benefits”

However, most participants expressed a desire to be more involved in cultural heritage projects, particularly those in the public sector. This aligns with existing literature emphasising community involvement in sustainable heritage management (43 - 45). The questionnaire findings highlight the community's recognition of cultural heritage's importance and their eagerness to contribute to its preservation and management for sustainable development.

4.2. Heritage Tourism Insights

The study highlighted that the respondents recognise the economic, cultural, and social benefits of heritage tourism in Luxor (Figure 3c), and comments of respondents as below:

“The presence of tourism increases financial resources, which helps the state to develop other sectors in the city”.

“It is of great benefit to them in terms of providing job opportunities and introducing the civilisation and culture of the community”.

“Multiplicity of foreign languages”

However, concerns were raised about time constraints imposed by tourism companies on visitors, affecting local businesses negatively. Scholars highlight the challenge of balancing authentic heritage experiences with tourist preferences (46). Respondents suggest improving marketing efforts to promote Luxor as a cultural destination, aligning with literature advocating for community-driven marketing to preserve authentic heritage experiences (47) which aligns with one of the respondents' comments:

"The products are of high quality and only need more local and international marketing".

4.3. Engagement with Traditional Practices

Additionally, respondents exhibit pride in various traditional practices, linking modern customs to ancient festivals and rituals (Figure 1b):

"All of them are customs and legacies that make us feel the old beautiful time".

Their appreciation reflects literature emphasising the empowering effect of authentic intangible heritage experiences on local communities (48). Engaging with traditional practices in heritage tourism in Luxor, Egypt not only preserves cultural identity but also fosters inclusivity and sustainable development, aligning with global sustainability goals (42).

4.4. Built Heritage and Layered Intangible Cultural Value

Respondents value Luxor's tangible heritage sites for their historical significance and layered cultural experiences that is reflected in comments such as:

"Carry the fragrance of the Ancient Egyptian history to this day".

The respondents recognised that the preservation of these sites as a testimony of their intangible heritage elements is crucial for maintaining the authenticity of Luxor's cultural identity:

"Both support the local community with traditional and handicraft industries. The Nubian House teaches girls these crafts".

However, challenges exist in balancing preservation efforts, particularly concerning the dominance of Pharaonic heritage over other layers (8). Addressing these challenges requires a community-centric approach to cultural heritage management (22).

4.5. The Luxor Market Area

Respondents highlighted the multi-sensory experience of the Luxor Market, emphasising its importance in creating meaningful connections with cultural heritage:

"The smell of incense"

"The smell of spices and the voice of the sellers"

"Aromatic scent"

Responses created a lively image of the market, such as:

"Some of the popular folklore songs and the old traditional songs of Luxor, the sound of sellers and tourists and the banging of dominoes on the table whilst playing, the smell of the area".

Here, findings contribute to heritage literature which suggests that enhancing multi-sensory experiences through digital technologies can improve visitor engagement and accessibility (49). While respondents appreciate recent developments in the market area:

“The path is shaded, and it gave a nice mood”.

“I became able to walk in the market; before the developments, walking was very difficult”.

they express a desire for inclusive development that extends to the local market, reflecting the importance of community-centred approaches to heritage tourism development in Luxor (45, 50):

“It has become a tourist destination, but it needs to be extended to the rest of the internal streets”.

“Developing the rest of the path (the Local Market), which is the same path, so that tourists enter the rest of the path (the Local Market) to see the way the locals live”.

This is important where the locals want to share their own personal experience with the tourists, they are not liking the divide and segregation that the planning of the Market currently provides.

5. CONCLUSIONS AND RECOMMENDATIONS

From the concerns and ideas of Luxor’s local community, which emerged from the questionnaire responses, the international interdisciplinary workshops were an opportunity for stakeholders to co-create suitable recommendations which form a framework. Stakeholders included architects, urban planners, heritage professionals, Egyptian government officials, local people, and students. Hence, the recommendations were developed from broad experiences which enhances their global adaptability and suitability. The workshop participants also had the opportunity to learn from each other and adapt their own practices and behaviours through engaging with the recommendations, to contribute to a more sustainable future for cultural heritage management within their own professional contexts. The flexibility and adaptability of the recommendations highlight the significant impact of the Luxor Living Lab (www.luxorlivinglab.com). These recommendations are suitable for various heritage contexts, supporting the global development of sustainable cultural heritage management systems that consider multi-layered heritage narratives. The recommendations include:

1. Recognising heritage as a catalyst for sustainable development and urban regeneration: this forms the initial phase of the proposed framework. Specifically, it suggests including cultural heritage into development plans to enhance sustainable development, aligning with existing global literature (14, 16, 23). This recommendation includes:
 - a. Shifting the perception of heritage as solely historical by engaging with communities to recognise their practices as valuable assets for driving sustainable development and community well-being in the present.
 - b. Promoting interdisciplinary collaboration to facilitate idea exchange and authentic policy development based on diverse experiences.
2. Engaging in community-centric heritage designs: workshop participants recognised the local community's strong interest in their cultural heritage in Luxor and emphasised the importance of community-centric cultural heritage systems for sustainable development, aligning with literature which emphasises the importance of community-centric cultural heritage design (26, 44, 45). The recommendation includes:

- a. Organising informal discussions between local communities and government bodies to foster transparent communication and prioritise the community's voice in cultural heritage management policies.
 - b. Promoting local events celebrating authentic heritage, designed by the community, to enhance social well-being and sustainable cultural heritage practices, to ensure long-term sustainability by incorporating local needs and traditions.
 - c. Continue the regeneration of the Local Market Souq to merge seamlessly with the Tourist Souq sharing the people experience.
3. Harnessing digital technologies to ensure cohesive heritage: Workshop participants suggested integrating digital technologies into cultural heritage to present layered heritage narratives from questionnaire responses. This addresses key issues in Luxor's heritage preservation highlighted by Pellini, Marconetto, and Ghenco (8), emphasising Pharaonic heritage over others, as seen in Luxor Temple's layers of Pharaonic, Coptic, and Islamic heritage. This recommendation includes:
- a. Using 3D scanning in exhibition spaces to showcase the site's original layers before conservation efforts altered them.
 - b. Building a database which the local community can engage with capturing and documenting their narratives and untold elder community stories to digitally preserve the layers of heritage they value.
 - c.

In conclusion, these recommendations are applicable to varied heritage contexts, and contribute to the development of a globally cohesive and sustainable community-centric cultural heritage management system which is reflective of distinctive layers of heritage. Hence, the study presented in this paper is not only relevant to the specific heritage context of Luxor, Egypt, and the surrounding community, but also has significance to international heritage contexts.

Acknowledgements

The research presented in this paper was led by the University of Lincoln in partnership with Ain Shams University in Egypt, and the support of Research funding from the British Council Going Global Partnerships 21/22, Grant ID 871135538. We are grateful for the financial assistance provided by the British Council, which enabled us to undertake this study and contribute to the advancement of knowledge in the digital documentation and preservation of layers of Heritage within cities with specific reference to Luxor's Heritage.

We would like to express our sincere appreciation to the British Council for their commitment to fostering international collaboration and research partnerships, as well as their dedication to promoting excellence in education and knowledge exchange worldwide. We would also like to acknowledge the support of our colleagues at Ain Shams University, Egypt, a team led by Professor Mohamed Salheen, for their role in distributing the questionnaire, and collecting and translating responses.

Abstract

Climate change is a global challenge, which is evidenced by increasing flooding globally. Current infrastructure techniques, that are defensive, in nature, exacerbate these issues, as they render communities unable to respond to environmental challenges. Hence, globally, communities are not resilient to climate change. This paper focuses on ‘Designing with Water’ and proposes integrating heritage water management techniques into modern infrastructure design to offer sustainable flood solutions, to not only live with water, but exist in unity. The paper is informed by the United Nation’s Sustainable Development Goals and comparative case study analysis, to generate recommendations for how to ‘Design with Water’ in the context of climate crisis, between: Hull, UK; the Historic Sukhothai Kingdom, Thailand; Wuhan, China. From this, the study advocates for an integrative community-based approach, which prioritises holistic, natural heritage solutions through understanding heritage wisdom and knowledge, to strengthen water resources and enhance urban resilience globally. The recommendations are adaptable in diverse architectural contexts, fostering an international shift towards integrating heritage management practices into modern developments.

Keywords: *heritage preservation, flood management; city resilience; community tradition; Design with Water*

1. INTRODUCTION

Water is central to human existence, it enables survival whilst also, on a global scale, being a historic place of ritual and shared community experiences [1, 2]. Despite this intrinsic connection between communities and water, the relationship is increasingly fraught with environmental disasters, such as flooding and drought [3]. As these natural disasters increase globally with climate change, cities and communities attempt to keep water out through designing defensive water infrastructure. However, this is not sustainable, and does not facilitate resilience within communities. Instead, this paper proposes that to achieve resilience, sustainability, and foster community well-being it is necessary to rethink water infrastructure by considering the heritage connection to water and learning from and adapting heritage knowledge and wisdom to modern water infrastructure [4, 5]. This project and the emerging recommendations are vital for addressing such pressing issues related to water, sustainable development, resilience, and regeneration, and is part of a wider initiative to integrate heritage into sustainable urban regeneration [5]. ‘Designing with Water’ is integral to developing innovative solutions to global issues of climate change, flooding, and drought [6], as architects, urban designers, engineers, and other stakeholders who are a part of water infrastructure design must integrate water into community lives to facilitate resilience and community wellbeing [7]. This project is a Creative Catalyst for Change (CCC), as it develops capabilities, addresses climate change challenges, broadens local community access, promotes community health and wellbeing, and fosters innovation through the project recommendations. The recommendations and guidelines outlined in this paper, informed by three comparative case studies in the UK, Thailand, and China, are adaptable to global contexts, to facilitate global resilience and climate change adaptation through ‘Designing with Water’.

2. HERITAGE WATER INFRASTRUCTURE DESIGN

In the current context of climate change causing increased flooding, drought, and issues of water access [8], it is imperative that water systems are reflective of the specific context of the community they serve to be usable [9]. To achieve this, engineers, architects, urban planners, and other stakeholders involved in water infrastructure design must conduct necessary evaluations of the local contexts, such as through case studies, interviews, and focus groups, to ensure the designs are usable and loveable for the community, as well as fitting with the local day-to-day and traditional needs [10]. In doing so, the resilience of the community will be enhanced through considered and reflective water infrastructure designs, as well as ensuring that infrastructure is suitable to its specific context to facilitate long-term sustainability [11].

Cultural heritage is discussed in literature as a vehicle in water infrastructure design for this necessary community resilience and sustainability, as, through analysing the past, designers can develop infrastructure of the future [12]. It is imperative to maintain human connection with water, by engaging heritage knowledge and infrastructure to design with water instead of against it [13]. Through engaging with heritage knowledge and analysing heritage water systems, engineers, urban planners, and architects can adapt heritage aspects to modern infrastructure designs [14, 15], thus ensuring the design is reflective of the specific heritage context and needs of the local community, whilst also exchanging knowledge between the past, present and future [16, 17]. In the Historic Town of Sukhothai, the hydraulic system, a present-day United Nations-protected heritage site, was the centre of civilisation as it worked with and adapted to the flood and drought seasons [18]. Hence, in the context of climate change, it is important to utilise heritage knowledge and designs to adapt to floods and droughts which are fitting to the local environment to ensure local resilience and sustainability by welcoming water into communities in positive ways. This approach is represented in the hydraulic system of the Historic Town of Sukhothai, which, instead of adopting a defensive global one-size fits-all approach to keep water out, integrates water into community life.

3. CULTURE'S CENTRALITY IN SUSTAINABLE INFRASTRUCTURE DESIGN

Since the adoption of the 2030 Agenda for Sustainable Development and its 17 Sustainable Development Goals (SDGs) [19] by world leaders, scholarly discourse has increasingly highlighted cultural heritage as a unifying force of these objectives [20]. Through engaging cultural heritage in design processes, infrastructure will be more sustainable as it will be reflective of the local communities' day-to-day lives and traditions, thus will be suitable and useable within its local context [21, 22]. This literature underscores the pivotal significance of culture in the pursuit of resilience and sustainability at both global and local levels [23, 24]. Notably, Bokova, a former UNESCO Director-General, states that cultural heritage embodies a "vision for peace and mutual respect" endowed with a unique "power to change the minds of women and men, and to shape a different future for all" [25]. Conceptualising heritage as a "people-centred process", Erlewein emphasises the necessity of incorporating cultural heritage into infrastructure development to ensure sustainability and useability [26]. Additionally, in 2020, the British Council commissioned a case study evaluation of its cultural heritage projects, to draw attention culture as the unifying 'missing pillar' of the SDGs [27]. By positioning culture at the heart of development policies, literature posits that infrastructure will definitively be human-centred, inclusive, resilient, and equitable [28]. Within this recent literature development, researchers highlight that whilst the safeguarding of culture is an objective itself, adopting cultural mindsets and initiatives in infrastructure development contributes directly to all the SDGs, such as safe and sustainable cities, decent work and economic growth, and reduced inequalities [29].

Despite this consensus of the unifying power of cultural heritage in sustainable infrastructure development, some researchers have stated their concerns. Centrally, their concerns lie in the degree of applicability of cultural heritage, due to its inherent ambiguity and complexity [30]. To overcome such

The DWW framework is informed by the United Nation’s Sustainable Development Goals (SDGs) [41], to further enrich the global applicability of the ‘Designing with Water’ recommendations [Figure 1]. By engaging with the ‘Designing with Water Framework’ and methodology, architects, urban planners, engineers, and other stakeholders in water infrastructure planning can ensure they integrate heritage design and community traditions into their designs, to enhance the usability, liveability, resilience, and sustainability of water infrastructure.

5. CROSS CASE STUDY ANALYSIS

This section presents three international case studies—Hull in the UK, the Sukhothai Kingdom in Thailand, and Wuhan Yangtze Riverfront Park in China—each present unique yet interconnected narratives about the importance of designing with water to achieve resilience and sustainability in the face of climate change. These cases highlight the significance of integrating cultural heritage with innovative water management strategies to enhance community resilience and well-being.

5.1 Case Study One – Hull, UK

Kingston upon Hull, known as ‘Hull’ (Figure 2), is one of the UK’s most vulnerable cities to flooding [42 – 44]. With climate change, this vulnerability has worsened; this is representative of the global situation, wherein communities are being more detrimentally impacted than ever by the effects of climate change, in droughts and floods [45]. Over 90% of the city is below high-tide level, with 95-98% of dwellings and businesses at risk of flooding [46]. Hull’s heritage and future are both centred around water, due to its proud maritime history [47]. This case study emphasises the global need to reimagine water infrastructure, due to international issues of flooding and drought due to climate change, to ‘Design with Water’ instead of developing one-size fits all defensive structures.

Figure 2. Kingston upon Hull, the city lies on the bank of the Humber Estuary (Arup, 2019).

Following the devastating floods of 2007, and the tidal surge of December 2013, a partnership between Hull City Council, Yorkshire Water, East Riding of Yorkshire Council, the Environment Agency, and the University of Hull, known as *Living with Water*, was developed to address the issue of flooding [47]. The central aim of *Living with Water* is to build community resilience through building “understanding across Hull and the East Riding about the threats and opportunities water brings to our region” [48]. As part of this, Arup completed a case study of Hull, to develop recommendations and findings to develop global resilient urban water systems through adaptation to different contexts [48]. From this, Arup identified some core findings which would guide sustainable water infrastructure development, and ensure the development of resilient communities:

1. Innovative funding and investment, targeted at local resilience measures and nature-based solutions.
2. Promoting water sensitive developments that promote health and wellbeing
3. Transparent and accountable government which engages with stakeholders and the local community.

To build upon this, in line with the ‘Designing with Water Framework’ (Figure 1), the findings of this project, developed from comparative case study analysis, integrate global heritage knowledge into these

recommendations. The recommendations presented by Arup [48], in the context of Hull, can all be enhanced through engaging with the cultural heritage of the local community and centring on the UN SDGs, to not only live with water, but to design infrastructure with flooding and drought in mind whilst maintaining quality of life. From this, the ‘Designing with Water’ recommendations present heritage knowledge and infrastructure as the unifying authority underpinning sustainable water infrastructure design, in the context of climate crisis [49]. The centrality of cultural heritage to achieving sustainability and resilience in contexts such as Hull, where flooding is a severe problem, is increasingly recognised in literature [39]. Hence, it is vital that architects, urban designers, engineers, and other stakeholders in water infrastructure design are guided by the ‘Designing with Water’ framework and recommendations presented in this paper.

5.2. Case study two – The Sukhothai Kingdom, Thailand

The Historic Town of Sukhothai is, along with its Associated Historic Towns, a protected UNESCO World Heritage Site [50]. The heritage site is home to an innovative and resilient hydraulic system which controls water resources (Figure 3), to both irrigate the fields during periods of drought and protect the community from floods [51]. The three towns which represent the site were linked by a water highway, known as the

Figure 3. The Sukhothai Kingdom water infrastructure, (a) © OUR PLACE The World Heritage Collection, (b) illustrated by W. Pittungnapoo, 2021

Thanon Phra Ruang, which emphasises the unifying nature of water within communities [52]. The water management system is visible in the Sukhothai Kingdom, and, instead of working against water in a defensive manner, the infrastructure invites water in to be used by the community. This adaptive use is central to resilience [39] and emphasises the suitability of ‘Designing with Water’ to encouraging community resilience.

The water management systems were, and continue to be, related to the rituals and wellbeing of the community [52]. Hence, this case study emphasises the importance of ‘Designing with Water’ to ensure community wellbeing when facing environmental challenges, such as the flooding and drought that Thailand has historically experienced [53]. In the 21st-century, in the context of climate change increasing floods and droughts internationally, the extensive heritage knowledge and ability to live with water evident in case studies such as the Sukhothai Kingdom must be adopted and adapted on a global scale to develop resilient and sustainable living.

Figure 4. (a) the promenade not during a flood, (b) the promenade during a flood.

Source: <https://www.sasaki.com/projects/wuhan-yangtze-riverfront-park/>

5.3. Case Study Three – Wuhan Yangtze Riverfront Park
Sasaki is an interdisciplinary architecture, planning, and design firm located in the USA and China. They embrace the importance of learning from cultural heritage to inform future visions of sustainability and resilience [54]. This includes water infrastructure design, such as their engagement in the Wuhan Yangtze Riverfront Park [55]. Known as a ‘the city of a hundred lakes’, Wuhan has historically had flooding problems [56]. Despite this, the floods represent an important part of Wuhan’s heritage, as they created fertile land for the early settlers [57], hence, ‘Designing with Water’ is imperative to community wellbeing, resilience, and cultural heritage integration.

Sasaki has developed plans in the Wuhan Yangtze Riverfront Park to integrate water, heritage, and community living, whilst reducing the negative impacts of flooding, through uniting the river, city, and the people. As part of this, Sasaki has proposed a series of sinuous secondary streams in the mudflats, to provide safe corridors for kayaking and passages

for aquatic wildlife [55], to instil a sense of community, resilience, as well as supporting biodiversity. The promenade is also designed with floods in mind, and its connection to the park means it can remain in constant use (Figure 4a and 4b).

Sasaki’s design considers the local heritage of Wuhan, in the integration of the Yangtze River Museum (Figure 5), as well as the wellbeing of the community, to ‘Design with Water’. Furthermore, the designs are reminiscent of the irrigation systems in the Sukhothai Kingdom, as their use is adaptable through the seasons, thus enhancing community resilience. Hence, due to this resilience, sustainability, and heritage mindfulness, the Yangtze Riverfront Park meets the criteria of the ‘Designing with Water Framework’ (Figure 1). This case study is an example of sustainable water infrastructure design successes, following the guidelines of the ‘Designing with Water Framework’ (Figure 1).

<https://www.sasaki.com/projects/wuhan-yangtze-riverfront-park/>

▪ DISCUSSION

By drawing parallels with the Sukhothai Kingdom's irrigation systems, the Wuhan project exemplifies the principles of the "Designing with Water Framework" [Figure 1] as a response to the international issue of climate crisis-induced flooding which is evidenced in Hull. Hence, the Sasaki project in Wuhan is an example of the potential of heritage water infrastructure to act as a solution to global issues of climate change. The inclusion of the Yangtze River Museum further embeds cultural heritage into the park's design, fostering a sense of identity and continuity for the community. This project demonstrates that modern water infrastructure can be both resilient and sustainable when it respects and integrates local heritage and environmental dynamics.

6.1 Significance and Impact

Collectively, these case studies illustrate that designing with water—embracing its challenges and opportunities—is essential for building resilient and sustainable communities in the era of climate change. The integration of cultural heritage into water management not only preserves historical knowledge but also enhances community engagement and well-being. These examples (Table 1) provide a blueprint for other regions facing similar environmental challenges, emphasising that adaptive, culturally informed, and ecologically sensitive water infrastructure is crucial for future urban resilience.

Table 1: Key parameters of the three case studies, highlighting their significance, global impact, and applicability.

<i>Parameter</i>	<i>Hull, UK</i>	<i>Sukhothai Kingdom, Thailand</i>	<i>Wuhan Yangtze Riverfront Park, China</i>
<i>Climate Challenges</i>	High risk of flooding due to low elevation, tidal surges, and climate change.	Historically experienced both drought and flooding.	Frequent flooding, historically created fertile land but now poses a significant risk.
<i>Cultural Heritage Integration</i>	Maritime history central to community identity and resilience strategies.	Ancient hydraulic system integrated into cultural and ritual practices, showcasing adaptive use of water.	Design incorporates local heritage, including the Yangtze River Museum, and fosters a connection between the river, city, and people.
<i>Community Engagement</i>	"Living With Water" partnership involves local councils, water companies, the Environment Agency, and the University of Hull to build community resilience and understanding of water-related threats and opportunities.	Water management systems historically linked to community rituals and well-being, highlighting the social importance of water infrastructure.	Sasaki's design involves community spaces and recreational areas that are functional even during floods, promoting community engagement and resilience.
<i>Water Management Strategies</i>	Focus on local resilience measures, nature-based solutions, and promoting water-sensitive developments.	Adaptive hydraulic system that manages water for irrigation during droughts and protects against floods, demonstrating efficient water resource management.	Creation of sinuous secondary streams for safe recreational use and aquatic wildlife passage, along with adaptive promenades and multifunctional spaces that remain usable during floods.
<i>Sustainability Goals</i>	Recommendations align with the UN SDGs, aiming to improve quality of life while addressing flooding and drought.	Demonstrates sustainable living through historical adaptive practices, suggesting these can be adopted globally to enhance resilience.	Project meets "Designing with Water Framework" criteria, enhancing sustainability and resilience through cultural heritage integration and ecological considerations.
<i>Innovative Aspects</i>	Emphasis on innovative funding, transparent governance, and stakeholder engagement to drive sustainable water infrastructure development.	Historical example of an adaptive and resilient water management system that can inform modern practices.	Combines heritage, ecological, and community aspects to create multifunctional spaces that enhance resilience and sustainability.
<i>Key Outcomes</i>	Development of resilient communities through heritage-informed, sustainable water infrastructure design.	Highlights the global applicability of adaptive water management systems that are integrated with cultural heritage for increased resilience.	Demonstrates successful integration of water, heritage, and community living, serving as a model for other regions to follow in designing resilient and sustainable urban water infrastructure.
<i>Significance and Global Impact</i>	Emphasises the importance of community-centred approaches and heritage integration in developing global resilient urban water systems. Sets a precedent for other flood-prone areas worldwide.	Provides a historical model for sustainable water management that can be adapted globally, showing the enduring relevance of heritage knowledge in contemporary resilience strategies.	Illustrates the effective fusion of cultural heritage, ecological sensitivity, and modern urban design, offering a replicable framework for cities worldwide to enhance resilience and sustainability in the face of climate change.

By learning from these diverse contexts, urban designers, architects, and policymakers can develop water management strategies that are globally relevant yet locally appropriate. The "Designing with Water Framework" [Figure 1] offers a comprehensive approach that integrates heritage, sustainability, and community resilience, demonstrating that innovative water infrastructure design can be a powerful tool in addressing the global climate crisis.

▪ CONCLUSIONS AND RECOMMENDATIONS

This research concludes that through the ‘Designing with Water’ concept presented in this paper, communities can exist in unity with their land, traditions, and infrastructure, to ensure liveability, usability, resilience, and sustainability. By designing water infrastructure with such guidance and the application of the ‘Designing with Water Framework’ (figure 1), architects, urban planners, and engineers can improve community wellbeing whilst ensuring their designs are resilient and sustainable in the current climate crisis context. The comparative analysis presented in Table 1 not only compares the three case studies but also highlights their significance, global impact, and applicability, emphasising how each example contributes to a broader understanding of sustainable and resilient water infrastructure design. This paper emphasises, in line with current literature (18, 39), the necessity of designing with rather than against water, by integrating and adapting heritage knowledge into modern infrastructure designs. This can be achieved through the following recommendations:

1. Engage with the ‘Designing with Water Framework’ to ensure that designs are reflective of community needs in specific local contexts, as public engagement is a clear example of community enrichment and liveability.
 - a. Within this, a fundamental understanding and consideration of people, as opposed to infrastructure, is necessary to ensure that the designs are liveable and loveable for the local community.
 - b. To achieve this, a cohesive case study of local needs, heritage, and traditions must be established through questionnaires and observations to address placemaking at a deep and local level.
 - c. As part of this, project managers, engineers, architects, and urban planners involved in water infrastructure design must include local stakeholders in discussions on infrastructure changes in workshops, making sure to invite a variety of sectors and people to ensure a wide range of views and perspectives.
 - d. This connection to the local community also prevents projects from becoming obsolete in the future, as it will work more efficiently with the land as it is informed by local experts, thus ensuring that projects are sustainable in the long-term.
2. When undertaking a heritage project, it is imperative to take an interdisciplinary approach to uncover heritage practices that may apply to modern practice, such as the hydraulic systems in the Sukhothai Kingdom which can inform modern infrastructure design as a response to the worsening floods of climate change.
3. Develop resilient projects and communities which work with floods rather than focusing solely on prevention strategies, such as the stilt houses found in Thai villages.
 - a. By following the ‘Designing with Water’ framework, stakeholders in water infrastructure design can reimagine flood threats as an opportunity to improve water resources, placemaking, and community resilience in the context of global climate change.
4. When undertaking an infrastructure project, project managers, engineers, architects, and urban planners must speak to local people to gauge their cultural knowledge so that the project is suitable for their lifestyles and landscape. This also prevents projects from becoming obsolete in the future, as it will work more efficiently with the land as it is informed by local experts, thus ensuring that projects are sustainable in the long-term.

The urban-rural distinction in the analysis of the depopulation of inner areas - The “Sicani area” in south Sicily

A. Gana-Nuñez

PhD student in Architecture, Arts and Planning, Dipartimento di Architettura,
Università degli Studi di Palermo, Italy

Corresponding author: E-mail: alejandrogana@unipa.it, Tel +39 3889785648

Extended abstract

Italy's negative demographic balance worsened following the 2008 recession, with a discernible migration flow from the southern to the northern regions. Sicily is a representative case in this regard, but it also exhibits significant internal variation on a local and regional level that is scarcely covered in the currently accessible literature. Furthermore, most of the current analyses on depopulation in Italy are conducted at the regional or municipal level, producing intersections with other variables such as the degree of rurality, which, either using the Degurba-Eurostat typology or the Italian Rural Development Plan (PSR) one, show significant association between rurality and depopulation. This contribution seeks to complement the available analyses on depopulation by addressing the increasing urban-rural contradiction, by incorporating intra-communal demographic data to distinguish between demographic variation in small inhabited centres and in sparsely populated or uninhabited areas. The comparison will be drawn from census data from the 2011 and 2021 series. Specifically, data will be analysed for the inner area “Sicani” in the south of Sicily, part of the SNAI, which has decreased its population by 19% between 2001 and 2021.

Keywords: depopulation; inner periphery; mediterranean area; local development; rurality.

▪ INTRODUCTION

Nowadays, rural areas are a scenario of demographic processes that have triggered a rural depopulation widespread in the developed regions, which is linked to structural transformations in agricultural production and new trajectories of population distribution and urbanisation (Johnson and Lichter, 2019). More specifically, in Italy, depopulation of agricultural and mountain areas is now taking place, indeed between 2001 and 2020 the population of inner areas varied by -1.4% (ISTAT, 2022). Additionally, national demographics show a diversity between Centre-North and South: while in the Centre-North the phenomenon seems to be confined to rather restricted areas, in the South and in the Islands it still affects vast territories (Del Panta and Detti, 2019).

A second element, characteristic of inner areas, is the low population density. According to ISTAT studies (2022, 4), population density in the three categories of peripherality of the National Strategy for Internal Areas (SNAI) decreases significantly as the distance from the centres of supply of public services increases, with ‘intermediate’ areas having a density of 106.3 inhabitants/km² ‘peripheral’ areas 58.6 inhabitants/km² and ultra-peripheral areas 32.3 inhabitants/km².

Faced with this problematic scenario, in 2014 the implementation of the SNAI began, which is the Italian policy to focus resources and target actions driven by public agencies to improve the conditions of areas particularly affected by territorial marginality, which in general have low access to essential services and mobility, but which are also characterised by higher rurality levels.

This article proposes a methodology for using available census data in the analysis of the demographic trends of inner and rural areas, more specifically at an intra-municipal scale, in order to introduce the rural-urban distinction in the description of depopulation, paying particular attention to one of the inner areas prioritised by SNAI: the Sicani area in Sicily. Although most of the current analytical models use the municipal scale, it can potentially mask demographic movements within the territory, in particular

in municipalities where the inhabited area occupies only a fraction of the surface; a situation that does not occur in the case of large and intermediate cities.

For this purpose, a conceptual reflection is developed that introduces the concepts of ‘inner areas’ and ‘inner peripheries’, also in relation to rurality. The SNAI is described as the Italian policy that deals with these subjects, and then the phenomenon of depopulation and low population density that inner areas face is briefly discussed. Subsequently, some references are then exposed with regard to the criteria currently applied for measuring peripherality, rurality and depopulation, and the implications of measurement at the intramunicipal scale

The paper then conducts a quantitative descriptive analysis, taking as context the Sicilian region, and subsequently focused on the Sicani area at an intramunicipal scale. The analyses developed aim to establish the relevance of demographic studies at this scale, which consider the rural-urban distinction to adequately contextualize the urbanization processes that underlie depopulation, which may be obscured in demographic analyses at the municipal scale. This study is based on the hypothesis that, by separately analysing the inhabited areas and the rural or scattered housing areas, within each municipality, we can identify distinctive trends between these settlement types.

▪ THEORETICAL FRAMEWORK

The concept of inner periphery has gained significant attention in recent decades in both academic discourse and the field of public development policies. This contrasts with the geographical notion of the periphery, which is based on the distinction of areas far from the centres of economic activity from the centres of concentration. The characterization offered by Copus, Mantino and Noguera (2017) of peripherality as "relational", is being interpreted considering a range of social and economic processes that underpin relationships across regions that have unequal economical and power conditions. From this angle, "inner peripherality" denotes a disconnection from "external" and global networks, and this is manifested in a lower level of development, diminished access to services and lower quality of life when compared to neighbouring regions.

In Italy, the term “internal areas” refers to a specific category of internal periphery, distinguished by limited access to public services, education, health care and transportation (De Toni et al. 2020). This concept has gained significant prominence since the National Strategy for Inner Areas (SNAI) was introduced in 2014. Aligned with the European Cohesion Policy and the place-based approach, this policy seeks to intervene in peripheral areas to counter the dynamics of marginalisation that affect them and focuses its actions on groups of municipalities aiming to foster the establishment of collaborative governances at the local level and their interaction with regional and national spheres. The policy proposes a categorisation of the peripheral character of Italian municipalities into 6 categories: pole, intermunicipal pole, belt areas, intermediate, peripheral and ultraperipheral. The ultimate purpose of the SNAI is to counteract the depopulation dynamics affecting inner areas throughout the national territory and more broadly rural areas (De Rubertis, 2019). This process is characterized as "growing urban-rural polarisation", with a particular focus on the Mediterranean regions of Europe.

Currently, the main instrument used in Italy for measuring territorial marginality in relation to inner and rural areas is the SNAI peripherality level, based on the distance of each municipality from public services and mobility networks, and used in various studies to evaluate different demographic dynamics in these territories (ISTAT, 2022; Vendemmia, Pucci and Beria, 2022). On the other hand, the main instrument at European level for measuring rurality is Eurostat's Degree of urbanization (Degurba), based on population density to distinguish between ‘cities’, ‘towns and suburbs’ and ‘rural areas’. This is one of the instruments used by De Rubertis (2019) to include the dimension of rurality in the measurement of depopulation in Italy.

The two instruments mentioned use the municipal scale for their analysis, which provides a fundamental information base to distinguish between territories. However, this approach can generate some

distortions, as it incorporates inhabited areas and rural or non-inhabited areas for each unit of analysis. This scale of analysis is also not very accurate for assessing the rural-urban distinction, as there are municipalities that coincide with urban centres while in many others, urban settlements cover only a minimal part of the municipal territory. The need to develop demographic analyses at the intra-municipal scale is highlighted by Canales and Canales (2012) to study depopulation associated with deagrarianization processes in Chile at the level of ‘settlements’, and Castillo-Rivero et al. (2021), who examines rural depopulation in Mexico at the local scale, specifically at the level of ‘villages’ or settlements with fewer than 2,500 inhabitants.

▪ **METHODOLOGY**

Census localities are a territorial delimitation that groups together a specific type of space use. Indeed, the ISTAT census defines four main categories of localities, which can be distinguished within a municipal area:

1. Town centres;
2. Settlements (nucleus);
3. Productive locality;
4. Scattered buildings.

Using localities as a reference for a demographic analysis allows the observation of contrasts within municipalities, particularly between inhabited settlements and areas of scattered houses, which is useful in the study of rural and inner areas.

In the first stage of the article, the regional data for the variables ‘periphericity SNAI’ and Eurostat ‘degree of urbanization’ are analysed to provide contextual information for subsequent analyses. In a second stage, a descriptive analysis is carried out at the regional level of the behaviour of the different locality categories in relation to: population 2021, percentage variation in population 2011-2021, population density 2021 and percentage variation in population density 2011-2021.

The Sicani inner area and its municipalities is then analyzed on the basis of population dynamics and housing density but using the distinction between town centers and areas of scattered buildings, for a better understanding of the demographic dynamics within the municipalities, taking into account the differences between populated areas and rural areas.

▪ **ANALYSYS OF THE SICILIAN CASE AND THE SICANI AREA**

In the period 2011-2021 the region of Sicily experienced a population loss of 3.56%, however this dynamic is distributed with wide differences within the territory. The SNAI indicator shows that the greater the peripherality, the greater the depopulation, indeed it is the ultraperipheral municipalities that lose the most population in the period (-9.82%). Similar trends were observed in the municipalities defined as rural according to Degurba, which decreased by 10.03% in the same period. Overall, the ‘towns and suburbs’ category and the ‘intermediate’ peripherality category are comparable in terms of the level of population variation, and both are below the regional average, that is, in better condition.

Figure 1. Graphs of percentage variation of population in the period 2011-2021 based on SNAI and Degurba peripherality levels, for the municipalities of Sicily. Prepared by the author with data from ISTAT and Eurostat 2018.

The category ‘pole and inter-communal pole’, which indicates the main cities, shows a loss of population (-3.19%) although less than the regional average. The Degurba ‘Cities’ category shows a similar situation (-3.29%). The ‘Belt areas’ category of SNAI is the one that shows the smallest demographic decrease and is related to urban and rural municipalities located in the peripheries of the main cities or service concentration centres. In this respect, the data at the municipal level show a clear relationship between a higher level of peripherality and rurality with depopulation. In other words, the municipal territories in peripheral conditions and with a rural status in terms of low population density are those that present a higher loss of population.

Nevertheless, an analysis at the intra-municipal scale can account for the urbanisation process that underlies depopulation, distinguishing this time not between municipalities, but between settlements and non-residential rural areas. By analysing data, such as population density and population growth, based on localities, it is possible to observe the rural-urban distinction from a perspective that has not been addressed very frequently.

Type of locality	Population 2021	% population variation 2011-2021	Population density 2021	% population density var. 2011-2021
Town centres	4.512.656	-4,76%	3772,2	-6,46%
Settlement (nucleus)	81.269	7,15%	645,5	-8,27%
Productive locality	1.785	23,53%	21,3	-4,99%
Scattered buildings	212.170	15,98%	8,7	16,23%
Total Sicily	4.807.880	-3,81%	186,1	-3,83%

Figure 2. Population data 2021, percentage variation of population and percentage variation of population density based on census locality types. Prepared by the author with ISTAT data.

A nivel de localidad pareciera que los datos censales se contradicen con los resultados a nivel At the locality scale, it seems that the census data contradict the results at the municipal level; in fact, it is the town centres (main and secondary) of each municipality that lose the most population in the period 2011-2021 (-4.76%), while the localities known as settlement (nucleus), which are smaller in size, increase their population (7.15%). In turn, the areas of scattered houses are those that proportionally increase their population to a greater extent (15.98%). These latter areas, which have the lowest housing density (8.7 inhabitants/km² at the regional level) are those that increase that density to the greatest extent

(16.2%), while the decrease in the density of town centres and settlements is more than double the regional decrease (-3.83).

An essential data provided by the demographic analysis of localities is related to identifying the territorial categories that increase population in a general framework of depopulation, which is relevant because the peripherality SNAI and "Degurba" urbanization indicators, when measuring Sicilian municipalities as a whole, only show categories with population decrease. This implies that, while rural and peripheral municipalities are those that predominantly lose population, the town centres within municipalities are the units that concentrate demographic decline, in favour of smaller settlements and rural areas with low population density.

The Sicani area, defined by SNAI as one of the priority areas for the implementation of this policy, and confirmed in the most recent perimeter 2021-2027, is made up of 12 municipalities belonging to the "free communal consortium of Agrigento" (former Provincia di Agrigento). As an inner SNAI area, this group of municipalities concentrates a high level of territorial marginality in the regional framework and a prevalent rural character according to Degurba, a condition to which is joined the loss of population in the period 2011-2021 (-11%) and the low population density (73 inhabitants/km²), which also decreased by 9 inhabitants/km² in the decade. The area's population loss is proportionally greater than the decline of all Sicilian municipalities in the outermost category (-9.82%) and in the "rural areas" category according to Degurba (-10.03%).

Figure 3. Demographic data and population density for the municipalities of the Sicani Inner Area, distinguishing between the category "town centres" and "scattered buildings". Prepared by the author with ISTAT 2011 and 2021 census data.

A second, more comprehensive analysis can provide further insights into the demographic framework of the Sicani Inner Area, this time using as a territorial reference the distinction between "types of localities" to differentiate between town centres localities and scattered building localities. Figure 3 compares the data for those two main categories excluding "settlements" as they are almost irrelevant in terms of population; the same for "productive localities" as they do not exist in the analysed area.

Reviewing the total results for the area, these two categories show clearly contrasting performances. For example, the average population density of the town centres of the area (3925 inhabitants/km²) is similar to the density of urban localities such as Taormina, Cefalu or Caltanissetta, and higher than the total density of urban centres in Sicily (3772 inhabitants/km²), while the areas of scattered buildings have a

Proceedings

population density (4.9 inhabitants/km²) much lower than the total density of Sicilian localities in the same category (8.7 inhabitants/km²). In the analysed period, the town centres of the area decreased their population density by 13.7%, while the areas of scattered buildings increased it by 20.5%.

With regard to the demographic dynamics of the Sicani area, the scattered building areas, whose population represents 6.5% of the total population of the inner area, increase their population by 20.6%, while the town centres decrease by 12.9%. All the urban centres in the inner area lost population, with Cianciana (-31%), Alessandria della Rocca (-25.3%) and Calamonaci (-21.8%) decreasing the most. Those with the smallest decreases are Villafranca Sicula (3.5%), Ribera (6.8%) and Burgio (8%). The areas with scattered buildings, on the other hand, mostly increase in population, particularly in Cianciana (689 inhabitants), Calamonaci (109 inhabitants) and Calamonaci (109 inhabitants), although there are a few cases where the population decreases, such as Santo Stefano Quisquina (-323 inhabitants), Burgio (-56 inhabitants) and Villafranca Sicula (-32 inhabitants).

The case of Cianciana is particularly interesting because although it is the one that loses the most population in absolute terms (-1047 inhabitants) after Ribera, it is the one that increases its population the most in its localities of scattered buildings, a trend shared by Calamonaci, although to a lesser extent, as this is the municipality with the smallest population in the area (1075 inhabitants in 2021). Also to be highlighted is the case of Alessandria della Rocca, which presents a high depopulation in its town centre, but also loses population in its locality of scattered buildings.

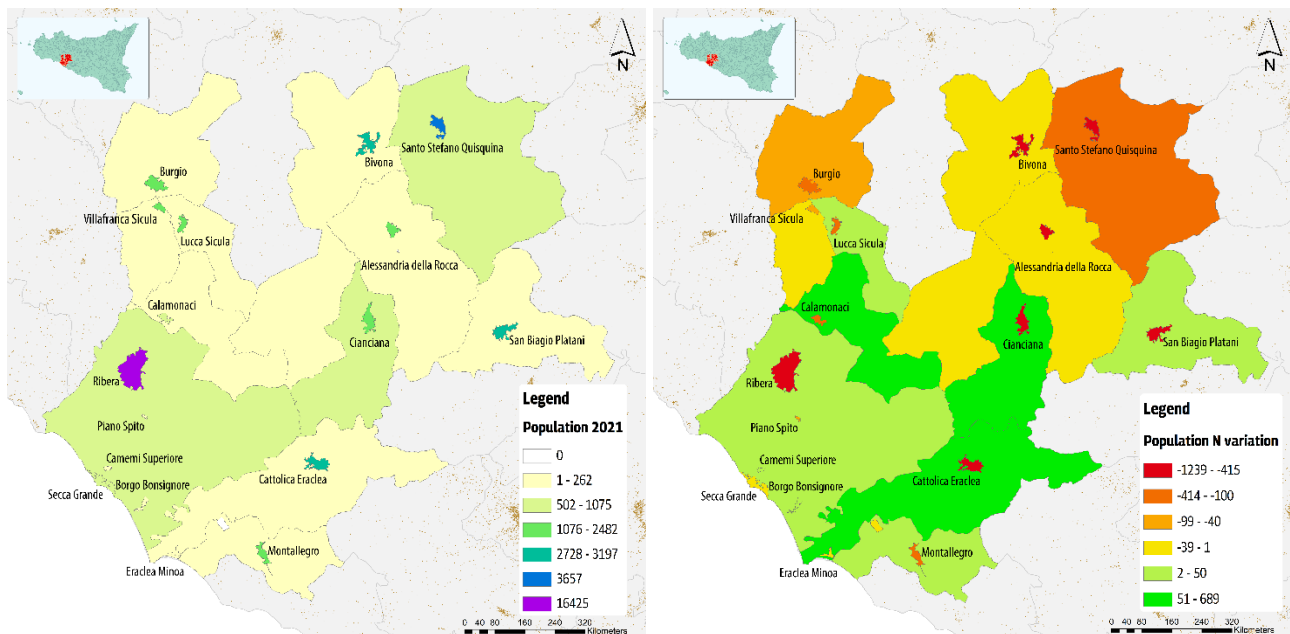

Figure 4. Maps of the internal Sicani area in Sicily. Population ranges 2021 and absolute population variation ranges 2011-2021. Prepared by the author with ISTAT census data.

The municipality of Ribera, with the largest population and population density in the area, seems to show low depopulation in its town centre and a slight increase in its area of scattered buildings, and therefore shows better demographic dynamism. Cases of relative dynamism are also Montallegro, with low depopulation and high density in its town centre, and high density together with an increase in population in its area of scattered buildings (46 inhabitants). Lucca Sicula also shows a similar trend, although with a smaller increase in its scattered buildings area. Intermediate conditions are shown by the municipalities of Bivona, San Biagio Platani and Cattolica Eraclea, which are also the most densely populated after Ribera.

The maps in Figure 4 provide an overview of the demographic dynamics described above with a territorial reference. The map on the left shows how the population is distributed in 6 groups, where it is possible to observe that the most populated areas of scattered buildings belong to the municipalities of Ribera, Cianciana and Santo Stefano Quisquina. The map on the right, which shows the absolute variation in population over the period, shows that the areas of dispersed houses closest to the coastal area are increasing in population, while those located further north and more closely linked to the "Monti Sicani" are those that are losing population. The main inhabited centres of all the municipalities lose population, although in absolute terms the areas with the lower depopulation are the north-eastern area of the hills and Montallegro, closer to the coast.

▪ CONCLUSIONS

The analysis by localities, at the intra-municipal scale, enables a different view of the demographic trends of the inner and rural areas, compared to the analysis at the municipal level. Thus, the first analysis of depopulation in the region of Sicily shows that it is the inhabited centres that are losing population in the most significant proportion, while the less inhabited rural areas with scattered buildings show a clear increase in population, at least in the last decade.

Although the data obtained seems to contradict the analyses at the communal level, which show that it is the rural and peripheral municipalities that are losing population to a greater extent, both results are rather complementary. De Rubertis (2019, 85) analyses at the municipal level showed that among the "hyper-rural" municipalities, specifically the "markedly agricultural" municipalities showed a certain dynamism, which may indicate a possible demographic recovery of certain rural fractions, possibly with higher productive activity, within a general framework of depopulation in Sicily.

The data indicate that in Sicily "belt areas", located in the peripheral rings of the main cities, that are increasing their population the most. These municipalities are not the ones that concentrate the greatest rurality, but they also face a strong functional influence from the urban areas. However, a demographic analysis at the locality scale might indicate that it is the non-urbanised areas of these municipalities that undergo the major population increase.

In the case of the Sicani area, composed mainly of rural municipalities according to Degurba, and mainly peripheral and ultra-peripheral municipalities according to SNAI, the analysis at the locality scale shows similar processes to those observed at the regional scale: the town centres are those that experience proportionally the greatest loss of population, while the areas of scattered buildings show a tendency towards population increase, even though the magnitudes are slight, given the small population of the municipalities analysed.

The proposed methodology is an interesting tool to deepen the demographic analyses of the inner areas, for a more complex understanding of population mobility trends in relation to the dimension of rurality. It can enable the development of a series of studies that cross the variables analysed here with others of a socioeconomic and employment nature, thus opening up perspectives for future research.

Abstract

This contribution aims to expose the challenges and potentialities of collaborative workspaces, starting from the example of the DumBO space in Bologna which promotes local identity, celebrates the urban landscape, and engages professionals, artists, and society in a collaborative effort to regenerate abandoned spaces. The name DumBO stands for *Distretto Urbano Multifunzionale di Bologna* (Bologna Multifunctional Urban District), and it is a place where creativity, culture, and community collide. The DumBO wide area located on the old rail yard of almost 40,000 square meters is under the property of Italian State Railways, which has the task of redeveloping and enhancing infrastructures that are no longer functional for railway operations. The open areas of DumBO have been partially renovated and transformed into spaces for the cultural industry where the professionals can pay for a low-cost service to have a co-working space and use it for exhibitions and other activities. Therefore, it is a place where associations, businesses, and citizens collaborate and contaminate each other's ideas, fostering new and innovative approaches to city development. It is a meaningful example of how a collaborative working space could also integrate society and the neighborhood; in other words, it is a project made for the community by the community. One still open question is: are collaborative workspaces really open to everyone?

In the context of New European Bauhaus (NEB), the “CrAFt – Creating Actionable Futures” European project, funded by the Horizon Europe program, sees citizens as active contributors towards climate neutrality. The ongoing research of CrAFt investigates how an area of collaborative workspace close to the city centre, yet at the same time away from it, given the actual inaccessibility to the same location, could be a valuable example of a fully inclusive urban regeneration.

Furthermore, the current research analysis is based on an empirical approach, public observation of space, surveys, and public alliances for a major public engagement. To examine these data, researchers in different countries have created a tool called the “NEB Impact Model” (NEB IM), which includes diverse indicators to assess the level of compliance with the NEB requirements in several urban contexts. The NEB principles of aesthetics, sustainability and inclusion shape the idea of the DumBO project, which encourages sustainability and economic development through the inclusive and alternative approach of the community. As such, it represents a collaborative workspace representative model of co-creation and co-design experiences in everyday life practices.

Keywords: *Urban regeneration, New European Bauhaus, Collaboration, Social innovation, Community*

1. INTRODUCTION

Bologna is an example of new forms of collaborative governance models and significant participation of citizens in local initiatives. The city was selected in 2022 as one of the 100 cities in Europe with the commitment to achieve climate neutrality. Bologna was the first city to implement the “City as a Commons” approach [1] and the “co-city” protocol, articulated in the following phases: “cheap talking”

(meant as dialogue interaction), mapping, practicing, prototyping, and modelling [2]. The application of the “co-city” protocol, the elaboration and adoption of the Regulation [3], based on that protocol and the “City as a Commons” approach, together with the active role of local stakeholders such as the Municipality, foundations, and other institutions, enforced the key role for the participatory processes in the local sphere.

In this context, a particular project called “DumBO - Distretto Urbano Multifunzionale di Bologna” (Bologna Multifunctional Urban District) appeared to promote social innovation and new community business models. It presents the constructive collaboration between the public and private sectors, as the property is public, but the management of the spaces is private [4].

Through transformations still in progress, the open areas of DumBO are getting an innovative space for the cultural industry with the creation of Collaborative Working Spaces (CWS). According to Capdevila (2017) [5], four existing typologies for CWS are fab-labs, maker/hackerspaces, living labs and corporate labs based on innovative approaches (explorative practices and exploitative goals). Moreover, Montanari (2020) [6] proposes another classification in terms of “Collaborative Spaces” and identifies six different typologies, such as corporate collaborative spaces, coworking spaces, creative or cultural hubs, fablabs and makerspaces, incubators and accelerators, social spaces (cafes, libraries, etc.) by defining four common features for them including variety, flexibility, autonomy, and collaborative ethos. Also, Mariotti et al. (2021) [7] propose four types under the umbrella of “New Working Spaces”, namely collaborative and creative working spaces (coworking spaces and smart work centres), makerspaces and other technical spaces (fab-labs and open workshops), other new working spaces (hackerspaces, living lab, and corporate labs), and informal new working spaces (cafes and libraries).

Thus, DumBO space could be characterized as a multifunctional place which includes several types of CWS, as mentioned above, by embodying typical and atypical forms. According to the typologies that Mariotti refers to, DumBO includes collaborative creative working spaces, and technical spaces like fab-labs and open workshops, with a significant inclusion of citizens from the neighborhood.

Moreover, these CWS promote innovative tools and a new form of situated learning. The origins of this definition come from Lave and Wenger in 1991 [8], and it has been understood in opposition to cognitive learning. The latter was based on notions and knowledge acquired by traditional education models, while the concept of situated learning introduced a novel approach that is more inductive, starting from the idea of legitimate peripheral participation.

This kind of learning, also described as “learning by doing”, has been used to describe, for example, the learning process happening in communities of practice presented by Amin & Roberts (2008) [9], and it has also moved to distinct aspects of civil society participation in public activities, as well as to all the education and research environments. “Learning by doing” means that people can discover new potentialities for their communities through concrete examples from everyday life practices. In the perspective of situated learning, social proximity plays a key role, especially in enhancing interactive processes and allowing knowledge exchange, collective learning, and innovation [10, 11, 12]. Knowledge exchanged is not normative and cognitive but also tacit and codified. Hence, the setting is where local and traditional knowledge is exchanged and transferred through passive or active participation and presence in a real (and not simulated) environment. With the growth of trans-local relations, the discourse around learning also englobes the need for connection and networking among people and places: a research stream also introduced “networked learning” as a subgroup of situated learning [13]. In another case, the term “knowing in action” means overcoming the “limits” of learning through spatial proximity, introducing relational proximity [9].

DumBO space could be a valuable paradigm for situated learning through interactive engagement of the community with different practices and tools. For instance, educational programs for young people with cultural and art aspects, continuous festivals, and alliances for specific topics exist. The actions and the

activities held there are a means to know the communities better and ensure that the citizens can be part of a new policymaking process. The sharing of knowledge is the key point for the involvement of people so they can produce more knowledge and transfer it to other users/active contributors. DumBO is a place where sociability meets sustainability and beauty with the presence of many cultural aspects such as *graffiti*, murals, and the reuse of abandoned buildings. The project has a valuable character as it involves a strategic area of the city, and it has an experimental role as an example of the temporary use of spaces open to the territory and citizens' participation. DumBO is a project in transition as space is a sphere of continuous changes, and everything is possible to happen [14]. In fact, the New European Bauhaus principles of "sustainable, beautiful, together" form the DumBO project, which encourages sustainability and economic development through the inclusive and alternative approach of the community. The result is a unique urban space that embodies the spirit of collaboration, creativity, and renewal. Thus, it is not just about another CWS but something more: a space of urban regeneration that sees and understands the citizens as active contributors.

2. URBAN REGENERATION AND CITIZENS' PARTICIPATION: NEW FORMS OF CIVIC ENGAGEMENT

It is heartening to see that DumBO's design process is open and inclusive, thanks to the co-creative and co-collaborative approach. The "City as a Commons" approach is deeply interconnected with the concept of collaborative governance and democracy. Additionally, it is based on participatory processes in which co-creation and living labs are valuable tools. In the planning literature, the term collaborative is linked to "communicative action" and is recognized as a theory of practice. It considers why urban regions are important to social, economic, and environmental policy and how the communities have the possibility and tools to organize to improve the quality of their places and living conditions [15].

Also, the concept of co-creation is a "mosaic" of ideas and norms from varied research traditions and activities, as well as sectors such as urban planning, design, innovation, marketing, and management. In urban development, co-creating partly builds on knowledge and experience from processes in the private sector, which are applied to public service delivery [16].

This term refers to the general knowledge about citizens and their experience with public services. Citizens can actively contribute through their knowledge and ideas to create new collaborations and include different participants, starting from the third sector to the local economy actors, in the entire process. In DumBO, different communities coexist, introducing an alternative approach of collaboration between diverse parts of the society: from the professionals of the cultural sector to community managers and young people who work as freelancers for the creative economy. Activities are organized for each target who lives and works in the area by including many types of actions and events like sustainable mobility, such as "cicloturismo", film festivals, and other initiatives of cultural and artistic interest.

One of the most nominated realities in DumBO space is the association "Bologna Attiva", a concrete example of public engagement through the active role of diverse stakeholders. Located within DumBO, it is a human, urban, and social regeneration project that aims to experiment with new responses to the challenges posed by the changing world of work [17]. At "Bologna Attiva" [18], a considerable number of co-working spaces, study rooms, proximity services for students, professional accompaniment paths, mutualism, and cultural and community activities have been created. Its objectives are to redefine the spaces of DumBO in line with the needs expressed by the city and the neighbourhood, favouring a civic re-appropriation of the area.

Furthermore, Bologna is a city that actively involves the civic society, so in DumBO space, another initiative that takes place is the "Assemblea Cittadina per il Clima" [19] (Citizens' Alliance for Climate): the citizens, together with other stakeholders, share their thoughts, and they contribute with recommendations to the public dialogue for the implementation of the "Climate City Contract" (CCC) in Bologna. Climate City Contracts (CCCs) are part of a multi-level co-creation process to support cities

in transitioning to climate neutrality within the framework of the NetZerocities [20] platform and the Cities Mission.

The main purposes of CCCs are the identification of the policy and gaps to steer the transition; the coordination of a network of stakeholders, national and EU authorities to deliver the conditions necessary to achieve climate neutrality; the creation of a one-stop-shop for multi-level negotiations to facilitate city activities. The CCCs support new inclusive and participatory forms of governance, circular and accessible economic and funding models, and new integrated urban planning strategies with increasing implementation of digital technologies and innovative management; they are signed by the Mayor, European Commission, and national or regional authorities. The CCCs include, amongst others, an innovative form of civic engagement through “living labs,” which include spontaneous and inclusive experimental activities. This process is interconnected with the Municipality of Bologna to ensure new forms of civic engagement and provide solutions to local problems and challenges. The examples mentioned above promote new forms of co-creation as the public space changes.

3. THE CONNECTION WITH THE NEW EUROPEAN BAUHAUS PRINCIPLES

The European Commission states that the mission of the New European Bauhaus (NEB) is an initiative connecting the European Green Deal to our daily lives and living spaces. It refers to creativity and interdisciplinarity as a movement in continuous change.

The main key points of New European Bauhaus are the following [21]:

4. it is a bridge between the world of science and technology, art, and culture;
5. it is about leveraging our green and digital challenges to transform our lives for the better;
6. it is an invitation to address complex societal problems together through co-creation;
7. by creating bridges between different backgrounds, cutting across disciplines and building on participation at all levels, the New European Bauhaus inspires a movement to facilitate and steer the transformation of our societies along three inseparable values: sustainability, from climate goals to circularity, zero pollution, and biodiversity; aesthetics in terms of quality of experience and style, beyond functionality; inclusion, from valuing diversity to securing accessibility and affordability.

