A. THE ORGANISING INSTITUTIONS

The conference is organised by

1. the **Research Unit of Urban Morphology and Design**, Directed by Dr. Aspa Gospodini, Professor of Urban Planning & Design, Department of Planning & Regional Development, **University of Thessaly, Volos, Greece.**

In collaboration with:

- **Department of Mediterranean Studies, University of The Aegean, Rhodes Island, Greece.**

Under the aegis of

- **IsoCarp (International Society of City and Regional Planners)**

B. THE ORGANISING COMMITTEE

B1. Academic staff

1. **Prof. Aspa Gospodini**, Professor of ‘Urban Planning & Design’, Director of the MSc Course ‘Urban Regeneration, Urban Development, & Real Estate’, Director of the Lab of Urban Morphology & Design, Department of Planning & Regional Development, University of Thessaly, Volos, Greece, Chair of the Organising Committee and the International Scientific Board;
2. **Prof. George Petrakos**, former Rector of University of Thessaly, Professor of Regional Planning, Department of Planning & Regional Development, University of Thessaly, Volos, Greece;
3. **Prof. Yannis Seimenis**, Professor of ‘Modern Mediterranean History’, Department of Mediterranean Studies, Vice Rector of Finance, University of The Aegean, Rhodes, Greece;
4. **Prof. Sotirios Dalis**, Associate Professor in ‘International Relations – International Politics and European Integration’, Head of the Department of Mediterranean Studies, University of The Aegean, Rhodes, Greece;
5. **Prof. Dimitris Kalergis**, Assistant Professor in ‘Architectural & Urban Design’, Department of Planning & Regional Development, University of Thessaly, Volos, Greece;
6. **Prof. Nikos Samaras**, Lecturer in ‘Urban Renewal in Historical centres and building complexes’, Department of Planning & Regional Development, University of Thessaly, Volos, Greece.

B2. The conference Secretariat

7. **Ms. Anna-Roskagia Vouza**, Dipl. Planner, MSc in Urban Regeneration and Development, PhD Candidate in Urban Planning and Design, Department of Planning & Regional Development, University of Thessaly, Officer of the conference secretariat;
8. **Ms. Irene-Maria Kachrila**, Dipl. Planner, MSc in Urban Regeneration, Urban Development & Real Estate, PhD Candidate in Urban Planning and Design, Department of Planning & Regional Development, University of Thessaly, Officer of the conference secretariat;
9. **Ms. Maria Akrivopoulou**, Dipl. Planner, Department of Planning & Regional Development, University of Thessaly, Officer of the conference secretariat;
10. **Ms. Anna Vasilakou**, Dipl. Planner, Department of Planning & Regional Development, University of Thessaly, Officer of the conference secretariat;
11. **Ms. Marina Oikonomou**, Dipl. In Economics, MSc in Finance, Cash Flow Officer, European Investment Fund, Luxembourg, public relations officer for European Institutions;
12. **Mrs. Effie Karanikola**, Dipl. Psychologist, Dipl. Planner, PhD Candidate in Urban Planning, Department of Planning & Regional Development, University of Thessaly, Secretariat Assistant;
13. **Mr. Isidoros Papas**, Dipl. In Chemistry, PhD Candidate in Public Administration, Chief Officer of Administration, Department of Planning & Regional Development, University of Thessaly, Secretariat Assistant.

B3. The Conference Informational Technical Support

14. **Dr. Georgios Giannikis**, Computer Scientist;
15. **Mr. Aggouras Panagiotis**, Computer Scientist, University of The Aegean, Rhodes, Greece;
16. **Mr. Dimitris Oikonomou**, Undergraduate Student, Department of Electrical Engineering, University of Thessaly, Greece, assistant in computer services at the conference venue.

B4. The Conference Financial Management

17. **Mr. Nikos Oikonomou**, Dipl. In Economics, MSc in Economics, Director of Property Management and Development Company, University of Thessaly, Financial Project Manager and Accounting Manager of the conference.

PREFACE

The series of international conferences on *CHANGING CITIES* aspires to bring together urban planners and designers, architects, landscape designers, urban geographers and historians, urban economists, urban sociologists, and urban policy makers, and investigate new challenges concerning cities and their future. The conference aims at becoming an international forum of transaction of ideas on cities' transitions. We have so far organised six conferences, with peer-reviewed Proceedings, taken place always in June, in venues with unique urban and natural landscape, built heritage and place identity.

- *CHANGING CITIES I: Spatial, Morphological, formal, and socioeconomic dimensions, 18-21 June 2013, Skiathos Island, Greece.*
- *CHANGING CITIES II: Spatial, Design, Landscape and socioeconomic dimensions, 22-26 June 2015, Porto Heli, Peloponnese, Greece.*
- *CHANGING CITIES III: Spatial, Design, Landscape and socioeconomic dimensions, 26-30 June 2017, Syros Island, Greece.*
- *CHANGING CITIES IV: Spatial, Design, Landscape and socioeconomic dimensions, 23-28 June 2019, Chania, Crete Island, Greece.*
- *CHANGING CITIES V: Spatial, Design, Landscape, Heritage and socioeconomic dimensions, 20-25 June 2022, Corfu Island, Greece.*
- *CHANGING CITIES VI: Spatial, Design, Landscape, Heritage and socioeconomic dimensions, 24-28 June 2024, Rhodes Island, Greece.*

All Changing Cities conferences have been welcomed by the academic community worldwide, usually attracting about 300 presenters from many countries - Greece and Europe, USA and Canada, Latin America, Middle East and North Africa, Asia, Far East, and Oceania. On this basis, we believe the 6th Changing Cities conference will also be a successful academic event.

The 6th Changing Cities conference puts an emphasis on the transformations of cities related to climate crisis; the main theme is '*Climate Crisis. Cities' transitions towards smart & green development*'. Cities are on the front line of climate change. First, cities are the main contributors to climate change due to concentration of population and various human activities such as industrial activities, people's everyday mobility and transportation of goods, etc. – all of which increase the flow of heat-trapping greenhouse gases into the atmosphere. Second, the impacts of climate crisis on cities are dramatic; Cities need to cope with the unprecedented challenges of climate crisis such as wild wood fires, floods, extreme weather conditions such as heat waves, heavy rainstorms, land drought, etc. Thus, cities as 'guilty' constituents to climate change, must also become vital protagonists in mitigating climate crisis. In this framework, the 6th Changing Cities conference welcomes the academic discussions on specific measures and policies of green and smart development of cities.

This year, about **350 abstracts have been submitted** from universities, research institutes, governmental organisations, and Ministries of environment from all over the world. In the conference, **will finally be presented 265 papers**. Among them, **54% of the papers have been authored by foreign academics** while **46% by Greek academics**- indicating the international character of the conference. For the first time the 6th Changing Cities Conference includes about 60 remote presentations organised in last day of the Conference mainly involving young researchers, PhD candidates, postgraduate students who faced difficulties to cover traveling expenses. The Conference Program includes **20 special sessions** that have been pre-organised by distinguished researchers enriching the academic discussion on portraying the impacts of climate crisis on cities and

highlighting green and smart urban actions and policies to mitigate the negative effects of climate crisis.

I would like first to thank the Organising Committee, the keynote speakers, and the members of the international scientific board who supported enthusiastically the academic organization of this conference – and especially those colleagues who have also pre-organized special sessions in this conference.

I would like to show our gratitude to all the academic supporters – **University of Thessaly, University of The Aegean**, and **IsoCarp** (International Society of City and Regional Planners).

I would also like to express our gratitude to the sponsors of this conference - namely **The Green Fund** politically supervised by **the Greek Ministry of Environment and Energy; The Secretary General of the Aegean and Island Policy in The Greek Ministry of Maritime Affairs and Insular Policy**; and **the elected Regional Authority of Thessaly**.

Chair of the Organising Committee & the international scientific board
of the series of Changing Cities Conferences

TABLE of CONTENTS

KEYNOTES SPEECHES	1
Justice, Design and the City	3
<i>Prof. Anastasia Loukaitou-Sideris</i>	
Innovations and challenges in contemporary global urban geographies: Defining sustainable pathways amid climate change, local economic stability and political cultural crises.	4
<i>Prof. Pietro Elisei</i>	
The landscape project: analysis and critical reading	5
<i>Prof. Em. Achille Maria Ippolito</i>	
Urban Flexibility and Dynamicity to achieve multiadaptive and multiresilient public spaces	6
<i>Ass. Prof. Marichela Sepe</i>	
Greenery in the Historic Environment. A Critical Future	7
<i>Prof. Dimitra Diana Babalis</i>	
Combining creativity and circular economy towards the regeneration of the urban ecosystem and the natural environment	8
<i>Prof. Em. Sophia Avgerinou Kolonia</i>	
Legends of possible flood destruction, contemporary waterscape resilience and political sustainability	10
<i>Prof. Em. Konstantinos Moraitis</i>	
Regional and local dimensions of Maritime Spatial Planning.	20
<i>Prof. Stella Sofia Kyvelou</i>	
Goals and Sub-Goals of the United Nations for the Sustainable Development of Cities	21
<i>Prof. Roido Mitoula</i>	
Designs that able disableism	22
<i>Prof. Alcestis P. Rodi</i>	
Photography as a critical thinking and living archive of changing cities and landscape.	23
<i>Prof. Dimitris Polychronopoulos</i>	
The New European Bauhaus: Heritage, Landform and Climate Change	24
<i>Ass. Prof. Riva Lava</i>	
Exploring character and physiognomy of vernacular settlements as a means of preserving cultural heritage through sensory identity	25
<i>Ass. Prof. Maro Sinou</i>	

Proceedings

of the International Conference on **Changing Cities VI:**
Spatial, Design, Landscape, Heritage & Socio-economic Dimensions
Rhodes Island, Greece • June 24-28, 2024
ISSN: 2654-0460

The post-2027 EU Cohesion Policy: Thoughts and suggestions	36
<i>Prof. D. Kallioras</i>	
PRE-ORGANIZED SPECIAL SESSIONS	38
FLEXIBLE, RESILIENT AND PROXIMITY PUBLIC SPACES FOR DYNAMIC URBAN REGENERATION	39
<i>Organized and chaired by Prof. Sepe Marichela</i>	
Flexible and adaptable places: a case of redevelopment plan based on long-term sustainability	41
<i>M. Sepe</i>	
Attractive and Liveable Public Spaces for Communities.	50
<i>M. Sepe</i>	
The Absence of Public Space Project in the Massive Production of New Settlements of the Program My House My Life in Brazilian Cities	60
<i>M. Mareggi</i>	
Safety and Adaptation for Urban Public Spaces	70
<i>F. Cicalese , M. Grimaldi , I. Fasolino</i>	
Valletta – The fine line between urban vitality and liveability	79
<i>A. Zammit</i>	
Activators. Complex Buildings as Public Space Generators	91
<i>E. Margione</i>	
Nature Based Solutions at Landscape Scale to Reduce Urban Hydraulic Hazard	101
<i>P. Balena , A. Leone , F. Miccoli</i>	
The Repercussions of the COVID-19 Pandemics and the Path Towards Urban Regeneration in Portuguese Cities.	111
<i>I. Madaleno</i>	
Enhancing Connectivity by Reducing Barriers between Plots: A Perspective from High Line Park in China's High-Density Urban Centres	119
<i>H. Gu , S. Mozūriūnaitė</i>	
Re-read the urban complexity into planning tools through the definition of urban proximity systems. The case study of Mantova.	120
<i>M. Borini</i>	
Unlocking the Potential of Placemaking. How to enhance citizens' engagement to analyse, design and implement urban spaces.	130
<i>S. Campioli</i>	
Commerce and public space: questioning roles, meanings, risks, and potentialities.	139
<i>A. Bruzzese</i>	

Proceedings

D. Papanikolaou

COMPONENTS OF URBAN DESIGN TOWARDS A SUSTAINABLE MEDITERRANEAN CITY	472
<i>Organized and chaired by Assoc. Prof. Maro Sinou</i>	
The water element in metropolises: the case of «Antonis Tritsis» Metropolitan Park	474
<i>K. Timotheou , Dr. M. Sinou</i>	
A multi-criteria evaluation method for accessing the developmental potential of Thermal Springs in Macedonia and Thrace	485
<i>E. Tsakiri , S. Yiannoudes , A. Psilopoulos , G. Touliatou , E. Mouzakitou</i>	
Elements of urban design to ameliorate urban heat island. The Case of Nikea, Piraeus, Greece.	498
<i>E. Tousi , A.Mela , A. Tseliou , E.Theofili , G. Varelidis</i>	
Presentation and Analysis of Accessible Cases that Contribute to the Development of the Greek Tourism Industry	508
<i>M. Poli , K. Vasilakakis , K. Malagas</i>	
Urban Cultures & Public Open Spaces - Digital Sound Installation as a Form of Public Art	519
<i>G. Touliatou</i>	
The sustainable reconstruction and new use of the old University building in the city of Ioannina	528
<i>G. Cheirchanteri , S. Tzortzi</i>	
Designing an urban open-space sound museum at the city of Ermoupolis, Syros	538
<i>K. Balourdou , S. Kyvelou , A. Tsaligopoulos , N. Chiotinis , N. Bobolos</i>	
Identification of spatial, social and environmental parameters for the design of pocket parks	548
<i>S. Kazamia , M. Sinou , N. Koyrniatis</i>	
BIM applications in design quality following project delivery	561
<i>O. Venetsianou</i>	
In Quest of Sustainable Tourism Strategies in Cultural Heritage Environments: two cases in Rhodes	569
<i>M. Moira , Ch. Zervou , A. Salahouri , M. Sinou</i>	
Palimpsest spatial narratives as an imprint of interactions between individual and collective memory	581
<i>L. Martha , M. Vounatsou , P. Panos</i>	
Creating Livable and Inclusive Urban Voids through Sensory Mapping: Addressing new Public Realm in Cities	590
<i>R. Perakaki , Dr. M. Sinou</i>	
Biomaterials in architecture and the principles of biomimicry, as tools for the transition to a circular economy.	600
<i>C. Dikou , N. Kourniatis</i>	
DESIGN FOR CLIMATE ADAPTATION IN URBAN PUBLIC SPACES: FROM ASSESSMENT TO INTEGRATED INTERVENTION	611

Organized and chaired by Assoc. Prof. Thanos Pagonis

Design for Climate Adaptation of Public Spaces in the context of Southeastern Mediterranean Urbanism	613
<i>A. Pagonis</i>	
City making in Times of Transition – Sustainable, resilient, inclusive and attractive public spaces as stepping stone for a future-proof built environment.	624
<i>H. de Boer , R. Cavallo</i>	
Navigating Transition: 20th-century Dutch Housing Neighborhoods and the New European Bauhaus.	637
<i>R. Cavallo</i>	
Data-driven classification of Urban Environments for Customized Assessments and Decision-Making	638
<i>Š. Verovšek , A. Halužan Vasle , M. Moškon</i>	
NEB Policies' Ecosystem in the perspective of the architectural design. Postindustrial urban regeneration in the Milanese metropolitan contexts	649
<i>F. Berlingieri , M. Bovati , E. Corradi , C. Cozza , I. Valente</i>	
Milan. A hotbed of experimentation in the transformation of post-industrial areas.	659
<i>G. Sempredon , A. Tognon</i>	
Post socialist suburban Urbanism – focus on public spaces' transitions	671
<i>K. Solarek , J. Zdunek-Wielgotaska</i>	
ECOLOGY & EKISTICS: PAST, PRESENT AND FUTURE	673
<i>Organized and chaired by Assoc. Prof. Nikolaos Patsavos</i>	
Ecology & Ekistics: Past, Present and Future	675
<i>N. Patsavos</i>	
Planning the Human Habitat – The Foundation of Contemporary Ecological Urbanism on C.A. Doxiadis' Ekistics	676
<i>V. Bekiaridis</i>	
The historiography of a Biological or Ecological urbanism?	677
<i>V. Tsesmetzis</i>	
Nature-Driven Sustainable Evolution of Settlements for Systemic Integration with the Environment	685
<i>P. N. Papagianni. , Y. Zavoleas , G. Smyris</i>	
Application of Ekistics' principles on architectural education (theoretical and compositional courses), focused on the typology of housing	695
<i>C. Nikoloutsou , M. Apostolou , G. Siapati</i>	
Doxiadis' Ekistics as a legacy on Arab urbanism and beyond; The Softscapes and Hardscapes of Modernity	709
<i>A. Kyriazis</i>	
Units, Elements and Doxiadis' Ekistics Disciplines through G.I.S. data and analysis	710

KEYNOTES SPEECHES

**CHANGING
CITIES**

Changing Cities VI, Rhodes, 24 - 28 June 2024

Justice, Design and the City

Prof. Anastasia Loukaitou-Sideris

Dean of the Luskin School of Public Affairs at UCLA
University of California, USA

E-mail: sideris@ucla.edu, sideris@g.ucla.edu

Abstract

Cities are sites of inclusion and exclusion. But few of the scholars who write about justice in the city consider the practices and processes of urban design. At the same time, discourses on urban design often neglect concerns about justice or the possibility of spatial interventions to change or create more just urban processes and outcomes. And yet, urban design interventions can have direct and important implications about justice in the city. This keynote talk will delineate the concepts of urban design for justice, the public city, inclusive urbanism, and design for difference, which compose the cornerstones of the recently published book *Just Urban Design* (MIT Press: 2022). The primary premise of the talk is that urban design can and must play an important and constructive role in the development of cities as a public good.

The talk will ground the theoretical discussion in empirical work by the author that shows how the unjust urban design of Los Angeles inner-city neighborhoods denies older inner-city residents some basic rights to the city. Walking in the company of older adults – mostly low-income immigrants – shows that their right to the city is severely compromised by dangerous and age-unfriendly sidewalks and public spaces. Still, certain urban design interventions can offer comfort and reduce the fears that many older adults feel when travelling the streets and sidewalks of their underprivileged neighborhoods.

Innovations and challenges in contemporary global urban geographies: Defining sustainable pathways amid climate change, local economic stability and political cultural crises.

Prof. Pietro Elisei

President of IsoCarp (International Society of City and Regional Planners)

International expert in urban and territorial planning

URBASOFIA, Director and founder

Email: dr.pietro.elisei@gmail.com

Abstract

Cities face many new challenges in an era of rapid urban growth, climate change and rapidly shifting social and economic conditions. This keynote will be an exploration of the key role of innovative urban planning in addressing these issues. It will be a discussion on how cities can create sustainable strategies that balance environmental needs, economic stability and cultural vibrancy.

The talk will present the latest methods and tools in urban planning that enhance resilience, adaptability and viable development. These include the use of green infrastructure, promoting the circular economy, encouraging community participation and the use of digital technologies. These practical solutions are being used by cities around the world to address current urban challenges.

The keynote will also look at the importance of stabilising local economies in uncertain times and the role of urban planning in the management of political and cultural crises. We will highlight how cultural heritage can boost the local economy, especially in small and medium sized cities. This can help to counteract urban decline. By combining theory and real-world examples, this lecture aims to provide urban planners and policy makers with the knowledge and tools they need to create sustainable, inclusive and dynamic cities.

The landscape project: analysis and critical reading

Prof. Em. Achille Maria Ippolito

A.S.B. - Cultural Association "architect Simonetta Bastelli", Italy
Sapienza Università di Roma

E-mail: achille.ippolito@gmail.com

Abstract

Always remembering Lucien Kroll's synthesis: "everything is landscape", consolidated by the European Landscape Convention, we must realize that the landscape project has a decisive role in the management of the territory and therefore within the theme of the climate crisis.

The projects, involving all the different disciplines interested and specifically useful, must be developed with a careful, analytical and future-oriented strategy. It is necessary to overcome the extemporaneousness of everyday life with long-term objectives, but visible in the various stages that follow one another.

The landscape project, even in its unity, must be able to support emergencies, natural events and catastrophes, fragility and climate change.

In the urban landscape, the value of public space is always a priority.

The landscape project therefore needs multiple disciplinary approaches, which, overcoming their respective boundaries, collaborate as a whole.

Since the beginning of this century, many things have already matured as the conditions and methods of creating landscapes have changed, expanding with new opportunities, known and debated, including issues relating to the climate, placing in first place the relationship between architecture and nature, with its implications in the urban landscape, placing the relationship between man and nature at the basis of the purposes of the landscape project.

In the critical rereading it is necessary to analyze carefully and methodically, in a contemporary scenario where cities are in crisis with an evident transformation.

The landscape project must not be included exclusively in planning, but its positive work can be included in individual specific themes, even small ones. We remember the interventions in urban public spaces and all the issues connected to parks.

The first discussion to open, in a scientific debate, critically rereading the projects and achievements, concerns abandoned areas, with urban redevelopment projects, also for the relationships between architecture and nature.

The most significant and emblematic cases may be: the construction on the piers of the port of Amsterdam with the new residential districts of the island of Java, Borneo and Sporenburg, with a waterfront that marks a new urban landscape; the Bo01 district, on a completely eco-sustainable basis, built in a disused port area, in Malmö, Sweden, with the motto "beautiful and sustainable", which arises from the European exhibition on living, held in 2001, entitled "The city of tomorrow for an ecologically sustainable information society in an era of well-being"; Le Albere, created in Trento, in 2013.

Keywords: *Landscape Project, Climate Change*, examples, critical reading

Urban Flexibility and Dynamicity to achieve multiadaptive and multiresilient public spaces

Ass. Prof. Marichela Sepe

Department of Civil, Constructional and Environmental Engineering
Sapienza Università di Roma; ISMED-CNR

E-mail: marichela.sepe@uniroma1.it

Abstract

In current territories, it is increasingly happening that crises of different types occur simultaneously. The coexistence of more than one risk determines further difficulties in resolving because commonly, since the risks are sudden and unexpected, we tend to treat the last risk more carefully, leaving out the previous one even if it is equally important, and very often without taking into account the positive or negative example of the event that previously occurred in another place, also for reasons due to different or non-integrated regional legislation (Sepe, 2023; Bohland et al., 2019)

Traditional approaches to spatial planning often do not take adaptive behaviour as a starting point, believing that urban interventions can be decided on the basis of facts and estimates that are available at the time of decision-making. This form of planning is based on a static perspective, which assumes a transformation according to predictable patterns, whose starting points are "actual, desired and potential" (De Roo, Porter, 2007).

While it is true that unforeseen events occur suddenly, it is also true that adaptive and dynamic planning can better support the creation of a new equilibrium through the identification of flexible spaces (Davoudi et al., 2013; Zolli, Healey, 2012)

Accordingly, flexible planning makes possible to use local peculiarities as a starting point for the redevelopment project, resulting in lower investment costs, shorter construction times and greater support from stakeholders. The various design possibilities that can be realized with respect to the existing situation are identified through quantitative and qualitative analyses, of which the latter determine the implementation of flexible planning (De Roo, Porter, 2007).

However, most of the methodologies used to analyse areas affected by different risks are aimed at focusing in particular on seismic risks without considering those relating to intangible aspects linked to the identity of the places or aspects related to urban health and liveability. And, more in general, in relation to design aspects, urban methodologies do not consider all the results of the analyses, maybe for the difficulty deriving from translate the complexity of collected data in project interventions.

Starting from these premises, this study – carried out in the framework of the research project PRIN 2020 SUMMA within the ISMed-CNR Unit (with the author's responsibility) and the relative agreement between Sapienza Università di Roma and ISMed-CNR - is devoted to define multiresilience and multiadaptation concepts, illustrate an analysis and design methodology of the urban space to be applied to areas characterized by multiple risks which require integrated and flexible interventions and define guide-lines for post-event reconstruction/regeneration/enhancement strategies.

Greenery in the Historic Environment. A Critical Future

Prof. Dimitra Diana Babalis

Department of Civil and Environmental Engineering, (DiCEA)
University of Florence, Italy

E-mail: dimitra.babalis@unifi.it

Abstract

One of the main goals of historic cities policy is for a greener urban environment that will help improve urban quality, health, and well-being, reduce urban heat impacts, and protect for urban risks bringing nature into the city. Consequently, the green living must focus on providing easy people's access to quality green spaces to address climate and health challenges. It is essential, therefore, to develop strategies and policies in urban greening to meet commitments such as: Green urban strategy; Green streetscaping strategy and so on. There is a growing research and community recognition that providing healthy green environment such as an essential infrastructure can play a key role in creating environmentally-friendly and culturally inclusive urban spaces. The raised questions are: How can historic city transform its 'Heritage Open Urban Space', (HOST) including streets, small streets, squares, small squares, historic gardens to create more accessibility for people to walk, cycle and shop and reactivate to welcome people safely back to urban quality? Are HOSTs set to be transformed into 'urban oases', showcasing as part of a drive to provide urban quality and mitigate climate change? However, to create a sense of place, and street for all users, historic cities must introduce innovative strategies to represent where different types of greenery can introduce the 'Green Infrastructure Approach' for climate change adaptation and social benefits.

Combining creativity and circular economy towards the regeneration of the urban ecosystem and the natural environment

Prof. Em. Sophia Avgerinou Kolonia

Department of Urban and Regional Planning, School of Architectural Engineering
National Technical University of Athens (NTUA), Greece

Email: skolonia@arch.ntua.gr

Abstract

The impacts of climate change, observed in recent decades, as well as the pandemic crisis are now resulting in degradation of the natural environment. The consequences of both the climate crisis and the pandemic are multiple, and addressing them requires a complex and multi-disciplinary approach. Priority must certainly be given to introducing alternatives for energy saving, reducing carbon emissions, ecological savings, including waste reduction and sustainable mobility. Changing production patterns with the support of recycling and the introduction of the circular economy would seem to be particularly effective means of promoting these trends. However, these actions can only bring comprehensive results if they are combined with additional measures to ensure quality life, adequate social housing, heritage preservation and the necessary social services. Therefore, a review of urban and broader spatial planning in a long-term framework is needed, following the recommendations of the global scientific debate on cities

There is a well-known relationship between culture, Creative Cultural Industries (CCIs) and urban development. A particular role has recently been taken by the recycling process in this context, so that many institutions are now recognizing and promoting this relationship with a view to Sustainable Development Goals (SDGs). Culture and CCIs cross many aspects of cities (economic, social, cultural), create social and cultural networks, and contribute to the local economy. CCIs are organized in a variety of ways: clusters, networks, hubs, and co-working spaces compose the so-called creative ecosystem that can thrive when cities provide a strong milieu.

Researched case studies and related theory argue that the majority of CCIs small medium enterprises are generally based in urban centers, flexibly exploiting the advantages of location, such as partnerships and cooperation with other relative enterprises, low costs of transporting raw materials and products, the ability to meet skilled labor, low rents, etc. Therefore, a privileged network is formed for their operation, defined by the favorable traffic conditions in particular raw materials, products and the presence of business and labor, which simultaneously constitute vectors of traditional knowledge. The resulting social and economic interactions reinforce this favorable environment and create a distinctive urban landscape. The CCIs sector is increasingly developing, highlighting opportunities for new jobs, collaborative economy, social innovation, start-ups and urban regeneration. It is often presented as a supporting factor for sustainable urban development, as it relies more on human inputs than material inputs.

Modern cities have a long tradition of creative and cultural activities, but the majority of has not resolved the issue of waste management. This is a multifaceted social, economic and urban-environmental issue whose resolution is of considerable research interest. The researches included in this paper will attempt, through innovative practices and tools, to link these two characteristics with the main objective of developing a strategy for a circular economy involving small and medium-sized CCIs, creating circular networks of cooperation and exchange within the urban fabric. Cities and industries may learn about the different solutions that can be adopted, considering their specific urban

and economic features, such as the socio-economic fabric, the availability of raw materials and technologies, or the position along the global supply chain.

Finally, local authority should play an important role in managing the overall cooperation and coordination among CCIs, traditional businesses, and final consumers. Local authorities must promote the adoption of recycling and upcycling practice among industries, and so the conversion of their production systems.

Legends of possible flood destruction, contemporary waterscape resilience and political sustainability

Prof. Em. Konstantinos Moraitis

School of Architecture

National Technical University of Athens, Greece

E-mail: mor@arsisarc.gr

Abstract

It seems completely reasonable, nowadays, to expand the concept of urbanism through the addition of the suffix “landscape”, “landscape urbanism.” Moreover, it is also completely justified to specify the term “landscape” as an attribute of the noun “urbanism” and refer to “waterscape urbanism” in particular; or to discuss, on a more extended scale, the waterscape planning in urban or peri-urban scale. We have just described an important thematic approach, associated with a number of the present conference subjects: to the agonizing interest for climate change, for urban resilience and why not, for cultural and historical references indicating that water management constitutes a matter of consideration immersed in the ancestral depths of memory. Thus, the notion “sustainability” in the title of our paper intensely refers to the awareness of our communities, recognizing that ecological care in general, waterscape control and prevention of natural deluge could not be fruitful without a frankly expressed political concern. “Political sustainability” may thus be interpreted as political volition for environmental sustainability and, as the need for political integrity, as the need for sincere political volition for social well-being.

In our presentation, we could insist on the didactic value of our planning and design paradigms. We shall thus present didactic paradigms, concerning a research contribution, and academic instruction approaches or didactic examples, addressed to the totality of the urban communities. We shall focus on the waterscape identity of the Hellenic territory of Thessaly in particular; a territory largely influenced during the last delusive floods by a neglected or, at least, by a non-foreseen negative environmental condition.

Keywords: *waterscape control; waterscape urbanism, environmental and political sustainability, Athenian Green and Blue Porosity, academic and cultural didactics; plain of Thessaly, Historic Botanic Garden of Thessaly.*

• INTRODUCTION: LEGENDARY IMAGINARY AND LANDSCAPE INTERVENTION PRACTICES CORRELATED TO WATER MANAGEMENT

It is significant to mention that the term “landscape” as it appears in neoteric Western European languages was first coined in 17th-century Holland, under the Dutch word “landschap”, initially signifying landscape painting and intensively connoting the interest of the Dutch society for the total control of place formation [1:62-64, 2:104]. We could furthermore mention that this environmental, economic, and political interest was strongly associated with the water-scape management of the country through ingenious infrastructural interventions that succeeded in transforming extended wetlands into agricultural productive land. It was in the same country that strong dikes protected coastal zones from the sea-water fury and that friendly canals offered to the urban territories a picturesque environment combined with a water-circulation system.

We should mention in addition that 17th-century Holland was the first European country to possess an electoral system of governance, and an extended socio-political corpus of middle-class land proprietors, owning private farmland or a small well-formed house at the borders of a well-organized system of canals. It is in the same context that we may present the agrarian, urban, and even the

ISSN: 2654-0460

ISBN: 978-618-5765-02-6

economic or political formation of the Dutch “Golden Era” 17th-century society, as immediately associated with its waterscape management and ingenious design [3].

The previous may be probably considered as the best possible example for a “fertile” introduction to the nucleus of our presentation: the economic and political prosperity of the Dutch 17th-century society and its economic and political progress were correlated to its waterscape resilience. Reversing the previous statement, we may convincingly state that the political conscience of the strongest middle classes of the Dutch 17th-century, was the prerequisite for the continuous environmental control and flood prevention exerted on their natural environment. This could be an important paradigmatic reference, that could be used as a comment for our contemporary anxiety, towards low waterscape central political management, or this is even more crucial, towards low environmental ecosophic conscience.

(1) Waterscape seduction buried under tons of oblivion and its regeneration through the concept of the “Green and Blue Porosity.”

Recent destructive floods in Thessaly, Greece are intensively correlated to a mediocre controlling approach, through an extended period of governance. The previous comment seems to be extremely important: it refers to a lack of decisive environmental interventions or even worse a continuous negligence of environmental interventions, under the governance of different, successive political parties. Looking backward, we may remark that the delusive result of September 2023 in Thessaly, did not need a clairvoyance vision to be foreseen and prevented, but rather a concise scientific and governmental management that seems to be largely neglected.

We shall not continue by offering a concise critical approach to the political and finally to the cultural loss of our environmental responsibility in the previous case of Thessaly; a concise critical approach, having to do with detailed scientific research. We may, nevertheless, present an undeniable realization, having to do with the waterscape system of the metropolitan area of the Hellenic capital city of Athens. In 2015, as part of a research approach to the previous urban territory, we decided to investigate a possible green landscape system that could be organized in the Athenian basin [4]; a systematic organization that could promote a network of existing or future possible parks, correlated through green planted corridors.

We refer to an “emerald necklace”, as a landscape network analogous to what Frederick Law Olmsted, had proposed in his 19th-century project for the Boston Park System (emeralds are precious stones of green color) [5:96-108, 6:83-93], or analogous to Baron Haussman’s Park Network for the urban reform of the 19th century Paris. We shall remark that our proposal for Athens was presented one hundred fifty years after the two previous urban examples and that it bears the title “Green Athenian Porosity”, in association with the well-known use, by Walter Benjamin, of the term “Porosität – porosity”; a term describing the way that urban void corrodes the urban buildings solidity. Nevertheless, a third comment seems to be more important; a comment presenting the political validity of the park systems and the landscape urbanism. According to Olmsted’s insight, analogous urban interventions are not solely a matter of aesthetic amelioration of the cities or a matter of a neutral environmental concern. They rather refer to the political rights of the citizens, to their democratic political rights. The 17th century Holland had to provide positive water management to its population, and neoteric democratic Western societies had to provide positive urban landscape conditions to their habitants, otherwise we could describe them as authoritative or at least as politically blind and irresponsible.

In our research proposal for the porous green system of the Athenian metropolitan territory, the “Green Athenian Porosity”, our proposal of eco-political intervention, soon reached a more intelligent design approach. Not only we could create a green network system, moreover, we could think of a waterscape network of streams and rivers that could be associated with the previous green network, creating a more complicated and surely richer system of green and water urban conjunct formations; a system of “Green and Water Athenian Porosity” (Figure 1) [7:345-349].

Proceedings

Our research soon realized that most of the elements of this desired water network, being apparent till the 19th and the first decades of the 20th century, were covered, foolishly, under the false belief that they could thus be used as building substratum or for other solid earth functions. Furthermore, the existing non-covered streams or riverbeds were extensively mummified through their transformation to concrete canals, presenting no real interaction with the surrounding still-existing natural influences of the urban environment. Could Athenian municipalities or Hellenic ministries actively participate in the revitalization of the underestimated Athenian waterscape?

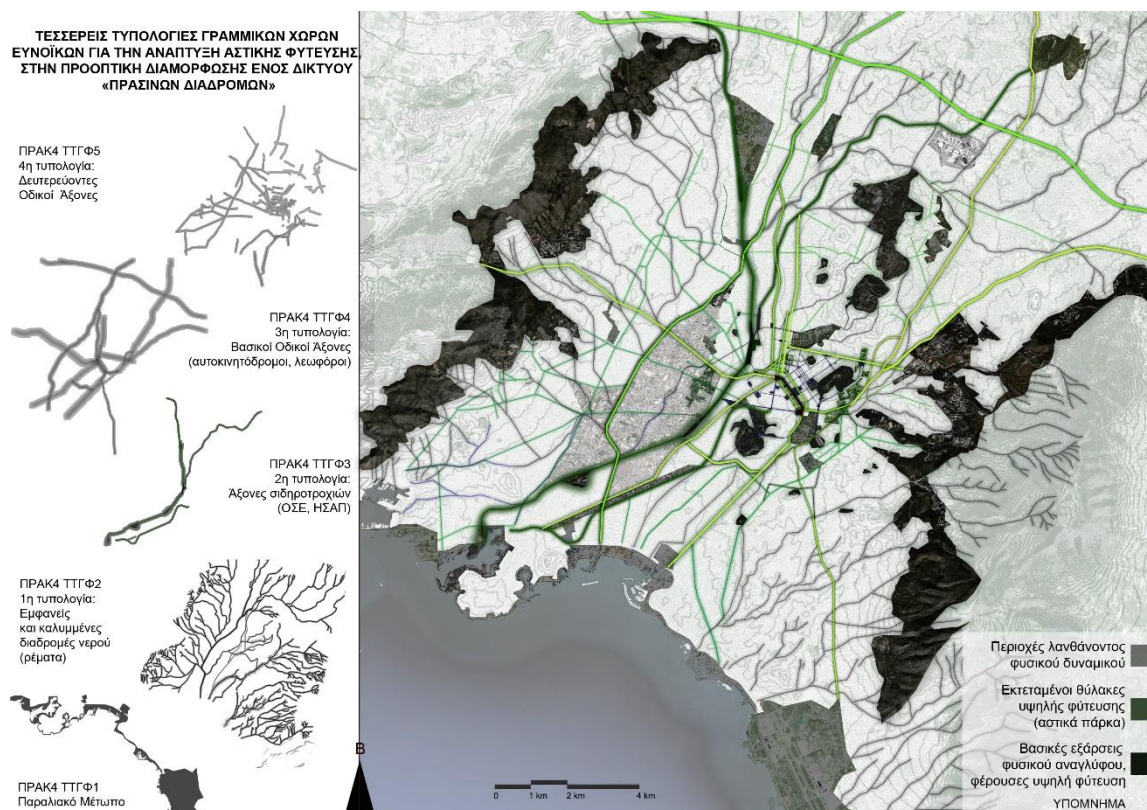

Figure 1. Map depicting the complex system of the green network (stronger green lines of proposed planted corridors) and green enclaves of existing or possible future parks (black spots), in correlation to the waterscape network of rivers and urban streams that had to be uncovered (thinner black lines). The total combined system has been described as “Green and Water Athenian Porosity.”

(2) Waterscape seduction buried under extended lack of environmental conscience and managerial negligence.

As a reply to the previous rhetoric questions, we may use Félix Quattari’s description, in his book on *Les Trois Écologies, The Three Ecologies* [8]. The French intellectual insisted on the three-fold necessary orientation of the ecological approach: on the “natural” ecological condition having to do with the control of the natural environmental factors, of the “cognitive” ecological condition having to do with the social conscience concerning environmental protection and, finally, on “social” ecology, correlating natural environmental conditions with social and political ethics, with the social and as we could add, with the political integrity of our societies. Thus, the notion “sustainability” in the title of our paper intensely refers to the awareness of our communities, recognizing that ecological care in general, waterscape control and prevention of natural deluge could not be fruitful without a frankly expressed political concern. “Political sustainability” may thus be interpreted as political volition for environmental sustainability and, as the need for political integrity, as the need for sincere political volition for social well-being.

We could now continue our presentation and explain that we shall not describe solely planning and design paradigms, we shall rather insist on their didactic value. We shall refer to didactic paradigms presenting, in addition to the previous research proposal of the “Green and Water Athenian Porosity”, academic instruction approaches or, furthermore, a tendency for extended didactic examples addressed to the totality of the urban communities. This last approach will be presented in our text through two urban landscape design projects that offer, in addition to their positive environmental contribution, exemplary narratives focused on the waterscape identity of a given Hellenic territory. They both refer to the territory of Thessaly, largely influenced during the last delusive floods by a neglected or, at least, by a non-foreseen negative environmental condition. In those two paradigms the need for political bottom-up apprehension is suggested, supporting the top-down scientific planning or design approaches. In this frame of reference, cultural guidance is offered to the citizens, indicating the importance and the threads of the waterscape as presented by legendary and historical references, in our case associated with the critical resilience of the plain of Thessaly.

2. WATERSCAPE DESIGN AND MANAGEMENT: ACADEMIC DIDACTIC PARADIGMS

We shall now present three paradigms of waterscape and management interventions, proposed in the context of diploma theses in the School of Architecture N.T.U.A.

Figure 2. Exemplary intervention at the stream of Pikrodaphni: conceptual plan (upper part), and correlation of the zone of the stream with a green urban plantation zone (lower part).

The first among them refers to a rehabilitation intervention, applied at an exemplary element of the “Green and Water Athenian Porosity” system, at the stream of Pikrodafni, a waterline running through a densely built part of the city. The project [9] noticed that the streambed has been distorted, partly covered, or narrowed and thus in a dangerous condition for a possible future flood. As an answer, the diploma thesis project proposed the re-naturalization of the streambed, uncovering it, increasing the curved parts of it, and suggesting, furthermore, its enlargements in such a way that a possible flood could be harmlessly decompressed (Figure 2). The streambanks were stabilized in a natural way through vegetal implants, without the use of concrete, and additional higher tree plantations at the length of the banks realized the association of the waterscape design with a green urban landscape.

Figure 3. Exemplary intervention at the urban zone and the neighbouring lagoon of the historic Hellenic city of Missolonghi: a central urban park zone combining a canal passing through the city and ending at the lagoon area (upper part), and a wooden structure offered to the strollers of the proposed water and green landscape formation (lower part).

The second paradigm refers to another waterscape network, not that of the Athenian territory but in the waterscape context of the lagoon, next to the “sacred” Hellenic historical city of Missolonghi. The project [10] (Figure 3) intended to restore the covered parts of a previously existing canal network, and even augment it, to create an extended visiting and touring system, in the interior of the city or next to it. Wooden constructions were provided for the important focal places of the previous canal network, as landmarks of reference, inspection towers, or structures for possible public group activities. The waterscape network was again, in this second paradigm, correlated to organized, designed plantation proposals; nevertheless, the project was not limited to a natural landscape intervention. Missolonghi is well known for its historic importance being correlated to the struggle for independence during the Hellenic Revolution of 1821. It is in this context that the term “political sustainability” acquired, in this case, a concise, aphoristic meaning. The Missolonghi lagoon and the city of Missolonghi in itself constitute a compound “cultural and historic landscape”, a compound “cultural and historic waterscape”; we ought to preserve both its natural and historical-political integrity.

 ISBN: 978-618-5765-02-6

Figure 4. Landscape intervention proposal, at the zone of Arachthos River, partly surrounding the city of Arta, in Epirus Greece.

The third paradigm refers to a proposed management of the Arachthos River, a waterscape at the periphery of the Hellenic city of Arta in Epirus, Greece. In this project [11] (Figure 4), the river zone was not limited to the quantity of water flowing in the bed but, again, as in the previous case of Pikrodaphni stream, it was extended to the wider green zone surrounding it; at a zone where the influence of the water could easily be seen. After defining the borders of this water-vulnerable area, interventions were proposed only at the exterior of it, while in its interior the area remains free of constructions, to be influenced only by the passage of visitors and water. Moreover, the project proposed a controlled, human-made flood every few years. Thus, the river could regain its old flow range, reform the riparian zone, and partly counterbalance the drawbacks of the existing dam. We could consider this controlled intervention as a means of natural environmental invigoration and, at the same time as a cyclic repeated “festivity” for the city aiming, according to the description of the project, “in the re-activation of the collective memory.” We could insist in this case on the term “cultural sustainability.” Nevertheless, is it cultural sustainability, a necessary compound of what we have already many times characterized, in our text, as “political sustainability”? That was a rhetorical question.

3. LEGENDS AND REAL LANDSCAPE INTERVENTION PRACTICES, CORRELATED TO WATER MANAGEMENT: THE CASE OF THESSALY

We have so far introduced our readers to important thematic approaches, associated with a number of the present conference subjects: to the agonizing interest in climate change that demands our environmental commitment, to the need for urban resilience and why not, for “cultural and historic resilience.” In this cultural and historical context, water management appears to constitute a matter of consideration immersed in the ancestral depths of memory; it surpasses the beginnings of history and goes back to Noah’s cataclysm or the Deucalion’s and Pyrrha’s flood in the Greek mainland. In the narration of the Book of Genesis of the Hebrew Bible, Noah had to build as a respond to God’s command an Ark. He succeeded thus in saving not his own family solely, but mankind itself and all land animals, from extinction during a disastrous Flood, a cataclysm, which God created after

regretting that the world was full of sin. An analogous legend refers to the Deucalion's and Pyrrha's flood [12:32-37], associated with the geographic territory of Thessaly in Greece, which has already been used as an introductory example of reference in our paper. We have just indicated that water management appears to be a matter of central concern in our known history and that its importance seems to have a deep mythical or even religious value, infiltrated in the cultural unconscious or the historical conscience of human societies worldwide.

Figure 5. After the delusive flood the two only survivors, Deucalion and Pyrrha, were throwing rocks behind them and, out of those rocks, a new tribe was born at the Thessalian plain, the tribe of the Hellenes, the Greeks. A 17th-century depiction of the legend, by Giovanni Maria Bottalla, (1635).

In the next two paradigms of professional projects, awarded in Panhellenic Architectural Competitions (both concern urban landscape and urban gardens interventions in cities of Thessaly), the architects directly refer to the legend of Deucalion's and Pyrrha's flood. The projects were completed, as a design proposal, some years before the last year's cataclysmic incidents in Thessaly. Nevertheless, they felt obliged to offer to the citizens or the visitors of the proposed landscape interventions, a didactic reminiscence insisting on the importance of the waterscape for the survival and fertility of the plain of Thessaly.

The first example corresponds to the redesign of a complex of two central urban squares in the city of Trikala, next to the river Lytheus [13] (Figure 6a). In correlation to the real place formation of the project and to the landscape intervention at the bank of the river, a guided route was added. It intends to combine a real promenade with digital narrations concerning the legendary and historic depth of the city: the references to the deified initiator of ancient medicine Asclepius, to the ancient, byzantine, ottoman and neoteric period, to the correlation of Trikala with the folk culture "Rebetiko" song, to the local resistance movement against the Nazi's occupation during second World War. To those multivalent narrations, one more was added; that of the Deucalion's and Pyrrha's legend, being constitutive of the geomorphology, the hydrological identity and the prehistoric depth of the territory in question.

Figure 6. An architectural competition awarded project, for the redesign of a complex of two central urban squares in the city of Trikala, next to the river Lytheus (upper part, Fig. 6a). The correlation of the waterscape formation to the green urban landscape is obvious. Analogous binary correlation of the waterscape and the green landscape design proposals we may observe in the second awarded project, that of the “Deucalion’s Cycle”, of the circular “Historic Botanic Garden of Thessaly” in the city of Larissa (lower part, Fig. 6b).

An analogous reference was proposed in the case of a second awarded project, that concerning the design of the “Historic Botanic Garden of Thessaly”, in the interior of a larger park zone in the city of Larissa; a historic botanic garden entitled “Deucalion’s Cycle” [14] (Figure 6b). According to the project, a circular garden was proposed, formed in such a way that its plan corresponded to the map of ancient Thessaly patterned in relief. At every part of it, a plantation of botanic species analogous to the supposed ancient flora would be provided, and metallic stands would be installed at the places of the map corresponding to the important ancient cities of Thessaly. On the stands, inscribed QR codes would offer the visitor digital narratives, concerning natural landscape information and mythological or historical references. What had to be added to this description, is the comment that the central element of this garden design would be a line of water, depicting the river Pineios, flowing from the Pindus Mountains through the Thessalian plain and emptying into the Aegean Sea. There, the river creates a large delta, well known for its beauty and many animal species, protected by international environmental treaties.

4. CONCLUSIVE REMARKS: DELUSIVE FLOODS OR CULTURAL AND “ECOSOPHIC”, ECOLOGICAL CONSCIENCE?

In his second volume of *Faust*, Johann Wolfgang von Goethe described the phantom of Helen of Troy, revealing the essence of beauty to the central hero of the narration, Dr. Faust [15]. According to Helen such an aesthetic apperception could be realized through a journey in the Hellenic landscape, from Thessaly and the plain around Pineios River to the landscape beatitude of Arcadia. Goethe surely referred to the supposed natural beauty of the landscape of Greece, a country, nevertheless, that he had never really visited. What seems more justified could be the assumption that Goethe’s praise of the natural aesthetic superiority of the landscape of Greece is rather associated with its cultural and political importance, metaphorically correlated to its perceptive value. It is this compound identity, natural – material and cultural or political and immaterial that we ought to preserve against the natural delusive floods, the negative climate change, or against the loss of social and ecological conscience. It is following those demands that we have used, in our present paper, the terms cultural and political sustainability.

It is in the previous context that we feel obliged to finish our presentation, insisting on the comment that five years ago, the representatives of the School of Architecture of N.T.U.A. participating in the advisory committee of the Hellenic Ministry of Environment and Energy, for the “Landscape Award of the Council of Europe”, insisted on the importance of the Greek proposal for the restoration of the lake Karla in Thessaly, for its recreation as a natural waterscape. According to them, this project could be considered as one of the most important European landscape intervention projects.

Figure 7. Swan on the lake Karla.

Karla, a 180km² lake was completely drained in 1962 to be transformed into agricultural cultivation land, though it previously offered, before its drainage, a unique fishing culture with extended fisheries of significant economic importance. Nevertheless, agriculture seemed to be unsuccessful at the saline soils of the former lake bed, and as the ecosystem of the territory was radically upset, the ambitious project of the lake renaissance was realized under the support of the European Commission. The lake was finally “inaugurated” in October 2018, and it now exists as an important reference to the need for the preservation and support of the precious and capricious Thessalian waterscape, of its natural and cultural significance going back to the reminiscences of ancient Greek mythology.

Regional and local dimensions of Maritime Spatial Planning.

Prof. Stella Sofia Kyvelou

Department of Economic and Regional Development
Panteion University, Greece

E-mail: skyvelou@icloud.com, kyvelou@panteion.gr

Abstract

The keynote address will highlight the regional and local dimensions of maritime spatial planning, both at the European level and in the context of the Eastern Mediterranean sea-basin with a focus on Greece. The paper draws conclusions and policy recommendations from the REGINA-MSP EMFAF project with case study the Region of Crete where relevant participatory processes have been implemented by Panteion University. Consequently, will be discussed the analysis of the positions of all interested parties (incl. the MSP authority that is the Ministry of the Environment and Energy), the presentation of good practices for the harmonious coexistence of uses (offshore wind farms, fishing, tourism, NATURA areas, marine protected areas, underwater antiquities, diving parks), the development of participatory planning at the regional/local level and the cooperation between levels of governance and finally the creation of a Community of Practice (CoP) as promoted by the REGINA-MSP project and the possible establishment of a Regional Community of Practice and Innovation for optimal energy transition solutions, with a focus on offshore RES.

Goals and Sub-Goals of the United Nations for the Sustainable Development of Cities

Prof. Roido Mitoula

Department of Economics and Sustainable Development
Harokopio University of Athens, Greece

E-mail: mitoula@hua.gr

Abstract

The 11th goal of sustainable development refers to sustainable cities and communities, and based on it, the solution of many key problems of cities is promoted at the global level. Today, many countries, having integrated the main directives of Global Goal 11 for the Sustainable Development of Cities and Communities in their domestic law and policies, are drawing up programs and taking initiatives and actions to achieve it. The ultimate goal is individual and collective well-being and sustainability in all areas of life in the urban environment. The comprehensive implementation of the 11th SDG is a collective undertaking, which requires the cultivation of a spirit of cooperation among all, having as the main stake the fundamental principle that "no one is left behind".

From the analysis of the policies promoted in recent years in the EU, it is observed that it has included almost all the areas covered by Goal 11, that is, Europe has oriented the goals of the United Nations Organization to European data, with the aim of achieving them by the European community.

However, the awareness in society and the active participation of citizens are necessary conditions to deal with the problems that cities are facing today. The first concern should be the change in mentality, mainly of the citizens who hold a position of responsibility, but also of each individual citizen, in matters concerning the city and its environment.

The European Union, as the most important coordinator of the processes of sustainable development, is constantly trying to give directives so that all cities and communities can work together to achieve goal 11. Many relevant programs are implemented by the EU states, but also directly by cities and communities. As far as the Greek state, is concerned that it implements a comprehensive policy to achieve goal 11, as sustainable planning is supported and environmental measures are taken to clean up waste management processes and public service processes and to encourage Greek citizens to environmentally upgrade their homes and be able to deal with climate change.

As far as Local Government Organizations are concerned, they are perhaps the most important bodies for implementing new measures and improving the existing situation in relation to the sustainability of cities and communities. Many Local Government Organizations today are very successfully orienting their actions with the aim of achieving sustainability and are an example for others to follow. But everyone's participation is necessary and the individual effort of every citizen is also very important! The sum of individual actions will lead to collective action and this to the solution of global problems and therefore to the final success of the 11th Goal concerning the sustainable development of cities and communities. Because, as Mother Teresa said, "I alone cannot change the world, but I can throw a stone into the waters to create many ripples."

Designs that able disableism

Prof. Alcestis P. Rodi

Professor of Urban Design and Planning
Department of Architecture, University of Patras, University Campus,
26504 Rio Achaia, Greece

E-mail: alcestis.rod@gmail.com, Tel +30 210 8131756

Abstract

From the white, non-disabled muscular male figure such as seen in da Vinci's Vitruvius Man and likewise Le Corbusier's Modular Man to the standardised user illustrated in architectural professional handbooks, norms of able-bodiedness were used to produce good design by dominating the mens et manus of designers.

In recent decades, 'Universal' and 'All-inclusive' design theories and practices have been monopolising access for everyone regardless of particular needs. Yet, emerging access studies are highlighting challenges due to evolving disability and inclusion concepts, intersectional perspectives, and varied bodily experiences.

Responding to this call for accessibility, designers meet the minimum requirements of accessibility codes through obligation by merely ramping the built environment, without considering the emotional impact of their designs, or the need for all users to be able to retain a sense of dignity as they enter and move through buildings and open spaces.

This presentation aims to demonstrate critical spatial aspects of disability and inclusion that can inform designers who pursue creative, rather than constraining, accessibility-focused spatial solutions. Beyond accessibility codes and regulations, it seeks to establish new architectural forms and introduce physical transformations based on site and culturally specific evidence that maximise possibilities for disabled people in both private and public spaces.

To this end, the presentation reviews disability from a historical perspective, outlines current accessibility thinking, and examines the role of experts and their impact on users. Aimed at upcycling everyday environments so as to enable movements, our research has analysed and evaluated the built environment of Athens, where the experience of dignity is ubiquitously threatened due to planning pathogenesis. At the scales of apartment, building, city block, and neighbourhood, it has examined factors in urban space that promote dignity and access for all people: adaptability, aesthetics, autonomy, efficiency, equitability, flexibility, perception, privacy, safety, and social interaction.

Its findings enrich access knowledge through innovative urban design paradigms with the potential to transform spatial environments into dignified spaces for all.

Photography as a critical thinking and living archive of changing cities and landscape.

Prof. Dimitris Polychronopoulos

Professor, Head of the Department of Architecture, Faculty of Engineering,
Democritus University of Thrace, Greece

E-mail: dpolychr@arch.duth.gr, Tel +30 6977894949

Abstract

In an era marked by rapid urbanization and dynamic landscape transformations, the art of photography emerges as a powerful tool not only for documenting change but also for fostering critical thinking about our evolving cities and landscapes. This paper explores the role of photography as a medium for capturing the different narratives of urban development, offering a deep understanding of the complexities of social, environmental and cultural change. On the other hand everywhere today, countless “would-be” photographers holding a mobile phone, having a strong desire to share personal experiences with others and preserve memories by highlighting their visual presence, with such intensity, that Susan Sontag may have been quite right in saying that "Today, everything exists to end in a photograph". Bridging visual analysis with multiple narratives of the city, the paper addresses how photography interprets and represents the ever-changing urban landscape, revealing layers of meaning and critique. In addition, the concept of photography as a living record is examined, wherein images serve not merely as static records, but as dynamic reflections of ongoing processes. Through an interdisciplinary approach encompassing visual analysis, cultural theory, and urban studies, today more than ever before, we can understand how photographers capture and interpret the dynamic interplay between human activity, architecture, and the natural environment. By considering photography as a critical lens, we uncover alternative perspectives on urban growth, decay and regeneration, prompting viewers to question assumptions and envision alternative futures. The paper focuses on a visual journey through changing cities, exploring the deep connections between photography, critical thinking and the evolving landscapes.

The New European Bauhaus: Heritage, Landform and Climate Change

Ass. Prof. Riva Lava

School of Architecture

National Technical University of Athens, Greece

E-mail: rivalava@hotmail.com, Tel +30 6934035960

Abstract

The European initiative of the New European Bauhaus calls on Europeans to bring forth and protect the values and qualities of our shared continent at a time of climate change, cultural expansion and revision. Especially Southern Europe and the countries of the Mediterranean face dire predictions in regard to rising temperatures and projected draughts, a fact that impacts not only the moderate Mediterranean climate, but also affects the landscape and the traditional forms of inhabitation. Beauty, Sustainability and Togetherness, as professed by the New European Bauhaus, bring new challenges and unlock new possibilities within the framework of preserving the Mediterranean culture- an old culture which has long nurtured freedom, wellbeing and simple living as an expression of a harmonious co-existence between landscape and man.

Exploring character and physiognomy of vernacular settlements as a means of preserving cultural heritage through sensory identity

Ass. Prof. Maro Sinou

Department of Interior Architecture
University of West Attica, Greece

E-mail: msinou@uniwa.gr

Abstract

The character and physiognomy of vernacular settlements and more specifically of the Aegean Island settlements, is a matter of investigation within the frame of city identity, city branding and placemaking. The overall question investigates the qualities which compose all the characteristics that act as magnets and attract thousands of people.

This paper addresses issues of city character, personality, physiognomy, image, branding, genius loci, sense of place and identity in order to obtain a clearer view on the parameters/criteria/factors that form them in the quest of preservation the identity of the vernacular Aegean settlements. The study proposes a simple tool that includes all the related parameters of value, which should be considered in order to preserve urban identity in great value historic settlements. The tool is in the form of a simple diagram and is addressed to all related stakeholders.

Keywords: *city character, city physiognomy, sensorial urbanism, cultural heritage, vernacular settlements*

1. INTRODUCTION

Several questions can be raised about character and physiognomy such as how is it possible to quantify them, whether they constitute planning parameters and act as parameter for the preservation of existing heritage. Can these two measures be related to the so-called spirit of the place? The local wisdom called genius loci by Norberg-Schulz, is associated with the spiritual sense of place in order to contextually sustain and preserve the quality of life and the local characteristics.

Character can be defined as the particular combination of qualities in someone or something that makes them or it different from others and also the way someone thinks, feels, and behaves. On the other hand physiognomy is defined as the appearance of a person's face. One can therefore say that character and physiognomy together consist a number of inner and outer qualities of a person. Moving to urban space analysis very often we come across the meaning of character and physiognomy of the city. Could it be that these two qualities if quantified could measure and define urban space identity?

Since ancient times, as early as the 15th century, travelers from central Europe travelled to the south in order to get to know the particular characteristics of the landscapes, the settlements and the people of the south. The environmental impact on health and long life was noted by the traveller Tournefort. In his description of the Greek island of Siphnos, he notes “*There are Men in Siphanto 120 years old: the Air, Water, Fruit, Wild-Fowl, Poultry, everything there is excellent*” [1].

Another aspect related is city identity and city branding. To understand the importance of city branding, it is important to clarify the concepts of city identity and city image. City identity is related to the fundamental essence and reality of a city. It encompasses the unique combination of qualities often derive from distinctive natural, cultural and historical characteristics. Branding, mainly developed from marketing strategies, is more and more used for city marketing and promotion, similar to products.

ISBN: 978-618-5765-02-6

A sense of place creates a personal identity, allowing the city to become more important to users and society. This last point is also suggested by Adams, who notes that “to walk through a place is to become involved in that place with sight, hearing, touch, smell and even taste”. Sensory landscape, also called urban sensescape, is the total experience of the city through all the senses, which also creates a sense of place for people, awakening memories, cultural connections and associations.

The concept of “sense of place” thus becomes an important criterion for understanding the built environment to which we belong. Sense of place represents the connection to the place where we live. The general feeling that is created in an individual after a crisis and the perception of specific environments is called “sense of place” and refers to the emotional connections that people feel or develop in a place [2]. Sense of place also derives from the effects of the design of the environment, the activity that takes place in it and what these forms and activities mean to people.

Cities, public spaces and the urban landscape in general can create this sense of place when people visit that space often and return because they have developed a sense of attachment and belonging in some way. This deeper connection to a public space makes it a place where people return and interact in a positive way. It is, therefore, important to move from public “space” to public “place”. A sense of place creates a personal identity, allowing the city to become more important to users and society. Despite the increased sensory bombardment, we have lost the art of appreciating the varied sounds, smells, textures, and qualities of materials, as well as the look and feel of the city and its component parts [3]. Every city has its own sensescape, yet our perceptive capacities are cramped because we do not sufficiently recognize or practice most of our senses. We have forgotten our ‘natural’ aesthetic knowledge, which is the science of sensory perception derived from the Greek word meaning to be ‘sensitive,’ ‘sentient,’ and to ‘perceive,’ ‘feel,’ and ‘sense’ [3]. Trespassing on our senses will be one of the critical battles in defining how our cities evolve in the future.

At the country brand personality level, studies differ from other investigations in terms of research methodology, using both qualitative and quantitative methods. According to Aaker [4], to study brand personality, products were categorized into three groups. Therefore, in this study, cities were categorized into three groups: functional cities, valuable cities, and functional and valuable cities. A functional city refers to a city with distinctions in economy, education, and industry. A valuable city signifies a city with cultural and traditional treasures, while a functional and valuable city possesses both characteristics.

The application of city identity principles to vernacular settlements involves adapting concepts traditionally applied to cities to smaller, often rural or less urbanized communities that possess distinct cultural, historical, and environmental characteristics. To set the general theoretical framework, a brief analysis of key-concepts follows, including City Identity, Personality, and Image as well as City branding, Brand Personality and Placemaking.

2. CITY IDENTITY, PERSONALITY, AND IMAGE

City Identity

City identity relates to the fundamental essence and reality of a city. It includes the unique combination of qualities and values that define and characterize a city, distinguishing it from other places. These qualities often derive from distinctive natural, cultural, and historical characteristics. Moreover, city identity is closely linked to the values that are of paramount importance in differentiating cities. While the term ‘place identity’ is commonly used in discussions about place branding and marketing, limited attempts have been made to fully understand it. Weichhart sheds light on this confusion by stating that we regularly befuddle put personality with the idea of a clearly identifiable put with it possess character and aesthetics, as well as the recognizable proof of inhabitants with a put or community, a city or locale, a neighborhood or a locale [5].

In the urban field, many architects and planners have thought a lot about the identity of cities and places, proposing many different definitions from different perspectives. Each definition emphasizes that each city is different due to a specific combination of subjective and objective factors. These

Proceedings

factors include climate, natural elements, memories, emotional aspects, social life, culture and physical structures. Urban identity is largely shaped by factors such as location, spatial form and how they relate to human-made features. The characteristics of a place include its location, how it interacts with the urban form, its various aspects, the space has its own characteristics, colors, structures, sounds, smells, temperature, wind movements and the presence of different social groups engaged in different activities. Buildings and urban areas reflect social contexts, lifestyles and cultural meanings, emphasizing the importance of material form and the relationship between the physical environment and its context. Therefore, one of the most important cultural expressions of a community is its physical layout [6].

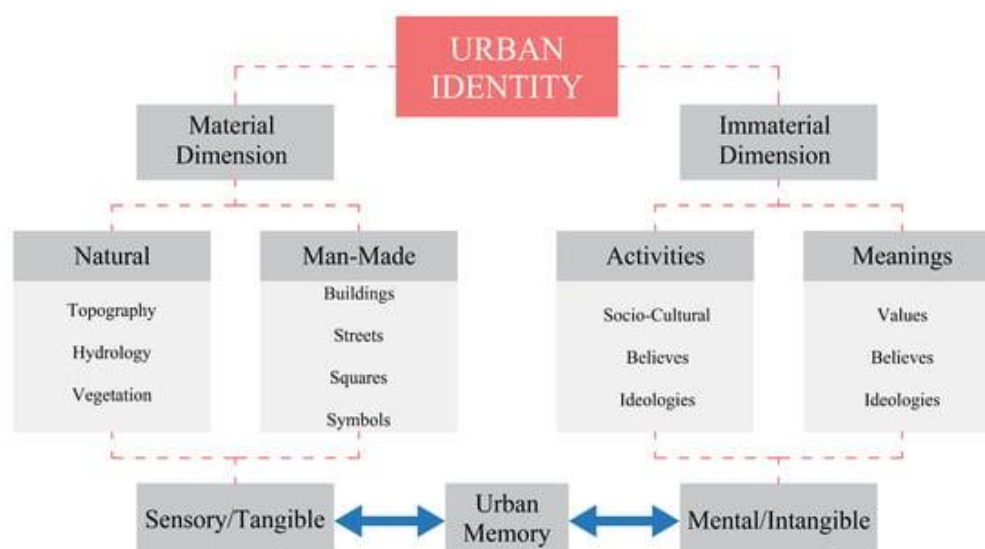

Figure 1. The components of urban identity [6].

Innovative design schemes may also play a role in forming the identity of a city since by becoming landmarks and promoting tourism/economic development they may generate new social solidarities among inhabitants grounded on ‘civic pride’ and economic prospects [7].

City Personality and City Image

The concept of city personality pertains to the distinct array of traits, characteristics, and values that define a city and set it apart from others. Much like individuals and brands, which are frequently associated with specific personality traits such as sincerity, excitement, or competence, cities can also be perceived and described based on their unique attributes. Despite the fact that some studies focus on city personality using the brand personality framework, Aaker’s framework fails to adequately explain city personality. In recent years, there has been an increasing amount of literature on city personality; however, several studies argue that these measurement scales suffer from limitations in generalizability. Several studies employed qualitative methodology to discover city personality by collecting data in one area and performing data analysis for quantitative information [3].

Hong-Bumm Kim and Sanggun Lee examined the causal relationships between city personality and city image, along with the possible effect of city image on visitors' revisit intention through empirical validation [8]. Their research model investigates the relevant relationships among the underlying dimensions of city personality and city image using a structural equation modeling (SEM) approach. The Brand Personality Scale (BPS), which consists of the five personality dimensions of sincerity, excitement, competence, sophistication, and ruggedness [4], is used in this context.

The image of a place can be defined as the sum of beliefs, ideals, and impressions people have toward a certain place [9]. Understanding the complex synergies of city personality and city image is crucial for urban development and planning, influencing how cities communicate their unique identities and attract visitors.

Understanding the interplay between city personality, identity, and image is crucial for urban development and planning. A cohesive city personality can enhance a city's identity and improve its image, thereby increasing its appeal to residents, visitors, and investors. Achieving this necessitates a comprehensive approach that considers the sensory experiences of the city, its historical and cultural context, and its strategic branding efforts. Urban planners and policymakers can leverage these concepts to create more vibrant, attractive, and sustainable cities. By recognizing and effectively managing a city's unique personality and identity, cities can distinguish themselves in a competitive global landscape, fostering economic growth and enhancing the quality of life for their inhabitants.

City Physiognomy

Physiognomy (from the Greek φύσις, 'physis', meaning "nature", and "gnomon", meaning "judge" or "interpreter") is the practice of assessing a person's character or personality from their outer appearance—especially the face. The term can also refer to the general appearance of a person, object, or terrain without reference to its implied characteristics. Notions of the relationship between an individual's outward appearance and inner character. The general appearance or external features of a material object; esp. the contour or configuration of a location, landscape, etc. Physiognomy is understood as the outside structure of the city, i.e. its general appearance, building forms, as well as the types of the building materials [10] (Figure 2).

Figure 2: Physiognomy of a person and built environment

In an attempt to make relations between human morphological characteristics and Cycladic building morphological characteristics three examples are presented in order to show that such elements can be confused sometimes as not significant but if inspected more carefully it is clear that they have a great value.

Figure 3: Morphological relations between people and building characteristics

In the first column Audrey Hepburn's eyebrows protect her eyes similarly to the thin asymmetrical horizontal stone called '*frydi*', the Greek word for eyebrow, protects the window. In the second column Elvis Presley's renowned hairstyle could be related to the plasticity formed at the top of the Cycladic roofs by the chimneys that not only are a functional element but also become an aesthetic component. Lastly, Marilyn Monroe, the beauty idol of the past century is well known by her asymmetrical hair style but more by her beauty spot. It could be argued that the subtle asymmetry in Marilyn's face may be one of the most important beauty parameters which can be also found so often in Cycladic Architecture.

3. CITY BRANDING, BRAND PERSONALITY AND SENSORY PLACEMAKING

Cities effectively endeavor for maintainable advancement and endeavor to offer their citizens a tall quality of life, which incorporates financial openings and a solid environment. To attain these objectives, cities embrace branding methodologies to attract investment and allure individuals to require advantage of the administrations and comforts they offer. City branding, moreover known as geographic branding or put branding, alludes to the method of creating and promoting a particular picture for a city or a particular location (Figure 4). A bit like items, cities around the world lock in in branding endeavors to set up themselves as the most excellent among their competitors. Strolling through city neighborhoods, it isn't unprecedented to discover expansive announcements featuring cities rather than well-known brands of clothing, shoes or gadgets. This wonder is especially predominant within the tourism industry.

Proceedings

Figure 4: Examples of city branding (<https://planningtank.com/city-insight/city-place-branding>)

Brand personality, on the other hand, is a concept that uses a metaphor to characterize a brand as human, referring to the set of human characteristics associated with a brand [4]. This concept can be measured following Aaker's findings that brand personality comprises five dimensions: sincerity, excitement, competence, sophistication, and ruggedness. The approach has been used in various contexts, including universities, countries, tourist places, and cities. In recent years there has been an increasing amount of research on city personality; however, several studies argue that those measurement scales suffer from the limitation of generalizability [11].

Several researchers have studied the components of City Branding in an attempt to classify the different aspects of value that can consist its identity and therefore form a branding strategy. Five broad categories can be identified in this stage of the research: **History** - Cities that have stood the test of time and have a rich history and culture have significant value. Over the years, these cities have been the setting for many events and have gained immense significance. Drawing inspiration from the principles that underpin these assets, a range of marketing opportunities can arise using traditional design thinking, ideas and processes. **Culture** - A city's culture also plays a vital role in shaping its identity. Customs, attitudes and local cuisine reflect the unique culture of the city. However, it is the interaction between the spatial characteristics of the city and its inhabitants that truly defines these cultural elements. A city, as a mere physical design, is incomplete without its users. It is through their presence and the experiences they create, both for themselves and others, that the city acquires its identity. Thus, the essence of a culture-based city brand image is based on these dynamic factors. **Architecture** - The buildings and structures within a city reflect its architectural style. This includes not only the physical design of buildings but also their layout and plans. In a literal sense, architecture shapes the "visual image" of the city. As such, the built environment serves as a manifestation of what the city intends its inhabitants to experience on a daily basis or as an enticing spectacle on special occasions. **Climate** - The weather conditions of a city have a significant impact on the lifestyle of its inhabitants. For example, tropical climates in some regions have a profound impact on the daily lives of the people who live there. This aspect becomes particularly important when creating a tourism brand for the city. It attracts people from colder regions seeking respite from the heat and vice versa. Incorporating this element into the branding process can effectively target and cater to these specific tastes and desires. **Economy** - The economic activities that drive a city's income have a significant impact on the lifestyle of its residents. For example, in some parts of the world, agriculture serves as the main economic activity. This reality shapes the lifestyle of the people living there. Once the different elements of urban branding have been

identified, it is crucial to understand how to integrate them harmoniously in order to create a targeted branding image for the specific urban facility (Figure 5).

Figure 5: The elements of Urban branding (graph by author)

By enumerating these elements and understanding how to use them in combination, a cohesive and compelling brand identity can be created. The cultural sector plays a central role in city branding strategies, as heritage images, events and the contemporary artistic expression feature prominently in the communication material of cities. Culture offers the advantages of recognition, historical continuity, collective representation and identification. It is considered a vital comparative advantage in contemporary cities, aligning with concepts such as C. Landry's creative city and R. Florida's creative class theory. Many cities are highlighting their cultural heritage, contemporary architecture and cultural activities as part of their efforts to revitalise urban areas. Often, specific 'cultural neighbourhoods' serve as a representation of the entire city, showcasing images of 'regeneration', architectural innovation and cultural production. In recent years, urban policymakers have used three basic techniques for naming cities, as identified by Kavaratzis and Ashworth [12]:

1. **Association of Branding with a Personality ("Personality Association" or "Personality Branding"):** This technique involves associating a city with a well-known personality, often from fields such as architecture, science, arts, or literature. By transferring human characteristics to the city, this approach aims to imbue it with a creative character. While this technique has been applied in various cities worldwide, it is usually led by formal organizations and mainly aimed at the tourism sector, often excluding contributions from the local community and informal actors.
2. **Signature/Flagship Building and Design:** This technique focuses on the design and construction of important public buildings, usually with cultural content, by well-known architects. Such buildings highlight a city's status as an 'international landmark' and enhance its global position, while also showcasing the governmental institutions responsible for their creation. Examples include the Pompidou Centre in Paris, the Guggenheim Museum in Bilbao, and the MACBA in Barcelona. However, it is important to note that iconic buildings on their own are not enough; they must form part of a wider set of effective policies that bring long-term benefits to the place and its inhabitants.
3. **Branding through Signature Events ("Event Branding" or "Event Hallmarking"):** This technique involves organizing large-scale sporting and cultural events, often referred to as 'mega-events' such as the Olympic Games or designated as European Capital of Culture. By

associating the city with these events, its position in the global networks of similar events is strengthened, demonstrating its capacity to host such occasions. The various events can be classified as mega-events, characterized as one-off, transient events, while hallmark events are those that occur sporadically in a particular location. Regardless of the size and short-term gains from a single event, it is critical to integrate it into a broader urban policy and create lasting links with the local community and its needs.

Sensory Placemaking

In the purest sense, the definition of **placemaking** is a process through which places that people want to live, work, or explore are created. Considering the definition of placemaking as this has been developed through the years, we need to first acknowledge Jane Jacobs [9] when she early discovered, that cities make sense only when they are designed by everybody for everybody, giving us an early hint about the importance of inclusion, community participation and ownership in the development of the built environment. Successful placemaking as a process, involves multiple steps and relates not only to the physical and built environment, but also to the people. To create a place out of a space means considering design, location, infrastructure, logistics, service, and the needs of the people you're creating the place for. Placemaking is catching on as another way to improve the quality of various places in a neighborhood, and by extension, the community and region in which those places are located as well and most importantly in helping neighborhoods and communities imagine and create a better and more resilient future. Project for Public Spaces, has developed a tool to help in evaluating the public spaces and has found that in order to be successful, they should generally share the following four qualities: be accessible; encourage people to be engaged; the space is comfortable and has a good image; and finally, it promotes social interactions where people meet each other [13].

4. FOCUSING ON THE CYCLADIC IDENTITY AND SENSESCAPE

A city's sensescape could be perceived as a dynamic interplay of sensory stimuli that profoundly influences urban living. Thoughtful design and management of these elements can lead to more livable, enjoyable, and sustainable urban environments, enriching the lives of residents and visitors alike. The concept of a "city sensescape" encompasses the diverse sensory experiences within urban environments, including sights, sounds, smells, tastes, and tactile sensations, all of which collectively shape how a city is perceived and experienced. Every city has its own sensescape [3]. Designing for the sensescape of a city is crucial for enhancing urban life quality, fostering vibrancy, engagement, and overall well-being.

Sometimes, people are sidelined and the focus is on the built or natural environment without considering the needs and aspirations of people. Sensory maps, combined with comfort parameters, can be a very promising tool in the scientific field of comfort and mapping, enabling the creation of a sustainable urban "sensory landscape". At this point, it should be noted that, by combining participatory design, an even more sophisticated collaborative sensory mapping methodology can be created.

Figure 6: Sustainable Coastal Design Indicator Toolkit [14]

An approach of analyzing the city considering the senses is presented in a research on sustainable urban design where the analysis focuses on five main areas: urban and environmental analysis, cultural and natural heritage analysis and sensory mapping. This classification allowed the identification of a series of indicators to be used in the urban analysis. The synthesis of the above-mentioned indicators has constituted a methodological tool with replication value, useful for the study of similar places. The specific indicators and parameters evaluated in the proposed method are presented in detail in Figure 6. These parameters can help stakeholders and designers to make decisions in similar projects [14].

Cycladic architecture, prevalent throughout the Aegean islands, epitomizes a distinctive identity forged by historical development and the Mediterranean environment. Characterized by cubic forms and whitewashed buildings, Cycladic vernacular settlements exercise simplicity, functionality, and harmony with the island landscapes. Emerging from ancient Greek civilization, Cycladic architecture embodies a minimalist aesthetic with clean lines and geometric shapes, utilizing local materials such as stone and marble. Contemporary interpretations blend tradition with modern design, prioritizing sustainability and cultural preservation. Heritage conservation efforts strive to maintain the architecture's appeal to tourists seeking an authentic Greek island experience. Cycladic culture is further expressed through vibrant local festivals, music, dance, and culinary traditions. In modern times, preserving Cycladic cultural heritage involves archaeological conservation, restoration of historical sites, and the promotion of traditional arts and crafts. Museums across the islands exhibit artifacts and artworks spanning millennia, providing insight into the region's rich cultural tapestry.

Regarding the Cycladic identity and considering all the above presented, one can wonder what are the qualities which compose all the characteristics that act as magnets and attract thousands of people in the Aegean Archipelago? Several questions can be raised about character and physiognomy such as how is it possible to quantify them, whether they constitute planning parameters and act as parameter for the preservation of existing heritage. Character can be defined as the particular combination of qualities in someone or something that makes them or it different from others and also the way someone thinks, feels, and behaves. On the other hand physiognomy is defined as the appearance of a person's face. One can therefore say that character and physiognomy together consist a number of inner and outer qualities of a person. Moving to urban space analysis very often we

Proceedings

come across the meaning of character and physiognomy of the city. Could it be that these two qualities if quantified could measure and define urban space identity (Figure 7)?

Figure 7: Cycladic views – characteristics comprise identity

5. CONCLUSION

This paper attempts to unite different theories of city identity in order to address a method of preserving heritage elements considering issues of contemporary living. Parameters of sustainability, sensory perception of space, culture and spirit of place were considered as well as the notions of city branding and city identity. The overall idea is that physiognomy, that is external parameters of the city when joint to character that is internal – embodied parameters are being perceived together than a more holistic approach is created. This more unified, holistic environment can be referred to as ‘topos’ meaning a deeper understanding of a location, of a site.

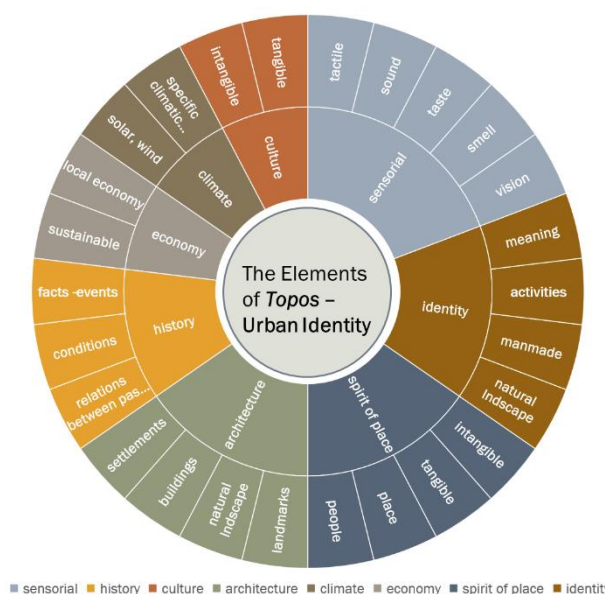

Figure 8: The elements of *topos* – urban identity

Hence, the elements of ‘topos’ as defined here can derive by composing the previous examined parameters of urban identity (Figure 8). The main categories are history, culture, architecture, climate, economy, sensory experience, spirit of place and identity. These categories can in their turn be classified into subcategories creating an easy to use indicator toolkit. This toolkit is an attempt to

bring together all the parameters of value that were identified by this research in order to create a simple tool for stakeholders to identify and preserve the significant parameters of historic settlements. The toll can be used as a checklist when evaluating a location or an intervention or as a pre-design tool for considering the concept of preservation and heritage in a design phase.

The post-2027 EU Cohesion Policy: Thoughts and suggestions

Prof. D. Kallioras

Department of Planning and Regional Development
University of Thessaly, Greece

E-mail: dkallior@uth.gr

Abstract

The European Union (EU) is a unique case of a supranational organization that undertakes an explicit commitment to the exercise of Cohesion Policy (already since the founding Treaty of Rome, in 1957) and to the promotion of economic, social and territorial cohesion. The exercise of Cohesion Policy is, on the one hand, the compensation for (or the supplement of) the creation and operation of the Single Market, and, on the other hand, a tangible manifestation of (community) solidarity. In principle, the problem that Cohesion Policy is called upon to remedy is the (cumulative) spatial asymmetry of the development process.

The period from 2020 onwards is marked by the establishment of the Next Generation European Union (NGEU) financial instrument, which was created in response to the need to deal with the effects of the COVID-19 pandemic crisis. The budget of the NGEU amounts to €750 billion that are going to be channeled until 2026 (and possibly until 2028). This amount comes from loans contracted by the European Commission, with the repayment expected to be made with the EU's own resources. The receipt of the loan resources constitutes the *de facto* issuance of a Eurobond (although such a thing, for political reasons, is not acknowledged) as it constitutes the issuance of mutual debt.

The central pillar of the NGEU is the Recovery and Resilience Facility (the so-called Recovery Fund). The budget of the Recovery Fund amounts to €672.5 billion (€312.5 billion are going to be channeled as grants and €360 billion are going to be channeled as loans). The Recovery Fund can be considered as experimentation on behalf of the EU as it can develop into an established practice to the extent that the absorption of its resources on the one hand occurs in a smooth manner and on the other hand brings multiplier benefits to their recipients. Being an indirect, though clear, confession of the inadequacies of the free market – which had already been demonstrated during the period of the economic crisis, 2008-2015 – as well as of the weaknesses of the Cohesion Policy, the establishment of the Recovery Fund may signal the evolution of the Cohesion Policy, constituting a leap in the direction of the EU's fiscal integration.

The keynote lecture expresses thoughts and makes suggestions against the backdrop of the formation of the post-2027 EU Cohesion Policy, and after the establishment of the Recovery Fund. The aim of the lecture is to ferment ideas on an issue of salient importance which, nevertheless, is not fully understood yet.

Flexible and adaptable places: a case of redevelopment plan based on long-term sustainability

M. Sepe

Department of Civil, Constructional and Environmental Engineering
Sapienza Università di Roma, ISMED-CNR

E-mail: marichela.sepe@uniroma1.it

Abstract

An urban project is carried out in the medium-long term, and it is necessary for its sustainability and the reduction of risks to foresee that use, times and design are flexible. Accordingly, also adaptation has to be considered fundamental in urban planning, as the uncertain and the sudden should become components of the design process with the same weight as the others, and consequently urban planning tools should be renewed or modified in order to contribute to the management of any crisis in an appropriate way.

Starting from these premises, aims of this study - carried out in the framework of the research project "PRIN2020 SUMMA #20209F3A37" within the ISMed-CNR Unit with the author's responsibility and the Sapienza University of Rome and ISMed-CNR related agreement - are to identify emblematic case studies of urban regeneration with respect to the concepts of flexibility, liveability and adaptation.

The emblematic case study that will be illustrated in the paper concerns the Quayside new area of regeneration in Newcastle-Gateshead, which will be completed in 2025. It will be showed with attention to the general plan, the Quayside details, and the public space aspects related to liveability, adaptability, flexibility, accessibility and sustainability.

Keywords: *adaptability; flexibility; public spaces; sustainability; place*

1. INTRODUCTION

Places influence the opportunities available to people such as cultural and social activities and are important for their sense of belonging [1].

Accordingly, in England six different types of place values [2] are identified which include: the exchange value of parts of the built environment; the value in use relating to the activities that take place there; the image value, which concerns the identity of the built environment projects; the social value and how much the built environment supports or is a threat to social relations; the environmental value and its resources; and the cultural value of the built environment.

In continuity with these aspects, other important factors for places - above all in sustainable urban regeneration plans - are the flexibility, liveability and adaptation [3-14].

The flexibility should be related to the entire lifespan of an urban project, starting from the early stages. An urban project is carried out in the medium-long term, and it is necessary for its sustainability and the reduction of risks to foresee that use, times and design are flexible [15-16].

In line with these concepts, also adaptation has to be considered fundamental in urban planning, as the uncertain and the sudden should become components of the design process with the same weight as the others, and consequently urban planning tools should be renewed or modified in order to contribute to the management of any crisis in an appropriate way.

In this way, the value of the place expands and refers to a complex and interconnected system of factors to be connected to both material and immaterial interventions in the built environment and to all those who have different interests in the place and in its quality.

Starting from these premises, aims of this study - carried out within the research project "PRIN2020 SUMMA #20209F3A37" within the ISMed-CNR Unit with the author's responsibility and the Sapienza University of Rome and ISMed-CNR related agreement - are to identify emblematic case studies of urban regeneration with respect to the concepts of flexibility, liveability and adaptation.

The case study concerns the Quayside new area of regeneration in Newcastle-Gateshead, which will be completed in 2025. It will be showed with attention to the general plan, the Quayside details, and the public space aspects related to liveability, adaptability, flexibility, accessibility and sustainability. Public spaces are an important part of this project as these are places conceived both with biodiversity and for leisure time, and include elevated areas with views on the River Tyne, break sites, sport spaces, bicycle supply areas, charging points for electric vehicles within the new multi-storey car park.

Positive aspects and possible criticalities resulted by the case study - also related to general topic of the study - will complete the paper.

2. FLEXIBILITY

The flexible city is based on tools for and urban planning and design which are not rigid and able to allow changes in the course of implementation of projects, in case of unforeseen events or new requirements and needs.

The principles of the flexible city should be related to the entire lifespan of an urban project, starting from the early stages. An urban project is carried out in the medium-long term, and it is necessary for its sustainability and the reduction of risks to foresee that use, times and design are flexible. Over thirty years of time, it may happen that a commercial land becomes a residential building, or a design phase may be delayed, requiring adjustments to the masterplan that can only be made in the presence of a flexible tool designed for places where people can work and live well. Architects, urban planners, legal professionals and developers, as well as the various actors involved in different ways in the design and construction process of the site or building, are required to design in an innovative way, offering the greatest possible degree of flexibility [16]. Flexible planning makes possible to use local peculiarities as a starting point for the redevelopment project, resulting in lower investment costs, shorter construction times and greater support from stakeholders. The various design possibilities that can be realized with respect to the existing situation are identified through quantitative and qualitative analyses, of which the latter determine the implementation of flexible planning [15].

To achieve this, it is necessary to obtain permits for flexible planning in agreement with all interested parties, even if not all of them will have the same weight in the decision-making process. Their influence will depend on the project and in general the owner and the initiator have greater importance in determining the decisions to be made, on the subjects to be involved and on times and methods. It can be expected that in large-scale projects, the public interest will be greater, while in small-scale ones the parties involved will have greater influence. Architects, planners and construction experts in the costs list the different stakeholder steps and the parties involved take note of all these information. Then all the subjects take a joint decision with respect to tasks and responsibilities with respect to the Plan, a decision which remains non-revocable for a limited period of time.

In the next steps initial scenarios are defined and determine the choices in the short term with respect to organizational, legal, financial and spatial aspects (Bergevoet, van Tuijl, 2016).

The planning of the initial scenarios only allows to work on further development during the execution of the project, in order to be ready for changes in the event of market changes or new ideas that can be implemented during the project's implementation. Investments are made in several stages, taking into account any unforeseen circumstances and distributing the risks over time. The unforeseen events can be of different types, from the increasing in energy costs to the worsening of the general economic situation; if there are many unforeseen events, many additional steps will be necessary for flexible planning, if there are few unforeseen events, the design process will require fewer adjustments.

Adaptation to the initial idea are made through assessments that can be made during construction by creating new initial scenarios. Reflective sessions are used to re-consider the development process together with the owner, initiator and stakeholders and propose a recalibration. The time factor in this process of changing the initial scenario has an important weight.

3. METHODOLOGY

The methodology which was used to identify emblematic case studies of urban regeneration with respect to the concepts of flexibility, liveability and adaptation First, keywords to search in urban design and planning and placemaking literature were selected; these include: urban regeneration, public space, placemaking, healthy, liveability, sustainability, climate change and inclusion. The case studies which were identified were then circumscribed to those belonging to European areas and to medium-size cities to better comprehend the impact of the regenerated public space in relation to the whole city. The identified areas were: Hafencity public spaces in Hamburg, Promenade du Paillon in Nice, the new Liffey Riverfront in Dublin, Superkilen park in Copenhagen, the Quayside in Newcastle-Gateshead.

As regards, the Newcastle-Gateshead quayside case study was interested by a regeneration process aimed at an urban change strongly linked to the local identity, paying attention to the participation and involvement of the population, to liveability of places, the long-term sustainability interventions and the creative economy. The general strategy and urban core plan which were adopted in March 2015 form a strategic planning framework for development in Newcastle and Gateshead up to 2030 [6].

The second data which were identified include: the presence of indicators and current strategies/policies related to healthy, liveability, sustainability, climate change and inclusion aspects. The third data was the new public spaces generated in the framework of the urban strategies and policies.

The fourth data concern the selected public space projects in themselves, namely: the kind of competition and the urban designer who won it; the data of completion; the cost; the goals of the project in relation of the selected keywords; the description of the project.

4. CASE STUDY

The case study concerns the quayside in Newcastle and the nearby Gateshead city in England. Newcastle upon Tyne is a city in the county of Tyne and Wear, founded in Roman period. Newcastle is located on the north bank of the River Tyne, the port of which developed in the 1500s and for a long time was one of the leading shipbuilding and repair centres in the world. Gateshead is situated on the southern bank of the River Tyne opposite Newcastle upon Tyne and is connected to it by many bridges.

In the seventies the industries suffered a major crisis and a subsequent closure of many of them, with a consequent economic decline [17]. The strategic actions for the redevelopment of abandoned areas in Newcastle concern the establishment of industries in innovative sectors, the construction of new homes and the lowering of rents of existing ones, the creation of digital services, the creation of a sustainable transport service, the increase in cultural and entertainment activities and events [18].

Since the early nineties, culture has taken on an increasingly important role in urban policies until it becomes one of the main elements around which to transform the territory through public investments aimed at involving the population in activities related to art and culture.

The regeneration process of Newcastle, which also took place through collaboration with the nearby municipality of Gateshead, aimed at an urban change strongly linked to the local identity, paying attention to the participation and involvement of the population, to the liveability of places, to long-term sustainability interventions and to the creative economy [17-20].

The general strategy and urban core plan which were adopted in March 2015 form a strategic planning framework for development in Newcastle and Gateshead up to 2030.

The Vision for Gateshead and Newcastle upon Tyne 2010-2030 is based on a shared framework of general strategic policies and more site-specific policies. The realization of a common plan was due to the recognition of the advantage that both Local Authorities can have in terms of economic growth and trade, employment development, housing growth, and infrastructure enhancement. The overall goal is to create two sustainable and attractive cities where people decide to live, work or visit them for their high quality and lifestyle.

3.1 The vision

The strategic objectives identified are 12 and will be included in the policies defined by the Plan for Gateshead and Newcastle upon Tyne 2010-2030. These include: SO3 To increase competitiveness by improving and expanding the role of the Urban Core as the regional destination for business, shopping, education, tourism and as a place to live; SO5 Expand leisure, culture and tourism providing for all age groups and diversifying the evening economy; SO8 Improve sustainable access to, within and around the Urban Core by promoting fast and direct public transport links to the heart of the Urban Core, increasing walking and cycling and minimizing through traffic; SO9, Ensure the development and use of land protects, sustains and enhances the quality of the natural, built and historic environment, making the Urban Core a high quality exemplar for Gateshead and Newcastle, and ensuring communities are attractive, safe and sustainable; SO10 Provide the opportunity for a high quality of life for everyone and enhance the wellbeing of people to reduce all inequalities; and SO12 To create a network of green public spaces connected and accessible by all.

The Plan identifies various themes for strategic policies, of which People and Place are the most transversal [21].

With respect to Placemaking, it aims to improve the quality of life through an attractive design and a sustainable and quality built environment, where the historical and natural heritage and the urban landscape are enhanced. The plan considers that the distinctiveness of places has an influence on people's well-being as well as on health and social cohesion.

Likewise, high-quality design is also seen as a key element in enhancing the positive characteristics of Gateshead and Newcastle. For the creation of a successful place, it is important to fully understand the context from different points of view, namely socio-economic, cultural, natural and built. The distinctive character of the areas within Gateshead and Newcastle is given by its natural topography and landscape and the rural and urban ones around it. The views of these places and their enhancement can therefore be distinctive features for the quality of the place. Public art can also be of support in this direction and if used in a sensitive and imaginative way it can help to improve the sense of place and/or improve the search for the road.

Specifically, the CS14 Policy deals with Wellness and Health to be maintained with initiatives that include: creating a living environment favourable to the elderly, creating an inclusive environment both natural and built, promoting healthy lifestyles, preventing impacts on residential services deriving from contamination of soil and water and air quality, providing adequate access to all health and social facilities, promoting accessibility for all the green spaces, and spaces for sport and leisure. The CS15 Place-Making Policy is aimed at creating environments that are attentive to the local character, safe, accessible, connected and inclusive; that respect the significant views and respond positively to the character of the River Tyne and its environment, the opportunities introduced by public art and local guidelines for design.

The CS18 Policy, which concerns the quality and interconnection of green infrastructures and the natural environment, focuses on protecting and improving the connection and multifunctionality of green infrastructures, the protection and enhancement of natural corridors, green networks with particular landscape value and trees, woods and hedges, the extension and connections of the Green

Proceedings

Infrastructure Network, the enhancement of open spaces and sports and leisure facilities and the improvement of the axis to the River Tyne and tributaries.

The CS16 Policy on Climate Change aims at sustainable development to be achieved with passive design, a good standard of the building fabric, flexibility from the outset to allow adaptability to alternative uses, and resilience to the impacts expected from climate change and the risk of floods. The policy also envisages reducing CO2 emissions and activating low-carbon energy solutions that comply with government guidelines. These guidelines will be followed by both the Gateshead and Newcastle Councils and both adaptation and mitigation will have to be achieved by also paying attention to the context, design and landscape, thus also improving their attractiveness.

Regarding the policies for the Urban Core, these focus on the quality of public spaces and paths and the protection and enhancement of the natural and built environment.

In particular, the UC12 Urban Design Policy underlines the importance of providing distinctive places in terms of quality of architecture and public spaces, to be obtained through: projects that enhance the positive characteristics of the context and the surrounding places, improving primary and secondary paths, using durable and sustainable materials appropriate to the character of the area. The readability of the Urban Core must be clear and instinctive also thanks to suitable visual connections where there are high pedestrian flows. All following a coordinated and holistic approach to the site that respects its character and enhances or creates an appropriate urban form.

The UC13 Respecting and Managing Views Within, From and Into the Urban Core Policy calls for attention to prominent views such as those from, through and into the River Tyne Gorge, major roads and major buildings and monuments of cultural interest.

The UC16 Public Realm Policy deals with the network of public spaces both regarding the improvement of existing ones and the creation of new ones in a logic of flexibility and adaptability to different uses, attractive design and use of high quality, durable and sustainable materials. This will improve the user experience, liveability and healthiness of the places and, thanks to the possibility of different and possibly temporary uses, it will increase the opportunities for social engagement.

The current presence of public art has created a strong sense of place, creating distinctiveness, strengthen the identity and attract internal investments. The UC17 Public Art Policy intends to enhance local distinctiveness and the Key Sites where public art can be included. It can also be integrated into the architectural fabric, into the floor, into street furniture, into lighting or into temporary installations and performances. Art can also help the legibility of the street increase the experience of the place and can be an opportunity for collaboration and creative work between people and maximization of the use of resources [21].

3.2 The regeneration project

The regeneration of the waterfront of Gateshead and Newcastle that began in the mid-1990s is transforming its former industrial destination into a contemporary place for leisure and culture, attractive and creative, characterized by liveability and healthiness [22-27].

The redevelopment actions, focuses on two neighbourhoods, namely Stephenson Quarter and Quayside. The Stephenson district is located between Quayside and Central Station and is characterized by abandoned areas linked to the area's railway past, by commercial and industrial buildings and with vast free spaces in disuse. The regeneration began with the completion of the Life Science Centre biomedical research centre connected to a large science museum, the Metro Radio Arena for concerts and performances, and the Central Square office building.

The other neighbourhood is the Quayside, which is the focal point of the city and where the first bridge over the River Tyne was built [17].

In 1996, on the occasion of the year of visual arts, attention had already begun to use public investments - together with those of private organizations - in the creation of new infrastructures such

as The Sage Gateshead (dedicated to music), "Dance City" (dedicated to dance), and "The Baltic" (contemporary art centre).

A further infrastructure that also became a symbol of the territorial dimension of the project is the Millennium Bridge over the River Tyne, a connection for pedestrians and cyclists to the Gateshead side.

Quayside has become one of the most vital and liveable parts of Newcastle thanks to the presence of spaces for the arts and socialization. Indeed, several public spaces have been created to connect residences and services, as well as a transport network with the use of eco-sustainable vehicles. Art, health, liveability and creativity are here understood as necessary ingredients for urban, economic and social regeneration. On the one side with the creation of galleries and exhibition canter in the industrial buildings of the nearby cultural village Ouseburn, on the other side with the creation of a music school within the Sage, open to children and people of all ages.

The Quayside is crossed on both banks by the River Tyne along which there is a cycle-pedestrian path of great interest for the views of both the bridges, the architectures, and the landscapes, offering a notable perception of liveability and healthiness. Another element of liveability is given by Quayside Seaside, the urban beach that is set up in the summer near the Tyne Bridge, with sand, deck chairs and cabins. The equipment of this area for the summer includes a climbing wall, games for children, and spaces for activities such as yoga and pilates.

The views of the bridges include the Tyne Bridge and the Gateshead Millennium Bridge which was designed by Wilkinson Eyre Architects and constitutes an element of attraction both for its architecture, for the particularity that it is a bridge that tilts, as well as for the possibility to walk along it. on foot and by bicycle.

The architectures that can be observed along the Quayside include the Sage Gateshead, regional music centre of international standing created by the Foster + Partners studio and the Baltic Centre for Contemporary Art, created from the recovery and transformation of a former grain warehouse from the 1940s.

Fig. 2. Newcastle-Gateshead, detail of the project (Source: HOK's archive)

A new plan will further improve the liveability and attractiveness of this place. The Newcastle Gateshead Quays Development Plan was presented by Ask PATRIZIA - Ask Real Estate and Patrizia - and was approved by the Gateshead Council's planning committee in November 2020.

Pandemic and consequent delays did not allow to complete the new area in 2023, but thanks to a flexible planning, the project will be completed in 2025. The plan's projects include arena, exhibition and conference centre, hotel and new public spaces. The general plan was entrusted to the HOK studio, AHR Architects is designing the hotel while the design of the public spaces has been entrusted to the Planit-IE landscape studio.

In particular, after a consultation process, the hotel that was originally adjoined The Sage International Conference Centre has moved to a new location characterized by a landscaped linear park, accessible to the public, with wide green spaces into the area and enhancement of biodiversity. The construction of the 58,500 m² complex was entrusted to Sir Robert McAlpine, while the ASM Global company will manage the campus for 12,500 people, with an area of 29,000 m² and 7,000 m² of flexible spaces for different types of events such as sports, conferences, exhibitions and festivals. Public spaces are an important part of this project as these are places conceived with biodiversity and designed for leisure time. These spaces include elevated areas with views of the River Tyne, seating areas, bicycle supply throughout the area, charging points for electric vehicles within the new multi-storey car park.

The total cost of the project is about 260 million pounds, and the ultimate goal is to create infrastructure projects to improve economic growth and quality of life and increase jobs. 4000 new jobs are expected and an income of around 60 million pounds per year. The Getting Building Fund, managed by the North East Local Enterprise Partnership, awarded 7 million pounds to create the link between north and south in the Baltic district and improve accessibility to the areas of the regeneration project. 2 million pounds were allocated for the construction of the exhibition and conference centre, public spaces, the arena, two hotels and the multi-storey car park. The conference centre will be 2,800 square meters and will be able to accommodate a flexible number of people, the exhibition space will be 6,300 square meters and the arena for outdoor events will seat 12,500 people. The designed public

Proceedings

spaces will cover an area of 2 km which includes roads, cycle paths, pedestrian crossings, green infrastructures. In this regard, the project includes seating areas and elevated areas with lookout points over the River Tyne, bicycle rentals and charging points for electric vehicles [22-29].

4. CONCLUSION

The paper illustrated the concept of flexibility in urban regeneration and the case study of Newcastle-Gateshead. In flexible planning, it is necessary to obtain permits for flexible planning in agreement with all interested parties, even if not all of them will have the same weight in the decision-making process. Their influence will depend on the project and in general the owner and the initiator have greater importance in determining the decisions to be made, on the subjects to be involved and on times and methods. It can be expected that in large-scale projects, the public interest will be greater, while in small-scale ones the parties involved will have greater influence.

The new spaces in Newcastle-Gateshead, which will be completed in 2025, are designed in accordance with the principles of biodiversity, inclusion and sustainability related to the strategic objectives and policies envisaged by the Plan and designed to accommodate outdoor activities to address the growing need for quality outdoor spaces, also due to the Covid-19 emergency.

An important aspect of this project is the flexibility both in terms of what can be done and how many people can be accommodated. In addition, accessibility is guaranteed 24 hours a day for all with walkways, lifts and escalators. The approach to the landscape was designed paying attention to the history, geology, microclimate and urban structure of the site. In this regard, the project includes seating and elevated areas with viewpoints over the River Tyne, bicycle rental and charging points for electric vehicles which will connect all the area increasing the value of place in its multiple meaning. Finally, the process of listening involved people living, working, studying, and visiting the surrounding areas in order to better focus on the needs, desires and expectations of those who will use these spaces and encourage all people to enjoy this part of the city.

Abstract

The needs of students in relation to university open spaces are diverse and concern not only the learning activities that take place inside the buildings but also those of moving from one space of a lesson to another, breaks for relaxation or lunch places for socializing.

Indeed, the well-being of a community is given by the livability, healthiness, accessibility, inclusiveness of the places it frequents and therefore, public spaces, especially open ones, if properly designed these can increase the quality of life of students, teachers, and the community of a university as a whole and, as many studies show, they can create the conditions for more profitable student learning.

Likewise, each place is different from the other and the public space, in addition to representing its society, must also be attentive to urban identity.

Starting from these premises, this study, carried out in the framework of the research project “LOVE Sapienza: Livable, enjOyable and attractiVE spaces for the community” - funded by Sapienza University of Rome with the author responsibility - aims to identify the main factors and elements that characterize best practices of public spaces in university campuses and propose a new methodology to analyze and design these spaces, adapting the original Healthy Place Method.

Keywords: adaptability, flexibility, public spaces, sustainability, place

1. INTRODUCTION

The relationship between health and urban design are complex because of the multiple elements which play different roles in the city system [1].

As several international studies on places [2] report, places influence the opportunities available to people, happiness [3] the sense of belonging and are important for cultural and social activities [4].

The definitions of the quality of the place indicated in the scientific literature are often related to terms such as liveability, quality of the built environment, sustainability and urban design according to the different practical and political traditions. Several other terms can be connected to the concept of quality of the place. Carmona [5] for example define 12 of local environmental quality: clean and tidy, functional, distinctive, safe and secure, robust, green and unpolluted, accessible, attractive, comfortable, inclusive, vital and viable, and fulfilling, which in turn are connected to a broad set of other terms and issues.

In particular, the spaces of a university campus or, more generally, of a university site mimic the functions of a city in a smaller dimension and, like this one, needs large open public spaces.

University open public spaces are important places not only for student training but also as places of socialization between students, teachers, technical-administrative staff, and, more generally, within the community which in different ways is part of the university life: family members, maintenance workers, cleaning staff, janitors, etc.

The needs of students in relation to university open spaces are diverse and concern not only the learning activities that take place inside the buildings but also those of moving from one space of a lesson to another, breaks for relaxation or lunch places for socializing.

Indeed, the well-being of a community is given by the livability, healthiness, accessibility, inclusiveness of the places it frequents and therefore, public spaces, especially open ones, if properly designed can increase the quality of life of students, teachers, and the community of a university as a whole and, as many studies show, they can create the conditions for more profitable student learning [6-20].

Likewise, each place is different from the other and the public space, in addition to representing its society, must also be attentive to urban identity.

Starting from these premises, this study, carried out in the framework of the research project “LOVE Sapienza: Livable, enjOyable and attractiVE spaces for the community”, funded by Sapienza University of Rome with the author responsibility aims to identify the main factors and elements that characterize best practices of public spaces in university campuses and propose a new methodology to analyze and design these spaces, adapting the original Healthy Place Method [1].

2. THE HOLISTIC APPROACH TO EDUCATION IN THE EUROPEAN AGENDAS

The UN SGs [21] and the New Urban Agenda [22] clearly refer to the importance of education in their principles as reported in the following.

Among the 17 sustainable goals to be reached in 2030, the fourth is Quality Education, whose objectives include: “4.3 By 2030, ensure equal access for all women and men to affordable and quality technical, vocational and tertiary education, including university”; “4.5 By 2030, eliminate gender disparities in education and ensure equal access to all levels of education and vocational training for the vulnerable, including persons with disabilities, indigenous peoples and children in vulnerable situations”; “4.7 By 2030, ensure that all learners acquire the knowledge and skills needed to promote sustainable development, including, among others, through education for sustainable development and sustainable lifestyles, human rights, gender equality, promotion of a culture of peace and non-violence, global citizenship and appreciation of cultural diversity and of culture’s contribution to sustainable development”.

The New Urban Agenda adopted during the UN-Habitat III Conference which was held in Quito in October 2016, is a document which contains many topics of interest related to the education topic. The interest in this document stands in the fact that each principle is treated in a holistic way and not in separate manner. Some of these are reported below.

“2. By 2050, the world’s urban population is expected to nearly double, making urbanization one of the twenty-first century’s most transformative trends. Populations, economic activities, social and cultural interactions, as well as environmental and humanitarian impacts, are increasingly concentrated in cities, and this poses massive sustainability challenges in terms of housing, infrastructure, basic services, food security, health, education, decent jobs, safety and natural resources, among others”.

“13. We envisage cities and human settlements that:

(a) Fulfil their social function, including the social and ecological function of land, with a view to progressively achieving the full realization of the right to adequate housing as a component of the right to an adequate standard of living, without discrimination, universal access to safe and affordable drinking water and sanitation, as well as equal access for all to public goods and quality services in areas such as food security and nutrition, health, education, infrastructure, mobility and transportation, energy, air quality and livelihoods”.

“32. We commit ourselves to promoting the development of integrated and age- and gender responsive housing policies and approaches across all sectors, in particular the employment, education, health-care and social integration sectors, and at all levels of government — policies and approaches that incorporate the provision of adequate, affordable, accessible, resourceefficient, safe, resilient, well-connected and well-located housing, with special attention to the proximity factor and

the strengthening of the spatial relationship with the rest of the urban fabric and the surrounding functional areas”.

“34. We commit ourselves to promoting equitable and affordable access to sustainable basic physical and social infrastructure for all, without discrimination, including affordable serviced land, housing, modern and renewable energy, safe drinking water and sanitation, safe, nutritious and adequate food, waste disposal, sustainable mobility, health care and family planning, education, culture, and information and communications technologies. We further commit ourselves to ensuring that these services are responsive to the rights and needs of women, children and youth, older persons and persons with disabilities, migrants, indigenous peoples and local communities, as appropriate, and to those of others in vulnerable situations. In this regard, we encourage the elimination of legal, institutional, socioeconomic and physical barriers.

“36. We commit ourselves to promoting appropriate measures in cities and human settlements that facilitate access for persons with disabilities, on an equal basis with others, to the physical environment of cities, in particular to public spaces, public transport, housing, education and health facilities, public information and communication (including information and communications technologies and systems) and other facilities and services open or provided to the public, in both urban and rural areas”.

“56. We commit ourselves to increasing economic productivity, as appropriate, by providing the labour force with access to income-earning opportunities, knowledge, skills and educational facilities that contribute to an innovative and competitive urban economy. We also commit ourselves to increasing economic productivity through the promotion of full and productive employment and decent work and livelihood opportunities in cities and human settlements”.

61. We commit ourselves to harnessing the urban demographic dividend, where applicable, and to promoting access for youth to education, skills development and employment to achieve increased productivity and shared prosperity in cities and human settlements. Girls and boys, young women and young men are key agents of change in creating a better future and when empowered they have great potential to advocate on behalf of themselves and their communities. Ensuring more and better opportunities for their meaningful participation will be essential for the implementation of the New Urban Agenda.

3. BEST PRACTICES: FACTORS AND ELEMENTS

The open public spaces of university campuses can be enhanced by inserting differentiated functions for physical activity, breaks, repairing from uncomfortable climatic conditions, socializations, organization of events and further ones improving the welfare of its community and become more attractive.

According with this holistic approach provided by the 17 SGs and principles of the New Urban Agenda, through a bibliographical research [23-26] an internet research on different campus websites (<https://you.ubc.ca/tours-events/campus-tours>; <https://www.ucd.ie>; <https://www.tudelft.nl/en/education/information-and-experience/preparing-for-a-bachelor/bsc-campus-tours/visitus-campus-tour>), visits by the author to universities campus (Figures 1-4), the factors and elements to identify best practices of public spaces university campus were decided. These include the presence of: green spaces; inclusive accessibility; shelters for shelter from the sun/rain; benches; tables; rubbish bins; poles for artificial lighting; urban furniture of quality design; artistic elements; play spaces; spaces for sports; study spaces; cycle-pedestrian paths; bicycle racks; charging points for electric bikes; proximity to subway and/or bus stops; dedicated means of transport to the campus; solar panels; water plazas; and wayfinding/signage.

The presence of green spaces was considered in relation to their size, the variety of typology, the possibility of seeing them only or of being able to use them in a different way.

Accessibility was considered from various points of view: both outside the campus, with dedicated parking, and inside the campus with paths without architectural barriers.

The presence of shelters was observed in relation to various aspects, both for repairing from the sun and from the rain, and in relation to the possible furniture for waiting for the harsh atmospheric event to end.

The benches were observed regarding not only to their presence, but also to their quantity, position, and proximity to tables and other furnishing elements and trees.

The presence of tables was also noted in relation to quantity and function and, as in the case of seats, proximity to other equipment.

The rubbish bins were observed regarding quantity and function for separate waste collection. With regard to lighting poles, these are identified with regard to their presence, quantity and location; it is also noted whether the lighting poles are solar powered or in any case energy saving.

The attractiveness of public spaces can be even greater if they have a quality project, designed with durable materials and a pleasant design. Artistic elements are another important element as art in its different modes of expression can make places more beautiful and therefore more livable and enjoyable.

The play spaces help to make the moments of breaks from lessons or periods in which they are not there more pleasant. Such games must be inclusive and also be designed for people with fragility. The spaces for sport together with those for games are fundamental places for aggregation and socialization in free moments as well as outside of lesson days. This were observed in relation to quantity and typology.

Spaces where people can study both outdoors and indoors cannot be missing to allow both off-site students and students who live not near the university or, simply, for those who want to study important places on a campus and these must be designed to be welcoming, equipped and suitable for shelter from difficult weather conditions.

The presence of mixed cycle-pedestrian paths or, if there is space, even separate ones, constitute an important element for connecting the often large spaces of a campus. In this regard, another element consists in the presence of racks for parking bicycles, as well as the presence of electric charging points for bicycles. Both elements must be analyzed in relation to their presence near the cycle paths and the quantity. The proximity of the campus to bus stops, underground trams near or inside the campus and/or the presence of small electric buses to connect the different public spaces are further elements of quality.

Orientation within the various areas of the campus and the presence of the various types of public spaces must also be adequately indicated with wayfinding, totems and signage on site and on an online map on the campus website. Finally, solar panels and water collection in water plazas are important in relation to sustainable aspects.

4. MAPPING BEST PUBLIC SPACE CAMPUS

According with the aforementioned European Agendas and the results of the research illustrated in the previous section, some first deductions include as follows. Campus spaces have several points in common with urban spaces, as buildings, open spaces and pedestrian paths can be observed in both. The quality of university outdoor spaces increases the quality of urban and university life and therefore public spaces should be designed in detail to meet the contemporary evolving needs of its community. Likewise, each place is different from the other and the public space, in addition to representing its society, must also be attentive to urban identity.

A well-organized space offers the possibility to establish connections between the physical and social environment, make the place meaningful for the students and can create the conditions for more profitable student learning.

To suitably analyze and design improvements of the campus public spaces, the methodology with which the university sites will be analyzed is the Healthy Place Design, conceived by the author and already tested in Europe, the United States and China. The method aims to detect factors which make places healthy and liveable from the user's point of view and identify appropriate project interventions to enhance or design these factors. For the purpose of this study, the method will be adapted to better fit the surveys of university campuses.

The part of analysis of the method – five phases - consists of different kinds of surveys, observations, and questionnaires. The part of design is composed by three phases and aims at identifying the project interventions.

Phase 1 of the method consists in the definition of the study area; it needs to go on the site in question in different days and hours and decide, through one or more inspections, what are the public spaces to include in the analysis.

Phase 2 is characterized by the observation of the characteristics of the place through three surveys concerning the kinds of activities, the perceptions, and the elements which contribute to the feeling of healthy and liveability of the place.

In the survey 1, the types of people – students, professors, residents, workers etc.. - and their activities are observed. It needs to observe the activities – break, study, sport, lunch, etc.. -from the quantitative point of view, to collect data concerning in what percentage the activities are present in that place and how influence its liveability and urban health. Then, it needs both measure and observe the presence of different typologies of persons from the quantitative point of view, expressed in low, medium, or high presence of people.

Accordingly, the frequency with which the activities are repeated or implemented and with what pace is measured: it is observed if that activity is carried out with a rapid, moderate or slow pace.

The survey 2 consists in identification of singular and mixed perceptions. The singular perceptions include the visual, sound, tactile, smell, taste perceptions, while the mixed one include those of chaos, serenity, disorder, joy, harmony, disorientation, uncomfotability and so on, and depend on the sum of one or more perceptions. Their quantity is expressed as light, medium and high amount percentage; the quality is expressed as pleasant and disturbing perceived perception.

The survey 3 of this phase consists in the observation of the elements which contribute to the health and liveability sensation such as constructed and natural elements, suitable pedestrian/bike paths, art product, sport areas, and good quality equipment and urban furniture - pavement, tables benches, lighting, wireless, solar panels; wayfinding/signage etc..-, and kind of accesses.

Figure 3 University of British Columbia Vancouver (Source: Author's Archive)

Figure 4 University of British Columbia Vancouver (Source: Author's Archive)

Finally, from the intersection of these data, a first outcome of the degree of healthy and liveability of the campus spaces is obtained, resulted from surveys on the place in object.

Phase 3 consists in a questionnaire administered to the campus communities who use the sites aimed at identifying factors and elements which give them the sensation of healthy and liveable place.

This questionnaire is mainly administered to common users of the place in object, including students, passer-by, locals, teachers, community in general, and visitors of different age and nationality. In case of specific objectives of the case study, privileged witnesses and stakeholders can be interviewed to allow a further interpretation of the site.

Questions may include the following and will be modified in accordance with the place characteristics. 1. This place gives you a feeling of liveability or discomfort/ health or unhealthy? 2. What are the elements that give you the above sensations? 3. What are the main facilities that give quality to this place? 4. What are the activities that you act in this place and how often?

5. According to the place healthy and liveability what could be done in order to improve these public spaces? 6. What is a healthy/ liveable university place that you remember in this city or elsewhere? 7. How the weather condition might influence the perception of healthy and liveability of this place?

The observation of the place carried out during the previous surveys allow the choice of the most suitable part of the area to administer the questions. Usually, the presence of fountains, benches, steps and other kinds of urban furniture around which people stop, constitute sites where students, teachers, and people who stay in a campus take a break and are more available to answer.

Phase 4 is that of the analysis of the traditional cartography of the campus in order to understand the elements that compose the place in terms of the type of built elements, natural environment (green areas, rivers, trees, hills, etc ..), and open spaces in the campus and in the surrounding area.

Phase 5 involves the construction of the map of urban health and liveability of the campus public spaces with the identification of sites and features that give to the people who use those places the perception of these factors.

The map will be the result of the different survey operations, analysis, questionnaires and observations, which were collected on the sites in object.

In phase 6, the check of the degree of healthy and liveability is carried out. This is obtained through the study of both intrinsic and extrinsic factors contained in the map and which are capable to determine urban healthy and. The intrinsic factors include the perceptions, orientation, and culture. Extrinsic factors include the architecture, facility, and urban furniture. The aim is that of identifying factors that can be improved according with the 25 principles of the Charter of Urban Health and Liveable Design concerning [1].

Phase 7 concerns the check of the emerged first design ideas with the users of the place through a questionnaire to obtain a “mosaic” of degree of pleasure of these.

Following the check of consistency with the Charter of phase 6 and the results of the phase 7, in phase 8 the identification of the project interventions in the areas in object with attention to healthy, liveability and flexibility is carried out through the overlapping of the results of the previous phases and a check of consistence with spaces and urban furniture and equipment already present.

5. CONCLUSION

The spaces of a university campus or, more generally, of a university site mimic the functions of a city in a smaller dimension and, like this one, needs large open public spaces.

University open public spaces are important places not only for student training but also as places of socialization between students, teachers, technical-administrative staff, and within the community which in different ways is part of the university life: family members, maintenance workers, cleaning staff, janitors, etc.

The needs of students in relation to university open spaces are diverse and concern not only the learning activities that take place inside the buildings but also the activities of moving from one space of a lesson to another, breaks for relaxation or lunch places for socializing.

According with these considerations, the study - carried out in the framework of the research project “LOVE Sapienza: Livable, enjOyable and attractiVE spaces for the community”, funded by Sapienza University of Rome – illustrated through the holistic approach provided by both the 17 SGs and principles of the New Urban Agenda, a bibliographical research, an internet research on different campus websites and visits to universities campus, the factors and elements to identify best practices of public spaces university campus. These include the presence of: green spaces; inclusive accessibility; shelters for shelter from the sun/rain; benches; tables; rubbish bins; poles for artificial lighting; designer urban furniture; artistic elements; play spaces; spaces for sports; study spaces; cycle-pedestrian paths; bicycle racks; charging points for electric bikes; proximity to subway and/or bus stops; dedicated means of transport to the campus; solar panels; water plazas; and wayfinding/signage.

To suitably analyze and identify improvements of the campus public spaces, the methodology with which the university sites will be analyzed is the Healthy Place Design, conceived by the author and already tested in Europe, the United States and China. The method aims to detect factors which make places healthy, liveable and happy from the user’s point of view and identify appropriate project interventions to enhance or design these factors. For the purpose of this study, the method was adapted - and illustrated - to better fit the surveys of university campuses.

Next steps – according with th research project objectives - will concern the test of the method in different campus with particular attention to the Sapienza University public spaces and the proposal of guidelines to improve or design livable, enjoyable and attractive spaces for university communities.

The Absence of Public Space Project in the Massive Production of New Settlements of the Program My House My Life in Brazilian Cities

M. Mareggi

Department of Architecture and Urban Studies, DASTU, Politecnico di Milano, Italy

Corresponding author: E-mail: marco.mareggi@polimi.it

Abstract

After the pandemic the design of public spaces become more relevant in the agenda of urban transformations, but only apparently as an established and widespread situation. The case concerns the design and implementation of public spaces in the new residential settlements of the Brazilian Program *My House My Life* (2009-2020). After an introduction on the Program, the paper presents an overview of the different conditions of public spaces in the PMCMV settlements on the island of Maranhão, a metropolitan capital area in the North-East of Brazil, as result of a field research, carried out by the author and some scholars of the State University of Maranhão in July 2022. First, the research reflects on the monofunctional islands, characterized by two types of settlements and very few connections to the urban grid of public spaces. Secondly, it examines the role of private property in defining proximity conditions through formal and informal services and activities. Finally, the discussion highlights the relevance of private actors (building companies during the design and construction processes and homeowners who live there) and the absence of a collective idea and perspective of urban space “out of private properties”.

Keywords: *social housing; facilities; public open spaces; informal public spaces.*

1. INTRODUCTION

Is the design of public spaces on the agenda of urban transformations worldwide? In the aftermath of the pandemic, academics, politicians and civil servants are confident that the answer to this question is affirmative. The lockdown that forced everyone to stay indoors in 2020 made us aware of the importance of the network of neighbourhood services and the continuity of open spaces, especially in cities and metropolitan areas [1]. A debate on the city of x minutes has opened up in the international debate, following the political slogan promoted by the French capital [2]. Everywhere, continuous pedestrian and cycle paths, squares and playgrounds near homes and workplaces, well-connected parks and pocket gardens have become important; public administrations have decided to invest in the design and implementation of such interventions [3, 4, 5, 6, 7, 8]. Only apparently this is an established and widespread situation. It is necessary to continue to monitor the development of this aspect of urban design, because situations of advanced progress in the definition of public space are juxtaposed with shortcomings and gaps in the design and implementation of a widespread network of public spaces and services. Different attitudes are noted from city to city and between consolidated contexts undergoing change and parts of expanding territories.

The case discussed in this contribution concerns the design and implementation of public spaces in relation to the construction of new residential settlements in Brazil, promoted by the Federal Program *My House My Life* (*Programa Minha Casa Minha Vida, PMCMV*). In particular, it reports on how the programme was implemented in São Luís, a metropolitan city, capital of the North-East State of Maranhão in Brazil.

After an introduction on the Program *My House My Life*, the paper presents an overview of the different conditions of the public spaces in the PMCMV settlements on the island of Maranhão, as result of a field research conducted in July 2022. First, the research reflects on the monofunctional

islands, characterized by two types of settlements and very few connections to the urban grid of public spaces. Secondly, it examines the role of private property in defining proximity conditions through formal and informal services and activities. Finally, the discussion highlights the relevance of private actors (building companies during the processes and homeowners who live there) and the absence of a collective idea and perspective of urban space “out of private properties”.

2. THE PROGRAM *MY HOUSE MY LIFE*

In 2009, the Federal Government of Brazil promoted public policies for social housing to create affordable houses for low-middle-income families and to support the construction sector.

To react to the 2008 financial crisis [9], and to mitigate political instability and support electoral interests [10], the Lula government, in its second mandate, took this opportunity in 2009 to launch the *Minha Casa Minha Vida* Program (federal law no. 11,977/2009) with the initial objective of building 1 million houses.

The objectives of the PMCMV concerned, on the one hand, the reduction of the housing deficit, which according to the João Pinheiro Foundation and the Ministry of the City in 2006 was 7,934,719 houses, corresponding to 14.5% of the country’s housing stock, which for 94% it concerned the population with an income up to 10 minimum wages [11]. On the other hand, the program aimed at increasing investments in the construction sector and the creation of new jobs in the related sectors, ranging from the extractive industry and the production of building materials, to building construction up to that of furniture and household appliances which allowed the use of homes. Thus, the production of homes of social interest and for the low-cost market guaranteed the social and redistributive purpose but it was first and foremost an economic program [12] and an anti-cyclical policy that hinged on building production. In fact, the construction companies could obtain special lines of credit to build homes in the first two income brackets (0-3 and 3-6 minimum wages) or in general tax relief and facilitations in the project approval process, with priority analysis for approval in the Municipalities [11]. In addition to businesses, these opportunities were also made available to *entidade popular*, legal entities resulting from popular mobilization, with a specific line of intervention and dedicated funds. These subjects, in addition to being responsible for the contracts and works, have the task of discussing the projects with social support and selecting the families who benefit from the interventions, a task which in the case of private companies was instead carried out by local authorities.

In eleven years (2009-2020), the Program *My House My Life* (*Programa Minha Casa Minha Vida*, PMCMV) has constructed 7.525.000 housing units all over the States of the Federal Union, and 5.399.700 were successfully delivered. The program concerns the development of a system to build housing units for low-income families, offering subsidies for families who did not exceed an average monthly income equal to 3 minimum wages (income band 1) and favorable financing conditions for the home purchase for families with incomes from 4 to 10 minimum wages (income bands 2 and 3, in 2009). The beneficiary selection criteria sought to give priority to families living in risk areas, families where the head of the family is a woman and families with disabled members. In relation to family income band 1 (corresponding until 3 minimum wages), the program offered the possibility of subsidies up to 90% of the value of the house; in turn, the other bands followed a popular market financing structure, with repayment quotas and subsidized interest rates. The guaranteed contributions to band 1 allowed 1,901,984 families to access housing at controlled prices [13].

According to Rufino, these residential settlements were mainly located in two contexts: the consolidated suburbs, occupying residual urban voids, in many cases adjacent to previous social housing interventions promoted by the *Banco Nacional da Habitação* (BNH), or in not urbanized areas, as «frontier outposts», in peri-urban fringe areas «discontinuous, often outside the pre-existing urban perimeter» [14: 67] and seen as starting points for further urbanization of natural land.

In 2020, after a brief interruption of the Program due to a political change in the Federal Government, the *Minha Casa Minha Vida* 2023-2026 Program was re-proposed to the Federal Congress on 14 February 2023, with some modifications (Provisional Measure No. 1,162) [15].

3. METHODOLOGY

The implementation of the program was investigated in a specific context, the island of São Luís, a metropolitan area around the capital of the North-East State of Maranhão in Brazil. These different interventions of Program MCMV have been developed and completed. A field research was carried out by an international team, composed by the author, and some scholars of the State University of Maranhão (UEMA), Brazil. Together they carried out field research in the settlements of São Luís, São José de Ribamar and Paço do Lumiar. These urban areas constitute the metropolitan conurbation without continuity solutions. The joint inspection was carried out in July 2022 and involved 11 residential complexes built as part of the program on Ilha do Maranhão.

In São José de Ribamar, the Nova Aurora, São Jose II and Nova Terra residential complexes were visited; instead in the city of Paço do Lumiar Primavera, the complexes of Morada dos Bosques and Cidade Verde; while in São Luís the residential settlements of Amendoeiras, Morada do Sol, Santo Antônio, Vila Maranhão and Luiz Bacelar. All the “non-neighborhoods” visited are aimed at families with very low incomes between 1 and 3 minimum wages (income band 1); only Cidade verde is an intervention aimed at families with a slightly higher income, between 3 and 6 minimum wages (income band 2). The latter is also the only residential settlement, among those studied that targets families with higher incomes.

A photographic campaign, interviews with local actors and residents and visits to some houses and artisan activities allowed to make direct contact and measure through direct experience the urban condition implemented by the Program *Minha Casa Minha Vida*.

The field research was complemented by a study of the urban planning and architectural literature, mainly bachelor's, master's and doctoral theses in Portuguese, and a redesign and schematisation of the urban layout at three different scales, representing the main morphological characteristics of the neighbourhoods and the architectural peculiarities of the building units, and highlighting the changes in the relevant areas of the dwellings [16].

4. MONOFUNCTIONAL ISLANDS OF TWO TYPES OF SETTLEMENTS

The interventions carried out on the island of Maranhão are all significant in relation to the number of housing units created, which range from 700 to over 2,100 for each complex. Nova Terra in São José de Ribamar, among the first interventions started in 2009 and built in ten phases, even exceeds 4,000 real estate units, all on one floor [17].

Figure 1. Nova Terra, São José de Ribamar, Brasil. The residential settlements; Scheme of built and open spaces and mutations (drawing: G. Eportentosi), Sport facilities (photo: M. Mareggi 2022)

The field research carried out on the island of Maranhão and the comparison with the literature allowed to highlight that this building production has used two types of standardised settlements in terms of the form of the residential complexes: on the one hand, isolated houses on plot (single, double or, in a few cases, four-family houses), organised by an orthogonal grid of streets, and on the other hand, closed fences of multi-family buildings controlled by a guardhouse, the so-called *condomínios feschados* or gated communities. [18].

4.1 Settlements of detached houses

A *first type of neighborhood* is made up of a repetition of single-, double- or in more sparse cases four-family houses, organized by an *orthogonal grid* of streets, potentially open, but often well delimited. They are mainly secondary neighborhood streets with sidewalks, often anonymous even in names, sometimes simply numbered. The private open spaces in front of the residences face them without barriers. In addition to the minor roads, there are a few main streets, two-way, in some cases with traffic islands (Morada do Sol). In the majority of the cases studied, the street grid comprises elongated rectangular open blocks. Sometimes the orthogonal system results in a simple double-comb system. The connection with the territorial road network is often unresolved and occurs through a single access to the settlement, which has no specific connotation. Even the road layout is extraneous to the upcoming road network. These residential settlements are therefore *islands*, sometimes limited by infrastructures or, more often, located in rural contexts without a pre-existing territorial layout. Around them, there are natural areas or partly cultivated land, where the gap between urban and rural is marked by the border road, or informal settlements made with waste materials (Morada dos Bosques), almost a sort of small *favelisation* around the interventions of the new PMCMV complexes. In this type of neighborhood, the maintenance of asphalt roads is poor and the presence of parking is rare, except in front of some rare public activities.

In this first situation, the settlements between 700 and 4,000 residential units are mainly composed of single-storey semi-detached houses, in one case also of single-family houses (Cidade Verde) and in two cases of 2-storey buildings with 2 apartments per floor (Nova Aurora and Primavera), where a relevant open space is assigned to each family. All the houses repeat the same internal distribution model, with a few variations.

Concerning the provision of services, the main street of the residential complex often becomes – over time and according to informal practices of functional and building transformation – a commercial and small craft facade. Thus, the buildings extend up to the street level (Amendoeiras), also occupying the narrow sidewalks with temporary coverings (Nova Terra), or by building a veranda as an extension of the house, open towards the street (Morada do Sol) and higher than the level of the driveway (Morada dos Bosques). Few commercial activities are scattered throughout the settlements, located in re-functionalized residential properties; often these are building additions that occupy the private space on the front of the house. The buildings with a different function and form than homes are very limited. Among these, in several neighbourhoods there are religious buildings, while there are a few nursery schools. In some there are health facilities, for example in Nova Terra, one of the first interventions in 2009 and among the largest in size, where there is a general health unit (*Unidades Básicas de Saúde*, UBS). The state of the provision of equipped open spaces and sports facilities is more complex. The inspections showed a discontinuous presence. Usually along the main road or at a central crossroads of the settlement, the plan has left some lots for gardens or leisure facilities. Where present and significant, there are lawns and equipment in a state of decay (Cidade Verde) or in use as a result of the requests of citizens and local associations, in the face of attempted occupations and privatizations for further residential expansions (Nova Terra). However, the absence of paved squares can be noticed, both in the street layout and in front of places of civil or religious representation, which are also absent or have no connotation.

4.2 Condominium colonies

If the neighbourhood of isolated houses on plots distributed in an orthogonal grid in a rural area is prevalent in these newly planned settlements, a second aggregation form is also present on the island, widely spread in the major Brazilian metropolises, for example in Rio de Janeiro [19]. This second type of neighbourhood concerns the *closed fences* of multi-family buildings, the so-called *condominios fechados* – a housing complex fenced and controlled by one or more guardhouses –, which here find a modest version compared to the homologous controlled citadels of the wealthy classes [20]. In the cases under investigation, these are 4-storey apartment buildings, repeated and located to form a linear sequence of low towers or symmetrically ordered around an asphalted courtyard used as a car park. The “condominium colonies”, such as groups of multi-storey buildings delimited by an enclosure, are closed within a curtain wall, with controlled access with security. The relationship with the road system is defined by a single entrance for each colony of condominiums, and the separation from the urban context they generate appears clear: the public sidewalks (rarely used) and driveway paths circumnavigate the fenced complex. Inside there are service spaces for collective use (loisir area, waste area, sports equipment), which are modest, small in size and show traces of poor use and neglect. Inside the enclosures, the ground is completely paved and there are only small green open spaces between the buildings. This type of settlement is found in both urban (São José) and rural (Vila Maranhão) contexts. The latter constitutes a sort of “Apache fort” in the natural landscape, where the distance from the city (a few kms) and the absence of services is counterbalanced by the spontaneous establishment of commercial and restaurant activities in precarious wooden or metal shacks along the only public access road to the fenced condominium colonies.

Figure 2. Vila Maranhão, São Luís, Brasil. The residential settlements; Scheme of built and open spaces (drawing: G. Eportentosi), Informal street trading (photo: M. Mareggi 2022)

It is worth noting that the two types of complexes studied, and the minimalist residential architecture that constitutes them, do not depend on the territorial context investigated. The repetitiveness with which the PMCMV proposes the same types of urban fabric and building typologies from North to South of the country is surprising [21]. It is a reiteration of a single functional program for houses and an *obsessive repetition* of architectural typologies in the settlements. In fact, the interventions paid more attention to significant production rather than to the urban quality of the complexes and the architectural quality of the buildings [22]. Furthermore, the same architectural typologies proposed by the Federal Economic Fund are taken up everywhere in the same form, without considering adaptations to different geographical, climatic and cultural contexts [23], with a standardized building production carried out on-site and not industrialized [14].

In contrast to the great homogeneity of the works carried out, there are some cases of different projects and interventions, adapted to the contexts and qualified in the architectural solutions, albeit in episodic cases, for example where inhabitants and associations have contributed to the definition of the interventions [24].

It is important to note that construction companies have generally preferred to create collages of closed urban interventions or on cheap land outside the city, often contributing to the creation of a periphery of the periphery or even new small, scattered and isolated settlements.

Both of these spatial configurations do not allow for a process of community building, with the service provision and social relations that this entails; rather, they only remain an opportunity for the production of houses.

5. PRIVATE PROPERTIES DEFINE PUBLIC SPACES

The description of the two types of settlements highlights the lack of public space design. In the first type, the neighbourhoods of detached houses, the role of backbone of the public space is entrusted exclusively to the grey infrastructure, with a function mainly related to urban road mobility, on which public services or commercial activities are usually located, without a specific urban and architectural character. In the second type, the fenced condominium colonies, the spaces of sociality are located within the private enclosure, whose access is designed for vehicles. The vitality of the public space is only determined by informal street-side activities, where present.

The lack of planning, design and/or implementation of public space in these settlements is largely compensated by the modification of private property. The focus is on the material actions that redefine physical space rather than temporary social actions (festivals, occupations, demonstrations), which this contribution is not focusing on. On the one hand, the mutations of private property are gradual and primarily concern the transformation of individual houses, which indirectly transform the street section and thus the public space. On the other hand, new informal and precarious spaces are being created at the edge of the road, on vacant land; these new activities seem to play a substitute role for the lack of design of spaces and services of public collective life.

About the first aspect, the inhabitants find themselves living in environments where privacy and security are guaranteed only in the closed domestic space. In the detached house, the open space is significant only on the main front of the house (4-5 meters deep); while it is very limited between the houses, on the sides and at the back. These privately owned open spaces, in a short time and in a self-managed way, change. Walls arise that delimit the property boundaries between the houses and create new open-air rooms at the back. Or verandas are installed on the main front, in masonry or light materials, sometimes precarious. Properties are frequently delimited by high walls on the borders, with an opening for car access. This causes a radical change in the road landscape which becomes closed. And the open settlement of isolated houses on plots becomes a grid of streets designed by the building curtains of the newly shaped patio houses. In extreme cases, the open space in front of the house is transformed into a new volume, to the point of becoming a building extension of up to two floors, both for residential and productive/commercial uses. Recurring is also a sort of private characterization of the sidewalks which become discontinuous in levels, shapes and materials, because each owner tends to characterize it and adapt it to his/her own home. This is a recurring use in low-density settlements in Brazilian cities [25] and is not specific to these places of social housing. The public space of the street is thus completely reduced to a mere area of vehicular circulation and its shape does not allow to feel and experience it as a public space dedicated to sociality.

Similarly, the creation of new informal spaces at the roadside determines an unplanned vitality of the street space, transforming it from a monofunctional to a multi-activity place. This happens in both types of settlements. The formal and informal opening up of activities determines new commercial and service streets that become meeting and resting places. They can be extensions of the dwelling or the occupation of empty spaces with light and precarious materials, located at the crossroads of mobility flows. These are economic activities, both sales and services, that seem to respond more to needs induced by the social context and seem to play a role of compensation for the lack of design of public and collective space, both functional and spatial.

Even with respect to the design of the roads themselves, it is worth noting how the field survey in the settlements of isolated houses on plot in São Luís has shown that the main street is only larger than the secondary ones, bike paths and parking plots are not present, and sidewalks are narrow; their materials and levels change according to the different houses. Very few public (schools, health centres, churches), commercial and workshop facilities are planned. Usually, the last ones have grown informally in enlarged parts of the houses or occupying sidewalks. Some little playgrounds and leisure areas are underused or, differently, some sports facilities are preserved by local communities against the new residential developments. Differently, the gated communities have few poor facilities in the

Proceedings

private fenced spaces. Moreover, a continuous and high wall defines the relationship of the settlements with the surrounding city, creating a strong physical barrier.

In general, the provision of public services, be they buildings or open spaces, is limited, when present, to a few equipment: «a sports field, not always positioned correctly, even in defiance of its solar orientation, a playground with unattractive games and a little or badly used social center» [26: 211]. The absence of a continuous qualified open public space adds to the lack of integration with the surrounding urban fabric, often not even where such integration would be possible.

6. CONCLUSION

The large-scale construction of new residential settlements for the low-income population has often led to the creation of monofunctional urban areas. The lack or absence of services highlighted does not allow to consider them “self-sufficient neighborhoods”, if by this we mean a complex set of residences and public and private facilities where the daily life of families can take place. Not even the partial transformations of houses into shops and services manage to bring about a change in the monofunctional trait of the settlements. These informal and self-built operations carried out by the inhabitants, necessary for the survival of the family, transform homes into a socio-economic asset [27], and create the dynamics of public space, but without conforming it to a continuous chain of places, able to become a backbone of social and public life, recognized and used by citizens [28, 29]. It does not have the ability to create consolidated urbanity, although it enlivens daily life in the proximity of activities and becomes a place for some occasional form of spontaneous sociality.

In these interventions, the weakness of defining only a street grid, with a few plots available for hypothetical public squares or gardens, emerges as a problem. The orthogonal grid does not seek relationships with the existing street grid and does not adapt to the characteristics of the ground and the environment. This highlights the lack of designing the city in its public dimension and contextualisation. *The My Home My Life* program thus manifests its nature: to produce houses and not to build livable cities. Similarly, the program does not express a shared idea of the space of collective life, except in the private dimension. This is also evident in the lack of design of public space in the face of the few existing public services, such as a health centre or a school. Even these do not become an opportunity to design a square, a meeting place, a playground. Also, the sequence of commercial activities and services does not foster the redesign of the pavement, so that it becomes a place for walking and meeting.

Perhaps this characteristic of the MCMV program is due to the political decision to entrust the design and management of the interventions to the real estate sector. The recurring criticism that the real estate sector is primarily motivated by economic considerations is only partly justified. The voices of public actors, such as local and public administrations and research and training institutions, seem to be scarcely present in the debate and do not play a leading role in urban transformation processes, nor a collaborative role with the productive sectors in order to convey an idea of a qualified public city. The lack of a public perspective and of adequate urban planning is undoubtedly the reason why the network of streets and public spaces of the new settlements is not connected to the existing city, and why the interventions are often located far from the city and the workplaces, in ultra-peripheral areas such as consolidated suburbs or non-urbanised areas [30].

The building companies that led the process of developing the PMCMV have thus conditioned the choice of construction sites; in fact, even in this publicly funded programme, building and real estate companies have continued to pursue a logic of construction intervention through the obsessive repetition of isolated houses or closed condominiums. In Brazil, market-oriented housing production has long adopted the same settlement logic [31], perpetuating an urban model of monofunctional residential, commercial or tertiary enclosures, juxtaposed but without relations.

Thus, the relevance of private actors – construction companies in the design and implementation processes of the programme and the homeowners who live there – and the absence of a collective

idea and perspective of urban space “out the private property” have produced a new disconnected and car-oriented city, with the absence of traditional or innovative public open spaces.

Abstract

There is a growing need to design and/or redesign usable, comfortable, but also safe urban spaces, roads and equipment, in which everyone can feel included. The pursuit of safe conditions, including the various forms of threat and crime, requires the integration of the different existing approaches to achieve effective and lasting results.

Urban planning can ensure that spaces dedicated to the community and shared use are transformed into as many common goods, thus satisfying citizens' legitimate aspirations to improve the quality of life, for which safety is important. The objective of this EU-funded project (Next Generation EU) entitled "SeTUP - Security Town through Urban Planning" is that the results of this research will lead to the definition of models that can be implemented in policies, plans and regulations.

This work is, in fact, an opportunity for a more careful reflection on the topic in order to identify the key aspects that allow Urban Planning to be oriented towards the environmental prevention of crime risk and the definition of specific actions, possibly to be contemplated in the municipal urban plan, for the adaptation, over time, of urban spaces to security criteria.

Keywords: *safety, adaptation, public spaces, urban planning, next generation EU - Prin 2022 PNRR.*

1. THE THEORIES OF CRIME

Urban safety refers to the measures and strategies put in place to ensure the well-being and security of residents within urban areas. It encompasses various aspects such as crime prevention, emergency response, infrastructure resilience, public health, and environmental sustainability. Creating safe cities is crucial for fostering community cohesion, attracting investment, and enhancing the overall quality of life for residents.

It is a concept that includes within a single definition a broad spectrum of phenomena ranging from predatory offences (robberies, thefts, muggings) to assaults and behaviours such as simple infractions or acts of incivility such as writing on walls, breaking bottles in the street, disturbing the peace.

As for theories and techniques, related to urban safety, there is a vast literature, extensively referred to by researchers over time, which has employed increasingly sophisticated and scientific approaches to understanding and solving the problems of crime.

Several studies have contributed to the formation of the modern understanding of the environmental approach, some of the main streams are briefly described below.

1.1 Eyes on the Street Theory

This theory is based on the concept of *natural surveillance* [1], which represents the controlling action exercised by citizens during their daily activities. The presence of people in the street performs a twofold task: firstly, it hinders criminal behaviour, as offenders generally tend to prefer places of action where they cannot be seen. Secondly, the presence of people increases the perception of security, as it multiplies the opportunities for control and help in case of need [2].

The reasons for urban unsafety are thus to be found in the lack of vitality generated by the insufficient functional mix. The latter stimulates the presence of people in the street, on the pavements and in urban spaces by ensuring eyes on the street, i.e. the informal control of urban space [2].

This is only possible in a living city, in high-quality urban environments that inspire trust and safety, and in spaces that citizens love and are ready to defend.

1.2 Crime Prevention Through Environmental Design (CPTED)

The CPTED method [3] suggests that the physical environment can provide opportunities for crime to occur, thus having a deterrent rather than a preventative effect.

Hence indicating that crime can be reduced by varying environmental factors. The aim of CPTED is to alter the physical environment to ensure that the ‘normal’ users feel safe, but make the ‘abnormal’ users feel uneasy and apprehensive about engaging in any inappropriate antisocial behaviour [4].

It is based on the “behaviourist theory” of operant learning [5]. Every behaviour takes shape based on environmental stimuli and can result in reinforcement or punishment upon the performance of a criminal action. By manipulating the environment appropriately, it is possible to induce specific reactions in individuals [2].

1.3 Defensible Space Theory

Design standards are at the centre of this theory, which aims to enhance architecture, land use, security, and lighting. The concept of territoriality is highly emphasised in this theory, as it is believed that it is crucial that residents feel a sense of belonging for the design to be effective.

Therefore, suggestions are made to encourage the territorial behaviour of residents whose presence could provide surveillance around their residences and advocate the construction of boundaries that reinforce natural territoriality to help residents intervene and prevent crime in their spaces [4].

The first architect to concretely translate theories into projects applied to cities was Oscar Newman, author 1972 of *Defensible Space: Crime Prevention Through Urban Design* [6], an approach applied in many American cities, particularly in working-class neighbourhoods.

Through the construction of closed streets, the control of access, the clear division of spaces and the restriction of crossings, some neighbourhoods showed an improvement in living conditions, a significant reduction in crime rates and the re-appropriation and care by the inhabitants of their living spaces.

1.4 Broken Windows Theory

According to the theory of broken windows [7], phenomena that do not constitute crime but break standards of care and maintenance of the territory and coexistence in public space are potential inducing factors for criminal acts.

The basic thesis is that along with episodes of petty crime, urban decay and social degradation also significantly influence citizens' perception of insecurity.

In a city, minor problems, such as graffiti, public disorder, neglect, filth, are the equivalent of broken windows, i.e. risks inviting more serious crimes: robbers and thieves know that the chances of being caught, or even identified, are reduced if they act in streets where potential victims are already intimidated by the prevailing conditions: therefore, any damage, any act of vandalism not promptly dealt with is considered to be highly indicative of a lack of interest on the part of the authorities and an invitation to continue the damage.

2. OBJECTIVE

Urban settings have often been the study object in the vast research field of perceived personal safety and fear of crime. The latter is an experienced feeling, distinct from actual safety, security or risk, and therefore needs to be approached differently [8].

Unsafety in cities is produced by a complex set of factors, including economic conditions and social problems, but also the way they are planned, designed and built, the way urban spaces are maintained and managed, and the way people identify with their environment [2].

In the wide range of urban spaces, this contribution aims to investigate a specific type of urban public space: the urban green areas. Greenspaces refer to a range of different public spaces including parks, gardens, greened thoroughfares and sporting fields.

Indeed, among the studies carried out on the urban safety concept, only a few have examined perceived personal safety in parks and other green areas [8].

They are an important element of urban design as they provide unique health benefits to residents. Although the health and social benefits of green spaces are well supported [9], emerging research indicates that green spaces can also generate crime.

This work aims at a more careful reflection on the complex dual role of urban green spaces, as valuable but also threatening, shows the need for knowledge on how it can be planned, designed and managed to improve perceived personal safety without reducing other benefits.

Studies of the relationship between crime and greenspace face several challenges, therefore, to understand trends in scientific research, a keyword search was carried out based on the following keywords: TITLE-ABS-KEY ("crime" AND "greenspaces"). This resulted in a cluster of 211 documents from the SCOPUS search covering a time horizon from 2002 to 2024. They were exported in .csv format and uploaded to the VOSviewer software. Once the file was uploaded to VOSviewer, a threshold was set for the minimum number of citations for keywords of 2, identifying 36 keywords shown within the co-occurrence map in Fig. 1.

Each keyword is depicted in correlation to a single bullet: the size is directly proportional to the number of citations found for that map. The arcs represent the correlations existing between the various keywords as a function of the documents in the cluster.

The overlap map (Fig.1) allows us to see how, in recent years, scientific research has proposed different themes and topics and which variables have been used to understand crime patterns.

There is a growing interest in the relationship between greenspace and crime, yet how particular greenspace types encourage or inhibit the timing and types of greenspace crime remains largely unexplored. Most articles link green spaces/areas, crime and security, urban areas, perception and neighbourhood issues. Few studies have considered multiple types of crime simultaneously, and consider crime is linked to socioeconomic factors.

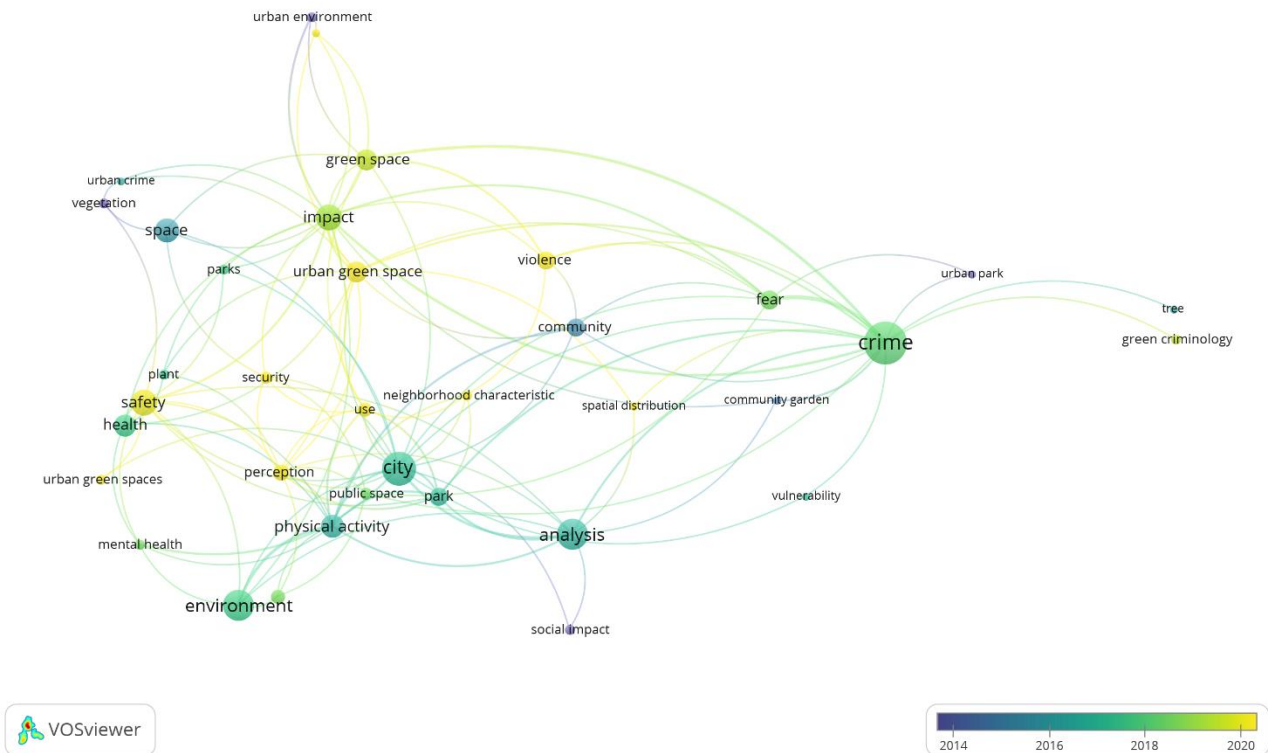

Figure 1. Overlay visualization of author keywords, 2002–2024, in Scopus, based on total occurrences.

3. URBAN GREEN SPACES

Green spaces are important reservoirs of urban biodiversity, improving functional and structural connectivity at the urban level. They contribute to mitigating the urban heat island effect, improving air quality and enhancing the health and well-being of residents while providing a habitat for urban wildlife.

Despite their many environmental and social benefits, they can be both a generator and a deterrent to crime. The crime-facilitating aspect of trees is justifiable by their view-obstructing effect. Following the “broken window theory” [7], poorly maintained urban greenspaces, such as overgrown vegetation and litter, can communicate a lack of oversight and attract criminal activities. So, the character of vegetation can be an important factor affecting perceived personal safety.

In densely forested areas, trees, particularly in low-lying or dense forms, are typically associated with lower perceived security and higher fear of crime due to trees’ view-obstructing effect [10]. In some cases, criminals may take advantage of the dense vegetation or other special environments in the park to conduct illegal activities (e.g. target selection, examining stolen property, disposing of unwanted goods and fleeing the scene), resulting in increased vulnerability to crime and reduced perceived safety for residents [11].

However, it should be considered that not all vegetation has this visually obstructing effect. Indeed, a well-tended area certainly does not block the view; widely spaced, high-canopy trees have a minimal effect on visibility; and low-growing flowers and shrubs do not appear to provide cover for criminal activities. Therefore, although the rule that vegetation helps crime may apply to forms of vegetation that reduce visibility, there are systematic exceptions to this rule. Careful design that favours widely

spaced, high-canopy trees and other forms of vegetation can help preserve visibility, not encourage criminal phenomena [11].

It should also be noted that the intensity and cause of fear varied according to social characteristics of gender, ethnicity and age and spatial behaviour with respect to park use. Park users, particularly women, avoided areas with poor lighting, dense understory vegetation or a high density of trees [12].

Figure 2. Sightlines through vegetation.

On the other hand, urban green spaces can be associated with reductions in crime, by attracting diverse people, providing a space for positive social interactions via outdoor activity [13] and promoting “eyes on the streets” or informal surveillance [1].

Attractive green landscapes and paths tend to encourage socialisation on the road and increase outdoor activities (e.g. exercising and cycling), which translates into more surveillance with more witnesses and a greater likelihood of intervention [1,10,14].

This increased vigilance on the part of community members can build collective efficacy, strengthening concern and vigilance in a neighbourhood.

Thus, echoing the concept of broken windows, a high-quality landscape around a house can discourage criminal activity [10], as well as redevelopment projects in which vacant lots and decaying urban spaces are transformed, making the environment more attractive and useful for residents, cause violence and crime to decrease [15].

Some researchers also believe that urban green spaces improve the psychological health of urban residents by reducing typical precursors to crime, such as stress and aggression [16,17] and enhancing happiness and social behaviour.

Moreover, through the simultaneous use of public green space, shared by residents of all ages, greater levels of community connection and cohesion can be generated [18]. This can further strengthen the commitment of residents to protect neighbourhood space and deter criminal activities.

The benefits provided by green elements are summarised in Figure 3.

Benefit	Explanation
Natural Surveillance	Greenery, such as trees and shrubs, can improve natural surveillance by providing clear sightlines. This makes it easier for people to see and be seen, discouraging criminal activities like vandalism or assault. Well-lit green areas contribute to a sense of safety by reducing hiding spots for potential wrongdoers.
Psychological Benefits	The colour green is often associated with nature, tranquillity, and vitality. When incorporated into urban spaces through parks, gardens, or even green walls and rooftops, it can evoke feelings of calmness and well-being among residents and visitors. This positive psychological impact can lead to an increased sense of safety and security.
Community Cohesion	Green spaces play a vital role in bringing communities together, promoting social interactions, and fostering a sense of belonging. When individuals feel connected to their neighbours and environment, they are more inclined to watch out for each other, forming an informal surveillance network that contributes to safety. Community events and activities held in green spaces also help reinforce relationships and encourage a sense of ownership, which can deter crime.
Physical Barrier	Greenery can act as a physical barrier, separating public spaces from streets or private property. This not only improves aesthetics, but also creates a feeling of enclosure and protection. By defining boundaries, green elements help users feel safer within the designated area.
Environmental Benefits	Incorporating green infrastructure not only improves aesthetics but also helps manage stormwater runoff and mitigate urban heat island effects. Creating a more sustainable and resilient urban environment enhances the overall quality of life and contributes to a sense of safety by addressing environmental concerns.
Wayfinding and Navigation	Green landmarks, such as prominent trees or lush plantings, can aid wayfinding and navigation within urban areas. Clear and intuitive pathways reduce the likelihood of users getting lost or feeling disoriented, thereby increasing their confidence and sense of security.
Programming and Activation	Activating green spaces with diverse recreational and cultural programming ensures continuous use throughout the day and evening. Well-utilized spaces are less susceptible to criminal activities due to the presence of people and increased guardianship.

Events such as farmers' markets, concerts, or fitness classes attract visitors and promote a vibrant, safe atmosphere.

Social Cohesion and Well-being

Access to green spaces and natural environments has been linked to improved mental health, reduced stress, and increased social interaction among urban residents.

Figure 3. Urban green benefits.

4. FINAL REMARKS

Nowadays, in the European Union (EU), ensuring urban safety is a priority, and several guidelines and initiatives have been developed to achieve this goal. EU encourages cities to develop comprehensive, integrated urban safety strategies that address various safety challenges holistically. This involves cooperation among various stakeholders including local governments, law enforcement agencies, community organizations, and residents.

The EU also promotes the implementation of CPTED principles, such as designing urban spaces in a way that reduces crime opportunities and improves residents' sense of security, in urban planning and development projects.

The growing demand for safer urban spaces is linked to a wide range of conditions that influence and alter the perception of urban spaces, making them appear unsafe.

The contribution emphasises that crime is influenced by many factors, but the environmental context - including green spaces - is considered a key component [9,13].

By prioritising green spaces, cities can improve the physical and psychological well-being of their residents while fostering a greater sense of safety and security. It is therefore believed that the proper design of urban green spaces can significantly improve the perception of safety in public spaces.

As parks are becoming important reference points for new environmental strategies in cities, and since fear of crime is often cited as a major barrier to the development and subsequent use of green spaces [19], it is essential for urban planning to investigate the causes and spatial configurations of fear if all community members are to be encouraged to increase their participation in public parks [12].

Police forces often allocate resources to respond to the perceived potential for crime and disorder in specific types of green spaces, such as urban parks [13], but the goal of making the city safer is not pursued, exclusively, by control (police, video surveillance) or repressive actions. The recourse to such actions, the excessive confidence placed in them, and the instrumentalization of the issue for political ends, only further fuels the perception of unsafety and obscures the great potential that urban planning has in this regard. Decisive in this sense are the physical elements of the urban environment, related to the way cities and spaces are planned, designed, built and managed. Careful design, taking into account security aspects, can reduce the probability of the occurrence of criminal events but above all increase the sense of trust and security felt by citizens towards urban space [2]. It is therefore considered necessary to address the problem by following an integrated approach that sees socio-economic actions flanked by physical, functional and managerial interventions on the built environment, aimed at influencing the vitality of the city, the perception of the environment, the sense of belonging to the territory and the informal control of the same.

Abstract

Numerous authors have debated the fine line between urban vitality and liveability, particularly when prioritising vitality strategies at the expense of liveability objectives. These debates are even more heightened in tourism-dependent contexts. This is epitomised by Malta's capital city, Valletta – a UNESCO World Heritage site undergoing rapid transformation that has in turn brought about numerous placemaking challenges. The city's urban structure, defined by its strict geometry, underwent numerous cycles of adaptation and restructuring along the centuries. Its main challenges, however, have come about more recently, because of several phenomena that are worth exploring, not least those related to its designation as European Capital of Culture in 2018.

Building on an ongoing ten-year research project, the paper first discusses the city's changing land use profile in recent years, through a detailed understanding of development planning permits and tourism clearances for catering and hospitality proposals issued between 2014 and 2022 – therefore in the run-up to, and post-, 2018. It then proceeds to translate the spatial implication of such permits on the ground, more specifically by understanding the proliferation, and subsequent public land take-up, of outdoor catering areas within prime streets of the capital city. The nightlife transformation of the city, as it becomes a new entertainment destination for revellers, has further tested the urban fabric's resilience and has led to numerous calls for its control and reduction from its residents, the Valletta Local Council and, notably, the Malta Hotels and Restaurants Association.