One of the main goals of NEB is to connect different realities from the citizens to experts, researchers, businesses, institutions, and creative and cultural industries to share new perspectives for the future and co-create and co-design actionable spaces and communities.

From the first steps, the DumBO space is a project which engaged the NEB principles, as sustainability, beauty and inclusiveness are well presented around the area through temporary interventions. In this context, it accommodates and encourages innovative ideas and artistic and creative expressions by bringing together social integration,

entertainment, culture, experimentation, sustainability, and collaboration between different realities.

DumBO offers multi-purpose spaces for rent to host many events such as conferences, public alliances, workshops, live concerts, and exhibitions (Figure 1). Specifically, the venues are the following:

- “Binario Centrale” mostly hosts multiple events;
- “Baia” is an open venue adaptable for concerts and public alliances;
- “Blocco 19” hosts several types of creative businesses, coworking, meeting rooms and training courses;
- “Emme300” situated in the central part of “Piazza Ravone” is ideal for storage functions but also permits to use it for alternative activities thanks to the small and flexible spaces;
- “Piazza Ravone” is the central square of the district and “Le Piazzole” corresponds to the long canopy, divided into sections across the square. They can host exhibitions and other events;
- “Interrail” is the last large building that makes up DumBO district, it is used as offices;

- “Maia store” is a new entry for the district, it is sales point and promotes local products;
- “Officina” consists of community space, coworking, study room and *bistrot*. The latter is in the central body of the “Officina” and develops on two levels;
- “Spazio Bianco” is suitable for multiple events such as small exhibitions, workshops, and private events thanks to its flexible structure;
- “Temporanea” is the building that recalls more than the others a station, with the idea of “temporary station”. It is well preserved, and it hosts temporary installations, concerts, exhibitions;
- “Vascello” is a large single nave-pavilion built with exposed bricks that gives an industrial charm sensation. It is perfect for activities that require something unique, like shootings and exhibitions.

3.1 The methodological approach: NEB Impact Model as a tool to discuss and regenerate

The New European Bauhaus principles are present in the space, which faces different challenges, from climate change to social poverty, housing issues and inequalities, so the local authorities and communities need to understand how to improve their everyday life practices and create active public spaces. In this perspective, the “CrAft – Creating Actionable Futures” European project, funded by the Horizon Europe program [22], includes all the NEB principles of sustainability, beauty, and inclusiveness, and it refers to the urban and social change through the citizens’ participation, by creating a tool to talk and engage different actors in the urban context. This tool, called the “NEB Impact Model” (IM), is a set of indicators addressing technical/environmental aspects, architectural/artistic quality, and social and governance ones. It is a guidance instrument that provides data and, eventually, solutions to be applied in a complex urban environment.

The contribution of the IM is to identify crucial points for systemic change towards climate neutrality and resilience by including various aspects, starting from sustainability (ecological, infrastructural, social, cultural, economic, aesthetic, legal, etc.) into innovative models for local collaborative governance and enrich the dialogue with the local stakeholders. The IM comprises 5 pillars, 17 impact categories and 46 suggested indicators (Figure 2) [23].

A brief description of the 5 pillars is the following:

- “The environmental performance” concerns all energy material and water streams to assess the energy used in buildings, infrastructures, and transport;
- “Healthy living” reflects how a physical environment provides the basic quality of life functions for its users and inhabitants;
- “Social-cultural performance” relates to the functional mix, diversity and accessibility of services and amenities for a particular location;
- “Economic performance” examines how an investment or project inscribes itself meaningfully in the local economic tissue;
- “Governance” measures the effectiveness of the process and the involvement of stakeholders as fundamental aspects of a project.

Figure 2. The current visualization of the NEB Impact Model (Source: D1.1: NEB Impact Model-update; version 14.07.2023, <https://craft-cities.eu/results/> - Last accessed 29 February 2024).

In the framework of the “CrAft” project, DumBO is a case study for implementing and testing the IM in Bologna. Corresponding to it, two other sandbox cities, Amsterdam, and Prague, are testing collaborative governance models influenced by the NEB approach to city transformation. In Amsterdam, the action areas are economic performance, governance, healthy environment, quality of life, and technical and environmental performance. Different pilot cases exist instead of Bologna, such as the Marineterrein Park [24] and Green Mile [25]. On the other hand, Prague focuses on integrating beauty towards the climate neutrality through many cultural events [26] in the city and reports the lessons learnt from the experience.

From April 2022, since the “CrAft” project started, the University of Bologna, in collaboration with the Municipality and “Fondazione Innovazione Urbana” (FIU - Foundation for Urban Innovation), including young researchers as well, started to implement some key actions and activities to understand how the NEB principles influence the public-hybrid space. Moreover, they investigated how degraded and abandoned areas can be renewed without losing their identity and carrying capacity.

In this context, DumBO is a space in transition, a temporary place for urban creativity with continuous engagement of local communities and is considered a sandbox city landscape where experimentation meets innovation. The term “urban sandboxing” refers to: “creating temporary, low--cost, and adaptable interventions in public spaces within a city, typically to test new ideas, designs, or policies before committing to permanent changes. The term ‘sandbox’ is based on the idea of a playground where children are encouraged to experiment and test their ideas without fear of failure” [17].

Urban sandboxing can take many forms, including pop-up parks, temporary bike lanes, community gardens and public art installations. By providing a platform for experimentation and collaboration, this approach can help cities to become more resilient, sustainable, and responsive to the needs of their residents.

Some tests related to the IM’s specific categories (environmental and technical performance, sociability and culture, governance) are under development and implemented in the DumBO area. Particularly, the current research is focused on the following aspects: sustainable mobility, healthy living, cultural heritage, artistic and spatial quality, arts mobilization, sociability, and economic performance. Thus, several indicators (that are included in the main impact categories such as governance, economic performance, social-cultural performance, healthy living, and environmental performance) help to measure and quantify data, which are useful in monitoring the status of the space and providing novel solutions where it is essential. As complex research, cooperation between stakeholders and expertise is fundamental.

In DumBO, many realities coexist, and cooperation between different pacts is mandatory to implement the Model. As the place includes multiple cultural and artistic aspects, a specific focus on the indicators that try to understand the peoples’ perceptions in similar spaces like DumBO is essential. Related to the main impact categories mentioned above, DumBO gathers many social aspects through collective activities that remind the citizens to be active in the space: it is an interesting experiment to see and understand how the different realities react and shape new forms of collaboration in diverse layers. Additionally, it is a place of urban creativity that uses artistic tools to regenerate the area and engage the local community of artists. Thus, the research is inspired by the methodology of social sciences, which includes the empirical approach and both qualitative and quantitative data. Both are crucial elements in studying and observing the space and, first, reflecting on how different elements are significantly involved in the urban regeneration of abandoned areas.

4. CONCLUSIONS

The CrAft research investigates how an area of collaborative workspace could be a valuable example of a fully inclusive urban regeneration notwithstanding the people perception of inaccessibility, given

by the structural urban origin of the area, of an area which is close to the centre, yet at the same time away from it, given its actual isolation.

To attempt at responding to the initial question “are collaborative workspaces really open to everyone?” we might certainly say that DumBO is an inclusive and open space for the community, which is conceived considering the different perspectives of people who live this urban space through everyday life practices.

However, as the challenges are many, there is a major necessity to include the NEB principles of sustainability, beauty, and inclusiveness for a more affordable environment towards climate neutrality. It is fundamental, in fact, to create inclusive spaces, not just to provide a whole package of services but also a quality life experience through creative and cultural aspects. DumBO is as well a place where people can understand the space and their needs in an emblematic way and be part of the changes. For example, the activities co-organized by different actors provide an alternative way to produce and share knowledge across the community, in other words, another perspective of “learning by doing.”

The CWS are places of social life, too, and are a point of reference for the digital nomad community and the citizens. Temporary residents, mostly digital nomads or employees in the gig economy and/or cultural industry, could eventually be active contributors by being included in local activities and initiatives. Thus, they live the whole urban experience through the engagement of other local citizens’ networks, so inhabitants, freelancer workers of the creative industry and digital nomads are connected to the local context by sharing knowledge and collective experience. The city is not just a transit place but a space of continuous changes. The CWS could be a significant economic resource for cities by considering a sustainable way of presence. Moreover, this could be an alternative and sustainable tourism model for contemporary cities with respect to identity and morphological characteristics. Places like DumBO do not offer just a co-working and co-living experience but a space for co-creation and co-design approaches, a new ecosystem of participation which promotes different forms of social actions. Also, in terms of sandboxing cities, DumBO is related to experimentation and creativity and introduces a new lifestyle for young people, as well as for other target groups with different activities and design perspectives.

The NEB IM, through its implementation in different urban contexts, is a potential tool for discussing current challenges with various stakeholders based on the territory. In addition, it helps to underline the peculiarities of contemporary cities and provide valuable data to the local authorities to use and deliver more sustainable, beautiful, and inclusive solutions towards climate neutrality. The NEB IM is applied to DumBO as a case study with the prospect of a more actionable future for the citizens, a new form of local collaborative governance model, in other words, to promote a new urban movement.

Abstract

The former Amicucci-Parmegiani paper mill in Tivoli, Italy, has been abandoned for a long time but is now the focus of a design competition for its restoration. This mill is part of a larger network of disused industrial paper mill settlements along the Aniene river, which reflect the area's history of production. The New European Bauhaus [1] strategy seeks to revitalize old structures by incorporating new approaches. In this case, a Sapienza startup has developed a remarkable example of renovating, repairing, and reconstructing the modern built heritage. Rather than discarding the past, it is important to work with the history of buildings and adapt them to current needs. This requires understanding and respecting the materiality and history of inherited structures. The proposed intervention strategy for the Amicucci-Parmegiani paper mill aims to preserve its industrial identity while incorporating a functional program that engages the community and showcases the building's history [2]. By following these principles, the renovation project will ensure the building's significance is maintained while meeting contemporary requirements [3].

Keywords: *building rehabilitation; urban upgrading; landscape redevelopment; retrofitting of built heritage.*

1. INTRODUCTION: VOIDS TO BE RETURNED TO THE CITY

The area in question has a long history of industrial activity, which has left its mark on the edge of the medieval urban fabric of Tivoli downstream [4]. Since the end of the nineteenth century, new construction and production technologies have been prominent in this fringe of the city. The massive industrial constructions have left a new margin of construction that has decisively questioned the ancient landscape relationships between city, land and river (Figure 1). It is evident that Tivoli requires regeneration, with the recognition of the values observed in the oldest and most recent forms of urbanisation. This should inform an overarching rethinking of the territory.

The Municipality of Tivoli, the proprietor of the building, has initiated a design competition with the objective of transforming the current industrial ruin, which has a significant negative perceptual-functional impact on the city, into an important and strategic opportunity for urban transformation. The former Amicucci-Parmegiani paper mill represents a waiting space, an urban void, so defined not because it lacks volumes but because it has lost its original functions and its meaning within the fabric of the city. The redevelopment of the area occupied by the building and its functional rethinking aim to generate a process of urban regeneration through the improvement of aspects such as the architectural perception of the context. This is to be achieved, in particular, through the redesign of the downstream façade, the attractiveness towards the city centre, mobility, the environment and integration with the surrounding landscape, sociality and economy. This is to be achieved, in particular, through the possibility of creating new public spaces and/or municipalities as closely as possible in connection with

the existing urban fabric. The area is of considerable scenic importance, given its position in close proximity to the historic centre and a number of important landmarks, including the Cathedral to the south and the valley formed by the course of the Aniene river, the waterfalls and the church of S.M. di Quintiliolo on the opposite side to the north, and the Sanctuary of Hercules the Victor [5].

2. THE FORMER AMICUCCI-PARMEGIANI PAPER MILL: ROOTS, TRANSFORMATIONS AND DECLINE

2.1. Industrial archaeology in tivoli: the values of a fertile territory

The medieval urban fabric of Tivoli is characterised by numerous ancient and modern canals. Since at least the 16th century, there have been numerous paper mills, ironworks and tanneries in the area, which were moved by water. From the beginning of the 20th century, structures were installed that had been in place since the previous century. These were fed by the waters of the Aniene, which were exploited through a system of underground canals. This enabled numerous paper mills, mills and factories to be fed [6]. As a consequence of these natural and industrial factors, the region became the site of the first hydroelectric power development and utilisation in Italy. Tivoli was the first city to benefit from electric lighting, produced by hydraulic motors in 1886 [7][8]. Huge industrial structures, predominantly constructed from reinforced concrete, are being erected on previously occupied sites, with the construction of new structures replacing and expanding upon existing ones. The context is that

of a medieval city with a walled edge comprising historic industrial concrete structures, including the former Amicucci-Parmegiani paper mill.

Some of these structures serve only to preserve the values of work and the memories of intangible data. Others stand out as involuntary monuments with the intriguing shapes of reinforced concrete, a material that has become a defining feature of industrial architecture. Finally, there are those that contain some technological or scientific innovation, such as power plants or avant-garde architectural construction solutions. The concept of heredity encompasses many elements, including environmental and conservation issues. The consequences of neglect have manifested in the form of collapses and serious deterioration. However, despite the laudable intentions of some renovation operations, they have already resulted in the loss of architectural elements of considerable value. One such example is the metal vaults designed by Gino Covre for the Tiburtina paper mill¹ [9].

Historically, the area was characterised by an organic connection between the building fabric and the naturalistic emergencies, with the presence of cultivated terraces.

The relationship between the buildings used for productive activities, the city and the residences of the occupants of the sector in Tivoli was somewhat unconventional. Despite the industrial development, there were no workers' quarters. This immediately highlights how the phenomenon of urbanisation, which was typical of the period of the Industrial Revolution, did not occur here. This is evidenced by the fact that the city did not experience the "evils" of many cities.

The causes of this positive development can be attributed to two factors. Firstly, there was a gradual process of growth over time, during which the search for spaces and functions took place within existing buildings. Secondly, the historic centre represented the residential district of reference, thus generating a balance between home and workplace, between living and working. Conversely, since the paper mills and other industrial plants were abandoned, there has also been a gradual exodus of inhabitants from the medieval quarter.

In the ancient industrial area of Tivoli, therefore, important remains of the classical age coexist with paper mills, factories and related infrastructures, including, in particular, canals. The heterogeneous and overlapping elements make it challenging to identify the historical character of each individual part.

2.2. Historical evolution of the paper mill

The Amicucci-Parmegiani paper mill is characterized by a continuous evolutionary development over time that began around the '20s and ended during the '60s. (Figure 2)

Phase 1: In the early 1920s, construction began on the first building, replacing an old barn. In 1925, the mill expanded eastward, adding a new section towards a nearby alley.

Phase 2: Between 1934 and 1938, a driveway courtyard with concierge and loading floor was built on the north side of Tani Square. In addition, a boiler room and a new building for staging were built in the eastern part of the courtyard.

Phase 3: From 1940 to 1946 there was a significant northward expansion of existing structures. The buildings were used for both main and ancillary functions, including technical rooms and production facilities.

Phase 4: In 1947, the downstream building was expanded eastward to accommodate the first line of paper machines. Another smaller building was added for processing with a Dutch beater. In 1949, further extensions of the central building and boiler room were carried out.

Phase 5: In 1951, the original building was expanded with a large canopy and the courtyard was rearranged for the unloading of raw materials. The boiler room was extended to the west and a new warehouse was built to the northwest, partly on ancient Roman ruins.

Phase 6: In 1952 a significant expansion occurred, expanding the continuous machine building to install a second line with a

Workshop attached. The extension also included two upper floors for the storage of straw.

Phase 7: In the early 1960s, the mill expanded further with the construction of a new production line in the Northwest, which involved the demolition of existing structures. At the same time, the offices adjacent to Piazza Tani were demolished and rebuilt to improve the unloading of raw materials.

The former paper mill is situated on a steep slope, connecting a high summit elevation with a lower valley floor elevation. The slope has a sharp inclination ranging from 80° to 90° and is divided into two sub-vertical sections, separated by a narrow terrace that accommodates “Via degli Stabilimenti”, a partially disused roadway. On 9 April 2009, a part of the paper mill collapsed, resulting in the immediate collapse of a section of “Via degli Stabilimenti” that passes through a tunnel. The collapse was likely caused by aftershocks from the L'Aquila earthquake. The slope is presently affected by two active landslide escarpments, as identified in the hydrogeological plan of the Central Apennine basins. However, these escarpments are only partially protected by deteriorating masonry support structures.

Figure 2. Present day situation: in the image (2020), we can see the actual state caused by the 2009 massive collapse, immediately upstream of a section of “Via degli Stabilimenti” that runs through a tunnel. (from the Technical-illustrative report of the “Design Competition for the construction of the auditorium and car park in the area of the former Amicucci Parmegiani paper mill” - source: Municipality of Tivoli)

3. THE 'NEW' PAPER MILL-MUSEUM: AN EXAMPLE OF RESILIENT URBAN REGENERATION

3.1. Methodology

The subject of this analysis is a section of the former paper mill complex, which is located in a strategic position overlooking the valley in which the Aniene flows. The mill has been decommissioned from all operational activities and is now in a state of complete disuse and deterioration. It is accessed via two main entrances: one on the north side of Piazza Tani and one from ‘Via degli Stabilimenti’. The factory, comprising five levels, reaches a maximum height of 30 metres on the north elevation and has a linear development of approximately 160 metres. The surface area of the interior spaces of the current building is approximately 20,000 square metres, for a total volume of approximately 92,000 cubic metres. In addition, there are a series of external spaces adjacent and functionally connected to the Paper Mill, with a total area of approximately 2,400 square metres included within the perimeter of the Amicucci-Parmegiani complex. In order to ascertain the surface area, the central portion of the building, which had collapsed since 2009, had to be taken into account. This had created a generally dangerous

specific plant, spatial and service equipment. This is represented by a very complex building programme, which can only be fulfilled if conceived in a way that is consistent with the existing object, albeit with different degrees of interaction with the architectural object and the context. The reference model of musealisation is that of alternative spaces, which are designed to facilitate rethinking the relationship between the observer and the work of art. These spaces emphasise the relationships that can be established between the visitor, the work of art, the document on display and the industrial structure. An essential aspect of the project is the integration of the existing listed buildings (the artifacts at the entrance of the former paper mill and the wall along Vicolo del Riserraglio) with the new redevelopment work through an overwriting operation. Additionally, the project encompasses the recuperation and renovation of the minor artefacts located at an altitude of 208.00, in addition to the maintenance and restoration of the wall along “Vicolo del Riserraglio”. This wall is characterised by a lower height than the existing wall and a similar horizontal profile to that of the new designed building, which defines the altimetric limit of the new building.

From the outset, the museum project sought to identify potential risks and elements that could oppose the decision to repurpose the property. This was done with the understanding that there was a risk of falling back into the practice of *damnatio memoriae*, which is the destruction of historical or architectural testimonies of strong interest. The provisions of the commissioning administration are equally stringent. In fact, the administration has expressed its personal interest in demolishing the ground floor, with access from Piazza Tani, in order to give the city a suggestive panoramic view of the valley. Furthermore, numerous studies have demonstrated that demolition activities result in significant CO₂ emissions into the environment. In order to address these concerns, it will be necessary to implement selective demolition operations, focusing on the non-constrained areas, with the aim of reconnecting with the historic centre and extending Piazza Tani. This will enable the full enjoyment of the admirable and evocative views. Additionally, it may be possible to highlight historical and cultural aspects of relevance related to industrial archaeology, such as the processing chain of the former paper mill. The relationship with the landscape of great value for the view of the valley below and the opening towards the countryside, as well as the opening on the ground floor to ensure visual integration with the Tower of Santa Caterina located in the western area of the complex, which represents a distinctive architectural and geometric sign, will be sensitive issues. However, they are not only of the immediate context, but also of the entire skyline of the historic centre of Tivoli.

European policies are becoming increasingly rigorous in supporting and promoting recycling and reusing construction materials. The Municipality of Tivoli, as the client for the musealization project, shares this perspective and has requested particular attention to the reuse of materials resulting from demolitions. Various techniques and strategies for reuse exist, but they can primarily be categorized into two approaches: the first involves disassembly, particularly for finished elements such as fixtures, structural metal elements, and prefabricated components. The second approach involves the demolition of components, such as concrete elements, followed by controlled crushing to separate materials. In this case, the materials are concrete and steel, which are then recycled and reused. This practice of recycling elements from demolitions or decommissioning is commonly known as upcycling. The term upcycling is based on the principle of giving a second chance to elements that are capable of serving new functions and being part of new contexts. Given the proven scarcity of available resources and the primary necessity to recover and reuse materials with this potential, the ongoing project aligns with this recycling logic. It envisages on-site storage of discarded materials and their reuse or sale to third parties as raw materials.

4. THE ADAPTIVE REUSE PROJECT

The proposal for the restoration and reactivation of the historic building that forms part of the former paper mill complex in Tivoli aims to establish a Paper Museum that serves as both a cultural hub and a historical testament to the role that paper mills have played in the city's industrial and economic history. This intervention is of great importance for the city and represents a significant urban regeneration project. Its aim is to create a cultural structure of high architectural quality that will perform the function of a catalyst for cultural and relational activities, capable of revitalising the entire urban area of reference [12]. Initially, the option of demolishing the entire building was considered in order to facilitate the design of the museum settlement from scratch. However, this was rejected due to the potential for the work to be redeemed and the substantial economic and environmental sustainability of the redevelopment and regeneration of the asset [13].

The project proposal entails the demolition of the existing volumes at the height of "Piazza Tani" (altitude +208.77 m), which are not subject to protection, and the construction of a new belvedere square, which will serve as a new equipped public space that connects the historic centre with the natural landscape. While prioritising the conservation of the perimeter of the paper mill complex, the project identifies three significant urban themes. The first of these is the landscaping of the north and north-west fronts along "Via degli Stabilimenti".

1. The project also proposes the development of urban connections between Piazza Tani and an elevated area, which could potentially accommodate a future auditorium or belvedere square.
2. A fundamental limitation of the project is that the maximum height of the summit must not exceed the level of Piazza Tani, which allows for an extension of the square and panoramic views of the valley and the Roman countryside.

The redevelopment project aims to optimise the panoramic views of the area while enhancing the urban fabric and architectural features. The functional reorganization of the paper mill ensures the preservation of significant elements while incorporating contemporary needs. This process involves the selective preservation and demolition of non-essential parts, with a particular emphasis on the preservation of historically significant elements. In accordance with the stipulated constraints, the project provides for the maintenance and restoration of the existing volumes that allow access from Piazza Tani. These volumes will house spaces for catering, information points and bookshops to the east.

Two distinct connection systems are proposed for consideration:

- a. An external public path is proposed to be constructed along the Vicolo del Riserraglio, which will lead to a new public terrace at a level of +204.00 m. This terrace will connect to a future "belvedere basso" square at a level of +199.00 m.
- b. An internal system within the building complex that provides vertical connections between the various levels.

The construction of a new connecting 'plug' is proposed as an extension of the portion of the old control space at the entrance, which is a constrained part of the existing structure. This extension will also include the lift area and a small linear extension. The new spine, which is aligned with the medieval tower of the convent of Santa Caterina, houses the entrance to the service rooms of the museum complex and the vertical connection systems, including the elevator block and new staircase, between the two main levels of the museum building, which are located at 209.00 m. The two aforementioned levels, 204 and 201.00 m.a.s.l., are in direct relation to the new 'low' square.

The functional organisation of the interior spaces is designed to define a promenade, as far as possible in relation to the residual fragment of the Paper Mill complex, in a manner consistent with the narrative of the production process. Nevertheless, the decision to establish, through the binding decree, the portion of the pre-existing building to be preserved, favouring the landscape aspects, prevents the definition of a route adhering to the original production process, as it provides for the demolition of

the eastern part of the complex. In this regard, the proposal entails the delineation of a principal exhibition area at an altitude of 204.00, which will serve as a venue for temporary exhibitions and multimedia installations pertaining to contemporary art and the memory of the paper supply chain. The objective is to establish a malleable space characterised by temporary installations with a fluid layout and a pronounced visual impact. Additionally, an annular path encircling the aisles of the boilers provides a view of both the external landscape and the extraordinary double-height spaces of the former paper mill (mill area and kiln area). This is achieved through a system of walkways.

On level 3, at a height of approximately 197.05, a multifunctional space is planned for educational workshops, events and public demonstrations. This will be created by the construction of an equipped area located below the 'kettle lane'. This is a longitudinal space of remarkable quality that, through the addition of simple furnishing elements and the implementation of an adequate system (lighting and air conditioning), can host permanent exhibitions, events and collective activities for approximately 100 people.

5. CONCLUSION

It is important to highlight how the heritage value recognised in the buildings gives priority to the location within the urban and territorial context, opting for selective protection in favour of the value of the surrounding landscape. Emphasis is therefore placed on the integration of the site into its valuable landscape context, rather than opting for a more conservative approach, focusing on the specific

conservation of the buildings. The case study reveals an intriguing positive anomaly pertaining to the safeguarding of an edifice of historical and artistic merit [14]. This situation has significantly impacted the redevelopment of an abandoned industrial site and the integration of a public construction value chain, thereby enhancing urban quality of life. The anomaly is linked to the protection measures imposed by the Italian authority responsible for the safeguarding of cultural heritage, which stipulate a gradual transformation process for different parts of the building complex. This has resulted in the partial demolition of certain structures, a practice that is relatively uncommon in the context of the protection of cultural assets. This selective protection is derived from a specific hierarchy of values attributed to the paper mill complex, with the original building core being accorded the greatest significance. This is situated in a valuable landscape context overlooking the Aniene River and the Sanctuary of SS. Maria di Quintiliolo. This landscape value was deemed to be of greater importance than the preservation of industrial buildings, reflecting a shift in the recognition of the significance of the landscape [15]. The approach is based on the integration of the site into its natural surroundings, rather than solely on the preservation of industrial history. This is achieved by reducing and demolishing parts of the modern factory in order to partially restore the original landscape. The podium opens towards the scenery, framed by the remnants of the former convent of Santa Caterina.

These principles have informed the criteria for the transformation and revitalisation of the area, as outlined in the Design Competition guidelines for the construction of the auditorium and parking area in the former Amicucci Parmeggiani paper mill. In addition to defining the utilisation programme and identifying areas for demolition versus preservation, the competition objectives placed significant emphasis on the landscape integration of the complex. This entailed considering the visual connections between the valley system of the former paper mills and the Sanctuary of Hercules Victor, as well as between the Sanctuary of SS. Maria di Quintiliolo and the opposite side. Maria di Quintiliolo is situated. At the urban level, the project for the recovery of the former paper mill included the creation of three new public spaces at different heights, with the intention of revitalising the urban significance of this landmark in the city of Tivoli. The ambitious project is currently underway and its impact will be assessed in the coming years to evaluate its effectiveness in transforming disused industrial assets into lasting public values and integrating them with historical heritage. In essence, the collective endeavour is not merely to conserve the vestiges of the past; rather, it is to imbue them with new life, transforming industrial heritage sites into catalysts for sustainable development and cultural enrichment. By demonstrating unwavering dedication, ingenuity, and a shared commitment to our cultural heritage, we pave the way for a more resilient and inclusive future, where the echoes of the past resonate vibrantly in the tapestry of our collective identity. As we chart a path forward, we envisage a future that embraces adaptive reuse, cultural tourism initiatives, and community-led empowerment strategies. By capitalising on the inherent resilience and cultural capital of sites such as the former Amicucci Parmeggiani Paper Mill, we seek to foster vibrant ecosystems where heritage conservation coexists harmoniously with economic revitalisation and social cohesion.

Abstract

After a significant period of economic and pandemic crisis, the challenge of climate neutrality is at the top of the new urban agenda and urban politics. The urgent need to implement policies to strengthen urban resilience (to any natural or technological disaster) is emphasized to achieve urban sustainable development. In addition, the European Green Deal promotes the acceleration of significant interventions in cities. Urban regeneration practices have been established to meet these challenges by offering effective solutions. In this frame, European urban authorities are promoting large constructions in buildings and public spaces as well as large-scale urban regeneration projects, capitalizing on valuable experience from the past. In Greek cities, so far, there have been no significant urban regeneration interventions driving notable changes, due to the cities' timeless issues compared to the ones confronted in Central Europe. Small land ownership, problematic urban planning, and weak public housing policy have driven to unregulated urban sprawl and residential expansion on agricultural land. All the above resulted in vulnerable cities with a low-quality urban environment. The consistently low role of urban regeneration in national spatial planning practices and the piecemeal and in some cases 'empirical' projects have not improved the built environment. The building stock is old and energy inefficient while open public spaces are few and far between. After years of specific spatial policies, combined with the new conditions determined by the climate crisis, the framework of the national urban regeneration policy is considered incomplete and problematic. In contrast to modern approaches that recognize the multidisciplinary nature of urban issues by proposing holistic interventions capable of dealing with the climate crisis, projects in Greece are usually limited to the beautification of external public spaces. In addition, the main problem of Greek cities, that is the imbalance between built and unbuilt space and the aging building stock, is not addressed. In this context, a series of questions are raised regarding the factors that determine and guide urban regeneration projects in Greece, so that a holistic policy and intervention framework can be developed. Therefore, a multi-criteria assessment and calibration methodology is required to guide urban planning decisions. This paper investigates the effectiveness of implementing a scientific tool that (a) collects data (b) evaluates and scores them using multiple criteria and (c) based on the conclusions acts as a decision-making system. The proposed methodology is deemed to become a tool of modern spatial policy. It can guide urban planning decisions aligned with the principles of the Green Deal and ultimately serve as an urban regeneration, resilience, and green development tool particularly useful for urban authorities.

Keywords: urban regeneration; urban resilience; new urban agenda; multicriteria analysis; Green Deal

1. INTRODUCTION

1.1. Urban regeneration: context and challenges, concepts, and strategies

In the history of cities, urban planning, and major urban renewal projects appear as consequence of their economic development. Urban regeneration and resilience present a complex interplay of challenges and opportunities in contemporary urban development. As cities evolve and face various socio-economic, environmental, and infrastructural pressures, the need for revitalization becomes imperative. Urban regeneration and resilience demand holistic approaches that address the intricate nexus of social, economic, and environmental challenges [1]. The challenges and requirements for interventions vary significantly from one country to another and are influenced by the prevailing social, economic, and political conditions, alongside physical design considerations. In addition to these, embracing community participation, sustainable practices, and innovative solutions is crucial for cities to successfully transform blighted areas into vibrant, resilient urban landscapes. This approach not only addresses the specific needs of local communities but also fosters inclusivity, environmental stewardship, and long-term viability, ultimately enhancing the quality of life for all residents. In this complex context, many challenges need to be solved through urban regeneration. Among these, the most important are the following: social inequality, environmental degradation, economic decline, and historical preservation. Addressing the above challenges is achieved through the utilization of a series of opportunities, such as community engagement, green infrastructure, mixed-use development, and innovative technologies.

All of the above are addressed through specific measures. The two main categories of measures, institutional and infrastructural, play crucial roles in achieving the goals of urban revitalization. Institutional measures, such as enacting laws and regulations, provide the necessary framework to support city policy objectives, while infrastructure projects directly contribute to enhancing residents' well-being and attracting investment. These measures are typically overseen by various levels of government authorities. To ensure their effectiveness, relevant agencies need to devise comprehensive strategies that tackle the multifaceted challenges of urban areas, encompassing socio-economic, environmental, and cultural aspects. This holistic approach is key to fostering sustainable and inclusive urban development [2]. Key strategies include:

- Place-based approach, as a strategy recognizes the unique characteristics, strengths, and challenges of each region, tailoring interventions to its unique context.
- Mixed-use development, such as residential, commercial, recreational, and cultural activities, in a single area to encourage vibrant, walkable neighborhoods reduces car dependency and enhances urban vitality.
- Sustainable Planning and Design including optimizing land use, minimizing environmental impacts, promoting energy efficiency, and prioritizing green infrastructure to create resilient, environmentally friendly urban spaces.
- Heritage conservation including adaptive reuse of historic buildings, revitalization of heritage sites, and promotion of cultural tourism, contributing to local identity and economic development.
- Community involvement and participation, which enhances ownership and social cohesion and ensures that regeneration initiatives are aligned with community needs and aspirations.
- Public-private partnerships (PPPs), which leverage the strengths and resources of various stakeholders to finance, plan, and effectively implement regeneration initiatives.
- Inclusive development and social equity which entails providing affordable housing, equal access to services and amenities, and opportunities for economic empowerment and social mobility.
- Smart city technologies such as data analytics, IoT sensors, and digital platforms that enable real-time monitoring, optimization of urban systems, and informed decision-making.

Contemporary regeneration policy indeed encompasses a range of urban planning interventions aimed at spatial reorganization within settlements or cities. Rooted in the principles of sustainable development, these interventions seek to revitalize existing built environments and may also entail the creation of new urban areas. The primary objective is to facilitate sustainable urban development that improves residents' quality of life and advances economic, social, and environmental well-being [3,4]. In summary, contemporary regeneration policy represents a comprehensive approach to urban development that prioritizes sustainability, inclusivity, and resilience. By addressing the spatial, economic, social, and environmental dimensions of urban change, these policies aim to create cities and settlements that are more livable, equitable, and environmentally sustainable for present and future generations.

Shifting policy toward integrated solutions that serve multiple objectives is crucial in contemporary physical planning. This necessitates a systematic evaluation process based on scientific criteria to inform decision-making. Then, by adopting innovative strategies, engaging stakeholders, and fostering collaboration, cities can revitalize their urban fabric, promote sustainable development, and improve the quality of life for residents.

1.2. Greek spatial planning and regeneration practices

In recent years, in Greece, spatial planning practices were initially introduced at the level of the urban planning scale to deal with issues related mainly to the organization of the development of urban centres and the problems that arise [5]. Already, since the 1980s, there has been a systematic effort for the country to acquire urban plans. At the end of the 1990s, the country acquired a new legal framework for urban planning (Law 2508/97, Official Gazette 124/A) and spatial planning (Law 2742/99, Official Gazette 207/A). Through the above laws, it is the first time that "urban regeneration" is included in the field of urban planning regulation [3], it is institutionalized as a distinct process and is strengthened with tools and financial mechanisms. Indeed, until the passing of the new housing law, regeneration did not exist as an independent tool within the spatial planning system. Law 2508/97, among others, introduced a strategic-type tool for interventions in the already-formed urban landscape of cities. It even became known that he gave the greatest weight, in terms of urban planning tools, to city regeneration, to which a whole chapter and enough articles and pages are devoted.

Although Law 2508 was passed by the Hellenic Parliament on May 22, 1997, it has been little used to date. The off-plan building and expansions of cities and settlements in the off-plan area prevented the application of the regeneration tools, as the regenerations referred to in Law 2508 are limited only to regions of approved city plans or demarcated settlements [6]. In addition, the procedures established by the specific law are complex and time-consuming, especially in matters concerning the formation and operation of the redevelopment body. The provisions of the law offer the municipalities a variety of options, however, the implementation of the articles concerning the areas and redevelopment agencies, seems utopian.

During the 2010s, it was sought to redefine how plans are harmonized at each planning level, to soften their hierarchical structure and promote the mutual feeding of planning levels. The institutional framework underwent successive changes, which were characterized in many cases by ambiguity - which possibly expresses the upheavals in Greek society during the 2010s following the financial crisis [7]. After 2010, the institutional framework of spatial planning in Greece is being reshaped considering the effects of the preceding financial crisis. In 2014, Law 4269 "Spatial and Urban Planning Reform - Sustainable Development" was passed (Government Gazette 142/A). Among other things, the new framework specializes in [6,8]:

- Avoiding conflicts and overlaps of planning levels that, as noted, were observed in the previous law.

Proceedings

- The clear distinction between planning levels at strategic (national and regional) and regulatory (local) levels.

Subsequently, with the law on spatial planning (N 4269/2014 "Spatial and urban planning reform - sustainable development") which was replaced by N 4447/2016, "Spatial planning - Sustainable development and other provisions", several issues were promoted, among which is the attempt to reduce planning levels by adopting Local Spatial Plans, to address issues related to overlaps, contradictions and contrasts between spatial and urban planning plans of different levels [4].

The main spatial planning system of the country (see L. 4447/2016, as amended by L. 4957/2020) includes a set of spatial frameworks and urban plans, which are prioritized in levels based on the geographical scale, their content, and the wider objectives they serve in the implementation of spatial policy. These tools are referred to as sets of texts, maps, and/or diagrams and are distinguished in strategic and regulatory nature [9]. Undoubtedly, the institutional framework is old and there is a need to reform it as it is rigid radically, it does not correspond to the Greek reality, especially concerning small ownership, and is focused only on planning. Small land ownership, problematic urban planning, and weak public housing policy have driven unregulated urban sprawl and residential expansion on agricultural land. [10]. Indeed, the particularity of the Greek space in matters of organization and comprehensive treatment is a given, as although it is a naturally heterogeneous environment, its acquired characteristics, and man-made interventions in it have intensified the problems and created a multitude of difficulties [11]. In addition to the above, it is noteworthy that no institutional framework nowadays has highlighted the need for a systematic collection and analysis of data to select the appropriate strategic decisions in urban regeneration. All the above resulted in vulnerable cities with a low-quality urban environment.

Due to all the weaknesses above, the practice of urban interventions in Greece has been limited almost exclusively to structural interventions in the free public (shared) space with a beautification character and the main goal of improving its quality and function in terms of aesthetics and urban equipment. Until recently, implemented interventions with an integrated approach, development directions were absent, and competent financing tools [8,12]. The consistently low role of urban regeneration in national spatial planning practices and the piecemeal and in some cases 'empirical' projects have not improved the built environment. The building stock is old and energy inefficient while open public spaces are few and far between. After years of specific spatial policies, combined with the new conditions determined by the climate crisis, the framework of the national urban regeneration policy is considered incomplete and problematic. In contrast to modern approaches that recognize the multidisciplinary nature of urban issues by proposing holistic interventions capable of dealing with the climate crisis, projects in Greece are usually limited to the beautification of external public spaces. In addition, the main problem of Greek cities, that is the imbalance between built and unbuilt space and the aging building stock, is not addressed.

2. MULTICRITERIA ANALYSIS (MCA) AS A USEFUL TOOL FOR URBAN REGENERATION PROJECTS

Urban regeneration and resilience have become critical agendas in contemporary urban planning and management due to the increasing challenges posed by rapid urbanization, climate change, and socio-economic disparities. Decision-making in these contexts demands a comprehensive approach that considers multiple criteria and stakeholders' perspectives. The most suitable urban transformation project always depends on many elements influencing each other. Therefore, different alternatives should be provided already during the ex-ante evaluation. Traditional methods of economic and financial feasibility, such as cost-benefit and cost-benefit analysis (CBA), are not suitable enough to understand complex cases. Multicriteria analysis (MCA) emerges as a promising tool to address these complexities by facilitating systematic evaluation, prioritization, and selection among diverse

Proceedings

regeneration and resilience strategies [13]. The review underscores the importance of MCA as a decision-making tool for enhancing the sustainability, inclusivity, and effectiveness of urban regeneration and resilience initiatives. Moreover, the paper discusses the challenges and limitations associated with the application of MCA in urban regeneration contexts and proposes avenues for future research and improvement. Finally, this paper investigates the effectiveness of implementing a scientific tool that (a) collects data (b) evaluates and scores them using multiple criteria and (c) based on the conclusions acts as a decision-making system. The proposed methodology is deemed to become a tool of modern spatial policy. It can guide urban planning decisions aligned with the principles of the Green Deal and ultimately serve as an urban regeneration, resilience, and green development tool particularly useful for urban authorities.

It is noticed that, in recent decades, many studies and research have been carried out trying to find the best solutions for successful urban regeneration interventions. In addition, the analytical literature has grown significantly with studies conducted using different approaches, as well as different variations of urban planning techniques (using different methodologies, methods, and data). In this context, the multicriteria analysis is useful in any urban regeneration program, because of the following advantages [14]:

- Allows identification of critical variables to be considered for the system under study.
- Enables expert judgment to be considered during the design process.
- Encourages a deep analysis of system variables.
- Allows for the comparability and structuring of multiple variables in order of importance.
- Allows indirect classifications to show the significance of many variables that, at first, and through direct classification, were not obvious.

Starting from qualitative and quantitative analysis, the purpose of the present contribution is to show the different steps to get to the most suitable project for the regeneration of degraded urban areas with a priority scale for the interventions proposed [13]. Generally, the objective of developing a methodology for creating a decision-making tool using public data, as outlined by Chatziioannou and Álvarez-Icaza (2017), is to establish a specific set of indicators. Indicators may be used for preliminary investigation, ongoing monitoring, or evaluation of final performance. Indicators can be used for ex-ante, in-itinere, or ex-post evaluations. The importance of indicators as tools for knowledge and analysis, design, and monitoring has already been stressed in several areas. These indicators can guide government public policies in the planning of urban revitalization projects. The aim is to design indicators that support the paradigm of sustainable urban revitalization and resilience by effectively covering and operationalizing diverse elements of the urban environment [14,15]. These indicators should encompass various aspects such as urban microclimate, public space, urban greenery, energy efficiency of buildings, mixed land uses, and more. By utilizing public data and integrating these indicators into a comprehensive framework, decision-makers can make informed choices that prioritize sustainable development and enhance the resilience of urban areas. Additionally, the development of a synthetic indicator derived from these specific indicators can offer a consolidated measure to guide future policy interventions and urban planning efforts effectively.

2.1. Materials & methods

A decision support system should make clear the objectives it should achieve, but also help achieve them [16]. This, according to Anagnostopoulos and Vavatsikos (2007), can be carried out in four interactive stages with the possibility of redefinition [17]:

1. Study and define the environment of the problem.
2. Search and design alternative ways of approach.
3. Choose the one that looks best.

4. Implementation and evaluation.

2.2. Stage 1: establishing the inventory of variables.

This stage considers the production of Table 1, which contains all the established sectors linked to the system under study to strengthen the effort of each urban area to revitalize and be resilient. Creating Table 1, which outlines the sectors linked to the system under study, is indeed a crucial step in the process of urban revitalization and resilience [14]. The final aims should be pursued without unnecessarily increasing the burden of information. Consequently, it is necessary to avoid all those confusing phenomena, such as redundancy, excessive generality, or lack of specific relevance of the information collected, which would be detrimental to effectiveness and efficiency [18]. This table serves as a comprehensive overview of the intervention area and helps in selecting appropriate indicators to measure progress toward the desired redevelopment goals. To begin this process, stakeholders must thoroughly understand the character of the intervention area [19]. This involves assessing its current state, identifying existing strengths and weaknesses, and understanding the dynamics of the local community and economy. Additionally, it's essential to evaluate the vision of the redevelopment agency for the area's future form post-intervention [19,20]. This vision should articulate the desired outcomes, objectives, and priorities for revitalization and resilience efforts. Indicatively, Table 1 can have the following format:

ID	Nomenclature of the Plan's Critical Sectors Against Urban Regeneration and Urban Resilience	Symbolization of the Established Critical Sectors for the Mitigation of Urban Regeneration and Urban Resilience within the Software MICMAC
1	Spatial Rejuvenation	Spatial_Re
2	Community Engagement	Com_Eng
3	Economic Viability	Econ_Viab
4	Environmental Sustainability	Env_Sust
5	Risk Awareness and Assessment	Risk_Awar_Ass
6	Adaptive Capacity	Adj_Cap
7	Infrastructure Robustness	Inf_Rob
8	High Population Density	High_PD
9	Mixed Land Use	MixedLU
10	Efficient Transportation	Eff_Trsp
11	Accessible Public Spaces	Access_PS
12	Urban Greenery	UG
13	Mixed Housing Types	M_HT
14	Compact Urban Form	CU_form

Figure 1. The established variables of the thematic study

Once the character of the intervention area and the regeneration vision are clear, stakeholders can proceed to select indicators that align with these goals. These indicators should cover various aspects related to urban revitalization and resilience, such as socio-economic development, environmental sustainability, infrastructure quality, community well-being, and others. By carefully selecting indicators that reflect the unique needs and aspirations of the intervention area, stakeholders can effectively monitor progress and guide decision-making toward achieving desired regeneration outcomes.

2.3. Stage 2: specification of the variables relations

Stage 2 associates the variables considered through a dual-input matrix. This matrix exposes, at a column level, the degree of dependence that each variable experience from the rest of the considered variables, as determined through the opinion of experts [21]. The latter exposes at a column level, and through the opinion of experts, the rate of dependence that a variable experience from the rest of the considered variables.

The first step is to identify the relevant variables considered important for the analysis or evaluation. These variables could be factors influencing a particular outcome, elements of a system, or indicators of performance. A dual-input matrix is then constructed, with variables listed along both the rows and columns. Each cell in the matrix represents the relationship between the variable in the row and the variable in the column. In the following, opinions are presented regarding the degree of dependence between the variables [22]. This could include assessing the strength of the relationship, such as high, medium, or low dependence, or assigning numerical scores or weights. Factors such as causality, interdependencies, feedback loops, and direct or indirect effects are considered. The typical structural analysis matrix includes values equal to “0” when there is no relation between the variables, “1” when there is a weak relationship, “2” when there is a moderate relationship, and “3” when there is a relation of high intensity [14,15]. For the sake of simplicity, only two values, zero (“0”) and (“1”) can be used interchangeably to indicate the absence and presence of relationships between variables. In this way, the determination of the connections between the variables of the thematic study will be possible without considering the intensity of the relationships. Therefore, the reliability of the results in qualitative terms will be intact [14]. This table provides a visual representation of the complex network of relationships between variables. Once the matrix is populated with dependence ratings, further analysis can be conducted to identify patterns, clusters, or outliers. The assessment dependency process can be iterative, involving multiple rounds of expert input, review, and refinement to ensure accuracy and consistency. Using a double-entry matrix and expert opinions to assess the dependence between variables, Stage 2 of the process allows for a systematic and structured approach to understanding the complex relationships within a system or context. This information serves as valuable information for subsequent stages of analysis, planning, or decision-making.

2.4. Stage 3: recognition of the key variables

In Stage 3 of the process, variables are classified based on their rates of dependence and influence, allowing for the calculation of direct interlinks within the variables along with indirect relations [14]. Each variable's components of its column and row in the dual-input matrix are summed. This involves adding up the ratings or scores assigned to the variable about all other variables, both as a dependent variable and as an influencing variable. The summation of components provides insights into each variable's direct and indirect relations within the system. Direct relations represent the immediate influence or dependence between variables, while indirect relations capture the secondary or mediated effects through other variables. Based on the calculated sums of components, variables are classified according to their levels of influence and dependence. Variables with high sums of components indicate strong influence or dependence, while those with lower sums indicate weaker relationships. A diagrammatic illustration is then generated to depict the location and classification of each variable based on the intensity of direct relations between them. The illustration typically consists of two axes: the Y axis represents the level of influence, while the X axis represents the level of dependence [14,23]. After achieving the tabular stabilization results, the diagrammatic representation shows the direct relationships between the variables but the resulting indirect ones. In addition, another Table can be created that will contain the justification of the relationships between the areas of the plan by conducting a literature review, to enrich the experimental-empirical results extracted by the group of experts with theoretical elements [15].

2.5. Results and decisions

After the problem is structured, alternatives are measured according to the above, and the next phase involved in the chosen procedure concerns the derivation of criteria weights. To give weight to the defined criteria and sub-criteria, a round of questionnaires can be created for a selected group of experts. The selection of experts is usually based on their previous experiences on the proposed topic. Experts with relevant experience and expertise in urban regeneration, urban planning, sustainable development, or related fields are identified and invited to participate in the weighting exercise. The selection criteria may include professional background, knowledge of the project context, and previous experience with similar projects.

Once the decision network consisting of the sub-networks benefits, opportunities, costs, and risks has been defined, the interdependence relationships between clusters and nodes are established. The alternatives cluster is related to all other clusters, while the other clusters may or may not be related to each other. Then, a pairwise comparison is carried out by answering a questionnaire to identify which of the two examined alternatives is of greater relevance.

Conduct a thorough assessment of all variables relevant to the urban regeneration project, including socio-economic factors, environmental considerations, infrastructure needs, community dynamics, and stakeholder interests. This assessment should consider both direct and indirect relationships between variables and their potential impacts on the regeneration process. Define specific lines of action or interventions that address key issues and contribute to the overall objectives of the urban regeneration project. These lines of action may include physical improvements, policy interventions, community engagement initiatives, economic development strategies, and environmental sustainability measures. Ensure that all lines of action are integrated and aligned with the broader goals and vision of the urban regeneration project. Each line of action should contribute to the achievement of specific objectives within the overall plan, while also complementing and reinforcing other interventions. Determine whether lines of action will be implemented sequentially or in parallel based on project timelines, resource availability, and logistical considerations. Some interventions may need to be implemented sequentially to build upon each other, while others can be carried out concurrently to maximize efficiency and impact. Develop a comprehensive, long-term plan for the urban regeneration project with defined timelines and periodic milestones. This plan should outline the sequence of actions, resource allocations, responsibilities, and monitoring mechanisms to ensure effective implementation and ongoing progress. Establish mechanisms for periodic review and adjustment of the urban regeneration plan to account for changing circumstances, emerging challenges, and evolving stakeholder priorities. Regular monitoring and evaluation will help identify successes, challenges, and areas for improvement, enabling timely adjustments and course corrections as needed.

3. CONCLUSION

Urban regeneration aims to transform cities into spaces that offer high-quality urban environments and improved daily living conditions. Successful urban regeneration efforts focus on revitalizing cities to make them attractive, livable, and sustainable. This includes creating visible and accessible areas for parks, open spaces, green corridors, social infrastructure, urban facilities, and affordable housing. To achieve these goals, urban regeneration interventions must be guided by scientific decision-making methods. One such method is multi-criteria analysis (MCA), which can play a crucial role in ensuring the success, sustainability, and social acceptance of urban regeneration projects. Key aspects of scientific decision-making include data driven planning, stakeholder involvement and sustainability considerations.

The benefits of using MCA in urban regeneration include, at least, comprehensive evaluation, transparency, flexibility, and enhanced social acceptance. MCA ensures that urban regeneration projects are successful, sustainable, and socially accepted by evaluating multiple factors and

involving stakeholders in the decision-making process. By adopting MCA, cities can ensure that their regeneration efforts are aligned with their core vision and goals, leading to vibrant, inclusive, and resilient urban environments.

Redeveloping military brownfields in Greece: searching and evaluating of good practices in European case studies and their applicability

K. Koleli

Civil Engineer, MSc Urban Regeneration and Development, Department of Planning and Regional Development, University of Thessaly, Pedion Areos, 38334 Volos, Greece

E-mail: pkoleli@gmail.com, Tel +30 6944817663

Extended abstract

Military brownfields, a variety of disused sites of defense forces, is a specific category within all brownfields. Common for military brownfields is their particular location and infrastructure in respect of the surrounding environment. Redeveloping these sites and disposing them for civilian use is a quite complex and multidisciplinary process. It is a planning challenge, differing from ordinary changes of use because of the unusually wide range of interested stakeholders and their expectations. Military brownfields are made up of large and small sites, urban or remote, and can include an extraordinary range of functional specialist buildings that can be recognized as heritage as they are a specific feature of wars, conflicts, and their aftermaths. As urban sites are a particular part of the city, that for a long time has been excluded from the active life of the city, and for this reason it is considered necessary to adopt new strategies for their re-appropriation.

The challenge in military base redevelopment, like other brownfield sites, will be to guarantee competitive advantages through revenue-generating activities that can transform these sites into reliable economic opportunities requiring clear and viable land-use strategies and investment while looking after the interests of all the parties involved. They are also affected of the new dynamics of real estate development and investment that now comes with a host of economic, social, environmental and ethical ‘baggage’ and the view that property markets should be viewed as “cultural entities, shaped as much by tradition, taste, technological and social innovation as by immediate levels of availability and demand”. Like all other brownfield sites, military ones are not solely discussed in technical terms anymore (e.g. contamination), but as an opportunity for saving resources and delivering sustainable urban development.

What is studied in this paper is the strong system of policy and funding frameworks of European Union that work synergistically to support brownfields redevelopment across the region as well as European projects and programs related to the enhancement, reuse, and regeneration of former military sites. One of this programs was the “2015–2018 MAPS-Military Assets as Public Spaces” initiative that has involved mostly former military barracks across nine European cities to provide feasible solutions aimed at the preservation and enhancement of tangible and intangible values. This program appears to be a remarkable reference that extracted key drivers for innovative reuses integrating collaborative practices such as: the involvement of local and state stakeholders, both public and private, to identify feasible reuse solutions of buildings and open spaces; the temporary reuse to experiment unexpected short-term and cheap functions and activities to enable the reuse in the medium and long term and the identification of former military barracks’ tangible and intangible values.

The conclusions of this study are used to create a framework for evaluation and assessment of the redevelopment of the military brownfields in Greece to date, taking into account the special legal status governing these sites.

Urban Regeneration In A Low Income Neighborhood. A Case Study In Lima, Peru

C. Giusti

Texas A&M University, Texas, USA

Corresponding author: E-mail: cgiusti@arch.tamu.edu

Extended abstract

The Santa Cruz neighborhood is composed of about 30 blocks of historically low-income residents located within a wealthy Miraflores district in the Mega City of Lima, Peru. This neighborhood was created when the walls of Lima were demolished and the city started its modern urbanization. In the early 1900 the former Hacienda Santa Cruz, west-south of downtown Lima became accessible due to new avenues built connecting it with downtown. This coastal area became attractive to mostly high-income Lima residents who wanted to get away from the too-congested downtown. The big Hacienda Santa Cruz was partitioned following a grid pattern, and a very small portion of it was sold to a few families of former slaves. With time, this small partition was subdivided into smaller lots, evolving into cheap housing, concentrating woodshops, car mechanics, plumbers, carpenters, and alike, with cheap land and property values. This low-income “enclave” evolved in an otherwise high-income district that benefited from having cheap labor nearby, while Santa Cruz residents benefited from having access to nearby city’s services and infrastructure, not a rare phenomenon in South American cities. This worked for about 100 years.

However, the growth of Metropolitan Lima, and the fact that Peru was becoming a gastronomic world attraction, pushed for expanding the supply of high-end restaurants since the early 2000’s. The availability of relatively cheap land in an otherwise wealthy district, attracted new investors who looked to city officials for support to claim this relatively cheap land, ensuring not only more businesses but also larger city incomes. What was a “low-income enclave” is nowadays a focus of growth: restaurants, cafes, and high-end stores are replacing car-repair, or carpenter shops; and new condo buildings are being built targeting high-income residents. With new investment, land prices increased, resulting in forced displacement of the local population; legal actions for evictions, repossessing of land, and active protests are now happening.

This process of urban regeneration is creating serious problems for former residents who are being mostly evicted. And we question: What is the role of the City in protecting business? Or former residents? Or new residents? This could be perceived as a typical case of gentrification. At the same time, local residents are reacting claiming their right to the city. What should City officials do to protect the neighborhood identity? Using city and press documents and our fieldwork in the area, we analyze the response of the City and its involvement in this process. We expect to shed light on what (not)to do when re-developing a place. At the end, who does the City work for?

Investigating the relationship of energy retrofitting of buildings with the real estate market in degraded urban areas.

N. Triantafyllopoulos

Department of Planning and Regional Development, School of Engineering,
University of Thessaly, Greece

Corresponding author: E-mail: ntriant@uth.gr, Tel +30 2421074415

Extended abstract

Buildings are one of the largest sources of energy consumption. Consequently, adaptation to climate change depends mainly on actions undertaken in urban areas, cities being simultaneously part of the problem and its solution. The European Union and states establish ambitious policies and measures to achieve targets for the energy upgrade of buildings. New technologies are developing rapidly, but important barriers prevent their implementation in space. In this work, this issue is investigated and connected with the functioning of the real estate market in vulnerable urban areas. It is argued that to take decisions on the energy upgrading of buildings, both by the owners and investors, in addition to the profit from reducing the energy costs, there needs to be tangible benefits from the increase of the market value of the buildings and the generation of capital gains. Surplus values can arise through urban regeneration interventions. Energy upgrade of a building is a financial investment in a capital asset, and energy policies are most effective when tangible benefits are made significant, using market forces; higher prices of energy retrofitted properties can motivate owners. For a property investor, the value increase of the asset is an important driver for energy investment, and decisions are primarily based on the property market fundamentals, the quality of the area in which it is located, as well as their expectations for it, and secondarily on the energy performance of the buildings, the impact of which is incorporated in their market value. This fact implies that the energy market is subordinated to the real estate market.

A deprived area of central Athens serves as a case study. Based on field research data, cases of energy renovation of buildings through a public-private partnership scheme are analysed. Urban regeneration initiatives are not mandatory for cities and states, unlike building energy upgrades, but they can organise energy-efficient and sustainable future smart cities and improve the functioning of the local real estate market by attracting private investment. The European targets for the energy upgrading of buildings can be the vehicle to promote urban regeneration to achieve significant multiplier benefits, combat urban decay, alleviate energy poverty and remodel the city, as the New European Bauhaus initiative targets.

Public Spaces, Public Streets, and the Right to Work

C. Giusti

Associate Professor, School of Architecture, Texas A&M University, Texas, US

Corresponding author: E-mail: cgiusti@arch.tamu.edu, Tel +1 9795744750

Extended abstract

This paper focuses on the use of public space in a developing country. Guatemala is one of the poorest countries in Latin America, with a high concentration of so called “informal” markets. The use of public space by street vendors, or informal vendors, is a common trend in many Latin American cities and its presence has shaped the debate of planning in the global south. This paper discusses one extreme case called “El Amate” Market in downtown Guatemala City, the capital of the country. Unlike other failing cases, El Amate exemplifies one innovative example of a planned re-location intervention within the city and may shed lessons for other cities in Latin America and beyond. The main downtown street, 6th Avenue, was, during the 1980’s and 1990’s, occupied by street vendors with negative consequences on city’s public health, high crime, and devaluation of downtown properties. The city, for about 10 years, tried to “clean” the streets expelling vendors, only to realize that them were re-occupied the streets soon after; this situation persisted until a more comprehensive solution was pursued with financial and professional support from the InterAmerican Development Bank.

After a detailed study of the rationale of the street vendors, and with a lengthy and comprehensive negotiation with them, authorities and vendors arrived to an agreement; vendors were to be relocated in a nearby ad-hoc location built for them called El Amate market. This meant that 677 informal vendors peacefully left the 6th Avenue and took all their belongings to the newly created market.

This paper engages the views of local authorities -planning and executing this re-location- as well as the views of those who went through the process. This is accomplished through interviews with relocated vendors, local retailers, city authorities, and through the use of local and national data on population, property prices and field observations.

Three immediate effects were observed: the city recovered its public space (that used to be occupied by the vendors); downtown absorbed new investment mainly in retail; and the new location for the street vendors is, still, accepted by the vendors and by customers. At the same time, vendors are still “informal” in the sense that they are still trading similar merchandise, meaning goods that are not complying with branding trade requirements, and many are not registered within social security requirements. We may call them “quasi-formals” as they are registered within the local municipality. The strict dichotomy of informal vs formal may be blurred and may not be a useful theoretical concept. At the same time, we discuss who has the right to occupy public streets. These themes are at the core of this study.

Shaping Smart Neighbourhoods: An overview of inspiring Digital Tools for Holistic Building Stock upgrades

K. Chadio^{1*}, V. Geropanta¹, A. Karagianni¹, P. Parthenios¹

¹Technical University of Crete, School of Architecture, Chania 73100, Greece

*Corresponding author: E-mail: kchadio@tuc.gr, Tel +30 6932732346

Abstract

As cities worldwide grapple with the challenges of urbanization and environmental sustainability, the need to work with the transformation of building stock seems fundamental, as it promises a profound impact on the well-being and daily experiences of residents [1]. This sector has emerged in the last few years and methodologically, it is being approached through experiments mainly concerned with energy performance. However, the various examples do not yet provide a strong input to the field of architecture and urban planning [2]. As such, innovation in this area remains scarce for holistic upgrades to enhance sustainability.

In this framework, the specific research aims to affront this gap and elucidate the specific domains within which we propose enhancements, by drawing information and knowledge from three different fields: urban policy frameworks, digital technologies for the built environment and architecture. Specifically, it aims at highlighting the transformative potential of digital tools in upgrading the architectural landscape of existing buildings as a unit and as part of a neighbourhood cluster. It is expected that analysing the synergies between these areas can be a valuable resource for policy makers, urban planners, and researchers.

For this paper, the methodology chosen is dual: on the one hand, it is offered a review of contemporary technologies such as for example Building Information Modelling (BIM), Internet of Things (IoT), and Artificial Intelligence (AI) among others, that have the potential to support architects and urban planners in their goal of improving the building stock. Through the use of a matrix, all benefits and goals of these technologies are being illustrated and further discussed. On the other hand, case studies of initiatives that demonstrate how existing and innovative tools can be used in a variety of contexts to improve building stock at both the individual and neighbourhood scales. The selected case studies cover a range of topics, such as occupant engagement, adaptive reuse, improving green spaces, and reconfiguring city blocks. etc. and will be analysed to identify best practices and present innovative design and planning solutions across a spectrum of parameters, offering valuable insights for practitioners and decision makers alike.

As a conclusion of the two methodological directions, the authors summarise the key findings and emerging trends, and provide an initial assessment of how this process enables change and allows the transition of any traditional neighbourhood into a smart neighbourhood.

Keywords: *holistic building upgrade, old building stock, digital technologies, smart neighbourhood*

1. INTRODUCTION

As urbanisation accelerates and 68% of the world is expected to live in urban areas by 2050 (UNPD, 2018), the demand for suitable and efficient housing, infrastructure, and amenities is rising. This swift urban expansion highlights the critical need to upgrade and optimise current buildings to support population growth, bolster urban resilience, improve energy efficiency, and develop livable, sustainable cities for future generations. Though, many existing buildings face obsolescence, where they no longer meet current standards, performance requirements, or user needs due to ageing, technological advancements, or changes in regulations [3]. Concerned with current standards, performance requirements, or user needs due to ageing, technological advancements, or changes in

Proceedings

regulations. Obsolescence can lead to decreased functionality, increased maintenance costs, higher energy consumption, and reduced occupant comfort and safety [4]. Addressing building obsolescence requires strategic interventions to meet the evolving needs of urban communities while minimising environmental impact and maximising resource efficiency. Sustainable approaches to building upgrades aim to maximise the lifespan and value of existing assets while supporting the goals of urban development and environmental stewardship.

In the global literature, case studies of building stock upgrade encompass a range of methods to improve sustainability and functionality. These methods include rehabilitation, where buildings are restored to a functional state while retaining their historical and architectural significance. Reuse and adaptive reuse strategies focus on repurposing existing structures for new functions, minimising waste and resource consumption [5], [6]. Reinforcement techniques strengthen building structures to meet modern safety standards and extend their lifespan [7], [8]. Restoration emphasises returning buildings to their original condition, often through meticulous repair and conservation efforts [9]. Maintenance practices ensure ongoing upkeep and performance optimization. Additionally, repurposing and part-demolition strategies selectively modify or remove sections of buildings to accommodate new uses or design concepts [10], [11], [12]. Energy efficiency measures [13], [14] and green rooftop installations further contribute to reducing environmental impact and improving overall building performance [9], [15]. Capacity Improvement methods are also integral, aiming to enhance the building's capability to meet contemporary demands while preserving its structural integrity [16]. Collectively, these methods represent a comprehensive toolkit for upgrading existing building stocks while promoting sustainability and resilience in the built environment.

It seems that the use of digital tools is an important opening in this new sector of architecture, and they strengthen and enrich it with very important consequences in politics, the built environment. The trajectory between digital tools, building stock upgrades shows an interest in how we can do future design at neighbourhood level.

2. RESEARCH PROJECT

In this paper the authors focus on residential areas, and they have 2 parallel goals. First, to see which technologies are used today in the transformation of building stock and second, to get to what transformative potential is. The authors' general research question is: If digital tools have transformative potential in upgrading the architectural landscape of existing buildings, in which areas is this more obvious? And where tools seem to better support this objective? Through a comprehensive analysis of technological applications and their outcomes, the research aims to contribute valuable knowledge to the field of urban development and architecture, informing future practices and policies aimed at fostering transformative change in residential building stock.

3. METHODOLOGY

The methodology is developed in two phases. The first phase is about documenting which digital tools are used in upgrading architectural landscape and have better potential to support architects and urban planners in their goal of improving the building stock. For this step, a review of literature is realised in scientific journals and in international conferences of the last 10 years. Then an identification process identified the main types of technology that have been mainly reported in the literature. A third search was then carried out combining the technology types with different design fields: e.g. "Virtual reality in the upgrade process of existing buildings" etc. Finally, using a matrix in which digital tools were categorised and grouped based on their specific applications, all benefits and goals of these technologies are being illustrated and further discussed.

Based on this database, the second step revolves around which of the tools presented has transformative potential. The transformative potential of upgrading the architectural landscape lies in its ability to reshape urban environments, enhance quality of life, and address contemporary

challenges through innovative design interventions. By reimagining existing buildings and urban spaces, architectural upgrades can catalyse positive social, economic, and environmental impacts. This potential is particularly evident in projects that integrate digital technologies, sustainable practices, and community engagement. Architectural upgrades can breathe new life into neglected or underutilised areas, fostering vibrant neighbourhoods and cultural hubs (design). They can also promote sustainability by incorporating energy-efficient systems, green technologies, and adaptive reuse strategies that minimise environmental impact (zero energy). Furthermore, upgrading the architectural landscape can stimulate economic development by attracting investment, tourism, and creative industries to revitalised areas (urban regeneration). Ultimately, the transformative power of architectural upgrades lies in their capacity to shape the built environment into more resilient, inclusive, and inspiring spaces that meet the evolving needs of communities and contribute to a more sustainable future.

3.2 Review of Technology

Research across approximately 30 papers has identified several key technologies prevalent in upgrading residential neighbourhoods today, categorised and grouped based on their specific applications (Figure 1). These digital tools play crucial roles in enhancing the existing building stock within neighbourhoods. Design and modelling tools, exemplified by Building Information Modeling (BIM) software, empower architects and engineers to develop intricate 3D models of buildings, laying the groundwork for neighbourhood-wide upgrade planning. Analysis tools, such as Geographic Information Systems (GIS), facilitate comprehensive assessments of building performance and environmental factors to inform retrofit strategies on a larger scale. Data visualisation tools aid in communicating complex information to stakeholders, fostering better understanding and engagement in neighbourhood upgrade projects [17]. Management tools streamline maintenance activities and resource allocation, ensuring efficient implementation of upgrades across multiple buildings. Highlighting technologies enhance stakeholder engagement by visualising proposed design changes in real-world contexts, making it easier to understand the impact on the neighbourhood. Optimization tools help identify cost-effective and energy-efficient upgrade strategies through rigorous performance analysis, ensuring sustainable development at the neighbourhood level.

Moreover, laser scanning / photogrammetry is a versatile tool in upgrading existing building stock, fitting into multiple categories (Figure 2). As a design and modelling tool, it creates precise digital models of entire neighbourhoods for comprehensive transformation planning. As an analysis tool, it identifies structural weaknesses and areas needing repair, while in data visualisation, it provides visual representations of neighbourhood conditions, aiding in understanding complex spatial relationships. As a highlighting technology, it pinpoints specific areas for renovation or repair, enhancing the overall neighbourhood upgrade process.

This categorization provides a structured framework for understanding and leveraging these technologies to enhance research and planning efforts within residential communities.

3.3 Case studies of holistic building stock upgrades

Successful implementations of digital technologies for holistic building stock upgrades were examined. Concerning Modelling and Design Tools, computer-aided design is the standard for creating construction documentation, while its limitations can be effectively addressed by implementing Building Information Modeling (BIM) systems [19]. Triantafyllidis & Huang, (2023) noted that creating BIM models for existing buildings is a time-consuming task, but with the workflow they developed, demonstrated that generating parametric BIM models using Visual Programming Language is feasible. Tang, (2023) used BIM technology to simulate and assess various reinforcement schemes, optimising design, evaluating structural performance and aesthetics, and establishing a collaborative digital workflow for enhanced project cooperation for Chinese construction. Additionally, parametric design Tools create and manipulate complex geometric forms and designs through algorithms and mathematical functions. d’Urso & Cicero, (2019) proposed a parametric model to examine and renovate alternatives of a typical earthquake-prone apartment block in Italy by improving the existing building stock in terms of seismic vulnerability in combination with its architectural image.

For spatial analysis, Péter Fejes & András Horkai, (2020) suggested in order to create a fast city model in the ArchiCAD software environment, Grasshopper plus Meerkat was the most expedient and simplest solution when data is available in a GIS format, while when an accurate model is not needed online CADMAPPER interface, is proposed as fastest and easiest method. On the other hand, Ahmed et al., (2024) revealed that the GIS-based model is validated as effective for energy-use mapping and data collection at the neighbourhood scale, aiding municipalities in developing energy-efficient, smart neighbourhood policies based on recommended energy-saving retrofit measures.

Data visualisation platforms are extremely useful for assisting in the communication of complex information to stakeholders, facilitating decision-making and securing buy-in for proposed upgrades [26]. Visual analytics techniques for comparing building performance under different scenarios and designs are presented in graphical representation of information [25]. On the other hand, 3D visualization and rendering software such as, V-Ray, Lumion et., enable realistic visualizations of proposed upgrades, aiding in understanding and visualization, by producing high-quality, realistic visuals, textures, materials, shadows, and lighting at fast rendering speed [27].

The study of Adeyemi, Rahman, et al., (2022), identified maintenance analytics methods for data-driven decision-making, finding data type influenced techniques, with a focus on building performance, maintenance work orders, operations, and end-user complaints. Rodrigues et al., (2023) created a SMARTS-based decision support model for CMMS to optimise building maintenance processes. Both studies indicated that new technological trends, such as Building information modelling (BIM), Virtual Reality (VR), Augmented Reality (AR), and Internet of Things (IoT) need to be combined.

Metallidou et al., (2020) proposed a smart building template that uses IoT technology to manage technical systems for energy efficiency and an automated remote-control method, supported by a cloud interface, to improve the energy performance certification of existing buildings. On the other hand, Digital Twins can be especially transformative for renovations, where integrating new designs

Proceedings

with existing structures often necessitates multiple adjustments, but still there is a need for further research to develop workflows into the digitalised renovation process [37]. According to Schwartz, D. and Bill, B. (2024) digital twins revolutionise facility renovation and design by enhancing visualisation, planning, and precision. Generated through tools like laser scanners and drones, these detailed models help engineers better understand existing conditions, optimise designs, and reduce construction errors and material waste. Moreover, Arowoia et al., (2024) studied DT in the field of thermal comfort and energy consumption of built assets. VR / AR technologies are still under research concerning the upgrade process. However, during the design and construction process, improved stakeholder communication, project understanding, decision reliability, error anticipation, and reduced iterations and delays from poor visualisation, can be achieved.

In the field of optimization, Huang et al., (2021) proposed a graphical multi-objective performance evaluation method with a developed plugin for Grasshopper, aiding designers in exploring thermal and visual comfort through interactive, performance-informed feedback on various design options. Li et al., (2022) utilized automated workflows and integrated multi-objective optimization using the Wallacei plug-in within Grasshopper to improve solar radiation exposure, maximize solar hours, and enhance block capacity, providing valuable guidelines for renewing residential blocks, addressing floor area ratio constraints, and promoting urban vitality.

As we mentioned before, Laser Scanning is a versatile tool. Confronted with the intricate and multi-faceted environments inherent in unplanned urbanisation, Salazar Miranda et al., (2021) generated detailed morphological maps using LiDAR data. These maps serve to inform urban planning evaluations regarding issues such as overcrowding, structural integrity, air quality, and accessibility within Rocinha, the largest favela in Rio de Janeiro, Brazil. Steadman et al., (2014) constructed the "Virtual London" model by using building footprint data from Ordnance Survey maps combined with height information obtained through LiDAR 3D scanning methods, while the CIRCUIIT project [3] suggested that using 3D building data and LIDAR can help calculate embodied materials stock by determining the built volume and surface area of walls, roofs, and floors. Lastly, the research project "MANSION AR tX Morphological, Architectural & coNSTRUCTION InFormatioN with Augmented Reality in Touring Experience," which involved contributions from the National Technical University of Athens, the Technical University of Crete, the University of the Aegean, and the company Senseworks, focused on the creation of a digital repository featuring 3D models of selected buildings, generated using laser scanners, drones, and digital photography. This repository allows users to access detailed architectural information through a virtual reality web application and a mobile application with augmented reality (AR) capacities. These technologies enable virtual tours and on-site exploration, offering a comprehensive and interactive educational experience by integrating historical data and architectural features into an immersive digital format.

4. CONCLUSION

In the realm of upgrading existing building stock at the neighbourhood scale, digital tools are categorised into seven distinct categories, each offering transformative potential. Design and Modelling tools enable architects and designers to breathe new life into neglected areas by exploring innovative design concepts. Analysis tools empower decision-makers to implement sustainable practices by providing insights into building performance metrics. Data Visualization tools effectively communicate the benefits of architectural upgrades to stakeholders, fostering inclusive decision-making processes. Management tools streamline project execution, maximising economic benefits and stimulating development. Highlighting tools emphasise the cultural significance of upgraded spaces, fostering vibrant communities. Optimization tools promote sustainability by integrating energy-efficient systems and materials. Collaboration tools facilitate interdisciplinary

cooperation, leading to more holistic and community-driven outcomes. Together, these tools offer a comprehensive toolkit for neighbourhood-scale upgrades, driving sustainable development and revitalization efforts.

The trajectory between digital tools and building stock upgrades in global literature reflects a growing interest in how future design at the neighbourhood level can be enhanced. Digital technologies enable more efficient data collection, analysis, and simulation, leading to optimised building designs and upgrades. This can result in improved energy performance, cost savings, and enhanced user comfort. Additionally, digital tools facilitate collaborative processes among stakeholders and enable better visualisation of design concepts. However, challenges such as the initial cost of implementing technology, data security issues, and the need for specialised skills can also arise.

These advancements have significant direct consequences on policies and the built environment. Policymakers are increasingly recognizing the potential of digital tools to support sustainability goals and drive innovation in building stock upgrades. Digital technologies can inform evidence-based policy decisions, streamline regulatory processes, and foster greater transparency in the construction and renovation of buildings. Furthermore, the integration of digital tools has the potential to reshape the built environment by promoting smarter, more adaptable neighbourhoods that prioritise sustainability and resilience.

In summary, the intersection of digital tools and building stock upgrades represents a critical opening for advancing future design practices at the neighbourhood level. The literature underscores the transformative impact of digital technologies on this industry, emphasising both opportunities and challenges that must be navigated to realise sustainable and innovative built environments.

Abstract

Though mankind has once considered itself as part of nature and its cycles, we live currently in a time of merciless and selfish exploitation of planet Earth's resources. Climate change, exploitation and destruction of natural resources, mass tourism before the COVID-19 pandemic, and other social and economic crises enticed many experts and scientists to start thinking of new, sustainable paradigms and solutions. As a result, a new regenerative paradigm that clearly indicates and warns of the fact that sustainability is no longer enough, since the concept of sustainability is considered to be a slower way of dying, is created. The regenerative paradigm encourages mankind to think of relations and recognizes the need for the development of human consciousness. It includes a new system of values and holistic perspective and emphasizes an inextricable connection between man and nature. Due to its adaptable character, with an indispensable positive action on all participants, the regenerative paradigm has and an all-inclusive potential to implement itself in a broader economy. Subsequently, from which its functional purpose arises – creating and encouraging changes in the social and economic sectors and as such is applicable, and is implemented, in many sectors. The regenerative paradigm represents a foundation of developmental regenerative tourism, a new scientific topic, for which progression, important Indigenous, cultural and traditional values of a local community, are especially important. The task of regenerative tourism is to encourage the realization of the potential of a space, as well as create net-positive benefits for all participants. As a unique multidisciplinary phenomenon, it has the broadness and the possibility to touch all spheres of society and reach all points of the world. Therefore, this paper presents an advanced assumption of the transformative power of regenerative tourism and the developmental potential of regenerating urban spaces. Within this context, by understanding regenerative tourism and using its transformative capabilities, it is possible to activate positive changes in space, economies and society generally. Thus, it represents the purpose and goal of this paper – to explain the meaning of regenerative tourism, show its transformative role through developmental potential in shaping and revitalization of spaces, observe it as an important tool in activating positive social and economic as well as spatial changes. Since it is vital today to create communities in harmonious coexistence with nature, it can be concluded that the transformative character of regenerative tourism can present the key potential of developmental potential for regeneration and shaping of future cities.

Keywords: regenerative paradigm; regenerative tourism, urban development.

1. INTRODUCTION

Uncontrollable technological development, which is the result of an industrial (degenerative) paradigm, distanced man from nature and the (re)connection to the natural world, with which man had lived once in synergy. As we feel the consequences of such views and decisions that were made, we are deeply aware of the seriousness of the situation we find ourselves, new ways of regeneration of mankind and the planet are generally sought.

To find novel solutions, many scientists and experts indicate that it is necessary to look deeply at the root of the problem, including each of us individually. Jaworski [1] says that attitudes and ways of thinking about the world and the way it functions must change, turning it from a defined machine-like world to a space that is open, dynamic, interconnected, and full of personal life qualities. In

Proceedings

of the International Conference on **Changing Cities VI:**
Spatial, Design, Landscape, Heritage & Socio-economic Dimensions
Rhodes Island, Greece • June 24-28, 2024
ISSN: 2654-0460
ISBN: 978-618-5765-02-6

addition, to create new ways of thinking and new models, Ghisi [2] points to responsibility and believes that we are all a connected whole, one system, which makes us interdependent, and vulnerable, but also responsible for Earth as one inseparable community. Similarly, Capra and Jakobsen [3] state that to solve certain situations, it is not enough to make changes within the established systems of the economy in general. Fundamental changes in written theories and practices are needed. Instead of developing and living the economy on knowledge aimed at conquering nature, they believe that the greatest challenge of our time is building and nurturing communities designed in harmony with nature.

The process of searching for new methods and solutions indicates that the present concept of sustainable development, which aims to mitigate the damage done, is no longer sufficient and, as such, is considered inadequate [4; 5]. Following this, Daniel Wahl [6] calls for the transformation of tourism because he believes that tourism can become a catalyst and a carrier of change. The regenerative paradigm ‘a new lighthouse for a better future of humanity’ [7] represents the basis of the development of regenerative tourism, a new scientific topic, which is also accompanied by the development of higher human consciousness.

This paper explains the term regenerative paradigm and its all-inclusive ways of regenerative action in the economy, with special emphasis on regenerative tourism, since tourism as an industry can connect every corner of the world and have a global and local impact on ecological, social, and economic renewal and regeneration of all communities. Considering that regenerative tourism is primarily characterized by local activities, and consequently globally, this paper particularly emphasizes the necessity of ‘localizing everything’ and the importance of local needs. In this paper, the progressive assumption of the transformative potential of regenerative tourism is presented. It also explains the role of regenerative tourism in renewing local resources, and consequently regeneration of other sectors.

Consequently, three key goals arise in this paper: first, explain the concept of regenerative tourism with an emphasis on the renewal of local resources and achieving positive changes on local and global level; second, show the developmental potential of regenerative tourism as an activator and initiator of changes; and third, show the significance of observing the broader concept of regenerative tourism as the new developmental dimension in the context of regenerative urban development, observing regenerative tourism as a tool that brings back the identity to the place and becomes an ‘expert’ for urban transformation and planning ‘new’ cities.

2. REGENERATIVE PARADIGM AND REGENERATIVE TOURISM

This chapter describes the concept of the regenerative paradigm, with the goal of deeper understanding of regenerative ways of thinking. Conceptual foundations will be described, while a special emphasis will be placed on the benefits that the regenerative paradigm brings with its implementation in different sectors of society, especially in tourism which is the focus of this paper.

2.1. Regenerative paradigm: definition and significance

All life on Earth occurs in harmony with nature and its cycles, which indicates mutual connection, but also interdependence. Nature represents a complete system in which man is integrated and, as such, they represent a part of that whole. Although there is awareness of the outlined facts, we are currently living in a time of ruthless exploitation of natural resources, when man is faced with the consequences of unsustainable, careless, and selfish decisions based on the thoughts and attitudes of the industrial paradigm.

To better understand the basic settings of the scientific and industrial revolution, and the beginning of their development, it is important to connect it with Sir Francis Bacon (1561-1626), a key person in the history of scientific philosophy, who made an exceptional contribution to the empirical research

development. His theory was based on the thinking that scientific knowledge must come from close observation of nature, filtered through inductive reasoning. He pointed out that man must 'torture nature and its secrets' to achieve a more rational order. His role as 'the father of the scientific revolution' is still felt today as we can see that nature is still treated as a 'resource' for excessive exploitation.

Since the industrial paradigm distanced man from nature, man 'forgot' to live in harmony with nature. Aware of the seriousness of the situation in which mankind finds itself, attitudes and thoughts about the world and nature around us, and the ways it functions, indicate that urgent action must be taken that will change the situation radically. It is necessary to refresh and renew knowledge that take us back to nature and therefore, different models and solutions that will help solving ubiquitous social and economic crises and soften the arisen consequences. Also, it is necessary to bring awareness of the subject for long-term changes and more responsible decisions.

To achieve these needs, recent discoveries in natural sciences like quantum physics and geophysics help us in this endeavour. Famous scientist, James E. Lovelock with his Gaia hypothesis opens a completely new look at the planet Earth. He shows that it represents a holistic system in which all its ecosystems (sea, rivers, mountains, glaciers, etc.) function interdependently, and all living organisms on the planet, that are interacting with the surrounding inorganic environments, form a synergistic and self-regulating system that has created and now maintains climatic and bio-chemical conditions that make living on Earth possible [8]. Inspired by this new perspective of a whole system of the planet Earth, Ghisi [9] translated it into the social and political context, indicating that we need to create new ways of thinking and managing models that recognize the fact that we are a connected whole, which makes us interdependent, vulnerable, but also responsible for Earth as an inseparable community.

In this process of search, based on new values, the regenerative paradigm arises, which brings new ways of thinking and deliberations, including holistic perspectives and practices, as it recognizes the need to develop human individual and collective consciousness, and contributes to a positive view of the future [10]. This way encourages changes overall, and for which, as Pollock [11] says, a change in human consciousness is needed. With a deliberate and conscious changing of personal perception of reality, people change the world around them. Considering that the regenerative paradigm recognizes the need to develop human consciousness and influences the change of the value system, it consequently acts on the social and economic sectors, and represents one of its key tasks. Therefore, it can be said that the regenerative paradigm is a worldview, by which we are reshaping the world for the benefit of all participants. A great challenge and task of the times in which we live is the construction and development of communities designed in accordance with nature [12]. According to the exceptionally pronounced flexible character of operations, the regenerative paradigm is offered as a correct solution for mankind. The regenerative way of thinking connects and brings awareness in the moment one lives and calls for cooperation and making decisions to raise the quality of life, as well as developing the local economy. Glusac [13] describes regeneration as renewal and regenerating as the ability to live in a new relationship in a lasting way. Given the meaning of the regenerative paradigm, which Chrisna du Plessis [14] defines as a 'co-creative partnership with nature, based on the strategy of adjustment, resilience and regeneration', her adjusting character of operations and positive action on all participants indicates the all-inclusive possibility of implementation in the economy generally. Following this, its functional purpose is visible – create and encourage changes in the social and economic sectors. For its efficacy and acceptable concept, it is recognized and implemented in many sectors, for example, in regenerative agriculture [15], urbanism and urban planning [16], as well as regenerative economy [17; 18].

Developing regenerative paradigm and regenerative economy, 'new beacons', for a better future of mankind [19], regenerative tourism is developed, a new scientific topic. Regenerative tourism, as Wahl [6] describes and sees, represents a 'multidisciplinary phenomenon', to whom all spheres of

society and points of the world are accessible, and which can be the carrier and catalyst of the regeneration of the whole system. By the above mentioned, regenerative tourism will be described further as a broader concept of a new developmental and regenerative impact on other sectors and the system as a whole.

2.2 Regenerative tourism and its transformative character

Regenerative tourism represents a broader concept of developmental and regenerative changes, both in the tourist sector and in the socio-economic systems, which combines distinct aspects of society in a joint effort towards transformation and regeneration.

The call of the United Nations World Tourist Organization [20] to a shared, planetary vision of responsible recovery of the tourist sector. It indicates the necessity of development, but also understanding regenerative tourism, since tourism, as a catalyst for positive changes and regeneration [6] is the key ally in achieving changes that are necessary to transform the world.

In its foundations, regenerative tourism questions the dominating paradigm of industrial tourism, focusing on the regeneration of all systems, while economic growth is put as the last priority point [21; 22]. It is thought that regenerative tourism is not against growth, but demands and implies development, which is useful to the whole system, and never acts as a detriment to others. Therefore, it can be said that regenerative tourism ‘generates a positive net-impact to all participants.

According to Ateljevic and Sheldon [23], the purpose of regenerative tourism is to operate in service of broader systems in which it operates. They consider tourism to be regenerative when it regenerates more from itself alone, which would mean that regenerative tourism means returning more than it was taken. As regenerative deliberation is taking us back to the principles of nature, regenerative tourism is not an industrial work line, but a living, networked system built in the natural system, which is called ‘nature’ and as such it is subjected to natural rules and principles [24]. Since tourism has a great global reach and above all the ability to act locally, it impacts creation but also accelerates innovation by incorporating tourist practices in local communities and ecological processes which raise well-being in general [25].

Developing from the regenerative concept, which relies on indigenous perspective and knowledge, regenerative tourism aims at improving and transforming the social and ecological system in which tourist practices take place [26]. Consequently, the Indigenous, cultural, and traditional values of the local community are markedly important for developing regenerative tourism, which gives a uniquely characteristic and recognizable space through its distinctive coexistence and symbiosis, making it attractive to tourists.

Regenerative tourism represents a holistic approach that encourages developmental and regenerative changes in the tourist sector and social and economic sectors, connecting different aspects and needs of society, and operates first locally, and then globally. This way it is an important part of the local and national economic community.

The perspective of regenerative tourism is not imaginable without the support of local economies by which the self-sustainability of the local community is encouraged but also enriches the tourist experience developing economic benefits for local communities.

3. REGENERATIVE TOURISM: THE KEY FOR URBAN TRANSFORMATION OF THE CITY

Starting from a progressive assumption that regenerative tourism can be a fundamental activator of change and transformation of the local community generally, the term regenerative urban development is further below explained, and the way regenerative tourism can take the role of an active tool in reshaping the urban spaces.

3.1 Regenerative urban development

Most currently present methods of urban intervention represent sustainable, ‘green’, passive models and ways, which are foremost focused more on implementing technologies, and less on long-term quality, regenerative operations. Taking into account fundamental settings of the regenerative paradigm, and all that has the prefix ‘regenerative’, it is clearly visible that the characteristics of regenerative thinking should be implemented in spatial intervention and decisions. Long-term cooperation and connection to the environment is necessary as well.

The Regenesi Group first proposed the term regenerative development in 1995. It describes an approach that is about enhancing the ability of living beings to co-evolve so that our planet continues to express its potential for diversity, complexity, and creativity. The Regenesi Group proposed that the core issue was cultural and psychological, and only secondary technological [27].

One of the initiators of regenerative urban thinking, Bill Reed talks of the necessity of transitioning from sustainable development to regenerative as far back as 2007 and indicates that the regenerative design process begins by attempting to understand how the systems of life work in each unique place. The role of designers and stakeholders is to create a whole system of mutually beneficial relationships. By doing so, the potential for green design moves beyond sustaining the environment to one that can regenerate its health – as well as our own [28].

To better understand the term regenerative urban development, Bill Reed’s graph image “Trajectory of Environmentally Responsible Design” [28] from 2008 (Figure 1) is shown below. It illustrates different developmental phases of the responsible design; from the basic approach to the advanced, emphasizing the importance of recognizing and including ecological and social factors in all phases of development.

The first phase, conventional practice, includes standard methods without a special focus on sustainability. Green design, which introduces basic ecological practices to lessen the negative impact on the environment follows. Sustainable design integrates additionally sustainable practices, balancing economic, ecological, and social factors. The most advanced phase, regenerative design, creates systems that improve natural and social ecosystems, emphasizing the holistic approach and interdependence of humans and nature.

The vision of regenerative cities and communities was first developed by the International Expert Commission on Cities and Climate Change, convened by the World Future Council jointly with HafenCity University in 2008. WFC Report [29] from 2014 indicates that the road to regenerative urban development begins with a switch in our thinking so that by-products conventionally considered 'waste' can be reframed and reused as resource inputs. Regenerative cities are productive centres that help to regenerate the materials and resources they use and foster a mutually beneficial relationship between urban areas and their surrounding territories. Although a regenerative city in its entirety still does not exist, many cities and urban units show the use of different elements of regenerative urban development in certain sectors and areas. Considering the complexity of the process of regeneration, since it represents a practice philosophy and process success in regeneration means to evolve, and continually develop new potential. Its dictionary definition addresses both the action and the source of this new potential: to create a new and to be born of a new spirit. [30].

Following the above, one can say that regenerative development is a transformational approach that tends to use the maximal potential of a place so that it would encourage and achieve an optimal realization of inhabitants through interdependence and the intertwined nature of man and space, its resources, and the possibilities of that space. Thus, reconnecting man (community) with the place. Regenerative urban development is tasked to create added value in all living systems, of which we are an inseparable part, and it has an all-inclusive role in encouraging innovative practices of regeneration of the city development adapted to the needs of the local community, but also the protection of the environment primarily.

3.2 Integration of regenerative tourism and regenerative urban development

Regenerative tourism represents a holistic approach that encourages developmental and regenerative changes in the tourist sector and social and economic systems, connecting different aspects and needs of society in joint efforts for transformation and renewal, acting primarily within a community (locally), and expanding globally.

Cooperation and joint creation, justice, and inclusion are important and recognizable characteristics of regenerative tourism. Therefore, it can be said that regenerative tourism is aligned with the process of regeneration with cultural and natural patterns and is integrated into local development [31], and as such it has a role in creating the identity of the space, shaping the space, local food production, i.e. regenerative agriculture and other present sectors of the local community.

The characteristics of regenerative tourism, especially its adaptable character and its power to operate on broader systems, give it the possibility to become an important element in reshaping the urban space, i.e. in the process of regenerative urban development, and also urban development generally. Planning and managing new cities, as well as renewal and reconstruction of existing ones should go through a deep change paradigm, i.e. fundamental settings. WFC Report [32] indicates that the urban metabolism must transform from its current, inefficient and extravagant work defined as a linear system, into a resourcefully effective and circular, regenerative system. Integration into regenerative urban development represents a synergistic approach that combines principles and fundamental characteristics of regenerative tourism in the process of urban development. Regenerative tourism contributes to the revitalization of city spaces through initiatives that include the renewal of natural resources, the strengthening and renewal of local, cultural customs and communities, and the promotion of indigenous practices. Regenerative tourism can serve as a tool for creating main guidelines of urban planning, but also as an initiator and regenerator of local the economy in which it is being implemented. It is also important to point up that regenerative urban development, defined by rules and development guidelines supports and encourages the regeneration of regenerative tourism, which ultimately confirms that regenerative tourism can regenerate other sectors.

Taking in account one of the key goals of regenerative tourism, which is to discover the potential of places and communities by developing a deep understanding of their unique features and histories

Proceedings

[33] a clear link with urban planning for which the potential of places is extremely important. Also, Regenerative tourism uses place-based processes which reflect, honour and enhance their unique social-ecological systems [34]. Subsequently, regenerative projects focus on identifying and progressing what places and communities can uniquely become rather than identifying problems and assigning universal solutions [35; 36]. By understanding the unique potential of a place, tourism stakeholders can develop reciprocal relationships with living entities and discover ways to align with and build the capacity of related social-ecological systems, which directly contribute to the development of regenerative urban interventions.

Furthermore, regenerative tourism enables net-positive impacts and effects on ecosystems by contributing to the conditions that restore systems and support them to self-generate continually [37; 38]. People, governments and enterprises all work in line to serve the broader systems that tourism affects and is affected by [37; 34]. In this way, tourism engenders net-positive effects and improved capacity for places and communities to flourish by adopting regenerative approaches. All aforesaid has an impact on the urban image of the city as well as the possibilities of urban planning.

Since this paper presents the progressive assumption that regenerative tourism represents a key to the urban transformation of a city, it is important to mention that the regenerative process leads humanity to thought-out relations of all living systems and encourages awareness. Reed [28] in his research points out that regeneration is not only creating surroundings and encouraging local habitats to become productive and healthier, but that effective regeneration demands inclusion of all that makes one place healthy. It can be our local community or families, a bit of land or a building itself. Any of these elements can be a starting point to understanding the whole system and have a key role in a living system, in the process of making a conscientious engagement.

4. CONCLUSION

The purpose of regenerative tourism is to act in the service of broader systems. Tourism is regenerative when it regenerates more than itself alone, which gives it a 'task' to include itself in shaping the space and communities it operates. In this paper, it is shown how regenerative tourism expands its role outside traditional borders of tourism, becoming an important tool in restoring the identity of urban spaces. It recognizes the need to develop human awareness and impacts the change of the system of values which consequently acts on social and economic sectors. The accent is on its all-inclusive role to encourage innovative practices of urban planning, as well as creating new, sustainable models of development of cities that are tailored to the needs of the local community and the environment. Guided by the thought of Watzlawick [39] there are two different types of changes, one that happens within the given system when it remains unchanged and one whose phenomenon changes the system. It clearly indicates that the quality of regenerative changes since its implementation creates permanent positive changes.

This paper gives a review of the literature to explain terms and advanced assumptions that regenerative tourism can be key for developing urban spaces. The increase in research on this topic indicates that there is a greater need and interest in regenerative approaches and practices. The recommendation for future research is to include fundamental settings of regenerative tourism in spatial planning by defining the needs of spaces, especially through engagement and cooperation with local communities and inhabitants. Through case studies in different contexts, given assumptions can be researched and identify the implementation of current inclusions and real needs of regenerative elements.

So, regenerative tourism, as a holistic approach can be key to reaching regenerative urban development. Its integration into local communities enables creation and the identity of the space, encourages shaping the space according to local needs and renews local food production, like regenerative agriculture, and other sectors. The characteristic of regenerative tourism is a key factor in transforming urban areas. Integration of regenerative tourism in regenerative urban development

enables creation of sustainable, resilient, and picturesque urban centres that promote the prosperity of local communities and environmental conservation.

Finally, all above can be concluded with a statement by Jane Jacobs [40], an American activist, author, and urban theorist, who says the following:

“Dull, inert cities, it is true, do contain the seeds of their own destruction and little else.
But lively, diverse, intense cities contain the seeds of their own regeneration,
with energy enough to carry over for problems and needs outside themselves.”

The spatial and social transformation of central residential areas by the Impact of tourism: the case of Koukaki in Athens, Greece

K. Maroukas¹, S. Manika^{1*}, A. Gospodini¹

¹ Department of Planning and Regional Development, University of Thessaly, 38334 Volos, Greece

Extended abstract

This paper investigates the socio-spatial impacts of short-term housing rental addressed to tourists in the area of Koukaki, a central middle-class residential district of Athens. Koukaki is located next to key archaeological sites of Athens, and the Acropolis, creating favourable conditions for short-term rentals by tourists. The complex phenomenon of online platforms of short-let rooms and flats, like Airbnb has developed rapidly all-over European cities in recent years; and recent research shows that it has been a critical factor for the transformation of urban space and the socio-economic profile of central residential areas. In Koukaki, Athens, our research shows that due to the rapid expansion of short-term renting, even fewer properties are available in the conventional long-term rental market. Land-uses shifted from ordinary commercial and service economic activities in a residential district to tourism-oriented commercial and service economic activities. Under such new conditions, the local population in Koukaki also changes rapidly, and this middle-class neighborhood is getting transformed into an international tourists' neighbourhood. In a more general context, the development of Airbnb phenomenon, a new and profitable activity of 'sharing economy' in Koukaki, Athens, is directly linked to the significant growth of cultural tourism in the last two decades and a change in the tourist identity of Athens which, in recent years, has become a 'city break' destination.

Extended abstract

The '15-minute city' model seeks through appropriate urban planning and design strategies to improve everyday life of citizens on a neighborhood scale. The main conditions contributing to the transformation of urban area into 15-minutes urban unit are as follows:

Sustainable mobility: Transportation on foot, bicycle and scooter is enhanced while public transports are also playing a significant part. On the contrary, the use of private cars is discouraged and operate complementary.

Urban Regeneration and Resilience: The survey of existing underused or/and abandoned buildings in the area, and their renewal and reuse according to the specific socio-spatial needs of the area are fundamental in the transformation of the area.

Lively public open spaces: Underused outdoor public spaces, and especially unlandscaped public spaces, are redesigned so that they are addressed to and accessible by all residents and visitors without exclusion; thus, the neighbourhood is capable to keep and develop permanent residents and attract visitors.

Dynamic local economy: In general, the neighborhood provides with the spatial terrain for flourishing new economic activities, especially for young people, boosting the local economy.

This paper is part of a doctoral research. As typical research cases, two neighbourhoods located in Greater Thessaloniki Area, have been selected: (a) the area around Myloi Allatini, an abandoned heritage industrial complex in the Municipality of Thessaloniki, requiring urban renewal; and (b) Elaiones Pilaias, a peripheral new residential neighbourhood now being under processes of planning in the Municipality of Pilea-Hortiatis. The research investigates how urban policies for the 15-minute city model can be implemented in these two categories of residential urban areas; old neighbourhoods under processes of urban renewal and regeneration, and new peripheral neighbourhoods under planning and design processes for the city's expansion. The doctoral research aspires to draw conclusions on planning and design guidelines for Greek cities willing to adopt the 15-minutes city model.

Revitalizing Urban Voids through Community Engagement

A. R. Vouza^{1*}, A. Gospodini²

¹PhD Candidate, Dept. of Planning and Regional Development, University of Thessaly, Volos, Greece

²Professor of Urban Planning & Design, Dept. of Planning and Regional Development, University of Thessaly, Volos, Greece

Extended abstract

Urban voids, often found as vacant lots, abandoned buildings, or derelict public spaces, present a unique challenge in the urban landscape. These neglected areas, which can arise from economic shifts, urban decay, or planning oversights, detract from the vibrancy and functionality of cities. Contemporary urban challenges, such as climate crisis, rapid population growth, housing shortages, transformation of work models and the need for sustainable development, highlight the importance of transition of urban voids as fundamental elements in pursuing more adaptable and sustainable urban environments.

This paper explores the role of community engagement in revitalizing these neglected spaces, emphasizing the importance of "bottom-up" methods of city planning where local residents are actively involved in the planning and implementation processes. Community engagement is critical for the successful transformation of urban voids, as it ensures that redevelopment efforts are aligned with the needs and aspirations of those directly impacted. This paper discusses various techniques for engaging communities in the planning process, including participatory planning workshops, surveys, focus groups, digital engagement platforms, placemaking activities, and temporary urbanism. Each method offers unique benefits, from fostering a sense of ownership among residents to facilitating inclusive, data-driven decision-making.

The methodology of this research combines theoretical analysis with an examination of good practices in successful case studies that elucidates the key principles, processes, and implications of adopting participatory planning approaches for urban void revitalization projects. Several examples are analyzed to illustrate community-driven revitalization projects, highlighting how collaborative efforts and extensive public consultations can transform neglected spaces into vibrant public areas that foster community spirit and economic activity.

The expected results of this research include a detailed understanding of effective community engagement techniques and their impact on revitalizing urban voids. By applying these methods, cities can transform neighborhoods into adaptive ecosystems, capable of rapidly responding to contemporary urban challenges and reshaping according to emerging realities and residents' needs. Community engagement is part of an ongoing process in planning strategies for urban regeneration and renewal of urban voids.

Traditional cultural events in contexts of depopulation - Carnival in the Sicani inner area in Sicily

A. Gana-Nuñez

PhD student in Architecture, Arts and Planning, Dipartimento di Architettura,
Università degli Studi di Palermo, Italy.

Corresponding author: E-mail: alejandro.gana@unipa.it, Tel +39 3889785648

Extended abstract

Rural areas and small urban centers in southern Italy are currently experiencing demographic loss, which has significant effects on the social viability of these communities, specifically affecting the local cultural and identity dynamics. These structural processes of population decline, which have been observed throughout the national territory, show even more significant impacts on territories with limited access to public services and undergoing transformations of the local economies, which have changed from traditional agricultural and craft-based production to technified agricultural production and the expansion of the third sector, specifically tourism. These processes must be interpreted within the present context of transformation and polarisation between urban and rural areas.

The cultural expressions historically rooted in the communities of the small villages in the Sicani area of Sicily are currently facing a decline in their social foundations that have sustained them for decades, particularly due to the increasing percentage of young population who are migrating to bigger cities. Consequently, traditional cultural events and festive manifestations, such as carnivals, secular expressions deeply felt by the inhabitants, which were once involved in widespread participation, are now at risk of lacking the necessary community organisation and audience engagement to make the festivity an instance for broad active participation. Despite these limitations, carnivals in the Sicani area continue to be integral to the local identity and are crucial in the collective memory of different generations.

Interviews conducted in these territories with carnival organisers and artists, specifically in the villages of Santo Stefano Quisquina, Bivona and Alessandria della Rocca, bear witness to the significance of this activity as a culturally rooted social event. The interviews reveal the active participation and artistic contributions of citizens, as well as the involvement of local collectives and associations. The content collected constitutes a firsthand narrative of the challenges encountered by carnival, along with other cultural events in the current context of depopulation of the so-called inner areas. The literature debate on the contradiction of public and private space in the performance of festive and performing events includes a brief historical analysis of the cultural practices surrounding carnival in these three villages. Additionally, analyses the role and content of ritual and creative elements present in these carnivals: the allegory, the float, the costumes and the anthem. These elements are instruments of critical and artistic reflection for the youth groups in these villages, where they express their concerns, rationales and expectations regarding the subject of depopulation.

A holistic approach to the Historic Urban Landscape of Athens. Focusing on the Interwar apartment buildings of the Fokionos Negri Street linear park

G. Eleftheraki

PhD(c), School of Architecture, National Technical University of Athens, Greece

E-mail: elefgogo@gmail.com

Extended abstract

The historicity of the urban center, and thus its potential to evoke memories, is something that fascinates us, as the city has something to say to us through its structure and buildings. The urban landscape contains all the tangible and intangible elements inherited from history, human creation, and tradition, as well as those from the current urban reality. It represents a carrier that humanity is obligated to preserve without interfering with the invincible force of change that is the city itself. UNESCO's approach to managing historic urban landscapes is holistic, integrating the goals of urban heritage preservation and economic and social development. Such a holistic approach to the historic urban landscape is needed in Athens, where the classical past often obfuscate people's perceptions of recent architectural and social history, but also of the way in which that history is relevant to them. In Athens, the legal framework protecting the architectural heritage of the city center promotes, for historical and political reasons, the archaeological richness and its neoclassical interpretation, neglecting the protection and promotion of important buildings and open spaces of the 20th century. These buildings complete the image and identity of the city as modern monuments, interpreting the mechanisms of its evolution and how people accept it in their daily lives. The research project "The Interwar Urban Landscape of Fokionos Negri Street: Documentation, analysis, interpretation" aims to study the historic urban landscape of the linear open space of Fokionos Negri, an area formed in the first half of the 20th century and hosts many buildings characteristic of "Athenian Modernism" and also, a very important area for the social and functional evolution of the Kypseli district and the Athenian center. The research objectives have a triple nature: architecture, landscape and society. One of the main aims is to identify and study buildings of particular architectural/historical/cultural value, which contribute in a specific way to the composition of the urban landscape, highlighting the overlapping layers of the city's history. These buildings relate to the spatial mechanisms of the urban production, applicable in each era and way of life, as well as the values and social background of the time. Such buildings are the interwar residential buildings, which are in no case protected and, also, threatened by modern building activity. In this presentation, we focus on interwar apartment buildings located along the Fokionos Negri Street through maps, archival research, personal observations, interviews of the owners and the patrons of the linear park, films and photo reports when the park was the central leisure pillar in Athens. By documenting, interpreting, and evaluating the architectural, natural, and cultural heritage of the early 20th century in relation to recent elements of the perceptual and functional whole of the urban landscape of central Athens, the research project aims to contribute to research and evaluation methods for the historic urban landscape of Greek cities that can be used to implement more sensitive and comprehensive protection and management policies.

AdjustABLE thresholds: reframing accessibility through traditional liminal spaces

N. Tomou¹, A. Rodi²

Extended abstract

This research reports on the reuse and reformation of thresholds in the traditional settlements of the Dodecanese, in order to establish inclusive public spaces. Today, although accessibility for people with disabilities is mostly improving in urban centers, rural areas have been overlooked. Greek traditional island settlements are directly related to tourism revenues and sustainability, as the focus turns towards the adaptive reuse of their cultural and historic centers. However, due to their unwelcoming terrain, as well as the lack of necessary infrastructures and policy provisions for people with disabilities, they still remain exclusive destinations.

The island of Symi, in the Dodecanese, is an important example of social exclusion for people with disabilities. In the past, many inhabitants were diagnosed with the diver's disease caused by the intense sponge fishing commerce. Characteristic elements that formed Symi's identity are the public stairways as main mobility arteries, the large landings as pauses for rest, as well as the private thresholds, testaments of the neoclassical influence in the local manors. These morphological elements became integral parts of the daily life of local women enabling social interaction. However, today they are not used anymore. Although thresholds and landings once were a practical solution to the local unfavorable topography and important locations of collective participation and memory, today they hinder social interaction and accessibility. In this framework, this research analyses in situ Symi's thresholds and landings, which are irrevocably correlated with the identity of the place. Furthermore, it comments on the oxymoron of inclusivity and inaccessibility that can be detected in the built fabric of the traditional settlements. For example, it is astonishing how a construction that once played a major role in the social life, as a place of gathering and decision-making, has now become the problem itself.

Up to date, the traditional settlements in the Aegean Sea are considered to be important examples of organic evolution, resilience and sustainable design. In an effort to demonstrate the need to handle disability as an integral aspect of both cultural and architectural heritage, rather than a technical problem to be solved, this research and its findings aim to be a stimulus for further investigation regarding the identity of traditional-historic settlements, spatial inclusion and urban design. In this framework, a typology of existing thresholds is presented and new design approaches are proposed, in order to ensure in the future inclusive historic and traditional built environments for all.

Places of worship and memory: the case of Greek-Orthodox refugees in Athens

G. Kritikos

Professor of Historical Geography, Department of Geography,
Harokopio University, Athens, Greece

Corresponding author: E-mail: gkriti@hua.gr, Tel +30 6938841816

Extended abstract

The Lausanne Peace Treaty of 1923, which ended the Greek-Turkish war in Asia Minor, called for the first obligatory exchange of populations in world history. It was based exclusively on the criterion of religion. As a result, almost 1.3 million Christian refugees were settled in Greece. This study will examine how memory and Christian belief informed the settlements of the Asia Minor refugees who were settled in Athens after 1922. It will analyse if and why religion was important to the social and spiritual life of these people. It will shed light on how religion informed the memory and produced urban landscapes after their establishment in Greece. Considering memory as a very selective process that produces new space, it will investigate how the Greek city was shaped or how memory was projected in the new urban landscape, not only by its policy-makers through their plans and decisions, but also at the local level through the actions, memories and experiences of the people who were settled there. The focus will be on the interplay between state planners, who sought spaces for the settlement, the Greek-Orthodox church that wanted to incorporate those people as new congregations and the refugees who transformed the space into place. This process of negotiating space between different communities will be concerned with the development of new spatial identities at communal or individual level through religious narratives and beliefs, imaginary and ideological formations, and collective memories.

The research will use the archives of the Leagues of Nations in Geneva, the archives of the Public Record Office in London as well as various Greek archives (the archive of the Centre of Asia Minor Studies in Athens, Venizelos' Archive, etc.).

Extended abstract

Along with the political, socio-economic and technological changes that emerged in the new millennium, cities have been under significant changes. Values of temporariness and sharing have appeared in different dimensions of the public life, driving spatial transformations, disrupting conventional relations between space, time, and use. New expressions of housing; co-working spaces; shared mobility; multiple forms of trade; sharing of goods and services; improvised uses in anonymous spaces;... all these urban dynamics that enable and empower temporariness and sharing in the urban spaces -termed Intermittent Practices (IP)- are the scope of the proposed presentation.

The IP are generating significant changes on the urban context and new challenges to policy, planning, and governance. Addressing this, the presentation aims to explore the impacts of the IP, particularly in the field of public space. Conducting focus groups with some of the key stakeholders in those processes, it will be analysed a set of dynamics and initiatives in the last decade in Lisbon, Portugal. The cases explored – most of them small and bottom-up initiatives, carried out by networks of people with similar motivations – demonstrated the ability to promote changes in the places where they occur and to multiply by other contexts, in a domino effect. Thus, it is hypothesized that despite their small initiative character, many of them achieve broader impacts, at an urban level. They also can produce changes at the public space level and in the way people use their cities. It is therefore important to follow their track, to take advantage of its potential and to consider them in future planning, but also to anticipate their risks. This exercise may allow anticipating urban transformations resulting from the development of IP, with the objective of encouraging more flexible architectures and a city that is more adaptable to the contemporary societal and urban dynamics.

The University Library and the City Museum of Volos as Cultural Spaces and Public Spaces.

E. Karanikola

PhD student, University of Thessaly, Greece

Corresponding author: E-mail: ekaranikola@uth.gr

Abstract

Public spaces have always served as meeting places and communication places in the city, and they are open and constantly evolving. Public spaces, among other things, contribute to improving the quality of life and the social cohesion. Through appropriate design and active community participation, municipalities can create vibrant and accessible public spaces that increase the quality of life and the well-being of residents. The spaces in Volos that are related to public space are the City Museum and the University Library, which essentially plays the role of a Public Library but remains closed after the severe storms Daniel and Elias that hit the city of Volos on September. In this article, we will try to convey the immense value that these two public spaces hold today in the city. To what extent these two spaces and how they have evolved into centers of culture and education for the city. We will emphasize to their contribution on interaction among individuals, the spatial relationships between

internal and external spaces, how they promote the functional relationships that allow interaction, the degrees of freedom provided to allow spontaneous activities, and new arrangements that augment the voice and the presence of often marginalized groups of users/identities.

Citizens enjoy visiting libraries, feeling comfortable and welcomed in these spaces, and they finding a sense of relaxation and pleasure that is necessary to encourage learning, as proven by our research on the University library. On the other hand, the

City Museum is a space that contributes to shaping collective memory and identity; it emits aesthetic, emotional, and intellectual stimuli in difficult times. And it is in constant dialogue with citizens.

Keywords: Public space, library, City Museum, Political, Culture, education, memory identity, democracy.

We were inspired this paper from a piece of our research that focused on public space. In particular, there was a questionnaire that included questions on the University Library of the University of Thessaly and the City Museum as public spaces.

I would like to provide here as an introduction a quote by Alice Garrigoux (1972). “The purpose of a public library is not just to store books and documents, but to provide a public service to all citizens. However, a public service only makes sense if it serves the needs of both, individuals and community, even if those needs are not readily apparent. A policy for public reading will only be achieved if the responsible politicians and administrators, as well as the public, recognize the usefulness of libraries for citizens of all ages and social professions. It would be futile to defend a purpose that does not have social acceptance.

The Library was established and started operating in September 1988, during the first academic year of the University of Thessaly. But it moved to its new facilities in the building of the previous Bank of Athens in 2005, leading to the closure of its branches at the Polytechnic School (Pedio Areos) and the Faculty of Humanities (Papastratou). In the beginning of our research the questions of our questionnaire did not cover in depth what we wanted to extract on the first place, we decided to delve deeper and understand what is happening abroad with libraries and what are the current challenges regarding their use. Thus, we decided to explore how libraries are dealing with the digitization of their collections, restructuring as meeting and community spaces, and developing relationships with

ISBN: 978-618-5765-02-6

the local community and students. Through this research, we hope to shed light on the role that public spaces play in contemporary society and suggest possible improvements in their operations. The University Library fills the gap left by many public libraries that should exist in Volos since its audience is not exclusively made up of students, professors, or researchers, but also includes other groups of the population who focus on literature, for example, and can be approached through qualitative research related to this subject. Additionally, the University Library can offer more resources and materials to its users compared to a public library. This can increase knowledge and education in the local community and provide access to information and content that may not be available elsewhere.

However, it is important to maintain a balance between the academic and general audience, so that there continues to be space and resources for all user groups. Also, the University Library should ensure that it provides services and programs that meet the needs and interests of all its users.