Using textual analyses as an analytical technique, the paper analyses the text from a selection of widely diffused newspaper articles and key opinion pieces written throughout 2022 and 2023 and that have generated debate regarding space appropriation, land use compatibility and heritage concerns in Valletta. The paper then discusses how specific planning policies have been created to suit, foster, and indeed accelerate Valletta's commercialisation, with significant consequences to liveability, under the guise of the strategy's objective to promote urban regeneration within the city. In particular, the discussion centres on the Valletta Strategy, a key policy document that has arguably helped shape most of the recent urban phenomena within the city.

The paper highlights the lack of safeguards for the commodification of space as a significant policy deficiency, suggesting policy pointers for a more resilient and liveable urban fabric, as Valletta witnesses slow, but persistent, calls for change from its frustrated residents.

Keywords: *vitality; liveable cities; placemaking; Valletta.*

1. INTRODUCTION

The debate surrounding urban vitality and liveability has been a recurring theme in urban studies, reflecting the complexity of balancing economic vibrancy with the quality of life for residents. Urban vitality refers to the dynamic quality of a city, characterised by economic activity, cultural vibrancy, and social engagement. On the other hand, urban liveability prioritises residents' quality of life, emphasising factors such as housing, green spaces, sanitation, safety, and overall environmental quality. These concepts often clash when strategies to enhance urban vitality come at the expense of liveability, especially in cities heavily reliant on tourism.

ISBN: 978-618-5765-02-6

Valletta, Malta's capital city and a UNESCO World Heritage site, serves as a prime case study in this discourse. The city has undergone rapid and significant transformations in the past twenty years, with investments in rehabilitating historic properties for tourism purposes and infrastructural projects that have transformed the urban spaces within the city as part of a pedestrian environment. These changes have been driven by various factors, including its designation as European Capital of Culture in 2018. Valletta's revitalisation, however, has come at the cost of reduced liveability and concerns about the decline of the social fabric in Valletta.

This paper outlines the balance between urban vitality and liveability in Valletta, providing an examination of changing land use patterns, policy impacts, public opinion, and the resultant urban fabric implications. The study employs textual analysis to examine the public discourse captured through key opinion pieces and newspaper articles. Additionally, it integrates on-the-ground observations to document spatial realities. This mixed-methods approach enables a comprehensive understanding of Valletta's evolving urban dynamics and the tensions between commercialisation and liveability.

2. UNDERSTANDING URBAN VITALITY AND LIVEABILITY IN THE CONTEXT OF TOURISM-CENTRED REALITIES

Urban vitality refers to the vibrancy of city life, often measured by the presence of economic activities, cultural events, and social interactions that occur within an urban space. Jane Jacobs' [1] theories emphasise the importance of diverse, mixed-use urban neighbourhoods with a strong sense of community to foster urban vitality. She advocates for pedestrian-friendly streets, local businesses, and a mix of residential and commercial spaces to promote social interaction and economic growth. Ebejer et al. [2] similarly discuss the importance of activity in urban spaces, contending that successful public spaces are characterised by the presence of people, as it creates a social contact and enhances the overall experience. The authors also emphasise the vitality of urban spaces, dependent on the diversity of uses and the exchange of transactions among people.

Liveability, on the other hand, pertains to the quality of life experienced by residents, encompassing factors such as housing quality, accessibility, environmental health, and social well-being. Related to this discussion is the 'right to the city' — a concept introduced by Lefebvre [3] that forms the foundation for examining the inequalities arising from social and spatial interactions and the changes in societal landscapes.

These concepts may be seen as two sides of the same coin – in that they are not mutually exclusive; however, prioritising urban vitality, particularly through tourism and commercial activities, can sometimes undermine the liveability of a city, creating tensions between economic development and resident satisfaction. The reality of urban tourism is that it now occurs in committed residential neighbourhoods, driven by factors such as low-cost airlines and online platforms like Airbnb, and resulting in a heavy reliance on the tourism sector in many urban economies [4]. In the early 2000s, urban and cultural policies in southern Europe shifted towards using tourism to revitalise historic districts, attract more tourists, increase property values, attract investments, create jobs and generate economic benefits [5]. As a result, cities, particularly their historic centres, have been transformed into tourist destinations and leisure-oriented spaces.

This phenomenon has led various authors [6, 7] to use the term 'touristification' to describe the transformation of urban spaces into tourist-dominated areas, which disrupts social relations, dismantles communities, and poses challenges to long-term residential life. Leccis [5] further highlights the lack of research on the relationship between urban planning and tourism development. Touristification processes have negative impacts on the physical, social, and economic environment of destinations, notable of which is the alienation of residents. It also affects residents' quality of life by exacerbating existing issues such as waste disposal and repercussions of outdoor commercial activity, notably noise. Chamizo-Nieto et al. [8] similarly examine the impact of urban tourism on

cities, noting how city modifications to accommodate tourists have displaced residents and sparked protest movements. The concept of tourism gentrification has highlighted tensions between residents and tourists. In this respect, Valletta is no exception.

3. VALLETTA'S URBAN TRANSFORMATION AND CHANGING LAND USE PROFILE

Valletta's urban form is characterised by its grid layout, fortifications, and grand public spaces, which were designed for both defence and civic pride. Over centuries, the city has seen various uses and adaptations — from a fortress city to a bustling trading port, and more recently, a vibrant cultural and tourist hub. Each transformation has brought changes to land use, infrastructure, and urban dynamics, thus influencing both its functionality and identity [9].

Following independence, efforts were made to repurpose historic buildings into government offices, incorporate cultural amenities to support tourism, and establish various businesses within the city, although the city kept on experiencing a population decline and a deteriorating urban fabric. While the increase in commercial activity and tourism in Valletta led to a rise in daytime population, the lack of evening activities and untidy streets in the city centre caused the capital to become deserted at night, resulting in environmental decay and a decrease in overall liveliness [10]. The inclusion of Valletta in the UNESCO World Heritage list in 1980 signified a commitment to heritage conservation, but also added a layer of complexity to development endeavours.

After 2006, Valletta underwent a regeneration process, driven by a combination of top-down placemaking efforts, investments in property by both local and foreign investors, and the agency of consumers and other co-producers. Projects included the restoration of historic buildings and the development of pedestrian areas alongside a comprehensive traffic management system, in turn leading to increased investment in catering establishments and boutique hotels. This has not always been supported by a clear vision and regulatory framework, leading to numerous instances of speculation by developers [11]. In turn, the transformative wave over the past decade, driven by Valletta's designation as the European Capital of Culture (ECoC) in 2018, has brought about multifaceted challenges. While the event spurred substantial urban renewal projects and increased tourism, it also further intensified pressures on the city's infrastructure and social fabric [12].

In this respect, two key recent developments within the city of Valletta deserve discussion:

- (a) *Development Planning Permits* – A surge in permits for outdoor catering areas and hospitality establishments indicate a shift towards a service-oriented economy driven heavily by tourism. This influx of permits has translated into a significant increase in commercial activities within the city, often at the expense of residential uses. The proliferation of outdoor catering areas, with the insertion of tables and chairs, while contributing to the city's urban vitality, has created concerns about the excessive use and appropriation of public space by private businesses. Valletta's transformation into an entertainment destination has also had profound effects on its urban resilience and liveability.
- (b) *Tourism Clearances and Hospitality Proposals* – The prospect of an increase in tourist numbers, a result of the ECoC designation, has necessitated additional hospitality and entertainment facilities. Tourism-driven clearances have thus facilitated the rise of hotels, guesthouses and entertainment venues. While these developments have boosted Valletta's economy, they have also contributed to the commodification of public spaces and have sparked debates about the sustainability and liveability of such rapid transformations.

The above shifts have visibly altered the urban landscape of Valletta. What was once a public space open to all has now been transformed by private interests. This transformation has resulted in a form of displacement in the city, not necessarily in terms of direct residential evictions typically associated with gentrification, but indirectly in terms of land use changes. As a result, older local establishments that are deemed less attractive or profitable have faced displacement due to commercial gentrification influenced significantly by tourism. This evolution has reshaped the character and identity of Valletta.

Furthermore, the increase in catering establishments and nightlife is perceived by residents to be excessive and inconvenient [13].

Previous studies [14] have already shown how the rising land value in Valletta has created a commercial gentrification that displaces local businesses, including traditional retail and food markets, causing residents to lose access to essential stores and services, particularly with the advent of the *Suq Tal-Belt* (Covered Market) project. However, the commercialisation of the site has been criticised [14, 15, 16] for detracting from its urban heritage value and limiting space for pedestrians. In turn, Deguara et al. [17] have exposed residents' concerns with leisure and nightlife, providing first-hand accounts of how urban transformation has affected daily life in Valletta and highlighting issues such as noise pollution, reduced accessibility, and loss of community spaces.

3.1 Land use changes — development planning applications and tourism clearances

Data collected from development planning permits and tourism clearances was obtained from the Planning Authority and the Malta Tourism Authority respectively. Three important sets of data were obtained for the period 2014 - 2022:

- 1 Change of use permits issued in Valletta, visualised as a Sankey diagram and clearly illustrating the significant land use change occurring vis-à-vis catering outlets – Class 4C and Class 4D food and drink establishments, without on-site cooking (snack bar) and with a kitchen (as a restaurant) respectively (Figure 1).
- 2 Amount of Class 3 tourism accommodation, comprising Class 3A hostels, small guesthouses and boutique tourism accommodation and Class 3B hotels, as well as Class 4C and 4D reclassifications in Valletta, with peaks pre-ECOC 2018, and with Class 4 uses remaining significant even thereafter (Figure 2).
- 3 MTA clearances issued for both Class 3 tourism accommodation and Class 4 catering outlets in Valletta, with notable peaks pre-ECOC 2018 and an understandable drop during, and in the aftermath of, the COVID-19 pandemic (Figure 3).

The data is further supported by a recent study carried out by Speake, Kennedy and Love [18], that discusses the scarcity of affordable property in Valletta, and the resulting increase in property prices and demand for luxury apartments and townhouses. The authors show how this has led to a significant development of tourism-related functions, such as upscale hotels, boutique accommodations, and the revitalisation of the city with a focus on tourism. Their research also concludes that around one-third of Valletta (particularly areas near Republic Street) has undergone gentrification and revitalisation, resulting in a visible contrast between affluent and impoverished sections of the city. The rejuvenated areas stand in stark contrast to the surrounding pockets of poverty in terms of development, visual appearance, functionality, and social characteristics. Further understanding the spatial distribution of these non-residential uses on the ground (Figure 4) illustrates the juxtaposition of incompatible land uses, particularly that of residential areas adjacent to nightlife zones, leading to conflicts and a diminished perception of liveability, as discussed further hereunder.

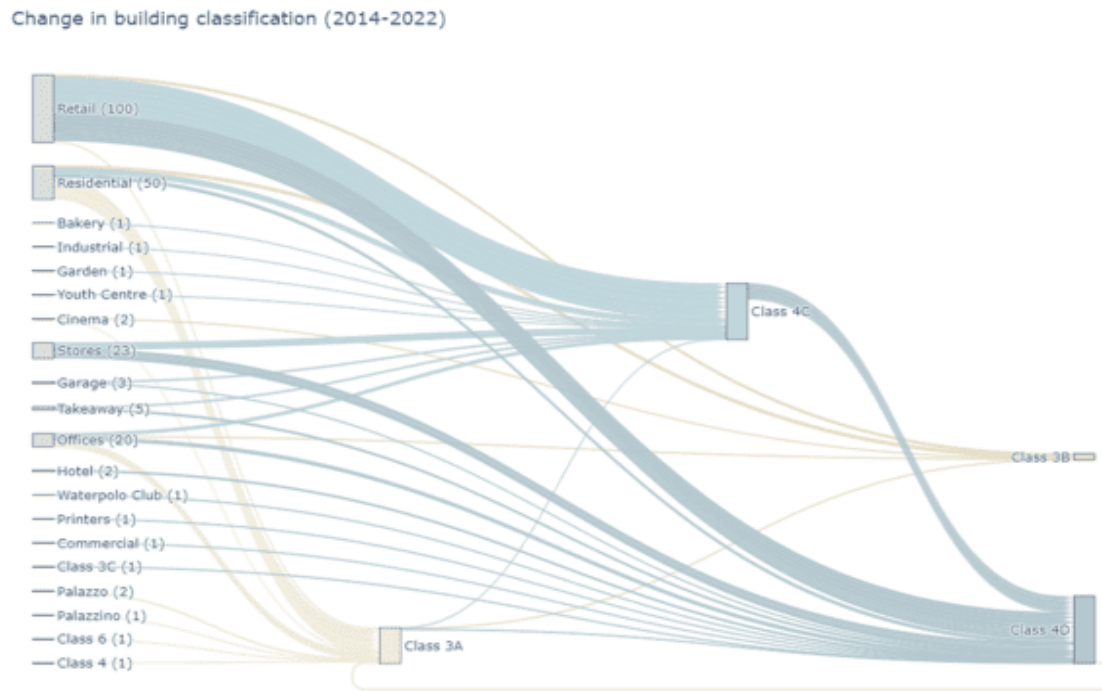

Figure 1. Sankey Diagram illustrating change of use permits issued between 2014 - 2022 (Data source: Planning Authority, Malta)

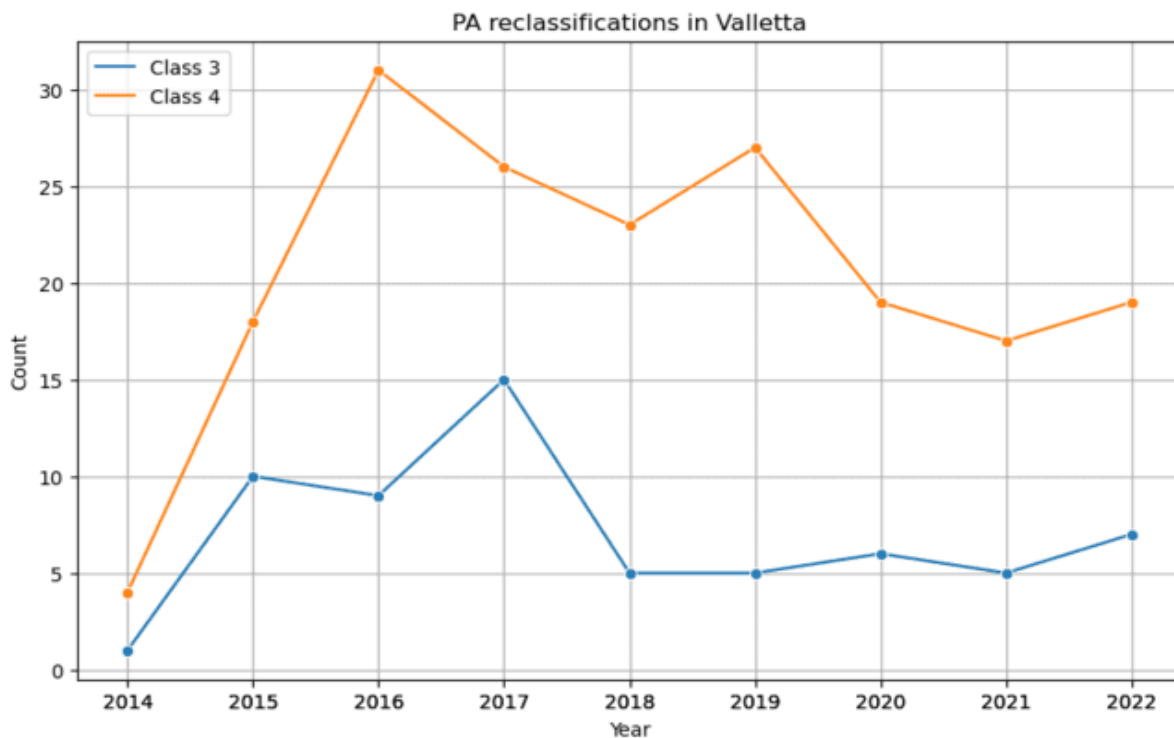

Figure 2. Change of use permits in connection with Classes 3A, 3B, 4C and 4D issued between 2014 - 2022 (Data source: Planning Authority, Malta)

Figure 3. MTA clearances in connection with Classes 3A, 3B, 4C and 4D issued between 2014 - 2022 (Data source: Malta Tourism Authority)

- Different catering types**
- Restaurants with kitchen (class 4D)
 - Snacks and coffee shops without kitchen (class 4C)
 - Ancillary ground floor catering use with hotels (class 3B)
 - Ancillary ground floor catering use with palazzo (class 3A)
 - Midstreet places
 - Formal places with tables and chairs

Figure 4. Plotting out of the various catering offers within Valletta's central core, as a stand-alone Class 4C/4D outlet or ancillary to Class 3A/3B at ground floor (Source: Author)

3.2 Proliferation of Outdoor Catering Areas (OCAs)

One of the most noticeable changes on the ground has been the mushrooming of Outdoor Catering Areas (OCAs). Restaurants and cafes have increasingly expanded their seating onto public spaces, taking up significant portions of prime streets. This trend has implications for spatial equity, pedestrian accessibility, and public space utilisation, as a significant amount of public land is taken up. Based on the previous analysis, and in tandem with several on-the-ground observations, four streets containing a concentration of OCAs may be singled out – along Merchants Street, along St. John’s Street, and within the intersection of Strait Street with Old Theatre Street (Figure 5).

Figure 5. Outdoor catering areas along Merchants Street, St John’s Street, Strait Street and Old Theatre Street (Source: Author)

On-the-ground measurements taken to establish the area of land occupied by the OCAs in each of these streets, reveals a land take-up that varies from 30-53% in Merchants Street (Figure 6), 24-61% along St John’s Street and 48% within the intersection of Strait Street / Old Theatre Street. This constitutes a significant amount of appropriated public urban space by catering equipment.

Figure 6. OCA land take-up along Merchants Street (Source: Author)

3.3 Valletta’s nightlife transformation – textual analysis of media and opinion pieces

Valletta’s nightlife transformation, characterised by the rise of bars and entertainment venues with live music, has led to noise pollution, increased waste, and conflicts between revellers and residents. Residents, the Valletta Local Council and the Malta Hotels and Restaurants Association (MHRA)

have all raised concerns about the night-time economy's impact on liveability, with matters coming to a head throughout 2022 and 2023 as Government identified several streets in Valletta wherein music could be played until 1am, receiving a backlash from residents and NGOs. The MHRA subsequently stated that such a decision “contradicts efforts in positioning Valletta as a high-end destination as agreed to by all tourism stakeholders through the national tourism policy” [19]. A textual analysis of twelve newspaper articles and opinion pieces with the highest engagement (most read and most article comments) over these two years was carried out to gauge public sentiment on these important issues. Python scripts were used to extract (scrape) both article content and its comments. For each article, common English ‘stop words’ were filtered out and engagement counts were calculated from the comments section. Key issues and common themes arising from this media are summarised in Figure 7.

Article / Opinion Piece Title (2022/2023)	Author	Key Issues, Common Themes
‘Pavements for citizens’: The sticker rebellion battling restaurant encroachment	Claudia Calleja	Space appropriation Public space commodification Land use (in)compatibility Regulation and control of nightlife activities, legal implications Quality of life for permanent residents Growing discontent among residents regarding noise levels / loud music Noise pollution Traffic congestion Waste management issues

3.4 Policy discussion: The Valletta Strategy

In 2009 a Valletta Action Plan was drafted to develop an Integrated Cultural Heritage Management Plan, aligned with the objectives of URBACT and in collaboration with several entities, NGOs and the private sector [10]. The document's six-point Rationale comprised restoration objectives, the creation of a competitive tourism market that hinged on a diverse tourism product and niche market, mobility objectives and an emphasis on the local communities within Valletta. Its vision for creating

commercial opportunities comprised both the promotion and maintenance of Valletta's commercial zone, as well as acknowledging the need to focus on developing alternative commercial areas that align with the upgrade of the residential area to ensure long-term sustainability. The Plan was never implemented and instead a new document was drafted – the Valletta Strategy [20].

The Valletta Strategy is one of the central documents that has been used by the Planning Directorate at the PA to justify the development planning applications discussed in the previous sections [14]. It has played a significant role in promoting Valletta's touristification by outlining objectives to promote urban regeneration through cultural and economic activities. The strategy categorises almost the entire city as a 'regeneration priority area' and facilitates the interpretation of planning regulations to allow for the development of boutique hotels, short-term rentals, and an increase in tourism-oriented retail and catering outlets, ultimately transforming Valletta into a tourist destination and helping the city's commercialisation.

4. DRAWING PARALLELS AMONG STUDIES

The above empirical work, together with previous local studies in relation to Valletta's liveability, relate to Cocola-Gant, Gago and Jover's [4] study regarding disruptions caused by tourism, further adding the contribution of Sánchez-Montañés, Romero-Ojeda and Castilla [21], who discuss the overtourism influences on architecture and urban spaces of historic centres (Figure 8).

5. URBAN VITALITY VS LIVEABILITY: THE BALANCING ACT

Valletta's journey highlights the complexities involved in balancing urban vitality with liveability. While recent transformations have boosted its commercial vibrancy, they have also strained its urban fabric. By examining land use changes, policy impacts, and public sentiment, this paper underscores the need for a more balanced approach to urban regeneration. While the Valletta Strategy's emphasis to leverage Valletta's heritage and strategic location, to attract investments and tourists, is positive in principle, the document lacks numerous safeguards. A rethought strategy is needed, which looks at the cumulative impact and/or land use concentration of specific land uses and that address liveability concerns in a tangible and effective manner by addressing key issues, notably the commodification of public spaces and the need to rebalance the land use offer within the city, especially regarding tourism accommodation, giving due regard to the incompatibility of some land uses. In tandem, a stronger role for enforcement in ensuring that encroachment limits for OCAs are not exceeded (in the short term) and to control night-time disturbances and, medium-term, to re-evaluate the city's urban spaces to rethink OCA limits.

In Michael Sorkin's words, "no urbanism can be spoken of outside its political dimension" [22: 58]. this is even more relevant and pertinent when dealing with Valletta's public urban space and its use, particularly for commercial purposes. in all this discussion, therefore, the role of the state remains a central one – first, to address and rectify the injustices of gentrification through the implementation of policies and institutions that consider local social and market conditions [23]; second, to address tourism requirements within an overarching strategy that protects local communities, not alienate, or exclude them. the concluding issues from this research (figure 8) have important policy implications in effectively addressing liveability objectives. this is a fine balancing act, requiring good governance structures that are defined by resilient community frameworks, but above all, a robust roadmap steered by the state as it sets its medium- and long-term urban regeneration objectives.

Phenomena / Issues — Literature				Empirical work in support of the literature		
Cocola-Gant et al. [4]		Sánchez-Montañés et al. [21]	Previous local studies -- Valletta's liveability	Analysis of permits	On the ground analysis	Media Analysis

Activators. Complex Buildings as Public Space Generators

Abstract

To be seen more as a collection of open questions rather than a description of possible solutions, this paper intends to focus its attention on the very old issue of architecture's capacity to shape our contemporary society. The paper opens by introducing some essential data reflecting the not-so-far future of our cities and questioning the role that architecture can play in pursuing sustainable transformations of public space.

In a scenario where the city is becoming the primary urban habitat, while the right to the city falls short, the paper addresses the case study of the so-called Complex Buildings as a possible theoretical and practical tool to face contemporary urban challenges.

Keywords: *Complex Buildings, Bento-Box Architecture, Architecture, Complex System Theory, Social Ecology*

1. INTRODUCTION

In April this year, an updated report on the World Bank and United Nations Department of Economic and Social Affairs (UN-DESA) website revealed that 56% of the world's population (about 4.4 billion people) live in cities, one billion of which reside in slums. This number is expected to reach 60% (or 5.2 billion people) by 2030 and 68% by 2050. Furthermore, it is estimated that continued global population growth could lead to an increase of 2.5 billion inhabitants in urban areas by 2050, most of them living in 43 megacities (cities with more than 10 million inhabitants) expected to emerge by 2030. These will contribute to the expansion of new urban areas, with an expected growth of an additional 1.2 million km² of built-up area by 2030 [1].

This unprecedented acceleration, which creates new urban dynamics, poses critical challenges for sustainable urban development. As of today, in fact, although cities are seen as the new engine for initiating a model of sustainable and inclusive growth, they are often analysed and planned from projections centred on the – now sustainable - connection of flows of means and goods, leaving out a fundamental datum of urban life: the citizens and their continuous research of a community. These strategies, where already applied, have highlighted how such a model of urbanisation mainly results in five phenomena: urban dispersion, low productivity, segregation, and exclusion. These phenomena can generate a counter tendency that is only apparently classifiable as *demographic decline*. It is instead an actual *exclusion process* fed by the stagnation or decline in the overall population of some countries but primarily by doped real estate projects that, in the name of a recognisable aesthetic, are helping to widen the gap between rich and poor, winners and losers, changing the anthropological profile of contemporary cities. In other words, paradoxically, in this contemporary context where *the city is becoming the primary human habitat*, "the right to the city" falls short. This fall is due to the marginalisation of fragile social groups pushed out from served urban areas and resettled in increasingly remote suburbs (if lucky, in dormitory districts; if less lucky, in slums) where access to equal opportunities - regardless of age, race, gender, sexuality, income or physical and mental health - becomes even more difficult. As a result, contemporary cities are increasingly subjected to bottom-up initiatives, such as *tactical urbanism* projects that, although masked as colourful short-term solutions and essential in reconnecting the citizens to the city, are, in fact, symptoms of a concerning problem: the incapacity of architectural and urban design to activate the public sphere. Nevertheless, these design projects and research demonstrate that even if we live in an era where social media seems

to be *the public place* (and they are effectively becoming it through the metaverse), collective public space within cities is increasingly needed. They unequivocally demonstrate that, although housing/social housing policies and projects are vital for making cities accessible to all, it is only through the *public spaces* and the *public facilities* that it is possible to guarantee "the right to the city" and epitomise the city's essence: to be the *generator* of civic and public life.

2. FINDING ARCHITECTURE IN URBAN THEORIES

"We are now officially part of the group of people who have been forced to leave the city." With this statement, two young architects decided to move away from Milan. They struggled to find an affordable house in a convenient area and ultimately chose to move to a small provincial city. Their decision was due to the challenges of sustaining a life in Milan from economic and social perspectives. This example reflects a trend that has emerged since the COVID-19 pandemic, affecting vulnerable social groups who, despite relying on the city's work opportunities, welfare, and leisure facilities, are choosing to leave. This phenomenon has led to an increasing demand for public transport connecting the city with the surrounding suburbs. However, the public transport system is struggling to meet these needs, causing people to rely more and more on cars and other unsustainable forms of transportation. This leads to a drastic increase in pollution levels that no facade defined as 'beautiful' or "ecological" just because studded with trees sustainable like diamonds can counteract. Ironically, the summa of all the green policies adopted by the Milanese Municipality has led the city to become, in February, the third most polluted urban area in the world for a few days. The Milanese experience thus highlights how it is increasingly necessary to rethink the term *sustainability* semantically, integrating within its meaning technocratic and political issues but also social matters in which architecture and urban design become the main tools for fostering new sustainable life models for all social strata. In other words, integrating the world of Design with the world of Social Ecology.

Some research and projects have been developed in the last decades to contrast these phenomena and transform the cities into more sustainable devices. Among them, the so-called "15-minute city" has gained prominence by proposing a model based on a temporal distance between the location of an individual's housing, workplace, and public facility, therefore proposing a sustainable and livable "city of proximity". However, recent studies show how this model presents a social mix fallacy generated mainly by short-term or top-down urban planning ideals that cannot address long-term community needs and structural discriminations related to equal opportunity and access to public and private services. It seems, therefore, that even the "15-minute city" theory still needs to adequately satisfy the contemporary need for equal access to the city and its services.

The critical role of public spaces and facilities in generating civic places and creating inclusive cities has been thoroughly described in studies conducted by Klinenberg, Latham and Layton [2]. In their works, public *space* is meant as *social infrastructure* and refers to the networks of spaces, facilities, and institutions that create affordance for social connection. These *social infrastructures* (such as libraries, cafes, community centres, art centres, sports facilities, coworking facilities, etc.) have a greater significance than just being functional spaces since they offer the opportunity to experience cities as welcoming and inclusive environments by triggering social, economic, cultural and political phenomena. In other words, a sense of identity.

Interestingly, these studies' authors - mainly sociologists, economists, psychologists and geographers, but surprisingly not architects or urban designers- have shown how these *social infrastructures* are extremely *sensitive to how their space* is designed and planned. However, even though this topic is becoming increasingly central in the discourse of many disciplines – from sociology, ecology and

sustainability to architecture and urban design – a significant gap within the literature still does not allow us to answer perhaps the most crucial question: How?

How can *the space* of these social infrastructures *trigger* social relationships and a sense of identity? More specifically, is this sensibility generated exclusively by function or by a complex relationship between space's form, function, and integration/hybridisation? How does this *relationship* affect/generate a collective public place in terms of space? Which spatial features and qualities make these architectural and urban places – namely social infrastructures – *generators* of inclusive processes?

Architectural and urban discourse has long recognised the impact of buildings and the built environment on human behaviour. A contribution to this topic is given by the *Space Syntax Theory*, which aims to describe the space-society relationship, bringing the spatial configuration to the core of the problem. Since its introduction in the 1970s, Space Syntax Theory has been widely influencing the architectural and urban design discourse by working with mathematical models and theorising a designing method generated from human interactions. In his essay *Space is the Machine* [3], Bill Hillier – the father of the Space Syntax Theory – tries to describe the complex relationships between humans and the built environment and how they mutually transform each other. In his text, Hillier identifies the *generating* capability of space in the semantic meaning of the word that indicates, for example, a building typology – say, school, house or church. This word is constructed from two generative ideas. The first is the idea of *a family of possible building forms*, and the second is the idea of *a family of possible social organisation forms*. Social Organisations are defined as a set of subjects which interact with shared behaviours. Therefore, the *idea of school* is associable with those recognisable *roles and relations realised in a spatial form* more than the idea of function itself. According to the Space Syntax Theory, this intricate relationship between space, form and behaviour not only describes «how buildings so easily change their function» - and consequently how the function is not essential in defining space - but also how, through the definition of space, it is possible to anticipate behaviours and vice versa.

However, this theory has also shown some critical methodological issues over time. Unfortunately, while on the theoretical level, the Space Syntax theory offers a potential solution to answer the questions above—describing how space qualities trigger social behaviours—and to offer an efficient multiscalar design method, its application overlooks the crucial aspect of the interplay between architectural and urban design, considering architecture as a backdrop of public life, nothing more than a container of public services and therefore bringing the problem back to the realm of function rather than that of space. Once again, another design theory misses the opportunity to overcome the misconception that architecture and urban design are two separate entities, where the former is designed to be exclusively aesthetically recognisable and technologically efficient and sustainable (at least in appearance), while the latter is reduced either to a matter of furniture or stretched to the regional scale to shape economic values.

Space Syntax Theory is not the only science that has tried to approach the complexity of the relationship characterising the urban context. Another important branch arises from the so-called Complex System Theory. Also known as Complexity Science or Philosophy of Complexity, this matter became a recognised research field in the Seventies. The first scholar highlighting the relationship between Complexity Science and Planning was the physicist Prigogine using cities as an example to explain his dissipative structure theory. From then on, Complexity Science has proved helpful in conceptualising various phenomena relevant to planning. Gathering these results, Allen and Sanglier [4] introduced the so-called *Complexity Theories of Cities* (CTC) in 1981. These theories represent one of the most innovative methods for observing complex properties of towns and forecasting urban developments. Over time, they have led to significant technological advancements

that have positively affected not only the field of planning but also that of physics and economics. The significant impact of CTC is undeniable. However, most of the research work developed so far has been rooted in a controversial assumption. Cities became the metaphor of Complex Systems due to the interaction between *urban agents*, namely human components, while space is nothing more than an *artefact* that can be interpreted both as the results or the means of human interactions. In other words, *Space* has a *passive role* in defining urban life. Also, CTC theories often depict architecture as separate from the city, which doesn't directly affect its surroundings if not for its urban position. In other words, these studies often view architecture not as one of the urban phenomena's generators but as a beautiful and environmentally efficient backdrop for complex urban relationships.

3. IF ALL THAT GLITTERS IS NOT GOLD, NOT ALL BUILDINGS ARE COMPLEX

The fundamental role of architecture in affecting urban areas has recently been brought back under the spotlight. This interest arose thanks to the New European Bauhaus initiative and the rising need for a specific architectural typology that, going beyond its functional aspects, can readapt itself in time while promoting or triggering new human behaviours and identity processes through its peculiar space. The authors of the A+T journals [5, 6, 7] have identified these particular architectural features within the so-called Complex Buildings. In the three special issues published in 2018, the authors describe how these buildings can trigger urban effects and new human behaviours by working as complex systems, presenting a space designed to dismantle the relationship between form and function. In. This work Complex Buildings are described as tools becoming effective through two essential aspects whose simultaneous presence seems unavoidable. The first is the *highly experimental space in which the traditional relationships between inside/outside and public/private are newly designed to transform architecture into a generator of new human behaviours*. The second is the *disassembled relationship between architectural form and function via a flexible in-time and in-space activity program*.

Unfortunately, the work is concluded with a selection of case studies in which the *Complexity of Space* is controversially reduced to a hybrid program of functions. But a *hybrid program of activity* is still a *program of activity*, and yet we do not have any further glimpse of spatial features leaving the “How” questions wide open.

So, if complexity makes Complex Buildings public sphere activators and complexity does not lie only within a hybrid program, what makes Complex Buildings Complex?

To answer this question, it is necessary to overturn the perspective described so far and understand complexity as a design matter that architects and urban designers must embrace to produce a generative space. In other words, this paper intends to consider *space as a complex system* and describe *complexity as a spatial problem* that architecture and urban design are called upon to address rather than a tool to justify its forms.

This is possible thanks to two recent publications by Morin (2022) and Estrada (2023). Estrada introduces its article by pointing out a crucial question that can be applied to all Complex System Theories (and therefore CTC, too): What makes *complex systems complex*?

The author tries to answer this question by pointing out some inconsistencies in the various definitions of *Complex Systems* that have evolved over time. From these contradictions and taking into consideration Morin's work on the matter of *Complexity*, the author develops a new definition of Complex Systems, which is based on the idea that *it is the nature of interactions between the elements that determine the complexity of a system* and not the presence of these interactions itself. These interactions, defined by Estrada as Morinian are relationships able to modify the behaviours or the nature of the elements, the bodies, the objects or the phenomena that constitute or influence a system. Put simply; these interactions behave like actual transformers of the nature of the parts constituting a system, of the system as a whole and of the environment where the systems exist.

Aren't these interactions supposed to be at the core of architectural production? Moreover, shouldn't this production result from a design process where the relationships between internal spaces, the spaces and the whole, the whole and the city, the final product and its inhabitants, and how these relationships mutually influence or transform the identity of these parts are central?

An emblematic – but unfortunately not well known – case study where these matters are placed at the core of the design process, is the so-called Edifício Transparente designed by the Spanish architect Manuel Solà-Morales in Oporto between 2000 and 2004 [8]. This project is part of a more comprehensive set of interventions for the redevelopment of the old bourgeois Vilas do Porto promenade and the new speculative waterfront of Matosinhos's suburban and port district. At the beginning of the year 2000, Solà-Morales is called to infrastructurally redesign the Avenida Marginal, a route between Matosinhos neighbourhood, the City Park (Parque da Cidade) and a system of ocean beaches spread along the litoral connecting the Douro River mouth to the Swimming Pool in Leça da Palmeira designed by Alvaro Siza in 1966. The main municipal objectives were mainly two. On the one hand, it was asked to develop a pedestrian connection between the Parque da Cidade and the Praia Internacional and, on the other, to reconstruct the protagonism of the natural form of the beach and the artificial prominence of the Castelo do Queijo through a connecting element able to dialogue with the horizon of the sea and ample urban distance.

To achieve these goals, the architect designed a white concrete viaduct where the park and the beach merge, redefining and fading out the boundaries of the Parque da Cidade itself. Two project heads limit this viaduct. The first is an out-of-scale roundabout substituting the former Praça de Gonçalver Zarco, specifically designed to host a car park in the middle and to provide a lively transition between the metropolitan road system, the City Park and the Atlantic beaches. The second head of the viaduct is a large transparent building for recreational use that directly connects the park with the beach via a ramp that extends from the park's dune to the highest floor of the building and then, unfolding itself within the transparent volume, reaches the shore.

The word transition may be used as a keyword to describe the space of this impressive building. Solà-Morales, introducing the ramp as the generator of architectural space, dismantles the relationships between plan and section, generating a promiscuous continuity between architectural and urban scale and between antithetical spaces such as interior/exterior, above/below and open/close. For example, by observing the original drawings - but even more, visiting this building - it is possible to see how the ramp allows the continuous transition of spaces that are no longer interior or exterior. For example, the City Park dune through the ramp is stretched until the building's terrace, an open area designed as a portico covered by an astonishing structural system realised in white concrete that gives figurative continuity between the architectural and the urban project. This transposition of the portico from the basement to the highest level of the building represents one of its most impressive experimental aspects. In other words, with this gesture, the architect declares that his compositional method lies in playing with spatial hierarchy, reversing the common understanding of spaces to introduce its original and dynamic use. In this way, the portico, usually distributed alongside the walkway to filter the architectural space from the urban ones, is suddenly abstracted and transposed in the highest part of the building. This design solution is far from casual since the architect, to reinforce it, detaches the structure from the sidewalk, inviting users to reach a different elevation to enter the building. However, transposition, ambiguity and promiscuity do not lie only in the relationships between architecture and urban context. These characteristics indeed lie also between the same internal spaces. The rooms hosting the main activities - interchangeable through time - are organised within suspended transparent pavilions placed at the centre of the building. All around, the ramp, enlarging itself, evolves into a space both of connection and staying, thus guaranteeing that continuous transition essential in generating promiscuous spaces that are neither open nor close, neither residing nor crossing.

Through this (in)constant transition between only apparently non-separable boundaries of antithetical spaces, the human movement within a four-storey linear building has paradoxically become predominantly vertical. At this point, it seems possible to understand that the architect, defining the Edifício Transparente's spaces, does not consider the relationships between form and function as a leading problem but rather the *abstraction* of spaces, the *human movement*, and the integrations between *architecture, city and landscape* (Morales, 2006).

The architect's words can support this hypothesis, so in the following lines, is reported a crucial interview released by Solà-Morale in 2006 for the *Arquitectura e Vida* journal, no. 76. The original text is in Portuguese, so this is an original English translation.

“The abstraction is created with two main options: the building is transparent (no façade) and ambiguous (no designation). However, someone believed its ambiguity and transparency indicated that it had neither utility nor programme. On the contrary, the bet was to use abstraction to design a content building, already defined by Kenneth Frampton as *Megaform*. A Megaform is a building whose architectural space is not dictated by a particular monographically use - as happens in naive functionalism - but by its promiscuity with the urban significance. Thus, in the Edifício Transparente project, architectural form arises from a responsibility assumed towards the place, more as an offer than an obligation, more as a generator than a product. The Transparent Building structure stands like a stadium tribune looking towards the Atlantic Ocean. It is made of concrete and glass and welcomes the passage of people moving from the top of the park hills to the beach while offering options for recreational, cultural and exchange activities. Although the original project proposed a clear and quantified programme of activity (comprehending the dancehall, the beach bars, shops and boutiques, exhibition spaces, laboratories, sports areas and also a luxury restaurant), the fundamental objective of the project was to create open paths where the movement of the human being would mix with the voices and the noise of the sea, under the protection of a gantry roof. The internal spatial organisation of the building is, in fact, that of a path. Ramps await the passage of people - athletes, visitors and all sorts of citizens - who, from the dunes of the Parque da Cidade, walk or cycle towards the beaches and cliffs of the Atlantic Ocean. These ramps show the variety of uses the different building parts can acquire. The continuous vision of this space of multiple, where the movement of people is the best performance, is combined with the constant contemplation of the ocean and the coast, of the park and the city, made possible by effective transparency. This building is neither a hotel nor a shopping centre, neither a cultural complex nor a conference hall. Instead, it could be all of these activities simultaneously or just some of them performed at separate times. Modern urban architecture's interest is in multifunctional, hybrid, adaptable structures. Only the old monumental building uses, the museums, the auditoriums, the cathedrals, and the town halls still defend the typological specificity and monographic architecture.

However, the contemporary city needs other flexibilities. It needs a design of a 'content building', namely a versatile building that can allow a multiplicity of space uses. The Edifício Transparente was a modern proposal generated from the public paths and interpreted as a fixed internal structure. Therefore, the ultimate goal was to expand the idea of transparency while simultaneously achieving a transitional space between the different scales of the site, accepting among the various possibilities even that of creating a large volume with only an apparently empty interior.” (Solà Morales, 2006)

4. INTRODUCING BENTO-BOX ARCHITECTURE. IT SOUNDS NICE, BUT IT IS NOT.

What has been described so far has highlighted how, more than ever, it is essential to observe the built environment as a complex system where all the elements mutually transform each other. In architectural and urban design terms, it seems essential to enable a new design approach where there is not so much distinction between the two disciplines, where both architecture and the city are designed starting from a more comprehensive strategy where the first is essential for the second and vice versa. Thus, it becomes the generator of new resilient urban polarities that are able to embrace

and include the original condition of a place and, through a new spatial conception, trigger new inclusive social phenomena.

This does not seem to be the case for the Prada Foundation building, recently realised by the well-known studio OMA in Milan, which restored a former industrial establishment set in a peripheral area of the city. As recently described by Elena Granata, the building *has an outcome of great architectural value, and the operation has given the city a place of excellence worthy of the great European capitals* (Granata, 2021). However, it still represents *an intervention that does not generate 'effects of place' because an absolute lack of relationship with the surrounding area prevails. It is a monolith, an erratic boulder, a mute presence outside its wall* (Granata, 2021). Observing the original drawings but also visiting the building itself becomes clear how its space, however much defined by the juxtaposition of contrasting principles (such as old and new, wide and narrow, open and closed, horizontal and vertical), although it presents a programme that includes diverse activities (such as an art gallery, a cinema, a library, an observatory tower, a restaurant, a multipurpose space as well as administrative and technical space), and, finally, although it entertains *supra-local relations on a national or international scale, it plays once again on the displacement between a refined and cultured interior and a popular exterior* (Granata, 2021). In other words, its architecture does not promote any spatial, cultural and social continuity solution between the two worlds, which does not entail a process of exclusion.

Fondazione Prada's building in Milan, with its extraordinary research for a specific aesthetic, is thus configured as an astonishing airtight container in which both the art collections and the public facilities are kept safe inside. Moreover, public activities are stored in internal containers that are architecturally well separated, thanks to the treatment of the façades. In this sense, the relationships between inner and outer space and between the individual parts that constitute the whole are profoundly dismantled.

We may define this project and similar ones as Bento-Box Architecture. Bento Box is a traditional Japanese all-in-one lunch box hermetically closed to the outside, incorporating smaller containers of different sizes interlocked by the matryoshka and Tetris double technique. This lunch box is specially designed to keep the food well separated and avoid promiscuity between the individual portions. Similarly, Bento-Box Architecture can be defined by large building enclosures comprising smaller units organised within well-defined borders that often force the architectural form. Also, these small units are designed as a space of separation without allowing any promiscuity solution that does not involve dismantling the space itself. As demonstrated by Fondazione Prada, this lack of spatial relations and continuity has as its ultimate result the triggering of those real estate processes addressing the issue of the suburbs by disregarding the suburbs themselves, namely by widening the boundaries of the fashionable and touristic urban centre by shifting - without approaching - the problems of the suburbs further and further away from the downtown area. In other words, those indirect positive impacts, such as attracting more valuable functions, do not lead to an improvement of suburban conditions, but rather, by raising the prices of housing estates and the services supplied, to the exclusion of the poorer and younger social classes, thus effectively making the city more and more inaccessible.

By their intrinsic characteristics, Bento Box architectures seem to be the generator of those *non-places* defined by Frampton in the fourth editorial of the *Oppositions* Journal. According to him, these *non-places* emerge from those buildings where the objectification of architecture *is granted absolute priority over any morphological - and sociological - consideration* (Frampton, 1974). So forth, we may say - borrowing Frampton's words - that Bento-Box Architecture *has the unfortunate tendency of inhibiting rather than facilitating the creation of receptive places, and doing so, through an abstract optimisation, leads to a manifest impoverishment of the environment* (Frampton, 1974). Moreover, these types of architectures, eschewing any complex relationship, cannot overcome the *frustration of utopia* described by Frampton as the result of the conflation of the *objects of elitist*

culture with the *elaborate rationalisation of the environment* (Frampton, 1974). Something that has been demonstrated so far by the Prada Foundation building in Milan, which was unable to activate the urban sphere except through the well-known process of gentrification.

Solà-Morales building seems, instead, to tell a different story from that of Bento-Box architecture. A story where the different spaces are so promiscuous that they end up being a new original place in which the semantic meaning of space became multi-layered and sometimes incomprehensible. This unreadability of common spatial meaning allows self-organisation, makes the space a complex space, and, therefore, transforms a building into a complex one. However, at this point, it seems essential to draw the strands of the discourse together and describe how such a building typology becomes a space activator.

As described in the case study of Edificio Transparente, promiscuity, dismantling some consolidated boundaries in the domains of space and function, generates new kinds of use of space, introducing a new rituality that brings back attention to the realm of architecture's purpose as defined by Saarinen. According to Saarinen, the purpose of architecture is *to shelter and enhance man's life on heart* (Saarinen, 1950). This reference to the shelter is not casual since, through it, Saarinen can demonstrate that architecture is much more than its utilitarian meaning [...] *has a much more fundamental role to play for man, almost a religious one* (Saarinen, 1950). The purpose of architecture then lies in this sense of religiousness and rituality that architecture embraces, *going beyond its purely functional aspects* (Saarinen, 1950).

This reinvented purpose put into play by Complex Buildings generates original architectural forms, thus allowing the space to assume a role that «goes beyond its purely functional aspect». To sum up, we may say that promiscuity of space and function, as also demonstrated by Solà-Morales's example, generates a new use of the space and, therefore, a new rituality that gives original meaning or purpose to that building typology.

Moreover, going back to Bill Hillier's theories, it is possible to say that this new architectural meaning will generate further social organisation forms, namely, renewed human behaviour. Finally, this generative quality of promiscuous space recalls those identity processes that are invoked by Frampton in the already mentioned editorials - through which it becomes possible to create a place, namely a space where human beings may come into being.

5. CONCLUSIONS

So far, complex buildings have appeared as tools to activate the public spaces of our cities. However, they are not a new architectural typology but rather have origins in all those new architectural experiments which, from the definition of the eight-hour working day at the beginning of the 20th century, have dealt with translating the organization of leisure time into spatial terms. Emblematic cases are the Soviet Workers' Clubs, the Italian Dopolavoro, the more recent Brazilian SESC, and the current experiments of the Urban Think-Tank.

The SESC Pompeia, a visionary project by the renowned architect Lina Bo Bardi, which she eloquently describes as the "Citadel of Freedom," embodies a transformative approach to architecture centred around the concept of leisure. This project envisions a dynamic and flexible interplay between form, space, and architecture, where the form is not dictated by function but rather anticipates it. This architectural marvel starkly contrasts the urban reality of São Paulo, a city often lacking in squares and public spaces. The *Citadel of Freedom* thus becomes the residence of pluralism and differences, where the anthropological character becomes the strength of an architecture that does not want to impose itself as an object but as a *place*, much in the spirit of Frampton's ideas in opposition. In this way, architecture becomes a centre for disseminating new values— such as education, culture, dignity, tolerance, respect for cultural diversity, and the heterogeneity of society — whose presence is fundamental for a livable public space.

It is precisely on these assumptions that the experience of the Urban Think-Tank is rooted. UT-T has been involved in numerous projects in South America and beyond in informal contexts. At the centre of their architectural experimentation is always the search for a spatiality that acts as a spark, capable of triggering processes of inclusion and sociability in fragile contexts. Their architectures, which have become real spatial prototypes of social activators, contrast with what happens in the case of the Prada Foundation. Their prototypes “serve as a lighthouse, responding and speaking to the community's common needs and collective pride”.

It is these lighthouses that our city needs, not golden lanterns. Welcoming, inclusive, livable spaces are not by definition a priori but for the daily experience of a space that transcends the distinction between architectural and urban scale and, in doing so, defines new sustainable rituals of inclusion and resilience.

Extended abstract

Nature Based Solutions (NBS) offer significant potential to address contemporary water management challenges, particularly regarding sustainable cities and their adaption to climate change. The relevance of NBS for water emerges, for example, thinking to their high potential to contribute to the achievement targets of the 2030 Agenda, such as SDG 11: *Making cities and human settlements inclusive, safe, resilient and sustainable* and SDG 13: *Addressing climate change*.

It is believed that NBS are even more important than traditional (structural) systems for mitigating hydraulic risk because they allow us to act on its causes, which means the reduction of the hazard, i.e. the intrinsic territorial conditions that expose the area to risk.

Hazard generates risk if damage conditions occur, due to the presence of infrastructures and people. In fact, risk is defined by the following formal relationship: $R=H*D$, where R is the risk, H the hazard, D the expected damage for infrastructures and people.

Through a case study for an area of Salento (Apulia, Southern Italy), this paper aims to give a contribution to reducing hydraulic hazard by the most efficient choice of type and location of some NBS.

It is then necessary to encouraging as much as possible the infiltration of rainwater runoff into the soil and, in consequence, into groundwater, where water is stored and available for a long time. This process is pursued first of all by the accurate knowledge of the runoff paths and, in consequence, NBS are positioned to intercept and to slow down the runoff “forcing” its infiltration. This process is the basis of the hydrological resilience of the territory, pursued specifically by the following project milestones:

- a) Definition of the hydrographic micro-network, through a digital terrain model of high resolution, (a starting raster of 8 m) reclassified to 4 m thanks to integrations obtained from the available analogic cartography.
- b) Interception of the runoff through landscape structures typical of the area:
 - dry-stone walls, which have been significantly increased and renovated, evaluating the permeability of the stone foundations, so that they act on the runoff as drainage trenches.
 - Redevelopment of the drainage ditch to the west of the town, whose impluvium is shaped by a grassy channel.
 - Reservoir to the South-east of the town, with a lamination basin effect on the floods.

The overall effect of the project responds to the strategic objective: mitigation of hydraulic risk by reducing hazards, i.e. “*soil conservation by soil use*” and landscape design.

Keywords: *hydraulic hazard; Nature Based Solutions; landscape structures design*

1. INTRODUCTION

The relentless urban expansion that began in the 20th century has resulted in the loss and degradation of ecosystem services and functions, such as microclimate and water resource regulation [1, 2].

Coupled with climate change, this has exposed cities and their surrounding territories to increased vulnerability and exacerbated hydraulic risks [3].

The primary causes lie in anthropogenic activities which have drastically altered the hydrological cycle, both at the regional and urban scales [4]. The widespread impermeabilization of surfaces and the consequent simplification of drainage networks have accelerated the “runoff response to precipitation” [4]. This phenomenon, coupled with the limitation or inhibition of water infiltration into the subsurface, has triggered a series of critical issues, including the inadequacy of drainage systems in handling urban stormwater, leading to flooding and significant pollutant loading into receiving water bodies [5]. These impacts cascade onto the quality of aquatic ecosystems and exacerbate soil erosion phenomena [6, 7]. It is estimated that extreme events have caused tens of thousands of fatalities and economic losses of \$650 billion in the past two decades [8].

In response to these challenges, it is necessary a new paradigm for landscape and urban planning. In consequence, research and its technical application have turned in many cases to Nature-based Solutions (NBS), defined as “solutions that are inspired and supported by nature” [9]. NBS have emerged as a paradigm capable of offering a multitude of benefits:

- **Ecological benefits:** NBS provide crucial ecosystem services, such as water and air management and purification, microclimate regulation, and biodiversity protection.
- **Social benefits:** NBS contribute to human well-being by providing green spaces for recreation and interaction, enhancing the quality of life in both urban and rural areas.
- **Economic benefits:** NBS generate employment opportunities.

Nature-based Solutions (NBS) have also proven effective in supporting resilience and sustainability goals [11, 3], with positive impacts on flood risk reduction and climate change adaptation [12, 13, 14, 15]. The advantage of implementing nature-based hydrogeological risk management strategies lies in conferring self-organizing and learning capabilities to the urban system, enhancing its response to future events for greater resilience [16], thus overcoming the dichotomy between adaptation and mitigation. The inherent multifunctionality of NBS [17] represents a strength compared to traditional “grey” structural solutions that are rigid (and therefore more fragile) and do not address the root causes of the phenomena [18]. The versatility of NBS allows them to be successfully integrated at different scales, from building, neighbourhood, catchment and urban point of view, bringing the urban water cycle closer to its natural counterpart [19, 20]. Recently, NBS have been classified according to the ecosystem services they offer and the urban goals they aim to achieve [21]. In particular, green roofs, green walls, rain gardens, retention and infiltration basins, drainage trenches and constructed wetlands can be introduced at both urban and landscape scales [21]. An additional advantage lies in the possibility of integrating NBS with grey infrastructure; the latter has the sole task of intercepting excess runoff, while green systems offer the benefits of resilience, biofiltration and infiltration of water, which then enriches groundwater bodies [22].

Despite the promising potential of NBS, further research and practical experience are needed to address, still existing uncertainties regarding the planning process and the integration of NBS with grey infrastructure [10]. An empirical approach is crucial, as NBS design is highly site-specific due to the vast array of applications. The only valid generalization lies in the centrality of natural elements in the chosen solution.

The literature reveals a stronger focus on the social and economic acceptability of NBS [23] compared to the analysis of the processes targeted by NBS implementation. This hinders the development of truly effective interventions. In other words, it is essential to quantify the ecosystem service intended to be achieved with NBS, necessitating careful consideration of the proposed solution’s efficiency.

Accordingly, this paper utilizes a case study to contribute to the analysis of the NBS design process, leading to the formulation of novel NBS proposals.

2. MATERIALS AND METHODS

The study area is the municipality of Presicce-Acquarica, located in Puglia, Southern Italy (Figure 1). The city faces significant urban flooding challenges due to its unique topography, characterized by a depression between two hill chains, situated to the east and west of the town (Figure 2). This results in frequent flooding from runoff originating from almost the entire surrounding area. To mitigate these issues, two drainage ditches were constructed approximately a decade ago to intercept runoff from the eastern hills (Figure 2). These defence hydraulic structures consist of drainage trenches that divert runoff from the eastern hills. While they offer some degree of risk control, their effectiveness is still largely insufficient, necessitating further interventions.

For this purpose, specific Nature-based Solutions (NBS) have been proposed, following these steps:

1. Identify the underlying causes of the risk.
2. Develop control strategies based on NBS.
3. Select NBS inspired by the existing landscape. The chosen NBS include:
 - A vegetated swale on the western side to drain runoff from that direction.
 - A runoff detention area on the southern side to intercept and regulate the flow of the stream originating from that direction.
 - Construction of dry-stone walls to intercept and infiltrate diffuse runoff, typical of the eastern and northern parts of the town.

The dry-stone walls deserve particular attention as these structures are a defining feature of the Mediterranean landscape, including the study area.

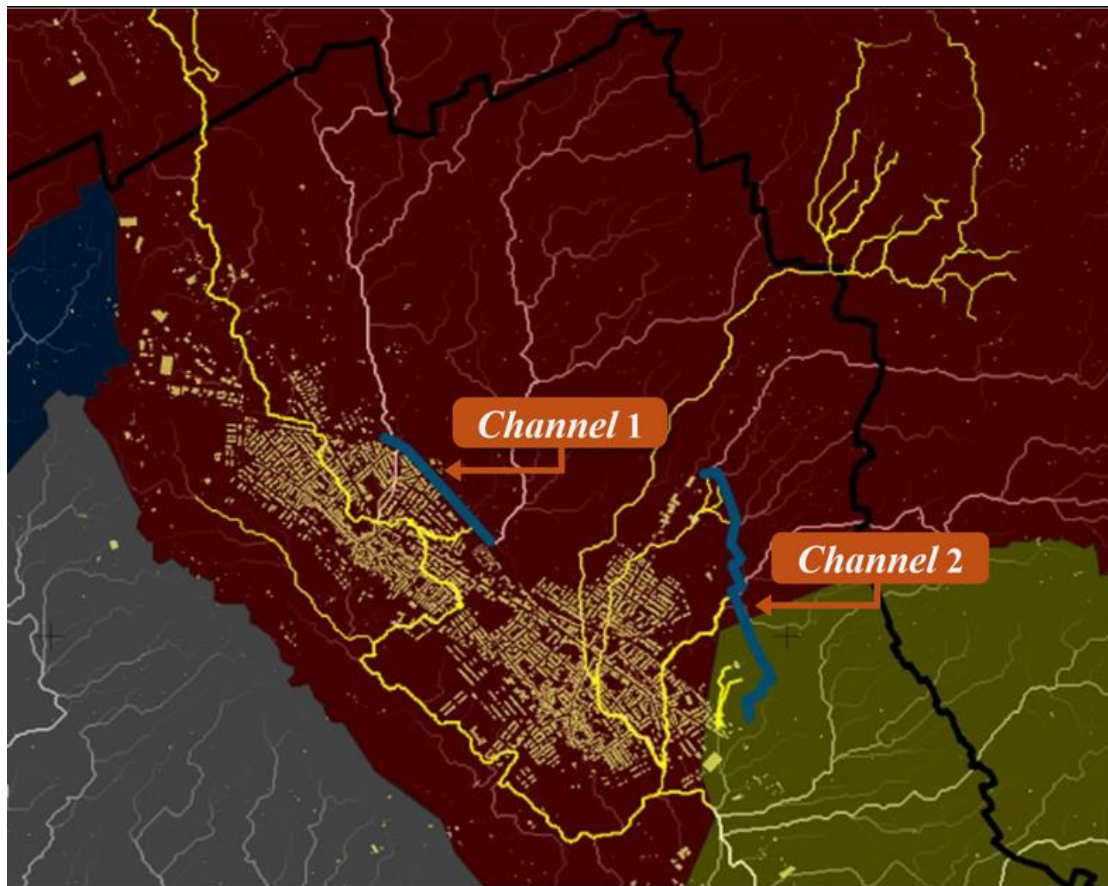

Figure 2. GIS-processed flow accumulation detail for the study area: the yellow flow accumulation represents the runoff that is not intercepted by the existing guard channels.

2.1 Introduction to Dry-stone Walls (DSW)

Dry-stone walls (DSWs) are a testament to a millennia-old traditional construction technique [24]. They are constructed solely by interlocking roughly shaped stones, typically extracted from the land on which the wall is built, without the use of binding materials [25, 26].

These structures are the result of a meticulous selection process of calcareous and/or calcarenite stone quarried directly on site. The stones undergo minimal shaping necessary for the proper execution of the structure and are adapted to the laying plane, all done manually.

Dry-stone walling, although rooted in the distant past, transcends mere landscape humanization, rising to the paradigm of a harmonious union between human and nature. It not only represents a tangible and unique sign of this encounter but also stands as a far-sighted solution, intrinsically eco-sustainable and endowed with exceptional functionality [24].

In 2018, the art of DSWs in seven Mediterranean countries (Italy, Croatia, Cyprus, France, Greece, Slovenia, Spain, and Switzerland) was awarded the prestigious UNESCO Intangible Cultural Heritage status, included in the relevant list as a transnational element. This recognition represents a significant celebration of the “Wisdom of Building,” a millennia-old tradition passed down from generation to generation [24].

2.2 Human-Nature Link: A Symbiotic Relationship

Dry-stone construction techniques serve as “guarantors of harmony, prevention, and environmental conservation” [25]. Through this technique, human intervention reshapes the landscape in a virtuous dialogue with nature.

Originally associated with rural contexts, its initial function was to delineate property boundaries. However, the DSW has evolved into a structurally significant element for the construction of terraces that have softened particularly harsh landscapes [24]. Thanks to this technique, slopes have been “smoothed” and made suitable for agriculture and forestry [27].

The harmony between dry-stone walls and the natural environment is evident in the rich biodiversity that distinguishes them. The structure favours the creation of microhabitats ideal for small fauna and insects, providing them with shelter, suitable sites for gestation and egg-laying, as well as feeding opportunities. The typical flora that thrives on the wall also contributes to the ecological chain, offering protection from the elements, shade and sunspots, and a microclimate that is varied in structure and its immediate vicinity, especially in terms of temperature and humidity [28].

2.3 Construction Technique: A Testament to Traditional Skills

DSW construction employs the technique of interlocking irregular stone blocks, juxtaposed without the use of mortar, in a variable order, to form a structure with two inclined faces towards a central core, composed of loose and unshaped smaller stones [26].

The base of the wall section, the foundation, lies below the ground level, arranged in two parallel rows of rough stones that define its width. Above the foundation rises the body of the wall, consisting of successive layers of stones without the use of binding material. These layers protect the central core, formed by stones of smaller size. Once the desired height is reached, the wall is completed by a cover of squared stones, the so-called cope stone, which levels the top of the construction.

2.4 Functions and Ecosystem Services: Beyond Physical Barriers

As discussed, dry-stone walls represent a landscape and cultural heritage of inestimable value, distinguished by ecological and functional characteristics of great relevance, as well as custodians of historical memory.

The original function of DSWs was to delineate properties, acting as fences for livestock and defining spaces dedicated to cultivation and grazing. Over time, their function has evolved, transforming them into retaining walls, such as terraces, now categorized as “ingenious natural solutions”.

This has allowed humans to practice agriculture even in areas otherwise impossible due to significant slopes. Terraces, in fact, interrupt the slope of the hillside, creating an embankment behind the wall, which offers multifunctional effects in addition to slope reduction: soil protection from erosion; increase in soil depth and organic matter content; reduction of the surface runoff velocity and consequent rainwater infiltration, which feeds the groundwater.

Given the hydrological cycle alteration scenarios described in the paper’s introduction, DSWs emerge as an element to consider in hydrological cycle management, assuming a new role in runoff interception, even in flat areas, such as the present case study. Indeed, their structure, if strategically positioned, allows for runoff interception, dissipating its energy and retaining rainwater, which infiltrates and feeds the groundwater.

This results in significant benefits of DSWs, such as:

- a) Contribution to the control of hydrogeological instability and the impacts of urbanization and climate change.
- b) Ecosystem services such as aridity mitigation. The stone acts as a dew catchment surface, thus guaranteeing a precious water reserve for plants and favouring a soil moisture level necessary for vegetative growth. This ecosystem service is essential for the arid and semi-arid Mediterranean areas, where water scarcity is a critical factor for the survival of flora and fauna.
- c) Role of true ecological corridors, favouring biodiversity conservation and creating habitat for diverse plant and animal species. The interlocking construction technique employed, in fact, presents gaps between stones, from a few millimetres to a few centimetres, which act as refuges.

d) Microclimatic regulation, because the mass of natural stones significantly influences the external thermal behaviour of the wall, acting as an excellent heat accumulator. There is then a gradual transition from high external summer temperatures to a cooler internal environment, with constant humidity at the base of the structure [24].

These are therefore ecosystem services offered by DSWs which allows them to be classified as “Nature Based Solutions” in all respects.

2.5 Design DSW as NBS

The foundation of a dry-stone wall is composed of highly permeable stonework, which structurally acts as a drainage trench that further promotes runoff infiltration (Figure 3). This inherent drainage capacity of DSWs has been utilized in the presented project, which proposed the restructuring and expansion of DSWs in areas where runoff is not adequately intercepted by existing channels, as illustrated in Figure 2.

To assess the runoff patterns across the entire settlement, a flow accumulation analysis was conducted in a GIS environment using a digital terrain model (DTM) with a resolution of 8 meters. The resulting runoff map, shown in Figure 2, clearly indicates that the existing channels in the eastern part of the settlement are insufficient to intercept runoff effectively. Furthermore, the further excavation of new channels or the extension of existing ones is not a feasible solution due to practical constraints.

Due to the limitations of the existing channel network and the need for improved runoff management, the project proposed the implementation of a strategic DSW network, as depicted in Figure 4.

Figure 3. Cross-section of the dry-stone wall proposed in the Presicce-Acquarica project.

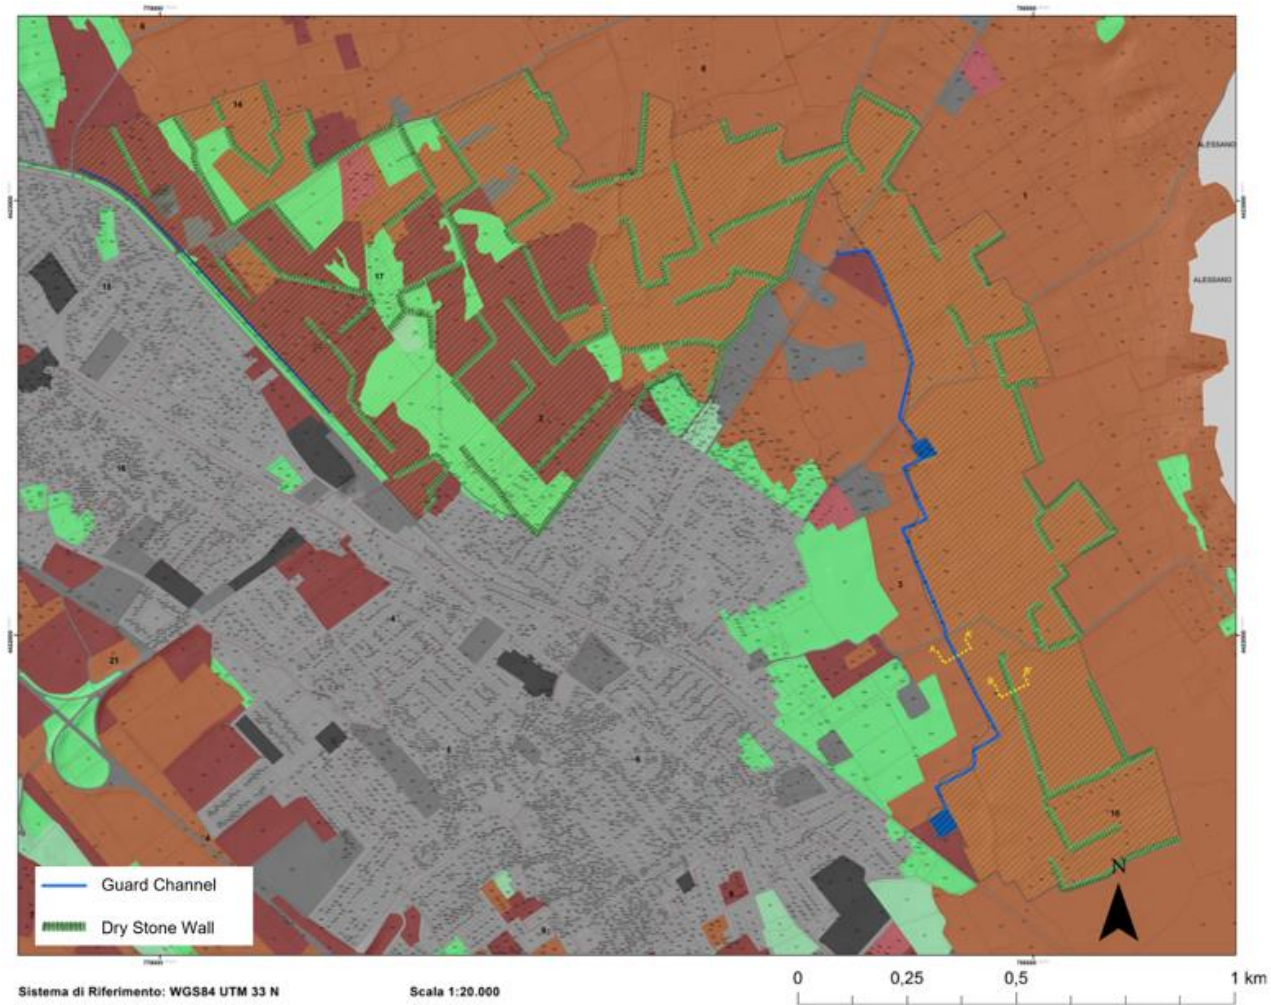

Figure 4. Implementation of a strategic dry-stone wall network in the study area.

3. DISCUSSION

DSWs can be categorized as NBS due to their contribution to biodiversity by creating a unique ecosystem. The moisture retained on the stones and penetrating the gaps between them promotes vegetation growth, which, along with the stones, provides habitat for diverse fauna, establishing a specific biocenosis [29].

This concept highlights the general principle that the physical diversity generated by landscape structures, such as DSWs, triggers the development of biocenoses, provided that space and time are allowed for the adaptive capacity of plant and animal species.

Extrapolating this concept, all environmental arrangements through landscape structures can be classified as NBS, as long as nature is allowed to take its course and “appropriate” the physical spaces. Beyond their role in fostering biodiversity, DSWs offer valuable solutions for mitigating the risk of hydraulic hazards in urban areas. This capability stems from their inherent structure, which facilitates runoff control through two mechanisms: the barrier created by the wall and the infiltration promoted by the loose stone foundations. Additionally, both structures create water impoundments, further reducing runoff volume, resulting in an overall decrease in the hydrological load on the territory.

By reducing runoff and the associated erosion potential, DSWs effectively lower hydraulic risk. Risk is defined by the following relationship:

$$R = P * D$$

where:

Proceedings

- P represents the hazard, or the system's inherent propensity to generate risk due to its intrinsic characteristics, such as climate, morphology, geological and pedological characteristics, and physical configuration of the landscape.
- D represents the expected damage, generated by the presence of exposed and vulnerable elements, indicating their susceptibility to harm.

This formula clearly underscores the importance of land use and landscape arrangement in risk generation. For a given set of infrastructure and expected damage, if the terrain is less hazardous due to its higher permeability to runoff, the overall risk is reduced.

In the specific case of runoff-induced hazards, the proposed solution involving DSWs entails runoff interception and infiltration, thereby lowering the hazard level.

4. CONCLUSION

This paper sheds new light on the significance of landscape planning and design, highlighting the potential of landscape structures as proactive measures for hydraulic risk prevention. As the adage goes, prevention is always better than cure.

The proposed approach follows a structured methodology:

1. **Problem Identification:** The first step involves clearly defining the problem, in this case, hydraulic risk. This entails a thorough understanding of the landscape system, including the factors contributing to the risk, such as runoff pathways (as illustrated in Figure 2).
2. **Adaptive Solution Design:** The next step involves devising adaptive solutions that aim to prevent the problem by reducing the hazard potential of the landscape.
3. **Leveraging Traditional Structures:** This paper proposes the utilization of dry-stone walls, ancient and traditional structures prevalent in the Mediterranean region, as effective risk mitigation tools. Their unique construction characteristics enable them to intercept and infiltrate runoff, thereby reducing the hazard potential.
4. **Nature-Based Solutions:** The proposed approach goes beyond mere risk mitigation, offering the added benefit of enhancing landscape quality and biodiversity. This aligns with the principles of Nature-Based Solutions, which promote sustainable and environmentally friendly approaches to problem-solving.

Abstract

This contribution discusses the images of the students' private geographies, in several Portuguese regions, as confinements made travelling forbidden across municipalities, during the pandemic outbreaks. This national directive had repercussions in the daily life of every citizen, and IGOT students only had online courses, during the second semesters of 2019/2020 and of 2020/2021. This research project took as object twenty-eight mental maps elaborated by the participants during lectures within the framework of the honor's degree in Geography, gathered in the first semester of 2021/2022, and twenty more by drawers of a master's degree Seminar on Fieldwork in Geography, in February/March 2022. The forty-eight maps manifested daily situations of isolation experienced inside the residences, within neighborhoods, municipalities, and cities. This contribution aims to point new urban planning post-Covid directions, particularly targeting public spaces. The research question is: What changes must be introduced in cities planning and functionality, to make them more resilient to future extreme events, natural or induced?

The paper presents the mental maps or *pandemaps* built by the University students during lecture seminars, registering the landmarks and public spaces they've visited during lockdowns, in Lisbon as well as in other Portuguese cities and rural towns. Previous research has focused world representations on the Southern Hemisphere (East Timor and Mozambique), Lisbon old city neighborhoods, (strolled by tourists in our days), and representations of the capital city of Portugal. During the COVID-19 outbreaks the students received classes through online platforms, but when they returned to face-to-face classes, they answered a questionnaire about their activities during the lockdowns and were asked to map the public and private spaces around their home and the city they lived, to study new ways to deal with future multilevel risks, such as floods, other pandemics or even earthquakes.

This permitted us to investigate the concept of 15-minute cities, as recent engineering and urban planning proposals recovered the Vicinity Units designed by the architects and urban planners Lúcio Costa and Oscar Niemeyer when conceiving Brasilia, in the 20th century. Spatial justice could be ideal if not only the allocation of trade and services would be at a walking distance from home, but also if the residence and the working place could be within the 15-minutes planned unit. The Planet and the cities would gain with this choice. Gardens and, in special, community food gardens, are new requirements. Post-COVID cities and neighborhoods should be greener; they should have a good number of green squares and open spaces, available to all citizens. The need to walk, bike, and participate in the urban turmoil that always characterized European cities, should be reintroduced, because conviviality is part of human nature.

Keywords: *food gardens; pandemaps; risks; urban planning; 15-minute cities.*

1. INTRODUCTION

In his 1976 article “What is a mental map?” Elspeth Graham, from the University of St Andrews, defines it as a model of the environment, which is built up over time in our brain [1]. Norbert Gotz and Janne Holmén [2] argue that images are framed, coded and so the conception of drawings of our street, for instance, involve a mental conversion. In this sense, mental maps are imaging that a person has about the locations and characteristics of places at a variety of scales [3, 4], from the local (a neighborhood), to the continental (Portugal’s location in Europe) and the global (the distribution of oceans and continents across Earth).

Mental maps can change with direct experience (such as travel by car, by public transportation or strolling on foot on our city and neighborhood) and indirect experience (such as media exposure and looking at other maps to find places where you can buy whatever you might need during the movement restrictions imposed in the COVID-19 outbreaks). Kevin Lynch’s “The image of the city”, first published in 1960, was pioneer in the field of urban mental maps conception and decoding [5]. According to Schenk: “developments in the areas of geography and urban planning contributed to the concept of the cognitive map or mental map becoming a paradigm for interdisciplinary research on the spatial orientation capacity of humans in the 1960s” [6]. These have been researched both by historians and geographers. The paper will continue with the methodology, results, and the proposals, towards the conclusions.

2. MATERIAL AND METHODS

In this case-study we’ve asked two groups of students to identify from memory the locations of landmarks in their neighborhood, such as the building where they live and the services (ATM, banks) and trading posts (cafes, supermarkets, markets, pharmacies) located close to their residence that they frequented to purchase basic needs (food, remedies, cleaning items, pocket money, etc.), during Corona confinements. Additionally, they had to answer geographic questions about themselves (e.g., city and place where they’ve stayed during confinements) as well as to explain practical aspects of their daily life during the pandemic movement restrictions (e.g., the number of times they abandoned their residence to shop, to go to the hospital, to visit relatives in need of help, etc.).

The mental map resulting from the compulsory “stay at home” period, due to COVID-19 virus outbreaks in Portugal, is quite different from any other experience of imaging our environment, as the students had longer time than usual to identify details of a route used frequently (e.g., to and from the grocery store, to and from a park, to and from a relative's home); they also had several opportunities to add details to their perception of the world, due to the length of travel restrictions. The resulting map is called a *pandemap* or map of the COVID-19 pandemic [7]. It is the student’s unique image, as Graham wrote: “His or her private geography” [1].

A first group of twenty master students was instructed first to design a *pandemap* of the neighbourhood where they usually live or the house/apartment and street where they stayed during the worst virus outbreaks. They photographed the image drawn with their mobile phone and handed out the sheet with their mental map to the professor. Later, at home, they were invited to revisit the spaces represented and asked to handle out a formal digital map of their *pandemap*, using Google Earth, Google Maps or Street View tools [8]. A second group of twenty-eight honours students was shown examples of *pandemaps* drawn by Brazilian scholars and then invited to represent either their house/apartment or their street and neighbourhood in a mental map of Portugal. The sheet of paper with their drawn *pandemap* was given back to us that later scanned the result, further discussing formal cartography conception with the class of second year students, in the curricular unit of Social and Cultural Geography.

3. RESULTS

The results were compared by building tables containing the students' responses to the inquiry and the type of maps drawn, some of which were representations of their apartment or house located in a Portuguese city, and others the surroundings of their locations during lockdowns. *Pandemaps* from the municipality of Lisbon were organised by neighbouring areas; then the mental maps of other Metropolitan Region of Lisbon municipalities have been ordered, dividing the Northern from the Southern Metropolis; third, the North, Southern (Évora) and Western parts of the country were also tagged and analysed separately; as well as detached provinces such as Ribatejo (Tagus River Basin); finally, the islanders and the foreigners have been examined in their specificities (Table 1).

Table 1: Question 1. Sex, number, and location of the students, during confinements

Regarding the Metropolitan Region of Lisbon (AML), it integrates eighteen municipalities, nine North of the Tagus River and another nine between Tagus and Sado Rivers. It has seventeen cities and possessed 2,871,133 inhabitants in the last census (2021). The most populous city is Lisbon, the capital city and main municipality, located to the north of the Tagus Basin, with 544,851 residents, followed by Sintra (385,954) and Cascais (214,134). Census data are available in the News Agency Lusa [9]. The metropolis is divided by the biggest river of the Iberian Peninsula and the students were

Proceedings

equally divided among these locations. Nevertheless, 46,4% of the honour's degree respondents resided in other country sites, either cities or countryside areas, against 30% of master's students. About 79% of the universe studied during confinements watched television, mostly movies and serials in the evenings, and 25% played games in their computer. Post-corona era governments should work better on public TV programming alternatives, from the news to latest cinema options, to permit that possible future confinements might not improve addictions to gambling and extra expenses with movie platforms, which payment is heavier for most household budgets. Those students who spent confinements away from their families were totally dependent on TV and computer connections, so national authorities must regulate internet distributors, to prevent total isolation and resulting depressions registered in students and among the public, in general.

About 50% of the universe of respondents observed no more than buildings and parked cars from their best window (Table 2). This proposes an urban planning recommendation for post-COVID-19 Era, which is to better isolate apartment house buildings with greenery, thus giving urban residents fewer depressive views in times of isolation. As Jessica Verheij argues: "the justice implications of urban greening strategies are often not addressed by policymakers" [10], even in case of Lisbon, elected as the "European Green Capital 2020", by the European Commission. Greenery, trees, and parks are repeated in this table, as they were by respondents to the Survey, and trees are scarce in old central neighbourhoods. As Andrea Boeri et al. wrote: "The pandemic has forced us to review our lifestyles and to practice different forms of social distancing, exponentially increasing the amount of time spent at home and fortifying the desire to spend more time outdoors." [11].

Table 2: *Question 3.* Describe the landscape observed from your best window.

The research question is: What changes must be introduced in cities planning and functionality, to make them more resilient to future extreme events, natural or induced? One of the most thought-provoking best practises are Lisbon's green corridors, designed back in 1976 by the Portuguese landscape architect Gonçalo Ribeiro Telles but only inaugurated by the end of 2012 [12]. The main green corridor of Lisbon, connects Monsanto Forest Park (dark green big spot, located West in Fig. 1) with the northern central Edward the 7th Urban Park, located in the vicinity of Liberty Avenue (a fancy boulevard), and leaves behind many old neighbourhoods. The green passageways integrate some community food gardens (coloured dots), totalling 21 in our days (Fig. 1), where residents grow their own legumes, cereals, horticulture species and kitchen spices. These corridors were one of the reasons why Lisbon received the title of European Green Capital 2020.

Figure 1. Green Passageways or Corridors [13].

Recent engineering and urban planning proposals recover the Vicinity Units designed by the architect and visionary Le Corbusier, in the first half of the 20th century, and develop the 15-minute community-life circle within cities, now actively introduced all over China, according to Li, Zheng and Zhang, Y.K. [14]. The self-contained city together with the vertical garden-city were the inspiration of Brasília, the capital of Brazil, designed by the urban planner Lúcio Costa (1957-1961), friend and great admirer of Le Corbusier, and built-up by the also famous architect Oscar Niemeyer [15]. The Brazilian capital was drawn to permit that every resident could have access to food trade and basic services within a reasonable walking distance. In Lisbon, the Portuguese capital city, 15-minute neighbourhoods already exist in Alvalade (N) or Arroios (central areas).

During lockdowns, the students that lived in these areas could walk to purchase their basic needs; yet students came from all over the metropolitan region (37,5 % from northern Tagus River and 16,7 % from Southern River municipalities), as illustrated. The respondents that resided in other localities not always were lucky enough to meet their needs without use of public transportation, where they could be infected, despite the face masks. Some were also gifted with nice views of Tagus River from their apartment window (see Figs 2 and 3), but greenery was absent and public spaces were requested to exercise, during confinements. The students missed contact with enlarged family members, and

Proceedings

close friends; they also missed going to the shopping malls; to the movies; to football stadiums; to dine out with their relatives and friends, and to attend concerts and music festivals.

Fig 2. Barreiro Google image (South of Lisbon)

Fig. 3. *Pandemap* of master's Student

Unlike the perspectives created during the pandemic, that a new and more sustainable world would come out of the COVID-19 virus outbreak, everything went worse. The supply of food and other goods became more difficult because of the start a new war in Europe and, more recently, in the Middle East, turning transportation logistics towards the old continent a nightmare. As Gejo and Rebottaro wrote: “The States, which had never ceased to be so, have returned to being the undisputed protagonists and are facing the bids for international dominance, giving war an unavoidable presence.” [16]. The solidarity created during the pandemic among states vanished.

This resulted into new and even unwanted use of public spaces, so much sought-after during outbreaks, because some old Lisbon neighbourhoods (Arroios, Mouraria) have been taken by immigrants without a job and a roof. Those possessions were given to them and also assured to almost any Portuguese resident during the COVID-19, but the social cohesion disappeared with the return to “normality”. Avenues, public squares, and parks in the capital city now have tents with unemployed or underemployed people, as the jobs became scarcer and the replacement of face-to-face jobs by online platforms, accessible to a few, degraded life expectancies for almost everybody in Portugal.

3.1 Fifteen-minute cities and some good examples of public squares

In December 2020, the City of Paris organized a Zero Carbon International Contest, to commemorate the 5th anniversary of the Paris Agreement [17]. Eighteen cities, including capitals like Paris or Madrid, participated on this event and launched the challenge to the academia: plan a more environmentally sustainable neighbourhood. During six months, scholars from local universities developed and presented their projects of green cities, to the so-called “Students Reinventing Cities” competition. Lisbon and other Portuguese cities didn’t participate, but Spain did, with Barcelona and Madrid [18]. The mayor of Paris also started implementing 15-minute areas, in the French capital.

In the Spanish capital, the Barrio Catalysts was targeted by one of the Zero Carbon International Contest winning teams that adopted a sustainable and holistic approach for the area of the Gran Blas Sur. In the existing buildings they worked on solar thermal energy and green roofs development. The team further proposed that the 5 hectares sector proposed should increase its green areas to up to 1 hectare. Another key component was a safe bike and pedestrian infrastructure, encouraging car and bike sharing [18]. Green corridors, like the already existent in Lisbon municipality, were also proposed in this San Blas neighbourhood of Madrid.

In Lisbon big avenues are shaded by platanus, jacarandas and silver lindens. As researched by Ana Luisa Soares [19], the most remarkable squares display: 1. Pine trees (*Pinus pinea*, 31), European nettle trees (*Celtis australis*, 98), Cypress (*Cupressus sempervirens*, 100 in Fig. 4) and olive trees (*Olea europaea*, 125), in Belém neighbourhood; 2. European white elms (*Ulmus laevis*, 26), Canary Island date palms (*Phoenix canariensis*, 10), Silver lindens (*Tilia tomentosa*, 20) and magnolias (*Magnolia grandiflora*, 5), in Central Misericórdia; 3. Fancy Santo Antonio possesses European nettle trees (4) and pomegranates (*Punica granatum*, 3); 4. Areeiro neighbourhood also has nettle trees (5), Casuarinas (*Casuarina glauca*, 8) and Coral trees (*Erythrina crista-galli*, 5); 5. Central Arroios possesses European nettle trees (36) and jacarandas (*Jacaranda mimosifolia*, 9).

Fig. 4. Empire Square located in Belém western neighbourhood of Lisbon (<https://construir.pt>).

4. CONCLUSION

The image students had of their environment during lockdowns was influenced by the location of their home. Even inside their apartment, the central piece was their bedroom, the preferred place to study, game playing, video watching and sleep space. There was emptiness in the student's lives during the pandemic outbreaks, and a change in lifestyle among youngsters. The mental maps displayed in this paper show the quite detailed imaging of the blank streets and the contiguous buildings, as well as the design of the public spaces located in the vicinity of their house or apartment. Nevertheless, the return of "normality" didn't give them better future, as the students returned to their classes and their hobbies but were presented with scarce job perspectives in the next future and had to remain in their parent's houses or apartments. The urban planners should plan better cities, like the 15-minute proposal, and build more houses and apartments, using the available workforce. The recommendation is to use less Artificial Intelligence (AI), as machines don't eat nor need a roof, but people do.

Enhancing Connectivity by Reducing Barriers between Plots: A Perspective from High Line Park in China's High-Density Urban Centres

H. Gu^{1*}, S. Mozūriūnaitė²

¹ PhD Student of Urban Design, School of Architecture, Vilnius Gediminas Technical University, Lithuania

Extended abstract

The rapid urbanisation process in China has slowed down and now it is transitioning into the phase of gradual development, with a major focus on enhancing the quality of urban public spaces. The prior implementation of rigorous urban development, guided by legal planning requirements, resulted in a diminished emphasis on urban public areas. This has resulted in lost spaces (Trancik, 1986) like corner lots and abandoned areas within extensive streets, while urban public spaces are encroached on by motorized traffic, leading to human-scale imbalances and reduced comfort.

This paper analyses the concept of lost spaces that occur during the development of densely populated new areas as a case study, focusing on the Bao'an Central District in Shenzhen, China. The analysis is based on Roger Trancik's theory of urban design. Trancik (1986) emphasises the importance of taking into account human experiences in small-scale urban areas while designing from a bird's-eye view. The initial focus of urban design should be on the inhabitants of the city, requiring specific spatial design strategies to influence human behaviour. The emerging urban hubs frequently have elaborate transport systems that divide the city core, while constructing towering structures and expansive urban developments on different parcels of land, which is resulting in disparities in the spatial dimensions of the city. This paper proposes a solution to the issues by taking inspiration and learning from projects like New York's High-Line Park and Seoul Sky Garden in Korea. The High-line project integrates park and street elements, repurposing disused elevated transportation structures to enhance user satisfaction. Expanding the range of events places in these parks improves their cultural and commercial value, while also enhancing their role in the city as a vibrant hub of activity. It also promotes connectivity between the city and the new parks via staircases, lifts, bridges and escalators enhancing engagement with the surrounding urban environment.

The Bao'an Baywalk project in the Bao'an Central District adopts the high-line park concept, bringing innovative effects and influences to the previously unused areas in the newly constructed high-density urban centre. (1) Minimising obstacles between plots and creating physical and visual links between different plots; (2) Introducing diverse viewpoints of the city, known as Sky-view, which includes the building facades above ground level and views from treetops. This brings new factors and concepts to consider in urban design and spatial design; (3) Incorporating three-dimensional (vertical) urban public space and connections at multiple scales, where the sky garden enables connections at a small scale between upper-levels of buildings and neighbouring plots; at a medium scale between streets through motorised traffic, and a long distance through underground spaces in the city.

Re-read the urban complexity into planning tools through the definition of urban proximity systems. The case study of Mantova.

M. Borini

Research Fellow, Department of Architecture and Urban Studies (DAStU),
Politecnico di Milano, Italy

Corresponding author: E-mail: martina.borini@polimi.it, Tel +39 3458160872

Abstract

The term ‘proximity’ describes a field of application that has been analysed by many researchers in the past and that has become a central concept in recent years to respond to the critical issues of contemporary cities, as highlighted by the Covid-19 pandemic. In this paper, proximity has been identified as an urban strategy to be included in city planning tools to guide urban regeneration processes that reshape a dynamic city with diversified functions, a mix of public and green spaces for communities, residential areas, productive and commercial activities, linked by slow mobility. A proximity-oriented system is necessarily measured by the need to rearrange units with their functional autonomy in the territory, relating to each other in a polycentric vision. Indeed, from an initial ‘Knowledge Framework’ it appears that the traditional articulation into neighbourhoods was not sufficient to re-read the urban complexity of Mantova in terms of proximity. This awareness has led to the reorganization of the territory into autonomous units, called ‘urban proximity systems’, capable of describing different modes of urban functioning. They represent heterogeneous areas in which ground proximity and identify some common strategies that can be proposed in the planning tools of contemporary cities, particularly in the Territorial Government Plan (PGT) of Mantova.

Keywords: *planning tools; urban complexity; community; qualitative services; urban proximity system.*

1. PROXIMITY: AN OLD CONCEPT FOR NEW MEANINGS AND INTERPRETATIONS

The two years marked by the pandemic have functioned as an accelerator of the effects induced by multiple global crises we are facing, engendering conditions of risk and uncertainty in communities. Amidst this precarious scenario of community life, proposals have emerged for urban reform based on enhancing proximity relations. The conceptualization of ‘proximity’ is deemed simple, easily comprehensible, and highly efficacious during the pandemic period. It allows the envisioning of new dimensions that can generate urban well-being on a neighbourhood scale, realized on a human scale, wherein all services are conveniently accessible within a short walking or cycling distance for citizens. This functional proximity, characterized by its diversified functions and integration of a mix of public spaces, residential areas, and productive activities, is complemented by a relational proximity facilitating connections among diverse individuals within the spatial domain. Being in proximity fosters the establishment of relationships, thereby enabling collaboration, idea-sharing, the cultivation of common identities between communities, and mutual care provision [1]. It should be noted that these basic concepts underlying the proximity approach are not novel within the culture of urban planning and its associated disciplines. Indeed, it deals with issues and principles that have been widely acknowledged, shared, and consolidated by numerous researchers in the international context. The concept of proximity was initially linked to the ‘neighbourhood unit’, which was introduced as early as 1929 in studies conducted for the New York Regional Plan by Clarence Perry. This concept proposed neighbourhood as a physically delineated unit, characterized by diverse functions and infrastructures aimed at fostering social interaction and cohesion among residents. This model was considered in the debate concerning the reconstruction of cities following the Second World War, spanning from Patrick Abercrombie’s Greater London Plan to the establishment of New

Towns. Inspired by the concept of Garden City of Ebenezer Howard, Peter Abercrombie introduced a polycentric vision centred on autonomous and distinct entities, known as neighbourhood units, that works as several small communities' functions [2]. While the modern movement was prioritized the efficiency and specialization of cities through the division into single-function areas, thereby drawing people away from the urban centres, the New Urbanism movement in the United States advocated for mixed-use neighbourhoods, encouraging a return of people to the city center. Furthermore, in London, a report was done by the Urban Task Force in 1999 [3], under the coordination of Richard Rogers, aimed at planning a city with a human dimension and sustainability, directly addressing the needs of its inhabitants. The dynamics of globalization and metropolitan expansion that occurred in the years, overlooked the concept of proximity and bringing in a radical shift in the economic scale of settlements towards efficiency and specialization. Consequently, this led to spatial dispersion and the multiplication of population, relationships, and services [4]. The modern cities, or 'cities of distance' as Manzini defines them, have expanded in a progressively fragmented and zoned manner, in which people must move through long networks from one functional proximity to another in continuous search of the services they need. With the recent pandemic outbreak, a radical spatial constriction has challenged the prevailing model reliant on long distances, reconsidering the concept of proximity. The necessity to reconsider the proximity is intricately linked to individual lifestyles characterized by the prioritization of essential services and slow movement within a nearby urban environment [5]. This period demonstrated the need to rethink cities within a human dimension, as initially defined by Jahn Gehl in 1960 and further elaborated upon by Carlos Moreno in 2016 with the concept of the 15-minute city. This urban paradigm prioritizes human beings and their needs, aiming to address their concerns by facilitating easy access to a variety of urban services within a 15-minute walking or cycling radius [6]. As a result of that, many cities are progressing from this recognition towards the experimentation and implementation of design solutions derived from these theoretical conceptualizations. Metropolitan areas are employing methodologies to inspire the revision of their urban policies and planning tools, with an emphasis on the concept of urban proximity. This aims to promote an organic vision of the city that is increasingly equitable, ecological, sustainable, and resilient. The administration of Mantova city has chosen to confront this urban challenge, initiating with the revision of the PGT, the Territorial Government Plan. As researchers from the 'Unesco Research Lab' at Politecnico di Milano, Mantova Campus, we are actively collaborating in this research endeavour. The aim is to verify and experiment some innovative practices and strategies into planning tools able to re-read the urban complexity of the cities, based on the needs of people.

2. NEW CHALLENGES FOR THE PLANNING TOOLS: THE CASE OF MANTOVA

Cities occupy a central position in public debate and international development strategies. They serve as hubs of both public and private innovation, fostering social interactions and sustainable collective mobility [7]. Nevertheless, the climate, economic, health, and demographic crises that cities have faced in recent years highlighted their fragile social, economic, and spatial structures. Confronted with these needs, cities are called to reconsider their existing structures fundamentally and innovatively. This entails effecting a transformation capable of harmonizing various urban policies and actions contained into traditional urban planning instruments, even those that may not be outdated, with a focus on proximity, sustainability, and inclusion. This stems from the current challenges posed by technological and revolutionary transitions, for which the existing urban planning tools often lack solid foundations and effective solutions. Indeed, these instruments were made up during a historical period characterized by different housing, employment, and mobility requirements, rendering them well-equipped to address contemporary urban complexities. For that reason, the revision of these planning instruments presents an opportunity to reorganize cities and territories through innovative paradigms of territorial governance, envisioning new modes of living,

working, and commuting, thereby fostering holistic urban development. However, starting a process of revising these instruments to define a urban dimension is a complex process and necessitates thorough preparation, study and confrontation between different realities, stakeholders, and actors, as well as the utilization of new resources. Moreover, this urban development must be based on strategic planning that can comprehensively analyse the territory, prioritize sustainable interventions, and guide planning on a human scale, ensuring easy accessibility to all amenities. In this process, local governments must play a leading role in ensuring the construction of a shared and strategic vision that considers the needs of the people along the way, starting from their active participation [8]. Some cities, such as Milano and Bologna, have already begun this process of revising their planning tools toward a city characterized by proximity. Among them is Mantova with its Territorial Government Plan. The PGT serves as an urban planning instrument of the Lombardy Region, to delineate the framework of the entire municipal territory. It consists of three main documents: the Plan Document, the Services Plan, and the Rules Plan. The Plan Document contains the cognitive elements of the territory and outlines the development lines intended by the municipal administration. The Services Plan defines the procedure for integrating public interest facilities, both material and immaterial, in the urban settlement. The Rules Plan contains regulatory aspects, quality criteria and elements of the built city. Each of these documents needs to be revised and updated considering the new awareness and need to govern the territory in terms of environmental sustainability, urban resilience, inclusion, participation, and proximity. This entails the development of a multidisciplinary tool that seeks to integrate social, economic, and environmental considerations. In collaboration with the Technical Office and the Municipality of Mantova, we are pursuing a double objective in this first phase of exploration: firstly, to deepen the knowledge of the socio-demographic characterization profiles able to highlight the needs and requirements expressed by the urban communities; and secondly, to assess the adequacy of the provision of proximity services, encompassing both material and immaterial aspects, based on an analysis of the Service plan. The aim is to recognize the nature of the components composing the city and to construct an articulated 'Framework of Knowledge' of the territory, which currently exists in a fragmented state. It entails moving away from the traditional perception of the city's organization around the neighbourhoods and embracing a more flexible and organic structure capable of responding to the changes that cities may encounter, as underscored by the lessons drawn from the pandemic experience. These insights can subsequently be used to define a system of neighbourhood strategies and actions that can be integrated into the city's urban planning tool.

3. RE-READ THE URBAN COMPLEXITY FOR SHAPING NEW 'NEIGHBOURHOODS'

Cities have grown as the automobile allows us to live further away from work and services. In this sense, people have changed their habits to adapt to the fast time of the 'city of distances'. With the pandemic, where our life experience has been forced into the space of neighbourhood, we have gained the realization that life in a post-fossil city can be considerably better in terms of living standards than the urban lifestyles we aspired to in the twentieth century [9]. The pandemic puts on the table the need to actively think about the future of cities. It is essential that this new awareness of proximity is incorporated into urban planning tools, to propose a model of spatial organization that considers the evolving needs of the urban community where neighbourhoods represent the crucial point of this new perspective. We must reconstruct cities starting from the traditional articulation in neighbourhoods, which represent elementary urban units with their functional autonomy, centrality and where the social life of the community takes place. This is possible by a set of functions, spaces, and services create for people. The spatial organization of our cities is undergoing a process of gradual decline, with many of the neighbourhoods that define this organization losing their attractiveness and functional autonomy. These areas are becoming increasingly anonymous and lacking in identity, gravitating towards a single center, which is usually the historic one, and becoming increasingly peripheral. This is defined monocentric model, and it is characterized by a centripetal force, whereby

Proceedings

political, economic, cultural, and commercial functions are concentrated. The possibility of developing cities towards a single centrality, to date is currently not capable of responding to the new challenges, urban and otherwise, that contemporary cities must respond to within a relatively short period. Furthermore, it is unable to meet the needs of the people who inhabit them. For this reason, proximity has begun to refer to a polycentric model, already used and consolidated in the past, characterized by a centripetal force that seeks to move certain issues away from the center, identifying in the territory functional and autonomous nodes linked by networks characterized by infrastructures, intercity relations, and mobility flows. These centralities are dispersed throughout the city and synergistically interact with each other, making the whole network of centralities more than the sum of its parts [10]. Proximity finds a new and fertile declination in the experiments of the polycentric urban model, for which the equal city is one of the differences [11]. In this sense, we have based our research on this model, which allows us to re-read the complexity of the city of Mantova from the urban dimension of the neighbourhood. Cities have always had neighbourhood but now they take a new significance as an urban form that allows us to fight the global crisis with the wish to improve the quality of people life. This is the motivation that led us to restart from the traditional neighbourhood, theorized in the past, to propose a model of spatial and functional organization on a human scale, based on urban service centres, sustainable mobility, green and public spaces, and other amenities that are easily accessible by all in the city.

3.1 Exploring a double analytical approach to investigate new proximity needs

Creating a dynamic city from the neighbourhood, characterised by different functions, a mix of public and green spaces, residential areas, industrial and commercial activities, requires a high level of awareness of the context and comprehension of its character. It represents a process of reinterpretation of urban complexity that requires study, preparation, and comparison between different realities. The activity with the Municipality of Mantova started from the awareness of the need to articulate a framework of knowledge aimed at grasping multiple elements of urban characterisation, working in the knowledge that managing the transformation processes of a territory requires the elaboration of a knowledge path of the complexity of the city. In this sense, it is important to think about a framework to be used as a reference for the formulation of the PGT provisions, capable of taking the form of a coordinated and continuous process of planning and implementation of activities, based on continuous review, and updating of data. At the beginning, we developed this way of processing and transmitting data, aimed at overcoming the quantitative analysis of demographic phenomena to arrive at a qualitative one, capable of recognising the composition, distribution, and structure of the population in terms of fragility. The survey process involved a series of mappings in which the different demographic dynamics of citizens are defined. These maps represent both the demographic status of individual citizens and households, as well as the dynamics of social component replacement (arrivals and departures) and natural component (births and deaths) within the community. The study has shown that to structure an image of the demographic consistency of the city, it is necessary to overcome a static vision linked to the reading of the absolute values of the population; for example, in the analysed period of six years described in the Table 1, from 2017 to 2023, the resident population of Mantova, although it presents a substantially stable overall demographic balance, in reality shows within it variations determined by the natural and social component that defines its demographic dynamics. This is visible in the Table 2, related to 2023, where against a percentage variation in the absolute value of the population of 0.48%, there is an internal dynamic of 9.95%. This data underlines the features of the communities settled in each neighborhood, describing an articulated and dynamic population framework capable of highlighting people's needs and strategies to be implemented in the future.

Table 1. Demographic variations during years determined by natural and social components

Survey Year	Resident population	Variation from previous year	Variation percentage	Survey Year	Resident population	Variation from previous year	Variation percentage
2017	49480			2021	49316	- 55	- 0.11%
2018	49529	49	0.10%	2022	49591	275	0.56%
2019	49585	56	0.11%	2023	49828	237	0.48%
2020	49371	- 214	- 0.43%	2024

Table 2. Description of demographic variations by natural and social components in neighborhoods

2023							
Neighborhood	Birth	Death	Enrolled	Cancelled	Residents	Natural replacement index	Social replacement index
Belfiore	4	10	43	26	948	1.48 %	7.28 %
Borgo Angeli	8	13	36	42	1338	1.57 %	5.83 %
Dosso del Corso	10	22	60	47	1411	2.27 %	7.58 %
Borgochiesanuova	13	21	134	84	2285	1.49 %	9.54 %
Pompilio	17	26	115	85	2153	2.00 %	9.29 %
Due Pini	1	3	20	20	523	0.76 %	7.65 %
Te Brunetti	12	16	44	49	1278	2.19 %	7.28 %
Fiera Catena	9	9	52	45	1123	1.60 %	8.64 %
Valletta Valsecchi	13	47	159	111	2904	2.07 %	9.30 %
Valletta Paiolo	38	157	386	199	6958	2.80 %	8.41 %
Centro	86	217	840	600	16687	1.82 %	8.63 %
Colle Aperto	15	24	82	106	1915	2.04 %	9.82 %
Cittadella	9	12	117	86	1219	1.72 %	16.65 %
Ponte Rosso	7	2	97	33	634	1.42 %	20.50 %
Virgiliana	3	9	23	38	535	2.24 %	11.40 %
Lunetta	27	39	183	159	3752	1.76 %	9.12 %
Frassino	6	11	46	13	741	2.29 %	7.96 %
Gambarara	2	9	39	32	498	2.21 %	14.26 %

In addition, the elaborations have point out the concentrations of demographic characteristics that can be associated with situations of potential social vulnerability. Vulnerability is understood as a state of life in which the autonomy and self-determination of individuals are permanently threatened by an unstable integration into the main systems of social integration and resource distribution [12]. This survey takes the form of a methodological experiment and makes use of the equipment that has been collected in the municipality's computer system over the years. Indeed, by using geocoding techniques to locate these demographic phenomena, it was possible to show the exact location of the phenomena affecting demographic mobility within each neighborhood of the city of Mantova. We considered in the research eighteen neighbourhoods, including the historic centre. Although it is divided into historic districts, in this first phase of the study experience it has been deemed as a single entity to understand its centrality in relation to other neighbourhoods. These were analysed individually, even if they can be represented in a single systemic view with their characterization.

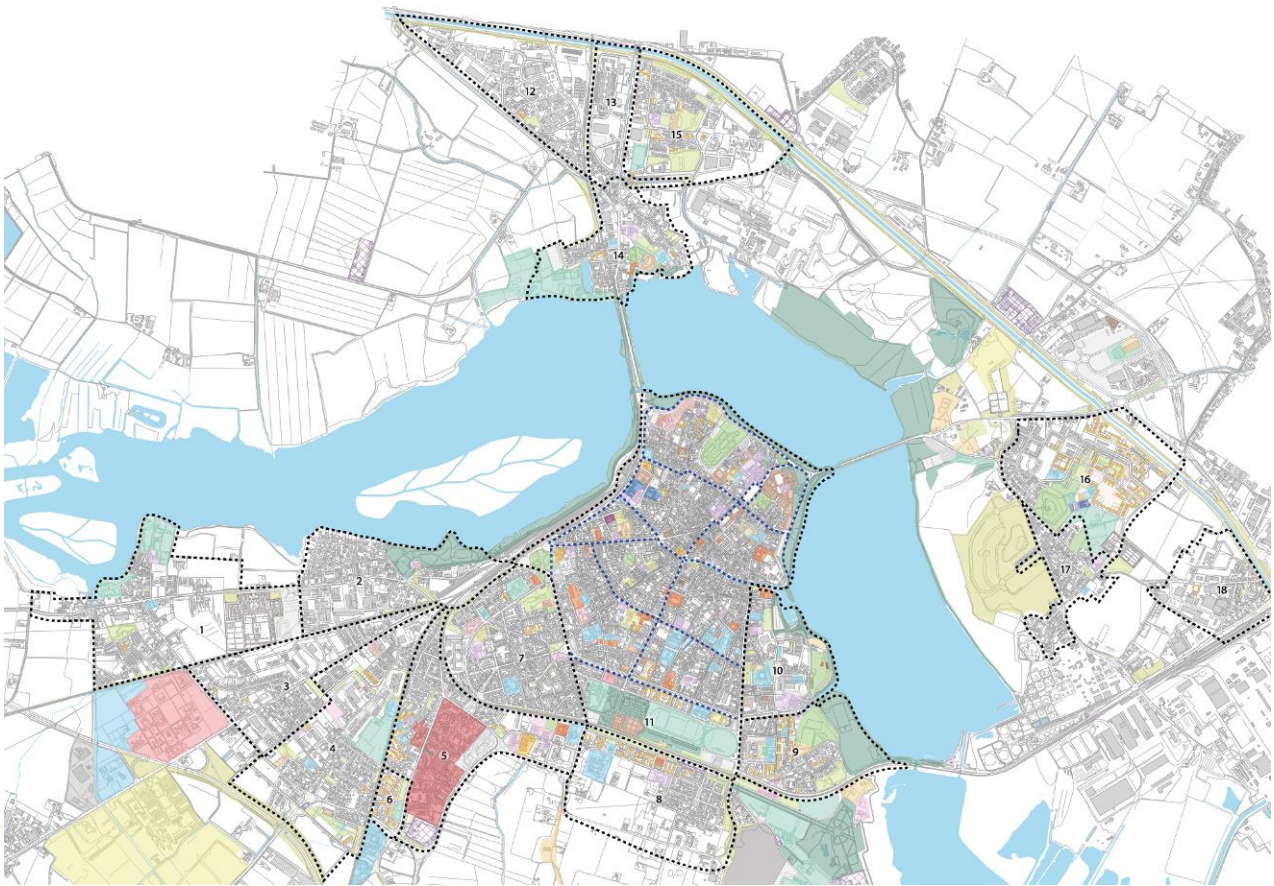

Figure 1. General map of provision of existing services divided into traditional neighborhood

The second part of the research, carried out in parallel with the reading of the characteristics of the population, focused on developing an analytical-interpretive framework for service systems. This framework considered both tangible resources, such as material amenities distributed and organized within the territory, and intangible values. This analysis entails reviewing the contents of the current Service Plan to ensure the adequacy and completeness of its analytical framework before updating all documents of the PGT by the Municipality of Mantova. Additionally, the survey facilitated this phase of updating and enhancing data regarding tangible and intangible services available.

The research has led to the production of six geo-referenced thematic maps for each of the neighbourhoods previously analysed, all contained in an atlas, covering: a reading of the provision of existing services; an analysis of the characteristics and densities of the settlement system; a survey of intangible services of social and proximity value; a map of mobility and accessibility; the green and water system; elements of urban characterization. These fact sheets are outcomes of reviewing planning tools and understanding the neighborhoods comprising various local contexts, emphasizing the unique features of each neighborhood. They also serve to assess the utilization and accessibility of available services in the city to search for greater proximity. The reading of the fragile characters of the population and the analysis of the endowment of services are developed simultaneously in our research to have an overall vision of the characters and needs of the city, to identify which services are essential and which can interpret the daily needs of the citizens. The final phase of the work was a moment of synthesis and recognition of the reflections that had emerged in the two previous sections and allowed us to question ourselves on the new needs of the city and its citizens in terms of proximity, trying to understand what strategies should be integrated into the urban planning tools to promote this urban approach [13].

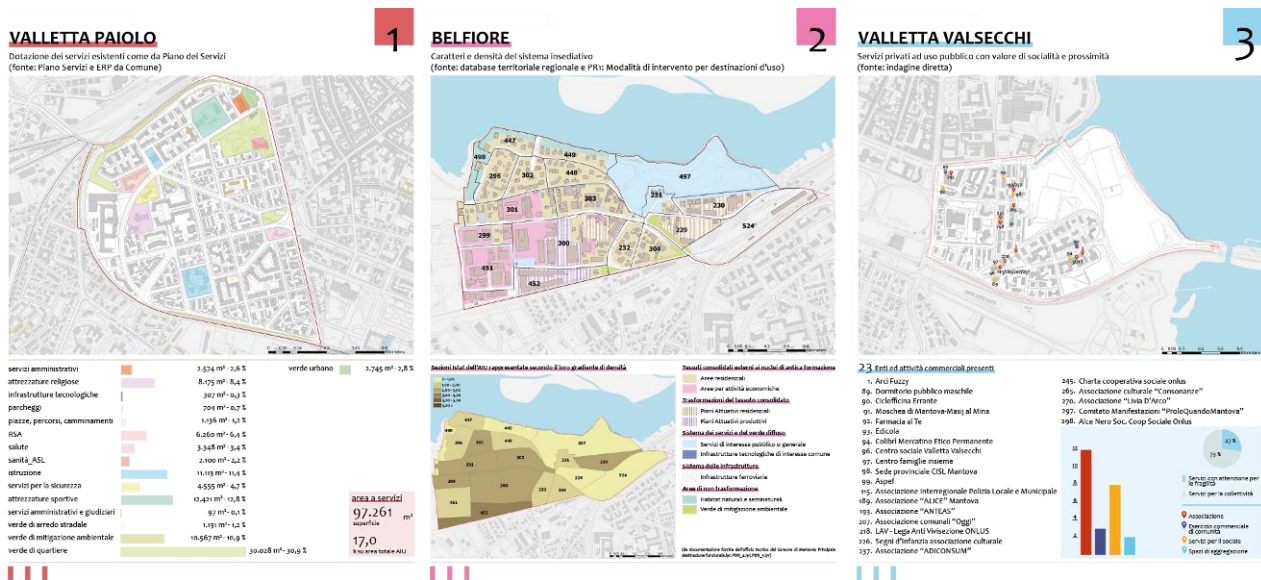

Figure 2. Examples of thematic map for each neighbourhood

3.2 The new needs demanded by the ‘city of proximity’ in urban planning tools

In this phase of evolution and necessary adjustment of urban planning tools to govern the sudden changes in the territory, exploring the issues of population size, land endowments, access to services by citizens and the human dimension of proximity, represents an opportunity that should be welcomed by all municipal administrations. This evidence has allowed us to direct our research, carried out in collaboration with the Municipality of Mantova, towards a new direction in the transformation of the city, to define urban proximity strategies that try to find a place in the PGT of Mantova, and in the documents that make up the Services Plan. In this phase of post-pandemic transition in which we find ourselves as urban planners, it is necessary to start again from these urban planning tools that govern the territory, going on to renew and rethink the existing public facilities to respond to the new environmental well-being, resilience, sustainable accessibility, and social inclusion of the urban system. These services are recognized as 'urban centres' that enhance the city, as they are attractive nodes within the territory, capable of creating synergies and effective links between all urban elements; this also makes it possible to understand how the types of services useful to the population have become more articulate and have evolved towards ever higher levels of quality [14]. With this in mind, we asked ourselves during the research process which route we should take to try to embed the strategy of urban proximity in urban planning instruments. It has become clear that the current organization of the city into administrative neighbourhoods, defined as elementary and geometric units delimited by rigid and unknowable boundaries, no longer meets the functional and social needs of the cities, which seeks to respond the demands of proximity.

4. A FUNCTIONAL AND SOCIAL REORGANIZATION INTO ‘URBAN PROXIMITY SYSTEMS’ TO SEARCH FOR GREATER PROXIMITY

Re-read the urban complexity through a dual approach has allowed us to synthesize and reflect on issues of proximity within an interpretive and multidisciplinary framework of different resources and characteristics of the territory, which dialogue together in a systemic vision. Given the concepts developed in this phase, it's apparent that prioritizing proximity could prompt a reorganization of the neighborhood's urban space. This would ensure residents have easier access to essential urban facilities and services. For this reason, the need to broaden the true meaning of these urban entities gradually became apparent in the research, as the need to measure the quality of daily life and living in the city in terms of the completeness and complementarity of the services available, the

opportunities and quality of urban life, environmental sustainability, social inclusion, and integration. It was decided to try to imagine a new concept capable of reinterpreting the notion of the neighbourhood as an elementary urban unit, geometrically delimited by rigid boundaries defined administratively by the municipalities to spatially subdivide their internal territory. The 'Urban Identity Areas', so prematurely named in our reinterpretation of complexity, represent the first attempt to define polarities in the territory, endowed with their functional autonomy and capable of reinterpreting the needs of citizens and the city in continuous evolution and transformation. The new perimeter of these areas redefines the rigid boundaries of the neighbourhood of Mantova, describing homogeneous parts of the territory that adapt to the different architectural, morphological, spatial, and social characteristics of the urban settlement. In this new vision, the 'Urban Identity Areas', although still recalling the form of the previous administrative units, seek to reinterpret the concept of boundary by defining variable and flexible borders that can change, overlap, and interfere with each other to quickly adapt to the different needs of urban settlement. These areas therefore aim to create an internal dynamism within the territory, where proximity allows the consolidation of new relationships, capable of generating an urban welfare that confronts the dimension of the sphere of identity, usable on a human scale, and where different functions are easily accessible to citizens in a few minutes on foot or by bicycle. The definition of these 'Urban Identity Areas' has attempted to go beyond the idea of a static neighbourhood, gradually approaching the description of dynamic polarities, increasingly capable of imagining a polycentric vision supported by relationships between different urban elements. They have not been able to guarantee the functional and social autonomy required by neighbourhood cities and imagined at the beginning of the work. This reflection, which has matured after a series of research experiments, has led us to realize that the spatial configuration we have hypothesized only takes up and modifies the edges of the original neighbourhoods, without reinterpreting them according to the new needs and different modes of urban functioning that proximity requires. It was decided to build on this awareness and redefine these areas by no longer considering them as individual autonomous entities, but as systems of centralities that function together; the name 'Urban Proximity Systems' was chosen for this reason. They represent areas that are substantially heterogeneous in terms of their spatial, morphological, social, cultural, and economic characteristics, and that functions both autonomously, ensuring the interweaving of short proximity networks, and in conjunction with other systems located in the territory. While the definition of urban identity areas was based on the external perimeters of the original neighbourhoods, to examine their characteristics, the opposite approach was taken to define urban proximity systems. The systems have been defined based on the identification of certain centralities of urban functioning linked to the presence of historical identities (nuclei of ancient formation), collective and social public services, gathering places for people, local commercial concentrations, and other amenities [15]; a series of urban places on a human scale, with a high pedestrian frequency, where everything is easily accessible and reachable for citizens. This is enabled by the relationships each polarity forms with those nearby, creating an interconnected system of identity centralities. Urban proximity systems thus become functional, autonomous concentrations within the territory, reflecting urban and social diversity in their relations with nearby living environments. [16]. The definition of these systems is the first tangible result of our research and allows us to imagine a possible reorganization of the city, different from the previous one of the neighbourhoods, in which proximity is tested as an urban strategy. In agreement with the Municipal Technical Office of Mantova, we have tried to divide the territory in 12 heterogeneous proximity systems, delimited by variable boundaries that change, modify, and adapt every time to the characteristics of the urban settlement that is in constant transformation. Given that proximity is a primary focus for the PGT, these systems were chosen as a common field of application for envisioning future perspectives and planning with proximity in mind. This includes promoting sustainability, resilience, inclusion, and accessibility. Our future challenge is to define design actions

Proceedings

within these systems, both temporary and permanent, to reactivate the internal dynamics of the territory and promote proximity as a crucial urban strategy.

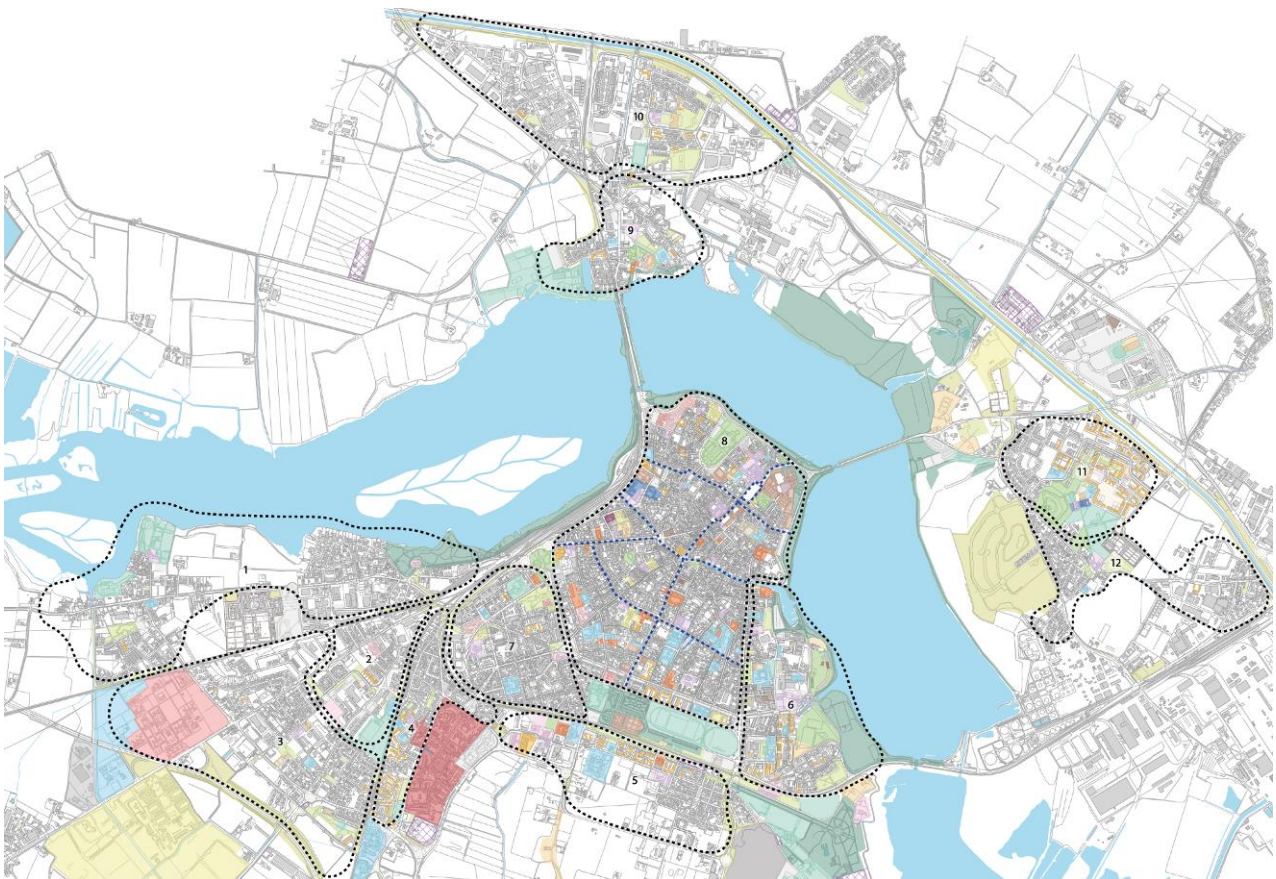

Figure 2. Identification of the 12 Urban Proximity Systems in the city of Mantova

5. CONCLUSIONS: EXPLORING LIVEABLE PROXIMITY SCENARIOS

During these years of post-pandemic transition, all the municipal administrations are striving to experiment with new urban planning approach centred around proximity. As Manzini stated in 2021, proximity seeks to reinterpret design themes such as sustainability, resilience, and inclusion, aiming to enhance liveability by providing multiple services and opportunities to those in close physical proximity. This approach fosters increased chances for social interaction, sharing, and community building, linked to an emotional dimension. Spaces for conviviality and relationships should be promoted to cultivate a sense of belonging and responsibility within the community that inhabits these spaces daily. The proximity dimension, in this sense, could enhance and activate networks of discussion and practice, seeking to identify innovative tools capable of meeting both people's needs and the city's public policies [17]. As described in this paper, proximity requires considerable effort and organizational change on the territory to improve the liveability and the quality of life. What emerges is the need to rethink proximity as an asset, as a social and economic value, as an inclusive and participatory process, not a mere service or even a model that can be applied uncritically everywhere but contextualized by rooting the design in local space and policies.

Unlocking the Potential of Placemaking. How to enhance citizens' engagement to analyse, design and implement urban spaces.

S. Campioli

Architect and PhD Candidate – Department of Architecture, Built Environment and Construction Engineering (dABC) of Politecnico di Milano, Via G. Ponzio n.31, 20133, Milan, Italy

Abstract

Placemaking is a flexible approach to creating vibrant communities around places, focusing on civic engagement, and enhancing local identity. Placemaking can take many different forms, depending on the specific needs and goals of a community. It is an open-ended process that looks at the involvement of a community as a key factor for the success of urban designs in all the step of its process. Due to its multidisciplinary approach, Placemaking can positively contribute to improve resilience, flexibility, and proximity issues. Promoting shared values and cross-sector collaborations for the creation of great places, Placemaking can foster social and spatial resilience. It supports flexibility both through its process and its outcomes. Then, Placemaking can also support proximity improving accessibility, walkability, density, mixed use, design diversity, and the users' experience for all ages. With these premises and with the aim to easier integrate Placemaking into planning, I suggest to use a meta-design that combines both the steps of the Placemaking process and three urban design scales with a selection and organisation of tools that should be added to the usual toolbox of architects; among those, most of them have been directly tested and applied by the author. This idea proposes co-design activities for each step of the Placemaking process to easier involve citizens and adopt a collective place-making approach. I think that a focus on Placemaking offers a practical, proactive, and integrated approach for addressing global change and urban challenges at every scale.

Keywords: Placemaking framework; Placemaking tools; liveable places; co-design; citizens engagement.

1. INTRODUCTION

1.1 Placemaking: the art of creating communities around places

In literature, urbanists, geographers, and planners consider Placemaking a basic, primordial human activity. Some of them state that making places is necessary for the well-being of the individual and the society, while others promote the idea that a sense of place is an innate quality and a necessary component of human interaction [1]. For the Placemaking Europe team, the definition of Placemaking is “an approach to urban planning and design that focuses on the people who use a space, rather than just the physical structures or buildings” [2]. The aim behind this notion is to design spaces that are attractive and important to the people who live, work, and play there, in addition to being useful. Placemaking inspires people to collectively reimagine and reinvent public spaces as the heart of every community [3]. It emerges that Placemaking is an approach and a process in which people are invited to reinvent public spaces collectively, so it addresses both the reshaping of an urban space and the engagement of a community. Based on the specific requirements and objectives of a community, it can take many different forms, considering the social, cultural, and physical identities that contribute to the definition of a place and its ongoing evolution. Placemaking projects can take many forms, such as designing public art installations, furnishing parks and plazas with benches and playgrounds or lighting, or planning neighborhood gatherings for celebrations, farmers markets, or festivals.

The current debate in Urban Design is animated by the topic of the livability of public spaces with a special focus on themes such as resilience, flexibility, and proximity. Due to its multidisciplinary

approach, Placemaking can positively contribute to improve those issues. Placemaking promotes the shared value, community capacity, and cross-sector collaboration that are the cornerstones of resilient cities and vibrant communities through a broad focus on creating quality places. The flexibility of Placemaking is recognizable both in its process and its outcomes. In terms of process, Placemaking seeks to skip over statutory planning stages and focus on concrete, relatively rapid changes in the built environment. Placemaking is described to have a cyclical rather than linear dynamic, with fluid process and many point of entry for the willing actors, so it is super adaptable to different cases. In terms of outcomes, due the involvement of several stakeholders, a Placemaking project must combine different needs so the design proposal should be very versatile. Having more flexible spaces also allows to change their use and makes room for temporary interventions. Placemaking can also support proximity improving accessibility, walkability, density, mixed use, design diversity, and the users' experience for all ages. It can consider all the dimensions of proximity such as geographical, social, cognitive, organizational, and institutional.

1.2 Research questions and objectives of the project

The considerations of this study were made within the development of the PhD research of the author with the aim to investigate co-design methods for the regeneration and improvement of public spaces with and for communities; and to investigate how those processes could be integrated into current urban plans. Since the academic field of this study is "Urban and regional planning" the perspective on those themes and approaches is a systemic thinking to define technical and political processes that can better develop a sustainable built environment to serve an ever-changing society and to improve people's lives.

Change is hard and there is the need to make it less difficult, so, the research wants to explore how supporting the change towards a systemic implementation of Placemaking through these lines of research: "How to disseminate the Placemaking approach where it is not well known?", "How is it possible to make Placemaking systemic (e.g. able to combine bottom-up and top-down initiatives within an urban)?", and "How is it possible to embed Placemaking into current urban plans?".

Starting from a deep reflection on Placemaking as an approach able to help all those who contribute to reshape and activate public spaces with the community, the idea has been to define a strategy to implement Placemaking into planning, considering the contexts in which that approach is not familiar and well consolidated. Since the focus of this paper is not as wide as the whole PhD research, it mainly addresses the challenges of how it is possible to unlock the potential of Placemaking and how is possible to enact a systemic change step-by-step. Then, the paper focuses on the outcomes that have emerged from the thesis to face these challenges.

2. METHODOLOGY

To develop this research, I adopted several methods such as the analytical approach, the interviews of experts, the research of case study, a practical experience with the leading team at a European level (Placemaking Europe), and the implementation of a project through a local practical experience in the city of Mantua (Italy). Initially, I started with the study of bibliographic references about co-design, civic engagement and the importance of designing great public spaces while enhancing the sense of belonging of communities; but, it was only thanks to my hands-on experience with the Placemaking Europe team that I truly understood the power of Placemaking and its purpose of creating communities co-designing and co-creating public spaces to make them more inclusive, healthy and safe. I was involved in a two-years programme named "Cities in Placemaking" [4], aimed at building awareness and practical knowledge of Placemaking in a way that allows it to foster important long-term change. Thanks to that experience, I learnt that is very helpful to guide administrations in the implementation of new ways of working through the sharing of new tools, new

methods, and successful case study. Also, the interviews with experts, public administrators and facilitators were very helpful in defining the most pressing concerns on the management of co-design processes within urban design. Thus, to answer the research questions and meet the needs of interviewers, I consider it appropriate to define a way to make Placemaking more familiar through the sharing of best practices, to create a flexible frame of reference to guide designers in the implementation of Placemaking step-by-step, and to create an organized toolbox with some Placemaking tools useful to manage the direct involvement of citizens.

2.1 Defining a Placemaking process

In terms of process, Placemaking seeks to skip over statutory planning stages and focus on concrete, relatively rapid changes in the built environment. Placemaking can be seen as a two-way process: both place shapes the community and community influences the space [5]. This mutual connection is called “virtuous cycle of place-making” [6]. Placemaking is described to have a cyclical rather than linear dynamic, with fluid process and many point of entry for the willing actors. Similar relation was described already by Lynch [7], who claimed that the image of the environment is created by the observer, but at the same time, environment exerts its influence on people who use it. In that sense, such an image is dynamic, as it is formed during the interaction between the observer and the place. That process fits well with the complexity of society, it is open to experimentations, improvements, changes, and ongoing re-evaluations. The Placemaking process is inclusive, dynamic, trans-disciplinary and collaborative, so the design of places is adaptable, flexible, focused on creating destinations and context specific. The process is centered around observing, listening to, and asking questions of the people who live, work, and play in a particular space to understand their needs and aspirations for that space and for the whole community. Once having created a vision for that space, it could be implemented through small-scale improvements that bring immediate benefits to the spaces and the people who use them. Placemaking encourages planners, designers, and engineers to embrace grassroots involvement and view a place in its entirety rather than focusing on isolated components. By doing so, common problems like traffic-dominated streets, safety in public spaces, inclusion and accessibility, urban health, spatial and social divide, climate action, nature preservation and so on, can be addressed at a small scale.

To define the process for my research, I evaluated several Placemaking procedures, but the most influential one was that of the Project for Public Spaces [8] that uses a five-step process, so I followed this direction customizing a bit each step. The Placemaking Process that I propose includes the following phases: get ready, evaluate the context, create the future vision, do short-term experiments, improve and implement. The first step aims to identify problems, needs or aspirations at a macro-level and to assess which stakeholders and partners should be involved. The second step is about the analysis of the context including for spaces, uses, activities, how people experience these spaces to identify strengths and weaknesses. The third step is about creating a vision, defining the goals, and planning. The fourth step is about putting the vision into action through prototyping and tactical urbanism, to unleash the power of acting together. The fifth step is about assessing and implementing the short-term experiments to fine-tune the vision and the design solutions of the overall project. These steps are mostly sequential, but, after the fourth phase, it is better to check whether the determined goals are achieved or not during the process itself. Moreover, the phase of doing short-term experiments is very useful and represents a key-point in Placemaking because it usually implies actions that can be reversible, modifiable, expandable, or repositionable. Casanova & Hernandez [9] state that working with the time factor, the intervention can acquire enormous versatility, becoming a temporary or ephemeral intervention, a test intervention, or even a mutating intervention with the ability to transform over time. So, after checking the design solutions it is possible to go back to the evaluation step to better verify the context and its real needs, then decide how to continue also

considering some improvements or different solutions. Since, the main purpose of Placemaking is creating community around places, there is the necessity to make the community and the place alive after the end of the process itself. This is another key-point of Placemaking because it should continue with the management part sharing a calendar with activities, festivals and other initiatives to ensure the continuity with the sense of belonging that has been created during the project phases.

2.2 A matter of scales and impact

Cities are very complex organic bodies that include many sub-systems such as energy, water and sewerage, food, transport, health, and biodiversity, as well as economic, social, and cultural systems. This network of systems, interconnections and flows can be described as a system of systems. Moreover, we could define cities as “Complex Adaptive Systems” (CAS) characterized by heterogeneity, interconnectivity, circular causalities and have sub-systems that operate at different scales [10]. An interesting contribution in that way is given by John Tillman Lyle, a former professor of landscape architecture at the California State Polytechnic University, Pomona. In his book “Design for Human Ecosystems” [11] he claims about the interdependence between ecosystems saying that “landscapes, like people, rarely stand alone”, everything is indeed related, at some level, to everything else. So, every landscape is joined with all other landscapes in a network of interdependence that extends over the entire earth. One of his key-concepts is that one of “scale”, or the relative size of the landscape in question and its connections with larger and smaller systems and ultimately with the whole. Scales provide a frame of reference for interventions, activities, and to identify the stakeholders for projects. Also considering the impacts on the subjects involved is a matter of great importance within co-design and Placemaking processes. Different groups of people will be affected by different scale of projects. So, the community of a specific neighborhood will be more interested in taking part in a process than the ones which live far away. A different case would be that one of a city center that usually capture the interest of many. Gardner J., Marpillero-Colomina A., & Begault L. [12] consider four scales of design for urban interventions (site, block or neighborhood, city, town, or country, and regional or national); and four levels of impact (individual, community, network and population).

Figure 1. Images created by the author to represent the scales of design for this research.

Since the aim of this research is to investigate Placemaking for the activation of public spaces, I choose to adopt only three scales of design (and their relative levels of impact) that are: place, neighborhood, and city.

The place represents a specific location, has definite boundaries and is usually small enough to be perceived in its entirety from a single viewpoint. Common examples include roads, paths, sidewalks, parks, public squares, natural areas, beaches etc. A neighborhood is a specific geographic area with a set of social networks within a larger city, town or suburb. Sometimes, it consists of a single street and the buildings lining it. Every neighborhood has its own character and peculiarity together with uses and specific activities that are not the same in each part of the city. Some neighborhoods have a

vocation to public services (since the plan includes this kind of zoning) or they could have artisan laboratories, or they could be mainly residential. Knowing the character of areas is important to deliver contextually responsive urban design, allowing the urban designer to understand and respond to the unique qualities of any site or neighborhood. A city is a large human settlement. It can be defined as a permanent and densely settled place with administratively defined boundaries whose members work primarily on non-agricultural task. It is a complex system and an organic body. A city scale usually covers an area that is small enough for an individual to know and personally relate to, but large enough to involve complex political decisions.

2.3 Placemaking tools

Placemaking is a process that wants to bring together different stakeholders, users, and local citizens, aiming to capture the local culture, knowledge and the collection of different ideas and aspirations. How is it possible to do that? How can we organise workshops to help people share ideas, collect proposals, and allow them to become city-makers? Tools are the answer, they are fundamental instruments to collaborate and co-create. For the Collins Dictionary online, a ‘tool’ is a power-driven instrument, it is anything used as a means of performing an operation or achieving an end. They really help in organizing the Placemaking process and in keeping the community pro-active.

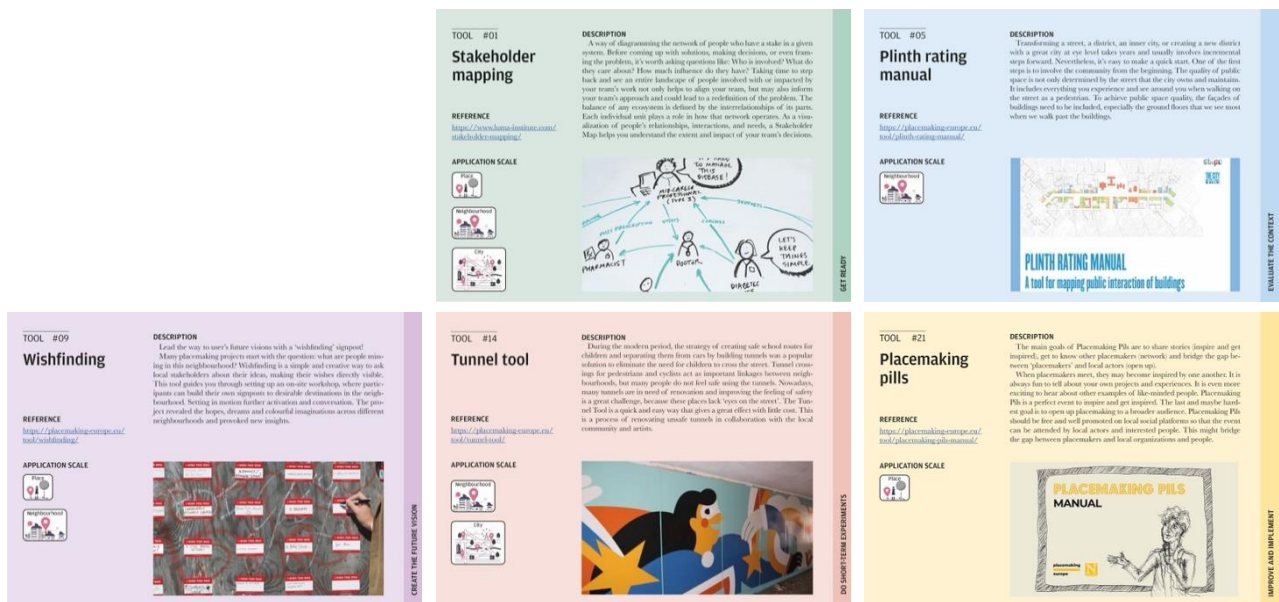

Figure 2. Some of the cards created by the author within the selection of tools presented in the PhD research referred to this study. Each color represents a different step of the Placemaking process.

There are a lot of Placemaking tools in the Web and many associations have created their own toolbox. For the selection of tools, I mainly referred to the “Placemaking Europe Toolbox” [13], a collection of curated Placemaking resources for all to access, learn from, and practice; and to the “LUMA workplace” [14], a platform that aims to create more human centered organizations and empower everyone to make things better through co-design and cooperation. From these sources I selected about twenty tools and some of them have been directly implemented and tested personally. That selection is not meant to be exhaustive, but to give an overview of the most impactful tools that can be used to apply Placemaking. Then, with the aim of creating an organized toolbox, I divided them into the five steps of the Placemaking process that I already explained, and I made it clear what application scale best fits to each. The organized Placemaking Toolbox provides a wide selection of

Proceedings

potential tools to collect data, analyze the users experience, define goals, collect proposals, define priorities, etc. for the co-design and the co-creation of great places.

Tools are thought to be helpful in the application of Placemaking with particular attention to put the actors involved at the center of the project from the very beginning, offering practical and tactical advice on topics like partnership, community engagement, and evaluation. This resource can be utilized flexibly, to fit the team's needs, and is meant to serve as a guide for anyone interested in starting a creative placemaking programme.

3. FINDINGS: A PLACEMAKING FRAMEWORK FOR A SYSTEMIC CHANGE

Placemaking is not a brand-new approach, it is already implemented in many parts of the world (in different contexts and with different peculiarities), but in most cases, it is not perceived as something that could be systemic and applied for a long-term change both between citizens and public administrators. To facilitate the implementation of Placemaking for a systemic change, for its dissemination, and to embed it into urban planning, I thought of creating a meta-design that combines the steps of the Placemaking process, the three urban design scales, and the selection of tools. The idea behind this “meta-design” is to create a set of rules able to give designers and facilitators a wider degree of interpretation. This output could be understood as a conceptual toolkit [15] made of a set of concepts, ideas, ways of thinking, intellectual notions, and instruments to make understanding, exploring, and acting upon a problem easier. Its aim is to generate a form of mental agility in thinking through city issues, to look at problems in a rounded way, from a multiple perspective and holistically. So, the Placemaking framework could be seen as a set of techniques and box of tricks. There is a metaphor that came into my mind when thinking about the frame of reference, is that one about the recipes, the ingredients, and the action of cooking. I can know all the best ingredients of the world, but if I miss the basic rules to create a tasty and healthy plate, I will not obtain a great plate! The same with Placemaking, I can know the best tools, but if I do not know how to start a Placemaking project and which tool best fits in each step of the process, I will struggle with the project management and community engagement. There is the need to know the approach, know the tools, know the steps of the process, their characteristics and have some guidelines to rule the project management before approaching it. Following the metaphor, I think that the Placemaking Framework represents the basic rules for good combinations so that everyone can create its own recipes.

The specific goals of the framework are manifold:

1. **SUPPORT THE SUBJECTS** that make city transformations with a frame of reference for those who are not familiar with Placemaking approach considering different scale of design and explaining the step of the Placemaking process, together with a collection of organised tools.
2. **INTERPRET THE PLACEMAKING APPROACH** to understand its common thread with the definition of criteria and the collections of tools divided into design scales and steps of the process.
3. **GIVE A DIRECTION TO URBAN TRANSFORMATIONS**, to create human-centered places that can achieve the self-fulfilment needs of people in addition to the basic needs.
4. **SHARE IDEAS** on how to engage citizens showing a variety of workshops and co-design activities that can be organised to let people participate and have a say in urban transformations.

The Placemaking Framework has a shape of a matrix in which the entries are the steps of the Placemaking process (in columns) and the application scales (in rows). In the intersection between rows and columns I can find the selected tools per each phase and each design scale. Some tools can be applied to many scales of design, and they are repeated in more cells. The only case of the first column has only three tools that are helpful for every design scale. Since it is a matrix, it is possible to query the framework in many ways, so, for example, if I had to create a whole Placemaking process

for a project that concerns an entire neighborhood, I can choose among the tools of the relative row of that design scale. In this case I can also have a look at the tools of other design scales to check if there are specific issues to assess or activities to make at a different level to guarantee consistency in the overall project. If I only need to find the tools for one specific step, I select the column and the scale of interest, and at their intersection I find the tools to choose from. The tools included in each sector are options with different shades, so it is possible to choose the one which best suits a particular situation. Although it would be better to consider and apply a complete Placemaking Process, it is possible to adopt the Framework also in case of a singular activity or including only some of the steps. This flexibility is part of the idea of the framework, and it is considered a way to start a new approach gradually.

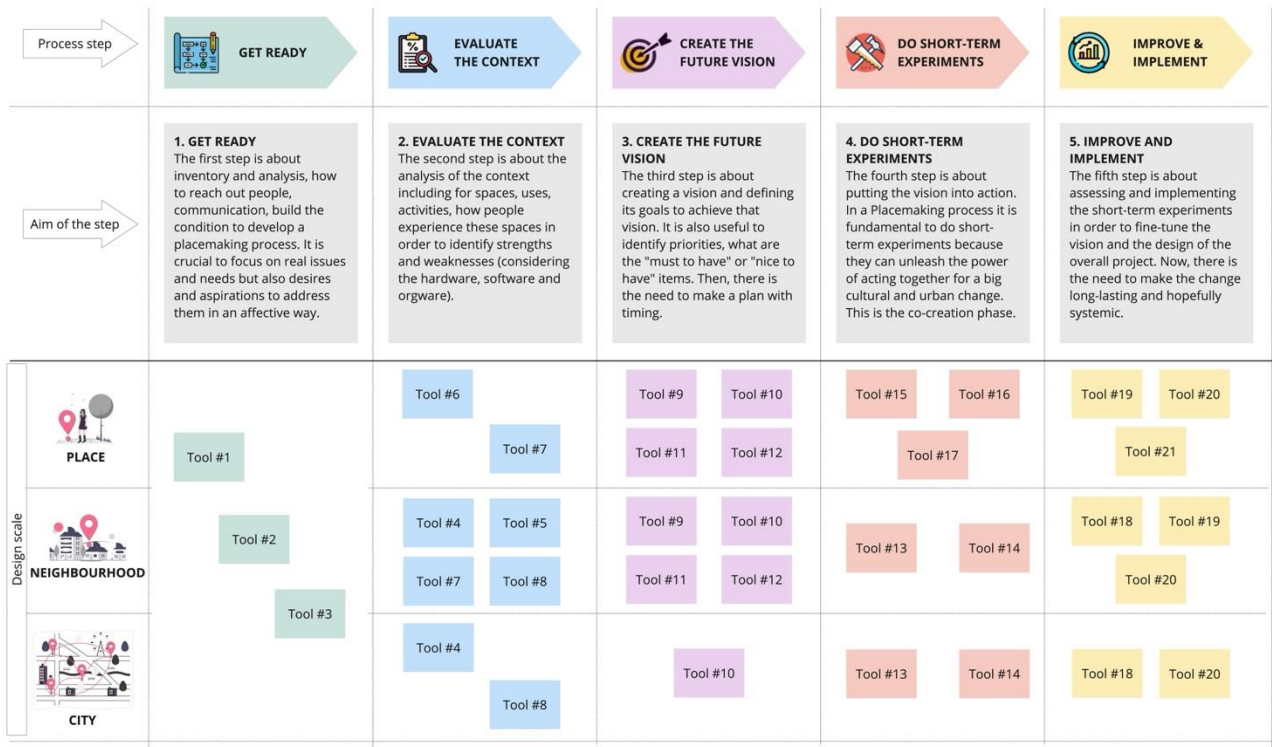

Figure 3. The Placemaking Framework created by the author.

5. CONCLUSION

To unlock the potential of Placemaking I think that there is the need to support a systemic change for its application to a broader perspective. This means defining a strategy to implement it into planning, considering the contexts in which that approach is not familiar and well consolidated. I think that the Placemaking approach can combine the widespread bottom-up initiatives with the usual top-down approach of public administrations through a more effective cooperation and dialogue between public and private. To achieve this, it is not only a matter of knowing the approach, or knowing its tools, but it also a matter of understanding its process and its perspective, so for this kind of change, having a frame of reference could be very helpful.

Thus, I thought to create a meta-design which can be perfectly accompanied by current urban plans and urban designs to start changing the perspective on them. To make this change there is the need to interpret current city challenges, reorganise the usual workflow, and adapt the usual process with an innovative approach. So, I felt the need to define a frame of reference with criteria, rules, and tools to be referred in applying the Placemaking approach. This work has been done with the aim to make Placemaking systemic and easier to adopt for designers, facilitators, public administrators, and all those who contribute to reshape and activate public spaces with the community; this has been done thinking mostly about the Italian context. Since the framework is plenty of co-design tools, it represents a way to enhance citizens engagement for the analyses, design, and improvement of urban spaces. I found very useful to create this frame of reference because to me it has been a way to make order to the myriad of tools and methods that I investigated during my PhD research and my experience with the Placemaking Europe team. Also, from many interviews with experts I had the suggestion to create a frame of reference, to have a guideline to be shared.

Moreover, I had the opportunity to apply and test the framework in the initial phases of the Plan for the Elimination of Architectural Barriers (PEBA) for the city of Mantua. During that project, I realized that is a very flexible frame of reference that can adapt itself to many different cases. Even if a designer does not start a Placemaking process for its own sake, it is possible to re-interpret current planning tools through the lens of Placemaking, re-arranging the step of the process to the phases of the urban plan.

To conclude, through Placemaking and the “Placemaking Framework”, this study wants to propose an urban development model that can easily combine bottom-up and top-down initiatives creating a collaborative process that is socially and culturally inclusive, foster resilience, flexibility, and proximity.

Commerce and public space: questioning roles, meanings, risks, and potentialities.

A. Bruzzese

Politecnico di Milano, Dipartimento di Architettura e Studi Urbani

*Corresponding author: E-mail: antonella.bruzzese@polimi.it

Extended abstract

The paper proposes a reflection on the nature of public space in urban centers, starting from its relationship with commercial activities.

In its various articulations, commerce has always functioned as an attracting pole. It has been capable of orienting flows and routes, providing visual "protection". It has also been able to connote significantly the public space facing it, if not, in some cases, occupying it, through forms of privatization. The relationship between commerce and public space, particularly neighborhood commerce and public space of proximity can be a formidable key to ensuring quality and urban vitality. Market dynamics and the often supra-local rules and laws are decisive in orienting the commercial offer. Nonetheless, a reciprocal and positive relationship between public space and commerce can occur, provided several aspects are considered.

Among others:

- the presence and observance of adequate regulations concerning the occupation of public land (to ensure sufficient levels of publicness, walkability, and urban quality);
- the take-over and care actions done by economic actors that do not result in exclusionary operations but, on the contrary, in fruitful cooperation with local actors (from sponsorships for management to forms of direct involvement);
- the need for stringent dialogue between various urban actors and trade associations (to consolidate a culture capable of recognizing the territorial and not just the economic role);
- in more general terms, the need to consolidate a culture of public space, acknowledging its role as central to urban quality in its most entire forms of 'publicness'.

The author has had the possibility to collaborate with the project *Cities*, a program of Confcommercio (the Italian General Confederation of Enterprises, Professional Activities and Self-Employed Work) aimed at reflecting – from the point of view of the economic actors - upon the city as a 'laboratory of change', building knowledge to improve urban centers and support neighborhood economies. Starting from the analysis of several cases in Milan and other Italian cities in which economic actors played a role in the transformation of 'innovative public spaces', observed within the *Cities* program, the paper critically discusses the potentialities and criticalities of the relationship between commercial activities and public space, returning some elements that emerged from the dialogue between different subjects.

Piazzale della Lana in Feltre, Italy. Urban regeneration projects

E. Pietrogrande*, A. Dalla Caneva

Abstract

The paper concerns a relevant area, named Piazzale della Lana, close to the historic city of Feltre. This is an area located in a strategic site of the city that has suffered transformations over time, not coherent today with the morphology of the place. Piazzale della Lana is on the edge of the historic city in a peripheral position with respect to the ancient core. It allows a crucial connection between the residential fabric of the ancient and contemporary city, having preserved a significant symbolic value for the residents over the years despite the state of abandoned condition in which it lies following its gradual disuse over time.

An essential premise of the urban regeneration project is the idea that the historic centre is a place of stratifications and meanings. The project is the result of a dialogue with historical pre-existences. This means giving new civic life to a building or part of a city not only through new functions and volumes, but above all by reinventing the form in order to generate new value to architecture and contexts, in a balance between memory and invention. This is why the heritage of history becomes relevant, recognising in the forms of architecture of the past our memory or identity.

The authors of this article are deeply convinced that the public quality of life in the city is connected with the formal choices made by the project plan. They think that it is possible to trace a close relationship of identification between the community and the architectural forms that create a sense of belonging in those places. One of the identifying forms of the city is certainly provided by the piazza, the place par excellence throughout history in which the community recognises itself.

The paper includes the results of students' workshops developed in the framework of the course on "Architecture of the city" taught on the master's degree in Architectural Engineering at the Department of Civil, Environmental and Architectural Engineering of the University of Padua, academic years 2022-23. The working method is based on the belief that the study of urban morphology and the history of the city are basic to face a design theme. The history is considered as an indispensable tool to know the deep reasons of the urban structure which is the memory and the image of the community. The methodology contemplates the urban form as a result of its spatial structure. Progressing from the study of how the area has evolved through time, students defined new proposals for the area that involved testing new building types.

1. INTRODUCTION

The Piazzale della Lana area is part of the urban context of Feltre, a town located at an altitude of 325 metres above sea level, at the foot of Monte Tomatico and west of the river Piave. It is located outside the walls of the historical centre at the point where the Renaissance Porta Imperiale (Imperial Gate) is. (Figures 1, 2). To the south it is bordered by Viale Monte Grappa, one of the main roads around the town. Its proximity to the historical centre makes it of considerable interest. In fact, the area, despite being close to the historical part of the town, is easily accessible by cars.

Figures 1, 2. Domenico Falce, view of the town of Feltre in the 17th century showing the area of the present-day Piazzale della Lana. View of Porta Imperiale (Imperial Gate), current state.

From an analysis of the plan of the Napoleonic Cadastre of the early 19th century (Figure 3) and other historical maps, it can be deduced that the Piazzale della Lana has always basically been a crossing point, which was gradually built up over time. It was a green area, probably dedicated to local cultivation. The volume that hosted the school activity until a few years ago had already been built, behind which a section of the Molini irrigation ditch ran and powered craft activities such as dyeing, wool processing and grain milling. The study area owes its name, indeed, to the processing of wool, and today, with its extension of almost 4,000 square metres, it is almost entirely used as a car park, which is largely exploited due to its proximity to the city centre (Figure 4). The area is entirely carriageable, even if minor, various and disconnected activities take place there. It is accessed from the north via a narrow subway through the built front opposite the walls, opposite the Imperial Gate. It is bordered to the north by the façades of three and four storey buildings, predominantly residential, uneven in design and dating from around the 1980s.

Figures 3, 4. Plan of the Napoleonic Cadastre (early 19th century). Current state planivolumetry representation (drawing by Francesca Madormo e Angela Polo).

Figures 5, 6. General view of Feltre, current state. View of the main building bordering Piazzale della Lana to the west.

Figure 7. Piazzale della Lana, view from the south-east, current state. In the centre is the abandoned building with barrel-vaulted roof.

The construction of these buildings took place without any evaluation of the public space that would have resulted, and which is now, in fact, unresolved in plan and inconsistent in elevations. These buildings lack elements of mutual correspondence in their façades and characters of dialogue with the elevations of volumes constructed in earlier times.

The monumental former Dal Piazz school building closes the Piazzale della Lana to the south-west. It had previously housed a wool-processing factory. The school has long since moved to more modern accommodation, leaving the complex in a state of abandonment, without a use and in an increasingly degraded condition. A preservation order protects this architecture of historical value protects and austere appearance, characterized by a symmetrical layout albeit unbalanced by the addition of a wing at the east end.

A building with rectangular plan and barrel-vaulted roof stands in the middle of the forecourt. Three of the façades, devoid of the plaster cladding, show the reinforced concrete frame and terracotta infill, while the main façade, set at right angles to the former school, is plastered and designed according to a monumental theme. In this case, only this façade has to be conserved in the design proposals for the redevelopment of the square. The façade and the former Dal Piazz school building are protected by the law as they identify the place and have characterised it for more than seventy years. Their demolition would change the memory that has characterised the place for centuries.

2. METHODOLOGY

The project proposals presented in this contribution deal with the theme of critical reconstruction of the historic city. This theme is part of the cultural debate at an international scale that began in the 1960s-1970s to respond to questions raised on urban form and to identify ways of constructing the contemporary city [1].

The experiences developed in the workshop of the Architecture of the City course provided an opportunity to pose the question and attempt to answer it: what idea of the city can we rethink today? Corresponding to this question is an idea of architecture that considers the project as the direct consequence of a conscious and critical relationship between new and old, understanding the word rethinking as the art of rethink the characteristics of the historic city.

Intervening within the historic city through a process of urban regeneration implies dealing with the values that these areas have sedimented over time and therefore a good practice of regeneration should not disregard the recovery of the old in continuity with the formal characters of the historic city [2]. This perspective brings the theme of redevelopment and urban regeneration closer to the term reconstruction, perhaps the most appropriate term for intercepting a criterion of work within the existing city. A word that does not exclude the terms regeneration and redevelopment, which, however, seem insufficient to meet the expectations of form of architecture whose aim seems to be, precisely, to give form to the places of human life: “Analysing urban architecture, one can attempt to classify the city according to many categories of judgement: economic, social, historical, technological, physical. Favouring only one of these perspectives leads to a partial result, necessarily limited by the borders of the chosen field of reference. Therefore, it may be important to try to overturn the now abused criterion that considers urban facts as an essentially economic or technological product, and instead place the accent on an aspect that has so far been rather neglected: the formal aspect” [3]. Facing the open challenges that await us and concern the preservation and care of the city's architecture, the projects presented here propose urban places capable of enhancing the quality of space and relations between the forms of the city, old and new, according to the principle of historical continuity. They resort to the typological and morphological repertoire of the place, recognising in the square, the courtyard, the street, the artefacts and the parts of which the monuments and forms of the city are made the tools to be applied to urban design, going beyond the reductive schemes of functionalism and the anti-urban ideologies of the modern. The reflection on the critical transformation of the historical city started from the reading of the ways of constructing space, the place of representation of the values in which the community self-identifies. According to Uwe Schröder, a careful and thoughtful analysis of the spatial conception of buildings and the city “can foster not only reflections on the form of places, but approaches capable of resolving some of today's social issues” [4]. The theory of spaces developed by the German theoretical architect is not just a tool for analysis, but for design too. Urban regeneration plans can become a valid tool for defining urban form when they consider architecture as a tool that deals with the construction of the quality of space, its role as a discipline that arranges volumes in space, designing relationships between physical forms. A good urban design cannot ignore the problem of the quality of urban spaces. It is the shapes of urban spaces, the spaces of squares and streets, that underpin the idea of the city [5]. As Carlo Moccia has well put it, referring to Uwe Schroder's studies on spatial relations, “urban form is investigated in its spatial value, measuring the degree of internality or externality that connotes the spaces of the city and recognising the relationships of concatenation between spaces of different character and hierarchy that organically make up the space of the city” [6].

3. DIDACTIC EXPERIENCE

We will now present some project proposals elaborated by the students of the fourth year of the Architecture of the city course at the Department of Civil, Environmental and Architectural Engineering of the University of Padua, under the guidance of the author of this contribution. Students worked in pairs with the aim of creating proposals for the generation of new spaces in which the Feltre community could recognise itself. Projects originate from the idea of defining a place of new sociality.

Figures 8, 9, 10. Federico Diddoro, Alessia Ferron, redevelopment project of the area named Piazzale della Lana in the city of Feltre. Project planivolumetric representation, general ground floor plan and view.

This condition is achieved through a process of articulation of the form designed for parts, process that actively participate in the reorganisation of the urban spaces for the community. Project proposals eschew the idea of asserting a strong centrality through a monolithic building, affirming instead the intention of a decisive openness with spaces related to the surrounding urban context: “A work of architecture cannot exist as an isolated object, as a reality in its own right, as a self-referential expression; on the contrary, it finds its reason for being in the close confrontation with the context, in the dialogue with the complexity of the surrounding space” [7].

The following three projects developed by the students Francesca Madormo, Angela Polo, Lorenzo Grego, Giovanna Maracci, Reyes González Maese and Esther Rodríguez Álvarez-Ossorio, should be read in this sense: recovering a formal continuity with the historic city, with its compact volumetric nature and simple geometric forms, and re-establishing new and significant relationships to inhabit the places of one's own time. The complexity of functions encourages an articulation of spaces within the area. This acquires the character of a small city within a city, conceived as a narrative composition of volumes and spaces, paths and courtyards. The urban project is disassembled into autonomous bodies architecturally characterised by form and materials, each corresponding to a specific function of the programme, held together by a network of internal and external walkways composing an articulated and richly evocative urban landscape. Composition by parts is adopted as an attitude to construct an urban place where each part interprets and evokes a repertoire of architectural arrangements already given by the formal experience of the historic city. The use of established

architectural spaces, passages, arcades, courtyards, loggias, halls would like to bind the project to the city and make familiar a civic place where everyone can recognize themselves in the clarity of architectural forms.

The project by students Federico Diddoro e Alessia Ferron plans to give the area a commercial and residential vocation by enhancing spaces for collective life and focusing on urban green (Figures 8, 9, 10). Fundamental is the focus on the area's relationship with its surroundings by favouring new paths and walkways. The area is spatially organized considering that the building next to the former Giorgio Dal Piazz school maintains the main facade which is subject to protection by the municipal administration, while seeing the rest of its consistency demolished. The general organisation of urban spaces and the arrangement of volumes derive from the application of settlement principles typical of historic city construction. Starting from the pre-existing building works that are confirmed, the one that used to be the Dal Piazz school and the façade of the building next to it, the new project volumes have been arranged to define three urban spaces.

Figures 11, 12, 13, 14, 15. Lorenzo Grego, Giovanna Maracci, redevelopment project of the area named Piazzale della Lana in the city of Feltre. Project planivolumetric representation, general ground floor plan and views of the new three squares.

The first, to the south in relation to the road, represents the new entrance to the city with its own formal recognisability. The second in succession, an urban square equipped with greenery, is imagined to restore value to the existing and new commercial spaces that overlook it. The third is the urban space on which the former Giorgio Dal Piaz school stands: it receives new meaning and role from the central position it occupies.

According to the idea of students Lorenzo Grego and Giovanna Maracci the project area becomes the ideal place for the beginning of a path and narration of spaces leading inside the walls of the historic centre (Figures 11, 12, 13, 14, 15). a sort of gateway from which to enter the ancient city by passing through Porta Imperiale and follow the main road inside the walls until reaching Piazza Maggiore, the culmination of the route. Starting from this premise, since the area is a kind of gateway to the city, it was assumed that three connected urban squares would be built as transition phases towards the historic city. The first square, the beginning of the route up to the city, is located to the south, opening on one side to Viale Monte Grappa. It welcomes pedestrians arriving at the area. The second square, which is reached by crossing an urban gallery, is the main project square around which the pre-existing urban buildings and the new project buildings are located. It is enriched with urban furniture to encourage social interaction. The third square is located in front of the former Giorgio dal Piaz school. On the square, this historic building reacquires importance and takes on new value.