The concepts of library, and the museum, as places open to the public is similar to the theoretical concept of Jurgen Habermas for the public sphere. The concept of public sphere proposed by Habermas is a space for critical discussion and is open to all. The public sphere is understood as a domain of social life where public opinion can be formed. (Habermas, 1991, 398). It can be seen as the breeding ground, if you want. Habermas declares several aspects as vital for the public sphere. Mainly it is open to all citizens and constituted in every conversation in which individuals come together to form a public. The principles of public space advocated by Habermas, (1991) such as freedom of speech and assembly, freedom of the press, and the right to participate in decision-making, are upheld in libraries. Through libraries, individuals have the opportunity to voice their opinions, engage in debates, and contribute to societal change. Overall, libraries embody the essence of public space as envisioned by Habermas, serving as inclusive and accessible spaces for intellectual exchange and democratic participation, and is the basis for emancipatory social thinking. The public library serves as an essential neutral space, free from the influence of government pressure and the capitalism. In today's information society, libraries play a crucial role in bridging the information gap created by dominant elites seeking to control knowledge. Acting as agents of change, public libraries have the power to level the playing field and democratize access to information for all individuals. By providing a space for learning, discussion, and free access to information, libraries are key players in promoting an inclusive and equitable society. This marked a true revolution in the world of libraries, which had previously been reserved for an educated elite. With the advent of the Anglo-Saxon-style public library, everyone now had access to knowledge, regardless of their level of education. The aim was to make a wide range of documents available to readers, from fiction books to academic works, as well as newspapers and magazines. Public libraries were thus opened to all audiences, including children, teenagers, adults, and the elderly. This democratization of access to culture and knowledge allowed many people to discover reading, to inform themselves, to entertain themselves, and to educate themselves. It also strengthened social ties by offering citizens a place for exchange and sharing. Thus, the Anglo-Saxon-style public library revolutionized the traditional concept of the library, transforming it into a place open to all, promoting social and cultural inclusion. In the reality, the public library itself is an institution formed by the government, so that in its implementation it certainly cannot be separated from the government's vision and mission. Even in practice, censorship imposed by the government also applies in the library or the museum. Management and information flow are also inseparable from the government. In addition to the government's strong influence in the administration of public libraries, the domination of capitalists in public libraries was inevitable.

Information society is a society that arises as a result of the information age, and is marked by the rapid exchange and consumption of information through various technological platforms such as the internet, social media, and digital devices as our research proves. In the information society, individuals are constantly seeking out new information to stay informed, make decisions, and

Proceedings

ISBN: 978-618-5765-02-6

navigate the complex world around them. In an information based society, the way we learn, work, receive healthcare, and interact with our government has been transformed by the digital age and the vast amount of information that is readily available at our fingertips.

In conclusion, the information society represents a new era in which information is the key driver of social, economic, and cultural development. It is essential for individuals to be able to effectively navigate and utilize the vast amount of information that is available in order to thrive in this rapidly evolving society.

In a book on public space, Thierry Paquot, a philosopher specializing in urban issues, emphasizes on the following point: “Public space is a singular term, the plural of which - public spaces - does not correspond to it. Indeed, public space evokes not only the place for political debate, the confrontation of private opinions that advertising strives to make public, but also a democratic practice, a form of communication, circulation of diverse points of view; public spaces, on the other hand, refer to places accessible to the public, frequented by residents, whether they live nearby or not. These are streets and squares, forecourts and boulevards, gardens and parks, beaches and trails [...], allowing for the free movement of everyone, with due respect for accessibility and free access”. And according to Michel Bouvy the public library is neither a luxury service nor a charitable work. It is a public service as useful as the school, (M. Bouvy, 2006).

The qualitative research we conducted to confirm that the theoretical approaches of the experts on libraries and public spaces. And here I present some elements that characterize the library as a public space, focusing more on the theoretical part of the research:

- The library is considered as a space that promotes access to knowledge and information for all citizens, regardless of social and economic status.
- As a public space, the library offers citizens the opportunity to meet, discuss, exchange ideas, and create communities.
- The library functions as a center of culture and education, offering education programs, exhibitions, presentations, and other activities that contribute to the education and information of citizens.
- The library promotes social cohesion and citizen participation in public life, providing spaces for meetings, events, and activities that encourage interaction and the exchange of ideas.
- Libraries are a different kind of space, a place of breathing, of resistance. They should be clearly described as spaces of freedom (of opinion of expression) and therefore as political spaces.
- The library is not utopian because it is a space that does not exist, but it is utopian because it realizes the utopia of gathering. It is utopian because it creates a public space as Jean Pierre Rioux noticed.

Based on the above, the library emerges as an important public space that contributes to the promotion of education, culture, and social cohesion.

The present paper also demonstrates how the library occupies, in the public space, a “strange”, paradoxical place. The library is an eminently political institution, but is not recognized as such, which has unfortunate (scandalous, dramatic) consequences. Throughout Europe, the library is considered by definition as a political and democratic space. The library is a public service necessary for the exercise of democracy. From the charter of Libraries, Article 3 we learn that: “Libraries are public spaces open to everyone, without discrimination based on race, gender, religion, nationality, or socio-economic status. They promote access to culture, information, and knowledge for all individuals. Libraries encourage diversity and pluralism, and ensure that everyone can feel safe and respected in this space”.

Normally, libraries are not virtual, disembodied, abstract, or utopian. On the contrary, they are rooted in space, specifically in the space of the city, in urban space and in political space. As well the University Library of Volos, which has been built in the city center and serves as a focal point not

Proceedings

only for the students but also for the entire community. Because it's a basic cultural space that must be harmoniously integrated into the urban organization and thus contribute, in intimate relation with other organs of cultural life, educational action, social action, and also to ensure the deep breathing of the city. And now it remains closed and cannot play her role due to the severe storm that hit the city in early September '23.

The fact that the library is located in a public building strengthens the political character of its activities. Because it is the "common house" as Jean-Pierre Rioux (1997) had wrote, a place where the community is virtually united, where it can gather. A place of unity, unity between generations, between educational or social status, between users, expectations, curiosities, or needs... The physical openness of the library building is a symbolic openness to the entire community - even if we are aware of the boundaries (socio-cultural) - of such a pursuit.

Another objective, also political, is assigned to libraries: it is education. In a republic founded on the education of citizens (and where school is a political passion, the only one, or the last one, capable of bringing hundreds of thousands of people into the streets), education is an eminently political issue. The claimed proximity to the public education service is therefore not innocent: it is an attempt to legitimize the library on the same level as school.

Many French architects as Laurent Baudouin architect of the library of Poitiers, or Gérard Thibault, architect of the Saint-Herblain media center, or Pierre Riboulet, architect of the Limoges library consider the library as a common space with multiple culture representations. However, Pierre Riboulet says: "In Limoges, I dreamed of the library as a single volume. It is perhaps, because, always all of us have the syndrome of the National: we always think the library as a big beautiful room, a unique room in a way, in the sense that what we need most today in the society we live in is this search, this meeting of unity, because we are in such a fragmented, dispersed, separated universe." Or they think the library as a community of books.

It's the same thing for some of the American's architects and they insist that if they reimagining the library as a dynamic public sphere institution, librarians can work towards preserving and enhancing the vital role that libraries play in promoting education, democracy, and community engagement. And they criticized US education for sacrificing education for democracy on the altar of (market) economic instrumentality.

The process of creation of modern libraries is based on a shared vision of the media library as a place of culture, education, social connection, and living together. It is therefore necessary to go beyond the simple concept of a library to think of a multidisciplinary and multifaceted space that can adapt to the needs and expectations of the local population. This also implies rethinking the traditional missions of the library and innovating by offering new services and activities related to contemporary cultural practices.

The symbolic construction of the library is also built through its architectural dimension and her interior design. The important is to create a welcoming space, open to its environment, which promoting the meeting and the exchange between users. Reflecting on the organization of spaces, highlighting collections, accessibility, and comfort are essential to guarantee a quality reading experience.

Finally, the media library cannot be dissociated from its territory and its inhabitants. It must be a place rooted in local life, in symbiosis with the cultural and social dynamics that surround it. Therefore, it is important to involve different local actors from the start in defining the project and to create lasting partnerships with institutions, associations, and cultural organizations in the territory.

In conclusion, creating a library is an opportunity to deeply rethink the public reading project, reinventing it in the light of contemporary issues and local specificities. This requires a participatory, collaborative, and innovative approach, highlighting the diversity of audiences, practices, and cultural discourses.

The municipality of Volos, in which we were working, suffered, like many towns in Greece, from the absence of public spaces and places suitable for hosting collective activities, favorable on the development of social cohesion. If we believe on the values of equality and solidarity, we want our city to remain a space of emancipation and connection between their residents rather than stay indifferent and confinements. Therefore, we want the library to restoring social connections, promoting access to culture for all, and leveling the social differences. Additionally, the library should actively collaborate with local organizations and institutions to address systemic inequalities and promote social justice. The University library is located in a central neighborhood where there were public services, as the Town Hall, we also aimed to open up to the city and animate it by attracting residents from the entire city.

On the other hand, the recently museum of the city The City Museum of Volos is housed in the three-story building of the former Papantou tobacco warehouse, on 17 Feron Street, in Palaios Volos. On the ground floor, there are spaces for temporary exhibitions and events, a shop, and a reading room. Below the exhibition hall, sections of water pipes from the middle Byzantine period (6th-7th centuries AD) are preserved and visible to visitors. It opened in December 2014 with the inauguration of the major temporary exhibition “Volos-Nea Ionia: so close, so far away”, dedicated to the 90 years since the establishment of the refugee settlement in Nea Ionia.

In the early 1990s, the need for the creation of the Volos City Museum began to mature and be adopted by the local community and municipality. From 1989 to 2000, the Municipality of Volos acquired the ex Papantou tobacco warehouse and three other buildings in the construction square OT 49, which was designated in 1997 as the space for the construction and operation of the Volos City Museum.

The Papantou tobacco warehouse was built around 1920 in an old district of the city, on which the city changes more slowly. Like other tobacco warehouses in the city, it housed refugees from Asia Minor until the establishment of the Settlement. There are here memories that affect the collectivity. The renovation of the building and the redevelopment of the surrounding area began in 2006 with funding from the Operational Programme of Thessaly and the Municipality of Volos. The study and supervision of the project were carried out by the Technical Services Directorate of the Municipality of Volos.

The restoration of the eastern part of the castle fortification, located in the courtyard area of the Museum, was carried out by the 7th Ephorate of Byzantine Antiquities, as part of the project “Conservation and restoration of the Castle of Palea Dimos Volos”. The project, with a total budget of 1.000.000 euros, was included in the Operational Program “Thessaly - Sterea Ellada - Epirus 2007 – 2013” and included works for stabilization, maintenance, restoration, and landscaping along the western, northern, and eastern sides of the defensive wall. In the museum courtyard, the wall was maintained along a total length of approximately 40m. The works carried out, apart from the obvious goal of stabilizing the antiquities, aimed to make the area accessible and visitor-friendly. The project for the conservation and restoration of the Castle of Palea Dimos Volos lasted from spring 2011 to October 2014.

The museum includes objects, photographs, and documents of all kinds and forms, related to the history and character of the city of Volos and the wider area of Magnesia and Thessaly. Chronologically, it spans from the incorporation of Volos into the Greek state (1881) to the present day.

A separate section is the digital collection, which includes audio recordings of events since 1991, the archive of the Municipal Television of Volos (1996-1998), interviews, photographs, videos, and other audio-visual material.

Following an agreement with the Social Anthropology sector of the Department of Architecture of the University of Thessaly, the City Museum of Volos has access to all the recordings gathered and being gathered by the Oral History bank of the Oral History Laboratory of the department. We may say that museums play a crucial role in the construction of social memory by preserving and

Proceedings

presenting historical artifacts and stories, and this is the role of the city museum of Volos. It helps the society to remember her past, learn from it, and shape her identity. This museum also contributes to the reproduction of culture, traditions, and values that are important to a particular society. Furthermore, the museum serves as symbol of the city's cultural richness and heritage. Over time, the museum can become an iconic landmark that are closely associated with the city's identity. In conclusion, museums are not only repositories of historical artifacts but also powerful agents in shaping social memory and culture. Exactly as the two great semioticians Yuri Lotman and Boris Uspensky define culture itself as the memory of a community. They have the ability to preserve, interpret, and exhibit the past, thus contributing to the collective memory of societies and cities. Lefebvre in *the production of space* (1991) called these display spaces representations of space, and reasoned that such structures are spaces designed by artists, planners, urbanists, and technocrats who both dissolve and organize societal norms. These spaces, built by certain subjects, form their objects by becoming subjects over time. One of the main reasons why this museum is so important, from a sociological perspective, is that it is essential in preserving and transmitting cultural memories. Museums serve as important repositories of cultural memory, preserving and interpreting objects and artifacts that tell the stories of our past. Through exhibitions and displays, museums bring history to life and allow visitors to engage with the past in a tangible way. The reconstruction of memory in museums involves not only the physical preservation of objects, but also the interpretation and presentation of these objects in a way that helps visitors understand their significance and historical context. By providing a space for reflection and learning, museums play a crucial role in shaping our understanding of the past and contributing to the collective memory of society. Overall, museums are essential institutions for the reconstruction of memory, serving as guardians of our cultural heritage and offering opportunities for reflection, learning, and dialogue. Through their collections and exhibitions, museums help us connect with the past, understand our present, and shape our future.

The museum cluster transforms the concept of the public sphere and clearly demonstrates the shift from public institutions to public space. In this societal transformation, the architectural aspect of the museum becomes crucial. As illustrated in the blueprints, this facet of the museum project is depicted as the gateway from the city to the museum, as the integration of the museum into the city, and as the coalescing and integration of the surroundings, leading to the creation of a larger plan for the “city of museums” that fosters unity, identity, shape, and organization within the city.

These expressions of the architectural aspect of the museum converge in the public space, which connects the museums within the cluster and the cluster with its urban surroundings. As such, the public space plays a critical role as a mediator between the museums and the city, as well as between diverse audiences and functions, areas and movements, between speed and leisure, exploration and convenience, tradition and innovation, entertainment and education, commercialism and intangibles, order and spontaneity, between the idealized city and the practical city we inhabit.

This highlights the immense importance of the linkages between the elements of the museum system and their connections with other urban systems, emphasizing the significance of accessibility, movement, connections, flows, and networks that they establish. Thus, through the museum cluster, I demonstrate the new requirements and expectations for public spaces in the modern era, as a multi-dimensional showcase, interactive and educational area, a space for engagement with heritage and the urban environment.

As the library the museum claims a role in the construction of the public space, as a democratic place for debate and encounter with otherness, but we required to distinguish it from physical public spaces. The reality we found ourselves confronted with is that the confusion between public place and public space, the difficulty in identifying the specific function and rules of the place, led to difficulties in cohabitation of different publics and incompatible appropriations with the desired mix of uses. The research led us to think that a public place revolves around a function, which determines its reception modalities and rules of use. It clarified to us that we do not welcome the public “as is”, based merely

on the notion of public service. This reception and connection are based on a specific public service mission, a specific service offer, but also on the perception of the establishment by the public and their partners.

The City Museum of Volos is an important public space in the city, where visitors can discover the history and culture of the area. Through the various exhibitions and activities held at the museum, people come into contact with the local heritage and learn about the past of the region.

The representation of history and interaction with the public at the City Museum of Volos are points of memory that preserve the tradition and identity of the area. Through exhibitions, events, and educational activities, visitors have the opportunity to explore the past and participate in an interactive experience that empowers and inspires them.

By highlighting the history and culture of the area through the City Museum of Volos, a space is created that connects the past with the present and keeps alive the memory of our ancestors for the future generations. Thus, the museum becomes an important part of the local community and contributes to the preservation and promotion of the identity and heritage of the region. The City Museum had revitalized a neighborhood that wasn't so rich and helped to the absence of public spaces and places to accommodate collective activities, and even dedicated public services for social, educational, and other policy needs. Every collective memory unfolds within a spatial framework. Space is where a specific moment becomes tangible, and it has always had a unique connection with experiences. And space holds condensed time in "its thousands of honeycombs" as says Bachelard, (20, p. 39), holds memories and create unites, limits, and gives identity to society and the individual, is finally sacred.

Today, the City Museum serves as a vital hub for the community, offering a place where residents can come together to connect with their shared history and culture. Through its exhibits, programs, and events, the museum actively engages with visitors, encouraging them to reflect on their personal experiences and consider their place within the larger community.

By showcasing artifacts, artworks, and stories that highlight the city's past, present, and future, the City Museum helps to preserve and celebrate the local heritage. It plays a critical role in transmitting knowledge and understanding from one generation to the next, ensuring that important stories and traditions are not lost over time.

Furthermore, the museum serves as a venue for dialogue and exchange, providing a space for citizens to come together to discuss and explore important issues facing the community. Through its programming, the museum fosters a sense of belonging and shared identity among residents, encouraging them to actively participate in shaping the future of their city.

In times of crisis or uncertainty, the City Museum serves as an inspiration of hope and resilience, offering a place of respite and inspiration for those who seek support and connection. By providing aesthetic, emotional, and intellectual stimuli, the museum helps to nourish the spirit and stimulate creativity, even in the face of adversity.

Ultimately, the City Museum stands as a testament to the power of culture and heritage in shaping individual and collective identity. By fostering a sense of pride and unity among citizens, the museum plays a vital role in strengthening the social fabric of the city and empowering its residents to build a more vibrant and inclusive community.

As a places of culture and access to knowledge, both the library and the museum, acts as a bridge between memory and projection towards the future. Through its resources and the mediation work that accompanies them, it allows individuals to connect with their personal and collective history, to access in their cultural roots. They also provide sources of inspiration, projection towards elsewhere, or attraction towards lives other than our own, which helps to develop the ability to look ahead, to imagine a future. By weaving this link between the past and the future, the media library contributes to the city and its inhabitants being able to reclaim their memory and collectively build their future. They help both to build the historicity of the city.

Extended abstract

As cities grapple with the challenges of burgeoning populations and limited space, the role of greenery in fostering environmental balance, community well-being, and sustainable urban development becomes increasingly imperative. It underscores the need for approaches that harmonise the growing demands for built spaces to enhance the natural environment in urban areas.

This study focuses on the significant factors of urban greenery in terms of social equity and natural habitat fragmentation, using Altstetten-Albisrieden, Zurich, as a real case. It aims to offer insights for optimising architectural design and urban planning in the process of urban densification and transformation.

The study adopts a mixed-method approach to examine the greenery in Altstetten and Albisrieden. It employs analytical tools, such as distance matrices and nearest neighbourhoods in QGIS, to measure the distribution and allocation of green space throughout the district. Associated with the demographic information of the district, the study further discusses social justice in relation to green space accessibility and suggests potential solutions to improve the public green spaces in the district. The study used a 30-meter hexagon grid to abstract the situation of natural habitat fragmentation in Altstetten-Albisrieden. The ratio between greenery volume calculated with LAI and development intensity consisting of building footprints, grey surfaces, and streets within a hexagon unit to gauge the spatial resistance of the unit. The relevant geographic data and information are sourced from the open-source data of the City of Zurich. The visualisation of the spatial resistance indicates the fragmentation of green spaces in the district and some possible paths and corridors for the natural habitats crossing the district.

According to the study, gaining a thorough understanding of the organisational structure of urban areas is crucial in promoting social equity in public green spaces. Additionally, the research emphasises the pivotal role that building types play in mitigating habitat fragmentation in cities. Structures with ample open spaces and rooftop green spaces have the potential to increase the permeability of green spaces between land parcels, allowing animal species to move more freely between nearby populations. This approach is a valuable tool in mitigating the effects of urban densification and preserving natural habitats.

Abstract

Public spaces are crucial elements of urban environments, contributing to social interaction, community engagement, and cultural exchange. This paper presents a number of various aspects of transforming schoolyards into vibrant public spaces, in the context of Greek cities, examining the potential benefits they offer and the challenges that need to be addressed.

Schoolyards are usually spaces with restricted access, where only educational activities take place during school hours. The typical image of a school unit in a Greek city, is that of a massive building inside an enclosed space, protected from the potentially dangerous external environment, both during school hours and afterwards. In the afternoon, locked and inaccessible schoolyards seem to be once again shielded from an unknown danger of the public space, working as urban voids inside the city. This contradicts the concept of continuity of urban space and appears to create a fragmented public space. According to the Greek School Buildings Organization, since the late 1980s until today, the expansion of the social environment of the school is encouraged, as there is provision for spaces open to the community within the school environment, such as the multipurpose room, the courtyard area, the library, the event hall. This could be an aspect of inclusive urbanism; however, rarely do we see examples of such open schools in the Greek urban environment.

Another dimension to consider is the focus of contemporary education, which is directed towards fluid and interrelated networks within the urban environment. The architectural design of school buildings and their open space must accommodate a shifting spatial context, fostering an environment that promotes dialogue and social interaction among students.

Urban centers face the challenge of lively public spaces, accessible by everyone. In this framework, with their central locations and existing infrastructure, schools have the potential to serve as hubs for social activities and cultural events, balancing the needs of students, teachers, and administrators with those of the broader community. Several successful examples of school units functioning as public spaces exist within European cities. By embracing innovative design solutions, participatory planning approaches, and collaborative governance models, Greek cities could unlock various opportunities for schoolyards as vibrant public spaces, contributing to the quality of urban life.

Keywords: *schoolyards; urban public space; Greek cities; inclusive urbanism; contemporary education*

1. INTRODUCTION

A public schoolyard typically operates six to eight hours daily during the week. During the remaining hours, everyone leaves the area, and the yard becomes inaccessible, a strictly delineated and isolated empty space around a public building. Just as with urban voids in a city, schoolyards, during the afternoons or evenings, when their use is restricted, either cause insecurity and discomfort to pedestrians or, at best, indifference, and a sense that the space cannot be utilized or exploited by the user. Those who use it during prohibited hours enter illegally, often leading to misuse or damage. Essentially, these spaces are not protected from vandalism, as many believe, simply by placing a hard

Proceedings

boundary toward the public space. On the contrary, this exclusion strengthens the indifference of the residents, creating an unapproachable environment for them, to which they have no access, or any obligation to look after. This article studies schoolyards as functional urban voids and examines their relationship with the surrounding urban fabric. The typical hard boundary of the yard spaces, which most often is implemented with a fence or an enclosure, emphasizes the discontinuity in the urban fabric, preventing access to this space. Various approaches are explored to integrate schoolyards into the Greek urban fabric, transforming them into open spaces for community interaction.

2. THE OUTDOOR SPACES OF A CITY - THE CASE OF SCHOOLYARDS

The outdoor spaces of a city are divided into private and public. Private outdoor spaces are either highly private, such as private courtyards, gardens, and balconies, or private spaces that function as communal areas, such as an undeveloped plot of land, the communal courtyard of a building, or its rooftop. Many of these spaces have access for a specific group of people, such as the residents of an apartment building, while entry is prohibited for others. Public outdoor spaces are distinguished between those that are freely accessible to everyone, such as public gardens, squares, and streets, and those spaces or structures where entry is not permitted to everyone but to a group of people with common characteristics. For example, in many countries, adults are not allowed to enter playgrounds without accompanying children. Not only this, but in some playgrounds, only children of a specific age group are allowed to entry. Similarly, public schoolyards are considered as public open spaces, where entry is permitted only to students and teachers, and only during specific hours of the day. In this category of public outdoor spaces, there is always a physical boundary separating them from the rest of the public space to define the area of partial accessibility.

The urban voids of a city are similarly being categorized. We are accustomed to defining an urban void as an empty public or private space located within the urban fabric, without any use, and showing signs of abandonment. Typically, these spaces have three characteristics: A) They have no role in the urban fabric, B) They are not easily exploitable due to deficiencies, C) They have many potential uses.

L. Lerup [1] defines the urban void as a residual, forgotten, and seemingly useless space in the city. I. de Solà-Morales Rubió [2] calls these voids “terrain vague”, marginal spaces without a clear role, with a potential to become something, “places of possibility”. P. Eisenman [3] introduces the term “urban interstitial space”, a transitional space characterized by arbitrariness, randomness, and indeterminate use. According to D. Polychronopoulos, who for the first time gives a positive connotation to the term "void," these spaces are "containers waiting for content" [4]. Thus, we can recognize in an urban fabric, “private voids” (open spaces within building blocks, rooftops of apartment buildings, undeveloped plots of land), as well as “public voids” (unused squares, abandoned parks or public buildings, and adjacent spaces of the road network). According to architect Andrea Rojas [5], there are three categories of urban voids:

1. Phenomenological voids (undeveloped spaces resulting from a disaster or natural phenomenon).
2. Functional voids (change or absence of use in the urban fabric).
3. Geographic voids (inaccessible places within the urban fabric primarily created due to their natural form).

The schoolyard belongs to the category of public outdoor spaces with restricted access. It serves as a common area for students, strictly delineated, within which outdoor educational activities take place during school hours. The image of a massive building inside an enclosed space, protected from the potentially dangerous external environment, both during school hours and afterwards, is very typical in Greece. In the afternoon, locked and inaccessible schoolyards seem to be once again shielded from an unknown danger of the public space, working as functional voids inside the city. This opposes the concept of continuity in urban space and appears to divide public space into accessible and forbidden

areas [6]. It is paradoxical that this prohibition extends even to the school's users during the afternoon hours.

3. THE BOUNDARIES OF A SCHOOLYARD

The boundary of a schoolyard is sometimes defined by hard materials with no visual contact with the surrounding public space and other times by perforated or light materials, and occasionally it is even rudimentary. This form can lead either to isolation and introversion or to connection with the city and extroversion. The relationship between a schoolyard and the urban landscape depends a lot on the form and materiality of this boundary. This connection (or this no-connection) with the city affects the pedagogical and social aspects of the educational process for the students. A boundary isolates the school environment from the rest of the public space. Simultaneously, it defines the points of entry and exit, making the school environment accessible when desired. The fencing is the primary characteristic of an enclosed yard, forming clear entrances and exits and reflecting an inward focus. This barrier hinders any relationship between the school building and the urban space.

The discontinuity of public spaces is not limited to schoolyards but also extends to many outdoor areas of public buildings. Public outdoor spaces are intended to be open communal spaces, but fences and closed entrances often discourage, or even deter, pedestrians. "The public space is the ground where the interests and goals of many different social groups meet. The more fragmented a society is, the more dysfunctional its public space becomes", as E. Filippopoulou states [7]. It is a fact that the contemporary urban space in most Greek cities is characterized by a lack of open spaces and greenery.

In relation to the city, the fence represents a direct vertical boundary that divides the public space into accessible and inaccessible areas, reflecting dualities such as inside-outside, introspection-extroversion, and order-chaos. As Kahn notes, "the fence symbolizes the function of a refuge" [8]. While there is enclosure (inside), there is simultaneously an escape (outside) from the external environment, which, in this case, is the city. The less someone can see and hear from the open public space, the greater their distance from the social life of the city. Conversely, it creates a negative sense of isolation for the passerby whose access to this space is restricted, especially when architectural elements such as difficult access, prominent fencing, or solid facades dominate. In many cases, there is not even visual contact.

The citizen's ability to access public space can be not only physical but also visual and psychological/symbolic [9]. This multifaceted inaccessibility reinforces the separation between the school and its urban context, emphasizing a disconnect, that affects both the students within and the community outside.

From a different perspective, Hardin's approach [10] argues that if access to common resources is unrestricted for everyone, without limitations, then users exploit these resources recklessly until they are depleted. Thus, the only way to use these resources properly is to use them in moderation, which is achieved through their regulation. In recent decades, it is a fact that rigid boundaries constantly expand [11]. In "gated communities," mainly found in America, the entire community area is isolated from the rest of the world with tall fences, and access to the public space of these communities is only allowed to the residents of the area. "Architectural elements such as inconspicuous or inaccessible entrances, solid facades, or iron fence openings do not attract the potential user to approach the space" [7]. Even aesthetically pleasing buildings and spaces can create a negative sense of distance if their architectural design is characterized by oversized scale or excessive monumentality.

According to Hardt and Negri, the concept of "commons" extends beyond traditional notions of community, which may limit individual freedom, and emphasizes open, free communication among singularities in a common space that emerges through collaborative social processes of production [12]. An emerging category of "commons" and less studied is the so-called "urban commons", which can serve as a means for both redefining production processes and managing public spaces [13]. Hardt

Proceedings

and Negri propose viewing the city as a producer of collective resources, emphasizing that cities serve as vibrant nodes where people meet, share resources, communicate, and exchange goods and ideas [12]. From this perspective, the city itself becomes a dynamic common ground for interaction and collaboration, encouraging participatory practices and community involvement, aiming to empower citizens and promote social cohesion.

A lot of researchers refer nowadays to inclusive design, which involves creating products, services, and environments that are accessible to as many people as possible, regardless of their age or ability. This concept is also known as universal design or design for all. It represents a shift in mindset towards a more inclusive approach to design [14]. Furthermore, inclusive urbanism is characterized by the integration of different social groups, providing equal opportunities for participation [15]. An accessible schoolyard open to the public undoubtedly contributes to this social aspect of design. Neal examined these parameters of the concept of public space: 1. Public space is not limited to specific physical areas but can refer to any physical or virtual space that allows interaction between individuals or groups. 2. Public spaces must be open and accessible to everyone, without material or immaterial barriers. 3. Public spaces should be available and relevant to all members of society. 4. The actual ability to use and stay in public spaces may be limited or hindered due to deficiencies in design, such as lack or inappropriate placement of seating, lack or inappropriate placement of greenery, unsuitable construction or paving materials, design complexity and inflexibility, as well as technical issues such as inadequate lighting or lack thereof, and even explicit or written prohibitions [13].

Until recently, the city served as a place for socialization, strolling, and meeting new people. Citizens enjoyed exploring the streets, squares, and other public spaces. The benefits of spending time in outdoor spaces have been widely recognized, with research showing that time spent in natural environments can have significant psychological, cognitive, social, and spiritual benefits. It has been found that the presence of greenery in public spaces encourages their use and promotes social interaction, contributing to social cohesion [16]. However, in recent years, the situation seems to have changed. The city has become increasingly hostile, and people tend to move from one private space to another using private means of transportation, mainly cars.

4. CONTEMPORARY SCHOOL ARCHITECTURE

The orientation of contemporary education is directed towards fluid and interconnected networks with the urban environment. According to K. Tsoukala [17], architectural design now needs to support a changing spatial framework with a strong communicative character, a school environment that encourages dialogue and social interaction. In the design of alternative models in educational buildings in Europe in recent decades, we encounter a fluid spatiality, where architects seem to be interested not so much in form but in a communicative atmosphere that promotes contact and togetherness (as seen in the school buildings of Hertzberger, Behnisch, Miralles) [31, 32, 33]. However, in most cases, the schoolyard remains strictly delineated, an autonomous space with no connection to the socio-spatial environment and the urban fabric [17].

Figures 1, 2. Herman Hertzberger School Architecture, Central Halls of schools (https://publik.tuwien.ac.at/files/publik_295229.pdf)

New models of interaction are emerging in both outdoor and indoor environments, integrating school outdoor spaces with the urban landscape. Despite protective measures against vandalism, some architects strive to connect educational spaces with urban public areas through various means, such as widening sidewalks to extend into building interiors, or by opening specific sections of the schoolyard to the community. Such example is the European School Copenhagen by NORD Architects and Vilhelm Lauritzen Architects in 2018 [18].

Figure 3. NORD Architects, Vilhelm Lauritzen Architects - European School Copenhagen (2018), school outdoor spaces as city public space (NORD Architects private archive)

The case of Primary school "Fran Krsto Frankopan", which is located on the north-eastern edge of the historic core of the city of Krk, utilizes the city's existing features – like streets, plazas, and boundary walls – to engage and enhance the surrounding urban environment. When the school and the city wall reconstructed, public spaces were converted into private spaces and vice versa. This approach eliminated the boundaries between public areas and school grounds, effectively integrating the school into the urban fabric [18].

Figure 4. “Fran Krsto Frankopan” school and Turato Architecture, Sports hall, Krk a) Public Street space as school space, b) school yard as city wall activator (Turato Architecture private archive)

In Greece, the approved Building Program guidelines mention the necessity of fencing, especially for kindergartens, and the requirement to create two entrances to the schoolyard. According to Greek Organization of School Buildings [19], from the late 1980s to the present, there has been an encouragement to expand the social environment of the school by providing spaces within the school that are open to the community. The multi-purpose hall, the courtyard with a theater, the library, and the event hall are some of the spaces within the school environment recommended by the Ministry to be used by the community.

A characteristic example of implementing these proposals is the 5th High School in Ilioupoli, Attica. Taking advantage of the new building program guidelines that provided for spaces within the school to be open to the community, the building designed by T. and D. Biris (construction completed: 1988) included a multi-purpose hall, library, gym, and an outdoor amphitheater, so that it could function for the entire community independently of the school during free hours [20].

Nevertheless, most active public schools in Greece show a strong introversion because of the design of the building, the schoolyard and their boundary in relation to the public street. The most particular example is the school environment of Grava, in Athens. According to the records of the Organization of School Buildings, the architectural design of Grava resulted from a competition in 1970 and its construction began in 1973 [21]. The winning architects were the modernists K. Papaioannou, K. Fines, and N. Chatzitheodorou, who had designed several public buildings during that period. The strict approach of the competition era aimed for a school that was introverted, looking only inward, towards its own spaces, ignoring and excluding the rapidly developing city around it. The schools were studied and constructed based on criteria such as orientation, sunlight, spacious courtyards, and ease of construction. Designed as a grid of successive rectangular buildings alternating with large outdoor spaces, it was clear and rational but introverted and strict, resembling a walled fortress. However, the basic principles for the operation of the vast complex were not upheld. Passages were 'cut off,' the corridors were isolated from the courtyards, and the school complex was filled with railings. In fact, since the late 1970s, the uses of the common areas have been modified, the courtyards have been isolated, and the accesses have been cut off to accommodate the need for mass housing for thousands of students, which at one point reached 14,000. As a result, the complex became fragmented, an enclosed space hostile to students. The school complex can still house up to 24 schools, which do not communicate with each other, nor with the immediate environment [21].

5. OPEN SCHOOLS IN GREECE

The last decade, many attempts have been made in all over the world to open the schoolyards to the local community, outside the school timetable and during the weekends. Such attempts are the program “School Playgrounds Open to the Neighbourhood” [22], developed in Barcelona, the OASIS project in Paris [23], the “Community Schoolyard” program in the United States [24]. All examples are trying to convert underused, paved schoolyards into green spaces for the community and turn them into local hubs. This would provide many residents with nearby access to parks and open areas. However, while some of these school programs have focused on greening their schoolyards and others have made their yards accessible to the public outside of school hours, very few have done both [25]. This dual approach is essential for the effective implementation of multiple-use spaces.

During the years of 2015-2019, an innovative program called “Open schools” took place in Athens. The program was established thanks to a founding donation from the Stavros Niarchos Foundation, coordinated by the Athens Partnership, and supported by the actions of the Ioannis S. Latsis Foundation. The ‘Open Schools’ program collaborated with more than 100 organizations and individuals to implement the actions [26]. Few years later, the “Open Schools in the Neighborhood” program was an initiative of the Directorate of Education and Sports of the Municipality of Thessaloniki, in collaboration with Creativity Platform (NGO), which coordinates the program, and with the exclusive donor being the Stavros Niarchos Foundation [27].

Figures 7, 8. Open schools in Athens (<https://athensopenschools.gr/>)

These pilot and innovative projects aimed to open up the school, the neighborhood, and the municipality to issues of pedagogy, creative engagement, empowerment, and support for children, parents, and citizens. The school was highlighted as a core element for improving the quality of life in each neighborhood, strengthening the concept of "community", while it served as a common space for meeting, collaboration, play, sports, and entertainment. The programs developed thematic activities and intercultural meetings after the school hours, when all typical schoolyards are locked down. Workshops on multilingualism, child rights awareness, sports and music workshops were some of the activities for all the local community.

From the evaluation forms, the great success of the program is evident [28]. By carefully examining the statistical data on the number of beneficiaries per action category at each school, we find out that the upgraded area of Plaka holds the first place with the most beneficiaries, followed by the downgraded area of Vathis Square. This demonstrates the multifaceted and highly democratic nature of the program, which can encompass under its umbrella a wide range of people with different economic, social, and cultural criteria. Reports indicate that neighborhood children and their parents have found a new space for expression and creativity, with more than 300 people attending some Open Schools on weekends. The success of the program has nationwide impact, as other municipalities in Greece are showing interest in opening their schools as well. Holding creative and alternative activities in schoolyards during the afternoons enriches children's daily lives, enhances neighborhood socialization, and offers democratic opportunities for continuing education and lifelong learning.

6. CONCLUSION

Since then, many local authorities open the schoolyards for the community in different Greek cities, especially in summer, which usually serve as play areas for children. Nevertheless, these attempts do not cope with any change in the design of the schoolyard, which is usually a large, fenced space paved with cement, without greenery, or any urban spatial elements.

There is a significant reason for incorporating schoolyards into the urban fabric, and this is the problem of lacking communal spaces and green areas. This issue is mainly evident in dense urban areas, such as Greek cities. In these cases, the use of schoolyards as open public outdoor spaces integrated into the broader green and pathway network of the urban fabric is more necessary than ever. Furthermore, the schoolyard of Greek schools presents significant deficiencies in its design. The dominant spatial design creates a lack of connection with public space, the urban fabric, and nature.

It prevents students from participating in various activities, while being characterized by inwardness and fragmentation [6].

Both from a spatial and pedagogical perspective, the design of the school environment, particularly the enclosed schoolyard, hinders the communication between the school and the city on an urban and educational level. This constitutes a significant issue with pedagogical, architectural, and social dimensions. The challenge for a school complex is to be open to the public environment without losing the original coherence of its building structure. The issue is particularly complex and directly related to educational, social, and economic issues, but it could be a way for people, to become visible and claim their space within cities characterized by isolation and exclusion. Addressing such complex issues requires the collaboration of residents, public authorities, architects, urban planners, and educators within a framework of participatory processes and pilot programs. Organized planning of all public outdoor spaces within an urban zone, adequate lighting during the night, visual contact to provide a sense of security, shading and planting, in continuity with the local urban pathways, maintaining schoolyard boundaries to protect students during school hours, designed with negotiation and permeability, and finally using the space under conditions set by local residents during free hours, are some of the aspects that need to be addressed in order to include schoolyards in a unified urban network, citizen-friendly and respectful of students.

To conclude, schoolyards in the Greek context are predictable public areas with some common characteristics. If they are treated as "functional urban voids," they could be transformed into open interaction spaces for the entire community and add to the inclusive urbanism. In their planning, primary consideration should be given to the basic use of the schoolyard, which intertwines with the urban fabric and "contributes to the transformation of an inward-looking and self-referential material framework into an 'open' space permeated by the public life of the city" (K. Tsoukala) [29].

Abstract

In the period from 1990 to 2010, star architects played a significant role in architectural communication. They managed to capture the spotlight on their designs, both on architectural level and within society. While architects have always enjoyed varying degrees of popularity, the influence of star architects during this period was particularly profound, shaping cities and directly influencing the identity of cities.

This period coincided with the emergence and development of technology - the internet, and later social media, which made architectural imagery more immediate, powerful, and influential. As a result, architecture became a discipline with rapidly flowing images worldwide. The end of this period coincided with the international financial crisis of 2007, which primarily affected "western societies". But what happened during this period? What are the lessons be learned from this?

The architecture produced during this period, especially architectural schemes created by major firms of star architects, redefined and reshaped the city's image. Flagship buildings generated image-landmarks within the cityscape, redefining skyline as a tourism attraction. The rise of tourism over these decades and the strengthening of tourism development had a prominent influence on cities. The term 'City branding' was introduced by the architectural brands of the time, defining the city's identity. Buildings undertook a predominant role in comparison (for example) to public open spaces. In enhancing the city's identity, photographs of flagship buildings, cut-off from their surrounding milieu, had a significant role, often overshadowing their relationship with the surrounding built environment.

In the realm of city branding, star architects play a pivotal role. Their iconic design-schemes became synonymous with urban identity, shaping the city's image and attracting tourism. Through innovative and 'photogenic' architecture, they contributed in defining the city's character, fostering its prominence on the global stage.

The aim of this paper is to investigate how the city's identity, as influenced by star architects, was shaped during the period 1990-2010 and how it changed afterwards when the influence of star architects was diminished. It's worth noting that our observations are spatially confined to the so-called "western world," roughly comprising North America and Europe. This is because the impact of the 2007 financial crisis led to a drastic reduction in architectural production, especially of star architects, in this region. However, this doesn't imply that the phenomenon disappeared entirely; rather, it shifted geographically. Architectural-schemes currently produced in United Arab Emirates and Asian regions with fast growing economies such as Hong Kong, Singapore, still exhibit these characteristics - i.e., particularly 'photogenic', dynamic, and solitary flagship buildings, cut-off from their surroundings. It's an architectural approach generating images of tourism attraction, highlighting the dynamics and prominence of these countries in the new era.

Keywords: city branding; urban identity; global influence; spatial dynamics; star architects

1. INTRODUCTION

The period spanning from the decade of 1990 to the end of 2010 witnessed a very important phenomenon in the world of architecture—the rise of star architects. These designers not only reshaped the skyline of the contemporary cities but also left a lasting mark on the fabric of urban life (Jencks, 2005) [1]. This period coincided with substantial technological improvements, such as the birth and expansion of the internet and the social media, which has as a result the capacity of the architectural imaginary to reach broader audience and to have bigger impact, not only, on the architectural community, but also on the general public. Consequently, architecture transcended its previous role and became an impactful tool for shaping perceptions, identities, and even local economies.

At this point, it is worth mentioning that the profile of the star architect existed in the past, but it never had the importance that it later acquired. There were architects in the past who had a significant influence on the community interested for the culture and some of them even on the broader society, but they never had the decisive role that we will encounter later. Architects, during the period we are discussing, through their creative work, gained the ability to express ideas, strategies, opinions, and proposals that could easily and quickly reach the broader public through new technology and acquire greater communicative power (Sudjic, 2005) [2]. These architects become known to the wider public like actors, writers, and other artistic personalities who, through their words and proposals, can influence the cultural developments of the era and the daily lives of citizens. Images produced by star architects become more potent. These images become alluring, attractive, and more dynamic. Visions for the contemporary city can reach citizens more directly and can significantly influence them. These creative proposals can find fertile ground among those seeking the transformation of the city through architecture and urban planning.

2. THE ERA OF STAR ARCHITECTS

"Star architects", often referred to as "starchitects", are architects who have achieved celebrity status, influencing not only the field of architecture but also popular culture. Their influence extends beyond their buildings to encompass broader cultural and social trends. Their creations, often emblematic of their architectural firms, become synonymous with urban identity and global influence. The characteristics of star architects' production are:

- a) Unique and recognizable designs: Star architects are known for their "signature" design strategy. Their buildings are instantly recognizable and frequently serve as landmarks. In most cases, these architects are formalists, meaning they focus on the form and aesthetic quality of their architecture, which is a main characteristic of their work.
- b) Influence on urban development: The works of star architects can transform cities, attracting tourism and boosting local economies. The "Bilbao Effect," named after the economic revitalization brought by Gehry's Guggenheim Museum, exemplifies how a single iconic building can stimulate urban regeneration and cultural tourism [3].
- c) Media presence and public profile: Star architects often enjoy a high level of media attention. They are featured in magazines, documentaries, and interviews, making their work and personalities well-known to the public.
- d) Brand and commercial influence: Star architects often have their own architectural firms, which become brands in themselves. These brands are associated with quality, prestige, and innovation, allowing star architects to attract high-profile projects. Their influence extends to product design, fashion, and other industries where their aesthetic principles are applied, as seen in the case of Zaha Hadid [4].
- e) Social and cultural impact: Beyond their architectural achievements, star architects play a significant role in shaping social and cultural narratives. Their designs often provoke discussions

about identity, sustainability, and societal values, contributing to broader conversations about the role of architecture in contemporary society.

3. THE CASE OF BARCELONA

Despite its rich architectural heritage and innovative urban planning, Barcelona has been significantly influenced by the works of several star architects, including Jean Nouvel, Enric Miralles, Zaha Hadid, and Herzog & de Meuron. These architects have left an indelible mark on the urban landscape of Barcelona, blending contemporary design with the city's historical fabric. Although the work of Frank Gehry, Zaha Hadid and West 8 remained in the project phase, they have also influenced Barcelona's theoretical architectural conversation about contemporary city planning and urban design.

Jean Nouvel: His influence is exemplified by the Torre Glòries (formerly known as Torre Agbar), a striking, cylindrical skyscraper that has become a modern icon of Barcelona. Completed in 2005, this building stands out with its colorful, illuminated façade, symbolizing the city's progressive spirit and technological innovation.

Enric Miralles: He contributed to the revitalization of Barcelona through projects like the Mercat de Santa Caterina. This market, with its undulating, colorful roof, not only revitalized the area but also integrated seamlessly with the surrounding Gothic Quarter, showcasing Miralles' ability to blend modernity with tradition. Moreover, his work on the Gas Natural Headquarters, one of his last emblematic projects, reshaped the city skyline. It engages in a dialogue with other high-rise buildings that are landmarks in Barcelona, such as Nouvel's Torre Glòries and Gaudí's Sagrada Família.

Herzog & de Meuron: The Swiss duo have made a significant impact on Barcelona with their design of the former Forum Building, now known as the Museu Blau. This distinctive structure, part of the larger 2004 Universal Forum of Cultures, exemplifies their innovative approach to architecture. The building's striking triangular form and blue façade contribute to Barcelona's contemporary architectural landscape.

Although designed and constructed during an earlier period for the preparation of the 1992 Olympic Games, Norman Foster's Torre de Collserola remains a prominent feature of Barcelona's skyline. It may have been among the first buildings to shape its skyline. Previously, only Gaudí's Sagrada Família held such a dominant role.

During the period we investigate, cities around the world competed for architectural prestige, believing that iconic structures would enhance their global standing and attract investment. The result was a proliferation of landmark buildings, each competing for attention and recognition. In Barcelona, the Forum Building by Herzog & de Meuron and the Torre Glòries by Jean Nouvel are testament to this trend, their avant-garde designs adding layers to the city's architectural tapestry. Furthermore, Barcelona's urban development has been heavily influenced by theoretical discourses such as the "Barcelona Model" [5], which advocates for sustainable urban planning, mixed land use, and social integration.

4. ARCHITECTURAL BRANDS / CITY BRANDING

During the period we investigate (1990-2010), the emergence of star architects, each with their distinctive architectural brands, coincided with a growing interest in city branding. This intersection between architectural branding and city branding was not merely coincidental but rather deeply intertwined, influencing urban landscapes and global perceptions of cities.

Architectural brands, epitomized by figures like Frank Gehry, Jean Nouvel, and Zaha Hadid, MVRDV, Rem Koolhaas were built upon unique design philosophies, innovative approaches, and iconic projects. These architects became synonymous with groundbreaking designs that challenged conventional norms and captivated global attention. Their creations, characterized by bold forms and avant-garde aesthetics, transcended mere buildings to become symbols of architectural expertise and cultural significance.

Simultaneously, cities worldwide recognized the importance of branding themselves to attract investment, tourism, and talent in an increasingly competitive global landscape. City branding initiatives aimed to craft distinctive identities that differentiated cities from their rivals, leveraging their unique histories, cultures and assets. The goal was to position cities as desirable places to live, work, visit and invest in.

The interrelation between architectural brands and city branding became apparent as cities sought to exploit the prestige and charm of star architects and their iconic projects to strengthen their own brand identities. Iconic buildings designed by star architects served as focal points of city branding efforts, embodying the values and aspirations of their respective cities. These architectural landmarks became powerful symbols of urban identity, attracting international acclaim and becoming magnets for tourism and investment.

Moreover, Kavaratzis and Hatch [6] argue that the dynamics of place branding are rooted in identity-based approaches, highlighting the importance of understanding the unique identities of cities in crafting effective city branding strategies (Anholt, 2007) [7]. This theoretical perspective sheds light on how architectural projects contribute to the identity and image of cities, providing valuable insights into the symbiotic relationship between architectural brands and city branding initiatives.

In the case of Barcelona, Joan Busquets' book "Barcelona: The Urban Evolution of a Compact City" (Busquets, 2006) [8] offers an insightful exploration of the city's urban development and its branding strategies. Busquets' work delves into how Barcelona has positioned itself as a global city through urban planning, architecture, and cultural initiatives, providing valuable context for understanding the city's branding efforts within the broader framework of architectural and urban development.

The symbiotic relationship between architectural brands and city branding fostered a cycle of reinvention, as cities competed for global recognition. This dynamic interplay was deeply rooted in identity-based approaches to place branding, as argued by Kavaratzis and Hatch. Their research emphasizes the importance of understanding the unique identities of cities in crafting effective branding strategies. Iconic buildings designed by star architects not only served as focal points of city branding efforts but also embodied the values and aspirations of their respective cities. This convergence of architectural branding and city branding underscored the crucial role of architecture in shaping the identity, image, and trajectory of cities in the contemporary world.

5. THE ROLE OF TECHNOLOGY AND MEDIA

The architectural image holds an important role within both the architectural community and the public sphere. In the architectural community, images serve as potent tools for communicating design concepts and expressing the creative vision of architects. These visual representations enable architects to communicate complex ideas effectively and fostering a shared understanding of projects. Beyond the architectural community, images play a crucial role in engaging the public and shaping perceptions of the built environment. Through renderings, drawings, and visualizations, architectural concepts are made accessible to a broader audience, sparking interest, generating discourse, and fostering appreciation for architectural design. Images serve as catalysts for public engagement, inviting participation in discussions about urban development and the future of cities. Thus, the architectural image serves as a bridge between the architectural profession and society, facilitating dialogue and collective imagination.

The rise of technology, particularly the internet and social media, has revolutionized the way architectural discourse and media operate. New digital platforms and social media channels have democratized architectural discourse, allowing for greater accessibility and participation. Architects and architectural critics can now reach wider audiences and engage in real-time conversations about architectural ideas, projects, and issues. Digital tools and social media platforms and online forums have facilitated the sharing of architectural content and ideas, fostering a global community of architects, designers, and enthusiasts.

However, the proliferation of architectural content on social media has also raised questions about the quality and integrity of architectural discourse. The emphasis on visual aesthetics and the culture of "starchitecture" sometimes overshadow more substantive discussions about the social, cultural, and environmental dimensions of architecture. Critics argue that the superficiality of social media platforms incentivizes sensationalism and spectacle over thoughtful critique and analysis, leading to a commodification of architecture and a loss of critical engagement.

6. STAR ARCHITECTS' PRODUCTION AND ITS RELATIONSHIP WITH THE URBAN FABRIC

The influence of star architects on the reshaping of contemporary urban landscapes is undeniable. However, it's crucial to acknowledge that their architectural production often prioritizes iconicity and photogenicity over integration with the surrounding urban fabric. The designs conceived by star architects are frequently intended to stand out as singular, attention-grabbing landmarks rather than seamlessly integrate into the existing urban context. This approach results in architecture that is more isolated and less interested in establishing meaningful relationships with its surroundings. As a consequence, the urban tissue may become fragmented, with iconic buildings standing as isolated entities rather than contributing to a cohesive urban fabric. While these architectural icons undoubtedly leave a lasting impression on the cityscape, their impact on the overall urban environment and social dynamics may be less substantial than desired.

The design philosophy of star architects often stands in contrast to concepts such as "urban acupuncture," as advocated by Jaime Lerner. In his book "Urban Acupuncture: Celebrating Pinpricks of Change That Enrich City Life" [9], Lerner proposes an alternative approach to urban design that focuses on small-scale interventions to revitalize urban areas. Instead of grandiose architectural statements, Lerner emphasizes the importance of subtle, localized interventions that address specific urban challenges and enhance the quality of life for residents. By targeting key areas with targeted interventions, such as pedestrian-friendly streets, public art installations, or green spaces, Lerner argues that cities can achieve meaningful transformations without sacrificing the integrity of their urban fabric.

Sennett's work "Building and Dwelling: Ethics for the City" [10] provides further insights into the relationship between architecture, urban design, and social behavior. In his book, Sennett explores how the built environment shapes human interactions and community dynamics within cities. He explores into the ethical considerations of urban design, examining the impact of architectural interventions on social cohesion, inclusion, and well-being. By considering the ethical dimensions of urban development, Sennett offers perspectives on the challenges and opportunities inherent in creating cities that foster meaningful human connections and collective identity.

In contrast to the integrated approach seen in projects like the Olympic Village, the architectural production of star architects often demonstrates a less cohesive relationship with their surroundings and the urban fabric. For instance, Jean Nouvel's Torre Agbar in Barcelona stands as a striking icon within the cityscape, but its relationship with the surrounding urban context is more ambiguous. The tower's unconventional form and reflective facade make it visually striking. However, its integration into the broader urban fabric is limited, with little regard for the surrounding context.

Similarly, Enric Miralles' Gas Natural Headquarters presents a unique architectural expression that commands attention, but its relationship with its surroundings is characterized by a sense of detachment. The building's dynamic form and use of materials create a distinct identity, yet its interaction with the urban fabric appears fragmented, lacking a coherent connection to the surrounding streets and public spaces. Overall, while these projects may contribute to the attractiveness of the urban landscape, their design priorities often prioritize individual expression over integration with the surrounding context. This can result in a disconnection between the architectural

object and its urban setting, leading to challenges in creating cohesive and vibrant urban environments.

If we move outside the Barcelona city center, where the urban fabric is already established and the new architecture frequently function as acupuncture in it, we will see that the situation may become more dramatic. A notable example is the Forum Area, situated at the intersection of Diagonal Avenue and the sea. This area was previously devoid of built references until it underwent urban redevelopment for the 2004 Universal Forum of Cultures. The Forum Area's design, characterized by skyscrapers and isolated buildings, resembles the layout typically found in American city downtowns rather than reflecting the intimate, pedestrian-friendly scale and character of a Mediterranean city. This departure from the Mediterranean urban typology may result in a disconnect between the built environment and the local context, impacting the overall sense of place and identity. The emphasis on tall buildings and open spaces, while creating a visually dramatic landscape, may contribute to a sense of fragmentation and lack of cohesion within the urban fabric. Furthermore, the design of such areas may prioritize functionality and “innovative aesthetics” over considerations of cultural heritage, social interaction, and environmental sustainability, further distancing them from the qualities that define Mediterranean cities.

7. POST-2010: SHIFTING TRENDS AND NEW PARADIGMS

The global financial crisis of 2007 marked a turning point for the architectural profession (especially in Europe), prompting a reassessment of priorities and practices. In the aftermath of the crisis, there was a shift away from grandiose projects toward more pragmatic and sustainable approaches to design. Scholarly insights from Florida [11] highlight the challenges facing cities in the post-crisis era, including issues of inequality, segregation, and urban renewal. Florida's work explores the socioeconomic dynamics that shape urban environments, offering valuable perspectives on the complex interplay between economic forces and urban development. By examining the impacts of the global financial crisis on cities, Florida sheds light on the urgent need for sustainable and equitable urban planning strategies.

Many cities began prioritizing adaptive reuse and urban renewal projects, breathing new life into neglected neighborhoods. Furthermore, the rise of grassroots movements and community-led initiatives signaled a democratization of urban planning and design. Iveson's research [12] offers a comprehensive exploration of grassroots movements and community-led initiatives in urban development. Through detailed case studies and theoretical analysis, Iveson illuminates the transformative potential of bottom-up approaches to urban renewal and placemaking. By highlighting successful examples of community-driven projects, Iveson underscores the importance of empowering local residents in shaping their built environments and fostering social cohesion.

In Barcelona's Poblenou district, for instance, residents and local organizations have played an important role in transforming former industrial spaces into vibrant cultural hubs [13]. This bottom-up approach to urban development represents a departure from the top-down, star architect-driven models of the past. It aligns with principles of community engagement, participatory planning, and adaptive reuse, showcasing how local initiatives can shape the urban landscape and foster inclusive, sustainable urban environments.

The post-crisis period following 2007 has seen a shift in architectural trends towards designs that prioritize integration with the surrounding urban fabric and foster stronger connections with the community. This departure from the iconic, photogenic architecture of the past reflects a growing emphasis on sustainability, resilience, and social responsibility in architectural practice. Architects and urban planners are increasingly recognizing the importance of creating built environments that respond to the needs and aspirations of the people who inhabit them. This has led to a renewed focus on human-scale design, placemaking, and community engagement. Rather than creating standalone

architectural objects or landmarks, architects are designing projects that seamlessly integrate into their surroundings, contributing to the vitality and character of the urban fabric.

Furthermore, there is a greater emphasis on fostering communication and interaction between buildings and their surroundings. Architects are exploring innovative design strategies such as adaptive reuse and mixed-use development to create more inclusive and sustainable urban environments. By prioritizing pedestrian-friendly streetscapes, public spaces, and social infrastructure, architects are enhancing the quality of life for residents and fostering a sense of belonging within the community.

In contemporary architectural practice, the integration of new structures into the existing urban fabric is essential. This process involves meticulous consideration of several physical parameters inherent to the built environment. Architects carefully evaluate building height and volume, ensuring that new constructions align harmoniously with the existing urban tissue and do not disrupt the visual continuity of the surrounding urban landscape. The selection of materials holds significant importance in achieving seamless integration. Architects often opt for materials that not only reflect the local architectural character, but also complement the adjacent built environment in terms of color, texture, and materiality. The attention to scale and form is indispensable in fostering architectural coherence with the character of the area. This requires employing design strategies to establish a dialogue between the new structure and its context, thereby enriching the urban experience. By adhering to these principles, contemporary architects strive to create designs that not only enhance the physical environment but also contribute meaningfully to the cultural and social fabric of the community.