The historic building, the former Dal Piaz school, is re-functionalised by transforming the interior with accommodation and spaces for a student residence, knowing that Feltre is a university citadel, hosting a nursing degree. The external image is maintained as required by the historical protection.

Figures 16, 17, 18. Reyes González Maese, Esther Rodríguez Álvarez-Ossorio, redevelopment project of the area named Piazzale della Lana in the city of Feltre. Project planivolumetric representation, general ground floor plan and views of the new public spaces.

The newly constructed building that limits the square on which the student residence stands, with its double-height portico, is designed as a canteen for students.

The third project proposal, developed by Reyes González Maese and Esther Rodríguez Álvarez-Ossorio, Spanish Erasmus students, is organized in the below summarized points (Figures 16, 17, 18). First of all, it is planned to move the parking spaces to an equivalent surface area on the opposite side of Viale Monte Grappa, with a raised pedestrian crossing that facilitates the connection and reduces vehicle speed. The proposal also includes the pedestrianisation of the entire study area to prioritise pedestrians in a safe and comfortable place. New paving will communicate cohesion with the surroundings. The façade of the barrel-vaulted building, which is protected for its historical-artistic value, will become a junction point between the ancient residential area and the more recently built fabric that develops around. The new square was also closed off to the south with a building along Viale Monte Grappa, giving independence from heavy car traffic. Regarding the former Dal Piaz school, spaces dedicated to various cultural activities and for all ages were planned.

4. CONCLUSION

The project activity highlighted the complexity of the question posed at the beginning, i.e. what idea of a city can we rethink, making us aware that one cannot exclude from design thinking the deep relationship with the heritage inherited from tradition, that the characteristics of the historic city and the morphological identity of the place constitute the lifeblood of the project. The idea of the compact city in its many different forms still seems to be a safe way and a valid operational tool for intervening in the historic city and resolving in the form of its spaces, buildings and monuments the relationship between architecture and citizens. In this perspective, the reconstruction project would have to deal more with the form, spaces, relationships, limits, hierarchies and sequences that define the character of the city. Aim that meet the aesthetic expectations of architecture, the memory of places and the identity in which a community recognises itself.

The beginning of an urban reconstruction process involving the degraded sites under consideration has highlighted two important issues. The first is that the historic city represents the reference for a critical judgement on the project. We must recognise the beauty of the pre-industrial city, of the city of stone whose formal results, the outcome of a millenary design culture, still seem to be the salvific antidote to the production of often insubstantial architecture. In the time of liquid architecture, in the era of globalisation, we can respond to the condition of crisis that pertains to us by taking a radical position against the prevailing conformism by deepening the sense of ancient thought that is a constant in our Italian and even European tradition: “If we want to raise the question of the identity of European architecture, we must first of all look back to our own origins and the evolution of our own civilisation. One must also, and above all, get rid of the precariousness of ideologies and recover confidence in the centuries-old heritage of knowledge and experience. Legitimate fears should not stem from a feeling of being outdated or obsolete, but from a lack of self-confidence, lack of knowledge and poor understanding of the cultural development that has accompanied us for millennia. Fears represent the real loss of identity of European architecture. The real danger lies in the commercialisation of values, the banalisation of concepts, the demythologisation of ideas and thoughts” [8]. The second decisive theme for the urban reconstruction of derelict areas is to think of the city and the project as a spatial phenomenon where the quality of places depends on the order in which physical objects are arranged in space. For this reason, it would be appropriate to consider the reconstruction of degraded areas in the logic of a development of spatial sequences that relate to others that already exist, enhancing important urban architectural themes.

The ancients still concern us [9]. They are a powerful resource for understanding our identity and not denying our memory.

Extended abstract

Contemporary cities are facing increasing challenges due to their fast evolution and need more efficient urban planning and development, potentially reducing costs and improving the quality of life for residents. Anthropogenic pressure in the consolidated city, concurrently with climate change, poses the need to find solutions that ensure the citizen's constant urban and social well-being in the enjoyment of public spaces. It is internationally recognized, nowadays, that intervening in the "greening" of cities provides short and long-term benefits in addressing climate change and contributing to human health [1]. Green Infrastructure like nature-based solutions fulfill a multi-scalar and multi-sectoral role and must be planned to ensure its production of ecosystem services starting from the local level which is the one most experienced by the inhabitants.

Central is the role of marginal areas, creeping between buildings or randomly carved out between lots, interstices between one dwelling and another, residual spaces that can become points of regeneration/mitigation and for preserving adequate levels of quality of life. These small areas in highly anthropized contexts represent a resource, despite the fact that to date they appear as non-places, spaces waiting for intervention to be in balance with their surroundings and to become possible poles of ecological and social reconnection thus providing space for nature-based solutions. The environmental and social benefits that nature in the urban environment can bestow depends of their proximity for easy access and use by a greater set of city-inhabitants [2]. Benefits include daily nature encounters, noise reduction, absorption of pollutants in water and air and also those related to identity and social interactions.

In this framework, identifying opportunities for enhancing public spaces and underused areas can play a vital role in fostering social inclusion and community engagement, helping the public sector create more cohesive communities under a climate change perspective.

Vegetation becomes, in this way, the leading element in the design of public space, giving places a new green identity, a work of "green mending": around the world initiatives are trying to occupy growing urban spaces by greening them with gardens, trees, flowers, trying to recover spaces that the gray of concrete had irreversibly invaded" [3]. Actions that promote nature-based solutions at a local scale represent small reactivation devices to trigger territorial transformations in urban voids of a city that is always over-cemented in which vegetation can rebalance in the relationship between the built and the natural environment by helping to deal with extreme climatic situations.

The contribution aims to bring forth a shared reflection on how territorial public bodies can benefit from the insights and recommendations proposed for a green and flexible use of proximity public spaces and interstitial areas within urban contexts.

Keywords: *proximity public spaces; ecosystem services; green mending; climate adaptation and mitigation; urban regeneration*

1. Climate change and cities

Climate change affects cities in numerous ways, spanning from environmental impacts to socioeconomic repercussions. Climate change adaptation strategies have a strong urban dimension, and cities have a major role to play in their implementation. It is nowadays widely recognized that

adaptation strategies are needed at local, regional, national, European and international levels to anticipate the negative effects of climate change and to prevent or reduce damage.

The need to act on climate change and biodiversity loss is recognized throughout Europe and around the world. In order to make progress in combating and adapting to climate change and to stop biodiversity loss and ecosystem degradation, it is necessary to fully integrate these issues into plans, programs and projects implemented in cities.

From an institutional view an emblematic approach has been set by the EU's Climate Change Adaptation Strategy, adopted by the European Commission in 2021 that proposes measures to develop awareness of adaptation in order to collect more and better data on climate-related risks and losses. The EU's Climate Change Adaptation Strategy [4] links directly to recent global agreements, such as the Paris Agreement, the Sendai Framework for Disaster Risk Reduction and the Sustainable Development Agenda as well as the EU implementation of these goals. It also connects directly to major EU initiatives like the Mission for a Climate resilient Europe and the Union's sustainable finance agenda.

The Strategy sets out how to adapt to the unavoidable impacts of climate change and become climate resilient by 2050. The Strategy has four principles objectives: to make adaptation smarter, swifter and more systemic, and to step up international action on adaptation to climate change. The Strategy is therefore in line also with the UN cross-stakeholder initiative of Making Cities Resilient 2030 for improving local resilience and the global network of mayors C40 of the world's leading cities that are united in action to confront the climate crisis.

Gencer et al. [5] clearly stated that the urban environment is stressed by often exacerbated effects of climate-related disasters. Furthermore "the frequency and severity of weather and climate-related disasters in urban areas are projected to increase in the coming decades".

The exacerbated impacts of climate disasters are caused by the human intervention in a direct or indirect way posed by air and water pollution, overuse of water, removal of natural elements and unplanned urbanization which perform as human-induced stresses. In the last decades the built environment has suffered more intense and frequent heat waves [6], as well as different types of flooding [7]. Those phenomena are significantly damaging the urban context and posing human lives at risk.

The intensity of the effects of this deterioration depends on the vulnerability of cities to climate-related disasters. Vulnerability is influenced by cultural, demographic, and economic characteristics of urban residents, city governments, built environment, ecosystem services, and over-exploitation of resources and environmental degradation [5].

The Climate Change 2023 Synthesis Report summarises the state of knowledge of climate change. The report recognizes the interdependence of climate, ecosystems and biodiversity, and human societies [8]. Global warming is demonstrated to have been caused by human activities, principally through emissions of greenhouse gases.

Observed widespread and substantial impacts and related losses and damages attributed to climate change related to cities, settlements and infrastructure are especially causing inland flooding and associated damages, flood/storm induced damages in coastal areas, damages to infrastructure and damages to key economic sectors. Except for the last typology the confidence in attribution of the observed impact to climate change is high or very high confidence [8].

Moreover, more than half of the world population and the major part of the societies' assets and economic activities is located in urban areas [9]. According to Giordano [10] there is evidence that this coexistence of factors transform cities both in a contributor to climate change and victim because of the vulnerability to the related impacts [11,12]. The World Bank confirms that today over 50% of the population lives in urban areas and this number will increase to 6 billion By 2045 [9].

While problems caused by urban climate phenomena are a growing concern with urban population growth and aging infrastructure there is still an effort to be made to implement urban climate adaptation measures [13].

Addressing the impacts of global warming on cities requires coordinated efforts among several and diverse actors at the local, national, and global levels to mitigate greenhouse gas emissions, adapt to changing conditions, and build resilience in urban communities. This includes measures such as implementing sustainable urban planning and design strategies, enhancing green infrastructure, improving disaster preparedness and response mechanisms, and promoting community engagement and capacity building. The urgency of those measures are claimed by the results of Lenzholzer et al. inquiries [13] that showed that there is a overall ignorance on how urban design influences the climatic characteristics in cities; even if new awareness-raising phenomena are moving, starting from the overwhelming awareness of the young generations in the wake of the Greta Thunberg's movement, much still needs to be done in increasing awareness.

A paradigm shift will require urban decision-makers and stakeholders to increase the institutional capacity of many communities to apply adaptation measures.

As stated by Raven et al. [14] "Urban planning and urban design have a critical role to play in the global response to climate change" and nature must find the place it deserves in the urban environment. Green Infrastructure are a main tool at the disposal of urban planners to provide ecosystem services that can be directly perceived by the inhabitants. The multi-sectoral role of those planned interventions generates biodiversity and provide services that increase the resilience to the effects of climate change following the path posed by Pope Francis' encyclical "Laudato si" [15]. for which everything is connected and we must take care of our common home.

Thanks to the Climate Change 2023 Synthesis Report the close linkages between climate change adaptation, mitigation, ecosystem health, human well-being and sustainable development are shared [8]. Grafakos et al. [16] clarify that a holistic analysis and a proactive planning offer solutions both to mitigation and adaptation policies across multiple sectors and levels of governance. Integrated city climate action plans should include a variety of actions and concrete measures for assessing progress. A synergic approach is able to implement short-, medium-, and longterm goals improving cost-effectiveness of the interventions such as urban greening and green infrastructure practices which take place in the public space. Many authors confirm that urban greening is highly relevant thanks to the capacity to absorb and store water, the capacity to contribute to the cooling of the surrounding areas (less effective but still present) and to the biodiversity enhancement [16].

For example, functional green areas can regulate rainwater flow thus reducing the risk of flooding. Ecosystems and their services can be used with success as a cost-effective alternative to building infrastructure, for example, to manage flood risks. Green areas and vegetation also provide cooling within cities and thus reduce the impact of heat waves and the effect of heat, and plants stabilize the soil, thus reducing the risk of landslides and erosion. This is directly related to the European Adaptation Knowledge Platform called ClimateADAPT, developed by the EEA. It highlights adaptation priorities at the local level, natural solutions aimed at adjustment and the integration of adjustment issues into macro-fiscal policy.

The urban climate context, which can be theoretically articulated in the 3 key elements of temperature, precipitation, and winds, plays an evident role in providing well-being within cities and related exacerbated conditions lead to higher risks to the more vulnerable parts of the society (children, elderly and people with disabilities or pre-existing medical conditions) [17].

The exposure to green space is in fact a critical element in linking urban green space and urban residents' health [18].

The revitalization of urban green areas complete the efforts to provide strategic planning through the concept of "build back better" thus maintaining biodiversity into cities. Supporting biodiversity provides clear carbon benefits by enhancing the natural environment's ability to absorb and store

carbon across soil and plants. Healthy natural habitats such as soil, wetlands and forests can absorb significant amounts of carbon. Damage to the biodiversity or physical environment of these areas can release this stored carbon, even indirectly, thus contributing to climate change and biodiversity loss.

2. The project of public space in the historic and consolidated city

During the recent pandemic there has been a rediscovery of the value of public spaces as a key element in ensuring a good quality of urban life: outdoor areas in which to reorganize activities that used to take place predominantly indoors, such as study or book presentations, theater workshops. In this context, the redevelopment of degraded urban spaces offers a unique opportunity to create vibrant and vital new urban places within walking distance of one's home in a city that is always too dense. High urban pressure presupposes intervening on the existing by developing an adequate knowledge of the available resources, the characteristics of the area, the memory of places and what they represent, in order to establish a stable relationship between old and new. A transformation that must not disrupt material and immaterial values as well as environmental balances but and at the same time must be able to accommodate new functions in relation to new needs [19].

It is a development of the city understood not as an extension of buildable areas but as a study and use of the existing urban structure, to intervene on a compact plot by soliciting a new urbanity as well as a new vision of public space at different scales from neighborhood to neighborhood to municipal. The morphological and functional criteria of open space in this case verge toward the negative of the fabric of the city, understood as a generating element of urban transformations to build both meeting places and to blur the boundaries between public and private, between built and unbuilt, between the realities of work and that of leisure. A reconfiguration of the city in which public space remains a place of excellence for social, cultural, material and immaterial exchange, "*restoring to it the primitive and noble flavor of a sphere addressed to collective practice, an ideological model of lifestyles, a recognized narrative form of evolution and growth of the city*" [20].

The role of the spatial composition of the city, which cannot have a rigid definition as society, especially after the pandemic experience, moves toward a much more fluid enjoyment of open space, seems evident. Thus, "*accidental*" and unconfigured places are taken into account and become the object of attention for open space design [21].

On the other hand, in the historic city, where the urban characteristics are well defined, the endowment of public spaces and gathering places today turns out to give ineffective answers to the high demand for the places of being, of the search for neighborhood areas where it is possible to find a state of environmental well-being and moments of sociability. However, people's lifestyles must be taken into consideration so that we do not end up with projects without identity in which the citizen does not recognize a sense of appearance, since they are either too much at odds with the context or not very permeable and accessible.

The lack of gathering places thus leads to realizing public life in informal but proximate spaces to which new functions can be attributed by reinterpreting them as opportunities.

This vision in the design of public space leads urban planning to constantly confront the existing, material and non-material cultural heritage, of which the citizen is the sole user. If we take into consideration urban areas in the historic city there is a radical change of gathering spaces, in relation to different lifestyles and different users that include not only local inhabitants, but workers and commuting students, tourists this leads to a diversification of the ways in which places are used, which overlap with each other sometimes in a contradictory way. The strong tourist pressure in large European cities, especially in capital cities, has led to an aggression of the main gathering places representative of historicity such as squares and even markets, where streams of visitors meet leading the citizen to seek meeting spaces in secondary but more intimate areas that still give the sense of authenticity.

Hence the search for places albeit informal but identity in a city with a well-defined fabric, leads to intervention in urban voids considered possible containers of activities and functions.

Intrinsic in the creation of areas for neighborhood sociality is the concept of proximity, thus a search for areas on which to intervene at the boundaries of housing; it is therefore the interstices, the places of urban waste that play a central role in the design of the public space of proximity.

In this perspective there is a revision of the built environment, to intervene on the undefined, on the spaces of waste, on those places that can become small neighborhood green polarities and give the sense of "breathing space" in a city now defined and still too little inclusive.

2.1 Designing between : the urban voids

The city understood as part of an evolutionary process, in which the transformation of places is linked to the succession of temporal and cultural aspects, which have led to the creation of densely built-up areas in which, nevertheless, small spaces of proximity defined by sometimes imprecise geometries have developed spontaneously, unintentional places, not determined by urban design but which can have fundamental ecological and social functions in highly cemented contexts.

The voids that have suddenly come to form between the dense and compact fabrics form inner suburbs, sometimes incurring where the contrast is marked by the occupation by tertiary activities of vast residential areas, and the location of social services and facilities far from the users [22].

Secchi speaks of a sometimes incurrent city where the "undefined," the spatial imprecision, identifies a particular condition of places and proposes a regeneration strategy to make potential that in-between space, formed by the layering of multiple identities [23].

Identity in an intervention of a "space between" is a factor that should not be overlooked; a place always has an intrinsic meaning, which comes from people's use and perception of it, and not always according to a negative meaning, since an unexpected urban landscape can result from a discarded place. In acting on voids, one is therefore also acting on giving new meanings to spaces that for better or worse have taken on an identity; if one thinks, moreover, that the concept of discard coincides with that of remnant, of what remains, of what is possible, its negative meaning is diminished since it opens the door to new perspectives.

We are in a historical period in which waste becomes the primary material for a recycling project, the trend today is to act on places exposed to degradation by rediscovering forgotten spaces in everyday life.

Acting leads toward the fragments of vacant land that parcel out the city " *opportunities in which the urban project rediscovers its effectiveness in the transformation of the contemporary city by operating predominantly at an intermediate scale, between the exterminated scale that detects the pulverized nature of settlements and the exaggeratedly reduced scale that dwells on the purely sensual aspect of individual buildings*" [24].

The design of the void does not stand as a simple spatial organization, but as an organizational structure of the open place highlighting the existing and directing future processes, as a narrative of different urban situations. There is an inversion in determining the form of space, of the full and empty relationship, in which it is the void a defines the full by penetrating and redeveloping it, to give a new form to the settlement [25].

In this perspective, new small polarities of proximity are created, which in a larger scale represent nodes in of a network of possible spaces, a work of green stitching of the existing is therefore carried out, micro-interventions that are part of the process of urban acupuncture agend or in nerve points in a local scale always referring to the territorial one.

2.2 The role of vegetation in the regeneration of proximity spaces

If the contemporary city is a fragmented space subdivided by many disconnected entities, building a network of small areas endowed with the right amount of vegetation means giving continuity not only ecological but especially social continuity.

It is a process of transforming an interstitial space in which we take note of existing ecological contaminations, Gilles Clément's spontaneous vegetated landscape, which autonomously reappropriates land taken from nature.

Figure 1. The Iris garden in Rome's historic Garbatella neighborhood was created by the community in a small space pertaining to the buildings

The hypothesis of a more naturalized anthropogenic habitat and its benefits on people's well-being is supported by various studies by Catharine Ward Thompson and finds confirmation in her research, in which she also condiscates the relationship between green space and proximity, which does not necessarily equate to the area located in close proximity to home, bensità proximity is the area that the inhabitant perceives as part of a neighborhood in which he or she moves easily: "*research in Scotland has shown that, for many people, regular use of green space is not limited to places within 300 m of home, and perceptions of the proximity and accessibility of green space can relate to what is perceived as part of the neighborhood or available for community use, rather than an objectively measured distance*" [26].

During the pandemic wave in spring 2020, there was a "biophilic attraction" , a sudden greening of private space, a rediscovery of nature and the concept of care, in this process is composed of elements of adaptation of outdoor space to sudden health and climate changes through the use of vegetation:

"there has been in private environments enhancement to the balconies and terraces -become new outdoor and green inhabited surface- in addition to the modification of interior arrangements, while in semi-public and collective ones, such as gardens and courtyards, the reappropriation of these (non)-places became new devices of social interaction and contact with the environment" [27]. Nature an engine both to reactivate social interaction and to make spaces adaptive to extreme uses or situations by creating comfort zones by applying in its resilience the concept of adaptation to public space design.

Figure 2. A variety of objects have been arranged that are reminiscent of the home environment according to the philosophy that the garden is an extension space of one's home

3. Conclusions

In briefly illustrating the trend of urban design, we wanted to dwell on the creation of neighborhood green spaces by considering the unused areas of the consolidated city, small interstitial neighborhood spaces that can become social occasions, new identities, born precisely from the layering of multiple events. In these spaces, it is interesting to bring out the interaction that is created between the state of abandonment, the reappropriation by a wild and spontaneous nature and the spontaneous interventions of citizens, even of artistic connotation, which generate places with multiple identities. From the environmental point of view, in addition to the extraordinary ability of plants to absorb air pollutants, particularly from urban traffic, green spaces contribute to lowering the heat island, rainwater runoff and purifying the soil component. We are witnessing periods of high heat stress and sudden weather changes in which vegetation is perhaps the only supporting material for public space

design, coadiuvante to counter climate change. While the ecological contribution of the plant element in increasing the of biodiversity in the urban environment has been evident for several years, during the pandemic the importance of nature in the city in promoting psycho-physical well-being and relieving the stress of an extreme event has become central in the interdisciplinary debate. Can not think today to design public spaces without the use of plant material, a protagonist in regeneration projects, especially of urban waste areas, nature is the key to redefining the places of relationships and community.

Listening to the population can lead to an understanding of the focal points of the urban fabric, in order to identify the areas where the greatest problems are concentrated and where in proves necessary to intervene with effective actions [28].

In this case, a Social Urbanism-oriented approach is adopted that is connoted by citizen participation in the process of change, with targeted interventions of redevelopment that we can define as light and fast: tactical urbanism.

In taking into consideration that the city is a dynamic place where flexible spaces must now be designed, Tactical Urbanism is based on the implementation of quick and low-cost actions to donate long-term social benefits in a very short time by creating new gathering spaces.

This approach has been successfully applied in dense, American and European cities composed of many unused spaces demonstrating how to act on the existing by giving a new identity to (non)places. In the "Asphalt Art Guide" compiled by Bloomberg Associates in 2019 there is an overview of the steps in the procedure for planning a tactical urbanism project , as well as advice for aspiring asphalt artists, there are also several successful examples of areas that with only the use of low-cost materials have become more welcoming and sustainable spaces. The guide compares different practices of redevelopment actions in various cities of the way bringing out the motivations behind the project such as reducing traffic, building neighborhood community, and enhancing cultural identity.

An approach acting on contained spaces makes social relations stronger as it is understood in the project carried out in Zaragoza by architects Patrizia Di Monte and Ignacio Gravalos who realized a low-cost project working on the temporary use of urban voids in the neighborhood of transforming these spaces areas the community as small gardens, play areas or for sports.

Overlooked interstitial areas, if consciously adapted, can improve the resilience and sustainability of contemporary cities. Citizen science and human-centric approaches where citizens are engaged in the sustainable renewal of public space are increasing [29,30] but remain exceptions. Citizens, though often forgotten, are the main users of such spaces [31], and must be part of the participated methodologies employed to make proximity public spaces resilient.

Authors' contribution

This paper is conceived as the result of a common effort by the authors. However, T.V. Di Giacomo wrote section 1 Climate change and cities and E. Paudice wrote section 2 The project of public space in the historic and consolidated city while the whole section 3 Conclusions was authored by both.

Abstract

Global communities are coping with the impacts of climate change in multiple ways. The spatial configuration of waterfront cities makes them vulnerable to extreme events and natural hazards, threatening infrastructures, lives, and livelihoods. Therefore, direct and indirect effects are anticipated in coastal communities, including both material and lived aspects of culture. On the other hand, according to the IPCC, the warming of the atmosphere and the oceans is due to anthropogenic changes, i.e. the way we live on earth and occupy space, the modes of production, consumption and lifestyles. These findings highlight the cultural dimensions of the causes of climate change and, at the same time, the cultural dimension of human responses. The case of the waterfront redevelopment of the Royal Seaport in Stockholm provides an insight into the intertwining themes of sustainability, adaptation, and the critical role of culture. A new neighbourhood, the flagship project of Stockholm's urban development strategy, is currently being developed in the port area, taking advantage of partially decommissioned industrial sites. Design proposals for the Royal Seaport site were drafted and discussed during the SOS Climate Waterfront Workshop held in Stockholm, Sweden, in May-June 2022. This paper reflects on the strategies and design tools proposed for the area by students and researchers within the frame of the workshop. The project *Hazarts* proposes a vision of a neighbourhood where our vulnerability to risks and hazards, as well as the many interrelations we depend upon, is displayed through art, with a focus on education and awareness. Green and blue infrastructures transform space into a flexible and multifunctional public space that absorbs disturbances while maintaining its functions, providing a safe place for cultural and artistic activities to stimulate a new attitude towards change, vulnerability, coexistence, and mutual interdependence.

Keywords: *waterfront cities; climate change; culture and creativity; flexibility; public space.*

1. INTRODUCTION

In times of unprecedented environmental disruption and social-ecological unbalances, creating long-term solutions with effective and innovative approaches to foster resilient cities, design sustainable urban waterfronts, and enhance the health and well-being of waterfront communities is crucial for maintaining the vitality of waterfront areas.

It is on this premise that the Marie Curie Research and Innovation Staff Exchange (MSCA-RISE) programme *S.O.S. – Sustainable Open Solutions for European urban waterfronts (SOS Climate Waterfront)* was set up. With seven cities involved from different latitudes of Europe - Rome, Thessaloniki, Stockholm, Lisbon, Gdańsk, Ankara, and Amsterdam - it aimed to enhance a sustainable research framework for the discussion of solutions and strategies, through a multi-disciplinary approach, building on conferences and design workshops held in the participating cities, where international researchers from various disciplines worked with students from the hosting institution to discuss scenarios and develop creative design proposals for the selected study areas [1].

Having participated as international researchers in the workshop held in Stockholm, the authors' aim in this contribution is to stimulate, starting from the design workshop output, a discussion concerning the role of culture and creativity to face the impacts of climate change. First, the paper develops a review of current policies and scientific literature concerning culture and creativity in the context of cities facing climate change and is followed by the presentation of a case study, the Royal Seaport area redevelopment in Stockholm, which was the selected study area for the SOS Climate Waterfront workshop. Being a large port-industrial area, the Royal Seaport's redevelopment proceeds gradually, in stages involving smaller sub-areas, of which only one has been completed to date. This allows for a provisional comparison between the results of the first realisation phases and the concept proposed as a result of the design workshop for the adjacent sub-area, still waiting to be transformed.

2. THE FIVE Cs: CITIES, CULTURE, CREATIVITY, CLIMATE CHANGE

Waterfront cities are vulnerable to extreme events and natural hazards at multiple scales and dimensions. Sea-level rise, extreme weather events, flooding, ice sheets, and various crises or shocks threaten infrastructures, lives, and livelihoods. Several direct and indirect effects are anticipated in communities, including both tangible (e.g. cultural heritage and historic buildings, sites, objects and artworks) and intangible (e.g. cultural values, identities, knowledge and language) aspects of culture, threatening cultural security [2] and underlining the cultural dimension of climate change impacts.

On the other hand, according to the 2021 IPCC report [3], the warming of the atmosphere and the oceans is due to anthropogenic changes, i.e. the way we live on Earth and occupy space, the modes of production, consumption and lifestyles that give rise to greenhouse gas emissions. These findings highlight the cultural dimension both of the causes of climate change and of the adaptive responses to climate-related risks. This means that adapting to and mitigating the impacts of climate change require integrated approaches to changing the way we live and act on the planet, which is intrinsically interdependent with our worldviews and value systems [4], i.e. our culture(s). In 2014, the aim of the *Sustainable Lifestyles and Education Programme* [5] was to promote the adoption of sustainable lifestyles as the common norm at all levels and in diverse contexts. According to Light et al. [6], changes of this magnitude could be achieved by introducing creative practices into the process which are able to affect emotions, thus, it is more likely to influence the willingness to engage in pro-environmental behaviour, achieve a shift in self-identity and long-term change.

Creativity, closely linked to cultural and art practices, is associated with originality, imagination, inspiration, and innovation and contributes to sustainable development [7]. By targeting values and attitudes [8], it provides the appropriate context for people to develop creative thinking and act imaginatively in pursuit of change, which in turn will generate diverse positive outcomes in cities at different scales and dimensions [6].

Additionally, the cultural shift towards strengthening social bonds, trust and social cohesion forms the foundation for vulnerable communities to develop appropriate mechanisms for recovering from natural disasters and coping with such stressors. For Blatchford and Young [9], culture and creativity go beyond their ability to shape identities and behaviours and are survival strategies that should be considered an essential part of any community's resilience toolkit. The contribution of cultural heritage in this sense is highlighted in the ICOMOS 2019 report *Future of Our Pasts: Engaging Cultural Heritage in Climate Action*, [10], as well as in the White Paper *Cultural Heritage and Climate Change* [11], stressing the embeddedness of culture and heritage in their socio-environmental contexts. Moreover, Fabricatti et al [12] note that the collaborative actions of heritage care and conservation, implicit in the definition of heritage communities proposed by the Faro Convention on the value of cultural heritage for society [13], can establish a virtuous cycle, strengthening social cohesion while reducing environmental degradation and stimulating urban regeneration.

The relationship between culture and the SDGs, set by the UN in 2015, is quite paradoxical. The 2013 UNESCO Hangzhou Declaration [14], emphasized the need for culture to be integrated into the post-

2015 development agenda with a dedicated cultural goal, as a driving force and enabler for sustainable development. However, culture is not among the 17 goals, and is rarely mentioned in a direct and specific way in a few of them (4.7, 8.9, 11.4, and 12.B). Although efforts to combat climate change have been on the world agenda for decades, greenhouse gas emissions still increasing [15] and global warming continuing apace [16], indicating a failure of climate change governance [4, 17, 18]. To accelerate change, turn good intentions into actions and redefine the role of culture and creativity in the context of sustainable development and climate, mass participation is required [18].

In the current global debate, culture is increasingly recognised in studies, works, policy initiatives and practices as a key driver of sustainable development for the achievement of the SDGs in the context of climate change mitigation and adaptation. In 2018, the report of World Cities Culture Forum on *Culture and Climate Change* [19], demonstrates impactful projects that highlight the convergence of cultural and environmental policy at the city level and aims to accelerate cultural action on climate change. It includes projects that promote citizen engagement, awareness and disaster preparedness, and the regeneration of urban environments through the provision of common public spaces, the preservation and integration of cultural heritage into public life, public engagement, environmental development and cultural involvement. It identifies cities as collaborative commons and serves as a significant tool which can influence, inspire and lead future city policies in addressing environmental and climate challenges through cultural creative actions. The *Thematic Indicators for Culture in the 2030 Agenda* [20], developed in 2019 by UNESCO for measuring and monitoring culture's contribution to the national and local implementation of the SDGs, aims to assess both the role of culture as a sector of activity and its cross-cutting contribution to different goals, targets and policies. In particular, all four dimensions of the proposed indicators highlight the interconnection between culture and the SDGs through a variety of bidirectional relationships. They aim to assess the spatial aspects of the quality of public spaces and cultural infrastructure, the contribution of culture to the transmission of local cultural values, knowledge and skills, and the promotion of inclusion and participation. They focus on equal access to cultural life, cultural education and creative freedom and expression. They assess the level of cities' commitment to the protection of cultural and natural heritage and to culturally sensitive planning and management. Finally, education for adaptation to climate change, the adoption of a sustainable consumption culture and the acquisition of skills for sustainable development are highlighted as separate objectives. The *New European Bauhaus* [21], launched by the European Commission in 2020, is a creative and interdisciplinary policy initiative that identifies cities as hubs of innovation where art, culture and creativity play a key role in assisting green transition, while building sustainable and inclusive communities through collaboration between citizens, experts, artists and institutions, experimentation and connection in its public spaces. The European Cultural Heritage Green Paper *Putting Europe's shared heritage at the heart of the European Green Deal* [22], produced by Europa Nostra in cooperation with ICOMOS and the Climate Heritage Network, aims at demonstrating the relevance of cultural heritage for achieving the goals of the European Green Deal, thus also enriching the New European Bauhaus by stressing the importance of including heritage side to side with culture and creativity [23].

The above documents attribute to culture and creativity a cross-sectoral dimension, strongly linked with all pillars of sustainability. They also make clear that for culture to be effective and for its transformative power to be scaled up towards the desired cultural change, collaboration between different groups - experts, scientists, researchers, artists, stakeholders and citizens – is essential. Such collaborations go beyond awareness-raising because they influence the way of thinking and living on Earth. Soden et al. [24] argue that this is due to art's ability to interpret and communicate scientific outputs (charts, diagrams and risk models) - which are often incomprehensible to the general public - in innovative, effective and attractive ways, addressing the emotional elements of the climate crisis and thus, transform cross-disciplinary cultural and creative actions into platforms for transformative processes. Both *Culture and Climate Change* and *New European Bauhaus*, through a variety of

Proceedings

actions in open public spaces in cities, promote inclusion and public engagement in the process, creating favourable conditions for knowledge dissemination - to a wider audience - and shared learning through creative cultural practices. Therefore, it is understood that since urban public spaces provide the essential space for cultural expression, participation and contact [25], when combined with cross-sectoral collaborative and creative cultural practices, this encounter can accelerate transformations; especially when politically supported and legitimised [18].

3. STOCKHOLM'S ROYAL SEAPORT REDEVELOPMENT: A CASE STUDY

The redevelopment of the Royal Seaport area in Stockholm – locally known as Norra Djurgårdsstaden – has been discussed and implemented over a wide time span, beginning in the Nineties and continuing until the present day. As large as 236 hectares, the area was the first working class suburb in Stockholm, accommodating since the end of the XIX Century industrial and port uses, including gasworks buildings, an electric plant, and the largest port of the city, as well as a residential area in the higher part. Part of the buildings have been decommissioned, while others, such as the electric plant, are going to stay in function. The plan for the port itself is to keep it active by integrating it into the future neighbourhood.

The Royal Seaport project is considered strategic by the policy documents first because of its location, well connected to the city centre, bordered by the Baltic Sea, and surrounded by the Royal National City Park, the major green wedge penetrating the city, second, because of the industrial heritage available for new “exciting uses” [26]. Once completed, the new Royal Seaport should accommodate at least 12.000 housing units, 35.000 working places, and 600.000 square metres of commercial activities. In 2015, the first construction phase came to an end, with the realisation of the Northern part of the project, a new neighbourhood placed between the existing working-class residential area of Hjorthagen, the gasworks, and the Royal National City Park. By examining the policy document “Sustainable Urban Development Programme” [26], the dedicated website [27], and the realised neighbourhood, a first evaluation concerning the use of culture and heritage can be attempted.

The Royal Seaport is presented as a model of urban sustainability to the international public, following the wide recognition obtained by the Hammarby Sjöstad district redevelopment, pursuing a sustainability profile based on technological innovation, in line with the Swedish policies [28]. This objective also aims at consolidating Stockholm’s role as a leader in the sector: as the then mayor and vice mayor clearly stated in 2010, the Royal Seaport would “support the marketing of Swedish environmental technology and contribute to the development of new technology that will cover all housing construction in Stockholm, Sweden and the rest of the world” [29].

Sustainability is linked, in the project’s statements, to cultural heritage as a means to build and strengthen identity, narratives, and sense of place. Cultural heritage valorisation is achieved by contrast through the search for a dialogue between the old and the new [30], within a perspective that considers natural and cultural heritage not as static data but as co-evolving with the city. A strategic planning approach facilitates the integration of the disciplines of urban planning and heritage conservation, opening new opportunities for a creative reuse of heritage. This kind of gesture is not neutral to the cultural and historic meanings of the pre-existing elements: heritage becomes a bearer of new values and meanings, compatible with its history but closer to the contemporary mindsets. The project is what selects meanings to be valued and reinterprets them as functional to the vision it aims at promoting. Such an approach can offer stimulating possibilities by departing from a logic of rigid constraints, but is not immune from major drawbacks. As a demonstration of how tangible these worries can be, we can compare how different heritages were treated in the already completed part of the Royal Seaport.

The gasworks – Värtagasverket – are a valuable complex of brick buildings designed by architect Ferdinand Boberg dating back to 1893. Shortly after their construction, to accommodate the growing number of workers, the city began to build housing units on the adjacent hill of Hjorthagen. The

neighbourhood grew throughout the first half of the XX century until the Sixties, and provides today a unique testimony of the historical evolution of social housing models in Sweden. Particularly relevant is the Abessinien housing complex, designed by Hakon Ahlberg in the Thirties and inspired by functionalist principles. Both Värtagasverket and Abessinien are classified as heritage goods of national interest with historical-cultural value [31]. While the gasworks have become the core and main identity symbol of the new neighbourhood, the pre-existing residential neighbourhood has been gradually marginalised while the project advanced. For instance, an emblematic decision was taken to relocate the public library to the newly built area, in a clear attempt to move the barycentre of the district's life, rather than the objective of integrating the old and the new the policy statements declared. This gesture can be viewed as representative of the will to privilege a specific kind of heritage and cultural meanings – that of technological development. This kind of industrial heritage is functional to promoting the image desired by the investors, and sustaining a model of elitist sustainability. As a matter of fact, the housing units in this area are going to be the most expensive in Stockholm, pushing the previous residents to move. On the contrary, a valorisation of the social housing heritage would have been coherent with an opposite vision, aiming to address the issue of housing accessibility, which is among the major social emergencies in the city.

It has been observed that the pre-existing neighbourhood could be seen as “standing in the way of the strategic framing of the project into a universal model for sustainable urban planning, because Hjöorthagen adds the kind of localness and historical heritage which makes it more difficult to portray the area as a universal role model for sustainable urban planning” [32]. As Choay [33] puts it, a set of losses including de-memorisation and semantic de-complexification, resulting from the process of globalisation and mondialisation, are at work in the redevelopment of the urban space.

This process has to be seen as inherently de-politicising. Port waterfronts, carrying histories of inequalities and class struggles, are subject to heritagisation processes where only the interpretations of the hegemonic groups are accounted for, namely those related to innovation, symbolised through certain material structures and technological features, while aspects connected to social relations and working-class struggle are marginalised. The expression 'heritage sanitification' [34] has also been used to describe such processes where narratives are simplified through the removal of controversial elements, in order to attract a wider public.

4. THE WORKSHOP EXPERIENCE: HAZARTS DESIGN PROPOSAL

The design proposal for Södra Värtan, part of the wider Royal Seaport area, was developed by Group VI within the frame of the *SOS Climate Waterfront* workshop held in Stockholm, in May-June 2022. The site analysis, based on data collection from urban planning documents and historical archives, site visits and guided tours of the wider area and supported by lectures from experts and academics, revealed valuable insights into the challenges, opportunities and weaknesses of the study area and framed the guidelines of the design approach.

If the city of Stockholm literally consists of islands, the area of Södra Värtan was interpreted by the group metaphorically as an island in perception. Lower than its surroundings due to topographical conditions and with a hard border marked by a dismissed railway, the area is disconnected from the city - despite being only a short distance from the centre - and the nearby green areas, thus contributing to keeping the waterfront out of the social and urban fabric. At the same time, the presence of historically significant structures, the proximity of contemporary creative hubs, social housing, industrial uses and port activities further contribute to the multifaceted identity of the area, which serves as a nexus of contrast and transition. This complex urban fabric, therefore, introduces a set of challenges related to interconnection, integration and balanced coexistence of natural and cultural resources within the context of urban development. On the other hand, the potential impact of sealed and contaminated soil, flooding risks and diverse hazards, water pollution and air quality,

the protection of the natural environment and biodiversity, the safeguarding of food safety and security and other climate change challenges are also considered in the design proposal.

Being aware of the centrality that the port activities have at present and are going to maintain in the future - also due to the increasing number of passengers reaching Stockholm by sea - the renewal project starts with the idea of transforming Södra Värtan from a transit space into a destination place for tourists and local people. The undefined intermediate space opens up to the Baltic Sea, and is transformed into a flexible and multifunctional public space that welcomes new uses to coexist with the old, restores the cohesion with the city, the green areas, and the sea. *Hazarts* incorporates a vision for a neighbourhood where vulnerability to risks and hazards is displayed through art and culture, with a focus on the importance of education and awareness of the many interrelations we depend on to build resilience and adaptation. Thus, the design approach is grounded on the identification, preservation, promotion, integration, and enhancement of the cultural and creative potential of the study area as necessary components of adaptation and resilience. The cultural and artistic dimension is emphasised with the aim of converting the area into an inclusive creative harbour for different cultures to meet, connect, learn, and co-create with respect to humans and nature.

The proposed design encourages walking and cycling over driving and promotes the use of public transport by extending existing lines and creating a transport node through the adaptive reuse of the old station, reinserting this historic building into the urban scene. The remaining heritage assets are integrated into the new development as part of a cultural corridor, which “hugs” the hill of Hjorthagen and acts as a connector, allowing the creative reuse of built heritage to serve as a backbone. This cultural corridor, as it runs through the area to Lidingö, articulates history, cultures, people and knowledge, and in synergy with the public realm, the artists and the new natural hazards research institute (conceived as a floating landmark) offers multiple, diverse and alternative approaches to educate on issues related to climate change hazards, mitigation, adaptation and resilience (e.g. exhibitions, workshops, seminars, video projections, agricultural skills, etc.).

To address the challenges of climate change, the proposal incorporates sustainable strategies based on green-blue adaptive infrastructure that welcomes different forms of change related to water, while strengthening the interfaces between humans, non-human species and nature. The integration of public waterway networks, the construction of wetlands, the promotion of porosity and rainwater harvesting systems achieve the absorption, storage, treatment and management of water, as well as biodiversity and sustainable human and natural ecosystems; furthermore, they create a social, educational, and experiential platform for the community (Figures 1, 2).

Hazarts proposes a culturally sensitive urban planning where green and blue infrastructure and technology transform space into a flexible, adaptable, and multifunctional public space that absorbs disturbances while maintaining its functions. Therefore, it provides a safe place that becomes the breeding ground for the development of cultural and artistic activities to stimulate a new attitude towards change, vulnerability, coexistence, and mutual interdependence.

5. WHEN RESILIENCE MEETS CREATIVITY: A CONCLUSION

Through a literature and policy review, this paper shows how cultural and creative mediation in all urban practices and policies can gather the requisite knowledge and serve as a lever for cross-sectoral learning and dialogue, inspiring communities, stakeholders, policy makers and governance systems with new, inventive and sustainable solutions to address climate change and the environmental unbalances in contemporary urban areas. Ultimately, by triggering new living experiences, such approaches – it is stated - can bring about the necessary systemic changes to move cities beyond the current impasse and towards a sustainable future on Earth.

However, practice can be quite different from theory. Through a case study analysis of Stockholm's Royal Seaport partial redevelopment, it is pointed out how culture and cultural inheritance can be simplified into instrumental narratives which tend to homogenise the coping mechanisms into a single, technology-driven, and marketable formula, rather than stimulate creative, locally-driven, and

Proceedings

therefore rich in diversity - which is the premise of resilience in the natural world – innovation/retroinnovation [35] to deal with the environmental crisis. This perspective can offer food for reflection - as in the experience of the design workshop - as a reminder of the substantial gap standing between policy statements, design concept, and actual realisation. The case of Hjorthagen sounds as a warning for any proposal to be aware of how delicate the steps from concept to construction are, especially if the many interests that may instrumentalise the design are considered. Being aware that any evaluation must consider such issues, it can anyway be emphasised that the background and overall aim of the proposed *Hazarts* concept arise from quite a different standpoint. Taking a step back from the dominant ecomodernist paradigm [36] and its off-the-shelf solution of a technological fix, its approach is at the same time more modest and more radical, sustained by the belief that, somehow paradoxically, placing human intervention in a humbler position has higher potential, as a strategy, to steer real systemic change. The project suggests to display human vulnerability and interdependence rather than human power to change the environment, aiming at stimulating a creative renewal of ecological relational thinking. Vulnerability, indeed, has been interpreted as a precondition of resilience from a socio-ecological co-evolutionary perspective, where human and non-human systems are considered as related to each other through a continuous reciprocal action-feedback process [37]. Green/ blue infrastructures are seen as part of this struggle to trigger renovated intercourse with natural processes, which rather than controlled or mimicked through engineered solutions are accompanied in their evolution and cyclical change by human care. The design proposal, through the image of a cultural corridor, conveys an idea of connection through culture, an invitation to develop a place-specific – though built dialogically, speaking to and with alternative worldviews – ecological culture, through an unbinding of individual and collective creativity. The meaning of education, in this context, is of a sort of maieutical, active and interactive approach, in contrast to prescriptive one-way educational systems. Flexibility of public space is here key to enable transformative practices. It contributes to inclusion reduction of inequalities, as it turns waterfront space into a safe place for individual and collective creative expression, fostering intergenerational and intercultural handover in space practice and management. Finally, *Hazarts* hopes to inspire a more reflexive attitude towards tangible and intangible inheritance from past generations, with specific attention to the multiple layering of meanings, leaving the question open to collective discussion about what should be transmitted to the future generations and how. A landscape approach, valuing interrelations rather than isolated landmarks may contribute to deeper, more complex and stratified understandings of the role of material heritage, cultural meanings, and creative practices in shaping the ecologies of the future.

Author Contributions

The present paper is a joint work of the two authors. However, paragraphs 1, 3 and 5 were written by Giulia Luciani, while paragraphs 2 and 4 were written by Natalia Chrysikou.

Cities are diverse, complex and dynamic systems. How can we plan them in a resilient direction?

C. Peraboni

Associate professor full time - Department of Architecture and urban studies (DAStU) of Politecnico di Milano, Via Bonardi n.3, 20133, Milano, Italy - E-mail: carlo.peraboni@polimi.it

Abstract

The UN-Habitat's definition of urban resilience refers to "...the measurable ability of any urban system, with its inhabitants, to maintain continuity through all shocks and stresses, while positively adapting and transforming toward sustainability. A resilient city assesses, plans and acts to prepare for and respond to hazards – natural and human-made, sudden and slow-onset, expected and unexpected – in order to protect and enhance people's lives, secure development gains, foster an investible environment, and drive positive change."

In this definition we find three key words (or rather three key concepts) that are extremely simple but at the same time particularly meaningful: assess, plan and act. In the belief that developing a resilient and sustainable city requires a roadmap of actions and activities that are both implementable and feasible, yet precise and ambitious in their expected impacts, the paper seeks to explore how we can use the resilience approach as a catalyst for sustainable urban development.

Through this vision cities can be interpreted as 'evolving places' formed by an intertwined set of structures resulting from diverse and competing forces, cultural and natural, whose patterns vary in response to the specific context. The paper proposes three 'meta'-themes to which to refer our design: Integrated Planning, Resilient Infrastructures and Responsive Preparedness.

And so, we can imagine the resilience like a catalyst for sustainable urban development. It ensures development gains are not lost when cities face shocks and urban residents can flourish in a safe environment while addressing major challenges such as climate change and rapid urbanisation.

Keywords: *responsive preparedness; resilient infrastructures; integrated planning; resilience, complexity.*

1. INTRODUCTION

For centuries, cities have been the context within which people's lives connect with a wide range of human activities, including services, government, education, commerce, markets, finance, etc. Today, they are the dominant way of living also by virtue of the complex processes of urbanisation underway. However, the history of cities has not always been a virtuous and happy story; cities have often been the scene of negative events related to phenomena such as overcrowding, unbalanced resource exploitation and factors critical to human health.

Many of these negative characteristics can be attributed to the difficulties in managing cities, which in turn are due to their high level of complexity [1]. Never before have cities been recognisable as a set of interacting entities and exhibit properties and characteristics that seem to multiply the complexity of the individual elements that constitute them.

Understanding the constituent elements, for example in terms of characteristics or dimensions, is not sufficient to understand cities as a whole [2]. The reflections proposed in this paper start from the awareness that cities are a significant example of a complex system and, consequently, the reflections developed towards understanding complexity methods are particularly relevant for studying them [3]. In recent years, the theme of resilience has spread significantly and has, retraced the trajectories of many other terms that preceded it and which then proved to be only partially capable of providing a

Proceedings

consistent and lasting contribution to interpretation and planning. It is therefore important today to reflect on the specificity of conditions that make the term 'resilience' significantly related to the theme of city planning.

The concept of resilience originates from the study of ecosystems, and its recognition as a characteristic of urban settlement was not immediate; studies related to the calculation of the ecological footprint of the city have highlighted that, compared to a natural ecosystem, urban settlements are characterised by a much more intense metabolism which requires a significant input of energy (currently mostly derived from fossil fuels) and presents a high demand for raw materials to satisfy various human needs. In addition, there is a similarly significant outflow of matter in terms of waste. The city can therefore be studied as a 'resilient urban ecosystem' precisely because it can be described as a complex system of human activities connected with both socioeconomic and biogeophysical processes. [4].

The heterogeneity of definitions of 'resilience' and the complexity of the idea of an 'urban ecosystem' make it particularly appropriate to make an effort of sharing and synthesis among territorial and environmental disciplines, in connection with social and economic ones, which can bring new awareness around a model of urban development oriented towards sustainability.

The concept of resilience has its roots, firstly, in materials engineering and, secondly, in ecological science (but it is often also used in psychology and in numerous other disciplinary branches); its different definitions, as well as their fields of origin and application, are often connected to quite heterogeneous formulations and assumptions, with the result that the term 'resilience' outlines different properties depending on the field of origin and application.

The adaptability of the concept of resilience to different disciplinary contexts results in an articulated series of definitions that can take on different meanings with reference to the scale and complexity of the ecosystem and urban settlement. Holling [5], drawing on a series of research conducted since the 1970s, highlighted three issues that differentiate human ecosystems from other forms of ecosystem organisation: foresight and intentionality, communication, technology. The analysis of these three conditions allowed Holling to construct an interpretative matrix of great interest, functional to framing the characteristics of resilience in ecosystems, economies and institutions.

Statement	Brief Explanation
Multistable states are common in many systems.	Abrupt shifts among a multiplicity of very different stable domains are plausible in regional ecosystems, some economic systems, and some political systems.
Sustainability requires both change and persistence.	We propose that sustainability is maintained by relationships that can be interpreted as a nested set of adaptive cycles arranged as a dynamic hierarchy in space and time.
Functional diversity builds resilience.	Functional groups across size classes of organisms maintain ecosystem resilience.
Emergent behavior emerges from integrated systems.	Linked ecological, economic, and social systems can behave differently from their parts. Integrated systems exhibit emergent behavior if they have strong connectivity between the human and ecological components and if they have key characteristics of nonlinearity and complexity as suggested in the "Rule of Hand."
Is adaptive management an answer?	For linked ecological/social/economic systems, slow variables, multistable behaviors, and stochasticity cause active adaptive management to outperform optimization approaches that seek stable targets.

Table 1 – Selection from the assessments of resilience in ecosystems, economies, and institutions [5]

The characteristics highlighted by Holling, and summarised in Table 1, allow us to fully grasp the meaning of urban complexity in relation to the complexity associated with choosing a resilient approach.

2. THE COMPLEXITY OF THE CONTEMPORARY CITY

The urban system consists of a complex and interconnected network of social, economic, environmental and spatial components that form dynamic relationships and connections within cities and urban areas. These elements contribute to the form, functionality, liveability, and, in general terms, the sustainability of a city.

The population of a city is a dynamic and constantly changing component, constituting a heterogeneous mix of ages, cultures and occupations. In this sense, the built environment defined by architecture, buildings and green and public spaces influences the functionality and liveability of the urban environment. The economic activities of formal and informal sectors drive the financial growth of a city and provide job opportunities. The growth and sustainability of a city's economy are directly influenced by its socio-demographic dynamics and its ability to manage its complexity.

Recent events related to the spatial manifestations of pandemic effects, have highlighted how the social fabric of cities encompasses cultural aspects and social networks that reflect the diversity, richness and uniqueness of urban life. The management and protection of natural resources and the environment within and around a city affect factors such as air quality, water resources, green spaces and biodiversity, which in turn impact the resilience, sustainability and liveability of the city. In this sense, integrated modes of transport and transportation networks within cities ensure mobility and connection through road and rail networks, public transport, bicycles, and pedestrian paths.

A specific consideration must be given to the theme of institutions, local government bodies, administrative frameworks and legal systems that govern cities. Good governance ensures that cities are well-managed and that public services are provided fairly, efficiently, and accessibly. Achieving inclusive, safe, resilient and sustainable cities for all requires local government officials to recognise the interdependence between global goals and local actions and to follow an integrated vision for urban development and resilience building. [6] [7]

This kind of approach requires a paradigm shift in how governance structures are managed not only between national and local governments but also among local governments, communities and private actors. Over the ten years of activity of the Resilient Cities Congress [8], several key governance principles have been identified to guide the way towards a sustainable and resilient future. Among these, creating opportunities to activate constant dialogue between various levels of government, public and private sector actors, representatives from different social sectors and community members is extremely important today.

All these components interact and influence each other within the city ecosystem. They form a complex network of interdependencies and interactions that must be considered in urban territorial planning and policies. Understanding and managing these interactions are fundamental for sustainable urban development and for improving the quality of life, resilience and sustainability of cities.

3. IN SEARCH OF POSSIBLE WORK TRAJECTORIES

The UN-Habitat's definition of urban resilience refers to "...the measurable ability of any urban system, with its inhabitants, to maintain continuity through all shocks and stresses, while positively adapting and transforming toward sustainability. A resilient city assesses, plans and acts to prepare for and respond to hazards – natural and human-made, sudden and slow-onset, expected and unexpected – in order to protect and enhance people's lives, secure development gains, foster an investible environment, and drive positive change."

In these definitions we find three key words (or rather three key concepts) that are extremely simple but at the same time particularly meaningful: assess, plan and act. In the belief that developing a resilient and sustainable city requires a roadmap of actions and activities that are both implementable and feasible, yet precise and ambitious in their expected impacts, the paper seeks to explore how we can use the resilience approach as a catalyst for sustainable urban development.

3.1 Integrated Planning

The history of planning and the strategies adopted by the public sector vary from country to country and are shaped by political contexts and the issues characterising different contexts and historical periods. Initial efforts primarily focused on urban planning to promote the health and safety of urban areas, gradually expanding to the areas surrounding cities experiencing uncontrolled expansion, and subsequently to rural areas experiencing conflicts over different land use needs.

During the 1990s and 2000s, economic development and growth, along with other global challenges, led to negative social and environmental impacts and the emergence, in international policies, of the concept of sustainable development, defined to encompass social, economic and environmental sustainability.

Integrated territorial planning became a tool to contribute to advancing sustainable development goals. This attention, supported by growing environmental awareness regarding natural resource degradation, pollution and challenges posed by climate change, prompted reflection to make planning systems more effective in meeting new needs. This was initially undertaken by European countries, gradually joined by countries from other continents.

Especially since the 1990s, progress in international law, science, technology and governance approaches triggered efforts by countries to revitalise and reformulate their planning systems to better address present opportunities and needs. In particular, two global conventions, the Convention on Biological Diversity (CBD) [9] and the United Nations Framework Convention on Climate Change (UNFCCC) [10], both signed in the early 90's, significantly contributed to directing efforts towards modernising territorial planning systems to incorporate biodiversity and climate change objectives. Both conventions contained goals requiring long-term territorial planning and the need to interact with project scales and different conditions.

Similarly, advances in science and environmental and territorial sensing technologies have significantly expanded knowledge about natural systems and changing environmental conditions, generating new tools for more efficient analysis, monitoring and assessment of environmental conditions supporting territorial planning.

Lastly, awareness has grown around different governance types that contribute to sustainable land, sea and resource use and the importance of good governance principles for decision-making processes, including active and meaningful participation of communities affected by resource use processes. Together, these developments have contributed to stimulating and supporting efforts to modernise planning systems for global and long-term territorial planning, also for biodiversity and climate change. [11]

The distinctive elements that emerge for modern territorial planning differentiate this type of planning from more conventional territorial/urban planning approaches. These are principles and processes that go beyond the typical technical role of the public sector planner oriented towards overseeing and authorising specific development proposals. Key characteristics include a long-term planning horizon divided into short-term (approximately 10-15 years) and medium-term (15-30 years), defining broad visions necessary to adequately address environmental transition-related changes.

Figure 1. - A schematic summary of governance characteristics [11]

Although there is no shared definition of 'integrated territorial planning' another fundamental characteristic common to all experiences is the need for integration between policies and plans at all levels of government and across all sectors at each level. The use of an ecosystem approach is also necessary for effective territorial planning, particularly to reflect the needs for biodiversity and climate change adaptation. The precautionary principle is another central element of territorial planning analysis and decision-making processes; it is essential for addressing the uncertainties and risks that are inevitable when planning for the future, especially for climate change. Finally, territorial planning includes conservation plans of all kinds and also aligns other formal or informal plans that have spatial aspects, including plans for adapting to climate change for building resilient ecosystems. The impacts and transformations generated by human activities on the environment are complex and involve both social and ecological aspects at various scales, generating both changes in social structures and the loss of ecosystem functions. To promote environmentally respectful urban growth, it is necessary to recognise design processes that relate urban, peri-urban and environmental planning, promoting an integrated process that focus on designing alternative urban models more sensitive to the environment (including 'resilient growth', 'low-impact development', 'sustainable cities and communities'). These techniques, increasingly rooted in design disciplines, will be important to spread in all countries, especially in contexts where urbanisation represents a significant share of human settlements.

3.2 Resilient Infrastructures

A second theme of reflection concerns the need to link resilience strategies to an understanding of the vulnerability of infrastructural systems that ensure the functioning of different territorial systems. To improve infrastructure resilience through strengthened governance, it is necessary to understand the value of existing infrastructures, to be able to assess their performance, vulnerability and feasible options to integrate their resilience.

This process also requires building a common understanding of the necessary shift from understanding 'infrastructure resilience' to a project-based approach, based on criteria that can produce 'resilient infrastructures'.

One of the main gaps is the lack of understanding of what it actually means and entails to think about resilient infrastructure in terms of planning, design and implementation strategies. In recent years, through the work carried out by member state delegations, the United Nations Office for Disaster Risk Reduction (UNDRR) has identified some of the main critical issues encountered in the production of resilient infrastructures: among these, the lack of a shared vision of which infrastructures fall within the scope of application; the level of resilience to be foreseen; the definition of minimum levels to ensure the improvement of infrastructure resilience. These elements can vary significantly depending on the country or the infrastructural sector, and therefore the principles for

the preparation of resilient infrastructures must necessarily confront the characteristics assumed by the conception of resilience at the national level, contributing to raising awareness and establishing a common basic understanding, but leaving the specific approach to resilience open and differentiated. The design of resilient infrastructure is generally presented by describing the characteristics of its performance: the ability to prevent, the predisposition to absorb, the capacity to recover and readapt, after the occurrence of traumatic events, in a timely and efficient manner. The experiences highlight that realising resilient infrastructures requires dealing with a multitude of considerations: recognising the changing nature of risks and uncertainties; the increasingly complex nature of multi-risk situations; the need to use transdisciplinary and systemic methods that take into account both the life cycle of the infrastructure and its interdependent and multisectoral nature. [12]

In this context, three different principles emerge that are relevant to the design and management of resilient infrastructures: conscious learning and proactive context, environmental integration, adaptability and capacity for evolution. [13]

Figure 2. - Resilient Infrastructures, the three constitutive components

Conscious learning and proactive context. As previously observed, the complexity and significant connectivity role of infrastructures make it difficult to understand the impact of resilience in infrastructure projects, making it challenging to prevent and absorb critical situations. Therefore, planners need to actively prepare to understand the extent of potential risks to which infrastructures are exposed in order to quickly detect anomalies and enable decision-makers to learn and develop strategies to optimise infrastructure resilience through disaster mitigation and rapid recovery. Conscious learning aims to improve knowledge about vulnerabilities and can therefore support decision-making processes to enhance resilience and make the best use of integrated knowledge systems in the infrastructure planning, monitoring, recovery and learning lifecycle. The results of continuous learning will serve as feedback to support other principles and should be made available to stakeholders involved in the use and management of infrastructure.

Environmental integration. This principle recognises the importance of working in an integrated manner with the characteristics and elements of the natural environment: biological factors (flora and fauna) and physical factors (land, air, water). Integration should take place with the awareness that infrastructure is exposed to various known and unknown risk factors, and that the nature of risks is constantly evolving. The concept of infrastructure must now necessarily be expanded to include aspects related to the immaterial and virtual dimension, while simultaneously including compensatory aspects aimed at identifying the design of 'grey' infrastructure as an opportunity to rethink and re-qualify compromised or marginal bio-ecological cycles. In this sense, environmental integration aims to identify opportunities to work with the natural environment positively, foreseeing reforestation operations to reduce the speed of rainwater run-off and protect critical infrastructure.

Adaptability and ability to evolve. Adaptive transformation is the ability to change the way infrastructural systems are managed, or to modify the desired outcomes of these systems, in response to changes in the broader context within which they operate. This principle recognises that, in a world facing the evolving risk of climate change, the requirements imposed on our infrastructural systems in the future may be different from those imposed on them today. Creating the ability to operate outside of normal conditions enhances infrastructure resilience by absorbing unforeseen events and changing as necessary to maintain operational/service continuity and flexibility. Ideally, infrastructural systems should be developed with this in mind, encouraging stakeholders to incorporate flexibility into supply chains, delivery methods, organisational structures and operational methods, including early warning, evacuation, etc. However, adaptability must go beyond the design phase, being part of a continuous cycle where the results of continuous learning are implemented as changes in infrastructure, management and relevant information systems.

3.3 Responsive Preparedness

A third theme of reflection concerns the topic of responsive preparedness. This theme has become an integral part of the reference framework regarding the issues of resilient city planning in relation to the impact that the painful and tragic COVID-19 pandemic has had on our lives. In that dramatic context, the importance of prevention planning, preparedness and operational and organisational response became evident as essential elements for a rapid and effective response to any type of risk. Emergency management involves managing risks for communities and the environment and concerns emergency services, recognising that in these situations, every individual and organisation potentially has a role to play. This is a theme addressed from different disciplinary fields and, for some years, has only marginally interested city planning.

Of particular interest around this theme is the work carried out since 2011 on responsive preparedness by the Secretariat of the Convention on Biological Diversity, which in 2019 published an educational report aimed at investigating the close interconnections between effective environmental management, the impacts of climate change and disaster responses.

The underlying idea is that risk preparedness requires a more systematic and comprehensive approach, which in the past has been mainly reactive rather than preventive, focused on post-event actions rather than planning and using the natural characteristics of the landscape to prevent disaster risks. This approach, called Ecosystem-based Disaster Risk Reduction (Eco-DRR), is characterised by risk management that incorporates ecosystem management tools, leading to a more innovative and systemic approach to sustainable risk management [14].

The document produced by the Secretariat of the Convention on Biological Diversity defines Eco-DRR as follows: "Ecosystem-based disaster risk reduction (Eco-DRR) is sustainable management, conservation and restoration of ecosystems to reduce disaster risk, with the aim of achieving sustainable and resilient development." [14]

An approach that includes specific attention to community-based responsive preparedness and to the broader general concept of nature-based solutions as ecosystem approaches that specifically address issues of climate change adaptation and disaster risk reduction. [15] [16]

In practice, this approach refers to nature-based solutions, including ecological restoration, integrated coastal zone management, integrated water resources management, green infrastructure and protected area management. The above-mentioned approaches are complementary and focus on developing holistic and integrated ways to improve the resilience of socio-ecological systems, reduce disaster risk and/or help people adapt to change by using ecosystems and biodiversity sustainably. They often emphasise participatory processes and community involvement, which are crucial for enhancing community resilience, improving adaptive capacity and ensuring that local benefits are realised.

It is a resilient sustainability approach that focuses on developing the capacity to address unforeseen changes, such as the impacts of climate change and disaster risk, and involves managing interactions between people and nature as socio-ecological systems to ensure the continuous and resilient provision of essential ecosystem services that provide adaptation and disaster risk functions.

The research report indicates seven key principles in the application of resilience thinking which are the result of a comprehensive review of the social and ecological factors that enhance the resilience of socio-ecological systems and ecosystem services provided; they are derived from work developed by the Stockholm Resilience Centre in 2014 [17] and are:

1. Maintain diversity and redundancy, for example, by maintaining biological and ecological diversity. Redundancy is the presence of multiple components that can perform the same function, and can provide 'insurance' within a system by allowing some components to compensate for the loss or failure of others.
2. Manage connectivity (the structure and strength with which resources, species or actors disperse, migrate or interact across patches, habitats or social domains in a social-ecological system), e.g. by enhancing landscape connectivity to support biodiversity and ecosystem services that contribute to adaptation and risk reduction.
3. Manage slowly changing variables and feedback (two-way 'connectors' between variables that can either reinforce (positive feedback) or dampen (negative feedback) change).
4. Foster complex adaptive systems thinking by adopting a systems framework approach.
5. Encourage learning such as by exploring different and effective modalities for communications.
6. Broaden participation, such as by dedicating resources to enable effective participation.
7. Promote polycentric governance systems, including through multi-institutional cooperation across scales and cultures.

These principles attempt to address the difficulty that 'hard' or engineered approaches have encountered in attempting to reduce the risk of climate impacts and disasters. The evidence is that these approaches tend to address individual hazards, risking increasing long-term vulnerability by not considering future risks or the interaction of multiple hazards. Due to their permanent and inflexible characteristics, these solutions can also become obsolete and ineffective in the face of unpredictable operational conditions.

Climate change impacts and disaster risks extend beyond political boundaries, and examining problems through an integrated or systemic approach can aid in problem solving across sectors and boundaries. Transboundary cooperation can enable the sharing of costs and benefits of adaptation measures and prevent potentially negative impacts of unilateral adaptation measures. Transboundary cooperation can also provide opportunities for socioeconomic development and the management of issues at appropriate ecosystem scales.

Therefore, there is a growing awareness for the implementation of ecosystem-based or hybrid approaches, as the evidence of their effectiveness and their potential to generate multiple benefits is clear.

4. CONCLUSION

In recent years, efforts of transformation towards sustainable development have focused on the urban dimension, with particular attention to technological aspects - as in the European context the Lisbon Strategy: a knowledge-based economy, or the document EUROPA 2020: A strategy for smart, sustainable and inclusive growth [...]. Given that by 2050 two-thirds of the world's population will be urban citizens [...], cities have been entrusted with a key role in combating climate change and developing new smart technologies to improve the availability of data aimed at defining new services for citizens and optimising dedicated infrastructure. This has led to the realization of ambitious experiments with the aim of increasing citizen participation in improving environmental quality standards and overall quality of life. Despite the European Union directing, also with specific regulations, the implementation of a wide variety of projects and models aimed at making cities smart and sustainable, these have not always been adequate and sufficient to achieve the underlying macro sustainability goals.

This approach, exclusive with respect to the totality of the population and territories, has led to a concentration of resources allocated to the implementation of transformative practices, mainly in urban environments of large cities, without taking into account a changed vision of territories, also represented by dimensions related to culture, art, customs and traditions; a vision that considers the spaces perceived by society as material and immaterial infrastructural references which are manifested through the variety of different organisational and technological models; a vision that considers the lived spaces that represent the experiences of every community, which through their interpretation elaborates the categories of its needs: memories, desires, fantasies [18].

In the last decade, we have been conditioned by a vision of urban development understood as a venue for interconnected technological and digital apparatuses, which sees large cities as the only opportunity for transformation, as they are considered the places where the interests and activities of key change actors converge.

We need to rethink all of this. It is necessary to redefine a model of territorial governance that can respond to the needs of an evolved community that is open to cultural processes and impulses and above all, is aware of environmental threats. Integrating SDG localisation paths into an international networking process does not mean concentrating all material and immaterial resources on large cities but indicates the ability to promote a sustainable transformation of the peculiarities that characterise individual communities.

Public spaces: new ways of use

T. Cilona

Department of Architecture, University of Palermo - Italy

E-mail: teresa.cilona@unipa.it

Abstract

The well-being of each individual depends - in addition to the state of physical health - on the possibility of being able to share spaces, moments of sociality, leisure, cultural exchange, capable of constantly renewing the sense of belonging in those places where human beings live and work. Often, however, such places are abandoned in a degradation stratified in time and space, characterised by a dilapidated building stock that should be recovered, valorised and utilised in aggregation facilities and services. In this study we will compare more or less virtuous examples in terms of redevelopment of public urban spaces in order to highlight the gap that exists in the *vision* and *governance* of some Italian territories. The *bad practices* without any planning regulations - certainly not to be repeated - serve as a warning, while the *best practices* described can be used for future redevelopment interventions, to be made effective and close to the real social and environmental needs of the chosen locations. Solutions that remedy problems and critical issues, giving a new meaning and function to public spaces while contributing to people's health, well-being and happiness through a collaborative process that starts from the bottom.

Keywords: *well-being, best practices, participation.*

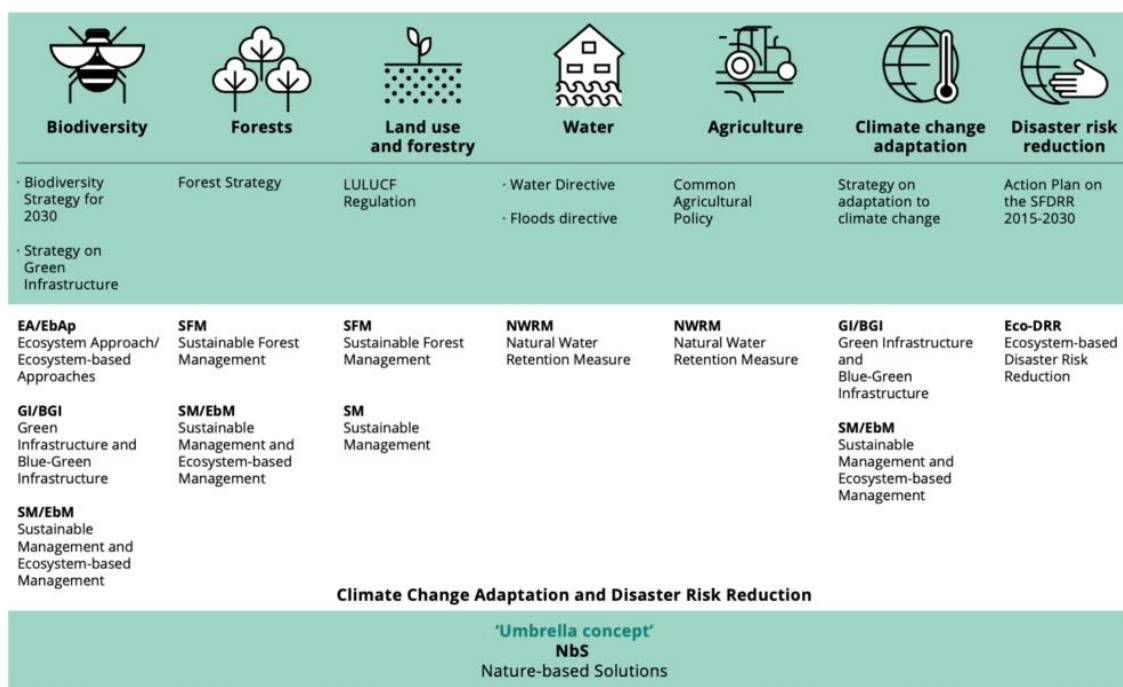

1. INTRODUCTION

Numerous studies on the quality of life in cities show that the behaviour people engage in within public spaces reflect the functions and meanings that define the space itself. In these places, depending on the moment, there is a diversity of moods of the inhabitants - such as dissatisfaction, malaise, restlessness - far removed from the concept of “*feel good*” where the psycho-physical *well-being* of citizens is only guaranteed if they live in cities with resilient and sustainable public urban spaces [6-7]. In recent years, we have witnessed a rediscovery of the role of public space and a growing interest on the part of local governments and the European Union, which are ready to invest economically, and not only, in these areas. The European Union, moreover, recognises that urban areas have a central role to play in combating climate change, as they are the main emitters of carbon dioxide and methane emissions and at the same time have a high fragility and exposure to climate risk. Moreover, cities are already the context in which most of us live, work and study: globally (54%), in Europe (73%) and nationally (75%). For these reasons, it is necessary to focus on strategic actions aimed at containing the consequences - such as floods, inundations, excessive heat waves (adaptation measures) - and reducing the phenomena that cause global warming (mitigation measures). In particular, the granting of economic contributions by the European Community has encouraged redevelopment projects in cities starting with public spaces, considered key elements for the liveability and vitality of inhabited centres as a whole, and lastly - linked to the moment we are living through, characterised by major climate changes that cause floods, inundations, landslides, excessive heat waves, global warming, etc. - the need to give back centrality to urban spaces in order to mitigate the impact of these changes. An effective method for counteracting the adverse effects of a changing climate is the “*technology of nature*” through *Nature-based Solutions* (are actions to protect, sustainably manage and restore natural and modified ecosystems that address societal challenges in an effective and adaptive manner, while providing well-being for humans and benefits for biodiversity) as outlined already in 2000 by the World Conservation Union (IUCN) (Figure 1).

Our cities offer many possibilities for the implementation of these measures, and a particular role is played by public spaces such as gardens, villas and parks, which are common goods that can be acted upon to build climate resilience, thereby increasing people's well-being and safety. It is therefore important to take care of the cities in which we live, produce, consume and move, so that the goals of Agenda 2030 do not remain unfulfilled: make cities and human settlements inclusive, safe, and sustainable (SDG 11); ensure sustainable patterns of production and consumption (SDG 12); promote action, at all levels, to limit the effects of climate change (SDG 13). The Danish architect Jan Gehl - founding partner of Gehl Architects, a research and urban design consultancy specialising in improving the quality of life in pedestrian - and cyclist-oriented cities based in Copenhagen - states "cities for people" are also "climate-proof cities" since most of the measures, certainly the most effective for climate mitigation and adaptation, are based on the reintroduction of nature into urban areas [5]. Nature that makes cities more liveable, healthy, attractive, comfortable and safe. In this study, two different ways of planning cities are analysed. The first, is a virtuous example that comes to us from the Emilia Romagna Region, with the European project "RepublicMed" aimed at identifying the best methodology to initiate a proper redevelopment of public urban spaces thanks to technical-economic studies and planning strategies useful to identify the inefficiencies of the current national planning tools. Interventions that following phases different - knowledge, identification, adaptation and application of the methodology in the chosen area - whose results are analysed and discussed in various meetings and study days in order to achieve collective and participatory sharing.

Figure 1. Nature-based Solutions (Photo by web).

The second case, not very virtuous, certainly questionable in terms of good urban planning practices, concerns the redevelopment project of a municipal green area in the city of Agrigento. The main purpose of *governance* is merely to obtain public funding without considering the negative effect produced, upon completion of the works, on the social, urban and landscape context of the city centre.

Proceedings

of the International Conference on **Changing Cities VI:**
Spatial, Design, Landscape, Heritage & Socio-economic Dimensions

ISBN: 978-618-5765-02-6

A havoc that unfortunately is repeated to the detriment of the city and its citizens who, in the past, have been deprived of another important green area called Villa Garibaldi - built by the Borboni in 1850, demolished and barbarically destroyed in 1949 - to build of inglorious the multi-storey buildings of the modern era of Agrigento [4].

2. THE CASE STUDY OF EMILIA ROMAGNA: A BEST PRACTICE

The Emilia Romagna Region has always been a pioneer in terms of *stop* soil consumption, urban redevelopment, "care" for cultural heritage and the well-being of the community. Already since the 1970s - before and more than other regions nationwide - it has built its cities by guaranteeing green areas, public spaces and services, livable, accessible neighbourhoods capable of stimulating in the population a sense of belonging, with an always attentive eye on territorial problems. This has enriched the concept of urban quality, ecological and environmental quality and, more recently, that of the effects of climate change in urbanised areas and the consequent risks to people and property [8]. The real challenge of the cities of Romagna was to create public spaces suited to the complexity of economic, social, climatic and landscape problems thanks to the inclusion of vegetation, in order to generate well-being, encourage physical exercise, support slow mobility, improve air quality and the mitigation of high temperatures in the summer period. In this scenario, the actions implemented in the cities of Emilia Romagna through the European project RepublicMed - Retrofitting Public spaces in intelligent MEDiterranean cities- developed in collaboration with the Politecnico di Milano and CNR Ibimet in Bologna - have taken on particular importance. The survey conducted here analysed interventions in the cities of Parma, Rimini and Modena where administrations, professionals, scholars and ordinary citizens, using the REBUS® method (REnovation of public Buildings and Urban Spaces, arise in 2015 as an original awareness and training course on climate change issues in an urban environment based on simulation games, characterised by theoretical lectures, field inspections and intensive design workshops) design high urban resilience neighbourhoods, with particular attention to public open spaces. Specifically, in the city of *Parma*, the Pasubio area in the San Leonardo artisan district on the edge of the railway subject to major urban transformations and a participative process for the recovery of the pavilions of the disused "Manzini" industrial area is redeveloped. For the city of *Rimini*, work is carried out in the weekly market area between Gramsci Square, the Roman amphitheatre, the former bus station car park and the AUSA linear park. Gramsci Square is a car park used for the weekly market. Surrounding it are the areas of the (disused) ex-autostation, and the after-work railway car parks, the CEIS kindergarten, the Roman amphitheatre and the AUSA park. With regard to the city of *Modena*, the Villaggio dell'Artigiano (Craftsman's Village) is redeveloped, a manufacturing district on the city's periphery with a post-war urban layout structured by craftsmen's buildings organised through a regular street grid with orthogonal axes (Figure 2) [10, 11, 12]. The final result achieved by the *stakeholders* was the design of the best performing project in terms of urban quality, landscape and thermal comfort of open spaces. The redevelopment takes place through "nature" - reintroduced into the city, not as a simple label or an aesthetic element, but as a concrete objective towards which to strive and which guides all design actions - applying a model in which urban interventions dialogue with each other and they harmonise. The aim was to create public places for meeting, discussion, comparison, spaces that must be reconquered to ensure social, cultural and democratic development thanks to the re-naturalization of the urban environment, the restitution of the naturalistic and historical identity and of the places, the resilience of the neighborhood system, of the return of public spaces to the community, of participation as a paradigm in the construction of the project and in the management of collective works. A praiseworthy path - to be imitated and replicated in other urban realities - undertaken by far-sighted policies where 'man' is placed at the centre of the cities. Moreover, let us recall that Emilia Romagna is the promoter of the project "Let's put down roots for the future - a tree for every inhabitant" - an initiative that aims to extend the wooded area in the Region through the creation of

Proceedings

green infrastructures in the cities to restore the natural ecosystem, create new woods and forest plantations near watercourses, upgrade agro-forestry systems, hedges and rows in a context of landscape enhancement and public use of the territory. It follows that the regional project, which includes the planting of 4.5 million new trees, also plays a key role in combating climate change and improving air quality. After all, we know that we can obtain many benefits from trees, some material, some immaterial, but very valuable. We all know the extraordinary versatility of wood or the possibility of obtaining edible fruits from certain species of trees. Less well known, however, are the intangible benefits such as, for example, the possibility of removing CO₂ from the atmosphere to combat the climate crisis, cooling urban areas in times of "heat islands", making the urban and peri-urban landscape more pleasant, or dampening traffic noise. Planting trees and caring for them means giving better living conditions not only to oneself, but also to all other people, both locally and globally. A very clear concept for the cities of the Emilia Romagna Region, unfortunately not understood in other Italian cities such as Agrigento, the second case study that we will cover in the next paragraph.

3. THE CASE STUDY OF A BAD PLANNING: THE PROJECT OF A GREEN AREA

The term urban redevelopment has been a common expression for some time but its meaning - sometimes - is ambiguous and the definition alone is not enough to understand what an intervention of this magnitude actually consists of. Often it involves putting an abandoned, degraded part of the city back into operation, a complex space, a place of "clashes" and mediations between economic, social and cultural interests that are very different in terms of needs, objectives and ability to influence

urban policies. Local administrators use it to indicate projects with very different characteristics and purposes: renovation of a building, new street furniture in a square, murals in neighbourhoods. Private operators, often together with the administrators themselves, talk about it when they transform public buildings into residential buildings or luxury hotels. Citizens' committees, cultural associations, on the other hand, use this definition when they modify the space in which they act, design a shared living, give new function to the places in which they live by transforming them into spaces of sociality and culture. The most frequent ambiguity is linked to urban policies which define as *urban redevelopment* projects for the renovation and reutilisation of properties or entire neighborhoods - favored by public subsidies - which generate inequalities following *gentrification* processes (process pertaining to urban sociology, which may include the redevelopment and physical change and social composition of marginal urban areas, with often unequal socio-economic consequences). Instead, for good urban redevelopment practice, an *integrated approach* is needed that implements interdisciplinary actions with the involvement of the inhabitants considering three dimensions: the physical, the cultural, the social. And it is precisely starting from this lack of *integrated approach* that we tell what happened in Agrigento for the "so-called" redevelopment project of the *Villa del Sole* to be carried out following a variation to the current urban planning instrument. The Agrigento P.R.G. is from 2009. The Municipal Council, within the framework of the AGENDA URBANA programme - Action 9.3.1 PO FESR 2014-2020, initial amount equal to € 2,100,000.00 subsequently increased to € 3,000,000.00 - proposed a variant to the urban planning instrument for the approval of the final project (first part). The variant, pursuant to Article 19, paragraph 2 of Presidential Decree 327/2001, was favourably voted by the City Council - resolution no. 82 of 26 July 2022 and approved with DDG (Territory and Environment Department) no. 136 of 01.06.2023 - on the basis of the final project only, on which a series of opinions had been rendered by the competent Authorities, including the Superintendence for the BB.CC.AA., which had established precise obligations for the Authority and outlined the characteristics of the subsequent executive project. Contrary to the opinion of the Superintendency, which provided for the preservation and replacement of the greenery, the Municipality of Agrigento divided the final project into two parts and proceeded to draw up the executive project (first part), relating only to the construction of the school building. The area is indicated in the current PRG as sub-area G3 (environmental protection and enhancement - equipped public green areas) and identified in the N.C.E.U. to Fg. 142 parts. 3642.

The green area, located in the city centre, was one of the two largest municipal villas in the city, characterised by a rich tree heritage, which was destroyed to make way for new volumes to be used as a nursery school and kindergarten. The area, over time, has undergone several transformations. Here, in the 17th century, stood a convent for Franciscan monks that belonged to the Diocese of Agrigento, which was transformed into a military district and then barracks in 1872. The building was destroyed in 1943 by Anglo-American bombing during World War II [2 - 3]. For several years, the area remained a place of ruins and rubble until, following the Agrigento landslide on 19 July 1966, the entire area was used to house the tent cities of the disaster victims (Figure 3).

a)

b)

c)

Figure 3. a) “Crispi” Barracks; b) the Barracks are destroyed by the bombings of the Second World War; c) the area is transformed into a tent city (Photo by web).

In 1968, a communal villa called “*Villa del Sole*” was built in that same space and officially opened to the public on 5 August 1973 [4]. Characterized by thick vegetation and a large fountain on several levels - with an adjoining lake - it was enriched in the 70s and 80s with wildlife (peacocks, ostriches, monkeys) and play equipment, becoming a very popular meeting point for families from Agrigento (Figure 4). Today, that green area no longer has greenery [1], almost nothing remains of the lush vegetation that constituted an important part of the city's arboreal heritage (Figure 5). The urban landscape has been brutally impoverished, in order to free up areas for new, intrusive buildings of dubious utility, not least because the city already has unused or underused school buildings. In fact, there are various concerns about the "purpose" of the redevelopment project which, as a matter of practice, should determine a positive impact on the quality of life, on the aesthetic aspect of public space, on the valorisation of urban resources, on the environment and on local economy [1]. In this specific case study, this purpose is unclear, the project would appear to be unsustainable. The survey carried out did not reveal any ISTAT data - indispensable according to urban planning standards - to justify the need, even potential, to build new school facilities for children. The only data relating to sizing are the minimum number (no. 25 children) and the maximum number (no. 28 children) for the nursery; while for the children's center the total number is 60 people (Figure 6) [1]. In addition, research on demographic trends shows that the number of children between the ages of 0 and 6 is decreasing. Numbers that make one think a lot about the project methodology used. On what forecasts, then, was the project based? In proper planning, every intervention in the area is closely linked to the real needs of the community, to the number of people who will use the places and facilities, paying the utmost attention to the surrounding landscape. In the present intervention, on the

Proceedings

contrary, the priority would seem to be only obtaining funding. And again, two very important aspects must be underlined. The first is that among the project documents there is no agronomic study necessary to identify, before cutting, the type of vegetation and the conditions of the individual trees and this in order to confirm their maintenance, or to plan their replacement with new ones plantings. In the executive project, as drafted, there is no trace of work on the public green, because such work was envisaged in the second section, which had never been drafted or approved as of the date of this writing. The second aspect, no less important, is that on 29 November 2023 the local administration inaugurated the start of the works without all the necessary permits being in place. The project lacks landscape authorisation, in accordance with Regional Law No. 5 of 6 May 2019 and Article 136 of the Cultural Heritage Code. The works project - in the order, verified and validated, then put out to tender and contracted, until the delivery and actual start of works on 28 November 2023 - concerns only the kindergarten. On 20 December 2023, the Superintendence warned the Municipality, suspending the newly opened construction site. Work suspended following reports from local citizens' associations opposed to tree felling. On March 26th, 2024 the construction site reopened and substantial excavations and reinforced concrete castings were carried out within the former green area (Figure 7). At this point, questions arise spontaneous. But, in Agrigento, what rules apply regarding urban planning? Why haven't the laws for planning new public works, for managing urban greenery, for limiting or eliminating the consumption of new land, been applied? Why cut trees? Why erect new buildings? Couldn't existing school structures no longer in use be recovered? At the date of writing of this contribution, the citizens is still awaiting an answer to these questions.

Figure 4. *Villa del Sole* - details of the spaces before the intervention (Photo by web).

4. CONCLUSIONS

Sustainable cities must allow everyone to live and inhabit in harmony with nature and the urban landscape, avoiding financial waste, consumption of new land and building speculation to the detriment of the environment [9].

It is necessary to redevelop what already exists, intervening primarily on public buildings - little or badly used - generating new opportunities, as opposed to overbuilding practices which have such a negative impact on the ecosystem.

The case study of Emilia Romagna is emblematic for the sensitivity, interest and vision of the administrations which actively dialogue with all interested parties and coordinate urban redevelopment interventions aiming at the inclusion of greenery - *a tree for every inhabitant* - rather than overbuilding.

For the city of Agrigento - *Capital of Culture for 2025* - unfortunately, this does not happen and new buildings are built instead of trees. For the future of the city, however, we believe that it would be necessary to recover and enhance the properties no longer in use, together with the care, enhancement, conservation and protection of the existing arboreal heritage.

Citizens' use of public open spaces and abandoned buildings, properly rethought and reasoned, would ensure greater liveability. We need a propensity towards *Nature-based Solutions* rather than the use of new volumes, together with a good ability to know how to read and interpret urban contexts.

"...Cities are like books and can be read (...) a city with carefully designed squares and parks creates pleasure for visitors and passers-by, but also for those who live, work and play in the city every day. Everyone should be able to see a tree from their window, sit on a bench near their home with a children's playground or have a park near their home. Well-designed areas and neighbourhoods inspire the people who live in them, while poorly designed and governed cities mistreat their citizens" [13].

But not everyone has an interest and sensitivity for this kind of reading...

Abstract

Public space provides a place for people of different cultures to meet and interact, it is a space where social integration and community cohesion is promoted.

The public spaces regeneration around industrial dismissed areas is a challenge and an opportunity for cities all over the World. These sites, which were once epicentres of industrial activity, are often characterised by environmental degradation and socio-economic problems. However, the regeneration of these spaces offers a chance to transform them into new, vibrant and sustainable places for the community.

The presence of disused industrial spaces can have a significant impact on the surrounding urban fabric, influencing the quality of the built environment and urban infrastructure. The abandoned industrial areas represent a widespread and complex phenomenon both in Italy and in the rest of Europe.

Although widespread throughout the territory, abandoned industrial areas are largely concentrated in the main urban economic centers: in these areas, the crisis of some traditional sectors of industrial production has triggered a progressive degradation, not only on the same production site but also on the immediate built context, eventually affecting the social and economic fabric as well.

This paper aims to carry out an ex-post analysis of some good practices of industrial dismissed area urban regeneration (London, Amsterdam, Rotterdam and Hamburg), focusing on the identification of innovative, sustainable and circular approaches adopted. The aim is to understand how these projects have also had benefits for the surrounding public spaces. The ex-post analysis will be carried out through the recourse to qualitative, quantitative and economic/financial indicators, relating to economic, cultural and environmental project dimensions.

Keywords: *urban regeneration, circular economy, urban spaces, industrial dismissed areas, ex post analysis*

1. INTRODUCTION

Urban spaces play a crucial role in cities, serving as places for meeting, socializing, and cultural activities, as well as green areas that enhance the quality of life for residents. These spaces, which include parks, squares, pedestrian streets, and recreational areas, help promote social cohesion by facilitating interaction among different communities and social groups. Additionally, well-designed urban spaces can foster environmental sustainability by reducing pollution and the urban heat island effect through the presence of trees and vegetation. They also impact the local economy, attracting tourists and stimulating commercial activities. The quality and accessibility of urban spaces are important indicators of the overall city well-being, reflecting the commitment of local administrations to create liveable and inclusive environments for all citizens

Florida (2002) emphasizes how cities with well-designed public spaces attract talent and investment, as such spaces are seen as indicators of a good quality of life [1].

Today, urban regeneration policies should focus on actions to make cities and human settlements inclusive, safe, resilient, and sustainable (Goal 11, Agenda 2030) [2]. According to the New European Bauhaus (NEB), the regeneration of public spaces plays a fundamental role in creating inclusive cities. This document highlights that the design of green areas, parks, and gardens contribute to

ISSN: 2654-0460

ISBN: 978-618-5765-02-6

improving air quality, reducing pollution, and mitigating the effects of climate change, such as the urban heat island effect [3]. The integration of natural elements into public spaces promotes biodiversity and the environmental well-being of cities.

Public spaces should be not only practical but also beautiful, creating environments that inspire and enhance the quality of life for citizens. The architecture and design of public spaces are intended to be attractive, promoting social interaction and a sense of community [3]. The NEB places a strong emphasis on inclusivity, ensuring that public spaces are accessible to all citizens, regardless of age, physical abilities, or socioeconomic background. This means designing spaces that are easily accessible and usable by people with disabilities, the elderly, and families with children. Creating inclusive spaces promotes social equity and community participation. In the context of the NEB, public spaces are seen as living laboratories where new solutions to urban challenges are experimented with. Citizen participation is crucial to the success of these initiatives [3]. Involving the community in the design and management of public spaces ensures that these spaces effectively meet local needs and fosters a sense of belonging and “collective responsibility”. Public spaces play a crucial role in reflecting and preserving the cultural identity of local communities. The NEB encourages the enhancement of cultural heritage through the design and management of public spaces, integrating historical and cultural elements that strengthen the sense of identity and historical continuity of cities [3].

1.1 PUBLIC SPACES IN ABANDONED INDUSTRIAL AREAS

The quality of urban spaces near brownfield sites represents a significant challenge and opportunity for urban regeneration. These spaces, often characterised by decay and neglect, can be transformed into viable areas through targeted regeneration interventions. The regeneration of these areas can significantly improve the quality of life for residents by providing new green spaces, recreational areas and public facilities. Well-planned regeneration initiatives can also foster environmental sustainability by reducing the ecological impact of brownfield sites and promoting urban biodiversity. In addition, the transformation of brownfield spaces into attractive locations can stimulate the local economy, creating new job opportunities and attracting investment.

Therefore, the regeneration of urban spaces around brownfield sites is crucial for the sustainable and inclusive development of modern cities.

The regeneration of abandoned industrial areas offers an opportunity to test innovative and technological solutions for urban development [4]. The implementation of smart city technologies, such as sensors for environmental monitoring, advanced energy management systems and smart mobility infrastructure, can transform these areas into models of sustainability and innovation. Furthermore, the integration of digital technologies in the design and management of public spaces improves the efficiency and quality of urban services.

Many abandoned industrial areas are provided of a significant historical and architectural heritage that can be enhanced through their regeneration. Conservation and adaptive reuse of historic industrial buildings not only preserve historical memory and local identity, but also offer unique and attractive spaces for new activities [5]. Projects such as residential lofts, art and cultural spaces, and centres for technology start-ups can coexist harmoniously with the industrial heritage, creating a dynamic mix of uses and functions.

Disused industrial areas, once redeveloped, can become catalysts for economic regeneration [6]. The development of commercial spaces, offices and cultural centres attracts new economic activities and creates jobs, stimulating the local economy. Furthermore, the valorisation of industrial heritage through cultural and industrial tourism can generate new sources of income for the community [6].

1.2 THE ROLE OF THE CIRCULAR ECONOMY FOR THE REGENERATION OF ABANDONED INDUSTRIAL AREAS

The circular economy plays a crucial role in the regeneration of abandoned industrial sites, offering a sustainable model that promotes the reuse of resources, reduces waste and minimises environmental impact [7]. This approach clearly differs from the traditional linear economy, which has led to resource depletion and increased pollution.

A key aspect of the circular economy in urban regeneration is the reuse and recycling of materials. During the demolition and construction of new buildings, materials such as steel, concrete and wood can be recovered and reused, reducing the demand for new resources and the waste generated [7].

Buildings can be adapted for new uses, such as offices, residences, cultural or commercial spaces, preserving the architectural heritage and reducing the need for new construction. Implementing energy-efficient technologies in converted buildings, such as advanced thermal insulation and efficient heating and cooling systems, reduces energy consumption and CO₂ emissions [8].

Sustainable resource management is essential for the circular economy. Systems for recycling and reusing rainwater and grey water can reduce demand for drinking water and improve water management. The integration of renewable energy sources, such as solar panels and wind turbines, helps reduce dependence on fossil fuels and minimise environmental impact.

The creation of sustainable urban ecosystems, through green spaces, biodiversity and the use of Nature Based Solutions (NEB), is another key element. Indeed, the creation of parks, gardens and green roofs not only improves urban aesthetics, but also contributes to biodiversity, air quality and mitigation of the heat island effect. Urban agriculture, with urban gardens and vertical farms, promotes local food production, reduces the carbon footprint of food transport and improves food security [8].

The circular approach also stimulates innovation and creates jobs in local communities, contributing to long-term economic sustainability [7]. Moreover, the quality of life of residents improves through green spaces and sustainable environments, making cities more liveable and resilient.

In conclusion, the circular economy offers an effective and sustainable framework for the regeneration of abandoned industrial sites, helping to create resilient and liveable cities that meet the environmental and social challenges of the 21st century.

1.3 AIMS OF THE PAPER

This paper aims to carry out an ex-post analysis of some good practices of industrial dismissed area urban regeneration, focusing on the identification of innovative, sustainable and circular approaches adopted. The aim is to understand how these projects have also had benefits for the surrounding public spaces. The ex-post analysis will be carried out through the recourse to qualitative, quantitative and economic/financial indicators, relating to economic, cultural and environmental project dimensions.

2. GOOD PRACTICES OF ABANDONED INDUSTRIAL AREAS

The urban regeneration of disused industrial areas represents a complex and multifaceted challenge for modern cities [9]. These spaces, often characterized by decay and abandonment, offer a unique opportunity to rethink and regenerate the urban fabric, transforming them into vibrant and sustainable neighbourhoods. Regeneration interventions aim not only to reclaim valuable land but also to improve residents' quality of life, stimulate economic growth, and promote environmental sustainability. In this context, it is crucial to adopt an integrated approach that involves various sectors of investment, including infrastructure and transport, commercial and residential spaces, and green and cultural areas. In this paragraph, some urban regeneration projects are examined: Greenwich Peninsula (London), Kop van Zuid (Rotterdam), HafenCity (Hamburg) and Zuidas (Amsterdam). These case studies are concrete examples of how cities can tackle these challenges and transform disused industrial areas into dynamic, inclusive and sustainable neighbourhoods and public spaces.

2.1. GREENWICH PENINSULA, LONDRA, UK

The Greenwich Peninsula, located along the River Thames in southeast London, has historically been an industrial area with activities including gas production and chemical manufacturing. By the 1990s, the area was degraded and underutilized, prompting local authorities and private developers to conceive an ambitious regeneration project to transform it into a new sustainable urban neighbourhood [10].

The Greenwich Peninsula regeneration project is one of the largest in Europe, covering an area of 150 hectares. The vision was to create a dynamic and sustainable neighbourhood combining residences, commercial spaces, offices, cultural facilities, and green areas. The project planned for the construction of 15.000 new homes, the creation of 13.000 jobs, and the attraction of millions of visitors each year [10].

This project incorporates circular economy principles through the use of sustainable and recycled materials in the built environment sector. For instance, in the construction of buildings and infrastructure, low-impact recycled materials were used, such as demolition materials from old industrial structures that were recovered and reused.

The buildings in this project were designed to be highly energy-efficient, reducing energy consumption through thermal insulation, LED lighting, and sustainable heating and cooling systems. The entire area is powered by renewable energy sources, including solar panels on the rooftops of buildings and a biomass plant that provides green energy to the entire area.

Additionally, advanced water resource management systems were implemented, including the recycling of greywater and the collection of rainwater for irrigating gardens and green spaces.

Furthermore, the Greenwich Peninsula adopts an integrated waste management system that promotes recycling and waste reduction. The buildings are equipped with infrastructure for separate waste collection and composting. The adoption of sustainable practices has significantly reduced the area's environmental impact. The use of renewable energy, efficient water resource management, and the promotion of biodiversity have contributed to creating a healthier and more sustainable urban environment. A focal point of the project is the O2 Arena, one of London's premier entertainment venues, hosting concerts, sporting events, and shows. The project included the creation of numerous parks and green spaces, such as Central Park and Riverfront Park, which provide recreational areas and improve air quality and biodiversity. These green spaces are designed to be accessible and inclusive, offering meeting and socializing places for residents and visitors. The project features sustainable connections to central London via a dedicated subway line and the Thames Clippers river service, along with extensive cycling paths, bike-sharing stations, and infrastructure for charging electric vehicles.

The Peninsula hosts cultural and artistic spaces, including art galleries, theatres, and creative studios. The Design District is a new area dedicated to creative enterprises, offering flexible and low-cost workspaces for artists and start-ups.

The regeneration of the entire neighbourhood has created an inclusive environment that promotes social cohesion. Public spaces, parks, and cultural facilities offer opportunities for interaction and community participation.

Finally, the regeneration of the Greenwich Peninsula has stimulated the local economy, creating many jobs and attracting new investments. The presence of new commercial and cultural activities has transformed the area into an attractive destination for both residents and tourist [11].

2.2 KOP VAN ZUID, ROTTERDAM, NETHERLANDS

The port area of Kop Van Zuid is located on the south bank of the Nieuwe Maas river in Rotterdam (Netherlands). The area was historically used as a port and industrial zone, but since the 1970s it started to decay, leaving behind vast brownfield and underused areas. At the end of the 1980s, the

city of Rotterdam decided to redevelop this area to revitalise it and create new opportunities for urban development [12].

The regeneration project of Kop Van Zuid aims to transform the area into a vibrant and multifunctional urban district, combining residential, office, commercial, cultural and recreational spaces. The development plan followed an integrated vision that includes improved accessibility, environmental sustainability and social cohesion.

The principles of the circular economy were incorporated into the project through the construction of new buildings and the reuse of existing ones. In fact, recycled and sustainable materials were used for both types of projects.

The buildings in Kop Van Zuid are designed to be highly energy efficient using advanced energy saving technologies such as thermal insulation, LED lighting and sustainable heating and cooling systems.

An efficient rainwater harvesting system has been implemented and grey water recycled for garden irrigation and non-potable use.

With regard to waste management, specific areas have been created within the district for separate waste collection

The Erasmusbrug Bridge, completed in 1996, is one of the symbols of Rotterdam and directly connects Lop Van Zuid with the city centre [12].

The construction of the De Rotterdam building within this district is an example of a sustainable, circular building. It is a multifunctional complex designed by architect Rem Koolhaas, housing offices, flats, a hotel and retail spaces.

The reuse of the Holland America Line building represents a virtuous case of adaptive heritage reuse. Today it has been converted into a luxury hotel.

The Luxor theatre building is the center of the neighbourhood, a venue for theatre performances, concerts and other cultural events, contributing to the vibrant cultural life of the neighbourhood.

The regeneration of Kop Van Zuid has promoted social cohesion by creating inclusive and accessible public spaces such as parks, squares and pedestrian paths.

The use of sustainable practices and green technologies have reduced the environmental impact of the district, which has become an example of sustainable urban development, improving air quality and urban biodiversity.

The regeneration of the district has also stimulated the local economy. Infact, the area has become an important centre of commercial and cultural activity, enhancing Rotterdam's attractiveness as a destination for business and tourism [13].

Kop Van Zuid has become a hub for innovation and creativity, hosting numerous start-ups, technology companies and coworking spaces. This dynamic environment has attracted young professionals and entrepreneurs, contributing to economic growth and urban innovation.

2.3 HAFENCITY, AMBURGO, GERMANY

The Hafencity waterfront regeneration project is one of the largest urban regeneration projects in Europe, located along the Elbe River in the heart of Hamburg, Germany. This project transformed a disused port and industrial area into a modern multifunctional urban district. Its planning began in the 1990s and the area covers approximately 157 hectares, with a wide variety of uses, including residences, offices, commercial and cultural spaces [14].

The vision of the Hafencity project is to create a sustainable, circular district that integrates modern architecture with Hamburg's maritime history. The plan envisaged and the construction of 6.000 new homes for about 14.000 residents and work spaces for more than 45.000 people [14].

The principles of the circular economy were incorporated into the project through the adaptive reuse of many disused historic industrial buildings. Old warehouses were converted into offices, residences and community spaces, reducing the need for new construction and minimising demolition waste.

The HafenCity buildings are designed to be highly energy efficient, using technologies such as thermal insulation, LED lighting and sustainable heating and cooling systems. The area is powered by renewable energy sources, including solar and wind power, to reduce the carbon footprint. There are also buildings that use geothermal systems for heating and cooling. HafenCity has implemented an advanced rainwater management system, including the collection and reuse of rainwater for irrigation and other non-drinking uses.

The project has promoted integrated waste management that encourages recycling and composting. The buildings are equipped with systems for separate collection and treatment of organic waste.

The district's landmark building is the Elbphilharmonie, an auditorium built on top of an old warehouse. This building combines historical architecture with modern design and hosts concerts, cultural events and offers a panoramic view of the city.

Characterising the area are numerous parks and green spaces, such as the Lohsepark and the Magdeburger Hafen. These spaces offer recreational areas and improve air quality and urban biodiversity.

The parks are designed to be resilient to flooding, a necessity given the proximity to the Elbe River. Adjacent to HafenCity, the Speicherstadt is the largest warehouse complex in the world, with historic buildings that have been preserved and converted into museums, office and retail space. This district is a UNESCO World Heritage Site.

In addition, HafenCity also houses the Science Centre, which promotes science education and research on sustainable innovation. This centre is an integral part of the initiative to make HafenCity a model sustainable and technologically advanced neighbourhood.

The regeneration of HafenCity has created inclusive and accessible public spaces such as squares, parks and waterfront promenades that promote social interaction and community cohesion [15].

Affordable housing has been built to ensure socio-economic diversity among residents.

The adoption of sustainable practices and the integration of green technologies have significantly reduced the neighbourhood's environmental impact. HafenCity serves as a model for sustainable urban development, contributing to climate change mitigation, the promotion of urban biodiversity and the creation of numerous jobs.

2.4 ZUIDAS, AMSTERDAM, NETHERLANDS

Zuidas is a business district located in the south of Amsterdam, the Netherlands between the Amstel and Schinkel rivers. Its transformation began in the 1990s, when the area was mainly occupied by warehouses and small industries [16]. The aim of the regeneration project was to create a modern business district that could compete with Europe's leading financial centres. The vision of the Zuidas project is to develop a multifunctional district that combines offices, residences, retail space, cultural facilities and extensive green areas. The development plan envisages the creation of 270.000 square metres of office space, 50.000 square metres of commercial space and 1.000 new homes [16].

The buildings constructed in this district have been designed to be highly energy efficient, using advanced technologies for thermal insulation, lighting, sustainable heating and cooling systems, sustainable materials

The area is equipped with renewable energy infrastructure, including solar panels and wind turbines. A rainwater harvesting system has been piloted to irrigate all green areas in the neighbourhood.

Mahler4 and Symphony are two office complexes located in the heart of Zuidas, characterised by modern and sustainable architecture. These buildings house major international companies and offer flexible and innovative workspaces. Zuidasdok is an infrastructure project that includes the construction of a new railway station to connect the district with the centre of Amsterdam, street improvements and the creation of public spaces, cultural and recreational spaces, including theatres, museums and sports centres. These spaces enrich the cultural life of the district and offer opportunities

for recreation and entertainment. Parks, squares and pedestrian promenades are designed to be places for meeting and socialising.

The district has become an important financial and commercial centre, enhancing Amsterdam’s attractiveness as a business and investment destination, hosting numerous start-ups, technology companies and coworking spaces [17].

3. IDENTIFICATION OF SECTORS AND INDICATORS TO EVALUATE THE SUCCESS OF ABANDONED INDUSTRIAL AREAS REGENERATION PROJECTS

After an ex post analysis of the good practices analysed in the previous section, the sectors of success in which cities have invested the most, for the waterfront regeneration, according to the principles of the circular economy were identified (Tab. 1)

Investment Sector	Zuidas, Amsterdam	Kop van Zuid, Rotterdam	HafenCity, Amburgo	Greenwich Peninsula, Londra
Infrastructure and Transport	Zuidasdok: railway station and roads improved	Erasmusbrug: bridge for enhanced connectivity	New road and rail infrastructure	Jubilee Line, Thames Clippers: improving connectivity
Offices and Commercial Spaces	Office complexes (Mahler4, Symphony)	Modern office complexes	Modern offices and commercial spaces	Modern commercial and office spaces
Residenzial	New housing, including affordable housing	New housing, including affordable housing	New housing, mix of luxury and affordability	15.000 new houses, mix of luxury and affordable prices
Green and recreational spaces	Parks (Beatrixpark, Amstelpark)	Parks and green spaces	Parks (Lohsepark, Magdeburger Hafen)	PARKS (Central Park, Riverfront Park)
Culture and Recreation	Theatres, museums, sports centres	Luxor Theater, Hotel New York	Elbphilharmonie, Science Center	O2 Arena, Design District
Environmental Sustainability	Renewable energy, water management, waste recycling	Renewable energy, water management, waste recycling	Renewable energy, water management, waste recycling	Renewable energy, water management, waste recycling
Social Cohesion	Inclusive public spaces	Inclusive public spaces	Inclusive public spaces	Inclusive public spaces
Innovation and Education	Spaces dedicated to start-ups and emerging technologies	Cultural and innovative spaces	Science Center, educational spaces	Cultural spaces, Design District

Table 1 Investment sectors of the analysed good practices for the waterfront regeneration

Also, from the ex-post analysis of good practices, a number of possible impact indicators were identified, related to the investment sectors identified in the previous table, that could be used to assess and monitoring the success of good urban waterfront regeneration practices.

Investment Sector	Impact Indicators
Infrastructure and Transport	<ul style="list-style-type: none">- % Reduction in average travel time- % Increase in the number of passengers on public transport- % Reduction in private vehicle traffic
Offices and Commercial Spaces	<ul style="list-style-type: none">- No. of new companies established- Office occupancy rate- % Increase in business volume of local companies- No. of new jobs
Residenzial	<ul style="list-style-type: none">- No. of new housing units built- % growth of affordable housing- Housing occupancy rate- % Resident satisfaction
Green and recreational spaces	<ul style="list-style-type: none">- Square metres of green spaces created or redeveloped- No. of visitors to parks and public spaces- % Improvement of air quality- % Increase in urban biodiversity
Culture and Recreation	<ul style="list-style-type: none">- No. of cultural events and participants- % Utilisation of leisure facilities- % Increase in cultural tourism- % Satisfaction of users of cultural facilities
Environmental Sustainability	<ul style="list-style-type: none">- % Reduction of CO2 emissions- % renewable energy used- % of water recycled and reused- Waste recycling rate
Social Cohesion	<ul style="list-style-type: none">- No. of participants in local activities- N- of community initiatives supported- % Reduction in crime rate- No. of participants in local activities
Innovation and Education	<ul style="list-style-type: none">- No. of established start-ups and innovative companies- % Funding and investment in research and development- No. of collaborative research projects- Rate of participation in educational and training programmes

4. CONCLUSION

Public spaces in contemporary cities play a crucial role in fostering social interaction and a sense of community among residents. These places provide opportunities for recreational and cultural, thereby improving the quality of urban life. Additionally, public spaces contribute to the mental and physical health of citizens by offering green areas for relaxation and exercise. They are also important for environmental sustainability, reducing the impact of urbanization and enhancing biodiversity. These areas promote inclusion and equity by providing access for all, regardless of socioeconomic status. Revitalizing disused industrial areas is essential for enhancing the quality of nearby urban spaces. It transforms neglected zones into vibrant, sustainable neighbourhoods, boosts local economies,

promotes social cohesion, and improves the overall livability of the city. The analysis of best practices has demonstrated the importance of an integrated and multidimensional approach to transforming disused industrial areas into sustainable and vibrant neighbourhoods [18]. These projects not only improve infrastructure and connectivity but also promote economic development, social cohesion, and environmental sustainability. The interventions have focused on key sectors such as infrastructure and transport, offices and commercial spaces, residential, green and recreational spaces, culture and leisure, environmental sustainability, social cohesion, and innovation and education. The use of specific impact indicators allows for measuring the effectiveness of interventions and monitoring progress towards the set goals. Indicators such as the reduction in average travel time, the increase in the number of public transport passengers, the creation of new jobs, and the improvement in air quality are fundamental for evaluating the tangible benefits of site and public space regeneration initiatives. The examined projects demonstrate how well-designed urban planning can lead to numerous benefits, including improved quality of life, neighborhood economic growth, environmental impacts, social cohesion, and more. The regeneration of these abandoned areas within cities makes public spaces more inclusive and promotes interaction among different communities [19]. A planning approach that considers all aspects of urban living, from mobility to sustainability, is essential for creating livable and sustainable neighborhoods. Involving residents and local communities in the planning and development process ensures that local needs and preferences are respected. In conclusion, the urban regeneration projects of Zuidas, Kop Van Zuid, Hafencity, and Greenwich Peninsula represent successful models of how disused industrial areas can be transformed into sustainable, inclusive, and thriving neighborhoods.

How to design flexibility. The challenge of local centralities

V. Crisostomi

Former Director "urban regeneration" PAU Municipality of Rome, contracts at University Rome

E-mail: vittoria.crisostomi@gmail.com

Abstract

Much life of in the city today is immaterial and needs a completely different method of design for actions and physical transformations for the well-being of the settlements.

The best challenge is the theme of local centralities in cities; these are points of accumulation of sociality, of activities surrounding residential life to qualify the daily well-being, but also to support the efficiency and organization of the city as a condition of development.

The common denominator of operations seems to be the word "connect". Connect horizontally by completing the road network and daily services, the continuity of the grid of public spaces. Vertically connect the different scales, in the sense that the centralities have to easily connect to the higher levels of urban benefits. Connect to mobility access nodes of public transport, which take on particular importance. In any place of the immaterial city life, there is a need to strengthen the networks of relationships in multiscale. Therefore, need another design task: "giving meaning to places". Give meaning to the places of primary needs; make sense of the places of connections. They will find must cure the existence of tissues and inhabitants living around and must be treated as a place of civil relations.

Two design imperatives are achieved: to take measures and feasible. Having considered predominantly parts of existing and living cities today, we must think about solutions with the maximum social impact in the shortest possible time, otherwise, citizens will find other ways of satisfying basic needs Only with "tailor-made" measures will adjustments become feasible and credible

Keywords: *urban design, flexibility, local centralities, urban relations, feasibility.*

1.The context and reasons for the problem

The quest for flexibility in urban planning tools today forces us to explore at the same time the strategic side of land governance as well. In fact, in the apparent "city of the eternal present," invisible processes actually flow, and in the seemingly stable life of cities, everything has inexorably changed. Corporate-dimensioned health needs to take the form of neighborhood health homes. It has totally changed the relevance of economic sectors, where platforms, aerospace and medicine have supplanted tourism trade construction. New roles in urban and large-scale logistics emerge. Also changing in parallel are the forms of space occupation that produce empty shells and new locational needs. The invasion of Airbnb, in much of the existing residential, is changing the face of the rental market, the supply in the market, and the profile of possible users. The aforementioned big data in reality is still often reserved only for business operators. The processes of territorialization have changed, in which digitization has expanded the possibility of residence-work distance, with less use of travel and less economic commitment in rentals, forever changing the forms of the compact city. The topical theme since much city life today is immaterial [1] but, invariably, it imposes physical, organizational, and performance actions and transformations for well-being in settlements and overall urban efficiency.

To complicate matters there is also a separation of society [2]. No longer mobile dragnets with a lively social elevator, but in the process of stiffening according to social stratifications. Are elites, the few with other incomes and power; of creative class well-articulated by culture and democracy but

without power or stages from which to communicate; a new form of people, comprising many subsets with service jobs, highly self-centered, which dialogues in very discordant ways and rivulets with power, each for small exclusive benefits.

With evidence, a completely different method of design is required. However, there remains a conservative way of working according to old mental structures and misunderstood approaches to multidisciplinary. It is now impossible to think of the current state as a degradation of the existing. Reality forces one to abandon the old reassuring but sterile paradigms of a depleting world.

It is exactly up to urban planners to do this work of rediscovery, description and design application. The path that is imposed, and attempted to be clarified here, is developed by holding together processes, pulverized social frameworks and new systems of relationships, with the invention of eventual new urban forms. What profiles will the concrete, material and tangible changes have in the now-built but different city where life flows? What actions even on the new systems of relationships that pervade it?

It is quite clear that average quantities, one size for all, typical of the references with which the 20th-century city developed, is no longer possible. One has to operate in a state of continuous tension where everything is variable and everything goes conflictually between polarization and marginality. The urban planner must abandon the certainties of operating correctly by moving in the mediality of urban events. It is no longer possible to use standards, densities, requirements and transportation models, only from a numerical perspective without being reworked from a performance perspective, producing well-being and settlement quality. The kaleidoscope of needs of peripheral situations requires differentiated and specific physical and social policies as well as knowing how to cultivate the places of endogenous organization and stabilization of bottom-up initiatives. (figure 1)

Figure1. Poster: cultivate the places of endogenous organization and stabilization of bottom-up initiatives

These suburbs, on the other hand, as a custom and design response, still receive renovations of isolated buildings and objects without a social project to use them. The Italian PNRR has attempted much in this regard, with little result. [3].

Culture requires transformations as a process that is "given space" between the flow of everyday life and in identity places. Instead, we see solemn forms of self-promotion for a few experts or enthusiasts and only self-centered museums.

Roma Capitale and the Metropolitan Cities are not a game of legal entanglements. Instead, they require the concreteness of a new supra-municipal collaborative form, blocked by a fearful anchorage to old institutional arrangements. Rome has a role as a key Italian node in international competition that needs the armor of consistent places and networks of equipment that no one cares about. Only then can they be clothed with laws and powers appropriate and necessary to the task.

At last, it is well understood that the urban planner is not just the manager of no longer stable locational conveniences or the holder of accounts, laws and quibbles, to which he has too often been relegated, even in favor of extraneous processes and a warped market.

Then what should the work of the planner be today? How to expand the role of architecture of urban facts while maintaining and using technical references and disciplinary knowledge? What do projects look like? What are the paradigms of a new design of the city of the future, already present and operating?

2. THE SEARCH FOR AND CONSTRUCTION OF CONNECTIONS.

We need a controllable path of experimentation that simultaneously captures the every day and the presence of the flowing city. The best-proposed challenge seems to be the path of design, or rather invention and regeneration, of local centralities in cities. The theme of attention to the urban environment is manifested and has long been taken care of all over Europe, pioneer Copenhagen [4], with specific profiles in the different cities and related morphologies of places. Rome in its general plan '08 identified 61 of them as 'the driving nodes of local identity from which the processes of qualification and modernization of the suburbs are triggered' [5] and provided design guidelines for them. Unfortunately, simply zoning for green or services in vacant areas and completion roads, are almost useless guides.

After sixteen years and COVID-19, local centralities are points of accumulation of sociality in local areas, of activities on the side of residential life, which qualify the daily life course. They make it necessary to go beyond the quantitative logic of the standard per inhabitant alone, in order to think about the whole of the functions complementary to residence. They must also offer within them adequate lift facilities for urban functions, the engines of the city's basic economy and development, places of leadership and valuable functions. And down to the building scale, where networked urbanizations are quite different from the current ones, energy communities according to integrated, larger-scale systems, the total reconfiguration of building forms and technologies must necessarily be conceived.

Exactly the intermediate dimension between city and building gives them a role of context and sociality, of local life, all to be explored, and at the same time a gateway to the system of necessary and complementary overall urbanity.

The common denominator of the operations, which are pervasive and essentially related to fostering systems of relationships, seems to be the word 'connect', to be used independently of the areas being planned. "Connect" gives consistency to local centralities, meaning to act to link the quality of life and fluidity of the local settlement system, to connect the interfaces of the local system with the outside, and to soften discontinuities in and between neighborhoods. However, it will also serve to improve not only the settlement quality of everyday local life but also to support the efficiency and organization of the city as a condition for development. The action of connecting in different ways is investigated below.

3. CONNECTING HORIZONTALLY

The initial constraint, which has now become a routine, strong push for smart working, has extended the possibility of efficient working encounters to infinite boundaries, enclosing them in the space of every PC. Instead, it has expanded the need for physical space proximity for many functions of individual service (pharmacy, bank, school, services to the person) before finding also distributed form and less habitual, for lack of time or pandering non-systematic movements. An awareness and aspiration for better well-being has been added, implying a demand for neighborliness that was previously almost absent and often satisfied by simply numerical endowments. The multipolar shape of settlements has also increased a conscious need for prosperity in the less barycentric areas of the city, with a generalized demand for better local settlement quality.

Local centrality has a meaning far removed from shortsighted parochialism or the suggestion of villages. Today, it has a precise depth as an agglomeration of sociality whose need, pre-existing but very clear now, is the search for well-being in the surroundings, given by the specificity of the places, the sense of place, the belonging to the place and the communities present, with attention to the signals and aspirations of the inhabitants [6]. The COVID experience strengthened the richness of non-physical relationships and extended geographical horizons on a global scale. The push towards local relations and use of space would therefore be incomprehensible without the other addendum of connections to long networks and the awareness of inclusion in the flowing life of the city and urban relations. These intangible realities account for the well-being generated by the balance of relationships with everyday places and the communities present there [7].

The subject under discussion of local centralities, far from being theoretical, offers no other form of representation than the drawing and physical image of actual use, which are often used in an immiserated manner. In these cases, the major object of design care must become the space between the buildings, the customs with which they are frequented, the forms of empty space and the modes of use permitted by their size and functional specialization.

Living between buildings, using the space between buildings is exactly where proximity is practiced and local centralities are formed. Many already are and many can become so with proper urban design and codification, [8]. Are they public spaces? Not entirely. Are they the open spaces? Not entirely. They are what contains proximity, identity, and sociality. (figure 2).

Figure 2. The spaces between buildings are what contains proximity, identity, and sociality. Sidewalk, trees, area 30 and shops, it doesn't take much.

Therefore, it is a question of designing spaces with and between buildings. It is necessary to try to make them appropriate to the relationships that normally take place between humans. Relationships specific to each social context, to be dressed in appropriate spaces and modes of use.

Materials are elementary, often neglected in the design of plans and often relegated to an almost derogatory category of 'street furniture' or misunderstandings of 'sustainability' and 'soft mobility'. Local life (of the fifteen minutes?) takes place as a normal extension of individual residence in these space-objects-uses. They are café tables or places for resting, greenways, compatibility with the passage of cars, pavements with the appropriate section, and the life of local commerce.

It must be a cautious search for the congruous dimension of the project and an ensemble capable of forming specialized networks over time [9].

Another requirement for the design of local centralities is not to deal with the leftovers of the built environment. This must be a unified design between spaces and modes of use, introduced in the plans as early as the 1990s, for example with the land morphology design of the plan of Siena. In other cases, such as Rome's plan'08, it gives an all-building and zoning solution for the 61 areas, chosen a priori, with a special I2 elaboration, indicating areas for urban and local services, for public green spaces, for roads far removed from real needs.[10].

To detail the difference, the simplest representation of the comparison of real examples and the ingredients used here. The proximity spaces in the former Fiera di Roma planned and designed in the participation sessions, are compared with the proximity spaces in the recently investigated European Eco-neighborhoods, created with careful planning to recompose environmental resources and urbanization.

The difference in the allocation of vitality and use identified by citizens and interest groups in the former Fairgrounds with the absence of daily life in the eco-neighborhoods, (figure 3a, 3b) even though they are products of famous architects, is quite obvious. "Various eco-neighborhoods [...] focus their design efforts more on the capacity of the solids to accommodate environmental instances and translate them into effective technical devices, relegating the role and character of voids as a structuring element of the urban form to the background, relegating it to a simple spacing element of volumes." [11]. In short, the issue of urbanity must be a primary concern of those who design spaces and neighborhoods.

The design material must be curved to an integrated system of spatial offerings within which processes of sociality take place. Completing the road network and ease of access to everyday services, to which we must add further fluidity of access with paths for soft mobility, for continuity of the network of public spaces, for coherence with natural morphologies, and with present objects or places of identity. Representation must simultaneously account for the objects and practices that can take place in a place, greatly extending the meaning of intended use.

4. CONNECTING VERTICALLY

The topic of relationships does not end on just one aspect. All local systems and centralities demand mobility to points of agglomeration of higher urban functions and urbanity, which makes vertical connectivity indispensable. A connected hierarchical system is a crucial factor in local life: awareness of the urban, its contemporaneity, belonging to a process and ease of access to a conscious journey. Without significant social economic and workplace development, local life also languishes. Proximity is enjoyed in the knowledge that it is part of a larger cycle.

In this vertical access to higher levels, the quality of the journey counts a lot, which should continue the well-being of proximity. Times, interchanges, modes of transport, timetables and connections must be met not by balancing networks but according to complex, non-mechanical user utility functions.

The need is not to connect nodes of a network but to connect people to places with a service of accessibility, of ease of relationship.

This is a topic of particular attention as the city, also as a result of the immaterial, is now taking the physical form of a multipolar organization. It is due very much to the points of exit of the rail transport network, or to the points of arrival of any means of public transport [12]. Are all attractors of new urbanization and functions also outside the compact city, of the confluence of visitors, workers and commuters, supports for additional profits of the real estate market. The classical residence cost - travel cost - time-distance model is more clearly activated and the processes of territorialization change in the built city. The presence or absence of nodes is crucial in the organization of local centralities exactly for the continuous accompaniment of connections and functions, between local systems and the urban system. A station lost in the countryside is not enough to offer an accessibility service, a vertical connection. The same travel comfort must be guaranteed at every point of the urbanized area, even if it is made by different modes and means of transport.

Figure 3a. Spaces and uses in neighborhood buildings Eco quartier BedZED

Figure 3b. Fill the void between buildings

Local systems lacking the organization of proximity and equal connection are called peripheries and not local centralities.

This dual way of fostering connections and interactions has the power to change the attractiveness of many areas of the city and to reintegrate marginal or peripheral situations into the normal cycle of urban life.

5. CONNECTING AT MOBILITY ACCESS NODES.

Until now, in the mobility nodes spaces and functions do not contemplate connections other than according to a multi-directional swarm, in the function of modal exchange. A concept that does not care about any other. In reality, there is a disordered swarming of many functions around, at different hierarchical levels, with poor degrees of care and no organization.

Therefore, interchanges, public rail transport stations, terminuses, and road penetration connection points are of particular importance. In the search for urbanity from local systems to the polarised densification of urban functions, the need to remain connected to the surrounding space remains. "[...] to arrive at a definition of the station as a driver capable of generating and spreading urbanity because within it, but also in its surroundings, the specific functions of mobility coexist and integrate with those of public space." [13] (figure 4) On the one hand, exchanges must continue to offer efficient systems of relations both with other points in the city and in access to the neighborhood networks that surround it. For these, we still see inhospitable places, often neglected, with hybrid forms of detachment from the context, which deserve urban planning control of the node, exchanges and access to surrounding neighborhoods.

On the other hand, building types, local mobility, station access systems, the age framework of the surrounding populations, schooling needs beyond compulsory education, local or specialized services and agencies such as banks or clinics, can define station functions in neighborhoods.

The space of local centralities and proximity must find a way to flow seamlessly into places of exchange.

In built-up areas, an identifiable and continuous intermediate circuit should be identified that gathers, facilitates and organizes local mobility for access to urban-level nodes and networks, and that optimizes possible integrations between transport alternatives. The role of local routes, formerly suffocated by overlapping and conflicting traffic flows for multiple and ambiguous road use, changes dramatically in meaning if they specialize in uses, and connect with continuity without unresolved gaps and unclear outcomes. They assume an integrating role between the fabrics, characterized by soft mobility, attention to continuous public space, accompaniment and enhancement of the ecological network and cultural heritage. Stations seamlessly enter the life of proximity and give meaning to local centralities. Stations from spaces of passage become places of identity for local communities with a process of integration and adduction into the surrounding fabric.

Figure 4. A station without surroundings and a station designed for the continuation of public space

6. SEVEN POINTS OF CONCLUSION.

To meet the challenge of designing flexibly using the case study of local centralities, it is clear from what has been considered so far that the profile of design action and the use of traditional urban planning content and tools changes completely. It should not be kept as the main objective, to provide prosperity and create local urban quality, that of 'accommodation' or 'regeneration'. It is to be followed that of building places for a balance of interactions and human relations in the flow of everyday life, of which hitherto unexpressed needs must be intercepted and satisfied, which are also the result of the new intangible living conditions of the inhabitants [14].

One* Obviously, one should not think of this planning of local centralities as a grand design of urban arrangement that rests on the city. Experience teaches us that places are formed for individual objects, for individual interventions and pieces of infrastructure linked to the often different administrative procedures, to the behavior of the actors and players present, depending on financial bargains and the convenience of profits. The pressures of citizenship are also fluctuating.

The area defined as strategic by Rome's plan, Pietralata/Tiburtina, is covered by no less than seven plans and major implementation projects such as the Tiburtina Station and the Pietralata business district. In addition, there are 4 completion implementation plans, 3 implementation plans under

approval and 1 public program, each revised and updated with variants replicated three to seven times [15]. Reality has taught us that individual interventions or public works such as a pedestrian walkway, a car park, or a road modification, are contained in implementation plans of different origins and duration.

The contributions of each one do not accumulate to the point of identifying an organic design of interventions and works but leave traces of fragments that nonetheless find unexpected coherence, or bad outcomes, given by daily uses and frequentations, and are inserted into the system of proximity. Perhaps, after some time, they will give rise to a unitary entity, rarely fully thought out as envisaged in the plans.

Two* Two design imperatives impose themselves here: measure and feasible.

Often in implementation plans for designing an urban area of normal complexity and with multi-level links, plan construction and representation tend to treat all the transformations necessary to the elements enclosed within the perimeter as fundamental components of the design, as if they all had to be realized together. Reality does not proceed in this way and many plans, the core intervention for which it was drawn up, for which actors and funding were also ready, remains tied to the interests of those who have to implement it, public or private, with indefinite and unfinished timescales. An example of this in Rome is the plan for Giustiniano Imperatore Avenue [16]. In this, having realized the building in compartment A dictated by the emergency, and a hotel that was never completed, the rest remained unimplemented, or could simply be implemented with the general plan regulations. Too many times have we seen phantasmagorical interchanges that have remained unimplemented for decades and phantasmagorical school conversions and completions that have remained abandoned.

Why this waste and overdesign? Much of the urban disorder can be related to these generous efforts of imagination not immediately linked to concrete actions.

Having mainly considered parts of cities existing and living today, solutions with the greatest social impact must be thought of in the shortest possible time. Waiting for implementation plans or variants has often made the effort futile: in the meantime, citizens have found other ways to satisfy their basic needs. Only with interventions 'tailored' to the moment, even changes or adjustments become feasible and credible.

Therefore, the grand design of areas in urban form must remain firmly in place, but with a sense of overall orchestration of operations, policy, of strategy, to maintain the flexibility and adaptability of individual projects to the variability of reality over time. Instead, we are left with a faux dirigisme that is widespread in urban planning language and rarely real in processes. The immediate fallout is that the traditional plan, of whatever scale, soon becomes obsolete. Secondly, the rigid definition of the perimeter of a traditional plan falls away. What is the perimeter of a local centrality if not its uses? And what are the transformations that enable them? The theme must take the form of a series of projects and works, even non-contiguous ones, leading to improvement according to an overall design option, suggested by the design in urban form.

Three* Thus another design task is imposed: 'making sense of places'.

Making sense of the places of connections. The nodes so far exist each with self-centered logic, all exactly inhospitable, with no attention to intermodality. They must not be impervious to the existence of living tissue and inhabitants in their surroundings and must be treated as a place of civilized relations.

Giving meaning to the places of primary needs. In the neighborhoods, in the suburbs, in the smaller centers, the places present for everyone's basic needs must be given a new appropriate and relevant added value as components of settlement quality. [17] Instead, the current poor conditions need physical additions and expansion of functions, good 'connections' in the system to become attractive, to become places in the city, both neighborhood and urban level. Everything should be measured in performance and not in object endowments, as BES variables are now beginning to propose [18].

Four* It is evident that the spatial model of the standards completely changes the references, that the categories of uses need many precise specifications. Measurements in square meters of available areas are to be retained as an orientation of dimensions, but they take on or can take on a whole other form in the areas and also in the built-up area, a whole other framework of possible uses specific to the social frameworks inhabiting the places. It is designed with a huge new abacus of functions, now with almost no difference between public and private, with a network of small functions that maintain everyday life. Green areas must also be immediately usable with continuity, identify and offer planned different ways of use. The measure of quality is not size but performance, continuous and balanced management, integration in space, morphology, and relationship flows.

Five* In reality, this need for points of sociability and a usable system of proximity, the result of the expansion of immaterial relations, is made up of small things but has the power to change the structure of the city. Many of the work actions, prompted by the wide possibilities of connections and networks, have moved out of the dimension of urban life and into workers' homes. Many others, in selective forms, have remained and grown on the urban and metropolitan or territorial scale, still requiring the flow of urban life and mobility as a service. One must abandon the idea of the local as a residue almost on a furniture scale, to admit that the city has a new, additional scale of urban design, that of local systems and centralities.

Six* The importance of public transport stations and terminals as an important interface between two hierarchical levels: local and urban/territorial is emphasized. Together with the space, accessibility maps should be designed, taking into account the points lapped by the urban system, in order to provide locally connected mobility towards gateways to the city.

In built-up areas, an identifiable and continuous intermediate circuit should be identified, which gathers facilitates and organizes local mobility for access to urban-level nodes and networks. The role of local routes, previously suffocated by overlapping and conflicting traffic flows due to the multiple and ambiguous roles of roads, finds forms of specialization and integration. They take on the role of connection between fabrics, between islands, characterized by all possible integrations with soft mobility and pedestrian mobility, attention to continuous public space, accompaniment of the ecological network and usable greenery, attention to places of history and identity. Everything is drawn from the actual design of today's built city, or researched in the planned new islands.

Seven* A project with such content forces a change in the investment model. Targeted and selected local mobility that is efficient and easy to stop at urban nodes implies a change in the direction of investment towards commuter transport and public transport in general. A major stumbling block is coordination with network or utility operators and corporate governance, which should also meet the territorial strategy. Different companies in the city, belonging to different institutional levels, with different interests superordinate to the municipal one, each have their own development policy, which is not always coordinated or integrated with the overall city government policy, except in terms of pricing research in the catchment areas. Finally, yet importantly, it would be necessary to have a precise cross-reference of interventions on technological infrastructures and urbanization for consistency between business and the immaterial city.

Just as much coordination is needed in municipal budgets where each of the small local interventions is allocated to different self-defined competencies or different budget items and with different spending methods. They would require coordination through either integrated programs or robust internal coordination.

The material image of the flow and being between people in places is the result of a complicated equilibrium construction of interactions. The urban planner must enhance the ability to prefigure the effects of a design, while also having technical knowledge that helps to see actions proportionate to needs as far as necessary.

Extended abstract

Talking about public spaces for dynamic urban regeneration in coastal Mexican cities, leads us pose inexorable challenges of a theoretical, methodological and environmental urban planning regarding the implications of sustainability concept and the role of the traditional policy of conservation of natural areas. The environment is subject to multiple pressure factors that threaten the integrity of the ecological processes and determine the urban environmental quality of tourism cities.

The paper addresses the importance of reassessing the role of the conservation of natural areas in the processes of urban regeneration as a premise to move towards scenarios of socio-environmental sustainability in coastal cities. Based on innovative theoretical contributions in the conceptualization of urban sustainability, as related to collective local awareness, the recognition of the socio-environmental value of the territory, sectoral and political administrative schemes, demands a comprehensive, inclusive and perfectible territorialized management.

From this perspective, the scope of the traditional biodiversity conservation policy is analyzed through decrees for the protection of natural areas that seem alien to the intense urban pressures and land occupation coastal cities. New methodologies are explored for the integral territorial analysis of a multidimensional and multiscale nature. All these apply to a concrete experience of the challenges posed by the regeneration of the Estero San José, a strategic area for the Sustainability of the City of Los Cabos, towards a renewed integral vision to the fulfillment of the SDGs.

Estero San José del Cabo, BCS, is the only coastal freshwater lagoon in the State of Baja California Sur, Mexico separated from the sea by a sandy bar. It is an estuarine wetland (coastal oasis) of high biological biodiversity in relation to its size and one of the most threatened by tourism development. Since 1994, it has been declared as State Ecological Reserve, a category Area subject to Ecological Conservation; it has an updated management program in 2004; it is also categorized since 2009 as a Wetland of International Importance by Ramsar Convention, "Riparian System of the San José del Cabo Basin and Estuary". It is an Area of importance for the conservation of birds at the national level because it contains a population of a threatened, endangered or vulnerable species and has been recategorized internationally for containing the most important population of a critically endangered bird species worldwide, "Mascarita Peninsular" (*Geothlypis beldingi*).

Despite existing legal framework for the protection of biodiversity, and despite that Estero San José del Cabo represents a strategic public space for the development of the city, the processes of land occupation in the immediate environment, both for productive activities upstream, and by the direct and indirect impacts of urbanization and beach management, demand innovative proposals. In particular, innovative proposals have to ensure the preservation of the hitherto invaluable ecosystem services provided by coastal ecosystems to advance flexible, resilient and proximity public spaces for dynamic urban regeneration.

Abstract

The new urban issue proposes a concept of 'periphery', no longer understood as a physical distance in opposition to central areas, but as a "transversal condition that includes all those more densely populated areas, where phenomena of degradation, marginality, social discomfort, insecurity and poverty are detectable" These deep changes, result of metropolisation processes lead to significant changes on the meaning of issues related to urban planning, landscape and environment and recall the urgency of implementing policies, strategies, procedures and tools that provide integrated solutions to the instances of environmental, social, cultural and economic regeneration of the city. The research 'Italy and China. Historic infrastructure and ecological networks for an integrated urban regeneration strategy', by the PDTA of Sapienza University of Rome, analysed the relevance of historical-environmental components as reference strategies to trigger urban regeneration interventions dealt with the theme of marginality, integration between different functions and uses of public space and generating unexpected and inter-scalar synergies. Public spaces marked by the presence of linear historical permanences (walls, aqueducts) are characterised by a static/dynamic dual aspect of marginality and centrality: marginality because although maintaining an intrinsic, static, value of memory, they often suffer from neglect and degradation; centrality because the dynamic dimension of the spatial trend characterises their signs as a true 'skeleton' in constant dialogue with urban environment.

Keywords: *Cultural heritage; historic infrastructure; marginal areas; public spaces; urban regeneration.*

1. A NETWORK OF HISTORICAL AND ENVIRONMENTAL NETWORKS FOR REGENERATING THE CONTEMPORARY CITY.

Processes of metropolisation, which have affected Italian and European cities in recent decades, have induced significant transformations in territorial arrangements, just as they have changed the meaning of issues related to town planning, environment and landscape. As a result of these processes, the contemporary city, connoted by a territorially unlimited dimension, is still strongly characterised by the presence of signs of its past (monuments, but also walls, routes, aqueducts, etc.) but presents aspects of strong heterogeneity and fragmentation of the tissues, as well as a structural lack of public spaces. As a result, localised conditions of marginality, social, economic and cultural, and environmental fragility are created, affecting not only the outermost urban areas but also central areas, and fuelling a profound sense of insecurity, often making the identity ties between settled communities and the territory fragile [1].

Furthermore, the new urban question proposes a concept of the 'periphery', no longer understood as a physical distance in contrast to the central areas, but as a 'transversal condition that includes all those more densely populated areas, where phenomena of degradation, marginality, social discomfort, insecurity and poverty are detectable' [2]. These radical changes as a result of the processes of metropolisation [3,4,5] lead to significant changes in the meaning of issues related to urban planning, landscape and the environment and recall the urgency of implementing policies, strategies, procedures and tools that provide integrated solutions to the instances of environmental, social, cultural and economic regeneration of the city [6].

Starting from the structuring character of permanences allows the construction of a network of diversified public spaces capable of reconstituting the relationships between cities and the permanences themselves, in architectural as well as social terms, reconfiguring inhomogeneous and fragmented areas to implement a broader regeneration of the urban form. It also allows for the initiation of new, integrated and inter-scalar strategies of public governance that play an effective directing role aimed at initiating processes of urban regeneration and territorial rebalancing[7].

Regeneration becomes a reference strategy, not only for urban planning, but also for social inclusion and local economic development[8], which assumes cultural heritage as the load-bearing framework in the definition of a new and more balanced territorial arrangement based on a system of networks, both historical and environmental, interactive and integrated, which becomes the framework of coherence of the strategic choices of a contemporary city regeneration process. A process that has as its main objective the priority of the protection and enhancement of cultural heritage common goods, on which to re-found the quality of the urban environment, the historical and cultural identity of communities and the very sense of the collective use of spaces.

In recent years, the new interest in strategies for the valorisation of cultural heritage in the broader sphere of urban regeneration, also in relation to the environment and landscape, has highlighted the convergence of many researches and experiences conducted at national and international level [9]. Researches and experiences that call the attention of a multiplicity of knowledge, and that have produced new points of view, in any case characterised by the tendency to overcome traditional approaches, linked to the concepts of separation and opposition between protection and transformation, in favour of a dimension connoted in terms of integration, interscalarity, interdisciplinarity, iterativity, which restores and is well suited to the characteristics of regeneration strategies [10].

From this perspective, the research '*Italy and China. Historical infrastructures and ecological networks for an integrated urban regeneration strategy*', by the Department of Planning Design and Architectural Technology (PDTA) of the Sapienza University of Rome, has analysed the significance of the historical-environmental components as reference strategies to activate urban regeneration interventions, addressing the issue of marginality, integration between different functions and uses of public space, and generating unexpected and inter-scalar synergies [11].

In the research, historical and environmental networks take on the 'sign' of invariants: naturalistic and anthropic, landscape and historical-documentary permanences and persistences become structuring and structural connotations to configure ecological, green and blue networks connecting components with different levels of naturalness; networks on which to build actions for the regeneration of landscape arrangements in their different structuring, characterising and detailed natural and anthropic components; networks for the valorisation of historical-documentary-architectural emergencies, architectural landmarks, historical paths and routes; morphological networks for the reconfiguration of open spaces, residual and disused spaces, fabrics, marginal constructions.

The methodological approach proposed by the research, starting from a contextualisation of the theme in the contemporary city, allows the regeneration processes to be addressed/pointed to the network of linear permanences (and more generally to a central role of cultural heritage). This contributes to reinforcing the identity ties between settled communities and territories (at the basis of every regeneration process), allowing at the same time a dilation (temporal, spatial and above all of meaning) of the value of the place and a progressive increase of contextualisation from permanence in the surrounding environment. Starting from the structuring character of permanences makes it possible to build a network of diversified public spaces capable of reconstituting relationships between the city and the permanences themselves, in architectural as well as social terms, reconfiguring inhomogeneous and fragmented areas to implement a broader regeneration of the urban form [12]. Permanences, from being marginal elements, become transversal threshold places in urban

environments where to build policies and transformation projects shared between public and private stakeholders, between institutions and citizens and, in particular, to play a leading role based on the awareness of the collective needs and symbolic value of cultural heritage.

2. THE CASE STUDY OF ROME, THE WALLS STRATEGIC PLANNING AREA AND THE WALL PARK

In Rome, the New PRG has represented the framework within which to carry out significant experimentation regarding regeneration of the historical heritage in general and, in particular, of certain distinctive identity signs of historical urban landscape. Among these, the case of the Walls is one of the most interesting because of the opportunities that can be created to reconfigure and re-functionalize them, transforming ‘margins’ of the historic city into a system of public spaces of interface and interrelation at the urban scale as well as at the local scale, also connected to a strong touristic and cultural vocation, participating in the definition of a new urban identity.

Figure 1. Map of Rome by J.L. Gottfried, 1632 (Author's property)

The Aurelian Walls, built in 270-275 A.D. by Emperor Aurelian and elevated by Honorius at the beginning of the Vth century A.D., are still one of the city's most impressive monuments and constitute the largest and best preserved fortification in the classical world. Today, they form a unique archaeological, historical and cultural system, a decisive urban infrastructure for the city's design and identity. They developed for about 19 km around the ancient city (about 13 km remain intact) with a brick structure, about 7 metres high and 3.5 metres wide, with square towers every 100 Roman feet (mt. 29.60); gates flanked by semicircular towers opened at the main streets. In their course they incorporated some important pre-existences such as the Porta Maggiore, the Castrense Amphitheatre, Piramide Cestia, and Castro Pretorio, maintaining their mark and role until the 19th century, even though they contained a much smaller and more concentrated settlement in the bend of the Tiber than the Roman city: some gates were modernised, some passages were introduced to make way for the

new roads (Figure 1.). The city walls still intact and largely walkable today constitute a unique heritage, an identifying sign of the city of Rome which, however, apart from a few individual episodes, has not been integrated with the consolidated urban system and is often not recognised as a resource but as a limit, an obstacle, often impassable, in the texture of relations of the contemporary city. Rome's new PRG (approved in 2008) has recognised in the Aurelian Walls one of the five Strategic Planning Areas, five structuring territorial situations for the requalification of the entire urban organism: 'signs' (natural or anthropic, completely or partially preserved) that have marked the city's development and its transformation plans over time, starting from the assumption 'that there can be no authentic and lasting conservation that does not entail innovative tension, at least in making sense of things' [13].

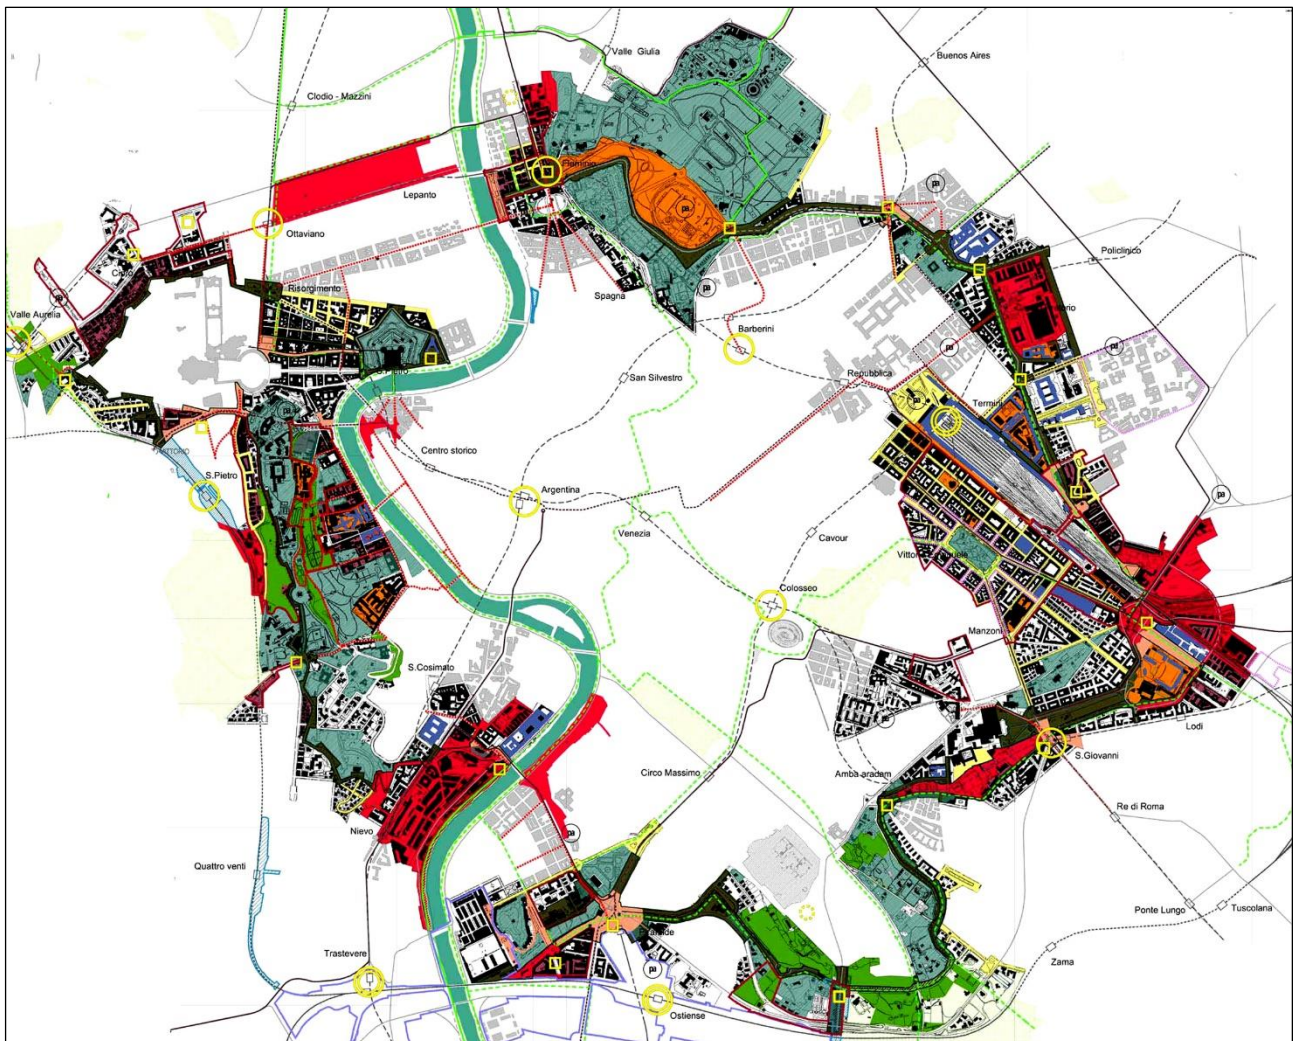

Figure 2. Strategic Planning Walls Ambit, (Author's elaboration on Elaboration I6.2 Objectives, scale 1:10,000, http://www.urbanistica.comune.roma.it/images/uo_urban/prg_adottato/i6_02.pdf)

The Ambits 'include the parts of the City to which the Plan attributes a strategic role' [n], great traces of urban morphology to be valorised according to a framework of coherence and structuring relationships to which general and specific objectives correspond. The Ambit of Walls is made up of the Aurelian, Vatican and Gianicolensi Walls, and is marked by a sequence of gates, towers, bastions, located along the route marked by some important crossings at the consular roads (Figure 2). The city walls represent a fundamental identity component of the city and of the historic territory [14], a sign that requires an overall strategic project of renovation and valorisation, an 'urban structure

Proceedings

of great proportions, capable of constituting a load-bearing framework that reinterprets the historic city itself in the systems of relations between it and the emerging urban configurations' [15] in continuity and coherence with the structural character attributed to the construction of the overall historic-environmental system.

The lines of intervention prefigured by the strategic planning framework of the PRG [16], refer to the construction of an integrated Linear Park of the Walls.

The integrated linear park is, in fact, constituted by the 'artefact' of the Walls and the spaces of its enclave (open spaces, green areas, services, etc.) following a flexible perimeter that privileges the linear continuity corresponding to an idea of overall unity that the Walls themselves give back. The Park is configured as a true public opera project characterised by identity and comprehensiveness. A project that must above all ensure the reconfiguration of a continuous system of public green spaces that articulates the walkability of the entire walled pathway and the re-functioning of the walls and related volumes for cultural and service activities.

From the point of view of 'planning by doing' [17], understood as an approach characterised by experimentation and processuality, aimed at bringing extraordinary procedures back into the Plan's reference contexts (an example of this is the Urban Project as defined in the PRG regulations), the design of the Park involves both already defined parts such as the area between Porta Metronia and Porta Latina (opened in 2009), Porta San Paolo - Via Giotto - Via Guerrieri (2013) and the Gardens along Via Carlo Felice (2020), as well as areas yet to be redeveloped (at Via delle Fornaci, Porta San Paolo and Porta Maggiore - San Lorenzo) [18].

The realisations of the single parts of the Park highlight its enormous potential in terms of preserving historical artefacts, of environmental regeneration and revitalisation within the urban contexts through which it passes, also opening up to new forms of sustainable mobility and collective use of spaces. At the same time, significant scenarios open up for the start-up of potential interventions in the vicinity of the Walls according to an idea of a 'planning conscious of the history of places and attentive to the values of contexts' [19].

3. THE CASE STUDY OF PADUA AND THE LONG WAY TO CREATE THE PARK OF THE WALLS

The case of the Parco delle Mura e delle Acque in Padua proposes an alternative approach to the theme of the regeneration of historical infrastructures.

The proposed way to proceed towards a shared and participatory process towards the construction of a project centred on public space and promotion of innovative uses that are compatible and sustainable with the historical-cultural value of the permanences [20].

The city walls of Padua represent an important documentary evidence of a fortification work of military engineering from the 16th century that has come down to our days, the first one built to defend a large city on the plains, due to the considerable size of the development of the perimeter walls (11,030 km, nineteen bastions and six surviving gates of the original eight) in a complex system composed of historical canals, roads and military areas inside and outside the walls for a total of approximately 1,100,000 square metres. 500,000 sqm.

Luigi Piccinato, in the 1954 PRG of Padua, had already understood the importance of the 16th-century walls and the canal-river system connected to them as an exceptional resource [21], and had drawn a green ring along the esplanade that was never realised, however, due to the strong pressures of settlement. Perhaps the most outstanding example is the construction of the hospital above the walls and the drainage of the Jesuit-San Massimo canal behind the Giustiniano hospital.

We have to wait until the mid-1980s until the idea that the 16th-century walls constitute an enormous resource to be valorised takes hold. In the long process of establishing the Park of the Walls and Waters, the Walls Committee played a fundamental role. The association was founded in 1977 on the

initiative of a group of academics, preservation organisations and simple enthusiasts, with the aim of studying, disseminating knowledge, safeguarding and enhancing the walls of Padua.

The Walls Park project has been pursued since 1986 by the Walls Committee through a design process shared with associations, the IUAV and with the support of the Region, Province and Municipality. The basic idea starts from considering the ramparts as a single system, going beyond the logic of restoration for the purposes of pure conservation. The Project defines a complex system of interrelation between the different values inherent in the nature of the park itself (historical-cultural, architectural, landscape, naturalistic, artistic) articulating differentiated levels of services (public spaces, functions, etc.).

In 2020, also on the initiative of the Walls Committee, the experimentation of a diffuse multimedia museum, MURA VIVE, was carried out, consisting of narrative environmental installations and didactic stations, which envisages diversified and interactive modes of use [22].

Figure 3. home page Mura Vive Padova project, multimedia storytelling museum (<https://www.muravivepadova.it/mura/lemura.html>)

At the same time, thanks to the interest aroused by the MURAVIVE initiative, a group of professors from the IUAV University of Venice and the ICEA and DEI departments of the University of Padua promoted and implemented a project financed with ESF European funds, called PAMU - Multimedia Park of the Walls of Padua, a website dedicated to the knowledge and virtual visit of the Walls complex.

Figure 4. Home page of the Padua Walls Multimedia Park website (<http://www.parcomurapadova.it/#parco>)

In the same years the Land Use Plan of the municipality of Padua, approved in 2014, in line with what is indicated by the Ptcp, precisely because of its circular and continuous shape around the historic centre, assumes the ‘Park of the Walls’ as a strategic hinge and junction between the system of large urban parks and the plot of the ecological network and green and blue infrastructures at the territorial scale. The plan brings into play new forms of planning capable of reinterpreting the identity of places without erasing their historical contextual value, with the aim of restoring ‘the role of contact between the historic centre and the suburbs and of symbol of the union between the different parts of the city’ [23].

The case of Padua allows a reflection on the experiences of ‘regeneration from below’ and on the objective difficulty of launching effective policies for the regeneration of the historical and cultural heritage: if the contemporary city is a complex of articulated, discontinuous and specialised situations [24], the historical infrastructures can play an important role in the construction of projects and paths of social innovation and of integrated and shared management, leading to a gradual process of re-appropriation and re-signification of related urban spaces, at the same time allowing to work on the aspatial dimension and to reconfigure social texture and symbolic values of the territory [25]. Furthermore, regeneration processes have by their very nature a character of complexity and overlapping’ and a “design attitude” (Ingallina 2004) aimed at “measuring oneself against a polyvalent and polysemantic concept of the city” and in which it must be possible to combine different modes of intervention [26].

4. CONCLUSION

In Europe, and even more so in the Italian context, urban regeneration strategies must be confronted with the preservation and transformation of the historical heritage, opening up the possibility to create new synergies between the transformation project and the recovery of identity and historical landscape values, especially for that historical heritage of a linear nature (historical infrastructures) that by its very nature is strongly linked to landscape (in the extensive definition given by the European Landscape Convention) (heritage approach to landscape, [27]). This theme today takes on a strategic and political reference [28] (national, international and community)[29, 30, 31] that is however matched by a plurality of analytical-interpretative and design methodological approaches, both due to the specificity of the geographic-territorial, socio-economic contexts and the relative regulatory frameworks, and due to a convergence, which registers the involvement of different disciplines such as ecology, sociology, history and technology.

The debate was initiated in the 1960s, with the first Gubbio Paper for the Preservation and Rehabilitation of Historic Centres [32], which affirmed the extension of the value of history ‘from the object to the context’, and laid the foundations to define a new approach for the conservation of historical heritage, albeit in a static and not yet processual form. The subsequent Gubbio Charter of 1990 [33] introduces the concept of ‘historical territory’ and proposes the global extension of the principle of conservation, as the true locus of innovation: in this perspective it proposes the passage from ‘conservation’ to ‘conscious transformation’, aimed at the recovery, valorisation, and fruition of the historical cultural heritage.

At the same time, Urban Planning has shown a progressive interest in the role of the cultural heritage not only in terms of conservation but as a strategic component of a heritage-led redevelopment [34] focusing on those parts of the contemporary city characterised by the presence of historical permanences and naturalistic components that constitute structural references for the definition of network systems, historical infrastructures and ecological networks, through a strategy of physical and social reconnection and of triggering new economies aimed at culture and tourism, starting from the awareness of the profound link between the quality of urban contexts and the opportunities for socio-economic development.

This new complex approach to regeneration has allowed for a dilation (temporal, spatial, and above all of meaning) of the historic asset and a progressive broadening of the different disciplinary fronts and approaches related to them. This has led to an evolution of the focus of attention from the monument to its surroundings, to the historic fabric, to the existing city, and to the historic networks that extend across the territory, starting with the urban network that connotes our cities and territories [35].

Dealing today with the issue of the regeneration of territories with high historical infrastructure (walls, aqueducts, routes, etc.) implies a change of approach, methodological and cultural towards a new conception of history: from a “static” merely regulatory logic to a “dynamic” structural-strategic systemic, and processual logic capable of combining in an integrated and interscalar way, the value of preservation with the instances of transformation of these territories.

The aim is to trigger real “processes of consolidation and enhancement of the forma urbis (...) more aware of the history of the places and attentive to the values of the contexts” [36] so that they can actively contribute to the processes of regeneration of the contemporary city: It is thus defined that desired change of sensitivity towards the “past” that starts from the “present” and is intended to define the “future” arrangement of the places through the regeneration of the historical urban heritage.

Abstract

This paper presents a joint research seminar held at the Politecnico di Milano on November 28th, 2023. M. Bradbury, who was in Milan for four months with a NEST fellowship, and C. Pallini collaborated on the seminar, with the contribution of A. Korolija, and E. Margione. The seminar was structured into two sections. The first explored case studies from New Zealand and the Netherlands, offering valuable insights into their climate change resilience strategies. The second section focused on Italy, particularly the Pontine Plain, facing numerous climate-related challenges. Some critical issues were identified during the seminar, such as integrating engineering and landscape design and evaluating alternative scenarios, which are pivotal in climate change resilience. The seminar also underscored the necessity of studying the effects of climate transition on towns, cities, and regions, which presents significant challenges to architectural and urban design across various scales.