One characteristic example of a contemporary building in Barcelona that exemplifies the principles outlined above is the Media-TIC building [14], designed by the architectural firm Cloud 9. Situated in the 22@Barcelona district [15], known for its innovation and sustainability initiatives, the Media-TIC building seamlessly integrates into its urban context while contributing to the vibrant fabric of the surrounding area. Another example is the Sant Antoni-Joan Oliver Library [16], a public library located in the Eixample district of Barcelona. Designed by architects RCR Arquitectes, the library is renowned for its innovative architectural design, which includes a striking facade composed of translucent glass panels and metal mesh. Finally, the Gabriel García Márquez Library [17], designed by SUMA Arquitectura, aims to serve as community hub and cultural landmark, emphasizing accessibility, sustainability, and social engagement. It seeks to enhance the urban experience while contributing meaningfully to the cultural and social fabric of the community.

8. CHANGES IN GLOBAL URBAN DEVELOPMENT

While star architects may have less influence in some areas, their impact is still felt worldwide. In Europe and North America, the trend has shifted towards more sustainable and community-focused architectural practices. The emphasis is now on creating buildings that blend seamlessly with their surroundings and contribute to the social and cultural fabric of their environments. However, in other parts of the world, the legacy of star architects remains vibrant and influential. In cities like Dubai and Shanghai, iconic structures by renowned architects serve as symbols of economic capability and ambition [18].

In Asia and the Arabic countries, the architectural landscape is still heavily dominated by the creations of star architects. These regions have embraced iconic architecture as a means of city branding and expressing their expanding economic power. For instance, Dubai's Burj Khalifa, designed by Adrian Smith (SOM), stands as the tallest building in the world, a testament to human ingenuity and aspiration. This structure not only serves as a landmark but also as a symbol of Dubai's rapid development and its status as a global city. Similarly, the cityscape of Shanghai is dotted with iconic buildings like the Shanghai Tower, designed by Gensler, which emphasizes both height and modernity.

The focus on landmark architecture in these regions highlights a different set of priorities compared to the more integrated approaches seen in Western cities. In places like Dubai and Shanghai, the architectural icons are often designed to stand out dramatically from their surroundings, drawing attention and generating global interest. This approach is deeply connected to city branding strategies that aim to elevate the international profile of these cities. The buildings are not just structures; they are statements of identity and ambition, crafted to attract tourists, investors, and global recognition. In this context, the role of star architects continues to be important. Their ability to create visually striking and innovative designs aligns perfectly with the goals of cities in Asia and the Arabic countries. These regions prioritize architectural landmarks that can serve as symbols of progress and modernity, even if this means that the buildings do not necessarily integrate seamlessly with their urban context. The influence of star architects in these areas underscores the ongoing relevance of iconic architecture in city branding and economic development strategies, illustrating how the architectural priorities can vary significantly across different parts of the world.

9. CONCLUSION

In conclusion, the era of star architects, spanning from the 1990s to the late 2010s, marked a significant period of transformation in the field of architecture. These architects gained unprecedented celebrity status and utilized considerable influence over urban landscapes and global perceptions of cities. However, as we transition into the post-2010 era, we observe shifting trends and new paradigms emerging in architectural practice and urban development.

The rise of sustainable and community-focused architectural practices in Europe and North America reflects a growing awareness of the need for more inclusive and environmentally conscious design approaches. Architects and urban planners are prioritizing integration with the surrounding urban fabric and fostering stronger connections with local communities. This shift is evident in projects that prioritize human-scale design, placemaking, and adaptive reuse, contributing to vibrant and resilient urban environments.

Meanwhile, in regions like Asia and the Arabic countries, the legacy of star architects continues to thrive. Iconic structures by renowned architects serve as symbols of economic capability and ambition, contributing to city branding efforts and global recognition. The architectural priorities in these regions often prioritize spectacle and innovation over integration with the urban context, reflecting a different set of values and aspirations.

Despite these regional variations, the role of star architects remains significant in shaping global urban landscapes. Their ability to create visually striking and innovative designs aligns with the goals of cities seeking to enhance their international profile and attract investment. However, as we move forward, it is essential to strike a balance between architectural innovation and urban integration, ensuring that iconic structures contribute meaningfully to the social, cultural, and environmental fabric of cities worldwide. By embracing more inclusive and sustainable design practices, architects can continue to shape cities that are not only visually captivating but also resilient, vibrant, and inclusive.

Extended abstract

The main aim of this paper is to present a tree story and investigate palm-migration and its consequences to cityscapes. Given that ‘nature’, and in particular plant elements, play a substantial role in shaping urban landscapes and social identities, this paper presents a new reading of the contemporary Greek landscape seeking the tools of this approach in relation to the Palm tree.

Palms in their majority, are considered tropical trees, in the sense that they originate from tropical and subtropical regions. However, nowadays palms are found all around the world, being ‘*great travelers*’.

Since antiquity, palms have been traveling a lot throughout the world, either as a product, fruit, a tree, or a myth. The perpetual journey of plants and trees has deeply reformed the alimentary and agricultural practices all over the world. The introduction of new plants in new ecosystems, changes their architecture, their inflorescence, and evolution, and sometimes results in new species, proving the creation of a hybrid ecosystem. However, a new balance is to be found on a social level, as well. Transplantation of plants in different cultural environments changes their content, and their social role and they are called to play a new role.

The term ‘Palmscaping’, was invented within the frame of my wider ongoing Ph.D. research project to indicate that palm trees have been introduced in the Greek territory several periods, each time in a different way, under different cultural conditions, and in a different socioeconomic frame. It seems that the conceptual content of Palm trees can easily be abolished, renewed, or enriched playing an active role in the contemporary Greek landscape. More specifically, palm trees are dominant elements in Mesolonghi, a small historical city in Greece, where they are not only part of the cityscape but also part of the social identity, collective memory, and history.

Mesolonghi’s rich history and unique ecosystem, tied with the continuous and persistent presence of palms, offer a compelling narrative. Through diagrammatic mapping, this project focuses on the consequences of the transplantation and distribution of Palms in the Greek landscape and opens the discussion about new methods of exploring the intersection of memory, urban experience, and temporality.

Keywords: *palm tree; transplantation; collective memory; place identity; hybrid ecosystem; Greek landscape; East-West; meeting with the ‘other’;*

Abstract

In recent years, the issue of accessibility for people with mobility difficulties, more and more "aggressively" introduced to all scales of urban planning, but also of its legal interpretation. Even if the "poverty" of the existing infrastructure is another factor that makes this development difficult, for the Greek standards, the design findings of recent years are at least encouraging, albeit in an embryonic stage.

Despite this fact, there are daily phenomena in which even these elementary infrastructures become the object of exploitation or/ and violation of elementary rules of civil behavior as well as an indication of civilization. Even if the fact that the specific reality has clear origins of elementary rules and level of education, urban planning must take further measures to deal with such everyday phenomena, by planning and constructing "smart" applications to prevent related phenomena.

This article attempts to propose a specific, intelligent, low-cost infrastructure, to prevent parking, in places reserved for people with mobility difficulties. The aim of the specific applications is not prevention with, police-type, countermeasures but the highlighting and social "targeting" of vehicles and users who resort to such methods. The user of the vehicle who will park in this type of spaces, which objectively are few to minimal in Greek cities, will be perceived, with the use of the specific infrastructures, in that the place that he parked his vehicle was not foreseen. therefore, the specific "violation" will also be noticed by passers-by or users of the land uses of adjacent buildings.

Keywords: *Disable people, Free parking spaces, Accessibility, Smart infrastructure, Mobility*

1. INTRODUCTION

Nowadays, accessibility, concerns the equal opportunity of all without exception the members of a society, without discrimination, social, racial, sexual and/or mobility, in access to all infrastructure, urban or not, without the slightest restriction, in contrast with the conventional design of the past, which for a big period, either directly or indirectly, created a series of discriminations against the above assumption of parity.

With the goal of seamless and autonomous access for everyone, indiscriminately combined with the protection and respect of the environment, planning today through comprehensive plans and actions, in fact owes, to take into account both the equal access of all to all the infrastructures of the built and natural environment as well as the provision of the specific possibility through a series of actions and interventions in existing infrastructures which carry the heavy "negative" burden of the planning of

past, taking into account a number of other data and factors today, such as the characteristic of population aging.

An additional element that must be highlighted, and the needs of this article will be emphasized, is also education the awareness of all agencies whether it concerns the planners of the aforementioned infrastructures or much more, the everyday users of the designed and built infrastructure which we daily observe to be a part of abuse from their unrestricted and, lack of education and awareness, use mainly by the users of motorized means of transport and especially the private car.

The requirement of an overall design in which each action complements the previous one but it will also be a stepping stone for the next one is today more imperative than ever and will continue to be since parity in access must in the future become a way of life, of planners and users, and not piecemeal treatment due to a requirement of the respective legislation which lead, until today, to design and construction discontinuities.

The existing national and international actions are oriented in all the aforementioned directions however, the scientific community itself must contribute either by highlighting these practices with a positive or negative sign either by proposing new actions and interventions that will contribute to the intended goal of equality in access, individually or in combination but also taking into account all the new data which must be introduced into the nowadays planning such as the influence of climatic and environmental factors and the need to address emergency situations with which, both the Greek and the international society and their respective cities, in recent years have been repeatedly confronted cases in which especially people with mobility difficulties and vulnerable groups of people in general they must have a special and distinct place in the planning to deal with such emergency situations for which the strategic planning has already set the basic parameters.

Therefore, undertaking the present article to focus from the general to the specific and in daily dealing with, elementary and in many cases rudimentary, urban infrastructures which are a burden of abuse much more of unconscionability than, now, of ignorance with the most typical and immediate cases being those of sloping ramps and especially parking spaces intended for people with mobility difficulties it will be sought to highlight this type of bad practices and above all to propose smart methods direct response to such practices which will gradually lead to dealing with such phenomena in the way of thinking of perception and the correct attitude towards such phenomena and not with the proposal of police-type practices.

2. ACCESSIBILITY, MOBILITY AND PLANNING WITHIN THE CONTEXT OF EXISTING LITERATURE AND LEGISLATION

Access and accessibility, are exclusively complementary and convergent concepts since access is about providing the possibility of equal participation in all aspects of social life whether this concerns participation in the productive process-work, or even leisure sports, education, etc. while accessibility concerns the planning and construction of the built and natural environment can be carried out seamlessly, autonomously, safely and without difficulties, both in infrastructure and services. Planning is particularly important and irreplaceable in that direction which must now be oriented towards the aforementioned direction of equal access for all without the need of customization or specialized design to the greatest extent possible given, additionally, that the percentage of residents, at EU level with mobility or other type of difficulties, form up 15% of the total population, while disabled people in general make up about half of that.

Figure 1: Percentage of population with long-term disabilities, aged 16 or over. Source: Eurostat

The first category concerns all persons with any type of disability, whether this concerns movement or any sensory characteristic of them, even mental ailments, and the second any type of human being who does not fit into the average type, which may concern other types of characteristics such as age-related (children-elderly), social (pregnant-parents with strollers), professional (carriers of objects) or even occasionally (temporarily injured). The corresponding products of this type of planning are characterized as accessible.

Dealing with this entire process must be perceived as a single chain, which in the official literature is called as "Accessible chain" links of which are separate interventions, material or not, in the built environment with the aim of the safe and seamless movement of everyone, including people with mobility difficulties, who move and operate in the respective networks. The specific process is characterized as a chain because precisely if even one of its links is omitted or due to misuse it is bypassed or ceases to function, then, correspondingly, the overall operation of the chain stops, with fragmentary effects, a phenomenon particularly pronounced both in the past and in our days.

In Athens, more than 70% of the total length of existing sidewalks, which amounts to an order of magnitude of 2,000 m, does not meet the basic specifications in terms of their geometrical characteristics (cross section >2.1m). And when it comes to sidewalks, it should be understood that we are talking about the basic infrastructure that people with mobility difficulties are called upon to use for their movements.

<u>Sidewalk width (m)</u>	<u>Length</u>	<u>Percentage (%) of total</u>
0	31	2
<1	706	37
1-2	619	32
>2	476	25
No data	86	4

Total:	1918	
---------------	-------------	--

Table 1: Percentage distribution of sidewalks in the Municipality of Athens based on their cross-section

The main reason for this phenomenon is none other than the car-centric planning of the basic infrastructure, including sidewalks and others, which "conflict" with the exclusive use of as much space as possible from the car, combined with a number of other historical elements. Unfortunately, the recent campaign of promoting electric mobility seems to have exactly these characteristics, which under other circumstances could be described as "revolutionary", given that this particular aid enables people, mainly, with mobility difficulties, to overcome obstacles which do not concern infrastructures as much as geomorphological elements, and have the possibility to access even more places and infrastructures that they did not have in the past. In other words, people with mobility difficulties as well as other wheelchair users, as mentioned above, temporarily injured, carrying parents with baby carriages, to have the possibility, using electric mobility, to have access to areas, in which during the past, with the use of motorized wheelchairs, on a range of infrastructures, such as roads with steep gradients, roads with worn infrastructure, roads with other obstacles, and their respective, surrounding uses, were not able to use.

Nevertheless, the majority of both the propaganda and the actual aid concerns the promotion of the private car. In essence, with this particular practice, the promotion of strengthening the occupation of more and more space by the private car and its users which constitutes the modern challenge and requirement of modern cities, is not achieved, while at the same time, with the lack of incentives, even financial ones, for electric mobility and for people with mobility difficulties it will not "get" the disabled people out of their homes to the city or even, in the best case, of the basic movements they have managed to carry out on a periodic basis (e.g. residence-work).

Finally, as a society we have to apart from the social reflexes which will oblige society itself and its participants to realize their obligations towards people with mobility difficulties and/or particularities to take basic political but mainly scientific initiatives and decisions, the combination of which will be the starting point (one more) for their equal contribution and participation in everyday life and the corresponding infrastructures of the city.

This goal has already begun to be achieved in terms of travel with a number of alternative means of travel which, however, are used by users who in the past also participated equally in mobility and city life. The necessity, however, to improve living conditions, both environmentally and at the infrastructure level, definitely combined with political and scientific initiatives, has led in a number of cities to the strengthening of the use of bicycles and micro-mobility, and to a clear reduction in the use of the private car. But in the case of people with mobility difficulties and in general people with disabilities, except from traffic, transport, urban planning and everything else, it is now also a question of humanity, democracy and above all the perception of the right to equal access and use of all the parameters of everyday life. There is therefore a huge necessity to highlight the dialectical relationship between improving urban everyday life and equal access for all, regardless, of the users and residents of a city or a wider urban area.

In Greece today, based on the current legislation, in a city, it is mandatory to provide 5% of parking spaces for people with any type of disability in all of its public spaces (M.D. of MIN.EN/124964/1561/2022- FEK 6213/B/7-12-2022, as it replaced under no 52907/2009 M.D. "Special arrangements for the service of disabled people in common areas of settlements intended for pedestrian traffic" (B' 2621)).

In addition, a number of their geometric-technical characteristics are also foreseen, based on which "the minimum width of these special places is determined at 3.50m". Of these special spaces, at least one (1) meets the parking requirements of disabled VAN type vehicles, or access to a vehicle from

Proceedings

the rear with minimum required dimensions of 4.50mX6.60m. In the section where the special vehicle seats for people with disabilities are provided, the appropriate connection of the level of the parking area with any adjacent sidewalk with an inclined level is also provided. Special parking spaces are marked on the ground and on poles with the International Access Symbol. At the same time as a series of other provisions of the specific M.D. and ignoring the fact of the difficulty of the process of locating a parking space for people with mobility difficulties, which can and must take into account a series of traffic urban planning and (mainly) social characteristics, such as a residence of a person with mobility difficulties near, or as close as possible, to its proposed location, or land use that attracts many movements and users during the day, such as public service, social space, etc. in any case, there are very few cases of Greek cities in which even the otherwise small percentage of 5% is covered, out of the totality of these positions. However, even in the case of their location, whether it is fake parking or cases of organized parking spaces or even for parking spaces that serve a specific use of existing building infrastructure, it is common for them to be occupied by private car users, since we are talking exclusively about this particular vehicle, who do not have mobility difficulties either and much more, as a consequence of this, they do not even have the right to use the specific, minimum, parking spaces.

3. THE SOCIAL PHENOMENON OF CAR DOMINATION AND ITS TREATMENT IN CORRESPONDING TERMS

In ideal circumstances there should be no discussion of the question of "right" for using of such parking spaces or not, but the specific issue should have been resolved in social and not legal or police terms but unfortunately it is currently beyond the scope and scientific area of this particular article. In exactly the same way of thinking, the aim of the article is the individual suggestion of smart infrastructure, which will act as a deterrent to the occupation of such parking spaces, intended for people with mobility difficulties, proposing at the same time a method and places for their pilot application.

Despite the fact that the factors under which such an infrastructure is called to be implemented have a purely deterrent and mainly social character, free from the way of police type measures, in contrast to a number of other similar applications which exist today, and, unfortunately, the vast majority have remained in their pilot nature and mode of application fatally, indirectly, both on the basis of the proposed pilot application areas, as well as in the proposed way of implementing them, easily one can assume, that the final goal is the implementation of police-type measures of direct or indirect future prevention.

The uncontrollable, for decades, through, of course, corresponding political practices of encouragement, of the presence of the private car in urban areas and especially in cities, the phenomenon of abuse as well as one, aggressive, for the car users which in nowadays could be condensed into the sentence "I have no problem but I consider electric skates unsuitable for the streets because they are silent and develop such speeds that they can fall on me and scratch my car" from car users is more than common. In other words, as if the public spaces-roads are exclusively intended for the car and the users of all other, mainly non-motorized, means use them abusively. Both corresponding social experiments, as well as an everyday image from the city streets confirms the assumption above precisely because the private car has imposed its own reality on the roads.

An ally in this joint effort, in terms of transportation, can be a series of other alternative modes of transportation in combination with the aforementioned new perspectives provided by electric mobility, based in sustainable mobility, and not exclusively the private car from the point of view of only the non-emission of gaseous pollutants. The use of the respective infrastructures by means used by people with mobility difficulties but also from other alternative means of transportation such as the bicycle and the means of micromobility is a solution that the scientific community has been putting forward for years, each time, that the specific infrastructures will not be occupied by illegally

Proceedings

parked cars. And if in an infrastructure with large geometric characteristics, length or width the point occupation still gives the possibility of passing through the occupied point, in the case of parking spaces for people with mobility difficulties, the possibilities are limited. In contrast to the electric car, which has monopolized the interest of transport electrification policies, however, it won't improve the image of the city in the slightest as the only change will concern the chosen fuel and not the number of vehicles circulating in the cities and the effects they cause. In contrast to electromobility, combined with a range of alternative means of transport which will concern both people with mobility difficulties and micromobility.

The reality above is, unfortunately, a daily routine for the average Greek city. This phenomenon, combined with the lack of basic infrastructure for the safe and smooth movement of people with mobility difficulties, make their appearance and movement deterrent in public areas, which are almost completely occupied by private cars. Temporary parking phenomena, which apart from the fact that in many cases, becomes permanent either by the same vehicle or by repeated ones, whose users adopt the same way of thinking and reacting each time, they work cumulatively as a result, the people with mobility difficulties, knowing the reality in advance with which they will probably be confronted, to avoid circulating on the streets or in free public spaces. Therefore, any dialogue, as it is perceived, is many steps backwards mainly in its starting point regarding whether these individuals move even rudimentarily finally on the streets and not a word about the parity of use of any existing infrastructures.

The phenomenon of "temporary" parking in places intended for people with mobility difficulties is unfortunately an established habit as if all the remaining space is for both movement and parking, a geographically limited size. Whether for road parking, or parking spaces that serve specific uses, based on the existing legislation as described above. The development and implementation of a specific infrastructure, which is proposed, aims to prevent the occurrence of such phenomena, which under other circumstances should have been the norm.

4. PROPOSAL FOR SMART INFRASTRUCTURE PLANNING AND ZONNING

A parking space intended for people with mobility difficulties has specific geographical dimensions. Specifically, as mentioned above, based on the existing legislation it is foreseen to be 3.50x 1.50 m. if it is a conventional car and 4.50x 6.60 m if it is a VAN type car. Although these dimensions, purely geometrically, appear to be sufficient for parking an ordinary vehicle there are not a few times when, either partially or exclusively, the specific positions are occupied. That data, as mentioned above, since it is known whether in the persons with mobility difficulties themselves or not, is a negative and unpleasant starting point for the specific people, to choose to move by using their private car, while it is very common, the phenomenon of refusing to move, precisely because of these unfavorable conditions but also of the fact that overall cities are inhospitable with dozens of obstacles for a simple conventional movement of even a few meters.

The aim of this proposal is the construction of elementary infrastructures which, with a social sign, will attempt to prevent such phenomena with a series of criteria which are described above. In particular, a metal structure is proposed to be placed at the rear boundary of a parking space intended for people with mobility difficulties with clear delineation and coloring of the floor in accordance with the provisions of 6213/B/7-12-2022 M.D. The specific infrastructures may have a dual role since first of all and given that it is proposed to be placed perpendicular to the road surface and parallel to the rear boundary of the parking space, they will prevent partial occupation of these special parking spaces, by vehicles of users without mobility difficulties which (partial occupation) constitutes in essence occupation of the parking space in its entirety. At the same time, with the use of a series of smart infrastructure, more specifically a smart barcode reader, with a particularly large range angle, the reader will be able to detect any existence of a specific Qr Code, which will be the most recognized for holding the right of a car user to occupy the position or not.

Picture 1. Suggestion of the proposed Qr code

The specific Qr code, can work exactly work the way the corresponding cards for disabled people with their own car, work today, which people with mobility difficulties or disabilities are provided by the respective Ministry after proving, based on the prescribed procedures, that they belong to the specific category. Basic difference both in the way of use and in the general philosophy of the proposal relative to corresponding existing methods is to isolate this type of illegal seating behavior for people with mobility difficulties in a social way and not with police-type measures. More specifically, today, when a vehicle that does not have the relevant card occupies the position in question then either the person with mobility difficulties, which is deprived of that particular position, or anyone else, must report the incident to the relevant police authorities who are obliged to intervene. However, apart from the fact that this particular way is far from the approach of our scientific team at the same time, there are not a few cases in which no one reports the incident, resulting in the continuous increase of similar phenomena, on the other hand, even in the event of a complaint it is handled painlessly or much longer in the time between the complaint and the intervention the vehicle has already left.

So, the specific metal structure which will be placed at the rear limit of the parking space for a person with mobility difficulties as well as the wide-angle Qr code reader, within a certain period of time will be able to locate the specific Qr code which will be placed in a discreet place, preferably invisible at the rear of the vehicle, during the parking process of each vehicle. Although the time interval may vary, a suggested time of 60 seconds from the moment that the vehicle stops is considered as sufficient, since it gives the necessary time to the reader to detect the code, on the other hand, it is not large enough to create the possibility of temporary parking phenomenon which, as mentioned above, is very common. After the specific period of time has passed, a piercing hiss from the particular infrastructure will start, who will point out that the specific vehicle is not intended for the specific position. Given that this particular infrastructure will not replace everything that is currently in place, it is obvious that any non-existence of the right to use the specific position can be certified, secondarily, by the existence of a relevant card or not. However, it will already have created these social conditions on the basis of which those who are moving to the area will be able to perceive the illegal use of an infrastructure intended for people whom, as a society, must include equally in their movement in public spaces and in the city as a whole, by car users who can use all the remaining 95% of the corresponding existing infrastructures, and given that said whistling is suggested to be particularly piercing, bordering on annoying, will have already targeted the user who resorts to the specific practice. Finally, given that the solution of police-style meters in not completely rejected, or even that those social conditions are missing on the basis of which we can today consider them unnecessary or even bypass them, the specific practice will be the starting point for them to be denounced given that, both due to the existing, today, infrastructure, and due to the fact that the period of time is particularly short the users of private cars who resort to such methods, in the great majority, are doing it completely consciously.

Alternatively, the installation of a smart magnetic card reader is recommended, which cards the user will procure in the same manner as mentioned above and bring into contact with the reader immediately after parking. If this is not happen, and the reader-sensor perceives the presence of a vehicle without the existence of a corresponding right then the process will be exactly the same as above, however, this specific proposal falls into a series of issues related to the personal data of the users of the cards and the corresponding vehicles, so it is proposed as an alternative solution.

Picture 2. Indicative images of infrastructure

5. SUGGESTION OF PILOT USE

Despite the fact that the concept of shared spaces, also nowadays, even in the scientific area of urban planning is particularly enlarged, the existing legislative framework clearly defines the designation of parking spaces for people with mobility difficulties, which must be located in such an area, both in terms of the number and its geometrical characteristics but also in terms of their proximity of the use they are planning to serve. Specifically, as described above “when the parking areas serve a building that houses services, banks, theaters, cinemas, etc., then care will be taken so that the parking spaces for people with disabilities are located at the shortest possible distance from them, if possible less than 50m.”. Accordingly, also in the specific areas both from lack of information about the role and character of the specific positions, as well as by a number of other subjective criteria, including the element of social outcry but also the sense of a much smaller risk of, police-style, punishment the phenomenon of their occupation by vehicles that lack the relevant right, is particularly common. Supermarkets are also a very indicative and everyday phenomenon with organized parking spaces, the specific spaces of which otherwise meet the other conditions while in recent years the phenomena of social automation have also been particularly intense when there are corresponding behaviors, of their illegal occupation.

With the pilot application of the specific infrastructure in such areas, so the above phenomena will be further formalized while the users of these spaces will also become familiar with the specific infrastructure for their possible future use in the urban road network. While the user of a private car will have more difficulty occupying a relevant position on the urban road network however due to a larger range of users per unit of time also the specific positions as mentioned above are usually filled in areas such as supermarkets where the feeling of temporary occupation but also the fatalistic treatment of the fact that it is difficult for people with mobility difficulties to make use of the specific land uses it is, if not more, just as intense without however this being proven by relevant research results. It is therefore estimated that the implementation of this specific infrastructure in places such as supermarkets will lead, on the one hand, to safe scientific but above all practical results and conclusions on the other hand, they will bring a large part of commuters into contact with the specific

infrastructure since it is one of the most massive land uses and an attraction of many hundreds of commuters every day while, finally, the ownership status of the specific land uses it is likely to make possible the simultaneous implementation of the specific infrastructure at dozens of sites in the same time in different geographical areas all over the country, so that any sample from their implementation might be, statistically, even safer.

6. SUMMARIZED

The question of access and accessibility, has been particularly intense in recent years, has constituted a specific field of scientific research and application. Apart from the scientific determination of a number of related disciplines, is also a question of equal access to all the urban, and not only, infrastructures of the area. People with mobility difficulties but also people with different habits and conditions of movement both in terms of the use of urban space and especially the road and street network as well as its corresponding infrastructures must be ensured for the possibility of equal access with people who do not fall into the specified categories. Even if the conversation today is limited to the aspect of access and not, yet, to the aspect of parity both planning and the corresponding legislative framework must be focused on the second direction. Obviously, the degree of difficulty of the specific goal might be different, as in cases of old parts of cities, both in terms of the structure of the road network, as well as regarding the age of the existing shells, science, technology and especially planning, they must take all those measures that will lead to a continuous improvement of these conditions.

Unfortunately today there are phenomena of abuse of even the basic infrastructures for people with mobility difficulties that exist in the urban area with the most typical example the occupation of special parking spaces. This particular phenomenon, in addition to a number of social characteristics regarding private car users who abuse the specific infrastructures, since it constitutes a negative reality, is also an inhibiting factor for people with chronic problems with mobility difficulties to move. In other words, a person with mobility difficulties or mobility peculiarities, knowing this reality will make the decision to move much more difficultly, if the movement he/she is about to make is not imperative. In this particular phenomenon the negative reality is also based, the rare phenomenon of the image of the presence and/or movement of people with mobility difficulties in the urban area as well as the corresponding structures and infrastructures.

With the proposed infrastructure, is being attempted, mainly in a social way and not with police type measures to prevent the abusive occupation of the, otherwise, few parking spaces for people with mobility difficulties or mobility peculiarities making more use of social automation rather than the civil and criminal code. In particular, the placement of specific infrastructure is proposed, which in a smart way and in a very short time will be possible to perceive whether a user of a private car who parks in such a parking space has the corresponding "right" or not. Private car users with mobility difficulties or mobility peculiarities will procure and place, in a discreet, perhaps not visible, part of their vehicle, a specific type of Qr code, or equivalent, which will be supplied by the respective official and certified body, such as the Prefectural Association of Disable People, or other bodies that may be proposed for further scientific research related to this topic. The specific infrastructure will be placed transversely at the rear of the specific parking spaces simultaneously creating "privacy" conditions but also acting as a deterrent for phenomena of partial occupation of the specific positions since it will also constitute their artificial limit. The specific infrastructure is proposed to consist of a "II" shaped metal arm which will be based on the ground while its geometric features are proposed to be such as to ensure that they will not be easily, if at all, destructible while at the same time they will meet a series of specifications related to road safety. The height of the arm, as well as the Qr codes reader, is suggested to be, in order of magnitude, at the height of the vehicle's license plate, the position of which, due to the different types of vehicles, may be partially differentiated. For this reason the recommended reader, should have a wide reading angle range so as to cover both the

Proceedings

different types of vehicles as well as the possibly different placement position of the specific Qr code by the owner of the vehicle which can also be determined at which point and height should be placed even if this placement takes place in an inconspicuous place, but be able to be read by the specific reader. Finally, the same reader (or another one), when motion is detected will be activated provided that this movement will last more than a certain period of time, a few seconds to ensure that it will not be perceived as movement, movements which do not contradict the terms of use and operation of the specific parking spaces, such as pedestrian crossing except for parked vehicles, two-wheeled or four-wheeled vehicles. When this movement stops and the obstacle remains after the lapse, also of a short time (60 sec are recommended), and has not noticed the existence of the specific Qr code, that is, the parked vehicle will not have a relevant permit, a loud piercing hiss will be activated, and will point out to the neighbors or passers-by, as well as the drivers themselves, about the offense committed.

As emphasized above, target of the measure is not a police- type police-style handling of arbitrary parking in spaces intended for people with mobility difficulties or mobility peculiarities but the activation of a series of characteristics which are left to the perception of the users of the structures of the urban environment about the fact of the necessity of the transformation of the equal accessibility of all from goal, that is today, into a reality.

Alternatively, the installation of a smart reader is also suggested with the help of which the local Municipality will have, by using the NBiOT Technology, and minimum, among other things, electrical energy requirements in a real time, view of the situation in which, the set of positions available within its administrative boundaries are, regarding their availability or not as well as the nature of the vehicles parked in them that is, if they are indeed from users with mobility difficulties and/or particularities or not. The electrification of the infrastructure can be carried out either by connecting to the central electricity supply system, since they will be placed within the urban area, or by installing solar panels and an electric battery Finally, for reasons of personal data protection the Qr codes will be the same for all those who are entitled to purchase them, by presenting the corresponding supporting documents proving the disability or special condition from the competent granting body, and not separate for each individual-vehicle so that any sample of occupying the specific positions as described above, to be exclusively statistical and not personal.

Extended abstract

For many years, small towns in Poland and Ukraine, which are often referred to as “post-socialist”, have been struggling with the spatial chaos of historical urban layouts resulting from the deformations of the socialist and post-socialist periods. These towns tended to be largely neglected and often struggled to maintain a sense of identity. After the political transformation, a process of “shrinking” was observed in these towns following the closure of unprofitable socialist factories. Poland’s accession to the European Union helped change both the appearance of towns and society’s attitude towards them. Small towns (known as ‘slow cities’, as opposed to ‘smart cities’) provide a counterbalance to large, fast-paced, populous cities and have become attractive as they have begun to offer better (cheaper) living and working conditions. Supported by European funds, towns are undergoing a spatial metamorphosis and there has been a renewal of regionalism and identification of their inhabitants with the local culture. However, as a result of rising property values, they are often subject to economic pressure, resulting in chaotic development. This has caused both Polish and Ukrainian towns to face similar problems related to spatial degradation and cultural heritage protection.

The article looks at the preserved urban heritage of the historic small towns of Poland and Ukraine, which were founded on similar roots, and makes a comparative analysis of their development during their socialist history, especially since Poland’s accession to the European Union and Ukraine’s independence, namely over the last 30 years.

Extended abstract

This research explores the intersection of augmented reality (AR) technology, authenticity, and the enhancement of onsite heritage experiences. As the demand for authentic encounters with cultural and historical sites grows, AR emerges as a transformative tool capable of providing users with a more objective and immersive understanding of heritage.

The concept of authenticity has long been contested in both heritage conservation and cultural tourism studies. There exist a range of interpretations of what is authentic, parting from objective or object-based authenticity centered on the material originality of the object and culminating in the most recent post-modernist views that see authenticity as an entirely subjective, individual experience. Once digital technologies are introduced into the equation, the concept of authenticity continues to expand, with questions arising as to the impact of digital reproductions, designs, and experiences on the authenticity of heritage sites and objects.

While the concept of authenticity has been extensively explored in both academia and practice, little research has been carried out to understand the intersection of these different concepts and how they relate to digital technologies. Past studies have primarily focused on the post-modernist perspective of authenticity when discussing digital surrogates and experiences. This research, in contrast, delves into how AR technologies can augment onsite experiences by seamlessly integrating digital overlays that offer a wider local context, thereby creating an existentialist perception of authenticity and potentially increasing the object-based authenticity of heritage sites.

Through case studies and practical examples, this research aims to showcase how AR can be effectively employed to create onsite heritage experiences that are both academically rigorous and engaging for diverse audiences. By leveraging AR, heritage sites can transcend physical constraints, enabling users to explore historical layers, artifacts, and narratives that are not immediately visible. This approach fosters a more comprehensive and nuanced understanding of the site's history, enhancing the overall authenticity of the experience. The discussion will also address the challenges associated with balancing authenticity and innovation in the development of AR applications for heritage sites.

Abstract

Tourism is perhaps the most important lever for development in Greek islands, but it is subject to strong fluctuations due to seasonality, especially in the most isolated areas. With the aim of improving the quality and diversity of tourism products, as well as the protection of natural landscapes and the preservation of the physiognomy of remote islands, the central authorities promote the development of alternative and thematic forms of tourism. Agro-tourism is an alternative form of tourism that combines rural and tourist activities. Agro-touristic landscapes become tourist attractions. Therefore, the natural and anthropogenic elements that make it up must attract visitors while stimulating their imagination. The landscape architect, possessing specialized knowledge from a wide range of scientific disciplines, is called upon to format and design a rural landscape in agro-touristic. Through the organization of the various uses and the design, the aim is the preservation and protection of the specific landscapes and the character of place, also the improvement and creation of attractive rural-touristic landscapes to be functional, aesthetically pleasant, meaningful and sustainable, to serve a variety of human needs and objectives.

Astypalaia, the westernmost island of the Dodecanese, is an island, unsaturated in terms of tourism, which is a geographical and cultural "bridge" with the Cyclades. It has been characterized as an ecologically important area and a landscape of superb natural beauty. The aim of the study was to design the landscape of an agro-tourism unit that hosts various activities during most of the year within private field of the coastal settlement of Exo Vathy, located in the north-eastern part of Astypalaia, while also providing open spaces for visitors to meditate.

The approach followed was, on the one hand, the gathering of general regional data, cultural, historical and architectural elements, information on the vegetation, crops, meteorology and soil of the island and on the other hand, the assessment of the natural and anthropogenic elements of the landscape. The bibliographic research and the visual analysis were processed with the views and wishes of the owners, regarding the utilization of visitors' free time in an agro-tourism unit, and the design guidelines emerged.

Use zones, facilities and services, accessibility and aesthetics were defined to make the landscape functional and attractive and to make the project potentially sustainable. The public space of the traditional settlement of Chora of Astypalaia and the settlements of the Cyclades were the source of inspiration. Special care was given to the preservation, protection and improvement of the landscape, with the use of plant material harmonized with the climatic data of the area and the existing flora, but also the construction of ecological technical projects, in an effort to integrate into the existing landscape.

1. INTRODUCTION

1.1 Agro-tourism and isolated island areas

Alternative or soft tourism is a qualitatively upgraded and particularly hospitable tourism, which with discreet integration of the guests brings economic benefits for the locals and creates a climate of reciprocity between locals and visitors, while at the same time it does not affect either the ecological environment, or the social-cultural character of the area [1]. "Agro-tourism" is the tourist activity that develops in a non-urban area, by those employed mainly in the primary and secondary production sector and in particular in family or cooperative small tourist units providing goods and services [2]. It is based on the exploitation of natural, cultural and human local resources, it satisfies the specialized personal needs of modern man and aims at the retention or return of the local population, the strengthening of agricultural income and the local economy and the rise of the living and cultural level [3]. Rural tourism develops, mainly, in non-saturated touristic rural areas and is one of the alternative forms of tourism, which connects the rural with the touristic activity. There are various forms of agro-tourism development: a) on farms, where the visitor shares food and accommodation with the owners -in the same or a separate house or in the form of a camp-, b) in a pension within the farm, c) in a cooperative promoting local products and d) in settlements that are built with materials of the vernacular architecture, so as to give the image of a "traditional" village [4].

Tourism is probably the most important driver of the development of the Greek island regions, but presenting, especially in the most isolated of them, strong fluctuations due to seasonality. With the aim of upgrading the quality and diversification of the tourist product, alongside the protection of the natural landscape and the preservation of the characteristics of the isolated islands, the development of alternative and thematic forms of tourism is promoted by the central authority. Agro-tourism is a gentle form of tourism and, at the same time, an important initiative that provides opportunities for development in isolated rural areas, contributing to the protection of their natural, cultural and social environment. The agro-tourism tourist is a visitor and at the same times a friend and admirer of the place. He is a traveller who seeks the quiet life, authenticity and beauty of each region, is interested in the natural and cultural heritage of each place and seeks to discover its secrets and come into contact with its unique and special elements. Thus, in agro-tourism, the visitor comes into contact with nature, the cultivation of the land and the collection of fruits, learns the local cuisine, makes traditional sweets, food and drinks, embroiders or weaves on the loom, observes the animals and the birds. He visits wooded paths, rushing rivers, peaceful lakes, discovers impressive waterfalls and stone bridges and is guided to archaeological sites, Byzantine churches and Venetian castles. The agro-tourism landscape emerges as a tourist attraction and therefore, the natural and human-made elements that make it up, should provoke the imagination of tourists and at the same time invite them to visit. The landscape architect, possessing specialized knowledge from a wide range of scientific disciplines, is called upon to format and design a rural landscape in agro-touristic [5]. Through the organization of the various uses and the design, the aim is the preservation and protection of the specific landscapes and the character of place, also the improvement and creation of attractive rural-touristic landscapes to be functional, aesthetically pleasant, meaningful and sustainable, to serve a variety of human needs and objectives.

1.2 Study objective

The aim of the study is to create an agro-tourism landscape with a variety of activities for most of the year, which will also provide outdoor spaces for meditation to visitors, in a seaside private field within the Exo Vathi coastal settlement, located in the north-eastern part of Astypalaia.

Figure 1. (left) The private field within the coastal settlement of Exo Vathi, located in the north-eastern part of Astypalaia Island, Greece (Provided by the author & [6])

Figure 2. (right) Astypalaia, the westernmost island of the complex of the Dodecanese, Greece [7]

2. SUBJECT APPROACH

The approach followed was, on the one hand, the gathering of general regional data, cultural, historical and architectural elements, information about the vegetation, crops, meteorology and soil of the island and on the other hand, the assessment of the natural and anthropogenic elements of the landscape. The literature research and visual analysis were elaborated with the views and wishes of the owners, regarding the utilization of visitors' free time in an agro-tourism unit, and the design guidelines emerged.

3. ASTYPALAIA

Astypalaia, the westernmost island of the Dodecanese (Figure 2), is a geographical and cultural "bridge" with the Cyclades and has been characterized as an ecologically important area and a landscape of special natural beauty. A strip of land about 100 meters wide, "Steno" (the Strait), divides the island into two parts, the inner and the outer island and gives it its characteristic, butterfly-like shape (Figure 1). The capital is the homonymous settlement or Chora, which is geographically connected to the port. Clusters of small islands and islets are located in the southeast and west of the island (Figure 1).

3.1 Demographic information

It is a semi-mountainous island, with an area of 97 sq. km, a varied coastline of 110 km and with 1,399 inhabitants [8]. Its population showed a continuous decrease until 1981, while after that it shows a small increase [9]. The largest percentage of the population (44%) is employed in the tertiary sector [10], mainly due to the development of tourism during the last time period. It is connected by ferry to Piraeus and the other islands of the Dodecanese, while there is also an airport with a relatively good connection to the airport of Athens and Rhodes Island.

3.2 Natural landscape of Astypalaia

The topography of Astypalaia is semi-mountainous (Figure 3) with two distinct lowlands in its southwestern and northeastern parts (Livadi and Vathi, respectively). The coastline of the island forms many small bays (Figure 3), with steep shores in several cases.

Figure 3. The coastline of the island forms many small bays [11]

Figure 4. In the coastal settlements there are olive trees, figs, tamarisks [12]

According to the meteorological station of Astypalaia [13] for the period 1977-2013, an average annual temperature of 19.27°C was recorded, while the average monthly values range between 11.68°C (February) and 27.20°C (July). The average minimum monthly air temperature of 7.73°C is recorded in the month of February, while the average maximum monthly temperature is recorded in July and amounts to 32.09°C. The absolute minimum value (-5.00°C) was recorded in the month of February, while the maximum (40.20°C) was recorded in the months of June and July [14].

The island is home to many rare species of flora and fauna [15], as well as endemic species of Aegean flora (Figure 4). Its eastern part, together with the cluster of 12 surrounding islets, is part of the NATURA 2000 network.

The vegetation there is characterized by bushy cypresses, skins and sparse gorse. In the western part, phrygic species dominate (*Sarcopoterium Spinosum*), while in the streambeds we find wickers, oleanders and figs. In the coastal settlements there are olive trees, figs, tamarisks, but also coniferous trees, reed beds and vines [16]. Intertwined with the landscape of Astypalaia is the presence of

aromatic-medicinal plants, which captivate visitors with their strong aromas. In the mountains grows the saffron plant, which is used in local cooking and confectionery.

3.3 Architecture of Astypalaia

The flow of the centuries is imprinted in Chora, with the medieval castle dominating the landscape (Figure 5). The very well preserved windmills are one of the dominant landmarks of the island. The architecture of the settlements is part of the Aegean style [17] and follows more the morphological characteristics of the Cycladic islands (Figure 6 &7). The dominant color of the buildings is white (Figure 6 & 7) and the public space within the residential fabric, following the morphology of the ground, consists of stone staircases with often crooked and irregular shapes, which highlight a synthetic freedom and plasticity and form a variety of stance points (Figure 7).

Figure 5. The medieval castle dominating the landscape of Chora [18]

Figure 6. It looks like a Cycladic island [19]

Figure 7. The public space of Chora [20]

4. READING THE LANDSCAPE

The topographic survey (Figure 8) of the plot identifies its boundaries, the proposed positions and contours of the new building tourist facilities, as well as the slope of the ground, which along its length forms strongly in the northern part and smoothly from the middle to its southern limit. The landscape of the area follows the form of the natural landscape of the eastern areas of Astypalaia, with bushy cypresses and lentisks, but as it is also a coastal area, there are reed beds to the south of the plot that reach the beach, conifers, figs and tamarisks (Figure 8). In the north-eastern part of the plot, near the municipal road, which leads to the beach and faces it, there are remains of old stone livestock facilities (photo on the right).

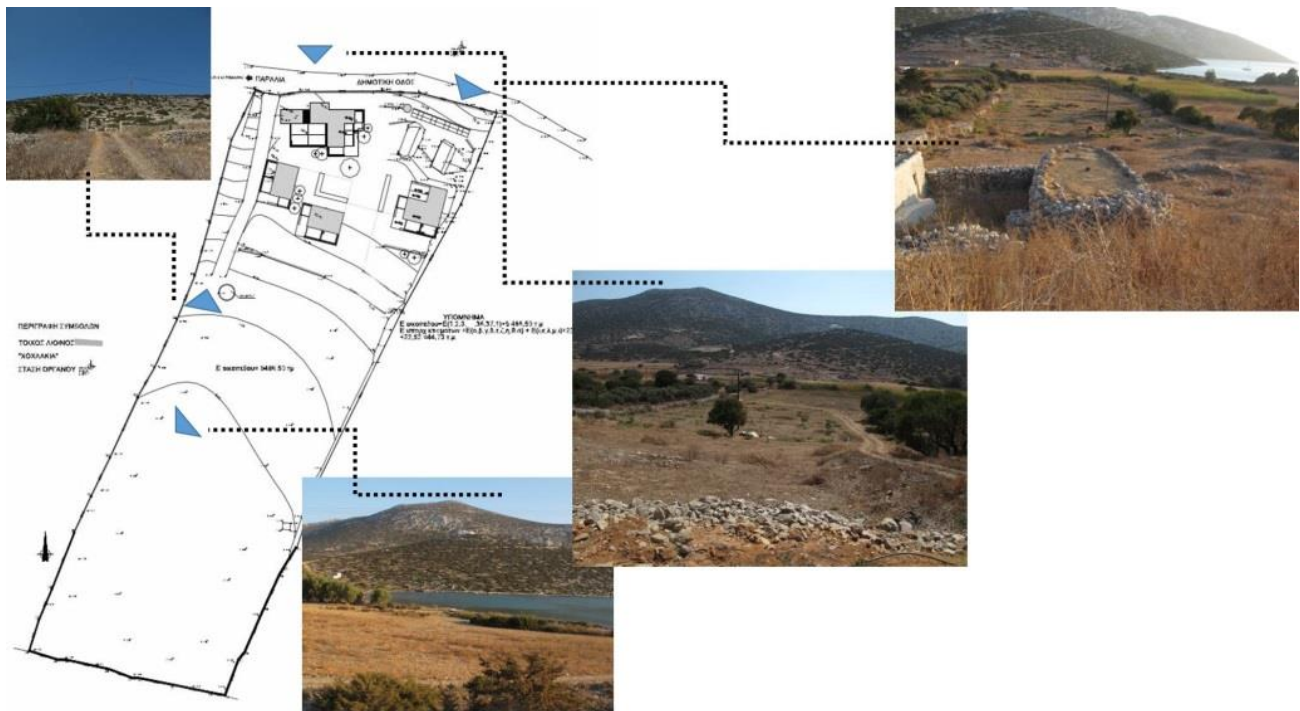

Figure 8. Visual analysis (Provided by the author)

5. DESIGNING AN AGRO-TOURISM LANDSCAPE

5.1 Design Guidelines

Following the owners' desire to make the specific space functional, attractive and sustainable for most of the year, the zones of use, facilities and services, accessibility and aesthetics were defined to serve a variety of human needs and goals. For the formation of the movement network and the places for visitors to stop and relax, the public space of the traditional settlement of Chora of Astypalea, as well as the Cyclades, was a source of inspiration, morphologically as well as in terms of structure and composition. Points of interest and activities with different identities are created (rest, recreation, cultivation, cooking, and exercise) (Figure 9). The organic lines of the olive grove define isolated spots for meditation and tranquility, constituting a Mediterranean approach for these spaces (Figure 10).

5.2 Design proposal

The landscape of the agro-tourism unit is formed by "borrowing" functional and morphological elements from the traditional settlements of the country and the rural landscape, but adapted to the needs of the establishment (Figure 18). The movement inside the space is made by stone paths, which

follows the slope of the ground and along its course, terraces, stopping and viewing points are created (Figure 11).

Figure 9. Concept diagram illustration (Provided by the author)

Figure 10. Design approach (Provided by the author)

Figure 11. Schematic cross-section along the plot and illustration of movement with sketches (Provided by the author)

The design proposal includes:

- Configuration of a car parking area to the left of the entrance to the plot with perimeter planting with shrubs (Figure 12, left).
- Bar & Shop selling local products. The remains of the old livestock facilities are preserved and turned into a bar and a small shop selling local products (Figure 13, right).

- Placement of an ecological swimming pool on two levels, near the eastern boundary of the plot, at a point that offers the possibility of a view towards the sea and the west. To the west of this, among the almond trees, hammocks are placed for resting under their shade (Figure 14, left).
- "The threshing floor": The path between the prickly pear trees leads to the threshing floor, a rest area with a view to the west, surrounded by peanut and fruit trees (Figure 15, right).
- "The square": The stone path leads, approximately in the middle of the plot, to the "square", a gathering place for the residents of the tourist unit, but also the visitors, where the plane tree dominates, surrounded by aromatic plants (mainly rosemary, lavender & honeysuckle) (Figure 16, left).
- Creation of a vegetable garden on the eastern border, separated from the "square" by a wall of wire mesh boxes with stones, which also functions as a backdrop for exhibitions or projections. Products from the vegetable garden are used in outdoor cooking classes under the almond trees (Figure 18).
- "The olive grove-a place of meditation": The lowest level of the plot, next to the reed beds, is formed into an olive grove with rhyming movements, where among the olives, gazebos and small openings offer the right space for meditation (Figure 17, right).

Figure 12. (left) Car parking space (Provided by the author)

Figure 13. (right) hop selling local products (Provided by the author)

Figure 14.(left) Ecological swimming pool and hammocks (Provided by the author)

Figure 15. (right) "The threshing floor" (Provided by the author)

Figure 16.(left) "The Square" (Provided by the author)

Figure 17. (right) "The olive grove - a place of meditation" (Provided by the author)

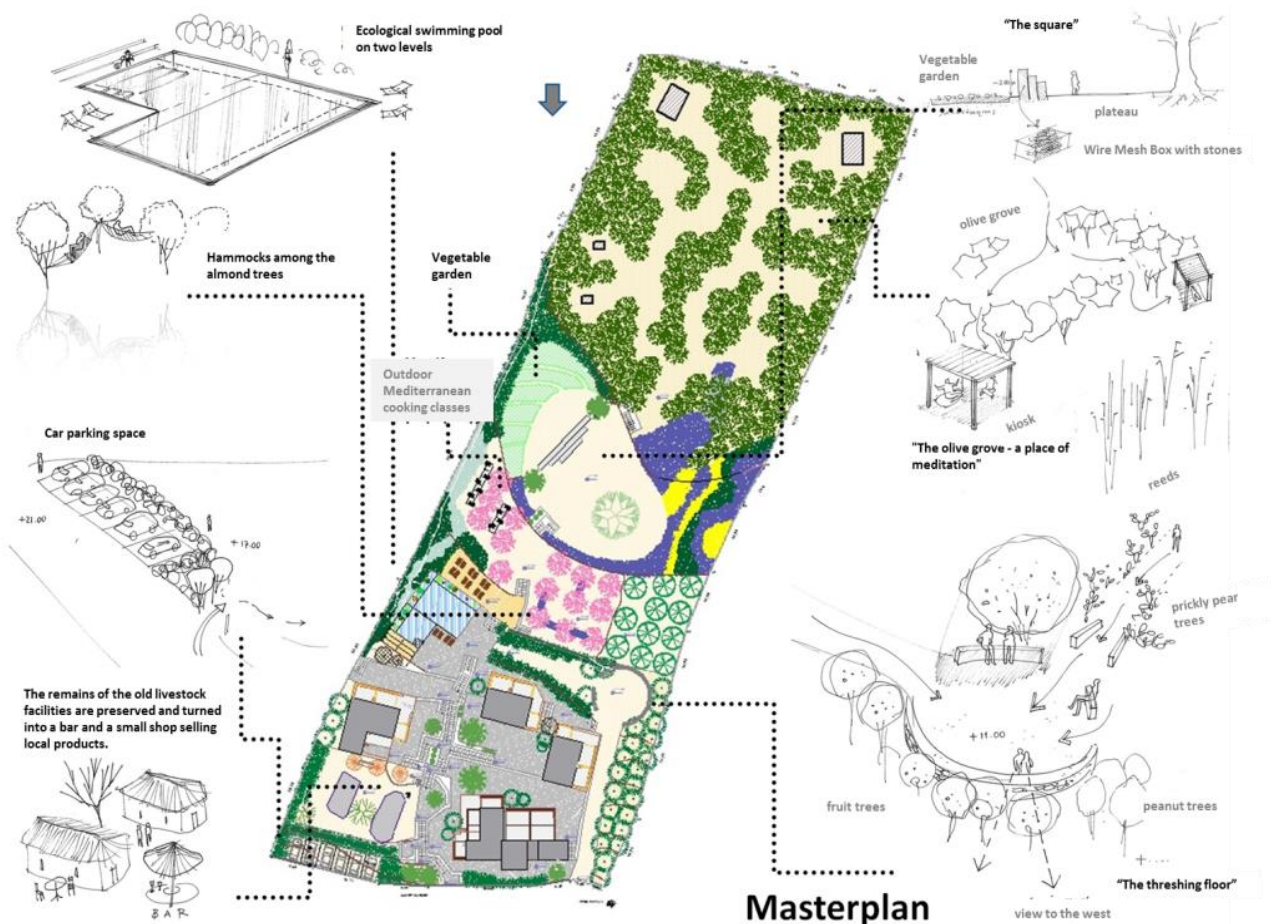

Figure 18. Masterplan and sketches (Provided by the author)

5.3 Materials

Special care was given to the preservation, protection and improvement of the landscape, with the use of plant material, which harmonizes with the climatic data of the area, but also with the existing

Proceedings

flora. It is proposed to use natural materials, colors and textures, but also ecological technical works, such as the swimming pool, in an attempt to integrate into the existing landscape.

6. CONCLUSIONS

The design proposal for the creation of an agro-tourism landscape in a private field in the Exo Vathi coastal settlement of Astypalaia combines the production, aesthetics and function of recreation. So, it forms the appropriate conditions for the promotion and rational utilization of the plot for most of the year with the parallel protection of the natural landscape and the place physiognomy, constituting at the same time, a potentially sustainable application of an alternative form of tourism in an isolated Greek island region.

Abstract

The climate crisis and the emergencies originating from natural disasters affect the ability of society to such an extent that direct and effective management is required. Focusing on architectural heritage and further on vernacular and historic buildings, measures concerning their adaptation to climate change impact as well as interventions for disaster prevention and preparedness, need to be developed. Heritage buildings have particular features which constitute their identities and contribute to culture and collective memory preservation. On the other hand, these features often limit buildings' accessibility and, consequently, possible adjustments for disaster prevention and preparedness, thus putting heritage buildings' sustainability under discussion. Undoubtedly, people with disabilities are more vulnerable to the impact of climate change and disproportionately affected by natural disasters, as they face considerable problems and inequality regarding disaster management. As a condition for inclusion, accessibility needs to be addressed as a core component of disaster risk management and resilience against climate change crisis to integrate inclusive and accessible design, with implementation in the built environment and particularly in architectural heritage. The research field of accessibility in architectural heritage environments has not been significantly investigated at the Greek national level, so it is deemed a challenge to generate relevant research. The detection and recording of the obstacles encountered, which can restrict the mobility of people with various types of disability, is crucial for the evaluation of heritage buildings' accessibility level, especially in the frame of evacuation during emergencies.

This paper presents a structured methodology for the investigation and evaluation of the accessibility of heritage buildings, in general and especially in case of evacuation of disabled people, focusing on different types of impairment (mobility, sensory, mental), the specific problems to deal with, and the relevant needs. The investigation is carried out under the prism of preservation of architectural heritage and in terms of traditional or historic structures, forms, materials, and construction techniques, which are considered possible generators of physical and intellectual barriers, in conjunction with evacuation procedures and warnings. Through the recording of the obstacles concerning access, the evaluation of the existing means, and the proposal of interventions in the context of Universal Design, the aim is to contribute to achieving accessibility for all and to make climate change resilient buildings. Enhancing heritage buildings' accessibility and thus their functionality, usability, and safety, also boosting their climate change resilience, is expected to largely contribute to heritage preservation and to settlements' and cities' sustainability.

Keywords: *accessibility; architectural heritage buildings; climate resilient buildings; disaster prevention*

Proceedings

1. INTRODUCTION

Undoubtedly, natural disasters related to climate change or other cause as well as human-caused ones, entail greater danger for disabled people. Belonging to the vulnerable groups, they face considerably bigger problems and often inequality regarding disaster management. The empowerment of vulnerable people, also in emergencies, by removing obstacles and constraints is widely emphasized (1 point 23). The detection and recording of the obstacles encountered in the built environment and particularly in buildings, which can restrict the mobility and perception of people with various types of disability, is crucial for the evaluation of these buildings' accessibility level, especially in the frame of emergencies and evacuation. This evaluation can lead to the necessary environmental and organizational modifications for the full participation and safety of persons with disabilities, and consequently of all people.

As historic and traditional architecture worldwide is deemed at risk [2], facing serious problems of obsolescence due to the contemporary culture homogenization and global socio-economic transformation, it seems that accessibility can constitute a pillar for heritage's sustainability. In this frame, the recording and evaluation of heritage buildings' accessibility and the relevant necessary modifications are critical. The enhancement of heritage buildings' accessibility is expected to boost their functionality and usability to a great extent, thus contributing to their sustainability. The evaluation and interventions are carried out in the framework of Universal Design. The application of its principles in the historic/ traditional environment, with the necessary adjustments and under the prism of protection and restoration, is determining.

The interface between two issues of great importance concerning the built environment, namely the ensuring of the unobstructed and autonomous access of all people to it, and the measures and interventions for friendly to the environment modifications which will enable its sustainability and resilience to climate change, is crucial [3]. The improvement of access and perception of buildings, focusing on heritage ones, is supposed to be a driver concerning disaster prevention, preparedness and risk management, and also resilience to climate change regarding the impact via natural disasters and the critical role of the accessible buildings in the accessibility chain in the built environment.

Within the frame of the investigation and evaluation of the accessibility of buildings, with the emphasis on heritage ones, in case of evacuation of disabled people during emergencies, the research focuses on four different groups of disabled people: people with mobility impairment, sensory impairment, particularly sight and hearing, and people with mental impairment. The problems they confront and their needs are examined and taken into account with the objective to structure a methodology for the evaluation of buildings' accessibility level. The proposed tool, in the context of this methodology, comprises an analytic list of criteria related to a building's general use by the aforementioned groups of people, and also its use in emergencies regarding evacuation and warning in case of a fire, an earthquake, a flood, or other. The methodology is structured for contemporary and conventional buildings, however being applicable to heritage buildings too, vernacular and historic ones.

Through the proposal of a tool for buildings' accessibility measurement and evaluation, the research aims to contribute to the creation of inclusive and accessible buildings which can ensure to the highest possible extent a safe and unobstructed operation and use, also in emergencies, for all including disabled people. This is expected to largely enhance disaster prevention, preparedness and risk management in the environment of cities and settlements, particularly regarding architectural heritage, boosting at the same time preservation, resilience against climate change crisis and sustainability.

2. PERSONS WITH DISABILITIES, ACCESSIBILITY AND ARCHITECTURAL HERITAGE

The perceptual features of the environment which mainly influence people while moving inside it can be described as: imageability, enclosure, human scale, transparency, complexity, legibility, linkage and coherence [4]. The built environment is characterized by both physical features, as those of urban infrastructure, and intangible features, as human scale and transparency, which affect and form people's walkability [5].

According to the "International Classification of Functioning, Disability and Health (ICF)" [6], in the framework of the World Health Organization (WHO), the term disability includes different types of impairment, physical, cognitive, intellectual, mental, sensory, developmental, or even a combination of the above. Disability creates a number of limitations or restrictions during interaction of disabled people with other groups, features of the society [7] and the environment. A person's functioning and disability are dynamic interactions between health conditions and contextual factors, including personal and environmental factors [8, 9]. The term "persons with disabilities" corresponds to a large and heterogeneous population which faces mobility restrictions for different reasons or in different periods. It encompasses the disabled people, the elderly, the pregnant women, the children of pre-adolescent age, the persons with temporary injuries and chronic ailments, the parents with children in strollers, and other groups.

The objective of full participation of persons with disabilities in all areas of social life, leads to necessary environmental modifications as well as to organizational ones and attitudes. Especially regarding the access to culture and furthermore to architectural heritage, United Nations' Universal Declaration of Human Rights [10 article 27.1] provides for all individuals' access to cultural commodities. In addition, the Convention on the Rights of Persons with Disabilities (CRPD) [11 article 30] emphasizes the right of persons with disabilities to participate in cultural life on an equal basis with others. Accessibility can ensure this right regarding the various activities, services and places related to cultural life, including monuments, sites and heritage buildings. Moreover, in the frame of the Amsterdam Declaration on the European Architectural Heritage [12], architectural heritage conservation is deemed an integral part of urban planning, thus taking into account social factors as inclusivity. By extension, the heritage protection and conservation context encompasses the factor of accessibility.

Focusing, further, on the included into traditional and historic settings buildings, the elements which constitute these buildings' identity often restrict their accessibility. Therefore, under the accessibility prism, the infrastructure which expresses history, place memory and architecture via the traditional and historic structures, forms, materials and techniques, and is related to distances, height differences and inclinations, is deemed a possible generator of multidimensional barriers [13]. As a result, persons with disabilities face physical (structural) barriers which hinder their approach and transfer within heritage spaces, and also intellectual barriers which do not allow them enjoy the full experience of the commodity of heritage. Nevertheless, each historic building or place is unique and the level of access to it that can be achieved is dependent on the characteristics of the site itself [14].

Furthermore, it should be highlighted that as architectural heritage has evolved into a cultural commodity [15] of cultural and economic value, its protection, conservation and enhancement including that of its accessibility level, increases heritage's efficiency, with benefits for the society. The above, always in the strict frame of protection and conservation, is vital for this significant asset's sustainability.

3. ACCESSIBILITY, DISASTER PREVENTION AND CLIMATE CHANGE RESILIENCE

3.1 Persons with disabilities and natural and human-caused disasters

According to United Nation Office for Disaster Risk Reduction (UNDRR) [16], a "disaster" is a serious disruption of the functioning of a community or a society at any scale due to hazardous events

Proceedings

interacting with conditions of exposure, vulnerability and capacity, leading to one or more of the following: human, material, economic and environmental losses and impacts. “Emergency” is sometimes used interchangeably with the term disaster.

Generally, in order to cope effectively with emergencies originating in natural and human-caused disasters and for the safe evacuation of a building, it is quite important to consider vulnerability of particular groups of population, such as disabled people. Specifically for critical infrastructures, evacuation of the population of people with disabilities is an issue of a high priority [7:15]. Undoubtedly the risks for them are much higher and it should be highlighted that mortality rate regarding the aforementioned is two to four times higher than that of the other population [17]. When evacuation is considered necessary, as in the case of a fire, for people with disabilities dealing with the emergency situation might be much more complicated compared to the other population. Their response to emergency in most cases is inadequate and usually costs their lives. A typical example is wheelchair users, encountering permanent or temporary mobility problems. The whole evacuation process which comprises the tracking of the evacuation routes and the journey towards the emergency exit, in their chairs and quickly, requires increased physical endeavor, especially in a harsh environment of dense smoke and high temperatures [7:7]. As for the earthquakes, the level of risk for people with disabilities is increased. During a building’s evacuation, many problems is possible to be confronted, such as difficulties in movement, in orientation, in the perception of hazards and warnings, as well as in emergency response coordination [18].

3.2 Persons with disabilities, accessibility and disaster preparedness and response

In the frame of the “European and Mediterranean Major Hazards Agreement (EUR-OPA)”, for the cooperation between European and Southern Mediterranean countries in the field of major natural and technological disaster, the recommendation 2013-1 on the inclusion of people with disabilities in disaster preparedness and response, was adopted [19]. The involvement of people with disabilities in preparedness and response against major hazards is deemed to reduce their vulnerability. A personal preparedness plan for disasters is expected to help people with disabilities to evacuate and survive, since emergency and care systems are poorly designed for people who depend on help or have disabilities. The evacuation plans, which can also be personal if needed, especially regarding persons with disabilities, are plans designed to help someone understand his exact position inside a building, so that to orient themselves upon the planned escape routes.

Based on the “Design for All approach”, involvement of people with disabilities in disaster risk reduction cycle seems to have an added value, especially in preparedness and response phases. Preparedness may include policies, training, planning and exercise for potential crises, whereas response refers to actions in order to resolve in effective way the crisis or emergency [20]. In regard to the preparedness phase, the so called strategic planning, people with disabilities could be trained in regard to disaster preparedness, enhancing their emergency response skills, and hence strengthening their opportunities to react effectively before, during, and after a disaster. The accessibility of buildings in this phase is crucial, especially concerning heritage buildings. Emergency response phase of the disaster management cycle may lead to development of new building codes and general standards for accessibility, rehabilitation and reconstruction. Any existing regulations or laws should be monitored and enforced to enhance emergency response for people with disabilities [7:17-18].

Focusing on the emergency evacuation planning and regarding circulation paths and notification systems in a building [21], these paths refer to the escape routes for continuous and unobstructed travelling from any position inside a building to an emergency exit. Components of a circulation path may include rooms, corridors, doors, stairs, smoke-proof enclosures, ramps, fire escape stairs, fire escape ladders, slide escapes, elevators etc. During an emergency evacuation, people who are unable to use stairways will probably need a place to remain temporarily and wait for instructions or

Proceedings

ISBN: 978-618-5765-02-6

assistance. These areas of the buildings which are described in buildings' fire safety plans, can be defined as refuge areas. The notification systems include alarms and public address systems [7:22].

3.3 Disabled people's general problems and needs regarding buildings' use in emergencies

Focusing on the aforementioned (see Introduction) four big groups of disabled people and concerning the problems they experience moving inside a building in case of emergency, especially during an evacuation, and also their relevant needs regarding the structural and mobile elements, the signage, the light and sound systems etc., the following are recorded [22]:

A. Regarding people with mobility impairment, they face (a) significant difficulty, given that the use of lifts is not recommended in emergencies, (b) need of more time and possibly of intervals for rest during a building evacuation, (c) need for other people's help to reach the emergency exit, (d) during the evacuation, possible loss of their necessary medical equipment and devices like walking sticks or walkers, which provide autonomy in movement, (e) possible difficulty regarding direction if there are not lower height signs indicating the escape route and the exit, and (f) difficulty in moving to the places of refuge if there are obstacles in the route. Moreover, this group needs structural elements as ramps and in case there are not any, portable ramps, evacuation chairs and for the wheelchair users, powered tracked stair climbers. They are also in need of handrails according to standards, for ramps and stairs, and other elements, light and sound systems etc. It is crucial for mobility impaired to know whether there are usable circulation paths (escape routes) inside a building, otherwise alternative evacuation routes and methods may need to be examined.

B. As for people with sight impairment, the problems faced during a building evacuation are (a) difficulty in perceiving an emergency, if the relevant warning is not audible, (b) difficulty in understanding the relevant information and generally the information material, if it is not audible or in Braille system and generally in a tactile form, (c) difficulty in evacuation, if the usual to these people exits are not in operation and (d) difficulty in moving towards and inside the places of refuge. This group's needs during evacuation are for audible alarm systems, warning and notices of danger, escape signs in Braille system and of color contrast, probably personal evacuation plans with alternative escape routes, and high lighting level not creating reflections, for the partially sighted persons.

C. About people with hearing impairment, the problems faced during a building evacuation are (a) difficulty in perceiving an emergency, if the relevant warning is only audible, (b) difficulty in understanding the relevant information and generally the information material, if this is not available in written form or with images too, (c) difficulty inside the places of refuge, if there are not interpreters in sign language or written notices. The needs for structural and other elements during evacuation are particularly for visual warning systems, lighted panels with scrolling messages, high lighting level which facilitates reading, possibly personal warning devices (in watch form). In general, people with hearing impairments can use the standard means and systems of a building, however it is extremely important for them to be aware of any existing visual notification systems inside the building.

D. Regarding people with mental impairment and the problems faced during a building evacuation, these are (a) significant difficulty in the evacuation of a place, (b) difficulty in perceiving an emergency, (c) difficulty in understanding the relevant information and guidelines, (d) confusion regarding the use of various precautions and (d) isolation in the places of refuge. The needs of this group are for elements as leaflets with description of the evacuation procedure in easy and understandable language with the use of images and symbols, use of color codes for the emergency exits, support of the "friends system" in which friends act as a team where one helps the other in emergencies, and presence of a trainer. In general, people with intellectual disabilities, cognitive impairments or mental health issues may not understand an emergency warning. As a result, cognitive impairments prevent a person from using all standard building systems for safe evacuation. In such a case, assistance plans need to be developed.

Proceedings

4. INCLUSIVE AND ACCESSIBLE DESIGN

Universal design is an inclusive design which integrates the understanding and managing of the diverse population's needs and concerns in the design of environments, as well as of products, programs and services, to be usable by all people to the greatest extent possible [23]. Regarding persons with disabilities, universal design is crucial for ensuring their access and participation to the activities taking place in the built environment. In this context, the various types and levels of barriers to heritage buildings' accessibility need to be addressed via this design, by certain measures and interventions. In every single case of heritage building, reasonable adjustments [11 article 2] comprising the necessary and appropriate modifications, can be applied. The objective is the effective integration of building's idiom elements and new elements appropriate for access and perception. The design incorporates also possibly required assistive technological devices for particular groups of persons with disabilities. Taking into account these persons' needs facilitates all people's life. Moreover, universal design is an innovative and dynamic strategy which focuses on constantly seeking better solutions in a context where technology, knowledge and awareness are rapidly changing. Thus, it is necessary to consider continually new solutions as a means of minimising technical and environmental limitations.

5. METHODOLOGY FOR BUILDINGS' ACCESSIBILITY EVALUATION IN THE FRAME OF EMERGENCY EVACUATION OF DISABLED PEOPLE

The following proposed methodology for accessibility recording and evaluation, can be applied in conventional buildings as well as in heritage buildings in historic centers of cities or in vernacular settlements. Although it emphasizes the condition of emergency evacuation, it is applicable generally in buildings for the evaluation of their accessibility level. This structured methodology comprises a process which consists of the following steps:

1. General building description with reference to the accessibility requirements according to the current regulations.
2. Recording of the building's population (employees, visitors etc.) including disabled people.
3. Listing of the general problems and the relevant needs which each group of disabled people, depending on the type of disability, encounters during building evacuation, concerning the building's structural and mobile elements, the signage, the light and sound systems etc.
4. Investigation and evaluation of building's accessibility in the frame of the planned evacuation procedure regarding each group of disabled people, and in the frame of warning in case of a fire or an earthquake. In this context, the escape route is examined for each floor in parts and in terms of geometrical characteristics, floor characteristics, signage (visual, audible and tactile). The starting point of the escape route is the room where a disabled person is possibly located in case of a fire or an earthquake, and the final point is the assembly point, usually outside of the building. The obstacles inside the building which can limit the mobility of the groups of disabled people, are located and recorded with the focus on the escape route. The building's structural elements (e.g. height and width of corridors, level differences), the mobile elements of the spaces (furniture, other equipment), the signage, the light and sound systems, can possibly act as obstacles.
5. Proposals for improvement of the building's accessibility in order to reduce or even eliminate the recorded obstacles regarding the evacuation in emergencies.

5.1 The emergency evacuation plan of a building

The evacuation of a conventional building is usually carried out via the main staircase and the main entrance/ exit, following the escape route which has relevant signage. If there are basements, people escape by using vehicle ramps or alternatively, and in heritage buildings too, the staircase. Getting out of the building, they are directed to the assembly point, if determined. Apart from the general evacuation plan, when required, there is usually provision for the creation of personal emergency evacuation plans for disabled people whose requirements for help cannot be entirely met by the

evacuation plan. Respectively, the disabled visitors can declare their requirements for help in case of evacuation. It is critical that a special evacuation procedure regarding each of the groups of disabled people is developed. The evacuation plan of a building has to be accessible to all, fulfilling the requirements of a conventional text and diagram, of a tactile form and of a simplified form with symbols and colors.

5.2 Recording and evaluation of buildings' accessibility level - synoptic and analytic tables

The following structured tables, namely the synoptic (Table 1) and the analytic one (Table 2), encompass the criteria for the assessment of the accessibility level of a building especially in case of emergency evacuation, focusing on persons with disabilities. Concerning evacuation, the escape route is examined analytically and in parts. The recorded data are assessed and the evaluation is accompanied by proposals for improvement interventions regarding the building's accessibility.

Table 1. Synoptic table of criteria for the assessment of the accessibility level of a building, in case of emergency evacuation

Floor	Inspection checklist	Evaluation - Improvement proposals
Emergency Exits - Floor - Ground Floor		
PARTS OF THE ESCAPE ROUTE		
1. Room where a Disabled Person is situated in case of a Fire or an Earthquake	Main room	
	Accessible toilet	
	Other (kitchen etc)	
2. Floor corridor		
3. Staircase (fire compartment)		
4. Route in the open area in front of the building		
5. Route to the Assembly Point		

Table 2. Analytic table of criteria for the assessment of the accessibility level of a building, in case of emergency evacuation (parts 4 and 5 of the escape route are not included)

Floor	Inspection checklist	Evaluation - Improvement proposals
Floor Emergency Exits Ground Emergency Exits	Number Position	
PARTS OF THE ESCAPE ROUTE		
1.Room where a Disabled Person is situated in case of a Fire or an Earthquake	Room's corridors' width, for the wheelchair user Space of 1.50m diameter for the wheelchair user to rotate Height free of obstacles Level difference/ bridged by a ramp or other Ramp -ramp gradient -ramp width -ramp landings (in the beginning and end of ramp/ in relation to ramp length and gradient) -double handrails at both 0.70m and 0.90m height from the floor -ramp kerbs -ramp surface material Room's door width (clear)/ opening/ to outside/ opening not requiring significant force Door color different from the one on the doorframe and the adjacent wall Door handle -type -length -height from the floor Room floor surface material Mobile furniture (for facilitating Disabled People) Room lighting -natural -artificial Room signage -visual -audible -tactile (in Braille system) -anti-reflective plates -of different color of the one on the adjacent wall Regarding emergencies: Alarm system and signage for evacuation -Audible alarm -Light alarm -Signs (with light) for the escape route	
2. Floor corridor	Width free of obstacles Space of 1.50m diameter for the wheelchair user to rotate Height free of obstacles Level difference/ bridged by a ramp or other Floor surface material Handles of no sharp end Regarding emergencies: Floor Evacuation Plan -provision of evacuation procedure regarding Disabled People -suitable form of sign plate for People with sight impairment -suitable form of sign plate for People with mental impairment -sign plate at suitable height for wheelchair users -anti-reflective sign plate -of different color of the one on the adjacent wall Regarding emergencies: Alarm system and signage for evacuation -Audible alarm -Light alarm -Signs (with light) for the escape route Evacuation system -powered tracked stair climber for evacuation through the staircase (in waiting position)	
3.Staircase	Type and form of staircase Width of staircase (clear) Stair landings/ length/ per number of risers Stair -Depth of the tread -Riser	

Surface material	
Slip-resistant material of different colour at the edge of the stairs	
Zone of a 0.30m width, of special tiles of type «DANGER», in 0.30m distance from the first and the last stair of the staircase	
Handrail -on both sides of the staircase -double handrails at both 0.70m and 0.90m from the stair edge -continuous throughout the staircase (the stair landings included) -overhanging both the start and the end of the staircase by min 0.30m -diameter -distance from the wall	
Staircase kerbs	
Staircase lighting	
Signage -visual -audible -tactile (in Braille system) -anti-reflective signs -of different color of the one on the adjacent wall	
Regarding emergencies: Alarm system and signage for evacuation -Audible alarm -Light alarm -Signs (with light) for the escape route Evacuation system -powered tracked stairclimber for evacuation through staircase (in waiting position)	

6. CONCLUSION

Enhancing buildings', especially heritage ones', functionality, usability and perceptibility, by ensuring their accessibility, will largely contribute to their sustainability as historic places, living places, and tourism and education destinations. Moreover, accessibility needs to be addressed as a core component of disaster prevention and risk management, and of resilience against climate change crisis. Given, generally, the unpredictable time of emergency events, enhancing the accessibility and perceptibility of buildings is deemed to constitute a basis for constant and effective addressing of environment's disasters and emergencies. The proposed in this paper methodology and tool for buildings' accessibility measurement and evaluation, are expected to contribute to the configuration of a holistic approach regarding buildings, inclusivity, disaster prevention and management, and climate change resilience. The effective combination and management of the above will benefit the society, the economy and the environment including architectural heritage.

Extended abstract

The present paper deals with issues of urban sustainability policies. It focuses on the case study of the city of Kalamata, a municipality in southern Greece, and examines the biocultural approach to municipal sustainable development policies since 2019.

Living in times of uncertainties and emergencies and in order to face challenges such as cultural diversity, climate change, environmental degradation, digital transformation, energy demands, migration, social exclusion, mortality and population ageing, pandemics, economic upheavals, growing inequalities, conflicts, etc., the local governments need to adopt innovative responses and new governance approaches as traditional practices fail to respond to the above issues.

To address these challenges effectively, we need a diversity of actors, resources and tools that can unleash our collective imagination and unite communities in common efforts to change the current status quo.

Culture and ecology have a powerful role to play in the regeneration of the potential of diverse communities and contexts and in their global interconnection for the benefit of all the people and of the planet also. To this end, cultural and environmental policies must be integrated into the concept of sustainability, both as an autonomous backbone of sustainability and as a contributor to its many dimensions.

To strengthen and substantiate our argument, the city of Kalamata is used as a case-study, where we conducted a qualitative survey using mixed methods to explore, among other issues, how residents and the municipality authorities perceive cultural heritage and to what extent it could be used as an asset for sustainability.

This paper presents the outcomes of ongoing field research, highlighting the necessity for multi-level governance with a bottom-up approach and synergies. The actors have confirmed that the biocultural approach to urban governance can address modern challenges. Vast majority of residents believe that utilizing cultural heritage is essential for local development. Renovations in the historical center of the city were perceived, by most of the residents, to have positive impact on cultural heritage as they consider that urban planning greatly improves social cohesion. However, the majority believe that social consultation was insufficient.

Data demonstrate that in Kalamata culture and creativity play the role of a visionary connector, as they help municipal authorities and residents to grasp the complex realities we live in and offer tools and spaces to participatorily design different, more sustainable ways of living together.

As a core outcome of the research is the imperative need to change governance values and culture to deal with current challenges and achieve SDGs.

Outreach activities in archaeological sites – Public Archaeology within the city

V. Kyriakopoulou

Extended abstract

In recent years there is a massive urge in public engagement programmes taking place internationally which combine various approaches from ‘bottom-up’ to ‘top-down’ and promote collaboration among community groups and heritage managers. In Greece, although there is a gap of communication between archaeologists and the wider public, there are certain activities run by museums, institutions or individuals and addressed to public and aiming at the protection, preservation and presentation of monuments and archaeological sites.

This paper deals with outreach activities taking place in archaeological sites within cities. The paper outlines main theoretical issues and definitions in Public Archaeology; it considers the current trends requiring commitment to sustainability, adopting inclusivity and ethics as the basis for a responsible practice; and it focuses on public engagement programmes that take place in Greece.

The paper presents programmes run by state and non-state institutions which are addressed to local communities, students or tourists and explore the value of these programmes in terms of the connection between people and cultural heritage.

The paper presents different case studies in order to show the similarities and differences of various agents, to approach the role of public archaeology and the potential of archaeological sites to raise awareness: Through archaeology, the public can learn what was successful and unsuccessful for people in the past who faced problems similar to those we face today. Besides, public may also learn about management and policies that could be sustainable or non-sustainable in time-periods of climate and sea-level change; or dynamics of population. Moreover, communicating archaeology with non-expert audiences can implant respect for cultural heritage, and connect descendant communities to their past.

However, academics have been trained to avoid storytelling due to the risk of inaccurate communication including insensitive portrayals and oversimplified issues. Parallel to this, outreach programmes are used to enhance the qualities of archaeological sites and their potential to translate complex ideas while retaining their richness. Thus, these programmes can maximize audience engagement.

Extended abstract

Social media exerts a profound influence on shaping the destination image of tourist attractions. China has developed an independent social media landscape, which has led to a noticeable void in understanding the experience of international visitors when they travel to China. Unlike prominent destinations like Beijing, Shanghai, and Xi'an, lesser-known cities face limited exposure beyond China's great firewall, hindering global access to information about these hidden gems. This research aims to unveil how international visitors and social media users perceive Chinese historic cities and explores the potential of international social media to promote the inbound tourism of less popular Chinese cities. Specifically, the study delves into user comments on YouTube videos about Suzhou Historic City in Jiangsu Province, renowned as the "Venice of the East" for its historic waterways, cultural heritage, and meticulous preservation efforts. The city is arguably one of China's most highly esteemed heritage destinations drawing a significant annual influx of domestic tourists. Despite this, concerted efforts to raise its international profile and boost inbound tourism revenue have proven relatively futile.

The research taps into the city's sizable expatriate population and looks at the marketing efforts of local Destination Management Organizations (DMOs) on YouTube. Employing a mixed-methodology approach, specifically text mining analysis and Partial Least Squares Structural Equation Modelling (PLS-SEM), the research assesses the relationship between the destination image crafted by local DMOs, visitor experiences and behaviours, and social media users' cognitive constructs of the city. Additionally, the study examines how visitors' feelings about Suzhou (affective responses) mediate positively or negatively in the three above-mentioned components. The findings of this research yield insights into the destination image of Suzhou as perceived by international visitors and social media, thereby providing a foundation for less popular Chinese cities to strategically leverage international social media platforms in promoting inbound tourism and enhancing the overall understanding of destination image dynamics.

Historical memory and colonial urban units of the period of Italian occupation in the Dodecanese (1912-1945)

S. Christofylakis

E-mail: stchristof@yahoo.com, Tel +30 6976810873

Abstract

The built environment as a palimpsest of historical memory enhances the possibility of multiple readings of the dynamics and goals; it was called to serve at the time of its creation, but it's also amenable to beautifying interpretations in terms of new dynamics and new goals that is subsequently called upon to serve. The historical path and identity of Italian expansionism is revealed, through both urban interventions architectural projects that imposed specific morphological characteristics which were enhancing the political image of the regime. The specific Architecture that dominated and was imposed during the Fascist version of the Kingdom of Italy and that obsessively claimed its ethno - racial dimension and supremacy, simultaneously includes the Fascist-Ethno-Racial and Colonialist dimension both during the pre-Fascist and Fascist versions of the Italian Monarchy. The modern type of development imposed by the colonial Italy on the islands (mainly in Rhodes, Kos and Leros) essentially involved a new kind of economic-production system in the colonies, a Euro-colonial type, "non-competitive with the metropolis" due to both "the torrential urban planning activity and the rapid processes of birth and change of the spatial forms imposed by the metropolis".[1]

Keywords: *Rhodes; Kos; Leros; Italian colonialism; Italian occupation in the Dodecanese.*

1. INTRODUCTION

The architectural production of the period of Italian occupation in the Dodecanese, with its extensive and intense presence in the tissues of the cities of Rhodes, Kos and Leros, was a specific morphological approach and process by the central and regional service structures of Italian colonialism. It was deliberately attempted to shape and impose on space all ideologies and social practice of the metropolis, through a specific synthesis, or mixture of colonial and fascist imposition. The cultural pressures being sometimes mild and sometimes extreme, the complete economic control, population changes by colonization, the attempts to adjust space to their interests and the fascist ideological orientation, were the dominant characteristics of the Italian occupation from 1912 to 1945.

The neoclassical morphological references of buildings inside (*Muslim School*) and outside the fortifications of the old town in the last period of the ottoman occupation in Rhodes.

2.THE ARCHAEOLOGICAL RESEARCH AS A PRETEXT OF ITALIAN EXPANSION TO THE EASTH

Images 5, 6, 7, 8 : The Archaeologists: Federico Halbher. Giuseppe Gerola. Alessandro Della Seta. Amedeo Maiuri.

The role of archaeology, in shaping the ideological background of Italian expansion in the Mediterranean through roman, medieval and fascist "modern" identity, was also decisive. The archaeologist Amedeo Maiuri, as reported by the Greek Consul in Bari, in a lecture organized by the fascist center of the city, in 1924, "characterized the monuments of Rhodes as beings of Italian style and art", concluding that "Rhodes ethnologically and religiously belongs to the Italian Nation, to whose possession it naturally returned due to its last occupation 11 years ago by the Italian army".[2] His predecessor in Rhodes, archaeologist Giuseppe Gerola, took a similar stance with Amedeo Maiuri, promoting the same ideological network to support the pro-fascist and fascist ideologies of Italian nationalism. Giuseppe Gerola supported and served the closed ties between archeology and colonial politics that were a serious means of promoting cultural expansionism. In 1930, in the obituary he wrote for his uncle and mentor Federico Halbher, he referred to the "...discreet activity of the late man who concealed a political and cultural penetration under the pretext of archaeological

research". The roman and medieval identity ("Romanita" - "Medievalismo") constituted a time-historical designation, as a presumption of historical "connection" and "continuity", while the new "Mediterranean" fascist identity should constitute a new recognizable geographic spatial designation. "Modernity" was a means of deconstructing local cultural-aesthetic references and a new reconstruction adapted to the particular context of fascist aesthetics and ideology. A new dynamic expression of a national character that would resonated the "totality, eternity and universality of the fascist revolution" as Bottai G. declared, in the review *Quadrante* in Dicembre 1933. [3]

3. PERCEPTION - REPRESENTATION - ORGANIZATION OF SPACE - MORPHOLOGICAL REFERENCES AND SEMIOLOGICAL AFFINITIES OF THE INTERVENTIONS

The creation of Italian Colonial Architecture in the area of the Dodecanese followed a path that is schematically delimited through the appointed governments of Mario Lago, 1923 – 1936 and Cesare Maria De Vecchi, 1936 – 1940. Mario Lago's period was the most important, because during the 14 years that it lasted, all the intervention programs were created and a large part of them were implemented. Governor Mario Lago worked closely first with the architect Florestano Di Fausto, and then with Pietro Lombardi. In the mid - 20s when the technical services were organized, but also in the 30s, new names such as Rodolfo Petracco, Armando Bernabiti and Mario Paolini emerged.

Images 16, 17, 18, 19, 20. The Architects: Florestano Di Fausto. Pietro Lombardi. Armando Bernabiti. Rodolfo Petracco. Mario Paolini.

This first period can be characterized as a fascist version of an Italian eclecticism, which drew the morphological elements of its buildings from the Knightly architecture (Gothic - idiom of Lindos), the Italian architecture of the mature renaissance and the Venetian architecture as an expression of an early "of Italian" orientalism.

The morphological redefinition and the morphological choices during the period of governor Mario Lago

Images 21, 22, 23, 24. Rhodes: During the government of Mario Lago with the addition of the portico and morphological redefining it was used as the Italian Club. 1925-1927, Architect Florestano Di Fausto. Palazzo di giustizia e tribunal (Courthouse), 1924, Palazzo lavori pubblici (Public Works Palace), 1928, Palazzetto San Giorgio - Ca' San Giorgio (Small Agios Georgios Palace), 1927, Architect Florestano Di Fausto.

Despite the morphological complexity of eclecticism, a recognizable vocabulary emerged, which was also the first colonial stigma of fascism in buildings and in the organization of space. In the last years of Mario Lago's rule, the fascist version of rationalist architecture was also used.

The morphological choices and references of buildings in Rhodes Kos and Lero during the period of governor Mario Lago

Images 25, 26, 27, 28, 29, 30, 31, 32. Rhodes: Casa del Fascio (Fascist club) and Casa del Ballila (Fascist youth club).“The trilogy of the period of Mario Lago”: Chiesa di San Giovanni, Cattedrale (Catholic Cathedral of St. John) - Arcivescovado (Catholic Archdiocese), 1925-1929 - Palazzo del governo (Government Palace), 1926 -27. Kos: Albergo Gelsomino (Jasmine Hotel), 1928-1929. Kos: Palazzo del Governo-Palazzo della Reggenza (Government-Palace of the Regency). The Albergo delle Rose (Hotel of the Roses). Leros-Portolago: Aeronautical base-barracks and the fascist youth club (Casa del Ballila).

The period of Cesare Maria De Vecchi's rule, despite its short duration, was very important for the final appearance of buildings through their morphological redefinition (mainly public buildings) in the city of Rhodes. The facades of the buildings in the city of Rhodes were covered with either a plaster of pseudo-stonework (*pietra finta*) or with slabs of processed poristone, to achieve a presence reminiscent of the buildings of the Chivalry period. A typical building is the "Union and Progress" club from the Turkish period in its three morphological versions. In 1939, the newspaper *Messenger of Rodi* (*Messaggero di Rodi*) highlighted the change in the appearance of the Court House after its morphological redefinition: "...and now it has become a new building, harmonious, characteristically rationalistic and modern of fascist architecture"[4] as well as the transformation of the Hotel of the Roses in its two versions. The milder theoretical approaches in Italy in 1933, although referring to the use of local elements of aesthetics and traditions, to constitute elements of harmony and balance, adopted the ideology and intention of "an Italian colonial vocabulary", through which "...This - the architecture - must be a clear and permanent sign of the dominant colonial race..."[5] while in 1936 they clearly stated that "... every nation that should export its own culture had better "colonize", and this cannot be done if it is not enforced with its own laws and its own buildings. Because since the dawn of time, culture and architecture have gone hand in hand" [6] "...The architecture of public buildings must command respect for the indigenous people. All constructions that are not private but public or religious of a colonial people in a land subject to its hegemony must express an idiom clear to both the subject peoples and the guests. There should be no doubt about the character of the culture and civilization of the nation that built those buildings. As we speak the Italian language in Rome, so we speak it in Tripoli and Benghazi, and so we must use Italian architecture"[7]. In the city of Rhodes, the Catholic church of Agios Ioannis (of the Knights), after its transfer and reconstruction on the coastal avenue, composed with the building of the Catholic archdiocese and the governor's office a single building complex (which formed the trilogy of the governor Mario Lago's period). It is perhaps the most typical example of colonial architecture of the 1920s. The sarcophagi of the great Masters were placed in the arcades, displaying the historical references of the Knighthood, while the governorate represented the political power and the Catholic church together with the Catholic archdiocese the religious one, concentrated in a focal point of the new city. The morphological references of the governorate in the Doge's Palace of Venice are clear, with embossed verbal quotations in the circular skylights and symbols related to the ideology and semiology of fascism.

The morphological redefinition of buildings during the period of governor De Vecchi

Images 36, 37, 38, 39. Rhodes: During De Vecchi's administration, the buildings accepted new forms redefinitions of mature fascist references, such as the Italian club building, renamed Circolo delle forze armate (Armed Forces Club) from 1938, the Albergo delle Rose (Hotel of the Roses) and the new Courthouse. The extension of the Courthouse was made by integrating the Palazzo dei lavori pubblici (Public Works Palace), and Small Agios Georgios Palace. The relief facade of the entrance to the Public Works Building it was replaced by three bas-relief fascist symbols and three bas-relief fascist symbols were added in height to the surface of the corner in the ex Small Palace of Agios Georgios in place of the bas-relief representation of the Saint.

It is interesting to emphasize the Western colonial attitude which faced the regional cultures in particular, within the context of an aestheticization which tends to conceal some of their sharp political and cultural particularities in terms of beautification. In this context, in the end, the form of things must be related to the projection of the orientalist elements that Western civilizations extract and re-introduce in their areas of control. In this sense, after all, these areas must adapt to the image of the orientalist interpreted past. Of course, this is not the only condition for the promotion of Italian cultural sovereignty in the Dodecanese. Italian Orientalism (as a Euro-colonial view and interpretation of the history and culture of the East) is then sidelined by a strong rationalism in its fascist version, with some wider individual modern influences as in the case of Leros. In his article, the architect Emidio Ciucci, in 1938, clearly captures the dominant positions regarding the architectural physiognomy of the empire:

"THE EMPIRE MUST HAVE A CHARACTERISTIC ARCHITECTURAL PHYSIOGNOMY. Rome at its height subjugated the peoples, imposed on them its own law, its own urban planning order, its own architecture [...] Where the Roman legions arrived, the markets, the temples, the amphitheatres, and all civil and military constructions wished to resemble those of Rome [...] Today

we are returning to a new era of apogee [...] Ancient ruins are not dead affairs, but trunks sprouting shoots [...] In recent years it has matured in Tripoli, Benghazi and elsewhere a Mediterranean character of our own which clearly dominates in that region and which is completely liberated from the Moorish elements and the spurious imitations of the early years [...] But avoiding the danger of spurious neo-romanticism we must let's also avoid that of leveling internationalism"[8].

Images 40. Newspaper Voce del Tana, July 8, 1938.

Here is clear the intention and effort of an architectural identity of a national character of Italian rationalism and its differentiation, from those characteristics, of the style and intentions of the historically recognized “international style”. The architecture of Italian rule, with its extensive and intense presence, leads to the finding that it was a specific expressive approach, which consciously attempted to shape and impose on the environment all the ideology and social practice of Italian colonialism, through a mixture of colonial and fascist enforcement.

4. CONCLUSION

The beginning of the Italian occupation in 1912 was the result of the expansionist rivalries of the great European powers in the region. In 1923 was the beginning of an overt alignment of the islands with their new metropolis, Italy. Mild or extreme cultural pressures, complete economic control and fascist ideological determination were the dominant features of the twenty years that followed. The 1930s was the decade of maturation, the imposition of fascism, the alteration of the population by colonization and the attempt to completely impose and appropriate the space through large-scale interventions in the built environment.

Government buildings were designed to meet the ritual needs of the cultural enforcement of the fascist version of the Italian monarchy

Images 41, 42, 43. Rhodes : The Government House in Rhodes in official receptions for the Italian Monarch in 1929. Quaternary Italo Balbo makes a speech on the platform out of the House of the Colonial Government during his visit to Rhodes next to De Vecchi and under the commanding presence Mussolini's portrait (Duce), 1936.

Images 44, 45, 46. Rhodes: parade of Italian army units on the beach boulevard in Madraki in 1937. Governor De Vecchi on horseback, in front of the armed forces club building, gives fascist salute. Religious event of the Catholic clergy for the Congresso Marian, September 1931. Event in the Piazza del Impero in front of the Palace of the Fascist Federation (Palazzo della federazione fascista) or Littorio Palace, in 1937.

Images 47, 48. Rhodes: Inside the Palace of the Grand Master, "The bread room" by the painter Gaudenzi Pietro. Embedded fascist symbols in the old city of the knights.

The year 1940 marked the beginning of the end of Italian expansionism in the Balkans. After a brief peak of occupying most of mainland Greece, most of the Aegean islands and the Ionian islands, in 1943 the Kingdom of Italy renounced its fascist version resulting in the dismantling of its military machine which, no longer able to dominate in the region, he left control to the Germans and the fascist Italians (R.S.I.-Rerubblica Sociale Italiana) until 1945, weakening any element of colonial cohesion. The so-called stone policy was implemented as a means of quickly appropriating historic buildings or totals of the city and the modernization as an enforcement tool.

The end of italian colonialism - the damages of war

Images 49, 50, 51. Rhodes – Leros – Kastellorizo

The built environment, regardless of its original purposes, can be maintained by redefining, however, preserving its historical memory. The buildings of this period, as a means of imposing colonial spirit and appropriating space, completed their cycle with the end of colonialism. As symbols of liberation and vindication, they were reuse, now serving the new non-colonial organization and structure of society. The buildings as units or as urban units with the authoritarianism of their structure, form and style constitute entities with memories of imposition of a colonial authority with and fascist character, and despite all their subsequent "political exoneration" by demolition or the removal of initial structural elements which declared the underlying political aims of their integration. Today the buildings are called to be the monuments of the collective historical memory of the colonial imposition and not to negotiate their preservation within the framework of a neutral historical landscaping. They can be the museum spaces that will host historical archives, exhibits from the Second World War, from the resistance against colonialism and even all those archaeological findings that concern our history and which remain hostage in Italy until today.

Extended Abstract

This paper expands on my previous Changing-Cities conference explorations of *urban scalability* while interfacing here with early notions of *Artificial Intelligence* affecting architectural form and space-making. Spanning from labyrinthine microscales of pre-existing urban fabrics to novel regeneration agendas with a focus on collective memory and politicized histories, a case study charrette project that contextualizes contemporary cultural programming is studied in response to a series of theoretical concepts.

The Gwangju (City of Light) Asia Culture Center (ACC) is situated in the environs of the South Korean Democratic Movement uprisings (May 18th 1980), locus of intense memory at a collective scale, and was the outset of a UIA-approved open international competition almost two decades ago, in 2005. At once a Memorial and Citizen's (public) Park, the ACC was tentatively envisioned as an uninterrupted outpouring of civic energy into a historic site of significance. Our submitted project announces, two decades before it became mainstream, an uncanny world of obsessive interfacing with Artificial Intelligence; a novel – even now – reality of tremendous prominence, dissolving barriers between *fictional* and *natural*, or phenomenal.

The urban scheme realizes *virtuality*, pragmatically. Through *photonics*, an allegedly utopian world of illusions comes alive; bonds between reality and chimera become tighter for the emergent era of *meta-virtuality*. Design agendas, as outlined, hover between the antiphrasis of *intangible actualities* – the presence of absence – as to explore *persistent dualities* – diptychs.

Exploring here a scalar territory beyond bigness, the text undoes the common problematic of architecture that simply evaporates under the pressure of immense service requirements, fire regulations, mechanical plants and *procedural* space – transitory areas. Typological questions are addressed by studying an Anti-Pompidou notion for 'shelled' elevated massing as smooth topography, rather than impenetrable objects.

Keywords: *scalability, urban memory, memorial, concourse, contextualization, landmarking, photonics.*

Protecting Built Heritage from Changing Waterscapes: Lessons from Cyprus

Abstract

At the easternmost corner of the Mediterranean Sea, Cyprus has numerous heritage sites currently threatened by the effects of climate change especially as it relates to changing water levels and other changes in waterscapes. This paper highlights the urgency of safeguarding built heritage sites from the changing waterscapes within and around the island of Cyprus, aiming to draw larger lessons regarding the protection of cultural heritage in the Mediterranean from sea level rise (SLR) and flooding. Drawing on archival and field research, the authors crafted a map that shows the proximity of heritage sites to threatening bodies of water in Cyprus. The paper focuses on two paradigmatic heritage sites on that map, which exemplify diverse challenges caused by SLR and flooding events intending to explore adaptive interventions for future water threats. The first site is the Grecian Hotel, a decaying structure in the coastal area of Varosha, that has remained abandoned for half a century due to the political conflict in Cyprus. The second site is the ruined Saint Nicholas Church situated inland, on the banks of a major water infrastructure, the Kouris Dam. Each heritage site is tied to unique aspects of the island's recent history. They are also intertwined with the environmental realities of the changing waterscapes (the Mediterranean Sea on the one hand, and a Water Reservoir on the other). To protect these sites from water-related threats, the paper draws on Charlotte Lake's proposal for 'environmental' and 'monitoring' buffer zones. It interprets these zones spatially and uses architectural design insights to outline strategies for physical interventions. These interventions aim to protect the sites from water threats while enhancing the spatial experience of both the built structure and the surrounding water. Our conceptual proposal for the creation of physical buffer zones is a versatile solution against flooding and SLR. It can be adapted to other similar contexts and serve as a design framework to guide stakeholders and heritage managers.

Keywords: *flooding and sea level rise, Cyprus built heritage, environmental and monitoring buffer zones, protective buffer zones, changing waterscapes*

1. INTRODUCTION

Our investigation focuses on the threats to heritage sites posed by water, specifically sea level rise (SLR) and flooding. We refer to water-adjacent sites as heritage sites that border significant bodies of water, including seas, rivers, reservoirs, lakes, and similar aquatic features. These water-related threats are particularly pressing in the case of islands and coastal regions where the effects of climate change are already quite evident. An analysis of the latest forecasts provided by the Intergovernmental Panel on Climate Change (IPCC) on SLR within the Mediterranean Basin, as presented in the Sixth Assessment Report (AR6), indicates a projected rise ranging between 0.52 meters and 1.22 meters by the end of the century in the region [1]. In their research in 2024, Vecchio et al. developed models that indicate that approximately 19,000 km² of the Mediterranean shorelines face an increased risk of inundation [2]. Furthermore, a 2018 study by Reimann et al. found that 37 of the 49 UNESCO World Heritage Sites (WHS) in low-lying Mediterranean coastal areas are at risk of 100-year flooding, and 42 are threatened by coastal erosion [3]. The study includes a map of WHS within the Mediterranean Low Elevation Coastal Zone (LECZ), showing extreme sea levels for each coastal segment under a

high-end sea-level rise scenario for 2100. These findings highlight areas in the Mediterranean where urgent adaptation is needed to protect WHS. In addition to this critical scenario for the Mediterranean, recent research provides natural disaster forecasting, risk assessments, site digitization, and interactive climate scenario maps to protect built heritage sites. New digital tools and models, combined with innovative adaptation and conservation practices, can address the effects of the climate crisis on waterscapes.

To better understand present and future challenges, we examine two heritage sites on the island of Cyprus: The Grecian Hotel in the coastal area of Varosha and Saint Nicholas Church, which stands on the banks of a human-made reservoir at Kouris Dam. These sites were selected because they encapsulate the complex and rapidly increasing challenges posed to heritage by their setting. To suggest spatial interventions aimed at safeguarding the Grecian Hotel against SLR and at protecting the church of Saint Nicholas from periodic submersion, we turn to a particularly helpful scholarly work: Charlotte Lake's exploration of UNESCO's buffer zones [4, 5], specifically her proposal for 'Environmental buffer zones' and 'Monitoring buffer zones', which directly addresses the risks posed by environmental pressures to heritage sites. We explore Lake's reinterpretation of the buffer zone concept for WHS in the context of climate change to guide the development of protective buffer zones for sites beyond World Heritage status. Finally, we assess this idea in the sites from Cyprus and demonstrate the use of protective buffer zones as a strategic spatial intervention for water threats.

2. CONNECTING CHANGING WATERS, BUILT HERITAGE, AND THE RECENT HISTORY OF CYPRUS

At the easternmost corner of the Mediterranean Sea, and dense with antiquities that reach back to the Neolithic era, the island of Cyprus is replete with coastal, inland, and mountainous archaeological sites, including UNESCO WHS as well as several traditional villages and significant examples of modern heritage. To assist our research, we created a map showing the location of heritage sites, bodies of water (e.g. sea, lakes, rivers, dams), and areas susceptible to flooding near rivers (Figure 1). This map provides a comprehensive view of the cultural heritage sites in Cyprus and their proximity to water features. This map serves as an important illustration of the multitude of coastal heritage sites at risk from SLR and flooding across the island. From this collection of sites, we selected two with particularly intricate relationships with water for further exploration: the Grecian Hotel and Saint Nicholas Church.

These sites relate to two major aspects of the island's recent history that have created exceptional, circumstances. The first is the recent political history of the island, which explains the abandonment and ruination of the Grecian Hotel (Figure 2); the second is the history of the rapid development of infrastructure, including dams, which provides the context for the Saint Nicholas Church (Figure 3-4). We explain each of these two recent historical circumstances, which contributed to accelerated physical decay in our paradigmatic examples. Let us begin with the political context, as it particularly affects the present and future of the Grecian Hotel.

Cyprus entered modernity as a British colony, and after it gained its independence in 1960, it channelled much of its efforts for socioeconomic modernization and nation-building toward tourism development. The beach of Varosha, on the southeastern coast of the island, was the fastest-growing tourist attraction; in a short decade, it transformed into such an international hub of tourism that it was even celebrated by the *Chicago Tribune* as a ‘mini-Miami’ [6]. All this changed dramatically in 1974 when a long-standing inter-communal conflict between Greek and Turkish Cypriots escalated to the point of a coup d’état by Greece and an invasion by Turkey, resulting in the division of the island along ethnic lines. This division, which lasts to this day, caused the forced movement of population, and long negotiations, under the auspices of the UN, which aim to resolve what has been called the ‘Cyprus Problem.’ The coastal strip of Varosha is a special part of this problem at the peace negotiations as it was fenced off and remained off-limits for almost half a century. This sublime urban ruin of luxurious hotels on the waterfront has become one of the most important modern heritage landscapes of the island [7]. This situation recently began to change with the unilateral appropriation of parts of Varosha by the Turkish Cypriot administration, which aspires to revive it as a tourist attraction. Regardless of the directions these new developments take, the modern heritage of Varosha is under threat [8], and its long abandonment has accelerated the decay of coastal buildings that can be instructive for this study.

2.1 Heritage by the water: The Grecian Hotel

The Grecian Hotel (35.098614°N; 33.967281°E) stands on the coastline as one of the most emblematic examples of the golden era of Varosha (Figure 2). Built in 1963 by the most renowned Greek Cypriot architect of the time, Neoptolemos Michaelides (1920–1993), it is among the most significant examples of Cyprus’s modern heritage [9]. Each component of the hotel was characterized by elegant concrete elements, formal simplicity, and the expressiveness of its structural elements. The nine-story reinforced concrete frame structure was strategically oriented perpendicular to the waterfront to ensure that every room offered majestic sea views that were complemented by private patios. The hotel was accessible from the west via a small vehicular road that led toward a glazed entrance beneath a slender canopy lettered with the hotel’s name. After entering the hotel, visitors

found a spacious reception hall, two lifts, a bar, lounge areas, dining rooms, and covered patios. An alternative route to the hotel was through the lower level, from the seaside where guests could access the area with 'pilotis' situated beneath the ground floor.

The composition of the overall volume can be divided into distinct architectural forms that were masterfully combined to create the hotel's complex. A substantial base supported by concrete columns anchors the base of the hotel to the landscape. Elevated a few steps above the sand, the base blended with the natural environment. Beneath the base were changing rooms and covered patios for bathers that opened towards the sea [10]. The tall six-story volume contained the rooms; from the first to the fifth floor, each level featured fifteen double rooms [11]. The crowning feature on the upper floor was a rooftop bar partially covered by a small canopy and pergolas. On the hotel's north side, a curved roof introduced a synthetic contrast to the rectangular lines of the hotel, highlighting the plasticity of the concrete and the modern construction techniques used on the island. This feature rested on concrete frames set in a grid and extended via a pergola to protect a vaulted lounge area with a veranda on the elevated ground floor. On the west side stood the main entrance to the hotel, featuring an impressive 'butterfly roof' (inverted pitch roof) in the form of a sculpted concrete canopy. Circular columns provided support for this canopy, leading visitors to the entrance through a glazed screen. The hotel incorporated a variety of shading elements, including overhanging slabs, pergolas, and canopies, all masterfully integrated into the design to prevent harsh sunlight from entering through the glazed surfaces. The metal frames of the glazing and balcony railings provide an additional layer of minimalist detailing that extends across all facades.

Today, the Grecian Hotel is a unique example of a built landscape that, due to its fifty-year abandonment and proximity to seawater, has experienced accelerated decay. A future examination of this degeneration will precisely offer insights into the pathology of concrete structure degradation in coastal environments at other sites, but this is outside the context of this study. What we focus on is the risk from SLR. 'Climate Central' has developed sea risk maps based on global warming scenarios, highlighting future coastal regions susceptible to SLR [12]. Notably, these maps show that the beachfront area around the Grecian Hotel is projected to be below the tideline, indicating significant changes in the dynamics between the site, the beach, and the sea. This proved the need for strategic adaptations to mitigate the effects of SLR, a topic that will be discussed further below after we present the other example.

2.2. Heritage in the Water: Saint Nicholas Church

While the above example of the Grecian Hotel exemplifies a case of heritage located near water, our second example demonstrates the case of built heritage already immersed in water, namely the dam's water. To understand the context of Saint Nicholas Church, let us zoom out once more to the larger processes of Cypriot modernity. In addition to the tourism development described earlier, Cyprus also advanced the creation of water infrastructure, including dams, which was deemed particularly important for the drought-stricken island to advance its tourism and agriculture. After the island's independence and up until the early 1990s, the United Nations funded a series of dam projects and other water infrastructure, with technical assistance from various countries. The most ambitious was the 'Southern Conveyor' project, completed in the early 2000s [13, 14]. One of the darker sides of this development project was the flooding of an entire village that involved forced relocations and the intentional destruction of cultural heritage. The example of Saint Nicholas Church is one of many monuments worldwide that were destroyed due to modernization and techno-politics.

Saint Nicholas Church (34.756725°N; 32.921105°E) was built in 1936 in the village of Alassa, in the southwestern part of the Limassol district. Constructed on the southeast side of the village, the small church offered more than a sacred space for the Christian Orthodox community of Alassa; like most village churches, it also constituted an emblematic reference to the overall spatial and social fabric. The plain design was characteristic of the building traditions of early ancient Byzantine churches in

Proceedings

ISSN: 2654-0460
ISBN: 978-618-5765-02-6

Cyprus, which are still found in rural areas and villages. The single-story basilica had a semicircular apse at the east end; a slender belfry with a cross on the top stood at the building's southeast corner. The floor plan emphasized the longitudinal axis, creating a clear, orthogonal shape extending from the entrance through the nave. The church was built with a locally sourced stone, with dry-stone walls and white plaster rendering, and topped by a pitched wooden roof with ceramic tiles. Carved stone frames, finished with light blue colour, embellished the openings, and created arches above the doors and windows, while decorative iron bars with small ornaments enclosed the glazed windows. An irregularly shaped perimeter wall, 1–2 meters tall and aligned with the old dirt road leading to the site, enclosed a small yard.

The church's role as a locus of Alassa ended in 1984 when the construction of Kouris Dam, the largest dam in the country, caused the gradual displacement of the community to a nearby hill, at a higher altitude. Over a decade, from 1985 to 1995, the villagers were forced to relocate, and the original village, including all built structures, was demolished except Saint Nicholas Church, which was left within the bounds of the new dam [15]. The church still stands within the dam's impoundment, and the fluctuating levels of water over time have caused its partial and periodic submersion. The varying water levels at times submerge the church, leaving only the bell tower to rise above the water (Figure 4). The submersion of the church has profoundly changed the site's setting and largely destroyed the building's structure (Figure 3).

Saint Nicholas Church forms an ideal site to study the effects of water, flooding, and the periodic submersion of heritage sites, offering insights into the interaction between building materials and the freshwater reservoir of the dam. The structure's response to the destructive forces of water unfolds along three key dimensions: the structural damage caused by water pressure; the progressive decay and corrosion of materials immersed in water; and the fluctuations of water levels that continually affect the saturation levels of the structure. These categories can effectively serve as a framework for examining other partially submerged heritage sites, in coastal areas, along riverbanks, or near inland seas. Therefore, the church serves as an informative model for identifying the effects of flooding, whether it is anticipated, as in the case of the construction of the Kouris Dam, or unanticipated, as with extreme weather events prompted by climate change. The site provides valuable insights into future flooding or periodically submerged sites.

3. 'ENVIRONMENTAL' AND 'MONITORING' BUFFER ZONES

To develop adaptation strategies for protecting the Grecian Hotel and Saint Nicholas Church we draw inspiration from Charlotte Lake's proposal for 'environmental' and 'monitoring' buffer zones, to then interpret them through architectural and spatial insights. Charlotte Lake's article in 2016 on 'buffer zone typology' based on contextual factors for World Heritage Sites (WHS) serves as a crucial reference for our exploration of adaptation strategies [16]. She illustrates the UNESCO buffer zone concept as one tool for protecting heritage sites through their settings while stating that multiple or tiered buffer zones found in some cases may offer better protection. Lake's study categorizes buffer zones into various typologies to address specific threats and contextual factors, including visual, environmental, human activity, affiliated elements, opportunity, administrative, and monitoring buffer zones. These typologies aim to address specific external threats posed to each site by the setting itself.

We particularly focus on what she outlines as an environmental buffer zone that addresses the physical and geological characteristics of a site's environment. Such buffer zones are intended to protect against natural disasters, to regulate natural resources, and to preserve flora and fauna that may affect the registered site. What Lake defines as monitoring zones, serve as areas to monitor, and record potential threats to cultural heritage sites [17]. Both categories (environmental and monitoring buffer zones) offer an opportunity to contextualize her proposal within the framework of climate change.

Proceedings

We propose that a combination of Lake's environmental buffer zones and monitoring zones, can establish a novel framework for actively designing buffer zones that effectively protect cultural heritage sites from current environmental threats. Monitoring zones on the one hand could provide data recording programs and early warning systems to identify changes in the environment that may threaten the values of a site and simultaneously protect the site from various environmental threats. Environmental buffer zones, on the other hand, could be expanded to include spatial/physical interventions meant to adapt to changing conditions to protect a site. While Lake's concept of environmental buffer zones addressed a broad range of natural disasters, we find her analysis particularly insightful for examining water threats like the rising issue of SLR on built heritage sites.

4. PROTECTIVE BUFFER ZONES THROUGH SPATIAL INTERVENTIONS

The interaction of the Grecian Hotel with water is quite different from that of Saint Nicholas Church. The periodic fluctuation of the water level within the dam sometimes leaves the church partly or fully immersed in water; conversely, the hotel merely has a proximity to water, and this proximity is gradually decreasing. The intriguing fact that connects the two cases is that, in the face of climate change, each of the two sites can shift to experiencing the situation of the other. In other words, the Grecian Hotel may experience partial immersion in water in the future due to SLR, while Saint Nicholas Church might end up on dry land, and no longer suffer from flooding, due to drought. This possible reversal reminds us to be attentive to the dynamic relationship between built heritage and water. It also suggests that both sites could benefit from a spatial intervention that protects them from the threat of water damage in the present and proves adaptable enough to offer protection in a future that promises even more environmental changes.

When addressing the contextual challenges of a site, the aim is to minimize the effect on the overall aesthetics and spatial configuration. Certainly, the very creation of physical buffer zones can alter a site's visual character, and for this reason, it is imperative that the design and construction of buffer zones be viewed as a necessary adaptation to meet new needs while prioritizing solutions that respect the site and ideally offer reversible options.