Keywords: *climate change; managed retreat; public space; architectural and urban design.*

1. INTRODUCTION

The devastating impacts of climate change, including a surge in flooding incidents, have long been a global concern. In 2023, these concerns were starkly realised as floods wreaked havoc worldwide. New Zealand, for instance, was struck by a catastrophic flood over the Anniversary Weekend in Tamaki Makaurau. Italy, too, was not spared, experiencing two major floods, one in the Emilia-Romagna region in May and another in Tuscany in November. These catastrophic events led to staggering economic losses and numerous casualties, highlighting the urgent need for effective climate change resilience strategies [1]. Against this backdrop, in 2023, the Politecnico di Milano and the Unitec Institute of Technology initiated a joint research project. This was made possible by the NEST funding scheme, a four-month research project run by Matthew Bradbury and Cristina Pallini. The Pontine Plain was chosen as a case study to explore how a managed retreat strategy might help protect towns and cities and productive rural areas. The region extends southeast of Rome between the Volscian Mountains and the Tyrrhenian Sea; it was once a vast wetland, subject to many reclamation attempts since the Roman times until it became a flagship scheme for Mussolini in the 1920s. In 1935, the wetlands were drained, and three new towns were built (Latina, Sabaudia and Pontinia) along with eighteen rural villages and over three thousand farms. Ever since the Pontine Plain has been an experimental modernist landscape, yet, over recent years, the effects of climate change have become more evident. Heavy rainfall in 2018 flooded both Pontina and the surrounding countryside. Heavy rain in March 2021 caused more flooding. A tornado destroyed greenhouses and farms between Sabaudia, Pontinia and San Felice Circeo in September 2022. These events strain the Consorzio di Bonifica del Lazio Sud Ovest drainage canals and pumping station network. Indeed, shortly after the floods of 2019, the local newspaper called for a 'second bonifica', a second reclamation... just as the old project drained the wetland, the future project should prevent future flooding.

The project started with a visit to the Pontine Plain, understanding the region's unique morphology directly, a transect from the Tyrrhenian Sea, the dune, the reclaimed wetland, and the Volscian

Mountains. We consulted with key stakeholders, most notably the Consorzio di Bonifica Lazio Sud Ovest. We planned the seminar by the end of the research period, with the primary objective of investigating strategies for enhancing resilience to climate change, specifically focusing on managed retreat and nature-based solutions. The idea was to explore how these strategies can contribute to developing urban resilience in Italy, particularly in the face of future flooding events. Managed retreat is a strategic response to the effects of climate change that plans the relocation of buildings, infrastructure, and people away from at-risk areas [2]. Nature-based solutions encompass techniques drawn from a study of ecological systems such as wetlands. These solutions can then protect, restore, and sustainably manage the ecosystems [3, 4, 5, 6, 7, 8]. The combination of managed retreat and nature-based solutions may help reduce the vulnerability of citizens to the impact of climate change while enhancing existing ecosystem services and biodiversity. The potential of these strategies to reshape the future of architectural and urban design is immense, inspiring a new era of innovation and resilience in the field.

2. MANAGED RETREAT IN AOTEAROA / NEW ZEALAND

Matthew Bradbury discussed the impact that the idea of managed retreat and nature-based solutions (NbS), has had in Aotearoa, starting with the response to a natural disaster: the Christchurch earthquake of 22 February 2011. This 6.3 size earthquake caused the deaths of 185 people and the destruction of 3500 houses, mainly in the area alongside the Ōtākaro /Avon River, about 1000 ha. To assuage the owners of the damaged houses, the government bought buildings and properties, then demolished and removed up to 8000 homes.

This has been an important precedent in Aotearoa/New Zealand for how the managed retreat process might work for climate change driven events such as the Anniversary Day floods.

Figure 2. Anniversary Day Flooding Tamaki Makaurau /Auckland
(<https://www.youtube.com/watch?app=desktop&v=f4j08NDyNtw>)

The increase in flooding around Aotearoa/New Zealand also pointed to the gap in policy due to lack of an appropriate strategy, the absence of council accountability, and a national planning framework. This has led to the writing of the Report of the Expert Working Group on *Managed Retreat: A Proposed System for Te Hekenga Rauora / Planned Relocation* [9]. This report also pointed to how the current legal authorities and the prevailing land planning system are inadequate to support the effective implementation of Managed Retreat, which implies a significant preplanning phase. Local governments find implementation of such planning challenging for several reasons, including cultural considerations around Māori land. Managed retreat processes are costly, and communities may prefer short-term solutions. The panel makes several recommendations. Firstly, there would be an acknowledgement of Māori rights and interests, then identifying risks using a regional-level risk guide, incorporating both top-down national direction and bottom-up community involvement. Regarding policy direction, the panel recommends formulating a Local Adaptation Plan (LAP) through a new committee comprising iwi, council, and crown representatives. This committee will select the appropriate MR actions for implementation, monitoring, and review. Matthew Bradbury concluded his review by discussed the main ways in which NbS reduced the risk to flood hazards through preserving and allowing room for natural river and floodplain systems and using wetlands to reduce or delay floods by trapping and storing surface runoff [10]. Matthew cited three example of ecological restoration, the Hōteio River restoration, the Waimea Inlet Coastal Wetland Restoration near Whakatū /Nelson , and the Wairio wetlands Lake Wairarapa, that could be used as models for building resilience to the effect of climate change induced events, in particular urban flooding. Dr John Reid, Climate Change Representative for Ngai Tahu, Otautahi/Christchurch Aotearoa/New Zealand, discussed the resurgence of a Māori deltaic culture in urban design. Dr Reid began by describing the pre-Pakeha culture of Ngāi Tūāhuriri in Otautahi/Christchurch, living in a delta. “Ōtautahi was an area flourishing with life: high in mauri. Back then, it was possible to travel in a mōkihi (a canoe woven from flax) from Kaiapoi to Taumutu. And the wisdom of how best to live on the delta is still held by Ngāi Tūāhuriri today.” [11].

ISBN: 978-618-5765-02-6

However, with Pakeha colonisation in the 19th century and the founding of Christchurch in 1848 the deltaic wetlands began to be drained, and a new city was constructed. Ngāi Tūāhuriri were doubly dispossessed of their land through contacts with European settlers and when the rich ecology of islands, wetlands, and rivers were destroyed through reclamation. Dr Reid discussed the implications of the Christchurch earthquake. Damage to buildings through seismic shaking and liquefaction occurred in the areas that had originally been streams and wetlands. In a way, the return of the indigenous landscape in the earthquake foretells what the shape of the city might be with the impact of Climate change and, in particular sea level rise and fluvial flooding.

In a subsequent paper Dr Reid discussed the way in which Climate change presents significant adaptation challenges that pose considerable risks to property, the built environment, and social well-being [12]. This is particularly concerning for Ngāi Tūāhuriri communities, as their homes are in vulnerable areas. The survival of Ngāi Tūāhuriri also depends on sustainable ecosystems. Without effective mitigation and adaptation strategies, the combined impacts of climate change, flood control measures, and intensive agriculture will have cumulative detrimental effects. In the Rokohouia Delta, a significant location in Aotearoa (New Zealand), the whenua of Ngāi Tūāhuriri, the region's indigenous people, employ strategies deeply rooted in their understanding of the interdependencies between humans and ecosystems [13]. Nature-based solutions (NbS), closely aligned with indigenous thinking, are pivotal in mitigating hydro-meteorological risks associated with climate change impacts. Initially, the study explored how indigenous-informed approaches to NbS could lessen climate change risks. However, it revealed additional dimensions. Beyond risk reduction, NbS holds crucial potential for cultural revitalisation and decolonisation. The regeneration of mahinga kai (wild food gathering areas) becomes a powerful tool for addressing long-standing Ngāi Tūāhuriri grievances. These grievances stem from destroying deltaic ecosystems, integral to Ngāi Tūāhuriri culture. NbS doesn't operate in isolation. It complements conventional infrastructure in responding to hydro-meteorological risks. Integrating NbS into decision-making processes enhances social cohesion and promotes ecological consciousness. Dr. Reid finally argued that indigenous knowledge can significantly inform infrastructure choices.

3. THE DUTCH EXPERIENCE

The discussion of how MR and NbS may be integrated was initiated by Anne Loes Nillesen - Professor of Urban Design at TU Delft (Department of Urbanism) who discussed the impact of climate change on the Netherlands, a country with a hyper-engineered landscape. Its low-lying areas were shaped by water and made habitable using terps, dykes, dams, and reclamations, while the peat and clay soils were used for farming and turf production, leaving the higher sections to urbanisation [14]. In some aspects, the Polder landscape can be compared to the Pontine Plain. Nillesen argued that climate change poses system-level challenges and calls for an integrated system approach focusing on soil and water systems, ecological systems, material flows, and logistical networks. Professor Nillesen presented several research-by-design studies from the Netherlands that explore future perspectives for coastal protection, adaptation to more extreme rainfall, deteriorating water quality and subsidence (including MR) for urban and rural areas. Professor Nillesen emphasised the importance of considering the social dimension and reaching a broad consensus when developing strategies to improve urban areas. Professor Nillesen highlighted the importance of collecting and interpreting data, as well as working with local stakeholders in the research and design process. As designers, Professor Nillesen argued, it is crucial to allow for various development perspectives over time in your designs: "We have to know the mechanism, yet our designs should always entail a spatial narrative." [15]

The second Dutch speaker was Remco van der Togt, Senior Landscape Architect with Strootman Landschapsarchitecten and guest lecturer at the Academy of Architecture Amsterdam [16], who discussed space and dynamics: a new Dutch approach to water and climate project in the Netherlands.

Proceedings

From being renowned for their fight against water using engineering, hard materials, and machines, Dutch designers and engineers have revolutionised their approach to water and water safety. The need to “give space to water” has become clear since the 1986 Plan Ooievaar [17]. More recently, the government launched the *Room for the River Plan* (Dutch: *Ruimte voor de Rivier*, 2006-2015) addressing flood protection and the improvement of environmental conditions in the areas surrounding the Rhine, the Meuse, the Waal, and the IJssel. Although the project area is in the Netherlands, its impact extends upstream into Germany, France, and Belgium [18]. *De-poldering Noordwaard* was the largest and most complex scheme of the *Room for the River* programme: about 28 miles of new levees were constructed: high and low, wide, and narrow. And dozens of new bridges, pumping stations and mounds were built. Natural processes are being used, instead of fought against, and water is given space instead of being kept out. Van Der Togt emphasised the importance of thinking out of the box, not fearing loss but believing in gaining something else. He stressed the role that Dutch landscape architects play in addressing current and future water challenges and explored the approaches employed in managing dynamic coastal and fluvial environments by comparing the Netherlands with the Pontine region. Through compelling examples, such as *Room for the River*, and the *Climate adaptation vision for the Wadden Sea coast in the 21st century*, the presentation illustrates an emerging practice that navigates climate challenges, including managed retreat strategies. An increased awareness of the interconnected nature of the problem calls for an increased need to break through traditional disciplinary separations, especially the interweaving of nature and technical know-how, working with hydraulic engineers and landscape architects to understand which buttons to push (water safety, spatial quality, etc.). The result may be a robust, ‘readable’ water landscape for nature to thrive, and for people to live and recreate in, a contemporary take on the century-old pattern of levees and creeks.

4. ITALY, AND THE PONTINE FOCUS

Dr Aleksa Korolija [19] and Dr Emanuela Margione [20] from Department ABC, Politecnico di Milano, talked about the reclamation projects of the Pontine Plane through historical maps. They described how some maps of the Pontine Plain pre-date the invention of topography as a disciplinary field; hence, pre-XIX century maps identify the marshes as a uniform area where no human activities are present. The only plausible reason to map the marshes was that of future reclamation. The speakers argue that this provides a modern researcher with maps of the reclamation attempts depicting a section crossing the plain for the first time and grafting onto the main built points, such as the watching towers and the scattered and poor bridges. Whether totally or partially implemented, the numerous reclamation schemes for the Pontine Marshes have accumulated a considerable mass of

data on each water body's physiology and the waters' origin to be re-routed [21]. Moreover, these schemes had already resulted in a wealth of waterworks and canals, repeatedly altering the natural order of the region: a good paradigm of the fragmented landscape which the Fascist regime wanted to make as homogeneous as possible. In this sense, the history of the Pontine Plain may be understood as a repository of projects, until “integral reclamation” was eventually accomplished in 1935. The conflict between the new towns established by Mussolini (Latina, Sabaudia and Pontinia) and the reclaimed countryside surrounding them made itself felt already after the Second World War when the whole region was subject to development plans by Cassa del Mezzogiorno (Development Fund for the South of Italy).

4.1 Present condition and future challenges

While local experts emphasise the deterioration of water quality and the rise of conflicting water demands for urban uses and agriculture, climate change's effects are becoming more evident. It may suffice to recall the tornado of 29 September 2022, which destroyed greenhouses and farms in the area between Sabaudia, Pontinia, and San Felice Circeo, or the heavy rainfall of March 2021, which caused flooding in several areas, straining the Reclamation Authority's network of drainage canals. At the seminar, Dr. Natalino Corbo, Direttore Generale del Consorzio di Bonifica del Lazio Sud Ovest, spoke about water shortage problems due to reduced rainfall and consequent lower water levels in surface water and central canals. To support the irrigation of the Pontine Plain the Consortium prepared the project “Sistema Integrato Ufente-Selcella-Linea Pio VI,” which includes two closely connected interventions: a weir/traverse on the Ufente River that will create a reservoir of

approximately 700,000 m³, to serve the collective pressure irrigation system and emergency irrigation; an intake structure with a lifting station in the Selcella canal at Migliara 49 left, and a new pressure pipeline which, after crossing the Appian Way, will transfer the flows into the Linea Pio VI canal. This project, showing a traditional engineering approach to the effects of climate change, will be implemented in 12 months and is of fundamental importance for Pontine farmers. A category particularly affected by climate change.

Stefano Conversi, PhD Candidate, Department of Civil and Environmental Engineering (DICA), Polimi, presented GIS mapping of the Pontine Plain. A landcover map shows the prevalent agrarian nature of the region both on the dune and the reclaimed wetland. The Digital Terrain model reveals the topography underneath what seems like an overwhelming flat topography. The blue colour on the DTM shows the area below sea level demonstrating the region's vulnerability to the effect of increasing pluvial and fluvial flooding. The mapping of the natural overland flood path and the artificial drainage system built by the Consorzio di Bonifica is equally revealing of both the natural flows into the areas below sea level, the so-called 'bathtub' and artificial drainage system in this area, including the pumping infrastructure at Mazzochio. The last map shows the extent and severity of future flooding.

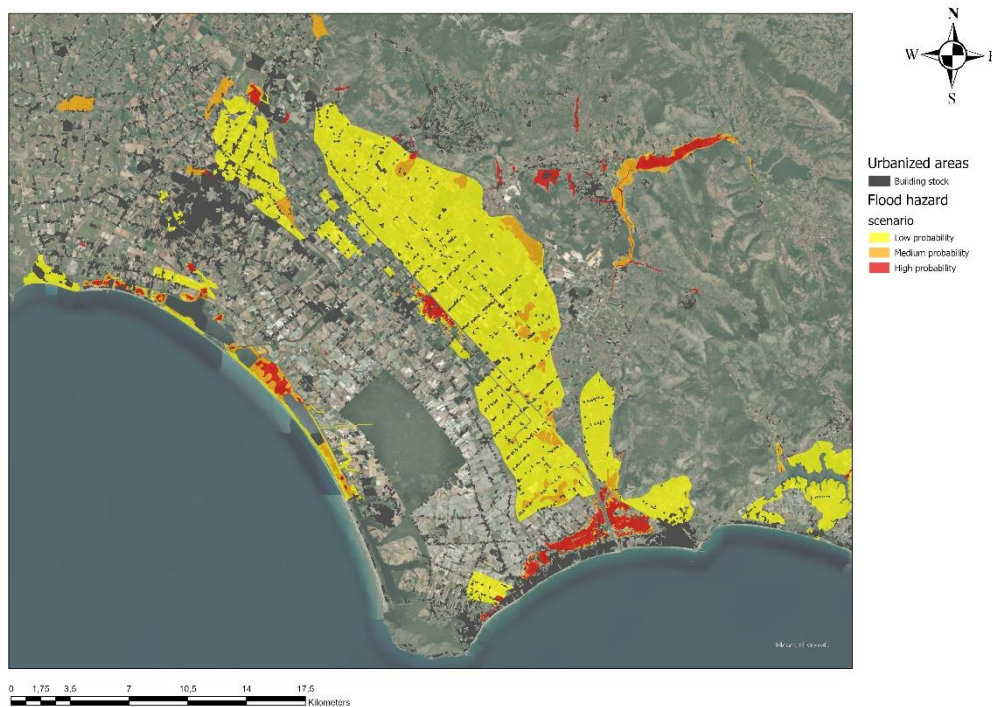

Figure 5: Agro Pontino: Flood hazard map.

Lucia Castellani – PhD Candidate, Department of Civil and Environmental Engineering (DICA), Polimi presented her sea water level rise mapping due to climate change on the Tyrrhenian coast, considering an intermediate climate change scenario from 2050 to 2100. To carry out this analysis, Dr Castellani requested a Digital Terrain Model of the Pontine coastline from the Italian Ministry of Environment, based on which she eventually analysed the current sea level rise considering the mean sea level and the contribution of high tide and storm surge. To conclude, she presented what would be the worst case of high tide and storm surges in 2050 and 2100 and highlighted the potentially submerged areas through ArcGISPro mapping.

Mario Giannini, PhD Candidate Department of Civil, Constructional and Environmental Engineering (DICEA), Università Sapienza, Roma spoke about different approaches to mitigate the probable

effects of Climate Change on the Pontine Plain [22]. Extreme events, such as those in 2018, demonstrate the vulnerability of coastal areas. When a large quantity of water reaches the ground quickly, the current drainage systems cannot convey water to the sea. In addition to the flooding, the same areas are increasingly subject to long periods of drought with consequent intrusion of saltwater into the aquifers and a reduction of freshwater for irrigation use. For these reasons, it is very important to understand the future scenarios due to climate change, to develop systems capable of mitigating and defending these areas from possible floods or droughts. These last three researchers mapped the underlying landscape and infrastructure of the Pontine Plain and, more significantly, the effects of sea level rise and fluvial flooding to highlight the future effects of climate change.

CONCLUSION

The seminar raised a wide-ranging discussion, first and foremost about urban design challenges in a changing climate. The designer's role is often restricted to the essential but limited task of optimally embedding technical interventions.

However, the Aotearoa /New Zealand examples demonstrate how intertwined managed retreat, NbS, and reclamation of indigenous rights can become. The instance of Christchurch serves as one example of how managed retreat, as a response to a natural disaster, might be enacted, the relocation of affected citizens through the paid removal of damaged housing. At the same time, the remaining land has been re-designed as a proactive flood control system using NbS to help protect the city from future flooding, both fluvial and sea level rise. The return of the pre-colonial landscape also offers a potential redress to Ngāi Tūāhuriri. In Dutch experience, we may include considering spatial quality in the regional flood risk management strategy development. The fundamental principle of this approach is the inclusion of a range of interchangeable (effective) flood risk reduction interventions at varying locations so that the criterion of spatial quality can become decisive in flood risk management strategy development.

In parallel, EU policies are targeting long-term strategies to increase the overall quality of the living environment, encompassing the built and the un-built (Towards a shared culture of architecture. Investing in a high-quality living environment for everyone, EU work programme for culture 2019-2022). According to this document, the living environment should empower the legacies of past societies to become part of future collective projections. For architects and designers, this is a call to leave behind self-referential gestures and embrace a thorough understanding of the relationships between identity features, resilience, and transformation scenarios. Moreover, a comprehensive, culture-centred approach to designing the places to live represents a common challenge for different lines of work and expertise. Dutch scholars and practitioners are leading the way in exploring how the climate transition affects towns, cities, and regions, developing design principles and strategies at different scale levels.

Along this line of thought, we could take from the Aotearoa/New Zealand practical solutions for managed retreat and from the Dutch scholars the notion of “technical landscape”, as specific fields of expertise aimed at mitigating the effects of climate change.

Abstract

The sustainable approach to urban renewal is increasingly pressing. Furthermore, for the large cities of Eastern Europe, mainly after 1989, when the territorial re-industrialization and the economic restructuring, led to migration flows and development of city into the surrounding.

Particularly the experience of Budapest is characterized by an urban context typical of Central and Eastern Europe, where is strong the interaction with the housing policy; the urban regeneration was at first restricted to the physical restoration, and only later on involved the social and environmental aspect (Fayman at al 2008; Keresztély, Scott, 2012). The local policies together with the global situation (e.g. the financial crisis) have contributed to shape the Budapest urban quarters that cannot be largely regarded as homogeneous areas (Földi, Kovacs, 2014).

The paper aims at adding a point of view on the case of urban transformation underway in Budapest. At first explores the evolution of the city structure; briefly illustrates the fragmented policies that led to public spaces and housing heterogeneity; by investigation on the new strategic approach to development, and its awareness on social sustainability, describes a social pilot project; finally explores the recent innovative vision for Budapest 2030.

Keywords: urban regeneration, public spaces, sustainability, Budapest 2030, climate change adaptation

1. INTRODUCTION

The sustainable approach to urban renewal is increasingly pressing; given the progressive depletion of energy resources and the need to limit both the environmental impacts and the land use to protect the environment [1,2,3]. In this scenario, the large cities of Eastern Europe, mainly after 1989, had to face the problems of the re-industrialization of the territory and of economic restructuring, all that led to migration flows and the expansion of city into the surrounding countryside [4,5,6]. In particular, the post-socialist countries are passed from an almost well-functioning planning structure to a system with no public coordination where the market actors could almost determine the plan of the city [7,8]. There was a transition from a system highly directed and protected, to one based on international trade, competition and free markets, with the breakdown of the state-led industries. Moreover, the fragmentation of public administration, due to the decentralization, produced new political importance and broader administrative responsibilities for the local governments. The so-called “neoliberal” policies prevail due to the disappeared of the socialism state, which left the ideological vacuum, together with the adaptation to “western” ideas. In this framework it is necessary to consider also the financial crisis and the structural adjustments to enter EU [7,8,9]. Also the brownfields development, in post-socialist countries, has distinctive factors like the military ones that are considered as memento of military sector restructuring [10] or the great amount of rural brownfields as a consequence of downfall of socialist agricultural cooperatives; however the industrial brownfields, still remain the main trouble to overcome in urban environment [11,12,13,14].

Actually, the main transformations of post-socialist cities during the recent twenty years are linked to the city centre and associated to the competition between citizens, investors and developers. In

particular the process of revitalization of the central area of Budapest seems to concern three principal kinds of stakeholders, such as inhabitants, investors and politicians [15].

Particularly, the experience of Budapest is characterized by: an urban context typical of Central and Eastern Europe, where is strong the interaction with the housing policy; the urban regeneration which was at first restricted to the physical restoration, only later on involved the social and environmental aspect [16].

Starting from these premises, the paper will show the case of urban transformation underway in Budapest, the most cosmopolitan and open among the capitals of Central-Eastern Europe, which like other socialist city has undergone great changes, overwhelmed by the market economy and by the values of consumer society.

The rational socialist planning for over 40 years had run the city according to a strict separation of centralized functions, in just ten years has assumed the characteristics of global society, with a new economy and major transformations regarding the organization, the structure and the urban space. The paper will illustrate: the different phases of development; the process of urban regeneration; the transformation expected for Budapest 2030. The conclusion will focus on the first observations concerning the main questions described and on the challenges for the 2030.

2. HISTORY OF THE PLACE

Budapest is the seventh largest city in Europe, created in 1873 with the union of three towns, Buda, Pest and Óbuda, situated on the two sides of the Danube (Figs. 1,2). The city is separate in 23 independent municipal districts, while the agglomerated territory counts 2.4 million population and 104 local municipal councils.

The decrease in urban population started from the 80s, in the 1990s was intensified by suburbanisation, meanwhile the city centre's residents are ageing and decreasing (in the beginning of the 90s the city lost 12% of its population, the periphery gained 16%).

The aggregate employment growth is less than 10% in the period from 1993 to 2011, and the urban performance is weakest among all the major Central and Eastern European cities (except Bucharest). The limited performances are due to an infrastructure deficit, that Budapest is trying to overcome with different projects (transport, etc.), and even if in delay compared to EU competitors there are signals of improvement related to relevant projects.

Nevertheless, Budapest is a strong outsourcing centre however is poor regarding financial services, productivity and foreign investment.

The main part of buildings dates 19th century, while during the interwar period the building constructions were limited, the first housing estates for workers were very poor and prefabricated (from 1960 a peak in 1970). After the political transition, it started a strong involvement of investors from west, south and north of Europe.

At the end of the soviet influence, the administrative decentralization and privatization have encouraged the inflow of foreign capital in the operations of redevelopment and new construction.¹⁷ Such transformation is achieved also through a range of urban projects and financial resources aimed at redesigning the identity of the places linked to the Danube. [17,18]

In the last few years, because of privatisation and European integration, the structure of the city is in continuing development.

As mentioned before, the main part of the buildings of Budapest dates at the end of 19th century, a residential neighbourhood raised around the city centre with buildings of 3-5 floors and inner courtyards (first phase). In this ring, there are also political buildings (Parliament) and cultural institutions (the Opera and museums). At the end of the century, in occasion of the Millennium international exhibition it started the first underground line of the European continent, and to close the city centre were set up Art nouveau buildings.

The second main phase of the development of the agglomeration occurred between the two World Wars, with the great development of industrial sector. In the third phase (socialist state) occurred the main transformations with the policies that push towards industrialisation and the huge migration towards the capital. Finally, in the fourth phase, after political changes of 1989 and 1990, the suburbanisation has a rapid acceleration, so activating a new period in the development of the suburban ring around Budapest [20].

After the political transition and the opening of housing and real estate market, a strong building activity was started in Budapest, in which investors from Southern, Western and Northern Europe were involved. Moreover, even if the central municipality of Budapest declared its political aim to contrast urban sprawl, it is a matter of fact that did not undertaken effective efforts and the suburbanisation has continued to attract part of urban development [20].

The system of privatization of housing, together with the fragmented structure of local government, caused considerable differences in the districts and neighbourhoods regarding the opportunities for urban renewal.

3. THE URBAN DEVELOPMENT STRATEGIES

In Hungary, the urban renewal is a multifaceted notion mainly used for physical regeneration, while the non-material aspects (social, cultural, etc.) are not entirely conceptualised. Only in recent times was introduced the social renewal, in addition to physical one, for the projects aimed at the social and cultural renewal of some neighbourhoods.

The expression “városrehabilitáció” is applied for diverse forms of programmes: entirely private real estate investments in former industrial plants (XIIIth district), the demolition of buildings in historical districts and reconstruction of new ones, more inclusive programmes aimed at the regeneration of an entire neighbourhood (IXth district). Moreover, the significance of “renewal” and “gentrification” are sometimes confused. Formerly gentrification was believed as a good event caused by “modernisation” of deprived urban areas, only recently it is realized that it could be negative [1].

The Municipality of Budapest and its districts have elaborated a number of strategic urban development documents, and all the districts have set up their strategies and rules of urban development.

Nonetheless, the overlapping of competencies and the competition between and within municipalities, especially in light of their endeavour to obtain EU financing hinders all kinds of cooperative planning in the capital.

In Budapest, the urban renewal of central districts has been a political aim only in the 1980s. Some plots had been designated and rehabilitated in the VIIth district and a more complex rehabilitation plan was prepared for the IXth district (middle Ferencváros). These were the first examples of urban renewal that, instead of demolishing run-down buildings replacing them with the construction of prefabricated ones, wished to concentrate on the renewal of existing housing. Following the political transition, urban renewal almost entirely disappeared once again from urban policies.

Figs. 1,2 Budapest, views of the city from the Danubio riverfront (Source: Marichela Sepe's Archive)

Privatisation of housing made the process extremely difficult, as it deprived municipalities of a key tool in terms of renewal, i.e. the property of buildings. Only one rehabilitation programme was launched during the first years of the 1990s, that of middle Ferencváros (Fig. 3). Based on plans prepared prior to 1990, the neighbourhood had already been designated as an area for urban rehabilitation that provided grounds for the local government to obtain exemption from the obligation of privatisation of dwellings.

In that period, in the city a legal framework of urban regeneration was almost absent, and the legal and financial framework of urban renewal was elaborated gradually with the Law on Condominium in 1994, and the official program of urban revitalization in 1996. The launch and implementation of renewal programs involved at first a group that included two districts rather decadent: Ferencváros (District IX) and Józsefváros (District VIII). These two districts were among the first to formulate clear strategies in 1990. The largest part of the housing stock was owned by the state so allowing intervention of local government. There were brownfields that allowed interventions on a large scale, and were established special agencies, for the revitalization based on Private Public Partnership (e.g. the SEM for IX Ferencváros, Rev 8 Józsefváros), that in 1990 had the responsibility of coordinating the process of regeneration in certain sectors of their respective districts. Through these companies, the local government was able to keep an active control on the renovation of old housing stock, while private entrepreneurs have had limited opportunity to enter into the recovery of these neighbourhoods. In the second group of districts it was organized less systematically the process of revitalization, in some way supported by local government measures. This approach is defined as a strategy of "limited support for urban revitalization"]19,20].

Among these neighbourhoods some examples might be identified, such as the "Theatre District" (District VI) where the enhancement has been realized in an integrated way by using the development of local infrastructure (reconstruction of the roadway, development of pedestrian areas, etc.) together with the development of cultural institutions, to increase the attractiveness of the district. In the district, "Middle-Terézváros" (District VI) a public program for the restructuring and conversion of loft was initiated. Furthermore in the "district of the Bar" (District IX) the growing flow of tourists and the growing demand for food services have encouraged the development of an area of bars and restaurants. Similarly, the local authorities of the District VI have supported the private initiatives with additional investments such as the restructuring of the road, the pedestrianization, etc. The examples mostly regard quarters for long time occupied by middle-class, with families mainly older, the buildings are normally renewed by local condominiums, and from outside the private investors play a limited role in the process, for example through sporadic housing projects of new construction. The behaviour of other districts in the city centre on the subject of urban renewal has been passive, relying upon market forces; this kind of strategy of local government - called approach "hands off"²⁰ - relates to the "Southern City Area" (District V), where the local government has developed retail and businesses instead of renovate the residential buildings. Since such renovation of housing is difficult because the vast majority of public housing has become privatized, soon after the regime change. This approach is typical of the districts where the social status of residents is traditionally high, and where the renovation of buildings is a process of self-generation because of the dominance of privately owned apartments and of a relatively high demand of these apartments on the market. The situation of the District VII (Erzsébetváros), in which is located the "Jewish quarter" despite seems to have good opportunities intervention was characterized by an "hands off". The local government here has followed a policy of *laissez faire*, very liberal, providing great opportunities for private investors.

The first strategic document entitled the Urban Rehabilitation Programme of Budapest was prepared, and adopted by the Budapest Municipality in 1997. The objective of the programme was "to help neighbourhoods to maintain and improve their urban values in order to develop their economic potentials and to fulfil their urban functions within the city". In the same year, the Fund for urban

Proceedings

ISBN: 978-618-5765-02-6

renewal of the Budapest Municipality was extended, in order to finance the programmes in the framework of the above-mentioned strategy. In this first period, the urban renewal was limited on the physical renovation of buildings and neighbourhoods. The majority of resources were allocated to the IXth district, and to a lesser extent to other inner city areas, in the Vth, VIth and VIIIth districts.

During the 1990s the available sites in the district have gradually disappeared, for the benefit at first of construction for offices and then of residential buildings. In the early 2000s it was started the demolition of existing buildings, since there were no empty areas for new construction, and the demolition of some buildings of great architectural value has fundamentally changed both the architectural environment that the social profile of the district. After decades of neglect and decline caused by the communist system, now in the city centre of Budapest is more and more evident a process of renewal of the built environment, which is complex and differentiated, leading to increasing heterogeneity of housing (in terms of quality and size), and a new emerging social mix (influx of heterogeneous social groups that coexist with long-term residents) [15].

At the beginning of 2003, the Budapest Municipality adopted its Urban Development Strategy (Budapest Városfejlesztési Konceptiója). The strategy incorporated the principles of the programme on urban renewal, and it was the first official strategic document in Budapest to clearly integrate the idea of sustainable urban and social development.

Preparing for European integration and the changing conditions of urban policies led to the formulation of new principles in urban renewal. New ways of thinking have emerged. On a global level the necessity of social sustainability of urban development is emphasised, in parallel to what emerges as the idea of “social urban renewal”. This new approach was presented in a programme document designating three neighbourhoods subjected to social urban renewal pilot projects. Two of these projects were immediately launched: in Bihari street, Xth district, and in the Magdolna quarter, VIIIth district. Here the renewal was later developed under the form of a long-run pilot project. In the third area, “Dzsumbuj”, located in the peripheries of the IXth district, the aim of the project was altered – the extremely run-down, socially stigmatised branded are going to be demolished. Contrary to a concept of urban renewal limited to the physical revitalisation of urban areas, social urban renewal is focussing on the integration of deprived neighbourhoods through diverse social, economic and cultural programmes, and on the gradual improvement of their physical environment with the involvement and participation of its inhabitants. Social urban renewal became integrated into the mid-term development strategy of Budapest, the Podmaniczky programme, that was adopted in 2005. Apart from social urban renewal, other types of programmes were also developed. Regeneration of public spaces, squares and streets together with the establishment of new cultural and tourism functions became a method applied for the revitalisation of more extended neighbourhoods. Since 2007, in light of the new period of EU programming (2007- 13), urban renewal has been recognised as a major issue in urban projects. In Budapest, the Magdolna quarter has been identified as a pilot project for social renewal, and all municipalities (districts and the Budapest Municipality) are now required to prepare their integrated urban development strategies in order to access resources in the framework of the Regional operative programmes (ROP).

4. REDEVELOPMENT OF DANUBE WATERFRONT

To face with the challenge of management this policy framework, Budapest City Council, on 24 April 2013, set up a long-term urban strategic vision called “Budapest 2030” leading to a 2030 strategic plan with the idea of “Redevelopment of Danube waterfront” and closest urban zone. It is a response to almost 30 years without a vision and a recent lack of resources. It shows the new comprehensive approach to urban development and consists of two main parts: a broad analysis and development topics and actions.

Budapest 2030 identifies four main challenges: territorial competition and cooperation across the EU network; handling climate change with a sustainable economy; overcoming short supply of economic

Proceedings

and development resources; and persistent low employment, combined with an ageing society. Three principles are put forward to respond to these challenges: liveability, which becomes a basic expectation as a part of putting the citizen first; sustainability, which means non-wasteful development that does not compromise future generations; equal opportunities, which refers to fair access to economic and social resources [21].

The concept has a major aim to establish sectorial development strategies according to social, economic and ecological condition, besides ecological and economic previsions.

It consists of 147 actions with 17 possible objectives: 1 Proactive urban development; 2 Government partnership; 3 A coherent Budapest; 4 Strengthening international visibility; 5 Bringing about a healthy environmental condition; 6 Climate protection and efficient energy use; 7 Development of a unique city character; 8 A city living together with the Danube; 9 Efficient and balanced urban structure - compact city; 10 Target brown field areas; 11 Intelligent mobility; 12 Knowledge-, skills and green-based economic development; 13 Self-sustaining urban management system; 14 Conservation and development of cultural diversity; 15 Optimising human services; 16 Flexible housing structure adapted to need; 17 Welcoming society. Among these topics, eight are linked to climate connected issues (from n.5 to n.12).

The actions for adaptation and mitigation in the various development plans and management are many and important in Budapest, which identifies the main challenges and opportunities in view of adaptation to climate change, to make Budapest a city climate resilient [22,23]. Also the commitment of Budapest to face the global crisis is evident in the Budapest 2030 long-term development plan, that pay attention to the social, ecological and economic issues, as to problems related to energy and climate change adaptation [22]. A good example are the projects of energy sustainability that are aimed to reduce energy consumption and emissions of greenhouse gases, but also to re-organize and revitalize the city's economy, its infrastructure and daily life [24,25,26].

5. CONCLUSION

The paper illustrated the process of transformation which is interesting Budapest. Many considerations are useful to understand how urban regeneration process can be improved according to new needs and challenges.

The main part of the buildings of Budapest was constructed at the end of 19th century, and, after political changes of 1989 and 1990, the suburbanisation accelerates rapidly, setting up a new stage in the development of suburban ring around Budapest.

From 1996 to 2002 Budapest started to think strategically at urban regeneration. In 1997 Budapest Municipality elaborated the first strategic plan, “Urban Rehabilitation Programme of Budapest” with the aim “to help neighbourhoods to maintain and improve their urban values in order to develop their economic potentials and to fulfil their urban functions within the city”.

In 2003, Budapest Municipality implemented the Urban Development Strategy, setting up the principles of urban regeneration programme starting to integrate the sustainable and social approach in urban development, that seems to be prepared for European integration.

So, the social urban renewal stressed on deprived neighbourhoods integration trough different social, economic and cultural programmes and citizens engagement in physical revitalisation of the environment. In 2005 this approach was included into Podmaniczky programme, the Medium-Term City Development. Moreover, the revitalisation of neighbourhoods used regeneration of squares, streets and public spaces and established new tourism and cultural functions.

Starting from 2007, the aim of regeneration has been a major issue, also considering 2007-13 EU programming. Magdolna quarter was recognized as a pilot project for social renewal, and districts and Budapest Municipality are currently forced to organize an integrated urban development strategy so to be able of request financing of Regional operative programmes (ROP).

Nowadays Budapest faces an environment with numerous significant challenges together with huge opportunities. In spite of prosperous cultural and creative assets and urban design, the latest economic crisis showed the need of competitiveness, and without a proactive plan it is not assured future growth. There are a diversity of expressed visions and suggestions for urban future; however they need to be transferred in harmonized plans for physical and economic development.

The future urban development is still uncertain, and now Budapest is in a strategic circumstance for developing different drivers that jointly could realize key elements of the new strategic framework for urban development, such as the population growth, new attention on culture and creative industries for urban development, the urban agenda in Europe and EU urban financing, the interest of World Bank and EU on Danube as a strategic level for intervention.

From the analysis of comparative data, Budapest result to have major assets and some good progress examples, although in general it is not getting better in city's comparative position.

To face with the challenge of management this policy framework and to bring forward purposeful urban redevelopment, Budapest set up a 2030 Vision leading to a 2030 strategic plan and a good idea on redevelopment of Danube waterfront and closest urban zone, to start a positive cycle for Budapest development.

The vision for a new positive circle for Budapest could be in the next 10-20 years but it needs a new point of view that must be developed and shared between Budapest City Government and stakeholders. There is the risk of failing in organising around a unique prioritising plan, in place of operating with multiple agendas that generate disorder and fail to activate internal and external resources. Danube is certainly a key catalyst, but it is more important to link it to wider agendas throughout development projects, and key agendas contain competitiveness, liveability, culture, and sustainability.

Regarding collaboration and partnership, the key role at this point is for the City of Budapest which needs to establish much stronger prioritisation and internal coordination of this development agenda. It will also need to establish a Budapest Development Board or Agency to develop a clear programme for the economic and cultural development of Budapest and for brand building and promotion of the city. The City of Budapest must also create a partnership with the districts.²¹

Some authors consider the case study of Budapest a good example of how regeneration strategies are negotiated in the context of post-socialist transformation. This transformation is a clear case of globalization and adaptation of urban development in logics oriented by market. The example of consolidation strategies in Budapest highlights many of the contradictions linked to the achievement of socially sustainable regeneration strategies and integrated in the post-socialist countries. Weak levels of state intervention, institutional fragmentation, and powerful market incentives to promote a speculative redevelopment tend to hinder the emergence of an effective social dimension. In Budapest there are processes of experimentation within a political space characterized by: market-led redevelopment, administrative fragmentation, autocratic style of government and new multi actor approaches, partly funded by the European Union, the socially inclusive regeneration.⁹ Following the regime change, in the metropolitan region of Budapest, the socio-spatial differentiation is started. The process of diversified urban development is the result of the existing different local structures, with the legacies of the past work and new regulatory environments (local urban policies, free market, etc.). With the post-socialist transition, the localization preferences of the main stakeholders (residents and investors) are changed causing a rapid change in the path of individual urban areas: the rediscovery of the city center, a slow and steady improvement of the historic residential neighborhoods, the gradual social erosion of residential areas, decline and subsequent reinvestment in brownfield, and an explosion and then stagnation in the peripheral areas. Finally, local forces increasingly influence urban development and the city's future appears to depend on the sum of the efforts, investments and quality of change of its neighborhoods.

Extended abstract

Contemporary cities face constant pressures from economic development, population growth, service diversification, as well as natural and anthropogenic risks. In this context, achieving sustainability and resilience in the built environment requires effective management through procedural, administrative, and legislative interventions.

An individual, a social group, and a community of people live objectively in a space that changes physically through remodeling, while simultaneously determining a new subjective perception of it. This dynamic turns space into a renewable resource both materially and spiritually, but especially emotionally. Master-planning space and its affective design create the identity of territories which generates stability. It is what makes the difference between existence itself (Sein) and living in itself (Da Sein) according to Heidegger (1927).

For a given space to become resilient, it must always be a space capable for people to live in by adjusting space according to their needs and aspirations or by adjusting space to certain purposes. Do we need to permanently reconfigure the space where we live in or not? To what extent do we keep certain permanencies or solidities? Looking back at urban history, space offers us personal identity through its preserved landmarks. Spatial changes can be generated by the evolution of concepts such as the concept of an individual in a society, the concept of family, and the concept of social groups. In this context, this paper refers to the evolution of the housing question - what we mean by both managed and regulated urban habitat and under-regulated informal habitat.

In all cities, land resources are limited; and therefore, development must take into account a sustainable balance of indicators. The city's centre usually includes several monuments which are preserved structures through time, exhibiting heritage values, and contemporary buildings that reflect the present needs of the society. Thus, restoration and reconfiguration of the existing built fabric shift its value as a cultural, functional or identity resource. Existing building spaces can be subject to restoration, reuse, and restructuring through interior interventions, new storeys or extensions. Existing buildings, even heritage ones, are often in an advanced state of degradation as a result of natural or anthropogenic hazards, as a result of complex risk analyses; and they require significant work for consolidation, restoration, and restructuring interventions. As an alternative, this fact has led to the reconfiguration of building spaces, superstructures, extensions, and insertions of the existing fabric into "new" assemblies through "spatial hybridization" procedures. The proposed case study is the historical centre of Bucharest, where hybridization has created controversial debates. The spatiotemporal dialogue opened by this approach reevaluates heritage as a development resource value, emphasizing the resilience dimension of the built space.

Keywords: *heritage, identity, spatial hybridization, urban development, sustainability, resilience*

1. INTRODUCTION

The city is a mosaic of built spaces from different periods, with diverse structures, forms, and materialities, enriched with histories, stories, and emotions experienced over time by the community. This wealth of values, which is constantly being rewritten, forms a distinctive imprint that provides cohesion, fosters a sense of belonging, and enhances the civic dimension of the community's identity. Preserving these layers remains a desideratum for stability. The disappearance of certain landmarks creates trauma, distorts the precious "mental maps" identified by Kevin Lynch (1960), alienates, and disrupts the balance. Space is not only a physically determined content (Sein) but also a life experience (Da sein) as Martin Heidegger describes it in his book "Being and Time" (1927).

The city, as a sustainable space with the adaptability capacities specific to an ecosystem—informationality, historicity, integrity, and fluent balance—becomes resilient if it can continually be lived in, by adapting to the needs and aspirations of the community. Historical and architectural value has exclusively constituted the criterion for identifying built objects that must be protected, but over time, interest has extended to the space with environmental value as a whole and to those minor components which, through their coexistence, contribute to defining the affective value of the built space (Gociman et. al, 2019). Francois Choay highlights in "The Allegory of Heritage" (1998) the relationship between historical heritage and its acceptance by communities as a point of reference and support for the community.

A primary research question of this work is how we reconfigure space while maintaining a balance between heritage values and present needs.

The main focus of the research refers to identifying ways of intervening in a built space affected by multiple aggressions (risks, age, pollution) such as the historic area of the city of Bucharest.

The research continues the results of the "Urbasrisk" project (Gociman et. al, 2016) by extending documentation and analyses with new case studies.

2. HABITAT TYPOLOGY – BUCHAREST'S CASE

As a result of different stages of development in its history, Bucharest can easily be described as an urban manuscript, composed of three major zones: the central protected area with numerous monuments, the large standardized residential neighborhoods built systematically by the communist regime, and the disorganized, unregulated slum-like areas. The central area, which grew organically along the banks of the Dâmbovița River, was heavily affected by bombings during the Second World War and later by the earthquake of March 4, 1977, which had a magnitude of 7.7 on the Richter scale, causing 3,000 casualties and \$2 billion in damages. Following this tragic event, leader Nicolae Ceaușescu decided to demolish and restructure the affected area, leading to the disappearance of 450 hectares of old built heritage, developed over time with many monuments, to make way for the new Civic Center of the city. The brutal intervention in the urban fabric included demolishing many monuments on the Arsenal Hill in Bucharest, where demolitions began to clear the land for the location of the Palace of the People. The current Palace of the Parliament is the second-largest building in the world after the Pentagon, measuring 110 meters in height, 275 meters in width, and occupying 6.3 hectares of land.

The Church of Saint Nicholas Monastery, founded in 1589 by Prince Mihai Viteazul on the Arsenal Hill, complemented over the time by other state institutions such as the Army Arsenal and the State Archives, became a cultural and functional ensemble with great historical value and spatial coherence. The relocation of the Mihai Vodă Church by structural movement over a distance of 241.9 meters, including 197 meters on a 2.8% slope, an operation led by engineer Eugen Iordăchescu, saved the building, but destroyed its context. Its relocation behind tall blocks distorted its spatial perception. The destruction of the surrounding residential neighborhoods and the displacement of the population created traumas.

Figure 9. Site Of The Demolished Mihai Vodă Monastery

Figure 2. Relocation of The Mihai Vodă Church

Figure 3. Studied area

Figure 4. First Price – Bucharest 2000 – authors: Von Gerkan Meinhard, Zais Joachim

The area was the subject of the "Bucharest 2000" competition won by Meinhard von Gerkan's team, with a proposal for a scenographic system of urban islands and towers around the Palace of the People to block its direct perception. Currently, Bucharest still has an old, neglected, and unconsolidated built heritage, affected by risks, earthquakes, and especially by the passage of time. The current administration's decisions are overshadowed by legal property issues and financial resources that limit interventions. The protection regime imposed in the central areas with a high density of buildings and historical monuments has generated research studies focusing on protective management policies. Documents prepared by multidisciplinary teams to substantiate regulations for Bucharest's general urban planning project, continuing research on hazard mapping, typology of exposed elements (population, built environment, natural environment), and their vulnerabilities, have identified GIS-located risk maps that illustrate an overlap of central protected areas with high heritage density over those with high vulnerability. This raises a significant operational management issue regarding interventions in the territory to reduce risk. The methodology developed in the "Urbasrisk" project, corroborated with research from the Technical University of Construction, has built an observational expertise system to determine structural vulnerability.

To create a balance between the deteriorated status of the existing built environment and recent demands of beneficiaries, a series of intervention options have been identified, including conservative maintenance, improvement through restoration consolidation, transformation through restructuring, reconfiguration, demolition, and replacement. The intervention matrix is generated by the relationship between the reference value and the current status value of risk exposed elements.

Code	Categories of interventions	
D	Restoration: conservation or maintenance works integrated into a complex intervention in accordance with specific regulations for monuments.	
E	Partial restructuring: demolition and reconstruction works of structural components involving partial transformation of the building: vertical movement, modification of floor levels, creation of new floors, redistribution of interior space of apartments without altering the total area, while preserving valuable characteristics.	
F	Global restructuring: demolition and reconstruction works involving the overall transformation of the building; compartmentalization at the building level, space accumulation, extension, alterations of enclosures while preserving valuable characteristics in relation to the whole ensemble.	
Replace	G	Demolitions
	H	New solutions

Figure 5. Categories of intervention on a built space

Similar research related to the preservation of old buildings as existential witnesses requires intervention procedures, with the concept of "adaptive reuse" being established. The typology of using old buildings is identified by Professor Dr. Michael Holleran's - *Analysis of adaptive reuse of historic buildings starting with retrofitting or dealing with old facades* through four types based on profitability criteria: reconsidering facades and architectural lighting, demolition of buildings that are

Proceedings

unprofitable based on cost-benefit analysis, intervention through accessibility to the relationship between private and public space at the ground level, making it more attractive, transparent, and “walkable” and the most appealing intervention is addition, “to have more floor area in a dense city and help keeping the old buildings from demolishing” (Bollack, 2013).

2.1. Comparing sustainability of reuse old buildings with new buildings

James Douglas highlighted the sustainability of building adaptation by comparing it with new constructions in his book “Building Adaptation” (2006). He argues that “reusing or upgrading old buildings is more environmentally friendly than redevelopment. The latter involves demolition as well as new-build activities, both of which expend more energy and waste than adaptation.” Stewart Brand developed the “Shearing Layers of Change” diagram in 1994, which he published in his book “How Buildings Learn: What Happens After They Are Built” in 1995. In it, he proposes identifying the rate at which components undergo changes over time with various optimal intervals. The “Site” remains eternal, with a lifespan ranging from 30 to 300 years, while the “Skin” or facade changes once every 20 years, and utilities (“Service”) have a lifespan of 7 to 15 years. The “Space plan” or interior layout varies depending on the building’s function – 3 years for commercial spaces and up to 30 years for residences. Finally, “Stuff” (furniture) can be changed at any time (Brand, 1994).

Figure 6. Shearing layer of Change (Brand, 1994)

“An old building next to a new one can create a striking visual interplay but the contrast is most intriguing when the structure itself incorporates both elements (...) These gleaming additions - many of them categorized as adaptive reuse - revitalize previously run-down buildings and areas or breathe new life into beloved structures that must be realigned to our modern priorities.” states Eric Allen in *Architectural Digest*. Adaptive reuse has been recognized as a method to improve the financial, environmental, and social performance of buildings (Langston et al., 2007; Bullen, 2007).

Ellison et al. (2007) note that refurbishing a building to meet sustainability standards can be 12% more costly than a standard reuse project. Similarly, Kohler and Yang (2007) argue that reusing buildings is less expensive than demolition. Thomsen and van der Flier (2006) suggest that adaptive reuse is preferable to demolition, which should be viewed as environmentally harmful. Their renovation study found that repurposing buildings produces less waste, uses fewer materials, and likely consumes less energy than demolishing and rebuilding.

Sustainable architectural design principles should also focus on minimizing environmental impact, creating a balance between the built and natural environments, and rehabilitating degraded areas.

3. “ADAPTIVE REUSE” IN BUCHUREST – CASE STUDIES

Overlapping of floors while preserving the footprint boundary, creating contrast through the dialogue of solid stone materials and curtain walls, the headquarters of the Union of Architects in Romania was achieved through the addition of floors onto an existing building (the former Headquarters of

Directorate 5 of the State Security during the Communist regime, partially destroyed during the Revolution of 1989).

Figure 7. The headquarters of the Union of Architects in Romania, Jean Louis Calderon Street

Six years ago, in the Old Town of Bucharest, on Doamnei Street, the historic monument building designed in 1886 by architect Adolf Lang for the "Naționala" Insurance Company regained its splendor, now housing the Hilton Garden Inn Hotel, opened after an extensive process of consolidation and renovation. The building is characterized by additional floor levels added in various periods, with a change in materiality from solid domination to curtain wall.

Figure 8. Hilton Garden Inn Hotel, Doamnei Street

Aggressive stacking both in volumetric conformation and in plastic dialogue, materiality, and chromatics. Hotel Sarroglia near Rosseti Square, Bucharest. Suffocating superimposition. Residential building on Regina Maria Boulevard. Incorporation, annexation of service spaces on the ground floor of the existing structure without aesthetic connections.

Apartment building on Maria Rossetti Street. Unarticulated incorporation without staircase, lack of harmonization, very aggressive aesthetics.

Figure 13. Novotel Hotel, Bucharest
Victoriei Avenue

Figure 14. Rosetti
Hotel, Maria Rossetti St.

Inaugurated in 2021, The Marmorosch Bucharest by Autograph Collection represents more than the emergence of a five-star hotel in the heart of Bucharest. It means, first and foremost, restoring to the city and its inhabitants the joy and splendor of a historic fragment by reviving the Marmorosch-Bank building, classified as a Class A Historical Monument. The most significant visible intervention on the exterior was the demolition of the insertion on Eugeniu Carada Street (1995, architect Tiberiu Boitan) and the integration of the corner towards the National Bank of Romania. The new wing facing Carada Street now features a new façade aligned stylistically and compositionally with the historic one.

The reconstruction of the access of the old National Theater, destroyed by the 1944 bombing, and its use as an entrance to the new Novotel Hotel.

The Rosetti Aparthotel is an additional volumetric extension, separated with junction and integrated chromatically. The old house becomes an access device for the Aparthotel.

Extension and additional floors added to an interwar villa with an office building in an ultra-central area of Bucharest at Roman Square, harshly criticized by the public opinion for suffocating the surroundings, chromatic contrast, and integration into the context.

Figure 15. Extension of The Academy of Economic Studies, Roman Square

The project begins with rigorous historical research and site investigation, tracing the building's evolution from its medieval origins in the 15th century to its transformation into the neoclassical aristocratic residence of Ion Oteteleşanu, the prefect of Bucharest. Surrounded by a romantic park, the residence was donated to the Romanian Academy after Oteteleşanu's death and repurposed into a school for underprivileged girls. The school's inauguration by King Carol I in 1893 solidified its austere and philanthropic image, becoming a significant landmark for building restitution. In 1954, the building became the Institute of Atomic Physics, undergoing severe modifications that stripped it of all decorations. Damaged by the 1977 earthquake, it was eventually evacuated and collapsed in 2011.

Figure 16. Existing façade

Figure 17. Restoration of Oteteleşanu Castle

The structural solution aimed at reinforcing the vertical elements from the ground up, effectively tightening the structure. The project proposes preserving the original elements and creating a central hall open on four levels, featuring a zenithal illuminator to serve as a light core, symbolising newness. The reconstruction and rehabilitation of the partially collapsed Oteteleşanu Castle, which has undergone numerous stages of functional and aesthetic reconfiguration, from noble residence to school for poor girls and research institute of the Academy, through the restoration of a period image and investment with a new function as a center of excellence in Materials Physics research.

4. CONCLUSION

Case studies have inventoried several intervention methods - floor addition while preserving the footprint, extension and floor addition through incorporation, extension through addition, interior reconfiguration, and remodeling.

The contemporary city is subject to constant pressure related to development, population density increase, diversification of services, but also exposure to natural and man-made risks. In this context, the sustainability and resilience of the built environment can be achieved through proper management, procedural, administrative, and legislative intervention.

This multipolar procedural development generates hybrid spaces. The individual, the group, the community, objectively exists, evolves, and lives in a space that changes physically through remodeling, simultaneously determining a new subjective perception of it. This transforms space into a renewable resource, both material and spiritual, but especially emotional. Mastering space, marking it emotionally, creates identity territories that generate stability and must be carefully configured.

Interventions that do not preserve the scale, materiality, and chromatics of the existing have been severely criticized by the profession and civil society.

For a space to be resilient, it must always be liveable, by adapting to human needs and aspirations, or by adapting to their determinations.

Looking back in time gives us stability, and space offers us through its invariants reference points of personal identity.

Extended abstract

The papers` goal is to understand the spatial quality of the private interface between the public and private realm and its perception and contribution to social life. Public, open space is the realm of public life, the space of spontaneous encounter and social activity. It provides an occasion for people of different backgrounds to come together on a daily basis. As such it constitutes a viable arena for being in and belonging to the world. On the level of neighborhood, it designates the space that can potentially foster social integration and strengthen community bonds. Whilst much research focuses on the design of public open space, less attention is paid to the equally important aspect of the transitional space between public and private and the boundaries that mark out this transition. The spatial quality of both is an important asset as it attracts residents and passers-by to engage in activities and public life at the crossover of the public and private realm in residential areas.

Drawing upon literature review a theoretical basis is built on the notion of this edge that is neither perceived as completely public nor private and simultaneously functions as boundary and seam. The paper investigates the boundary through the lens of the legal concept of ownership and possession clarifying territories and affiliations. It dives into the psychological perspective related to the need for safety and privacy, whilst also looking into its social perspective as a space for frequent meetings in the form of low-intensity, passive encounters and potential, active, social engagements. The study expands on the perceptual capacity of humans and consequent spatial properties that foster the spatial experience of both, inhabitants and pedestrians alike. It elaborates on its quality as an experience zone, where activities in both areas are mutually perceived, before possibly transforming into a zone of exchange. In closing, the investigation also looks into transformative aspirations of residents, where conceived space may turn into a constraint. When affordances are observed, inhabitants might expand their territory into public space, which is personalized by affirmation or remediation. The paper concludes with an outlook in future empirical research, where the outcome of this investigation will serve as the base for the analysis of an exemplary residential street block of a settlement for the displaced in Nicosia, Cyprus.

Keywords: *public and private realm; edge; transition; spatial and social experience; belonging.*

INTRODUCTION

Public, open space constitutes the public realm, where public life thrives and a sense of belonging and community can be established. But, public life also entails activities that spill out from the interior to the exterior private space, when these are in close proximity to and sensually perceptible from public space. In this case, then, both constitute the public realm. The purpose of this paper is to investigate the hypothesis that edges, boundaries and transition zones in neighborhoods are as important as the public space of a street or a park for social contacts to thrive and a sense of belonging and community to evolve. In this context some questions arise concerning the importance of social contacts for human well-being and where and how those contacts happen. In addition, it is important to investigate if and why public, open space in a residential neighborhood is a classic case for social contacts and their further development into community bonds. As the social reality is closely linked with the material reality, the paper elaborates the necessary, physical characteristics of edges, boundaries and transition zones along other important aspects to support public life and the resulting

feeling of belonging and sense of community. It also looks into the fact that plot boundaries are not irrevocable despite of their legal status of ownership and that edges, boundaries and transition zones may, therefore, expand into public, open space through appropriation and possession.

SOCIAL CONNECTIONS AND BELONGING

Physical existence or being in the world, sets human beings in relation to the physical and social world, which is essential for human experience (Heidegger, 2008). Positive social connections and belonging are fundamental and universal needs of humans that influence their overall development and wellbeing (Baumeister and Leary, 1995; Cohen, 2004). Meeting this need happens on different levels, through active and intense, social interactions with the immediate social environment, family, friends, colleagues etc. and through rather passive than active, low-intensity chance meetings in the public realm or at the edge between public and private.

People, who are socially excluded and lonely, seek their salvation in social connections with strangers, as even social acceptance by strangers is proven to have a positive, psychological effect (Baumeister and Leary, 1995; Leary, 2010). Gehl (2011) continues this line of thought by arguing that social connections with strangers in public, open space, even if passive and of low intensity, can potentially stimulate future, more active, social contacts. Stronger bonds between people are developing through familiarization, which is instigated by repetitive visual encounter that ideally leads to recognition of individuals in the community. It also promotes the common good, the acknowledgement of a common code of conduct, and, in general, common social and cultural values (Amin, 2006).

RESIDENTIAL NEIGHBORHOODS

Public, open space is the realm of public life, the space of spontaneous encounter and social activity. It provides an occasion for people to come together on a daily basis. As such it constitutes a viable arena for being in and belonging to the world. On the level of neighborhood, it designates the space that can potentially foster social integration and strengthen community bonds. Whilst much research focuses on the design of public open space, less attention is paid to the equally important aspect of the transitional space between public and private and the boundaries that mark out this transition. The spatial quality of both is an important asset, as it attracts residents and passers-by to engage in activities and public life at the crossover of the public and private realm in residential areas.

The neighborhood is the smallest unit of the urban environment and is characterized by residences located in proximity to each other. Neighbors are a group of people that share experience in a territory (Gusfield, 1975). The residential street in a neighborhood is, therefore, an ideal space for social encounters, as it involves a limited number of people that have, to some extent, common interests and a common background. A sense of community is built as neighbors familiarize with each other by meeting and interacting, in a formal or informal and planned or unplanned way, on a daily basis whilst performing regular activities in open space (Kim, 2007; Capon and Blakely, 2007). Community spirit is characterized by shared experience and emotional connection, mutual mattering, integration and the feeling of being a member and, hence, belonging to a group (Davison and Rowden, 2012, McMillan and Chavis, 1986).

A social activity between neighbors takes place, every time they meet each other on the street or the interstice between the street and the residence. Such fleeting, human, interpersonal relations are a source of information about the surrounding world and help to maintain already established contacts in a rather relaxed and undemanding atmosphere. The characteristics that define the edge and its adjacent zones play an important role, as they influence if and what people can see and hear and if they spend considerable time outdoors. “The more time people spend outdoors, the more frequently they meet and the more they talk” (Gehl, 2011, p.13). Therefore, walkability in public, open space is one basic necessity beyond the design of the edge, boundary and transition zones in neighborhoods.

Proceedings

Edges, boundaries and transition zones in neighborhoods

The edge is “the outside limit of an object, area, or surface” (Oxford Languages, 2024). It is a linear break in spatial continuity and is also understood by Lynch (1960) as a boundary between two areas. It may be seen as a barrier that is disruptive and closes off one space from another, whilst also limiting the degree of visual and physical penetrability. It may also act as a seam that is visually and physically porous and, therefore, welcomes exchange and joint experience. The boundary is “a line which marks the limits of an area and is a [dividing](#) line” (Oxford Languages, 2024) between two areas. It separates public and private space, interrupts flow and hinders and enables movements between the street and the private plot (Hoogkamer, 2019). Its physical properties differentiate two sides, an inside and an outside, always depending on the position of the observer. Open boundaries, which are rather passive, non-obstructive and permeable, afford crossing and enable necessary access and social contact (Benjamin, 2018). For Cullen (1961) perceiving the city while moving through it always implies a separation into an internal here and an external there based on the position of the observer, the space he is in and the space beyond. This helps the observer to break down the urban experience into identifiable parts but also understand the separation of the public here and the private there. He also sees that “porticos, balconies and terraces have this ability to communicate. They draw us outwards” (Cullen, 1961, p.36) and extend the inside in the exterior.

Gehl (2006, 2010) does not only look into the edge or boundary but rather focuses on the semi-private transition zone between public and private, open space. The street space and the space in-between the street and the residence for him are one entity, which potentially links activities on either side of the boundary and brings pedestrians and residents into contact with each other. Passers-by, who are walking along or waiting on the street, are simultaneously seeing and hearing activities that spill outside of the residence. Outdoor, stationary activities of inhabitants, such as resting, enjoying the climate and drinking coffee, or feeding cats, gardening, cleaning and maintaining, on the other hand, can be observed by pedestrians, whilst residents themselves are also following the life on the street. Lynch (1981) calls the urban condition that allows people to perceive activities in a neighborhood, transparency or immediacy, which provides a sense of life and helps us to understand the world. The transition zone, hence, is a passive experience zone, where people frequently meet in the course of daily activities. These activities optimally enrich and inspire each other and potentially turn the border zone into an active exchange zone of common activities such as talking and exchanging information and goods (Gehl 2006, 2010). MacCormac (1983) also recognizes the private space as important to enliven the public space of housing areas through interactive uses. This is also supported by Banerjee (2001) who suggests not to focus on the spatial distinction between public and private space but rather to look into the concepts of public life and social space beyond ownership. Alexander et al. (1977), too, recommend to understand the edge of public space rather as zone that has a volume than a line without thickness. They see the significance of the edge as vital for a vibrant neighborhood life, which is why special attention needs to be given to the design of the boundary and the threshold of the private residence. This is confirmed by studies in residential areas that have shown that this in-between space is with 69% of activities the most active outdoor space in comparison to activities on the street that account for 31% (Gehl, 2010). Gehl (2011) enumerates some international examples, such as the steps and landings of Brooklyn’s brownstone buildings, the porches of North-American residences, the stoops in the Netherlands, the front gardens of English semidetached houses, the front yards of low-rise row houses in Australia and the edge zones of traditional Japanese city houses.

SOFT EDGES IN NEIGHBORHOODS

Streets with soft edges have the most extensive activity level. Studies conducted in Copenhagen in 1982 have investigated the effect of soft edges on the level of outdoor activity in neighborhoods. They investigated streets that were comparable in relation to their residents and the dwellings, which were row houses. Whilst some streets had row houses directly connected to the streets, others had

Proceedings

row houses with front yards. Despite of their far-reaching conformity, streets with front yards or soft edges had a double to three times higher degree of activity (Gehl, 2010). This depends on the details and activities that can be experienced in those transition zones and the rhythm of opportunities offered (Jacobs, 1993).

Soft edges do not demarcate public and private space sharply. They are permeable to movement and exposed to view and consist of space that is expanding beyond the outer walls of the private residence. This could be simply balconies, stairs or entrance zones or they could cover more space in the form of porches, front gardens, front yards and terraces with benches and chairs. In any case, due to their visibility and accessibility from the street, they are semi-private areas that invite to participate. A further characteristic of soft edges according to Gehl (2006) is the evocation of interest and excitement due to a richness in good detail on eye level and in contact with public, open space, which allows people on either side of the boundary to see, hear and meet each other. Close up, visual contact is important as the social field of vision of humans lies below seven meters, where all details can be visually experienced. Ashihara (1983), who investigated the relation of street life and street characteristics, suggests that the relation between the street width and the building height should be below one for street life to thrive.

Vision allows people to take possession of their spatial and social environment from a distance (Robins, 1996). Even though, sight is a remote sense, it cannot be denied that social communication functions properly and hassle free and increases in short distance from one another. It influences intimate, social connections and interactions, as looking at one another is reciprocal and accompanied by facial expression (Frisby and Featherstone, 1997). This goes along with an intensification of communication and the exchange of intense feelings (Gehl, 2011). Close distance also allows for all senses, including hearing, smell, and touch to be used. Each sense supports the understanding of spatial relationships, the orientation in space and the assessment of spatial qualities (Rodaway, 1994). Hearing, as an omni-directional sense that cannot be deliberately turned off, also catches traces of social life and therefore provides a sense of liveliness and pleasure (Urry, 2002; Frisby and Featherstone, 1997). In proximity to others, it enables more intense, reciprocal communication. Similarly, smell, which is also a subversive sense based on proximity, cannot be evaded but creates closeness and familiarity and evokes strong feelings and memories (Porteous, 1990; Tuan, 1993). When multiple senses are engaged simultaneously, the environment is experienced as immersive, which subsequently generates rich emotions, emotional attachment and strong memories (Gehl, 2006; Pallasmaa, 2005)

A research conducted on front yards in an Australian city also stresses the importance of their design in relation to the affordance of activities, as this influences the sense of community. The front yards, which were investigated, were commonly used for recurring, necessary, and recreational activities. Questionnaires revealed that residents were using their front yards on average one hour per week day and two to five hours on a weekend. The majority of the respondents thought of their front yards as an outdoor extension of their living area and that their visual accessibility promotes socializing. They also confirmed that the front yards are characterized by a distinct, personal expression. The investigation concluded that the front yards are a frequently used, semi-public space, where interactions between the public and private occur. This is based on the walkability of the streets and the contribution of the front yards to the street scape. The design of the boundary and the semi-public zone are strongly influencing activities and behaviors but are also clear symbols of a strong ownership whilst also promoting a sense of belonging without compromising the sense of safety (Swapan, et al. 2019).

The quality of the residents` experience rests upon the fact that the boundary is clarifying territories and affiliations. Therefore, it needs to be spatially formulated in such a way that it is separating private and public space and restricting movement. Only when it is clearly legible, it is protecting the private sphere, which is crucial for contacts with others and the basic human need of feeling safe (Gehl,

2010). Safety is also supported by activities taking place on either side of the boundary and the visibility of those activities on both sides, which Jacobs (1993) formulated as *eyes on the street*. Forms of soft edges can be subtle ones, such as landscaping, changes in pavement and height differences, canopies, steps and stairs or more restrictive, linear boundaries such as hedges and fences with gates. But it may also just be formulated by some tables and chairs that are occupying territory. The boundary between the public and private is a sensitive issue, though, as it should both, allow for contact with public life and guarantee privacy. Carmona et al. (2010), therefore, suggest the use of adjustable filters, where residents can choose the degree of privacy or communication with the public. In any way is the soft edge an important aspect that contributes to the quality of housing and the surrounding urban area, the residential neighborhood (Gehl, 2010). The contrasting necessities of sense of privacy, sense of safety and sense of belonging, therefore, need to be balanced (Doolittle and MacDonald, 1978).

The quality of pedestrians' experience, on the other hand, depends upon a close up, rich visual contact, that engages all senses and a rhythm of visual opportunities in form of activities and material aspects that passers-by can experience (Gehl, 2006; Jacobs, 1993). A study of Appleyard (1981) also points at the impact that car traffic has on the pedestrians' experience and subsequently on social interaction, which is much more enhanced on streets with light traffic in contrast to those with heavy traffic.

DIALECTIC OF SPACE

It is obvious that the material reality is closely linked with the social reality. Whilst the space is produced by society to enable social practice, it is also shaping the social practice simultaneously. Lefebvre's (1991) three-dimensional dialectic of space differentiates spatial practice, representation of space and space of representation. All three are intertwined and interact constantly in-between accordance and confrontation.

Spatial practice refers to the perception of the outside world, the everyday social activities that happen and are interlinked with each other based on the physical properties of space. It stands for perceived space and how space is perceived through the collaboration of the mind and the senses but also on the expectations of residents on the representation of space (Lefebvre, 1991). In this sense the edge zone between public and private plays a pivotal role in shaping everyday experiences and activities. Representation of space or conceived space refers to how space is conceived. Society has various images of spaces that overlap, that, on one hand, resemble each other but are also different to a certain degree. The meaning associated with these images is visualized by specialized professions that exert power due to their knowledge. As a form of preset spatial practice, it provides an organization frame that is enforced on ordinary people and restricts their practice and choice (Lefebvre, 1991). Ownership is just one aspect of conceived space and refers to the right to control and exclude, which is supported by the legal system but does not require actual control (Chang, 2015). The design of the public street is, in this regard, a top down approach that usually does not involve impetus from residents but is prescribed.

Space of representation or lived space is a symbolic reading of space that overcomes the predetermined representation of space and is based on experiences, values and social norms. It evolves in an interactive process, where ordinary users change and appropriate space based on their imagination. This is one of the reasons why built boundaries change over time (Benjamin, 2018) and expand beyond legal ownership.

Gibson (1979) calls these spatial qualities, which afford the performance of an individual's action, affordance. The number of affordances that an individual recognizes, depends on the individual's perception of the surrounding space in combination with his imagination, which might be more broad-minded or limited. Affordances refer to conceived as much as to lived space. Social possession is part of lived space, where actual control on space is taken on with the intention to remain in control. It works as a self-evident act of communication that is backed up by the social norm of respect for

Proceedings

possession (Chang, 2015). This may be realized in the case of the public street in form of flower pots and beds, tree plantations, chairs, benches and tables or garbage bins. But, it may also materialize in garden extensions, barbecue areas or storage spaces that spill into adjacent public, green, open space. The legal aspect of ownership and the clear demarcation of public and private property seem to be, to some degree, more fluid than the legal frame work would suggest, as people in their lived reality of everyday life, tend to overcome such legal meaning and predetermined categories through spatial manifestation that stretch the boundary between the two (Blomley, 2005).

CONCLUSION

Edges, boundaries and transition zones in neighborhoods are in combination with public space, such as a street or a park, the very space, where social contacts, which promote a sense of belonging and community, happen. Social life can be fostered by repetitive, chance encounters in open space, for which the residential neighborhood is an ideal arena due to its small size, the limited number of neighbors and the consequent, frequent but relaxed encounters on a daily basis.

Certain spatial characteristics play a primary role in enabling these neighborly contacts of which walkability, light car traffic and the scale of the streets adapted to human perception are the most significant. But more importantly, aspects that concern the edges, boundaries and transition zones need to be met, in order for this spatial amalgam to become an experience zone, where neighbors can frequently see and hear each other during their daily activities. To motivate people to walk in their neighborhood, this transition zone needs to be rich in good detail and activities at the eye level, so that it evokes interest and stimulation. In order to safeguard that this space is semi-private and inviting to participate, the boundary should not be sharply demarcated but permeable to movement and view. This guarantees that both sides are exposed to each other and activities of passers-by and residents together constitute the public life of the neighborhood. When these criteria are met, then, this passive experience zone can turn into a more active zone of exchange, where chance encounters can slowly evolve into more active and deeper social contacts and, in the long term, into a feeling of belonging and a sense of community. These so-called soft edges also contribute to the feeling of safety as more people are potentially noticing what is happening on the street. The boundary also stands for clarifying territories and affiliations, important criteria which need to be met in order to protect the private sphere of the residents. Spatial conditions should, therefore, be sensitively designed to balance sometimes contrasting human needs of sense of privacy, sense of safety and sense of belonging.

It is apparent that the social life and the physical environment are intertwined and influence each other. Space is produced by society to enable social practice and, at the same time, shapes social practice. Spatial practice, representation of space and space of representation constantly negotiate space. Representation of space or space that is conceived by specialized professions, such as the public street, is predetermined and shapes social practice. But it might also be turned partially into a space of representation or lived space based on experiences, values and social norms as well as affordances in relation to space. This materializes in the form of appropriations, where residents take on partial possession of public space and stretch the boundaries between public and private.

Future empirical research will use this theoretical basis for an in-depth analysis of an exemplary residential street block of a settlement for the displaced in Nicosia, Cyprus. The area is characterized by small, walkable streets with very little traffic, small front yards towards the street and small backyards towards pocket parks. The settlement's previously conceived space has, in its fifty years of existence, gone through many alterations, adaptations and appropriations by residents, which will be analyzed on a typical case.

Abstract

Always remembering Lucien Kroll's saying: "everything is landscape", consolidated by the European Landscape Convention, we must realize that the landscape project has a decisive role in the management of the territory and therefore within the theme of the climate crisis. The projects, involving all the different disciplines interested and specifically useful, must be developed with a careful, analytical and future-oriented strategy. It is necessary to overcome the extemporaneousness of everyday life with long-term objectives, but visible in the various stages that follow one another. The landscape project, even in its unity, must be able to support emergencies, natural events and catastrophes, fragility and climate change. In the urban landscape, the value of public space is always a priority. The landscape project therefore needs multiple disciplinary approaches, which, overcoming their respective boundaries, collaborate as a whole. Since the beginning of this century, many things have already matured as the conditions and methods of creating landscapes have changed, expanding with new opportunities, known and debated, including issues relating to the climate, placing in first place the relationship between architecture and nature, with its implications in the urban landscape, placing the relationship between man and nature at the basis of the purposes of the landscape project. In the critical rereading it is necessary to analyze carefully and methodically, in a contemporary scenario where cities are in crisis with an evident transformation. The landscape project must not be included exclusively in planning, but its positive aspect can be included in individual specific themes, even small ones. We remember the interventions in urban public spaces and all the issues connected to parks. The first discussion to open, in a scientific debate, critically reading the projects and achievements, concerns abandoned areas, with urban redevelopment projects, also for the relationships between architecture and nature. The most significant and emblematic cases may be: the construction on the piers of the port of Amsterdam with the new residential districts of the island of Java, Borneo and Sporenburg, with a waterfront that marks a new urban landscape; the Bo01 district, on a completely eco-sustainable basis, built in a disused port area, in Malmö, Sweden, with the motto "beautiful and sustainable", which arises from the European exhibition on living, held in 2001, entitled "The city of tomorrow for an ecologically sustainable information society in an era of well-being"; Le Albere, created in Trento, in 2013.

Keywords: *Landscape Project, Climate Change, examples, critical reading*

1. INTRODUCTION

Lucien Kroll [1] was the precursor and with his concepts the precursor of the European Landscape Convention [2]. With the Convention, the Landscape Project takes on a fundamental role in "Landscape management" and "Landscape planning" [3]. In this role the relationship with the theme of the climate crisis becomes crucial. The projects, in fact, must involve different disciplines and must be developed with a strategy that is attentive to all the problems connected to the territory, with the climate situation among the first objectives. The Landscape Project, despite its different contributions,

must be unitary and must be able, in addition to the specific design purposes, to deal with issues relating to emergencies, natural events and catastrophes, fragility and therefore climate change.

The Convention was presented in 2000 and since then, in these twenty years, there has been continuous evolution. Conditions, purposes and methods of creating landscapes have changed. The debate and research have brought important contributions. As regards the discussion relating to the climate, the relationship between architecture and nature has become fundamental.

It is also important to underline the role that *Changing Cities* has had in the various editions, with the significant scientific contributions.

2. LANDSCAPE PROJECT

The Landscape Project operates on different scales, from large territorial interventions to small scale, whether agricultural or urban. In this regard, we remember the interventions in urban public spaces and all the issues connected to parks.

In the management of everyday landscapes, for any transformation intervention, valorisation is the basis of the Landscape Project. "The management concept is based on two key ideas: the dynamic character of the landscape and the protagonism of the landscape agents. The methods associated with management are quite distant from those used in physical land or landscape planning. On the one hand they operate with more abstract, less tangible categories, on the other they possess a clear personal - and up to a certain point subjective - dimension to the extent that they imply social mediation work. [...] Management processes must not be conceived or applied as immediate or final tools, but rather as a complex and organized sequence of actions that require variable times depending on their nature." [4].

The European Convention is explicit on transformations, recalling that "actions" must be "aimed at a sustainable development perspective" and referring to the "transformations caused by social, economic and environmental development processes". Management includes, with full rights, all the skills of landscape architects, both for "natural environments" and for "built environments". In particular, a global and multidisciplinary approach is necessary for the management of natural resources. This area includes complex issues, such as the protection or restoration of plant and animal biodiversity, pollution and health, phenomena connected with climate change, the sustainable use of natural resources as well as the circular economy and therefore ecosystem services. [5] The management of built environments includes the problems of the urban landscape, with all the issues connected to the city and its regeneration. This includes new urban development interventions and recovery and redevelopment projects. In both cases, at the center of every action is sustainability, understood in a broad way, [5] and the relationship between architecture and nature; in the city in the urban landscape, designing with nature concerns both the individual building and the entire area. [6] Vegetation has a triple function: technical, ecological and aesthetic-landscape, with numerous effects on the environment and can be used as real biotechnology. [7] We must aim for effective demineralisation, starting from minimal interventions, with water and vegetation, moving on to structural interventions also connected to forestry and urban agriculture. From this perspective, all the open spaces of the city [8] fall within landscape architecture, where, however, gardens and parks have a leading role. [9]

For the specific areas of competence of the Landscape Project we refer to the IFLA indications: "public and private parks and green spaces; squares and plazas, public places, and city monuments; pedestrian areas and traffic restricted zones, promenades; sport complexes such as stadiums, arenas, grounds and pitches; playgrounds and recreation spaces for children, young people and adults; special installations like climbing walls, cycling and skating courses, and golf courses; outdoor swimming pools, bathing areas and beaches; camping and caravan sites; spa parks and recreation spaces; horticultural exhibitions and concepts for other outdoor fairs; botanical and zoological gardens; graveyards and memorials; open spaces around public and private buildings; car parks; planting of

Proceedings

industrial and commercial sites; design and integration of roadside and motorway service areas and rest areas; private gardens and courtyards; roof gardens and patios; planting of conservatories and indoor spaces”. [10]

Franco Zagari questions himself: "But what is landscape design in practice? It's a topic often confused with other creative approaches. His attitude towards the contexts of intervention proceeds not by generic determinations from the general to the particular, or from the plan to the project, or from morphology to typology, but instead by thematic sequences always defined with precise directives in time and space. It is a logic for relationships between activities and flows, rather than for relationships between objects, with a strong vocation to welcome and integrate different knowledge and different opinions, open to involving as much as possible any instance that proves responsibly available. On the border between philosophy and economics, the objectives of a landscape project are principles of orientation and new centrality, while beauty, work and listening to the vocations of the places are the core values. When a community is involved and responsible for a place then that is where the heart of the game is played.” [11]

3. THE ROLE OF LANDSCAPERS

As far as designers are concerned, their projects and their principles depend greatly on their studies, training and previous experiences. Diana Balmori, precisely frames the difference in planning between architecture and landscape: “Architects think of architecture as object, and of landscape as background to that object, just something you put the object on but not something that has anything to do with the object itself. The famous dividing line given is five feet from where the building ends is where the landscape starts. That explains the separation in a very graphic way. While many of the arts have really been moving away from the object, architecture has really become more and more object-oriented. The change in the relationship between the two has a lot to do with the fact that space has become more important than the object. That elevates the status of landscape on the one hand and diminishes the status of the object. That's the beginning of the change. It's quite evident that this is happening now so architects have suddenly become more interested in landscape. It is now space that interests us. And landscape is the discipline in which artistic ideas are being debated. It has become the place in which to have the debate. [...] The real points of agreement are outside of both professions in a way. It lies in the new definition of nature, a definition that has dramatically changed. [...] Landscape can be like poetry, highly suggestive, and open to multiple interpretations. Landscape can create a meeting place where people can delight in unexpected forms and spaces, inventing why and how they are to be appreciated. I think this sense of invention, of not knowing how my landscapes are going to be used is exciting. People use spaces in ways I hadn't imagined. I love that”. [12]

Even if there has been a great evolution in the last twenty years, the role of landscape architects must be revisited, also based on individual and specific skills. The landscape project has taken on different roles and meanings and therefore landscape architects must fit the project within a large and complex system, in a new relationship with nature. The relationship with the physical, social and cultural context is the premise for each project, giving rise to the different approaches of landscape architects. One of the main aspects, which can be seen from the roles of landscape architects, is the way of understanding planning, which goes beyond the concept of a plan to place ecology at the centre. Gilles Clément even states that “the lack of planning is a biological advantage!”. [13] Many think that the methods specific to the urban planning discipline are outdated and that the landscape, especially through infrastructure (green infrastructure and ecological infrastructure) can be the driving force.

Paolo Bürgi illustrates the themes "with which we must necessarily deal today, not only in the field of landscape architecture: the recycling and conversion of exploited territories, the curious and careful observation of the complexity that surrounds us, the care of places transformed, manipulated or to be saved, the themes linked to food, energy, the environment and sustainability, the creative reinterpretation that draws inspiration from the historical culture and future development prospects

Proceedings

of a place" and recalls the values intrinsic to beauty: "at the base, the timeless themes and profound values linked to the sensitivity of approach to the place, to the art of landscape design and to its essence remain fundamental. Beauty, for example ("Nature has given you the gift of the knowledge of beauty" said Lorenzo the Magnificent to Michelangelo), the need to create something for the spirit and for the serenity of thought, the ability to express the poetry hidden in things . [14]

The relationship with nature is often the fundamental theme for landscape architects, with a dialectical relationship in the various modalities, from interventions in natural places to nature projects in the city. The relationship with nature, in any place and at any time, in the urban and agricultural landscape, includes all issues connected with the problems of environmental sustainability and therefore climate change.

In the urban landscape, landscape architects have paid much attention to projects for parks and gardens, also considering them experimental laboratories for sustainable design and environmental, climatic and social functionality. In the professional field, a lot of attention is given to the garden, to its rediscovery, to the relationship with tradition, but in an innovative way. Studies, experiments and projects are multiplying, with autonomous and multiple methods also based on the climate. Gardens and parks certainly represent a point of reference for the regeneration of cities, but they cannot be separated from all other open urban spaces, with the square first and foremost. The theme of open urban spaces is at the center of the planning and profession of the landscape architect.

4. CLIMATE CHANGE

The theme of climate change is among the primary interests of the landscape architect, distinguishing the phenomena that arise from human actions compared to natural ones. [15] The United Nations Framework Convention on Climate Change [16] is among the first to use the term "climate change" for any type of climate change regardless of the cause. In the past, the phenomenon was attributed above all to natural elements, while in recent decades it has been acquired, as a scientific assumption, that most phenomena can be attributed to anthropic actions. It must be kept in mind that the scientific data on the phenomenon is increasingly dramatic. The Sixth Assessment Report of the Intergovernmental Panel on Climate Change IPCC, [17] presented in Interlaken, Switzerland, in March 2023, indicates the main critical issues and concludes with a clear message: something must be done now (by 2030) or it will be too late. The report also proposes possible interventions; in practice it is a sort of instruction manual for combating climate change, to be kept in mind with the utmost attention. The report, in essence, provides a precise picture on the topic of current and future losses and damage that affect ecosystems and individual people, calling for precise and timely interventions. One of the authors, Aditi Mukherji, said: "Climate justice is crucial because those who have contributed the least to climate change are disproportionately affected" and pointed out that "Nearly half of the world's population lives in regions highly vulnerable to climate change Over the last decade, deaths from floods, droughts and storms have been 15 times higher in highly vulnerable regions." [18]

Accelerated climate change adaptation actions are essential in the coming years to close the gap between existing and necessary adaptation. The solution lies in climate-resilient development from which the importance of landscape design arises, with different purposes related to energy sources, mobility and the relationship between architecture and nature. The report specifies that coordinated policies, international cooperation, ecosystem management and inclusive governance are key to effective and equitable climate action. Regarding the role of landscape design, the report highlights the opportunity that urban areas have on a global scale for ambitious climate action that contributes to sustainable development.

Let us remember what Giuseppe Scarascia Mugnozza writes in reference to the urban climate. "The urban environment is characterized by climatic conditions that are quite different from those found in more natural systems such as wooded or rural areas. [...] In fact, many urban and suburban areas

Proceedings

have higher temperatures than their surrounding rural environment; this temperature difference constitutes an urban "heat island". The average annual air temperature of a city with a million or more people can reach up to 12°C higher than its surroundings, especially at night." [19]

The European Union weather service [20] has released some important data relating to the last few months. This year's March was 1.68°C warmer than the fifty-year March average of the pre-industrial era 1850 - 1900. 2024 was the warmest March. warmest ever recorded in the world, with a global average of 14.4°C, 0.73°C higher than the average for the thirty-year period 1991 - 2020 and 0.10°C compared to the previous record of March 2016, adding to a series of ten consecutive monthly records: the average temperatures from April to March 2023 are the highest ever recorded. Before the publication of the Copernicus data, 2023 had already been confirmed as the warmest year on record since 1850, with the increase in global average temperature close to the 1.5°C limit.

5. ARCHITECTURE AND NATURE

The topic was extensively covered during the third edition of *Changing Cities*, [21] but here it is important to report some concepts that refer more directly to the topic of climate change.

In recent decades the relationship between Architecture and nature, extending to the urban landscape, has taken on a clearer and broader role, linking itself, with environmental sustainability, directly to climate issues, therefore to well-being and its perception.

In studying the relationship between Architecture and Nature in the context of the urban landscape [22], the theme of sustainability, with the repercussions linked to the issue of climate change, in fact, involves, with the utmost attention, the design of open urban spaces. These spaces have always played a role in the design of the urban landscape, but recent experiences demonstrate, incontrovertibly, that in the design, or redesign of an urban area, one must start from public spaces and their connections. Even if the landscape project is based on a multiplicity of disciplinary contributions, at its basis there are the phenomena that study the vegetal aspects, as it has numerous effects on the environment and can be used as a real biotechnology for the ecological recovery of the areas degraded both in urban, peri-urban and extra-urban environments. The use of vegetation has a triple function: technical, ecological and aesthetic-landscape, with immediate effects on the climate. In urban areas, we must strive towards effective demineralisation of the landscape, both with minimal natural interventions, with water and vegetation, and with structural interventions connected to urban forestry and urban agriculture; both in a systematic and not extemporaneous and random form.

Operational analysis can be classified into four specific areas of study: architecture, open urban spaces, infrastructures and neighborhoods.

As regards architecture, in recent years, the use of vegetation has had a further development, deepening and perfecting the technical aspects and those more properly connected to linguistic expression, in different ways: on the fronts, on the roofs, on the internal. [23] For the roof garden there are numerous examples that demonstrate the relevance and effectiveness of the use of the turf, with shrubs and trees, becoming a tool for environmental rebalancing, with safe and proven results aimed at improving the microclimate. For vegetal façades, the shade produced by the vegetal wall mitigates solar radiation, decreasing the heating of the facades in summer and in winter it becomes a protective screen from the elements.

Both roofs and vegetal facades, at all times and in every place, improve acoustic and thermal insulation. The contamination of the positive aspects that are transmitted to the environment is important, improving the microclimate, contributing to the absorption of CO₂, limiting the production of smog and the formation of the urban heat island, also reducing radiation along the roads.

For open urban spaces the need is to build an urban network, which allows for true and complete regeneration, overcoming isolated cases.

Infrastructures have the important role of stitching and connection, as a sign of continuity and matrix of a network; fundamental for the purpose is the interconnection between the mobility system and the natural system. Among these, in the foreground we have green infrastructures that offer ecological, economic and social benefits through solutions in harmony with nature. [24] Gorm Dige announces that there is ongoing EEA research, which will be published in a report, “to demonstrate how green infrastructure helps mitigate the negative effects of extreme weather and climate events, which are among the natural hazards most expensive and deadly in Europe and in the world”. [25]

Lastly, the neighborhood. For this purpose, the term eco neighborhood is used alongside the name sustainable neighborhood, addressing the environmental dimension of the intervention, i.e. energy efficiency, the reduction of environmental impact and therefore the climate.

6. URBAN LANDSCAPE

In compliance with the European Landscape Convention, as an urban landscape we must understand the entire city territory, as we perceive it, regardless of its presumed qualities, with its complexity and completeness.

The original matrix of the contemporary city dates back to the era of the industrial revolution, as in those years the great urban expansion began, with the birth of metropolises. Its structure, maintaining the ancient center as the focal point and identity of historical memory, is organized with the peripheral neighborhoods: the residential ones, with offices and shops and the working-class and popular ones, often without primary services. [26]

Towards the end of the 19th century, urban planning began, including important urban restructuring interventions that often redesigned the urban landscape. “Yesterday the city was a world, today the world has become a city” as Lewis Mumford wrote, more than half a century ago. [27] Since 2007, city dwellers have outnumbered rural dwellers.

The urban landscape, on a general level, is memorized and classified in the global form of an international megalopolis, with similar archetypes and symbols, but in every single city it is possible to identify the characters and identities. We must observe and read the internal divisions of the urban fabric, aware that every internal differentiation is also linked to the different external connections. The contemporary city is looking for its new identity, through sudden and unexpected changes. The main functional structures are modified, redefining roles and connection networks. Cities, especially megacities, are changing their role and the very essence that has been at the basis for centuries.

Public space, all the new places of the urban collective, are strategic urban spaces, due to their location and use, but also because they are often the main nodes of social and economic relations. Even in the absence of particular symbols, they take on a symbolic role. For these reasons, the redevelopment of degraded urban areas passes through the redevelopment of open public spaces, where perception, visibility, symbolism, sustainability and climate become the keys to understanding a new urban landscape.

Since the end of the sixties of the last century, there has been a progressive and irreversible conceptual and programmatic change. The traditional city is entering into crisis, the debates, research and proposals are numerous, but the very way of doing urban planning is certainly entering into crisis. The presumed assumption of control over the entire urban structure collapses. The city is transformed by social and economic changes, by the new habits of citizens, by the decisive contribution of new telematic technologies. The urban landscape is not only that of the large metropolises and within the latter there is not only the historic city with the central representative areas and consolidated neighborhoods. There are peripheral areas, abandoned areas, but, in some cases, there are also agricultural areas, and above all peri-urban areas with the phenomenon of urban sprawl. The contemporary urban landscape includes all the different environmental situations, as they have been inherited and as they have been planned and therefore as they are modified, but we must take

advantage of the phenomena of redevelopment and regeneration to address issues relating to climate change. The purpose is the future city as a perceptive subject and as a protagonist of transformations: a landscape to be perceived in a state of well-being, aware of the intersection between landscape and environment. [28]

7. SIGNIFICANT AND EMBLEMATIC CASES

There are many important and significant examples, in different countries. Three emblematic and symbolic cases are reported, known and already reported in various research, published in books and illustrated at conferences, including *Changing Cities*.

The example of the piers of the port of Amsterdam is among the most important. At the beginning of this century, new residential neighborhoods were built on the artificial "islands" built between 1874 and 1927, with a waterfront that marks a new urban landscape: the island of Java, Borneo and Sporenburg. [29]

The island of Java, (Figure 1) is located in the Oostlijk Havengebied, in the area of the Eastern Harbor District; the neighborhood project, of 6,000 inhabitants, people; it was designed by Sjoerd Soeters and among its purposes it has the utmost attention to the environment, with water always the protagonist. The original pier was divided into five new small islands by building four new channels. It is a truly new eco-neighbourhood as, with the exception of the "slat" near the eastern access bridge to the island, reused for offices and residences, all the pre-existing buildings have been demolished. On the longitudinal fronts there are block buildings with the street side 27 meters wide and a height between 5 and 10 floors. The buildings located on the northern side, only residential, are intended for social housing, while the southern ones, for the free market, have commercial activities on the ground floor. On the fronts of the four new canals there are terraced houses. All different from each other, but with a front of 4.5 meters, which recalls the memory of the central streets of the city. As regards open public spaces, as it was not possible to create large squares, the internal courtyards were made public and a system of urban voids was organised. [30] The vegetation fills the courtyards in a compact form and in rows; the presence of grassy surfaces is widespread; numerous buildings with vegetation on the fronts. The presence of water is a constant not only for the canals, but also for the presence of pools and fountains.

Borneo (Figure 2) and Sporenburg, (Figure 3) [31] falling within the Vinex ministerial program for housing development, were supposed to be high intensity, but after public-private negotiations they were built, with a master plan designed by the West studio 8 at the end of the nineties, especially extensive housing. [32] This is an innovative interpretation of the canal house: new types of three-storey houses, which go beyond the traditional terraced type, with patios and hanging gardens. The intervention programme, including public housing, subsidized housing and free market housing, includes 2,500 homes. In Borneo, always in correlation with water, there is a vegetal heart, while for Sporenburg the vegetal elements are above all in private spaces. The perception of the context is immediately and directly delegated to the specific characteristic that derives from feeling on an island, even if in reality they are located on two peninsulas. Water is the characterizing element both in public spaces and in homes; all residences with mostly glass facades have a view of the water. The mobility system is centered on pedestrianism and the network of bridges. Much attention was given to the visual perception of all internal routes, both in terms of the margins and partial and final views. [33]

The Bo01 neighborhood in Malmö, Sweden, (Figures 4 – 5 – 6) was built on a former industrial area serving the port. Usually named West Harbour, is almost entirely composed by an artificial peninsula, about 140 acres, built in the late 1800's for the Kockum shipyards. The 30 hectares of the area are located in a strategic location between the old town, the sea and the urban parks system. Consists of nearly 800 dwellings in low - medium high buildings, but the 54 storytower, 190 meters high, designed by Santiago Calatrava, the Turning Torso, it rises. The reason why they constructed Turning Torso was to re-establish the skyline of Malmö, after the elimination of Gru Kockum, in 2002. The idea comes within the framework of the European exhibition on living and involved Central Government, local government and entrepreneurs. Entitled "the city of tomorrow for an informed society ecologically sustainable, in a well-being era" held in Malmö in 2001. The restoration project of the entire area and the General Plan of the new district coordinating by Klas Tham. The guiding principle was focused not only on physical environmental sustainability, but also on the social one, with the motto "beautiful and sustainable." An human scale neighborhood, with a city appearance. In this context, the concept of sustainability is used for the neighbourhood, for the open public spaces and for buildings. The whole neighborhood is on a human scale, completely pedestrianised, with small roads and paths that led to important urban scenarios, strongly and constantly connected with natural elements. Expertly, the built alternates itself with urban voids, designed and natural, including the two parks: the Anchorpark, with vegetable elements typical of the region and the Dania, with herbaceous stretches towards the sea. The mobility system, both within the neighborhood and the one connecting to the rest of the city, is organized favoring pedestrian routes, bicycle routes, public transport, even with shared car, that means it is extremely convenient considering time and cost. The masterplan was organized through a continuous sequence of sites on the banks of the Canal that empties into the basin of the Öresund. The building types essentially consist of line house and court house, with a multiplicity of languages and forms. Designers, more or less known, were different. Among them, in addition to Swedish and Danish architects, we address Ralph Erskine, from England and Mario Campi, from Switzerland. Of extreme value even the sea front characterized by soft colors in harmony with the surroundings, and by great spaces directly interconnected with water. The connection takes place through a series of terraces that represent a true place of urban collective. The same is for public open spaces, connected by a precise-lined paths made from trees. The entire urban fabric is articulated in continuous dialogue between architecture and nature. In addition to the vegetation, a hegemonic role is represented by water, according to different fields and methods. Internal paths joins and connects with the canal system. The South-facing facades of the building are totally glazed to help a proper climate control. All aspects related to bio-architecture have been applied in buildings and in urban open spaces. From a technological point of view any aspect was not overlooked. The role of natural system for the purpose of social sustainability, is very interesting,

Proceedings

focusing on the quality of urban spaces, intended as comfortable living in the natural system, connected with the hanging gardens and vegetal walls, mostly implemented with climbing plants. The choice of species was made by ensuring biodiversity. Should be emphasized that vegetal walls, as well as social aspects strongly cooperate for thermal insulation and have an important collaborative role in collecting and draining rainwater towards the tanks. From these tanks, water flows into open-air network of channels, alongside roads, in order to reach the sea, after being purified. These elements, in harmony with others, set up the urban landscape. The aspects connected to energy are also very important, extremely innovative and articulated, designed to power the neighborhood exclusively with energy produced on site from renewable sources. We already mentioned glazed walls and green roofs, but also collaborate solar panels and windmills. There is a wind turbine 80 meters high which every year produces enough energy to power approximately 200 residential units. Moreover, there is also a system, which extract heat from the bedrock of the subsoil. Were performed a number of cavities, 90 meters deep, which are filled with hot water, during summer; the heat is preserved and stored by the bedrock. During the winter it is extracted and used as the biogas extracted from waste. The latter, from every single dwelling, is collected and disposed at the level of the same quarter by directly reusing what is recoverable from bio-waste, first of all for the fertilization, and then to create energy. [34]

“The environmental sustainability of the neighborhood is closely related to its energy efficiency, obtained thanks to a supply from predominantly renewable sources and the reduction of consumption. In fact, the neighborhood appears to be a concrete example of the application of design strategies and plant technologies aimed at reducing emissions of climate-altering gases into the atmosphere, in total harmony with the increasingly high-performance standards required by the European Commission regarding sustainable urban -ty and eco-compatible construction.” [35]

In Italy: in Trento, the Le Albere neighborhood [36] was created in 2013, designed by the Renzo Piano Building Workshop studio. It stands where the Michelin factory, now abandoned, was, with the specific task of environmental redevelopment. It consists of 300 homes, offices and commercial activities with a surface area of approximately 12 hectares, with a park of over 5 hectares and almost 3 hectares of open urban spaces. In the complex there is also the Science Museum, Muse, and the Congress Center. The project focused on reconnecting the area with the existing city fabric and on recovering the relationship with the river environment, with the aim of returning to the city the areas that had become marginal. The facades of the buildings are characterized by wooden grilles in front of the windows; the green color predominates. [37] Renzo Piano writes that "the entire project is conceived and created to [...] be reasonable and sustainable on a management level, because the basic inspiration on which this new century opens for an architect is to understand that the fragility of land must not only be defended by saving money but also by searching for the best architectural expressions [...] this is an ethical quality of the Le Albere project which has strictly to do with my vision of the future... Le Albere is a classic example of transformation of brownfields, abandoned industrial lands, into greenfields, a cemented ground that becomes largely green..." [38] The theme of sustainability, also aimed at the problem of climate change, addresses the energy aspect with a

Proceedings

centralized system that optimizes the resources and reduces management costs by paying close attention to energy saving in buildings equipped with photovoltaic panels; fixtures and cladding are made to contain thermal dispersion. Summer and winter air conditioning is managed by a central unit for the needs of the entire complex. A system of canals feeds two large bodies of water on which the buildings "float". The plant system is organized around a transverse axis of rows of trees; the courtyards of the buildings are open so that the internal gardens can be seen from the outside; the park from the residential complex reaches the bank of the Adige river. [39]

8. CONCLUSIONS

There are no conclusions to be drawn on the merits of the treaty, but we must hope for a total, comprehensive and shared commitment so that the landscape project is increasingly sustainable, also with reference to climate change.

Sacred Mexican plants: the value of native flora for sustainable urban green spaces

P. Granziera

Facultad de Artes, Universidad Autónoma del Estado de Morelos

Avenida Chamilpa 2000, Cuernavaca (Morelos) México

Email: patgranz@gmail.com

Extended abstract

In the design of landscapes, botany should play a fundamental role together with aesthetics and science. In this context, the value of native vegetation, can be an additional element of support for the overcoming climate crisis.

The purpose of this paper is to underline the importance of recovering the value of autochthonous Mexican plants, showing not only their importance as part of the Mexican historical and collective memory but also as forces that can provide sustainable urban green spaces.

In pre-Hispanic Mexico the whole of the cosmos was animate and the deities were represented in anthropomorphic form as well as in the form of animals and flora. As a result of the high value placed on plants and flowers by Mesoamerican people, gardens were well stocked with ritual and medicinal plants. Dominican friar Bartolomé de las Casas describing the gardens of the Aztec emperor, affirms that Montezuma had orchards and gardens with all kinds of flowers that one could find in his kingdom. Flowers were very much appreciated by pre-Hispanic people because they were offered to the gods and flowered branches were also given to leaders to strengthen them for their tasks and to affiliate them more closely with the divine powers.

As the years went by, and with the arrival of plants from other countries (during Colonial times) along with the development of allopathic medicines, the knowledge and use of native plants in Mexico has disappeared little by little. Only indigenous peoples have maintained this knowledge in different ways. In the same way, the famous pre-Hispanic gardens have been forgotten and the few archaeological remains of these gardens have not received due attention. As a result of this, the Mexican appreciation of native aromatic and ornamental plants has been fading during the years. In fact, the preference for non-native plants is quite common in contemporary Mexican public and private gardens. This limited knowledge of native plants is evident in the designs of urban green spaces by the most acclaimed Mexican landscape architects, who seem to prefer non-native plants that generally require more water and maintenance. In the design of urban landscapes, it is important and strategic to use native plants in order to support local environment. Contemporary landscape architects should deepen their knowledge on Mexican flora and consider botany as a fundamental discipline for the creation of green spaces.

Extended abstract

The territory of the Netherlands is strongly characterised by landscapes of outstanding natural value: areas of approximately 10 square kilometres that are distinct in terms of their characteristics and conformation, forming a system of national parks with four main objectives: 1) the protection and development of nature and landscape; 2) outdoor recreation; 3) education; 4) research. The most important and extensive area is the Nationaal Park Hollandse Duinen.

The historic Voorlinden agricultural estate is just next to the Park, with the eponymous Museum of Contemporary Art, designed by Studio Milani in 2016.

The thesis project, assisted by the landscape atelier Arscape, aimed to create a botanical collection that could work in parallel with the park system and be a forerunner for the tangible development of its guidelines. The opportunity of academic work has allowed the development and experimentation of a design model capable of being innovative in the use of plants, starting however from the character of that specific territory; a project dropped into that place, tailored to its specific geomorphological characteristics, its history, its invisible traces and its current setting as a museum and informative centre.

It is a creative workshop in which the acclimatisation gardens' plants and the ones grown inside the greenhouses, reinterpreted in a contemporary key, populate the collective space: autochthonous but now disappeared plants, or new ones that can be adaptable with the current climatic conditions of the place, coexist in a continuous process of experimentation of migratory plant cells. Their shape on the ground, an emanation of the imprint of the waves beyond the dunes, tell something about their proximity and their final purpose, namely their responsible and creative knowledge and re-population. The dissemination of the history of the place through traditional museum-type systems and through the form of the designed space, ignites synapses between the place of production and the countries from where the visitors come from: the latter will bring with them 'postcard seeds' as a memory of the experience made to be repeated at home. The challenge that today's designers have to face, supported by researchers and any expert in the botanical, climate or engineering field, is that of not losing sight of the history, form of the territories and the communities that live there, broadening the concept of sustainability towards the idea that it is a matter of social, economic and constructive sustainability. Acting this way, they will be able not to distort the territories in an undesirable globalisation of the communities and places in which they live.

Keywords: *crowdsourcing; participatory mapping; open data; building attributes; Athens*

1. INTRODUCTION

The territory of the Netherlands is strongly characterized by landscapes of outstanding naturalistic value: terrestrial and aquatic environments with specific flora and fauna, areas of approximately 10 square kilometres that are distinct from North to South of the country in terms of their characteristics and conformation.

These areas were identified and subdivided in the first decades of the 20th century and subsequently named National Parks of the Netherlands.

Altogether, there are 20 parks in the European territory of the Netherlands, covering a total area of 135,030 hectares, more than 3% of the total area of the country.

In addition, there are many natural reserves and smaller parks scattered throughout the country, as well as country estates and other natural areas with more touristic purposes, such as campsites and golf clubs, which are always integrated into the surrounding landscape, respecting the natural environment around them.

National parks have four main objectives:

- the protection and development of nature and landscape;
- outdoor recreation;
- education;
- research.

The most important and extensive area is the Nationaal Park Hollandse Duinen (Dutch Dunes National Park), which stretches along the entire coastline from North to South over approximately 60 km of coastline. (Fig. 1)

The Dutch Dunes were formed more than 5000 years ago because of rising sea levels. They therefore synthesise and bring together various aspects of the dune culture, referring to height, to the presence of drinking water, to displacements and continuous structural variation due to winds, not least due to human action.

Men over the centuries have in fact played a decisive role in the development, but also in the degradation of these areas: in past centuries grazing and agriculture have impoverished and modified the development of the dune's fauna and flora, also causing the uncontrolled multiplication of various tree species.

A further impoverishment of the dune ecosystem certainly occurred during the Second World War: bunkers and anti-aircraft guns were scattered over them, some of which are still present today.

Starting from the awareness of the degradation of certain dune landscapes, the main objective of the European project, "Life Dunes", was to restore severely neglected dune areas to allow plants and animals, that had become rare, to repopulate these natural spaces.

In the dune restoration project trees, bushes and improperly accumulated plant soil were removed in a timely manner, letting nature have a new rebirth.

Several valleys and natural pools were recreated to restore the habitats of amphibious species, such as the magnet toad, or large mammals such as deers; the rebirth of many tree species was also ensured. The valleys were thus populated with alders, birches and buckthorns, which provided protected spaces for animals in general and nesting sites for birds in particular.

The sea buckthorn berries, for example, are a source of nourishment for migratory birds that stop here before setting off on their long journey South.

As of most European socio-cultural projects, one of the strengths of "Life Dunes" has been the active involvement of the local population in the regeneration, maintenance and restoration of the dune areas.

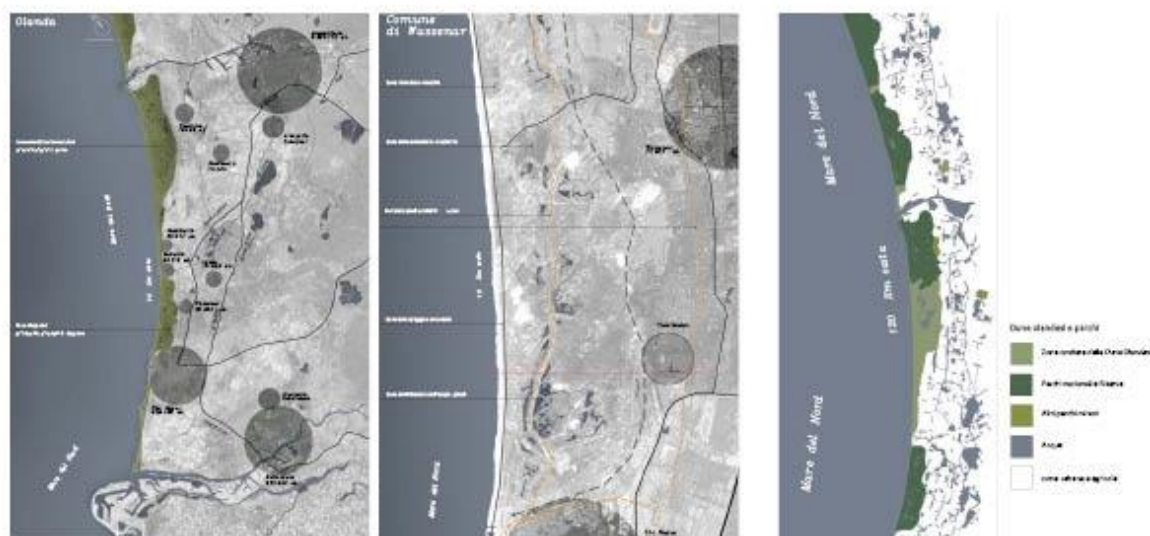

Fig.1. Focus on Dutch Dunes National Park and paths: extract from the thesis project.

2.THE VOORLINDEN ESTATE: FROM FARM ESTATE TO COLLECTION OF CONTEMPORARY ART

The southernmost area of the Dune Park is the Meijendel area.

It separates the sea from the Voorlinden Estate, a totally flat green piece of land that is the site of the homonym contemporary art museum and the setting for the "Landscapes collections-the Voorlinden experience" project.

The earliest records of the Voorlinden Estate in Wassenaar date back to around the 17th century, a period in which a series of agricultural estates were established along the important road from The Hague to Haarlem, where villas and parks were built over time. In a landscape characterised by dense forests, beaches, dunes, open polders and fields of bulbous flowers, these historic places provide an interesting window into the past.

In the 18th century the estate was inhabited by the Portugese banking family Lopes Suasso. The mansion was situated on the left of the current driveway, near the greenhouses and service housing. This property covers about 40 hectares and its conformation as an agricultural estate remained virtually unchanged until mid-19th century.

Landscape architect Johan Zocher Sr (1791-1870) designed a park in the beginning of 19th century, later constructed by his son J.D. Zocher jr (1820-1915).

When esquire Ir. Hugo Loudon (1860-1941) acquired Voorlinden in 1912, he commissioned the construction of the current mansion, designed by British architect R.J. Johnston, who also conceived the surrounding gardens with their characteristic geometrical divisions and brick terraces.

In this same period, Leonard Springer (1855-1940) reorganised the landscape park to reconnect the estate with the new mansion.

The villa becomes the focal point of the intervention, with a wide visual opening on the front; the driveway is populated with both native and exotic tree species. The non-native trees are mainly placed in visible and prominent positions in the park, along the paths and at the edges of the open field.

Some of these special trees still grace the Voorlinden estate today, such as the bald cypress along the access road and the silver maple on the north-western edge of the forest, in front of the country house.

Proceedings

of the International Conference on **Changing Cities VI:**
Spatial, Design, Landscape, Heritage & Socio-economic Dimensions
Rhodes Island, Greece • June 24-28, 2024

ISSN: 2654-0460

ISBN: 978-618-5765-02-6

This rearrangement defines the character of Voorlinden's green areas, transforming the original park into a green collection, a kind of open-air botanical museum.

Since 1950 Voorlinden is owned by the Dutch Post, Telegraph and Telephone company. The country house was used as a training centre. Employees lived here as residents.

Today, the country house, the gate at the entrance, the stables and the double service houses at the Voorlinden estate are national monuments.

In 2011, the ownership passed to the Dutch entrepreneur Joop van Caldenborgh, founder of the Caldic chemical industry and a major global collector of contemporary art.

In 2016, Mr Van Caldenborgh commissioned a museum in Voorlinden to host the Caldic Collection.

3.THE VOORLINDEN MUSEUM PROJECT AND STUDIO MILANI ARCHITECTURE

The museum is inserted in the North-east side of the property, in a space among the thinnest trees, a few dozen metres from the Villa, remaining autonomous yet on an axis with it, without obscuring its original geometries, perspectives and proportions.

The new contemporary art museum, on a single level and with a rectangular floor plan, measuring 180 metres per 80 metres, was initially designed by the Dutch architectural studio Kraaijvanger.

A special feature of the project is the white metal roof perforated by 115,000 inclined solar cylinders that bring natural light into the halls, while minimising the use of artificial lights inside.

Glazed facades reflecting the surrounding landscape contribute to the perceptive fluidity between inside and outside.

Three main objectives were dictated by Mr Von Caldemburg: the quality of light, the level of safety, and the aesthetic quality of the technical details; safety signs and installations disappear both in the white walls and in the floor design.

A wedge that cannot be eliminated from the framework of the overall project is undoubtedly the intervention of landscape architect Piet Oudolf, a well-known representative of “The Dutch Wave”, who creates a new garden around the museum, modelling the terrain organically, with planes and knolls which remind the course of the dunes. A colourful sea of herbaceous plants and wild flowers, showing their continuous seasonal metamorphosis. One can savour the scent while strolling all around through small paths, or enjoying the green perspectives from inside the museum, as if they were real living impressionist paintings.

During the construction process, Mr. Joop Van Caldelborg entrusted the Siense architecture studio “Andrea Milani” with the completion of the design concept of the work, as well as the artistic direction for its completion.

The definition of the external facades and the interior design proposed by Milani's studio thus reinforces Von Caldemburg's emotional and cultural bond with Italy and establishes the indissoluble relationship between the plant material, the external landscape and the works of art contained within. In fact, the Siena-based studio brings to Voorlinden the way of conceiving the project in a comprehensive and meticulous manner, besides their unique design thinking, based on the concept of *site-specific*, *timeless* and therefore *iconic* results.

A vibrant travertine cladding reinforces the monolithic form of the museum, thanks also to a detailed and punctual laying pattern, which recomposes the texture of the entire original stone block chosen for the museum.

A clean geometric system, in which the compositional lines and the play of shadows define a metaphysical volume, that works in assonance with one of the preponderant materials of the territory: the sand of the dunes.

The surface material breathes with the surrounding landscape, working as a boundary space between architecture. The perimeter floor, made in large format, is laid dry on travertine strips, with the same cutting criteria as the facades, and merges on two sides with Piet Oudolf's garden.

Inside, the design of the art shop, the ticket office, the bookshop and the auditorium composes clear spaces in which the proportions and millimetric manufacture define unprecedented surfaces in terms of shape and orientation, recovering the same meticulous and skilful approach to design, to the definition of details and the laying of finishing materials.

The new layout of the Voorlinden estate, which was asked to Studio Milani in order to complete the contemporary art museum system inaugurated in 2015, envisaged a project to create a complex and stratified cultural compartment that would be a reference for the area north of The Hague.

FIG. 2. Auditorium and Library, Voorlinden Museum from Studio Milani

4.3. THE LANDSCAPE DESIGN AND CONTEXT

The Voorlinden Museum is located in a part of the Netherlands that is not yet characterised by major museum complexes, as Amsterdam or Rotterdam are; this is why it holds the gift of uniqueness and exemplarity.

The thesis project developed by Caterina Cipriani and assisted by the architect and landscape designer Annunziata De Comite (Arscape) was born with the aim of amplifying the ‘‘Voorlinden experience’’ by inserting itself into the landscape and creating an emotional and formal stitching between the Estate, the coastal dunes and the Wassenaar diffuse residential area. Thus the idea of the ‘‘Voorlinden Landscape Collection’’ was born, which in a spatial and functional continuum from the nearby Clingenbosch Sculpture Garden arrives to the entrance of the Meijndel Park behind the Villa, crossing the estate.

The flow of experiences within the estate is composed of individual collections organised along a step-by-step path made up of meanings of use around the concept of a collection:

- 1_ *Open air art collection*: the sculpture park of Clingebosch
- 2_ *Experimental botanical collection*: the parking area-garden of acclimatisation
- 3_ *Botanical collection from the world*: the Green House and its vegetable garden.
- 4_ *Wassenaar Dunes collection*: the underground car park-art storage with roof garden
- 5_ *Original art collection*: the Voorlinden museum and villa
- 6_ *Territorial botanical collection*: the Meijndel Dunes.

Starting from the limits of the place subjected to natural-historical constraints and its evolutionary-historical peculiarities, conceptual axes were identified, capable of shaping those constraints as opportunities for a contemporary reinterpretation of the place.

FIG. 3. Spatial relations, master plans and planting matrices: extract from the thesis project.

A condition that immediately appeared necessary was to keep cars and tourist buses away from the heart of the estate by immediately defining the rules for accessing and moving within it, i.e. mainly on foot or by bicycle. The aim was to empathise with the landscape and breathe in the design and thematic balances developed within it. The didactic artistic route that brings together the art and plant collections as well as the existing botanical areas, both natural and experimental, becomes tangible and can be experienced in a tactile and olfactory manner, in a calm and reflective time.

The car park therefore also becomes part of the collection and an introductory chapter to the whole experience.

These are acclimatisation gardens in which the cars are physically plunged in a vegetal system on two levels: on one hand, the plant essences intended for the pre-treatment of rainwater along the canals perimeter to the car parking areas, before being reintroduced into the territorial drainage system; on the other hand, the choice of trees and shrubs coming from the neighbouring greenhouses which, following acclimatisation, can be reintroduced into the adjacent portion of the Dune park.

From here we proceed to the heart of the project where the “Green house”, built to replace the existing agricultural greenhouses, reinterprets the theme of the 19th century greenhouse as an educational but also convivial space.

It is a large greenhouse made of glass, designed according to the profiles of typical Dutch houses, following along the line of the milky Dutch sky that inevitably also recalls the variation of windswept dune silhouettes.

Dedicated to the knowledge of dune environments, the greenhouse is an exhibition space for eight dune landscapes, from as many countries in the world, where, as in the Netherlands, dunes are a distinctive feature in the landscape.

Habitats with different climates and configurations are compared with a field research program, in order to test and verify the behaviour of various dune species in continuity with the coastal dune restoration and regeneration activities mentioned above.

The aim is to create a sort of *nursery of coastal vegetation* that has disappeared or has been degraded over time.

The interior of the greenhouse provides a flowing walkway between the restaurant-café area and the retail space for seeds and products from the “Voorlinden garden-collection”, a vegetable garden which is developed in front of the main elevation of the greenhouse.

The use of glass and metal structures for the perimeter walls and roof was complemented by a material that is highly evocative of the local building tradition, functional to its climatic and transparency requirements: the glass brick.

The use of the brick is formally connected to the perimeter walls that delimit certain areas within the estate, partly maintained in the project as a frame for the greenhouse and as a functional separation between the car park and the vegetable garden.

The contrast between the solidity of the car park and the apparent fragility of the garden, animates this architecture with an unusual dynamism for such apparently flat countryside, together with the play of ephemeral shadows, the morning mist and the iridescent greys of the Dutch skies.

The open square of Voorlinden's vegetable garden, designed with reference to the shape of Dutch polders or peat bogs set in large corten steel tubs, counterbalances the covered square of the greenhouses with the dune islands of the various continents.

The regular pattern of the basins is crossed by an organic pathway that connects the acclimatisation gardens with the entrance to the roof garden of the underground collection.

Along this pathway, the vegetation develops according to a planting scheme that, like a shock wave, gradually dematerialises and thins out from the sea towards the greenhouse building: thus we pass from small, fragrant shrubs in shades of grey and purple, to two-coloured herbaceous plants and vegetables scattered like small, autonomous sculptures. Moving away from the pedestrian street, going to the opposite direction, the vegetation changes consistency and colour, fading and softening thanks to the masses of decorative grasses that change colour throughout the year.

The central area occupied by the open-air seating of the café-restaurant is enlivened by ancient fruit trees, bringing back a domestic atmosphere in which the idea of harvesting and direct consumption becomes more tangible.

Giant medlar trees from Holland, persimmons, quince trees, cherry trees and strawberry trees inebriate the air with colours and scents in the flowering and ripening seasons of their fruit.

Their foliage generates natural shadows for visitors, relaxing or feasting in the square in front of the greenhouse.

The entire intervention is uniformed by a finely designed stone carpet, that makes the areas of permanence and social gatherings precious and elegant. Asphalt made from recycled plastics was chosen for the roads, while a medium-small gravel was used for the “beach” around the garden ponds, in order to slow the pace and make the experience of walking while observing and smelling comfortable.

The opportunity of an academic work allowed to elaborate and experiment a design model able to be innovative in the use of vegetable matter, starting however from the character of that specific territory; a project dropped in that place, adapted to its geomorphologic characteristics, to its history, to its invisible traces and to its current museum and popular configuration.

That's how that the planting system, designed according to a form consistent with the design original idea, does not try to imitate nature and its alleged disorder, but rather seeks that “contemplation as a geographical experience of space” of which Nogue speaks (1 note “Other landscapes” p.38) that pertains to highly symbolic, and in our case also evocative, landscapes.

With this aim, the project is not only technical, but also spiritual, with the goal to create possible alternative views within the proposition of a life scenario.

Similarly, the concept of the autochthonous is also applied in a fluid and interpretive manner because what is autochthonous today was probably not autochthonous yesterday but has also worked for the creation of an evolving scenario.

This is why in our case we can speak of a creative workshop in which the plants of the acclimatisation gardens and the plants grown inside the greenhouses populate the collective space: indigenous but now disappeared or unseen plant essences, assonant with the current climatic conditions of the place, coexist in a continuous process of experimentation of migratory plant cells.

Their shape on the ground, an emanation of the imprint of the waves beyond the dunes, tells of their proximity and of the ultimate aim, bringing back knowledge and responsible and creative repopulation.

Another topic that is indispensable for us in today's landscape, alongside the emotional geography of spaces and the interpretation of conceptual assumptions such as the meaning of autochthonousness, is the dissemination of the history of the place through traditional museum-type systems and above all through the shape of the space designed to trigger synapses, between the place of production and the countries of the visitors <,who will carry with them “postcard seeds”, the memory of the experience made to be repeated at home.

A step further than simply communicating the starting fact, i.e. the loss of quality of a natural, historicised territory and the damage it causes.

Not a news item among the many, albeit serious, reports on the state of degradation of the climate and the planet, but an awareness based on a tangible memory of an experience that will be recounted and tried to be replicated, of which one will become an actor in the first person.

For this purpose, objects were imagined containing the seed of that experience and linked to the world of technology and the meaning of connection, network sharing, as well as the concept of production as creation.

A series of “smart” objects and experiences that allow access to a database of botanical collections, to an app that allows the user to connect with Voorlinde: adopting a plant, following it on its path of birth-growth and verification of acclimatisation experiments to habitats different from the original ones, up to the end of the life cycle with sowing and re-pollination.

Objects that allow you to take a part of the Voorlinde journey with you and, once at home, transform and evoke your experience in the museum.

In an era of fast images that are increasingly aseptic and empty of meaning, detached from the contexts in which they are dropped by unrealistic and uncreative artificial intelligences, doing architecture and landscape design means, more than in any other era, knowing how to deal with places and their formal and socio-cultural culture.

We must guarantee the coherence, ethics, legibility but above all the innovativeness and uniqueness of a creative design path by critical reading of the contexts and the natural and anthropic processes that have generated them and the assumption of responsibility for the possible error in producing a new vision of them.

The metaphor expressed by André Corboz of the “territory as palimpsest” is as pertinent and topical today as ever.

In urban or agricultural and natural territories, we can always identify visible and invisible traces that can be recovered, erased, or reinterpreted in order to evolve, supporting or directing the transformation processes underway.

In all this, the project cannot and must not be secondary in the transformative and creative process and must freely aspire to beauty, now often demonised and debased as a mere aesthetic concept and unnecessary when compared to those of environmental sustainability and lowering CO2 emissions.

We cannot, however, make an argument of exclusivity of values, but of critical synthesis in the forms designed and in the use of raw materials applied, whether they are animated or not, to aspire to architecture as the art of inhabited space.

The need to reduce the impact of what is built is inescapable, but constructive and economic sustainability cannot be applied at the expense of cultural, social and historical sustainability.

The challenge that today's planners will have to face, flanked by researchers and any expert in the fields of botany, climate or engineering, will be that of not losing sight of the history and shape of the territories and the communities that inhabit them, broadening the concept of sustainability towards the idea that it is a matter of social sustainability, and then also economic and constructive sustainability, so as not to distort the territories in an undesirable formal globalisation of the communities and places in which they live.

Abstract

Since the history of humanity has always been intertwined with that of water resources, it is possible to interpret water contexts in the light of our actions feeding a bond of exchange and mutual dependence.

Water landscapes, with their fragility and vulnerability, represent the mirror of those territories which today are perhaps most affected by the ongoing climate crisis and which therefore demand to be rethought in terms of protection, management and planning.

This research concerns the Mantua water system, a complicated field of application which faces the challenges of climate change with a series of environmental conditions that appear far from those in its birth and development.

More specifically, the investigation concerns the area located north of the city of Mantua (Lombardy Region, Italy), an area with strong agricultural vocation characterized by the scattered presence of small and medium-sized urban centres. The territory analysed is linked to the Adige-Garda-Mincio-Tartaro-Canalbianco water system which carries out a series of functions aimed at the hydraulic defense of the territory.

Mincio river is a central concern. It plays a key role for these landscapes, as its course intersects the entire stretch of the district, constituting an important ecological corridor that connects Lake Garda to the Po river. The large waterways in this territory, the dense network of multifunctional canals (irrigation, reclamation and mixed use) and the natural conformation of these places make this area exceptional for experiencing the coexistence of a multiplicity of different landscape scenarios.

Working with the water resource, naturally elusive but at the same time conditioned by the will of man, involves an effort of accommodating the breadth of nuances that it entails. The plurality of gazes that it attracts is remarkable: water as an ordering element, water as a structural element, water as an instrument of identity construction, water as an element of sensorial attraction and so on.

The water system is therefore analyzed and interpreted in the light of this physical and semantic richness, putting into practice a series of observations that converge in different but strongly complementary readings.

To preserve and pass on the multilevel nature of this resource, the research proposes the recovery of the principles at the base of the systemic approach. The project aims at using the overall heterogeneity of water and the interaction of its different aspects as an element of strength and a starting point for the development of a landscape design in line with the complexity of these places.

Keywords: *Water system, landscapes, complexity, systemic approach, Mantua*

1. WATER STORIES AND ARTIFICIAL STORIES

The history of humanity has to do with the history of water.

And the history of water is not unique, it is a history made up of many stories, narratives of communities that have based their lives on the presence and use of this resource [1].

Vito Teti, in “History of Water”, describes the character of water as pervasive and heterogeneous in its relationship with every form of life. In its plural logic, “water performs its necessary functions, articulates and shapes its cyclical flow and drain, giving rise to different geographies and histories, modifying, depending on the places, times, interactions with other physical and historical factors –

first of all the shaping or destructive action of men – its ways of being, its material presences, its very symbolic values.” [2].

The impact of man’s transformative action on water landscape is an unavoidable aspect. This is testified by various publications, but we can also notice it by crossing the landscapes in which we live, where, depending on the case, it is possible to come across the ancient remains of Roman aqueducts, rather than the rigid and rectilinear path of the most recently canalized rivers.

In this regard, Francesco Visentin, professor of Human Geography, underlines how "the history of rivers and bodies of water can be read as the history and evolution of the control of a moving element, water" by men and their will [3].

The recent, and unfortunately numerous, environmental disasters that have hit the Italian water system are at the same time the mirror of an accentuated climate crisis and the clear story of a living, dynamic, uncertain, variable, transitory, and above all free agent.

What is even more shocking, emphasizing the fragility of liquid matter, is not only the number of disasters occurred in the last period but the speed and diversity of the different episodes. Andrea Rinaldo, the first Italian in the world who received the “Stockholm Water Prize”, also called the Nobel Prize of water, during his lesson “The government of water in the changing world” held at the beginning of the year at the National Academy of Lincei, invites the audience to reflect on the speed of the cycle, describing the episodes of flood and drought as two sides of the same coin [4].

The images of these events, with their expressive power, demand the need for a change, certainly in our way of acting but above all in our way of thinking.

In this direction find place all those studies that in recent years are trying to shift the point of view, embracing a less anthropocentric perspective of the subject that in some way explores the theme of water, reasoning in an unusual and oscillatory way, outside the box, just like water would do.

With this background, the contribution of each discipline is proving to be fundamental. The work of everyone, from architects, to geographers, to engineers, to artists, to photographers and any other profession, constitutes the engine that feeds the construction of a new imaginary of water landscapes. Taking as an example the studies pertaining to Landscape Architecture - the field in which the following study is placed - and considering the various experiences that are offering more flexible and resilient attitudes to the theme, it is impossible not to mention experts such as Mathur and Da Cunha who, going beyond the recurring trajectory interested in the man-nature relation, have long supported a description of water as an autonomous and omnipresent entity, which is everywhere, even before being in a well-identifiable location [5].

In other words, we are facing a real proliferation of ideas and contributions that wish to clarify the role of water in relation to our landscapes and their design.

A cultural movement that has also strongly affected the different universities, each with its own tools and insights. Among the examples, we recall the recent "Water in the landscape. Cultivating Hydrologic Imagination in Environmental Design", a thematic blog conceived and launched by the University of British Columbia school of Architecture and Landscape Architecture that, in a perspective of constant exchange and growth, aims to offer knowledge and provoke curiosity to outline new paths of investigation. The following research finds place in this complex context dominated by the paradigm shift, a scenario that attempts to look to the resource with its agency and its capacity to act as a living and changing element.

2. THE MANTUA NODE

The context explored is located north of the city of Mantua (Lombardy, Italy), an area with a strong agricultural vocation characterized by the presence of small and medium-sized urban centers. The chosen area has a strong liquid characterization due to the presence of a complex water system that starts from the Adige, continues with Lake Garda and advances further south with the Mincio, Fissero, Tartaro and Canalbianco towards the Po, entering the innermost meanders through a dense network

Proceedings

of canals. From a hydraulic point of view, this interaction of water bodies is associated with the "Mantua node", the focus of this research (Figure 1).

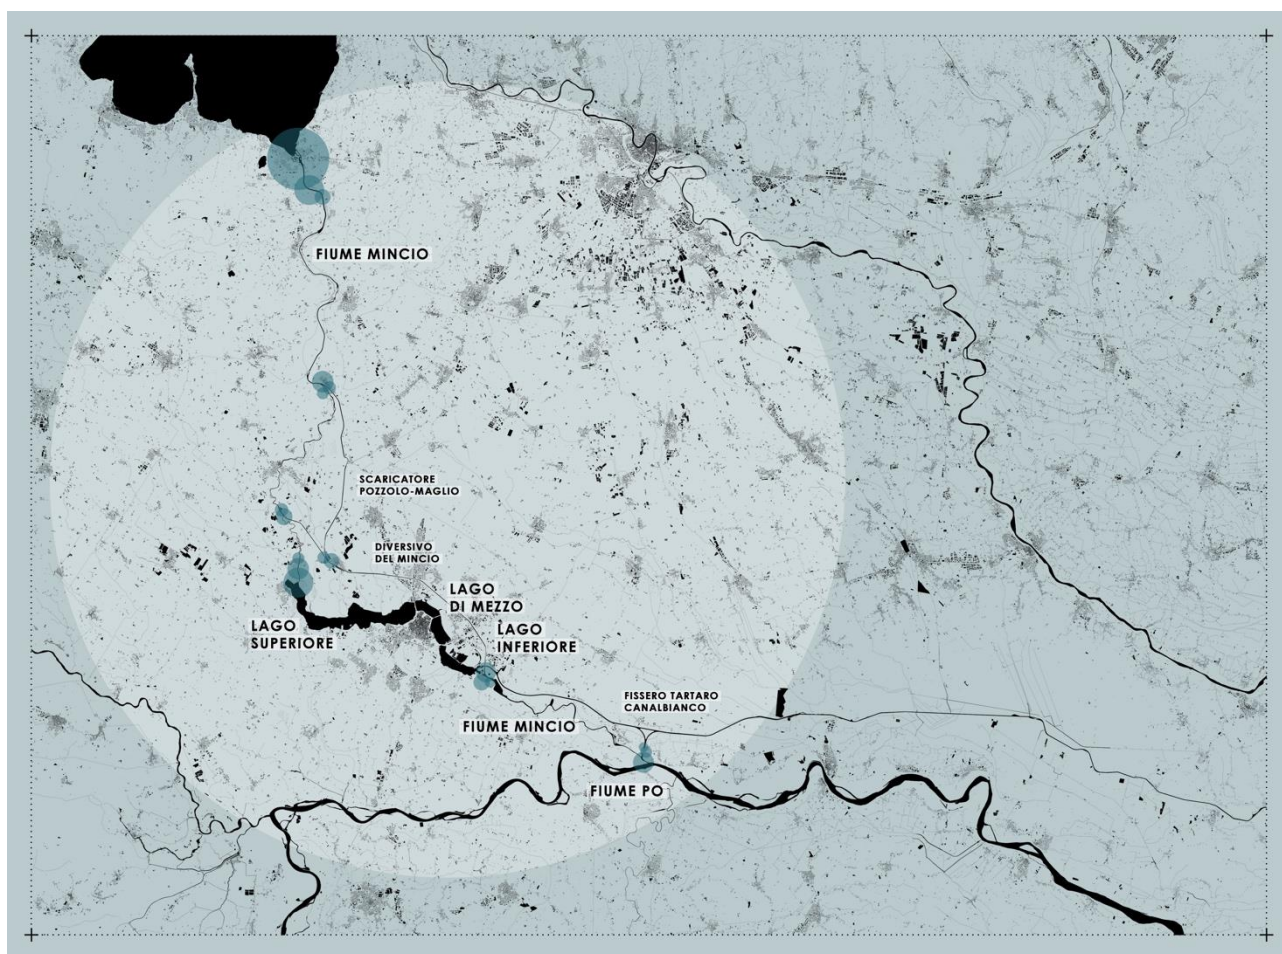

Figure 1. Frame of the investigated water system with focus on the Mantua node and its main intersection and confluence points. Graphic elaboration by the author.

A water system like the one just illustrated allows the coexistence of a multiplicity of different landscapes, which fit perfectly into the previously described framework, made of paradoxes and contradictions.

We are talking about a context that also finds space in one of the most provocative prefigurations of recent times, the so called “Viaggio nell’Italia dell’Antropocene” [6]. A story that, thanks to the narrative and geographical skills of Telmo Pievani and Mauro Varotto and the cartographic sensitivity of Francesco Ferrarese, imagines and stages a new Grand Tour in the Italy of 2786, exactly a thousand years after the challenge made by Goethe. An undoubtedly dystopian journey that however tries to give substance to those various scientific evidences that have been predicting for some time a sudden rise in sea level, which would therefore lead to the submersion of the city of Mantua, the disappearance of the main water system with the various canals and the birth of a new coast in the area of the morainic hills, at the base of Lake Garda.

To find even more concrete evidence, it is not necessary to look far back in time, just remember the summer of 2022, when the Po was in the spotlight due to the presence of a massive drought, later assessed as a "record drought", the "worst hydrological drought ever observed since 1807" [7]. Not long after, a year after this serious drought that had provoked a strong damage to the entire territory and its populations, several Italian newspapers announced the disaster caused in Emilia-Romagna by

the flood, which, with the flow of the Po growing by a meter and a half in 24 hours, completely overturned the situation.

In an area like the Po Valley that is constantly witnessing change, those who work daily for the sustainable management of water resources, in their various local declinations, are the Land Reclamation Consortium, which deals with the hydraulic defense of the territory and the distribution of water for irrigation using a multifunctional approach.

Two activities related to water that have gradually made this area an artificial context, the result of human genius: "We can show foreigners our plain, all shaken and almost remade by our hands [...] We have taken the waters from the deep riverbeds and from the marsh depressions, and we have spread them on the arid lands. Half of our plain, more than four thousand kilometers is equipped with irrigation". Retracing some passages from the texts of Carlo Cattaneo, such as this extract from "Notizie naturali e civili su la Lombardia" of 1844, Giorgio Bigatti describes the Lombard countryside as an "artificial land" [8].

Today the city of Mantua appears to our eyes in a condition, often considered obvious and natural, but which actually is the result of a century of projects and transformations at different scales [9].

In other words, if the Mantua territory had not been reshaped by man, it would today present a very different relationship with water, much more immersive and in some cases precarious. Consequently, the cultivation system, settlements and other activities that today constitute the identity and character of these places would most likely not exist, or at least not be the same.

Among the various hydraulic constructions carried out in this area over time, there are two works that have affected more the separation between the land and water space, reducing to a minimum the possibility of mutual mixing.

The first, the oldest, can be attributed to the engineer Alberto Pitentino who, during the 12th century, began major hydraulic works that can still be seen in the presence of the three lakes that today surround the city of Mantua.

The second instead, carried out in the second half of the last century, concerns the construction of two canals that run alongside the natural course of the Mincio River (Figure 2). The first is the so called "Scaricatore Pozzolo-Maglio", which, with a length of 14 km and a flow rate almost double respect to the natural course of the river, diverts the excess flow at Pozzolo and continues southwards, in the Maglio area; the second is the so called "Diversivo del Mincio", a canal with banks entirely made of concrete, which collects the water flows from the territories on the left bank of the Mincio and transports them for about 18 km to the south, upstream of Formigosa, by-passing the city of Mantua [10].

As further highlighted in a study conducted on the area by a group of researchers from the C.N.R. (National Group for the Defence of Hydrogeological Catastrophes) and the Department of Earth Sciences of the University of Modena, these hydraulic interventions, combined with the even more damaging extractive activities typical of the area and the strong urban development that has occurred since the 1950s, represent the cause of serious damage to the geomorphological conformation of the territory, the hydrogeological situation and the landscape [11].

Therefore, if on the one hand these transformations prove essential from the point of view of security and territorial progress, on the other hand it is inevitable not to think of them as elements of possible landscape compromise.

3. PLURAL WATERS, UNSTABLE COEXISTENCES

Considering landscape as the perception that people can have of the surrounding territory, as well as the outcome of the interaction between man and nature, it is appropriate to look at the landscape reading considering the coexistence of concrete elements and more ephemeral manifestations.

This research therefore attempts to develop a systemic story that can give voice to the dual soul of this liquid landscape, that ambiguous duplicity that already in the nineties had induced Franco Farinelli to speak of the landscape as a "bat-word" [12].

The complexity of the landscape was therefore investigated through the filter of water by putting into practice various decoding processes borrowed from an initial phase of literature review.

The review of some thematic texts, carried out with the awareness of an inevitable incompleteness and of the contradiction that a theme like this implies [13], allowed us to focus on four families of contrasts that the relationship with water suggests: protection-transformation, abundance-scarcity, surfaces-networks and tangible-intangible.

Clearly labile oppositions that have not been explored in the disjunctive perspective but rather in the conception of the “and-and”, a vision that takes the paradox as a foundation and allows for further considerations and meanings. Robert Venturi, whose critical thinking has repeatedly gone beyond the architectural discipline, emphasizes how accepting contradictions is not an easy task. “The simultaneous perception of multiple levels requires efforts and hesitations on the part of the observer”, it demands an attitude with a multiplicity of focal points to oscillate between different concepts, avoiding exclusivity of meaning and searching for unstable coexistences [14].

It was precisely during this first phase of work that a transversal observation gradually emerged. It corresponds to the detection of a double posture to the theme that, in a certain way, recalls one of the most recurrent thematic nodes in architectural disciplines, and, more generally, in anthropological thought: the debate between form and function.

In the specific case of landscape architecture, and considering the theme of water landscapes, the form-function binomial has been translated and re-proposed in the hydrography-hydraulics pair.

As described in the well-known Treccani dictionary, hydraulics is the science that theoretically and experimentally deals with problems related to the motion of water, while hydrography is the science that deals with marine and terrestrial waters in their various physical and biological aspects.

The in-depth study of various sources has allowed this research to broaden the semantic extension of both words, arriving at the representation of a much more complex constellation of meanings, where hydraulics is not only motion but also balance, regulation and control of water, and hydrography also encompasses geological or geographical issues, the theme of surveying and the effects that waters cause on the landscape (Figure 3).

The choice was therefore to select some of the meanings found in each of the two areas explored, investing them with a new meaning and giving life to two new interpretative keys that partly reflect the classic projection provided by the sciences and partly constitute a unique and personal vision. The two interpretative processes were thus defined: the "reading of hydraulic characters" and the "reading of hydrographic phenomena".

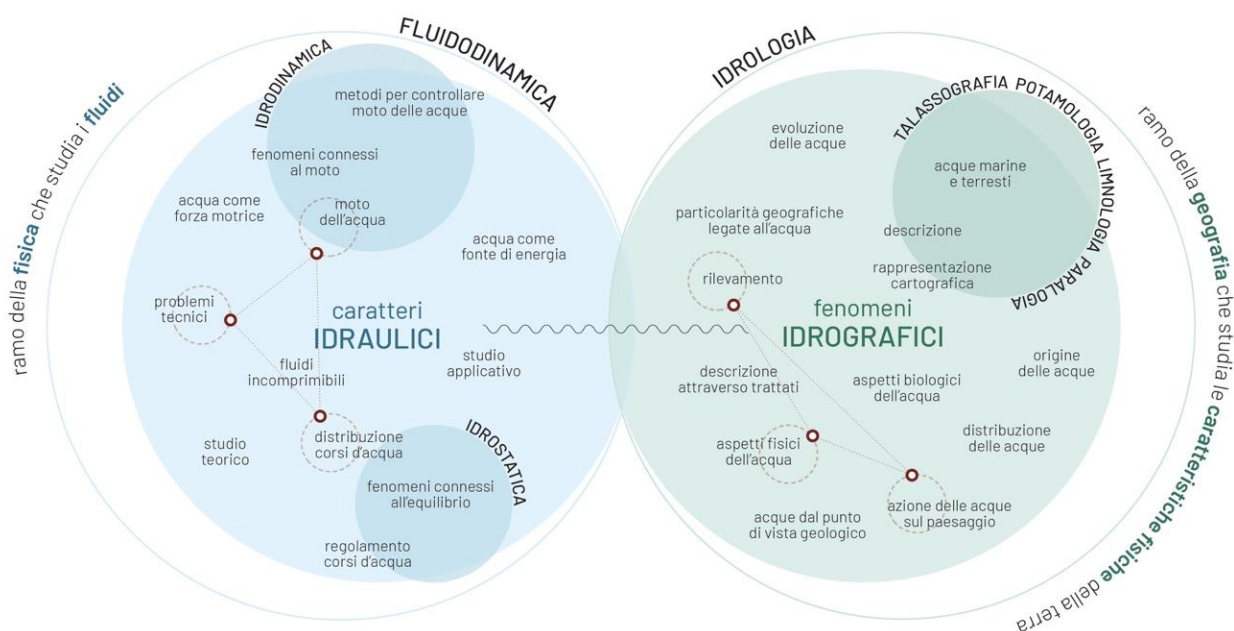

Figure 3. Cognitive framework around the hydraulics- hydrography binomial.

Graphic elaboration by the author.

The two readings have been applied to the Mantua case in the belief that the juxtaposition can provide a fertile contribution in the direction of rediscovering, and promoting, meaningful relations between the different elements that constitute these water landscapes.

The use of this approach has two immediate outcomes: on the one hand, the increase in knowledge of the territory examined from a systemic point of view, on the other, the expansion of the representations that make it consultable and shareable.

3.1 Reading of hydraulic characters

“What we call reclaimed landscape is one of the most successful examples of “cyborg-landscape”. If a gear in the landscape-machine breaks or gets jammed, in a short time the artificial stability that allows to separate water from land is interrupted and the equilibrium stopped.” [15].

The reading of the hydraulic characters has pointed interest towards all those distinctive signs of the Mantua water landscapes connected to the dynamics of water and its functions with particular attention to motion, technical issues and aspects connected to distribution.

Proceedings

The cartographic representation that emerged from this reading highlights a series of different components. The network of canals with the indication of the different purposes (land reclamation, irrigation and mixed); the points of intersection and the deviations of the same system; the troughs, concentrated in the north-eastern area, on the border between the high and low plain, where the aquifer is located at a shallow depth and the water can naturally emerge and move from the source to a specific destination; the irrigation extraction points, through which the water is captured from the river or another watercourse with variable methods (gravity, lifting or spring) and dissipated in the surrounding countryside; the hydraulic artefacts, some with irrigation purposes and others aimed at land reclamation; the navigable network that constitutes an invisible link between the waters of “Lago di Mezzo” and those first of the Po and then of the more distant Adriatic Sea; the set of harbors, some for tourist use and others for commercial use; the characteristics of the soils with the distinction between morphologically depressed areas, river terraces, surfaces made up of lateral migration deposits, floodable areas and raised surfaces, with the aim of highlighting the strong relation between the functioning of the waters and the nature of the land; finally, to conclude, the main network of canals, that is the supporting skeleton of the dynamics linked to the waters, both in terms of irrigation and reclamation. Since this is a restitution that is mostly oriented to the technical aspects of the water, we also find indications regarding the flow rate of the hydraulic artefacts and the capacity of the irrigation intakes.

3.2 Reading of hydrographic phenomena

“In the search for a semiotics of the landscape, [...] one can arrive, among other things, to feel the need to further investigate perception. In relation to this, for example, I was induced to introduce the notion of Iconema [...]. Iconema as an elementary unit of perception, as a sign within an organic set of signs, as a synecdoche, as a part that expresses the whole [...]” [16].

Regarding the second process, the reading of the hydrographic phenomena has turned attention towards all those exteriorities or appearances of the Mantua water landscapes that can be evaluated for their perceptive impact. With reference to the scheme, the attention in this case is directed to the physical aspects of the water, to the possibility of gathering of these characteristics and to their effects on landscape structure.

The cartography emerged from this reading highlights a series of components, partly already reported through the reading of the hydraulic characteristics, here deciphered differently through a series of cognitive and experiential processes. In other words, in this reading, the different factors are observed with a less technical and more identity-based perspective.

In the representation it is possible to find the hydraulic artefacts, whose presence is distinguished in three different degrees depending on the level of complexity of the system and, consequently, the degree of recognizability that it assumes in the landscape; the agricultural system in which, in addition to the widespread predominance of arable land, the emblematic presence of four crops emerges: the permanent meadows in the Mincio Valley, the rice fields located in the trough belt, the orchards in the high plain area and the poplar groves, mainly located in the Po river belt; the set of embankments with the presence of different altitudes and observation points in the landscape; the network of canals, which, compared to the previous reading, is examined through a different approach: some sections are reinterpreted with respect to their course (sinuous and meandering or rigid and rectilinear), others are distinguished by the strong impermeable character due to the presence of cement, others are highlighted for their significant naturalistic value or, on the contrary, for the division that their path entails. What further enriches this type of representation is the set of 19th century cartographic inserts (recovered from the online portal Arcaum) that have been applied in an experimental manner. The different fragments are arranged with a juxtaposition method that can be associated with the patchwork technique, with the aim of offering an immediate comparison between different temporal

thresholds and suggesting some considerations linked to distributive effects and gradients of landscape transformation.

4. CULTIVATING METAMORPHOSIS AND DESIGNING RELATIONS IN WATER LANDSCAPES

The two landscape appearances here described contribute to providing a particularly complex vision of the Mantua water system where the ordering and structuring nature mixes with the perceptible and identifying component.

The outcome of this part of the research is the systemic and informed restitution of a portion of territory from which the local peculiarities connected to the water resource clearly emerge.

Considering this evidence, it is appropriate to identify an adequately broad interpretative key that can constitute solid theoretical foundations to accommodate the genesis and development of bold projects.

In this critical process, the perspective notoriously transposed starting from the territorial research of the academic André Corboz [17], which today is condensed in the expression of “landscape palimpsest”, plays a crucial role. According to this vision, recovered and analysed over the years by many scholars, the landscape is understood as a set of layers or thicknesses, material and semantic, which have progressively sedimented through a process of continuous additions and subtractions [18]. In this sense, the landscape is like a manuscript, scratched and rewritten several times, in which large quantities of signs, traces and memories find space [19].

Corboz's interpretation, despite its constant relevance, seems to be less exhaustive in relation to an elusive and dynamic subject of study such as water.

A perhaps more suitable option for this investigation is to think of water landscapes as an assembly of different entities and movements constantly subjected to transformative processes [20]. In other words, with further reference to the thought of the geographer and philosopher Jean-Marc Besse, who has made an important contribution to the development of global ecological thought, it would be more appropriate to speak of landscapes as “sets of metamorphoses” in which forms and functions change over time, evolve, but do not decay, on the contrary, they persist differently.

In this sense, it is as if the metaphor of the manuscript left space for other possible ideas of landscape that do not necessarily concerns with cancellations, but rather with continuous deviations and mutations.

Besse's belief according to which “the transformed component always exists, even if otherwise and in another way” recalls the “practice of elsewhere as identity” suggested by Marco Belpoliti in the book “Pianura” in relation to the dynamism of the Po river [21]. The river, but more generally all the characteristic features of these water landscapes, such as canals, embankments or floodplains, suggest an inherent ambiguity, more or less broad: being multiplicity, being diversity and contradiction, being movement.

In a landscape like this, where the power of action cannot be eliminated but only redirected elsewhere, it is then necessary to assume a moving perspective that allows to cultivate present and possible metamorphoses. In this sense, we should look at the design of water landscapes as a design of relations [22] between heterogeneities, as project able to grasping the interactions between different dimensions, enhancing their dynamism. The kaleidoscopic character of waters, changeable and polymorphic, is potentially the starting point for the development of a conscious and sustainable water landscape design.

Abstract

Humans and environments are intertwined through sensory experiences, with visual perceptions significantly impacting emotional and psychological states. Research has explored spatial visual complexity's role in image processing, cognitive load, and stress relief, as well as the positive effects of fractal properties on stress reduction and emotional responses. While fractal properties in natural landscapes are crucial for understanding visual complexity, they can be further analysed through the geometrical properties of spaces. By integrating 1/f noise analysis, the complexity of signals processed by the brain is further enhanced, offering significant potential for understanding 1/f noise's impact on visual perceptions, which remains underexplored in urban research. This study examines 1/f noise values and their effects on visual perceptions and physiological responses in various spatial complexities. In a pilot test, participants viewed images with different spatial complexities and 1/f noise values while their brain activity was monitored with an EEG device. The study aims to preliminarily explore changes in live brain activity and note potential trends between stress levels, engagement, and attention focus across a limited range of 1/f noise values. The initial results of this study suggest the potential for larger-scale experiments to further investigate the impact of spatial complexity measures such as 1/f noise on brain activity using EEG, highlighting the ongoing need to refine urban design practices to better cater to the psychological needs of urban populations.

Keywords: *1/f noise, visual complexity, stress reduction, EEG, restorative environments*

1. INTRODUCTION

Humans experience their environments through various senses, and understanding the ways in which the sensations work together can be critical for designers to optimise the city from a strictly functional-based design to a perceptual restorative design paradigm. Researchers from related fields have extensively explored this topic, paying particular attention to vision and visibility analysis. The concept of 'visualism', which places vision at the top of a sensory hierarchy, often results in 'visual privilege', where visual information dominates interpretation. This notion has been frequently criticised in related works [1,2,3,4]. However, it is still valuable to learn more about vision, particularly in large-scale landscapes, since vision is the only sense capable of engaging with landscapes over long distances [2,5,6,7].

Visual perception has a strong connection with humans' emotional and psychological states. Researchers have found that the visual stimuli in cities affect people's stress levels and cognitive load [8,9,10]. On the other hand, fractal patterns in nature can make people feel less stressed and improve their emotional health [11,12,13]. In particular, fractal properties, as well as repeating patterns at different scales, were related to reduced physiological stress markers [14]. It has been proven that having a glance at natural elements, such as vegetation in parks, trees along the streets, and even plants throughout windows, can improve citizens' cognitive performance and reduce negative emotions [15,16].

For exploring the possible method to engage visual complexity as a factor in urban design, this study uses 1/f noise analysis as a visual complexity quantification parameter and electroencephalography (EEG) to understand the detailed relationship between visual stimuli and biological response. In the field of visual cognition and environmental studies, 1/f noise is a signal that represents a frequency spectrum where the power of the signal inversely correlates with its frequency [17]. Its characteristics include being self-similar and fractal [18]; the pattern looks similar and regular on all scales; it is usually found in natural environments; and it has been associated with aesthetic and psychological benefits [19,20,21,22,23]. EEG, a non-invasive method that measures brain activity, provides insights that enable researchers to observe how cognitive load impacts the brain's responses to external stimuli [24]. Our research tends to further explore the relationship between 1/f noise and brain activity in urban environments. Beginning an exploration towards the understanding of how different levels of visual complexity affect stress and cognitive responses and the way that 1/f noise as a parameter can contribute to designing urban spaces could be crucial to promoting well-being for better urban futures.

2. LITERATURE REVIEW

Spatial visual complexity is a pivotal concept in environmental psychology, visual cognition, and related interdisciplinary areas [8,25,26,27]. One of the most efficient ways to analyse visual complexity is through fractal dimensions. Researchers have found recurrent self-similar fractal structures in nature [26,28,29,30], which allow the studies to simplify and analyse the visual scenes from an infinite scale to a sizable portion of the whole scene. Consequently, researchers can have an overview of the brain response to the whole scene that shares the same fractal dimension, providing insights for understanding the hierarchical order of visual processing [31].

Electroencephalography (EEG) is a non-invasive technique that measures brain activity by placing electrodes on the scalp. It is a powerful tool that demonstrates brain activity with five basic brainwaves: Alpha (α), Beta (β), Theta (θ), Gamma (γ), and Delta (δ), that are categorised by different frequencies and brain states [32]. In the visual-environmental related fields, there are many studies that have proved the efficiency and precision of using EEG and fractal dimensions to analyse the human biological response to environments, focusing on understanding the visual stimuli, complexity, and cognitive process [33,34,35]. Specifically, Dorosti and Khosrowabadi have investigated the fractal dimension of EEG signals, giving insight into the fluctuation between visual complexity and the fractal dimension and their proportional relationship with the significant brain activities in the centre-parietal and parietal regions [35]. Namazi et al. [33] and Namazi [34] also supported the statements about the visual-cognitive relationship made by Dorosti and Khosrowabadi [35], with further research on the relationship between fractal patterns in stimuli and their impact on fixational eye movements and EEG signals. Additionally, Purcell et al. [36], Joye [37], Joye & Berg [38], and Hägerhäll et al. [39] describe the evolution of using EEG and fractals as methods for analysing environments. The discussions focus on the roles of fractal patterns in shaping aesthetic preference [36], how EEG responses to exact and statistical fractal patterns [37], and the significance of fractal patterns in nature and natural elements with their physio-psychological benefits [36,37,38,39].

In relation to environmental studies, Ulrich's psychophysiological framework emphasises the significance of complexity in shaping human preferences for natural environments [30]. Ulrich utilised Kaplan's evaluative matrix with components like coherence, mystery, and preference, demonstrating that the cognitive load is directly impacted by visual complexity. In comparison with urban environments, natural scenes are typically less visually complex and more restorative as they reduce the cognitive load [29]. Further, Cooper et al. find that the fractal dimension of streetscapes affects perceptions of quality and engagement. Suggesting that engaging the vegetation in the urban environment can enhance the aesthetic quality of streets and positively contribute to residents' perceptions and well-being [25]. Valtchanov and Ellard, on the other hand, used the fractal dimension

to analyse the complexity of a natural scene, finding that natural scenes can enhance cognitive engagement while reducing cognitive load [8].

By connecting the fractal dimension with visual complexity, studies found that higher visual complexity can make environments more interesting, engaging, and stimulating for observers; however, it requires a higher cognitive load with less restorative perception, which might lead to a higher level of stress and intensify the possibility of negative mental issues [24,29,30,31].

Given the potential that fractal dimensions have shown in past studies in broadening our understanding of spatial visual complexity, with this study we explore another parameter, founded on the same grounds of fractality taken as a quantification of visual complexity. This parameter is called 1/f noise, otherwise referred to as ‘pink noise’. Mathematically, it produces a line in a log-log spectral plot with a slope approaching -1, indicating the presence of a scale-invariant scaling relationship that is typical of fractal structures [40]. Some studies have investigated using 1/f noise as a method to analyse the urban environment [41,42,43]. Le et al., for instance, noted the visual discomfort in urban scenes [41]. They have found that in modern urban environments, the unnatural 1/f noise stimulates large amounts of hemodynamic responses in the visual cortex. Meanwhile, in Flitcroft et al.’s studies, they compare both indoor and outdoor scenes in the urban area with the natural scenes, with the same findings as with 1/f noise analysis that urban scenes require a higher cognitive load and increase visual discomfort, which leads to a higher development of myopia in cities [43].

This study will focus on some urban typologies to explore possible reactions of brain activity to 1/f noise ranges. Carmona’s works deliver a comprehensive understanding of typology as an advanced classifying method that considers physical attributes with design, functional perspective, social interaction, and management practice [44,45,46].

Current studies on the relationship between visual stimuli, 1/f noise, and cognitive and psychological processes lack statistical correspondence with bio-signal data [41,42]. Besides, there is a need for methodologies that integrate urban design and neuroscience to underpin this topic and explore more in-depth 1/f noise as a parameter for designing restorative urban environments [41,43]. In this study, we begin some exploration of possible relationships between visual complexity and brain activity through the integration of 1/f noise analysis, images as visual stimuli, and EEG responses. The research is hoping to set the groundwork for exploring 1/f noise potentials as a parameter in designing restorative urban environments.

3. METHODS

3.1 Data collection on-site and image selection

The image collection was based in Shenzhen. On a single day, under consistent weather conditions, we used a Sony 6400 camera equipped with a tripod to maintain a viewing height of 1.60 m. A total of 592 urban street scene photographs were taken at an approximate focal length of 50 mm using a zoom lens. These images were then rigorously screened, resulting in the selection of 502 photos with focal lengths between 45–55 mm. These photos were manually classified into five urban typologies typically found in Shenzhen: urban parks, urban streets, housing estates, shopping malls (indoor and outdoor), and science and technology parks.

3.2 Experiment Design

The experiment was conducted in a controlled dark room environment (Figure1), with a large screen measuring 1.904 metres in width and 1.071 metres in height used as the display device. The centre of the screen was positioned at a height of 1.60 m. We conducted the experiment with 8 participants from the Southern University of Science and Technology. During the experiment, the 11 selected images were displayed randomly, with a neutral grey image serving as an interval. Each participant was exposed to each image, and brain activity was recorded as a reaction to the visual exposure. We employed an EMOTIV EPOC X, a 14-channel wet sensor EEG device, to record brainwave activity

in the theta (3–8 Hz), alpha (8–12 Hz), beta (12–30 Hz), and gamma (30–100 Hz) frequency bands. The Fast Fourier Transform (FFT) was used to obtain the spatial frequency power intensity for each band. Invalid high-frequency and low-frequency information was filtered out, and fitting calculations were performed to determine the slope of the power spectrum.

Figure 1. Snapshots from the experiment.

Figure 2. Snapshot of recorded brain activity and corresponding colours for each frequency.

3.3 Data processing: 1/f noise and brain activity

To calculate the 1/f noise value, images first undergo conversion to grayscale, followed by the application of a discrete Fourier transform to transition the grayscale values from a spatial representation to their frequency components. By squaring the absolute values of the Fourier transform, the power spectrum is obtained, which quantifies each frequency component's contribution to the image's structure. The 1/f noise value is derived from the slope of the log-log plot of frequency versus amplitude, focusing on the frequency range between 2 and 80 cycles to emphasise the frequencies that most significantly represent structural information in the image. (Figure 3). For brainwaves, the real-time high-precision brainwave frequency data were segmented into eleven 25-second periods (including both test and rest phases) and eleven 15-second periods (eyes-open test phases only). The peak, trough, and average values of the four types of brainwaves were then obtained, and these values were averaged across eight groups of data. To obtain these data, we employed the HSL colour model to extract the brainwave signals corresponding to four colours (each colour corresponding to one of the four frequencies detected by the EEG measurement), frame by frame (Figure 2). The sum of the amplitudes of the four types of brainwaves in the frame with the

Proceedings

largest overall amplitude was set to 100%, and the amplitudes of other frames were proportionally mapped.

Figure 3. Image 01 (urban parks) and related 1/f noise diagram.

4. RESULTS

The comparison between 1/f noise slope values and specific brainwave patterns has yielded insightful results with different urban environment types (urban parks, shopping malls, science and technology parks, urban streets, and housing) eliciting distinct physiological responses (Table 1).

Housing features the steepest 1/f slope values (-1.275 and -1.414), which indicate lower visual complexity, and also has higher theta proportions (mean theta proportion: 38.4%) associated with relaxed and creative states and lower beta proportions (mean beta proportion: 1.9%) indicating lower cognitive effort.

Urban Street images represent flatter 1/f slope values (-1.07 and -1.14) and exhibit lower theta values (mean theta proportion 34.6%), indicating less relaxation, but also lower gamma (mean gamma proportion 0.006%), indicating lower cognitive load.

The Science and Technology Park images represent a wide range of 1/f slope values (-0.98 and -1.27) but consistently feature the highest gamma proportion (mean gamma proportion 1.1%), suggesting these environments require more cognitive effort and alertness.

Table 1. Table of 1/f and EEG calculation result

Type	Image	1/f noise	theta_Average	gamma_Average	alpha_Average	beta_Average
Urban parks	01	-1.359	40.209	0.012	33.572	2.345
	10	-0.982	36.120	0.006	25.736	1.799
Shopping malls	02	-1.286	36.869	0.007	34.196	2.852
	07	-1.119	33.362	0.008	30.890	1.789
I-Parks	03	-0.985	38.020	0.011	30.100	2.278
	09	-1.265	33.191	0.011	30.989	2.646

5. DISCUSSION

This study investigates the possible role of 1/f noise in shaping human perceptions in urban environments. The study of physiological responses to different levels of spatial complexity through EEG data offers a unique window into how human brains interact with their visual environments (Figure 4). By correlating these responses with specific types of visual stimuli, we can draw deeper insights into the cognitive and emotional effects of spatial complexity.

We ask the question of whether environments that mimic the fractal patterns found in nature can help reduce stress and promote mental health. This study takes some tentative steps to expand upon existing literature that links naturalistic elements in urban settings with reduced stress and increased cognitive engagement. The exploration relates to how spaces designed with complexity similar to natural environments could facilitate cognitive restoration and stress reduction more effectively than monotonous urban landscapes; however, a lot more research is needed to corroborate this.

The study acknowledges limitations, such as the controlled setting of the experiment, which may not fully capture the complexity of real-world environments. Additionally, the sample size and demographic homogeneity could bias the results, limiting their generalizability.

Future research should aim to replicate these findings in more diverse and dynamic urban settings to enhance their applicability. Longitudinal studies could also explore the long-term effects of exposure to environments with varied 1/f noise levels. Expanding the demographic breadth and incorporating multidisciplinary approaches could provide a more comprehensive understanding of how urban design influences human health and well-being.

6. CONCLUSION

The initial results observed in this study show potential for conducting a larger-scale experiment to investigate the relationship between special complexity measures, like 1/f noise, and the impact on brain activity as measured with an EEG device. The study moves towards investigating the importance of considering sensory inputs in the design of urban environments.

Ongoing research is crucial to further discern how different special complexity measures, like 1/f noise, and other design elements affect human health and behaviour. Continuous study will help refine urban design practices to better meet the psychological needs of urban populations for better futures.

Acknowledgements

We would like to deeply thank Lin Shenrujun and Chen Chuisong for their constant and precious support throughout the overall development of this research. We would also like to thank Xue Yuting, Yang Yunan, Lin Shenrujun, Chen Chuisong, Zhang Xi, Xiang Qiuya, Huang Jingfei, and Chen Junpai for their contribution as members of the Future Spaces Vision Lab (School of Design, Southern University of Science and Technology) for working at exhibiting the content of this research at Nanshan Museum (Shenzhen) for the Shenzhen Design Week 2024 (Shenzhen Creativity-Technology Empowering Urban Innovation).

Ethical considerations

Ethical approval was obtained by the Medical Ethics Committee of the Southern University of Science and Technology and the School of Design of the Southern University of Science and Technology.

Abstract

The presence of species of food interest within cities responds to the demand for more sustainable food systems, such as those based on urban proximal farming, in more inclusive cities where urban agriculture may also serve social functions and climate change adaptation strategies. The use of agrobiodiversity in urban planting design allows for the employment of resistant and resilient genotypes to cope with the multiple stressors of city environments. At the same time, food-related species help increase awareness of the importance of biodiversity for feeding cities, regenerate dysfunctional urban spaces, and promote agroecological transition. The grapevine (*Vitis vinifera* L.) is an emblematic food species for urban climate adaptation strategies and landscape design, owing to its high plasticity and hardiness in extreme environments. Urban vineyards are becoming a challenge in land use for the multifunctionality of cities. In the Botanical Garden of Rome, there is a large collection of Italian autochthonous grapevine cultivars, which serves as a precious gene database for assessing the resistance of genetic types to the urban environment through eco-physiological determinations. These determinations have shown that local grapevine varieties, such as those from the Latium region (Central Italy), exhibit better adaptation to Rome's microclimates. Therefore, the implementation of the grapevine collection with a core collection of regional grapevine germplasm has been considered. The design of a small-scale urban vineyard based on regional agrobiodiversity will serve multiple purposes, such as *ex-situ* agrobiodiversity conservation, opportunities for citizen food education, communication of the value of viticultural landscapes in terms of land preservation, and promotion of wine tourism by highlighting local grape-wine culture and traditions.

Keywords: *agrobiodiversity conservation strategies; climate change adaptation; landscape design; Mediterranean cities; Vitis vinifera L.*

1. INTRODUCTION

The presence of species of food interest within cities responds to the demand for more sustainable food systems, such as those based on urban agriculture, capable of performing productive, social, and environmental functions like adaptation to climate change.

The use of agrobiodiversity in the design of urban open spaces may represent a strategy for the sustainable use of genetic resources, thanks to genotypes resistant and resilient to the multiple stress factors of cities [1]. At the same time, the use of agrobiodiversity in urban landscape design allows for increased awareness of the importance of sustainable food systems, based on local productions, where the productive landscape can provide agro-food products but above all environmental services, such as maintaining soil fertility and increasing carbon storage, thereby contributing to the regeneration of dysfunctional urban spaces [2,3].

Given the simplification of food consumption that has occurred over time, the conservation of autochthonous agro-biodiversity, a heavily eroded biological heritage, is of great importance for the protection of local identities and the landscape enhancement of the territories where it has evolved.

There is a very strong link between typical and traditional agro-food productions, territories of origin, and the landscape, which also constitutes the element of uniqueness and irreplaceability of places [4]. The grapevine (*Vitis vinifera* L.) is an emblematic species for climate adaptation strategies in the urban environment, thanks to its high plasticity and adaptability even in extreme conditions. Historically, grapevines have been constantly present in Mediterranean cities as elements of public and private gardens, as well as main agrosystems in the farms of metropolitan areas [5]. Urban vineyards represent a growing phenomenon of interest, and numerous small-scale vineyards are being designed to perform multiple functions: conserving agrobiodiversity, providing environmental services, strengthening the culture of the vine and wine and their landscapes. Therefore, urban vineyards can represent a challenge for the use of urban space aimed at the multifunctionality of the city.

In terms of viticultural biodiversity, Italy is one of the countries in the world with the greatest richness of native grape varieties. The Italian viticultural database (Italian Vitis database - an open-source platform cataloguing Italian grapevine varieties, selected clones and biotypes) lists about 500 accessions, making the country's wine offering unique due to the great variety of grapes and thus oenological products.

In the Botanical Garden of Rome, there is a large collection of native Italian grapevine cultivars, which constitutes a valuable genetic database for assessing the resistance of genetic types to the urban environment. Eco-physiological determinations conducted on various Italian grapevine varieties in the collection have shown that local vine varieties, such as those from the Latium region (central Italy), show better adaptation to the microclimate of the city of Rome [6,7].

This study reports on the design. Criteria of a small-scale vineyard dedicated to the native grapevine varieties of Latium, to: (i) conserve the regional native agrobiodiversity *ex-situ*, (ii) provide opportunities for citizens' food education, (iii) communicate the value of the diversity of vine landscapes as identity elements of the territories, and (iv) promote wine tourism, through the enhancement of local wine culture and traditions.

2. AGROBIODIVERSITY CONSERVATION AND LANDSCAPE IDENTITY

2.1. DOC Wines and Wine-growing Areas of Latium

Protected designations play a fundamental role in enhancing native genetic resources and conserving agro-biodiversity. In Italy, there are 173 DOP (Protected Designation of Origin) and 143 IGP (Protected Geographical Indication). Of the 685,000 hectares of vineyards (Istat, 2022) in Italy, 77% is claimed as surface area for the production of Protected Designations, involving 43.7% of wine-growing companies. In the Latium region, the vineyard areas intended for the production of quality wines are also predominant. There are 27 DOC (Controlled Designation of Origin) wines in the region and 3 DOCG (Controlled and Guaranteed Designation of Origin) in the region (Fig.1). Many designations are predominantly or even exclusively based on native grapevine varieties.

The 27 DOCs are distributed across the regional territory in different geographical areas, distinguished into 4 main wine-growing zones, which approximately correspond to the territories of: (1) Vulsinia, (2) Castelli Romani, (3) Ciociaria, (4) Agro Pontino.

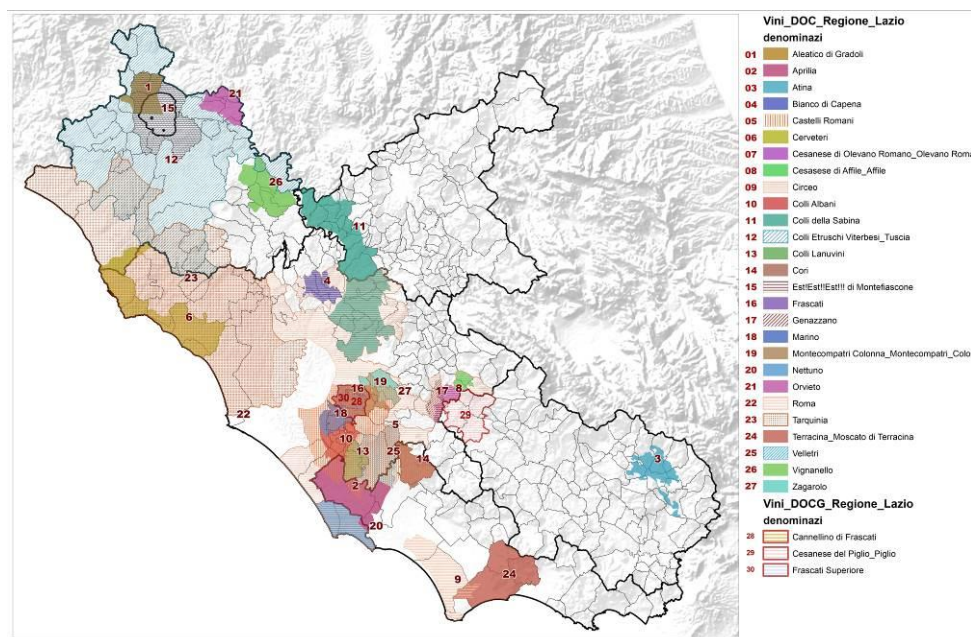

Figure 1. Perimeter of the wines' Designations of Origin in Latium.

(1) The Vulturna or Tuscia area, which includes the province of Viterbo, boasts several DOCs, including the well-known *Est! Est! Est!* di Montefiascone, Aleatico di Gradoli, Orvieto DOC (on the border with Umbria), Vignanello DOC (west of the Tiber River), Colli Etruschi Viterbesi (between Tuscia and Maremma Laziale), Tarquinia and Cerveteri DOC (in the coastal strip of Maremma Laziale).

(2) In the central area of Latium, which includes the Metropolitan City of Rome and the Castelli Romani, numerous DOC wines are concentrated: Frascati, Castelli Romani, Colli Albani, Colli Lanuviani, Nettuno, Velletri, Aprilia, Montecompati-Colonna, Zagarolo, and recently, the DOC Roma.

(3) In the Ciociaria area, which includes the province of Frosinone, the most famous production is Cesanese, in addition to Atina DOC.

(4) In Agro Pontino, Circeo DOC and Moscato di Terracina represent the main wine quality productions.

The figure 1 highlights the perimeters of the different DOCs of Latium, from which it can be noted not only the diversity of the incidence of quality viticulture (Protected Designations) within the region but also the association of the DOCs with very diverse geomorphological and, more generally, environmental characteristics of the territory.

2.2. Viticultural Biodiversity and the Identity of the Latium Landscape

Native grapevine varieties, i.e. local genetic resources, are products of the co-evolution of a biological system with its innate environment, where various factors related to the geological, geomorphological, pedoclimatic, and microclimatic characteristics of the territories play a significant role. Italy is an extraordinarily heterogeneous country, predominantly vertical with hills and mountains, where the Utilized Agricultural Area (UAA) hosts the majority of the vineyard surfaces. Recognizing and enhancing this diversity is a competitive factor for the Italian viticulture and wine sector.

The knowledge of the different expressions of the genetic characteristics of grapevine varieties based on the environment allows for the prioritization of high-quality grape and wine productions obtained

in particularly suited areas. Protected designations also enhance this richness of diversity by admitting in the technical protocols the recognition of sub-zones, often historically significant areas, associated with a particular grapevine variety. These areas represent sites with the best viticultural suitability and are identified through the methodology of viticultural zoning, a complex multi-scalar approach aiming the physical characterization of viticultural environments.

The Lazio coast extends for 360 km, where viticulture in sandy soils allows the cultivation of the own-rooted vines, an Italian peculiarity. The exposures of the slopes create peculiar microclimatic conditions, in which the characteristics of the vines, from the morphometric characteristics to the biochemical components of the berries, can take on peculiar traits, that cannot be reproduced elsewhere.

In the following figures, the areas of the DOC wines of Latium have been superimposed with the map of "landscape systems and areas" (Fig. 2), with the "land use" map and the geo-lithological map (Fig. 3), to assess, through thematic mapping techniques, the possible relationships of the DOC areas with the diversity of the landscape-environmental factors of the regional territory.

The figure 3 highlights a great diversity of soils of different lithological origins, from sandy to volcanic and alluvial ones, which give unique characteristics to the grapes and wines [8,9].

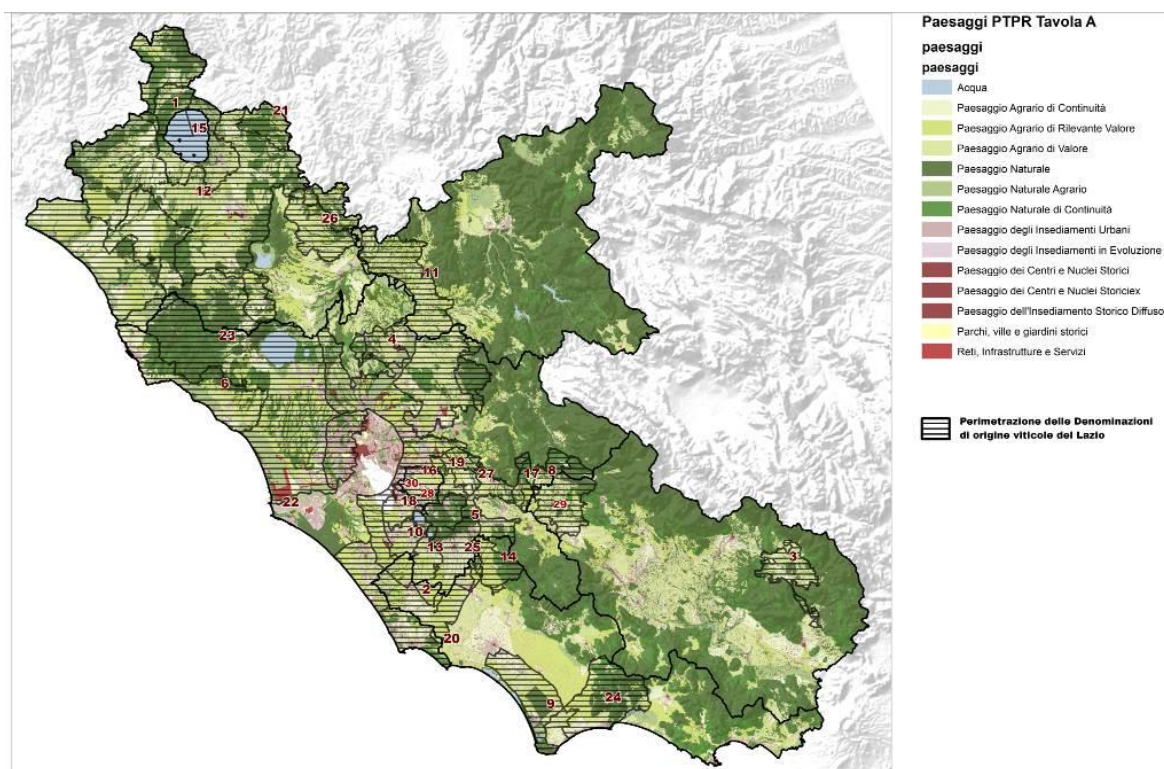

Figure 2. Graphic reworking of thematic maps, including the shape file of the areas of wine Designations of Origin in Latium, overlaid to the map of the landscapes homogeneous areas of the Regional Landscape Planning.

Proceedings

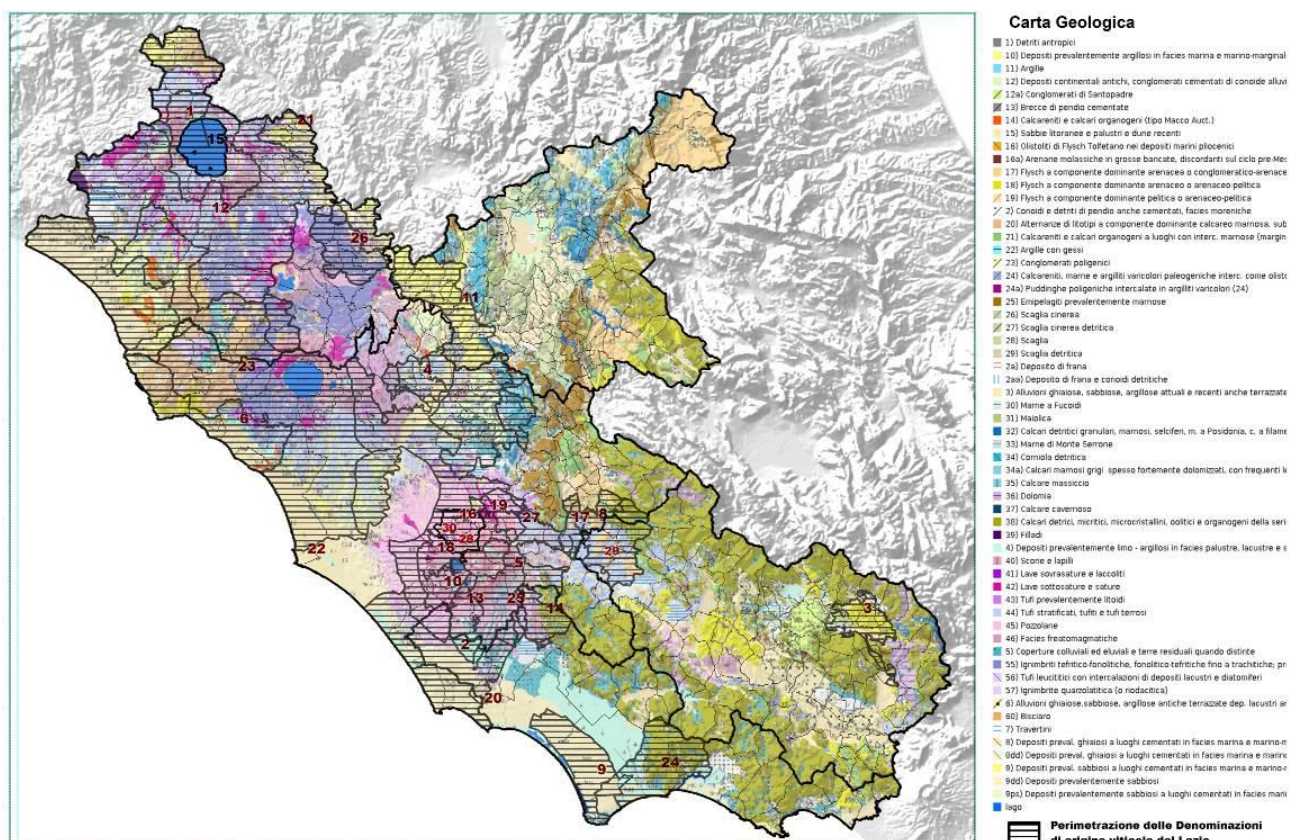

Fig. 3. Graphic reworking of the geological map, with superimposition of the areas of the wine Designations of Origin in Latium (black striped screen).

The hills, which cover approximately 50% of the regional surface, are eminently of volcanic origin and the soils have a composition that varies from area to area. The soils of the *Colli Albani* are sandy and clayey, very permeable and rich in minerals. In particular, on the western side of *Colli Albani* the vines offer more mineral wines, thanks to a friable tuff soil, rich in potassium and phosphorus; while in *Colli Romani* the volcanic soils with arenaceous, clayey and marly sediments contribute to determining the structure and properties of the oenological products. The areas of Maremma Laziale, Agro Romano and Agro Pontino have clayey-limestone soils with alluvial residues, favouring the production of more aromatic and structured wines.

On the other hand, the pedoclimatic environment can be influenced by many factors, mainly exposure and elevation, which can determine significant variations in wine characteristics [10]. In the Vulturno area, from volcanic soils and under the influence of the microclimatic factors induced by the Tyrrhenian Sea and Lake Bolsena, it is produced the wine called *Est! Est! Est!* of Montefiascone DOC and the aromatic wine Aleatico di Gradoli.

Close to the coastal strip, characterized by a Mediterranean climate, with mild winters and summers refreshed by sea winds, there are important grape-wine growing areas, like those of Circeo and Terracina DOC wines. The continental climate of the hinterland, with strong diurnal and seasonal temperature variations, can lead to less favourable conditions for wine production, while in the Castelli Romani area, some production areas are positively affected by the influence of the lakes and the proximity to the Tyrrhenian Sea.

Considering the transformations of the uses of the agricultural land in the Latium region, from the time of the Etruscans and Romans to the present day, including the more recent history of Lazio wineries, it is clear how human action has been strongly impactful and determinant in transforming

the environment for this productive activity, always with the goal of valorising productive territories and the identity of local products [11].

The viticultural landscape is an expression of the “terroir”, which is the result of the characteristics of the natural environment transformed by humans for their productive activities, according to different cultures and traditions. In the technical protocols of Protected designations, Article 9 specifies the "link with the geographical environment," based on natural factors as well as human factors, history, and viticultural tradition. Protected designations even go as far as to support the so-called heroic viticulture, including mountain viticulture, terraced areas, and small Mediterranean islands.

3. A SMALL-SCALE URBAN VINEYARD BASED ON REGIONAL AGROBIODIVERSITY AT THE BOTANICAL GARDEN IN ROME: A RESEARCH PROJECT FOR LANDSCAPE ENHANCEMENT

3.1. Aim of the project “Latium Vineyard”

The “Latium Vineyard” aims to complement an existing collection of Italian native grapevine varieties (“Vigneto Italia”) present at the Botanical Garden Museum, dedicating central importance to the genetic resources of Latium region and the of the metropolitan city of Rome in particular. This centrality is justified based on historical, cultural, and biological considerations, also due to the location of the Botanical Garden in the historical landscape of the city of Rome.

In line with the objectives of botanical collections within botanical gardens, the “Latium Vineyard” aims to represent the viticultural biodiversity in its reconstructed environment, promoting biological and cultural values related to genetic resources and landscapes.

With its "taxonomic" classification of grapevine varieties based on the DOCs in which they are admitted for vinification, or based solely on the presence in territorial niches, the “Latium Vineyard” aims to be a place for the representation and knowledge of the viticultural heritage of the Latium Region and the metropolitan city of Rome. It may serve as a study site for viticultural research, experimentation of innovative viticultural management practices, but also as an exhibition space, where cultural initiatives and educational activities related to the culture of the grapevine, wine, and the landscape identity of the territories, can be promoted.

Therefore, the project of this urban vineyard implies a multidisciplinary approach, including viticultural knowledge, landscape design, exhibit and multimedia design, with the aim of promoting education on the topic of urban viticulture as expression of urban agriculture and of disseminating the results of scientific research that may be conducted within it.

3.2. Description of the Vineyard Collection Project

Current Status and Location of the project area

The project area is located within the Botanical Garden of Sapienza University of Rome, adjacent to the collection of Italian native grapevines (“Vigneto Italia”), in the historic center of the city. The area identified for the so-called “Latium Vineyard” extends over a surface of approximately 230 square meters, currently occupied by a collection of bamboo plants, to be relocated and reused (Fig. 4).

Fig. 4. The Botanical Garden of Rome and the project site of “Latium Vineyard”.

Project configuration of the “Latium Vineyard” with the planimetric distribution of grapevines.

The physiographic variability of the Latium region and its relationship with territorial wine productions has represented the design criteria for the collection vineyard, particularly in the distribution of native varieties within the rows. The spatial distribution of the grapevines, according to the Latium region's planimetry, aims to emphasize the relationship between geographical denomination and typical product (Fig.5).

From a morphological and distribution perspective, the “Latium Vineyard” will be terraced with double rows on each terrace (width of 3 meters). The available space and slope allow for the construction of 4 terraces, each hosting 2 rows of vines with planting distance 0.80 x 1.85m. The training system will be the classic Guyot, thus the vineyard architecture will include supports and wires for canopy management (Fig.6).

The distribution of grapevines within the area follows a spatial criterion that mirrors the region's planimetry and the distribution of different DOCs across the territory. Along the first rows (lower terracing), the grapevines of the coastal strip and small islands are placed; in the upper left area, the Vulsinian grapevines are grouped; in the central zone, numerous grapevines from the Castelli Romani and the Metropolitan City of Rome are allocated; while in the rows arranged on the right margin, grapevines from Agro Pontino and Ciociaria are reserved.

Through this approach it has been represented the biodiversity and the environment (see following paragraph) of the 30 protected denominations of origin in Latium (27 DOC and 3 DOCG) and the native biodiversity of the IGTs.

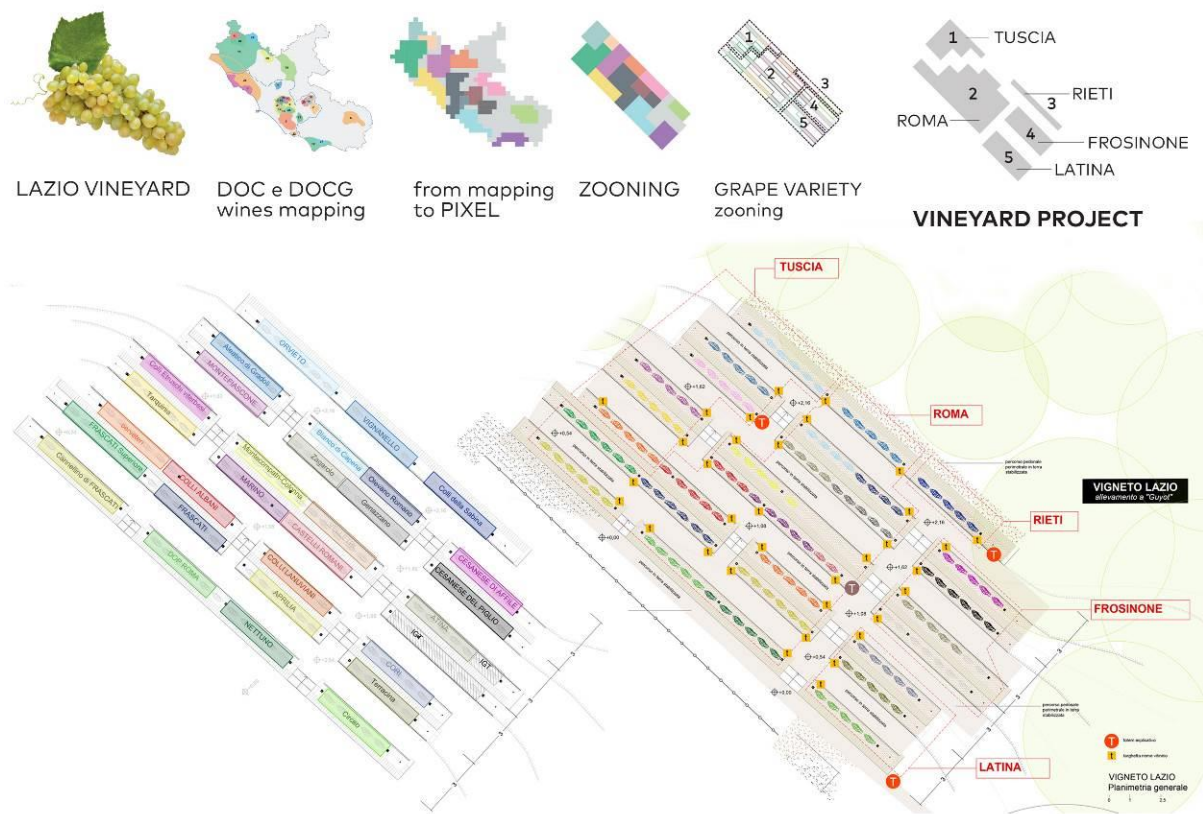

Figure 5. Project Concept: Spatial Distribution of Grapevines in the Project Area based on the Geographic Distribution of DOCs in the Latium Region.

Figure 6. Project rendering

Aspects related to visual and multimedia communication

The vineyard collection will function both as an exhibition space and as a storytelling device to promote the identity of the landscapes of Latium region and the preservation of local autochthonous germplasm.

Identifying signage, supported by references to multimedia content, can guide visitors in exploring the peculiarities of the various regional grapevine varieties.

It is planned to install 4 totems with descriptions of the different geographical areas and 30 labelled posts, one for each DOC and DOCG, with a description of the grapevine variety and the landscape of

the innate territories. Additionally, metal inscriptions with pre-spaced letters will be embedded in the paths, identifying the geographical denomination related of the grapevine variety (Fig.6). QR codes placed on the posts will link to a portal where users can acquire information and further details.

4. CONCLUSIONS

The conservation of agro-biodiversity is of great importance for the protection of local identities and the enhancement of landscape values in territories, given the relationship between native biodiversity and the identity of traditional landscapes. On one hand, ecological and environmental factors (mainly pedological and climatic components) are crucial for optimizing the genotype-environment relationship. On the other hand, the diversification of territorial products, reinforced by cultural and traditional factors of local production chains, results in a visible diversity of unique and irreproducible landscapes [11].

The landscape is the visible manifestation of this interaction between man and the environment, in which the physical components of the territory count as much as the immaterial ones, which include historical and cultural factors, which are promoted and valorised, transferring the relationship between man and the environment onto the semiological level of interpretations and recognition of local identities [12].

Many cities have recognized that landscape identity is an irreplaceable value by initiating marketing strategies that leverage the promotion of local agro-biodiversity to increase the attractiveness of their territories and contribute at the same time to promoting the transition to more sustainable food systems, as advocated in food policies promoted by some metropolitan cities, such as Rome. In this contest, the collections of the Botanical gardens may play a crucial role in promoting values related to food systems and landscape heritage.

Acknowledgements

The project of the collection “Latium Vineyard” is funded by the Research agreement between the University of Tuscia (Department for Innovation in Biological, Agro-Food, and Forest Systems) and Sapienza University of Rome (Department of Environmental Biology - Botanical Garden Museum) (2023-2025), provided to R.B and M.C.

Abstract

Urban streets play a crucial role in providing accessible public spaces for psychological restoration, especially in densely populated areas where demand often exceeds supply. However, the resilience of these spaces faced unprecedented challenges during the pandemic, with widespread psychological distress affecting urban populations worldwide. This has prompted a re-evaluation of the design and nature of future public spaces to ensure resilience in the face of public health crises and psychological challenges. In response, this study focuses on the vibrancy of high-density streets in Causeway Bay, Hong Kong, a bustling commercial district. Walking behaviour is widely regarded as a way to promote the vitality and sustainability of urban space. Through a longitudinal study involving video recordings and Geographic Information System (GIS) analysis, the research delves into street vibrancy under psychological distress, represented by walking behaviour. By examining stationary activities and their spatial, morphological, and design factors, the study aims to uncover patterns that can inform future urban design guidelines. The findings not only contribute to understanding the dynamics of high-density urban streets but also offer insights for creating resilient and vibrant urban environments that prioritise psychological well-being. Ultimately, this research serves as a valuable resource for urban designers and architects seeking to enhance existing environments and develop future cities that are responsive to the psychological needs of their inhabitants.

Keywords: *psychological distress, high-density streets, Hong Kong, street vibrancy, urban activities.*

1. INTRODUCTION

The phenomenon of intense high-density urbanisation is currently being experienced worldwide, with over 50% of the global population residing in urban areas [(a)]. Urbanisation has consequently emerged as a significant issue in the 21st century [(b)]. This heightened attention is due to the growing acknowledgement of the reciprocal influence between the urban environment and public health, as well as the profound impact of cities on people's living conditions and lifestyles [(c)]. Hence, urban areas are increasingly recognised as one of crucial factors for achieving sustainable development and enhancing human well-being in the future [(d)]. However, the adverse effects of urbanisation are eroding advantages of urban residents' health [(e)] via deteriorating ecological environment [(f),(g)], social isolation [(h),(i)], overcrowding [(j)], lack of public services or poor infrastructure [(k)] and so on, all of which are increasing human health risks. Thus, how to alleviate various issues caused by the development of rapid urbanisation and promote the health and well-being of citizens towards sustainable development goals in urban areas has become an essential focus in academic research. Walking behaviour has been extensively researched, advocated for, and called upon one of the many sustainable behaviours in urban areas [(l)]. While the relationship between walking and sustainability is not fully explored, certain studies are placing emphasis on this connection [(m)]. Generally,

Proceedings

of the International Conference on **Changing Cities VI:**
Spatial, Design, Landscape, Heritage & Socio-economic Dimensions
Rhodes Island, Greece • June 24-28, 2024
ISSN: 2654-0460
ISBN: 978-618-5765-02-6

walking behaviour is widely considered a cornerstone of sustainable transportation [(n),(o)], perceived physical environmental sustainability for individual and a significant factor affecting community sustainability [(p)]. Simultaneously, walking behaviour has also been shown by many studies to have a positive promoting effect on individual physical and mental health, and has attracted the attention of researchers from different disciplines [(q)]. At the individual scale, relevant study on physical health of individuals indicated that walking behaviour can promote individual physical health [(r)] and mental health [(s)]. On the other hand, for its impact on individuals, walking behaviour contributes to creating high-quality social experience and encourages people to engage in relaxed social contact [(t),(t)]. In brief, the sustainability of the regional environment is intricately associated with public activities represented by walk behaviour manifested through pedestrian activities in urban settings.

2. SOCIO-SPATIAL RESILIENCE FOR WALKING BEHAVIOUR

More than 40% of Hong Kong's total area is composed of parks and natural areas, but less than 25% are development zones [(u)]. With a population density of 6.5 persons per kilometre, Hong Kong is one of the world's most densely populated cities [(v)]. With the COVID-19 upon Hong Kong, the pandemic disrupted daily routines and affected the mental and physical health of local residents. A significant decrease in walking frequency has been observed and obtained among residents, and their activities have not yet fully recovered to pre-epidemic levels [(w)]. The pandemic requires prompt and efficient measures for recovery planning and crisis management. While the majority of cities, with slow and relatively rigid traditional planning mechanisms, require long-term growth targets [(x)]. Under the pandemic, Hong Kong has identified the imperative and urgency for urban planning transformation, which calls for more nuanced and adaptable planning. This inquiry not only reconsiders alterations within land use, infrastructure, and other environment elements, but also includes the individual behaviours and habits [(y)]. For example, with the opportunity of changing towards sustainability caused by the pandemic in Hong Kong, promoting green and active mobility in the open space through the management of public open space has been proposed [(z)]. Moreover, considering the severe contradiction between people and land in Hong Kong, coupled with a lack of resources, makes it an ideal location to conduct research on the social resilience of urban spaces under epidemic conditions.

the concept of spatial resilience originated from the establishment and discussions of The Resilience Alliance [(aa)], Cumming et al. work has arisen the definition of space resilience as follow: spatial resilience, refers to the ways in which spatial variation in relevant variables, with both internal and external factors of the system, interact system resilience across multiple scales [(bb)]. The study by Adger et al. define social resilience as the ability of groups or communities to cope with external pressures and disturbances brought about by social, political, and environmental changes [(cc)]. Other relevant studies have shown that, under natural disasters or pandemics, the quality of socio-spatial resilience has a significant impact on post-disaster restoration and human wellbeing of local residents [(dd)] via social activities, lifestyle, walkability et al. The work of Zhou et al. reviews the resilience research and proposed a disaster resilience model based on the multiple perspective [(ee)]. Based on the impact of public health risk, Wu et al. proposed five principles for designing resilient urban spaces after disasters, and elaborated on their technical prerequisites and basic elements [(ff)]. It has great research value and significance for resolving social and environmental issues in high-density areas and promoting sustainable transformation from the spatial resilience perspective of urban areas.

From an individual perspective, pedestrian comfort is used to measure an individual perception of the surrounding environment. Pedestrian comfort is affected by a number of factors such as wind speed, temperature, relative humidity, clothing, activities, solar radiation, noise, and air quality around buildings [(gg)]. Studies have revealed that tree planting patterns, street orientation (but not aspect ratio), and neighbourhood morphological attributes significantly affect pedestrian comfort in the

baseline configuration of streets in Hong Kong [(hh)]. From the perspective of assessment system, the Hong Kong Building Environment Assessment Method (HK-BEAM) and the building research establishment environment assessment method (BREEAM, UK) provides a static evaluation form to improve pedestrian comfort by indicators-based approach, while there are still some deficiencies in complex environments and human scale. Existing relevant research has explored various issues under the pandemic such as the thermal comfort or response [(ii),(jj)], walking environment [(kk)], space environment and health [(ll)] et al., while there is short of relevant comparative studies of pedestrian comfort in Hong Kong under psychological distress.

With this study we aim at detecting spatial resilience in Hong Kong under high-levels of psychological distress during COVID-19 through behaviour monitoring in an iconic high-density neighbourhood. Visualising socio-spatial resilience under psychological distress in correlation to morphological conditions can help with the understanding of urban morphology characteristics that could improve pedestrian comfort and consequently promote walking behaviour under psychological distress conditions for future cities planning and design.

3. METHOD

3.1 Study Area

Causeway Bay (CWB) is formed by numerous department stores and shopping centres, conveniently located adjacent to the Victoria Harbour. Notably, the Hong Kong Planning Department's shopping survey reveals that Causeway Bay ranks as the second most frequented shopping area in Hong Kong, characterized by its bustling atmosphere, high-density traffic and multitude of towering commercial edifices [(mm)] Given its vibrant and densely populated setting, Causeway Bay emerged as an optimal site for our examination of pedestrian comfort amidst the ongoing pandemic. The study area is located in Wan Chai district, Hong Kong, as shown in Figure 1. The street configuration of Causeway Bay (CWB) is intricate, featuring a frontage comprised of various establishments such as shopping centres, restaurants, and shops. These spatial patterns offer outdoor pedestrian areas for both local residents and tourists. In this study, three distinct urban areas have been selected as the focal points of investigation. The first area (R01 & R04) includes identified landmarks such as CWB Mass Transit Railway (MTR) Station, Hennessy Road, and Hang Lung Centre. The built environment in this area primarily consists of medium to high-rise buildings, predominantly serving commercial purposes and housing office spaces. Additionally, it involves multiple pedestrian streets. The second area (R02) is composed of Jinghua Centre, Jinlilong Centre, and other similar establishments, characterized by vibrant streets and high foot traffic. The third area (R03) mainly is a street that predominantly encircles the prominent shopping mall, Hysan Place. Whereas, the thoroughfare is lined with street vendors street snack bars, restaurants, and real estate consulting establishments. All streets are equipped with well-established infrastructure and demonstrate a high level of modernization.

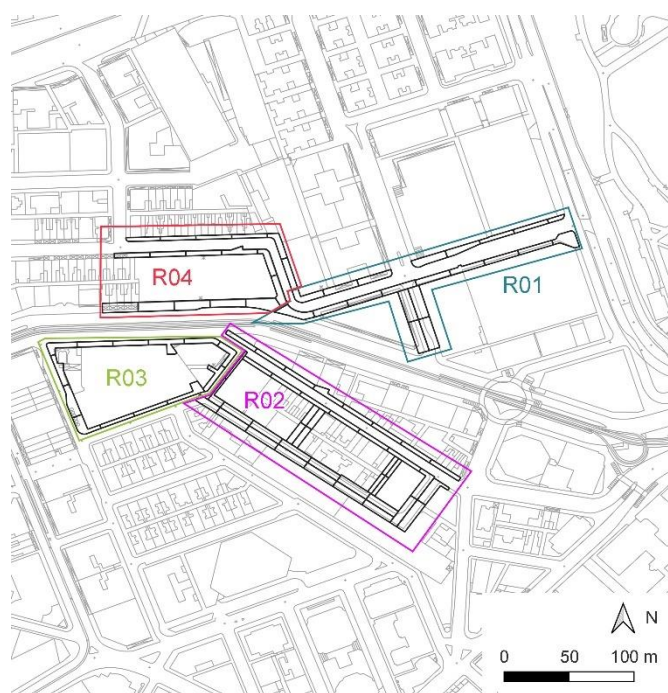

Figure 1. a) Location of CWB and study route, b) Location of Wan Chai in Hongkong

3.2 Data collection and validation

We conducted a longitudinal study in Causeway Bay streets, videos were recorded twice a day for 7 days. Through videos, the aim consisted in detecting and observing spatial resilience in one of the most iconic districts in Hong Kong Island by performing behaviour mapping of activities and standing behaviours on the streets. After data review and invalid data filtering, the usable data comprehended the following days: April 8, 2020 (two rounds), April 18, 2020 (two rounds), May 16, 2020 (two rounds), June 10, 2020 (two rounds), June 24, 2020 (two rounds), July 4, 2020 (two rounds), and July 18, 2020 (two rounds). We then conducted statical analysis considering transportation, accessibility, and streets configurations in relation to standing behaviours.

4. RESULTS

4.1 Statistical results of spatial distribution

Based on the calculation of the number of standing behaviour event in each street, the following visualisations of the mean, standard deviation and coefficient of variation of the number of standing people in each block based on multiple different time and spatial distributions can be obtained, as shown in Figure 2, 3, 4.

Figure 2. Geographical distribution map of daily standing population based on average.

Figure 3. Geographic distribution map of daily standing population based on standard deviation.

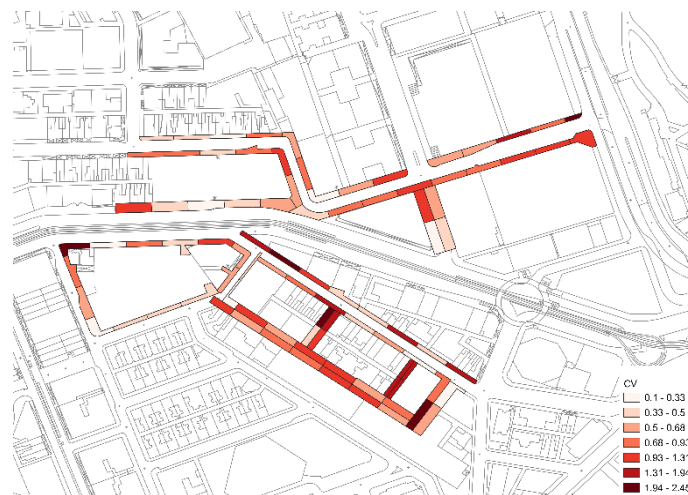

Figure 4. Geographic distribution map of daily standing population based on coefficient of variation.

4.2 Global/Local Moran's I results and Local Indicators of Spatial Association (LISA) results

Based on the number of standing people obtained, the relevant spatial autocorrelation analysis and LISA analysis results are as follows: among them, the Moran's I index based on the aggregate data was 0.386 (Figure 5), and in the spatial autocorrelation analysis calculated for subsequent daily data, the highest value of the Moran's I result was 0.421 in the data set on April 8, 2020 (Figure 6). The lowest value was 0.161 on July 4, 2020 (Figure 7).

4.3 Correlation Analysis and Variance Inflation Factor (VIF) Results

Based on defined groups of dependent and independent variables, VIF calculating results are shown in Table 1. Based on the VIF results and the source of the variables, the variables $x1$ (CV), $x2$ (SD) and $x3$ (Average) were excluded, which is the same as the results of the previous round of analysis. Furthermore, the results of correlation analysis of y (Number of standing behaviour events), $x4$ (Dummy variable of standing behaviour events), $x5$ (Distance to nearest entrance), $x6$ (Distance to nearest MTR) and $x7$ (Distance to nearest bus stop) are as shown in Figure 8.

5. DISCUSSION

Based on the results of the geographical distribution maps, it is evident that the topological proximity between standing events and adjacent bus stops/building entrances is relatively close in some locations (Figure 2). Observations from video recordings reveal that most standing behaviours are concentrated at street corners and intersections where multiple streets converge. The coefficient of variation analysis (Figure 3 and 4) further indicates that these locations maintain a stable frequency of standing events without significant fluctuations. This consistency suggests that certain spots inherently attract standing behaviours due to their spatial configuration. Additionally, the results of both global and local Moran’s I results, being greater than 0 (Figure 5, 6 and 7), demonstrate a positive spatial correlation in the overall standing behaviour data. In this study, higher Moran’s I value signifies a more positive correlation of standing behaviours.

Despite the positive spatial correlation, the correlation analysis of the four variables examined in the study indicates only a weak association with standing behaviours (Figure 8). This finding suggests that while there is some connection between the environmental variables and standing behaviours, it is not particularly strong with current data set. However, this does not undermine the importance of understanding the environmental design elements that influence standing behaviours, especially under conditions of psychological distress. This finding is consistent with the conclusions of previous research by authors [(nn)], which indicate that studies conducted under psychological distress help elucidate the impact of design variables on individual behaviours experiencing it.

To fully comprehend the impact of these design elements, further theoretical and empirical investigations are necessary. Future research should explore the psychological factors that drive individuals to engage in standing behaviours at specific locations and under varying conditions.

Although experimental methods in psychology and medicine have been well-developed, they are still in the early stages of application in urban planning and architectural design [(oo)]. Zapata et al. [(pp)] 's work has indicated that by integrating psychological insights with spatial analysis, a more comprehensive understanding of standing behaviours can be achieved. This will aid in designing urban environments that cater to the needs and behaviours of individuals, promoting comfort and well-being in public spaces.

6. CONCLUSION

Beside the psychological distress induced by the pandemic, some spaces were found more resilient than others. More specifically, street corners and street intersections showed more positive values for standing behaviours in public spaces. These findings indicate more potential for fragmented morphological conditions supporting accessibility and walkability in dense conditions. Although correlations were still slightly weak, there is a lot of potential for future studies in deepening the understanding on how urban morphology and public space design can support walking behaviours by providing favourable conditions for pedestrians in high-density cities.

Extended abstract

The undeniable evidence of climate change and its ensuing crises stands as a stark testament to the epochal shift known as the “*Anthropocene*”. From the melting polar ice caps to the increasingly frequent and severe extreme weather events, the Earth's systems are manifesting the consequences of human activity on an unprecedented scale. Architecture can be seen as both part of the problem leading to climate change as it shapes the interaction between human and nature but as part of the solution too. In order to address the fields where architecture can shape the solutions, we need to understand the new conditions. We assume that under the effects of climate change, landscape and terrain relief is becoming more dynamic as it is subject to constant changes. Water is a crucial element leading to this new dynamism. River floods and rising sea level are becoming significant factors that shape urban and natural landscapes. In the face of dynamic landscapes shaped by climate change and increasing occurrences of floods, architecture undertakes a critical role in adapting to and mitigating these challenges. Drawing from the philosophical concepts of Gilles Deleuze, particularly his notions of “*rhizomatic*” thinking and “*assemblages*,” architects envision new strategies that transcend conventional linear approaches to design. Instead, they conceive of architecture as part of complex networks and interactions within ever-changing environments. Diagrams, inspired by Deleuze's emphasis on multiplicity and interconnectedness, become tools for understanding and navigating these dynamic landscapes. They represent not static blueprints, but rather fluid processes that respond to shifting environmental conditions, fostering resilience and adaptation. By embracing Deleuzian concepts, architects engage with the inherent complexity of climate change and floods, seeking innovative solutions that blur the boundaries between built and natural environments, and promote sustainable relationships between human habitation and the ever-transforming landscapes of the Anthropocene. A further reading of this approach can provide insights not only to handle the immediate effects of climate change, but to also reach a better understanding of the relation between human and nature. Diagrams and Deleuze's concept of interconnectedness helps to understand our relation with nature as a constantly transforming procedure where architecture shapes this interconnection.

Abstract

The Hanbury's Blue and Green project aims to restore areas of the Hanbury Botanic Gardens between Ventimiglia, Italy and Menton, France. Funded by the Fondazione Compagnia di San Paolo, the project focuses on habitat restoration and improving the use of terrestrial and marine ecosystems. Key interventions include: Restoring coastal wetlands and *Posidonia oceanica* beds; Creating a kitchen garden for traditional cultivated and wild species; Controlling invasive alien species; Establishing new museum spaces.

This paper focuses on the initial steps taken towards the creation of the kitchen-garden. It identifies the main actors involved in its co-design and the involvement of experts for the landscaping of the site through naturalistic engineering works.

The project emphasizes preserving traditional knowledge about natural and agricultural biodiversity. It aims to raise awareness of ecosystem services provided by local plants used for food, nutraceuticals, and medicine. Additionally, it will stabilize a degraded pathway and reconstruct a historic pergola with ancient Moscatello vines. Overall, the project seeks to enhance sustainability and biodiversity in the Hanbury Botanic Gardens.

Keywords: *Ecosystem Services; Nature-based Solutions; Protected Areas; stakeholder involvement; Italy*

1. INTRODUCTION

The Hanbury's Blue and Green project, which aims to restore areas of the Hanbury Botanic Gardens located between Ventimiglia, Italy and Menton, France, has received financial support from the Fondazione Compagnia di San Paolo. This represents a significant step towards environmental conservation and sustainable development. The project's objectives include the restoration of natural features of the Hanbury Botanic Gardens as well as the promotion of biodiversity, protection of ecosystems, and raising public awareness of the importance of preserving natural heritage.

The project employs innovative restoration techniques and strategic interventions with the objective of establishing the Hanbury Botanic Gardens as a model for the harmonious coexistence of human activities and the environment. By focusing on habitat restoration, the project enhances the ecological value of the area while creating a space where visitors can learn about and appreciate the rich biodiversity of the region. The objectives of the Project are in alignment with those of the Management Plan (MP) of two Special Areas of Conservation (ZSC) – IT1316118 Capo Mortola and IT1316175 Fondali Capo Mortola – San Gaetano, which was approved in 2016. However, despite this approval, the plan has yet to achieve concrete results.

The project represents a framework of actions and interventions on land and at sea, which are coordinated with other national and European projects. Activities are envisaged for the regeneration of degraded areas and habitats through techniques of habitat restoration and the prevention and limitation of existing pressures.

The two ZSC, Capo Mortola and its Seabed, are part of the Natura 2000 Network established in accordance with the European Habitats Directive and extend to approximately 50 hectares on land

Proceedings

of the International Conference on **Changing Cities VI:**

Spatial, Design, Landscape, Heritage & Socio-economic Dimensions

Rhodes Island, Greece • June 24-28, 2024

ISSN: 2654-0460

ISBN: 978-618-5765-02-6

and 339 hectares at sea [1]. The two ZSC overlap with the Regional Protected Area of the Hanbury Botanic Gardens [2], which was established in 2020 and encompasses approximately 20 hectares on land and 462 hectares at sea. This area is referred to as the ‘Capo Mortola Marine Protection Area’. The project is coordinated by the University of Genoa, which has a perpetual concession for the compendium (State Heritage) of the Hanbury Botanic Gardens and is the managing body of the regional protected area and of the ZSC, in accordance with Regional Laws 31/2000 [3] and 28/2009 [4]. The partnership, which involves scientific research, the public administration of the area and the associations involved in its protection and enhancement, assumes a significant value. At the same time, it creates a new link of possible collaborative development between Liguria and Piedmont, between sea and hinterland, involving the University of Turin and a development agency in Asti. The local community was already engaged in the Strategic Environmental Assessment process at the time of the MP's adoption, and this engagement is reinforced through the involvement of schools and associations, with the definition of the design details of certain interventions being a notable example. The project proposes the implementation of a series of coordinated interventions with the objective of restoring and improving the use of terrestrial and marine ecosystems. These interventions are designed to reduce the pressures caused by the expansion of invasive species in priority riparian habitats and by the anchoring of pleasure boats on the *Posidonia* beds. In addition to the aforementioned renaturalisation measures, communication and dissemination actions are to be implemented with the objective of raising awareness at a territorial level, and not only (considering the international attendance of the Hanbury Botanic Gardens), of the value of natural capital, environmental problems and nature-based solutions in a framework of enhanced sustainability.

Among the many activities that are taking place as part of the project, one of particular interest is the realisation of nature-based solutions related to the community garden or kitchen garden, as well as the redesign of the Muscat vinyard, which was formerly present in the protected area.

This paper focuses on the initial steps taken towards the creation of the kitchen-garden. It identifies the main actors involved in its co-design and the involvement of experts for the landscaping of the site through naturalistic engineering works.

2. ASSESSMENT OF POTENTIAL BARRIERS BEFORE TACKLING THE PROJECT

Some actions, even among the most challenging ones, replicate experiences that have been quite successful in past years. However, the main critical issues may in some cases concern the respect of time schedules, which may be affected by weather and sea conditions. Nevertheless, these criticalities appear to be surmountable, having considered a sufficiently long period for the entire project to allow for a temporal rescheduling of activities.

A number of actions have already been included in the ‘Capo Mortola’ ZSC Management Plan or the ‘Capo Mortola Seabed’ Management Plan. There are no criticalities in the issue of authorisation by the competent bodies that were consulted at the time of the drafting of the aforementioned plans and with which there are assiduous contacts. In the case of the movement of sediments that have accumulated over time in the terminal stretch of the Rio Sorba, the intervention meets the periodic requests/signals of the Fire Brigade regarding the need to restore a correct water flow, obstructed precisely by excessive graveling. Furthermore, it aims to reduce the mass of flammable *Arundo donax* reed. However, important criticalities may arise from the difficulty of eradicating invasive species and consolidating the establishment of planted species. It cannot be ruled out that subsequent interventions to control invasive allochthonous species may be necessary. Such interventions could be carried out as part of the ordinary maintenance of the Regional Protected Area.

In the case of the fire risk reduction actions, although they are a prevalent action within the ‘Capo Mortola’ ZSC MP, it is believed that agreements still need to be formalised with the owner of the area bordering the Hanbury Botanic Gardens compendium (Grimaldi). In this regard, however, the lead partner has been directly involved by the same property in the drafting of an overall plan for the

Proceedings

environmental redevelopment and sustainable use of this area. Nevertheless, it is possible that further resources may be made available by the Grimaldi's private property. With regard to the preparation of a prevention plan, it is notable that all the owners of the areas west of the Hanbury Botanic Gardens have expressed great interest. Furthermore, the availability of recent data, collected as part of cross-border projects on a regional scale, can be highlighted as a valuable resource.

3. NEW EXHIBITION AREA IN THE BOTANIC GARDEN DEDICATED TO TRADITIONAL PRODUCTS OF FOOD OR NUTRACEUTICAL INTEREST, CULTIVATED AND WILD

Article 8(j) of the Convention on Biological Diversity [5] is dedicated to the subject of traditional knowledge, innovations and practices. Each Contracting Party shall, to the greatest extent possible and in an appropriate manner, respect, preserve and maintain the knowledge, innovations and practices of indigenous and local communities embodying traditional lifestyles relevant to the conservation and sustainable use of biological diversity. Furthermore, they shall promote the widest possible application of such knowledge, innovations and practices, with the approval and involvement of the holders of such knowledge, innovations and practices, and encourage the equitable sharing of the benefits arising from the use of such knowledge, innovations and practices.

This commitment is frequently overlooked or not adequately managed on a scientific basis. Consequently, there is a pressing need to safeguard traditional knowledge of both natural and agro-sylvo-pastoral biodiversity before it is irrecoverably lost.

The FAO also incorporates a socio-economic and cultural dimension into its definition of biodiversity [6], recognising traditional knowledge as an integral component of agrobiodiversity. This phenomenon can be attributed to the interaction between the environment, genetic resources, systems and management practices adopted by culturally diverse populations, which result in the utilisation of environmental resources in disparate ways.

The University of Genoa has been conducting ethnobotanical research for a long time, utilising internationally standardised methodologies to document the multifaceted applications of medicinal plants. This research has contributed to the establishment of small museums or structures dedicated to the topic in inland Ligurian villages. The University of Turin offers university courses whose curricula include the appreciation of historical varieties of food. In addition to the aforementioned motivations, there is the possibility of a recovery and reutilisation of degraded areas near areas or routes that are less frequented by visitors or even forbidden, within the Hanbury Botanic Gardens.

One of the project's objectives is to disseminate knowledge and awareness of the ecosystem services provided by plants utilised in the traditions of the Ligurian territory, with a particular focus on the Imperiese area (linking the Ligurian Alps hinterland and the coastal area of the Riviera di Ponente). These plants are employed for food, nutraceutical or medicinal purposes.

The project aims to contribute to the conservation of the components of biological diversity related to food and agriculture, as well as all the components of biological diversity that make up agricultural ecosystems (agro-ecosystems). This includes the varieties and variability of plants at the genetic level, which are necessary to maintain the key functions of agro-ecosystems, as well as their structure and processes. The reclaiming of a highly degraded area of the Regional Protected Area of the Hanbury Botanic Gardens, which still contains buried debris from the Second World War and is partly overgrown by weeds, while stabilising the escarpment of a path, is a further objective. The historical reconstruction of the Hanbury Botanic Gardens with regard to the Hanbury Garden and Vineyard is also a priority.

The action includes an initial detailed planning phase shared with the community, in particular with local schools and university students from the University of Turin. At the same time, genetic resources of food and agricultural interest that meet the criteria of Italian law 194/2015 [7] will be selected from checklists published in scientific journals and national and regional registers. This phase will be

Proceedings

followed by the creation of a new garden exhibition area dedicated to traditional plants and products of food or nutraceutical interest, cultivated and spontaneous in a degraded area along a little-frequented pathway. This area is situated close to the area where the restoration of a wetland is planned and is worthy of being enhanced with didactic/educational functions with respect to the themes of Natural Capital, Ecosystem Services, together with those of historical and, more generally, cultural themes. The area in question has been historically documented as the site of the Hanbury family kitchen garden at the turn of the 19th and 20th centuries. As a result, a 'Kitchen Garden' will be created here, after a light consolidation using NBS techniques. This cultural-environmental showcase will represent a showcase of plants of alimentary or nutraceutical interest, which are widespread in the Ligurian tradition, particularly in the province of Imperia, both cultivated and spontaneous.

Additionally, plants will be planted along the recently reconstructed pergola on the eastern perimeter wall of the Regional Protected Area. The plants, which are indigenous to the area, belong to a historical variety of vines cultivated in the region. By incorporating this variety into the landscape, another route that has not yet been finished will be completed. In line with the themes and materials exhibited, educational experiences will be developed to be included in an updated catalogue of the annual educational offerings, which will be presented to schools and educational institutions.

4. EPISTEMOLOGICAL ISSUES AND RESEARCH METHOD

The research project will analyse the co-design process of the Nature-based Solutions (NbS) envisaged within the Hanbury Botanic Gardens (GBH), with the objective of applying the principles of Vegetal Geography [8] in order to overcome the main problems that have emerged from recent research on NbS in Italy.

There are now numerous projects concerning NbS financed in Europe, and specifically in Italy, thanks to public and private funds.

In particular, the EU has played a pivotal role in the realisation and study of significant NbS, both in terms of social impact and economic expenditure. The EU has made substantial funds available, especially through the Horizon Europe programme. Indeed, the programme has financed 76 projects over the past decade, with a total investment of 665 million euros. These projects have involved 71 countries and 1,391 partners [9]. Approximately one-third of the projects had a focus on urban areas, while seven projects involved marine and coastal areas. One project in which the University of Turin was actively involved was the 'Productive green infrastructure for inclusive urban regeneration' (proGIreg) project [10], which aimed to create experience and expertise in the implementation and management of NbS in the urban areas of Turin. Another project that took place in the city of Turin was CONEXUS [11], which enabled the University of Turin to observe and learn how other international realities approached the topic of NbS. The two projects mentioned above share an approach based on the quadruple helix model [12], where representatives from public institutions, society, academia and business come together to co-design and manage NbS.

Nevertheless, the implementation and management of NbS does not always result in the desired outcomes.

A recent study currently in the process of publication [13] has identified three key issues regarding the co-design and subsequent management of NbS. Firstly, NbS are considered 'diagonal green' (liminal space/solution), which means that they are not clearly recognised at the administrative level, making it difficult for anyone to take management responsibility for them. Secondly, the concept of NbS is not widely understood by the general public. Such initiatives are often perceived as experimental and not as a common good with a lasting impact. Some citizens argue that it would be more useful to allocate funds and time to the management of existing green spaces. However, this approach would not respect the principle of additionality of European projects, whereby funds are used for new initiatives that can bring progress, rather than for existing ones. This lack of

understanding and conflicting opinions highlight the need for more education and awareness on the benefits of NbS.

- NbS are sometimes designed primarily to meet human needs, while the needs of other living beings, such as the plants themselves, are only taken into account if time and funds permit. This can lead to plants being regarded as ‘living objects’ serving a human purpose, rather than as living beings that make up an ecosystem. This results in a lack of respect and understanding of the genuine needs of other living beings, particularly plant species. This approach is at odds with the One Health approach, which is promoted by the European Commission [14].

Nevertheless, numerous academic publications on urban green space and NbS demonstrate the significance of recognizing the value of all living beings within an ecosystem. However, there appears to be a discrepancy between academic communication and the reception and practical application in diverse contexts beyond the academic sphere.

In order to address the aforementioned gaps, it is proposed that a shift be made from a quadruple helix approach to a quintuple helix one. In the quadruple helix approach, the environment is one of the key actors involved in the decision-making process [15].

The following three macro-questions will be addressed throughout the project:

1. From the perspective of the actors, what are the benefits and political implications of transitioning from a quadruple to a quintuple helix?
2. How might such a transition occur, and what actions might be taken by those involved in the quadruple helix to facilitate it?
3. Who might represent the interests of plants and in what contexts?

5. PRIMARY RESULTS AND NEXT STEPS

The preliminary results indicate the responses of the actors in the project area. It is evident that experiments with NbS sustainability over time are necessary. However, the additional actor, the plant world, requires more time to be considered (due to the complexity of the co-planning phase). Furthermore, there is a need for technological adaptation to the entry of the plant world as a policy actor (such as the use of plant health monitoring sensors), and there must be a profit margin for companies from this. It is of the utmost importance to simplify the language used in academic contexts in order to facilitate communication and education of students and citizens about this change. Furthermore, it is essential to ensure that the results of design and management are accessible to all. The voice of the plants can also be represented by citizens at the earliest stages of the project, as they are often the most knowledgeable and experienced about the subject matter.

The subsequent phase of the project will entail the acquisition of further information through additional interviews and focus groups, with the objective of formulating a preliminary proposal for the co-design of NbS with an additional actor.

Extended abstract

Landscape design of public space-with ecological and social emphasis and goals-can become a catalyst to improve livability and to reveal or reimagine a place's identity. Mobility infrastructures that used to disrupt continuities between fabrics and landscapes can be redesigned today as active connectors between neighborhoods, people and natural elements.

This paper aims to present the conceptual approach and the outcomes of a 2022-23 Landscape Design Joint Studio and its International Intensive workshop that had the opportunity to participate in ongoing discussions of the administration and in proposing landscape design strategies, for a real project currently under study. Studio's main aim was to redesign spaces generated by mobility infrastructures and to restore the disrupted continuities between people and its urban and natural landscapes. From the territory to the streetscape, this project can reclaim public spaces through landscape tools and methodologies. Through lectures, project discussions and participatory exercises, students and professors reflected on the increasing complexity of public space and the agency and roles of the disciplines that design it. Urbanists, architects and landscape architects—from policy-makers to practitioners and academics—brought some light to these new spatio-functional and disciplinary scenarios in guest class lectures.

The studio aimed to find new public space and landscape models and structures for the city of Montcada i Reixac, Barcelona that might link neighborhoods in the municipality and reinforce their morphological richness and their dynamic and connected condition, to become a local and territorial articulation, defined by a singular commitment in the city / nature relationship, capable of achieving optimal urban, social and ecological cohesion. The goal of the studio was to reconnect the urban fragments of Montcada i Reixac segregated by diverse infrastructures and to rethink the leftover spaces along the railway and under the viaducts of the C33 motorway that cross and divide the municipality as potential connectors. These spaces, currently barren or occupied mainly by parking, can be turned into new public leisure spaces for citizens, as well as into ecological stepping stones between the natural systems around: the river Ripoll and the Collserola and Serralada de Marina mountains. The proposals to be presented rethought urban space and its relationship to adjacent natural elements, increased ecological continuities, reestablished lost connections, reclaimed vacant neglected lots and enhanced the site's historical identity through urban landscape strategies and actions in a variety of scales.

The ecosystem potential of peri-urban greenery

E. Mussinelli, A. Tartaglia, G. Castaldo*

Politecnico di Milano, Department of Architecture, Built Environment and Construction Engineering, Italy

*Corresponding author: E-mail: giovanni.castaldo@polimi.it, Tel +39 0223995712

Abstract

The effects of climate change are increasingly manifest on a global scale, with the growing intensity and frequency of extreme weather events, such as droughts and floods, cold and heat waves. The fundamental role of greenery in adapting to and mitigating climate change and, more generally, in improving the quality of urbanised contexts has long been recognised by scientific community and international policymakers. Peri-urban contexts are territorial areas in which it is possible to envisage structural and systematic mitigation and adaptation actions facing climate change and environmental pressures, with even substantial actions of green infrastructuring and ecological reconnection. These actions can contribute to improve the landscape quality of these areas, often abandoned and/or degraded, as well as to increase their usability (leisure time, sports, outdoor activities, etc.). The article presents some research experiences carried out by the ENVI-Reg research group, coordinated by Prof. Elena Mussinelli, that provided methodological and scientific support for the elaboration of plans and projects on an urban, metropolitan and territorial scale in Italy. The selected research projects provide contributions to the evaluation and quantification of the ecosystem potential of different green infrastructure solutions in peri-urban landscapes.

Keywords: *peri-urban greenery; peri-urban agriculture; territorial and urban planning; ecosystem services.*

1. INTRODUCTION

The effects of climate change are increasingly evident. Rising average temperatures and the increased frequency and intensity of extreme weather events – prolonged dry spells, heat waves, heavy downpours, floods, and frosts – are impacting ecosystems and progressively affecting daily life [1]. Urban areas are particularly vulnerable to climate change impacts due to high population density and the concentration of economic activities. In cities, the adverse effects of climate change are often exacerbated by microclimatic phenomena such as the urban heat island effect [2], characterized by local overheating of urban areas due to the morphological and material properties of the built environment¹. This issue is particularly critical in Italy during summer, significantly affecting comfort, accessibility, and usability of open spaces, and posing a considerable risk to public health, especially for the most vulnerable populations.

To address climate change, the international community has mobilized to implement mitigation and adaptation strategies² aimed at reducing greenhouse gas emissions. These strategies include the adoption of renewable energy sources, enhancing energy efficiency in the built environment, optimizing agricultural and industrial production processes in a circular manner, and improving land-use efficiency with the goal of reaching no net land take by 2050 (EU “Fit for 55%” plan). These

¹ In particular, the surface heat island (SUHI) is defined as the difference between the temperature of urbanised surfaces and the temperature of surrounding rural surfaces. This type of urban heat island occurs when the city is surrounded by wetlands or vegetated areas that tend to be cooler than the urban matt surfaces. The term Urban Canopy Layer Heat Island (CLUHI), on the other hand, refers to the difference in temperature of the air layer below the average height of buildings and the air temperature of the rural surroundings.

measures aim to enhance the adaptability of local contexts to changing climatic conditions by implementing interventions that increase the resilience of both ecosystems and urban systems. The role of greenery and nature-based solutions (NBS) and green-blue infrastructure (GBI) in climate change adaptation and mitigation, and more broadly in improving urban environmental quality, has long been recognized by the scientific community and international, national, and local authorities with expertise in spatial planning and programming [3, 4, 5]. NBS and GBI provide significant ecosystem services, offering multiple direct and indirect benefits derived from the functions and processes of natural systems [6, 7].

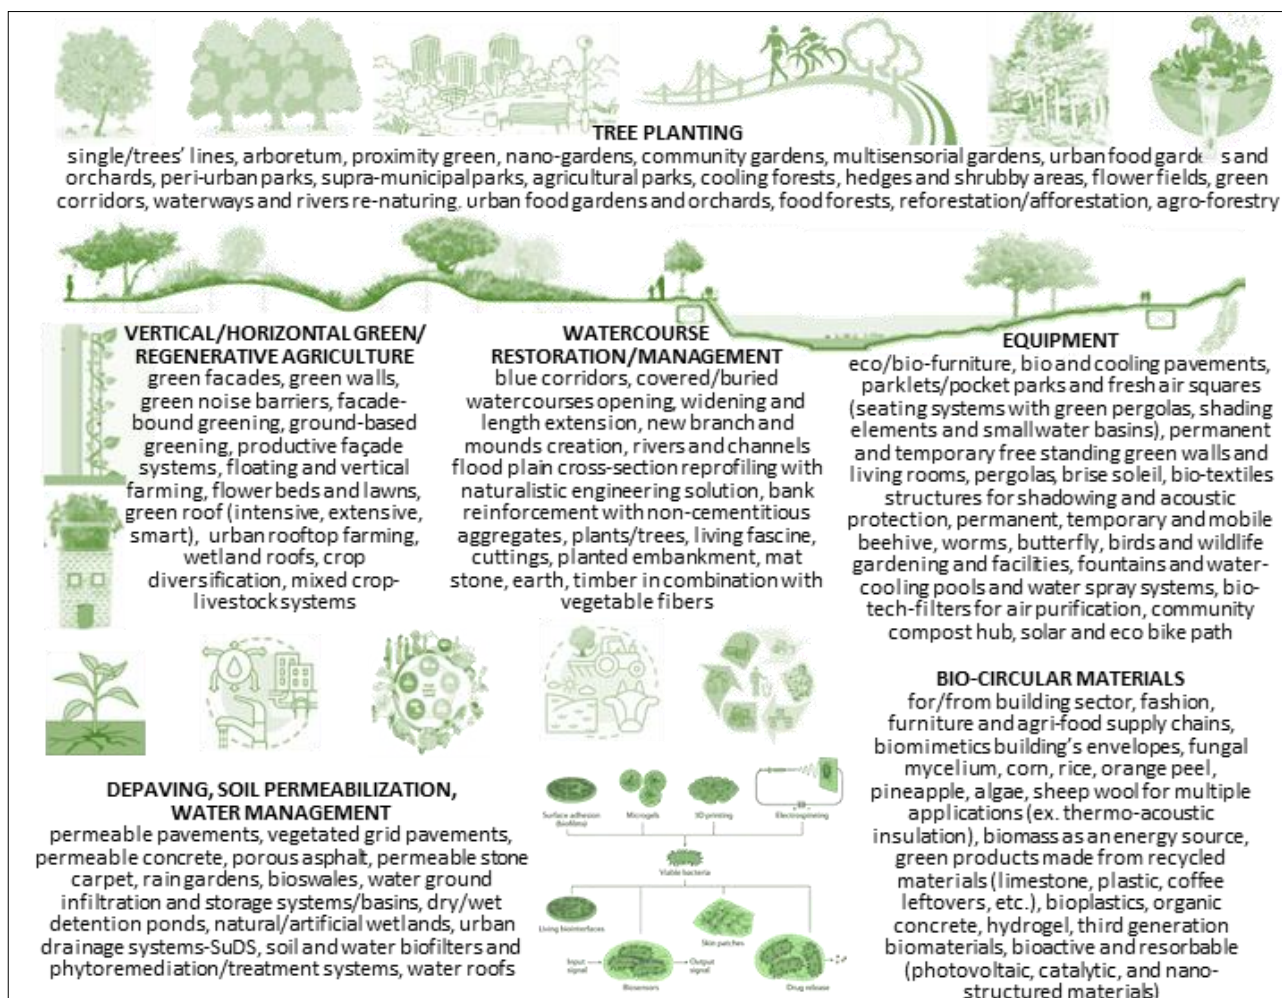

Figure 1. NBS and GBI for the quality of the built environment (authors' elaboration).

Peri-urban areas frequently represent strategic contexts for implementing structural and systemic mitigation and adaptation actions to address climate change and environmental pressures. These areas allow for significant green infrastructure and ecological reconnection interventions due to the greater availability of space and reduced interference with human activities [8]. Additionally, these interventions can enhance the landscape quality of these often neglected or degraded areas, increasing their usability by providing facilities for leisure, sports, and other outdoor activities, thereby benefiting the entire urban area of reference.

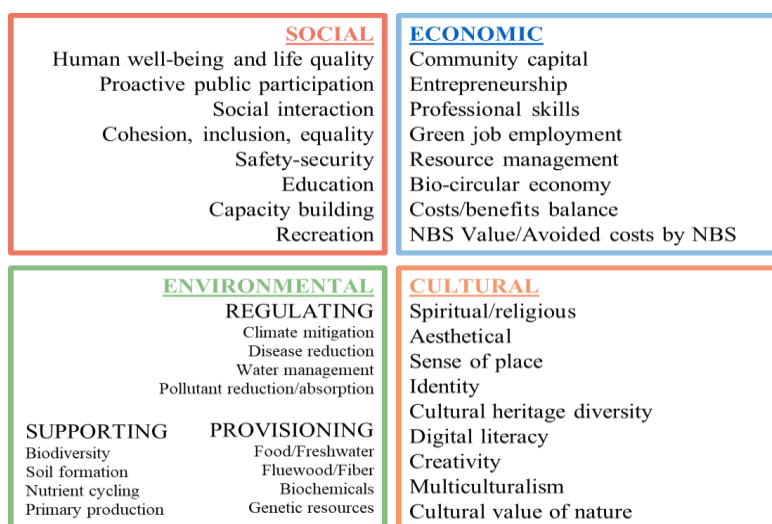

Figure 2. NBS' ecosystem services (authors' elaboration).

2. RESEARCH EXPERIENCES

The ENVI-Reg research group at the ABC Department of the Politecnico di Milano, coordinated by Prof. Elena Mussinelli¹, has been extensively involved in environmental design research. Their expertise lies in developing interventions aimed at transforming the built environment to generate ecosystem benefits at urban and territorial scales by integrating nature-based solutions (NBS) and green-blue infrastructure (GBI). Their work also focuses on enhancing the usability and quality of open spaces. This article presents three research case studies that explore the ecosystem potential of NBS in peri-urban contexts, detailing the methodological, analytical, and design approaches applied at three distinct scales of intervention: territorial, metropolitan, and urban.

2.1 Lodi Provincial Coordination Territorial Plan

The first research experience involves the activities conducted by ENVI-Reg² to support the drafting of the new Provincial Coordination Territorial Plan (PTCP) for the Province of Lodi.

In the Lombardy region, characterized by high population density and widespread conurbations, the Province of Lodi stands out due to its dispersed settlements and extensive agricultural system between the Adda, Po, and Lambro rivers³. This area, acting as a bridge between the Milanese metropolitan system and the lower Lombardy plain, boasts significant environmental and landscape resources⁴.

In recent decades, the locational advantages (proximity to Milan) and infrastructural assets (notably the motorway linking Milan with Bologna and southern Italy) have attracted numerous economic activities and expansions (production and logistics). These pressures have caused considerable soil

¹ Coordinator and scientific responsible: Elena Mussinelli; Working Group: Fabrizio Schiaffonati (Dean), Roberto Bolici, Daniele Fanzini, Matteo Gambaro, Andrea Tartaglia, Raffaella Riva, Giovanni Castaldo, Davide Cerati, Annamaria Sereni.

² Research Contract “Attività di Ricerca e analisi di supporto alla redazione e formalizzazione dei contenuti del nuovo PTCP della Provincia di Lodi fino all’adozione”, tra Provincia di Lodi e Politecnico di Milano-Dipartimento ABC. Research responsables: Elena Mussinelli e Andrea Tartaglia. Working Group: Raffaella Riva, Giovanni Castaldo, Davide Cerati, Annamaria Sereni.

³ 80% of the territory of the Province of Lodi is designated for agricultural use, compared to the regional average of 39%.

⁴ In the provincial territory, there is a regional park (Parco dell’Adda), established in 1983, which contains significant wooded areas. Additionally, there are two Nature Reserves (Monticchie and Adda Morta), four Local Parks of Supra-municipal Interest (PLIS) (fiume Tormo, del Brembiolo, dei Sillari, della collina di San Colombano), six Special Protection Areas (ZPS), eleven Special Areas of Conservation (ZSC), and a UNESCO MAB Biosphere Reserve (MAB Po Grande).

erosion and fragmentation of natural and agricultural systems. Between 2007 and 2018, over 1,200 hectares were affected by soil sealing, about 1.55% of the provincial territory¹. As of 2023, the urbanized surface of the Province of Lodi totals 10,216 hectares, while the urbanizable surface amounts to 8,424 hectares, including 4,131 hectares for residential and 4,292 hectares for other urban functions (commercial, productive, tertiary, services).

Over the past decade, the development model in Lodigiano has been ineffective socioeconomically. Unlike other Lombardy provinces, the Lodigiano population has remained stable over the last ten years, with negative indicators and poor economic performance². Additionally, this model has led to negative environmental impacts, as highlighted by ARPA Lombardia reports³ and the INEMAR inventory (2017), including problematic air pollution levels.

The updated PTCP addresses these issues by identifying six development objectives with specific targets: land consumption reduction; decarbonization-ecological transition; decarbonization-energy transition; territory and tourism attractiveness; agricultural excellence; and sustainable mobility.

The PTCP's soil consumption reduction measures – aligned with Regional Law 31/2014 and Lombardy Regional Territorial Plan (PTR) guidelines – were seen as an opportunity to develop a collaborative model among municipalities for efficient soil use, balancing transformation needs with environmental protection. By defining criteria for land consumption reduction and land use optimization (location, accessibility, functional and ecological-environmental compatibility, and soil ecosystem quality), the PTCP provides a framework for Lodigiano municipalities to update their urban plans, aiming to reduce urbanizable areas and detail the provincial ecological and green network at urban and peri-urban scales.

The PTCP identifies peri-urban areas as strategic for containing transformation pressures and ensuring the continuity of environmental networks (Ecological Network and Green Network). It designates several agricultural and natural areas around main urban centers to facilitate the redesign of peri-urban fringes, foresee the ecological and recreational reconnection of built and natural systems, and improve the territorial resilience to climate change. These “agricultural areas of interaction - buffer areas (AAt)” are governed by PTCP technical regulations (art. 47), prioritizing forestation, reforestation, afforestation and agricultural production enhancement.

Overall, AAt areas cover 4,660 hectares, 5.9% of the Province of Lodi's total area and about half of the Lodi area's urbanized surface. Maintaining these peri-urban fringes in a natural state or for agricultural production conserves and enhances the ecosystem services provided by these free soils, (with a CO₂ storage capacity of about 60 tons CO₂/ha⁴).

¹ Approximately one-quarter of the impermeabilized land is due to the significant expansion of mobility infrastructure (roads and railways). Another significant portion, nearly 30%, of land consumption is attributed to the development of productive activities and the establishment of large service facilities, both public and private.

² Per capita GDP has remained essentially unchanged over the last 15 years, while the regional GDP has increased by 18%. The provincial GDP marks the worst performance compared to other provinces in Lombardy. The number of active businesses has decreased by 9% in the last decade, and the per capita disposable income of households is the lowest in all of Lombardy.

³ “Rapporti sulla qualità dell'aria della Provincia di Lodi” by ARPA Lombardia (2022, 2021, 2020, 2019, 2018).

⁴ The calculations on carbon storage in provincial soils were developed using the InVEST “Carbon Storage and Sequestration” model, along with land cover data provided by the European service Corine Land Cover. The data were processed using the Simulsoil software in a GIS environment (<http://www.sam4cp.eu/simulsoil/>).

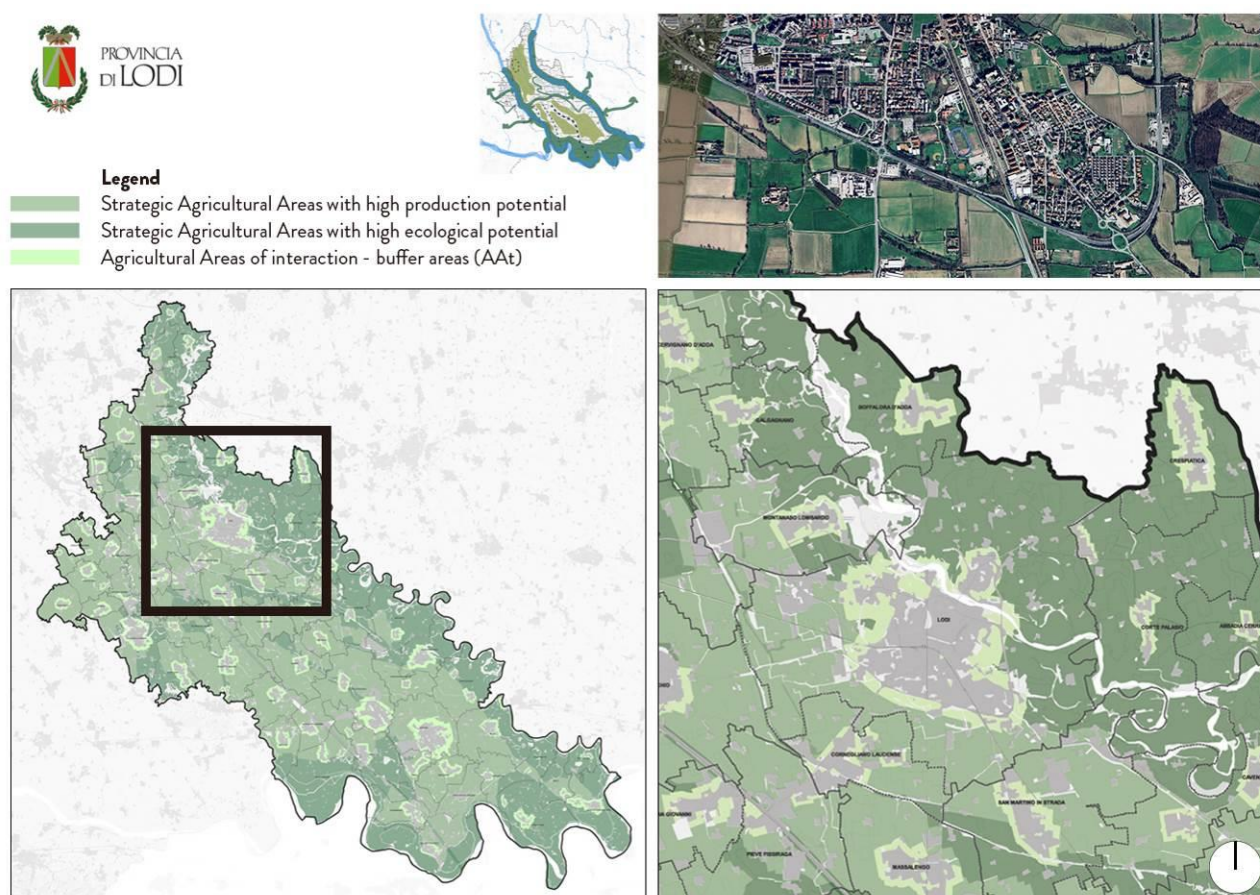

Figure 2. Agricultural areas, Tav. 13, PTCP Province of Lodi (authors' elaboration).

2.2 Studies and proposals for the environmental and landscape context of Porto di Mare in Milan

Since 2017, the ENVI-Reg research group has conducted several studies on the south-east quadrant of Milan, developing project proposals in collaboration with Municipality 4 of Milan and various cultural associations.

The large settlement system along the road axis connecting the city center to the south-east metropolitan area (corso Lodi) and metro line 3, with its peri-urban extensions, demonstrates a clear inter-municipal dimension. Due to historical and morphological factors, this area has exceptional characteristics: limited urban sprawl, large agricultural areas, and vast open spaces. Unlike other city quadrants, there is an absence of conurbative dynamics toward the hinterland municipalities. The potential for ecological connectivity is high, thanks to large parks such as Valle del Lambro (900,000 sqm), Forlanini (600,000 sqm), Monluè (100,000 sqm), Idroscalo (750,000 sqm), and Parco Agricolo Sud Milano. These parks integrate cultural and landscape ecosystem values from Porto di Mare to Vaiano Valle, Ticinello, Vettabbia Park, and the Cammino dei Monaci, connecting farmsteads and abbeys of Chiaravalle, Mirasole, and Viboldone.

In this context, multiple transformative pressures are emerging that may threaten these environmental and landscape features. Interventions for the Milan-Cortina 2026 Winter Olympics, such as the Olympic village at Scalo Romana and Palaitalia in Santa Giulia, add to the substantial transformations already carried out and planned real estate developments (e.g. transformation of the Porta Romana railway yard, A2A tertiary tower in Piazza Trento, Symbiosis project, PII via Lorenzini-Adamello, Vaiano Valle Nord plan, Porta Vittoria, Ortomercato, Ex Macello, Scalo Rogoredo, Santa Giulia Nord, Spark 1 and 2, Bosco della Musica). This list highlights the relevance of new volumes, the

influx of new inhabitants and employees, and the significant economic and financial interests involved¹. These interventions often transform free areas without integrated assessments of their complex environmental impacts (anthropic load, heat island effect, mobility flows, energy consumption, resource use, etc.).

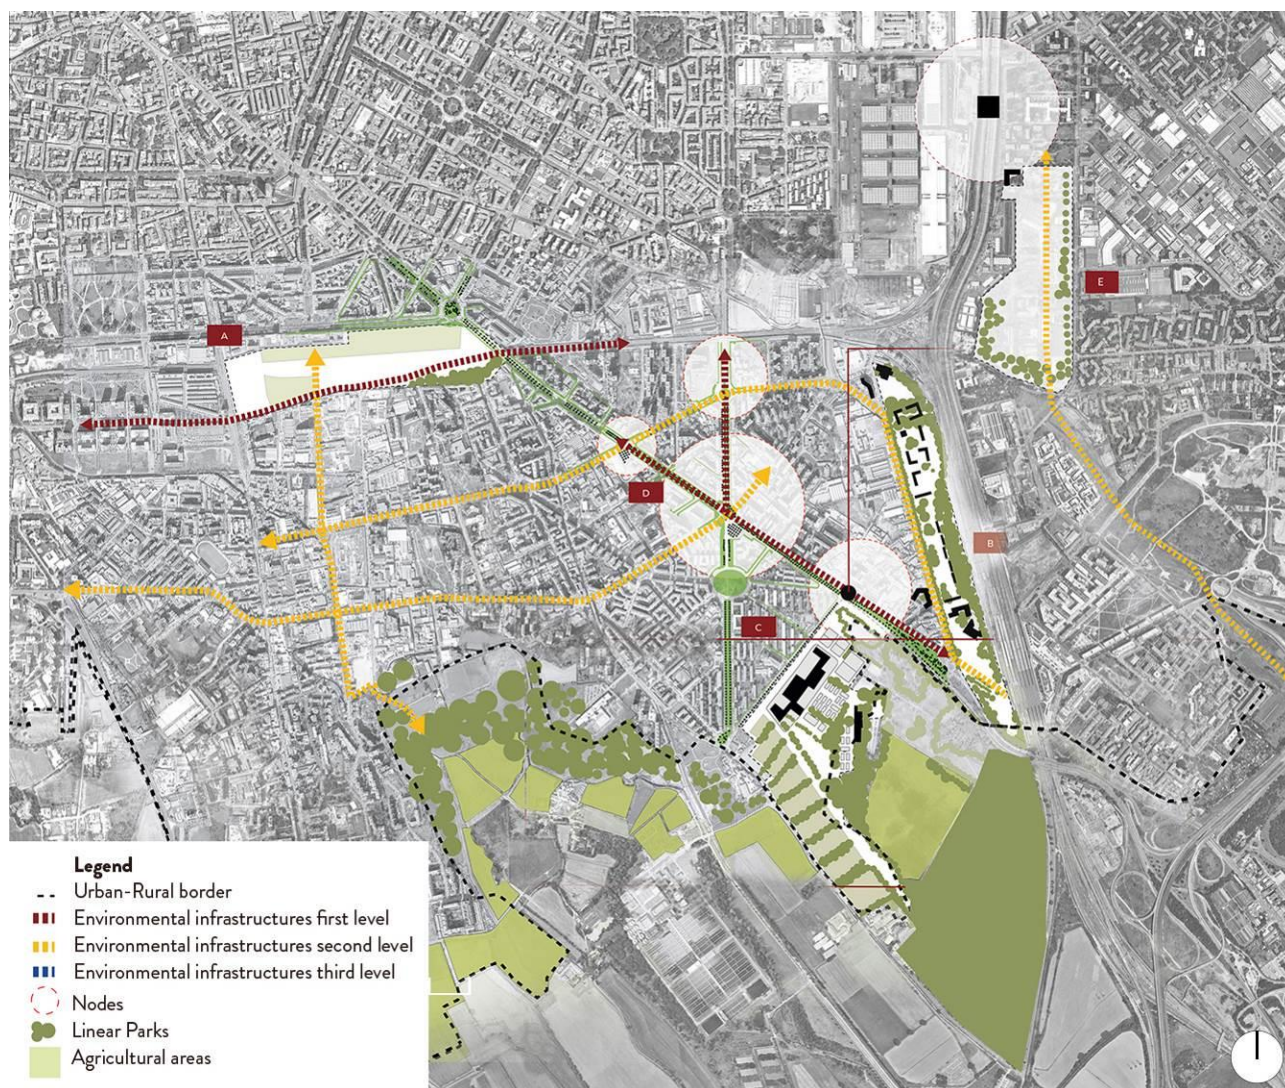

Figure 4. General masterplan for the South-East sector of Milan (authors' elaboration).

In addition to the previously described planning framework, the transformation program for the Porto di Mare area must be considered. Milan's Territorial Government Plan designates this area for the establishment of a Great Urban Function², including public services and strategic private functions, alongside other urban uses (art. 16, NTA, PdR, PGT of Milan). This area spans more than 1 mil. sqm and is primarily green (e.g., Parco Cassinis), but also includes mixed settlements on the northern and

¹ Overall, the listed interventions cover a territorial area of over 750,000 square meters, with a gross developable area of approximately 730,000 square meters.

² In the past, several transformation proposals have been made for the Porto di Mare area, ranging from the Palace of Justice to the establishment of tertiary-commercial activities. These proposals were inconsistent with the area's intended uses and incompatible with its landscape and environmental characteristics.

Proceedings

western edges (historic farmsteads, sports facilities, craft activities, abandoned warehouses, and unauthorized settlements).

Given Porto di Mare's pivotal role as a transition between the city and countryside – connecting the Mazzini district to the Abbey of Chiaravalle and the Agricultural Park – its high ecosystem potential is crucial for enhancing the environmental and recreational quality of the peri-urban area. The ENVI-Reg research group conducted in-depth studies and developed proposals to redevelop, protect, and enhance the area, aiming to limit soil consumption and expand park areas.

In 2018, in collaboration with the Urban Curator TAT cultural association¹, a proposal was developed for a new sports facility, an Olympic swimming pool, aligning with the area's history and the city's needs [9]. The project includes landscape redevelopment through the removal of unsuitable structures, preservation of some existing sports facilities, allocation of areas for agricultural production, and enhancement of natural elements through new plantings [10].

Figure 5. Masterplan for Porto di Mare Area developed by Li Yingkai, Hua Chuanwang, Hua Youchen, Dong Wenjing, Urban and Landscape Regeneration Studio, A.Y. 2022-23, Politecnico di Milano.

Further design experiments were conducted in the “Urban and Landscape Regeneration Studio” led by Prof. Paolo Debiaggi² (academic years 2022-2024) as part of the “Sustainable Architecture and Landscape Design” master’s degree course at the AUIC School, Politecnico di Milano. These proposals emphasized an ecosystem approach, focusing on soil de-sealing, conservation and recovery

¹ Urban Curator TAT is a cultural association based in Milan, that promotes studies, projects, publications, conferences and debates, with a particular focus on the regeneration of public space. It emphasizes active citizen participation and aims to raise awareness among institutional entities. It was founded in 2016 by university professors, architects, engineers, urban planners, and scholars of socio-economic issues.

of historical artefacts, and environmental enhancement for climate change adaptation. Recurrent elements include the use of NBS, formation of wetlands, integration of productive and equipped green areas, and valorization of rural landscape elements. The environmental interventions proposed include forestation, reforestation, and afforestation, with the planting of about 15,000 trees (capable of absorbing approximately 200 tons of CO₂ per year) and the de-sealing of 50,000 square meters of soil.

2.3 Strategies for the environmental development of Codogno

The third research experience involves the scientific and methodological support for developing environmental, social, and economic strategies underpinning the new Territorial Government Plan of Codogno, in the Province of Lodi¹.

Codogno, a city of approximately 15,000 inhabitants, is located in the agricultural heartland of Lodi. It is intersected by major road and railway infrastructures along the north-south (Via Emilia and the Milan-Bologna railway line) and east-west (Pavia-Cremona connection, Ex State Road SS 234, and Pavia-Cremona-Mantova railway line) axes. The urban fabric features a historical center surrounded by a tree-lined road belt and a residential and service expansion area developed since the mid-1950s. Since the mid-1980s, the area's tradition of artisanal and industrial production, combined with national infrastructure development (e.g., the two-lane variant of SS 9, the ring road on former SS 234, and the railway station between the Milano-Bologna and Pavia-Cremona-Mantova lines), has led to the creation of a significant production cluster (Mirandolina) west of the city along Provincial Road SP 126, covering over one million square meters and accounting for nearly one-third of the urbanized area.

While this production cluster has brought socio-economic benefits, it has also caused significant agricultural land erosion, putting pressure on the ecological-environmental system (e.g., the Local Park of Supra-Municipal Interest (PLIS) of Brembiolo).

The research developed a trans-scalar interpretative and planning approach to integrate superordinate policies (European, national, regional, and provincial) with Codogno's specificities. The "Codogno 2050" proposal promotes the systematic use of NBS to support carbon neutrality, mitigate climate change effects, and improve urban life quality, with a special focus on redefining the peri-urban area. This is the only area suitable for significant environmental and recreational enhancements and ecological reconnection with the broader ecological and green networks.

The result is an environmental master plan that redefines peri-urban green spaces for new uses and management through NBS, improving ecosystem services. It includes new plantations, water storage reservoirs, groundwater recharge wells, and forest areas for climate resilience. Additionally, it proposes new horticultural and renewable energy facilities, bicycle and pedestrian paths, and services for sustainable mobility and tourism. During development, the interventions' benefits were quantified using impact indicators to optimize solutions and maximize performance, integrating usability and landscape enhancement.

The master plan organizes peri-urban green areas into three parallel bands: an environmental mitigation band adjacent to the built fabric with concentrated plantations; an agricultural production band with integrated photovoltaic systems; and a final band for plantations and naturalistic engineering to improve Codogno's climate adaptation (e.g. sustainable drainage systems). Specifically, about 100 hectares are allocated for fruit and vegetable production (50 ha for fruit trees

¹ Research Contract between Municipality of Codogno and ABC Department of Politecnico di Milano, Research Group ENVI-Reg "Studi sulle dinamiche di trasformazione del territorio e ricerche per la costruzione delle strategie di sviluppo ambientali, sociali ed economiche". Research responsables: Elena Mussinelli e Andrea Tartaglia. Working Group: Davide Cerati, Giovanni Castaldo.

Proceedings

and 50 ha for vegetable gardens), yielding approximately 2,500 tons/year of produce, matching the average annual consumption of nearly 17,000 inhabitants. These plantings can absorb about 75 tons of CO₂. Additionally, avoiding transport emissions for this produce saves about 30,000 tons of CO₂ eq, about 0.7% of total provincial emissions. Forestation, reforestation, and afforestation efforts over 150 hectares increase CO₂ assimilation capacity to 750 tons/year and biomass production to about 2,500 tons.

Figure 6. Masterplan "Codogno 2050" (authors' elaboration).

3. CONCLUSIONS

The research experiences presented in this article highlight the relevance of nature-based solutions (NBS) and green and blue infrastructure (GBI) in mitigating and adapting to the effects of climate change, as well as in improving the environmental quality of cities.

In relation to the different scales of intervention and context conditions, specific ecosystem functions of peri-urban green spaces can be identified. In the case of the Province of Lodi's PTCP, peri-urban areas are identified as strategic areas to guarantee the continuity of green ecological networks, contributing to territorial resilience. The approach adopted allows transformational pressures to be contained and agricultural and natural areas to be enhanced. In the proposals for the Porto di Mare area, the nature-based interventions aim at landscape redevelopment and the improvement of the environmental and fruition quality. In the "Codogno 2050" master plan, the systematic use of NBSs not only contributes to climate change mitigation and adaptation, but also demonstrates a specific function in terms of agricultural production services.

Moreover, these research experiences demonstrate the necessary close correlation between planning level and the project level of peri-urban green areas: only strategic visions of a vast area, then coherently declined at a closer scales, allow the ecosystemic potential of peri-urban green areas to be fully exploited.

Abstract

This paper is dealing with urban greening and urban design in the historic environment. To this end, the raised main question is: How we cope with urban changes and greening in historic cities?

To respond significantly to the current scenario sustainable planning and design can lead positively to these changes. On the other hand, issues on resilient strategies and the implementation of adaptable measures to mitigate climate emergency in historic environment must be clearly faced. Solutions that can be focused within the core of the city at risk to face urban heat islands as well as intensive rainfall leading to flooding must be planned and designed. At the same time, protection, and revitalization of the 'Urban Heritage' of outstanding value should be emphasized on properly climate change adaptation methods. However, opportunities exist to link Urban Greening with Urban Design to help maximize not only the aesthetic of the Historic City but also the functionality and quality of a space to satisfy community needs.

The paper identifies innovative strategies and proposals within the Florence UNESCO Area, to help greening public urban spaces and at the same time mitigate climate emergency.

Keywords: *Urban Greening, Urban Design, Urban Heritage, Florence UNESCO Area, climate change.*

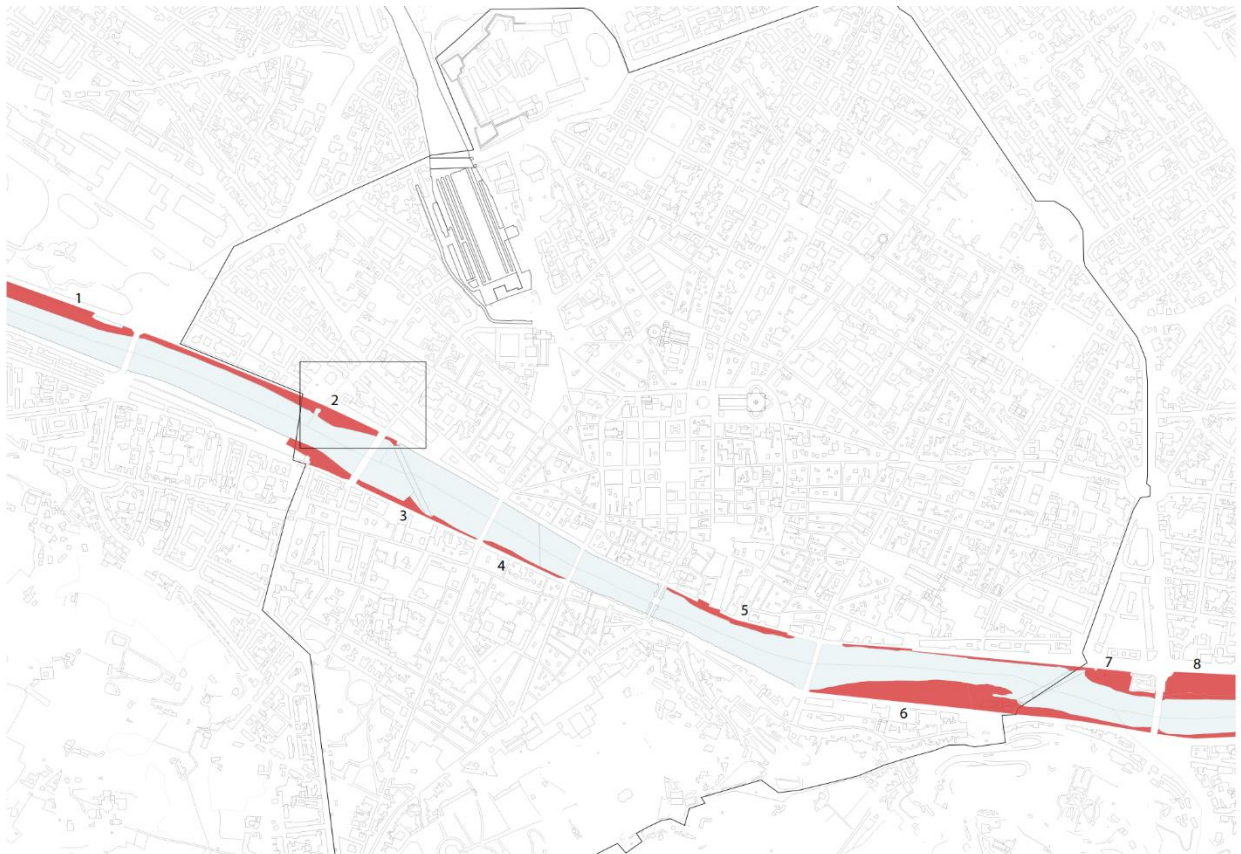

1. INTRODUCTION

In the Transforming City, to address ongoing gaps, public open spaces need to be re-designed to integrate green and blue infrastructure for everyday life. However, a balance needs to be found between functionality of an urban space in historic environment, historic value, and socio-economic revitalization of a context. Resilience design can provide placemaking for human activity while providing an effective buffer on the site. In turn, design strategy provides movement on routes and streets to encourage sustainable connectivity through core environments of great beauty and history. On the other hand, it is important to identify future challenges in relation to build environment and climate change, to ultimate proposals that would be more resilient and adaptable to recent issues whilst delivering high-quality planning and design.

It is only through resilient approaches that it can be delivered quality places for this emerging reality for historic environment at risk. In some instances, the need to work across different disciplines to incorporate expertise may create some difficulties. The integration of engineered solutions with contemporary thinking on nature-based infrastructures to support both urban quality, aesthetic and promote innovation can become desirable. For instance, we see Green Infrastructure, (GI) been used as a first principle to sustainable mobility. However, Urban Green Infrastructure, (UGI) must be considered as a framework of principles to link sensitive urban environment to support both long-term and short-term sustainability goals. But the main aim is to link urban policy

and planning to urban and landscape design.[1] To this end, innovative thinking can be challenged for more integrative, innovative, and smart design for the next future. Moreover, there is the added value to attract investment in variations of place to promote interactivity, connectivity and maximize urban quality.

Figure 2. Florence *Lungarno Vespucci*: Before and after. The green-blue riverfront proposal with green spaces for enjoyment and well-being

2. URBAN HERITAGE AND SUSTAINABILITY. AN EVOLVING PROCESS

In 2011 the ‘UNESCO Recommendation on the ‘Historic Urban Landscape’, (HUL) in paragraph 3 clearly defines the notion of “Urban Heritage including its tangible and intangible components constitutes a key resource in enhancing the liveability of urban areas and fosters economic development and social cohesion in a changing global environment”. [2] For the future, in fact, the HUL notion includes concerns of a changing global environment and the possibility to manage built environment more sustainably within effective planning and design to achieve a balance between urban growth and quality of life. [3]

The expanding notion of cultural heritage led to a holistic contextual view to include the concept of landscape. (4) Accordingly, the HUL approach needs to be particularly considered for protection, urban quality and improvement for health and well-being of the environment of historic cities and historic city centres. Central to this thought, a HUL can be considered as a lived space, an urban environment with variations in time and space. (5)

Proceedings

of the International Conference on **Changing Cities VI**:
Spatial, Design, Landscape, Heritage & Socio-economic Dimensions
Rhodes Island, Greece • June 24-28, 2024
ISSN: 2654-0460
ISBN: 978-618-5765-02-6

In turn, the main components for the new scenario in a sensitive urban environment are presented as follows: (a) *Heritage* (tangible and intangible) to be preserved and evaluated; (b) *Climate Change* (floods, rainwater, heat, pollution) to be faced and adaptation; (c) *Nature and Green elements* (process, aesthetic, function) to be inserted to add value, (d) *Time* (dynamics, evolution etc) to be considered for sustainability issues. Research findings [6] emphasized the need for integrated strategies between urban and nature to fully align with climate change emergencies and people needs.

3. GREEN INFRASTRUCTURE AND NATURAL APPROACH

In recent years different conceptualizations are developed regarding the definition of Green Infrastructure, GI such as: (a) *Facilities* to manage stormwater (rain gardens, bioswales and so on); (b) *Connected Ecosystems* with multiple functions and benefits; (c) *Planning approaches* to better match built environment and natural resources for social benefits. However, GI multifunctionality spatiality and location requires inevitably negotiation on planning decisions. Several studies demonstrated that GI can be integrated into strategic planning approaches. A more common European conception is focusing on classifies any vegetation, open space, and their ecological function, or the ecosystem services they provide. A more United States Conception considers a GI as an approach to natural drainage through engineered or natural systems to manage stormwater (permeable pavement or permeable surfaces, landscaping to store, infiltrate, or evapotranspiration stormwater, heat mitigation and so on). Often GI benefits and functions depend on how is sitting and design with urban ecological and infrastructures systems. [7]

For sure, GI refers to a natural approach that provide social, economic, and environmental benefits through urban design. As a strategy is to design an urban environment that tactically integrates a network of green spaces. The question is: How could be possible to gain the typical benefits of GI within a historic environment including green opportunities, vegetation, urban heats islands, improving health and well-being, providing social benefits, carbon sequestration, crime reduction?

To this end, investing in GI offers the opportunity to enhance the existing infrastructure and protect the environment while green technologies can revitalize urban core areas to meet climate change emergency. But major benefits are included in: (a) *Enhancing public open spaces* by designing and greening areas, streets, and squares; (b) *Creating liveable places* by landscaping open spaces for more safety and protection from urban risks; (c) *Improving urban image and connectivity* by good urban design and management of streets and spaces; (d) *Integrating policies, strategies and actions* by integrating strategic planning process. In a historic environment delivering sustainable and healthy places which allow nature-based systems can ensure more intimate spaces that locals and visitors can benefit from the value that nature brings. This provides the opportunity to create dynamic and resilient ecosystems that must also be controlled by a good City Action Plan. [8]

4. THE ADDED VALUE OF URBAN GREENING

Currently, Green Infrastructure, GI has been conceptualising extensively to address issues of climate change emergencies as well as supporting efforts to improve mental and physical health via access to nature The key benefits of Green Infrastructure approach is the ability to be adaptive to the spatial of a context. [9] This flexibility allows GI to move across the landscape, engineering and

Figure 3. Florence *Piazza San Firenze*. Proposal for a Green Square. Urban design with planters and city-trees to mitigate climate change and city's pollution

planning processes in a more responsive way and in this adaptive way GI can be best linked to urban design. Good urban design allows people to deal with heritage and nature offering an added value and help to maximize aesthetic, quality, functionality, and protection of a space. At this point, urban greening has a positive influence on the design process. Solutions with contemporary thinking on nature-based drainage systems or tree-planting used to support both aesthetic quality, urban heat islands and green mobility to support short-term and long-term sustainability goals. In doing so, GI can be aligned with future-thinking urban design processes.

5. FLORENCE UNESCO AREA: URBAN DESIGN TO FIT LOCAL STRATEGIES

Florence UNESCO Area as a sensitive urban environment needs to implement strategies and projects that meet each district's specific needs. In the city centre historic patterns are clear such as Roman/Medieval/Renaissance areas of unique image, characteristics, and needs. Recently, the adoption of the new *Structural Plan* and *Action Plan* put the perspectives for a vibrant and innovative City Centre.[10] Additionally, to reduce City Centre's risks, improve historic context systems, and adapt to changes from overtourism, natural hazards, human-made disasters, climate change the new *UNESCO Management Plan* played an important role.[11] The Plan reflects on ongoing processes and is in a constant state of reinvention and reinterpretation to explore and promote the elements that make public space engaging and characterful. Among the new introductory issues, a *buffer zone* of 27ha has been introduced to extend preservation of 'outstanding universal value' and environmental sustainability. Opportunely, it encourages the comprehensive City's Planning processes to reinvent and protect historic and natural environment and regenerate public open spaces as the heart of placemaking focusing on social, cultural, and environmental significance. To address common issues in fact, the regeneration of small-used spaces and squares, or the development of less car-dominated streets can be a valuable tool to create quality; to adopt urban design principles for local distinctiveness while inspiring local people and visitors.[12]

Figure 4. Florence *Fortezza da Basso*: Before and after. Proposal for a green cycleway

In addition to create spatial and visual landmarks, a resilient placemaking must be developed as a common strategy among planning and design decision-making. A sustainable and resilient approach means reducing the vulnerability to withstand challenges that may result from major urban risks. All current planning and design policies reflect on the preservation of cultural heritage of the Florence UNESCO Area but also on climate change emergency and how to face this with innovative thinking.

5.1 The Proposed 'Greening Strategy'

A comprehensive Green Strategy can work to improve City Centre's resilience. Urban Greening can fill the gaps and responsiveness to the different zones. The Florence City Centre faces many natural and human-caused risks, that can have environmental, social, and economic impacts such as:

1. *River floods* that can damage historic buildings and disrupt streets and transit services
2. *Climate change* effects that can put a serious threat characterized by hotter, drier summers and risks of flooding
3. *Extreme natural events* that can influence negatively people's health and well-being by increasing urban heat island phenomenon
4. *Lack of pedestrian and cycle movement* that can add value, comfort and greenery in the city centre
5. *Over tourism* that can create a lack of human scale and can have an unpleasant impact on human wellbeing.

Consequently, local population, including low-income people with disabilities, older adults may be less able to prepare from natural hazards and climate change impacts. But effectively managing of urban, one can avoid environmental degradation, cultural heritage damage and economic loss. To mitigate the effects of climate change, opportunities to manage the environment with more efficient and renewable technologies are essential. Similarly, to respond to climate change by protecting natural resource areas, maintaining tree canopy, ensuring protection of riverfront, and increasing the ability of greening is advised.

In particularly, to respond to the above-mentioned emergencies it is important to find specific urban strategies as follows:

1. *Green River* introducing Green Infrastructure, (GI) approach to evaluate and protect the built environment

Figure 5. Florence *Piazza dell'Unità*. Proposal for a Green Square

2. *Green Public Open Spaces/Squares/Small Open Spaces* to create urban quality and resilience
3. *Green Roads/Streets/little Streets/Green Gateways* for sustainable mobility and connectivity
4. *Active Travel* reinforcement of sustainable green pathways and cycleways and public transport for health and well-being
5. *Green overtourism* with introduction of green cultural open spaces to respect existing Cultural Heritage and introduce innovation on the selected sites. [13]

The proposed 'Greening Strategy' is firstly aiming to increase awareness, to experiencing the impacts of climate change such as flooding risks, urban heating, and pollution. To this end, trees and green spaces must be considered as essential infrastructure, that can help reduce temperatures on the ground. On the other hand, urban greening can improve health and well-being, reduce heat impact, and bring nature into the city. Achieving a greener historic environment by innovation must be considered an ambition programme for a more resilient city.

7. DISCUSSION

Urban Greening in sensitive urban environment can help to raise awareness and quality of space dynamics and can have a great significance in urban design processes. It also helps to mitigate climate change where a sustainable and resilient approach is undertaken. Urban Greening can address the urgency of an urban regeneration, not only from a spatial point of view but also a deep concern on the economic, social transformation of a city. On the other side, a Greening Strategy highlights the importance in transforming a historic environment that must be based on new challenging thinking. By using nature-based systems for protection and quality of the Heritage Urban Landscape, HUL as defined by UNESCO, a great opportunity is presented for a much-needed dialogue in urban renewal outcomes with local authorities, planners, urban designers, and local communities.

Regarding the proposed Green Strategy withing the Florence UNESCO Area, a key conclusion is that it requires support and clarity to sustain quality in the delivery of urban design processes. Therefore, a toolkit is needed to make the most of what has been defined and in term of goals by the City's decision-making. Nevertheless, in academic research and professional practice thinking, there is a great consideration on whether HUL is being applied in practice and due to the differences in regulatory systems at various planning levels.

Relevant to these considerations is that the HUL Approach in action can offer an innovative thinking to urban transformation. It can also encourage local authorities to face more easily challenging questions on urban emergencies.

Note

All proposed projects and drawings in this contribution have been developed in the framework of the Architecture Degree Course of "Fundamentals of Urbanism". The Design Studio was coordinated and held by Dimitra Babalis at the Department of Architecture, (DiDA), University of Florence, Year: 2022-2023.

Extended abstract

Resilient cities embody a complex relation of interconnected elements, where the realms of economy, society, governance, and environment converge within the intricate framework of inhabited and open space configurations. Indeed, architecture and urbanism dwell in same space relations and temporalities that is associated with new modes of consumption and production. Although architecture as an autonomous discipline creates its own network of relations embedded in the design philosophy of the time and place it is always associated with the social, cultural, political, economic, technological, psychological and historical relationships of a community. Thus, as a discipline it tends to take an action to develop a better understanding of the emerging conditions that generate resilient cities within the context of changing power relations, social, economic and cultural contingencies. Architects and planners are exploring ways of rehabilitating the urban environment as they face the challenges of sustainability, the preservation of ecosystems and new modes of space consumption. These discussions focus on the performative qualities of the urban environment as well as the preservation of natural resources in cities. At the heart of the evolutionary discussions of resilient cities lies a quest for lively and sustainable living environments, characterized by safe neighbourhoods, vibrant social networks, and reduced poverty and scarcity. Within this context, the notion of "resilience" emerges as a key paradigm for modern urbanism, shaped by several factors including industrial diversity, demographic shifts, public sector imperatives, and the evolution of robust infrastructural frameworks encompassing transportation, distribution, culture, and knowledge dissemination. To maintain a healthy and active life people are in search of safe neighbourhoods where less poverty and active social network has the dominancy. This search has spurred a migration from dense urban cores towards suburban landscapes, where communities seek to establish new patterns of open space utilization, with green areas where *nature* plays the crucial role in the establishment of this new system.

This paper argues that *open architecture* and *open planning* can influence the future urban environment by questioning the physical space and social life associated with the changing patterns of public life and open space configurations. The consideration of openness to be more responsive to the needs, requirements, and desires of the public, to provide a system of responsive environments, equality in the distribution of open green spaces, and access to nature will be the discursive issue of resilience in the 21st century. The concept of openness in architecture not only corresponds to the physical qualities of space but it appears to mean so many different performances in architecture like to create a sense of freedom, flexibility, adaptability, accessibility, collectivity and participation. This paper will focus on the ways of design strategies developed with the discourse of "openness" enhancing urban vitality, improving living environments, and revitalizing public spaces with historical significance in the establishment of resilient cities and open space configurations. It will explore the formation of open spaces under four trajectories which are based on structural, performative, procedural and conceptual for understanding the dynamics of resilient cities.

Keywords: open architecture; open planning; resilient city; nature; responsive environments

Extended abstract

Waterfront areas have long been focal points of significant and often conflicting interventions, as well as hubs of economic and technological shifts, shaping the identity and landscape of cities.

"In recent decades, urban waterfront regeneration has emerged as a compelling global phenomenon, as these projects shape vital relationships between places, uses and future visions. Extraordinary opportunities revealed by changing functions, economic environment and social conditions. In addition to that, we must have also in mind the ten principles for a sustainable development of urban waterfront areas as declared in the 2000 Berlin Expo and the 2030 Agenda for Sustainable Development Goals, concerning on the crucial impact of climate change.

Urban waterfronts which were previously used as industrial facilities are becoming a field of ambitious architectural and landscape transformations. The restoration of such territories helps to improve the quality of urban space and improve its ecological properties. Many cities around the world create innovative waterfront projects, attempting to connect the city with the water environment and also to combine all the above with the constant improvement of public places and their social life.

In this paper, an integrated regeneration design of urban waterfront of the city of Patras is presented within the two steps of an open architectural competition held in 2021. Patras waterfront is a valuable economic, social and cultural element of the city. Although, there wasn't in the past a structured intention to formulate a coherent vision, unifying the fragmented pieces of the waterfront area, visually and spatially.

In this context, having in mind the international contemporary practices for restoration of the former industrial waterfronts and also the urgent need to contribute to the lost ecological and social balance of the city, the presented proposal of "green flowscapes" attempt to create a new unified image and personality for the city waterfront in terms of architectural, functional, social and environmental aspect. By a flowing, flexible, adaptable and accessible to all public space, the design proposal shapes a new continuous ecological zone for public recreation and daily social life, which positively added to the historical character of the city of Patras, giving also more chances for an urban resilient future.

Landscape recovery in Naples Metropolitan City: a project for Mount Faito

M. S. Lux

PhD candidate, Department of Architecture, Built Environment and Construction Engineering (DABC),
Politecnico di Milano, Milan, Italy

Corresponding author: E-mail: mariastella.lux@polimi.it, Tel +39 3401374593

Abstract

Starting from the evidence of an alarming trend of land consumption and reduction of natural resources, the experience of landscape design and restoration carried out on Mount Faito (Naples, Italy) is presented and discussed. The reference context offers a significant example to reflect on the landscape value of natural areas in close proximity to densely populated urban areas. Moreover, the history of Mount Faito, its infrastructuring, tourism peak and then decline and abandonment suggests a critical reflection on human responsibility in its impact on fragile and rare ecosystems. The proposed landscape restoration project is based on the guiding principles of conservation and reuse, landscape continuity, nature-based education & learning, and accessibility & inclusiveness.

Keywords: landscape recovery, Natura 2000, Mount Faito, design competition.

1. Introduction

The anthropogenic transformations of the natural environment extend beyond the urban environment, encompassing a broader footprint and diverse modalities. Sparse urbanization and infrastructural expansion contribute to soil consumption, reaching in Italy a significant intensity of 76.8 km² of new artificial coverage of the soil solely in 2023, equivalent to 21 hectares per day [1]. This phenomenon represents a pivotal aspect in the path of adaptation to Climate Change: while policymakers are addressing the regulating aspects, researchers and designers have the responsibility of working towards the recovery of existing structures, to limit further unjustified consumption of land and resources.

In this scenario, surviving natural areas are invaluable to communities, especially those close to large, densely populated urban areas that truly act as an outlet and resource serving overpopulated neighborhoods. This contribution introduces a project focused on the recovery and landscape enhancement of Mount Faito, Naples, Italy. The project area is a mountainous region at approximately 1000 meters above sea level within the Metropolitan City of Naples. It holds significant environmental, historical, and cultural value and its strategic location has made it an exceptional mountain retreat close to the city. However, following intense tourist development between 1850 and 1980s, the area is currently experiencing a period of decline and abandonment.

The current situation prompts reflection on the need to reconsider the relationship between the city and its natural context, and human responsibility in leaving behind disused structures. The 9th edition of the design competition "Premio Convivialità Urbana" promoted by the association Napoli Creativa, proposed this theme for a call for projects aimed at envisioning potential processes for environmental and landscape regeneration and the rediscovery of this place. This contribution offers a detailed historical and landscape overview of Monte Faito to convey at least part of its complexity and richness. It then presents the guiding reflections that accompanied the project proposal developed by the author together with colleagues Architect Chiara Chionna and Architect Alice Cappello, which was awarded 3rd place in the aforementioned competition.

2. SHORT HISTORY OF MOUNT FAITO

Monte Faito is located on the Sorrento Peninsula, i.e., the landmass that separates the Gulf of Naples from the Gulf of Sorrento. The history of this place is ancient and intimately connected to that of the Neapolitan and Sorrentine coasts [2]. The earliest evidence found on Faito dates back to the Roman era (9th century BC), when the area was identified by the name "Monte Gauro", likely derived from the term *taurus*, or "Monte Lattaro" (Milki Mount), recalling the milk produced there. In any case, the terminology clearly refers to aspects of abundance and the presence of valuable resources for the human communities settled nearby. Another activity historically practiced in the area was the preservation of snow, known since the time of the ancient Greeks, and firstly testified in this area for the first time in the 17th century. Traces of the "snow industry" are still visible today, with large pits dug in the ground, where snow was alternately layered with beech leaves until the pit was full, to preserve the snow until the summer season and then bring it to the nearby towns.

In the 19th century, the Mount Faito became for the first time a favored destination for hiking within the Monti Lattari system, thanks to the connection via a carriage road with the city of Castellammare di Stabia. The key role of Count Girolamo Giusso should be recognized in this respect. He was one of the founders of the Neapolitan section of the Italian Alpine Club and he designed and personally funded the construction of a road that led from Quisisana in Castellammare to the top of the mountain based on an old mule track. Count Giusso also acquired several properties on the mountain starting in 1874, slowly transforming the landscape. For instance, he supported forestry experimentation, with sylvan transformations primarily inspired by economic criteria, as well as efforts to experiment with new species and to explore any possible uses of the mountain. In this area, Count Giusso attempted the cultivation of chestnut, altering the cutting cycle and planting new chestnut groves. Thus, even at that time, an intentional and conscious landscape management approach was observed, imparting an alpine character through the use of resinous plants, thus combining utility with the sense of landscape beauty. The forestry transformation was also accompanied by architectural work, with the construction in 1879 of a Swiss-style chalet that fully realized the utopia of making Faito "an alpine valley" [3].

It was only after World War II that Mount Faito was considered a tourist destination. The ownership was transferred to the Southern Secondary Railway Company, known as "La Vesuviana" and, in

1952, the cable car was inaugurated, connecting the mountain summit to the town of Castellammare in just 8 minutes. Also, a village for summer holidays was built.

Figure 11. Historical picture of the arrival of the cablecar (Source: Profaito).

3. THE LANDSCAPE SYSTEM

The Sorrento Peninsula is situated in the northern part of the Tyrrhenian-insular microclimate, and in particular in a climatic region classified as a “transitional oceanic Mediterranean bioclimate”, which is an oceanic Mediterranean climate transitioning from low and mid-altitude areas to mountainous zones. The morphology of the terrain, characterized by a sudden rise in elevation, stops the humid air masses coming from the west, resulting in increased precipitation and significant snowfall, which at higher elevations can easily reach 50 cm. However, the impact of climate change and global warming is clearly recorded in the area and both the frequency and intensity of precipitations and snowfalls significantly decreased in the recent decades. In this region, the proximity of the mountain to the marine coast concentrates a remarkable variety of different environmental systems within a relatively limited area, significantly increasing the biodiversity and botanical variety of this area. The spatial mapping of the different ecosystems involves the identification of species-specific clusters that may overlap to varying degrees, contributing to environmental complexity. In the case of Monte Faito, the main identifiable species-specific systems, or vegetational zones, include the beech forest, the coniferous forest, the chestnut forest, the holm oak forest, the mixed forest and the Mediterranean maquis. Each zone is characterized by dominant species (complete list in Table 1):

- the beech (*Fagus sylvatica*), accompanied by a rich undergrowth adapted to low light conditions with species such as Holly, Apennine Anemone, Wild Squill, and Bird's-nest Orchid;
- conifers such as Pines, Firs, and Cypresses, planted at different historical periods by humans for construction wood supply and to impart a distinctly alpine character, continuing to be planted in reforestation efforts by the State Forestry Corps and/or the Mountain Community;
- the Chestnut (*Castanea sativa*), with a rich undergrowth of herbaceous plants including Bracken Fern and Male Fern, and some tree-shrub species like the Hop Hornbeam and Downy Oak;
- and the Holm Oak (*Quercus ilex L.*), which tends to form dense forests, though it is more commonly present in mixed forests with other species;
- the evergreen shrubland with shrubs such as Myrtle and others, along with herbaceous plants.

In addition to its rich vegetation, Monte Faito hosts numerous animal species and serves as a significant habitat for various birds, that live and nest there. Human impact is also evident in this aspect, as it has significantly influenced the faunal composition through hunting and, more indirectly, by exploiting and encroaching upon natural habitats. The main bird species inhabiting these slopes include some common birds such as blackbirds (*Turdus merula*), sparrows (*Passer domesticus italiae*) and chaffinches (*Fringilla coelebs*), seasonal birds like robins (*Erithacus rubecula*) and swallows (*Hirundo rustica*), and birds of prey such as kestrels (*Falco tinnunculus*) and buzzards (*Buteo buteo*). The chestnut groves and beech forests are home to *Certhia brachydactyla*, *Troglodytes troglodytes*, *Aegithalos caudatus* and many others. Among the mammals, there are small rodents such as voles (*Microtus savii*), rats (*Rattus norvegicus*), and mice (*Mus musculus*), as well as larger animals like foxes (*Vulpes vulpes*), hedgehogs (*Erinaceus europaeus*), moles (*Talpa caeca*), and stone martens (*Martes foina*).

The specific characteristics of this landscape meant that it was subject to certain environmental protection measures established at both the European [4] and national levels [5]. Monte Faito falls within a Special area of conservation defined by Natura 2000 for habitat conservation, as shown in Figure 2.

Figure 12. Mount Faito is part of the areas protected as part of Natura 2000 network.

Table 1. List of vegetation zones with the main botanical species

VEGETATION ZONE	BOTANICAL SPECIES	MINIMUM ALTITUDE (m a.s.l.)	MAXIMUM ALTITUDE (m a.s.l.)
beech forest	<i>Fagus sylvatica</i> <i>Ilex aquifolium</i> <i>Anemonoides apennina</i> <i>Scilla bifolia</i> <i>Neottia nidus-avis</i>	800	1800
coniferous forest	<i>Pinus sp.</i> <i>Abies sp.</i> <i>Cupressus sp.</i> <i>Larix decidua</i>		
chestnut forest	<i>Castanea sativa</i> <i>Pteridium aquilinum</i> <i>Dryopteris filix-mas</i> <i>Anthoxanthum odoratum</i> <i>Quercus pubescens</i>	750	900
holm oak forest	<i>Quercus ilex</i>	0	600
mixed forest	<i>Alnus cordata (Loisel.) Desf</i>

4. THE ARCHITECTURAL SYSTEM

As mentioned in the historical introduction, Monte Faito has been a summer vacation spot and a location for winter sports since the post-war period. During the years of most intense anthropogenic activity, the area was enriched with a series of constructions and infrastructures, which were subsequently abandoned and left over. Today, remnants of this past represent a significant environmental challenge.

In particular, the area under consideration for the 9th edition of the design competition "Premio Convivialità Urbana" [6] features a large area for sports facility (Figure 4 – A), that includes various sports fields for soccer and tennis, as well as an outdoor swimming pool. These fields are still partially used but the overall condition in terms of maintenance and safety are very poor. Among the architectural structures, there is a chalet (Figure 4 – B), currently ruined and inaccessible, located near the sports fields, and a dairy (Figure 4 – C) where dairy products were once produced, situated in a short distance along the main road. In a more isolated position lies the gallop (Figure 4 – D) where horses were once bred and trained, which is now completely abandoned.

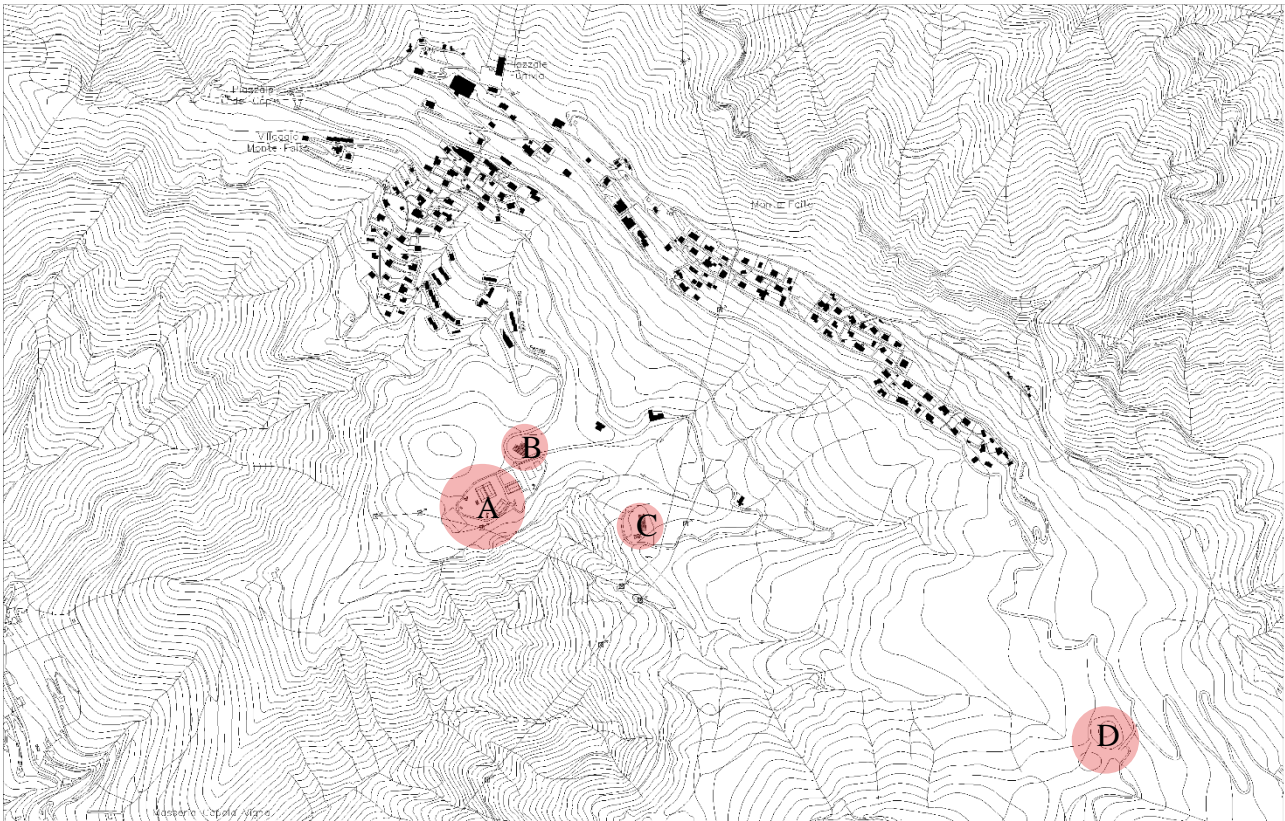

Figure 13. Area of Faito village and focus areas of the design competition: A-sports fields, B-the chalet, C-the diary, D-the gallop.

The competition call also required the participants to redesign the landscape system including a modern sports centre, a wellness area, an events area and a local food and wine culture centre, in order to make the place attractive all year round. More in details, the call specified the following requests for the reuse of the different areas:

- the sports centre, where spaces will be redistributed by creating a football pitch, a basketball court and a tennis court for the training of competitive teams and the swimming pool
- the chalet to be used as a wellness and conference centre.
- the diary to be used as a centre for local food and wine culture with a tasting and sales area.
- Finally, in the beech forest, the former gallop of Pian del Pero is to become, as it was once, a riding school with stables.

The call for projects required a redesign proposal considering the four areas as a unique landscape system.

5. THE “FAITO FRAME” PROJECT

The proposal developed by the author in team with C.Chionna and A.Cappello was presented to the competition jury with the title of “Faito Frame” (Figure 5). The Faito Frame concept arises from the need to integrate various functions and requirements while maintaining the recognizability and coherence of the project, even in physically distant locations. The Frame originates from the observation of existing structures, particularly from a redesign of a building type currently present in the sports center. In this new interpretation, the Frame is an asymmetrical wooden frame used to highlight and make key points of the project recognizable. Specifically, it highlights the entrances to the main functions (the wellness center and conference room in the chalet, the food and wine center in the diary, the riding school at Pian del Pero and the playground and outdoor sports areas).

Proceedings

Additionally, the repetition of several frames outlines a promenade that characterizes the reorganization of the sports fields area.

The objective of the project is to recreate a coherent and interconnected landscape system, with particular emphasis on existing structure recovery, fostering education on nature awareness, expanding accessibility to a diverse audience, and employing sustainable materials. Active and sustainable mobility are promoted as well, with the enhancement of trekking and bike paths and thanks to the existing connection with a cable car. The value of the proposal lies primarily in redirecting attention to a place with high environmental qualities in close proximity to a city densely populated and lacking in green areas like Naples. The area already has the potential to offer significant Ecosystem Services to the surrounding urban areas, including recreational opportunities that have historically characterized the region's history and development. The project aims to restore a balance between the natural qualities of the location and human presence, guided by a new awareness of its ecosystemic value.

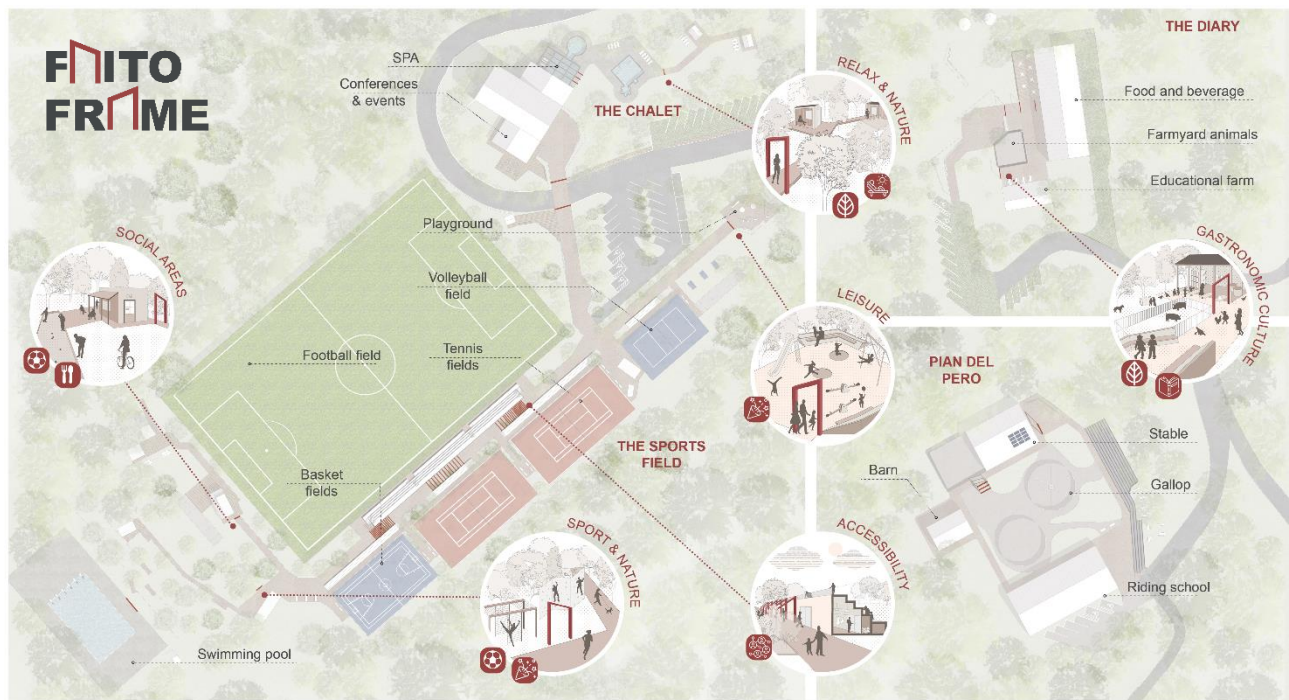

Figure 14. The masterplan of "Faito Frame" project (Source: M.S.Lux, C.Chionna, A.Cappello)

The guiding principles of the project are discussed hereafter and can be of inspiration for similar projects.

CONSERVATION AND REUSE | In both the chalet and the diary, the inclusion of new functions is based on the restoration of existing structures with the intent to preserve their architectural characteristics. The additional structures, such as the indoor pool of the wellness center and the riding school structures, have been designed to balance functional needs, reversibility, and architectural coherence. The service buildings scattered among the sports fields have also been maintained and repurposed to host ancillary functions, such as ticket offices and storage spaces.

LANDSCAPE CONTINUITY | The project aims to enhance and expand the use of the existing facility on Monte Faito without drastically altering the perception of those familiar with the area, while also attracting a potentially broader audience. The proposed approach is based on the recognition of the value of preserving and enhancing the perception of the landscape, in defense against the negative possible disturbances produced by new infrastructure [7].

Proceedings

NATURE-BASED EDUCATION & LEARNING | Various measures have been adopted in the project to encourage users to adopt a respectful and attentive attitude towards the natural environment. The adopted measures include the change in paving at the pedestrian crossing to encourage car-drivers to slow down and give priority to pedestrians and cyclists in a space where nature asserts its prominence. Similarly, parking areas have been strategically placed near access points in all project areas to establish a boundary beyond which users can fully immerse themselves in nature. Seating areas along the main paths invite users to stop and observe their surroundings. Finally, the educational farm near the Latteria offers a practical opportunity to learn about and experience nature and animal respect, educating users of all ages.

ACCESSIBILITY & INCLUSIVENESS | Accessibility to all users is the main criteria guiding the choice to redesign the sports fields reorganizing the spaces along a central promenade. The promenade is designed to allow access for emergency and service vehicles to all sports fields. Internal spaces have been designed to facilitate use by users with reduced mobility, not only by meeting regulatory requirements but also by simplifying paths and distribution.

Additionally, the architectural project was developed in order to provide a good flexibility of use, in order to optimize the interventions and justify the costs. Last, a specific attention was given to the choice of materials. The project prioritizes the use of sustainable materials that align with the context. Wood has been used for new architectural volumes and cladding, while external paving choices have focused on draining materials with minimal impact, ensuring the area remains easily accessible without compromising environmental quality (green pavers for parking areas, stone, earth floors, wooden planks, and draining architectural concrete).

6. CONCLUSIONS

The design experience on Mount Faito offered a broader opportunity to consider the landscape value of natural areas in close proximity to densely populated urban areas. The history of Mount Faito, its infrastructuring, tourism peak and then decline and abandonment suggests a critical reflection on human responsibility in its impact on fragile and rare ecosystems. The situation described, which recurs in numerous other contexts in a similar way, also offers a significant working cue for planners and landscape architects to devote their skills to addressing the complex issue of landscape recovery and management of the remains of past uses, which cannot simply be forgotten.

Resilient Sugar Heritage: Design Strategies for Post-Industrial Site and Unmarked Cemetery Sugar Land 95

G. Campagnol

Intructional Associate Professor, Department of Architecture, Texas A&M University, United States.

Corresponding author: E-mail: campagnol@tamu.edu, Tel +1 9792099767

Extended abstract

Sugar Land flourished as a model company town for the Imperial Sugar Company, the first sugar refinery in Texas and the oldest extant business in the state. But before it became in the 1920s one of the “best planned and equipped communities” in Texas for its size, Sugar Land had been called the “hell-hole of the Brazos,” defined by its dependence on convict labor and its identity as a segregated community. The latter continued even after the improvements of the early twentieth century. In its heyday, Sugar Land demonstrated industrial and residential characteristics like other sugar towns in South America, the Caribbean, and the United States. Now considered “one of the fastest growing cities in America,” Sugar Land has fading out its historic identity and is easily mistaken as one of Houston’s suburbs. Its industrial core, closed in 2002, and included in the National Registry in 2017, has been on the cusp of several redevelopment plans. The Sugar Land 95 are the 95 African-American individuals unearthed during a construction in Sugar Land. Archaeologists found evidence that the 95 individuals belonged to the state of Texas' convict leasing system and were buried in the unmarked gravesite. The first bone was found in February 2018, by a backhoe operator clawing through the dirt on land owned by the Fort Bend Independent School District. By the summer, the remains of 94 men and one woman, all African-American victims of convict leasing, had been recovered on the future site of a career and technical education center. Ranging in age from 14 to 70, the inmates had muscular builds but were malnourished, their bones misshapen from back-breaking, repetitive labor. They were buried in plain pine boxes sometime between 1878 and 1911. In a design studio project, students are encouraged to reflect on the African-American heritage and to design a "memorial chapel" for the Sugar Land Heritage in the former industrial core of Imperial Sugar, on the waterfront to the Oyster Creek (on the right) and across Hwy 90 Alt and Kempner St. The post-industrial historical site includes three landmarks (designated structures of historical significance: the Char House (1925), Three Bays Warehouse, and a water tower), the Children's Museum, two smokestacks and the Imperial Sugar Silos. The project scope includes a memorial for the Sugar Land 95 heritage. Each student departed from a conceptual project informed by an analysis of precedents and critical thinking. Students would then work individually or in teams to design a memorial in the industrial heritage core, addressing the post-industrial site, its heritage and the connection to the sensitive urban area of the newly discovered cemetery, known as Sugar Land 95.

Land use planning and spatial plans: A crucial parameter for the energy transition.

I. Lainas

PhD Candidate, University of Thessaly, School of Engineering, Department of Planning and Regional Development

E-mail: iwlainas@gmail.com, Tel +30 697 2669982

Extended abstract

The European Commission's green transition policies are setting increasingly ambitious energy and climate targets, which directly impact the spatial policies of the Member States. At the European level, in response to the recent energy crisis following Russia's invasion of Ukraine, a specific action plan for the Union's energy autonomy, known as REPower EU (COM(2022) 230 final), is being introduced. This plan, along with the revised Energy and Climate Plans of the Member States, aims to significantly increase the penetration of renewable energy sources. It achieves this through more simplified and rapid planning and licensing procedures, as well as predefined areas known as RES go-to areas.

Similarly, under the Union's Green Industrial Plan (COM(2023) 62 final), new priorities and commitments are outlined to ensure strategic autonomy in certain critical manufacturing and mining sectors. Among other things, Member States should incorporate specific provisions into land use plans. These provisions aim to create an industrial ecosystem for producing clean technology products (as outlined in the Net Zero Industry Act) and to facilitate the exploitation of critical raw materials (as per the Critical Raw Materials Act).

In the case of Greece, the framework for implementing the spatial dimensions of the European policies related to the green transition, remains an issue. On the occasion of the current implementation of the ambitious program for the country's urban and spatial planning reform, this paper aims to highlight the multiple challenges that spatial planning, both on land and at sea, particularly within Greece's industrial and renewable energy sector, faces today. These challenges are crucial for the country to successfully meet its ambitious energy and climate goals.

Among other specific issues, the paper explores the following:

- a) Impacts of specific EU Initiatives on spatial planning policies: The influence of specific European Union energy and climate initiatives on the spatial policies of Member States.
- b) Readiness of the Greek Planning System: Assessing the degree of readiness of the Greek planning system to adapt to and address new developments.
- c) Planning Tools for Implementation: Identifying the planning tools that can be effectively utilized to implement policies in Greece.

Among the main conclusions, it is noted that spatial planning is expected to play a key role in the timely and integrated implementation of the ambitious energy and climate policies of the European Union. Additionally, at the national level, there is a need to continue efforts in the complex task of reviewing existing spatial frameworks and developing, for the first time, maritime spatial frameworks. These developments are crucial to achieve the required harmonization of spatial plans with the modern European framework for energy transition.

Extended abstract

This paper addresses the research issue of city transformation towards resilient cities facing climate change and the development of strategy for the regeneration of marketplaces in Poland. It introduces a manual and toolbox designed to develop and implement a comprehensive action plan for marketplace regeneration.

Marketplaces, comprising separate areas or structures such as squares, streets, and market halls, serve as vibrant public spaces that play a crucial role in urban settings. They enhance the quality of life for residents and contribute to the overall attractiveness of a locality. Managing marketplaces is central to addressing problems related to sustainable development, encompassing economic, environmental, and social considerations. The regeneration of marketplaces necessitates an integrated approach, encompassing organization of work, space modernization, image transformation, and community activation. These efforts should also respond to contemporary challenges and incorporate pro-environmental solutions.

In this context, the “Go the Market!” strategy aims to make a significant contribution to resolving a various issues affecting Polish cities. These include the maintenance and new use of public spaces, their environmental and structural regeneration, social integration, protection of cultural heritage, and enhancing the quality of life in cities.

The paper presents outcomes of the GOSPOSTRATEG project, that include the pilot design and implementation of market regeneration and a regeneration strategy document as a tool. The manual is built upon that implementation experience. The strategy is developed by the consortium of three institution participating in the project City Initiative Association, Gdansk University of Technology and Academy of Art in Gdańsk, Poland. It is funded by the Gospostrateg programme from the National Centre for Research and Development in Poland.

Go the Market! strategy was developed based on the pilot implementation project of market regeneration in Gdańsk-Oliwa district in Poland, known as the “*Market in Oliwa*”. This initiative was a research endeavour supported by a scientific program and stands as a significant outcome of the broader research project titled: “*The public markets revitalisation strategy with the use of the social catalyst entrepreneurship method, brand repositioning and placemaking as a tool for local development policy*” project number: Gospostrateg1/392278/6/NCBR/2018, conducted within the framework of the GOSPOSTRATEG program financed by the National Centre for Research and Development in Poland. Presently, the strategy is accessible to institutions interested in understanding and implementing it at either the city or national level.

The correlation between urban and regional planning and the vulnerability of cultural heritage sites in climate change.

E. Maistrou

Architect, Emeritus Professor NTUA, President of Council of Architectural Heritage of ELLINIKI ETAIRIA
Society for the Environment and Cultural Heritage

Corresponding author: E-mail: elmais@central.ntua.gr, Tel +30 6932 297437

Extended abstract

Climate change has direct and indirect effects on archaeological sites, monuments, historical buildings, historical towns, and villages. The rise in temperature, as well as extreme weather phenomena, such as excessive rainfall, wildfires, and storms, pose significant threats to the above heritage sites and elements. The paper investigates the potential contribution of urban and regional planning to mitigating the effects of climate change on cultural heritage sites, and the need for a policy framework and a management plan that will promote and monitor the spatial planning proposals, having in mind that adaptive planning and management plan is based on the cycle of analysis, application, evaluation, and revision.

Reference will be made to three case Studies that have been implemented within the framework of the program LIFE-IP AdaptinGR – Boosting the implementation of adaptation policy across Greece. First case study will be the archaeological site of Messina which interact directly with the immediate natural environment and landscape, second one will be the old town of Corfu which is a typical example of a historical urban landscape, and the last one will be the historical villages of Zagorochoria which have a strong relationship with a rural and forest landscape.

A general conclusion that will arise from the above is that the ability to manage any Heritage site and to adapt it to climate change impacts, depends on the legal and policy support given by government, and to the will of local communities to review their practices, in the light of climate change. The relationship between the broader landscape and human activity determines the degree of resilience of the larger area in which a heritage monument or site is located.

Extended abstract

Climate change is widely acknowledged as one of humanity's most critical challenges. The European Union (EU), recognising the criticality of the issue, was mobilised to enhance the adaptation of its Members-States to climate change. In April 2013, the EU endorsed a strategy on adapting to climate change.

The Greek National Climate Change Adaptation Strategy (NCCAS) was adopted in mid-2016 (L. 4414/2016) along with establishing a National Council on Climate Change Adaptation. It has a 10-year time horizon and outlines broad policy directions and adaptation actions in vulnerable sectors. The main objectives of the NCCAS are to estimate the immediate and long-term expected impacts of climate change on the Greek territory based on vulnerability assessment analysis; identify the priority areas that need climate change adaptation measures to be taken; outline the measures requiring legislation to ensure the adaptation to climate change is effective. These objectives are thoroughly analysed through the Regional Climate Change Adaptation Strategies (RCCAS).

The concept of resilience was introduced in urban and regional planning theories in the late 1990s. Urban resilience could be acknowledged as a dynamic process of adaptation based on the ability of cities to learn and adapt to these new conditions. Other researchers point out that resilience in urban and regional planning refers to the ability of cities to respond to challenges such as complexity, uncertainty and insecurity, to create a new approach or priority for adaptation and survival.

This paper focuses on highlighting (a) the principles, priorities and tools of the Greek spatial planning system so that it can fully respond to the new challenges climate change introduces, (b) the need to put resilience against the effects of climate change at the centre of spatial planning policies in Greece, (c) the challenges spatial planning needs to meet to achieve the resilient development of Greek cities, (d) the proper design of spatial planning guidelines to enhance the adaptive capacity of Greek cities to the effects of climate change, (e) the need to use the capabilities modern technologies provide in investigating the above issues.

Flood risk mapping in areas of archaeological interest. Methodological approaches and challenges encountered in Greek case study areas.

E. Dimitriou

Geologist-Water Resources Management, Research Director, Institute of Marine Biological Resources and Inland Waters – HCMR

Corresponding author: E-mail: elias@hcmr.gr, Tel +30 697 221 3674

Extended abstract

Flood risk mapping is an essential precautionary measure for identifying areas vulnerable to floods that need protective infrastructure and specific risk management plans. Areas of important cultural and natural heritage are among the zones of high priority for protection when they are prone to natural disasters but various challenges exist for studying and implementing antiflood mechanisms in these areas. In the specific research effort different flood risk mapping approaches have been tested in Greek cultural heritage sites to analyze the local risk factors and propose protective measures. The results indicated that the current climate change models do not provide enough information to assess efficiently future flood risk since daily precipitation predictions are only available, which can be used by a limited number of flood risk assessment models. Nevertheless, multi-criteria, hierarchical mapping methods proved to be efficient in areas that classical hydraulic models are not applicable due to high terrain variability and spatially dense constructions. Modern technologies such as the use of Unmanned Aerial Vehicles (UAVs) to produce Digital Elevation Models (DEMs) of high accuracy with photogrammetric algorithms can contribute to the improvement of the flood risk assessment framework in areas of cultural heritage where physical interventions and extensive in-situ measurements are under restrictions.

Sustainable construction technologies and materials as tools for mitigating the impact of climate change.

P. N. Maravelaki^{1*}, K. Kapetanaki¹

¹School of Architecture, Technical University of Crete

*Corresponding author: E-mail: pmaravelaki@tuc.gr

Extended abstract

In recent years, we have been confronted with the effects of climate change in various areas, including the protection of cultural heritage sites. The increase in temperature and the increasing occurrence of extreme weather conditions resulting in fires and floods are factors that, on the one hand, accelerate the deterioration of monuments and, on the other hand, make their maintenance more complex, since climate change should be considered in planning their restoration. Compatibility, reversibility, and sustainability are additional requirements that should be met when choosing materials and techniques for monument conservation and restoration. Therefore, monument deterioration can be mitigated by using cutting-edge materials and new technologies, as well as by studying traditional building materials that have proven to be incredibly durable over time. This study will present four pilot case studies that involved cultural heritage adaptation studies conducted within the LIFE-IP AdaptInGR Project framework. The study focused on four traditional towns in the archaeological area of ancient **Messini**, the old town of **Corfu**, the traditional villages of **Zagorochoria**, and the archeological site of **Delos**. Every research location has unique characteristics with regard to the historic period and condition state of the monuments as well as the local climate. Ancient **Messene** is a significant archaeological site dating back to the fourth century BC that is under threat from climate change due to the relief and materials of the structures (porous sandstone). Cleaning, repairing, and waterproofing sensitive surfaces using UV- and moisture-resistant compounds can help prevent surface damage to exposed columns and sculptures. Furthermore, compatible conservation joint mortars will be proposed to consolidate the structures. Listed as a UNESCO World Heritage Site, **Corfu's** old town is a dynamic "organism" that is always in use. To reduce the impact of climate change on architectural surfaces, it was proposed to apply compatible ecological cement-free coatings and mineral paints, as well as the use of cool materials in buildings and paving to reduce temperature. Another important mitigation of the climate change effects deals with the management of the rainwater. The usage of native stone has contributed significantly to the preservation of **Zagorochoria's** traditional settlements. This observation was an important part of the study on preventative methods against climate-induced deterioration of architectural surfaces. It was also suggested to utilize cement-free mortars that are frost resistant, to clean open spaces from agricultural residues and to maintain the flood protection natural systems, such as the traditional paths of cobblestone. The case of the Archaeological Site of **Delos** is the most iconic illustration of the effects of climate change, as part of the ancient port is below sea level while another part is in imminent danger. Based on this degree of risk, it was proposed to carry out the necessary restoration and consolidation studies with compatible materials and the installation of a real-time monitoring system (GIS) to assess the condition of the monuments. To conclude, in all the cases studied, comprehensive recommendations for precautions against fires and floods, which inadvertently shield architectural surfaces from meteorological events, were presented; those measures that can be combined with the restoration materials can safeguard architectural surfaces from environmental events.

A methodology for developing studies on the adaptation of cultural heritage sites to expected climate change impacts.

V. Pougkakioti

MSc, MEng Civil Engineer NTUA, Climate Change and Energy Research Associate at ELLINIKI
ETAIRIA Society for the Environment and Cultural Heritage

Corresponding author: E-mail: vaspoug@gmail.com, Tel +30 6979359316

Abstract

This paper presents the development of an integrated methodology tailored for examining the adaptation of cultural heritage sites to projected climate change impacts. This methodology enables the assessment and prioritisation of risks expected to affect and exacerbate the vulnerability of cultural heritage sites. Furthermore, it enables the formulation of a comprehensive strategy aimed at bolstering their resilience. Originating from the collaborative efforts of the ELLINIKI ETAIRIA - Society for the Environment and Cultural Heritage (ELLET), this methodology constitutes a pivotal component of the “LIFE-IP AdaptInGR programme”. Structured into four sequential steps, it commences with a comparison of climate data spanning the reference period 1971-2000 and two future intervals: 2031-2060 and 2071-2100. This examination is conducted under three distinct emission scenarios: RCP2.6, RCP4.5, and RCP8.5. The data are derived from a selected regional climate model that reflects the climate characteristics of the wider area of the cultural heritage site under consideration. This analysis is followed by an evaluation of extreme weather events and climate changes posing the greatest dangers to the cultural heritage site. The second step involves understanding the intrinsic characteristics of the site, alongside potential non-climatic issues, focusing on geological and topographic features, monument structures and materials, site infrastructure, and the institutional protection framework. The third step pivots towards a qualitative assessment of the site’s vulnerability, synthesising the findings of the preceding phases and utilizing the methodology outlined by the Intergovernmental Panel on Climate Change. Finally, the fourth step describes a series of illustrative actions that could contribute to the cultural heritage site’s adaptation to the most severe climate changes anticipated to impact it by 2100. This methodology has already been applied to the archaeological sites of Ancient Messene and Delos, the Old Town of Corfu, and three traditional settlements in Zagori.

Keywords: *cultural heritage; climate change; climate data; adaptation; vulnerability.*

1. INTRODUCTION

According to the findings delineated in the Sixth Assessment Report of the Intergovernmental Panel on Climate Change (IPCC), it is unequivocally established that climate change exerts its impact across all inhabited regions. Substantiated evidence supports the assertion that anthropogenic emissions and human activities stand as the principal drivers behind the surge in extreme weather occurrences, encompassing heavy rainfall, droughts, abrupt temperature fluctuations, sea-level rise, and wildfires [1]. Projections indicate that the sustained escalation in greenhouse gas emissions will invariably exacerbate the climate crisis and foster a conducive environment for the perpetuation of such phenomena [1].

At the same time, climate change is predicted to have intricate and dynamic effects on cultural heritage sites, comprising archaeological sites, historical settlements, historic cities, and individual monuments, along with the intangible values they represent [2]. The array of climatic variables precipitating these effects, alongside with the different rates of occurrence in different geographical areas, correspondingly alter the severity and duration of these impacts. Extreme events such as

ISSN: 2654-0460
ISBN: 978-618-5765-02-6

torrential rainfall, fires, and storms pose palpable and substantial threats [3]. Equally consequential, though less obvious, is the latent danger that besets cultural heritage entities due to the incremental alterations engendered by the constantly changing climatic environment (e.g., accelerated evolution of material deterioration, such as corrosion, chemical deterioration, cracking, or impact on daily living conditions, changes in the ecosystem, etc.) [3].

To the aforementioned, the existing situation and possible non-climatic issues, such as urbanisation pressures, infrastructure development, industrial activities and tourism inflows that may burden a heritage site should be added. These factors, combined with climate change, have the potential to increase the susceptibility of heritage assets to accelerated deterioration, jeopardizing their long-term preservation [4,5].