To demonstrate our proposal for physical buffer zone, we describe two conceptual proposals for protecting the Grecian Hotel from predicted SLR and the Saint Nicholas Church from water-level fluctuations and flooding. The protective buffer zones described below are at this point a design framework to guide stakeholders and heritage managers; they are not to be seen as literal design solutions, as those would need to be reformed and adapted for each site and context. The proposed design framework outlines key principles such as adaptive design, sustainable materials, monitoring methods, and continuous reassessment, all of which serve as fundamental elements in creating protective zones regardless of the site.

The gradual rise of water in the case of the Grecian Hotel, first necessitates initiative-taking measures to prevent water from overflowing the hotel's structure and expedite its deterioration. One could imagine a new adaptable pier with seawalls that prevent seawater from entering (Figure 5). Functioning as a 'breakwater' these protective seawalls would serve as a physical barrier against SLR, and they would be placed a few meters away from the main hotel structure. They will gradually be integrated into the sandy beach towards the hotel's entrance. The seawalls would stand higher than the projected SLR for this area. An integrated overflow mechanism would direct excess water into a moat for storage and other applications. This would create a controlled, water-filled moat, maintaining the connection of the hotel with the sandy beach and the sea while alleviating the danger of flooding. In terms of seawall construction, the Climate Technology Centre & Network can provide valuable insights that can be useful for such projects [18]. In terms of the experience of users, the encircling rectangular pier could offer a corridor for guests to explore the hotel from sea level, allowing for a comprehensive tour that highlights the hotel's connection to the water—and would also

demonstrate the protective measures that have been taken to address the effects of climate change on site.

This adaptable pier would provide an adaptable boundary that would serve as an environmental buffer zone for water corresponding to the constantly changing needs of the seawater levels while offering unobstructed views and access to the hotel and the beachfront. This should be a minimal structure that aligns with the perpendicular lines of the hotel, constructed with resilient materials and contemporary building techniques, capable of enduring water pressure and aligns with sustainable design principles. Additionally, we propose the implementation of a monitoring buffer zone that collects data and analyses them to notify stakeholders and site managers of potential threats and extreme weather events. This can be achieved through the installation of a sequence of sensors strategically placed on the base columns of the hotel and on both sides of the surrounding seawall to monitor fluctuations in temperature, humidity, and water levels.

The above proposal is a starting point and requires further interdisciplinary development, including a conservation and restoration strategy for the concrete structure, which falls outside the scope of this research. Such further research would not be possible without an in-situ investigation and documentation of the current state of decay, and at this point, this is not impossible for the Grecian Hotel due to the ongoing political conflict. Furthermore, it should be noted that any measures to protect the Grecian cannot be adequate if they are pursued in isolation, and they must be accompanied by a comprehensive strategy towards the larger urbanized coast of Varosha, where the Grecian sits. Nonetheless, at this point, the above proposal for a buffer zone can be a springboard for managing the modern cultural heritage on the coasts of Cyprus, or even beyond.

A similar concept can be applied to Saint Nicholas Church, because here too, the establishment of an environmental and monitoring buffer zone would provide crucial protection for the ruined structure. In this case, the protective buffer zone would again take the form of a physical boundary with walls constructed to prevent water from flooding the church. The space between the church and the barrier would become a 'dry zone,' further enhancing its protection. The new structure should again be minimal, to avoid overshadowing the church itself. A circular design for the boundary not only offers a protective embrace to the church but also allows for an uninterrupted tour around it, enhancing the visitor experience (Figure 6). This structure must be created with state-of-the-art, sustainable materials resistant to water, capable of withstanding water pressure and adjustable to changing water levels. Such a structure would prevent fluctuations in saturation levels that endanger the stone and other materials of the church. A new drainage system suitable for flood management should be installed in the dry zone, in case of overflows within the reservoir. Lastly, the new boundary could be used as a platform for visitors to observe the monument within the water of the dam. This solution seeks to combine the spatial experience of the water around the church while preserving the site and materials from it, as we saw at the site in Varosha. Also, as described in the proposal for the Grecian Hotel, a monitoring station could be placed within the circle's perimeter to record the water levels and to identify potential environmental threats to the site. This monitoring process could provide valuable insights into the adaptive transformation of the structure and protection of the church.

Figure 5. The Grecian Hotel after its completion in 1964 (a); conceptual proposal (b). Images created by Anastasia Psoma.

Proceedings

Figure 6. Saint Nicholas Church and the village of Alassa prior to dam construction, 1963 (c); the church submerged as a result of high-water levels in 2019 (d); the church at a point of low-water levels in 2014 (e); conceptual proposal (f). Images created by Anastasia Psoma. [The information presented is sourced from aerial photos from the Department of Lands and Surveys, Cyprus]

Because of its geographic location, the examination and documentation of the church is a somewhat easier operation than in Varosha; in times of drought or low water levels within the reservoir, when the church can be accessed, researchers and practitioners could document the site, conserve the structure, and implement a physical buffer zone for the protection of the site. As mentioned above, the accelerated decay of the structure calls for future multidisciplinary research, focusing on the structure's pathology and degradation that moves beyond the frame of this article.

The above experimental proposals for physical buffer zones are at this point conceptual and can be generalized to other cases, where the details of the design, materiality, and geometry of each intervention can vary. Multiple other heritage sites found in Cyprus are in danger from SLR and flooding—coastal sites as well as sites near riverbanks, dams, and lakes across the island can benefit from this strategy. Heritage sites of the island that will be affected by SLR can be spotted using the online tool from the 'Climate Central' Program on Sea Level Rise based on their elevation and proximity to the sea. Additionally, areas and specific heritage sites of the island that are likely to be affected by flooding can be observed from the WDD (Water Development Department) [19] 'INTERACTIVE Flood Risk Maps.' These maps offer scenarios for the near future and project outcomes for the year 2080, considering the impacts of climate change and flooding episodes.

For example, the Medieval Larnaca Castle, a historical testament to Cyprus's fortifications and coastal defence, faces an environmental threat from climate change. Due to its proximity to the sea, it is vulnerable to SLR and saltwater exposure, necessitating careful preservation efforts to protect it. Furthermore, Cyprus is home to numerous ancient maritime sites like the ancient harbour of Amathous and shipwrecks, which face various challenges from climate change. These submerged sites are threatened by SLR, coastal erosion, increased acidity, salinity, and warming of the waters, all of which can accelerate material erosion and cause further destruction [20]. Other examples from Cyprus and the Mediterranean basin could benefit from the implementation of such interventions.

5. CONCLUSION

The lessons drawn from the Grecian Hotel and the Church of Saint Nicholas can guide the strategic design of buffer zones that protect from water threats while preserving the spatial experience and heritage value of buildings [21]. Building on this initial framework, further research is crucial to refine the strategy for water-related threats like flooding and SLR. Additionally, exploring its effectiveness against other environmental threats not covered in this study is paramount. The proposed integrated 'environmental and monitoring' buffer zones can emerge as a promising tool for integrating climate adaptation strategies into heritage management practices, ensuring the resilience of built heritage. Additionally, tools, methods, and strategies that international experts and relevant international organizations have developed could be integrated into a larger framework for the protection of the cultural heritage of the island and other coastal sites. The examples from Cyprus resonate with other sites on the island and elsewhere that are facing similar threats. Our focus on water is not by any means assuming that climate change is the sole threat to heritage sites, but rather, we present this climate emergency to emphasise the multiplicity of dangers that heritage professionals need to account for in the protection of built heritage. As we confront the challenges of climate change, a multidimensional perspective that incorporates spatial interventions and adaptive strategies can pave the way for a more sustainable and resilient future for our built heritage.

Acknowledgments

We extend our sincere thanks and gratitude to the Sylvia Ioannou Charitable Foundation for the scholarship awarded to Anastasia Psoma under its 10th Scholarship Programme (2022–2023). This scholarship supported her master's thesis which inspired this article.

Extended abstract

This article aims to systematically map and analyse the intertwined pressures affecting heritage sites in the coastal area of Varosha in Cyprus. This area contains rich heritage from various historical periods of Cyprus, including the modern era; for half a century now stands as a ruinous urban waterfront. Varosha's beach quickly became a bustling tourist spot during the 1960s-1970s, earning praise as a 'mini-Miami' by the Chicago Tribune. In 1974, a longstanding conflict between Greek and Turkish Cypriots led to a coup d'état by Greece and an invasion by Turkey, dividing the island along ethnic lines and prompting population displacement and ongoing UN-mediated negotiations. Varosha's coastal strip, emblematic of this conflict, remained fenced off and inaccessible. Over the last 5 years, recent efforts to reclaim parts of Varosha, notably the Turkish president's announcement of the partial opening of the area, have triggered international reactions and raised concerns among local communities. According to press reports from Turkish and Turkish Cypriot sources, nearly 400,000 visitors, have visited Varosha since 2020, when a section of the area was opened, establishing it as an 'alternative tourism destination'. Concurrently, ongoing efforts to document and classify properties have been undertaken in collaboration with the T/C Chamber of Architects and Engineers. Numerous groups and individuals have researched potential strategies for Varosha's waterfront. Suggestions vary from developing it for tourism, to transforming it into a museum. Rather than presenting a competing proposal, this paper advocates for mapping all the pressures at play. This approach aims to enable the formulation of more informed proposals in the future. We present the following themes for a research agenda to uncover the multitude of ongoing pressures shaping the uncertain future of this modern urban coastal landscape:

- Geo-political local and international pressures and recent debates regarding the area's future.
- Environmental factors, specifically water-related pressures, such as the imminent threat of sea-level rise endangering Varosha's coastline.
- The detrimental effects of the harsh coastal environment on concrete structures, are exacerbated by 50 years of neglect and the absence of legal protection.
- Socio-economic and development pressures from the Turkish administration, aiming to 'revive' Varosha as a tourism hub, amidst the rapid tourism growth in other cities of the island.
- Sustainability concerns related to potential redevelopment and demolition, conservation challenges, and opportunities for adaptive reuse.
- Ownership issues and conflicting agendas among stakeholders.
- Conflicting memories and aspirations for the area from the Greek Cypriot and Turkish Cypriot communities.

This article highlights how the array of pressures on Varosha provides an opportunity for a comprehensive reassessment of the intricate dynamics shaping this urban landscape, signalling the importance of further research with potential implications for future decisions concerning the site.

The search for identity - Transformation of Novi Pazar's historic city centre

Š. Župljanin

University of Belgrade – Faculty of Architecture, Serbia

Corresponding author: E-mail: zupljaninsejla@gmail.com; Tel +381 628555125

Extended abstract

The connection between culture and identity is based on a spatial level, not only on social relations. The concept of urban identity reflects people's perception of being uniquely connected to a particular place. Over time, the physical environment will change the social life and thinking of the city. Therefore, the concept of urban identity is such that the process of change affects it. Urban heritage defines the identity of cities that develop over time, including the symbolic meaning of people, whether citizens or visitors, due to historical events related to it. Because of this, urban heritage is considered to be of great importance because it signifies the identity of the city. Nowadays, we frequently confront the issue of cities undergoing a transformation that leads to the loss of their original identity. As cities undergo constant change and redevelopment, they risk becoming less recognizable, posing challenges for residents in terms of perception and memory. That is why it is more difficult to preserve historical and cultural heritage, local originality and identity in that city. In the context of Novi Pazar, *Stara Čaršija* represents a historical-cultural complex that is struggling to maintain its identity. The history of Novi Pazar showcases the complex interactions of different cultures, religions and political forces over the centuries. Its specific and unique character represents an amalgamation of these influences, creating a city with a rich and diverse heritage. The historical core of the city, functioning as its bustling business and commercial center, along with the Fortress of Novi Pazar, which was once a vital part of the market, represents one of Serbia's most well-preserved urban heritage complexes of its type, and has been recognized as a spatial cultural-historical entity of great importance within the Republic of Serbia. *Stara čaršija* is deeply connected with the identity of Novi Pazar. It defined Novi Pazar as a trading town, and shaped its urban development to a great extent. Its specific architecture is what makes it an exceptional cultural heritage and ambient entity. The theoretical framework of the research in this paper is the urban development and transformation of Novi Pazar, with the main focus on the period from the 20th century to the present day. The focus of the study is on examining the urban, cultural and historical factors that defined the identity of the *Stara čaršija* complex throughout history, as well as on determining the factors that are causing its gradual collapse.

Abstract

The research proposes an integrated cultural approach between urban design and the enjoyment of heritage assets, with the aim of rededicating archaeological areas to contemporary city life through the use of digital technologies. The community, due to the principle of economic circularity, will benefit from the enhancement of public spaces resulting from innovative methods of land use that encourage cultural tourism and the promotion of activities. Therefore, the aim is to involve citizens during all phases of the project with different approaches: qualitative research, surveys, interviews and living labs. The research takes full advantage of the potential of digital technologies to reach a wide audience in the process of re-appropriating the places of the contemporary city.

Keywords: *archeology; participatory mapping; phygital reality; digital technologies; digital twin; altera Roma, public spaces*

1. ARCHAEOLOGICAL HERITAGE AND URBAN DEVELOPMENT IN SANTA MARIA C.V.

Santa Maria Capua Vetere, a city of approximately 33,000 inhabitants located in the district of Caserta, nearby Naples in the South of Italy, represents a peculiar case of planning for medium-size cities, embedded between urban development, the rural component, and cultural assets. The city of Santa Maria C.V. has a dual cultural identity linked both to the evident built heritage and to the archaeological substratum of ancient matrix, currently mostly not visible [1].

The municipal plans of the city in the past century focused to providing for an ordinal design of local interests of an incremental type, parameterized to the economy of their territories and aimed simply at the development of building areas. Thus, no account has been taken at all the landscape and historical-cultural values present within the territory as potential incubators of local development, but instead reference has been made solely to land rent, reducing urban planning to an exclusive determinant of land use for building purposes [2].

A lot of urban experiments developed over the past two centuries have often create a threat to the historic character of cities and the sets of material and spiritual elements that are an expression of their image. This threat, which we find mentioned within the 1987 Washington Charter, has had its field of implementation in the last sixty years on the territory of the city of Santa Maria C.V.

The International Charter for the Preservation of Historic Cities (Washington, 1987) is a document drafted by the International Council on Monuments and Sites (ICOMOS) with the aim of complementing the "International Charter on the Conservation and Restoration of Monuments and Sites" (Venice, 1964), defining the principles and objectives, methods and tools to safeguard the quality of historic cities, to promote the harmony of individual and social life and to perpetuate the set of even modest assets that constitute the memory of humanity [3].

Regarding to Santa Maria C.V., the physical transformation guided by the city's previous urban plans, was mainly explicated through private interventions based on the renovation of existing buildings, implemented through demolition and reconstruction in compliance with the indices and parameters

Proceedings

of the relevant implementation rules. It is amply demonstrable the high negative incidence of this kind of intervention in historical cities [4].

The observation of the changed relationships between existing heritage and new recent construction (figure 1), for example, is an emblematic expression of the loss of quality and historical identity of the historical centre, based predominantly on the continuous spread of typological features consolidated over time that are expressed predominantly through a set of building units articulated around a common open space and connoted by the sequence of doorway, hallway, staircase and courtyard.

Figure 1. The historical centre of Santa Maria C.V. showing the dense urbanization that cancelled the archaeological identity of the city.

The city of Santa Maria C.V. possesses not only its own cultural identity related to the evident built heritage but also an archaeological identity referring to the submerged latent heritage of ancient Capua. The northeastern part of the current administrative boundary of the city under consideration largely includes the territories of ancient Capua that lies submerged and were represented in many pictures and paintings since the 16th century [5] [6].

From the ruins of the Roman and Longobard city that survived the Saracen fury unleashed in 841 A.D., which also radically and irreversibly destroyed the political and socioeconomic history of the ancient city, in the Middle Ages, around the most important Roman monuments, some civic aggregations gave birth to the three hamlets of S. Erasmo, S. Maria and S. Pietro, to be considered as a whole the origin of the urban core of Santa Maria C.V.

The spaces between the three small medieval towns became rapidly urbanized while some surviving structures of ancient Capua, such as the Amphitheatre located extra moenia, were assigned the role of military garrisons related by location to the nearby rural villages. Although distant from each other, the three villages preserved the large open space already the site of the ancient Forum of the People in pre-Roman and Roman times as a place of confluence and socioeconomic exchange. In addition, the urban scene of the three hamlets was characterized by the imposing environment of ruins marking the original urban topographic footprint. Profound territorial transformations occurred during the seventeenth century when the reorganization of properties and the demolition of ruins erased the contours of the ancient insulae and determined new directions of development (figure 2). In the eighteenth century there was the urbanization of the area of the ruins encompassed by the three hamlets contemplating the construction of convents, barracks and numerous stately buildings of landowners and clergymen whose facades contributed to the perspective backdrop of the major

alignments of the urban structure. During the nineteenth century there were also several renovations of religious buildings and important existing palaces, which were also joined by new private buildings of the nineteenth-century bourgeoisie. In 1844 the railroad reached S. Maria C.V. marking the beginning of its economic revival. After the construction of the Villa Comunale, completed in 1926 acting as a counterbalance to the railroad, the main urban route of Santa Maria C.V. would be strengthened, indicating urban development in a longitudinal direction accompanied by the construction of late nineteenth- and early twentieth-century buildings in eclectic style and the reorganization, arrangement, and reclassification of the existing mobility system.

The features of the physical structure of the city are thus configured through a typological homogeneity although with different sizes and styles, participating in the formation of a specific urban scene where the street and the square are defined by the continuity of the facades of the buildings. The building volumes, organized in a courtyard, occupy a limited contour strip of the blocks within which are enclosed large areas of private greenery, vegetable gardens and gardens that will represent for a long time an important indicator of environmental quality and that will make Santa Maria C.V. deserve the nickname "city of gardens."

In the post-World War II period, there was an urban sprawl that, overcoming typological rules and spatial ridges, will contribute to the formation of the suburbs, not being able to build new completed parts of the city but only fragmented expansions, mainly social housing neighbourhoods lacking urban equipment and public buildings.

In the last twenty years many historical buildings have been demolished and rebuilt in screaming conflict with the rules of urban layout and overall values. In addition, the courtyards that characterized the typological tradition of urban blocks have often been saturated; in this way the only spaces that historically had contributed to elevating the environmental quality of the city of Santa Maria C.V., even if not directly visible and accessible from the street, have been erased, leaving the scene to new buildings with a very poor architectural language and weak accessibility.

In this regard, the repercussions of such operations have reduced the quality of architecture, public space and, above all, create a strong risk to delete the archaeological identity of the city [7].

Figure 2. The ancient forum area of the Roman city incorporated into the existing buildings.

2. STRATEGIES FOR THE VALORIZATION OF THE HISTORICAL CENTRE

In the new Municipal Urban Plan (Piano Urbanistico Comunale) of the city, approved in December 2023, special care was taken to extend the area of historical protection to a large part of the urbanized territory, which largely includes the land of ancient Capua as represented, enclosed by defensive walls, in many historical pictures.

In implementation of the directives of the Municipal Urban Plan, a Renewal Plan for the Historic Centre is being drawn up in recent months, which has already developed specific direct surveys to recognize and establish to what extent, beyond dating, in the permanence of the encroachment of that particular ancient urban fabric lies an equal permanence of values of historic-artistic and environmental interest on which to orient urban planning decision-making. As many as 1400 buildings were analysed and catalogued by collecting the main administrative, historical, functional, morphological, aesthetic and maintenance characteristics as well as the presence of archaeological traces, processed within a GIS system.

The direct survey of the characteristics of the urban territory of historical layout identified by the new PUC of Santa Maria C.V. considered the subdivision of the urban and building fabric into blocks. The buildings inside each block were subsequently numbered, identified by observation of the roofs detectable in updated orthophoto maps or recent aero photogrammetry and subsequently verified in the direct field survey.

For each building, which was assigned a unique identification code, a survey form was compiled where not only typological and dimensional characteristics, state of maintenance, static consistency, age of construction and intended use were recorded but also evaluative comments and critical judgments in the form of scores.

The database thus constructed was used by exploiting the analysis and representation capabilities of GIS tools, which, by linking to georeferenced vector layers, made it possible to derive integrated readings between the different features and return thematic tables from which to deduce the most appropriate categories of intervention (figure 3).

The surveyed features constitute the cognitive base on which the permissible transformation interventions of each building were identified with a view to the preservation and enhancement of historical and architectural values. The classification considered the presence of archaeological remains, usually found in the subsoil a few meters below street level, or sometimes incorporated in the wall structures in elevation.

Especially in function of the new urban roles of the contemporary city, the Renewal Plan aimed at the definition of innovative conservation strategies, as well as recommended by UNESCO (Recommendation on the Historic Urban Landscape, 2012), which invites to discard the idea of conservation to the bitter end that does not contemplate metamorphosis processes that respect the spirit of the historic fabric in which they are located [8].

According to the well-established principles of restoration and integrated preservation of the historical heritage, to identify the modalities of conservation intervention on the existing buildings, different rules were applied, in each case placing the centrality of critical judgment at the basis of each choice [9].

The research, currently ongoing, aimed to identify approaches of intervention and urban planning choices for the municipality of Santa Maria C. V. that, on the one hand, are consistent with the historical and archaeological identity of the territory and, on the other, propose modern languages capable of integrating and framing urban heritage conservation strategies within the broader objectives of general sustainable development of the territory based on liveability, mobility, accessibility and, sustainable urban regeneration.

In addition, the Renewal Plan has identified all buildings dating from after World War II that qualify as environmental detractors for which vertical and horizontal thinning actions will have to be planned, specifying incentive and relocation mechanisms to free up improperly occupied areas. Specific

Proceedings

reference is made to historic rural gardens and courtyards to be recovered, redeveloped, and networked where possible, also contemplating urban restoration and redevelopment to recover the archaeological identity.

The enhancement of the historical, landscape and archaeological resources of Santa Maria C.V. aims first and foremost to expand the liveability and knowledge of the cultural values of the local community but also and above all of tourists with a view to the economic development of the city. This strategy was also based on the suggestions of the main international guidelines on sustainable tourism such as the manual "*Achieving the Sustainable Development Goals through Tourism - Toolkit of Indicators for Projects (TIPs)*" drafted by the World Tourism Organization (UNWTO, 2023) [10] and especially of "*The European Tourism Indicator System. ETIS toolkit for sustainable destination management*" [11]. The latter represents a voluntary management tool that collects data, grouped according to sets of indicators, to build a monitoring and self-assessment system. The indicators are useful for defining strategies and actions for the development of sustainable tourism that can enhance resources, avoiding indiscriminate consumption, and manage tourism activity effectively. The ETIS is based on 27 main indicators and 40 optional indicators divided into four main categories: tourism site management; social and economic impact; economic value; and environmental impact. The toolkit prefigures a process built in seven steps: raise awareness; create a destination profile; Form a Stakeholder Working Group; Establish roles and responsibilities; Collect and record data; Analyse results; Enable ongoing development and continuous improvement. The process steps are also supported by strictly operational tools, from data sheets to information databases that support strategy implementation.

The process is only in the conception stage, but the basis of the strategy is to expand the knowledge of the area by potential tourists and the city's residents themselves.

Fundamental supporting activity for expanding knowledge of the area is the use of digital technologies to ensure at least virtual accessibility of the city's exceptional archaeological heritage. The archaeological sites that can be visited are extremely limited in comparison with the wealth of finds as catalogued and protected by the Superintendence of Archaeological Heritage. The application of such technologies is described in the following paragraphs and constitutes the backbone of the enhancement of Santa Maria C.V.'s cultural heritage.

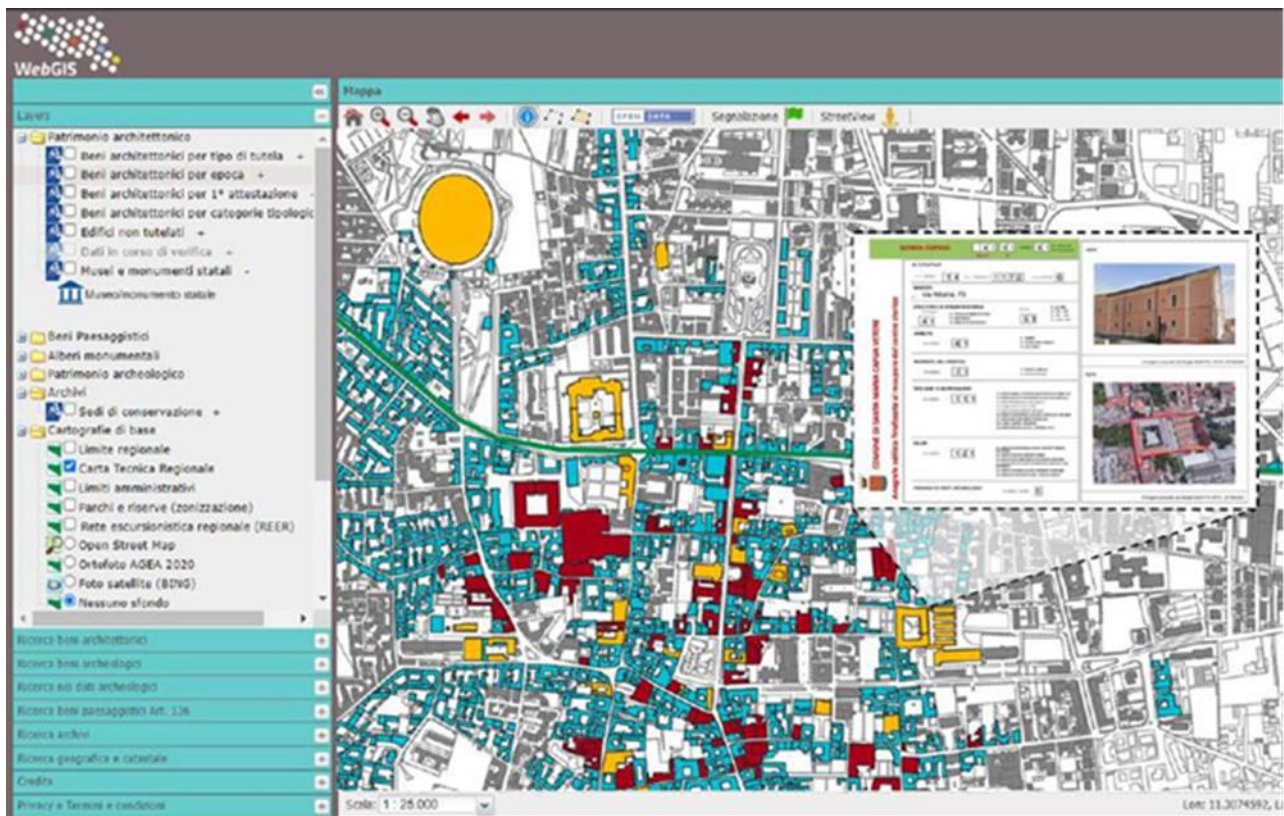

Figure 3. The GIS, collecting the main architectural and functional data of the historical buildings, aims at developing strategies for the restoration of the archaeological identity of the city.

In addition, combining these activities with the more general ones contained in the objectives of settlement rebalancing, realization of social housing, development and optimization of the commercial and tertiary network, enhancement of the environmental heritage, urban greening and environmental design policies will structure the future scenario of the city of S. Maria C.V. by recovering the neglected identity of a city of nature and culture, a city made up of monuments, cultural heritage, gardens, parks, cyclopean paths railway lines, residential fabrics recovered and integrated by public services and facilities [12].

3. DIGITAL TECHNOLOGIES FOR THE CULTURAL ACCESSIBILITY OF ARCHAEOLOGICAL HERITAGE (A.P.)

A proper understanding and valorization of ancient Capua, the "Altera Roma", as the second city of the emperor once was called, need an integrated cultural approach that focuses particularly on the area's specific features. The archaeological remains from the Roman period are numerous and widespread, yet many are partially or entirely buried, thus inaccessible for the main part.

In addition, the vast archaeological heritage of Santa Maria Capua Vetere faces challenges in valorization due to the difficulty in expropriating private buildings and excavating buried remains. Organizing an accessible system for the main archaeological sites, some of which are excavated but encompassed within private properties, also presents difficult organizational and management issues. Archeological heritage is also not properly estimated for its potential value by private owners that sometimes conceal archaeological remains out of fear that their properties could be classified as constrained by the Superintendency.

Culture must thus become the primary strategic tool, addressing the inhabitants' inability to assign proper value to their sites. a necessary driving force to trigger a positive process of knowledge and

Proceedings

appreciation of the widespread archaeological heritage as a common good and a factor of uniqueness of the city of Santa Maria Capua Vetere. This value should first be recognized by local communities, and only later offered to cultural tourism, as a symbol of their collective memory. To trigger this effect the ancient Capua must be perceived as an active presence in the modern city. It is necessary to identify the significance of these archaeological sites within the contemporary city to enhance their value and redefine their mutual relations. The project for the enhancement of archaeological sites must not, therefore, be resolved in the definition of appropriate ways of fruition and musealization of the findings, but must set itself the ultimate goal of rededicating the areas of interest from archaeological excavations to the life of the contemporary city, giving the vestiges of the ancient world dignity and value, through a conscious enjoyment of these assets, assisted by innovative techniques (and technologies) of communication, which allow an active and emotional experience of the archaeological heritage.

Figure 4. Ancient Roman cryptoporticus incorporated into the former Bourbon prison building: a 3d model to unveil their intimate static-morphological relationship

Digital technologies play a crucial role in solving accessibility problems (both physical and cultural) and offering alternative experiences through digital storytelling to engage local populations. Virtual archaeology has played an educational and popular role in recent decades, reconstructing monuments, cities, and territories to communicate ancient cultural heritage to different audiences. It enables a correct and immediate understanding of the past, even elements that are not accessible or have disappeared, through user-friendly fruition tools.

Information and Communication Technologies (ICTs) enhance our ability to access data, information, and knowledge, shaping new forms of interactive experiences not only in terms of knowledge but also in urban performance. This research aims to establish a new relationship between

the modern city of Santa Maria and the ancient Roman city of Capua Vetere, still buried underground, through digital technologies.

In recent years, the link between representation, drawing, and 3D digital surveying has become increasingly vital in Digital Cultural Heritage. Technological developments in surveying, 3D modeling, and advanced representation techniques have allowed researchers to improve their analyses of archaeological remains. 3D models generated can support analysis and interpretation, enabling the creation of information tools and Virtual Reality models for the promotion and narration of archaeological heritage, especially inaccessible ones.

Additionally, GIS and web-based platforms can provide scientific information to scholars and local communities, raising awareness of the quality and consistency of archaeological assets, including those hidden or inaccessible.

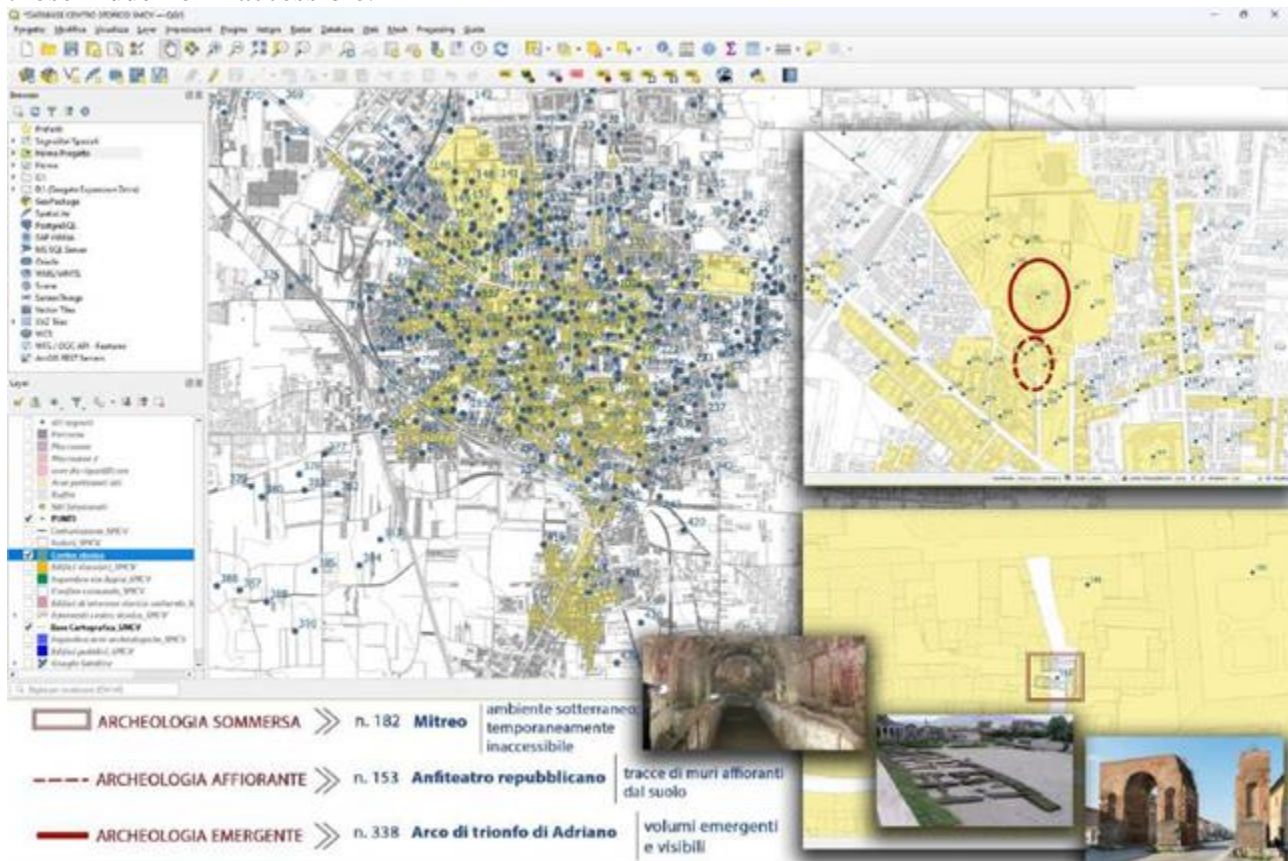

Figure 5. Mapping the archaeological remains in the historical center of the modern Santa Maria Capua Vetere.

The use of digital technologies for surveying and representing archaeology has a significant communicative and learning impact, enhancing understanding and appreciation of archaeological sites. Virtual Reality (VR) transports observers into virtual environments, overcoming physical limitations and reconstructing the original buildings and structures. It enables greater information sharing and accessibility to archaeological sites for tourism and research purposes. Both Virtual Reality and Augmented Reality (AR) promote interactive and engaging representations, increasing the observed-observer dialogue and relating tangible and intangible values of buildings with a human-centric approach into a “phygital reality”^[13-14-15] able overcome what impossible to be solved just in the physical dimension. An integrated approach is proposed, combining digital surveying for knowledge and preservation with advanced digital representation techniques for enhancing and experiencing inaccessible ancient heritage assets.

The goal is to reintegrate archaeological areas into the life of the contemporary city through digital technology utilization. A GIS mapping of the entire submerged archaeological heritage is proposed, alongside the creation of a narrative web GIS, using user-friendly storytelling techniques (ArcGIS StoryMaps), to disseminate knowledge and attract even non-expert audiences to the archaeological assets lying beneath the modern city (figure 5). The first step in overcoming the physical and consequently perceptual fragmentation of the archaeological heritage sites of ancient Capua was the construction of thematic maps, explorable and questionable, with recognizable paths of knowledge capable of connecting even very different archaeological sites by linking them to a common identity. In the case study of Santa Maria Capua Vetere, the creation of a GIS map is useful for a consequent hypothetical reconstruction of a reliable urban simulacra that represents, even to the large public, the real extension of the vanished roman city. The aim is to give a fast and self-explanatory evidence of the real large extension of the ancient Capua, thus providing to the inhabitants the awareness of them consistency and of their potential.

The reconstructive hypotheses we propose are based on accessible asset to be surveyed, historical documentation and archives: 3D models of key archaeological assets (such as the Triumphal arch, Amphitheater, Mithraeum, Catabulum, and the Cytoporticus), placed on the hypothetical map of the ancient Capua are just the first step to trigger immersive and augmented experiences, digital storytelling, and appropriate site-specific installations, including exhibition panels and/or street art murals near the assets, to allow for experiencing the contemporary city as a place of learning and archaeological site exploration where traditional museum strategies are impractical, creating a hybrid ancient-modern space based on the archaeology-architecture blend.

Figure 6. The so-called Catabulum, embodied in a private building.

The issue is the re-signification of the archaeological heritage thanks to the possibility new forms of digital experiences, allow us to overcome the current isolation of archaeological areas in the city. The design of an infoscape [16] to unveil ancient Capua is based on the coexistence and integrated use of different digital technologies, which together foster effective forms of communication and interaction between the physical and digital worlds, in a network of physical places and narrative routes. From

Proceedings

of the International Conference on **Changing Cities VI:**
Spatial, Design, Landscape, Heritage & Socio-economic Dimensions

fragments to clusters by means of narrative plots: each archaeological site, thus, becomes a node in a larger network, made by the intersection of thematic routes traced from the area's major attractors and aimed at redefining a new landscape, made up of onsite visits and immersive experiences in digital spaces, physical relationships between places and/or connections only of a cultural nature, to produce information and knowledge. According to this goal also «the concept of space is considered here in its multiple possible declinations that include both physical aspects- in this sense, experienced, in situ, situated and embodied places- and virtual aspects, understood as two- and three-dimensional, immersive, simulative and virtual (AR, VR, XR) digital places where technology is the experiential medium, hybrids, i.e. where systems (cognitive and instrumental) contaminate each other to the point of blurring and collapsing [17]. The proposed infoscape is an integrated project that tends to configure new spatial relationships, between physically distant places (through thematization of paths), between lost buildings and real remains, between real and digital spaces, in order to generate a new model of an accessible diffuse museum, in which digital information is not only attached to the single object or place, but is recombined, remixed and recontextualized, creating ever new physical and semantic geographies by means of a narrative plot involving the experiential capacities of the visitors.

Conclusions

The research developed so far on the historical center of the city of Santa Maria C.V. has highlighted the considerable archaeological heritage present underground, analyzing the data provided by the Superintendence of Archaeological Heritage and gathering information, through direct inspections, about the characters of the buildings and the technological, architectural and landscape conditions that characterize the urban spaces close to the archaeological resources. The conditions of extreme urban density and historical stratification of architecture as well as building demolitions and replacements applied in recent years prevent access to archaeological sites by the public, whether tourists or ordinary local citizens. The prevailing private ownership of the buildings limits the necessary and appropriate enhancement that is possible only in the few accessible archaeological sites or acquired by public administration.

The analysis developed on the cultural assets and the knowledge of the boundary conditions have provided basic information that will be processed, through appropriate tools, for assessment of the degree of transformability of the buildings to design the conditions of physical access. However, the time and cost for an adequate transformation for physical accessibility prompts the priority use of digital technologies for virtual accessibility and dissemination of knowledge of the archaeological heritage, also in view of the promotion for tourism purposes of the city. It is necessary to highlight the city is a candidate for nomination as “European City of Culture 2027” and aims to attract a large audience of tourists who today visit the city in a very marginal way and only as a reflection of the close Vanvitelli's Royal Palace of Caserta.

Finally, we have proposed an integrated cultural approach between urban planning and the enjoyment of heritage assets, with the aim of rededicating archaeological areas to contemporary city life using digital technologies. The community, due to the principle of economic circularity, will benefit from the enhancement of public spaces resulting from innovative methods of land use that encourage cultural tourism and the promotion of activities. Therefore, the aim is to involve citizens during all phases of the project with different approaches: qualitative research, surveys, interviews and living labs. The research takes full advantage of the potential of digital technologies to reach a wide audience in the process of re-appropriating the places of the contemporary city.

Abstract

Walking is the simplest and most effective way to perceive the landscape. It is a way to stop and think about the values we recognize in the surrounding spaces. Walking is considered both a practice and a phenomenon, a dynamic that is happening here and now and that shapes the city landscapes of Béjaïa in Algeria and Loulé in Portugal while we experience them. In the article, two case studies are shown to present the act of walking as a relevant way to understand Mediterranean cities, especially those landscapes. The result involves reasoning through walking journals that help us to reconsider the importance of landscape values, including genius loci, architecture, culture, colors, rhythm, and more. The reading of a landscape leads to different levels with both scientific and humanistic approaches. As a living structure, the landscape is constantly evolving; therefore, its analysis must also consider the dynamic elements of the landscape. The text discusses the importance of maintaining a walking journal as a research method in the two case studies. A popular tool among academics worldwide, particularly those who use qualitative approaches, the walking diary enables the documentation of characteristics seen when exploring areas, both inside and outside of cities. In this research, special attention is given to sketching and drawing as methods of recording perceptions and making sense of the landscape as a whole. Artistic sensitivity is something extra, sometimes unnecessary, but it can make a difference in contemporary design that is increasingly conscious, researched, but also open and communicative. The article aims, therefore, to show the results of that practice of analysis through a sensory exploration of two different Mediterranean cities by walking.

Keywords: *Walking, Perception, Mediterranean Cities, Landscape, Genius Loci.*

1. WALKING AS A METHOD OF RESEARCH AND A TOOL FOR PERCEIVING LANDSCAPES

Walking is a natural act that allows us to explore, absorb, and immerse ourselves in the landscape we traverse through the full engagement of the body and senses. In a chapter titled *Walking the Past in the Present*, published in the book *Landscapes Beyond Land*, Christopher Tilley emphasizes that it is insufficient, in the study of landscapes and environments experienced by humans, to rely solely on external knowledge - such as reading landscape and historical maps, interpreting aerial views, analyzing photographs and narratives, etc.; he suggests instead using walking as a research method and a tool to reveal the features of environments. Walking provides internal knowledge acquired through perception at a human scale. *"Walking in the landscape is an attempt to understand it at a human scale. The limits of this knowledge are the limits of my own body and how this body limits and facilitates my perception. The goal is to acquire an 'internal' knowledge of archaeological sites such as megalithic monuments and settlements in their landscape contexts, as opposed to knowledge gained through mediated representations that can only provide an 'external' perspective"* [1]. Walking is also regarded as a participatory research method; it allows experiencing real situations within societies and being in direct and close contact with people, to understand their culture, way of life, social dynamics, and their impact on the spatial structures of environments [2]. This approach is

ISBN: 978-618-5765-02-6

known as ethnographic walking. This type of walking is widely used by anthropologists, including British anthropologist Tim Ingold, who teaches at the University of Aberdeen and authorizes several books and scientific works in this field. Ingold is particularly interested in perception; he argues that any interaction with the environment stems from a set of present elements and cannot be carried out independently of the world [3]. In the field of art, walking is approached in three different ways: sometimes as a main subject, sometimes as a medium, and sometimes both as medium and subject. For decades, numerous artists have used walking to create works reflecting social phenomena or describing individual situations. This practice allows artists to immerse themselves in the space around them through movement. This natural act, often performed spontaneously, allows artists to enrich themselves with new ideas and to imagine and design representations of the spaces they traverse. Among the famous artistic works created through walking is that of Richard Long, who traverses natural landscapes, leaving marks on the ground to signify his passage, like alignments of stones or tracks on the earth. One of his most well-known works, which has significantly influenced contemporary art and connects three main concepts: Landscape, Culture, and Art, is titled *A Line Made by Walking* [4]. This work is also considered a participatory act. Similarly, Canadian artist Janet Cardiff works with participants using AudioWalks, where people are guided through urban spaces while listening to surrounding sounds or music [5].

1.1 Sensory perception through walking

To understand the sensory aspects of the landscape, the researchers must wander and explore all facets of the site. They must smell, observe, touch, listen, and even taste later to interpret these elements through their sensory perception [6 ; 7 ; 8]. The smells and aromas encountered, the heat or cold felt when moving from one place to another, the sounds, the wind, the textures - all these are elements that allow for a sensitive understanding, forging a bodily relationship with the site, a process possible only by walking [9]. Yannis Hamilakis, an archaeologist and professor at Brown University, introduces an important concept related to walking: sensory memory. In his book *Archaeology and the Senses: Human Experience, Memory, and Affect*, he critiques the superficial vision traditionally attributed to archaeology, which overlooks the often forgotten affective characteristics. He argues that mere physical engagement is reductive and does not allow for a complete understanding of ancestral heritage. In a study on Minoan palaces, the author proposes a new way to approach historical sites, based on bodily engagement through walking and founded on the principle of multi-temporal and sensory archaeology [10].

2. WANDERING AS A MEANS OF REDISCOVERY AND INTERACTION WITH THE URBAN LANDSCAPE

In his book *Urban Wanderer*, Xiaohui Lin argues that getting lost in the urban environment enhances our interaction with it, thus offering us the opportunity to travel through its different facets via an enriching experience. According to Xiaohui, wandering allows us to connect the body, mind, and land; indeed, during the act of wandering, we are freed from all pre-established considerations and judgments that can be associated with the environments we traverse, allowing us to perceive them differently [11]. Meanwhile, Bradley Garrett emphasizes the importance of urban exploration through wandering, considering it a way to rediscover, explore, and even reinvigorate abandoned or neglected spaces in the urban environment. Garrett focuses on urban explorers who practice wandering, viewing them as highly significant figures in the city. He develops the concept of infiltration, meaning traversing urban spaces that are forgotten or marginalized and considered weird - places no one would imagine exploring or simply passing through. This is also considered a political and cultural act and a form of engagement in the city. In his study presented in *Undertaking Recreational Trespass: Urban Exploration and Infiltration*, conducted with a group of urban explorers in London over four years, Garrett highlights the importance of free and spontaneous urban exploration that alters our perception

of environments. The explorers observed by the researcher transgressed all conventional and natural boundaries in city exploration. They traversed on foot through the London underground networks and sewers, old buildings, cranes, etc. [12]. This is crucial for us, as it allows for a profound interaction with the city, ensuring we do not overlook many elements, even those that might sometimes seem subtle or mundane to our minds.

3. TWO CASE STUDIES: BEJAIA IN ALGERIA AND LOULÉ IN PORTUGAL

3.1 Case study: Bejaia, Algeria

Bejaia, also known as Bgayet in Kabyle (local language) or *Bougie*, is a crucial city in Algeria and the Maghreb region. It is located in the southern basin of the Mediterranean Sea and occupies the heart of the North African coastline. Situated 230 kilometers from Algiers, the capital, Bejaia enjoys a strategic position in northern Algeria thanks to numerous features, including its easily accessible natural site and port, one of the country's foremost. Its geographical location has attracted the interest of many civilizations that have traversed the Mediterranean region. Several writers and historians, including Louis Salvator, have written about this city. In his book *Bougie la perle de l'Afrique du Nord*, he describes the iconic symbols and captivating history of Bejaia [13]. Many traces of these civilizations, which have shaped the city's landscape, are still visible today. The urban fabric of Bejaia consists of two main parts: the old city or medina, which includes all the precolonial urban configurations, and the lower city, built primarily after Algeria's independence in 1962.

Figure 02: Aerial view of the city of Bejaia. Source: www.skyscrapercity.com. Accessed on: 18-02-2021

3.1.1 Exploring the cityscape of Bejaia by walking

To begin our framework of study, wandering constitutes the first step in our field research. During this initial phase, we explored the urban fabric of Bejaia, which is divided into two main parts: the old city and the lower city. We wandered freely to gain an initial contextual understanding. Guided primarily by our natural curiosity, we posed various questions as we moved through the city's different neighbourhoods. Thus, we could appreciate, through our perception, several "spatial qualities" related to the physical and sensory characteristics encountered. Furthermore, we interacted

with the inhabitants and observed the urban scene" and the activities there. We used participant and non-participant observation to grasp the cultural aspects and anthropogenic characters of Bejaia's urban landscape. During this exploration, we climbed to the city's heights, up to Mount Gouraya, passing through the historic neighbourhoods of the old city. We descended to the sea and the fishing port. We traversed the lower city, exploring the plains and heights of the ZHUN of Sidi Ahmed and the peripheral areas and spontaneous urban fabrics of Taghzouit and Sidi Ali Lebher. In parallel, the morphological study allowed us to trace the various transformations that have shaped the city's urban landscape. Through this study, we identified the paths used by walkers in the past, which gave us an insight into the routes that have persisted and evolved over the years. This morphological analysis is combined with the sitological study of the landscapes of the old city and the lower city, organized according to three main frameworks: primary, secondary, and tertiary. On the other hand, iconographic analysis was used to interpret many old photos and engravings collected throughout our research, employing the denotative code method [14 ; 15] and the connotation method [16]. Several routes in both parts of the city have been identified and explored at different times of the year, using the walking journal as the primary tool for data collection.

Figure 03: Photos taken in the old city of Bejaia. Source: Taken by Yacine Mansouri, 2023.

3.1.2 Landscape values between the old city (medina) and the lower city of bejaia. What impact on the urban and sensory experience?

The sensory experience in the old city of Bejaia (medina) is particularly interesting. Our walking explorations revealed that this part of the city is very rich in landscape qualities, significantly influencing the perception and attachment of both residents and tourists. However, several urban elements need to be addressed and could be revitalized to enrich the city's landscape, including old stairs dating from the precolonial period. It is also important to note that ongoing restoration work must consider sensitive and affective aspects to provide an enriching experience.

The lower city of Bejaia exhibited a wide variety of spatial configurations, with spontaneous fabrics (mainly containing illegal constructions) and planned fabrics (such as Zones Urbaines Nouvelles - ZHUN). The created spaces show a certain visual homogenization and uniformity of landscapes due to the standardization and application of typical models, mainly in the construction of residential cities. This monotony, observed in many parts of the urban landscape, results from the need for more consideration of sensory elements, which reduces the immersive experience. On the other hand, discontinuities in the urban experience and breaks between different landscape components are observable, such as the disruption of the city-sea relationship in a significant part of the city, creating a sense of disconnection, especially towards the rear port of Bejaia. Moreover, the disregard of identity and cultural elements in the design has generated meaningless spaces that do not preserve

collective memory. Many lessons can be learned from the urban landscape of the old city and applied in the processes of requalifying the urban spaces of the lower city.

3.2 Case study: Loulé, Algarve (Portugal)

The Algarve (literally "the west" from Arabic) is the southernmost region of Portugal. It faces south and east towards the Atlantic Ocean and is characterized by a typical Mediterranean climate. The center is represented by Albufeira, the Barlavento zone is west of Sagres, while the Sotavento zone is east to the Spanish border. There are three geographical belts in this area: the serra, the barrocal - where Loulé is located - and the littoral. The serra is a unit of shale boulders rising to more than 500 meters, the peaks being Serra de Monchique and Serra do Caldeirão. The rocks are dark and the vegetation dense, with oak and chestnut groves. Terracing is abundant in that area. The barrocal, at the foot of the limestone hills, has reliefs of shale; almond, fig, and carob trees cover the ground in such quantities that, seen from a high point, they look more like dense spontaneous forests than crops in which man intersperses cereals, broad beans, and peas. The barrocal is identified by slight limestone hills on which almond, fig, and carob trees grow. In contrast, the littoral is made up of clear limestone rocks, with whitewashed constructions of limestone, dark patches of tree groves, clumps of mastic trees, oleanders on the water's edge, and low fans of dwarf palms [17 ; 18].

Figure 04: Photos taken in the city of Loulé. Source: Daniele Stefàno, 2015.

3.2.1 Exploring the city of Loulé by walking

The walks lead to an understanding of how the landscape changes. The Conselho de Loulé encompasses all three geographic belts, with a very diverse landscape. In contrast, the city of Loulé is located in the vicinity of the Algarvian beaches, which are renowned for a large influx of tourists. For this reason, and for possessing a remarkable historic center, it is an important point of passage for many people.

Services are concentrated in the northern part. The historic center of Loulé represents a major cultural identity for the region; rich in artistic and architectural assets, it is defined by a very compact mesh. The city, in which a salt mine is also located, is laid out horizontally on a slight ridge and is visibly structured in three parts: The Santuario da Nossa Senhora da Conceição, which constitutes a landmark to the west, the historic center, and the peripheral area in which the mine is located to the east.

Figure 05: Sketch of the historical center of Loulé. Source: Daniele Stefano, 2015.

3.2.2 Drawing to acknowledge landscape values

What emerges from the drawings and sketches made by walking, on the one hand, is the richness of the flora of the surrounding landscape and, on the other, a very identifiable typically Algarvian architectural style. Bright colors between deep blue and yellow predominate, recalled in turn by the endless graphic patterns of the azulejos. The city of Loulé is a centrality with its strategic location near the tourist beaches. Despite this, its interior is sharply divided between the historic center, modern fabric, and recent expansion. In the latter part lies the mine: with a passthrough role between the countryside and the city.

The arid, undulating land of the Algarve contours Loulé's recent expansions. Among the Mediterranean plants, mostly grasses, the mine's elevator-tower stands out. The mine, on the other hand, is a rather neglected area, defining the eastern edge between recently constructed buildings. On the surface, it is an uncultivated field of grasses, while the underground rooms are the reddish-yellow color of rock salt, the ore mined here. The Loulé rock salt mine arose because of the geological mutation that came about from the separation of Europe and Africa that created the Mediterranean Sea 250 million years ago.

By drawing, it was possible to collect all these data and put them together in an overall image that resituates the complexity of the Mediterranean landscape made up of historical and natural stratifications. In particular, it turned out to be a way to highlight the distinctive values we recognize in the landscape.

Figure 06: Sketch between the city and the countryside. Source: Daniele Stefàno, 2015.

4. THE IMPORTANCE OF USING A WALKING JOURNAL FOR OUR RESEARCH

The walking journal has proven to be a highly relevant tool in the context of our current research. Used globally by many researchers, mainly those who adopt qualitative methods, it allows for recording qualities encountered during wanderings, whether in urban environments or beyond. In our study, this tool served a dual purpose: On the one hand, as researchers, we used the walking journal to record all our impressions and sensations, as well as our emotional and affective reactions to the different characteristics perceived in the spaces we traversed, in the form of texts, drawings, photos, and even sound recordings.

The two case studies are the result of two separate works and compared here by analogy. The walks through the selected urban routes were carried out several times over the year, during different seasons and in varied weather conditions, to account for temporal variability and to provide a complete and nuanced understanding of the city's qualities. Moreover, walking was practiced both during the day and at night, allowing the capture of the diurnal and nocturnal dynamics. Alongside our subjective experience, researchers also recorded their sensations and perceptions throughout the predefined routes and locations. They thus compiled several walking journals during guided walks.

CONCLUSION

This research demonstrates the crucial importance of walking as a research method and a tool allowing for total immersion in the environments traversed. Thus, walking surpasses being merely a means of transportation to become a powerful tool for discovery, requalification, and valorization of our landscapes and urban spaces. As demonstrated in this study of two Mediterranean cities, Bejaia in Algeria and Loulé in Portugal, this practice reveals all layers of complexity in our living environments. It enables the integration of operations that take into account all characteristics of the landscape and primarily prioritize the human, cultural, and sensory dimensions during the implementation of planning and development operations, thus promoting richer and more suitable living spaces adapted to our needs. The walking journals used in this study prove to be a powerful tool for capturing all multisensory elements and interactions during the walk. Using this tool allows researchers to reveal aspects often missed by other methods used in urban and landscape analyses. On the other hand, the study highlights the exceptional richness of Mediterranean cities in landscape

Proceedings

qualities that now require deep exploration to be valorized through the implementation of studies that place the practice of walking at the heart of the methodologies used.

Abstract

Starting from the common assumption that Public Space is important for a society because it is (potentially) the focus of its cultural life, the concern on which the present text develops upon is: do we have the Public Spaces we deserve and if not, what do we do about it? Concurrently; is it possible that we can redefine abandoned semi-urban, or open-air areas of historical significance considering Digital Art Installations, by means of raising awareness or creating novel significance, as an added value to their existing circumstances? Indeed, once a Digital artwork is installed within a Public Space, the latter ceases to be simply the material essence of its built forms, or the permanence and non-permanence of its architectural elements and details. Instead, a new condition develops, as space and artwork combined change our understanding of the existing reality and affect our perception of what such an environment is.

The present paper discusses the potential of using a Digital Sound Art installation as a strategy for the reinforcement of the Roman Baths of Kyllini, Elis, in the Western Peloponnese Region: a significant Historical, relinquished place of exquisite natural beauty, with rich archaeological and cultural heritage connected to thermal bathing. Following a visual and auditory mapping of the area, we examine this device as a coetaneous experiment upon how an audio-visual material is created through a critical interpretation of place; and how the transformational power of Digital Art can affirm conscious behaviors on culturally important, public open spaces. The concomitant research is inscribed within the research project "LOUTROTOPOS: Critical mapping and visual narration of thermal springs in the Hellenic Territory", which investigates a wider network of places of thermal resources in the Hellenic periphery upon these methodological and conceptual premises.

Keywords: *Sound Installation; Culture; Public Open Space; Abandoned Places; Ancient Roman Baths; Kyllini, Elis.*

1. INTRO: WAITING

The paper discusses the conceptual framework for a sound installation project proposed for Kyllini Roman Thermal Baths. This is part of the funded research project "*Loutrotopos: Critical mapping and visual narration of thermal springs in the Hellenic Territory*", that investigates networks of places of thermal resources in the Hellenic periphery. The objective of the research project aligns with the regional planning policies for remote places in the Hellenic periphery, based on the preservation of the cultural identity and the promotion of endogenous local resources, highlighting the fact that thermal springs are geographical places with a unique physiognomy and developmental potential. Kyllini's ancient Roman Baths lie in a peaceful but neglected area at the northwest of Peloponnesus, 9km from Kyllini cape. The proposed sound installation is conceptualized as a strategy for the cultural reinforcement of the specific area of the Baths.