The objective of this paper is to outline a methodology for evaluating the anticipated effects of climate change, applicable to various heritage sites, with a focus on identifying and prioritising the potential risks that may heighten their vulnerability. By adhering to this methodology, it becomes feasible to delineate a set of proposals for adapting to climate change. This methodology has already been applied to the archaeological sites of Ancient Messene and Delos, the Old Town of Corfu, and three traditional settlements in Zagori. These cases were chosen because of their different geographical location, their monumental character, their regional importance, and the sensitivity they are believed to have to the expected impacts of climate change.

The above studies are part of the wider work of ELLET in the eight-year «LIFE-IP AdaptInGR - Boosting the implementation of adaptation policy across Greece» program, in which it participates. Among others, ELLET is responsible for investigating the effects of climate change on cultural heritage and proposing appropriate adaptation measures in order to strengthen domestic cultural heritage's resilience.

2. ADAPTING CULTURAL HERITAGE SITES TO CLIMATE CHANGE: A METHODOLOGICAL APPROACH

To formulate a methodology applicable to the adaptation of domestic cultural heritage sites to climate change, an initial examination was conducted encompassing European and international experiences in monitoring and addressing climate change impacts on cultural heritage. For instance, within the European Union (EU), significant efforts have been made to develop frameworks and initiatives aimed at assessing and addressing the vulnerabilities of cultural heritage sites to changing climatic conditions. Through programs like Horizon 2020, the EU has funded numerous research projects focused on understanding and mitigating climate change impacts on cultural heritage. One of these is the Climate Heritage project, which has facilitated collaboration among researchers, policymakers, and heritage practitioners to develop innovative strategies for climate adaptation in cultural heritage management [6]. Internationally, organizations like UNESCO have spearheaded efforts to raise awareness and develop strategies for safeguarding cultural heritage from climate-related threats. The UNESCO World Heritage Centre, in collaboration with the International Council on Monuments and Sites (ICOMOS), has published guidelines and reports emphasizing the importance of integrating climate change considerations into heritage management practices [7]. These initiatives underscore the significance of adopting a proactive approach to monitor and address the multifaceted impacts of climate change on cultural heritage.

Furthermore, to develop a methodological approach for the adaptation of cultural heritage sites, the strategies of both the European Union (EU) and Greece in response to climate change were examined [8, 9, 10]. It is noteworthy that the EU's Climate Change Adaptation Strategy delineates measures aimed at enhancing resilience and adaptive capacity within cultural heritage management practices across Europe [8]. Moreover, the EU-funded Climate-ADAPT platform offers an array of resources, including case studies and best practices, to bolster adaptation efforts across various sectors, including cultural heritage [11].

Proceedings

Similarly, the Greek National Adaptation Strategy (NAS) encompasses a series of proposed actions and measures for adapting cultural heritage to climate change. The primary thrusts of these proposed actions include: a) enhancing knowledge and evaluating risks associated with climate change impacts on cultural heritage, b) managing climate change risks, c) integrating protective measures for cultural heritage and adaptive policies into broader national strategies, and d) providing training and education for both professionals and the public [10].

At the same time, the concept of 'vulnerability' as a key step in any adaptation planning process was explored, and various approaches to this concept were evaluated [12, 13, 14]. It was decided to incorporate the IPCC's proposal, as formulated in the Third Assessment Report [15].

The above review resulted in the development of the definitive methodology for conducting studies on the adaptation of cultural heritage sites to climate change. This methodology is outlined in four sequential steps. The initial step comprises a climate data analysis, while the subsequent step entails comprehending the intrinsic characteristics of the cultural heritage site, alongside potential non-climatic stressors. The third step involves a qualitative assessment of the site's vulnerability, and the final step outlines a series of illustrative actions aimed at enhancing the cultural heritage site's adaptation to the most severe climate changes. The methodology has been already applied to the archaeological sites of Ancient Messene and Delos, the Old Town of Corfu, and three traditional settlements in Zagori.

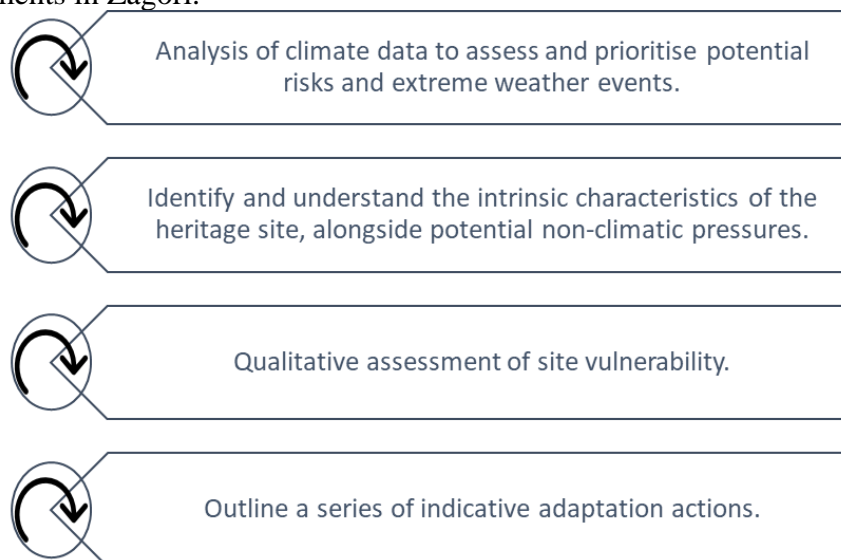

Figure 1. The basic steps of the methodology developed for studies on the adaptation of cultural heritage sites to expected climate change impacts.

2.1 Climate data analysis

The initial step for any study on the adaptation of a cultural heritage site is the analysis of several climate data in order to assess and prioritise potential risks and extreme events related to climate change.

The methodology developed used variables and indicators that have already tested on the IPCC assessment reports [15, 16, 17, 18, 19, 20, 21]. For the case studies of the archaeological sites of Ancient Messene and Delos, the Old Town of Corfu, and three traditional settlements in Zagori, in which the methodology was applied, the National Observatory of Athens (NOA) provided time series data in the form of climate variables and indicators. The original data were retrieved from 2 state-of-the-art RCM simulations carried out in the frame of EURO-CORDEX (Coordinated Regional Climate Downscaling Experiment), with a horizontal resolution of about 12 km (0.11°) spanning three periods:

the control 1971-2000, the near future 2031-2060 and the distant future 2071-2100 periods. The regional climate model (RCM) used for simulation and data analysis was selected by comparing precipitation and temperature records from 1974 to 2004 with simulations from different RCMs with a spatial resolution of 12 km (0.11°).

Climate projections were analysed for three of the four representative concentration pathways (RCPs) described in the IPCC reports as critical for the formulation of mitigation and adaptation policies [15, 16, 17, 18, 19, 20, 21]. Specifically, the analysis focused on the climate emission scenarios RCP2.6, RCP4.5, and RCP8.5. These scenarios include emission and concentration time series for all greenhouse gases, aerosols, and chemically active gases, in addition to land use data [15]. Population growth rate, economic activity, lifestyles, energy sources, technological development, future land use, and climate change policies are the primary criteria that influence the RCPs. RCP2.6 is a scenario with significant mitigation that seeks to keep global warming below 2°C above pre-industrial levels, RCP4.5 is an intermediate scenario (the same applies to RCP 6.0, which was not used in the analysis) and RCP8.5 is a scenario with extremely high GHG emissions.

Figure 2. Global mean surface temperature increases as a function of cumulative total global carbon dioxide (CO₂) emissions from various lines of evidence. Multi-model results from a hierarchy of climate carbon-cycle models for each RCP until 2100 are shown (colored lines). Model results over the historical period (1860–2010) are indicated in black. The colored plume illustrates the multi-model spread over the four RCP scenarios and fades with the decreasing number of available models in RCP8.5. Dots indicate decadal averages, with selected decades labeled. Ellipses show total anthropogenic warming in 2100 versus cumulative CO₂ emissions from 1870 to 2100 from a simple climate model (median climate response). Temperature values are always relative to the 1861–1880 period, and emissions have been cumulative since 1870. Black-filled ellipse shows observed emissions to 2005 and observed temperatures in 2000–2009 with associated uncertainties [19].

The statistical significance of differences between the values of climate variables and indicators derived for the reference period and those for the two future periods and the three emission scenarios was assessed using the z-test. The null hypothesis H_0 that the difference between the means of the two samples is not statistically significant was tested for each sample. When the result was z critical two-tail z and $P (Z = z) 0.05$ at a confidence level of 95%, it indicated that H_0 was invalid and that the differences between the samples compared were statistically significant.

Proceedings

Through this process, the statistically significant expected climate changes up to 2100 for each cultural heritage case study were documented. The analysis of climate data and exploration of the most prominent climate changes and risks can be replicated at other sites.

2.2 The intrinsic characteristics and potential stressors of the cultural heritage site

In light of research conducted at archaeological sites like Ancient Messene, Delos, the Old Town of Corfu, and traditional settlements in Zagori, alongside climate data analysis, it's vital to document the intrinsic features and non-climatic stressors impacting cultural heritage sites comprehensively. Each case study faces a range of pressures beyond climate change, necessitating thorough examination alongside climate data analysis. Important factors include the site's geographical location, geological and topographic features, monument structures and materials, site infrastructure, and the institutional protective framework. Furthermore, cultural heritage sites often face stressors arising from contemporary lifestyle demands, rapid tourism expansion, and challenges related to mobility.

According to Mason and Jouhki [22], understanding the interplay between climatic and non-climatic stressors is essential for effective heritage conservation. This entails considering various factors such as socioeconomic dynamics, urbanization, and land use changes alongside climate-related vulnerabilities.

The integration of existing conditions and potential non-climatic pressures affecting each heritage site is critical. When coupled with the impacts of climate change, these factors can significantly undermine resilience over time, jeopardizing the integrity of the heritage asset. This underscores the urgent need for holistic assessment and the development of mitigation and adaptation strategies that encompass both climate and non-climate stressors.

Fatorić and Seekamp [23] emphasize the importance of incorporating non-climatic stressors into conservation strategies to ensure the long-term sustainability of cultural heritage sites. By addressing both climatic and non-climatic threats, heritage managers can enhance the resilience of these sites to future challenges.

2.3 Vulnerability assessment analysis

To evaluate the threats posed by climate change to a system or cultural heritage site, it is essential to assess its vulnerability. This process enables the identification of the site's needs, facilitates the proposal of an integrated adaptation strategy, and helps prioritize mitigation measures.

Following the publication of its Third Assessment Report in 2001, the IPCC introduced vulnerability assessment as a methodology for evaluating the risks of climate change [15]. In this paper, the vulnerability assessment is presented as a crucial initial step in developing or implementing measures to address the impacts of climate change across various human activity sectors. This approach offers advantages over traditional risk analysis, as it not only examines the system's exposure and sensitivity to one or more risks but also considers its capacity to adapt to changing conditions and establish equilibrium within them.

McCarthy [24] describes system vulnerability as the degree to which a system is likely to be severely affected by climate change. This approach is based on exposure, sensitivity, and adaptive capacity.

Exposure is the extent to which a system may be affected by a hazard due to its geographical location [24]. For instance, a coastal area embodies a multifaceted and perpetually evolving social, spatial, economic, and environmental framework, rendering it inherently more susceptible to the impacts of severe weather occurrences in comparison to an inland locale [25,26]. Sensitivity is the extent to which a system is negatively or positively affected by climate-related events due to its intrinsic characteristics (i.e. the sensitivity of the building materials and structures; 3) the sensitivity of the native and/or cultivated vegetation) [24]. There may be direct or indirect effects. Adaptive capacity is related to human activities (institutional provisions, technology, infrastructure, management practices, land use management), but it can also be a system attribute [24].

According to the following equation, vulnerability (V) is a function of exposure (E), sensitivity (S), and adaptive capacity (AC):

$$V = (E + S) - AC$$

A system's high vulnerability arises from its high exposure, sensitivity, and limited adaptability. In contrast, the vulnerability of a system decreases as adaptive capacity increases and exposure and sensitivity parameters decrease.

In this methodological step, the linkage between the initial two methodological steps is established: 1) identification and prioritisation of primary climate risks up to 2100 across various RCPs, and 2) examination of the intrinsic characteristics and potential non-climate-related challenges the cultural heritage site is facing. Figure 3 depicts an application of qualitative vulnerability assessment to the Old Town of Corfu. This illustration enables the determination of the extent to which climate change will impact its resilience and identifies the most vulnerable features.

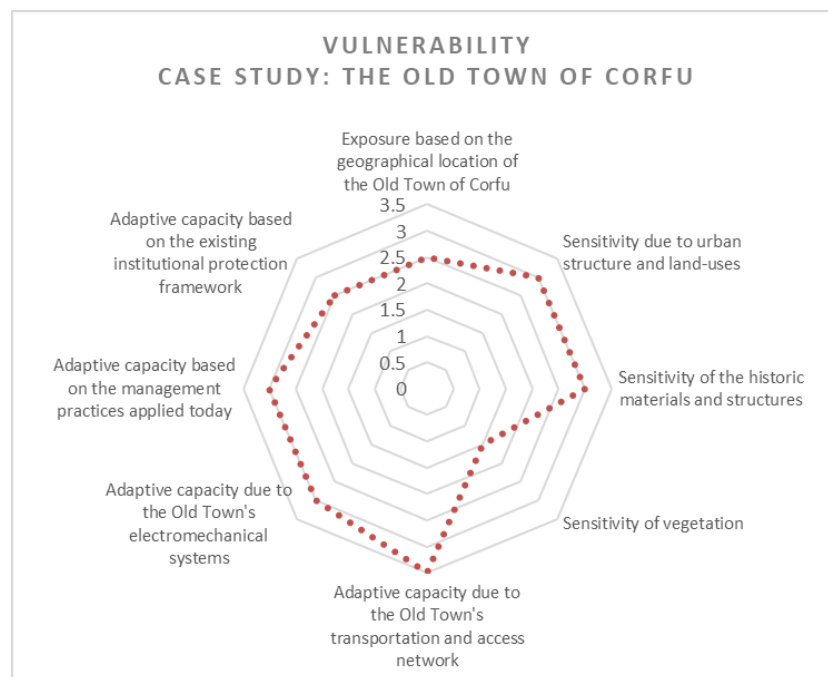

Figure 3. Assessment Analysis of the case study of the Old Town of Corfu [4].

2.4 Adaptation strategy plan

Building upon the literature review of the proposed adaptation strategies (see Section 2) and applying the methodological steps presented in Sections 2.1, 2.2 and 2.3 for the analysis of the case studies of the archaeological sites of Ancient Messene and Delos, the Old Town of Corfu and the traditional settlements in Zagori, an integrated strategic adaptation plan can be developed. This strategic adaptation plan aims to strengthen the resilience of these sites against anticipated climate change impacts. The plan's structure may encompass the following dimensions:

- Adaptation measures to address climate change: Various proposals can be devised to enhance resilience and optimize the functionality of each cultural heritage site.
- Institutional strategies: Recommendations for institutional tools should be proposed to enhance the protection of each cultural heritage site from climate change effects.
- Emergency Preparedness Action Plan: Formulation of proposals is necessary for timely response and effective management of emergencies arising from climate change and extreme weather events.

- Information, education, and awareness: A series of proposals should be crafted to disseminate information, educate, and raise awareness among the public, students, and professionals.
- Spatial Monitoring System: Proposals should be developed to better understand the impacts of climate change on the materials and structures of the monuments within each cultural heritage site and to monitor the effectiveness of implemented measures

3. RESULTS AND FURTHER DISCUSSION

The methodology employed in this study, applied to case studies encompassing archaeological sites such as Ancient Messene and Delos, the Old Town of Corfu, and traditional settlements in Zagori, has brought to light three critical concerns.

The first concern centers on the formidable challenges inherent in collecting data regarding the current state of cultural heritage sites in Greece and the additional stressors they face, such as visitor impacts and traffic. Evaluating this complex situation demands continuous monitoring and meticulous recording of the condition of cultural assets, conservation efforts, and restoration interventions. An accessible database for both administrative and scientific stakeholders is essential to effectively address these challenges.

The second concern arises from the intricate task of discerning between hazards induced by climate change and those inherent to a cultural site itself. The occurrence of extreme weather events and environmental changes is closely interlinked with a site's existing condition, including its level of conservation, urban layout, land use, infrastructure, and management practices. Thus, addressing this issue necessitates a multidisciplinary approach to concurrently research and tackle both climate change impacts and site-specific vulnerabilities.

The third concern pertains to the transition of sites to new management systems, necessitating collaboration among multiple services and institutions. This underscores the imperative of developing integrated and comprehensive management plans aimed at safeguarding cultural heritage sites against diverse pressures and threats. Such plans should encompass tasks ranging from maintaining and restoring historic building stock to protecting cultural resources and natural environments, as well as ensuring the efficient operation of infrastructure, traffic, transport, and electromechanical systems. Achieving these objectives demands coordinated efforts and the active involvement of relevant stakeholders.

Extended abstract

Climate change constitutes a multifaceted threat for the Greek landscapes, as for those of the Mediterranean in general, intensifying the need for a systematic approach to adaptation. Developing the methodology for this approach at the Regional level has been the task of subproject A2D2 of the LIFE-IP AdaptInGR project. It is this comprehensive framework of methodologies for climate change adaptation that is presented. The framework provides interrelated guidelines based on four pillars. It begins with landscapes, and their overall understanding and classification at the scale of a Region, followed by an assessment of these landscapes to determine their characteristics, their value, and their vulnerability to climatic hazards. It continues with climate impacts, monitoring, assessing and identifying the regions most vulnerable to hazardous phenomena, such as flooding, drought, desertification, wildfires and sea-level rise, utilizing geospatial data, climate models and fieldwork, while considering topography, land cover, land use and socio-economic conditions. The resulting data base is organized based on specific targets. Building upon the first set of measures, the framework implements a series of planning scenarios, incorporating previous studies, resilience projects and emergency preparedness action plans, to evaluate the efficacy of proposed adaptation strategies and prioritize actions based on estimated risks. A key component of the framework is the enactment of the resulting protective measures for monitoring, preventing and updating data, in the national policies. Lastly, enabling the involvement of stakeholders, local communities, government agencies, NGOs, and scientific experts in raising climate change awareness of the public and the authorities (through seminars, and educational activities), holds a crucial role in this process. In summary, the proposed framework employs a holistic approach to climate change adaptation in landscape and land use, by prioritizing vulnerable regions and proposing measures that integrate available tools, scientific knowledge, public and private actors, policies and information dissemination to enhance landscape resilience.

Extended abstract

The dynamic nature of landscapes, as a result of complex natural processes and human activities, provides the ideal ground to study the multidimensional impacts of climate change. In recent years, a few methods have been proposed that allow for rapid landscape-scale assessment. Despite that, there is a lack of implementation of said methodologies in the Greek region, which is characterised by great landscape heterogeneity. In the context of the ongoing LIFE IP AdaptInGR (LIFE 17 IPC/GR/000006) project, the Society for the Environment and Cultural Heritage, in collaboration with the National Observatory of Athens, carried out a study using the transect methodology, aiming to assist climate change adaptation efforts. A holistic landscape appraisal was conducted at three spatial scales: a transect zone at the Southern part of the Peloponnese peninsula, extending from Pylos to Monemvasia (240 km long, 1.416.6 km²), 35 landscape areas and their respective landscape views. An assessment of the threat climate change poses on landscape integrity was materialized, taking into consideration climatic parameters, phytoclimatic, wildfire, erosion indices and human activities. The indices were calculated on a daily basis for the reference period 1971-2000 and two future periods (near-future 2023-2060 and end-of-the-century 2071-2100) under three emission scenarios namely RCP2.6, RCP4.5 and RCP8.5). The results of the study indicate climatic shifts, which, in combination with land-use pressures will lead to landscape degradation, due to increases in wildfire frequency and intensity, flooding and soil erosion. The already imposed preservation measures have not yet set a comprehensive framework for anthropogenic activity, which may further exacerbate the effects of climate change. This study provides useful input for the introduced regional and national climate change adaptation plans, highlighting the importance of landscapes in the identification of knowledge gaps and the prioritization of regions vulnerable to climate related hazards. The transect method facilitates landscape evaluation, conservation and planning for climate change adaptation.

Extended abstract

To investigate climate change risks in Northern Greece, this study employed a multi-scale approach utilizing landscape analysis methodologies and two aridity indices in different climate change scenarios. Landscape Character Assessment and Regional Unit Analysis were developed and adapted for rapid landscape description and evaluation in Eastern Macedonia and Thrace regions. Using literature review, geographic databases, field work -involving survey protocols and UAV technology- and GIS, the delineation of 104 distinct Landscape Description Units (LDUs) and twenty-three landscape character areas was performed. Thereupon, De Martonne and Emberger bioclimatic indices, along with related climate indices, were utilized to project climate change impacts in the whole region under different climate change scenarios (RCP4.5 and RCP8.5) and future time periods. The results show that the largest part of the rural areas in the southern and eastern parts of the study are characterized by semi-humid and Mediterranean bioclimate. These categories reflect intense evapotranspiration, and successively lead to increased irrigation requirements for crops. Nonetheless, the largest part of the study area ranges from humid to extremely humid, mainly due to the high elevation and northern geographic location. Still, a shift towards arid bioclimatic conditions is expected in the near future. While there are notable predicted impacts of climate change in the area, they are quiescent and of less immediacy compared to areas in Southern Greece. However, combined with anthropogenic pressures, these impacts may lead to landscape and ecosystem degradation prior to the expected time. Hence, water management is of central significance when delivering proposals for climate change adaptation, particularly in relation to ever-expanding irrigated crop intensification. In addition, safeguarding vulnerable landscapes and controlling urban sprawl constitute priority measures. In conclusion, Emberger and De Martonne indices, combined with rapid landscape assessment methodologies, comprise reliable tools to identify the areas most threatened by the changing climate and anthropogenic activities and propose tailored adaptation measures.

Extended abstract

High resolution climate information on both seasonal and long-term timescales is an essential component of a country's comprehensive framework for responding to the risks of climate change and for the implementation of its adaptation policy and strategies. The availability of climate projections on high spatio-temporal resolution is necessary to assess regional climate change signals and their impact over the complex topographical area of Greece, thus contributing to national adaptation policies. The lack of local high-resolution seasonal forecast predictions and long-term climate change projections prohibits the assessment of risks and vulnerabilities and the effective development of local adaptation measures.

CLIMADAT-hub is a 2-year project implemented in the framework of H.F.R.I (Hellenic Foundation for Research & Innovation) call "Basic research Financing (Horizontal support of all Sciences)" under the National Recovery and Resilience Plan "Greece 2.0" funded by the European Union – NextGenerationEU. The project aims to bridge the gap between available climatic information and the information required for assessing climate risks at the local scale by creating high resolution observational gridded datasets, as well as statistically downscaled seasonal forecasts and climate change projections for Greece. CLIMADAT-hub will produce high-resolution (1km) daily observed gridded datasets for several meteorological variables utilizing data from multiple observational meteorological networks in Greece. These observational datasets will serve as reference datasets to statistically downscale seasonal forecasts and long-term climate change projections under various emission scenarios. All produced datasets will feed a public data repository and an online data visualisation tool enabling the assessment of local, regional and national climate change risk, vulnerability and adaptation potential. This output is of key significance for a variety of sectors and socioeconomic activities that are most vulnerable to climate change in Greece, including human health, energy demand, tourism, forest and peri-urban fires.

Keywords: *long-term projections, seasonal forecasts, online data visualisation tool, adaptation potential*

**MNEME: TANGIBLE AND INTANGIBLE EXPRESSIONS, THE
RELATIONSHIP WITH PLACE IDENTITY AND SUSTAINABLE
PLANNING & DEVELOPMENT**

Changing Cities VI, Rhodes, 24 - 28 June 2024

Abstract

In our presentation landscape, cultural and historic landscape, in cities or outside them, will be interpreted as the important substratum of the mnemonic inscriptions. Arcadia could be used as a par excellence analogous paradigmatic landscape, to which post-Renaissance and neoteric Western societies returned, using it as an example of primordial absolute physical, bodily, and political liberty, as an example of landscape, where continuous, unrestricted joyance exists. Arcadia was thus described as a place of idyllic imagery, as a paradigmatic visionary phantasy of pastoralism to which poetic metaphor and symbolic art depictions were continuously directed. Nevertheless, analogous correlations could be addressed to the Hellenic landscape in general. “The essence of beauty”, Helen of Troy affirms to fictional doctor Faust in the second volume of Goethe’s well-known magnum opus, “could be presented through a pilgrimage to the landscape of Greece”, being at the same time in immediate association not solely to aesthetic qualities but, moreover, to the neoteric post-Enlightenment aspirations for political democratic formations. A “pilgrimage” Helen of Troy suggested, analogous to those that the Western Europe intellectuals attempted during 18th and early 19th century, analogous to the one that John Gordon Byron ventured, going back to the historic roots of social freedom and European cultural formations.

It is in the previous described context that we shall present, in our proposal, landscape guidance as a possible museographic proposal to the precious Hellenic landscapes, as a “re-invention of memory”, organized through mnemonic landscape networks, in cities or outside them, in association to historic, cultural, and political narrations. It is in the same context that we may also present examples of the didactic usage of the urban open-air public places, urban squares, or urban gardens as didactic cultural and historic formations, offered to the citizens or visitors of the designed landscape in question.

Keywords: *historic memory; cultural landscape; landscapes of memory; landscape museographic guidance; urban didactic landscape formations.*

1. INTRODUCTION: MNEMOTECHNICS AND “LANDSCAPES OF MEMORY”

It is well-known that Francis Yates in her famous analysis of *The Art of Memory* in her homonymous book, intensively correlated memory, mnemonic inscriptions, with place references and explained that this was a key mnemonic method for “mnemotechnics”, the method used in previous historic societies, to organize and preserve remembrances [1]. We could thus speak of “landscapes of memory”, being completely immaterial, creating the imaginary, mental scenography where memory references may be installed, or we may speak of “real”, material landscape formations, where tangible indications reveal memory references and intangible values as well.

It is in this context that we may refer to the term “Arcadia”, using it as an imaginary reference that was accepted for millennia as the illusionary landscape of absolute pastoral social freedom and erotic primordial liberation, as an unspoiled landscape of harmonious wilderness [2]. In correlation to the previous imaginary, idealized landscape reference, the real visiting guidance to Arcadie, to the geographic region of the central and eastern part of the Peloponnese peninsula in Greece to which the archaic name “Arcadia” refers, could bring the traveler in contact with real monuments, or we could present the whole area as a monumental extended landscape of material mnemonic inscriptions and seductive phantoms of the past.

Proceedings

In a broader cumulative sense, public architecture and even a large part of urban landscape formations have to do with cultural values, presented and promoted not only in specific monuments but also in a larger sense, in building and urban design. We may thus insist on the landscape formations, designating them, in many exemplary cases, as cultural and political indications of historic “mneme”, as the largest place formations presenting the cultural and even political identity of the human societies.

2. CULTURAL AND HISTORIC LANDSCAPE: THE EXEMPLARY REFERENCE TO ARCADIE

We have already clarified that in our presentation landscape, cultural and historic landscapes in cities or outside them will be interpreted as the important substratum of the mnemonic inscriptions. Arcadia and Arcadie, already presented in the first introductory paragraph of our text, could be used as a par excellence analogous paradigmatic landscape, to which post-Renaissance and neoteric Western societies returned, regarding it as an example of primordial absolute physical and political liberty, as an example of continuous, unrestricted joyance.

Arcadia was thus venerated as a place of idyllic imagery, as a visionary landscape to which poetic praises and symbolic art depictions were continuously directed, in many cases correlating primordial wellbeing with cultural excellence. It was in this sense that Lorenzo Dei Medici, the famous statesman and de facto ruler of the Florentine Republic, appreciated as the principal patron of the 15th-century Renaissance culture in Italy, used to describe the Villa Fiesole in Tuscany (where the head house of the famous Renaissance Academia Neoplatonica was installed) as the realm of Pan. Pan, the ancient Greek god of shepherds and flocks, of rustic music and the impromptu free-form musical improvisation, companion of the nymphs, was imagined inhabiting in the wilderness of the Arcadian mountains. Lorenzo, moreover, identified metaphorically the illustrious philosophers of the Academia Neoplatonica with Arcadian shepherds [2].

In the succeeding centuries, European historical references, in literature and art depictions repeatedly returned to imaginary visions, analogous to the previous, as expressions of unrealized cultural and political desires. Famous baroque painter Nicolas Poussin presented his approach to the Arcadian imaginary through his famous paintings under the title “Et in Arcadia ego”, a Latin statement that may be translated in an explanatory way as “I too, was born or lived in Arcadie” [3]. In this proverbial sentence, it was supposedly death which was speaking, explaining that in the context of the Arcadian beatitude, even there, the end of human life is unavoidable. Poussin’s symbolic indications were closely accompanied by a succession of painting presentations, associated with images of political inspiration or fantasies of body liberation. Arcadia was thus correlated to the lost primordial pastoral condition of social equity, or as presented in Johann Wolfgang von Goethe’s *Faust*, to the correlation to ancient classical Greece, the latter being regarded as the natal place, the natal political landscape of democracy.

3. A “LOVE AFFAIR” OF TOTAL FREEDOM: MNEMONIC EMBLEMATIC INSCRIPTIONS AND THE HELLENIC LANDSCAPE IN GENERAL

In the second part of Goethe’s *Faust*, the central fictional hero of the narrative, Dr. Faust visits the Teutonic devil, Mephistopheles, asking him for the revelation of the essence of beauty [4]. The devil explains that Faust must direct his aesthetic search to ancient Greece and helps him to meet the phantom of the legendary Helen of Troy, who finally returns to life as a guiding companion of the fictional German protagonist of the book. Helen and Faust, during the narration, will declare their love for each other, love that would be associated with the Arcadian dream. There, in Arcadia, Faust declares, that their love would be absolute and free. “Arcadia, near to Sparta’s lands. / Allur’d to this bless’d region, hither / Hast fled to brightest destiny: / Thrones change to bowers that never wither; / Arcadian be our bliss and free!” [5].

Nevertheless, analogous correlations could be addressed, as we already implied to the Hellenic landscape in general. The essence of beauty could be presented, Helen of Troy affirms to fictional doctor Faust in this second part of Goethe's well-known magnum opus, through a pilgrimage to the landscape of Greece, being at the same time in immediate association not solely to aesthetic qualities but, moreover, to the neoteric post-Enlightenment aspirations for political democratic regimes. This second part of Goethe's narration was written during the period of the 1821 Greek Revolution, and the pilgrimage that Helen of Troy suggested, seems to be analogous to the Grand Tour that the Western Europe intellectuals attempted in Italy and later on in Greece, during the 18th and early 19th century; analogous to the one that John Gordon Byron ventured, going back to the historic roots of social freedom and European cultural formations [6]. The literary "love affair" that Goethe described, was in its most important essence the metaphor for the "love", the metaphor for the desire for freedom that Western intellectuals were projected on the symbolic substratum of the Hellenic "chora", of the politically and culturally constitutive apperception of the Hellenic landscape [7].

Figure 1. "Pericles' Funeral Oration" by Philipp Foltz (1852). Pericles delivers his speech in favour of the war and, in extension, in favour of the Athenian democracy is depicted in the context of the Athenian monumental landscape, being presented as the emblematic reference for the neoteric political desire for democratic regimes.

4. MNEMONIC LANDSCAPE NETWORKS, AS A POSSIBLE MUSEOGRAPHIC PROPOSAL

Could we neglect the political and ethical connotations of the Hellenic landscape, as previously presented in our text, or have we to insist on its mnemonic value in association with the contemporary need for the re-evaluation of natural or urban Greek landscape, for the contemporary re-evaluation of their place identity? As an answer to this rhetorical question, we shall choose to continue our presentation, indicating that the mnemonic importance of Greece in general as the cradle of the first formation of democracy may probably be projected to the natural Hellenic landscape on the whole, to sublime mountains as Olympus and Parnassus, where the ancient Gods or the Muses, the inspirational goddesses protecting literature, science, and the arts, inhabited. Nevertheless, it could also be projected to the urban landscapes of Greece, to Athens for example, where Pericles, the ancient Athenian politician was depicted by neoteric art reminiscence, glorifying Athenian democracy.

It is in the previously described context that we shall propose, in our presentation, landscape guidance as a possible museographic approach to the precious Hellenic rural landscapes, as an approach for the "re-invention of memory", organized through mnemonic landscape networks in extended regions of the country, in association to historic, cultural, and political narrations. It is in the same context that

Proceedings

we may also present examples of the didactic usage of the urban open-air public places, urban squares, or urban gardens as didactic cultural and historic formations, offered to the citizens or visitors of the designed landscape in question.

Figure 2. What seems to be even more important for the history of Greece is probably not the earthly consistency of the surrounding countryside, of the surrounding ‘Arcadias’, but the historical or even the legendary navigation in the undulating continuity of the inscribed seascape. “Et in Arcadia Ego” by Nicolas Poussin (1637-38, on the left), and “Ulysses and the Sirens” by Léon Belly (1867, on the right).

4.1 Presenting mnemonic landscape networks in an extended regional context.

Following our previous schematic proposals, we could present several indicative mnemonic itineraries in rural areas, as applied in Arcadie, the peri-urban territory of the city of Sparta, and the coastal zone of the Greek city of Nafplio. In addition, a fourth itinerary could be presented, a navigation approach to the insular network of the North Aegean Sea. In the first case, implementing the theoretical rhetoric previously presented in our text, several visiting networks were investigated. They were designed in reference to the different historic layers of the Arcadian past, to the ancient and Byzantine nodal monumental places or the settlements of the Greek tradition. Then we proposed, as part of our university lessons [8], as an object of a research project, the designation of a palimpsest, composed of the previous superimposed historic layers; a palimpsest that could be used as a system of organized guidance for the future visitors [9]. An analogous visiting network was also proposed for the peri-urban territory of Sparta, being important for its well-known ancient history [10], and a third network was designed for the coastal zone of Nafplio. This last network would be promoted under the title “Landscapes of Hercules”, correlated with neighboring places to the city of Nafplio, associated with legendary references to the “Hercules’ Labors” [11].

Figure 3. The network of traditional villages in Arcadie (upper left) and the important places of historic reference at the peri-urban zone of Sparta, in correlation to river Eurotas (upper right). The important wetland of the coastal zone of Nafplio and its correlation to Hercules’ Labors, to Hydra of Lerna in particular (middle) and finally a proposal of sailing and visiting itineraries to the isles of North Aegean (bottom).

Finally, a network of sailing itineraries was proposed, directed to the islands of the North Aegean, associating portal destinations at the periphery of the islands, with visiting networks in the interior [12]. Visiting networks in many cases associated with important historical references. In the verses of *The Isles of Greece*, Lord Byron poetically commented, “Where burning Sappho loved and sung, / Where grew the arts of war and peace, / Where Delos rose, and Phoebus sprung!” [13].

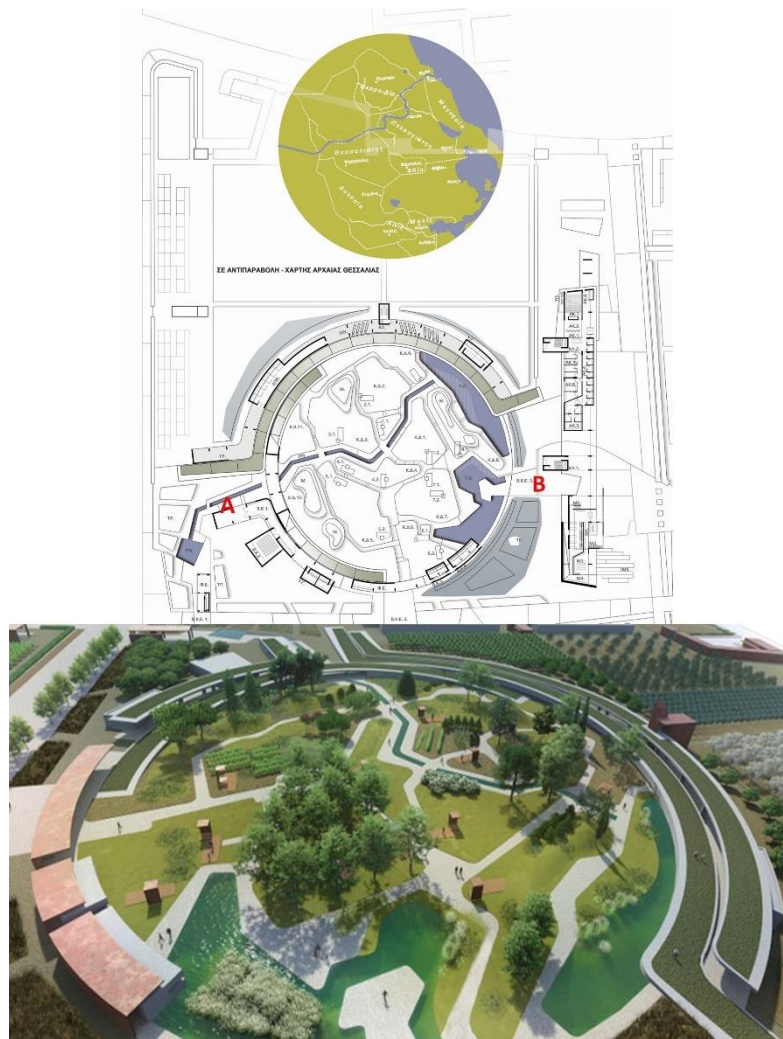

Figure 4. Binary correlation of the waterscape and the green landscape design proposals in a project awarded in a panhellenic architectural competition; the circular Historic Botanic Garden of Thessaly in the city of Larissa, under the title “Deucalion’s Cycle.”

4.2 A first case study of a mnemonic landscape network, in the urban context of Larissa Thessaly

Analogous proposals associating landscape design to historical mnemonic references were proposed in the three projects of intervention in an urban context, which would be presented subsequently. The first of them refers to the reinterpretation of the historic identity of the Greek region of Thessaly, as inscribed in an urban landscape intervention in Larissa, the capital city of Thessaly. A circular botanic garden was designed, under the name “Deucalion’s cycle” (14). It represents, in the form of the garden proposed, the map of ancient Thessaly, planted with the indigenous species supposed to exist during antiquity, in each part of the region presented. We refer therefore to a historical botanic garden correlated, moreover, to the legend of the ancient flood, wherefrom only two humans, Deucalion and Pyrrha, survived. The association with the legendary cataclysm would be restricted to a neutral narrative, if not associated with a recent analogous delusive incident that turned Thessaly from a landscape of agricultural wealth to a landscape of environmental destruction. Accordingly, the

Proceedings

mnemonic references presented in this garden design project may acquire an important environmental didactic validity. In addition, metallic totems placed on the points of the map where important ancient cities existed, offer the visitor the possibility to approach digital narratives, presenting to him the cultural and historical past of the city of Larissa and Thessaly.

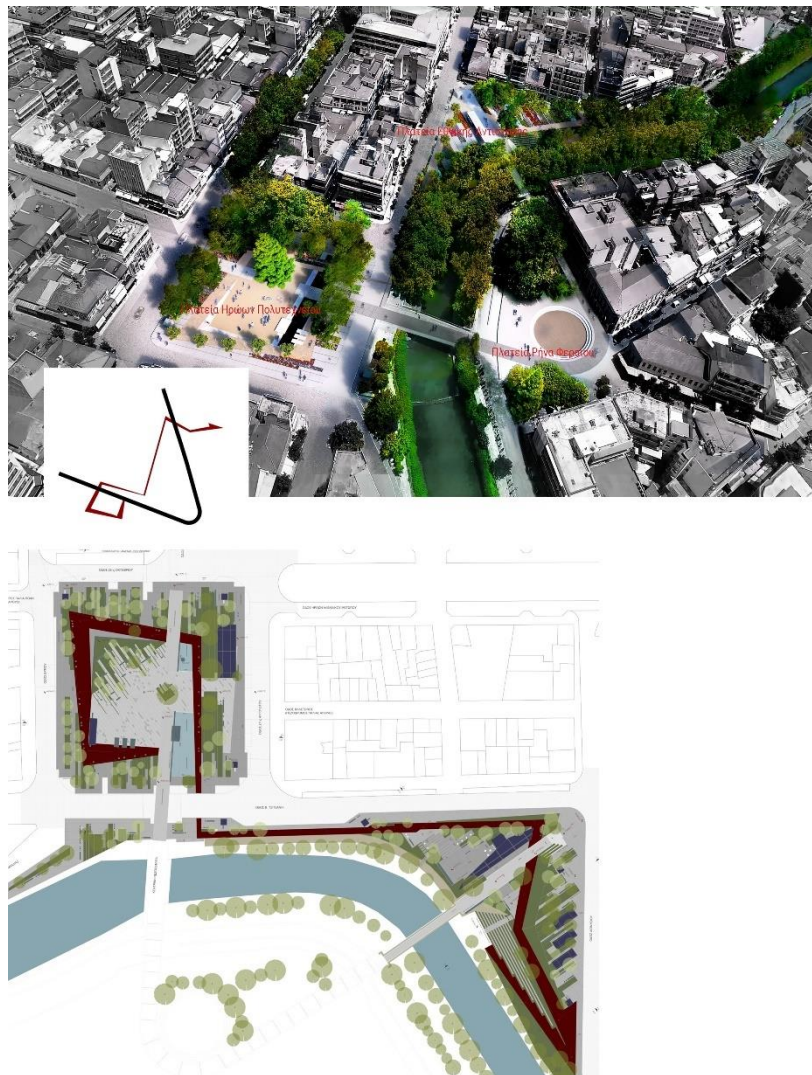

Figure 5. A second project, awarded in an architectural competition, for the redesign of a complex of two central urban squares in the city of Trikala (upper part). What must be explained in addition is the design of the reddish-colored pedestrian corridor (middle and lower part of the figure), on which metallic totems offer the visitor the possibility to encounter digital narratives.

4.3 A second case study of a mnemonic landscape network, in the urban context of Trikala Thessaly

Let us present a second project, relative to the previous, a rehabilitation project for the complex of two squares in the city of Trikala, next to the river Lytheus, again in Thessaly (15). The correlation of the waterscape formation to the green urban landscape, as presented in Figure 5, is obvious. On the surface of the two squares, and the intermediate pedestrian zone connecting them, a reddish-colored pedestrian corridor was designed, as a possible itinerary of hybrid guidance. Metallic totems, analogous to those proposed in the previous project of the circular Historic Botanic Garden of

Thessaly in the city of Larissa, present to the visitor the cultural and historical past of the city and Thessaly, as in the project previously described.

4.4. A third case study of a mnemonic landscape network, in the urban context of the municipality of Kaisariani in the metropolitan area of Athens

The third project to be presented refers to the redesign of the two central urban squares of the municipality of Kaisariani in the metropolitan area of Athens, proposing again as in the two previous projects, a hybrid guidance system combining a real place designed visiting itinerary with digital offered narrations (16, 17).

Figure 6. Maps of the western Minor Asia coast and the Black Sea region, wherefrom the first inhabitants of the contemporary municipality of Kaisariani arrived, as refugees, in 1922, would be formed on the floor of the central square of Kaisariani municipality. QR codes inscribed on metallic plates inlaid on the square floor, at the exact locations of important Minor Asia origin places, would offer to the visitors, passing by, narratives concerning the historical and political past of the municipality.

The contemporary municipality of Kaisariani was created in the place of a refugee camp, formed in 1922, to house refugees from the Greek cities of Minor Asia and Pontus (the eastern Black Sea Region of Turkey); refugees that were trying to survive under conditions of extreme poverty. Later, the first built structures were produced and a municipality at the periphery of Athens was created. Nevertheless, the important historic adventures of the territory did not stop. During the Second World War, the installations of the Rifle Range, existing in the municipality of Kaisariani as an athletic center, were used by the Nazi forces occupying Greece as an execution place. There on the 1st of May 1944, two hundred members of the Hellenic Resistance were shot; we refer to an incident able to inscribe its place of reference in the historical and political memory of the world.

In association with the previous historical memories, maps of the western Minor Asia coast and the eastern Black Sea Region of Turkey would be formed on the floor of the central squares of Kaisariani

municipality; maps of the regions wherefrom the first inhabitants of the contemporary municipality of Kaisariani arrived, as refugees, during 1922. QR codes inscribed on metallic plates inlaid on the square floor, at the exact locations of important Minor Asia origin places, would offer to the visitors, passing by, narratives concerning the remote historical and political past of the municipality, as well as the closer to us period of the Nazi occupation of Greece.

Those narratives would also refer to the contemporary conditions of the refugees' flux arriving nowadays at the southern Mediterranean part of Europe, and, in addition, they could create a multilevel communication among inhabitants of Athens with differentiated ethnic, cultural, or religious origins and language differences. The central message of this contact would refer to the realization that cultural formations are scarcely uni-ethnic, and that multicultural coexistence has to be accepted as a possibility of positive osmosis.

5. CONCLUSION

We have just reached the conclusive part of our presentation, navigating through important historical landscapes of Greece; "navigating", metaphorically, through the Hellenic "terra firma", the Hellenic solid ground, or even proposing a real navigation itinerary in the seascape of North Aegean Sea. We proposed possible mnemonic pilgrimages that may return to previous centuries, closer to us or more remote, or even to the fascinating realm of Hellenic mythology. Finally, we decided to visit the urban landscape of three different Greek cities, Larissa and Trikala in Thessaly, and Kaisariani in the Athenian metropolitan area. In those projects, urban public space and urban cultural landscape were considered as the par-excellence "topos", in Greek, the par excellence place of collective memory, of historic mneme as an important condition for the invigoration of social, cultural, and political conscience.

The role of place in the formation of collective memory of Cypriot villages

E. Konstantinidou¹, I. Geddes^{2*}

¹ Associate professor, School of Architecture, National Technical University of Athens, Greece

Extended abstract

This paper aims to highlight the ways in which the emergence and evolution of a place is linked to "memory". Given that the spatial dimension of the landscape (both the natural and built environment) constitutes the field of projection of memory, the paper deals with the relationship of collective memory with the place as an important, determining factor in its formation. Thus, it highlights the correlations of memory with spatial references, the "emplacement" of memory, its spatial imprint and expressions, and its relation to the formation of "place identity" across time through the concepts of continuity and spatial memory.

The field of research concerns settlements in the Larnaca region of Cyprus, focusing on Kalavastos and its neighboring villages (Choirokoitia, Tochni, Psematismenos, Maroni). The study area is of great interest as it covers a wide field of historical reference, monuments and landscapes of cultural and historical importance, traditional settlements, as well as interesting geomorphology, richness, and variety in the natural landscape. Thus, an area with unique physical, spatial, and social characteristics featuring a strong historical, cultural, and political identity.

The exploration and analysis of the research area is implemented with different methodological tools (morphological analysis and space syntax analysis). "Mapping" focuses on the structure and composition of the settlements, exploring the creation and evolution of settlements, their development in place and time, and the relationship with the natural environment and geomorphology.

The comparative analysis, between Kalavastos and neighboring villages, concerns spatial relations, references, correlations, interactions, and differences, aiming to discuss issues concerning the ways that different methodological tools of "reading" the place unveil its character and identity. Specifically, the analysis explores the memory-related components of the place, the correlations of memory with spatial reference, the relationship of collective memory with place, the ways in which the emergence and evolution of a place are linked to "memory" and the importance of the mnemonic function for forming "place identity", highlighting how this might interact with sustainable development.

Extended abstract

Recent history is characterized by abrupt and extreme changes such as, wars and climate change which raises the need for a more flexible and adaptable definition of spaces on all scales and therefore requires a fast response for the unexpected needs created by crises conditions.

This paper introduces a strategy to better navigate unexpected conditions that are likely to occur more often in upcoming years. The strategy is based on observations into changes occurring on various sites across Israel during recent months, in which the power of community and civil organizations took central roles.

On October 7th, many communities in southern Israel were significantly damaged within a few hours, resulting in the evacuation of the survivors. The refugees were scattered all over the country, temporarily staying in hotels, guest houses, boarding schools and office buildings as the war began. This abrupt change of reality created unexpected situations, where new needs and response programs emerged. Support and aid centers were spontaneously created by civilians, in public, religious and academic buildings, existing public institutions were repurposed as kindergartens and schools for the evacuated children, hotels housed uprooted communities, and existing kibbutzim doubled their size, becoming a temporary home for the displaced. The transition revealed networks and movements between the new "spontaneous residential neighborhoods" and improvised public spaces, outlining new urban qualities in the existing cities - innovative, flexible, and dynamic space, both in private and public realm.

The next phase was a search for longer-term responses of a period of three to five years, required for rebuilding the disrupted living environments and restoring the community and the lost sense of home. Some of the responses considered by evacuated agricultural communities in this phase were as surprising as housing whole communities in high-rise buildings in the big cities.

This paper will claim that cities have the capacity to evolve and adapt to changing needs with dynamic typologies, and a non-rigid design methodology. We will showcase the recently acquired knowledge, based on observation, documentation and mapping of the spontaneous changes and evolving typologies, to outline a set of design tools for various scales, fitting fast and abrupt transitions, relevant for a changing reality, as a basis for an alternative adaptable architectural language.

We believe that current events, while a hundred million people are forcibly displaced worldwide, prove the need for adaptive and flexible systems, in which community and civil organization can assume a pivotal position. The proposed strategy is a layout for such a system, which might be needed anywhere, sooner than we can comprehend.

Extended abstract

The abstract proposes an anthropological research of the Albanian immigration, focusing on the historical, cultural and political dimensions of the immigration experience. It is crucial to state in advance that we do not intend to represent or evaluate the experiences of all those who crossed the Albanian-Greek borders, but rather to highlight these experiences as a significant political matter. From this point of view, the phenomenon of immigration is not understood through a dichotomy of good/bad but instead seen as a crucial formation process of our present societies. Thus, our aim is to reveal a reality that is, actually, already there. The main concepts of this proposal are mneme, place, identity, and immigration. Before we describe how these concepts interact, we should first question the meaning we place upon them. Mneme stands here as a relation of past and present time, a constant recreation of our cultural and political reality through history. Therefore, it is not considered a field of the past nor a static condition unchanged through time. On the contrary, it continuously forms, interferes and clashes with our present ways of being. Mneme is not only a ‘per se’ living history, but a vibrant living reality, which connects our past with our present existing spaces.

The connection of “mneme” with space and place could be described as an interdependent relation. As stated at the description of the session, “Memory ‘needs’ place; ... to be projected on it”. If we attempt an instant exploration of “mneme” in place, we can highlight museums, monuments, or statues and buildings of historical significance. In the context of a deeper analysis, we can extend the perception of place and invoke memory in the spaces of our cultural behaviour, our political choices, and the ideologies. All these previous spaces contribute to the formation of “place identity” and “collective identity”, as they remind us of our common past and request our common present. Thus, memory, identity and place are significant and co-related, precisely because they demand and simultaneously cover our need for collectivity.

Nevertheless, I have not yet posed the crucial questions of this proposal: What happens when collective memory and identity do not have a place to be projected on? What happens when ethnic groups cross their homelands and move to places with no spaces of their own? What happens when immigrants cannot find museums, historical buildings and neighbourhoods that carry their memory and identity? What happens when collective memory and identity do not have the cultural space to be expressed? Through the history of Albanian immigration in Greece, we shall look for “mneme” and identity in places which were not - and maybe still are not - visible. We shall investigate these concepts as political and cultural demands - not as given facts. We may try to find how collective “mneme” and identity could be transformed when a place is missing and maybe hope to re-“view” our reality through our history.

Keywords: *politics of mneme; Albanian immigration; place identity; collective identity; minorities.*

The concept of the monument in the age of the Enlightenment: Towards a genealogy of mnemonic structures

N.-I. Terzoglou

Abstract

The relation between architecture and memory, between the built environment and its mnemonic function for people and society, attains an exemplary character in the concept of the ‘monument’, and, especially, in the idea of a ‘public’ or ‘historical monument’. Nevertheless, as Françoise Choay has shown in her study titled “L’Allégorie du Patrimoine”, the concept of the ‘monument’ is constantly transformed through historical time and is receptive to different interpretations by antiquaries, philosophers, historians, travellers, and architects, according to the worldview and the spirit of the age.

Consequently, as the concept of the ‘monument’ changes over time, the relation between architecture as a material structure of the past and the social function of memory is transformed as well. In other words, the ‘memory of the stones’ as an immaterial, intangible cultural heritage and its various semiotic forms and manifestations are subject to radical metamorphoses through history.

The 18th century, when the new spirit of the Enlightenment started to unfold itself, was a turning point for those transformations. The explosion of archaeology as a systematic study of ancient monuments led to emergent Neoclassicism and was intimately connected with various changes in the understanding of historical time. During the era of the Enlightenment, architecture became an allegory of time and a symbolic space of mnemonic values, norms, and epistemic ideas that could bridge the past, the present, and the future.

What were the main concepts of the ‘monument’ in the 18th century? The aim of the present paper is to investigate this question through the elaboration of a genealogy of selected transpositions of the concept of the ‘monument’, as these are articulated in various textual sources of the Enlightenment discourse. In that way, we hope to understand the ‘book of stone’ through the ‘book of paper’ (Victor Hugo’s conceptual duality from his novel “Notre-Dame de Paris. 1482”) in order to shed some light on the values attached to architecture as a mnemonic structure. The working hypothesis behind this research is John Ruskin’s intuition, expressed in the ‘Lamp of Memory’, from his major book “The Seven Lamps of Architecture”: “We may live without architecture and worship without her, but we cannot remember without her”.

Keywords: *mnemonic structures; genealogy; historical monument; antiquities; regimes of temporality*

1. INTRODUCTION: TIME, SPACE, AND ARCHITECTURE

The relation between architecture and memory, in both its material and immaterial aspects, is a complex one. Architecture is a prime example of a type of heritage where material remains and immaterial ideas merge into dialectical fusions that are value-laden. The dialectic between the built environment and the mnemonic identity of people and societies attains an exemplary character into the concept of the monument, and, especially, into the idea of a ‘public’ or ‘historical monument’. However, in order to formulate epistemic principles concerning the preservation, renewal and careful animation of historical monuments, there is an absolutely essential prerequisite: a concept or an idea of *what is* a ‘historical monument’ must be already constituted within the architect’s or the historian’s

mind. The above proposition might seem to be a tautology, a quite obvious statement, but, actually, it is not. I will try to show that a concept or a notion of a historical monument is not a natural, given fact of consciousness: it is, rather, an ideological and cultural construction [1].

Françoise Choay writes: "...the concept of a 'historical monument' is not a cultural invariant but a specifically occidental, western invention" [2]. This invention began during the Renaissance, which constituted Antiquity as a historical object, and was brought to completion in the era of the Enlightenment, when a monumental and national heritage acquired didactic, patriotic and esthetic values for the establishment of ethnic identities [3]. This ideological structure involved complex interrelations and dynamic interactions between memory,[4] norms and significations [5].

The working hypothesis behind this claim could be an intuition of John Ruskin, expressed in the crucial chapter called the 'Lamp of Memory', from his major book *The Seven Lamps of Architecture*, written in the middle of the 19th century, in 1849. Ruskin believed that, 'We may live without Architecture, and worship without her, but we cannot remember without her' [6]. In other words, one of the major ethical functions of architecture relates to memory, collective as well as individual. I argue that architecture is a vehicle through which structures of time, such as memory and history, become space. Through architecture, time is crystallised into permanent spatial symbols of mnemonic and historical values.

However, an introductory clarification and elucidation is necessary. The focus of the present talk is on the concept of the 'monument' in its general meaning, which denotes any remnant or building of the past that is considered to have a *historical value for a subsequent era*. Therefore, a conceptual distinction is needed between a 'monument in general' and a 'monument in particular'. The latter refers to all the buildings that were 'living monuments' *by definition or par excellence*: namely, those that were conceived, designed and realized with a deliberate mnemonic function and destination from the very beginning. Ancient trophies, steles and altars with epigrams, triumphal arches are all monuments with a mnemonic function *by destination*. Alois Riegl uses the term 'intentional monuments' (*gewollte denkmal*) to characterize them [7]. He then proceeds to make an important conceptual distinction, writing: '*In contrast to intentional monuments, historical monuments are unintentional...Since those who fashioned the works which we have subsequently termed 'historical monuments' wanted primarily to satisfy their own practical and ideal needs...without as a rule intending to leave testimony of their artistic and cultural life to later centuries, when we call such works of art 'monuments', it is a subjective rather than an objective designation. It is not their original purpose and significance that turn these works into monuments, but rather our modern perception of them*' [8]. In other words, an 'unintentional' monument or a 'monument in general' or a 'historical monument' has a commemorative value as a result of an *interpretation* that is taking place independently of its original conception or intention. Riegl believes that the Italian Renaissance marked the beginning of this complex process, which involves valuations, ideologies and a certain historical sensibility [9].

I therefore will focus my attention on the subsequent phase of this process, during the Age of the European Enlightenment. And I will attempt to trace the conceptual evolution of the ideas referring mostly to the 'unintentional' monument, as defined above by Riegl, for two main reasons: firstly, because 'unintentional' monuments display the dynamic interaction between matter, history and memory in an exemplary way and, secondly, because they reveal the Modern value conflicts regarding the meaning of architectural remains more clearly. Indeed, as Manolis Korres has shown, the various ideologies for the preservation, conservation and restoration of ancient monuments, as they were codified since 1883, display a complex articulation of divergent values in many layers of meaning: truth claims regarding stylistic integrity, age, authenticity of material or structure, and emotional, aesthetic, artistic and picturesque qualities that can be attributed to a building, its parts or its environment [10]. According to Korres, some of those values are 'transferable' or 'reproducible', while others could be characterized as 'intransferable' or 'irreproducible'. Memory-value, emotional

Proceedings

value and the value of the monument as a symbol triggering off spiritual, social, political or religious associations can be both, depending on their conscious interpretation by the beholder, their subjective readings and appropriations [11]. The pioneering study titled “*The Modern Cult of Monuments*”, written by Riegl in 1903, is still probably the best systematic analysis of the conflicts between memory-values of the past and functional and artistic values of the present that a monument, as a bearer of identity and continuity, can induce [12].

Consequently, as Choay has shown in her book, *L’Allégorie du Patrimoine*, the concept of the monument is constantly transformed through historical time, especially in European Modernity, and is receptive to different interpretations by antiquaries, philosophers, historians, travellers and architects, according to the social worldview and the cultural spirit of the age [13]. Choay claims that the concept of ‘heritage’ (patrimoine) is a late 20th century invention, which replaced the organic memory of the ‘intentional’ monument, and the abstract intellectual construction of the ‘historical monument’. This last idea took two ‘cultural revolutions’ in order to emerge as a western narrative: the Renaissance and the Industrial Revolution [14]. The notion of heritage, as it surfaced after the 1950’s, reflects a ‘third cultural revolution’, which Choay calls ‘electro-telematic’, and Eero Tarasti, ‘techno-semiotic’. According to Choay, ‘heritage’, in its contemporary use, denotes mainly an economic dimension, which commercializes the historical past and transforms culture into a fetishized object of commodity, destined to be consumed by globalized, homogenized tourist flows [15].

Charalambos Bouras aptly wrote, ‘*The value of the remnants of the past is transformed when the value-system of life changes*’ [16]. As the concept of the ‘monument’ changes in different historical periods, the relationship between architecture as a material condensation of space-time and the social function of memory is also modified. For example, as Manolis Korres argues, during Antiquity ‘...consideration for the “authenticity of the material” was subordinate to consideration for the “integrity of form”, and the concept of “historical memory” was applied to the whole object and not the individual blocks’ [17]. In other words, the ‘memory of the stones’ as an immaterial cultural heritage and its various semiotic forms and manifestations is subject to radical metamorphoses throughout history.

I claim that Modernity, and especially the 18th century, when the new spirit of the Enlightenment started to unfold, was a turning point for those transformations [18]. The explosion of archaeology as a systematic study of ancient ruins led to the emergent Neoclassicism, and was intimately connected with radical changes in the understanding of historical time. During the era of the Enlightenment, architecture often became an allegory of time and a symbolic space of values and epistemic ideas that could bridge the past, the present and the future. This is evident in the various connections and interrelations between archaeology and Neoclassicism, between the architectural remains of the distant past, and the formation of a new ideal for a ‘modern’ architecture of the future [19]. In other words, architectural monuments during the 18th century play a complex role in articulating ideas of time and philosophies of history with social and spatial projects which express an orientation towards the future. It seems that architectural monuments and architectural ruins in space could function, not only as a reminder of a distant past, but as an instigation of a new way of life for the future.

This epistemological shift of the Enlightenment attitude towards archaeology and space is related to that which Jochen Schlobach has named ‘the Discovery of Cultures’, namely the re-evaluation of the plurality of different civilisations which belong to distinct spatial and geographical environments. According to Schlobach, this new cultural understanding is due to a radical historical thought that was developed during the Enlightenment, a change of paradigm in the concept of historical time, which sought to combine the theory of cycles with the theory of progress. Schlobach sees such a combination in Voltaire’s philosophy of history, which enables the bridging of the Enlightenment ideal of the universality of human reason with the given variety of cultures in different spatial and geographical circumstances [20].

What were the core concepts, the main conceptions of the idea of the monument in the 18th century? The aim of my talk is to investigate this question, through the elaboration of a brief genealogy of basic conceptual transpositions. Those transpositions are articulated in various textual sources of Enlightenment discourse, written by architects, philosophers, antiquaries and historians of art. According to Michel Foucault, a genealogical research, contrary to a search for the origins and the continuous evolution of certain ideas or events, focuses on the provenance of historical concepts. This provenance is characterised by radical discontinuities, ruptures and heterogeneity [21]. In that way, I hope to understand the ‘book of stone’ through the ‘book of paper’ (Victor Hugo’s famous conceptual duality from his novel *Notre-Dame de Paris* from 1832) [22], in order to shed some light on the values attached to architecture as a mnemonic structure.

2. TWO DIVERGENT CONCEPTS OF THE MONUMENT DURING THE ERA OF THE ENLIGHTENMENT

Following a preliminary investigation of various textual sources, I propose the working hypothesis that during the ‘long 18th century’ (from around the 1670s to the early 19th century) we can trace *two distinct ideas and concepts* of the monument in Enlightenment discourse. I prefer to call them ‘ideal types’ of the monument, following Max Weber’s term from his *Methodology of the Social Sciences*. According to Weber, an ideal type ‘...is formed by the one-sided accentuation of one or more points of view and by the synthesis of a great many diffuse, discrete, more or less present and occasionally absent concrete individual phenomena, which are arranged according to those one-sidedly emphasized viewpoints into a unified analytical construct (*Gedankenbild*)’ [23]. In other words, an ideal type is a conceptually pure mental construction which acts as a logical norm for the general description, analysis and classification of reality [24].

The first ideal type of Enlightenment discourse conceives the monument as a concrete and unique object destined for private pleasure and arousing individual curiosity. This approach is evident in writers such as Jacob Spon and Bernard de Montfaucon. It is condensed in a very specific textual expression: ‘antiquities’ or ‘*antiquités*’, coming from Varro’s term ‘antiquitates’ [25]. The antiquarian approach towards the monument is directed to an aesthetic and sensuous observation, registration, description and accumulation of the various remnants of the past. This empirical approach is passive and psychological.

The second ideal type of the monument conceives it as an abstract and general field of historical relations, meanings and values that aim at a collective instruction and education, which can serve public knowledge. This approach can be traced in writers which belong to various public committees after the French Revolution in France, such as Aubin-Louis Millin and Félix de Vicq d’Azyr. It is significant that, to designate this new concept of the monument, those writers usually refrain from using the old type antiquities and adopt new expressions, such as ‘public monument’ (or *monument public*), ‘historical monument’ (or *monument historique*), or even ‘national monument’ [26]. This second idea displays a more energetic and active relationship to the past, which it classifies and organises into wholes based on types, series, species and abstract criteria, with an educational purpose for the present and the future. This rational approach is intentional and logical. The monument ceases to be thought of as an isolated, empirical, curious and unique object and becomes part of a totality of historical meanings, an organic component of a structure of conceptual relations. New feelings and values are connected with the second ideal type of the monument: the glory of a nation, the idea of human progress, the public space of a common and collective knowledge.

Antiquities belong to the past. Historical and public monuments, through their didactic and paradigmatic nature, belong to the present and the future. In other words, I claim that, during the 18th century, a radical transformation, a Foucauldian genealogical discontinuity, took place: memory became an indicator of the future and history catered for utopian visions. And this happened through

a very precise medium: architectural space. Étienne-Louis Boullée's utopian projects for an ideal city made up of various public monuments is a characteristic proof of the above transformations [27].

Those two basic ideal types of the concept of the monument were not successive in a linear and clear logic. There was a transitional phase, where the two concepts co-existed and mingled. Those transitions are the most difficult to analyse in the history of ideas. Let us refer briefly to some examples highlighting our main thesis.

3. ANTIQUITIES

The first ideal type of the monument, namely its antiquarian approach under the concept of antiquity, was clearly codified in the work of Jacob Spon *Voyage d'Italie, de Dalmatie, de Grèce et du Levant*, published in 1679. In the Preface to this work, Spon lists the main reasons that instigated his journey: the satisfaction of his personal curiosity and the desire to accumulate more inscriptions of the various antiquities than all previous writers on the subject [28]. Reading Spon's account, we gain the impression that the term 'antiquities' signifies a random accumulation of curious singular objects, destined for a cabinet of curiosities [29].

Bernard de Montfaucon's *L'Antiquité expliquée et représentée en figures*, published in 1719, is only a more systematic exposition of the same empirical logic: antiquity here means the sum of all visible objects that can be represented through sensible images [30]. The concept of the monument under the aegis of antiquities can still be felt in James Stuart and Nicholas Revett's *Proposals for Publishing an Accurate Description of the Antiquities of Athens*, circulating from 1748. The categories through which ancient monuments are evaluated are still private curiosity and individual taste. But the glimpse of a new idea can also be discerned. Those antiquities do not solely refer or belong to the distant historical past. They can serve as models and examples for the artistic and architectural creativity of the present [31].

This same idea features prominently in the Preface to *The Antiquities of Athens*, published by the same authors in 1762. But the empirical logic that sustains this first ideal type of the monument still prevails: Stuart and Revett conceive their work only as a material accumulation of further examples of antiquities, as an '...addition to the former Stock' [32]. The work and thoughts of Stuart and Revett mark the transitional phase between the monument as an antiquity and the concept of a historical monument. The work of Julien-David Le Roy *The Ruins of the Most Beautiful Monuments of Greece* (firstly published in 1758 and re-issued in 1770, as an expanded second edition) belongs to the same ideological transition, which it articulates in a more rational, systematic and theoretically informed way [33].

The passage from the first ideal type to the second can also be attested in the various articles and writings of the *Encyclopédie* published by Diderot and D'Alembert from 1751 onwards. In the first volume, the authors of the *Encyclopédie* are still making use of the term 'antiquités', thus revealing their adherence to the first ideal type of the monument conceived of as an isolated and concrete object. For example, after the famous *Discours Préliminaire* written by D'Alembert, in the *Explication Détaillée du Systeme des Connoissances Humaines*, where the three modes of human understanding are correlated with the classification of the various contents of the *Encyclopédie*, antiquities are grouped under the faculty of memory which surveys facts. More specifically, they form one of the three subdivisions of civil history (*histoire civile*). We read, 'If it is true that History is the painting of past times, the antiquities are their projects almost always devastated...' [34].

The association of antiquities with the ravages of time and private memory reveals a melancholic and deterministic attitude towards the past: those antiquities seem to be forever entangled within the labyrinths of fate, destruction and loss. In the same volume we encounter the direct connection between the ruined and deformed state of material fragments and the concept of antiquities, in the eponymous article [35]. The emphasis on the partiality of the ruin, on the aesthetic autonomy of fragments and antiquities seen as isolated objects that we encounter in the early volumes of the

Proceedings

Encyclopédie is probably related to the ‘poetics of ruins’ inaugurated by Diderot. Roland Mortier has adequately analysed this new attitude of Diderot towards the past, where the mutilated fragment of the ruin is preferred to the state of entirety of a well-preserved monument [36].

Nevertheless, 14 years later, in the 14th volume of the *Encyclopédie* published in 1765, in the article ‘*Ruine*’ we read that we can apply this expression to palaces, tombs and ‘public monuments’ [37]. Contrary to the first volume of the *Encyclopédie*, dating from 1751, and the predilection of Diderot for the partiality of the ruined fragments of the past, we encounter a novel tone, through the reference to the ‘public monument’ which replaces the old term of ‘antiquities’. The new idea of a public monument carries a connotation of completeness and refers to a state of wholeness that the term antiquities lacked. Moreover, in the article ‘Monument’ of the tenth volume, also published in 1765, the term now designates whole buildings such as mausoleums, pyramids and triumphal arches. In order to characterise those edifices, the author of the article uses the term *monument historique*, probably for the first time [38].

4. HISTORICAL MONUMENTS

In this new perspective, the historical monument is not only a means for a solitary and subjective *rêverie* on the destructive character of time, but also a vehicle towards precise knowledge, an objective appreciation of great events of history, a didactic instrument for the present. During the 15 years from 1750 to 1765 we can trace a conceptual and gradual transition and transformation inside the *Encyclopédie* from the first to the second ideal type of the monument, namely from a devastated ruin or fragment, a unique object of curiosity, to an indicator of a set of historical events or relations which serves a didactic purpose. As Choay writes, ‘historical monuments’ became those: “...sets of buildings not deliberately erected for memorial purposes but endowed with this status due to the value attributed to them by national history” [39].

This change of conceptual tone and emphasis is evident after the French Revolution of 1789. The monument ceases to be thought of as an isolated, empirical, curious and unique object and becomes part of a totality of historical meanings. The new concept of the monument attains its value as an organic part of a historical nexus and structure of logical relations. At the same time, since this second ideal type of the monument is now public and belongs to the nation and the state, it acquires a new paradigmatic-didactic value as a space of common, collective knowledge. New expressions are used to describe the feelings and concepts that a historical monument (as it is now called) can arouse: the glory of a nation, the idea of human progress, the general history of an empire, or the public space of a common and collective knowledge [40].

The above transformation of the attitude towards the concept of the monument is evident in the text *Antiquités Nationales ou Recueil de Monuments* written by Aubin-Louis Millin in 1790. Millin urges the revolutionary government to protect the historical monuments of France as a living testimony of the nation’s general history, as an educational material precious to the citizen of the future [41]. Four years later, Félix de Vicq d’Azyr develops in detail this educational and national concept of the monument in his seminal text *Instruction sur la Manière d’inventorier et de conserver, dans toute l’étendue de la République, tous les objets qui peuvent servir aux arts, aux sciences et à l’enseignement*, presented before the Commission of Monuments. Vicq d’Azyr proposes a novel subject as the real protagonist of a national education delivered through the monumental heritage of France: the French people themselves (*le peuple français*), who are friends of the country. Here, the historical monument becomes an organic part of a general politics of equality, of a public instruction through libraries, museums and temples [42].

The new concept of monument, serving a national and public education, requires novel methods of classification, a systematic re-ordering of the material objects of the various arts and sciences into abstract types of conceptual relations [43]. Architecture is not exempted from this fervour of classification: according to Vicq d’Azyr, the exemplary character of certain monuments of

Proceedings

architecture can serve public education perfectly [44]. This ideology is already apparent in Armand-Guy Kersaint's *Discours sur les Monuments Publics* dating from 1792. Kersaint proposes the erection of a National Palace and the inauguration of a Public Museum, thus transposing the idea of the monument from the past to the present and the future, proving our main argument [45]. In Kersaint's discourse, the monument becomes a living symbol of public ideas, a vehicle for the education of civic virtues, a moral machine for the establishment of democratic values [46].

Kersaint's concept of the public monument found in Etienne-Louis Boullée's utopian drawings and projects the perfect architectural expression. Boullée, in his text *Architecture. Essai sur l'Art*, written around 1790, connects the concept of the public monument with an ideal city of the future which serves educational, moral and civic values and needs [47].

5. THE MUSEUM, THE CABINET OF CURIOSITIES, AND TWO PHILOSOPHIES OF HISTORY

I propose that the second ideal type of the monument, namely the historical monument as an abstract system of knowledge and national education, led to the inauguration of a completely new spatial and architectural type of modernity: the museum. Nikolaus Pevsner has shown how the idea of the museum was a completely modern concept and has delineated its history [48]. Andrew McClellan has further contributed a crucial idea: the museum as a public institution, open to all citizens, with classified and organised collections of monuments and works of art was a creation of the French Enlightenment after the Revolution. More specifically, the opening up of the Louvre in 1793 marked the inauguration of the first truly modern public museum [49].

This new spatial type and its specific symbolic functions could not have emerged if the concepts of the historical or public monument had not been forged by the Enlightenment discourses of Armand-Guy Kersaint and Aubin-Louis Millin, and by various utopian visions. For example, as Anthony Vidler has demonstrated, the utopian and monumental project for an ideal public museum by Étienne-Louis Boullée has greatly influenced the evolution of the new building type [50].

The modern type of museum replaced an older concept for the display of objects: the cabinet of curiosities. Whereas the cabinet was an empirical piling up of unique and bizarre objects in a random fashion [51], the modern museum is a rational structure and constitution of historical space and time according to principles of classification, which possess a highly abstract nature. Behind the cabinet of curiosities lies the concept of antiquities. Behind the modern museum lies the concept of a public monument.

I will conclude by formulating another working hypothesis which needs further studies to be confirmed. I claim that those two distinct ideal types of the monument which characterise 18th century thinking have a specific philosophical background. This background is related to the philosophy of history which was developed during the long 18th century [52] and closely connected to that which Trevor-Roper named the 'philosophical history' of the Enlightenment [53]. Ernst Cassirer proved that the Enlightenment possessed a keen sense of historicity, inaugurating the modern process of '*the conquest of the historical world*' [54].

Panajotis Kondylis has shed light on this process, in his major study, *Die Aufklärung im Rahmen des neuzeitlichen Rationalismus* [55]. There, he identifies two major strains of the Enlightenment attitude towards historical time: the normative and the causal. The normative ideal puts an emphasis on man's moral freedom, his intellectual ability to control time according to his rational purposes and plans. The causal ideal is more focused on necessity and man's incapacity to transcend the chain of natural factors that pre-determine his behaviour, his actions and his sense of time. According to Kondylis, those ideals correspond to two divergent tendencies in the philosophy of history of the 18th century: the universal-normative and the causal-relative.

6. NORMATIVITY AND CAUSALITY: TWO REGIMES OF TEMPORALITY

The universal-normative philosophy of history is optimistic and believes in human progress, in the existence of a normative goal which governs a general and paradigmatic historical sequence of a totality of events that lead towards the future. The causal-relative philosophy of history is pessimistic and recognises the partial and unique character of every historical cycle of events, the inevitable growth and decline of human civilisations [56]. Those two distinct philosophies of history, like their corresponding concepts of the monument, sometimes co-existed, in a state of a slow transition from the causal-empirical to the normative-rational ideal. The thought of Voltaire and Montesquieu prove that normativity and causality, teleology and determinism, optimism and pessimism could create tensions and ambiguities inherent even within a single work of the same author [57].

I propose the following idea: the causal approach to historical time is related to the concept of antiquities whereas the normative approach to historical time ties up with the concept of the historical monument. In other words, behind the two basic concepts of the idea of the monument during the 18th century, lies a deep philosophical structure of reading time and history. The two ideal types of the monument correspond to two distinct philosophies of history. According to R.G. Collingwood, those two philosophies of history can be codified as backward-looking and forward-looking, respectively, the first exhibiting past history as a ‘*play of irrational forces*’, the second forecasting to bring about a millennium where ‘*the rule of reason shall have been established*’ [58].

In the first instance, time is a random and passive sum of events outside the rational control of man. In the second instance, time is a rational and active sequence of aims and purposes, a logical chain of ideas that man can create and control [59]. Time-one is subject to faith and fate. Time-two is subject to reason and prediction, organisation and prevention. Can we trace the exact place and author where the transition from time-one to time-two occurred?

According to Kondylis, the real father of a normative concept of historical time is not Voltaire but Turgot. By assuming as a principle an obligatory ethical telos of the historical evolution, Turgot managed to subjugate natural causality to the demands of human and social reasoning. Thus, he formulated the mature idea of a theory of progress, where time can be designed and controlled to fit human aims [60]. This concept of time that is orientated towards the future corresponds to the second ideal type of the public monument as an agent of future progress, as a symbolic carrier of morality and rationality. The Enlightenment philosophy of historical progress can be considered as the ideological counterpart of a metamorphosis in the concept of the monument.

In other words, the new era ushered in by the Enlightenment could be felt when causal time was surmounted by normative time, when antiquities were overcome by historical monuments, when the cabinets of curiosities were replaced by the public museum and when ‘*vanitas*’ gave way to hope for the future. The transition from time-one to time-two was mediated by the power of architecture to transform ideas into living traditions and to condense philosophical worldviews and mnemonic structures in stone.

Architectural Heritage as a parameter of sustainable development of the place. The case of Chora

D. Katraouzou

Researcher PhD, School of Architecture, National Technical University of Athens, Greece
Corresponding author: E-mail: dkatraouzou@gmail.com, Tel +30 6977464236

Abstract

The subject of this presentation is the decoding of the 'special' and unique identity of the island of Folegandros in the South Cyclades and the importance of highlighting and protecting its cultural heritage as a parameter of sustainable development. Especially, in the face of the threats posed in recent years by hurried, uncontrolled and unsustainable tourism development within the context of unconstrained consumerism and an escalating climatic change. At international level, it has been observed that 'the Greek islands have taken a battering since the late 60's and many have lost the simplicity that attracted musicians, writers and famous architects who found inspiration in the landscape and the Aegean Sea. As Folegandros remained self-contained for many years, it has not yet witnessed a similar level of 'development' as other islands (i.e. Mykonos and Santorini) in the region have. Technological developments mainly in transport services and the internet access reduced the distance between the island and the rest of the world, which has resulted in a big change. Its authentic architectural heritage and landscape, reflect the timeless historical and socio-economic conditions in combination with the peculiar stone and natural rock formations that constitute its distinct geological environment. They form the basic expressions of the island's identity that transpire its important and characteristic comparative advantage. Heritage preservation and urban development should no longer be considered contradictory or incompatible. Consequently, we aspire to guide both, state and local authorities, as well as residents, engineers and craftsmen, in the direction of the correct management and conservation methods.

Keywords: *Folegandros; Kastro; landscape identity; architectural heritage; sustainable development*

1. INTRODUCTION

In the aftermath of a protracted, laborious and extremely painstaking scientific research, with an in-depth analysis of the historical, architectural and urban planning identity of the Folegandros Chora settlement in the context of the wider local environment, we derived the conceptualization of the parameters that made it 'unique'. The current settlement of **Chora** (or Folegandros), which impresses the visitor with its architectural physiognomy, is undoubtedly the result of an evolutionary process of development and structural transformations. However, a decisive parameter in its architectural design was the rebuilding of its fortified core (the Castle) from scratch that continues to be inhabitable to this day, making it one of the few rare and well-preserved castles of the Cyclades. Subsequently, safeguarding its conservation and well-being is pivotal. Values that are timeless and compatible with the human condition, such as plasticity, human scale and intimacy are the qualitative characteristics of the settlement while the staggered arrangement of its volumes due to its gentle adaptation to the slope and the morphology of the area, contribute to the general harmonization of the residential complex with the wider impressive landscape. It is admirable of the residents of Folegandros (*Folegandrites* in Greek) that over the centuries, despite the unfavourable ground conditions, including the barren landscape which was extremely difficult to cultivate, having yielded twice as much work effort they managed to tame the soil rough texture, thus surviving as an autonomous productive unit. This viable system model of self-sufficient sustainability, that they had created and

Proceedings

has been long-established is nowadays superseded by the influx of new trends and traits. This fairly new 'modern model' of life that is mainly based on easy and profitable tourism entrepreneurship, has been encouraging residents to relinquish the former traditional subsistence practices. By thoroughly examining the successive phases of the development of the settlement, from its genesis as a fortified core, combined with the typological and morphological evolution of the residence and the public space, we aim to 'read the geometry' of the place and its architectural landscape, as well as to decode the dynamics of the relationship between them. This presentation has been based entirely on the author's PhD study [1]. The thorough and highly detailed architectural design of an entire settlement, assisted by digital applications that is the only systematic digital data collection and research currently available for the building stock, compelled by numerous systematic and inexhaustible in situ site-investigations- has become the key to a better understanding of the settlement that allows for making inferences and drawing certain conclusions along with -proposals for sustainable development. Research material from rare bibliographic and archival sources, was of pivotal importance to the process of investigating the development phases of the settlement, as well as to the identification of the corresponding changes that occurred in its urban and architectural structure over time.

2. FOLEGANDROS' IDENTITY

Methodologically following a global holistic view of the residential development of the settlement of Folegandros Chora we have endeavoured to unveil its 'special' architectural heritage, through its 'dual' nature: as a fortified settlement (Castle-Kastro) and as a traditional settlement (Village-Chorio) together, in the framework of its viability towards a sustainable development. The location of the Castle as the first residential core, was not accidental. It is built on a geographically strategic position overlooking the sea, on the sharp edge of a vertical 'freak' cliff, which rises about 210 meters above sea level. Sailing in a boat, the view of these cliffs, glistening in the light, was seen by Bent [2], when he visited the island. Ecstatic by this sight, he likened them to a huge strip of rust stretched along the coast, thus confirming the reputation of Folegandros for its 'iron' form. According to one version, Folegandros' internationally known name 'Polycandros', is due to the Phoenician word 'Phelekguduri', which means 'made of stone' signifying also its rocky geomorphology. Thus, the Castle was practically inaccessible from the sea, whilst at the same time its location offered the advantage of a full view of every sea vessel, considering also that it only takes a glance to visually travel to the neighbouring islands (Milos, Kimolos, Siphnos, Serifos, Antiparos, Paros, Naxos, and up to the uninhabited Cardiotissa nearby). It is worth mentioning that the term "castle" in the historical area and time of the Cyclades mainly refers to a form of settlement organization rather than to typical fortified constructions. This specific one (Figure 1) belongs to the category of castles whose outer enclosure is made up of dwellings in a row and where their outer wall constitutes the outer wall of the overall castle, a system of Greek origin [3]. The geometry that characterizes the general arrangement of its elements indicate that it satisfies all the specifications of conformity and organization of the basic defensive elements that constitute a castle, i.e. the walls with ramparts, the gates (3 in total, though only the central one 'loggia' and the 'Paraporti' are visible today) and its towers, while from the latter only parts of some or traces at the base are preserved, thus documenting similar assumptions.

Figure 1. General Plan. Chora's Castle.

Proceedings

Overall, it presents a roughly triangular shape with side dimensions of approximately 118, 120-126 and 60 meters. It is a fort with the possibility of 'passive' defense only with the potential of 'flank cutting', in the cases of small pirate raids. At the same time, it was an important refuge for the inhabitants at a time when intense riots prevailed in the Archipelago spreading endless insecurity. Inside, the two roads (Down and Inside-Back Rouga) represent the most spacious streets of the castle with their greatest width mainly towards the eastern side of the castle and near the Paraporti, whilst the two roofed passages (*diavatika or stadia*) are also points of interest. Based on historical documentation, it has been argued that it was built by the Latin family of Gozzadini, with colonization by Siphnians and then Cretans in the 1577 AD, at a time when the island was already deserted and the oldest Venetian castle that Sanoudos, Duke of Naxos, had built on the site of '*Paliokastro*', had already been destroyed. The colonization of Folegandros is attributed to them, as according to Slot [4] Kimolos and five more islands with settlers from Siphnos, had developed a type of agricultural economy based on wheat production, at a time when the trade of the product was in great demand in the Mediterranean. The main distributor of wheat exports from the Cyclades to Southern France were Franco-Levantines relying on a network of consulates in the small islands of the Archipelago. Subsequent history attests to the success of these colonisations, both economically and mainly culturally. At least in the case of Folegandros, the construction of the castle became one with the place, while its adaptation to local conditions and the character of the inhabitants had a two-way effect on the aspect of 'economy' and 'moderation'.

2.1 THE 'GEOMETRY' OF THE CASTLE- RESIDENCE TYPOLOGY

The systematic study of the typology of the dwellings that make up the Castle's built fabric, has proved that it is the result of scientific and methodological planning and was created as a single composition that was completed in one phase. In particular, there was almost complete standardization in a row with the repetition of a typical 'one-room' unit, in narrow-fronted plots of minimum area (approximately 20 square meters), with plot dimensions of approximately (3x8-8.50)m. external and (2.61x7.35)m. internal, repeated in row, that comprised 94 single-room units, as independent dwellings per floor, according to the status of 'floor ownership'. The small unit cell of a single house (*monospito*) of the castle was systematically repeated with the small exception of some larger-scale houses, mainly mansions. Whilst, removing the intermediate load-bearing walls and replacing them with full-body beams '*axonia*'. Such full-body beams had most certainly been imported from other places, as there was no similar timber on the island for their construction. Notwithstanding this, it has also been speculated that some may have come from ship masts.

Depending on circumstances, this small 'cell' house turned out to be larger than what we have been anticipated, and such development has nothing to do with the size but with the provision of improved living standards (Figure 2).

Among them, key elements were the climate as well as the structure of the soil topography. The mild and relatively warm winter of the island and its defensive expediency contributed to the architectural solution of the simple small one-room house with a roof, the 'single house' unique archetype in the Aegean, whose modest, closed and compact volume did not require additional heating. A fireplace, the well-known '*parostria*', was more sufficient for cooking or boiling water than for heating the small place.

Figure 2. Chora's Castle. Down Rouga.

Since the logic of 'minimalism' and 'economy of land' was followed inside and outside the castle, except of a few mansions located on the outskirts of the settlement or some individual cases of buildings of other use, no space was wasted for additional unnecessary enclosures. A wooden divider, the 'tavlado', appears to roughly separate the rear sleeping area from the kitchen, while the bed was essentially a wooden structure with storage space underneath. Regarding the openings in the facade of the typical multiple unit, it has been argued that there was only one entrance-exit door on the ground floor and one at each floor, with independent access, as in the case of the castle of Kimolos. All the exterior staircases of the castle that are still in place today are made of stone and they are particularly steep, with steps of 25-28 cm wide and up to 32 cm high. The most common case that is considered to be authentic is the (Γ)-shaped staircase with the lower arm starting perpendicular to the road and the elevation, while the upper arm, smaller than the first one, rests entirely on the landing that joins the two support legs. The staircase leads to a wood-framed cantilevered balcony (secondarily supported by the bulk volume of the staircase) from where the first floor residence is accessed, thus offering independence in movements towards the ground floor and upper floor. Because of its big bulk volume, the space underneath, which is called 'koiti', is quite spacious and provided space for auxiliary uses (w.c.). In the past, their use was concerned with the periodic rearing of domestic animals (e.g. pigs) and was a place for gathering all the unwanted bio-waste of the household, which according to testimonies, it was transported with animals to the fields, creating domes 'troulous' that were covered with soil and turned into fertilizer for crops. The ergonomics of this type of staircase had been thoroughly studied. It was protecting the lower courtyard from the winds, providing shade in the summer and, at the same time strengthening from a defensive point of view the wall inside where the fireplace was located. On the flat stairs they placed a clay container that through a canal 'canalos', rainwater from the roof, was collected for domestic use. Due to the hard limestone bedrock of the rock on which the castle was built, it was not easy to carve a cistern

for each house. It was constructed only where the morphology of the ground allowed it in hollows, or due to a slope as in the residences of the northern rear side towards the cliff and the sea, while there was probably a cistern for public use inside the castle, which no longer exists. But the importance of the castle does not stop here. As evidenced by the painstaking application of a grid 'Kannavos' articulated with the Venetian "passo" (foot)- about 1.75 meters in length- the architecture of the Castle is a product of design, including its strict overall implementation and adherence, during the construction phase.

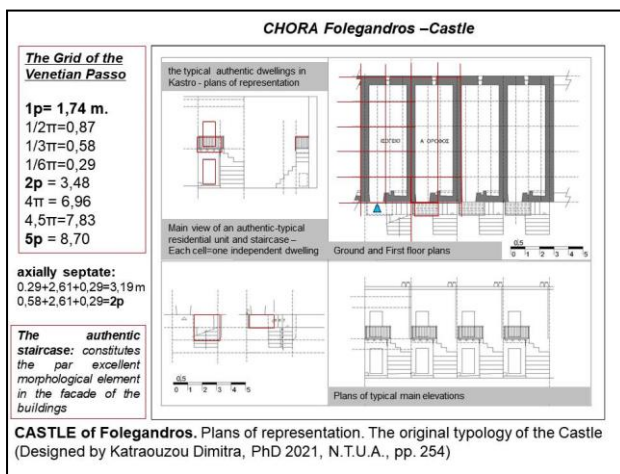

Figure 3. The original plan by the Grid of V. P.

So, this unique monument that was built in one phase, manifested an architectural solution with a strictly applied geometry as a whole, that did not allow interventions in its main features. According to an important observation, almost all parts of the Castle structure are multiples and sub-multiples of the Venetian passo (1 v. passo=1.74m.), as shown in the print impression of an excerpt of the graphic representation of the original design (Figure 3). Its general dimensions (118x52,80x120) m. equal to (68x31x69) Venetian p., whereas the total length of the narrow-fronted housing unit (cell) is equal to 5 Venetian feet (or 4,5 vp.), while the internal width is 2,61m. equal to 1,5 vp. A similar standardization also appears in the individual elements of the facades etc. Another important observation is that, the typical dimension of 1.75 m. that Le Corbusier considered the average height

Proceedings

of man, coincides with one Venetian passo (1vp.) As a modulo, the dimensions of the human body, such as the height, its members' length, its step opening, along with any possible movements constitute the 'external measurement unit', according to which the architectural form is derived, since as a work of necessity it must also be fit for this purpose. As most of the architectural elements of the Castle of Folegandros are associated with this measurement unit, or multiples and submultiples of it, it is reasonable to reduce that the aesthetic and ergonomic correlation with the 'human scale' led to the successful creation of such a 'large-scale project'.

2.2 FOLEGANDROS. THE ARCHITECTURAL LANDSCAPE

Since 1988, the Castle has been characterized by the Ministry of Culture as a 'historic monument'

since "it is one of the few settlements that preserves unchanged its basic characteristics and many of its original elements". In 1973 the entire settlement of Folegandros was declared "a place of historical and special natural beauty that needs state protection" (Figure 4).

Figure 4. Folegandros. Chora's Castle, windmill and Monastery.

However, even in the case of the castle for which there was a prior design, the participation of the inhabitants obviously contributed to an adaptation of 'Western standards' to the facts of Greek nature. This specific location gave the castle excellent natural fortification and made it invulnerable and almost invisible to any sneaky pirate on its north side, as the stone wall was exposed without plastering, so as not to stand out. Due to their natural gray shade built from local stones, they acquired a single feeling with the rocky environment and integrated completely into the landscape, they seemed to grow up from the rocks. This evocative scene from the perspective of the Castle is complemented by the hill of Panagia that rises towards the NE, the monastery of the same name that stands out as a landmark, and a wide cobbled serpentine path that starts from almost the level of the castle and is marked with white lime color, following its ritual ascent (in a zig-zag), and ends up at the great temple of Panagia, with a quarter of an hour's walk. From there, it only takes a few minutes to reach the location '*Paliokastro*'. Furthermore, the location where the settlement was developed, is a hub where starts a second network of routes of vital importance that fed it and accommodated the provision of the necessary supplies for its daily survival. Ensuring the acquisition of raw materials, precious drinking water, communication with the little ports (*araxovolia*), and its direct connection with the production area in two nearby locations. The first, which used to be fertile and cultivated, stretches out on the slope, right below the church of Panagia. The second, which is located by the smooth hillside of Plaka, and stretches to the west, is the largest and most fertile. Over centuries of toil and endeavour, the farmers wisely shaped the land in stepped terraces, '*belts*' or '*stairs*', as per local linguistic expression. The relatively steep ground slope of about 50 degrees, descending to the sea, was smoothly shaped in small-surface embankments, which are flat small land sections held in place by dry stones that carefully follow the elevational curves of the ground. Thus, retaining the scarce soil and water, valuable arable land was created and provided for centuries on the rocky island, where the limited agricultural wealth of the Folegandrites, such as cereals, and particularly wheat, were produced. The two aforementioned slopes are the only well-cultivated areas in direct contact with the Chora in the eastern part of the island, as this part is rocky and completely devoid of vegetation with steep coastlines. The wide path, known as '*Kalderimi*', bordered by dry stone paddocks in 1930 (today

Proceedings

covered with asphalt) connects the castle of Chora with the other side of the island high up, where today is the agricultural settlement of 'Ano Mera'. This used to be a significant productive area which was also formed in terraces on either side of the ridge of the linear massif (Figure 5).

Ano Mera, in contrast to the densely built Chora, gives the impression of a strongly scattered settlement, as it essentially consists of clusters of rural individual buildings in the form of complexes where the traditional building of *'themonia'* predominates. These are small, self-contained agricultural units, which primarily include a basic dry-stone single room building, with other auxiliary spaces around it mainly for agricultural activities, such as: water tank, oven, cellar, winepress, a miniature vineyard and always a 'lemon house' (*lemonospito*).

Figure 5. Ano Mera. Chora is in second level.

The special geomorphology, the mild climate and the intensive daily tasks of the inhabitants in outdoor activities enabled these simple rural buildings to develop into important architectural entities. The island's lacy 'dry stone walling' landscape was built from end to end with skills and knowledge passed down through generations from masters to apprentices. It presents a remarkable example of traditional work of art, known as *'xerolithia'*, which is part of the identity of the Cyclades and has been included in the list of UNESCO's intangible cultural heritage since 2018.

2.3 THE EVOLUTION OF HABITATION IN THE SENCE OF 'ECONOMY'

Its capital Chora (or Folegandros) lies on the northern side of the island and today is constituted by two dissimilar entities: the Castle (Kastro) which is the most important cultural sight in the whole island, and the surrounding traditional settlement (Chorio), that gradually merges with the outlying houses and the surrounding landscape. Then the urban structure of the extension of Chora followed the general rules of the Castle and the architecture of the 'outside the walls' area, forming the subsequent traditional settlement, as it exists today. On the principle of the land being the primary resource for the 'family economy' to develop, people had to build their settlement again. "*Pholygandros boasts of only one town, which is walled, and called 'Inside', (μέσα) and of a colony outside this wall, of better-class houses, which is called 'Outside' (έξω) and a Pholygandriote knows of no other names but these*" Bent says in 1883-4. After all, the Castle, now a place of the aristocracy, continues to remain to this day its most interesting and qualitatively richest residential part. The islanders, previously fearful and entrenched within the walls of the castle, had acquired a certain way of life 'within limits'. A considerable amount of time had to go by until they shed their previous insecurity and their daily habits. Besides, considering that as a rule the residence was designed in a secluded form for defense purposes, it was made of solid walls without or very few but tiny windows, and a single entrance-exit, so that it could immediately be controlled in the case of malicious intruders, at the time that threatening dangers were in abundance. The fortified settlement of Kastro that once upon a time protected its inhabitants from foreign intruders (pirates) and was tantamount to a shell of life for their daily needs and activities, has transcended time to become a holiday resort attracting tourists (the new foreigners). Thus, being a valuable resource for its residents and visitors alike. Therefore, the fact that tourist traffic has increased exponentially on the island, while at the same time the said Castle is still an inhabited settlement, is somewhat concerning. The first general governing principle is the 'economy of space': transcribed to significantly reduced public space, demonstrated with narrow streets and platform instead of squares, in order to save space and provide as many houses as possible. The second governing principle was that the overall arrangement should be in such a way so that the residents could defend themselves effeciently but also had the opportunity to escape in

Proceedings

case the settlement was raided. Reliable bibliographic information states that until 1779 the inhabitants still lived inside the walled city (castle). The opinion holds that traditional architecture is identified with the anonymous and that its character has been produced by an evolutionary process that is lost in the passing centuries. However, it is argued that the Castle of Folegandros, which is the primary core of the settlement, is a product of concept design and planning of a relatively large-scale project that was built with bare hands. As is the case of other islands of the Cyclades (which have been studied, e.g. Antiparos) [5], here too it is a matter of official architecture which, however, anticipated wider social needs such as those of ordinary citizens alongside the ruling class. Starting from the volumetric soft integration of the whole with the elevational lines of the plateau morphology on the outcrop of the rock to the construction and morphology of the buildings themselves. Their main materials are stone and wood, with secondary lime, sand, clay soil for waterproofing and algae. All these materials as analyzed were present on the island (only pozzolan for waterproofing the cisterns seems to have been supplied from neighbouring Santorini). As for the wood, they used '*phides*', a type of wild cedar (from Cardiotissa), while there are testimonies that they used to be abundant on the island. The uniform perception in the organization of the space and by extension in the formation of the facades of the houses, was demonstrated with the use of similar materials and methods of construction, where the frequent repetition of similar elements further indicated a strong homogeneity. The first noticeable difference, however, is in the fact that the village (Chorio) consisted almost exclusively of single-storey buildings, as opposed to the predominantly two-storey Castle houses that (despite the later dilapidated ones -because of their destroyed first floors- mainly on the western side) dominated the castle. A consequence of this leading to the second key difference between the area of the settlement outside and inside the castle perimeter, was the lack of stairs to ascend to the upper floor. Nowadays, the quality of the public space 'inside' and 'outside' of the castle is high. The whitewashed facades of the buildings as a whole, further unify morphologically the settlement inside and outside the castle. On the single front of the street facades, the gaze stops at the stairs. Their repetitive intense volume emphasized the presence and austerity of the unitary building on the one hand, while on the other, they added a certain diversity and plasticity to the flat facades. Thus, a vigorous sculptural effect is resulting from the alternating sun-flooded and shaded surfaces forming in the dwellings' yards. Although in our times, the simple one-room dwelling, where the islanders used to rest from a day's work, does not support the modern needs, the streets of the settlement, however, that constituted the basic area of social life, as evidenced by their uniform width that extended up the stairs, convey to us today a magic and a poetic eternity. Regarding the relationship between public and private space, it appears that the original network of pedestrian streets, which are preserved to this day with the same layout and proportions inside the settlement, were then extended in the countryside outside the boundaries of the built-up settlement. The appropriation of public space was achieved by the residents through caring, cleaning and aesthetically upgrading it in common that further reinforced coexistence and social contact. It should be noted that even the passer-by (resident or visitor) is compelled to stop, to look, to 'co-negotiate' and to participate that further affirms him as a member of a 'collective organization'. He cannot pass as a mere observer. There is a process whereby we all see and are being seen, observe and being observed. By reversing the interpretation of the terms 'inside' and 'outside' in practice, the way people 'inter-communicate' with other people also changes, thus turning the architected space into a 'living theatrical stage' of continuous action, where the human scale and extroversion prevail. Needless to say that the way in which "the public space is used by the residents", as well as the way it is "maintained, cared for and supervised daily by the members of the local community, create the feeling for the passing visitor that is somehow inside an intimate outdoor large room" [6], rather than in an unfamiliar and impersonal space.

3. THE EVOLUTION OF CHORAS' SETTLEMENT – URBANITY CHANGES

To this day, the castle 'part of the landscape', that once dominated, carries the image of a densely populated settlement. Its three external elevations do not at all give the impression of a blind solid Castle defensive wall with a handful of tiny openings, such as small toxic hatches. Four centuries of Castle life have resulted in a multitude of reconstructions, additions and alterations. The adaptation of the original residence to contemporary living standards and the gradual elimination of the fear of pirate raids brought about changes such as the annexation of several units for increased living space, the addition of balconies, storerooms, sanitary areas, stairways, the increase of the number and size of openings, especially at the outer wall of the Castle. Significant changes were also brought about by the introduction of new uses, especially hotels and rooms for rent. The settlement as it was already formed until the end of the 20th century is characterized by the following urban planning units (Figure 6).

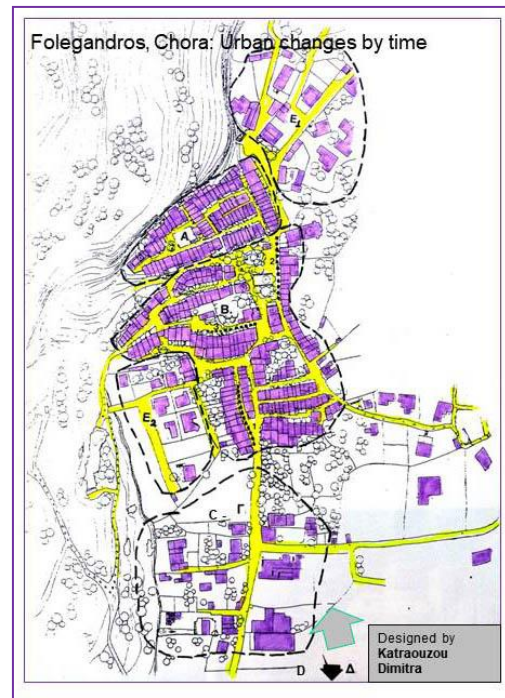

Figure 6. Chora's urban evolution-Units.

Figure 7. Chora. Themonies' area/D

The walled residential core of the Castle, where the two-storey volumes predominate is defined as area (A), while in the traditional settlement, that forms the main extension outside of Castro, defined as area (B), the single-storey buildings prevail by far. The third section, defined as area (C) mainly consists of mainly of the 19th century mansion type buildings, scattered within large properties along the road known as "Calderimi" in the direction of the Ano Mera settlement. The fourth section in the western hillside, defined as area (D), comprises scattered agricultural buildings, known as 'Themonies' (Figure 7).

The Castle area (A) remains the first in line of preserved authentic ensembles, followed by area (B) as the next best preserved section in terms of retaining its traditional identity. On the contrary half of the building stock in the third section that is area (C) comprises buildings that alter its traditional character. The last section which is defined area E (1&2) comprises buildings designed as hotel establishments,. As they exhibit a proportionally dominant effect, any association with the traditional character of the other sections of the settlement is unequivocally compromised. It is noteworthy that, until thirty years ago, the (E1) area had not been built, while at the base of the hill only the school building stood out. Towards the cliff the towering figure of a ruined lonely windmill has been standing for centuries as a landmark in the wider stony landscape. The settlement's preservation in the original low tones, was required to be preserved at all costs, as means to safeguard the superiority of the Castle's dominance. Including the wider projection of the characteristic architectural buildings and their defining features (e.g. skyline) such as the domes of the churches above the roofs of the houses and the modern buildings until they recede gently into the relief of the built environment. However, the transformation of many rural buildings from 'themonies' (an integral part of the remarkable dry-stone 'xerolithic' landscape of the island), into 'tourist hotel complexes' may be the biggest upheaval

Proceedings

of its mild image (unit D). Furthermore, the overall disproportionate expansion of the settlement with the addition of exclusive use hotels buildings or luxury homes (villas), completely changed the calm and balanced physiognomy of the settlement. The construction of private use swimming pools in houses and hotels, combined with landscaping water-loving plants, not only has severely comprised the ambience of the landscape physiognomy of the landscape exacerbated the problem of water scarcity on the already arid island.

3.1 PROTECTION – PROGRESS – SUSTAINABILITY

Nowadays, these issues often remain intractable, not only for Folegandros, but also for other islands' cultural sites. The balance between the morphological variety and the absolute austerity of the architecture of Folegandros Castle is the key to the harmony between form and function. Therefore, if only one house per height had been saved or restored to its original layout, it would function as a museum element of the Castle, further saving its historical character and providing a respect incentive for its users. Fortunately, the mild tourism development of the previous decades has allowed the island to maintain most of its character and physiognomy to this day, so that even in the case of occurrence of the abovementioned concerns, they would still be manageable [7&8]. The 'carrying capacity' of a place is an important and finite evaluation methodology, especially concerning tourism, as it is defined as the "potential ability to cope with needs, demands or pressures without affecting its cultural values, its natural resources and in general, the possibility of its sustainability" [9]

The unprecedented construction of new buildings in the last decade in the periphery of the settlement's limits, in order to meet accommodation demands fueled by hypertourism, could be disastrous if construction continues at the same rate in the future (Figure 8 & 9). Especially in the sensitive area of Plaka -because of its panoramic location- such development would be particularly catastrophic for the entire settlement. It should be noted that the main danger for Chora is due to a potential increase on the number of tourists that would affect its appearance, not only morphologically but also by undermining its succeeded sense of 'urbanism' which generates this 'pure and simple type of habitation'!

Figure 8. Chora in two times.

Figure 9. Chora's explosion.

Arguably, the question of how we would associate ourselves with the relevant debate between the residents and the tourists could reasonable arise. In other words, if we were requested to take a stand to support or not, new construction that would be dictated by market demands. As a consequence, our pure and simple answer would be manifested by our commitment to preserve the natural and cultural quality of the landscape, through our political vigilance and participation based on the objective of the sustainable development of the island [10]-not only for the present but also for the future generations of residents and tourists alike. The protection and preservation policies should be focused on two objectives: i) the non-disturbance of the unique and relatively well-preserved local environment including its sustainable development by the current development model of the island, ii) the protection of the residential cell, against the alteration of its character and its aesthetics, from the rapid, out-of-scale and anarchic construction due to 'overtourism'. The basic idea is that, through

Proceedings

the revival of the network of old paths the space itself can tell its story, which will be gradually revealed through the relationship between the stone-built structures of the architectural heritage and the landscape that gives birth to them, as in an '*open air ecomuseum of architectural heritage*', with 'outdoor exhibits' and through an 'open debate' between the public: tourists and residents. To promote cultural tourism with the concept of architectural tourism, it is necessary to contact and inform visitors the motto of the place might be "*island without car*" as a walking destination. The promotion of alternative forms of tourism such as 'agrotourism' perhaps is the only way to protect the island's identity! [11]

4. CONCLUSION

The guiding principle of collectivism that the traditional society of the inhabitants had developed, functioned protectively for the island, as it was based on the common benefit and the respect for the place itself including its built environment and the common good. Measures such as protection and guarding that could be introduced by the competent public authorities are necessary now, as was previously done by the residents themselves. In the interest of the current and future residents, the love and care of the inhabitants for Folegandros, as well as a high sense of responsibility for its future, is required above all. Its 'unique' architectural character is an element of special cultural, environmental and economic value, and a point of reference for its tourist promotion. Heritage preservation and urban development under no circumstances should be considered contradictory or incompatible.

Extended abstract

Memories are gradually disappearing, and time took its toll on Nicosia Airport, a unique example of Modernist Aviation Architecture.

As it is left abandoned for nearly half a century due to political circumstances, the building is quietly fading away in the landscape, in the buffer zone, in the outskirts of the Cypriot capital.

Built in 1968, the Airport was the main arterial connection to the island for less than a decade, when it was interrupted by the Turkish invasion in 1974. Despite its abandonment, the building has survived untouched, and its architectural and structural integrity remains intact.

However, the memories of the place are fading away; the people who remember it are decreasing and the political negotiations for resolution seem to be moving further apart. Its fate is uncertain.

This paper argues that this 20th century building has unique architectural, cultural, and historical value. Its design concept and architectural details captured the essence of Mediterranean vernacular architecture. Its tangible and intangible cultural heritage is in danger of disappearing and an urgent endeavour is required from both communities, Greek Cypriot, and Turkish Cypriot to enhance and revitalises its significance. This shared heritage has the potential to be sustainably developed and become a hub of shared memories for both communities. A carefully studied proposal for its adaptive reuse and restoration could be a unique pilot project that could reignite viable negotiations of a 50-year political uncertainty. The study focuses to capturing the memories, 'mneme', and making an attend to provide some suggestions for its adaptive reuse, considering UNESCO'S SDG16.

The study's methodology (interviews, etc) aims to unearth memories of Cypriots from Greek Cypriots, and Turkish Cypriots. Dwindle memories, could be awakened, and recorded for the current and next generation. The study will aim to initiate the creation of an archive that could be treasured by both communities.

The paper argues that in the current climate, where relationships between the two communities are softened, it is timely to open a pathway for an initial study for a future sustainable project that would focus on People, and Place, and enhance a sense of Belonging.

Abstract

Nestled in the Appia Antica Archaeological Park, the settlement of Santa Maria delle Mole is characterized as a 'dormitory city' on the southern outskirts of Rome. Its urban growth has developed in an uncontrolled speculation, neglecting its innate connection to the surrounding landscape, which represents one of Rome's main cultural asset. Since the 1970s, efforts to curb rampant building have been driven primarily by its environmental and archaeological significance. Only in 2020, with the annexation of the area to the Park territories, did the incessant building come to a halt, ushering in a new era for archaeological conservation and enhancement.

This article would explore the methodological approach that harmonizes archaeological analysis with landscape and urban quality assessment. It would also explore the complexities of the historical identity of Mugillae's imagery and outlines how this process has informed design strategies and narratives for the enhancement of the site. In this line, it aims to outline a programme to revitalize and promote community engagement through a holistic and sustainable approach.

Keywords: *heritage design; mapping; archaeological landscape; memory; heritage communities*

1. INTRODUCTION

The Appia Antica Archaeological Park is a national heritage site that traverses the southern half of the Italian peninsula along the route built by Appius Claudius Caecus to advance troops towards the south and the Greek world. Stretching alongside Rome's expansion, it, together with the Via Egnatia, which crosses the northern Greek peninsula, formed the direct connection between the two capitals of the Roman Empire, Rome and Constantinople. The "Regina Viarum," as it was called in ancient times, was only recognized a year ago with the prestigious designation of UNESCO World Heritage, making it the only preserved Roman road to enter the list of sites.

Rediscovered and retraced by young Europeans traveling in the 1700s and 1800s during the *Grand Tour* era, this road has been a source of inspiration as material and intangible infrastructure for the artistic and intellectual movement in which today's European Culture has its roots anchored. The imagery of the Roman countryside is known to all, inhabited equally by the ancient ruins, maritime pines, and agricultural-pastoral activities of a world both submerged and dormant. The aesthetic value and cultural potential of this landscape, releases to be rediscovered and relived.

For Rome, the Appian Way represents the umbilical cord that leads to the origin of the city, which finds its conceptual origins in the communities settled on Monte Albano since protohistory and still today constitutes "the backbone" of Italy's capital city. As such in ancient times - yet today - this reality takes the form of an urbanistic *decalage* of the urban settlement fabric that leaves room for a territorial reality and its productive, agricultural and industrial functions, crossed by communication routes and waterways, limits and connectors of human settlement.

During Rome's expansion phase, this reality was challenged by land consumption for urban expansion amid intense speculation, also responding to the housing emergency characterizing the mid-20th century. However, during the same years, a movement of intellectuals, journalists, politicians, archaeologists and urban planners forced into the debate the issue of defending the historic and

archaeological landscape from overbuilding. By infiltrating their perspective and interest into the dynamics of urban planning, would lead to the creation of the *Appia Antica Archaeological Park* and the *Castelli Romani Regional Nature Park*.

In this context, those satellite urban centers that arise in the area were motivated from the beginning by a twofold force. On the one hand, building speculation, which even upon the return of the housing emergency, did not stop the consumption of land, and on the other hand, the newborn city communities began to suffer from the absence of public spaces and of a urban planification attentive to the values rooted in the surrounding territory and landscape. Starting from the 1970s, a period of assemblies, disputes, and struggles began, with the communities of the small inhabited centers created within the new Archaeological and Natural Park leading the defense of the territory, both in its cultural and environmental aspects.

One of these disputes concerns the site of Mugillae, an urban void threatened by land speculation, situated between the settlement of Santa Maria delle Mole in the municipality of Marino and the agricultural estates forming a green belt between the Appia Antica Archaeological Park and the Castelli Romani Regional Natural Park. This piece of land -and others-, which constitute a strategic strip of territory to prevent overbuilding portions which are in fact affected by the same cultural and environmental values as the landscape context, and thus in fact more desirable in the real estate annuity arena, were annexed in 2020. This major achievement, acquired on paper, nevertheless needed timely planning that could *de facto* integrate urbanized and natural realities in the area.

Figure 1. Map of the Appia Antica Archaeological Park and the most recent annexation - drawing from the authors

In the same year the municipality of Marino launched in collaboration with the Facoltà di Architettura della Sapienza Università di Roma -already involved in the problematic of the area - a series of workshops carried out by the students of the International Master ALA (Architecture, Landscape, Archaeology) for the enhancement of four key spots for the integration of those areas attached to the

Proceedings

reality of the Archaeological and Natural Park and in direct contact with the urbanized settlement reality [1]. One of these key points was the Mugillae site, which was the subject of intense interdisciplinary activity to the development of an enhancement project aimed to safeguard the heritage still threatened by the expansionist desires of real estate agents and, above all, to return it to the legacy communities of residents.

2. MUGILLAE TODAY AND THE MISSING ROMAN CITY

Santa Maria delle Mole is a neighborhood in the Municipality of Marino, in the Region of Lazio. Has a population of 25.000 inhabitants (2011), a total area of 16.000m² public green area, and a total projected build area of 180 Project area 180.000m². It means that the actual situation leads to a 0,64m² per person, way less than the recommendation by the World Health organization (a minimum of 9m² per person), or by the Italian Planning Law (a minimum of 18m² per person). The lack of public space has been one of the first and most important demands of the newly formed community, organized into a dense network of associations dedicated to various territorial defense themes.

The lack of public space was in fact one of the first and most important claims of the newly formed city community organized into a dense network of associations dedicated to a variety of land defense issues. This condition led to the emergence of numerous active citizenship projects, which very quickly identified the claiming of undeveloped urban parcels as the first option for solving the problem. To preserve these spaces for public use and avoid further construction, it was necessary to impose a legal constraint on real estate speculation. Given the significant presence of archaeological assets of various epochs and types in the surrounding area, which had already served as a limit to building expansion, the citizens' committees soon recognized the surrounding archaeological landscape as a common resource. During this overdevelopment, the local community supported the preservation of the archaeological heritage, seeing it as an opportunity to reclaim public spaces and to protect and enhance not already built areas.

Thus, many initiatives were born, dedicated to discovering the histories of the territory and the areas surrounding Santa Maria delle Mole, to verify and search for assets that could testify to the public nature of the area and redefine new urban and landscape functions. The activists' initiatives were met with broader involvement from a citizenry that, initially a result of the capital's overpopulation, was now seeking its own community identity [2].

Figure 2. Manifestation against the building speculation - november 2019 - pictures of the authors

At the same time, a shared sense of community, rootedness, and collective identity blossomed, intertwined with the notion of an ancient city, Mugillae, said to have existed nearby. According to the topographer Nibby in the 19th century, the archaic city of Mugillae was located in that part of the territory, from which the area's toponym derives. This town was founded between the 4th and 3rd centuries BC, situated between Santa Maria delle Mole and Falcognana. The city was a fortified

Proceedings

military outpost defended by square tufa walls, strategically located near the border with the territory of the Latins, between today's Via Ardeatina and Via Appia. It was the first city destroyed by the early expansion of Rome, and since then, few ancient sources about its existence have animated historical research to identify it on the ground.

Considering the geographical configuration of the small hill facing the Appian Way, Nibby hypothetically located the ancient city in this strategic position on his famous map in the 19th century. Even though archaeological surveys in the area have not proven the presence of the ancient city, the community has a strongly rooted perception of its bond with a common past as a source of identity. This period of contention stimulated the formation of an imagined historical identity linked with the legacy of this ancient city.

Nowadays, the area holds high landscape value, acting as a hinge between the Appia Antica Park and the Roman Campagna and containing only archaeological structures related to the presence of a villa, considering the Roman cistern still preserved in the area. In the community's imagination, starting from the hypothesis of the city's location of Mugillae, promoted by historians and antique dealers, the existence of an archaic city became rooted in common perception. This belief has established itself in historical and geographical cartography, becoming part of the toponymy and collective imagination.

None of the investigations conducted has been able to support this hypothesis, yet in recent developments, this place has become a symbolic area due to building speculation and is considered a public space belonging to the entire community. This function represents an unprecedented patrimony of values that deserves not to be overlooked. Among the enhancement strategies, it offers an excellent opportunity to educate about the distinction between material and immaterial values linked to the past and, in terms of planning, a design of the public space that provides an opportunity to socialize experiences and political content of communal life.

The site, assumed to have been the location of Mugillae more than two centuries ago, presents itself today as an urban void, preserving a Roman cistern within it, amidst a mixture of urban space, archaeological remains, and agricultural landscapes. Although there is no direct archaeological evidence of the ancient city, a comprehensive mapping of the non-monumental traces found before and during urban expansion has been instrumental in bringing the area's neglected archaeological heritage to light. This mapping, which details the typology, chronology, and functional attributes of these traces, serves as a fundamental reference for subsequent design proposals.

Figure 3. map of the area evidencing the urban void, the connection to the Appian way and the mixed urban pattern - drawing by the authors

3. METODOLOGICAL FRAMEWORK: MAPPING BORDERS, MOBILITY AND IDENTITY

3.1 ASSIGNEMENT:

The so-called site of Mugillae in Santa Maria delle Mole, located in close proximity to the primary historical route, the Appian Way, finds itself as a void between two conflicting worlds. On one side lies the agro-pastures of traditional rural life, and on the other, the rapid spread of concrete developments that have largely neglected the provision of open public and green spaces for the community. This oversight has been vehemently voiced by the locals through protests, a reality we considered extremely important to take into account in our project proposal. The power of these protests lay in their defense of the area under the principle of protecting the narrative and values of its history as a basis of an identity in process of conception.

Our task as a team was to understand this site's unique position, both in the contemporary and historic world, and the community's needs, integrating it into the broader archaeological park and enhancing its value as a public space. The site, embedded within the urban fabric, has the potential to serve as a cornerstone for not only integrating the area into the archaeological park but also fostering a sense of unity within the community. This potential is recognized by the community, who have fought for the site's status as a public space, highlighting the presence of a monumental Roman-era cistern and its multi-scalar relation with the surrounding landscape.

Figure 3. Roman-era cistern - picture of the authors

We carried out site surveys and mappings activities to document the area's historical and actual state, both material, immaterial, imagined and real characteristics and its historical value and significance. These activities were not only based on abstract processes unanchored from the terrain, such as laboratory activities, in the classroom away from the site, but also involved a recognition of the site through the tour. Walking, discovering, recognizing, getting lost, changing perspective, seeing the unseen and learning from that as a necessary stage for a deep apprehension of the site. This complex process also included assembling historical records and conducting interviews with local residents and community leaders to understand their perspectives and needs.

Social interactions were crucial in shaping our understanding of the site's importance and the community's desires for its future. These sessions provided a platform for residents to voice their concerns, ensuring their input to be a direct influence on the design process. Through these engagements, we aimed to bridge the gap between the community's historical consciousness and modern urban needs.

Our primary design goal was to transform the site into a vibrant public space that honors its historical significance while addressing the current lack of green spaces in the town. The design aimed to enhance the area's historical value, making it a focal point for cultural and social activities, thus promoting a deeper connection between residents and their heritage.

The project was not only supported by local associations but also by institutions that commissioned the project. These institutions hoped to use the project to promote a broader cultural action capable of countering the social degradation associated with the phenomenon of commuting to Rome. This commuting pattern has turned the town into a "dormitory city," where residents sleep but do not engage in significant social or cultural activities locally.

In summary, the need to integrate Mugillae into the archaeological park and the community's daily life through a combination of historical research, community engagement, and design workshops, lead to create a space which reflect the community's identity and needs, providing a meaningful public space that celebrates the past while addressing contemporary urban challenges.

3.2 THEORETICAL APPROACH:

Cities are the outcome of human activity, sometimes regulated and sometimes improvised. Mankind has produced in them objects, artifacts, supports, related to the specificities of human life. With the use and construction of cisterns or other kinds of systems for water harvesting and canals for its distribution, roads, bridges, new crop systems for food production, etc., we have been constantly leaving traces in the territory and landscape. All these interactions between people and their territory are mapped. ‘Mapping’ provides a methodological contribution to archaeological interpretation as well as to design, both from a conceptual and practical point of view. The agency of mapping is positioned as a basic tool for working from a critical perspective of the archaeological/urban/natural/landscape/architectural relationships. Abstracting from the conditions that may appear at first sight for their interpretation, ‘mapping’ stands as a trigger of new interpretations for potential application in project situations where there is a dialogue between past and present.

Water moves, and while moving it alters the territory. Sometimes in a drastic and other in subtle ways, when done through man's hand, the changes tend to acquire visibility of an almost immediate tenor in relation to the (usual) times of nature. Water probably is the element that has the greatest impact on the transformations of the landscape, history and territory. A river, like a border, can be either what keeps us apart or what brings us together. On a time plane, the register of water could help to create bonds with the past. By understanding water as an element that enables transformations, we can determine tools for designing and interpreting that allow us to rethink our relationship with water as a foundational element for the development of civilizations.

Our landscapes are undoubtedly fundamental elements of our collective memories. We can define it as the platform where our history and culture are kept. We even preserve those landscapes that no longer exist through oral and written narratives where landscape (remembered, imagined) is the support of the story itself. Reconsidering history as a part of our daily lives, linking it to our heritage and memories through material culture, creates a platform for understanding the complexity of our landscapes. The origin of cities has been linked to a great extent to singular geographic conditions. Over each city’ particular landscape, an overlapping of infrastructural elements that have produced over time variations in the original territory.

Humanity is constantly transforming its territory. We produce new geographies, living landscapes in constant change that are the result of superimpositions, hybridizations and intertwining of histories. Therefore, it is necessary to have new approaches to their interpretation, to consider the city, its visible and invisible history, the territory in which it is inserted and the potential imagined futures in an integrated whole, and not as a sequence of disjointed elements [3].

Mapping a site can trigger countless glances from/ towards it. It is in its operative character that it establishes clear and varied possibilities: “Based on the concrete constructions of reality made by the map, not only new conceptions of the cartographed reality open up, but also new possibilities to transform it.”. The cartographic practice undoubtedly requires walking, roaming, creating a route so as to absorb the concrete data of each site and transform them into information. Information that converges into tools that enable new approaches to the design processes of projects aimed to transform the human milieu. As a creative practice, *mapping* goes beyond the condition of reproduction or representation of what exists, extending to places where the discovery of unknown or unimagined realities allows the elaboration of new ideas about the territory. “Thus, mapping unfolds potential; it re-makes territory over and over again, each time with new and diverse

consequences.”[4]. *Mapping* requires an intentional, analytical and critical view of territory and landscape.

“The map does not reproduce an unconscious closed in upon itself; it constructs the unconscious. It fosters connections between fields, the removal of blockages on bodies without organs, the maximum opening of bodies without organs onto a plane of consistency.

(...) The map is open and connectable in all of its dimensions; it is detachable, reversible, susceptible to constant modification.”[5]

A map can be significantly more than a simple two-dimensional object. While maps stimulate our perception of the environment in which we find ourselves, they contribute to preserve, interpret and enhance the memory of the sites. In this way, we believe it is nourishing for the archaeological practice linked to the architecture/landscape project to approach the joint work from the perspective of landscape cartography. Inquiring into what exists, to discover the past and therefore imagine what is yet to come.

3.3 FROM THEORIES TO PRACTICE:

By considering our theoretical approach, and by prioritizing in our project the conceptual significance of the cistern as the sole archaeological presence in the area, underlined the importance of water in the function of the site and its historical connection to villa culture. This connection provided a basis for how such activities could relate people to the territory, justifying our design proposal.

The information collected through mapping, pinpointed both real and hypothetical archaeological data and elements within the area, also possible paths and activities to be held in the site. Related to those historical elements considered hypothetical, two aspects were taken into account: the collective memory of the community, which has been significantly influenced by the urban and territorial policies affecting Santa Maria delle Mole, and the potential to conduct preventive archaeological investigations during the project's implementation to verify these hypotheses. Through mapping, a possible paths system was defined, formulating routes based on scientific foundations to trace the ancient roads in the area.

Our goal was to, by using and supporting historical research and analysis, inform the design process in diverse scales. We aimed to highlight the productive vocation of the territory and the monuments that trace its continuity and contextualize their transformations over time. Using the traces of the antique landscape and the use of land identified on the maps, both in a conceptual and material foundation -a "device"- lead to develop the architectural design narrative. This also involves preserving materials and on-site historic traces to ensure their transmission to future generations, hoping they will become part of increasingly valid systems of understanding and value.

Informed by this process, we identified the need for a city identity, which we translated into design through the concept of the Roman *limitatio*, creating borders and thus defining the city. Also, the need to anchor this identity to tangible heritage, consisting of the cistern, symbolizing the villa and its interaction with the territory through collective activities. Leading us to create the Eco Museum, which allowed us to achieve different goals: provide new and enhanced public spaces, and link city life with the surrounding territory to promote inclusion, sustainability, memory, and a tool to bond ancient and contemporary narratives.

The mixed use of drawings, models, photography, social interaction, written register, collages, as a whole synthesized on *mapping* as a tool and device, played a crucial role in this process. It detailed the typology, chronology, and functional attributes of the traces found, serving as a fundamental reference for subsequent design proposals. This comprehensive understanding of the site enabled us

to integrate historical research with contemporary planning needs, ensuring that our intervention would be deeply rooted in the cultural and historical fabric of the area.

By emphasizing the interaction between the community and its historical landscape, our project aimed to foster a stronger sense of place and identity. The Eco Museum, as a central feature of our design, was conceived not only as a repository of historical artifacts but also as a living space where the community could engage with its heritage through collective activities. This approach aligned with broader objectives of promoting cultural heritage, sustainability, and community inclusion, positioning our project as a model for integrating historical preservation with modern urban development.

4. MAPPING AS A DEVICE: DOCUMENTING, INTERPRETING, DESIGNING

Having chosen as the scale of preliminary observation analysis the territorial scale (imposed by the context of the oldest part of the Appia Park, in the municipality of Marino, where the area is located, such analysis has taken into account the previous field surveys available from bibliographic sources, the study of remote images, in depth diagnoses[6]; analysis of historical, cartographic and archival and toponomastic documentation[7]; analysis of ancient sources[8]; geomorphological studies[9]; ethnoarchaeological and anthropological investigations[10]; excavations on sites of particular importance in the perspective of the reconstruction of the landscapes in their context.

The Roman-era cistern in the area served as both a sign and document underlying the proposed integration into the archaeological park, enabling the allocation of part of the town to public space in line with recent urban policies. During the design phase, direct analysis and surveys focused on this element, evaluating aspects related to its conservation and its symbolic role in the project.

The information was collected in an archaeological map that was able to pin point on the area (and therefore able to be interpolated with the other analyzes that had been done) both real archaeological data and those of a hypothetical nature. The latter took in consideration two things: taking into account the memory of the community, which in the specific case of our area have received a powerful updating in contrast to the urban and territorial policies that have affected the town of Santa Maria delle Mole; and the possibility during the realization of the project to carry out a series of preventive archaeological investigations aimed to verify these hypotheses or in the case of the road system in the territory they tried to formulate using a scientific basis and trace the road in the area [11].

The realization of an interpretative map of the archaeological vocation of the territory, interpolated to the others created to investigate the characteristics of the current landscape, revealed a scenario that shows agricultural and productive use of the territory as a distinctive element that has continued through time.

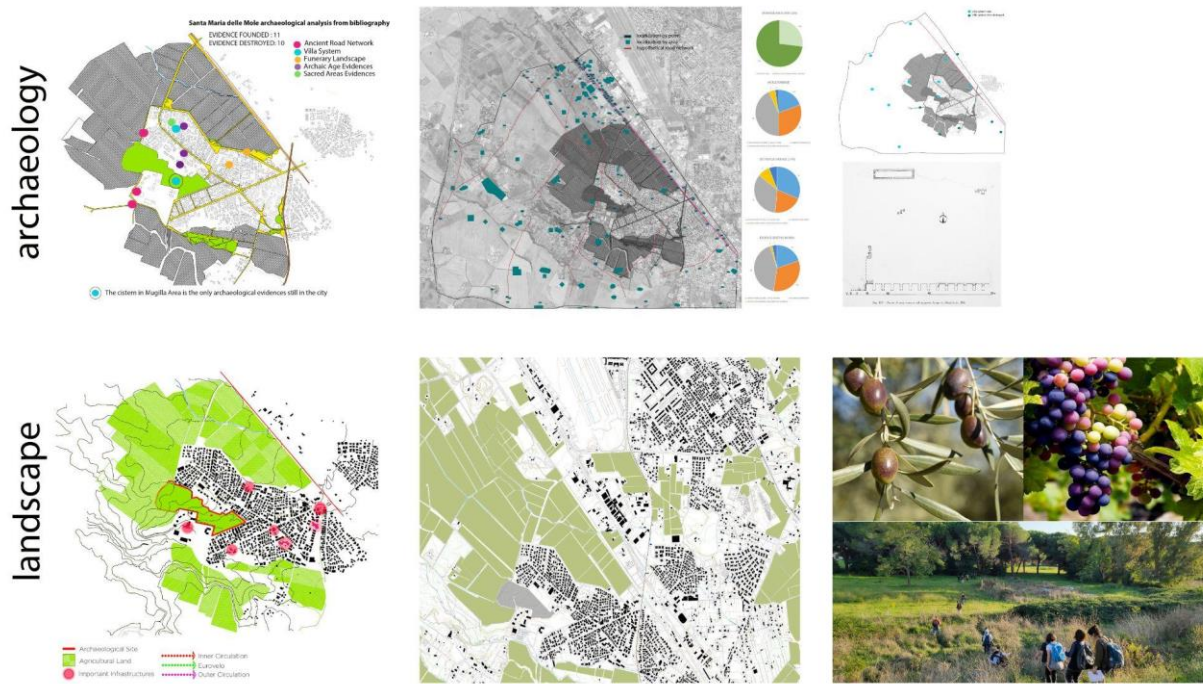

Figure 4. Archaeological and landscape maps - drawing by the authors

The cognitive process therefore led us to define the project strategy and suggested us to interpret the assigned area, showing evidence of the agricultural use of the territory, as a fundamental junction capable of relating the urban landscape and that of the surrounding area characterized by agricultural use. This made sense since the area is in a marginal position compared to the built-up area; the extension of the area to the entire perimeter of the urban center which has the same characteristics of "marginality" allows an organic action with a view to connecting the entire city fabric to the surrounding landscape, by infiltrating the layout of public spaces.

5. THE ENHANCEMENT PROJECT

Developing a project on this peculiar site, meant to address the complexity of an area characterized by an undefined perimeter and heterogeneous features. The material heritage of the community, often not monumental, were interpreted as part of complex historical frames in the evolution of the Appia park landscape and are enhanced through the creation of a network of paths and activities thus narratives, according to the archeological interpretation, leading to the historical reading of the landscape.

Marino's urban shape made no contribution to us, since it was not the result of urban planning, but the outcome of building speculation. The proposal did not seem to be a single space with an delimited programme, but rather an intervention on a territorial scale that would help the inhabitants to build their own cultural identity. The need to create, strengthen, and unite the community lacked a unifying element that could function as a social amalgam. From this project we seek to highlight those characteristics of the territory, the landscape and the history in such a way that they are positioned as a platform on which to build identity, i.e., community. With these goals in mind, the urban void had to be able to generate broader dynamics, oriented not only towards the urban front of the constructed area, but also towards the surrounding landscape of the archaeological park. Numerous analyses, both on the maps and on the field, confirmed our first impression: it was fundamental to identify a new compositional logic that would reverberate a cultural dimension throughout the city.

The composition of our group, as varied disciplinarily as culturally, allowed us to develop a work based not on material memory, which in fact had proved to be fragmented and not referable to an ancient urban dimension, but on the intangible heritage that the population shared. How to find in this an infrastructure to justify useful forms or strategies in the assigned area?

We started various mapping activities about the boundaries of the town and in relation to the park: all the streets were dead ends and the threshold with the park fenced off. So we realized that it was a city without a border and therefore we imagined a ring, which could be structured analogically to a Roman border. We then added to this structure the need for devices that could materially and immaterially define the border and tell the memory of the sites destroyed by speculation.

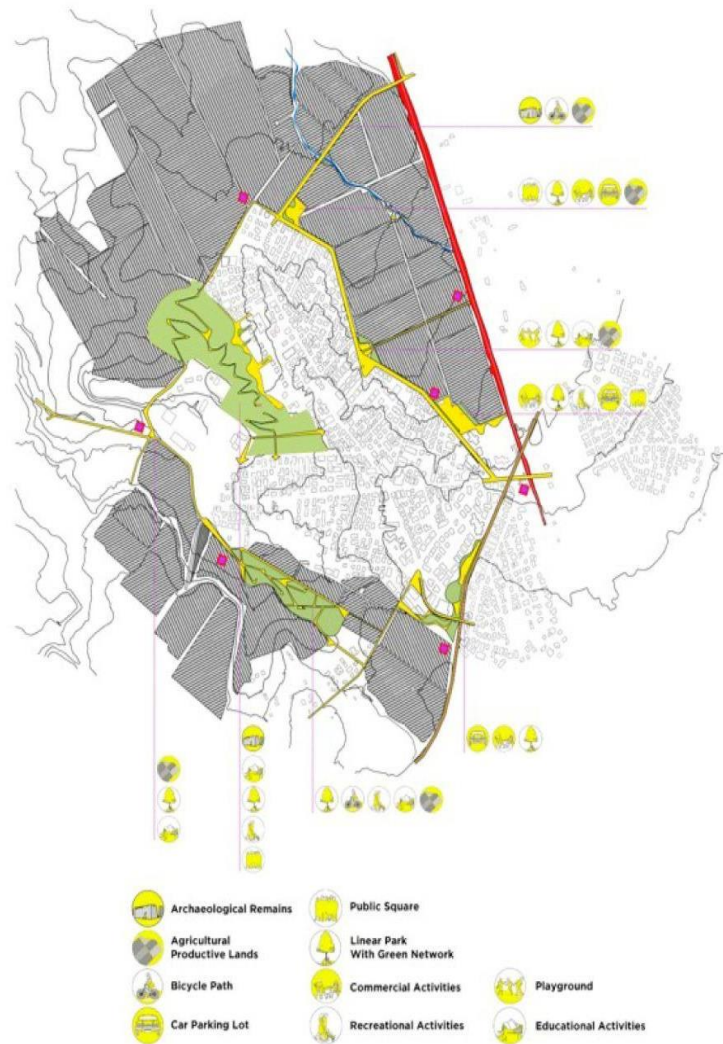

Figure 5. Masterplan of intervention, the idea of the Ring - drawing by the authors

François Hartog [12] explains perfectly how the vision of *historia magistra vitae* has been since Homeric times a way of declaring the present through the past by the use of an *exemplum*. It is with this philosophy that we looked at the structure of the territory in the Roman world: how was the urban boundary managed in relation to the context surrounding the city?

Thinking back to the Roman strategy, we have organized space according to the gradual transition that at least in part must have affected the area of Santa Maria della Mole. The parallelism proposed to define the border landscape of urban centers in ritual practices (and therefore of Roman social and

spatial management) of the *limitatio*: an ancient strategy to design the “borderscape”, flagged by terminus (physical landmark of the borders line). In this regard, the surviving monument at the basis of the agricultural use of the territory in ancient times could qualify itself (through appropriate design techniques) as a terminus/landmark of the past, able to disclose its meaning, making them temporal kaleidoscopes of signs in the landscape. From the *urbis* to the *orbis*, without new volumetries but with only the structuralisation and hierarchization of spaces so that the void is not occupied by a "new" autonomous element, tending towards the spectacularization of itself [13]. This structure has allowed us to give a directional adjective to a space that lacked it, also defining a modulation which leads to a greater awareness of the path by the user [14]. The idea is to involve the whole community within a public space that is conceived as a border: intended as a permeable membrane, a point and a moment of passage that requires to be managed through gradual experience that is able to offer the cognitive tools necessary to access one condition to another. With this motivation, it was decided to divide the area into functional areas, each of which constitutes a place and an educational moment that allows a multidimensional experience aimed at understanding the values contained in the landscape.

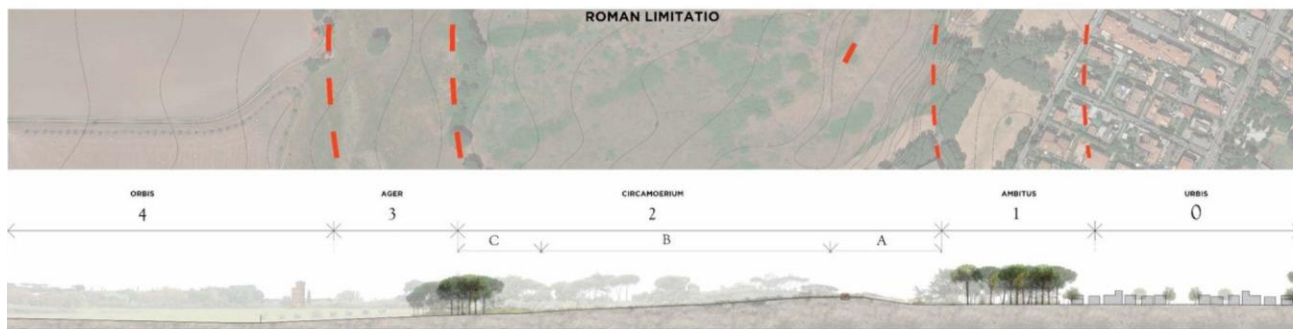

Figure 6. representation of the roman limitation on the area - drawing by the authors

Thus, the *ambitus* (public use, not built area) in a contemporary key became the park with an urban character, equipped primarily for a neighborhood use, with supplies for sports or spaces for everyday use: a large square and several sports fields, a watercourse and green areas with tall pine trees. We removed the border of the fence and allowed open access into the park leading into the archaeological site as the *Ambitus*, creating playgrounds, pavilions and seating spaces under the naturally abundant *Pinus* trees, where social activities such as festivals, farmer markets and Christmas markets can function.

Assuming the natural boundary identified by a small rise in elevation, we defined the next area, or the *circamoerium*: location for holy sanctuaries related with educational activities. In this area, at the top of the small rise, stands the only archaeological evidence that has been reconstructed as a cistern. In our vision for Marino, the *circamoerium* is composed of three sub-categories: we used the natural slope leading up to the cistern as an embedded theater where public gatherings for social or political demonstrations can take place. In conjunction to the introduction to the first historical pavilion that informs the visitor about the myth of *Mugillae* and the villa, this entire section with the cistern as the core articulates as the *circaemoerium*. From here onwards into the *Ager*, a trail raised over the revived agricultural field leads through a series of cultivation-specific pavilions oriented in organic positions towards the cultivations they have been designated for. These range from the “Olive Pavilion”, the “Grape Pavilion”, to the “Urban Crops Pavilion”, where not only ancient agricultural tools and historical information are displayed, but active educational activities with the cultivations can occur under a public paradigm. The end of this trail leads to a local winery/restaurant that processes the production of the field and can generate a socio-cultural space between producers and consumers. The tail of this trail has been integrated into the Green Ring and can connect back to the Appia Way, tying the intervention into a cohesive, holistic system of connections. These cultivations are in fact

Proceedings

the intangible component of the local heritage, an indissoluble link with the past. The position of the cistern is decisive and by no means accidental, it is there so that it could irrigate the hillside, so we decided to restore its original landscape function, but in its contemporary configuration it becomes an urban vegetable garden and not a unit with an agricultural-productive character. This ring provides a more direct connection to the prominent Appia Antica, that is also integrated with the renowned Eurovelo biking trail across Europe reaching the *orbis* (the external world) [15].

The proposed eco-museum entity is therefore not an exact volume or perimeter, but a series of spaces and activities that narrate not only a production cycle but the tradition of a place with roots that do not refer to an artefact or a specific event, but to the identity that the inhabitants have chosen. Even the path traced, although it has its own direction, can be overturned or fragmented: all the areas described retain their own specificity and autonomy, while participating in the narrative of a collective space. Quoting Ferlenga [16] again, we can say that the meaning of the place has not been exhausted over the centuries, so much so that it continues to shape spaces and stories.

The stories are also echoed in some of the landmarks we have designed: just as in ancient times there were *termina*, we have re-elaborated the model into landmarks that can constellate the landscape, both urban and rural. We have a reinterpretation of the ancient *Terminus*, a concept in which a God, in the form of stones, defined the limit of the space, was carried out as landmarks in the shape of Totems. Taking this as a conceptual basis, we set a series of landmarks located along the pathways in which the archeological evidence spread in the area were curated as part of its musealization in the open field. Small obelisks with a didactic function that offer a resting place with seats but also surfaces to display plans and data useful for understanding the eco-museum, with information on history of the site, they become the voice of 125 destroyed archaeological sites in the vicinity (from roads to villas, funerary monuments to sacred).

Thus, we offer new collective spaces, suitable for the most diverse users, local as well as external. Cultural heritage is linked to territory and memory, which act as vectors of identity. Commemoration no longer becomes an act addressed to the past, to absence, but a moment of reflection on the present in which one's identity is reworked and reaffirmed. Memory no longer has the form of the ancient but conquers a place: a place of memory.

The lack of a perfectly delineated form or image of the past has allowed us to make this place more real and less idealised, definitively entering the dimension of local identity. Paolo Zermani's words are useful here to describe this approach: 'the journey into the immaterial does not mean escaping from the front of reality but taking on an inner material endowed with sensitivity' [17].

Our idea constitute an interesting experiment within the experiences of public archeology, incorporating in the installation's appropriate strategies for the realization of happenings and temporary configurations of the spaces. The "dynamic process for intervention phases" strategy could therefore qualify as an elastic tool for the progressive systematization of knowledge and places within the park.

Places of Multiple Identities

Extended abstract

Throughout history cities have been regarded as places bestowing identity that ideally transcends ethnic and cultural differences and social divisions. But in recent years, with the rapid transformation of the urban environment and the extensive population movements, cities are conceptualized as fragmented places of multiple identities. Contemporary cities are shaped by the different ideologies, beliefs, and diverse cultural dynamics they incorporate. In today's reality defining the cultural identity of a certain place is not always an easy task. Symbols of the past, monuments, artifacts and written historic works, stand as reminders of what a place used to be, as significant mnemonic cultural references. But they do not delineate the current condition of a constantly changing reality.

Mneme, the ability to preserve a set of ideas or behaviours through time, goes way back, as far as the cultural constructions of human history. It does not always operate in chronological sequences but acts as more of a selective process.

Philosopher Danniell Dennet uses the word memes in order to define belief systems, that form cultural entities on their own, and spread almost like a virus, from generation to generation, as replicators of ideas, reproducing similar but not exactly the same set of other ideas. The term meme is coined by the British evolutionary biologist Richard Dawkins. It also relates with the term mneme and describes a mechanism of cultural evolution based on memes, a notion that is analogous to the theory of biological evolution based on genes. In this sense the notion of cultural identity could be seen as something much more complex. As sets of different ideas and shared behaviours, combined together in different ways, forming different kinds of narratives. It can also be seen as a constant process of transformation that incorporates not only the past, but also the present and connect us with the future. Following Modern Athens' historical and cultural evolution, it seems that the particular and rather complex urban fabric of the city reflects an unorthodox urban development that has been occurring since the very beginning of the 19th century. Throughout the years as the city seeks to establish its very own identity, as a contemporary modernized European Capital, its urban environment is mainly characterized by radical economic, political and social change, having direct impact on the city's landscape. Although the city is linked from the very beginning to its mythical and glorious past of antiquity, its urban form, illustrates contemporary Athens as a place of a more complex identity, that relates to the rest of the Western Capitals not only by stating its similarities, but also by accentuating its "differences".

Extended abstract

This paper concerns Vradeto, a settlement in central Zagori area, the investigation of place identity as well as the policies required for its protection and sustainable development. The settlement, which has currently few permanent inhabitants, was recently included in the World Heritage List of UNESCO as a «protected cultural landscape».

The present research is part of the students' project entitled: "Protection and conservation at the scale of an urban center or historic settlement", in the MSc "Protection of Monuments", NTUA. The research aimed at highlighting the attributes of the settlement that make it unique in historical, cultural, environmental, societal and architectural terms. The research was based on the analysis of the settlement at different spatial scales and levels, a bibliography review, map analysis and fieldwork.

The outcome of field research has pointed critical features contributing in the making of the village's individual character. Of major importance is geomorphology and the landscape that encouraged the development of nearby settlements with different characters, all belonging within the network of the Zagori villages. More specifically, fieldwork was based on surveying and mapping architectural elements and spatial qualities, as well as on interviews with the inhabitants to identify the role of the village in the network of settlements. This part of the research was particularly challenging as the settlement is nowadays least inhabited, with only two permanent residents and few seasonal.

In such a settlement of 'absentees', the memory of few permanent and seasonal residents is a key-parameter in approaching the cultural characteristics of Vradeto and the way in which they were inscribed in the site. The network of churches and their association with rural and social life, the paths and their daily use to meet their basic needs, the festivals and celebrations taking place in public space, the natural environment with Vikos River and other streams, are significant elements of both intangible cultural heritage and place identity.

In this methodological framework, there has been an attempt to understand all the phases of evolution and eventual abandonment of Vradeto, investigate contemporary needs of inhabitants and their concerns for the future, and define the policies required for the preservation of the settlement's identity and its sustainable development. There is a prominent risk of over-tourism and rapid development without respecting place identity and resilience, with negative consequences for both the natural and the built environment. In the case of Vradeto, the research points as best policies both soft tourism development, and 'de-development', the main pillars of which are social care, autonomy and self-sufficiency.

Keywords: *memory, settlement of the absentees, village settlements, Zagori*

1. INTRODUCTION

The present work was carried out in the framework of the MSc "Protection of Monuments" - Direction A' for the course "Protection, design and management of historic buildings, ensembles and landscapes"

The exercise aimed to identify the characteristics that constitute the image and spirit of a settlement called Vradeto in Zagori, in order to create a strategic framework for the development of its protection and enhancement. A key tool of our methodology were the tabs for each building, created and completed during our visit to the settlement in order to collect all the necessary data. The main source of information were the interviews of the few inhabitants, but also the very few bibliographical references listed in the full issue of the study.

2. GENERAL CHARACTERISTICS

In the first phase, various data on the wider area of the settlement were analyzed in order to study the way it developed as well as other factors that may have influenced its development over the years. Its relationship with the surrounding settlements, as well as with other larger urban centers and its role within this context were key factors to define its position on the map.

The natural environment, the terrain and its components have created an environment of ravines, deep gorges, rich vegetation with a strong presence of water and snow. There are references to the settlement dated as far back as 1616, which may indicate that it has existed in its place for over 400 years. This gives the settlement a variety of values, the most important of which is the historical one.

3. GENERAL INFORMATION ABOUT THE SETTLEMENT

The settlement is located between two gorges on the southwestern slopes of Mount Tymphi and is the highest village of Zagori in the prefecture of Ioannina, just above the gorge of Mezaria, resulting in a stunning view of the landscape. The general picture that the settlement presents today is that of abandonment. Dense vegetation covers the few buildings while the majority of the buildings are nothing but ruins. The settlements that were once directly connected to Vradeto are Kapesovo to the south through the 'Stairs of Vradeto', Tsepelovo to the east and Monodendri with Aristi to the north. The urban development is interesting considering the historical data available. The inhabitants of the settlement mainly occupied areas around farming, while to a lesser extent agriculture existed exclusively to serve the needs of the settlement. If needs were not met, there was access to other settlements from which the inhabitants could further supply. Conditions changed abruptly in 1930 when the inhabitants started to migrate to larger urban centers.

Analyzing the data (old photographs, old maps, field study, etc.) it was found that the settlement was most likely built on a junction of an older network and over time developed organically around this core. The location of the nucleus cannot be ruled out that it was chosen exactly at the point where there seems to have been a junction in this road to the summer and winter paths to Kapesovo, which later on shows corresponding junctions to Tsepelovo. The core later evolved southwards, forming the second phase of the network's development. The next phase of the network comes after the expansion of the settlement to the north as inferred from its position in relation to the buildings. The final phase is identified as the extension of the asphalt road in 1973.

The settlement in its initial phase seems to have had no squares at all. Some places that are nowadays identified as such, are either additional configurations (e.g. central square realized in 1973), or the demolition of an older buildings without constructing another one in its place.

The majority of roads are currently in poor condition. The analysis showed that there are many interventions and they are generally considered to be inappropriate. The roads that are maintained still in the best condition until this day are located near the paved road from which one reaches the village. Cars enter the village up to the point of the central square.

The most important points of interest near the settlement are the "Stairs of Vradeto" and the "Beloi" site. The infrastructure is generally in good condition and can serve the few inhabitants of the settlement. This is of great importance for the development proposal, as for further increase of the population and consequently of the needs, the current infrastructure (electricity, water etc.) is not sufficient.

The majority of the buildings are built by the middle class, but are not poorly built. The typologies recorded are specific and not particularly varied. Generally, the buildings are not in good condition and as individual buildings are of no particular value.

The buildings are mainly residential. When the settlement was inhabited, small industries were housed within the dwellings and therefore there is no evidence of the uses of the buildings besides recent times. Today there is very little variation in uses which is limited to the modern core of the settlement, the square with the church.

The networks that form between the settlements are an element of the cultural heritage of a wider network that expresses a way of life of the people who once lived there. Vradeto was the center of intersection of these networks. **Its importance is highlighted when one considers its role as a hub in a wider network of routes.**

Today, due to the dense vegetation, the view of the landscape that the settlement once had has been lost. From the old photographs it can be concluded that there were no trees in the settlement, possibly there was intensive logging. The settlement retains to a satisfactory degree the old production structures, although in poor condition. The threshing floors, animal sheds, underground storage of the houses and many others, could perhaps form some "trails of tradition".

All of the above express the current state of the settlement through a cartographic, photographic, anthropological and experiential point of view. All together, they form a strong identity for the settlement that can as an element evolve into a development resource with the right conditions of protection and promotion in a wider cultural network. The lack of enhancement of the settlement is the main reason preventing its protection.

4. LEGISLATIVE FRAMEWORK

In the first phase, the settlement is protected by Greek legislation with Π.Δ.594/Δ/1978 (ΦΕΚ 404/Β/1965) and Law 423/Δ/1995 (ΦΕΚ 615/Δ/79). Each of them protects the settlement from a different aspect. This chapter has attempted to approach the broader legislative framework governing the settlement. Methodologically, all relevant references to the legislation were examined, then a critique of the legislation was made as it was assessed as general and that some observations do not apply to Vradeto, and in a subsequent phase an assessment of the implementation of the legislation was made. Finally, very interesting conclusions were drawn about the proposals for the enhancement of the settlement relating to the legislative aspect.

SWOT analysis

After all the relevant data, concerning the settlement were collected, a SWOT analysis table was completed, where all the above-mentioned data were listed in order to record the strengths, weaknesses, opportunities and threats of the settlement. This methodological step was crucial in order to have a comprehensive view of the data so as to evaluate them.

5. STRATEGIC DEVELOPMENT FRAMEWORK FOR THE PROTECTION AND PROMOTION OF THE SETTLEMENT

The next stage was to define the strategic objectives for the design of a strategic plan for the development, protection and enhancement of the settlement, which were identified through the work and through experience with the settlement. As the paper concludes, the most important objective becomes the protection of the settlement itself. In order for this to happen it was deemed necessary

Proceedings

to increase the population through various methods presented in the thesis. It also becomes imperative to make the settlement a pole for naturalistic activities since there are several natural resources (ravines, viewpoints, lakes, etc.) very close by. In the same context, it is proposed to create an environmental-research center so that the area can further develop the contact with nature of potential tourists. A strategic objective is the development of the economy in general, based on the local resources that the settlement once had (pastures, traditional trades, etc.).

The settlement today is not defined. It is proposed to draw the boundary on the basis of the registered properties as derived from the land register. Once the boundary exists one can partially define uses as well as building restrictions. In addition, there is a need to further refine the morphological rules that apply today. An important legislative measure would also be the legal characterization of buildings or elements within the settlement of the man-made and natural environment as worthy to protect.

Economic measures and incentives are an important part of the strategic plan. Priority is given to measures that will develop the domestic economy with a view to achieving domestic self-sufficiency. Various amounts can be provided through financial projects to create “cooperatives” or to promote local products towards larger markets. In addition, financial funding can focus on supporting specific uses within the settlement that will also ensure self-sufficiency. Incentives should also be given to rehabilitate buildings, following their evaluation.

With regard to administrative arrangements, it is considered necessary to maintain and frequently monitor the existing road network, as the weather conditions are severe it is quickly damaged. At the same time, there is a need for a further expansion of traffic parking spaces, as well as the expansion of public transport to and from the settlement. At the scale of the settlement there is a need to support or create infrastructure (environmental, energy digital and cultural) to serve the strategic objectives set out earlier. Within the settlement there is a clear lack of maintenance of its network and a complete absence of the necessary urban equipment. The lack of emergency and disaster prevention infrastructure is a significant disparity.

As far as architectural proposals are concerned, they are divided into two categories, public space and buildings. More specifically, for the public space, it is proposed to restore and maintain the existing cobblestoned paths, all the frontages with curtain walls in order to restore the image of the public space, the maintenance of the covered entrances and other elements that constitute its image. With regard to the buildings, it is proposed that they be assessed, also on the basis of their degree of risk of collapse, as well as their value as individual buildings in relation to the wider context of the settlement. Finally, it is proposed to establish a network of cultural routes taking into account all the man-made and natural features of the settlement and its surroundings.

In conclusion, several other measures and projects which do not fall into any of the above categories are mentioned. Some of these include subsidized programs for the recording of oral history, strengthening of local tour groups, organizing seminars about traditional building techniques, and promoting to the public information about the values of the settlement, for example through a guidebook to be made available to visitors.

The Ship in the Museum, in the Palace, in the Kyrenia Castle, Cyprus

Digital survey

Documenting large architectures with an accurate survey has recently become possible even with a limited budget. Digital survey tools based on both active and passive solutions, offers today versatile opportunities for the architectural documentation, regardless of the building's dimension. This lecture presents an extract of Terrestrial and Aerial Photogrammetry and Terrestrial Lasergrammetry. We accomplished a digital survey of the Kyrenia Castle in Cyprus during a specific workshop (activated for one week in May 2018) producing the first (partial) digital model of this building. The castle is a medieval fortification organized in an almost square plan with a side of about 150 meters and walls up to 30 meters high. Following the appropriate protocols and best practices for digital documentation of heritage buildings, the workshop coordinating committee, in synergy with the museum management unit, has accomplished on an articulated experience. The research includes studies on the morphology of the castle, its stratigraphy, the museographical aspects, the restoration issues, and the production of multimedia contents for technical and/or general public access. The castle currently hosts an archaeological museum displaying the Kyrenia Shipwreck, which indeed holds a preeminent role in the history of modern underwater archaeology.

Different levels of interiority

During the workshop, we experimented different alternative solutions for the redesign of this museum, following an established design methodology. The designer who is establishing a new function within an existing building is always dealing with a high number of formal constraints. In the case of a heritage building the number of formal constraints increases dramatically. We intend here by formal constraints the given condition that delimits the designer's freedom in determining forms within the project. The contextual setting of such a condition is therefore delimiting the different possibilities of the project. Constraints are not only those given by regulations and codes but are also the consequence of the search of meaning in the designers' intention. As a meaningful *μεταφορα*, it is like writing a comment to an existing text, a genre widely in use in the mediaeval tradition of religious literature. Therein it was not possible to write freely, it was possible to write only in relation to the sacred text and its different levels of meaning. Jacques Derrida was the first to establish this approach in modern philosophy giving birth within the architectural field to the so-called de-construction. It became an architectural style, which, by misinterpreting the sense of de-construction, was characterised mostly by broken forms. Within the contemporary production of museum architecture, especially within archaeological areas, it is possible to parameterise the different levels of meaning and relationship that the formal constraints given by the context (the castle), could establish within the content (the collection). Within the specific case of the castle, the projects established a formal and meaningful relationship between the container, the castle, and the content, the archaeological collection. The design activity determined how and where the visitor is

Proceedings

able to read the meaning levels. As an example, we designed the museum entrance as a gate across a sacred limit, the *τεμενος*, which in the case of a museum acts as time gate. It became the place where the visitor goes across two different times, the contemporary time, and the trip in the past that the museum effectively impersonates.

Extended abstract

The universality of the Acropolis, and especially of the Parthenon, as a symbol of Hellenism represents a development not of antiquity, but of the post-antique world. During the Roman era, the high regard that Plutarch expressed for the buildings of the Acropolis was purely personal, since no *national* consciousness of Greek identity yet existed. The Acropolis monuments were simply admired as classic works of "ageless beauty" produced under Pericles (Pericles, 13.3). If we tried today to distinguish a national spirit embodied in ancient architecture, we would have to ask ourselves how much “Ionicity” would the Ionic temple of Artemis at Ephesus have evoked? Or how much “Aeolianism” would the Aeolian-style temple of Athena at Assos have imparted? Do such buildings convey an ethnic identity? Does architecture itself reflect nationality, or merely location?

Although being a Greek (versus a “barbarian”) is an ancient distinction that can be traced from Homeric times, a more cohesive, nationalistic sense of Hellenic identity or “Greekness” is a development of the late eighteenth century preceding the Greek Revolution. Disregarding the role of Christianity and Byzantium in the survival of Greek language and culture, a newfound national value was given to “Hellenism”, which was perceived as having its cultural roots in pagan, polytheistic ancient Greece. The European discovery of Greek antiquity during the European and Greek Enlightenment would provide an ideological background to the Greeks’ subsequent struggle for independence. Europe’s educated elite who embraced ancient Greek culture and philosophy were the ones who would give particular aid and support to the Ottoman-ruled Greeks to free themselves and form their own nation.

The narrative surrounding the Greeks’ national aspirations soon found its material existence in a monument – the Periclean Parthenon – which, despite its 1687 destruction and other tribulations, had retained most of the elements of its form. The ancient monuments of the Acropolis gave meaning to the current quest for independence as a *Greek* struggle and represented the material proof of its historical authenticity and legitimacy. For Greece’s Bavarian court of Ludwig I and his son Otto, the preserved Acropolis monuments were thought to lend weight and meaning to their own role as concerned hellenophiles aiming just as the ancients did to impose order within a wild, uncivilized region. The recognition of the Parthenon in particular as a symbol of Greekness created emotional links with the romantic movement of European neoclassicism.

Consequently, the "arrangement" of the Acropolis’ space – its "return" to a form resembling as much as possible that of the fifth-century BC sanctuary from the Golden Age of Pericles – was necessary for the modern nation’s absolute union with antiquity. No other architectural “interference” could be allowed to distract from this crucial connection. The intervening centuries between then and now did not exist. The newly founded Greek nation’s interventions on the Acropolis were a self-evident restoration consistent with the romance and naivety of the time. The contrived “unchanged” appearance of the Acropolis summit would forever confirm the “unchanged” spiritual bond between new and ancient Hellenism. Ultimately, the Greek Revolution itself predicted the fate of the age-old Athenian Acropolis – but as a victim or a victory trophy?

Abstract

This paper delves into the intricate intersection of memory, place, and identity, exploring how new technologies, particularly Apple Vision Pro, illuminate this nexus. Leveraging the capabilities of digital twins and virtual reality, we embark on a multifaceted exploration to deepen our comprehension of how memory is intricately woven into landscapes and urban environments of cultural and historical significance. Through this approach, we discern key visual elements that evoke memory and heritage within physical environments.

Innovative applications through tools such as Apple Vision Pro can facilitate image extension to define place identity, where the technology informs the viewer on cultural and political entities of a varying timeline. Concurrently, visual storytelling techniques curated with Apple Vision Pro showcase the dynamic evolution of landscapes and the preservation of cultural heritage, offering new insights into the interplay between memory and physical environments. Furthermore, the integration of Virtual Reality (VR) technologies enables the recreation of historical landscapes and urban-scapes. This immersive approach invites users to transcend temporal boundaries, immersing themselves in reconstructed environments and experiencing the past in a dynamic and engaging manner. Semantic Image Search capabilities implemented using Apple Vision Pro streamline research efforts, facilitating the exploration of mnemonic landscapes. By uncovering images related to specific themes or keywords such as monuments, tradition, or cultural identity, we deepen our understanding of the intricate connections between memory, place, and identity.

This research investigates a methodology to connect digital twins and virtual environments with urban and non-urban environments and landscapes to illustrate the concepts of cultural, historical, and environmental sustainability. Central to this approach is defining the resilience of the current state, its evolution into the future, and emphasizing the significance of the past. These technologies not only facilitate a historical and cultural embrace but also evoke a nostalgic feeling of returning to a specific place years later. A methodology is introduced to analyze and quantify this approach of identity and its evaluation over time. This methodology outlines the integration of technologies necessary to achieve the goal of revitalizing public urban places through cultural and political memory.

Through these innovative applications, this paper contributes to the advancement of research in digital twins of spaces, urban transformation, and cultural heritage preservation. By offering novel insights into the complex relationship between memory, place, and identity in the digital age, we pave the way for a deeper understanding of our collective past and its impact on the present.

1. Introduction

Virtual and augmented reality environments present an interest in researchers, engineers, and architects nowadays because of the established visual production and communication of ideas in modern culture. The same attention is given to the newly publicly introduced technology of Large Language Models (LLMs) with the commonly accepted tool ChatGPT. This paper briefly shows one of the latest developments in the field of artificial intelligence and its potential applications to the field of architectural and space representation. This study briefly discusses how LLMs can be effectively used to understand the space in which we are located, whether this is a square, a monument, a landscape, or a building with significant importance. LLMs are artificial intelligence systems that generate text/translate visual images using generative pre-trained transformers (GPT) architecture [1]. The paper presents some possible use cases of LLMs in urban understanding. Given the benefits of the LLMs, they are also prone to limitations such as biased results, prompt injection attacks, and colossal requirements of computational resources [1]. It is to be noted that the LLMs are helpful but are still in the early stages of development and need further in-depth research and evaluation for efficient use in transportation systems [1]. This work aims to address the integration of such technologies into the infrastructure and, more precisely, to the identity of a place. Recent advancements in multimodal large language models (MLLMs) have achieved significant multimodal generation capabilities akin to GPT-4. These models predominantly map visual information into language representation space, leveraging the vast knowledge and powerful text generation abilities of LLMs to produce multimodal instruction-following responses [2]. Specifically, we introduce augmented reality, which is connected to the multimodal generation capabilities of LLMs, to understand, illustrate, and predict the identity of a place.

Augmented Reality (AR) merges computer-generated data with the real world, enhancing people's perception of reality by integrating synthetic information into the live view of the physical environment. In AR, the physical world retains its predominant role, with computer-generated elements complementing and enriching the user experience. This technology falls within the realm of mixed reality [16], where virtual and real-world objects coexist seamlessly in the same space. AR systems such as the Apple Vision Pro enable real-time interaction by combining real and virtual elements within a real environment while also accurately registering virtual objects in three-dimensional space.

Genuine environments, whether urban or periurban landscapes are undeniably fundamental to our existence. However, they are not isolated entities merely existing in tangible form. Reality and its material expression are always accompanied, sustained, and perpetuated by intangible mental phenomena such as memories, fantasies, desires, and even fears, which manifest in symbolic or semantic expressions [15]. Over the past decade, AR has presented intriguing opportunities and practical applications for revealing cultural heritage, promoting historical materials, and facilitating interactive visualizations of heritage items [17].

Archeoguide was one of the first AR systems, which was built at the archaeological site of Olympia in Greece from 2000 to 2002 [18]. It provided personal AR tours and reconstructed the ruined cultural heritage sites to understand and experience the past. The equipment that has been used to make the 3D of the monuments possible is a head-mounted display (HMD) with an external camera and a compass, a backpack with a computer, a battery, and a wireless communication equipment [18].

An additional study aims to improve the identification and examination of spatial structures in architectural heritage settings by creating a "digital multi-parametric methodology." The study seeks to provide an all-inclusive online platform for evaluating and modeling environmental data by combining digital instruments like drones and thermal cameras with traditional surveying methods. The methodology is validated by conducting a case study on partially abandoned settlements in the Doris Municipality, Greece. The objective is to comprehend the relationships between spatial entities,

Proceedings

the constructed environment, and the natural landscape, ultimately aiding in the evaluation of sustainability and resilience. [27]

Highlighting the significance of public urban and peri-urban spaces as catalysts for social identity and cohesion, the municipality of Kaisariani, situated on the outskirts of Athens, presents another compelling project. The redesign of the square aimed not only to provide visitors with recreational opportunities but also to offer them the chance to explore a virtual narrative of the historical and cultural heritage of the surrounding area. This initiative intertwines physical and virtual networks, offering visitors within the physical space and beyond the opportunity to engage with the cultural landscape through virtual navigation primarily. The creation of this virtual visiting network enables continuous data collection, enriching both the virtual tour structure and future utilization of the physical space. The square's surface was transformed into a map depicting the eastern part of the Aegean Sea and the western coastal zone of Minor Asia. Metallic signs embedded in the square floor feature QR codes, inviting visitors to embark on a virtual journey through the history of the Hellenic communities in Minor Asia [15]. Through such initiatives, which emphasize social interactions and the public display of collective affiliations, the crucial role of public spaces in shaping identities becomes evident.

2. Identity of Place Definition

Place identity, as a fundamental concept in human-environment relations, encompasses a variety of psychological theories and dimensions. Initially, place identity is defined as the aspects of self that shape an individual's personal identity in relation to the physical environment through a complex interplay of conscious and unconscious thoughts, emotions, values, and behavioral inclinations [5]. Various studies have further explored this concept, establishing connections between it, subjective regional identity, and attachment to places. Place identity has been described as a combination of physical processes, man-made elements, and the meanings attributed to places, emphasizing the diverse components that contribute to a place's identification within the spatial system [6]. They perceive the identities of places in varied ways, distinguishing them by considering diverse elements like physical features, cultural attributes, historical associations, experiential ties, and more [7]. There are mediating variables that impact the place's identity during the transition from the past to the present and the future.

Identity consists of two primary components. The first is the intensity, which signifies the strength of belief, and the second is the degree of positive connection with the object of identity [13]. Overall, place identity serves to distinguish regions from one another, drawing on elements such as nature, culture, inhabitants, language, and historical connections [7].

2.1 Evolution of Place Identity

The evolving nature of society, characterized by technological advancements, urbanization, and globalization, continually reshapes the physical and cultural landscapes of places, altering the ways individuals perceive and engage with their environments. Amidst these transitions, individuals navigate the complexities of past experiences, present realities, and future aspirations, shaping their evolving sense of place identity. Place identity, conceived as a subjective social construct, emerges as individuals distinguish one place from another, drawing on subjective cognition and objective physical settings. Memory plays a pivotal role in this process, serving as a mechanism that intertwines sensation with intellect and links present conditions with past experiences [10]. As memory intertwines with place, it becomes evident that places acquire identity not solely through material substance but also through intangible processes, collective memories, and ideological formations [10]. This dynamic interplay between memory and place underscores the significance of the "emplacement" of memory, highlighting the intricate relationship between collective memory and the formation of place identity [10].

2.2 Transforming space identity in society and architecture.

The dynamic nature of societal changes and architectural evolution has significant impacts on both society and the architectural community. The swift progression of urbanization and globalization in society necessitates a reevaluation of cultural identity and social interconnectedness. As communities embrace new influences and experience architectural changes, old values may undergo a transition, which can affect social unity and collective memory. Furthermore, political interventions and global events such as globalization have the potential to disturb the historical flow and redefine the narrative of a location's identity. These changes force communities to balance the conservation of their cultural traditions with the need for progress, impacting the citizens' sense of identity and ongoing connection. These shifts require the architectural community to reassess design ideas and approaches to creating places. Architects are faced with the challenge of balancing the preservation of historical identities with the accommodation of modern demands and aspirations. This necessitates a meticulous equilibrium between conservation efforts and inventive design interventions that protect cultural heritage while promoting adjustment to contemporary circumstances. Moreover, the impact of worldwide trends and international cooperation significantly influences architectural discussions, resulting in the development of novel paradigms and design methodologies.

Environmental psychology is crucial for comprehending human behavior in constructed environments [12], assisting architects in designing spaces that evoke people's emotions, values, and memories. The analysis and improvements of current theories in environmental psychology provide guidance for design techniques that prioritize the well-being and user experience. This reflects the shifting dynamics of place identification in a rapidly evolving world [11]. The alteration of a community's surrounding natural environment over time reshapes its social structure, consequently impacting the identity of the place [11].

3. Technological Tools: AR Technology & LLM integration

3.1 AR and VR technologies

In this section, the evolution, applications, and emerging challenges of Augmented Reality (AR) and Virtual Reality (VR) are outlined, identifying their transformative impact on place and identity.

AR technology enriches the real world by overlaying digital content like images and sounds onto the user's environment in real-time, seamlessly integrating digital elements into their surroundings. Conversely, VR immerses users in simulated environments, disconnecting them from the physical world through devices like VR headsets that control visual and auditory perceptions. This immersive experience enables users to explore various environments and scenarios, ranging from lifelike to fantastical realms [23].

While definitions of AR and VR were more clearly defined and popularized in the 1990s, studies about these technologies can already be found in the late 1950s [23]. Early AR and VR systems struggled with accessibility and practical use. For example, the ARCHEOGUIDE project, an early 2000s initiative funded by the EU to enhance archaeological site tours with AR, involved the use of Head-mounted displays, a laptop with several hardware attachments as well as heavy backpacks, which highlights the significant logistical complications of early AR implementations [26].

In recent years, AR and VR have found widespread application, for example, in architectural design and education [19]. Today, these technologies are increasingly integrated into infrastructure projects to enhance visualization [22] of complex infrastructure systems [23] or for guided tours in museums [24] [20].

Despite advancements in AR and VR, challenges remain in the widespread adoption of AR and VR in said fields. Issues include complications in outdoor environments due to temperature and

luminance changes, device user-friendliness [21], localization method accuracy [21] and practicality, and high latency [23].

Latest technology like the Apple Vision Pro, a mixed reality headset, offers high-resolution displays and spatial audio capabilities, enhancing user experience. The Apple Vision Pro incorporates eye and hand-tracking technologies by using a total of twelve cameras, six microphones, and five sensors to enable intuitive interaction with virtual environments without the need for conventional controllers. Two onboard processors, one specifically designed to calculate inputs, are included to reduce latency, making it possible to transmit sounds and images within 12 milliseconds, which is an important aspect of reducing motion sickness [25].

Future research in AR technology may focus on addressing challenges like occlusion, localization method accuracy [22], enhancing device affordability and performance, and developing standardized AR tools for better application integration and comparison across academic and engineering communities [24].

3.2 Augmented reality in the infrastructure world

Apple Vision Pro overlays digital content in real-world environments. While standing at Monastiraki Square in Athens, one can view the surrounding area and simultaneously access historical images and information from outputs like ChatGPT or other large language models (LLMs).

The device's spatial mapping ensures that digital elements are accurately placed onto real-world objects and stay fixed in the user's physical surroundings, as it has the ability to adapt to the physical environment by using, for instance, a LiDAR (Light Detection and Ranging) sensor. Furthermore, Vision Pro makes it easy to interact with multiple windows, as the user can open various applications and information sources and is able to place them around himself. Precise eye tracking enables intuitive navigation, as one can select virtual content by simply looking at it. Hand gesture recognition is another key feature, allowing users to resize, move, or close application windows with simple gestures. Besides, voice control and Siri integration provide hands-free operation by allowing users to issue commands and search for information [25].

All these features make it easier and more accessible for users to connect real-time information from LLMs like Chatgpt with locations, creating a deepened understanding of place and identity.

3.3 LLMs and Generative AI in the infrastructure world

Large language models (LLMs) are AI systems trained on massive datasets that enable them to perform complex language tasks. With billions of parameters, LLMs can infer context, generate responses, translate languages, summarize text, answer questions, and even assist with creative writing and code. These capabilities are revolutionizing fields like chatbots, virtual assistants, content creation, research, and translation, making LLMs a cornerstone of modern AI. Large language models (LLMs) are a category of foundation models trained on immense amounts of data, making them capable of understanding and generating natural language and other types of content to perform a wide range of tasks [3]. LLMs have become a household name thanks to the role they have played in bringing generative AI to the forefront of the public interest [3]. This technological advancement has occurred alongside the evolution of machine learning, machine learning models, algorithms, neural networks, and the transformer models that provide the architecture for these AI systems. LLMs are a class of foundation models that are trained on enormous amounts of data to provide the foundational capabilities needed to drive multiple use cases and applications [3].

LLMs represent a significant breakthrough in Natural Language Processing (NLP) and artificial intelligence and are easily accessible to the public through interfaces like Open AI's Chat GPT-3 and GPT-4, Meta's Llama models, and Google's Gemini tool, IBM's Granite model with the products Watson Assistant and Watson Orchestrate.

3.4 LLM Tools to Describe Place Identity: An approach with ChatGPT.

ChatGPT, when combined with DALL·E, showcases numerous notable abilities in generating outcomes. DALL·E, the AI system that creates realistic images and art from a description in natural language, is directly integrated into ChatGPT [4]. ChatGPT's advanced natural language understanding is demonstrated by its capacity to comprehend and interpret intricate prompts regarding historical eras and hypothetical futures. The generation of intricate prompts for DALL·E exemplifies ChatGPT's aptitude for imaginative cognition of the future development of space. It creates narratives by combining historical facts with imaginative elements that are appropriate for specific time periods. The integration of ChatGPT with DALL·E showcases the cross-modal capacity of AI systems to convert textual descriptions into visual representations. ChatGPT demonstrates its profound understanding of historical facts by integrating well-known historical aspects of a specific space into the image generation prompts, showcasing its comprehensive knowledge of the past up to the present time. The tool has the ability to demonstrate urban developments based on the AI's proficiency in generating realistic future scenarios. The diverse functionality of AI is demonstrated through its ability to be utilized for educational, creative, and speculative purposes. Additionally, we emphasize AI's ability to connect the divide between written and visual communication, thereby creating fresh opportunities for generating content and ideas.

4. Methodology and Discussion

4.1 Methodology

This section outlines our approach to evaluating the identification of spaces. Initially, we determine the specific location or space that we wish to analyze, either by capturing our own photograph of the space or by locating it through Google Street View. In this section, we provide a detailed explanation of the methodology employed to establish the identity of the LLM tool. Finally, we present the incorporation of this data into the Apple Vision Pro to enhance the current environment with the identification produced by ChatGPT. Figure 1 depicts the concept of place identity and how it is visually represented through the use of technology.

Based on the work performed by ChatGPT and DALL·E in creating and processing complicated prompts and visualizing information, we created a methodology pipeline. To carry out our preliminary assessment, we needed to collect input data from which we could derive context. During the first stage of our method, we decided to use rapid formulation. During the first stage of our method, we opted to utilize prompt formulation.

Concretely, we obtained the image of Google StreetView and instructed ChatGPT to ascertain whether it recognizes the space. We provide the name of the space as additional context and information in situations where recognition fails. Subsequently, we depended on a crucial element that involved creating clear and accurate questions to obtain information. This involved skillfully employing natural language processing (NLP) techniques to analyze and organize user inputs into clear prompts, addressing their informational requirements related to space identification and providing historical and cultural insights.

As mentioned before, ChatGPT is trained by utilizing an extensive amount of data, which encompasses photographs and historical records. LLMs are employed to measure identity by soliciting space-related information, such as inquiries about the construction date of a square, the identity of its builder, the evolution of its structure and its usage from ancient to Byzantine to modern times, and the architectural trends that influenced the emergence of new standards and design approaches during that period.

The utilization of DALL·E is a result of combining Apple Vision Pro with the visual depiction of the space. An interaction involving the utilization of Apple Vision Pro in Google StreetView, along with

a real-time conversation with ChatGPT, whether through written or spoken language, simulates a discussion with someone who possesses knowledge about the subject matter, like a tour guide equipped with comprehensive information or gained expertise. Taking this a step further, we aim to convert the textual information into a visual representation, specifically an image. We request DALLE to develop an image depicting the spatial changes over various time periods throughout the years. We specifically requested an image depicting Monastiraki Square during three distinct periods: ancient times, the Byzantine era, and a speculative future scenario set 50 years after the completion of this project in 2074.

We proceed with an iterative process of improvement, recognizing that the provided images are not derived from accurate historical images and sources but rather serve as a means of generating imaginative representations. Therefore, we proceed with the feedback loop, which enables the user to observe the produced image and offer input regarding its precision and aesthetic attributes. The main issue of these technologies lies in their limited accuracy in generating photographs and their inability to produce photos from historical sources, instead relying on generating them from scratch. However, it should be noted that ChatGPT offers references to websites where users can access and review information about the space. The final stage of the process focuses on delivering the output and facilitating user interaction. We accomplish this by presenting a polished image to the user through a user-friendly interface, specifically the Apple Vision Pro. Afterward, users are able to engage in an interactive exploration using the Apple Vision Pro, enabling them to interact with the generated content. This includes actions such as zooming, editing, or overlaying supplementary information, which enhances the educational and creative experience. Figure 2 illustrates the methodology of place identity, which is based on a technological approach involving LLMs and augmented reality.

This pipeline emphasizes the integration of NLP and computer vision, enabled by machine learning methods, to not only produce spatial identification of content but also create an interactive and dynamic platform for creative and instructional objectives. The pipeline is designed to be iterative, with user feedback immediately influencing continuing enhancements and adjustments, ensuring that the system adapts to user needs and technical changes.

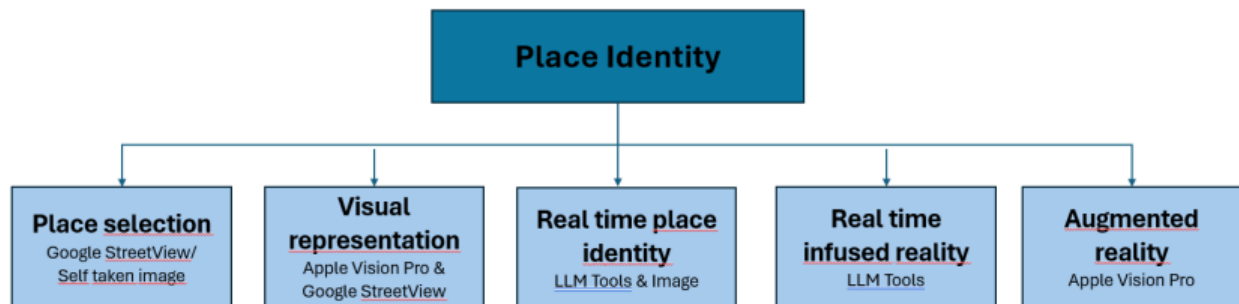

Figure 1. Place identity and its representation by technology

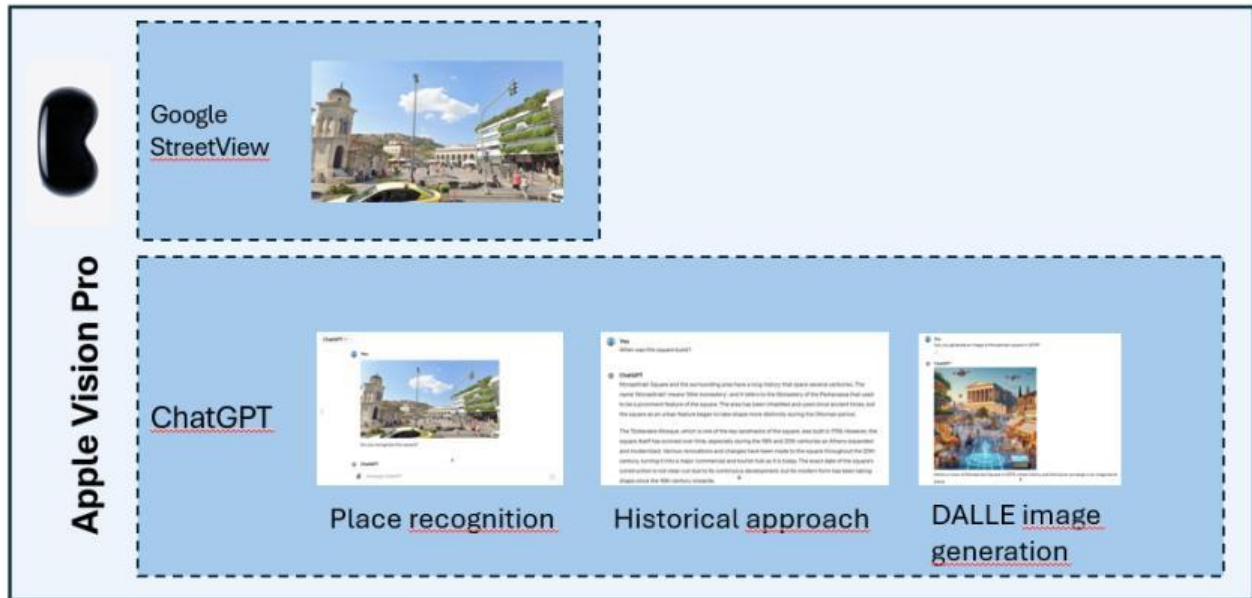

Figure 2. The methodology of place identity is based on the technological approach with LLMs and augmented reality

4.2 Use Cases and Discussion

For this methodology, we explored Monastiraki Square, which is one of the most vibrant squares in Athens, Greece, and has a long architectural, historical, and cultural importance. ChatGPT immediately recognized the square and was able to answer all the questions we asked. The approach that was wanted would have been to discuss with ChatGPT whether it was a real tour guide or a historian and architect altogether. It gives us information on *"the mixture of architectural styles, including the Tzistarakis Mosque with its distinctive dome, which now houses part of the Museum of Greek Folk Art, and the Byzantine Church of the Pantanassa."* We also received cultural information: *"Monastiraki is known for its flea market and vibrant atmosphere, a mix of ancient and modern that's characteristic of Athens."* When asked: *"Can you show me pictures from the ancient times of the square?"* ChatGPT answered: *"Finding authentic pictures of Monastiraki Square from ancient times would be quite challenging, as the concept of photography did not exist until the 19th century. However, there are historical records and drawings that provide us with an understanding of what the area may have looked like."* We were not able to show any illustrations of the square. *"I'm sorry for the confusion, but as an AI developed by OpenAI, I currently don't have the ability to browse the internet or access external databases in real-time, so I can't retrieve or show existing images or drawings from external sources."*

To build a visual understanding of these times, we requested the representation of these eras, as shown in Figure 2. The goal is to correlate the different time periods with the space identity and its evolution. More accurate results could be obtained by combining tools such as ChatGPT and Gemini. While Gemini does not recognize the square with its current technology, it is able to show a search in the network and accurately find an ancient representation of Athens as given by <https://ancientathens3d.com/>, a similar approach someone would follow on a Google search. The result of this approach is shown in Figure 3.

(a) Ancient representation (b) Byzantine representation (c) Future representation

Figure 3. DALLE generated images on three different representations of the Monastiraki square.

✦ I cannot unfortunately show you a picture of what Monastiraki Square looked like in ancient times as there are no depictions of this specific area. However, I can show you a recreation of what Athens looked like in ancient times:

Figure 4. Gemini provided a representation of Monastiraki Square.

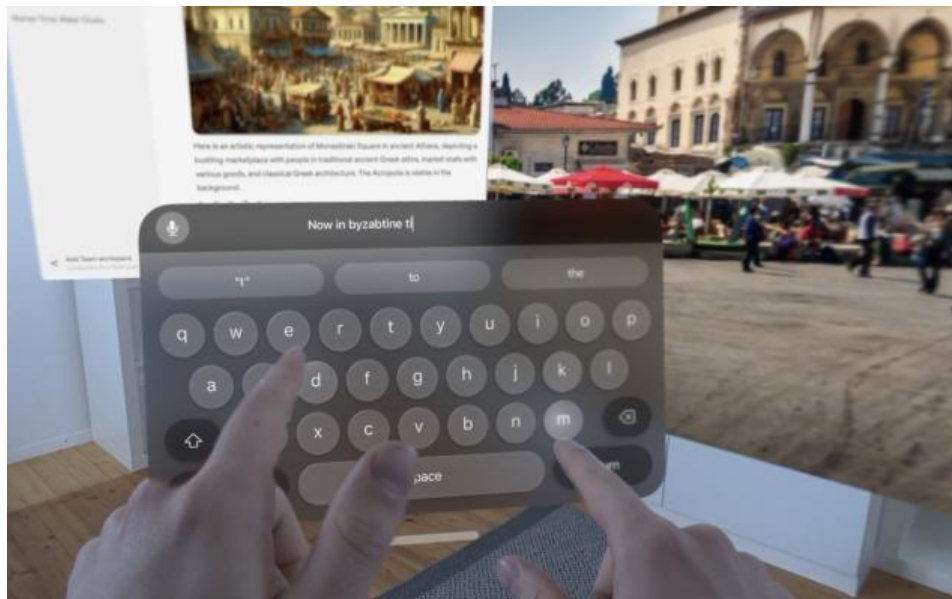

Figure 5. The space visual represented with Apple Vision Pro

In these examples, we show the powerful ChatGPT tool, but as shown and described in the methodology, there are a few advancements that need to be considered. For instance, there is a need for customized training models for these tasks. During the work of this pipeline, we show the

importance of the improvement of the LLM tools to adjust their capabilities on space identity, and Llama is the most capable openly available LLM [4]. The significance of the Llama tool by Meta is the fact that it allows further training on new, more specific tasks. The vision is to enable developers to customize Llama 3 to support identification analysis and historical correlation of places. More specifically, the LLM model can be re-trained, specializing in the space's identity and its historical, cultural, and political transformation throughout time.

4. Conclusion

This study has critically explored the transformative potential of augmented reality (AR) and large language models (LLMs) in redefining public urban spaces through the lens of cultural and political memory. By integrating AR with the sophisticated capabilities of LLMs, particularly through platforms like Apple Vision Pro and ChatGPT, we have outlined a robust methodology to enhance the identification and appreciation of place identity in urban environments. Our findings demonstrate that AR can significantly enrich the physical experience of a location by merging digital information with real-world contexts, thus allowing for a deeper engagement with the historical and cultural layers of urban spaces. Virtual Reality (VR) further extends these capabilities by creating immersive environments where past, present, and future narratives of urban landscapes can be experienced, offering users a unique perspective that is not possible through traditional means. The use of LLMs, exemplified by ChatGPT, has shown promising results in generating detailed narratives and visual representations that anchor the memory of a place within its physical attributes. These models not only facilitate a richer interaction with the environment but also act as repositories of cultural memory, capable of conveying complex historical and social narratives through their generative abilities. The integration of these technologies into the study of place identity suggests a dynamic and innovative approach to urban design and heritage conservation. The ability to overlay digital twins with real environments in AR, combined with the narrative and analytical power of LLMs, provides a powerful tool for architects, planners, and heritage professionals to explore and interpret urban spaces in ways that were previously unattainable. Future research should focus on refining these technological tools improving their accuracy, user-friendliness, and accessibility. Additionally, further exploration into the ethical implications and potential biases inherent in AI-driven interpretations of cultural and political memories is crucial. In conclusion, this research paves the way for a new era of urban and architectural design, where digital and physical realms merge to enhance our understanding of place identity. By harnessing the power of AR and LLM technologies, we can not only preserve but revitalize the memory embedded within urban landscapes, ensuring that they remain dynamic, relevant, and meaningful for future generations.

Urban planning methods as tangible and intangible expression in Constantinos Doxiadis and Adriano Olivetti's approaches: Revisiting their work via the lenses of urban-scale digital twins

M. Charitonidou

Principal Investigator and Postdoctoral Researcher, Athens School of Fine Arts, Greece

Corresponding author: E-mail: m.charitonidou@icloud.com, Tel +30 6947460886

Abstract

At the heart of the paper is the development of methodological tools that offer the possibility of developing new forms of participatory planning by linking the use of artificial intelligence and big data in urban planning with the holistic approaches of urban planning of Constantinos A. Doxiadis and Adriano Olivetti. The paper pays special attention to the role of tangible and intangible expression in Doxiadis and Olivetti's thought, and to how their approaches understood the relationship with place identity and sustainable planning and development. Particular emphasis is placed on the concepts of 'entopia', 'ekistics', and 'Ecumenopolis' in Doxiadis's thought, on the concept of 'concrete utopia' in Olivetti's approach, and on the role of visualization via the use of computers in the case of Doxiadis Associates Computer Centrer (DACC). Urban scale digital twins, which have as a core characteristic the possibility to be updated in real-time thanks to the use of technologies such as big data and artificial intelligence, aim to compare different strategies during the processes of decision-making concerning urban and spatial planning. At the core of the paper is the comparison of the ongoing and growing use of urban scale digital twins applications in decision making in urban planning with the methods of visualization used in the case of Athens Center of Ekistics.

Keywords: Constantinos A. Doxiadis; Adriano Olivetti; big data; urban scale digital twins; concrete utopias; artificial intelligence; digital universalism; Ecumenopolis; tangible and intangible expression

1. INTRODUCTION

Urban scale digital twins, which have as a core characteristic the possibility to be updated in real-time thanks to the use of technologies such as big data and artificial intelligence, aim to compare different strategies during the processes of decision-making concerning urban and spatial planning. At the core of the paper is the comparison of the ongoing and growing use of urban scale digital twins applications in decision making in urban planning with the methods of visualization used in the case of Athens Center of Ekistics [1]. The paper also intends to shed light on the tension between the real and the ideal at stake during the process of abstracting sets of variables and processes in the case of urban scale digital twins [2]. The use of digital technologies in the field of inclusive cultural heritage aims to shed light on the connections between the tangible and intangible aspects of urban planning. Within the framework of their endeavor to incorporate digital technologies in their research, Alison McCandlish and Gayle McPherson, for instance, "explore the use of two complementary digital methods: digital cultural asset mapping and digital storytelling to reveal hidden heritage and engage the local citizen's voice" [3].

The paper places particular emphasis on the concept of Ecumenopolis in the work of Constantinos A. Doxiadis [4], and the relation of urban governance in the thought of Constantinos A. Doxiadis and Adriano Olivetti to contemporary urban planning practices based on the use of artificial intelligence and big data. According to Doxiadis, Ecumenopolis would "form a continuous, differentiated, but also unified texture consisting of many cells, the human communities" [5]. Moreover, special attention is paid to Adriano Olivetti's understanding of urban planning methods as concrete utopias [6,7,8]. Both Doxiadis and Olivetti, instead of framing their practice and theory within the frontiers

Proceedings

of specific disciplines, tried to reflect on strategies of reconstruction beyond conventional models. Their way of thinking at the intersection of different domains of practice explains why the examination of their activities is essential for understanding the role of urban planning in enhancing political emancipation. Both holism and interdisciplinarity lie at the heart of Doxiadis's approach to the understanding of human progress. Doxiadis drew a distinction between interdisciplinary and a condisciplinary science. In "Ekistics, the Science of Human Settlements", published in *Science* in 1970, Doxiadis highlights: "To achieve the needed knowledge and develop the science of human settlements we must move from an interdisciplinary to a condisciplinary science" [9].

2. THE ROLE OF URBAN SCALE DIGITAL TWIN IN DECISION-MAKING IN URBAN PLANNING

Recently, within the field of smart cities, the notion of urban scale digital twin has acquired a central place. The term 'digital twin' refers to the digital representation enabling comprehensive data exchange and can contain models, simulations and algorithms describing their counterpart and its features and behaviour in the real world. A 'digital twin' is a digital representation of a physical process, person, place, system or device. The term 'digital twin' firstly emerged in the field of manufacturing sector to refer to digital simulation models that run alongside real-time processes. 'Digital twins' are digital replicas of physical entities [1]. Their creation is based on the use of advanced technological applications, such as sensing, processing, and data transmission. Digital twins are used in the field of urban analytics, as well as in the field of computational social sciences. Digital twins enhance evidence-based operational decisions and experimentation on urban policies. The current state of research concerning the role of digital twins in shaping urban policies is characterized by a dichotomy between scholars that focus on the technological and sustainable benefits of the use of urban scale digital twins and researchers that criticize 'digital universalism'. Digital twins enhance evidence-based operational decisions and experimentation on urban policies.

The European Union has set the following goals regarding sustainable urban planning strategies: firstly, the empowerment of "urban actors towards common goals; secondly, the development of people-oriented urban planning strategies that aim to contribute to the social equity of communities; thirdly, the development of digital platforms and other digital tools that intend to enhance interactive and proactive approaches in urban planning decision-making, and "the creation of integrated, open, and functional technological infrastructures for the development of programmes and the provision of services (data-driven planning)". Among existing urban scale digital twins that are either in operation or under development are the twins of the following cities or districts: that of Athens in Greece, that of Dublin Docklands in Ireland, that of Herrenberg in Germany, that of Vienna in Austria, that of Zurich in Switzerland, that of New York in the United States of America, that of London in the United Kingdom, and that of Helsinki in Finland. Other note-worthy urban scale digital twins are those of Cambridge, Gothenburg, Munich, Newcastle, Paris, Rennes and Rotterdam. Two programs that play a major role in shaping sustainable urban planning methods are the European New Green Deal, the Agenda for Sustainable Development and its Sustainable Development Goals, which is also known as SDGs. The former – the European Green Deal – is based on the intention to achieve zero net emissions by 2050. This program places particular emphasis on achieving a circular economy by 2050, and on protecting biodiversity. Digital twins are also used in the domain of cultural heritage, as mentioned by Marijana Ćosović, and Mirjana Maksimović, in their paper entitled "Application of the digital twin concept in cultural heritage" [10, 11], as well as by Li Xin, Gu Hongyu, Seo Eun Kyeong, Wu Qitao, Yin Guojun, and Deng Bangkun, in their paper entitled "Towards Cultural Heritage Digital Twin: Concept, Characteristics, Framework and Applications" [12].

3. THE ROLE OF ‘ENTOPIA’ IN CONSTANTINOS A. DOXIADIS’S THOUGHT AND THE ROLE OF ‘CONCRETE UTOPIA’ IN ADRIANO OLIVETTI’S APPROACH

Doxiadis believed in the potentials of ‘entopia’ instead of utopia or dystopia. Doxiadis defined ‘entopia’ as the place that is practicable-that can exist. Informing regarding this term is its etymology: “εν” in Greek means “in”, and “τόπος” in Greek means “place”. Doxiadis referred to the term ‘entopia’ during his Trinity College lectures in 1966. An analysis of this notion is included in his book *Between Dystopia and Utopia*, which was published that same year [13]. According to Doxiadis, architectural or urban design strategies could be characterized as ‘entopian’ if they take into consideration environmental and physical limitations, and the networks that concern the social aspects of architectural or urban projects. Moreover, Doxiadis pays special attention to the capacity of architectural or urban design strategies to respond to the dynamic parameters concerning the settlements. Within such a framework, Doxiadis conceptualized the so-called ‘ekistic grid’ as a tool aiming to provide architecture and urban planning solutions able to promote ‘entopia’. Doxiadis was convinced that ‘entopian’ architecture and urban planning projects should place particular emphasis on the following five elements and their interconnections: Nature, Man, Society, Shells and Networks (Fig. 1).

At the center of Olivetti’s vision was the search for the elaboration of new models of civil cohabitation. Of great significance for understanding Olivetti’s political agenda is the way he conceived the relationship between democracy and community. Olivetti gave much importance to the relationship of citizens to institutions. Four seminal works for understanding Olivetti’s vision are his books entitled *The political order of the communities: of the state according to the laws of the spirito* [*L’ordine politico delle comunità: dello stato secondo le leggi dello spirito*] [6], *For communitarian economy and politics* [*Per un’economia e politica comunitaria*] [14], *City of Man* [*Città dell’uomo*] [15], and *Society, State, Community* [*Società, Stato, Comunità*] [7]. As Italian sociologist Franco Ferrarotti has underscored, Olivetti’s utopian vision could be characterized as ‘concrete utopia’ in the sense that his understanding of communities as concrete goes hand in hand with his conviction that communities are determined by geography and history [16].

connections of elements
intezual cohesion of conceptions

Figure 1. Diagram by Constantinos A. Doxiadis concerning “connections of elements” © Constantinos and Emma Doxiadis Foundation

4. THE CONCEPT OF ‘EKISTICS’ IN DOXIADIS’S WORK AND THE ORGANIZATION OF DELOS SYMPOSIA

According to Constantinos A. Doxiadis, ‘ekistics’ refers to the science of human settlements. According to Doxiadis’s theory of Ekistics, the Elements of ekistics are divided into five parts, namely nature (human), human (antrophos), society (society), reflection (shells) and networks (networks). He highlighted that he originally used this term during an ensemble of lectures he delivered at the National Technical University of Athens in 1942. Important for understanding the approach of Doxiadis is his concept of ‘ekistics’, which he analyses, among other texts, in the study entitled *Ekistic Studies — Ekistic Analysis [Οικιστικές Μελέτες Οικιστική Ανάλυση: Οδηγίες για τη Μελέτη των Χωροταξικών, των Οικιστικών και Πολεοδομικών Προβλημάτων και για την Ανοικοδόμηση της Χώρας]* published in 1946 [17]. According to Doxiadis, ‘ekistics’ operate at three levels: firstly, general ekistics; secondly, urban planning, and thirdly, building design and construction.

Analyzing the history and legacy of the Delos Symposia, which were organized by Doxiadis and British planner Jaqueline Tyrwhitt between 1963 and 1975, one can understand how important interdisciplinary was for Doxiadis’s approach. Doxiadis died on 28 June 1975.

Proceedings

Twelve Delos Symposia were organized in total. Mark Wigley, in “Network Fever”, examines the debates around networks and urban dynamics that took place in the framework of Delos Symposia. The core theme of the first Delos Symposium was “The present crisis in human settlements”. Among the topics that were addressed during the first Delos symposium, which was held in July 1963, were “The present crisis”, “Objective causes of the crisis”, and “Subjective causes of the crisis”. Among the contributors to the first Delos Symposium were American Anthropologist Margaret Mead, Swiss Architecture Historian Sigfried Giedion, and Canadian Philosopher Herbert Marshall McLuhan [18]. The “Declaration of Delos” refers to the document yea was signed during the final meeting of the first Delos Symposium at the ancient theatre of Delos. This Declaration was signed on 12 July 1963. In the “Declaration of Delos”, the participants expressed their interest in exploring ways that would:

- establish a new discipline of human settlements
- initiate basic research of the most far-reaching kind
- bring together specialists from other relevant disciplines to work together on projects in this field
- work out new methods of training the men who could assume leadership and responsibility in the sphere of action
- attract some of the best young minds into this new area of research, development and practice.

Characteristically, Giedion highlighted the following concerning the importance of the development of interdisciplinary reflections during the discussion that accompanied the signing of the “Declaration of Delos”: “At present a lawyer cannot understand a physicist, but we need to create a new type of specialist, and this is something this gathering could help to bring about- of course with the help of the younger generation. It is only now that both generations can work together without one feeling frustrated or suppressed” [19].

The central topic of the second Delos Symposium was the exploration of “A Framework for a New Discipline of Human Settlements”. The third Delos Symposium was devoted to the theme “Problems of Living at High Density”. The fourth Delos Symposium, which was held in 1966, was centered on the topic “Nature and Human Settlements” was focused on issues related to urban mobility and transportation planning. The fifth Delos Symposium, which was held in 1967, was dedicated to the topic “Strategy for Human Settlements”. The sixth Delos Symposium, which took place in 1968, was devoted to the theme “Man and His Settlements: Need for A Policy”. The seventh Delos Symposium, which was held in 1969, was centered on the theme “Society and Human Settlements”. The eighth Delos Symposium, which was held in 1970, was devoted to the topic “Networks and Human Settlements”. The ninth Delos Symposium, which was held in 1971, was dedicated to the topic “Our Buildings (Shells) and Human Settlements”. At the core of the tenth Delos Symposium, which was centered on the theme “Synthesis of all issues discussed in previous symposia and specific proposals addressed to national and local governments and authorities”, were environmental concerns and the expansion of urban networks. The last two Delos Symposia of 1974 and 1975, that took place at the Athens Center of Ekistics and the Apollonion settlement at Porto Rafti, had the same theme: "Action for Human Settlements". Some of the reflections on the role of ‘ekistics’ in offering citizens “equal chances in all aspects and expressions of the social system in space” that were presented by Doxiadis during the eleventh Delos Symposium are included in his article entitled “The twelve radical changes needed for action for human settlements” published in *Ekistics* in 1974 [20]. The last Delos Symposium, which was held in 1975 two weeks after Doxiadis’s death, placed particular emphasis on the ideas that Doxiadis developed in the four books he published in conjunction with the first UN Habitat between 1974 and 1976: *Anthropopolis: City for Human Development* [21], *Ecumenopolis: The Inevitable City of the Future* [22], *Building Entopia* [23], and *Action for Human Settlements* [24].

5. THE RESEARCH PROGRAM “THE HUMAN COMMUNITY” AND DOXIADIS ASSOCIATES COMPUTER CENTER (DACC)

In the 1960s, Doxiadis Associates coordinated the research program entitled “The Human Community” [25]. Pivotal for this research program was the Doxiadis Associates Computer Center (DACC) that was established by Doxiadis Associates in 1964. The research program entitled “The

Proceedings

of the International Conference on **Changing Cities VI:**

ISBN: 978-618-5765-02-6

Human Community” was centered on the exploration of the habits of the residents of Athens and aimed to explore their adaptation to the growth and pace of the postwar city. The Human Community project used the rapidly expanding city of Athens as “laboratory” and its research team produced a systematic analysis of the communities within this urban framework. The “The Human Community” project included a time-allocation study as well as for a study of residents’ satisfaction with their community. The findings could also be used for a subsequent launching of comprehensive effort in order to determine the relationship between urban design policy-making and satisfactoriness of community functioning.

A turning point for the Doxiadis Associates was the purchase of the computer Univac 1107, which was among the best computers of that era. This computer was placed in the courtyard of the building complex on the ring road of Lycabettus, under a sculpted owl-symbol of wisdom, created by Frosso Efthymiadi-Menegaki. It was protected by a bulletproof glass “wall” and illuminated at night. In 1969, C.A. Doxiadis (the owner of Doxiadis Associates) decided to install a Univac 1107 in Doxiadis Associates’ premises at the cost of \$500,000 (\$3.3M in today’s prices). A computer center with air-conditioning and bulletproof windows was set up for the installation. The fact that at that time only four similar computer systems existed in Europe and around ten more were operating in the US underlies the project’s importance. The computer was presented through a series of events to opinion leaders including businessmen, journalists, and scientists and was made available for third party use. The way in which Doxiadis Associates Computer Center used Univac 1107 in the framework of the research project entitled “The Human Community” is pivotal for understanding the articulation of computational urbanism. For this reason, it would be interesting to compare these early moments of the use of computer technology for urban analytics to the current trends in visual mapping of parameters in the cities to take decisions concerning urban planning, with particular emphasis on social and environmental equity.

6. CONCLUSION OR THE ECOLOGICAL ASPECT OF CONTSANTINOS A. DOXIADIS'S APPROACH

An important book for understanding the role of sustainability in Doxiadis's thought is his book entitled *Ecology and Ekistics* [26]. Doxiadis completed the first draft of *Ecology and Ekistics* in the summer of 1975, shortly before his death. Gerald Dix became its editor and the final version was published in 1977. At the core of the book entitled *Ecology and Ekistics* is the argument that a condition of global ecologic balance is of pivotal importance for providing environments that can offer to man or anthropos satisfactory conditions. Of great significance for achieving such balance is the balance between the global ecosystem and human settlements. Doxiadis believed that this would become possible through the establishment of a so-called 'global ecological balance'. Doxiadis was particularly interested in the environmental issues concerning architecture and urban planning. More specifically, as Panayota Pyla highlights, "one can argue that Doxiadis was a pioneer in environmental thought from the 1940s, because the concept of ekistics, shaped during his early career as a coordinator of postwar reconstruction in Greece, sought to integrate people and environments in a comprehensive system" [27]. Doxiadis conceived 'ekistics' as a new way of understanding the science and art of human settlements. More specifically, he argued that 'ekistics' aims to co-ordinate "economics, social sciences, political and administrative sciences, technology and aesthetics into a coherent whole", creating "a new type of human habitat" [28].

Another term that is at the core of Doxiadis's work is that of 'Ecumenopolis'. This concept started off with the hypothesis that urbanization, population growth, and the development of means of transport and human networks would lead to a fusion of urban areas, leading to megalopolises forming a single continuous planetwide city. Doxiadis employed different concepts to refer to different understandings of urban dynamics corresponding to different historical eras. For the city of the 20th century, he used the concept of 'megapolis', arguing that its main characteristic was the perpetual intensification of mobility flows, which would break the limits of the cities, altering not only their structure, and their very meaning. Doxiadis was convinced that the age of automobility demanded the founding of new urban types, which would be organized like beehives around multiple centres.

Doxiadis's "Towards Ecumenopolis", a confidential report that was prepared in January 1961 in the framework of the Research Project "The City of the Future", and was focused on how to devise a different approach concerning the city of the future. In this report, he understood infrastructure as a skeleton of a body covering the entire globe and resulting from the balance between settlements, production and nature. We could relate the concept of Ecumenopolis in Doxiadis's work to the exploration of "strategies for the symbiosis of the global city with the natural world" [27]. Through the concept of Ecumenopolis, Doxiadis aimed to turn ekistics into a strategy for global environmental protection. According to Doxiadis, "global ecological balance" would be achieved through the functional organization of the earth's land to accommodate the competing needs of production, settlement, recreation, and environmental protection. The ultimate goal was clear: "In the [future] we will have built the great, universal city and garden of man with water running in its arteries bringing life and guaranteeing its inner balance and peace." [29]

Extended abstract

Buyuk (big) Kaimakli, a Greek Cypriot neighborhood of the divided capital of Cyprus is separated from the Turkish Cypriot Kuchuk (small) Kaimakli by the Green Dividing Line. The remaining old population received flows of displaced people. Refugees in their own island- country found a new home after the events of 1974, middle-class groups in the end of the last millennium, and low-income immigrants from Europe, Asia, and Africa in the beginning of this millennium. The conditions of the no-Man land area, that divides the Kaimaklis, the capital and the island in two also attracted creative and activists' groups that added more layering on the people's amalgamation.

The existing 'Mneme' of Kaimakli suffered together with the indelible traumas of the Division in the island; its population was aging; its young members were leaving the area. The new layers of Human topographies brought their own 'Mneme' that started coexisting in the cultural landscape of Kaimakli. As new Kaimakli residents, we were involved in various of its activities together with its primary population. As members of the NGO Urban Gorillas, we enacted the Pame (lets go) Kaimakli festivals since 2013, a bottom-up approach with democratic participatory methods. We dealt with various thematic, such as the 'Open houses' "Open Windows", 'Open Kitchens', Adopt and Artist' 'Istories Allosfos' etc. They all aimed at social sustainability with creative mode to bring together disparate groups of people as elder people and children, immigrants, and artists etc. The festivals served as catalysts to trigger social mechanism among the residents, facilitating their voice to be heard, their presence to be seen, their rights to be pursued etc.

Besides the immaterial processes, the cultural, creative, and artistic activities, we introduced material infrastructures as ephemeral entities to facilitate the diverse needs for social creative expression such the modularized Agora with a vast variation of assembling, the inflatable structures etc.

Both the material and immaterial constituent elements of the Pame Kaimakli festival led to ephemeral and spontaneous urbanism as a response to the injustice of the planned, official urbanism.

Being 'there' and 'construct' synergic, catalytic collaborations between students, minorities, activists, 'normal' residents, students could serve as a model of unofficial community-based planning, tailored for Kaimakli, and not only?

Respecting, remembering, enjoying the 'Mneme' of the 'Topos' is often a challenging approach as it can be entrapped in romanticization and romanticization of our built environment. In this presentation we will point out the merits of the old Mneme and the highlight the importance of receiving the inserted Mneme by the ever-shifting populations due to Political, Climatic, and other Crises. Could his coexistence of Mnemes give birth to emerging Mnemes that could well be blended in cultural landscapes such as in Kaimakli? Could this be a way out of responding to the ever-growing conservatism, and xenophobia while enriching our Mnemes of the Past and the Presence, while facilitating Socially and Environmentally Sustainable Mnemes to emerge?

Keywords: *Human Topographies; ephemeral urbanism; Mneme of the Topos;*

Extended abstract

We understand our social identity in relation to others but we mostly perceive others implicitly, through the traces of their interactions with physical space near us. What if our urban environments could remotely mediate these traces, allowing spatially unrelated people to experience each other's presence collectively? Territoriality is an intrinsic characteristic of human behavior. We act territorially not only out of necessity but also instinctively, out of a natural propensity to exert control on our surrounding environment. We also act territorially reflectively, as a response to territorial behavior we experience from others on objects or territories we relate to. Moreover, we act territorially imitatively, when we join a social group's behavioral dynamics out of companionship. Territoriality, as the propensity to exert control on a place or an object, involves the psychological association with it. Importantly, according to social identity theory, territorial interactions that emerge between individuals reinforce perception of social identity because they provoke individuals to reason what unifies them and what distinguishes them territorially from others. This paper discusses the theoretical grounding, design, development, and early experiments, of a city-scale physical telepresence public art installation project of wirelessly connected giant inflatables placed at multiple sites that can enable visitors in each site to physically experience the presence of visitors in other remote sites, questioning our perception of locality, belongingness, and social identity. Cubic-shaped inflatable beacons, each containing 8,000 cubic feet of air, landmark selected locations in a city. The beacons share collectively the same volume of air forming a city-scale closed system. Anyone can animate any beacon by sending bursts of air to it using their mobile phones. Sending, however, a burst of air to a beacon requires removing the same burst of air from another beacon. Beacons illuminate, revealing the identity of the neighbourhoods they exchange air with. Watching a beacon deflate signifies someone from another neighbourhood uses this air to inflate their local beacon. Watching a beacon inflate signifies someone from the same neighbourhood uses this air to publicly manifest their presence in your common neighbourhood. Depending on people's location, point of view, and level of engagement, patterns of cooperation or competition may slowly build up across neighbourhoods, reflecting the two categorical ways with which we perceive our socio-locational identity: "us versus them" and "here versus there". The paper contributes to the discourse on environmental legibility, human territoriality, and social identity, arguing that the construction and perception of socio-locational identity can be influenced by design of locative physical telepresence media. It contributes to the field of shape changing interfaces by presenting novel methods to design and actuate shape changing interfaces for monumental scales.

Abstract

The element of water maintains a deep, timeless and bidirectional relationship with built space and the evolution of human society within it. This paper, explores how water is affected by cities and how sustainable water planning and management, may affect cities both on a microclimate level, as well as on a psychosocial, economic and cultural levels. In modern times, public health science, but also urban planning, investigate the benefits of water in psychosocial well-being. Focusing on the local scale of metropolises, characterized by densely built urban fabric and construction materials with high heat capacity, the present paper analyses Urban Heat Island effect, as well as the factors that improve urban microclimate. In this framework, guidelines for designing water elements are defined, aiming at regulating the microclimate, and also the comfort conditions of users in urban public spaces. «Antonis Tritsis» Metropolitan Park is the largest park in the Attica basin; it has a significant proportion of water elements in relation to its size while it is located in an extremely dense urban fabric. Hence, it is considered as an important case study of blue infrastructure. The aim is to highlight the benefits of the water element in the urban fabric, the good health and well-being of citizens due to both encouraged social interaction and interaction between citizens and natural environment. Thus, the park may act as a pilot case study, a point of reference for sustainable water management practices throughout Attica.

Keywords: *urban water, sustainable water management, comfortable urban environment, blue infrastructure, microclimate management, well being, A. Tritsis Metropolitan Park*

1. INTRODUCTION

This paper examines the multifaceted property of water as a main factor in shaping a holistic and sustainable living space for living organisms at the scale of the modern metropolis. The research aims on methods of adaptation to the environment and on the needs of such large-scale residential areas. The overall objective is to strengthen the connection between mankind and water, which is not only biological and physical, but also affects other areas of his life, namely mental health, economy, culture and society, as has been seen since antiquity. It has been observed that in areas where was access to water, there was development, for example along the sea coast and along rivers. In today's world, sustainable urban environments with water element that promote the psychosocial well-being and all living creatures that cohabit in them, is called Blue Spaces (BS). The research concentrates into two main objectives. Firstly, the planning of sustainable water management aiming to protect water resources and regulate the microclimate to improve the comfort levels of users in densely populated cities and secondly, the impact of the water element on social interaction and well-being of users and their connection to it. The major urban centers of the Mediterranean, due to their large populations, are characterised by coastal development, which transforms the coastline through the creation of buildings and infrastructure for housing, tourism, trade and transport; a phenomenon that interferes with the natural movement of water, but also its quality, with the landscape itself and its biodiversity. In the article entitled "Urban Blue Spaces as Therapeutic Landscapes: "A Slice of Nature in the City", in addition to the psychosocial well-being offered by BS, the medical term "therapeutic landscape" is

outlined. In BS, according to the authors, the concept of recreational activity is strong and directly linked to their beneficial effects on physical and mental health[1].

2. THE RELATION OF WATER TO THE BUILT ENVIRONMENT,

2.1 The importance of water in the urban microclimate

Massive bodies of water, such as oceans and large lakes can be described as heat reservoirs, as water has the maximum specific heat capacity of the materials around it and thus in large quantities it acquires the highest heat/thermal capacity of most materials on land, maintaining its temperature for longer, with so-called thermal inertia. For this reason, areas around large water masses are characterised by mild winters and cool summers. The form and design of cities have a bidirectional influence on the local climate, but also on the microclimate, with micro-meteorological variables such as air temperature, humidity, sunlight, as well as wind in open spaces and around buildings [2].

Within a city there is a constant alternation of sunny and shaded areas and this depends on the density and morphology of the built environment, the area and type of vegetation and the local weather conditions. The materials most commonly used on the surfaces of constructed space are asphalt, cement, brick, stone and other building materials, which are characterised by high heat capacity, of course less than that of water, and low albedo. This increases the temperature of the city and creates the **urban heat island effect**, which is even more observed at night. The small urban water elements cool the surrounding air during the day in the summer. However, during the night they remain warmer [3]. This is occurring due to cooling by evaporation, a phenomenon that occurs on all water surfaces. Water has the ability to reduce the ambient temperature by up to 3°C, within a radius of about 30-35m [4].

The research '*Really cooling water bodies in cities*' (REALCOOL) investigates the thermal effects of typical urban water bodies in the Netherlands and concludes that shaded water bodies, such as small canals, fountains and jets, have an improved effect on local temperature reduction [5]. Furthermore, moving water elements are considered to be more effective in regulating the microclimate than stagnant water element, as overheating of the water is avoided. More efficient practice is strategically dispersed water features on the area. Water and wind elements work in a complementary way at the local scale to regulate the microclimate. Dependent on the geomorphology of the landscape, but also the geometry of the buildings and the wind paths, a phenomenon called natural ventilation is created. Therefore, it is easy to comprehend that water surfaces have the ability to affect the microclimate of their area, but also to enhance the biodiversity and aesthetics of the landscape. By using moving water as waterfalls, fountains, jets, etc., or horizontal water surfaces in the suitable locations and quantities, such as canals, lakes and rivers, in combination with wind flow, it is possible to regulate the overall microclimate of an area within a city. The following table summarises the factors related to water elements and microclimate.

Parameters affecting the design of water elements, with the aim of regulating the microclimate			
parameters	characteristics/ properties	benefits	risks
vegetation	shade, water needs, evapotranspiration	shading, reduction of topical temperature	obstruction of wind flow and natural ventilation
general microclimate of the area	typical weather conditions	cloud cover, alternation of sunny and shaded areas	extreme/unexpected temperatures
type and size of water bodies	temperature absorption, phenomenon intensity	large water mass, greater evaporation	dazzling effect due to the reflectivity of the materials

surfaces	lower heat capacity than water	wind phenomena - sea breeze/land- offshore breeze	at very high temperatures, the phenomenon does not work
pavings	transmittance	water-permeable pavings enhance cooling by evaporation	impervious, stagnant water without drainage
inclination of surfaces (including water bodies)	different incidence angle of radiation	vertical or sloping surfaces absorb more radiation and cool more	horizontal water surfaces cool less
possibility of movement	jets in continuous or periodical motion	oxygenation of water, reduction of local temperature	easier spread of diseases
urban morphology, urban planning, architectural geometry of buildings	solar radiation/sunlight reaching surfaces	cooling by evaporation in summer/ solar heat gains in winter	overheating of stagnant water in summer, less solar heat gains in winter
general geomorphology of the area	wind, complementary operation with water	natural ventilation in summertime	strong winds in winter
human activities	function and needs of the space	aesthetic improvement	misuse, contamination and waste disposal

Figure 1: Parameters affecting the design of water elements, aiming of regulating the microclimate. (source: creation of the author)

2.2 Comfort and water element

Primarily for the protection of mankind and secondarily to ensure its comfort, it is necessary to design areas or zones in the city with a conducive microclimate and then to create comfortable outdoor public spaces in harmony with the natural landscape. By exploiting the local microclimatic characteristics, the appropriate comfort conditions can be created, with natural mechanisms for passive solar heating, cooling and lighting [6]. These conditions are divided into categories according to the sense they serve. These are the thermal, visual, acoustic and olfactory comforts that provide the visitor with physical and mental satisfaction. Thermal comfort is directly affected by the temperature of the air at 1-2 m from the ground, the temperature of the materials with which people come into contact, such as the materials from the seats. Visual comfort which is described by certain characteristics of the ambient light, such as quantity, uniformity and colour rendering [7]. The aim is to achieve maximum natural lighting during the day, without creating the phenomenon of glare, and at night, the most necessary and highest quality artificial lighting to avoid the consumption of excess energy and avoid disturbing wildlife. Also, visual comfort is not only about lighting, but also about the pictures the visitor receives, such as unobstructed views and natural elements, i.e. vegetation and water elements. Acoustic comfort, on the other hand, is not directly related to climatic conditions, apart from strong weather phenomena, but to human activity, which can have adverse effects. Lastly, olfactory comfort, which is often overlooked, although it is quite important, has to do with air quality, pollutants, proper ventilation without constant humidity, and in general with the smells one may encounter in the area. All of the above, ensuring comfort conditions in combination with the support of psychosocial needs, constitute a holistic sustainable tool for the improvement of public urban open spaces, for the optimal quality of life of the users. The importance of the existence of the water element in the built environment has more than an essential role, which serves the strategies of sustainable planning on multiple levels. A methodological tool entitled: "Small urban space network design parameters for comfort" was the basis for the **Figure. 2**, which **contains the effectiveness of water in regulating comfort** [8]

	Comfort			
	thermal	visual	acoustic	olfactory
water element	regulation of the local microclimate	aesthetic upgrade	flowing water, fauna that uses water	air quality when there is a flow of running water/ odour generation in the case of stagnant water

Figure 2: Comfort conditions in urban public space and the water material that regulate them. (source: creation of the author, based on the article «Small urban space network: the perspective of a green network including small and very small urban spaces as an answer to the scarcity of available public space in city centers»)

2.3 Blue infrastructure and water management practices in the urban landscape

The prosperity of coastal metropolises relies on their coastline, not only economically because of trade and industry, but also for the well-being of its own inhabitants. Many studies have been carried out in recent years to redefine the relationship: city and water. This applies to all forms of water within the city and collectively they are studied as Urban Blue Infrastructure (UBI); often UBI is associated with Urban Green Infrastructure (GUI), as in most cases they coexist. Large urban parks, for example, are identified as Green - Blue Infrastructure (UBI) because these green spaces contain UGIs, which deliver benefits to residents, supporting human health and well-being by bringing people closer to nature [9]. UBIs include all surface waters, whether natural or artificial, such as flowing water, i.e. rivers, streams, canals and creeks, but also stagnant water bodies, such as lakes and large ponds. Also, the shorelines of seas and rivers, with piers, harbors, docks and other types of water extensions [10] are part of this type of infrastructure. Their overall benefits are quite geared towards meeting urban needs through sustainable solutions and optimal ecosystem management to reduce the impacts of climate change [11]. This is because UBI solve practical comfort issues, as mentioned above for the water element, and contribute to reducing the Urban Heat Island effect, especially when combined with Green Infrastructure. The sustainable water management practices which are used in UBI have as a common denominator functionality, avoidance of alteration of the natural environment and circular economy to reduce the consumption of conventional energy. Some of these are rainwater harvesting, permeable surfaces and rain garden.

The biggest issue that the application of **rainwater harvesting** solves is the stagnant water on the impervious surfaces of cities, where unfortunately in today's large cities and metropolises, there are few natural surfaces and / or mainly artificial surfaces and the soil does not have the possibility to absorb quantities of water. The main reasons for using this practice are first to enhance water availability and reduce the demand for fresh water from the city's main water supply network and second, the artificial enrichment of the underground aquifer and improvement of water quality.

The overlay practices of **permeable pavements** and **rain gardens (RG)**, can be combined to carry out rainwater harvesting [12], filtering and reuse, as shown in the sketch in **Figure 3**. Also, the **filtering** and **reuse of grey and black water** from the neighbouring buildings in the area can fulfil the same uses as recycled rainwater.

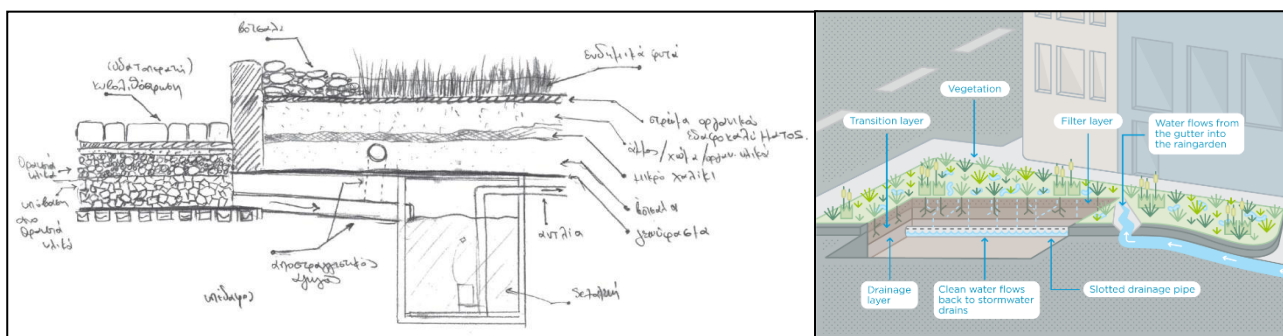

Figure 3: Rainwater harvesting with the combination of permeable pavings and rain gardens. (source: creation of the author, with information drawn from Greek Architects, 2014 and Commercial Stormwater Harvesting Systems, 2021. (right), Urbanwater.melbourne.vic.gov.au (left)).

All this, combined with renewable energy production, increases the resilience of cities to climate change and makes the local economy flexible. In conclusion, in an overall picture, UBIs in the urban fabric address the following issues listed in **Figure 4**.

Benefits of Urban Blue Infrastructure (UBI)	
Social	Coverage of the 5 basic human needs, by Carr etc.
	Interesting stopping points and movement zones for observation, meeting and relaxation
	Informing and raising awareness of water in society
	Access for all
	Encouraging physical exercise
Economic	Zero energy consumption
	Production of sustainable energy (clean energy)
	Use of materials with high durability for less maintenance
	Selection of local materials to reduce the waste of energy for transportation
Environmental	Strengthening urban resilience to climate change
	Reducing the risks of flooding, drought, but also ensuring water supply and drainage.
	Minimise fresh water consumption by collecting rainwater for reuse.
	Filtering and recycling of surrounding urban wastewater with artificial and natural treatment systems, grey water recycling
	Sustainable drainage system
	Protection and enhancement of biodiversity
	Ecosystem services of water bodies, through the concentration of larger populations of rare bird species and other wildlife.
	Improving the quality and quantity of water in the city

Figure 4. Benefits of blue infrastructure. (source: creation of the author)

To conclude, the connectivity of green and blue infrastructure in a city carries many advantages, such as the creation of wildlife corridors, allowing people, animals and wider biodiversity to co-exist and evolve, whether environmentally, socially or culturally.

3. CASE STUDY - THE METROPOLITAN PARK "ANTONIS TRITSIS"

3.1 General

The Metropolitan Park of Environmental and Educational Activities and Social Economy Development "Antonis Tritsis" is an important green area of Attica and the neighbouring municipalities, for many years with a wide variety of flora and fauna. The relationship of the study area with the main green spaces in the Attica basin is complementary and necessary, as it is the largest green space in terms of area and serves almost all of western Attica (**Figure 5**). Almost throughout its area there is a special water collection of six artificial water reservoirs (ponds) and an elongated channel connecting them. These ponds host and shelter rare aquatic flora, because they have been integrated into the environment, as they were originally waterholes from seasonal streams. Water conservation in the park's ponds was and is a key point of attention, because the main water supply is the aquifer, the wells and water reservoirs are still dependent on seasonal rainfall. The level of the aquifer has declined due to urbanisation, climate change and the overall poor management of the water element in the Attica basin.

Figure 5 (left). Location of the Antonis Tritsis Metropolitan Park in relation to the Attica basin, the main road network and green spaces. **Figure 6** (right). Aerial photograph of the study area in Antonis Tritsis Park. (source: google maps, edited by the author)

The landscape of the park, due to its diversity, allows the simultaneous existence of different uses that require space and facilities for intense activity, but also for relaxation. The uses of the park range from daily, to occasional or infrequent. It is undeniable that it is a very satisfying solution to escape from everyday life and to get in touch with nature. The proposal is being implemented in the northern part of the park to deepen sustainable water management strategies, but with the aim in future studies to extend these practices throughout the park, as well as to upgrade them (**Figure 6**).

3.2 Methodology and Results

The methodology applied is first the theoretical recording of the case study in relation to the history and evolution of the place, but also the collection of data, such as the urban characteristics, the needs of the wider area, and the climatic data of the area, for the subsequent selection of the appropriate practices to be proposed. Secondly, a field survey of the study case was carried out, with photographic recording and observation of the existing conditions in terms of flora, fauna, uses, the general situation and the needs of the study area. More specifically, in the first phase, the field survey is composed of data that were collected from users and residents of the city through digital questionnaire. In a second phase, the surface temperatures of the materials used on site are monitored.

Proceedings

3.2.1. Questionnaire

The digital questionnaire was divided into thematic sections in order to carry out quantitative research on users, their characteristics and their relationship with the site, as well as qualitative research on their needs and suggestions regarding the study area. A total of 498 responses to the questionnaire were collected (participation period December 2022 - January 2023).

Figure 7. (left) Level of satisfaction - comfort, **Figure 8.** (right) Opinions in relation to water elements.(source: results from the questionnaires by the author)

As shown in **Figure 7** the prevailing comfort conditions in the open spaces of the park in relation to the participants' satisfaction regarding thermal, visual and acoustic comfort, as well as resting and walking areas. The shading and rest areas are what is lacking in the park. In the **Figure 8** the vast majority of participants believe that the water elements in the city are important and contribute to the mental wellbeing of citizens, nevertheless they are unaware of the existence of ponds in the park. Furthermore, a very high percentage of participants (63.3%) consider the design and implementation of public spaces that promote sustainable management of environmental issues and at the same time serve citizens as utopia. In summary, the following conclusions were drawn from the questionnaire.

1. The water element offers relaxation and well-being and this is the main reason for visiting the site, followed by education and entertainment, with sport being a low preferred choice, but not negligible.
2. The need for new park equipment to provide safety and comfort (lighting, seating).
3. The creation of spaces in the park for themed activities such as experiential education, connecting with nature and relaxation, and lastly, spaces for children and also dogs.
4. Access to the park by public transport is poor and is a key reason why the park does not have a hyper-local character; therefore it is most often visited only by those living in neighbouring areas.
5. Sustainable solutions for the protection of the environment and the sustainable management of the park are significantly accepted and legitimate.
6. Need for areas with continuous vegetation and water. To this day there are no such spaces in the country and thus the participants consider that the blue infrastructure is not a possible project to be implemented.

In conclusion, water is an element that addresses users' psychosocial needs for well-being, through encouraging them to walk and exercise around it, but also to socialise. While at the same time there is a major shortage of blue infrastructure in the study area, as in many dense urban environments.

3.2.2. Documentation of thermal characteristics

The collection of local data in relation to microclimatic conditions for more targeted analysis was aimed at surface temperature.

Figure 9. Temperatures of the current park materials. Day: 29/12/2022. Time: 14.30-15.30. (source: created by the author)

On the day when the data were collected it was sunny with thin clouds, the temperature was around 9-15°C and there was high relative humidity. As can be easily seen from **Figure 9**, the time when the monitoring was held, it was the hottest time of the day, as the materials had absorbed radiation since sunrise and from then on, as the sun "setting", the radiation would decrease. The extremities of temperature recorded were the highest in the wooden seat in the sun, at 30°C, and the lowest was in the under-tree plantation, at 10 °C, where moisture is retained in the soil. In general, the materials most utilized in the built environment, such as cement, soil, gravel, tile and stone, in the sun maintained temperatures between 18-22 °C, while in the shade, for example, cobblestones were 9,7 °C. And lastly, a difference was also seen between the new and old materials, where the cement at that time had reached 21,4 °C, while the pebbled pavings had reached 18,3 °C.

4. PROPOSAL

The proposal is based on a thorough study of sustainable practices that will combine to protect the environment and create a suitable space for wildlife and the residents of Attica, that will upgrade the park both aesthetically and environmentally. The proposal is divided into two axes: 1) Sustainable water management 2) Visitor well-being and their connection to water. The design adds to the study the aspect of visitors, their well-being, information and socialization, through the planning, chosen

uses, equipment as well as the materials. The Metropolitan Park A. Tritsis on the one hand is still a space within the urban fabric and unhindered access for everyone is necessary, but on the other hand the use of natural materials benefits the hydrological cycle and maintains the natural beauty that the park offers to the residents. Therefore, paving should be varied to meet firstly the direct transport of water to the ground and secondly, the needs of the circulation in the area. The elements of the proposal are the following:

- Rainwater harvesting through Rain Gardens (RG), with native plants to filter and store rainwater for reuse (circular economy). For optimum results, it is proposed to place RG throughout the park, especially on the south side, to avoid runoff in the form of streams during heavy downpours to neighbouring municipalities.
- Collection, recycling and reuse of grey water from the buildings (central café - othonian courtyard buildings with new uses on the west side of the park - theatre - stadium etc.) and removal of pollutants in sustainable ways.
- Sustainable management of waste water - black water separately for each building complex (underground bioreactor)
- Placement of underground tanks (at strategic locations) to collect and store filtered water, i.e. rain and grey water, for irrigation, cleaning and also to supplement recycled water in the ponds whenever required (especially in the warmer months).
- Continuous flowing water to oxygenate in the canal and create visual, acoustic and thermal comfort in an important part of the park.
- Creation of an Outdoor Water and Energy Museum to educate citizens of all ages about water and sustainable water management.
- Generation of renewable energy, using the canal and general water flow in the park (Outdoor Museum area).
- Information and education of visitors, through games and activities about the elements of water.
- More general use of sustainable materials, with the aim of saving energy and easier maintenance and the use of water permeable materials.

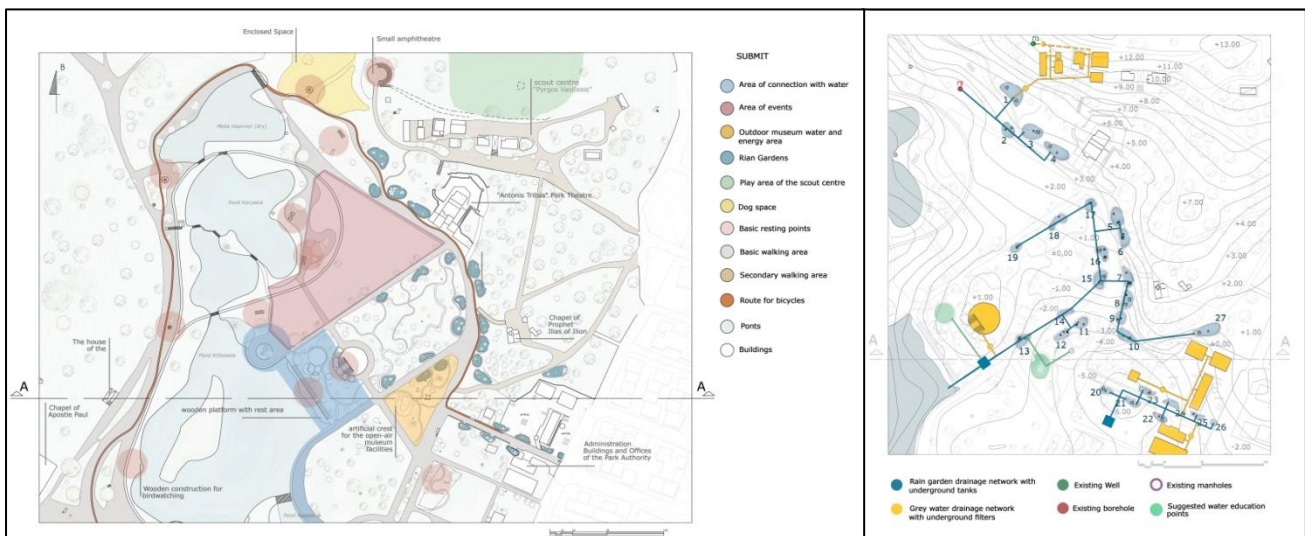

Figure 10. (left) Master plan of the proposal, Figure11.(right) Water management diagram. (source: created by the author)

In **Figure 10**, can be seen the master plan of the proposal, the separation of the areas according to their use. The zones are defined by the previous study. The aim is to meet as much as possible the park's water demand through water reuse. This aboveground system is supported by an underground

Proceedings

system of pipes and tanks (**Figure 11**). Their location on the site depends on the altitude, distance from the RG and the estimated amount of water.

5. CONCLUSION

The connection with the water element is a major component of people's well-being. Blue infrastructures, that are urban spaces where residents can come into contact with the water, have always been places in the urban fabric that have been chosen not only for operational purposes, such as trade, transport, or recreation, such as sports, but also for mental peace and tranquility. In addition to mental relief, people in blue infrastructure can also enjoy physical relief, as the water, depending on its volume, can regulate the local microclimate of the area and, by extension, the comfort conditions of urban spaces on a thermal, visual, acoustic and olfactory level.

Regarding the case study, the redesign of the park is a challenge that needs to be addressed, so that the citizens of Attica not only do not consider sustainable solutions utopian, but become an integral part of their everyday life, as the questionnaire highlighted the need for this. Information and awareness-raising is necessary, in a first stage and in a second stage, or even in combination, to implement these sustainable solutions in large and small areas within the city.

On a practical level as emphasized by the thermal monitoring in the field, the water-permeable materials in combination with continued shade, and the water bodies in various shapes are capable of regulating the microclimate of the area in a natural and sustainable way.

It is clear from the above that multi-faceted research can have combined effects and benefits on many levels. The cooperation of different research disciplines, such as medicine, architecture, planning, urban planning, agriculture, physics, etc., can therefore highlight the positive results that a multifaceted sustainable approach to the issues facing the modern everyday life of urban metropolises in relation to the water element can achieve.

Abstract

The research project "*LOUTROTOPOS: Critical mapping and visual narration of thermal springs in the Hellenic Territory*" investigates a network of places with thermal resources, which were selected according to the official map of thermal springs issued by the Greek Ministries of Tourism and Health. Following typical regional planning developmental strategies for remote and inaccessible places in the Hellenic periphery, the project focuses on the potential of enhancing endogenous local resources, highlighting the fact that thermal springs are geographical places with a unique physiognomy, reinforcing thereby their fundamental linkage with the concept of healing, as a cross-cultural holistic practice of well-being with uninterrupted historical continuity.

Within this conceptual framework, we visited and researched thermal springs in Macedonia and Thrace and identified their particular developmental advantages as well as problems. They are distinguished for the exceptional beauty of the natural landscape (such as Pozar and Eleftheres), the architectural heritage (such as the Byzantine and Ottoman installations in Agistro and Lagadas) or the special status of public use (such as the Baths of Echinis and Paranestio in Xanthi). However, we also identified several problems, such as abandonment, desolation, abuse, and disconnection from the architectural and natural landscape.

At the current stage of the research project, we applied a multi-criteria evaluation method that led to a qualitative classification of thermal springs in several regions, including Macedonia and Thrace. In line with the methodology of the research project, we selected the criteria according to multiple parameters, such as historical, geographical, cultural, social, architectural, aesthetic, landscape, urban, functional, place-image, etc. The findings were visualized in an interactive map, which will subsequently be used for the creation of visual narrations in the form of multi-channel videos that will showcase and promote the places of these thermal resources in the context of their interdisciplinary, cross-cultural and historical value.

Keywords: *thermal springs; critical mapping; visual narration; Macedonia; Thrace.*

1. INTRODUCTION

According to data from the Hellenic Geological and Mineral Research Authority (EAGME, formerly IGME), Greece is particularly rich in natural springs, having 822 recorded springs of thermal mineral waters, of which 750 are considered exploitable for their therapeutic properties. Despite this rich heritage, the thermal springs of Greece have not managed to attract a large number of international visitors compared to similar destinations abroad, which rather indicates a lack of an ingrained culture of thermalism, while the common perception of the primacy of the biomedical / therapeutic dimension of waters often associates these natural resources with the concept of illness and limits - arguably incorrectly - the image that we have of the average visitor, as a person of health interest. On the

Proceedings

contrary, the recent turn of the World Health Organization towards a more holistic view of health as a biopsychosocial condition of well-being, makes the study of thermalism particularly interesting from the point of view of a wider interaction between an individual and their physical and social environment, as well as the correlation of human behavior with a holistic view of health. The same turn also substantiates an approach to thermalism from a historical and folklore point of view, as these values are found equally in ancient naturalism as well as in the anonymous traditional practices of good nutrition, exercise, moderation and balance; values that are ultimately embedded in a recognizable behavioral, environmental and sociocultural context.

All of the above indicate that any inquiry on the potential of such natural resources as places for sustainable development, must perceive them as broader assemblies that encompass material and immaterial cultural heritage characteristics, which are inextricably intertwined with history, folk culture, alongside evidence-based documented medical and therapeutic practices connected to the springs. This perspective is aligned with the regional planning policies for the development of remote regions of the Greek territory based on the preservation of cultural identity and the promotion of endogenous local resources, highlighting thermalism as a holistic, body-centered and intercultural practice with uninterrupted continuity in Hellenic history and tradition.

Based on the above, the research project aims to examine in depth - and ultimately highlight - the cultural wealth of places endowed with thermal springs, in parallel to and inseparably from their basic function as thermalism destinations that support a therapeutic practice. For this purpose, it makes use of a research methodology based on mapping, a process that includes the identification, collection and organization of multifarious elements, material and immaterial, that the place image of a Loutrotopos consists of. The basic principles that this mapping process follows are a) the analytical and thorough investigation of each individual place, b) the investigation of their historical development, the identification and justification of temporal continuities and discontinuities and the recognition of its palimpsest structure and c) the comparison between different places and the identifying correlations and interactions between them. Finally, at the same time and through mapping, it attempts to discover the causes that led to the decline of the Loutrotopoi (plural) as spa destinations, in parallel with the weakening of the Greek spa culture, which once flourished. Overall, the approach aims to take into account *all* the various elements, combinations and correlations that shape and ultimately define the cultural identity of each Loutrotopos.

2. HORIZONTAL MAPPING

Work package 05 of the research project included introductory research to prepare for a more specific work plan and select the thermal springs that would be further explored. The ultimate goal of this preliminary work was to identify a profile of these springs and their networks. We carried out bibliographic research on official sources, websites and archives of public bodies or reliable private companies, in cross-reference with the official map and data on thermal springs of the Ministry of Tourism. We also looked up other, unofficial sources, websites, social networks, tourist websites and books to identify 'folk' places of thermalist interest that may not (in some cases, yet) be officially recognized by State authorities and are not included in the map of the Ministry or in official studies. In addition, we identified criteria for the evaluation and selection of places with thermal springs, as described in detail below, and designed a record sheet to formalize the research and the map on which they will be marked.

The thermal springs were grouped according to the administrative regions of Greece. Based on this classification, each researcher was assigned to prepare a brief explanatory report for their evaluation. The research team held a series of meetings to discuss the findings, present the introductory reports, and select thermal springs of interest for the next stage of the project. While the official data from the Ministry of Tourism provided information for their institutional recognition, we employed an additional 16 criteria according to the scope and methodology of the research project, on the basis of

Proceedings

historical, geographical, cultural, urban and other parameters as well as parameters related to the operation, reputation and type of the thermal springs. The list of the thermal springs (grouped according to the 8 administrative regions of Greece) along with their classification criteria were input in an excel file. Each thermal spring would get an evaluation grade from 1-4, where 1=none, 2=small, 3=large, 4=absolute agreement on each criterion, while at the end there was room for "observations" with any comments that the researcher considered important about the respective spring. The criteria are listed below:

1. **GEOGRAPHICAL LOCATION, ACCESSIBILITY:** The ability to access a thermal spring, through land, air or sea transport. Accessibility depends on the geographical location and varies depending on whether the spring is located in a central urban area, the periphery, or in an inaccessible area like remote islands, mountains and border regions of Greece. [Grade: 1 inaccessible areas. (By definition, border, islands, and mountains above a certain altitude) 2 when it is on a rural network but far away, 3 when it is in proximity to a large urban center and a good road and 4 when it is adjacent to or within main cities or towns].

2. **INTEGRATION INTO THE NATURAL ENVIRONMENT:** The natural landscape is considered as part of the cultural heritage; as such, it includes natural configurations in areas of particular geological formation, protected areas of flora and fauna with global scientific value, and places of natural beauty that need to be preserved. Thermal springs are considered thusly as parts of natural landscapes with significant natural features such as the terrain, vegetation, atmosphere, colors, textures of rocks and geological elements, etc. [Grade: 1 when the spring is in a city or on a road, or in a location with no natural landscape, 2 when it is on the outskirts of a city, 3 when it is in the natural environment and 4 when the environment is of particular beauty, such as Natura areas, forest, mountain, lake, etc].

3. **INTEGRATION INTO AN URBAN ENVIRONMENT:** Settlements of any scale (village, town, city, metropolis), are considered as potential urban places, and condensers of human civilization. Thermal springs are developed in relation to settlements, to a greater or lesser extent. This relationship is two-way, as the development of a settlement may be due to a thermal spring and vice versa. [Grade: 1 when it is far from large cities and outside small settlements, 2 when it is on the margin of a small settlement, 3 when it is in a small and medium-sized settlement, or near a large city, and 4 when it is within or on the boundary of a large city or within a town].

4. **INSTITUTIONAL RECOGNITION OF THERMAL SPRING:** Greece is one of the richest countries in natural sources of mineral water, hot and cold, with varying physicochemical composition and plenty of indications for application in modern natural hydrotherapy. According to data from the Hellenic Geological and Mineral Research Authority (EAGME, formerly IGME), in Greece there are 822 recorded sources of thermomineral waters, of which 750 are usable in relation to their healing properties. For the official certification of a natural resource located within a designated geothermal field as 'thermal', a joint decision of the Minister of Environment and Energy and the Minister of Tourism is required, following the agreement of the Committee for the Protection of Thermal Natural Resources, as well as the recommendation of the Hellenic Survey of Geology & Mineral Exploration and the Coordinator of the Decentralized Administration regarding the available flow and temperature. [Grade: 1 to an unidentified spring that has not submitted a file, 2 to a spring that has submitted a file, 3 to a spring that has received a Government Gazette and 4 to a spring with authorized license].

5. **OWNERSHIP:** As documented according to official data from the Ministry of Tourism, it refers to the status of operation, maintenance and touristic development of a thermal spring, by a public or private body or a combination of both. Regarding hydrotherapy facilities, 38 belong to municipalities, 37 to private individuals and 7 to the state. Note. The operating status is subject to change. The data for the study have taken into account the existing status. [Grade: 1 the thermal spring that is private property, 2 the thermal spring whose facilities are a combination of private and public entities (e.g.

Proceedings

reduced prices to certain groups of patients, Hellenic Public Properties Co), 3 the thermal spring that has facilities belonging to the municipality or the state, 4 the thermal spring that is located in a natural environment without infrastructure and is freely accessible to the public].

6. **THERMALISM INFRASTRUCTURE:** Thermal springs that are attached to hydrotherapy facilities, isolated or connected to built infrastructure, i.e. groups of buildings related to thermalism activities, and the different healing and wellness practices offered by the place. This includes the thermal infrastructure, the tourist accommodation, the development projects and their spatial planning are directly linked to the development dynamics of the thermal spring. [Grade: 1 when there is no infrastructure (such as a natural trough on the beach, next to a river, etc.), 2 when there is rudimentary infrastructure or ad hoc ones, 3 when there is a hydrotherapy center but no hotel or hostel, 4 when there is full infrastructure (hotel, hydrotherapy center, etc.). Note: this criterion refers to whether infrastructure exists in general regardless of whether it is currently operating or not. While the criterion concerning the current state of operation (see below) examines whether the facilities are operating presently].

7. **TYPE OF TREATMENT:** In Greece, thermal natural resources are officially certified for specific types of hydrotherapy (balneotherapy, inhalation therapy, drinking therapy) and mud therapy. [Grade: 1 drinking therapy, 2 inhalation therapy, 3 mud therapy, 4 thermal bath therapy].

8. **OPERATING TIME PER YEAR:** It refers to the period of time during which a thermal spring is accessible. If it is a hydrotherapy center, the hours, days and period within its operating time. [Grade: 1 when open only with special status (such as appointments or only a few hours) or not at all, 2 when open 6 months with store hours, 3 when open year-round with store hours or open for 9 months all day or with store hours, 4 when open all year round and almost all day].

9. **CURRENT STATE OF OPERATION:** Several thermal springs are currently abandoned and non-functioning; others are under-functioning in a formal or informal way (as in Lagada baths and Eleftheres respectively). Some free-access thermal springs (unfenced facilities) are considered as presently operational. [Grade: 1 when facilities are currently not operating, are abandoned, 2 when there is an informal or typical operation in a very small part of the facilities, 3 when facilities are operating with deficiencies and 4 when they are operating normally].

10. **FREE USE BY THE GENERAL PUBLIC:** Thermal springs that exist in an open-air, unfenced state, that have a natural flow in the environment, forming ponds, troughs, etc. located in a public place and therefore access by the general public is free at all hours, days, seasons. Accessibility to the general public may be temporary and unrelated to ownership (may be a concession by the owner). [Grade: 1 spring that is not accessible and 4 springs with open access facilities for the general public].

11. **TIMELESSNESS – AGE:** This is important for our particular scope of research considering that thermalism, as a healing practice, according to reports by Herodotus and Hippocrates, was born 2,500 years ago in the Aegean Sea. The operation of certain thermal springs over time is documented through archival material, photographs, literary texts, archaeological findings, written or oral testimonies, such as myths, stories, etc. The score on this criterion depends on the historical periods for which there is evidence for the operation of the thermal spring. [Grade: 1 the modern facilities created in the late 20th or early 21st century, 2 the springs operating since the beginning or middle of the 20th century, 3 the springs for which we know that they have been operating since the 19th century, 4 the thermal springs with known and uninterrupted operation since antiquity or Byzantine times].

12. **CULTURAL HERITAGE:** Recognition of places with particular historical importance, carriers of tangible and intangible cultural heritage. The material heritage includes building facilities such as monuments, oaks, baths or other bathing infrastructures of the past, which, due to their particular architecture, homogeneity and location, have exceptional global historical, architectural and scientific value. The intangible cultural heritage of a thermal spring is traced in written or oral evidence, representations, tools, and objects that reveal knowledge and techniques of historical significance, or

describe myths and stories of healing practices and thermalism, worship of gods in related sanctuaries and other body-centered bath practices. [Grade: 1 if the installation is modern, 2 if there is a reputation for use in antiquity or earlier, 3 if there are any minor archaeological remains or if the spring is located near a major cultural site, 4 if there are important archaeological and other historical findings or if the spring is located within an archaeological site or site of great historical and cultural importance].

13. **GEOGRAPHICAL NETWORK OF THERMALISM:** The possibility of organizing and integrating thermal springs that have common characteristics, as nodes in an expanded network. They can be related to geographical proximity, integration into a network of geomorphological parameters, cultural heritage, correlation with an urban place, type of thermal spring and its therapeutic property, etc. [Grade: 1 when the thermal spring is isolated in a geographical location, 2 when there is a relative geographical proximity, 3 when it is in close proximity to other springs, 4 when it is part of a larger system of thermal springs].

14. **COMBINATION WITH OTHER ACTIVITIES:** According to the new bio-psychosocial model of the World Health Organization, the concept of health is not limited only to the absence of disease, but also extends to the presence of physical, mental and social well-being. This is exactly the idea that thermalism comes to serve, which can be combined with other cultural, athletic and leisure activities. Thermal springs can offer similar parallel actions and be recognized as a supralocal tourist destination. Apart from the facilities of the thermal spring, the existence of activities such as sea bathing, hiking, speleology, observation of fauna, flora, visiting cultural sites, etc., in its immediate vicinity is considered. [Grade: 1 when there are no other activities nearby, 2 when there are at a distance of half an hour or up to 20 km on a mountain and 40 km on a road axis by car, 3 when there are activities in the vicinity and are accessible by car, 4 when there are several other activities in the immediate vicinity of the spring, accessible on foot. Each researcher should judge and grade based on these data].

15. **DEVELOPMENT DYNAMICS:** As a matter of fact, Greek thermalism attracted the first form of tourism in the modern Greek state. However, and although from a geological point of view Greece could become one of the largest thermal centers in Europe, its springs remain mostly unexploited and thermal tourism has never managed to gain significant traction compared to its archaeological and leisure destinations. Still, many resources exist in proximity, to each other and with other points of interest (POI), forming networked entities with a high potential for growth through empowering strategies. Development dynamics is a complex criterion that utilizes findings from all the previous criteria in critical reciprocity. A thermal spring can therefore be evaluated on the basis of a combination of elements, such as location, correlation with important elements of cultural heritage, integration into an interesting natural landscape or in proximity to a large urban center, or combination with other activities, etc. [Grade: 1 for minimum development dynamics, 2 for small, 3 for moderate, 4 for high].

16. **IMAGE AND REPUTATION, SUPRALOCAL DIMENSION:** The positive image attached to a thermal spring (brand) as perceived by the general public; how famous it is, how often it appears in the media, in google searches or how it is perceived by the public (e.g. on public reviews). The breadth of this reputation, local, supralocal, national or international. [Grade: 1 for unknown or only locally known springs 2 for springs that are known in the area of the prefecture and at a distance of up to 100 km, 3 for springs that are known in the wider region and somewhat in Greece and 4 for springs that are known throughout Greece and abroad].

3. VISUALIZATION

In the next stage, graphical symbols were drawn based on the criteria and placed on a map. The graphic symbols consist of circles, coloured surfaces and a cross. Specifically, in each symbol there are 5 concentric circles with different color, thickness and type of line, depending on the type of criterion and its score. Between the circles the surfaces created (rings) have colors with different

Proceedings

intensity corresponding to scores. The cross corresponds to four criteria and the score is given by the line thickness of each of its legs. A further criterion is represented by the position of one of the inner circles with the score corresponding to each of the four quadrants of the circle.

The symbols corresponding to the thermal springs are placed on a map of Greece. Each symbol is drawn in 16 different layers, in order to provide the possibility for the comparative observation of all thermal springs for each criterion. Also, the map is drawn at several scales of analysis, so that it is possible to monitor the thermalism in Greece as a whole and in regions. The map is digital and is linked via hypertext technology to a multi-criteria database (excel) that includes the scores and observations of the researchers, as well as reports of the researchers evaluating each spa. The above can be seen in the figures.

A/A	CRITERION (1-16)	GRAPHIC SYMBOL
01	Geographical location, accessibility	Red 1, color intensity
02	Integration into the natural environment	Green, color intensity
03	Integration into an urban environment	Red 2, color intensity
04	Institutional recognition of thermal spring	Gray, color intensity
05	Ownership	Cross - right, line thickness
06	Thermalism infrastructure	Cross - up, line thickness
07	Type of treatment	Circle position in each quadrant
08	Operating time per year	Cross - bottom, line thickness
09	Current state of operation	Purple, shades
10	Free use by the general public	Purple, solid – dashed line
11	Timelessness - age	Cross - left, line thickness
12	Cultural heritage	Blue, intense color
13	Geographical network of thermalism	Red, line thickness
14	Combination with other activities	line thickness
15	Development dynamics	Number of outer minute circles
16	Image and reputation, supralocal dimension	Yellow, color intensity

Table 1. Graphic symbols of multicriteria analysis

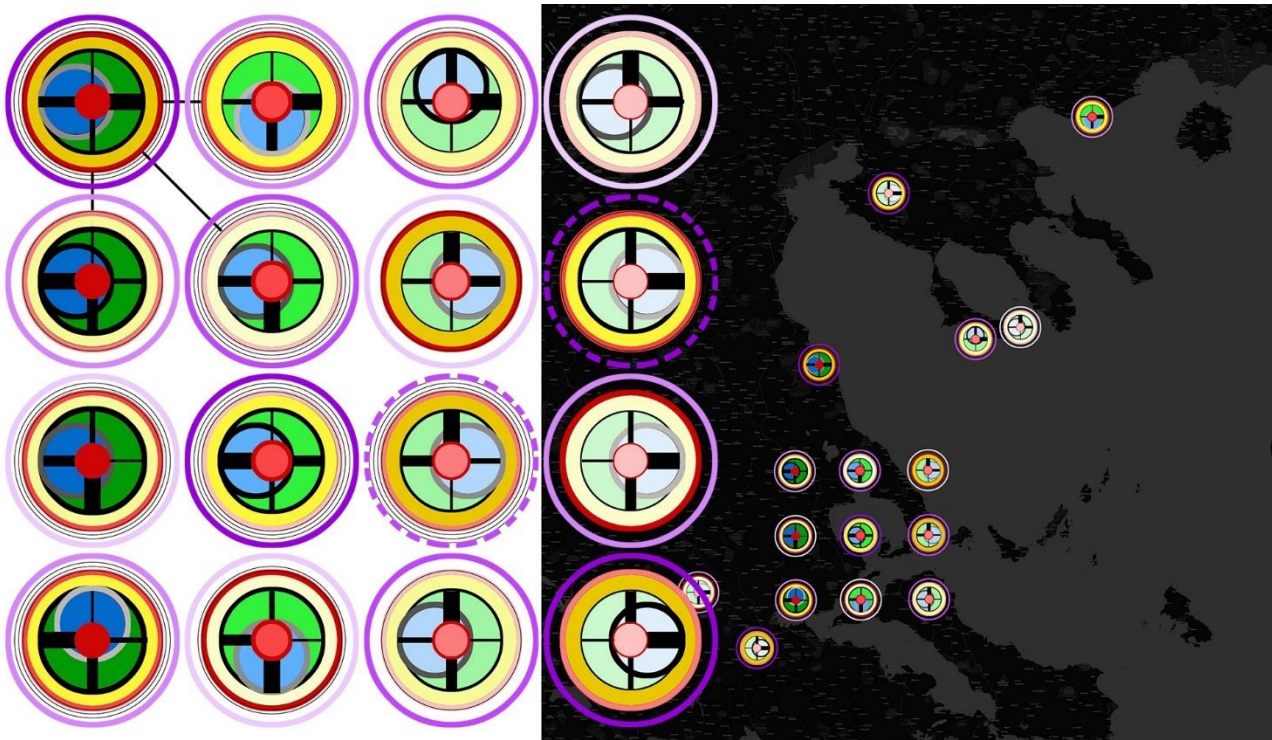

Figure 1. Graphic symbols of multicriteria analysis on a map

4. MACEDONIA AND THRACE

4.1. Multicriteria Analysis

In Macedonia and Thrace there are 30 certified thermal springs. Together with Sterea Ellada (36 certified spas, 13 of which in Edipsos and 10 in Kamena Vourla) they stand as the two regions richest in thermal springs in Greece. These are mainly individual facilities that are not connected to larger thermalism settlements. The thermal springs of Macedonia are particularly distinguished for their exceptional natural surroundings (such as the proximity to waterfalls, lakes, the sea) and for the Byzantine and Ottoman facilities with ceramic tiles and ornamental decorations (such as the thermal baths in Agistro, SEDES and Lagadas). A problem found in their historical consistency is the disruption of the architectural landscape by self-serving contemporary building facilities, that rather cover the architecture of the old baths instead of highlighting it; as it typically happens in Lagadas where the elongated contemporary building creates a barrier against the view of the old baths; or in Agistro, where the large-scale hotel literally ‘swallows’ the little, yet historically significant and well-preserved, bath building from the Byzantine era. But the most important problem that is recognized on a larger scale is the widespread desolation of formerly prosperous facilities that are either not operational today or operating in a rudimentary manner. Among the reasons for this situation, we find the large size of the facilities and the binding institutional framework that makes them difficult to maintain by a private individual; along with their remote location, that makes them less accessible compared to other destinations. Still, their importance to the collective heritage of each place is found significant, once we account for the nostalgic recollections of the local inhabitants who talk with nostalgia about a glorious past, when the facilities were crowded with visitors. Unfortunately, only worn-down traces of this past remain today...

Central Macedonia

	Analysis	Conclusion
01	3 springs are in places with difficulty in access, 5 springs are in a provincial lowland network but relatively far away, 5 are in proximity to a large urban centre and a good road and 3 are next to or inside central cities (Souroti, SEDES, Lagada).	Springs are equally distributed in hard-to-reach and central areas.
02	5 springs are in the outskirts of the city, 6 are in the natural environment and 7 are in an area of special beauty (Pozar, Apollonia, Kanistro and Agia Paraskevi of Halkidiki, Doumbia and Alikí Kitrous).	Several springs are located in natural surroundings, and several in areas of special beauty.
03	7 springs are far from large cities or outside small settlements, 8 springs are located on the border of a small settlement, and 1 spring is located on the border of a large city (SEDES in Thessaloniki).	In the majority of them, the thermal springs are not located in urban areas, but in small settlements.
04	The Picrolimni mud treatment centre is not a certified thermal spring, 4 springs have submitted a dossier for evaluation, 5 have received a gazette and 6 operate legally.	Most springs operate legally and are certified.
05	3 springs are privately operated, for one thermal spring its facilities are a combination of private and public entities, 12 springs have facilities owned by the municipality or the state.	Most springs are controlled by government agencies.
06	4 springs have rudimentary or improvised infrastructure, 3 have hydrotherapy or drinking water facilities and the remaining 11 have full infrastructure, hotel, hydrotherapy.	Most springs have healing and hosting infrastructure (regardless of the fact that most are currently suspended)
07	4 springs are for drinking therapy, 2 for mud therapy and the remaining 10 for balneotherapy.	Most springs offer thermal balneotherapy.
08	7 springs today are not working and the remaining 9 are open all year round and almost all day.	About half of the springs are currently suspended.
09	7 springs are not working today and several of them are abandoned, in one there is a formal operation in a very small part of the facilities (Lagadas), and 8 are working normally, of which only 4 have treatment facilities (balneotherapy or mud therapy).	The overall picture is that most springs today are not working or underperforming.
10	13 springs are not accessible and 3 springs are freely accessible to the general public, of which only one is a bath of mud spring (Alykes Kitrous).	Thermal bath springs are not freely accessible to the general public.
11	3 springs have contemporary facilities created in the late 20th or early 21st century, 4 springs have been in operation since the early or mid-20th century, 3 springs are known to have been in operation since the 19th century, and 6 thermal springs have known and uninterrupted operation from antiquity or Byzantine times (Souroti, Picrolimni, Giannes, Lagada, Agistro, Sidirokastros).	There are several springs for which there is evidence of long-term operation.
12	In 4 springs the facilities are contemporary, in 5 there is a reputation for use in antiquity, in 2 there are some ruins of minor importance or the spring is located near a major cultural site, in 5 there are important archaeological and other historical findings.	There are several sources that have historical significance.
13	6 springs are located in geographical locations that are inaccessible and for 10 there is a relative geographical proximity.	No geographical network of correlation of the springs is found between them.
14	In 5 springs there are no other activities nearby, in 4 springs there are activities within half an hour, in 6 springs there are activities in the vicinity and are accessible by car and for one (SEDES) there are other activities nearby (of the city of Thessaloniki).	They generally exist in the vicinity or at close distances from springs and other activities.
15	One spring shows minimal development potential (Loutrochori), 6 have low potential and 9 have high development potential.	The dynamic growth index of the thermal springs in the region is relatively high.
16	Four springs are relatively unknown or only locally known, 5 springs are known in the area of the prefecture and at a distance of up to 100 km, 3 springs are known in the wider region and 3	The reputation of most springs is local or supra-local, although one spring (Pozar) is among the best known internationally and two are of great reputation.

Proceedings

springs are known throughout Greece and abroad (Poazar, Sidirokastro, Agistro).	
---	--

Eastern Macedonia and Thrace

	Analysis	Conclusion
01	3 springs are in inaccessible areas, 3 springs are in a provincial lowland network but relatively far away, and 1 is in proximity to a large urban center and a good road (Krinides Kavala).	Most springs are not very easily accessible.
02	5 springs are in areas of outstanding natural beauty, and 2 are in the natural environment.	Generally, they are integrated into the natural environment.
03	3 springs are distant from large cities and settlements, 2 springs are on the boundary of small settlements, and 2 springs are located in a small-medium settlement.	In general, no spring is located within or on the boundaries of a major city.
04	3 springs have received a Government Gazette and authorized license (Traianoupolis, Krinides and Psarotherma) while 4 springs have received only a Government Gazette. Only 1 spring has filed an application and is awaiting recognition.	So almost 90% of the springs are certified.
05	6 springs (75%) belong to the municipality or the state, while only 1 is privately owned (Eleftheres).	Therefore, only 25% of springs are proprietary.
06	2 springs (Traianoupolis and Eleftheres) have full infrastructure, with hostel, hydrotherapy center etc. 2 springs (Krinides and Psarotherma) have only a hydrotherapy center without a guest house. 3 springs have informal (Paranesti) or rudimentary infrastructure (Echinos, Parenesti and Potamia).	Most springs have some decent infrastructure.
07	7 springs are for balneotherapy and 1 for mud therapy (Krinides)	Almost all springs involve balneotherapy.
08	3 springs are open all year round, 2 springs are open six months at store hours, and 2 springs are open only by special appointment or closed.	Many springs seem to have limited hours of operation.
09	3 springs operate normally, 1 spring operates with deficiencies (Potamia), 1 spring (Paranesti) operate informally and 2 springs are abandoned (Traianoupolis and Eleftheres).	Most springs operate but not all of them officially.
10	4 springs are freely accessible by the general public, while the rest 3 have restricted access.	Half of the springs are freely accessible by the general public.
11	1 spring dates back to the late 20th century, 4 springs have been operating since at least the 19th century. The baths of Eleftheres have been known since antiquity, but the thermal town was built in the 20th century. 2 springs have had a diachronic function (Traianoupolis from the 4th century AD and Krinides).	Most springs have had a historical past, either remains or tales about their function, which attests diachronic function.
12	2 springs have archaeological findings (Traianoupolis has Roman baths from the time of Trajan and the baths of Eleftheres have remains of Ottoman baths). 1 spring is close to a great archaeological site (Krinides is located in the wider area of Philippi, one of the most important archaeological sites of Macedonia where one can find ancient thermae, the ancient agora, the ancient theater of Philippi, etc.). 3 springs maintain a reputation for functioning since antiquity and 1 spring is a modern facility (Echinos).	Most springs are within archaeological and historical environments that attest their diachronic presence.
13	All springs are located in relatively close proximity to each other.	The springs can constitute a geographical thermalism network.
14	2 springs have other activities in close proximity. 4 springs have other activities within half an hour. 1 spring has no other activities nearby.	The average of 'other activities' for all springs is within half an hour.
15	1 spring has great development potential (specifically at the baths of Eleftheres about 21 forest acres have been declassified in order to build a new hydrotherapy center as well accommodation and catering facilities). 3 springs have moderate development potential (for example, Echinos, although inaccessible, has interesting infrastructure in nature as well as Potamia, the surrounding natural and archaeological landscapes and their connection with the baths of Echinos). The remaining 3 springs have little development potential.	Some springs can be further developed due their proximity to nature, existence of thermal infrastructure and other activities or archaeological landscape nearby.

Proceedings

16	5 springs are known in the wider region and in the Greek territory (especially Krinides), 1 spring is known within the boundaries of its prefecture (Traianoupolis), and 1 spring is only locally known (Potamia).	Some but not all springs have a wider or supralocal reputation.

4.2. Travelogue

Figure 2. Map of thermal springs in Central, Eastern Macedonia and Thrace

The travelogue was organized in November 2023, with the aim of getting to know the thermal springs of Central, Eastern Macedonia and Thrace first-hand. The trip lasted four days and 11 locations were visited. The route is shown on the map.

On the first day of the travelogue, the first stop was Alykes Kitrous in Katerini, a thermal spring for mud therapy. Alykes is a coastal wetland, a lagoon at the mouth of three rivers, Axios, Loudias, Aliakmonas, in which there are therapeutic mud baths. It consists of an earth pit with mud next to the salt pans. Its use is informal, and access is free to the public; which contributes to Alikis Kitrous' natural resource remaining a lived place. According to the testimonies of residents and salt pan workers, the baths are often visited by busloads of people. But when the Travelogue visited the place, it was found to be deserted.

The next stop was Loutrochori Skydras, otherwise known to the locals simply as "Baths", due to the existence of a thermal spring. This is a small, country village with a square, church, a park and the thermal spring found as you drive straight to its centre. It is assumed that ancient baths existed there from the time of Alexander the Great, but no archaeological findings exist to substantiate this claim. The residents also claimed that years ago the village had a lot of visitors because of the 'baths'. However, its current image exuded abandonment and decay. What is considered as 'spa facilities' lie mainly as a privately owned swimming pool that once operated in the backyard of the local priest's residence.

The third stop was the famous Pozar Baths (thermal springs of Loutraki Aridaia). These are perhaps the most famous thermal destinations in Greece, with a large number of visitors coming from Greece and abroad throughout the year. The word "pozar" is Slavic and it means fire. The thermal spring is located on the border with North Macedonia at the foot of Mount Kaimaktsalan. There is evidence that establishes the operation of the Pozar Baths since antiquity. Their main feature is the waterfalls

from the stream of Agios Nikolaos fall next to a natural cavity of warm water, offering the visitors a unique landscape along with an impressive multi-sensory experience, at the same time. Integration with nature is absolute. The facilities are extensive and renovated. The baths operate under public administration, carrying a low cost of entry for the bathers. In several other parts of the river in the wider area there are additional thermal spring outlets, which have been shaped into pools by the residents and visitors. In the area there is also a speleological park with 17 caves and findings from prehistoric times. Every July there is an annual music festival, the "pozaritika".

On the second day of the travelogue a visit was made to the mud therapy facilities of Picrolimni in Kilkis. Picrolimni is a small, roughly circular lake located 33 km north of Thessaloniki. It was known since antiquity for its healing properties. The facilities that once operated there are now abandoned and in ruins. The privately owned business was closed due to financial reasons. The natural scenery is amazing. The large flat areas of the adjacent moor with the bushes moving in the wind and the cloudy sky combined with the deserts, seemed 'haunted'. An evocative atmosphere was created when visiting this place, along with a sense of regret for all that existed before and lie today destroyed. We encountered the same sentiment in a video on YouTube, through the penetrating descriptions from members of a local institution, and especially through the testimonies of residents who used to visit the mud facilities when they were in operation.

For the Sidirokastro baths, located near Promachonas in Serres, just before the border with Bulgaria, the prevailing feeling is that they are cold, medical facilities. The contemporary modern buildings, the hydrotherapy centre and the hotel, dominate the area and unfortunately fail to highlight the Byzantine legacy that the baths once carried. The old Byzantine buildings have been destroyed and the hammam has been renovated twice, in 1930 and 2000. Most of the bathing pools are covered and still carry their Byzantine architectural characteristics. There are also waterfalls in the area. Since 2023 the baths were operating illegally with a debt of 2 million euros and their operation is currently suspended.

Next stop was the baths in Agistro, which are very close to the border with Bulgaria. There lies one of the most important Byzantine monuments, a magnificent domed bathhouse, covered with luxurious tiles and a marble fountain, which unfortunately has been literally swallowed up by the modern hydrotherapy centre and hotel. The natural landscape in the surrounding area is remarkable.

On the third day a trekking expedition started with a visit to the abandoned baths of Nigrita, a provincial town about 25 km from the city of Serres, located in a purely agricultural landscape with straight, even roads crossing the plain of Serres, north of Mount Surpa. Ten years ago, a spa and a fountain with drinking mineral water operated at the site. The ruins of a Byzantine bathhouse are still preserved there and remain unused. Further on, among trees and meadows, old baths from the facility are now used as watering troughs for animals...

From the coastal road between Amphipolis and Kavala, south of Mount Pangaion and about 45 km southeast of Kavala, a small perpendicular road leads to the valley of Marmaras, an area of particular natural beauty. There lie the thermal springs of Elefthera, which have been known to exist since antiquity. What the visitor sees today is a mysterious settlement in abandonment and in full integration with the lush surrounding nature, giving the impression of being haunted. The bath settlement consists of 31 that still remain standing, the oldest of which is an Ottoman bath of the late 18th century. The area became a spa town when in 1908-1910 the tobacco merchant Zachos Zachou took over the rights to exploit the springs from the Ottoman government. The architectural design project was undertaken by renowned architect Aristotle Zachos, who also designed a few hotels nearby (Amphipolis, Pangaion). Today the settlement is completely abandoned, but it is occupied informally for long periods of time each year by groups and individuals who have taken advantage of the facilities to turn them into makeshift residences. Within the premises there is a working swimming pool, and there are several natural 'pools' on the riverbanks which receive many visitors.

The region of Eastern Macedonia and Thrace includes 3 of the most unique spa destinations in northern Greece: Thermios Paranestios Baths east of Drama, located on Mount Rodopi in an inaccessible location, Psarotherma on the island of Samothrace and Thermios Echinios Baths in Xanthi. In all three cases, these are makeshift free-use facilities in beautiful locations with particular characteristics for each one: the 'troughs' of Paranestios are sheltered in tin shacks; the Thermes of Xanthi are located on a hill overlooking a valley; and the Psarothermas (plural) consist of a series of open-air rectangular pools featuring the famous 'hot pedestal' on top of the hill facing the sea. It is a rectangular pool measuring approximately 2 x 3 metres and 80-100 cm deep, which is visited daily during the summer by hundreds of holidaymakers. During our trek we visited the Thermae Echinou of Xanthi. The community of Thermes is located 45 km from the city of Xanthi and consists of four Pomak settlements hidden in the mountains: Upper Thermes, Middle Thermes, Lower Thermes and Loutra Thermes. It is hidden in nature alongside streams where hot water gushes out, drawing from the rich geothermal field of the wider area of Xanthi. It is said that, in the past, the Pomaks used to put their sheep and goats in the natural pools of thermal water created on the hillsides, in order to cure them of orthopaedic and other problems. There are over 40 springs in the wider area where thermal water gushes out. The springs attract visitors from all over the region of Eastern Macedonia and Thrace, Thessaloniki and regions of the southern Balkans. In 2021 a number of individual open-air pools (baths) were created. Integration with nature and the mountainous Pomak environment is absolute. Although it is a very hard-to-access place, these exceptional infrastructures with their particular sculptural aesthetics and their relationship with nature attract a large number of admirers. It should be noted that the facilities are very clean and neat, as they are well-taken care by both their managers and their visitors.

On the last day of the trek, we visited two loutrotopoi in Thessaloniki, the SEDES baths in the east of the city and the Lagada baths in the north. The SEDES thermal baths are located at the eastern edge of Thessaloniki, namely, in direct relation to a metropolitan urban area, developed in a pine wooded area of 500 acres which extends on both sides of the road leading to Halkidiki. The baths used to be operational, but the facilities are now in ruins. Their architecture, although not of Byzantine period, their integration into the natural environment and their proximity to the large urban centre make them quite interesting. There are some remains of ancient baths and constructions of Byzantine architecture on the site, which could possibly show potential. The baths of Thermi have been known to exist since antiquity.

The last stop was the Lagada Baths. The bathing facilities are located in the settlement of Lagadas, 20 km north of Thessaloniki. The main street of the settlement carries the name "Loutron" (transl. "bath"), which signifies the great importance these hold to the local community. In the facilities, which resemble a large multi-purpose park, modern and old structures of Byzantine heritage coexist. Unfortunately, same as in Sidirokastro, the Byzantine heritage structures are concealed by the contemporary building which imposes a cold generic façade of pure medical character. The operation of the facilities today is found to be inconsistent and lacking: while there were reportedly supposed to be a number of outdoor and indoor pools in operation, our visit found that only the two Byzantine pools are in operation, while the rest of the bathing facilities are abandoned in an old and dilapidated wing of the modern building. It is worth noting that the word "unacceptable" is mentioned about 30 times in the visitors' book. Although the premises are surrounded by a large span of open green spaces, which would have us expecting that the facilities' integration into the natural landscape would be at least acceptable, unfortunately, the landscape again shows a great deal of decay with most of the outdoor facilities being in a state of under-use, obsolescence and desolation. As in other similar cases, the bathing facilities are managed by the municipality.

Overall, the majority of the eleven Loutrotopoi in Central & Eastern Macedonia and Thrace that we visited were found to be either non-operational or operating below their nominal potential, and the general impression we acquired is one of decline. An interesting correlation that we found is that the

Proceedings

level of decline increased with the size of the infrastructure; or, that the prosperity of the Loutrotopoi was inversely proportional to the scale of the facilities attached to them. This makes sense, once we connect the cost of maintenance to the utilization of the facility: where maintenance costs were high, the facilities were under-utilised, and the lack of maintenance was evident; in contrast, where the natural landscape was taking prominence and the structures were make-shift and freely utilized and maintained by the visitors, the situation was much more acceptable and the visitors were happy to join in the general vibe. Ultimately, it looked like the facilities that were more tightly (or genuinely) connected to the natural landscape attracted more visitors.

5. CONCLUSION

As the above study shows, both through multicriteria analysis and in situ empirical observation, during our field trip the most important nominators for the sustainable operation of places with thermalist interest proved to be the type and scale of the facilities, the type of use (public, free, open-air or private, controlled, covered) and the proximity / embeddedness to an interesting natural landscape. Accessibility does not seem to be as important, since the large number of visitors at the Pozar Baths, which are located in a remote area of true natural beauty, find no problem coming in large numbers every year, while other places which are located conveniently close to an urban area, e.g. such as SEDES, Traianoupoli and Lagada, still remain unpopular and, by result, in decline.

This creates the premises of a discourse about the notion of ‘capitalization’, which now appears irrelevant to a discussion about a Loutrotopos’ potential for development; since intangible qualities such as ‘genuineness’ surface as a much more resilient classifier of value, than medical capacity and infrastructure. Furthermore, the value that comes from the institutional certification of a spring’s healing properties, and/or the organized infrastructure that’s attached to it, seems to be disproportionately unimpactful to the wider public, considering their manifest acceptance of makeshift structures and/or untreated natural formations as places of healing, regardless of the fact that bathing in untested and uncertified waters potentially holds great hazard to public health. This draws an argument that a Loutrotopos’ appeal lies beyond the mere certification of the medicinal value of the thermal spring, as it is arguably evident that the value of ‘topos’, namely the intangible quality of a place, is equally critical to the value of ‘loutro’, namely bathing in healing waters.

In conclusion, our research showed rich and tangible evidence that ‘Loutrotopoi’ are, above all else, inextricably embedded in a wider socio-cultural context that also includes folk culture and a hard-to-grasp sense of place, which is by no means measurable by prescriptive quantitative metrics. This calls for the development of an expanded set of qualifiers, along with tools that reflect a holistic understanding of the problem, unearth and examine the character of the subject area, and connect specific medicinal requirements with a humane sense of healing.

ACKNOWLEDGEMENTS

The research project «*LOUTROTOPOS: Critical mapping and visual narration of thermal springs in the Hellenic Territory*» is funded by the H.F.R.I. under the call “Funding of Basic Research (Horizontal support of all Sciences), National Recovery and Resilience Plan (Greece 2.0)” in the field (S.F.7) Humanities and Arts” with Host Institution the University of West Attica and coordinators: Georgia Touliatou, Efrossyni Tsakiri & Efrossyni Mouzakitou.

This project is carried out within the framework of the National Recovery and Resilience Plan Greece 2.0, funded by the European Union – NextGenerationEU (Implementation body: HFRI).

Abstract

Mediterranean cities, with their specific climatic traits of hot summers and mild winters, are highly susceptible to the urban heat island (UHI) effect, exacerbated by urbanization practices. The UHI, characterized by elevated temperatures in urban areas compared to surrounding peri-urban regions, stems from human activities like using heat-absorbing construction materials and dense urban development. Factors such as urban topography and geometry contribute to heat retention by hindering natural ventilation. Poor urban planning worsens thermal discomfort in outdoor spaces. This paper details an experimental study in a post-refugee urban neighbourhood in the Attica metropolitan region, designed in the 1930s. The area's urban layout, featuring open public spaces in each city block, facilitates landscape design experiments. Using ENVI-MET software, the authors explore diverse UHI mitigating strategies, including high albedo materials, and water bodies. The findings contribute valuable insights for future research and analysis in mitigating the UHI effect in the urban Mediterranean context.

Keywords: *landscape design; urban design; thermal heat island; Athens-Piraeus; urban greening; high albedo materials*

1. INTRODUCTION

The theoretical discourse on the quality of life in urban centres has sharply highlighted the role of natural elements in the urban fabric since the early Industrial period. The theoretical discussion begins with references to the poor living conditions of factory workers in the early industrial centres of Great Britain [1] initiating a reflection on the balance between anthropogenic and natural elements in urban environments. In the first decades of the 20th century, the idealization of the countryside led to the urban planning practice of garden cities, with well-known examples such as Letchworth Garden City in Great Britain [2]. In the subsequent decades, environmental concerns on the quality of life in metropolitan areas put in the forefront the role of open public spaces. Urban regeneration across various scales, is gradually being associated with a series of environmental issues, which acquire measurable form through quantitative recordings, environmental indicators, and relevant measurements [3,4]. For Greece, Law N.1337/83 constituted a milestone in highlighting the significance of open public spaces by recognizing its contribution to improving the quality of life. According to recent relevant literature, different scales of outdoor spaces can positively contribute to the improvement of urban microclimate [5]. Particularly, in the metropolitan area of Attica, the necessity for such holistic interventions is deemed essential due to a variety of factors. A fundamental parameter is the fact that many parts of the urban fabric were created under the pressure of historical circumstances, related to significant demographic flows. One such demographic flow that determined the future of urban and rural areas in Greece was the refugee influx following the Asia Minor

Proceedings

of the International Conference on **Changing Cities VI:**

Catastrophe of 1922. Despite the pressures for a fast-housing rehabilitation, most of the urban refugee settlements, followed basic design principles, including the presence of outdoor spaces of different scales within the city blocks [6,7]. Surveying the entirety of the refugee settlements in Attica in previous research the refugee enclave of Nikaia serves as a fruitful field for exploring different landscape scenarios and their impact on urban microclimate [8].

2. THEORETICAL CONTEXT

2.1 Contemporary challenges of urban microclimate in Mediterranean cities and the role of open public spaces

Urban microclimate challenges in Mediterranean cities, marked by temperature extremes and changing precipitation patterns, pose multifaceted issues affecting liveability and sustainability. High temperatures, heat waves, and prolonged intense sunlight contribute to thermal discomfort and heat stress for residents in these urban environments. [9]. Moreover, climate change has led to alterations in precipitation patterns, resulting in water scarcity, and affecting the overall microclimate [10–13]. In addition, the accelerated growth of Mediterranean cities has led to increased impervious surfaces, reduced green spaces, and a rise in energy consumption, exacerbating urban heat island effects [9,10]. According to relevant literature, the phenomenon of urban heat islands is associated with the rise in temperature in urban areas compared to suburban and rural areas.

The term was first introduced in Luke Howard's work, *"The climate of London"* (1833), focusing primarily on the temperature increase in urban areas during the night [14]. Urban thermal stress in Mediterranean cities arises from factors such as buildings serving as heat reservoirs, surfaces with conventional materials impeding natural cooling, restricted air circulation, lack of vegetation for water evaporation, and the re-emission of long-wave solar radiation. The term "urban thermal stress" characterizes warm enclaves within cities, encompassing both daily and nocturnal temperature variations. In the case of Athens, according to research conducted at 30 stations in the city and suburbs, this difference reaches up to 10°C [3]. This phenomenon is more pronounced during the summer period and affects the temperature of the atmospheric air as well as the surfaces of buildings and urban outdoor spaces (ibid). It is particularly intense in warm climatic zones, including the Mediterranean basin [15,16]. Especially in urban centers classified under tropical and subtropical climates, the issues are even more pronounced, with researchers thoroughly studying alternative urban topographies aiming to mitigate the phenomenon [17]. Illustrative of the scale of the problem is the fact that 30 cities in Europe and over 120 cities worldwide are grappling with the urban heat island issue (ibid).

A natural consequence of this phenomenon is the increased energy consumption for providing thermal comfort inside buildings, thereby burdening the energy balance of cities. Additionally, the use of conventional materials that absorb high levels of solar radiation adversely affects temperature variations in cities [18]. Furthermore, higher population densities further intensify the challenges related to heat, air pollution, and congestion in urban areas. Given all these, well-designed open public spaces act as vital components in enhancing thermal comfort by providing shade, natural ventilation, and greenery, mitigating the adverse effects of high temperatures. Moreover, green public spaces contribute to biodiversity, improve air quality, and offer recreational opportunities, fostering a healthier urban environment [19]. Open public spaces serve as social hubs, facilitating community interaction, cultural activities, and public gatherings that contribute to the social resilience of urban areas [20]. Specifically, the proximity of residential areas to urban green spaces is particularly beneficial for the elderly, children, and individuals with respiratory problems [19,21].

As exemplified in the book *"Urban Microclimate: Designing the spaces between buildings"*, modern design approaches focus on creating suitable microclimatic conditions for various outdoor activities [22]. From this point of view, integrating sustainable design principles, such as increasing green

infrastructure, promoting mixed land use, and incorporating climate-responsive architecture, is crucial in addressing microclimatic challenges.

3. Previous Studies on mitigating UHI in the Mediterranean Region

Urban planning and design significantly influence Urban Heat Island (UHI) mitigation. Well-designed urban layouts with blue-green infrastructure, high-albedo materials, mixed land uses, and smart growth principles reduce heat retention, enhancing microclimates. Reflective surfaces can play a role in mitigating climate change by reducing the demand for cooling energy, which in turn decreases greenhouse gas emissions associated with energy production [10]. The diminished heat absorption due to increased solar radiation reflection is a key contributing factor. It is advised to strike a balance between positive and negative impacts by employing medium albedo (approximately 0.4) on walls, while surfaces such as pavements are recommended to have high albedo values (exceeding 0.7) [11,13,23,24]. Studies also explore the microclimate effects of high albedo surfaces, including their impact on local air temperature, humidity, and wind patterns [10,13]. Ongoing research continues to refine our understanding of the benefits and potential drawbacks associated with high albedo surfaces in different contexts. When studying the Urban Heat Island (UHI) effect, researchers also typically focus on various water-related elements to understand their influence on urban microclimates [25]. In particular, Mediterranean cities often have natural or artificial water bodies like lakes, rivers, fountains, or coastal zones. Researchers study how these water bodies act as cooling elements, moderating temperatures in the surrounding urban areas [26]. Evaporation from water surfaces can contribute to cooling. It is important to mention that the majority of studies focus on large-scale water body elements. There are a few studies that examine the impact of different scales of water body elements on UHI [27]. Urban greening, as a UHI strategy, involves integrating vegetation and green spaces within urban environments to enhance overall environmental quality [16,28,29]. In the context of ENVI-met simulations, consideration is given to various types of urban vegetation, encompassing trees, shrubs, and green roofs [25]. ENVI-met facilitates the modeling of shading effects induced by green elements, allowing an examination of their impact on temperature patterns across different urban locales [30]. Vegetation aids in cooling through evapotranspiration, releasing water vapor into the atmosphere. Studies on mitigating Urban Heat Islands (UHI) offer valuable guidance for optimizing urban planning strategies to maximize cooling benefits in urban design.

4. About the selected case study

According to relevant literature, European cities exhibit significant diversity in their socio-spatial structure and organization. Mediterranean metropolises display a hybrid condition, balancing between compact urbanity and forms of urban sprawl [31]. Specifically, in the case of Greece, both urban and rural areas were decisively affected by the settlement of the Asia Minor refugees in 1922 [8]. This demographic influx of 1.5 million refugees drastically altered the country's growth rate [32]. Out of the 47% of the refugees that settled in urban areas, 48% were directed towards the urban agglomeration of Athens-Piraeus (ibid). As a result, a total of 46 refugee settlements were created outside the urban fabric of Athens and Piraeus [6]. The pressure of historical circumstances inevitably influenced the design of the urban space, as it became vital to secure housing for a large number of new residents in a short period. Despite the challenges of refugee housing rehabilitation, the building blocks in the urban refugee settlements typically ensured the existence of open communal space (Fig.1 and 1a). There were also examples of refugee garden suburbs, as seen in the case of Nea Filadelfeia [8]. However, in most cases, these were settlements with high building densities. After the 1960s high building coefficients have been granted, significantly influencing the urban topography, as seen in the case of Nikaia. Despite the above-mentioned difficulties, the value and significance of urban outdoor spaces were recognized through Law N1337/1983 and Presidential Decree 23.02.1987

Proceedings

[33]. The area of study provides an urban layout of city blocks connected through intermediate open public spaces and pedestrian alleys. These spaces facilitate further research on the role of open public spaces in mitigating urban heat islands by employing different design strategies.

3. METHODOLOGY

ENVI-met, a crucial environmental modeling tool, enables comprehensive simulation of temperature, wind patterns, and air quality at a high spatial resolution. This capability significantly aids in understanding how design choices influence the local climate, making ENVI-met indispensable for researchers and practitioners striving to shape sustainable and comfortable urban environments. The study focuses on exploring the impact of various Urban Heat Island (UHI) mitigating strategies on a city block scale, in the post-refugee settlement of Nikea, Piraeus Prefecture. The city block, with varying building heights from 3m to 15m, incorporates a communal open space. Assessing microclimatic characteristics, the study performs six environmental simulations for two selected summer days, representing typical and warmer conditions. Simulations include existing configuration (Existing Configuration), replacement of pavement with high-albedo concrete (Design Scenario 1), and addition of water elements (Design Scenario 2). Spatial air temperature distribution is analyzed at 16:00, the warmest hour, and midnight, encompassing a comparison between daytime and nighttime temperature variations.

4. RESULTS AND DISCUSSION

4.1 Existing configuration

Figure 2 outlines air temperature distribution at 16:00 during a typical summer day in the current configuration. Temperatures range from 30.5 °C to 32 °C, with asphalt-covered streets exceeding 31.5 °C. Warm air from these streets affects the northern areas, gradually cooling towards the central and southern regions. In tree-covered and concrete pavement zones, temperatures range from 30.8 °C to 31.4 °C, while the south and east experience lower temperatures (30.5 °C to 30.8 °C) due to shade from nearby buildings. PET indicates 'extreme' heat stress in the west, with the central and east areas experiencing 'moderate' and 'strong' heat stress. Midnight sees a decline in air temperature, with a range of 28.0 °C to 28.6 °C. The southern and eastern parts record the lowest temperatures (28.0 °C to 28.3 °C), and the central region, featuring tree cover, ranges from 28.3 °C to 28.4 °C. Surrounding streets exceed 28.6 °C. Figure 3 illustrates notable air temperature reductions, especially in the western part, where daytime temperatures exceeded 3.0 °C. In other areas, reductions fluctuate between 2.5 °C and 3.0 °C.

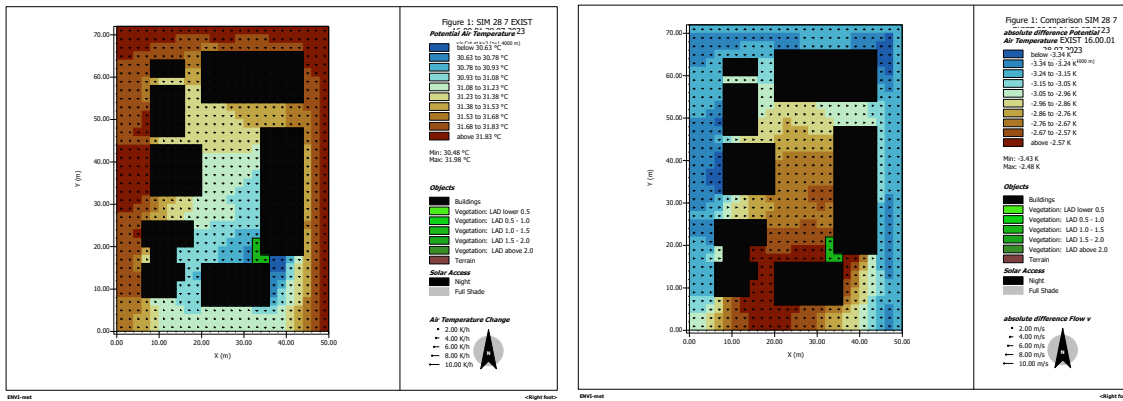

Fig. 2: Simulation 28_7_2023 existing situation, 16:00, authors’ work

Fig 3: Simulation 28_7_2023, existing situation- comparison day – night, authors’ work

Figure 4 depicts air temperature distribution at 16:00 on a warm summer day (21_7_2023), showing a notable 4 °C increase in both maximum and minimum temperatures compared to a typical summer day. The study area exhibits a thermal pattern differentiation, with temperatures ranging from 34.0 °C to 37.3 °C. Higher temperatures are observed in western streets, exceeding 36.3 °C. PET values reflect increased heat stress ('extreme') in the west and slightly lower stress levels ('moderate' and 'strong') in the central and eastern areas. At midnight, a predictable temperature decrease is observed, with a range of 30.0 °C to 33 °C. The most significant reductions (exceeding 4.0 °C) occur in the western and northern parts, while other areas experience temperature reductions ranging between 3.0 °C and 4.0 °C (Figure 5).

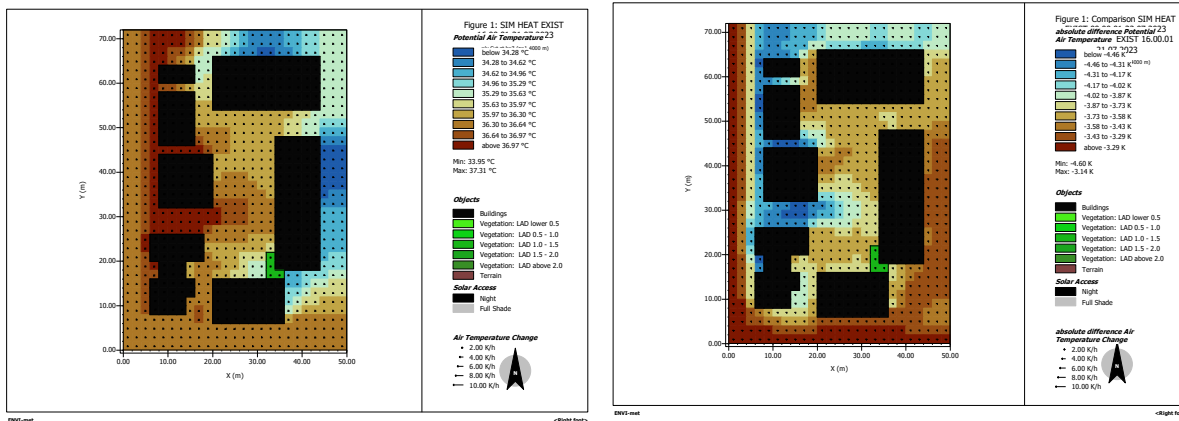

Fig. 4: Simulaton 21_7_2023, 16:00 existing situation, authors’ work

Fig.5: Simulation 21_7_2023, existing situation, comparison day – night, authors’ work

4.2 Design Scenario 1

Figure 6 illustrates Design Scenario 1 at 16:00 on a typical summer day, revealing air temperature patterns resembling the existing configuration but with reduced minimum and maximum temperatures (30.2 °C to 31.6 °C). A slight decrease of approximately 0.5 °C, attributed to high albedo pavement materials, is observed compared to the current setup. Unaltered surrounding streets continue to exhibit the highest temperatures, exceeding 31.5 °C due to asphalt heat retention. Warm air from these streets penetrates the study area, elevating temperatures in the northern part and gradually cooling toward the central and southern regions. In the central part, air temperatures range from 30.5 °C to 30.9 °C, exhibiting a slight decline from the current configuration. The south records the lowest temperatures (30.0 °C to 30.5 °C), with a minor reduction (about 0.1°C) attributed to shading, tree cover, and high albedo pavement compared to the existing setup. PET values, though

slightly lower, still indicate elevated heat stress levels, with lower estimations in the central and eastern areas ('moderate' and 'strong' heat stress) and 'extreme' heat stress in the western part. At midnight, the area maintains consistent thermal patterns compared to noon, featuring lower air temperatures ranging from 27.9 °C to 28.6 °C. Figure 7 depicts air temperature reductions between 2.3 °C and 3.2 °C, notably observed in the surrounding streets. In the southern and eastern parts, the smallest temperature variation (28.0 °C – 28.2 °C) indicates a 0.1 °C reduction from the existing configuration. The central part, with tree cover and high albedo pavement, experiences temperatures ranging from 28.2 °C to 28.3 °C, reflecting a 0.1 °C reduction. However, surrounding streets continue to produce the highest air temperatures, potentially exceeding 28.6 °C, contributing to a heat load similar to the existing configuration.

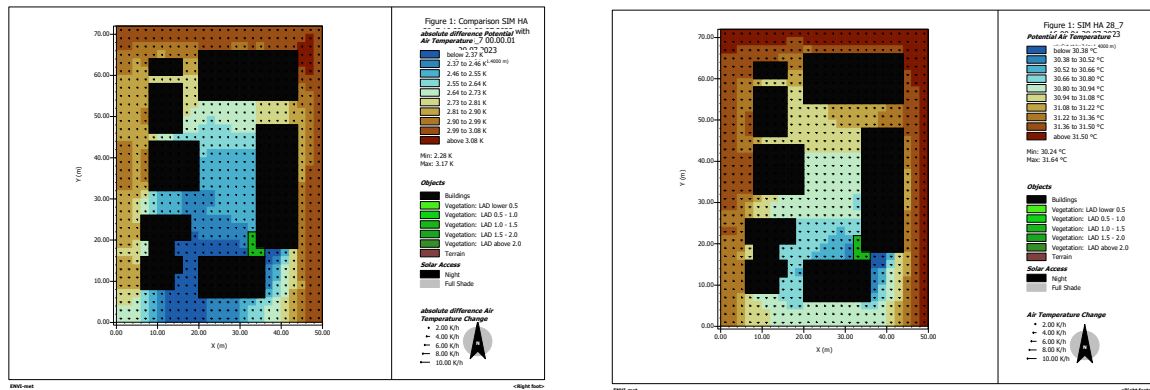

Fig.6: Simulation 28_7_2023, 16:00, scenario with high albedo materials, 16:00, authors' work
Fig.7: Simulation 28_7_2023, 16:00, scenario with high albedo materials, comparison day and night, authors' work

In Figure 8, Design Scenario 1 at 16:00 on a warm summer day displays an increase in both minimum and maximum air temperatures (3.5 °C to 5 °C) compared to the typical summer day of the same scenario. The spatial distribution shows temperatures ranging from 33.7 °C to 36.5 °C, with the highest values exceeding 37.0 °C in the western part's surrounding streets. The central part experiences temperatures between 35.6 °C and 36.2 °C, while the lowest temperatures (below 34.0 °C) are found in the eastern part, likely due to shading from nearby buildings. PET values align with thermal conditions, reflecting higher heat stress levels in the western parts and lower levels in the central and eastern areas, corresponding to 'strong' and 'extreme' heat stress conditions throughout the study area. At midnight, a decrease in air temperature compared to noon is observed, with consistent maximum and minimum values. The air temperature ranges from 29.8 °C to 33.2 °C, and the most significant reductions, exceeding 4.0 °C, occur in the western and southern parts of the examined area. In other regions, air temperature reductions fluctuate between 3.3 °C and 4.0 °C (Figure 9).

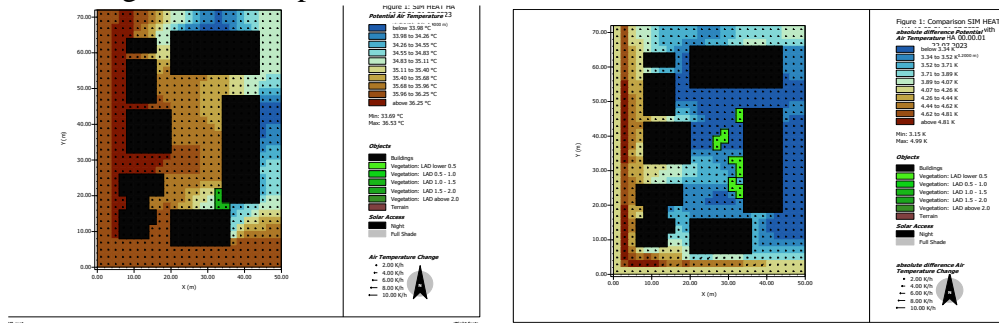

Fig. 8: Simulation, 21_7_2023, a scenario with high albedo materials, 16:00, authors' work
Fig.9: Simulation, 21_7_2023, a scenario with high albedo materials, comparison day and night, authors' work

4.3 Design Scenario 2

Figure 10 shows air temperature distribution in Design Scenario 2 during a typical summer day at 16:00. Thermal patterns are similar to the current configuration and Design Scenario 1. With strategically placed fountains, minimum temperatures decrease by over 6 °C in specific areas. Maximum temperatures in surrounding streets see a slight reduction of 0.4 °C, possibly due to the fountains. The study area follows a thermal pattern, with warm air from surrounding streets gradually cooling towards the central and southern regions. Fountains contribute to a significant cooling effect, with the central part experiencing the lowest temperatures (25.1 °C to 28.9 °C), a reduction of up to 5.5 °C compared to the existing configuration. PET values indicate 'moderate' to 'strong' heat stress, with 'extreme' heat stress in the western part. At midnight, temperatures range from 21.3 °C to 28.6 °C, with a decrease from noon ranging between 2.5 °C to 3.4 °C. The central part and areas around the fountains show the least temperature variation (21.3 °C – 25.7 °C), indicating a potential 5 °C reduction compared to the existing configuration. Surrounding streets register higher temperatures, contributing to a slightly lower heat load than the existing configuration, likely due to the fountains' cooling effect.

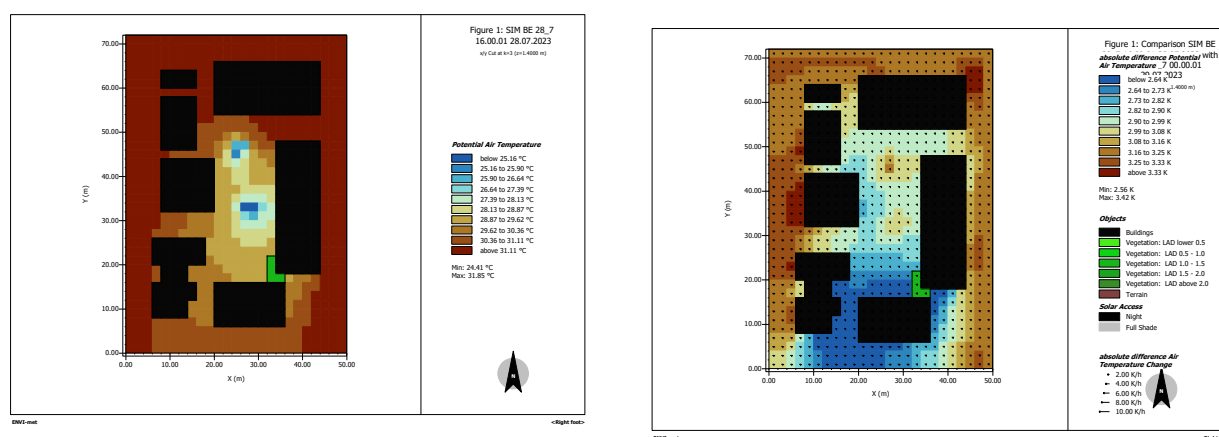

Fig.10: Simulation 28_7_2023, 16:00 scenario with water body elements, authors' work

Fig.11: Simulation 28_7_2023, comparison day and night, scenario with water body elements, authors' work

In Figure 12, Design Scenario 2 at 16:00 on a warm summer day displays similarities in minimum air temperature values, but an increase of around 5.5 °C in maximum air temperature compared to the typical summer day of the same scenario. The air temperature varies from 24.2 °C to 37.3 °C, with the highest values exceeding 36.0 °C in the western part's surrounding streets. The central part, featuring two fountains, experiences the lowest temperatures, ranging between 25.5 °C and 29.4 °C, showcasing the significant cooling effect provided by the fountains. PET values are slightly lower than those in both the existing configuration and Design Scenario 1 during the warm summer day. For most of the study area, PET values range between 'moderate' and 'strong' heat stress, while higher PET values corresponding to 'extreme' heat stress conditions are observed in the western part. At midnight, there is a decrease in air temperature compared to noon, with consistent maximum and minimum values. The air temperature ranges from 22.4 °C to 33.2 °C, and reductions compared to noon vary between 3.2 °C and 4.8 °C for most of the study area (Figure 13).

5. CONCLUSIONS

This study assesses urban heat island (UHI) mitigation strategies in a densely populated area of Athens, focusing on a city block in the Nikea post-refugee settlement. Microclimatic simulations for a typical and warm summer day were conducted under three scenarios: existing configuration, Design Scenario 1 (high-albedo concrete pavement), and Design Scenario 2 (addition of two fountains). While adverse thermal conditions were observed in all scenarios, Design Scenario 2 showed the most favorable outcomes, demonstrating the cooling effect of fountains. PET estimations indicated thermal discomfort levels across scenarios. The highest air temperature and PET values were consistently observed in surrounding streets with low-albedo asphalt, while lower values occurred in shaded areas. Despite nighttime air temperature decreases, thermal discomfort persists. The study suggests that incorporating water elements, as demonstrated in Design Scenario 2, may positively impact the UHI phenomenon. Future research could explore the cooling effect of water elements across multiple city blocks and develop a design methodology for application in similar urban settings. Combining various UHI mitigating strategies holds promise for improving outdoor thermal comfort in hot Mediterranean metropolitan areas, particularly during heat waves.

Extended abstract

The participation of disabled people in daily life has gained increasing significance and is strongly promoted by international regulations and governments. The inclusion of disabled people in social and economic activities offers them equality, high satisfaction, and essential social and economic benefits for all stakeholders. Adding to this issue, high participation promotes society's sustainable development and should be strongly encouraged. According to research by the University of Sussex, the European market has suffered a loss of USD 148 billion by not sufficiently serving the needs of disabled people. Also, more than 1.3 billion people present some kind of disability. These figures show an important and lucrative market segment, which should be more emphasized. People with disabilities (PwDs) have specific needs, and monitoring and responding to them with tailor-made services is recommended. Applying universal design, most needs of everyone, especially people of every type of disability, including the elderly with reduced mobility and people with temporary difficulties, can be satisfied. Tourism is a primary industry worldwide, and its accessibility is gaining significant interest. Tourism companies are losing too much money because, in many cases, they do not provide sufficient services that are accessible to all. Tourism is an essential need for disabled people, and places providing proper services gain significant social and economic benefits. Greece, with its distinctive natural environment, landscape, and cultural identity, has a strong tourism industry, and offering more accessible services can achieve higher returns. The current study presents and analyses accessible places and edifices for disabled people in Greece, particularly accessible hotels and beaches, while suggesting improvements. In this framework, research focused on online discussion with a group of twelve (12) disabled people and experts. The outcome shows that although services provided to disabled people have significantly improved in the last decades in Greece, there is still room for significant improvements. The present paper introduces a holistic approach focusing more on the autonomy of disabled people and the provision of higher-quality services in all travel chain. More accessible beaches and hotels are recommended. The provision of accessible information about the provided services is essential, and towards this, the use of new advanced technologies is helpful. The creation of a fully accessible small island as a model and the proper promotion of this initiative are proposed. The study provides essential insights for policymakers and academics to improve their knowledge about the examined subject and the quality of the services provided services.

Keywords: *accessible tourism; Greek tourism industry; disabled people; a holistic approach.*

1. Introduction

The tourism industry's importance is indisputable. Tourism has traditionally focused on those who participate rather than those who are excluded [1], such as those who are marginalised, omitted, overlooked, or ostracised from travel based on factors such as low socio-economic status, ethnicity, indigeneity, age, gender, sexuality, ability, or the intersectionality of these areas of identity.

The growing population of elderly and disabled people around the world requires exceptional support and services. According to the World Health Organisation [2] report, over 1.3 billion people (or 16% of the global population) live with some form of disability, constituting the largest minority group in the world. Adding on these spouses, children, and caregivers, the final figure exceeds 2 billion people. Almost 50% of people aged more than 60 have some disability. Also, travellers with disabilities tend to have 2 to 3 escorts. Consequently, there is a significant market opportunity for destinations and companies that sufficiently serve these people, which can significantly enhance their revenues [3].

Accessible tourism involves collaborative processes between stakeholders, enabling people with various access requirements—including mobility, vision, hearing, and cognitive dimensions of access—to function independently, with equity and dignity. This approach ensures the delivery of universally designed tourism products, services, and environments for the benefit of people with disabilities (PwDs) [4]. Tourism is an essential need for PwDs, and studying in detail their needs, more convenient services should be provided [5], seizing the opportunity for more people to travel, leading to increased visitors, longer stays, extended tourism seasons, and consistent income for the tourism industry, and local economies. Furthermore, societies and governments reap significant gains from new employment opportunities, augment tax revenues, and provide an accessible environment for both residents and visitors. Offering accessible services in all travel chains, including hotel accommodations and beaches, is essential for those people to travel more. Therefore, countries that invest more in PwDs needs are expected to have significant economic and social benefits. In addition, respecting the environment, these efforts lead to higher sustainability.

Greece has a strong tourism industry, and emphasising accessible tourism will have significant benefits. The study aims to identify the main issues and obstacles that limit the further development of accessible tourism in Greece and propose some improvements. The current paper further discusses accessible beaches and hotels.

An online focus group technique was applied, and participants (n=12) with some disability and those with significant work experience and knowledge of the tourism industry were selected. The study's primary outcomes show that although considerable progress has taken place in the last years regarding accessibility, much more action is required. A more holistic approach that includes sufficient services in all travel chains of PwDs is needed. Also, the services of beaches and hotels should be better adjusted to the real needs of PwDs.

The current study provides significant insights and knowledge on an exciting subject for policy-makers, practitioners, and academics.

2. Literature review

In this part of the study, the relevant literature about fundamental issues on disability, accessible tourism in general, and the Greek reality are briefly presented.

On a global basis, PwDs are the largest minority group [2, 6]. Estimations [7] indicate significantly high percentages of PwDs in some countries (e.g., United Kingdom: 20.7%) and demonstrate that walking disability is the most recurrent type of impairment. The high figures of PwDs will further increase due to the ageing population and diseases [8]. The International Classification of

Functioning, disability, and Health (ICF), supported by the World Health Organization (WHO), suggested the 'biopsychological model', which combines biological, psychological (thought, emotion, and behaviour), and social (economic, environmental, and cultural) factors related to PwDs' daily-life [9]. Thus, participation, inclusion, and equality are highly required, and travel and tourism are basic needs for all.

Although increased globalisation leads to a uniformity of consumers' lifestyles, the emergence of various forms of thematic tourism is significant. It requires specific actions and services according to the travellers' needs [10]. Over the last decades, the focus has shifted from 'disability and tourism' to 'accessible tourism', and there is an increased academic interest in this topic [11]. Accessible tourism is a relatively new and evolving research field. The first definition of accessible tourism is removing barriers that prevent impaired people from enjoying a tourist experience [4, 12]. It has evolved, reshaping the entire tourist environment (physical, informative, online, attitudinal aspects, etc.), adopting the universal design to allow its use by all population groups, regardless of age, condition, capacity, or impairment [4,12, 13]. The complexity of disability as a physical and social phenomenon presents a challenge to be addressed in future accessible tourism studies [14].

Accessible tourism involves collaborative processes among stakeholders that enable people with access requirements, including mobility, vision, hearing, and cognitive dimensions of access, to function independently, with equity and dignity, by delivering universally designed tourism products, services, and environments. This definition adopts a whole-life approach where people benefit from accessible tourism provision throughout their lifespan, including those with permanent and temporary disabilities, seniors, obese individuals, and families with young children [4, 15]. Thus, stakeholders such as governments, international agencies, tour operators, and end-users, including PwDs and their organisations (DPOs), are involved and should collaborate to provide the proper services in an accessible tourism context. A thriving tourism product needs effective partnerships and cooperation between private and public enterprises [16] and across many national, regional, and international sectors [3]. Finally, a facilitative and supportive legislative framework focused on the real needs of PwDs is required [17].

Increasing market opportunities for accessible tourism have been identified due to improved quality of life. Disabled tourists tend to be loyal, spend more, and enjoy longer stays in their destinations, and they have 2-3 escorts/caregivers, although their behaviour differs from country to country. This situation is strongly influenced by welfare policies that determine the disability model implemented and affect the extent to which PwDs are integrated into day-to-day life. WHO [18] considers the accessibility of tourism facilities, products, and services fundamental to any responsible and sustainable tourism policy. Northern European countries are regarded as champions in this respect.

Accessible tourism is already profitable in many parts of the world and is expected to increase rapidly [19]. In 2012, accessible tourism contributed 3% of Europe's GDP (786 billion euros) [20]. In Europe, relative to population, France had 10 million people, and the United Kingdom had 11 million people with accessibility needs. Spain also has a significant part of PwDs who are eager to travel, and in the Netherlands, younger travellers with disabilities are interested in travelling. In 2012, the more attractive destinations for people with specific accessibility needs were America, Africa, and the Middle East. Regarding countries, China (61 million), the United States (32 million), and Brazil (32 million) were the most favourite destinations [21].

Access to information is essential for travellers with disabilities, and technological advancements offer vital solutions [22]. Because of their complex needs, which require more explicit services [23], these technologies facilitate PwDs' daily lives within and outside their homes [24, 25, 26].

Research in the field is a critical issue that has shifted the focus from demand to supply. The travel experience of PwDs includes different stages with distinct characteristics, and those require in-depth study [27].

Emphasis on accessible buildings, facilities, public spaces, and information used by PwDs is essential and encourages those people's participation in social life [28]. Providing accessible and easy to use from PwDs hotel websites is vital [29]. In addition, accessible hotel accommodation is essential for PwDs. Those should be designed in such a way as to meet the needs of individuals with disabilities, mobility limitations, or those with other requirements, and must provide various amenities to ensure that all guests enjoy high-quality tailor-made services. Wider doorways and hallways to accommodate wheelchairs and mobility aids; lowered light switches and countertops to reach easily; toilets adjusted to those people's needs; tactile signage and visual alarms for guests with hearing or visual impairments; and accessible spaces and pathways throughout the property are all crucial [30]. In addition, accessible beaches are essential for travellers with disabilities. Technology offers high awareness toward the wide use of hotels and beaches by PwDs [31]. Finally, a more holistic approach is required in which PwDs enjoy services in all sectors of their daily lives [25, 32], including their travel experience.

In Greece, the rights of PwDs are constitutionally guaranteed and promoted. The introductory legally binding text on the rights of PwDs is the UN Convention on the Rights of Persons with Disabilities (UNCRPD), signed on December 13, 2006, and entered into force on May 3, 2008 [33]. Greece ratified this convention by law on April 10, 2012. The guiding principles of the Convention include respect for dignity, autonomy, choices, independence, non-discrimination, full participation in society, diversity, and equal opportunities [33].

Greek governmental organisations have issued specific guidelines for building infrastructures and public spaces [34], considering the PwDs' needs.

Greece has a strong tourism industry. In 2023, annual revenues were 20,456 million euros, which increased by 15,7% of those in 2022, and the number of travellers was 32,735 thousand, which rose by 17.6% relative to 2022 [35]. The facilitation of accessible tourism will significantly contribute to extending the tourism period and increasing revenues and tourism traffic, the two significant challenges of the Greek tourism industry. According to the INSETE study [36], Greek tourism services need to become more diverse, equal, and inclusive to achieve sustainability goals and accommodate the needs of PwDs, need to raise awareness, improve accessibility to public spaces, ensure access to accurate information, provide reskilling and upskilling opportunities for tourism employees, and targeted actions should be implemented by the private sector to facilitate the travel experience of those people.

Relevant studies are scarce in Greek literature, but the main ones are briefly presented below.

A study [37] about accessible tourism in Crete reached contrasting conclusions. In most service areas, disabled tourists were highly satisfied, as many hotels, archaeological sites, and other locations met accessibility standards. Conversely, the study's participants noted deficiencies in transportation and urban planning for tourism purposes. The authors concluded that with the necessary focus and investment, Crete could emerge as a significant, accessible tourist destination.

To increase accessible tourism figures, the development of accessible infrastructure and training of stakeholders is recommended for the two areas of Drama in Greece and Mersin in Turkey, as both destinations have significant advantages. This study is part of the MEDRA project, which promotes the development of accessible tourism in these two destinations and can be further applied to countries with similar characteristics [38].

Another study [39] examined the potential of accessible tourism in Greece and found that the supply and services to disabled customers are not entirely satisfactory. Demand for accessible tourism in Greece remains low due to the lack of appropriate infrastructure and easy access to public transport means at Greek tourist destinations. Furthermore, the Greek tourist industry does not fully comprehend the dynamics and size of the accessible tourist market.

A study [40] that focused on assessing the satisfaction of tourists with disabilities who visit Greece found problems in infrastructure, such as transportation, accommodation, and entertainment, and the provided services are not appropriate for those people to move around safely and comfortably. Tourists are delighted with employee services, but no established mechanism exists to certify, monitor, and evaluate accessibility standards.

It is recommended that Greece and the Republic of North Macedonia cross-border cooperate to develop standard brand services and promote accessible tourism. This will offer significant, mainly financial benefits to both countries and promote sustainability in degraded border areas [41].

The sustainability and quality services issues in accessible tourism have been overlooked in Greece. In contrast, the importance of accessible tourism in developing the Greek tourism industry is high. Particular attention should be paid to ‘design for all’. Also, several accessible beaches were introduced in 2004 to serve athletes in the Olympic Games and Paralympics, but most should be created to serve this customer segment. Available specific wheelchairs to facilitate the movement of PwDs, accessible showers and chemical toilets, resting areas, kiosks and parking areas to accommodate the needs of these people are essential [42].

Conclusively, the above studies highlighted the significance of accessible tourism in Greek tourism and identified specific problems, mainly related to the lack of proper infrastructure. Similarly, the current study emphasises the potential issues and difficulties of accessible tourism in Greece.

3. Methodology

Technological improvements have facilitated the emergence of online focus group [43], which was applied in the specific study to collect the required information. This research method gathers several participants in a virtual environment to interactively discuss issues they know very well with a group moderator [44]. The role of a moderator, who is mainly a study researcher, and he/she leads the discussion, is critical [45].

In the specific research, twelve participants (n=12) from various fields related to the study’s objective discussed the examined issues using Zoom services, and valuable information was collected. All the respondents have rich experience and knowledge of the subject under examination. The discussion lasted three (3) hours. The first author of the study was the focus group moderator.

The following table 1 presents the study’s participants and their professions.