A sound installation consists of both the material components that constitute the sound composition, and also, it refers to a model-of-an-action, which this organization sets. Henceforth, an analysis of a sound installation takes into account two aspects, that which refers to the material and that which refers to the kind¹ [1]. A sound composition can be firstly examined in terms of what it is *per se*, secondly in terms of the form it takes in order to be transmitted and thirdly in terms of its relation to the space it appropriates once it is installed. Sound is vibration that bears no shape or volume, at least, not a visual or haptic one. Despite its invisible nature it composes and articulates a certain language producing its own symbols. Within this language the system is sensually and cognitively presented. The essence of language is the 'account', which is a unit of knowledge that holds a cerebral quality, a sensual quality, and an emotional quality. Intellectuality, sensation, and emotion are parts of the same intellectual whole. Such a language also serves the kind cause. The cognitive appreciation of the sound serves its material cause, which is related to the dimension of real space. Moreover, sound is associated to the 'real time' and 'real space'. It is not enclosed in any kind of meaning other than the one its receiver specifies. Although the 'meaning of the sound' is bound, it does not separate itself from the environment to which it is transmitted and belongs.

We are ultimately surrounded by sound sources, that occur simultaneously, so how do we sort out all these information? Our brain carries out the task of reconstructing and sorting them using the functions of attention and working memory. The analysis of an auditory scene depends upon the properties of binaural hearing, which also processes the frequency information that comes from different sound sources. Due to the function of memory, sound provides knowledge about spaces by literally moving us, because sound is a vibration and as such it penetrates and resolves through the human brain in the human body. A great number of visual and sound artists are working upon the subject of the knowledge the audition brings to our perception. Jez Riley French's works are focused on this intermediate space between the digital and the physical space making evident the reciprocal relationship between spatial environment and digital artworks. "Waiting" (2014-2017) is the title of a multi-media art project developed in eight parts, where each part includes still images as projections of a more or less familiar, rather indifferent, black-and-white natural environment where nothing happens. It also includes a composed arrangement of sounds that resonate above and below our range of hearing, which are standing in contrast to those that images conventionally hint at. Sound suspends the immobility of what we see meanwhile, our memory rearranges the dimension of the *real* [1].

2. ABANDONED PLACES: ANCIENT ROMAN BATHS, KYLLINI, ELIS

Travelling along the West Peloponnesian coast we arrive at Kyllini's Roman Baths where we clearly see the need to make a record, as complete as possible, of such a unique landscape. Our recording is based upon an audiovisual cartographic approach regarding:

- 1.A. The wider features of the landscape; its flora and fauna
- 1.B. The specific natural/geomorphological features that attributes to the identity of the space and
- 1.C. The details regarding the "memory of space", for example, particulars that are connected to its historical aura.

This type of recording offers some interesting traces, which concern:

- 2.A. Architecture and the environment of Kyllini's Roman Baths
- 2.B. The present state of Kyllini's Roman Baths.
- 2.C. Sound Installation as a strategy for the reinforcement of the extreme significance of the place.

The concomitant research has provided the following observations:

¹According to system of classification by Aristotle, there are four major indispensable parameters that a work of art should fulfil in its essence : The material cause , the kind cause , the creative cause, and the terminal cause.

Proceedings

1.A. *The wider features of the landscape; its flora and fauna:* At the northwest of Peloponnese, a coastal region extends from the area of Kalogria beach to the headland of Kyllini cape, along an inland region of captivating beauty, characterized by diverse geomorphology, rich biodiversity, and historical significance. The interplay of natural elements and cultural heritage renders this landscape a veritable microcosm. The substrate along the coastal region is sandy and not very deep (max. depth 15m), hosting the beds of “*Posidonia oceanica*”. These sandy beaches are potential nesting areas of the loggerhead turtle “*Caretta caretta*”. The beach from Kalogria to Manolada is backed by a dune system with typical vegetation such as “*Ammophila arenaria*” and “*Euphorbia paralias*”. Further up the dunes, there is a strip of “*Juniperus phoenicea*”, “*Pistacia lentiscus*”, etc. After the dunes the coastal forest of *Strofilia* starts, which is gradually substituted by agricultural land.

Further south, towards the end of the gulf of Patras, the beach is comprised of fine sand, backed by low-lying dunes down to the mouth of Kotichi lagoon where the sand-strip becomes narrower. The “*Posidonia oceanica*” beds are extensive and have a high density of plants. This marine phanerogam hosts great numbers of both animal and plant organisms. Many epiphytic macroalgal species and many species of gastropod use the leaves as substrate for their growth. The seagrass “*Cymodocea nodosa*” grows in the very shallow waters of the area. It is the characteristic vegetation of the lagoon and it replaces the “*Posidonia oceanica*” beds at the Kyllini harbour.¹ On the sand dunes of the beach, during the summer months, sand lilies grow. We are in the westernmost tip of the Peloponnese. Moving from this point towards the inland, at coordinates 37° 56' 0" N, 21° 9' 0" E we find the beginning of the Kyllini Peninsula Landscape Zone. The interpenetration of the zone of the Chelonitis gulf and the zone of the Kyllini gulf create a common place/landscape, roughly delimiting it, from the route of Pinios river and its estuary to the cape of Kyllini and the salt flats of the Lechaina area².

To the east, the area of the peninsula is flat. The rural cultivated landscape is a continuation of the rural landscape of the plain of Elis with the name Kampos of Gastouni. In this particular zone, vines, olive trees, fruit and vegetable crops dominate. Few parts of the area can be characterized as a non-purely cultivated landscape because there are also extended green houses and some industries. A distinguished feature of the area is the agricultural cultivated landscape of the hills with predominant types of citrus fruit and olive trees.

1.B. *The specific natural/geomorphological features that attribute to the identity of the space:*

Further east, after 9km from the Ionian coast at Kyllini cape³, we are finally reaching the ancient Roman Baths. They are located in the middle of a wooded area of an amazing beauty, interrupted by large pieces of arable land. It is the area where the forest reaches all the way to the beach, ending in rare sand dunes with dense vegetation of large tamarinds and cedars. Ancient Roman Baths are placed in an indeed beautiful green area, with an ancient pine (*Pinus halepensis*) forest, centuries-old eucalyptus (*Eucalyptus globulus*), plane trees, oaks (*Quercus macrolepis*), beeches, lindens, figs, willows, combined with large areas of arable land with olives, vines and citrus. Specifically, the area is characterized by a genuine Mediterranean diversity of ecosystems and habitats that combines

¹ <https://natura2000.eea.europa.eu/Natura2000/SDF.aspx?site=GR2330007>

² Ibid. The Kyllini gulf includes three areas of national value and three landscapes of regional value. The land, water and sea areas of the Kotychi lagoon, the *Strofilia* forest and their wider area (Achaia - Iliia) were designated as the “Kotychi - *Strofilia* Wetlands” National Park because they are distinguished for their great biological, ecological, aesthetic, scientific, geomorphological and pedagogical value. The purpose of this distinction is the protection, preservation and management of the landscape, as a natural heritage and a valuable national resource.

³ Ibid. The wider area has been designated as protected, in “Places of Community Importance” (Directive 92/43/EC) in the Cir. of Western Greece in accordance with the Commission Decision of 19 July 2006, concerning the approval of the list of sites of Community importance for the Mediterranean biogeographical region from south to the north [notified under number E (2006) 3261] (2006/613/EC) the “Coast Sea Zone From Cape Kyllini to Toumpi - Kalogria”

coastal wetlands (lagoons, marshes, salt marshes, marshes, reed beds, riverside tree stands) with extensive systems of coastal forests and limestone hills with typical Mediterranean vegetation (mainly phrygians and sparse stands oak).¹

The anaglyphic land-form of the area does not offer strong fluctuations. It is mainly characterized by very low to zero slopes, while the soils are quite fertile, which leads to the intensive cultivation found in the area. This is precisely the characteristic that reigns the area of the Roman Baths with the sense of peacefulness, that endows the ambience of tranquility to the experience of the thermal baths. The harmonious blend of fragrances, gentle variations of color and the amalgamations of sound-frequencies arriving through the forest, make palpable the exquisite beauty of the Roman Baths area. The landscape is characterized as an area of hilly/semi-mountainous landscapes. Geographically, the region showcases an interesting variety of geological formations, ranging from gentle undulating hills to rugged mountain ranges. Almost flat lands prevail in most of the area. Between them emerge the limestone hills Mavra Vouna (240m.) and the small hill Kounoupele (47m.). The verdant valleys, nourished by perennial streams and rivers, sustain a plethora of flora and fauna, fostering ecological diversity. Dominant features include the olive groves, interspersed with vineyards and citrus orchards, which contribute not only to the scenic charm but also to the region's agricultural productivity.

1.C. *Its relationship with the possibility of the "memory of space" to contain more information than that found in the visible order of things, such as, for example, its historical aura:* Kyllini is mentioned for the first time in Homer's "Iliad" where Otos from Kyllini was killed during the Trojan war. According to Pausanias, Kyllini was founded by the Arcadians who had migrated to the area of Mount Kyllini. In ancient Greece, it was one of the most important ports of the Peloponnese, because it was the main entrance to ancient Ilios. With the arrival of the Franks in 1204, a new town called Glarenza was created, which together with the rebuilt port of Kyllini, gave the area great development. In the Middle Ages, Kyllini was particularly known for the export of its products, such as raisins, wine, oil and cotton. In 1428, the area passed to the reign of Constantinos Palaiologos, the last Byzantine emperor, yet, he was forced to demolish the port to prevent it from falling into the savages of the pirates. Since then, Kyllini turned into a simple settlement².

Heading from Kyllini to the ancient Roman Baths we shall meet the Chlemoutsi (also known as Chateau Clermont) a medieval Castle built within the early 1220s by the Crusader rulers of the Territory of Achaia as their primary fortification. It is maybe the most important fortress of the early period of Frankish rule in Greece. Chlemoutsi remains as one of the foremost imperative and best-preserved castles in Greece, keeping up its Frankish character intaglio³.

A quite narrow provincial road, crossing a woodland of eucalyptus trees that were planted at 1890-1892, relocated from France with the help of the company SPAP that exploited the Baths at the time, lead us to Loutra Kyllini, which was an independent settlement until 1912. After the recognition of the Municipalities and Townships, the village Kastro was recognized as a Township and Loutra became a part of the Kastro Township. Nonetheless, next to them we find another settlement of warm

¹ <https://natura2000.eea.europa.eu/Natura2000/SDF.aspx?site=GR2330007>

Based on this rare diversity, the Landscape Zone of the Kyllini Gulf includes three (3) areas of National Value and three (3) landscapes of Regional Value. In this zone, the land, water and sea areas of the Kotychi lagoon, the Strofilia forest and their wider area (Achaia - Ilios) were designated as the "Kotychi - Strofilia Wetlands" National Park because they are distinguished for their great biological, ecological, aesthetic, scientific, geomorphological and pedagogical value. The purpose of this distinction is the protection, preservation and management of the nature and the landscape, as a natural heritage and a valuable national natural resource.

³ Ibid. Chlemoutsi castle has been declared a Cultural Heritage Monument by UNESCO and soon inside the castle it will be housed in a model museum.

springs and showers called "Litzi" (the word *Litzi* means *Bath* in Latin). We finally have arrived at the large complex of carefully constructed Roman baths (thermae), which, in the past years, as well as nowadays, attract numerous guests.

Overall, the Kyllini Baths have been known since ancient times for their thermal springs, whose waters, fumes and mud are therapeutic. The sulfur compounds found in the water are responsible for the beneficial qualities of the lychee spring water, which aid in the prevention of numerous illnesses, including those pertaining to the digestive tract, skin, joints, and respiratory systems. Furthermore, the spring waters have an antibacterial and anti-inflammatory impact due to their high amount of "hydrosulphide". Some of the visitors take "mud baths," which involve covering their bodies with the ameliorative mud and then being washed with the therapeutic water that naturally emerges in the same location [3].

2.A. Architecture and the environment of Kyllini's Roman Baths: The abandoned Roman Baths stand as a witnesses to a bygone era, where echoes of ancient indulgence and societal sophistication resonate throughout the tranquil landscape. Nestled in the middle of verdant hills of dense natural growth, this once-grand bathing complex were a testament to the opulence and engineering prowess of the Roman Empire. Renowned for their mineral-rich waters, the baths served as communal spaces for relaxation, socializing, and wellness rituals. Approaching the site, weathered plinths fenced by thin metal net emerge from the surrounding vegetation, hinting at the grandeur that once defined these thermal sanctuaries.

As we approaching the metal fence which frames the Roman Baths, we encounter a network of interconnected rooms and corridors, each serving a specific function within the bathing ritual. From the caldarium, with its heated pools and steam rooms, to the frigidarium, offering respite from the summer heat, these spaces provided a holistic experience for body and soul. Despite the passage of centuries and the ravages of time, the abandoned Roman Baths retain an aura of mystique and elegance. Amidst the decay, traces of the baths' former splendor still linger, offering a glimpse into a world where leisure and luxury were paramount.

Sadly, nature has begun to reclaim the site, with ivy creeping up weathered walls and wildflowers blooming amidst fallen stones. The main chamber, with its soaring ceilings and arched windows, once echoed with the sound of cascading water from ornate fountains, is now covered with a thin carpet of mosses and lichens. Fragments of marble benches and alcoves bear testament to the meticulous design and meticulous attention to detail that characterized Roman architecture underneath the eternal blue sky. Long black plastic sheets layered over the ancient construction; hence, this is the only protection towards the irreversible deterioration of the valuable ruins.

2.B. The present state of Kyllini's Roman Baths: Once more, nestled within the topographical era of West Peloponnesus lies an inland region of captivating beauty, characterized by a diverse geomorphology, rich biodiversity, and historical significance. The interplay of natural elements and cultural heritage renders this landscape a veritable microcosm. Archaeological vestiges punctuate the landscape, bearing witness to the region's old history. Ancient ruins, including temples, theaters, and fortified citadels, provide tangible links to the significant past of the area, inviting scholarly inquiry and cultural exploration. These remnants serve as repositories of knowledge, shedding light on the social, political, and artistic dimensions. The specific countryside is comprised of traditional villages characterized by their whitewashed dwellings. The relevant settlements serve as bastions of local heritage, preserving age-old customs, artisanal crafts, and culinary traditions. Their habitants are the permanent visitors of the Killini Roman Baths. Weather allowed, mingled with other national and international visitors, they all offer some insight into the sociocultural fabric of the population that overcrowd the specific place.

Even so, neglect is always present: Some parts of the Roman Bath's yard shrouded in a cloak of tangled undergrowth. Nature, undeterred by the absence of human care, has woven a tapestry of putrefaction. Amidst the encroaching wilderness, span the sluggish therapeutic waters, on the soil of

Proceedings

which patches of swampy, marshy earth by the overflow waters is making our staying quite difficult. Plastic cords out of use are freely looping underneath faunas, whereas a metallic tube is in use, pouring water for the visitors to collect it, using their own paraphernalia. As we approach the metal fence which frames the Roman Baths, we encounter a network of interconnected rooms and corridors, each serving a specific function within the bathing ritual. From the caldarium, with its heated pools and steam rooms, to the frigidarium, offering respite from the summer heat, these spaces provided a holistic experience for body and soul. Sadly, nature has begun to reclaim the site, with ivy creeping up weathered walls and wildflowers blooming amidst fallen stones. The main chamber, with its soaring ceilings and arched windows, once echoed with the sound of cascading water from ornate fountains, is now covered with a thin carpet of mosses and lichens. Fragments of marble benches and alcoves bear testament to the meticulous design and meticulous attention to detail that characterized Roman architecture underneath the eternal blue sky.

2.C. Sound Installation as a strategy for the reinforcement of the extreme significance of the place: Then, there's a question that remains: Is it possible to awake the interest for an abandoned, open-air area of historical significance, using the power of art to stimulate our brain and as such, being appreciated as a value over the existing redundant situation? We took under consideration the fact that the form of art, which would be allowed to be placed in an area under authoritative protection protocols should not infringe but append to the cultural experience of a visitor. Under the certain circumstances, a Digital form of art appears as the ideal, intangible intervention into the place. Indeed, once a Digital artwork is installed within a Public Space, the latter ceases to be simply the material essence of its built forms, or the permanence and non-permanence of its architectural elements and details, along with its state of preservation. Instead, a new condition develops, as space and artwork combined change our understanding of the existing reality and affect our perception of what such an environment is.

3. FOREST (FOR A THOUSAND YEARS...): CONCEPTUAL STRATEGIES FOR A SOUND INSTALLATION AT KYLLINI'S ROMAN BATHS

The recordings made during the audiovisual mapping of West Peloponnesian era, gradually focused on the specific site of Roman Baths, led us to examine the hypothesis of creating a Digital Sound Installation in situ, according to our thought of casting attention to the cultural importance of the specific place. Considering that Sound installations are closely related to the site on which they are situated, we foremost propose a study on the architectural, sociological, historical, and other contextual data that is gathered under the term *site-specificity*. The material following the present proposal is gathered from the sound sources of the greater and the liminal environment of the Roman Baths, as it is previously described in detail. It is aspired from Lacey's three methods for producing sound installations [4]: elemental (installations driven by the elements, or those that use elements to generate sounds), resonant (using resonant features or structural vibrations), and electro-acoustic (loudspeakers).

In order to understand the impact of sound to human's perception we need to briefly discuss the auditory function. Once sound-waves reach our ears, they are converted into electrical signals, reaching the sensory receptors of the auditory system. The pattern and intensity of stimulation encode the auditory-information, which consists of three properties; *pitch*, *timbre*, and *loudness* (that gives us indications about *spatial location*). Then, the information is sent to the auditory cortex via the auditory nerve, where the electrical signals are processed and interpreted. Pitch refers to the perceived frequency of a sound, allowing us to differentiate between high and low tones. Timbre, is what gives different sounds their unique qualities; it allows us to distinguish between the sounds of 'coastal wetlands (lagoons, marshes, salt marshes, marshes, reed beds, riverside tree stands)' and the sounds of 'coastal forests (phrygans, oaks)', even if they are sharing the same tone. Spatial location refers to

our ability to determine where a sound is coming from. This is made possible by the brain's ability to analyze the slight differences in sound arrival time and intensity between our two ears [5].

By stimulating brain function, sound activates our emotional centers. Certain frequencies and rhythms can trigger an almost instantaneous emotional reaction. The scientific field of psychoacoustics, involves the study of how humans perceive and interpret sounds, incorporating elements of psychology, acoustics, and neurology to understand the auditory experience. Psychoacoustics has given us a numerous piece of research, explain how and why the brain releases different chemicals in response to various auditory stimuli, influencing human's mood and emotional state. The perception of sound regulates a critical stand in our everyday experiences since it formulates an interpretation of the complexities of the sounds we are exposed to, moreover it dictates their psychological effects upon us.

Nonetheless, while we analyzed the material of the era (most possibly any auditory material collected from any similar places), we distinguished two kinds of sounds: the simple and the complex. Most of the natural sounds are complex, a mixture of sounds, which are characterized as fundamental sounds of greater volume and some simple ones characterized as higher or harmonic sounds. The categories were identified, in order to supposedly arrange the sound theme of the sound-piece's parts. The relevant taxa describe the specific feature and application of a sound Installation, constituting the sonification. By definition, sonification represents changes in data with changes in one or more sound attributes [6]. Manipulatable perceptual dimensions of sound are mapped to correspond to changes in data at the stage of orchestration. Before this stage, any changes are included in the synthesis of digital sound, which are depend on the creator's decision at the stage of data arrangement.

A taxonomic classification system regarding integrated/site-specific/background, where the new sounds blend in with the background ambience, and oppositional/borrowed/foreground, where the new sounds stand out as separate entities from the background, will be useful. Synthesis may use attributes of both classes in order to align the audio material and its arrangement with respect to an auditory interpretation of place. Such a practice comes in accordance with the thought that sound stimulates the cerebral function of memory to recognize elements of the environment that we are in and affirm sensations.

In order to design a sound Installation, we need to understand how our ability sustains auditory information, to 'see' why sound affects us in such unfathomable ways and face how less we know about auditory world. Considering our poor knowledge on auditory function, in a site-specific sound Installation, the work proposed is arranged on the idea that the composed sounds are incorporated, yet, amplify the already 'heard' or 'known' sounds. At a certain degree of abstraction, a sound-piece composed by the auditoria recordings of the area means that someone insists on something. Precisely, this persistence and the incomparable attribute of the sound to remind and represent in memory "rare sand dunes with dense vegetation of large tamarinds and cedars" commits its listener to an existential affiliation to the spatiotemporal circumstance. Hence, a sound artwork results from the creator's intention to situate a listening relationship unique to the site and its visitors, including its concept, content and form.

To forward the idea in respect, at the arrangement of a sound-piece for a Sound Installation to an open landscape, certain things should be taken into account such as:

- A. The physical characteristics of the auditory material; spatial proportions, eigenfrequencies of materials and the environmental humidity.
- B. The cultural characteristics of the auditory material; the voices and the sounds from distant activities that were audible in a specific space.
- C. Thus, (taking into account the wave nature and the frequency variety of environmental sounds) the sound-waves, when interposed by natural bodies or artificial objects, undergo spectral distortions (in terms of their temporal spectrum, intensity and frequency composition). Subsequently, sound shows

differences in intensity, due to attenuation both in the atmosphere and in the material substances they dash against.

In any event, sound is a multidimensional stimulus, which presents particular features in its recording, its processing and its transmission. In order to create a sound Installation based on the auditory scanning of natural sounds (while it follows the sound mapping of the area), the recording process attains measurements in different spatial points and at different times. Then, the production of sound (since it is a pulsating vibration), and the form of its installation (since it requires an evaluation of the factors that interfere with sound propagation), acquires a mapping record of: a) the quality of the atmosphere, b) the direction and intensity of the wind, the nature of the soil and the type of plants that thrive in it and c) the sounds of human activity in the space of Installation or those that come from the surround area and blend within the space. An Installation of a sound-piece requires technical decisions regarding: the type of sound system that is going to be used, the relative calculation of the distance between the transmitter and the receiver's spectrum as well as the height and the angle of the speaker's placement [7].

Technology allows sound engineers to create a three-dimensional soundstage that surrounds the listener with a so called 'auditory experience'. Certain innovations contribute spatial auditory experience, mainly: a). The binaural recording, which uses specialized microphones placed inside ear-shaped molds that capture audio with an enhanced sense of depth and accuracy, b). The amplitude panning, which is based on the manipulation of the amplitude of audio signals and the control of their position in a stereo field, supports the recreation of the spatial characteristics of a sound source, c). The wave field synthesis, an advanced technique that involves using an array of speakers to create precise wave-fronts, resulting in a truly enveloping soundscape that can be experienced from different vantage points [8].

Additionally, software and creative audio technologies have made it possible to accurately control sounds in order to create any desired brain response. An interesting approach, in order to generating immersive creative experiences is the application of ambisonic audio technology. Through the use of ambisonics, three-dimensional audio scenes can be created, employing a system of several microphones and direction recording. As an aftermath, digital sound installations elicit particular feelings and immerse listeners in multisensory realms through the meticulous design and engineering of aural aspects within their installations. Sound may influence the story told in an artwork, whether it's the soft rustle of leaves in a forest or the sound of footsteps echoing in a eucalyptus' leaves covered pathway [9].

In their sound Installation *Forest (for a thousand years...)* (2012), Janet Cardiff and George Bures Miller obfuscate the boundaries between art and location. They welcome us to a forest's entrance, to sit on a wooden bench and just listen to the natural environment. The sound was released from thirty speakers that we are unable to define where they are placed. A near synchrony of recorded and natural sounds at the same moment, making it difficult to tell which sound is live and which is recorded. On a bright day, we can clearly detect the impending storm, then serenity, then a loud branch snap above us (as captured in the recording). The sounds are those of a war: large explosions, machine gun fire and whistling screeches. Next, vocalists approach, then move away to allow us to hear the once more the sound of wind through the trees. Their sound-scape, genuinely affecting and frightening, soak us to the History [10].

4. STONE CIRCLE: OUTRO

A number of academics, historians and thinkers, have made an effort to determine the origin of sound art. For the contemporary west world, the field of "sound art" emerge in the begging of 20th century. However, since sound-art installations incorporate programming, audio-data, and audiovisual art, among other techniques, it has been determined as a multidisciplinary art field on a constant development. Within the sound-art field, Haroon Mirza presented recently the *Stone Circle*

Proceedings

(2018), a sophisticated technology driven sound Installation in the landscape of Marfa, Texas, which remained at sight until 2023. The artwork consists of a circle of eight stones, placed around the ninth central stone, mounted with solar panels that charge a bank of batteries to power a sound and light score that is activated with each full moon. Complex patterns of electronic sound and light are translated from energy generated by the sun [11].

Crucial to our appreciation of sound Installation art is the science of psychoacoustics, which investigates the ways that sound patterns that affect cognition and reflect to human's behaviors. It also explores the effects of sound on learning and memory functions. For example, background music or particular aural cues can enhance focus and memory recall [12]. A perusal of psychoacoustic gives a precious insight to the knowledge acquired in order to create a sound installation for a public open (or not) space. Unimpeachably, the composition of a sound-piece acquires a wide knowledge both in theory and practice, adhered to the broad field of sound-studies.

The current paper discusses a proposal for a sound Installation to the abandoned place of Roman Baths at Kyllini, Elis, as an artistic, immaterial practice that will reinforce the cognitive appreciation of the place, thus, advance its cultural significance. It is based on the premise that sound installation generates auditory stimuli along with all the scientific and physical characteristics that surround them, aiming to make use of the emotional and physiological reactions they elicit. The concept addressed by the current paper stands in the reverse of the existing abandonment, in land and history as well as in human's activity and mindsets, following a case study. A mapping methodology generated the approach of a particular place that brought an extensive description of the inherent natural elements that can be used as sound-sources. It is organized according to a deductive reasoning, starting with a general and ending to a specific view of this historically important Greek region.

The methodological collection of data is followed by an auditory analysis, along with examples of relevant artistic sound Installations, to address the necessary concerns that an engagement with a sound Installation in situ demands. Beyond this project, the suggested framework is a helpful resource for describing and contrasting sound installations from several significant angles. In fact, the approach that the present paper suggests, might apply to any remote, open public space. A sound Installation's significance stands to its inherent power to affirm the complex relationship between individuals and public spaces, to greet more conscious attitudes and behaviors, for that cause, to composes mindful ethics and practices and dare us to re-think about an art-project planning as a hub for reevaluating our urban culture.

Between Legitimacy and Illegality: Informal Migrant Settlements as “Right to the City”? The Case of Sicily in Italy

F. Lo Piccolo¹, V. Todaro², S. Siringo^{3*}

Extended abstract

The phenomenon of informal settlements in European cross-border Mediterranean countries, such as Italy, Spain and Greece, represents a complex issue from an urban planning perspective, addressing crucial issues related to squatting, land management and spatial conflicts. At the same time, it raises fundamental questions concerning citizenship rights and the 'right to the city'. In the specific context of the rural contexts of Southern Italy, the analysis of the spread and socio-spatial dimensions of informal settlements highlights gaps and inefficiencies in reception policies, contributing to episodes of social exclusion and marginality.

In this context, the need emerges to explore whether informal migrant settlements can be interpreted as forms of claiming citizenship rights and the 'right to the city'. The question arises as to the role of public institutions in recognising these rights and managing the phenomenon appropriately. Through an exploratory methodological study focused on Sicily, this work aims to understand the phenomenon of informal migrant settlements at the local level, trying to identify possible unwritten 'rules' of informality.

The analysis focuses on Sicily as a case study, using a scientific approach that aims to highlight the dynamics of the phenomenon and its interaction with public institutions. This exploratory approach aims to delineate the socio-spatial context of informal settlements, with a focus on the relations between migrants and local communities.

The aim is to contribute to a deeper understanding of the dynamics related to migrants' informal settlements in order to develop more effective and appropriate policies. The reading of this study provides a relevant interpretative key to address issues of spatial justice and the 'right to the city' connected to migratory phenomena, especially in the rural and urban contexts of Southern Italy. The research thus fits into a broader framework of analysis of social and spatial dynamics, offering significant contributions to orient future policy and urban planning interventions.

Is Athens changing into a divided city? Growing inequality and its imprint on the city space

E. Tzoumaka

National and Kapodistrian University of Athens, Greece

Corresponding author: E-mail: h.tzoumaka@gmail.com, Tel +30 6972130340

Abstract

The notion of the “divided city” has been employed to describe a wide range of political, economic and socio-cultural antagonisms and conflicts and their spatial manifestations. During its trajectory as the capital city, Athens has endured many crises. In the decades 1930-1940, Athens has been, beyond doubt, a “divided city”. In the afterwar period, socially inclusive housing solutions, relying almost exclusively on private actors, self-promotion and homeownership, guaranteed social cohesion and upwards social mobility.

This paper, taking into consideration significant social and spatial changes from the late 2000s onwards, attempts to trace evidence that could potentially refer to a “divided city”. From an interdisciplinary perspective, it examines new forms of inequality, segregation and exclusion in the metropolitan area of Athens, especially in its central districts, and their impact on Athens’ urban development model and culture, on both the city image and the lived experience and quality of life.

The paper focuses mainly on housing issues, which are a crucial manifestation of inequality and conflict, and attempts to highlight their interweaving with international as well as inherent dynamics. Even in the post-crisis period, housing precariousness of the most vulnerable groups (either native or refugees and asylum seekers), indebtedness of households, the recession of homeownership (especially for younger generations), homelessness and other factors undermine social cohesion and peace. The paper will also address other crucial parameters such as continuing immigrant and refugee inflows, tourists’ and professionals’ mobility, ongoing urban regeneration projects and other strategic plans in progress.

Keywords: Athens; post-crisis; divided city; housing; inequality.

1. INTRODUCTION. THE NOTION OF THE “DIVIDED CITY”

Inequality is inherent to the modern metropolises. As Van Kempen argues “the undivided city is a myth and utopia at the same time” [1]. The notion of the “divided city” has been employed to describe a wide range of political, economic and socio-cultural antagonisms and conflicts and their spatial manifestations. It implies a great variety of definitions, approaches and methodologies; other -related- definitions for cities used in urban studies are “dual”, “fragmented”, “fractal”, “partitioned”, “polarized”, “quartered”, etc. [2]. In the last decades, the literature on divided cities anchors to a broader critique of globalization and the economic restructuring involved. Most theorists agree that, in contemporary urban contexts, new and diverse kinds of conflicts arise and old ones are intensified; more and more cities are becoming polarized, ghettoized and fragmented. Despite the homogenizing trends, the process is complex and varies between different urban contexts, while, in most cases, different kinds of conflict interweave. [2]

The term “divided city” implies the existence of different areas within a city and, most of the time, the dichotomy between prosperous and impoverished areas; a clear connection is also made between a divided society and a divided city. Social polarization and inequality result in spatial segregation [1]

Soja uses the term “metropolarities” in order to describe the intensified socio-economic inequalities inherent in the new urbanization processes; he adds that United Nations reports of the 1990s had

foreseen that “urban poverty will become the most significant and politically explosive problem” of the 21st century [3]. Entrepreneurialism (often in the form of privatization of public spaces) plus intensified immigration (one of the constitutive processes of globalization) contribute to the swelling of the two poles and the squeezing of the middle classes [3]. On the other hand, compared to the past, social movements are organized around more pluralistic axes of inequality formation: class, race, ethnicity, gender, sexuality, age, residential location, immigrant status, housing, environmental justice, cultural identity, and so on [3]. Los Angeles dominates in literature on divided cities as a dystopia brutally divided between “fortified cells” of affluence and “places of terror” where police battle the criminalized poor [4]. As a consequence, cities are becoming places where far from encountering difference, people actively contrive to avoid it; “cities of difference” (as Stevenson describes them) are not places where diversity is celebrated on the ground, but places of watchfulness and suspicion, of enclaves of homogeneity, where mingling with strangers is to be avoided [5].

Most interpretive schemes in urban studies draw from the context of hypersegregated metropolises of the USA, and during the last decades, the dominant paradigm has been the socio-spatial polarization of global/world cities [6]. In Sassen’s model, places, such as London, New York and Tokyo, have emerged as the dominant “command centres” of the complex international urban network of finance, communication and information flows (5). Among other issues, Sassen stresses the denationalizing of urban space and the formation of new claims by transnational actors: global capital and disadvantaged (mostly immigrant) populations; they claim their rights to the city [7]. It is doubtful if Sassen’s model is suitable for metropolises of the periphery. The metropolises of Southern Europe, for example, including Athens, still do not fully comply with the North-European-American urban development model. For this reason, other theorists stress the interaction between global and local dynamics (glocalization) [6]. Nevertheless, neoliberalism tends to implement similar strategies around the world.

The complex nature of such phenomena requires multi-factor analysis, and each city should preferably be treated as an autonomous case study, avoiding reductionism to over-generalized models. This paper will concentrate on Athens as case study and -after a brief overview of the past decades- will examine the most significant social and spatial changes from the late 2000s onwards that contested the city’s urban development model and culture. Focusing mainly on housing patterns and related cultural issues, such as the lived experience of the city and life quality, it attempts to identify if contemporary Athens is gradually “changing” into a “divided city”.

2. LEARNING FROM ATHENS’ HISTORY

2.1. From interwar segregation to afterwar inclusion.

During its trajectory as the capital city, Athens has endured many crises.

In the decades 1930-1940, Athens has been, beyond doubt, a “divided city”, after receiving a large number of refugees from Asia Minor, as well as successive waves of internal migrants. As a consequence, the capital city experienced intense urbanization and urban expansion.

There was a sharp dichotomy between the refugee settlements outside the city limits, on one side, the central districts of the native middle strata and the peripheral “garden cities” (exclusively bourgeois communities), on the other side. Spatial segregation coincided with social and political polarization, and played a significant role -among other crucial factors- in the “Battle of Athens” (December 1944); the “red” (refugee) neighbourhoods remained stigmatized during the first postwar decades. [8]

In the afterwar period, Athens received massive migratory waves from other regions due to political reasons, rural poverty, and search for job opportunities. A substantial part of the housing stock and infrastructure was destroyed during the war. Intensive housing production in postwar Athens, based mainly on private initiative, followed a dual model: apartment building activity through the “antiparochi” (land for flats system) in the older districts, and self-built -often illegal- housing in the

new satellite settlements (with retrospective “legalization”); the authorities have tolerated and even stimulated these practices and many social groups made profits from the whole procedure [8] [10]. Socially inclusive housing solutions and homeownership guaranteed social cohesion and upward social mobility, and helped heal (or just covered) the wounds of the divided society. Although criticized, the state’s policy of “non-policy” functioned effectively against homelessness and social unrest and Athens had low socio-spatial division compared with many other European metropolises [9].

After 1967, the Dictatorship suppressed illegal building in the city periphery, so new working-class populations migrating to Athens were packed in dense inner-city areas, wherever old building stock was available for rent; this resulted in a mixture of social classes in vertically differentiated flats, while traditional working-class families remained fixed in their western area properties. [8], [10] In the late 1970s, the deterioration of the quality of life in the central area resulted in the suburban exodus of the upper and middle classes, which continued and intensified in the following decades.

2.2. The effects of European integration. Globalization trends

For Athens, the 1980s was a transitional period. Joining the European Economic Community was followed by an attempt to integrate European policy directions; at the same time the production of built space remained bound to existing practices and domestic individual interests, creating an almost homogenized urban environment [11].

The 1990s constitute a turning point for the neo-liberal restructuring of Greece to adjust to European and global standards. Athens saw the organization of the 2004 Olympic Games as an opportunity to rebrand and upgrade itself in the global hierarchy of metropolises, acquiring a focal role in the Southeastern Mediterranean. The Olympic transformation of Athens involved an unprecedented urban regeneration and public investment program; an aggressive expansion to the whole Attica region took place, to procure space for infrastructure and venues required [11]; [12]; [13]. The whole planning was implemented under a “state of exception”, ignoring environmental and social consequences, and failing to anticipate the future utilization of the venues [11]. Important flagship projects were also implemented in the centre of Athens, the most emblematic one being the Unification of Archaeological Sites. All projects emphasized the aesthetic upgrading of the city centre and the enhancement of tourist and cultural industries [14].

At the same time consumerism and lifestyle gained ground, transforming the cityscape for the needs of an emerging “creative class”: shopping malls, new museums, new cafés, art spaces and multi-purpose buildings, urban lofts, etc. [15]. During the Games, “clearance” operations took place in the central areas of the city, to improve its image; homeless, drug addicts, and even stray animals, were temporarily removed from sight [16].

Since the 1990s, the liberalization of the housing market and the rapid expansion of mortgaged loans from private banks made access to housing less socially inclusive and set the floor for household indebtedness. During this period the demand for high-standard suburban housing increased [10]. But cheap housing demand rose in parallel due to successive waves of immigrants and refugees of multiple origins. Athens gradually developed into a multi-ethnic metropolis; in 2011, immigrants represented more than 10.5 % of its total population, reaching even 21% in the Municipality of Athens [6].

Immigrants spread in the entire Attica region following job opportunities and were unevenly distributed across space. Significant differences exist amongst immigrants of different nationality and origin; Albanian nationals showed a capacity to spread across large city areas and this contributed to overall low segregation levels, while, on the other hand, immigrants from central and eastern European countries, as well as from Asian and African countries tended to concentrate in smaller communities [17]. Until the outburst of the financial crisis and despite the lack of welfare and integration policies, immigrants and refugees managed to find affordable accommodation in low-rent

apartments in the densely built central districts of the city; this resulted in a socio-spatial mix in the neighborhoods around the city center, vertical segregation in apartment buildings (immigrants on the lower floors, even below ground floor level) and no ghettoization in ethnic enclaves [18]. The inflow of immigrants considerably increased the size of the lower socioeconomic pole [10].

3. ATHENS FROM THE LATE 2000s ONWARD

3.1. The socio-spatial aspects of the crisis

In December 2008, a wave of massive protests burst out for several days in Athens and many other Greek cities, as a consequence of the assassination of teenager Alexandros Grigoropoulos by a policeman. In these protests participated mostly young people (among them many migrants) with no previous experience in demonstrations; mass rallies were followed by the occupation of public buildings, “sieges” of police stations, attacks on banks, but also considerable damage to private property and some looting of shops [19], [20].

This outburst of anger is retrospectively considered as a prelude to the forthcoming crisis. It uncovered various underlying tensions and contradictions, not least in the consumption-led model of urban development [15]. Even in the 1990s and early 2000s, that is during a period of economic growth, 20% of the population was living at risk of poverty and Greece had one of the highest rates of youth unemployment and under-employment in the EU [20]. The young generation, codified as “Generation 700 Euros” before the crisis, would become much poorer in the forthcoming years and more than 400.000 would decide to leave the country.

In the late 2000s, the outbreak of the global financial crisis fiercely affected South European regions and cities in the form of debt crisis and internationally imposed economic adjustment strategies. In Greece, the IMF/EU/ECB loan enforced strict cuts in welfare and social provisions [21]. Greek cities (according to Eurostat 2014 data) faced the highest rate of poverty and social exclusion risk amongst all densely populated areas in the EU, that is 34,1% of their population. Indicatively for the wider metropolitan region of Athens, the proportion of the severely deprived population rose from 9.5% in 2010 to 20.0% in 2015 [22]. A shocking manifestation of extreme poverty was the increasing number of scavengers looking for valuable materials (usually scrap metals) or of people just searching for food in the city’s recycling or garbage bins [23]. The sharp growth of unemployment (27%, and over 50% among the youth) and decrease in salaries and wages (approximately 40%) [15] resulted in housing precariousness and deprivation of the most vulnerable groups (both native and immigrants) and a dramatic increase of homelessness [10]. Many tenants were forced to search for cheaper apartments or share dwellings with other family members or friends, while younger ones returned to their parents’ houses. Over-indebtedness, increased taxation, and a significant increase in housing expenses made homeownership less attractive and not affordable, especially for younger generations [10]. Athens’ urban development model was contested. A special law protected the first residence from liquidation, but the Workers Housing Organization (OEK) and the Public Agency for Planning and Housing (ΔΕΠΙΟΣ) were abolished in 2010 and 2012, according to the memorandum agreements [10]. In 2015 the housing overburden concerned 29% of urban dwellers, and 40% of poor households [22].

The crisis aggravated existing social inequalities and induced social and political polarization and conflict. Its spatial impact was manifest in Athens’ central area, as well as in its more distant neighbourhoods: closed stores, derelict spaces of consumerism that once thrived (e.g. Stadiou and Patisision Street), reduced economic and professional activity. Social mobilizations of various kinds originated “from below”; most prominent was the “movement of the piazzas” (2011), which began with the occupation of Syntagma Square (the focal point for the anti-austerity movement) by “indignant” crowds and spread rapidly to many other Athenian smaller piazzas, town squares in the rest of Greece, and as far as Thessaloniki [24], [21]. Anti-austerity uprisings, demonstrations, and battles with the police severely injured the historical centre: burnt buildings, even historical

landmarks, and an urban environment hostile for its inhabitants due to the extensive use of tear gas. A legacy from the years of the crisis is the disproportionate presence of the police in public spaces [25].

3.2. Immigrant and refugee issues

During the recession, many immigrants were forced to repatriate or relocate, but for the newcomers -mostly undocumented immigrants and refugees- the living conditions were much worse [26]. Refugees and asylum seekers in particular (mostly from Afghanistan, Iraq, and Syria), among them many unaccompanied minors, found themselves in the most extreme deprivation and many deaths were reported during the “refugee crisis” (“a crisis within a crisis”, as reported by the media), which culminated in the years 2015-2016. Informal and spontaneous shelters appeared in the area surrounding the port of Piraeus, in Victoria Square, in Pedion tou Areos public park, and other central areas of the city. A large grassroots movement of solidarity -ordinary citizens alongside a wide spectrum of other agents- were mobilized to deal with the emergency and offered support (shelter, collective kitchens, etc.) [25].

During the multifaced crisis, refugee housing issues were managed by a system of international and local agencies and NGOs. A dual accommodation model has emerged: official refugee camps in the Attica region, on one side, which segregated refugees from residential areas, often in overcrowded conditions, and urban accommodation programs in free shelters or rented appartements (such as the ESTIA program), on the other side, which offered only a temporary (short-term) solution to the problem. [26], [10]. In many districts, there still existed low-rent houses, often low quality and less desired, that allowed refugee accommodation programs to be implemented [10]; these programs had positive effects on local economies and neighbourhoods, as well as on the integration of a part of the refugee population [14].

Another aspect of the crisis was the criminalization of immigrants. Representations of the centre of Athens as a ghetto dangerous for indigenous inhabitants, because of the high concentration of immigrant populations, appeared in the media even before the crisis [27]. Immigrants were accused of further degradation of already neglected and deteriorating central areas of the city, such as Gerani or Plateia Theatrou (near Omonoia Square), where petty delinquency, as well as organized crime, prostitution, illegal trade, protection circuits, and drug dealing thrived.

The hostility against immigrants gradually developed into a “social movement” from 2008 onwards and culminated in performances of racist violence in Ag. Panteleimonas and other central districts with intense presence of immigrants; the neo-Nazi organization named Golden Dawn, which even succeeded to enter the Greek Parliament in 2012, was the basic but not the only organizer of such violent acts [27], [28].

Police operations were organized to “sanitize” certain areas and buildings and reoccupy public space. For example, the “Xenius Zeus” operation (2012) evacuated several private or public buildings in the city centre, where immigrants -mostly young men from North Africa and the Middle East- found an inexpensive, although crowded and unsanitary, shelter. Some of these buildings were informally hired, others were squatted by their residents (with the help of NGOs) and transformed into informal community centers [26]. The “ghetto discourse” was intertwined with the inner-city revitalization agenda; the economic crisis together with the criminality discourse stigmatized neighbourhoods and created a very fertile ground for real-estate speculation and changing of ownership [16].

3.3. Restructuring urban space through neoliberal strategies

In the 2010s the centre of Athens underwent a double crisis: on one side the spatial manifestations of the recession and on the other side the consequences of decentralization of important activities and functions due to the great infrastructure works (Spata airport, suburban rail, new highways) constructed on the occasion of the Olympic Games [11].

Proceedings

Structural readjustments towards neoliberal practices were intensified during and in the post-crisis era. During the period 2011-2014, based on the first memorandum Public Properties Company SA (ΕΤΑΔ ΑΕ) and the Hellenic Republic Asset Development Fund (ΤΑΙΠΕΔ) were established to promote the privatization of the Greek State's property [11]. Large and privileged tracts of land along the urban coasts of Piraeus, Hellenico, and Vouliagmeni (the so-called Athens Riviera) were sold to investors at very favorable terms [24]. The "Ellinikon" Project, in the place of the former airport, the largest urban development project in the history of the Greek State has raised severe criticism [11]. Several plans had been developed, formally announced and then abandoned in the past. According to the Lamda Development plan the site will be transformed into a new town within the city, with 25,000 residents and 20,000 workers and visitors per day; it will include a park, luxury homes, hotels, a casino, a marina, shops, offices, and, among others, towers up to 200 meters high [29].

Another major plan in progress (of public character but with financial support and guidelines from the Stavros Niarchos Foundation) is the Faliron Bay Metropolitan Park. It aims to restore the communication of the urban tissue with the seafront, and is supposed to provide generous public space, including cultural, educational, sporting and recreational facilities [11].

Such major projects are called upon to find the balance between global competitiveness and local sustainability and identity [30]. They raise issues related to the use of the public space and the degree of its appropriation. For example, will these public spaces on the coast be "open", to whom, and under what conditions? [30] Will the redeveloped area be an organic part of the city or a playground for affluent Greeks and foreigners?

Another project intensely discussed in the period 2011-2014 was "Rethink Athens", an attempt to revitalize centrality through the pedestrianization of the central Athens boulevard, Panepistimiou. The project was criticized by a large part of the scientific world and was finally suspended because the EU denied financial support [11], but revived in another form in 2020 as "The Great Walk of Athens" (it also didn't work out as planned and marketed). Inner-city and neighbourhood regeneration programs, in general, focused mainly on pedestrianization, redesigning and cultural projects neglecting, on the other hand, social initiatives, though in a context of increasing poverty and socio-economic polarisation [16].

Another tool of the neoliberal agenda aiming to regenerate the central area of Athens is gentrification (the "dirty word", according to Smith [31]). Alexandri argues that gentrification in crisis-stricken Mediterranean cities is driven by free-market housing policies, accompanied by new entertainment and nightlife uses, alternative art and cultural projects, plus tighter control of the public space [32]. In Athens, suitable for gentrification were areas where the system of antiparochi was not extensively developed, mostly enclaves of the working class (Thissio, Psiri, Gazi, Petralona, Metaxourgio). In Metaxourgio gentrification began in 1995, and operated gradually and softly, based on private initiative, and not fiercely, by the state or by corporate capital, banks, and investors [33]. During the crisis, the return of the middle classes to the collapsing city centre became a major goal among dominant political circles. Key to the success of urban intervention in degraded areas is the creation of a safe environment; police surveillance contributed to the displacement of "unwelcome" groups (mostly undocumented immigrants), while, at the same time, poorer households were excluded from incentives given to gentrifiers [32].

3.4. New challenges in the aftermath of the crisis

In the late 2010s, Athens gradually turned into an all-year destination for tourists and, during the pandemic, into a preferable residence for digital nomads; these new prospects for profit attracted the interest of foreign investors and real estate funds [10]. A combination of gentrification and touristification concentrated housing property in the hands of speculative agents, reducing the affordable stock mainly in the city centre. The majority of new transactions involved foreign buyers, many of them benefiting from the Golden Visa Scheme, one of the cheapest in Europe. The

devaluated housing stock of the city (even lower floor apartments) is being renovated to be used by middle-class tourists and gentrifiers. Many investors buy whole buildings and gain profit from the rent gaps. The short-term rental sector (via platforms such as Airbnb) has disproportionately grown, affects rents and prices (even in peripheral areas of the city), and causes displacement of lower-income groups. [10], [9]. The most affected areas are the Historical/Commercial Centre, Koukaki, Exarchia, and Metz.

As a consequence, access to affordable housing is getting more and more difficult for tenants, especially for newcomers such as students or refugees. Extremely high rents and housing prices go together with inflation, energy crisis and increasing cost of living, while salaries and wages remain extremely low compared to European standards. Most affected are younger generations, who have reduced access to mortgage lending and present declining home-ownership rates; this imbalance between generations is also linked to the country's demographic decline [14]. Furthermore, urban accommodation programs for refugees are no more available. The problem is not exclusively Greek or Athenian. Madden and Marcuse suggest that "housing is under attack" everywhere, especially after the global economic meltdown of 2008, and it is "caught within a number of simultaneous social conflicts"; the most immediate is the conflict between housing as lived, social space and housing as an instrument for profitmaking [34]. Affordable housing has become a major concern in EU too.

The prolonged confinement and other governmental measures during the COVID-19 pandemic have deepened systemic inequality, segregation and social, spatial and environmental injustice in the city and have imposed unprecedented restrictions on people's democratic rights [35]. Housing inequality, in particular, became more evident as family members were obliged to work, attend school lessons on line, and perform household simultaneously, sometimes in very limited space and with poor digital equipment and skills. The pandemic affected the most vulnerable social groups, aggravated psychological and other health problems, contested human relations and bonds, and encouraged abusive behaviour; all these effects seem irreversible as we see in everyday incidents of violence against women, among teenagers, etc.

In prior periods the popular strata found solutions to ameliorate their housing, living and working conditions. Efforts to regulate housing policies on a long-term basis were absent until the present, but current socio-spatial challenges cannot be addressed either with the policies of the past or with emergency haphazard measures [9]. The policy of "non-policy" is no more relevant; on the contrary, there is a growing need for decisive policies, that take into consideration the society, not only the economy of the city. There are various suggestions for reclaiming affordable habitat. State-procured social housing for rent is a well-known practice in many European countries, but absent in Greece today. Cooperative housing and collective ownership models have proved effective in other European countries (there are already such initiatives in Greece). Most recently the state has implied measures to control the short-term rental sector and further restrictions are discussed. Programs, such as "Renovate and rent", intend to encourage house owners to renovate their houses for long-term rental. Special programs are also designed to facilitate the accommodation or homeownership of young couples. Low incomes and the constantly rising cost of living undermine such initiatives.

Intensive construction activity both in central Athens and the suburbs might give the false impression that the city has recovered from the crisis. Old hotels are restored, office and commercial buildings (some of them abandoned for years) are being transformed into hotels or luxury residences, devitalized spaces return to urban life, and commercial uses connected to tourism (restaurants, cafés, bars, mini-markets) proliferate. On the other side, professionals, artisans and small-scale trade are displaced from their traditional spots; all these mixed uses and activities that contribute to the lively and attractive character of the city centre become gradually expulsed. Consequently, the identity of many central areas is contested and risks being monopolized by tourist and leisure activities; at the same time, in many neighbourhoods favoured by the short-term rental sector the life quality of the inhabitants progressively degenerates.

The new dynamics have not yet crystallized, but a most important issue is that the emerging urban development model, based almost entirely on tourism, may prove less resilient to future crises (e.g. climate crisis, a new pandemic, wars and new refugee flows).

4. CONCLUSION

21st-century Athens is decentralized and at the same time re-urbanized. The old division between East and West Athens, with the central area of the city functioning as a point of encounter, seems to be gradually replaced by multi-fractured urbanism, where different social groups reside and move in different areas of the city, without meeting each other anytime and anywhere [11]. The suburbs seem more and more disconnected from the centre; in the Southern burbs, in particular, a new city of affluence (in public discourse compared to Dubai) is developing, that has little reference to the history and culture of the Greek capital. On the other hand, central Athens is being touristified and -simultaneously- gentrified, which means that most users of public space are visitors.

The current image of Athens is marked by sharp contrasts: luxury new hotels and renovated apartment buildings stand in proximity to ruins from the crisis era, and euphoric tourists stroll beside homeless and drug addicts. Athens does not comply with the socially and spatially polarized global city model as this was depicted by S. Sassen, because it lacks a substantial upper social pole which comprises members of the international corporate elite [16]; it might also be exaggerated to describe it as a “revanchist city” [31]. However, Athens is experiencing important socioeconomic inequalities and marginalized populations, among them poorly integrated migrants [18]. Additionally, the rapid touristification of the city and the uncontrolled real-estate market reduce the margins for the implementation of socially just urban policies and produce further inequalities and exclusion [14]. Sharp inequalities erode the social fabric and may produce social conflict.

Considering all the above issues, we conclude that Athens is potentially developing into a “divided” city unless decisive long-term policies are implemented to fight social inequalities and injustice, as well as their spatial manifestations.

Extended abstract

In 1948, the year of the Nakba, more than 800,000¹ Palestinians were displaced from their villages to the West Bank and Gaza and other neighbouring Arab countries. Many refugees settled in the Jordan valley, staying as close as possible to their hometowns in hopes of returning back to their villages. The year 1967 yet marked another Nakba for the refugees in the Jordan Valley – home to almost three hundred thousand Palestinians at the time, of which a large number was Nakba refugees – Israel occupied the rest of the West Bank and Gaza, and forced thousands of Palestinian refugees in the Jordan Valley eastward toward Jordan. The Israeli occupation aimed to have as few Palestinians as possible in the region. Many communities were depopulated and destroyed in preparation of the Israeli settlement expansion and the exploitation of the agricultural lands and the natural resources. This paper explores the emergence of these refugee camps and other communities/new ‘villages’ that were intended for settling Palestinian refugees while renouncing their right of return. Palestinian refugees were forced to reconstruct the tent into a more durable structure, and reshape the spaces around them to accommodate their perpetual needs - their attempts at peacemaking and ensuring their unforgotten citizenship. It sheds the light on the architectural dilemma of temporariness that is expressed in the permanent status of refuge and their life in limbo. It will further explore the emergence of Aqabet Jaber refugee camp, the Arab Development Society and Marj Na’jeh as case studies. Aqabet Jaber was a desert like area lacking adequate infrastructure for any human settlement thus the living conditions were dire. The Arab Development Society was a Modern scheme developed by a Palestinian philanthropist as a model village prior to 1948 in order to assist the farmers and strengthen their presence and resilience, and was later inhabited by orphaned refugees. Marj Na’jeh was built as a permanent community for Palestinian refugees in the 1950’s, and the refugees were allowed to cultivate the land and settle permanently. They represent the urban and architectural experimentation in the Jordan Valley after 1948 and the unformulated urbanism that resulted at the time, 1967 and the current conditions of these structures.

Keywords: *refugee camps, permanence, temporality, architecture, urban development, Arab Development society, Marj Na’je, Aqabet Jaber*

Extended abstract

This research investigates the emerging architectural configurations of Jerusalem northern and eastern villages, and their role in transforming these villages into transients' zones that serve the change of the demographic balance of Jerusalem city from one hand, and the creation of an in-between transient zones on the other hand. The research emphasizes the power of architecture in the superimposition of new political realities and its ability of transforming communities' life's. This may take place by shedding the lights on the emerging architectural mutations of these villages, caused by planning policies and tools of spatial segregation implementation, and the emergence of new exceptional zones in these areas. The research suggests that these transformations lack the ability to offer a sustainable social life, wither physical environment, for both nature and the emerging community. The physical transformation of these areas, and the replacement of the social groups there, have transformed the zone into a transient urbanity.

Due to the implementation of "Greater Jerusalem 2020" plan, a wave of migration takes place, where many of the east Jerusalem Palestinian inhabitants, under the impact of economic circumstances and the planning policies restrictions, are forced to move from the city central zones to outskirt villages. These villages, which still considered as a part of the Greater Jerusalem borders, have been segregated from Jerusalem central parts, by the implementation of the spatial forced tools, the segregation wall and the checkpoints. Due the dramatic rise of the population densities in these areas, the limited ability for urban expansion, and the absence of planning policies and architectural standards, a rabid transformation in the physical environment took place. The formerly rural environment has been transformed into new urban settlements typical for very high densities, vertical and huge mass-buildings inward/ introvert architectural topologies, the superimposition of a continues 'stone carpet', the absence of green and open spaces, and the emergence of mixed land uses. The transformation of the area's physical character has attracted new social groups and causing a dramatic change of its social identit

The research aims at studying this phenomenon. First it emphasizes the reasons that led to the transformation of these zones; it unfolds the role of architecture in shifting the area from a rural to a transient urbanity. It analyses the characteristics of the emerging architecture and how it functions as a tool of exclusion. Two villages are taken as case studies: Anata (located to the east of Jerusalem) and Kofur Agab (located to the north of Jerusalem).

Keywords: *transient urbanity; architecture mutations; social groups; spatial composition; Jerusalem*