Participants Number	Participants Professions
1	A person with kinetic problems (hemiplegia)
2	A person with kinetic problems (triplegia)
3	A person with cognitive impairment
4	A person with visual impairment and a guide dog
5	A person with hearing impairment
6	Architect-Caregiver of a person with tetraplegia
7	Caregiver of a person with visual impairment
8	Hotel manager

Proceedings

9	Professor in social sciences
10	Executive working on tourism board
11	City Hall's high-ranked manager responsible for minority issues
12	Designer of disabled people services

Table 1: Study’s participants and their professions.

The primary outcomes of the focus group discussion are presented in the following part of the paper.

4. The focus group discussion outcomes

All the participants agreed that all stakeholders should try to make our environments and the tourism experience more accessible and our societies more inclusive. In Greece, a more holistic approach should be applied. Complete accessible services must be provided in all the basic infrastructures such as transportation, hospitals, public services, shops, etc. Creating an accessible environment is a long-term project; despite past years' efforts, there is still a long way to go. Public transportation, buildings, streets, pavements, and squares are inaccessible to disabled persons. There are many obstacles for pathway drivers of blind people on the sidewalks, which usually end up in inaccessible places and they have narrow spaces. Ramps and pedestrian access boards are not correctly constructed, and some obstacles are placed on them. Various attempts have been made to implement access laws, but unfortunately, they do not sufficiently apply.

Understanding tourists with disabilities' needs is a complex issue. Specific geographical, cultural, political, and sectoral contexts influence the nature of tourism management and the accessible tourism visitor experiences. The needs of each individual vary, and analysis of the tourist experience must consider the type of disability/dimensions of access (mobility, hearing, vision, cognitive, and others) and the required level of support. There are travellers with severe disabilities who require a high level of support in their accommodation and travel experiences at a higher cost. On the other hand, travellers with mild forms of disability travel more easily without too many changes in infrastructure. However, if more convenient services for people with severe disabilities are provided, more of them will probably travel. Going on holiday, disabled travellers need more specific, reliable information and advice about their travel destination. These issues are resolved by the virtual websites offering valuable tips.

City Hall’s Manager for minority issues (participant no. 11) mentioned that they intend to train their employees to assist PwDs and mark appropriately various places in the city that PwDs (with hearing and vision problems) usually visit.

Disabled participants (no. 1-5) declared that the absence of a lift or an adapted bathroom in the hotel accommodations often turns a pleasant trip into a betrayal. To avoid these unpleasant surprises, reliable information about accessible places and details is necessary. Many small and large-scale operators, local or not, must also provide this information. Sufficiently trained hotel employees should offer high-quality services to PwDs. Those people using tourist guides collect valuable information to avoid unpleasant circumstances and to know well in advance what they will meet. Regarding the interior part of the hotels, “*the height of the reception counters must be 80 cm and not the 120cm that we usually find*”, and ramps should also be provided. All the switchers must be at lower heights than usual, and the food counters' heights at the restaurant areas should be adapted for wheelchair users. The availability of accessible toilets in hotels is essential; those should have sufficient room space. Of course, there is expected to be a long indoor ramp or access mechanism to the hotel pool and a blind access guide in the outdoor areas.

An architect-caregiver (participant no. 6) mentioned the importance of accessible beaches based on the successful operation of the first organised beach on the Voula peninsula (S. Athens) at the current PIKPA social welfare rehabilitation centre, which provides access to PwDs and mainly to people with mobility disabilities. This project was very successful, mainly because of its comprehensive intervention. It took care of the entire accessibility chain, i.e., seamless access from the point of entry to use and exit without gaps and omissions. Similar projects should be applied to other beaches within or near big cities. Another successful initiative is implementing the seawater access mechanism solution of SeaTrac on 225 beaches on the Greek coast, which allows elderly people and people with movement difficulties to enjoy their baths.

A professor in social sciences (participant no. 9) proposed transforming a small island into a model 'accessible island' with all the required infrastructure. This initiative must be properly promoted.

Executive in tourism board (participant no. 10) highlighted the importance of volunteers' participation in assisting PwDs travel and accommodation experiences, mainly in 'smaller places', and towards this, the creation of a relevant database, where they will state dates and location of availability, to help PwDs on their journey is essential. He mentioned that "*accessible tourism is much broader and more human than a technology solution or a certification mark*".

5. Discussion and Conclusions

The provision of fully accessible services to PwDs facilitates the participation of these people in daily activities. Travel is an essential need of PwDs. Understanding the relationship between disability and tourism contributes to developing accessible tourism, which is gaining significant importance in social and financial terms, and countries heavily invest in this direction. The involvement of all stakeholders in designing services for all people is necessary. In addition, the continuous assessment of the satisfaction of tourists with disabilities from the infrastructure, tourist products and services they use during their holidays is essential to offering tailor-made services [40].

Greece is at the forefront of the global tourism industry, and by investing more in accessible tourism, significant benefits are expected. The primary issue is to provide tailor-made services to PwDs' needs. Towards this, and based on the disabled people and experts' perspectives, the current study identifies some main issues that may contribute to the further development of accessible tourism in Greece.

The primary outcome of the current study is aligned with similar studies [39, 40, 42] that although the Country has improved the provided services to PwDs, more improvements should be made, mainly in infrastructures. In addition, a more holistic approach should be adopted that is focused on improvements in all travel chain of those people.

Tourists with disabilities require reliable, accessible information for all travel experiences. This includes information on accommodation facilities, transportation options, hospitals and tourist attractions. Virtual navigation systems and specific platforms inform and assist PwDs in travelling more easily. Fully accessible hotels and beaches are essential for travellers with disabilities, and both should be adjusted to their needs. Regarding the accessible hotels, lower heights in the reception and the switches, ramps, accessible toilets, and easier access to swimming pools are among the most required issues. Beaches should offer fully accessible services from the time a disabled person arrives there until departure. Sufficient employee training is vital to providing high-quality services to PwDs. Also, creating an accessible small island as a model that offers fully accessible services all year round is recommended. The involvement of volunteers in facilitating the PwDs' travel experience is essential, particularly in small destinations. More advanced services may mobilise people with more severe disabilities to travel. Also, all these people travel with caregivers, and their needs and opinions

should not be ignored. All of the above must be promoted appropriately, mainly through electronic platforms.

Overall, the study highlights the importance of collaborative efforts, awareness, and investment in infrastructures and technology to enhance accessibility in tourism for PwDs. The Greek tourism industry should see this segment more as a business opportunity. Hotels and beaches must be adjusted to PwDs' needs and continuously assessed. Emphasis on traditional Western European markets to attract travellers with reduced mobilities is recommended.

Studies focused on this issue provide valuable insights and knowledge to policy-makers, practitioners, and academics and lead to the improvement of the services offered. More in-depth qualitative interviews and quantitative studies with a large sample could be applied in future studies.

Urban Cultures & Public Open Spaces - Digital Sound Installation as a Form of Public Art

G. Touliatou

Department of Interior Architecture, Faculty of Applied Arts and Culture,

Extended abstract

Once a Digital artwork is installed, a new condition develops and the space around it changes. Particularly, Digital artwork and Public space along, constitute an instrument of measuring space and time, a sum of knowledge that is capable of re-organizing our spatiotemporal perception. Hence, a number of questions rise, such as: Is the environment of any Public space suitable for hosting a Digital work of Art (by means of an artwork could saturate a place in its conceptual manifestations)? Is any Digital artwork powerful enough to transform -through minimal and marginally discreet or indiscreet interventions- the Public space in such a way that we shall be able to experience it in a more conscious way?

In this sense, we can understand the thinking that considers Digital Art Installations in Public Spaces to be subversive structures of architectural power, since as soon as they appear they lure us into the beautiful world of genuine aporias: What is that composes the identity of the place? Why the limitations of the place are a matter of awareness (considering that our understanding depends upon the recognizable, the marvelous and the uncanny elements that define the identity of a place)? How the additional element of an Art Installation makes us aware about certain spatiotemporal notions that we were unable to realize as significant?

The text is based on the way which our senses are triggered in our contact with both the physical and the digital elements, thus, it specifically refers to a Sound Installation in a Public Space. The immateriality of the medium and its power to enkindle cerebral activity lead us to examine the function of digital Sound artworks as a conceptive operation itself and at the same time, as a project of a contemporary idea, which responds to present, social and existential issues. See it as a memory revitalization, a sustainable proposition, an interesting statement, an experimental hypothesis or a brilliant strategy, a Digital Sound Installation exists in a broader sense, as a profoundly subversive force, addressing to the multidimensional, different approaches and discourses upon the cultural renegotiation of the Public open spaces.

Keywords: *Digital Art; Sound Installation; Cultural Renegotiation; Public Open Space; Social Engagement*

1. INTRO: URBAN WINDS

The conditions are changing our observation, the frame changes the text. Therefore, endowed with mobile ratios that are affected by regularly altering causes, this is ultimately a world of intentions. What it is interesting here, is the conditions of this world continuously are changing our perception of it; changing the subject, the object and our cognition of the space and time. Matters of cognition, the space and the time, the ambience of an environment, the scale of the things, their proportion, the intervals of our attention, and the vectors of the motions around us are constantly twinging our sense of understanding. Mainly because we need to hold on our thought in order to implement our thinking on any subject of a real situation.

"The gaze perceives the world under conditions, knowledge is obtained under conditions", Nietzsche wrote in the *On the Genealogy of Morals* [1], to remind us that the understanding of the world is governed by circumstantial preconditions such as identity, gender, geographic and social origin,

Proceedings

of the International Conference on **Changing Cities VI:**
Spatial, Design, Landscape, Heritage & Socio-economic Dimensions

cultural and political systems of value in relation to an indefinite, predominant current system of values. All these evasive preconditions create the basis for the birth of idiosyncratic behaviors, since they connect to an already, educationally shaped, ability to perceive the world. Our ability regulates our capacity to internalize new information and relieves its interaction with the old ones.

If all the above are happening as true, then, we cannot be sure of the true value of the assumptions and theories we cherish to address to ourselves –or to others- thereafter, the only thing that remains for us to do is to create narratives about that which we think we know for sure, or, on the contrary, narratives which are consciously given as unsure. Yet, some artists create art-works, not to acquire a recognition of a truthful confession, far beyond that, they expose the complex relationship that sustain their existence, thus, their relationship to the world. To propose such a traumatic relationship is a starting point, where the preconditions produce conditions, and that's a very intriguing development of the start we made.

Diving deeper in to this aspect and more often than not, if our starting point is the succession of forms, our findings are forms of discontinuity, whereas, if our starting point is the discontinuous forms, our findings are forms of succession. There is a peculiar link between our intentions and findings, which leads from the circuit of seeming repetitions to the circuit of apparent "fragmentations". As a result, a communication based on free-associations arrives that allows the emerging of gaps, and if there are no better circumstances, in this zones where meaning is in dispense, artists find a lush place to experiment. To experimented, here means, to assume different, or even new, relationship between the parts of a narrative, between utterances and fragments, traditions and new revolutions. It also means an exploration of an environment that does not allow the development of the concomitant relationships, on the contrary, it opens a field for investigation [2].

This act that often appears as a mapping technique. Mapping is an exercise in analogy, a process of interpreting a real place, condition, situation, event, in an abstract (graphic) language, while at the same time it evolves the process of transforming an abstract finding into a legible object. Digital Media artists experiment in this field with the scale of things (conditions, situations, events) and the senses of vision and audition as the limited and psychologically dependent possibility of human's perception addressed to the world. Moreover, their artwork presents us with its own Aesthetics that concerns the interrelated and inseparable relationship of the subject (human) with the object of its attention (environment). Yet, a digital artwork cannot rhetorically impose a certain concept on the Public space, or a significant aesthetic quality. All it can do is offering to the visitor a powerful stimulus to reconsider his cognitive process and communication with the space in which it stands. In the present text, the digital artwork specifically refers to a Sound art Installation.

When an object produces sound, it produces pulsating movements that are transmitted to the environment. The relevant description would pictorially present us with spherical sound waves that are emitted in all directions through the air, at the level of the atmosphere. Certainly, to approach the occurrence of sound we need to assume a "transmitter" a "transmitted object" and a "receiver". In this sense, the transmitter is a sound-generating body and the receiver is the human body, explicitly, the skin and the ear. The transmitted object (that which is transferred between transmitter and receiver) is the sound-signal, a 'signifier'.

Herman Kolgen [3] seems to know a lot about the skin, much more about hearing and even more about acoustics, how the hypothalamus of the human brain "disorganizes" and its functions are "deregulated" when it receives certain sound-signals. "Urban Wind" (2015) is a Sound Installation, part of a larger series entitled "Windfields". The common element that runs through all parts is based on the dynamic characteristics of the wind, the flow of air, so, het places sound sensors in various locations of the city that receive data from the speed and direction of the wind. Gathered data are analyzed into groups of clusters of sounds that they governed by their own rules (accordions) and are finally transmitted as an euphonic "soundscape". Harmonies you've never heard or thought before, make you feel the contraction of the tiny muscle at the base of each and every pore.

2. 2066

In a poetic and an ultimately urban sense, Public Space is the place of physical coexistence of individuals, while a non-relational flow between Art and Public Space is often observed, a situation that is frequently represented through its typical qualitative features, that are, the "individual", the "space" and "art". If we think about the Installation of a digital Sound-piece, any any surface of the built volumes in a Public Space turns into an osmotic membrane, as if any kind of material alters to a piece of blotting paper. The limitation of the urban space changes into a correlation: the transit of the relationship between individuals and space and the activity of continuous exchange of meaning between the sound-piece and the space, are in a constant negotiation at the level of the perception, to the person who experiences it. The physical (or architectural) and the digital (or audio) elements are mutually absorb each other.

Indeed, the immaterial nature of a digital sound-work gives a feature of an identity to the common abstract world we share, a world that changes spatially from step to step, temporally from one moment to another. Furthermore, as a creative act a sound art-work repeatedly cross the line between being eligible and ineligible in its shift to formulate and address an aesthetic and for that critical subject-matter. Regarding the duration of this time-based media, a digital sound-work seems to insist on a communication with the individuals that experience on the open public space that hosts it. This condition of communication is like a slowly liberating process regarding the humans. By catching our attention, it creates for us "capsules" of time intervals within which we can think about how this element of the space affects us. The slot of time during our uncertain wandering between what we know about a space and what is really "happening" in it, offers us the possibility to understand the multi-significant aforementioned identity of the public space in which we have found ourselves in.

By all means, to move freely in an open Public space (in any space) presupposes the apprehension of the nature of the environment in which we move, understanding somehow its identity. And while an open space entails many kinds of contradictions, we let the information we get from it to be recorded as subconscious knowledge, until a moment where an unexpected event "happens" and overturns our perception of it. In other words, when we are entering in an environment where there is a digital sound Installation, something is created that develops our thinking as it simultaneously reminds us of something familiar and introduces us to something unutterable. Suddenly we hear "something".

Hans Rosenstrom's [4] sound installation "2066" (2016) provokes to a visitor a strong doubt about their ability of their senses, puts them in an alertness to what is happening and whether that which is happening is revealed in the tangible dimensions of the Real. Three transducers, (his chosen type of 'speakers'), are inserted into five granite boulders, placed in the open space of Värtapiren harbor terminal in Stockholm, Sweden. The speakers transmit a vibration to a metal rod that penetrates the stone and is attached to a small metal plate. If someone lies on the surface of one of these stones and rests his head on the metal plate, the vibration from the speaker is transmitted as clear sound into her/his head. At the same time, these auditory pieces on ideas about how the world will look like in 50 years from now, seem to arrive from indeterminate sources, testing our power for a perceptual representation of space.

Space is an entire whole to which 'I' continuously refer to, in order to determine my position. Such a relation becomes possible in the appreciation of the dimensions interposing between oneself and any other point of this space that is clear to one's ability. A shift sweeps the space in its entirety, in order to succeed in being finally pinpointed by its subject. Such a shift is only perceptible within the spatial and, of course, temporal dimensions. It cannot be perceptible otherwise and in this sense, it can be said that space is a kind of form of the 'content' shift as well as the word is a kind of form of the 'content' knowledge. Further to that, the public space includes certain segments occupied by objects, as well as unoccupied, free segments, which in order to define them, one delineates them within a kind of mind-set. It is 'named' (i.e. 'free space') in order to be somehow intelligible, somehow

measurable in order to be nominated with an apprehension. Which changes, not only in each step but also, at any and every second that the focal function shifts.

An appropriation of a space often ends to an invention of ‘a topos of personal projections’, accompanied with an assertion of a name and meaning. It gradually becomes the prerequisite locus of a series of personal, positive or negative, signs and connections. Then, space, as both prerequisite and a terrain of a appropriation, refers to:

a. the reproductive ratio (i.e. systems of perspective) and
b. the empirical proportion (i.e. the individual, subjective state of perceiving the space and the empirical, objective state which answers to one’s requirement for apprehending the notion of space). Our individual sense of a space is engaged with the observations about perceptive debilities, cognitive reductions: the visual pyramid does not exhaust the entire possibilities of apprehending a space. Because the view differs as we move from a specific point A to a specific point B, although neither the space nor the perception about the space changes. Being at the point A delimits the entire entity of the space, because being at a certain point leads to an overview of a certain sight. However, a certain point of view cannot verify the remaining part of the space (the one that is not included in the territory covered from the sight A) as a non-existing. Moreover, the perception of the space is developed through ceaseless negotiations made by the individual who acts in it. At long last, space is a state of perception, likewise time is a matter of perception. Our perception of space and time coincides to the perception of our being (the recognition of the ‘I’ who witnesses the space). Indeed, the subject of the perception is always there, the subject itself is the reason and the ‘account’ of the perception [5].

We need to have these in mind in order move on to the auditory space, for the auditory ability is not bent on our intentions, it is not driven by a pre-determined focus of our perception (from A to B). The sense of audition is directly related to the all-dimensional perception of space, for that reason, it presents us with a vast spatial and functional range. Then, even the "silence" of one space is different from the "silence" of some other place, only because their physical and cultural characteristics differ. The mixture of the physical with the cultural characteristics is an obscure matter as it can be seen in the distinction between ordinary listening and reduced listening. According to Schaeffer [6], ordinary listening is divided into the four categories; listening, hearing, attending and understanding. Reduced listening is achieved by repeated listening, which enables the listener to focus on the intrinsic features of a sound, disconnected from its context. Reduced listening is a tool for investigation and for shifting listening attention intentionally, from the contextual to the inherent features of sound.

Criticism of reduced listening points out the difficulty of recognition of the contextual associations of a sound. Still following Schaeffer, in *Sound Unseen* (2014) he explores acousmatic sound (a sound that one hears without seeing its cause), a characteristic group of sounds we are dealing with in our everydayness. When both of our ears are stimulated, the difference between the intensity and the frequency at each ear, over time, has a major effect on sound perception: The term *binaural hearing* is essential for localizing sound sources; sound arrives at each ear at a slightly different time and with quite different intensity. The brain uses these differences to determine the location of sound in space. As a result, an analysis of an auditory scene depends upon the sensitivity of binaural hearing to the frequency information that comes from different sound sources [7].

3. L'OBJET SONORE¹

We arrive at two interesting bench marks; the first one deals with our conscious awareness of our auditory sense of listening and the second one responds to our engagement with the product of our hearing. I shall continue with some specifications in correspondence to the chain "transmitter - transmitted object - receiver", since they entail important aspects to the design of a sound installation for an open public space. Conscious awareness of hearing is an activity that consists of the semantic chain "stimulus – transduction – perception". Though to some degree is affected by later processes of cognition and various levels of conscious processes, hearing is itself pre-conscious. The conscious awareness of listening is as an attentional process, which means that it is active and concerned with the chain "cognition, memory, interpretation and interaction". Built upon the ability of hearing, listening moves beyond the plain auditory function, in as much as, it includes short-term and long-term memory along with the notion of interpretation. For that reason, listening is considered as a conscious activity. To elucidate the matter I shortly give the relevant theoretic approach of Barry Truax [8], Michel Chion [9] and William Moylan [10].

Truax described three general modes of engaging with the acoustic soundscape: listening-in-search, listening-in-readiness, and background listening. Listening-in-search is listening for something by means of actively seeking it out from the acoustic range of relative silence to all-encompassing sounds. According to Truax, this is listening "**...at its most active, involving a conscious search (...) for cues (...) detail is of the greatest importance, and the ability to focus on one sound to the exclusion of others (...) is central...**" (Truax, p.22). Listening-in-readiness is when something that is important or significant becomes audible, even though one does not consciously listening for it. As such, it represents "**...an intermediate kind of listening, that in which the attention is in readiness to receive significant information, but where the focus of one's attention is probably directed elsewhere.**" (Truax, p.22) This mode of listening "**depends on associations built up over time, so that the sounds are familiar and can be readily identified even by "background" processing in the brain. (...) Even when a sound is unfamiliar or unexpected, this type of listening is ready to treat it as new information and evaluate its potential significance.**" (Truax, p.22). Background listening occurs when a sound is still not an object of attention, yet, it cannot be ignored. Background listening "*...occurs when we are not listening for a particular sound, and when its occurrence has no special or immediate significance to us.*" (Truax, p. 24). This usually occurs when the sound is familiar and expected element of the sound environment.

Chion also described three general modes of engaging with the acoustic soundscape: **causal listening, semantic listening and reduced listening**. **Causal listening** is triggered in order to gather and identify information about a sound's cause (source). According to his obvious semiological approach, causal listening is the common mode of listening, a primary mode of understanding the world around us. "*When the cause is visible, sound can provide supplementary information about it (...) When we cannot see the sound's cause, sound can constitute our principal source of information about it.*" (Chion, p.25). **Semantic listening** is triggered in order to understand and interpret the meaning that 'transmitted object' carries, such as language. It involves a learned association of sound patterns and meanings, thus, "*...is entirely differential. A phoneme is listened to not strictly for its acoustical properties but as part of an entire system of oppositions and differences.*" (Chion, p.28). **Reduced**

¹Pierre Schaeffer (1967) distinguishes the term L' objet sonore, as an "auditory object for human perception" separating it from its quality as a "computational or electroacoustic object for composition".

listening describes a mode of attention focusing to the qualities or characteristics of the sound itself. **“Reduced listening takes the sound – verbal, played on an instrument, noises, or whatever – as itself the object to be observed instead of as a vehicle for something else.”** (Chion, p.29). Further, he insists that **“...the descriptive inventory of a sound cannot be compiled in a single hearing. One has to listen many times over, and because of this the sound must be fixed, recorded.”** (Chion, p.30).

Moylan described four general modes of engaging with the acoustic soundscape: First of all, the critical listening and the analytical listening; their difference involves isolation versus context. Critical listening focuses on the qualities of the sound itself, enabling an **“...evaluation of sound quality out of context...”**. Analytical listening searches for the relationships between sounds for an **“...evaluation of the content and the function of the sound in relation to the (...) context in which it exists.”** (Moylan, p.90). In support of these two listening modes, Moylan conceptualizes some crucial elements, that are: *sound event*, *sound object*, *perspective*, and *focus*, a familiar contextualization due to Tschumi’s views regarding the group of perspectives that the notion of a *city* includes [11]. These conceptual elements underlie those of Truax and Chion. Thus, the sound object formulation is closely related to the *L’ objet sonore* of Pierre Schaeffer. A **sound event** refers to the shape or contour of sound over time, **“the shape or design of the musical idea (or abstract sound) as it is experienced over time”** and **“...a complete musical idea (at any hierarchical level) that is perceived by the states and values of the artistic elements of sound (...) the sound event is understood as unfolding over time, and is used in analytical listening observations”**. By contrast, a **sound object** is defined as a focal point for evaluation, considered outside of their original context: it is the object of critical listening. In this sense, a sound object is **“...sound material out of its original musical context”** and **“...a conceptualization of a sound as existing out of time, and without relationship to another sound (except its possible direct comparison with another sound object).”** (Moylan, p.91). **Focus** is the act of directing one’s attention to specific elements in the environment in order to apprehend information. **“Focus is the act of bringing some aspect of sound to the center of one’s attention”**. **Perspective** is the hierarchical level at which one is focusing. **“Perspective is the perception of the piece of music (or of sound quality) at a specific level of the structural hierarchy”** (Moylan, p.92).

In need to assemble, sound affects us; it alerts, distracts or concentrates us, while it develops into the space around us. To return to Truax, sound often functions as an auditory listener’s engagement and immersion to the space. Among our genetic ability and our perceptual vagueness of listening while we are traversing through our cities, the idea of designing a digital sound Installation for an open public space appears as an arduous task. Hence, to work upon it, we need to take on an advance survey regarding the space in quest along with the conditions that affect the propagation of a sound-piece: Particularly,

I. A complete record of the referent open Public space need to be made, which concerns observations about:

a) The wider spatial arrangement of the elements surrounding the space, b) The complex principles that govern the identity of the space and c) The elucidation of information than is not found in the visible order of things, such as, the identity of the society that grows around it, which include but are not limited to: a) Observations about the historical, cultural, social and economic conditions that have shaped the present state of the place, b) Apprehension of the structures and balances that develop between the specific open public space and the individuals it hosts and c) The artistic intention of the one who observes and records, as seen through the choices and the decisions made and appeared in the recording material and its arrangement.

II. An evaluation of the properties of sound in reference to the exact conditions of a given open public space; an in situ case-study on:

a). Refraction (fluid change), b). Diffraction (acoustic shadow), c). Clarity (sound permeability), d). Reverberation (acoustic quality of a space), e). The linear and non-linear acoustics, f.) The aero-acoustics. g). Speed (depends on atmospheric temperature, thus, the medium through which a sound-wave is propagating, h). Due to the sound-wave nature (frequency, wavelength and amplitude), the spectral distortions that sound-waves undergo once they interposed by natural or artificial objects, then, during their propagation, sound-waves can be a). Reflected, b). Refracted c). Attenuated by the medium [12].

While sound is a pulsing vibration, a precise evaluation of factors that interfere with its propagation comprises also a significant matter of attention. The main factors affecting sound propagation in open spaces are:

a) The distance between transmitter and receiver: This is an important issue because it determines the perceived intensity of the sound in relation to its nature (spherical, cylindrical or plane wave), b) The height (from the surface of the ground) and angle (any change above or below of 45° from its axis) of the transmitter: The relative adjustment is necessary, especially in those cases where the receiver does not have a strictly specified position in space, c) The atmospheric absorption of the sound: The levels of humidity in the atmosphere significantly affect sound propagation, while the change in values affects its clarity and speed, d) The direction and intensity of the wind: The wind tends to bend the sound waves towards the ground, in the direction of its breath, e) The nature of the ground: It includes the anaglyph form of the ground and its height variations which affect a smooth sound propagation. Also, the quality of the soil and the type of nature that thrives into the place in quest are an important regulatory element of sound propagation. Specifically, vegetation on an outdoor scale does not have a fixed form, so their growth curve (the height and the density of foliage), mainly the inclusion of their evergreen or deciduous character in the seasonal change, needs to be taken under consideration [13].

Moreover, Digital sound is a subject analysed under different scientific fields that offers a desirable knowledge towards a composition of a Digital sound Installation for an open spaces, such as:

a). Electroacoustics; a field that examines electronically generated (synthetic) sounds, particularly *sine wave*, a periodic wave whose waveform (shape) is the trigonometric sine function, rely on electroacoustic engineering. b). Audio signal processing; a field referent to the electronic manipulation of audio signals using analogue and digital signal processing. c). Environmental acoustics; a field of studies concerned with the control of noise produced by human activities and machineries, thus, anything else that might be considered as auditory disturbance. d). Musical acoustics; a field dedicated to research and describe the physics of music and its perception, in other words, how sounds employed as music work. It includes among others: the human voice, computer analysis of music and composition; the perception and cognition of music. e.) Psychoacoustics; the research on this field tries to explain how humans respond to what they hear, whether that is noise or music. In many branches of acoustic engineering, a human listener is a final arbitrator as to whether a design is successful, for instance, whether sound localization works in a surround sound system. f). Bioacoustics; a field of studies on sound production and hearing of animals and plants, thus, recently evolves human functions and organs [14].

4. OUTRO: THE FORTY PART MOTET

Janet Cardiff's [15] *The Forty Part Motet* (2012), originally produced by Field Art Projects supported by Arts Council of England¹ presents us with an excellent example of the power of sound Installation to create three-dimensional audio scenes. The sound-piece is based on Thomas Tallis's sixteenth-

¹ <http://www.fieldartprojects.com/index.php/about>

century choral composition *Spem in Alium Nunquam Habui (In no Other is my Hope)*. Forty speakers arranged in eight groups of five forming a large oval. Each singer's voice, recorded separately, emanates from a single speaker. In an immersive installation, where each speaker initiates a different vocal recording. The voices meet together to produce a composition that envelops the audience, which is able to emotionally interact with the artwork. The use of spatial audio technology overlapping to acoustic engineering approaches, turning the audience to active participants in the meaning-making process.

With their intangible form and their technologically autonomous nature, we could see the digital sound art-works that move through entities of a space, as a sustainable resolution for culturally re-advancing an open public space. Auditory perception is responsible for interpreting and understanding our sound environment. Since it awakes our cognitive functions, we can see how sound provides for us a more consistent knowledge about the space. Yet, the construction of a sound Installation coincides to the creation of a system. A system relates to the notion of 'concept' that provides an account for the system and it lays the foundation for its manifestation. The materialization of a concept refers to the creation of a spatiotemporal dimension defined by the ambiguous relationship of "here" and "now" and the social dimension defined by the complex relationship of "me" and the "other". Thus, it is always a subject of continuous experimentation, an open and therefore unlimited in thought and means process [16].

To avoid any misunderstanding, a digital artwork cannot be a decisive metaphoric or a metonymic attitude, decisive for the identity of the space. As a digital art Installation cannot be a substitute for a deficient relationship between ourselves and the world, it also cannot take the place of an object of desire within a traumatic "void". It is not the counterfeit corpus of an absence of a political, social, personal care for our environments. Although, it can be some kind of (metaphoric, metonymic, etc.) expression of such an absence, inscribing the site of our relationship with an experienced loss, of a deficit or the "void" [17]. Thereafter, a digital sound-work (by definition ephemeral in its duration; any projection of personal affiliation is short-lived) leaves an open feedback system for the "individual", the "space" and the "artwork" itself [18]. By any social or individual connotation (carried through memories, propositions, statements, hypotheses or strategies), a digital artwork exists as a profoundly subversive force, an exemplary subject that offers the exciting prospect for us to cultivate possible ways in which, digital and physical public spaces could be designed to expand each other's conceptual existence.

Abstract

The concept of "sustainable development", which appeared at the end of the 20th century, is a tool for criticizing various development options based on a long-term planning policy and has essentially connected the environment to several social and economic issues. In order to achieve a sustainable urban development, it is necessary to combine different urban planning models, that will have some features in common, such as interconnected public spaces, as well as the provision of effective and efficient public transport. One of these models of urban planning is the "compact" city model, which was first mentioned in the Green Paper on the Urban Environment (1990). One of the objectives of this model is the renovation of empty and abandoned buildings and the creative readjustment of their uses, as well as traffic relief through the reduction of motorized travel.

In the context of the cities' transition towards smart and green development, this paper will focus on the reconstruction and adaptation of the original use of the old University building of the city of Ioannina. The main goal of this paper is to enhance the importance of the sustainable reconstruction and reuse of the specific building, in accordance with the specifications of inclusive design in urban areas, taking into account its historical and social identity.

The building was constructed at the end of the 1950s, and has remained vacant since 1996. In 2000, a partial reconstruction was carried out in the northwest part of the building, where public services such as the tax office and the transport and communications department of the regional unit of Ioannina were housed, while the rest of it still remains unused and in poor condition. The building is only 1.4 km far from the city center, therefore its reconstruction and transformation into an energy self-sufficient building, as well as, the relocation of the public services located in scattered buildings around the city of Ioannina, to it, will contribute to the green city development. Principal aim is to concentrate a large number of public services in one building and provide easy accessibility for all city residents, and the corresponding use of "green" means of transport.

Keywords: *sustainable urban development; "compact" city model; green development; Ioannina*

1. INTRODUCTION

The accelerated growth of cities, the disproportionate consumption of natural and social resources, and the traditional systems that cities rely on for resource provision make cities unsustainable. The world is at an unprecedented level of urbanization, with half of the total population living in cities, consuming 60% to 80% of global energy production, while the urban population is expected to grow from 7 billion to nearly 10 billion by 2050 [1].

According to the report of the Brundtland Commission and the procedures of the UN Commission on Environment and Development, one of the strategies aimed at limiting energy consumption, reducing pollution and protecting natural areas is the reuse of urban areas and utilization of existing buildings [2].

Due to the urgency of the climate crisis, in the last decade the planning of cities has become the basis of sustainable development having people as a priority, making the city more environmentally friendly and accessible for all people [3], connecting its history to the aesthetics and architecture [1]. The main objective of sustainability is the improvement of the environment and it requires a radical change in the structure [4] and operation of modern cities, in a way that satisfies the needs of the present generation, without limiting the satisfaction of the needs of future generations [5]. Sustainable cities should minimize their use of resources, create open spaces that are attractive and useful, minimize the need for car travel by prioritizing low-energy modes of transport such as walking, cycling and using public transport, provide personal safety in public spaces and be accessible, affordable and inclusive for people with disabilities and people from different cultures [6].

The purpose of this paper is, in the context of the smart and compact city, to highlight the concept of a sustainable and resilient city through the reconstruction and reuse of the abandoned part of the old University of Ioannina.

To be able to achieve a sustainable urban development, different urban planning models must be combined, which, however, will have some features in common, such as interconnected public spaces, as well as the provision of effective and efficient public transport [7]. The debate on the ideal form of a city is as old as the science of urban planning, while the environment has been the most recent element introduced into this debate [8].

The "compact city" model, which, in recent years is been found in a large number of urban policy texts and aims to increase densities and revitalize urban centers with significant energy, economic and social benefits, [8] is one of the leading examples of sustainable urbanization. Compact city planning and development, over the past 30 years or so, has been the preferred response to sustainable development challenges [9].

2. THE "COMPARE CITY" MODEL

A key issue that arises in the context of the debate on the sustainable city, is the search for the urban planning model or models in terms of: the distribution of functions, the density and the hierarchy of its structure (center – local centers – suburbs). Some people argue that by changing the shape, size, density of housing, design and location of activities in cities, will result in energy gains of “up to 150%”, from reducing motorized travel, increasing efficiency in production, distribution and consumption of energy and a more rational utilization of renewable and non-natural sources [8].

The form towards which several researchers converge is that of the “compact city” [8]. In the “Green Paper on the Urban Environment” in 1990, the European Commission has advocated such an urban model as the most sustainable, giving as much emphasis on the criteria of architectural "urban design" as on the arguments of ecological sustainability [2]. The 'compact city' model suggests that future growth needs should primarily be met through densification within the current urban boundaries [2] According to the President of Technical Chamber of Regional Department of Western Greece, Vassilis Aivali, the urban form of the compact city, in relation to other urban forms, gathers the most environmental benefits for achieving sustainability. These benefits of compact urban development do save land and space, saving energy, the reduced demand for transportation and the resource efficiency [10].

The basic principles of a sustainable urban planning that will fuel the development and management of the compact city are the following:

1. Coherent housing development.
2. Mixing of land uses alongside integrated urban and transport planning.
3. Securing and protecting important open and green spaces.
4. Strengthening of city centers and other central areas.

In particular, with regard to coherent residential development, the main objective is to contain housing development within the existing urban structure. Increasing population density and activities can be

achieved through 'land recycling', which means a more efficient use of land. The exploitation of the abandoned or underutilized areas of the city in which the natural environment has already been encroached by urban infrastructures, the reuse and utilization of the empty building stock, the addition or extension to existing urban structures are the most important measures in the direction of the greatest possible exploitation of it [11].

2.1. CHALLENGING COMPACT URBAN DEVELOPMENTS

Although the environmental benefits of the compact city are especially important, it is questionable whether the characteristic of high density could become socially acceptable [12], since it would probably require a change in people's priorities, sequencing the values of nature and environment [2]. Although research and policy support more compact cities, referring to greater density, diversity, mixed land use, sustainable transport and green spaces, promoting this model today in Europe as an optimal form of urban development, this approach to sustainable urban development is associated with some conflicts and controversies, since the research to date regarding its energy efficiency demonstrates uncertainty in what it entails with high energy benefits compared to other urban models [8][9].

More specifically, with regard to transport, which is responsible on average for 40% of a city's energy consumption, it is strongly disputed that the compact urban form implies a reduction in motorized travel [8].

In addition, the "compact city" produces high levels of noise pollution due to the close proximity between residences, transport lines, business activities and service facilities, so the concentrated impact of dense populations on the environment and the lack of planning to control noise pollution can have direct negative effects on human health [9].

Finally, studies such as Breheny's, 1992, 1997 and Neuman's, 2005 argue that there is a case for compact urban developments to increase land and housing prices creating social exclusion of some groups, as well as according to Burton, (2000) even to increase crime levels [9].

In the search for a universal model of the sustainable city, Guy and Marvin (2000) consider it crucial to recognize that there is no single future, vision or model, but many different ones that can co-exist, supported by different sets of social interests, bridging the techniques and social considerations of each city [13]. Therefore, it is important to highlight the possible consequences of the different proposed city models, in the light of the criteria for a sustainable development and always in relation to the most important objectives that have been set [2].

3. SMART CITY AND ACCESSIBILITY FOR ALL

We could give many definitions for the meaning of a "Smart City". Although the original goals of a Smart City were primarily technology-oriented, contemporary views of Smart Cities point to the inherent importance of people, community, and governance. The concepts of 'for all', 'accessibility' and 'inclusion' are increasingly encountered in the dialogues about modern smart cities [6].

The term accessibility is defined as "the characteristic of the environment, which allows all persons, without discrimination of gender, age and other characteristics, such as physical condition, perception, nationality, to have access to it, which means all people to be able to autonomously, safely and comfortably approach and use the infrastructure, as well as the services (conventional and electronic) and the goods available in the certain environment" [Greek Law 79/A/9-4-2012].

The goal of having inclusive and accessible cities is a globally recognized need [13]. Cities across the European Union are making efforts to make the physical, built and digital environment more accessible for people with disabilities (mobility impairment, visual or hearing impairment) as well as for disabled people such as the elderly, pregnant women, people with temporary injuries, parents with prams, etc., with the aim of being able to fully participate in all areas of life. Accessibility is essential

for the equality, autonomy and independent living of all people, improves the quality of life and contributes to the creation of inclusive cities that thrive [15].

Globally, many built environments fail to meet the accessibility needs of people with disabilities, despite the fact that people with disabilities fight to improve their accessibility of the built environment [6]. Although in the past decade, new initiatives and practices have been developed in various sectors in order to make cities more accessible for all [15], as Mr. Antonis Harokopos (President of the Regional Federation of Disabled Persons of Western Greece and the Southern Ionian Islands) points out, “we continue to see and experience deficiencies, mistakes, inappropriate and outdated planning in infrastructure, transportation means and systems of movement, parking, poor workmanship on roads and sidewalks, up to the drivers of vehicles who park in front of ramps and crossings or on sidewalks” [16].

There is an urgent need to revise construction, urban and architectural planning, in order to take into consideration, the needs and requirements of people with disabilities [6]. A city is accessible when all its residents can live in it and use all objects and services without problems, such as being able to use public transport for their transportation, moving around the streets without encountering obstacles, have direct access to all public buildings and receive information in forms so that they can read and understand [15].

4. THE CASE OF IOANNINA

4.1. HISTORICAL REVIEW - URBAN PLANNING DEVELOPMENT OF THE CITY OF IOANNINA

The city of Ioannina, also known as Ioannina, Giannena or Giannina, is the largest city of the Region of Epirus as well as of the Decentralized Administration of Epirus - Western Macedonia. It is built in the center of the basin, on the western shore of Lake Pamvotida (altitude 470m.) where there is also the picturesque island (Island of Ioannina), on which there is a small settlement and various monuments and attractions, such as the last residence of Ali Pasha are found [17]. Furthermore, the city of Ioannina is the Region's main attraction pole of Epirus, since it gathers a large part of the urban population as well as the employment of the Secondary and Tertiary economic development sectors. In addition, the city attracts a large number of students, who consist an important part of life in the city.

The residents of Ioannina, especially the prominent Epirotian intellectuals, had attempted to establish university schools since the early 1950s. The building complex chosen for study began its operation as a University institution in 1964. The first department established that year was that of School of Philosophy as a branch of the corresponding School of the Aristotle University of Thessaloniki starting its operation with two hundred students, while in 1970 an independent Higher Educational Institution (H.E.I.) was founded in Ioannina.

During the period of the Ottoman Empire, the city had a confused urban structure and until its inclusion into the Greek state, consisted of districts-mahalades, which replace the concept of a building block. Also, the market was of great importance in influencing the organization of the city, giving that way to the city the characterization, at the beginning of the 19th century, of the "city-market". In the second half of the 19th century, the development of the city is polycentric, combined with the central position of the settlement in the wider area. The city of Ioannina will change after its accession to the Greek state in 1913. The general urban planning policy followed by the Greek state regarding the newly incorporated cities has decisive effects on the formation of its urban structure. In 1915, a zoning plan for Ioannina was drawn up, while in 1934 the first decree for the city plan was issued. Since 1984, successive expansions of the city plan have been observed, resulting in almost a doubling of the settlements included in the city plan.

The residents of Ioannina and especially the prominent Epirotian intellectuals had attempted to establish university schools since the early '50s. The building complex chosen for study began its

operation as a University institution in 1964. The first department established that year was that of School of Philosophy as a branch of the same School of the Aristotle University of Thessaloniki starting its operation with two hundred students, while in 1970 an independent Higher Educational Institution (H.E.I.) was founded in Ioannina.

The study area is located in a central part of the city, between the historical and commercial center of Ioannina and the new University, thus creating an open front of communication and connection of the city and its inhabitants. In the area around the plot of the old University of Ioannina, it is observed that most of the buildings around it are two or three-storey ones. In addition, the space around the study area is mainly for residential purposes and is accompanied by ground floor shops. There are also buildings that house educational and housing areas as well as a student residence building of Ioannina located in the southeast part of the plot.

4.2. STUDY AREA – THE BUILDING OF THE OLD UNIVERSITY OF DOMPOLI

The research of the present study focuses on the building of the old university of Ioannina located on Dombolis street. The construction of the building dates back to 1950, in the 70s a section was added to the south-east of the plot, since 1996 it has remained vacant. In 2000, a partial reconstruction of its northwestern part took place to house some public services, such as the tax office and the transport and communications department of the regional unit of Ioannina. Until today, no repairs have been made to the remaining unused part of the building, as a result the building does have considerable damages. The unexploited part of the building is the one located at the front of the plot, where the central entrance to the building complex is located, and is visible from the main road (Dombolis Street) (Figure 2).

BUILDING OF THE OLD UNIVERSITY OF IOANNINA

Figure 1. Plan of the building of the old university of Ioannina (created by the authors)

The building complex is housed in a plot of land with a total area of 10.231,14 m² and has a Π layout around an atrium, which is currently used as a parking space. The complex consists of 4 floors and the total area of its floors is 13.569,67 m², while the total area of the vacant building is approximately 6.925,40 m² (Figure 2).

Figure 2. Floor plans of the old university of Ioannina (Department of Environment and Urban Planning of Ioannina)

In the context of the transition of cities towards smart and green development, with the aim of utilizing the existing buildings of the city and having free access for all citizens as a guiding principle, is proposed the reconstruction and adaptation of the original use of the old university building of the city of Ioannina. It is highly suggested the transfer, to the unused part of the building of some public services which are scattered in the city or can be accessible only by car, away from the center, so as to make it easier to serve the residents, to minimize their movements and especially their need for motorized travel, since the building is located only 1.4 km away from the city center.

In 2017, the Department of Environment and Urban Planning of the Municipality of Ioannina relocated to the building of the former Katsikas Town Hall, which is located 6.0 km from the city center. The Department of Urban Planning supports the entire Prefecture of Ioannina, therefore it deals with a lot of people, both with the public and with engineers, as a result of which their movement to this service is mainly done by car. Therefore, its return to the city and its housing in the empty building of the old university of Domboli street, will have a beneficial impact on the accessibility of the citizens as well as to the environment, through the reduction of energy consumption for movement.

In addition, there are some services of the municipality of Ioannina that are housed in separate buildings in the center of the city and which can be moved to the Domboli building, such as the Directorate of Administrative and Financial Services housed in a building on Kaplani Street, as well as the Directorate of Technical Services in Koletti Street, the Customer Service Center Division and the Planning, Organization and IT Division located in El. Venizelou street. The Organization of Social Protection - Solidarity & Preschool Education (OKPAPA) of the Municipality of Ioannina is housed in the city center, in Averof Street, while the Roma branch of the Community Center is housed in KE.PA.B.I., which is located in Archbishop Makariou Street. Therefore, the OKPAPA's services

could also be transferred to the building of the old university of Domboli, so that they are concentrated and no more movements between the services are needed [18] (Figure 3).

Figure 3. Map of the scattered public services in the city of Ioannina (created by the authors)

4.3. TRANSPORTATION AND ACCESS TO THE BUILDING

The transportation in the city of Ioannina is carried out mainly with the use of a car, walking and the use of city buses.

The city of Ioannina is connected to a public transport network in order to serve the citizens within the city's urban complex. The Municipal Bus Service of the prefecture has been active since 1952 and today it has 60 buses, which make 800 daily routes with a total of 415 stops throughout the prefecture [19]. Just outside the building there is a stop which is served by 2 lines 10 and 12 [20], therefore the routes going to this stop should be increased and these buses should be fully equipped so that citizens who have some kind of disability such as mobility problems, can move on their own. Additionally, the traffic lights in the study area have to be replaced with sound ones.

A ramp should be built in the building for the access of people who move in a wheelchair or use a stroller, As well as an elevator and toilets for the disabled should be constructed. In addition, public service counters must be positioned to accommodate wheelchair users.

For the hearing impaired (deaf and hard of hearing people), a "tele-interpretation" station needs to be installed on the ground floor of the central building, facilitating them both in their dealings with the municipal services and in communication, in general.

As far as people with visual impairment are concerned, it is considered necessary to have suitable routes with corresponding guides in each area, an audio description of the area they are in, using an application on their mobile phone and the appearance of strong color contrasts in any obstacles. In

addition, at the entrance of the building, relief plans of the spaces should be placed, ensuring their full accessibility, whereas in all spaces, there should be signs accompanied by texts in braille.

4.4. ENERGY INDEPENDENT BUILDING

One of the goals set by the European Green Agreement with the aim of carbon neutrality by 2050, is the energy efficiency of buildings [21]. Buildings constitute one of the largest sources of energy consumption in Europe and are responsible for around 40% of EU energy consumption and around 36% of greenhouse gas emissions from energy consumption [22]. The instruction aims to achieve a zero-emissions and fully decarbonized building stock by 2050, stating that from 2028 all new buildings should have zero greenhouse gas emissions, the buildings which house, are used or owned by public authorities from 2026, while residential buildings undergoing large-scale renovation will have a time limit until 2032 [23].

The reconstruction of the building will be carried out according to the green transition and energy autonomous buildings. Therefore, the installation of photovoltaic systems will be able to fully cover all the needs of the building in terms of electricity, such as lighting, hot water and the operation of all electrical devices installed in the building. The need for heating or cooling the building can be achieved by installing solar systems or with an electric boiler that will also be powered by photovoltaics. The lighting in the building will be done by installing low energy consumption led lamps. In addition, a thermal facade and energy frames with thermal break should also be installed. Finally, permanent external shades will be installed to protect the building's shell during the summer months, but they will provide the possibility of natural lighting, ventilation and, of course, will not prevent the necessary sunlight entry to the building during the winter.

5. CONCLUSION

The compact city is a popular urban planning model, which is currently being promoted in Europe as an optimal form of urban development. With the term "compact city" it is argued that the implementation of policies aimed at increasing densities and revitalizing urban centers will have significant energy, economic and social benefits. The primary objective of sustainability policy is the improvement of the environment on a global scale, which requires a radical revision of the structure and operation of modern cities. In the context of the transition of cities to sustainable development, a key issue that arises is the search for the urban planning models that correspond to it and in particular in terms of: the distribution of functions, the density and the prioritization of its structure (center - local centers - suburbs).

This work aims at the regeneration and reuse of the building of the old university of the city of Ioannina, in the context of the "compact city" in order to contribute to the sustainability and resilience of the city. The transfer of public services located far from the city center as well as services housed in different buildings within the city is considered necessary in order to reduce energy consumption and the use of motorized modes of transportation.

Furthermore, the reconstruction of the building will contribute to the easy accessibility of the building and services by all residents of the city as well as to its energy autonomy, with the installation of photovoltaic systems and the installation of a heat-insulating shell, providing, at the same time, significant energy, economic and social benefits.

SUMMARY

Sounds are part of cities and the "emotional" landscape. They are as much an element of urban identity as the visual landscape. However, the relationship between soundscapes, heritage and attractiveness has not been sufficiently researched to date.

The aim of this research was the design and implementation of an urban Open-space Sound Museum in order to promote the rich cultural and historical aspects of Ermoupolis and also increase the attractiveness of the city. The sub-objectives of the research were a) to record and evaluate the environmental noise in the study area and to capture the sound identity of the city, b) to connect the cultural heritage of the study area with its soundscape, c) to redefine cultural tourism through the actions of the Open-space Sound Museum. The methodological approach incorporated both, perceptual and objective assessment tools regarding the sonic characteristics of the case study area. Furthermore, an extensive literature review was conducted.

Additionally, the planning and future installation of an Open-space Sound Museum holds an educational value with the potential to raise environmental awareness among citizens and visitors. The protocol shaped in this research can be adapted with minimal modifications to other areas of rich cultural and environmental values.

Keywords: *Soundscape, city sound identity, Ermoupolis, intangible cultural heritage, tourism, Open-space Sound Museum, public space.*

1. INTRODUCTION

Urban residents face a series of environmental pressures with both short-term and long-term effects. Therefore, sustainable solutions are of major importance [1]. Sustainability is directly connected with conservation and recognises the value of intangible heritage as a cultural resource. The cultural soundscape is a resource and a sustainable tool for social, educational, spiritual and economic local development. Culture shapes a city's identity, community identification, historical continuity and collective representation. This is an important comparative advantage of up-to-date touristic city [2]. This research attempted to find the connection between culture-tourism-soundscape and sound identity in cities. The aim of the study was to create an urban Open-space Sound Museum in order to increase the attractiveness of the city. It is a museum designed for public space allowing visitors to navigate through the proposed path. Such an experiential approach allows visitors to get familiar with the cultural identity of a city and actively participate in its historical continuity.

For this research the sound environment of Ermoupolis in Syros Island (Cyclades, Aegean, Greece) was studied, with focus on the cultural and touristic aspects of the city. Therefore, quantitative and qualitative data were collected in order to define the area's sound identity [3]. Furthermore, in order to portray an accurate representation of Ermoupoli's sound identity, urban noise was studied in an effort to promote urban quietness [4]. Finally, the proposed Open-space Sound Museum, serves as an

educational tool, as it raises awareness on cultural issues, while contributing towards urban well-being.

2. THEORETICAL VIEWPOINTS

Increased quality of life in urban environments can be achieved through the promotion of cultural and natural heritage, including the preservation of history, social equality, vibrant neighborhoods and biodiversity [5].

Neighborhoods contain the basic urban elements needed to function autonomously. Kevin Lynch, an urban planner, in his book 'the image of the city' [6], described the parts of a city and its micro-scale such as the neighbourhood: streets (daily routes), boundaries (natural boundaries such as the sea or mountains), sub-areas, nodes (squares, crossroads) and landmarks.

In sociological terms, the neighbourhood is a living body of the city that evolves with the people who live in it. However, national or international events change neighborhoods. The downward trajectory of a neighborhood is usually: economic prosperity, acute socio-economic crises, institutional and political reconstruction, economic decline [7]. In the case of Ermoupolis, many neighborhoods were "silent" due to the abandonment of their inhabitants (internal migration phenomenon), with environmental, social, aesthetic and economic consequences. This change is reflected in the soundscape.

2.1 Urban Sound Environment

The sound environment in the city is composed of biological sounds, i.e. the voices of all living things in a city (biophony), geophysical sounds, such as the rustling of leaves, the sound of the wind or the sea (geophony) and man-made sounds, i.e. those produced by human works (anthropophony) [8].

The perceptual construct of the sound environment is called the soundscape and is defined as "*the sound environment with emphasis on the way it is perceived and understood by an individual or a society*" [9]. It encompasses everyday sounds and includes sound events of culture and civilization. Each soundscape is created according to the physiognomy of each area and its soundmarks. The soundscapes of the city help to capture the sound identity [10].

Additionally, the sound identity of a city, a neighborhood or an area, is part of the memory of the inhabitants about the culture, the use of the land and sound [11]. Important information about the quality of the sound environment and the acoustic comfort of the surrounding space is derived from the sound identity. In cultural spaces, the interaction of space and cultural sound (landmarks and soundmarks) is related to sound recognition, experience and sound perception.

The propagation of sound in the urban environment is significantly influenced by structural elements. Factors affecting the transmission of sound include the dimensions of the source and receiver locations, the width of the space that shapes the transmission, the materiality, morphology and height of buildings, road layout, volume, open and enclosed space, altitude above sea level, land use and weather conditions. The main physical phenomena that influence the quality of a soundscape are reflection, reverberation, diffusion and absorption of sound waves [12]. Usually, due to the structural materials, several phenomena are observed together, at the same time.

Noise is a multifaceted issue and is subject to both a quantitative and qualitative evaluation [13]. It can be dealt as a sound of increased intensity that can be measured using a sound level meter, or as a negative sound that can be described through a perceptual assessment [14]. Urban noise provides information about the environment and also about the cultural sounds it covers [15]. According to WHO, people can feel comfortable with sounds up to 53 dB during the day and 50 dB at night. Above this threshold, noise becomes harmful to human health. That has a serious effect on acoustic comfort and quality of life of the citizens and visitors [16].

Subjective research tools similar to the CRESSON method that involves expert interviews and questionnaires, can be used to obtain perceptual characteristics of sound environments [17].

2.2 The cultural factor

Cultural environments are the inseparable unity of culture and the natural environment (important cultural landscapes). They include elements of tangible and intangible cultural heritage and associated values, characterised by uniqueness and authenticity [18].

Intangible cultural heritage is manifested in oral traditions and narratives, music and dance, religious rituals, festivals, idioms, social events, theatre, celebrations, soundmarks etc [19]. It is a living reality that changes, develops, enriches and is passed on to future generations, adapting to social and cultural changes. It is an element of the collective identity and memory of a place.

Soundmarks [20] are sounds that are unique and have a distinctive quality that is highly associated with specific people or a community [21]. For example, the church bell or the town clock stand as soundmarks of several areas. Several soundmarks are now extinct or currently absent from an urban environment. Therefore, several “iconic” soundmarks are protected under an UNESCO scheme. Several extinct sounds are documented through literature and oral history and other means. They remain, however, as authentic memory imprints in the city. The authenticity of a sound comes from memory, the impression of the past, its perception and interpretation in the present and the experience of the city's inhabitants. This is captured as personal experience and part of the sound identity [22].

2.3 The tourism factor

Tourism is a complex, dynamic phenomenon with social, economic, cultural and environmental components. It is an ideological formation of history, nature and tradition, largely based on personal perceptions and experiences. The link between tourism and cultural management is authenticity, i.e. the sense of memory [23].

During the last eighteen years, the economic crisis and the pandemic of Covid-19, have affected the tourism sector worldwide. Industry leaders have understood the scale of the problems and are moving towards sustainable directions. The issues raised are: (a) cultural, such as authenticity, promotion and preservation of cultural heritage; (b) environmental, such as sustainable management of natural resources; and (c) social, such as accessibility, inclusion, modernisation of information media, etc. [24] (all of which served as design criteria for the Open-space Sound Museum).

Sounds are part of the traveller's sensory experience. The soundscape can be the main attraction of a place, accompanying and impressing tourists during their visit [25]. The soundscape in relation to tourism has two aspects: a) what the tourist hears or wants to hear, and b) what is caused by the management of the tourist asset: the effort to attract tourists results in a noisy soundscape, which has consequences for the quality and attractiveness of the place.

This study examined the tourist soundscape as an element of the sound identity of Ermoupolis. However, research on sound and tourist experience remains limited [26].

2.4 The museum

Museums are an integral part of the city and its culture. They are a reminder of the history of a place. The new museum model needs to be extroverted, both spatially and metaphorically, and be interactive with its visitors. The COVID-19 pandemic also led to the 'opening' of the museum to open spaces. The aim was to be approached by the public [27].

The museum is a symbol of a city's prestige, enhancing its attractiveness. It is a vehicle of memory and culture, an educational tool for citizens and visitors to a city and all that makes up and surrounds it. It must be up-to-date, open and inclusive [28].

The museum presented in this paper is original and has been designed from the outset in open space. The Open-space Sound Museum is directly related to the two factors of research, culture and tourism in the open space of the city. It attempts to transform the whole city into a network of identifiable urban spaces through the soundscape.

3. METHODOLOGICAL FRAMEWORK

For reasons of objectivity and impartiality, the study of Ermoupolis followed a methodological protocol based on acoustic ecology method, ecoacoustics tools and CRESSON qualitative recording tools [29]. The following table (Table 1) lists the steps and tools of all approaches:

Study on the selected area	Acoustic Ecology Approach	Eco-Acoustics Approach	Methodology by CRESSON*
Step 1	Step 2	Step 3	Step 4
<ul style="list-style-type: none"> • Discussions with locals. Understanding the city. Identification of areas, important landmarks and echoes of Ermoupolis. • Literary research (books, essays, articles, literary texts, documentaries about the area). • Experimental soundings and test soundings to find final areas • Selection of five final regions and points 	<ul style="list-style-type: none"> • a study of the soundscape of the five areas • photographic documentation • Final sound and noise sampling • Data collection based on legal data (Directive 2002/49/EC) • Design in plan, topographic and sectional views (AutoCAD, Photoshop, Rhino) • Spectrogram 	<ul style="list-style-type: none"> • Extraction of acoustic biodiversity indicators (using R statistical software) • Acoustic Complexity Index • Normalized Difference Soundscape Index-NDSI • Noise index of the energy equivalent Leq 	<ul style="list-style-type: none"> • Interviews with five local experts: after listening to one-minute extracts for each point, followed by a semi-structured dialogue • Documentation and analysis of the interview data • The emergence of a city's sonic identity <p>* Centre for Research on Sound Space and the Urban Environment</p>

Table 1. Steps and methodological tools

3.1 Definition of the study area

The factors that contributed to the choice of Ermoupolis were its urban physiognomy, the historical and cultural life of the city and the tourist interest it receives throughout the year. Also its interesting soundscapes (variety of geophonic, biophonic and anthropophonic sounds) and the accessibility of the city for soundwalks. [30]. The collection of bibliographical data on Ermoupolis was framed along three axes: Geographical-Natural, Historical-Architectural and Social-Cultural Context. The scientific literature on the theoretical framework of acoustic design was also studied. Discussions with the inhabitants of Ermoupolis and questionnaires, followed by intensive research of bibliographic and audiovisual material, helped to identify the main landmarks and soundmarks.

The recordings were made in the first half of September, when the tourist traffic was tolerable and the weather was clear, without Cycladic winds. Until the 14th of September 2021, sound sampling was carried out in 3 stages: experimental-research, first level, final level. The preliminary stage consisted of soundwalks and test recordings, where observations and data were collected. Then 5 sub-zones were selected: the main square of Miaoulis, the promenade, the market street, a natural boundary of the city, a neighbourhood. The final recordings were made in 13 locations. The material was then classified and indicators were extracted using appropriate software (objective evaluation). The last step was the semi-structured dialogue (qualitative characteristics of the sound identity).

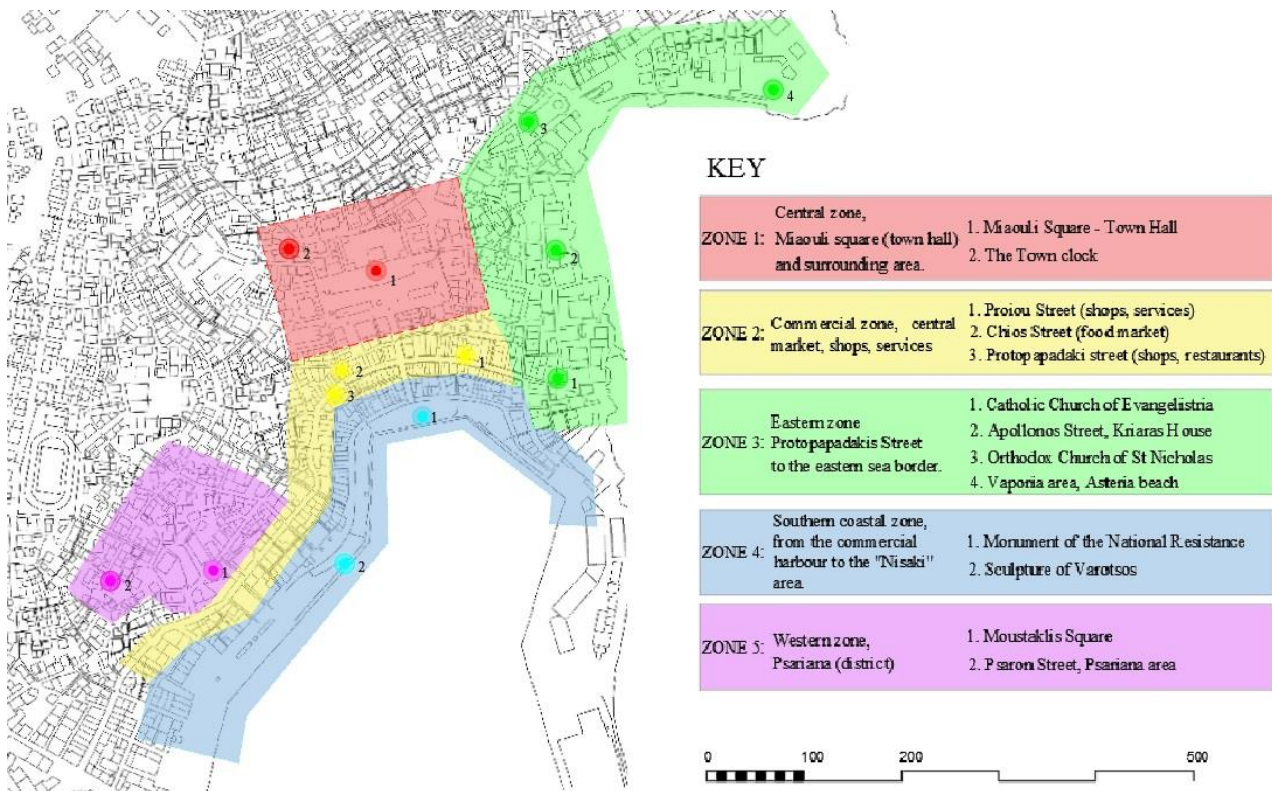

Figure 1. Map of sampling points

3.2 Evaluation tools

a) Objective evaluation tools:

1. Trial and final sound samplings required special recording equipment: a digital recorder and a sound level meter. A specific recording protocol was followed to ensure correct sampling and to avoid natural phenomena such as diffraction and reflection caused by the researcher.
2. Photographic documentation of every point.
3. was written some information about each location, such as buildings, greenery, weather conditions, prevailing winds, comments about the soundscape. And, of course, the date and time of each recording (one in the morning and one in the afternoon).
4. Once the data had been collected, it was processed in the appropriate software, from which the indicator values and spectrograms were obtained [31].

b) Subjective evaluation tools - Methodology of CRESSON

5. Citizens' questionnaires: the questions were related to the study area and the suggestion of cultural soundmarks and landmarks with psychoacoustic characteristics (nice, comfortable, indifferent, etc.) [32].
6. Primary soundwalk - assessment of the quality of the soundscape: During the soundwalk, the researcher listened to understand, collect information and record data. In parallel, objective evaluation tools were used [33].
7. Semi-structured interview: The data collected during the soundwalks were classified. One minute samples of the recordings were selected by the researcher. These were given to a sample of five people relevant to the city and sound science. The questions were about the recognisability of the points and elements heard in the soundscape, the acoustic comfort, the personal feeling of the interviewee. The procedure was repeated for all 13 points, for both recordings (morning and afternoon) [34].

Proceedings

4. THE STUDY AREA

Ermoupolis is a city that counts exactly two centuries. It is associated with the most important historical events in Greece. Its case remains unique: its financial, cultural and social life became a model for other cities [35]. Today, social and religious divisions and conflicts have been eliminated. The cosmopolitan style of European Ermoupolis and the great financial contrasts no longer exist to the extent they once did. In recent years, Ermoupolis has witnessed major changes in the use of space. This was caused by the historical financial meltdown of Greece until 1950, the collapse of industry and the rapid development of tourism in the second half of the 20th century. The abandoned industrial area with the shells of old industrial buildings considers a 'necropolis'.

The rapid development of tourism in the second half of the 20th century had an impact on the landscape and the soundscape. The lack of parking spaces for cars, the increase in the number of two-wheeled vehicles, the additional demand for water and electricity during the summer months, the touristisation of some areas and, of course, noise pollution, are some of the observations recorded during the survey of the city.

4.1 The soundscape of another time

Literature research on Ermoupolis has attempted to give a sense of the soundscape of the past. From its foundation until the middle of the 20th century, the city was divided into two halves: economically, socially and culturally. The east side was the wealthy area, with great mansions on the sea. On the west side was the shipbuilding and repair zone, the main shipyard and its associated outbuildings; the workers' area. The western side of the city was also the marginal side. The middle class was gathered in neighborhoods such as Vrondado and Psariana, in the middle of the city. The ruling class of Ermoupolis had imposed the Europeanisation of the city, with obvious influences on many aspects of social and artistic life. It's not a surprise that the daily life of the west side is deliberately concealed in 19th century literature, for reasons of external projection [36].

The Asia Minor affair in 1922, a huge number of refugees has settled in the western part of the city, bringing their own culture. The cultural divide in the port bipole expanded: on the eastern side, European plays and operettas could be heard in the Apollo Theatre, the philharmonic orchestras in the square and european music in the ballrooms. On the west side were the traditional dances and songs of Asia Minor, Turkey, Peloponnese and Thrace, the mocking carnival songs, the zebekia. [37]. The new industrial face of the city maintained a good economic level for many years. After the Second World War, the cosmopolitan style faded down. Ermoupolis gradually took on the characteristics of a Greek provincial city [38].

4.2 The soundscape of today

Ermoupolis opens up through its cultural life and its musical history: from the philharmonic orchestra, which is still active today, to the rebetiko music school. During the summer months in particular, prestigious international festivals, cultural events and happenings are organised all over the island to promote artistic education and quality of life.

The intense rhythms of the city are concentrated around Miaouli Square, where the Town Hall is located, a hub of the city. Tourist traffic throughout the year, especially in the summer months, the constant movement of boats, taxis, buses, cars and motorbikes in the port, especially from May to November, the tourist marina with its boats, the constant white noise of the Neorio, the sound of the sea and the wind, complete the soundscape of today.

5. SURVEY RESULTS-DISCUSSION

The quantitative survey carried out in the study area led to the following results Ermoupolis is an urban area with rural elements: the main problem was traffic noise, which masks or resonates with other sounds. This did not happen everywhere, but on the main roads. On the coastal road, for

example, where traffic was continuous, the noise had a constant intensity and monotony. In urban areas, motorcycles were a major source of periodic noise. The main causes were: a) the modification of motorcycles to deliberately create noise, b) the high speed at which they traveled, c) the marble surface of the roads, which causes reverberation. The first two are against the Urban Noise Directive. From the qualitative survey, the following results were certain: in certain locations noise masked sounds that the listener would expect to hear them, such as the sound of the sea, the Neorio, idioms, etc. Cultural sounds such as bells, music, the Divine Liturgy were recognisable, authentic and created a sense of acoustic comfort. Some noisy sounds, such as the boat and the Neorio, created to the interviewees a sense of security because these sounds were associated with economic prosperity and connection with the surrounding islands and the country's major ports. Soundscapes such as Miaouli Square evoked memories of personal experiences. The intimacy of the human element in the neighbourhood's soundscape evoked feelings of calm and elation, but also feelings of indifference as they projected an abandoned area devoid of vitality. Certain qualities and atmospheres, such as the liveliness of the square, the commercial activity in the market, the Orthodox and Catholic masses, the old man singing in the neighbourhood, etc., were perceived by the majority of interviewees as very comfortable and pleasant. Noise from motorcycles on main roads was perceived as annoying. The tourist soundscape in September was not classified as noisy (not too many tourists) because the sounds were integrated into the daily flow of the city. The absence of some old cultural sounds (extinct sound phenomenon) was unpleasant, especially when they were replaced by other modern sounds. In some other places there was the sound masking phenomenon. For example, the white noise of the Neorio covered the sound of the sea at the recording location.

6. PROPOSAL: OPEN-SPACE SOUND MUSEUM OF ERMOUPOLIS

The Open-space Sound Museum of Ermoupolis is aimed at the inhabitants of the city, students and pupils, visitors and tourists, inviting them to get to know the city through an experiential walk and to create memories. The accessibility of the soundwalks allows everyone (the disabled, the elderly, the visually impaired, mothers with prams, etc.) to participate at their own pace.

The museum allows visitors to get to know Ermoupolis by suggesting listening points through an easy-to-use application that is easily installed free of charge on a smart device (Wi-Fi will be freely offered at the selected points).

The proposed path will be displayed on an interactive map (Figure 2), with twenty key points. Each point will give the opportunity for experiential participation and interactive presentation of the history of the site. The listener can follow the sequence of points or navigate freely through the city, recognising and discovering the points of interest. The aim is to revive the historical representation of Ermoupolis' soundscapes and, of course, the promotion of current sounds and cultural qualities of the city.

The museum will operate in time zones during the day. The visitor will be able to choose to walk in one of the proposed zones or in all of them, as he will receive different sound stimuli.

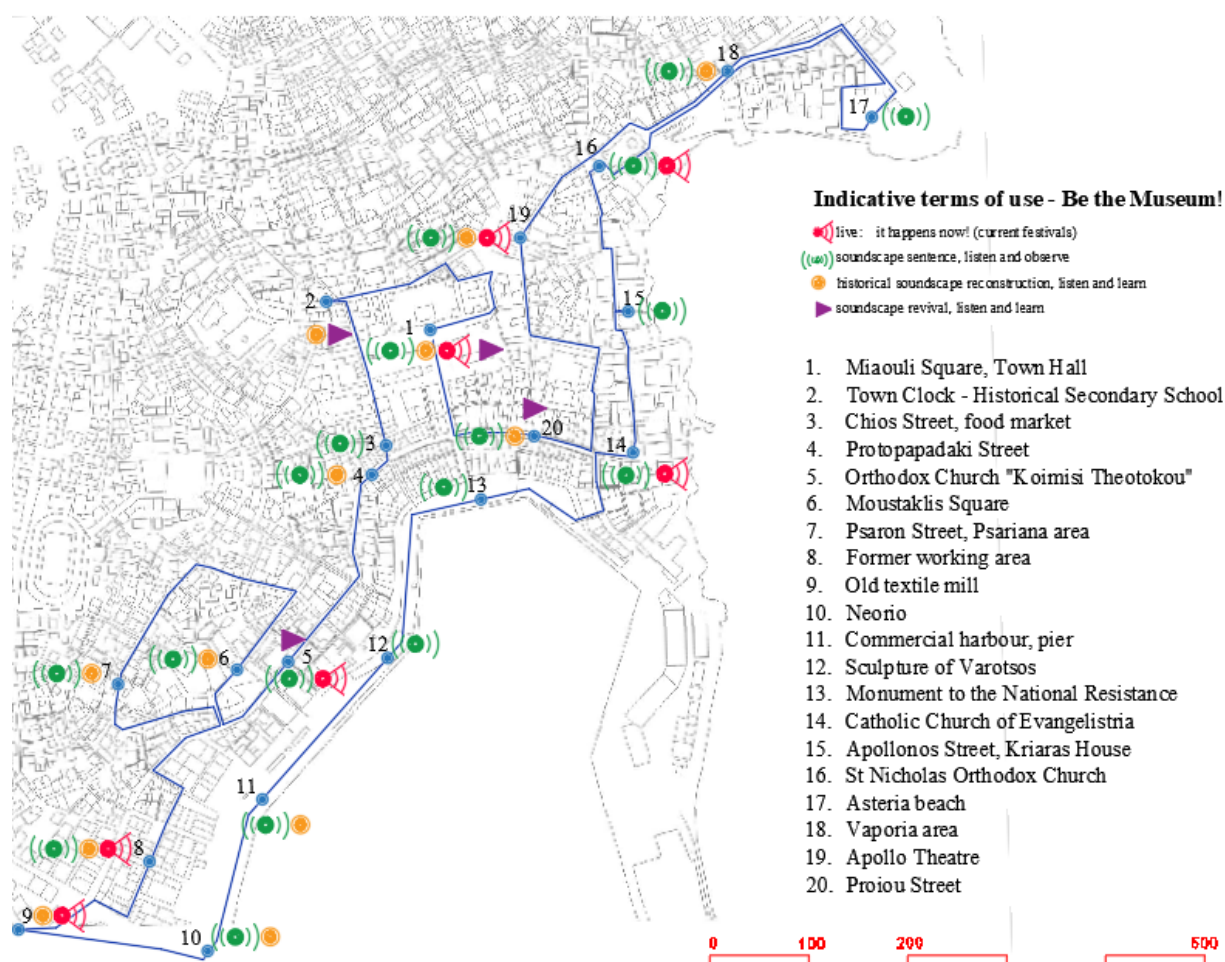

Figure 2. Interactive Application Map

The interactive map shows the points of interest of Ermoupolis as dots, each represented by a different symbol and colour with an explanatory key. Touching the dot opens a new digital window with information about the reference point, the area and the museum's digital facilities. The dots will be numbered from 1 to 20 (this may change during implementation). There will also be QR codes on landmarks around the city that, when scanned with a smartphone, will link to the museum app. Listening stations with speakers or headphones and a seat will be installed at locations where 'historic' soundscapes will be recreated. The listener will be able to sit and listen.

The museum has co-benefits for the city and the environment. The open-space sound museum starts a dialogue with the public space and reconnects the neighbourhood and the citizens. It educates citizens, tourists, children on the culture of the city and also on environmental pollution. It also preserves cultural heritage through the soundscape.

The museum has no costs or expenses for printing, as digital tools are used. The soundwalk is pedestrian (zero ecological footprint). The specificity of the object challenges the traveller to experience the place in a season with sunshine, less wind, normal temperatures, such as spring and autumn. In this way, the tourist season for the island is extended.

7. CONCLUSION

The study captured and recorded the sound identity of the city. The results of the whole study contributed to the proposal of solutions and measures against noise pollution in the city. The recording and assessment of noise assisted in understanding the problematic areas.

The recording of important soundmarks and the possibility of revival and reconstruction proposed by the Open-space Sound Museum, links the soundscape to the cultural heritage of Ermoupolis. The actions of the Open-space Sound Museum add value and quality to cultural tourism, always with a view to authenticity, knowledge, entertainment and the safety of the visitor. The experiential walk allows the visitor to learn, evaluate and reflect on issues of environmental awareness.

The main objective of the project is to redefine humans and their philosophy towards the environment and their activities. The historical past is projected through the soundwalk as it is contained in the sounds and images of today. The soundwalk becomes a historical sonic anatomy that feels the history of the place in the qualities that the soundscape conveys. The perception of these qualities is the attractiveness of the Open-space Sound Museum in the city.

However, Ermoupolis is a living city. The study of Ermoupolis revealed the need to upgrade its neighbourhoods to a new sustainable urban form. The local community should take care of the quality of life of its residents and visitors at the level of the neighbourhood, the street, the sign, the citizen.

The creation of an Open-space Sound Museum in the city of Ermoupolis is part of the sustainable planning of the city: it improves the overall sound environment, revitalises the neighbourhood and promotes the intangible cultural elements of the city. This also makes the city more attractive. The Open-space Sound Museum acts as a research and educational tool, improving the sound environment and raising awareness of noise pollution. Once piloted in Ermoupolis, the ultimate goal is to extend the project to other cities or settlements in Greece and replicability value.

The Open-space Sound Museum is a sustainable proposal that can be implemented in many cultural areas in Greece and the Mediterranean, as it can be transformed to meet the needs of each city and its civil society. The Open-space Sound Museum can become a repository of the city's memory and at the same time a shaper of its contemporary identity.

Abstract

The major scope of this paper is the investigation of pocket parks and their special characteristics and design parameters. Pocket parks are a type of small-scale urban green spaces and their size is determined by the availability of land rather than by fixed standards. This makes them a unique solution to the urgent need to increase urban greenery in cities with scarce space for larger green areas. Despite their limited size, this type of park contributes to the sustainable development of urban areas and consist a solution for the requirements of the UN's 17 Sustainable Development Goals (SDGs) for sustainable cities.

The paper focuses on examining in detail the characteristics of pocket parks; these design parameters that make small green spaces able to attribute the benefits of urban greening of a larger scale. It identifies the spatial, social and environmental design parameters and presents the typology of small green spaces according to their characteristics. This research and listing of parameters assist in understanding the important elements of a small park. Well-known and representative examples of pocket parks, among the first of their kind and some of the most recent, from the Greek and international urban space, are studied in order to identify the above parameters and compare their characteristics. Emphasis is placed on comparing the results in terms of spatial characteristics, in order to highlight the minor importance of area and size in this type of urban green.

The paper presents an attempt to parameterize a small-scale urban green. The aim is to confirm the assertion of the definition for the adaptability of the pocket park in any vacant urban space through the recording of the parameters and, in the continuation of this research, through the development of a method that combines the data and examines the relationship of all the necessary characteristics in order to create a dynamic form of a successful pocket park.

Keywords: *Pocket park, small green spaces, urban green spaces, design parameters, pocket parks' characteristics.*

1. INTRODUCTION

Urban parks are mostly implemented as large green infrastructure projects exclusively for recreational activities and economies. Currently, 54% of the world's population resides in large cities and is expected to increase to 68% by 2050. [1] The World Health Organization considers that the minimum ratio of green space in cities per inhabitant should not be less than 9 m²/inhabitant, when in the Attica it is 2.5 m²/inhabitant, in Athens 0.96 m²/inhabitant and in Thessaloniki 2.14 m²/inhabitant [2] In almost all big cities in Greece, there are far fewer green spaces than necessary. At the same time, the availability of large urban gaps for urban green space development is insufficient in densely populated cities, in contrast to the small gaps that are spread throughout the urban fabric. Small green spaces, such as pocket parks, by definition can be developed in these small urban vacant lands.

The subject of this research is the pocket park as a type of urban green space that could be developed in any potential urban gaps. It is known by the terms pocket park, mini-park or vesty park, which is a type of small-scale urban green space. Through the study and analysis of the pocket park are identified the characteristics of pocket parks, particularly the spatial, social and environmental design parameters. Then it attempts to create a possible typology of parks in order to record the elements

Proceedings

that make its park function. Finally, through the analysis and comparison of typical examples of small-scale parks, the spaces are evaluated, and their individual characteristics are compared in order to assure their contribution to the city and its sustainable development independently of its size.

2. INCREASING GREEN INFRASTRUCTURE IN A DENSE URBAN AREA

The concept of sustainable development formed at the end of the 20th century, which essentially connected the environment with various social and economic issues. Sustainability or sustainable development is a tool for criticizing various development options and it is based on a long-term planning policy. The new plan, called *Transforming our world: The 2030 Agenda for Sustainable Development*, included a declaration of 17 sustainable development goals and 169 sub-goals. Among the goals, the 11th is about making cities and human settlements inclusive, safe, resilient and sustainable, and it is defined specifically in sub-goal 11.7 the imposition to provide universal access to safe, inclusive and accessible, green and public spaces, in particular for women and children, older people and people with disabilities by 2030.[4] Urban greening is essential for the creation of a sustainable urban environment. Urban open spaces and green areas have a significant impact on the quality of the urban environment, the quality of life of its inhabitants and its contribution significantly to improving the city image. Their positive impact is undeniable in environmental, economic and social terms. They contribute to improving air quality, cooling and ventilating cities, connecting with the natural environment, providing places for recreation, relaxation, meeting and communication, safety, while at the same time they create an attractive environment, stimulating entrepreneurship and increasing land values.

However, public green spaces are scarce and any effort to create green interventions in cities, such as small parks or green islands, is limited to a few small areas, so its development is now essential to change the local ecosystem and improve the living conditions of citizens, visitors and people passing through these areas. In view of the above, there is a need to increase the amount of green space in the city, and therefore to find ways of securing spaces within the urban fabric and exploiting potential gaps in each neighborhood. Courtyards, pocket parks, parklands, semi-open spaces and pedestrian walkways are familiar urban forms that can be transformed into essential urban green spaces to fill the gap in the original design and create a green network.

In line with the UN goals and granted the existence of densely populated megacities with lack of urban green spaces or generally organized green infrastructure networks, the case of pocket parks is examined as very small urban green spaces that can be developed and adapted in any available urban space in the city and in any neighborhood.

3. DESIGN PARAMETRES OF POCKET PARKS

Pocket parks are very small urban green spaces, whose main characteristics are their size, location, functions and users, and finally their ecological impact on the urban area. The design parameters are divided into three categories: spatial, social and environmental.[based on 5,6,7]

The spatial parameters include all the choices regarding the design impact of the park, the plot with its size and boundaries, its location and the type of neighborhood it addresses, the possibility of visibility and multiple entrances, the openness and clear separation from the sidewalk, the surface and surfacing materials, the seating area, and the choice of the main use, the central element. A pocket park with natural elements, protected from urban noise and equipped with "flexible" seating can promote a positive social perception of these dormant micro-spaces and their function as social meeting places.[8] In addition, accessibility and visibility from the street are critical. The need for fencing, visibility and seating means that people's ability to relax in a space is directly related to their sense of control and security.[9] These specific characteristics regarding the final spatial dimension

of the park can be considered as practical guidelines for the design of functional and successful pocket parks.

<i>Spatial characteristics</i>	<i>Size</i>	<i>1-3 plots in area Their dimensions tend to be proportional to the concept in which they are designed.</i>
	<i>Location</i>	<i>Located within the city Usually within blocks, between buildings, or at the end of streets. They are directly visible from at least one side. Serve a population of about 500-1000 people and an area within a radius of about 400 meters from all dwellings in the service area (10 minutes walk).</i>
	<i>Type of town/neighborhood</i>	<i>Urban shopping centers Mixed-use residential neighborhoods Residential neighborhoods</i>
	<i>Entrances /Accessibility</i>	<i>Accessible from 1 to 4 sides by road Safe access for everyone</i>
	<i>Openness</i>	<i>Degree of openness/closure Number of party walls from underlying buildings Open sides Natural/artificial fencing</i>
	<i>Surfaces and Covering Materials</i>	<i>Vegetation (greenery, trees, vines) Surfacing material Walls of adjacent buildings Shading</i>
	<i>Urban equipment</i>	<i>May include urban furniture (benches, trash cans, lighting) Fixed and mobile chairs and tables</i>
	<i>Focal point</i>	<i>Fountain, pavilion, amphitheater, Main function for the park</i>

Table 1: Spatial characteristics of the pocket park. (table created by authors)

The social parameters include the users, the functions of the park and its benefits for the community. These parameters are determined by the context of the pocket park's integration environment, by its development area. The activities hosted depend on the characteristics of the common area and the needs of its potential users, which also determine its objectives. A pocket park can be located in a business district, a community center or a residential area. It can be designed to provide relaxation, but it can also be configured for community gatherings, events, or educational programs. They can serve as a playground for children, a gathering place for friends, a place to eat, a courtyard in dense suburban areas, or a garden for the community. In addition, these activities can be expanded to include urban agriculture, education, lectures, community kitchens, film screenings, readings, etc.[10] The users and their diversity affect the park's potential and determine the park's amenities and design to accommodate their age, social, and cultural differences. Equipment is selected based on the needs of the most frequent visitors or residents of the area, such as seniors and children in a typical neighborhood or workers in an office district. Therefore, the type of area affects the use of the park, with different social groups visiting the site at different times of the day.[11] Benefits and objectives may include physical fitness, social adjustment, psychological rehabilitation, mental and moral improvement, restoration of attention and neighborhood enhancement; neighborhood involvement in the park design process is encouraged to keep the park clean and safe.

<i>Social characteristics</i>	<i>Functions and Activities</i>	<i>Relaxation _Sitting benches for standing Gathering _Spaces for social interaction Events, education, Sports _open green space Play _Playground Community garden _urban agriculture Public art and literacy opportunities</i>
	<i>Users</i>	<i>Neighborhood residents Citizens of all ages, genders, etc. Welcoming and attractive design for a variety of users</i>
	<i>Benefits or objectives</i>	<i>Located in public or private space- targeted always to the public Enhance the concept of neighborhood Offer the possibility of isolation Psychological rehabilitation Restoration of attention (art) Improve physical fitness Social integration</i>

Table 2: Social characteristics of the pocket park. (table created by authors)

The last category of parameters concerns the environment. Size or shape is not as important a criterion for creating a successful park as the amount of green space available. Small urban parks, such as pocket parks, must be designed to provide the necessary conditions for environmental restoration, all these specific elements of the natural environment to be restored: greenery, grass, soil, flowering plants, shrubs, trees, water, and a size that allows all of these elements and potential users to coexist. [12] Solar access and shading are critical factors influencing the use of a public space, and the creation of spaces in-between contributes to the quality of the user experience. Utilizing solar access and providing natural or artificial shade are important elements of park design, that with appropriate management of lighting and ventilation affect visitor comfort. The orientation of the park is also important for greenery and visitor comfort.[13] Also, the park environment can be designed with environmentally friendly features, including the use of greenery, emphasis on high-efficiency lighting, or the use of solar energy.[14] These design choices contribute to the improvement of the microclimate and the quality of the environment, promoting the comfort and safety of visitors. Furthermore, the creation of a network of green spaces in the city contributes to the preservation of biodiversity and environmental sustainability, while their interconnection with each other and with other facilities and infrastructures improves the social and territorial cohesion of the city. Finally, the connection between public space and other areas of daily use allows the creation of alternative mobility, such as the creation of pedestrian and as links between parks, thus enhancing the social and economic vitality of the area.

<i>Environmental characteristics</i>	<i>Sustainable strategies</i>	<i>Solar access– Shading_ Maximizing natural shading areas Ventilation Acoustic absorption Optical isolation from the street Orientation Trees and Green</i>
	<i>Environmental Design</i>	<i>Lighting_ sufficient lighting at night Environmentally friendly materials_ Permeable surfaces High-efficiency lighting, use of solar energy</i>

Proceedings

<i>Connecting Green</i>	<i>Creating the green infrastructure network. (ecological routes, habitat networks, riparian zones) Attracting insects and birds. Concentration of plant species</i>
<i>Location and Connection</i>	<i>Explore empty spaces in densely populated areas Provides pathways that lead somewhere Encourages pedestrian movement Connects to the transportation network Connects to near recreational, cultural and community facilities</i>

Table 3: Environmental characteristics of the pocket park. (table created by the authors)

3.1. TYPOLOGY

Pocket parks due to their specific characteristics are difficult to be standardized. Their physical parameters, size, shape of the plot, location vary as do the neighborhoods, their users and the surroundings in which they are created. What they have in common is that they offer to the inhabitants of the neighborhoods a refuge from the rhythms of the city and a 'mean of connection' with nature. They offer different possibilities and functions (passive recreation parks, playgrounds, community gardens, urban orchards, vegetable gardens, outdoor art spaces, gathering places). The following types of pocket parks can therefore be identified on the basis of the function-activity parameter. [based on 15,16]

The limited space that characterizes a pocket park means that a combination of these design elements must be used to make it attractive to many different users.

Open space is one of the most flexible design elements and can support both active and passive recreational activities. Depending on the demographics of a community, playgrounds can be an important feature of a pocket park. They provide opportunities for families to get outside and give children a place to focus their energy and exercise. Community gardens are now recognized as an international phenomenon, and urban gardening is widely seen as a way to improve the local food supply as well as a recreational activity. No precise definition of community gardens has been ascribed, as this would impose arbitrary limits on creative community responses and their local needs. [17] Urban squares or green courtyards can be integrated into a pocket park as a passive recreation area. As a stand-alone design concept, the urban plaza park was popular in large, highly developed urban areas and was promoted as a refuge from the hustle and bustle of the city. Primarily a rest area with tables and seating, an urban plaza may include some aspects of the natural landscape such as trees, flowering plants, vines, or water features.

<i>Functions</i>	<i>Benefits</i>	<i>Park elements</i>	<i>Users</i>

3.2. Funding, Management and Maintenance

Ownership includes responsibility for funding and maintenance. It is not a design parameter, but influences the parameters of the above categories. Depending on the ownership status, sites can be categorized as private public spaces, community-owned, municipal-owned, and public-private partnerships. In private public spaces, a private investor owns and maintains the public space without burdening the municipality and limiting municipal control over the space. Typically, such a space has gates and limited hours of operation. In community spaces, residents organize themselves and apply for permits and initial funding to acquire land, fences, gates, benches, and plants, and take responsibility for operation and maintenance. In municipality spaces, the government owns the site and it is fully responsible for funding and maintenance. This allows for more hours of public access, but limits the local community's sense of ownership and level of participation in the care of the site. In the public-private partnership, the private sector (or a fundraising partner) does not own the space, but raises funds or donates money in cash, materials, or civic equipment in exchange for displaying their logos on the space. This reduces the financial burden on the government while highlighting the social responsibility of the private sector. [based on 18,19]

3.3. Case studies

The pocket park is not a new idea. It was a product of the reconstruction of Europe after World War II. They were created as a way for war-ravaged communities to rebuild public spaces despite shortages of labour and raw materials. Pocket parks could be built inexpensively and relatively quickly in any residential area.

Pocket park in Central Harlem, New York, United States (1965)

The first pocket park is located in Harlem, New York. It is an abandoned urban vacant lot between two buildings that used to belong to the church. On the initiative of the Religious Society of the Community Church of Christ in Harlem and the Park Association., the first pocket park was created in the elongated urban vacant lot with only one open side, shaped like a jacket pocket, on West 128th Street, in Harlem. Located between two existing buildings in the central core of the city, the park is a narrow, linear space. Its walls are covered with ivy, and the space is shaded by several species of native trees.[20]

The term pocket parks was first used in 1960 in New York City to describe green spaces similar to those described above, with a maximum area of one hectare. The idea of pocket parks was adopted by the government and the private sector in the United States as a tool to deal with the urban and social crisis that developed in the 1960s. The need for small open spaces and urban greening has since been addressed with pocket parks, which provide a unique opportunity for "green" breathing space in urban areas. New York City has an abundance of pocket parks, both old and new.

John F. Collins Park, Philadelphia, United States (1979)

One of the most famous is that of John F. Collins Park located in downtown Philadelphia. The park was constructed in 1979 and it is designed by landscape architect John Francis Collins, from whom

Proceedings

the park takes its current name. The park occupies an area of 360 sq.m. The park's longest side is approximately 37 m. It is defined by ivy-covered walls and the whole is shaded by a variety of native trees. In the center of the park is a waterfall fountain constructed of vertical cast concrete pedestals with shallow steps that provide access to the fountain's thin layer of water. Two decorative iron gates recall the private ownership of the public space. The concrete pavers used throughout the park differ from the more traditional red brick pavers of the surrounding neighborhood. One of the park's most unique features is its furnishings, which include movable chairs and tables. In 2011, the park was renovated and reopened to the public as John F. Collins Park.

Floating Pocket Park, Paddington, United Kingdom (2017)

The Floating Pocket Park at Paddington Basin, on the Grand Union Canal is the first of its kind. It is a 730 sq.m. floating park in the heart of Merchant Square.

The floating park is built on two decked platforms connected to the ground at two points and there is also a separate small pontoon designed to encourage wildlife such as birds and ducks to settle.[21] These paved platforms are made of recycled materials and provide greenery to attract birds and insects, as well as recreation space for the users of the area. In particular, on the first platform there is artificial turf and large elongated beds with low plants (different types of plants, shrubs, herbs, aromatic plants, etc.) and small trees. The beds are elevated, forming a boundary with the canal surface, and removable deckchairs are placed onto the turf. The second area consists of hardscape floor, with four beds of herbaceous plants as central decorative elements. It consists of a modern pavilion bar, a canopy for visitors and it is formed a special area for public and private events with a capacity of 120 guests. In addition, free Wi-Fi in the floating park encourages remote working. Both areas are open to the public all year round. The most important element of the park is the greenery that has been developed to encourage wildlife and the park includes a separate float designed to attract ground-nesting birds.

The specific feature of this pocket park and the reason it has been chosen for the research is its very construction as a floating park. Although an open space and in a densely populated area, it is located away from vehicular traffic, which contributes to the acoustic comfort of the users, the element of water which dominates contributes significantly to the cooling of the park, and in combination with the vegetation contribute to the thermal and visual visitors' comfort created by the whole configuration of the space.

Navarinou Park, Athens, Greece (2009)

The self-managed Navarinou Park is a park in the center of Athens. There was a clinic in the area as early as 1907, which was closed, sold and demolished in 1972. For many years, the land was leased as a parking lot, until the end of 2008. Faced with the threat of the construction of an office building, the residents initiated an event in March 2009 and occupied the site, demanding the transformation of the land into a high green space. The residents took immediate action, breaking up the asphalt, bringing in trucks of dirt, planting trees and flowers, and transforming the parking lot into a park. The park, which has been continuously redesigned, formed into five functional zones: a main gathering area (around a plane tree), a peripheral area with ornamental plants and improvised seating, an activity zone with an amphitheater and a stage for events, a playground, and the park's orchard, which is planted with olive and citrus trees, as well as fruit and vegetables. Although the site was completely paved as parking lot, then the asphalt reduced only on the main driveway and the rest of the ground is made up of soil, gravel and in places mosaic. [22] At the end of 2018, it was decided to convert the entire park into a playground in order to front a series of problems related to both the degradation of the surrounding area and the lack of policing.

The Butterfly Garden, Pocket Garden in Kipseli, Greece (2020)

The Municipality of Athens is trying to achieve the regeneration and maintenance of spaces that have been abandoned for years, and the creation and use of more public spaces. In 2020, a regeneration

program begins with the creation of pocket parks on vacant lots in the Municipality of Athens. Through the "Adopt Your City" program, each potential plot will be assigned to a private company to cover the costs of rehabilitation and maintenance of the park during the initial period of adaptation, while the needs of the plants increase and the visits of the crews become more regular. The agreements vary from case to case, but generally the sponsors adopt the green space for one year. After that, the municipal green services take over. The first park was created in Kipseli. It is a flower garden with various representative species. The individual beds are bordered by a low evergreen fence and the planting of climbing and flowering shrubs transforms one side into a vertical green garden. In addition, the park has special signs next to each plant with useful information about its identity, as well as structures for the nests of useful insects. Thousands of plant species contribute to the creation of an ecosystem that benefits the neighborhood. Its uniqueness lies in this diversity of species and in the environmental benefits resulting from the rehabilitation of a plot of such a limited area.

3.4. Detecting Parameter in Constructed Parks

Pocket parks, as already mentioned, do not have specific characteristics or a precisely defined size. They can have different shapes, areas, uses, users, and even materials and site compositions. A comparison of the study examples may reveal similarities between them.

Table 5: Comparison of case studies. (table created by authors)

Comparing the four examples, two from the Greek reality and two from foreign countries, one of the first created in their cities and the other the most recent, we can distinguish their basic characteristics and their adaptability to the features of the site and the character of each area.

Spatial characteristics of a park

Size - location: all four parks occupy a plot of land. In the case of the floating park, the plot was created by occupying the surface of the river rather than an existing one.

Openness - Entrances/Accessibility: The entrances to the parks are different. John F. Collins Park has visibility from both narrow sides in terms of buildings and plantings or additional elements, has two entrances that are controlled because of the private status of the land, a metal gate with adequate visibility into the park. Navarinou Park has three free sides as a plot and with free visibility from most of the sides due to tall trees and low shrubs. The other two parks have a specific passageway for entrance, the flower beds, although surrounding them, are low enough for full visibility to the park and from inside to the street.

Floating Pocket Park,
Paddington, Un.
Kingdom

The Butterfly Garden, Kipseli,
Greece

Figures 5,6,7,8: Area maps of the four parks. Source: google maps

City/neighborhood type: In the first example at John F. Collins Park, the park is in a commercial area, the butterfly garden is in a pure residential neighborhood, and the other two are in mixed-use neighborhoods.

Surfaces and Cover Materials: The materials used do not vary from park to park, hardscape material on pathways or throughout, sections of land with large trees or additional low planting beds as in the floating park.

Urban Equipment- Focal point: The main element of urban furnishing is the seating benches, even the smallest park, the one of the butterfly garden, has two benches. All four examples have a focal point, a central element, this is either a tree central flowerbed in the butterfly garden or the meeting point around the banana tree like in the Navarinou park and the bar with the canopy in the floating park.

Social characteristics: Every park serves the users of its area, either they are the employees of the Collins Park commercial centre area or the resident one of Kipseli. They provide a place to rest and relax, as in the case of Navarinou Park, or they offer more functions, such as a playground and events, as in Paddington Park.

Environmental characteristics: The common feature of all the parks is the greenery. The shade and coolness that the park features provide improve the microclimate. The main factor of this benefit is the choice of species and their placement. Then the collection of many plant species to maintain biodiversity and attract birds and insects, or the selection of plant species for each season as in the floating park. And also the effort for connection with the surrounding green areas, the creation of green routes at the neighborhood level to achieve a green network connection are the most important environmental impacts of the above parks. In terms of environmental features, it is essential to be mentioned the recycled (Paddington Park floats) or reusable materials (Navarinou Park) or even the solar park lights used by the Athens Municipality's 'Adopt your city' program.

4. CONCLUSION

In conclusion, through the study and the comparison of examples, we see that their size vary and it is not as important as the other design parameters. They adapt to each type of plot and each type of neighborhood and the better the adaptation and the inclusion of area users, the more successful is the park. They adapt and respond to the range of needs of urban areas whether they are dense commercial city centers or dense mixed-use or even pure residential neighborhoods. It explores the most appropriate design of activities that are relevant to the surrounding population and funding programs to realize the potential of each context even if it concerns as self-management. Their most recommended and common location is near frequent pedestrian traffic, for visibility and for attracting users. Perhaps for the Greek reality, and specifically the Athenian landscape, their common location is any vacant corner plot of land left over in the dense urban fabric. Of course every neighborhood needs a green corner and by this argument no location could fail. However, the other aspects change depending on the context; particularly the desired activities and the design, and the most appropriate funding and maintenance program.

The four study cases reflect the adaptability and transformational potential of the pocket park, with the most important being: 1-The provision of public spaces in dense and high-value environments such as downtown commercial areas (John F. Collins Park, Philadelphia) 2-The reconciliation of the capitalist interest in profit and the need for green space for recreation and socialization in culturally diverse communities (Floating Pocket Park, Paddington) 3-The attraction of biodiversity in

residential neighborhoods (Butterfly Garden, Floating Pocket Park, Paddington) and 4-The community engagement and participatory planning (Navarinou Park, Exarchia)

In this type of project, urban planning is an afterthought design, as the choice of areas to be regenerated does not depend on a plan or large-scale program. These are interventions that come to correct the original design. The pocket park is a product of urban 'interior design' for the benefit of society, a platform, a real social network where people can meet and communicate.[23] Pocket parks are easy to create, as mentioned, as they occupy little space, are low costs projects and satisfy the needs of the local population. They are chosen to be located near notable sites or landmarks, on busy roads or not, and of course in places where there may be easy access. Even the most tiny park benefits its area environmentally. Studying the area and involving social groups and volunteers in the action can further enhance the social benefits and the economic ones as their maintenance depends on them, an important link in order the park never decline and be deserted. But why is it important to study, aggregate features and compare pocket parks? According to William H. Whyte through research, observation of public spaces and questionnaires to users to identify the elements and features that make some public spaces more used than others, it was observed that planting, seating, permeability, flows, focal points, sun access and shade provision were more important than the size of the park or its shape. Although his research concerned New York City squares and small parks, the users' side visitability criteria highlight the importance of the rest of the spatial characteristics of an urban green space. Therefore, the identification of these parameters theoretically through documentation and practically applied through the observation of widely known parks, leads to the need for a standard that ensures these elements without limiting the design freedom required for a neighborhood park of limited size. This standard could be derived through the method of parameterizing pocket park characteristics, and since the biggest issue of this type of greenery is size and specifically the area availability - urban gaps - parameterizing spatial characteristics, independently of the size, it is necessary in order to assure the creation of successful pocket parks. Through parameterization a family of results is obtained rather than a single standardization result. Thus, computational morphological searches do not invalidate human imagination, but instead extend its possible limitations. Parametric logic, in this case, is concerned with the design of spatial elements based on the description of the relationships between them, particularly geometrical relationship. In this sense it allows the redefinition of the final result, by changing one or more components of the object. [24] It is not about defined shapes but about correlations and interconnections of points, lines, surfaces and forces. Therefore, the parameterization of these values will bring about a set of results that ensures the realization of successful spatially pocket parks, excluding from the limitations the size and, in this case, the limited area that it is available by the potential urban voids of densely populated cities.

BIM applications in design quality following project delivery

O. Venetsianou

Department of Interior Architecture, University of West Attica, Athens, Greece

Corresponding author: E-mail: ovenets@uniwa.gr Tel +306938166811

Extended abstract

Building information modeling in Architecture is known as a digital tool that ensures quality in the construction process as it facilitates accurate design, project coordination and cost control. BIM is used in all parts of a project life cycle, starting from the initial concept to building maintenance and facility management. This paper explores possible BIM applications in controlling or enhancing building quality during the building operation phase. Following the project delivery, a series of networked sensors monitor the building's performance and alert in case of maintenance needs. Would it be possible to use this monitoring infrastructure to gather information regarding building use and compare it with design intention, thus creating a type of feedback for the architect? How could this information be organized and become useful in moderating existing designs? Could this type of data be stored and be useful in future projects? What are the best data dissemination strategies? The aim of this study is to propose a conceptual framework for the use of BIM for monitoring user satisfaction following the project delivery stage. The study will cover three phases: First, an extensive literature review regarding design quality measuring strategies. Secondly, the study will explore applications of the BIM-based Digital twin in order to record building use and possible issues regarding user expectations via on-site testing, suggesting a possible link between the BIM collaborative design environment (CDE) and collaborative decision-making processes. Finally, this study will explore BIM applications in design visualization and design option simulations focusing on the degree by which these methods improve decision-making capabilities on issues regarding form and aesthetics. BIM applications in monitoring architectural design quality indicators and collaborative design decision-making processes will be explored through selected case studies.

Keywords: BIM ; architectural design quality; design quality indicators; collaborative design; open data

The value of architecture

It is asserted that architectural design interventions enhance the retail value of property, promote local economies, and contribute to sustainable development. However, most architects have limited feedback on the outcome of their design. There is a lack of robust evidence on the value of good design and an evident need for definitions, frameworks and demonstration methods. Design awards are generally accepted as an assessing method in architecture. However, award systems are based on peer review decisions, often with a lack of transparency, and rarely provide an opportunity to engage users. Such award schemes are concerned with the architectural quality of the building, so they aim at rewarding "prestige" and "headline" designs, without paying as much attention to function and built quality.

In an attempt to raise public awareness on the value of Architecture and the importance of good design, the Architect's Council of Europe published a study on 2020 [1], aiming at addressing a communication challenge and the need to explain the worth of architects' work in terms that make sense to decision makers, such as financing institutions and the general public. The report demonstrates evidence and facts that would supplement the compelling visuals and storytelling that architects are good at already and assist professionals in proving the value of their work. The profession has been weakened by a common misconception that architectural work is driven mainly by aesthetics. This report aimed at finding suitable tools to document and evaluate the different types of value created by good design. Post Occupancy Evaluation was highlighted as a key tool for

architects and clients to support the quality of projects and identify good practices, as well as economic, environmental, social, and cultural value. POE serves as a valuable resource for architects looking to enhance their understanding of how design decisions translate into real-world performance and user satisfaction. The ability to demonstrate value with data is crucial for winning projects. The importance of measuring design value has increased with outcomes-based procurement that focuses on the value that a building delivers rather than just its form.

Architectural Design Quality and Post Occupancy Evaluation Indicators

The need for systematic methods to evaluate and assess the quality of architectural and urban design led to the concept of Design Quality Indicators. DQIs gained prominence in the latter half of the 20th century as architects, planners, and researchers sought to develop frameworks for evaluating design quality. It could be asserted that a culture of performance measurement was initiated following the publication of *Rethinking Construction* [2] in the UK. Assessing architectural design quality often requires collaboration between architects, engineers, environmental scientists, sociologists, psychologists, and other stakeholders. One key aspect of the DQI should focus on the design intent for the building [3]. In Gann et al (2003), the proposed DQI tool assesses design quality against this intent, reflecting individual respondents' personal and/or professional views. A DQI typically consists of a conceptual framework, a data-gathering tool, and a weighting mechanism, which work together to provide a comprehensive assessment of design quality. The weighing mechanism is essential, as each stakeholder has different priorities regarding the building value. It is essential that DQIs capture diverse perspectives and considerations and account for the cultural, social, historical, and contextual factors that influence architectural design.

The DQI serves as a mediator between customers, end-users, designers, and producers. The process structures questions about the design and provides easily accessible information to design teams. There are subjective and objective DQIs: Subjective design quality indicators are aspects of design quality that are based on personal opinions, experiences, and preferences rather than objective, quantifiable measures. These indicators reflect the views of individuals and groups involved in the design process or using the building. Some examples include user satisfaction and experience, emotional response, perceived value, cultural relevance and contextual fit. Objective design quality indicators are measurable and quantifiable aspects of design quality that can be assessed using specific criteria or standards. These indicators are based on tangible attributes of the design that can be observed, analysed, and compared systematically, such as functional performance, technical performance (structural integrity and compliance with building codes), energy efficiency, material quality and cost-effectiveness.

Advancements in data analytics and computational design have facilitated the development of data-driven DQIs that leverage quantitative data from various sources such as building performance simulations, sensor networks, and user feedback to inform design evaluations. DQIs related to issues such as usability, accessibility, comfort, and user satisfaction are reflecting a shift towards more user-centric design approaches. Finally, due to the increasing concerns over climate change and environmental degradation, DQIs related to sustainability and resilience have gained prominence. This includes indicators for energy efficiency, renewable energy integration and carbon footprint reduction. Following project delivery, DQIs increasingly incorporate life cycle assessment (LCA) methodologies to evaluate the environmental impact of buildings throughout their entire life cycle, including materials sourcing, construction, operation, and demolition. Some of the most commonly used platforms and certificates are LEED and BREEAM. The WELL Building Standard focuses on improving the health and well-being of building occupants, while Passive House (Passivhaus) is a performance-based standard for energy-efficient building design. It must be stressed however that the value of a building design is a multi-factor concept and a fixation with indicator measurements may result in boring and unattractive buildings.

Proceedings

Post Occupancy Evaluation (POE) in architecture involves assessing the performance of buildings after they have been occupied to understand how well they meet the intended design goals and user needs. The assessment of design quality based on the model by Vitruvius; *functionality* (utilitas), the arrangement, quality and interrelationship of spaces, *build quality* (firmitas), the engineering performance of the building, which includes structural stability and the integration, safety and robustness of the building's systems and fittings, and *impact* (venustas), the building's ability to create a sense of place and have a positive effect on the local community and environment [3]. However, understanding the value of buildings is a big challenge, as different types of building users have different priorities and perceptions of good design. Facilities managers, clients, occupants, owners, visitors, maintenance staff, have varying perspectives on the same facility. The less tangible the aspect to be measured, the harder it is to describe numerically. More often than not, users cannot express their preferences due to lack of technical knowledge and vocabulary [3]. However, the more demanding customers are in their requirements, the better the design outcome [4].

POE involves collecting data, feedback, and insights from building occupants, stakeholders, and other relevant parties [5]. There are three levels of POEs, depending on accuracy, time needed to be performed, tools and levels of invasiveness of user privacy. These are *indicative POEs* which are non-invasive analyses with interviews and photographic surveys, *investigative POEs* which include questionnaires, video recordings and measurements and *diagnostic POEs* which utilise sensor networks in order to monitor and optimise building performance [6]. Apart from evaluating building performance, POE provides valuable insights and feedback that can inform future design decisions [7]. By understanding how occupants use and interact with the building, architects and designers can make informed decisions to optimize building design, operation, and management practices in future projects. Thus, POE promotes a culture of continuous improvement in architectural design and practice. There are several organizations, platforms, and tools that facilitate POE processes and provide resources for evaluating building performance and occupant satisfaction, such as the Building Research Establishment (BRE), US Green Building Council (the organization behind LEED) as well as other toolkits, online platforms and tools. The RIBA Report "Building Knowledge: Pathways to Post Occupancy Evaluation" is a resource that offers guidance on conducting Post Occupancy Evaluation (POE) in the context of architecture and design [8]. This report, developed by the Royal Institute of British Architects (RIBA), provides pathways and frameworks for architects and practitioners to effectively evaluate the success of their design projects. Thus, by emphasizing the importance of evaluating buildings in actual use, a more evidence-based approach to design is promoted, focusing on the long-term impact and value of architectural interventions.

BIM

BIM applications play a significant role in enhancing architectural design quality both during the design phase, as well as following the project delivery. BIM is a digital representation of physical and functional characteristics of buildings. These digital representations are often used to support decision-making throughout the building lifecycle, from initial planning and design to construction, operation, and maintenance. Thus, BIM supports the collaborative design, construction, and management of building and infrastructure projects.

During the design phase, BIM is used as a strong design visualization tool. Highly detailed 3D models of buildings, enable stakeholders to visualize the design in a realistic manner before construction begins. This helps in identifying design flaws and making necessary modifications to improve overall quality. Architects assess design quality by visualizing aspects such as spatial layout, circulation patterns, daylighting, and views within the building model. Additionally, clash detection tools help identify conflicts between various building systems (mechanical, electrical, plumbing), thus ensuring coordination and avoiding modifications during construction. The accuracy of the study results in significant cost reductions. BIM software also includes features for cost estimation and quantity

Proceedings

takeoff resulting in accurate material quantities and better cost control. Finally, BIM applications assist architects in ensuring regulatory compliance by integrating building codes and regulations into the building models. By generating accurate documentation drawings and reports for building permits, architects can verify compliance early in the design process, minimizing the risk of costly revisions and delays at later stages of the project.

Simulations and analyses within the BIM environment help architects identify opportunities for improving design quality and meeting performance goals. By analyzing factors such as building orientation, materials, and HVAC systems, architects can optimize the design to enhance energy efficiency, thermal comfort, and daylight penetration. Simulations may also be used in various scenarios and analyses in order to evaluate the impact of design changes, operational strategies, and retrofit interventions on building performance and occupant satisfaction. By simulating different scenarios, such as adjusting HVAC systems, implementing different lighting strategies, or redesigning workspace layouts, stakeholders can assess the potential benefits and trade-offs of different strategies before implementing them in the physical environment. This was evident in the BIM Speed competition (2022), where building professionals and students were invited to demonstrate a housing renovation project, using the purpose-built BIM-SPEED platform for collaboration, in a way that allows energy saving for the occupants, improves their comfort while reducing the time and the cost of the overall process. The competition was organised by the BIM-SPEED project, funded by Horizon2020 [9].

Collaboration tools within BIM software enable real-time communication and coordination among architects, engineers, contractors, and clients, improving overall project quality through enhanced teamwork and information exchange. The Common Data Environment (CDE) is a centralized platform for sharing and accessing project information. It is a repository where all project information, data and documentation are stored in an accurate and updated manner. Information is shared, managed, and accessed by all project stakeholders throughout the lifecycle of a construction project. The CDE provides collaboration tools for commenting, markup, issue tracking, and workflow management. DQI tools integrated into BIM platforms enable real-time collaboration and feedback, allowing architects to gather input from clients, consultants, and other project stakeholders to evaluate and enhance design quality. Collaborative design review sessions may be organized, where stakeholders can assess design quality collectively. Thus, stakeholders can resolve issues promptly, and ensure that design quality indicators are effectively integrated into the project workflow [10].

BIM applications support iterative design processes where architects can explore multiple design alternatives and evaluate their impact on design quality. DQI tools help architects compare different design options based on predefined quality criteria, enabling them to optimize design solutions to achieve desired outcomes. By analyzing data such as building performance metrics, material quantities, and cost estimates, architects can make informed decisions to improve design quality and project outcomes.

Digital Twin applications in Post Occupancy Evaluation

The integration of POEs in BIM provides a single source of storage of POE and building data. However BIM models present limitations during the integration with different data sources and systems, mainly the lack of automatic updating. Therefore, the concept of the Digital Twin emerged. In the context of buildings, a digital twin is a virtual representation of building or physical infrastructure asset. It includes not only the geometric aspects of the building but also real-time data from sensors, IoT devices, and other sources placed in the physical building. Thus, a dynamic and accurate digital replica of the physical asset is created. The digital twin continuously synchronizes with its physical counterpart, allowing for real-time monitoring, analysis, and simulation of building performance and behaviour.

A digital twin is composed of a series of elements. These are [6]:

1. a physical asset, its virtual counterpart and data connecting them
2. a visualisation platform
3. an acquisition layer, such as an IoT system (i.e. a system of monitoring sensors)
4. a BIM model, which consists of the relevant geometry
5. AI tools for data analysis
6. synchronization between the physical and the virtual component

A digital twin can continuously collect and analyze data on energy consumption, indoor environmental quality parameters such as temperature, humidity, air quality, and lighting, occupancy patterns, equipment operation, and maintenance activities. By comparing this real-time data with design specifications and performance targets, stakeholders can assess how well the building is performing in practice and identify possible areas for improvement. For instance, occupancy values are standardized during the design stage, as they are based on building regulations (i.e. fire regulations or energy models). Actual occupancy and space use may vary significantly in reality [6]. All building systems and components, such as HVAC, lighting, thermal insulation, and building envelope are thus evaluated. The real-time data regarding building use and performance can be compared with the design intention, i.e. the architectural and engineering specifications, performance targets and user requirements established during the design phase. By analyzing the data in relation to the design intent, stakeholders can identify discrepancies, deviations, or areas where the building is not performing as intended.

Occupant feedback and satisfaction could also be captured by building monitoring sensors. For instance, by tracking occupancy patterns over time, building operators can gain insights into space utilization, occupancy densities, and peak usage hours. Additionally, occupancy sensors can be equipped with additional features such as motion detection or infrared sensors to capture occupant movements and interactions within spaces [6]. User feedback systems, such as interactive touchscreens, mobile applications, or web-based platforms, allow occupants to provide real-time feedback on their satisfaction levels. This feedback can be collected through surveys, rating scales, or open-ended comments and can be integrated with building monitoring systems to provide a comprehensive view of occupant satisfaction and preferences. Wearable devices, such as smartwatches or fitness trackers equipped with environmental sensors, can collect data on occupant physiology (such as heart rate, skin temperature, and activity levels) in real-time [11]. By correlating physiological data with environmental conditions, building operators can assess the impact of indoor environmental quality on occupant health and well-being.

This feedback can provide valuable information and insights into how well the building is meeting the needs and expectations of its users, allowing architects to identify areas for improvement and optimization. By continuously monitoring building performance and comparing it with the design intention, architects and designers can iteratively improve their design practices and inform future projects. This feedback loop enables a more data-driven approach to design decision-making, leading to better-designed buildings that more effectively meet the needs of their users and perform optimally over time. Additionally, digital twins can leverage historical performance data and machine learning algorithms to predict future building performance and anticipate potential issues. By analyzing patterns and trends in data, stakeholders can forecast energy usage, equipment failures, occupant comfort levels, and other key indicators, allowing proactive measures to be taken to optimize building operations and maintenance.

POE using Digital Twins

It is possible to create an occupancy-oriented digital twin for facility management by providing real-time data on occupancy patterns and space utilization within buildings. Sensors play a crucial role in

Proceedings

the occupancy monitoring process. These could be IoT, camera-based sensors and PIR sensors. They are used to monitor occupancy levels, detect entries and exits from different rooms, and optimize maintenance activities based on occupancy data. By collecting data on occupancy, sensors enable the digital twin to accurately represent the physical building and its usage patterns, allowing for better space management, organization, and maintenance. The calibration and efficient operation of sensor systems are essential to ensure the accuracy and efficiency of the digital twin in reflecting the real-world occupancy dynamics.

The case study presented in Seghezzi, E. et al (2021) focuses on an existing office building at Politecnico di Milano, Italy, which houses the Department of Architecture, Built Environment, and Construction Engineering (DABC). The building is used by university staff for research and administrative activities, and the maintenance and cleanliness of the spaces are crucial aspects of facility management. The IoT sensor network installed in the building consists of camera-based sensors with embedded deep learning algorithms. The sensors are integrated with an online platform, which allows for data visualization, storage, and download.

The findings of the case study highlight the importance of preliminary analyses, supported by Building Information Modeling (BIM), to optimize the planning and installation of the IoT sensor system. The BIM model and the series of simulations that were possible to be made helped identify critical areas for monitoring, determine the number and placement of sensors, and reduce implementation costs. The study emphasizes the significance of data quality, system efficiency, and accurate monitoring of occupancy for effective facility management.

Dissemination Practices

Research and innovation should be encouraged in architectural practices. By developing research strategies, collaborating with universities, and disseminating findings, architects can enhance their services, build relationships with clients, and stay competitive in the industry. Collaboration between universities, practice, and industry is essential to demonstrate the value of design, and there is a need to develop the research and POE skills of practitioners and students. Current practice in building design usually results in feedback from users not being communicated in a form that can lead to design improvements. Information arrives either too late or not in a usable format [3].

The dissemination of Post Occupancy Evaluation (POE) results can vary depending on the objectives of the evaluation, the stakeholders involved, and the context of the project. One of the most common ways to disseminate POE results is through a comprehensive report or documentation that summarizes the evaluation process, methodology, findings, and recommendations. This report may include qualitative and quantitative data, analysis of key performance indicators, and insights into occupant satisfaction, building performance, and design effectiveness. These findings could be presented in workshops, and seminars conducted for project stakeholders, including architects, designers, building owners, facility managers, and occupants. These presentations provide an opportunity to share findings, discuss implications, and engage stakeholders in a dialogue about potential improvements and next steps.

Findings may also be disseminated through academic publications, journals, and conference proceedings, particularly for research-focused evaluations, as well as online platforms, websites, and digital repositories dedicated to building performance evaluation and research. However, most architects do not often read academic journals, so it is important to disseminate findings in an appropriate and usable format [2]. Professional organizations and associations in the fields of architecture, engineering, and construction may communicate POE results through newsletters and other media. The disseminated material can be integrated into educational and training programs for architects, designers, and building professionals.

Conclusion

Proceedings

Architectural quality assessment is really about defining the goals of a project and documenting its success in achieving them. The DQI documents the variety of physical, aspirational and emotional needs of a building's occupants and serves as a valuable tool for initiating discussions about design priorities, possibilities, and consequences. While it does not provide an absolute measure of design quality (there are subjective and objective indicators of quality), it helps articulate the subjective qualities perceived by different stakeholders involved in the design process and building use. Although a fixation with indicator measurements may result in boring and unattractive buildings, the attempt to document design value helps practitioners learn more about it. Value is thus created from feedback. Economic, environmental, functional, health, social and cultural value is documented and thus communicated.

By incorporating asset management data into a BIM model, architects can create a digital twin of the building that provides valuable information for ongoing operations, maintenance, and renovations, ensuring long-term quality and efficiency. It is evident that advanced digital technologies such as BIM and digital twins in buildings play a crucial role in achieving high design quality and sustainability standards in contemporary architectural projects. However the quality of the data involved is important, as it could lead to inaccurate results. POE is a time consuming and costly process, that should be supported by national policy, by establishing guidelines, setting objectives, facilitating collaborative processes and promoting a culture that values design excellence. POE data is valuable for all stakeholders in the construction industry, so incorporating POE findings into curriculum and training materials that are disseminated helps educate future practitioners about the importance of evaluating building performance and occupant satisfaction.

Abstract

The study focuses on the investigation of aspects of sustainable tourism in cultural heritage environments. Culture heritage sites not only are historical environments but have specific importance in terms of characteristics and cultural value. Issues of sustainability in historical places are examined in two different sites, the medieval castle of Rhodes and the park of Rodini, which is considered one of the first designed parks in history. The two cases are linked by a central axis which is one of the main entrances to the castle, a path with special importance especially during the tourist season. Parameters of sustainability which will be examined at a later stage of the project are now identified and a relation between the two cases is attempted.

Keywords: *sustainable tourism, sustainable development, heritage sites, Rhodes*

1. Introduction

In a world increasingly threatened by the climate and environmental crisis the word "sustainability" and "sustainable management" of places and environments, buildings and monuments of exceptional importance, is of particular concern to tourism and the alternative activities that are currently being developed to transform and enrich the travel experience. Rhodes is an island with a long history of remarkable tourism development, with a rich historical and cultural heritage and unsurpassed natural beauty. The methodology of the research consists of literature review on issues of sustainable tourism in historic environments and the investigation of specific parameters in two case study areas in the island of Rhodes. This study explores two cases of sustainable tourism that focus on the visitor-tourist's perception and interaction with the man-made cultural and natural resources of the city of Rhodes.

The first case explores the implementation of sustainable tourism practices in UNESCO World Heritage Sites, with reference to the Medieval City of Rhodes. As one of the most important historical and cultural landmarks, the Medieval City faces the challenge of balancing the economic benefits derived from tourism with the imperative of preserving its unique heritage. The research delves into key aspects of sustainable tourism management, including conservation and preservation efforts, community involvement, cultural awareness and education, infrastructure development, crisis management and collaborative partnerships. Through a comprehensive analysis of strategies implemented in Rhodes, this study aims to contribute knowledge and lessons to the broader discourse on sustainable tourism at UNESCO World Heritage Sites.

The second case concerns the reconstruction of an ecological park in the city of Rhodes with the aim of creating a sustainable and ecologically sensitive natural environment in the field of educational tourism. The ecological park will function as a place for alternative voluntary biophilic activities and will combine recreation and education, allowing visitors of all ages, but especially children, to discover the fauna and flora of the island and gain important knowledge and experience about sustainable development. The study proposes to manage and redesign the park so that it can serve as

Proceedings

a platform for environmental education and awareness-raising for the protection and conservation of the natural environment, thus enhancing the ecological awareness of the younger generations through activities related to water, waste, endemic plants and animals and indigenous local seeds.

2. The City Tourist of the 21st Century Identity, Cultural and Sustainability

Historic European cities, such as city of Rhodes, constitute a complex, open and extremely interesting field for the development of alternative experimental models of experiential urban tourism. The present paper focuses on the possibility to search for the particular idiosyncrasy of the city and the charm of its discovery by means of specialized, custom-tailored offerings in tourist targeting. The possibility to develop and offer choices beyond mass facsimiles, in the form of a customized navigation through the urban landscape and historic time.

In an age of flux, mobility, and perpetual acceleration, but also of widespread standardization in consumer products and services, as is notably the case in the sector of mass tourism, there is ample room for identifying and employing a multitude of different types of approaches to the characteristic idiosyncrasy of a city on the part of its casual visitor.

Urban sites offer today's traveller an equally fascinating field for exploration, new experiences and knowledge. Even during the brief time of their visit, today's visitors of modern historic cities of the 21st century, in this particular case of Rhodes, inadvertently come across the complex nature of the city. The limited time they have at their disposal is an insurmountable obstacle in effectively "reading" the palimpsest of the living city. Thus, their perception of the city is largely based on *viewing*, more specifically, on hastily and haphazardly viewing the city, instead of *living* it, on mass-consuming a plethora of images instead of coming into contact with the substance and the spirit of the place. In this way, modern-day visitors tend to obtain a fleeting, voyeuristic spatial impression of the city, due to the inevitable inability to manage and interconnect the abundance of visual fragments and information they collect [1].

Modern-day mass tourism is characterized, in the overwhelming majority of cases, by programs that are pre-scheduled to even the smallest of detail. The predetermined duration of travel, coupled with information obtained in advance from travel ads, brochures and websites, make for a rigid schedule largely based on being ensnared by the alluring appeal of images rather than on making informed choices or venturing into random exploration. Visitors experience a place through its visual representation and position themselves in this image. Thus, any special feature of a place is neutralized and defused as standardized exoticism and the visitor is converted into a collector of images and impressions [2].

"The uniqueness of any city lies in the specific arrangement, form and function of its spaces and the intersection between these spaces and individual and collective experience. In other words, it is in the idiosyncratic coincidences of time, space and culture that individual urban identities are forged and the rhythms of city life created" [3]. The territorial reality of the city is not exclusively defined by the constructs and form of its built environment. The city is not like its map; quite the contrary – the city is characterized by a stratification of architectural material, collective memory and history.

Authenticity and Identity as multi-faceted concepts have long held a central position in tourism studies. Since the 1970s, it has been argued that escaping from the pressures of society in order to search for more "authentic" experiences is a primary driver in tourist motivation. Modern theories on seeking escapism, authenticity and identity point to each of these concepts as critical in understanding dimensions of tourism and leisure experiences.

3. Case study analysis: a) Implementation of sustainable tourism practices in the Medieval City of Rhodes

The present Medieval city of Rhodes contains elements from the Byzantine, Ottoman and Chivalric periods and this makes it a city of great interest for the preservation of its monuments through time. In 1988 the Medieval City of Rhodes was included in the list of UNESCO World Heritage Sites, a title it retains to this day [4]. The aim of the 20-year Programmatic Agreement (1985-2005) was to undertake action for the preservation, protection and promotion of the monuments of the Medieval City and to take rescue measures in dilapidated monuments, buildings and archaeological sites. Unfortunately, the lack of long-term planning in line with sustainability standards has contributed to the abandonment of residential use and the transformation of the area into a one-dimensional tourist zone, with many problems. The present local inhabitants are much fewer in number due to the tourist growth that the island suffered in the 70's, who systematically converted their residences either into leisure centers, guesthouses or shops of all kinds.

The Medieval City is a living historic city where urban planning and preservation should be addressed considering the pressure of tourism on the inhabitants and the preservation of the city's multi-layered character. The aim is a sustainable and modern city that uses its cultural heritage as a driving force (Figure 1). A list of parameters that appear to be mostly significant are briefly analyzed in order to have a better understanding on the critical aspects that need to be addressed on a historical settlement sustainable analysis. The implementation of sustainable tourism practices in UNESCO World Heritage Sites, such as the Medieval City of Rhodes, involves a multi-faceted approach involving various aspects of conservation, community engagement, visitor management and economic development.

Conservation and preservation:

Strict regulations and guidelines are enforced to preserve the architectural integrity and historical significance of the Medieval Town. Restoration and conservation efforts are undertaken to ensure the long-term preservation of historic buildings, monuments and infrastructure.

Sustainable building practices are encouraged to minimize the environmental impact of construction and renovation projects [5].

Community Involvement:

Local communities are actively involved in decision-making processes related to tourism management through participatory approaches. Economic opportunities are created for residents through the promotion of local businesses, cultural events and handicrafts. Programs are implemented to raise awareness among local people about the importance of preserving their cultural heritage and the benefits of sustainable tourism [6].

Visitors' management:

Sustainable visitor management strategies are implemented to avoid overcrowding and minimize the impact of tourism on the area. Visitor education initiatives are implemented to promote responsible tourism behaviors, such as respect for historical structures and cultural patterns. Tourism flows are monitored and regulated to ensure a positive experience while maintaining the authenticity of the site.

Cultural awareness and education:

Educational programs and guided tours are offered to visitors to enhance their understanding of the historical and cultural significance of the Medieval City. Interpretive signage and multimedia resources are used to provide context and information about the heritage of the site. Cultural events and festivals are organized to celebrate and highlight the rich cultural heritage of the Medieval City.

Infrastructure development:

Sustainable infrastructure projects are undertaken to improve accessibility, transport and amenities for visitors while minimizing environmental impacts. Pedestrian-friendly zones and alternative transport options are promoted to reduce congestion and pollution within the site. Green building practices are incorporated into new construction projects to minimize energy consumption and carbon

Proceedings

emissions. Environmentally friendly materials are used and energy is conserved through the use of passive systems for heating, cooling and lighting [7].

Crisis management and risk mitigation:

Comprehensive crisis management plans are developed to address potential threats such as natural disasters, vandalism or political instability. Regular risk assessments are carried out to identify and mitigate potential risks to the cultural and natural heritage of the area.

Cooperative partnerships:

Collaboration with local and international organizations, government agencies and stakeholders is promoted to implement sustainable tourism initiatives. Sharing knowledge and best practices with other UNESCO World Heritage Sites contributes to continuous improvement and innovation in sustainable tourism management. Through the implementation of these sustainable tourism practices, the Medieval City of Rhodes aims to balance the economic benefits of tourism with the preservation of its cultural heritage, ensuring the long-term sustainability and resilience of the place in the face of evolving global challenges [8].

Figure 15: Sustainable tourism aspects forming a multi-faceted approach (source: authors)

The actions for the restoration of the monumental ensemble were also enriched in 1985 by the Medieval Town Office with the aim of constructing new networks, restoring road surfaces, maintaining-restoring medieval fortifications, shaping archaeological sites and maintaining-restoring public and private properties. The whole project aimed at transforming the old town into an intellectual Centre of national and global renown. A major objective remains the upgrading of the old town as a place of residence, which is proving to be a key issue in regeneration projects and is difficult to address successfully. In 2012, a new urban planning plan for the Medieval Town of Rhodes was approved with the aim of improving living conditions and protecting its monumental character. Over a period of 20 years, the urban character of the Medieval Town will be improved by dividing it into areas with different uses. The new plan reinforces all sectors and neighborhoods on equal terms by

Proceedings

allocating green spaces, playgrounds, sports facilities and a community Centre in each of them. It also maintains the limited traffic that prevails in the Medieval City with minor changes to avoid noise and exhaust within the walls. In 2011, regulations were implemented to promote the principles of sustainable mobility. It is necessary to improve the quality of life with the appropriate infrastructure and configurations so that permanent residents stay and new ones come [9].

Restoration actions have a social and economic character in addition to the preservation of the monuments. That is, they aim to restore the neighborhoods of the Medieval Town, increase its population and develop tourism. To achieve this, they do not comply with or infringe the institutional framework for the conservation of monuments. To date, monuments are not included in the urban planning regulations and are not treated as part of the fabric of the Medieval City. For this reason, the development of the historic center must be based firstly on the redevelopment and promotion of its monumental wealth, then on their integration with other uses and finally on a soft approach to tourism. It is essential that restoration efforts create a site of cultural interest as a place to be visited, but also to be in line with modern scientific concepts and theoretical approaches to monument conservation. Sustainable residential development seeks to ensure quality of life, safeguard ecological resources and preserve and enhance architectural capital for present and future generations [10].

The Medieval City has very good accessibility by public transport, as the main bus station is a few minutes' walk away. Also, due to its central location, it is directly connected to the port and the new town. Efforts are currently being made to make this connection with electric vehicles as the construction of cycle paths and pedestrian walkways are in the immediate plans but are progressing slowly. Regarding car use, since the 1970s measures have been taken to restrict car access to the historic center of Rhodes, although parking is allowed by residents. There are controlled entrances for vehicles and the use of electric cars is encouraged. In Rhodes during the summer, the demand for parking is high due to tourism. Only 2,000 parking spaces are offered when demand peaks in summer at 4,000 spaces. This has led to the arbitrary use of every available free parking space. The municipality tries to enforce regulations and impose fines, but illegal parking remains one of the main problems in the area. In winter, the situation is very different, as the demand for parking is significantly lower. It is therefore necessary to think of alternative solutions such as design parking areas further away and serve citizens and tourists with electric vehicles. The medieval city of Rhodes can thus remain connected to the modern city, while keeping its identity intact, mainly for its inhabitants, but also for the tourist community.

With a quick glance at the spaces of the Medieval Town we can list many abandoned green spaces. These spaces can be redesigned and reused by citizens and tourists alike, adding a special character by creating sports areas, playgrounds, and green zones.

As far as education is concerned, the Municipality of Rhodes has expanded its cooperation with the University of the Aegean in the field of tourism, with the common goal of enriching and upgrading tourism education. The University of the Aegean with its academic staff, has the ability to contribute to the local community and its economy, approaching scientifically the issues that concern it. The priority as set by the Municipality of Rhodes and the Directorate of Tourism, is that education is a need for the stakeholders, creating training and certification programs for tourism professions and professionals in many different sectors of tourism. Through the educational process, the adoption of a "socially responsible" attitude towards the development and management of sustainable tourism is achieved through attitudes, projects and practices.

Finally, regarding to tourism businesses, it emphasizes the adoption of standards, environmental management practices and environmental education programs for their staff, as well as the promotion of local products in businesses, while for tourists it proposes seminars on local traditions and the environment.

Figure 16. The Medieval castle of Rhodes from above and an interior street view

b) Ecological park in Rhodes. Educational activities for children regarding sustainable development.

Ecological parks serve as vital hubs for environmental education and sustainable development initiatives, offering immersive experiences for visitors to engage with nature. In Rhodes, Greece, the establishment of an ecological park presents an opportunity to foster environmental stewardship among children through tailored educational activities focusing on water conservation, waste management, and plant and seed management [11]. The significance of ecological parks is analyzed in promoting sustainable development and explores Greek and international case studies to derive best practices for educational programming [12]. Ecological parks play a pivotal role in biodiversity conservation, ecosystem restoration, and environmental education. They serve as living laboratories where visitors can learn about the interconnectedness of ecological systems and human activities. By providing immersive experiences in natural settings, ecological parks foster a sense of appreciation and responsibility towards the environment.

Each of these activities is designed to be interactive, engaging, and age-appropriate, catering to children of varying ages and learning styles. By combining hands-on experiences with informative discussions and guided exploration, these activities aim to instill a sense of environmental stewardship and empower children to take positive actions towards sustainability in their daily lives and communities.

In terms of **sustainability practices – parameters** taken into account these parks are focusing on the following issues:

a. **Water Conservation:** Interactive workshops and demonstrations can educate children about the importance of water conservation, highlighting the finite nature of freshwater resources and the significance of responsible water usage. Activities may include water audits, rainwater harvesting simulations, and discussions on water-saving techniques [13]. More specifically, in a Water Audit Workshop children can participate in a hands-on workshop where they learn to conduct water audits to identify sources of water wastage and opportunities for conservation in their homes and communities [14]. In a Rainwater Harvesting Demonstration they can observe a demonstration of rainwater harvesting systems installed within the park, learning about the importance of capturing and utilizing rainwater for irrigation and other non-potable uses [15]. Also in a Water-saving Techniques Discussion, through interactive discussions and role-playing exercises, kids can explore practical water-saving techniques such as turning off taps while brushing teeth, fixing leaky faucets, and using water-efficient appliances [16].

b. **Waste Management:** Hands-on activities such as waste sorting games, composting demonstrations, and upcycling workshops can raise awareness about the importance of waste reduction and recycling. Children can learn about the environmental impacts of improper waste disposal and explore

innovative solutions for waste management [17]. Explicitly, a Waste Sorting Game will push children to engage in a fun and educational game where they learn to sort different types of waste into recycling, compost, and landfill categories, emphasizing the importance of proper waste segregation [18]. In a Composting Workshop every child can participate in a hands-on composting workshop where they all can learn how to compost organic waste materials such as food scraps and yard trimmings to create nutrient-rich soil for gardening. As well, in an Upcycling Craft Session kids will unleash their creativity by repurposing discarded materials into new and useful items through upcycling craft sessions, promoting the concept of waste reduction and resource conservation.

c. **Plant and Seed Management:** Gardening activities provide opportunities for children to learn about plant life cycles, biodiversity conservation, and sustainable agriculture practices. Through planting sessions, seed saving workshops, and guided tours of botanical gardens, children can develop practical skills and ecological knowledge related to plant and seed management [19]. In a Planting Session, children could get their hands dirty as they participate in planting sessions to establish native plants and trees within the ecological park, learning about the importance of biodiversity conservation and habitat restoration. Likewise, in a Seed Saving Workshop, they would learn about the lifecycle of plants and the significance of seed saving for preserving genetic diversity and promoting food security through interactive workshops and demonstrations. One other idea is a Botanical Garden Tour. Other actions may include tours in Botanical Gardens. Guided tours of the park's botanical garden provide children with opportunities to explore diverse plant species, observe pollinators in action, and gain insights into sustainable gardening practices such as companion planting and natural pest control methods [20].

d. **Green Infrastructure:** Integrating green infrastructure elements, such as rain gardens, permeable pavements, and green roofs, into the design of the ecological park can demonstrate sustainable stormwater management techniques and enhance biodiversity. Interpretive signage and guided tours can educate visitors about the ecological benefits of green infrastructure and inspire replication in urban settings [21].

e. **Renewable Energy:** Implementing renewable energy technologies, such as solar panels and wind turbines, within the ecological park can showcase clean energy solutions and reduce reliance on fossil fuels. Educational displays and interactive exhibits can illustrate the principles of renewable energy generation and encourage visitors to adopt energy-saving practices in their daily lives [22].

As opposed to **social implementation** strategies following interventions are included:

a. **Collaboration with Schools:** Partnering with local schools can enhance the reach and impact of educational activities within the ecological park. By integrating environmental education into school curricula and organizing field trips to the park, children can reinforce their learning experiences and apply knowledge gained in a real-world context [23].

b. **Community Engagement Events:** Hosting community engagement events such as eco-fairs, tree planting initiatives, and clean-up campaigns can mobilize local residents and foster a sense of ownership and pride in the ecological park. These events provide opportunities for hands-on participation and promote community cohesion around shared environmental goals [24].

c. **Multi-stakeholder Partnerships:** Collaborating with government agencies, non-profit organizations, businesses, and academia can leverage diverse expertise and resources to support the ecological park's educational initiatives. By fostering multi-stakeholder partnerships, the park can access funding opportunities, technical assistance, and knowledge exchange platforms to enhance program effectiveness and sustainability [25].

In terms of significant facilities and **amenities** a Café and a playground within the park can offer valuable insights. Incorporating an ecological cafe and playground within the park adds valuable dimensions to the overall experience, providing opportunities for sustainability education and eco-friendly leisure activities:

The Ecological café can offer:

- a. Sustainable Menu: The ecological cafe offers a menu featuring locally sourced, organic, and seasonal ingredients to minimize carbon footprint and support local farmers and producers. Emphasis is placed on plant-based options to promote sustainable food choices and reduce the environmental impact of meat production [26] [27].
- b. Zero Waste Practices: The cafe implements zero-waste practices such as composting food waste, using biodegradable packaging and utensils, and offering incentives for customers to bring their own reusable containers and cups [28].
- c. Educational Workshops: The cafe hosts educational workshops on topics such as sustainable agriculture, food waste reduction, and ethical sourcing practices, providing visitors with opportunities to learn about the environmental and social impacts of food production and consumption [29].

The Ecological Playground can offer:

- a. Natural Materials: The ecological playground is constructed using natural and sustainable materials such as untreated wood, recycled rubber, and natural fibers, creating a safe and eco-friendly play environment for children.
- b. Biodiversity Features: The playground incorporates biodiversity features such as native plantings, butterfly gardens, and birdhouses to encourage wildlife habitat and ecological diversity within the park.
- c. Educational Play Elements: Interactive play elements within the playground, such as water play areas with recirculating systems, sensory gardens, and nature-inspired climbing structures, provide opportunities for children to learn about ecological concepts while having fun [30].

By integrating an ecological cafe and playground into the park, visitors are not only provided with amenities for relaxation and recreation but also opportunities for hands-on learning and engagement with sustainable practices. These features enhance the park's appeal as a destination for families and reinforce its role as a center for environmental education and community empowerment.

Finally, Monitoring and Evaluation can play an important role in the implementation of the project and future interventions for improvement:

- a. Impact Assessment: Regular monitoring and evaluation of educational activities are essential to assess their effectiveness in achieving desired learning outcomes and behavior change among children. Surveys, interviews, and observation methods can be employed to measure changes in knowledge, attitudes, and behaviors related to sustainable development themes.
- b. Feedback Mechanisms: Establishing feedback mechanisms, such as suggestion boxes, online surveys, and focus group discussions, allows participants to provide input on the quality and relevance of educational programs. Incorporating feedback from children, parents, educators, and other stakeholders enables continuous improvement and adaptation of educational content and delivery methods [31].
- c. Long-term Tracking: Tracking the long-term impact of educational interventions on children's environmental attitudes and behaviors can provide valuable insights into the effectiveness of the ecological park's sustainability education efforts. Longitudinal studies and alumni surveys can track participants' continued engagement in environmental stewardship activities beyond their initial experiences at the park [32].

The analysis of the significant design parameters for creating a successful ecological park as identified in this research can be summarized in the following diagram emphasizing in the most significant thematic.

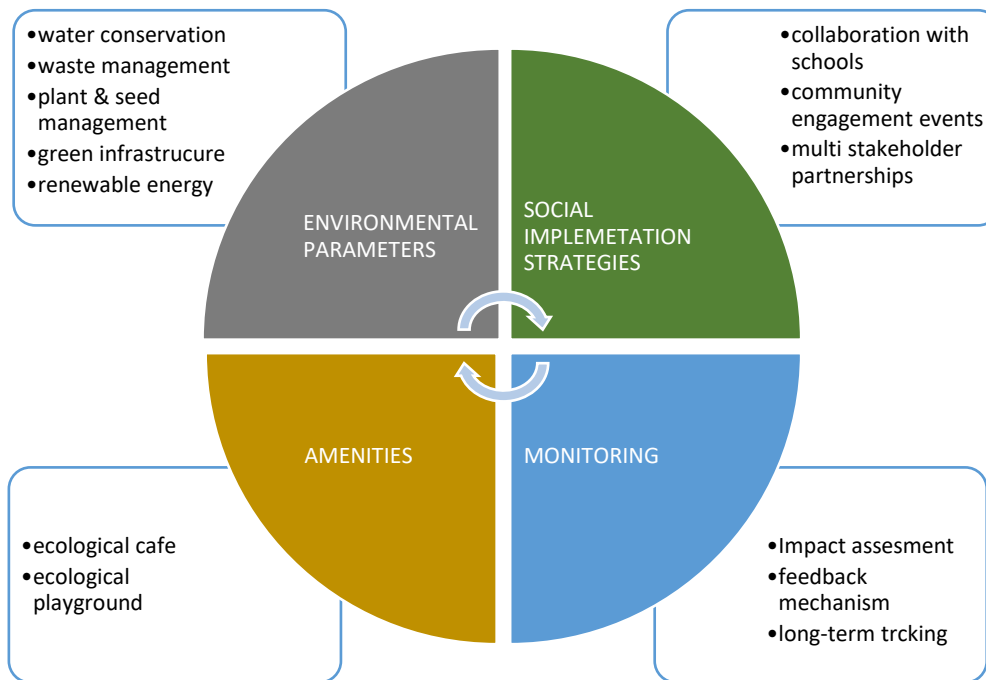

Figure 17: Significant thematic areas when designing an ecological park for children (source: authors)

The site that was selected as a case study is the Rodini Park, located in Rhodes, Greece. It is one of the oldest parks in the world, boasting a history that stretches back to ancient times. This verdant oasis is renowned for its lush greenery, tranquil streams, and shaded pathways, offering visitors a serene escape from the bustling city life. The park is thought to have been a favorite retreat for the Roman emperors and, according to tradition, was also a place of learning where students of the famous orator and philosopher Cicero once studied. Today, Rodini Park continues to captivate visitors with its natural beauty and historical significance, featuring a variety of trees, flowers, and wildlife, including peacocks that roam freely within its grounds.

One of the park's most notable features is its ancient tomb of the Ptolemies, which adds an element of historical intrigue to its natural charm. The park's design, with its carefully planned landscaping and use of water elements, reflects the ancient Greeks' and Romans' appreciation for harmonious, nature-centric environments. Visitors can enjoy leisurely walks along the well-maintained paths, relax by the serene ponds, or explore the ruins that hint at the park's storied past. Rodini Park not only provides a peaceful retreat but also serves as a living museum, preserving the heritage and natural beauty of Rhodes for future generations to enjoy.

Figure 18: The case study area for the ecological park

4. Conclusions

The ever-faster pace of life and limited financial capabilities of our day force the majority of tourists to take short vacations of only a few days. At the same time, however, there is an increasing demand for interesting breaks from the workaday rut providing experiences that are markedly “different.” There is widespread interest for city tours characterized by the experiential perception of the particular identity of a place instead of the mass consumption of a standardized tourist product. For a stroll around town, that offers him or her the opportunity to combine city walks with history, landscape, history and cultural memory.

In the first case, through a comprehensive analysis of the strategies implemented in Rhodes, this study aims to contribute valuable knowledge and lessons to the wider debate on sustainable tourism at UNESCO World Heritage Sites. By examining the specific case of the Medieval City of Rhodes, this research seeks to provide information on effective approaches and best practices for balancing tourism development with heritage conservation and community engagement.

The findings of the study will provide practical guidance for policy makers, site managers and stakeholders involved in the management of UNESCO World Heritage Sites worldwide. By identifying successful strategies and highlighting the challenges faced in Rhodes, the research will facilitate informed decision-making and the development of tailored solutions for other heritage sites facing similar issues.

Furthermore, by sharing lessons learned and best practices that emerged from the Rhodes case, this study aims to promote collaboration and knowledge sharing among stakeholders in the global tourism community. By promoting dialogue and collaboration, the research contributes to the promotion of sustainable tourism practices that ensure the long-term preservation and enjoyment of UNESCO World Heritage Sites for future generations.

Ultimately, the study aims to inspire and empower stakeholders to adopt sustainable tourism approaches that not only protect cultural and natural heritage but also contribute to the socio-economic development and well-being of local communities. Through the dissemination of knowledge and lessons learned, this research aims to make a substantial contribution to the conservation and promotion of UNESCO World Heritage Sites around the world.

In the second case the establishment of an ecological park in Rhodes presents a unique opportunity to engage children in environmental education and promote sustainable development initiatives. By

designing educational activities focused on water conservation, waste management, and plant and seed management, the park can empower future generations to become environmentally conscious citizens. Drawing inspiration from Greek and international case studies, Rhodes can create a dynamic educational environment that fosters a deep appreciation for nature and encourages sustainable living practices. Through collaborative efforts between government agencies, educational institutions, and civil society organizations, the ecological park in Rhodes can serve as a model for environmental education and community engagement on a global scale. The successful implementation of educational activities within the ecological park in Rhodes requires a multifaceted approach that engages stakeholders at all levels and integrates best practices from Greek and international case studies. By fostering collaboration, innovation, and community participation, the park can become a catalyst for sustainable development and environmental stewardship in Rhodes and beyond. Through continuous monitoring, evaluation, and adaptation, the park can ensure the effectiveness and long-term impact of its educational initiatives, empowering children to become active agents of positive change in their communities and the world.

Abstract

This paper explores the complex relationship between collective memory, the reuse of abandoned buildings and the redefinition of public space through educational synergies and activities involving artistic creation. Collective memory, linked to public space and shaped by present needs, was examined based on a specific methodology and through performative events, photographic, audiovisual and architectural works and actions. The workshop was implemented by the Departments of Interior Architecture and Photography and Audiovisual Arts of the University of West Attica with the participation of Professors, students, artists and residents who used public and private space as a platform to express and negotiate their collective identities, values and personal narratives through artistic and participatory processes. The research through these actions in an abandoned house in Kerameikos and the wider area, familiarized the participants with the space and turned it into a field for the recall of memories, enhancing the interactions between the participants and the space and redefining individual and collective memory. The interdisciplinary and intercultural approach aimed to explore how collective memory activates and transforms spatial relations, highlighting the role of art, identity and social dynamics in creating an open evolving archive. The dialectical relationship between the artistic expressions of the participants and the spaces enhanced the sustainable development of the specific area, strengthening the community's relationships and giving it new perspectives. The paper concludes by emphasizing the role of the educational process in understanding and activating collective memory to create new hybrid spaces through art. This dynamic phenomenon requires interdisciplinary collaboration and offers insights into how narratives of the past shape contemporary landscapes and collective identities, linking the past to the present and future of community and space with new palimpsest narratives.

Keywords: *workshops; collective memory; visual art; performance; experiential space; architecture*

1. INTRODUCTION

The aim of the paper is to investigate how collective memory is activated, constructed, transformed and also transforms spatial correlations through an interdisciplinary and inter-artistic approach to public space. It also explores the roles of art, identity and social dynamics in shaping new spatial practices and narratives. Collective memory is directly related to space and the city in general, as it is a main component of representations, through specific rituals that enable historical narrative [1].

As repositories of collective memory, public spaces embody the history and experiences of communities, bringing to the fore important events or individuals and preserving collective memories for future generations. They can also play a crucial role in shaping collective identity and sense of belonging. Some of them, such as neighbourhoods, cultural centres or places of worship, may have particular significance for communities, reinforcing shared values, traditions and narratives [2]. Moreover, the way spaces are designed, used and experienced is influenced by social, cultural and

Proceedings

ISSN: 2654-0460
ISBN: 978-618-5765-02-6

historical factors. Public space is not only the set of material formations that define it, "but the way in which each and every one of us, together, assigns meaning to these material formations." [3] The codes and symbols that we perceive as users or observers of public spaces - as well as the meanings - are not necessarily intrinsic and interwoven with the icon itself but are based on a cultural and historical context and norms that can vary in time and space [4]. Urban planning decisions, architectural trends and zoning regulations can reflect and perpetuate social norms, power dynamics and historical narratives. Within this context, spaces become dynamic fields of contestation and negotiation, where different social politics or other groups that coexist in the community may compete to shape collective memory and historical narratives. Conflicts over spatial changes (renaming streets, removing statues or changing the use of historic sites) highlight the complex ways in which memory and space intersect. As Harvey argues, "*the freedom to make and remake our cities and ourselves is one of our most precious yet most neglected of our human rights*" [5]. Spaces can undergo transformations or redefinitions, leading to changes in the way they are remembered by utilizing a system of sorting the narratives they embody.

Halbwachs in his theory of social memory claims that "it is in society that people acquire their memories. It is also in society that they recall recognize and locate their memories". Since societies are an evolving system it follows that collective memory is not static but dynamic, subject to interpretation, revision and forgetting over time.

2. CASE STUDY: WORKSHOP [UN]VISIBLE PLACES

The educational workshop that took place in the Kerameikos area, tried to highlight not only on a theoretical but also on a practical level, that the perception and production of visual and architectural space is not only related to what we see but also to what we hear, what we feel, or what we remember. According to Piaget the perception and intuition of space results from the observation of things, as well as from our actions in relation to them. Through different spatial and kinesthetic conditions, the way we move through space in combination with our senses, and memories of place, constitutes a living set of situations expressed through architectural and visual thinking and practice. The aim of the workshop was the birth of a new place of ephemeral habitation between the imaginary and the real through the exploration of the possibilities of the coexistence of live performance, architecture and visual art action with the already recorded image and the resulting image as an open, evolving archive.

2.1 Synergies and collective practices

The educational action was held in collaboration with the Departments of Interior Architecture and Photography and Audiovisual Arts of the School of Applied Arts and Culture of the University of West Attica. The public and private space was used as a platform for participatory design. The participants, (professors, the group "Communitism", students, artists and residents), were involved in all stages of the action, from planning to implementation. Lippard argues that art is deeply rooted in the experiences and histories of local communities and emphasizes the role of participatory art in preserving local cultures and promoting community identity [6]. Goldbard also believes that participatory art can empower communities and strengthen cultural democracy, emphasizing the importance of active community participation in the artistic process [7].

Collective art practices in the public space focus on participation, cooperation and creativity as well as the active involvement of citizens in common social, cultural and political issues. The 'right to the city' is practically expressed through participatory processes that, when carried out in public space, can play an important role in activating shared, public life [8].

Workshop participants expressed and negotiated their collective identities, values and narratives through various forms of artistic expression and participatory processes, enriching the individual and collective experience of the community. The ephemeral interventions and the transience of the

installations invited the community to experience the familiar in a new way, integrating art into everyday life.

2.2 Research context and process

The proposed spatial-art installations, since it incorporated elements of interaction with the space and with the participants and the residents, was a springboard for dialogue within the public and the wider social context, but, above all, it triggered new thoughts and reflections on the space of habitation and memory, on the immaterial and the material, on the private and the public, on individual and collective memory.

In this research framework the following questions were posed:

1. How are traces and information about individual and collective memory preserved?
2. Can the reuse of abandoned spaces be achieved through the activation of artists and communities?
3. Can archives be created of as many individual and collective, visual and ephemeral performance events that have occurred and are occurring in the city?
4. How can mixed media interventions and actions affect the sensory experience and memories of the community by creating through a montage of 'realities' - new unseen worlds and narratives?

In the short period of three days, the students worked in three groups, a group to record the experiences of personal memories of the residents, a group to create visual and architectural proposals and a group to create the final archive.

Figure 19 The building on Salaminos and Paramythias streets with students in the workshop

An abandoned neoclassical 19th century residential building, on Salaminos and Paramythia streets (Figure 19), the pedestrian street itself and the archaeological site of burial monuments "Public Signal" were chosen as the place of intervention. The venue of the workshop contributed to the formulation of the proposals that emerged through the combination of art and architecture, aura and material elements with the concept of memory as the central axis.

The source of inspiration for the workshop was the literary text *The Invention of Morel* by Adolfo Bioy Casares [9]. In the work, the central character, a narrator, records the reality of the five senses using a holographic recording and reproduction device. This recording leads to the physical death of the recorded subjects and objects and then to their "revival" as memory. Through the repetitive projection of events as idols onto the real world, its nature is altered but also mutated. The narrator is involved in the process of recording reality, first by meticulously writing a diary, and then by self-

Proceedings

inscribing it as a record of holographic similes. The diary-witness is gradually corrected and completed, like a blurred memory that keeps coming back until it is elucidated, attempting to achieve the absolute accuracy and fidelity of the record of reality.

In the novel, the structures of reduplication or multiplication through the process of holographic projection in space serve as memory, which reduplicates reality by contributing to the confusion between reality and its representation. The assemblage, the montage of time and space that is attempted leads to a non-linear interpretation of time and reality, involving the past and the present, the real and the imaginary, in order to produce a disoriented space where the geographical field is not concretized. As Robert Humphrey states "the purpose of editing is to transgress or modify the arbitrary and conventional boundaries of space and time. The quality of 'stream of consciousness' requires a movement that is not strictly that of 'clockwork'. It requires, on the contrary, the freedom of switching back and forth, of mixing the past, the present and the imaginary future" [10]. The whole story can start again, the last year can be repeated over and over again and the line, the line of narrative, the line of time can become a circle. The recapture of the concept of representations in space-time uses memory as a model and constitutes the basic mechanism for recording and reproducing reality [11]. The function of memory and the archive is the nodal tissue of the novel and educational action as the basic mechanism of recording and reproducing human being and space-time. At the same time, the complex functions of memory involved in this process undermine the absolute fidelity of technological reproduction, or the identification with the original, which according to Virilio leads to the disappearance-erasure of the original [12].

This novel was used by the workshop as a methodological tool, due to the reconception of the linear perception of space-time, as it reimagines history and geography, but also due to the activation and reconstruction of individual and collective memory. Collective memory functioned here, as in the project, as a means to help fill in the gaps in individual memory and the participants' experiences in terms of shared, universal experiences - such as the experience of death or love - giving individual experience the perspective of parallelism and repetition. And as Cassares' hero wishes for the inscription of his existence in the consciousness of his beloved, who has never met it except in their holographic projection, "*My soul has not yet passed into the image" ...but to the man who, on the basis of this reference, will invent a machine capable of gathering scattered presences, I make an appeal: Search us, Faustine and me, make me enter the heaven of Faustine's consciousness. It will be an act of mercy.*" [9].

The participants identified with the role of the narrator of the project, using their individual experiences and their personal narratives in relation to the space and their personal experiences. They created artistic and architectural works that, together with the recorded experiences of the local inhabitants, were finally integrated into an open archive-diary.

A first exploratory process involved understanding the history, structure and scale of the building, which was a residence and a carpentry workshop, as well as the surrounding urban space. This process of becoming familiar and acquainted with the space took place through the use of movement and drama therapy techniques and exercises in order to activate the senses that connect the body with the space and the text. The observations on the interaction of the human body and the creation of geometric relationships with space were recorded by exploiting the digital technology and the artistic view of the students. Then, the participants created artworks, photographs and videos as well as spatial compositions with their personal objects, proposing visual and spatial interventions with staged approaches. The interaction of works and spaces in different spatial conditions served as a springboard for the creation of ephemeral artistic environments, linking the individual with the collective memory of space (housing and urban space). According to Halbwachs, each individual memory is a perspective on collective memory, that this perspective changes according to the position I occupy and that position, in turn, changes according to the relationships I maintain with other groups [13].

Proceedings

Figure 20 Performative Events and Ephemeral Scenographic Environments

At the same time, simple ephemeral stage constructions were designed and implemented that contributed to the exploration of the relationship between space, body and text, spatially translating concepts that link memory and recollection, with space. The ephemeral scenographic environments acted as platforms for performative events (text reading visual experimentation with digital media and lighting), altering the everyday image of space by proposing a new image and experience (Figure 20).

According to Walter Benjamin, "to dwell is to leave a trace". The participants recorded in different ways (text, video, recordings) the experiences and memories of the inhabitants of the area and the different actions. The concept of the archive functioned as a footprint where human existence left its mark, contributing to a new reading of the city as an active, evolving field. During the compositional process, urban space and the dwelling as a unit became a rewritten site of ephemeral events, a new hybrid archival site.

The workshop concluded with the creation of a final organized archive that included the recording of the experiences and memories of the residents of the area, the recording of the actions and artworks and their display in an open exhibition and presentation at the intervention site and at the Benaki Museum.

3. METHODOLOGY

The strategies used to exploit collective memory to redefine abandoned spaces in the urban landscape are as follows:

- Inviting a set of independent artists or groups to collaborate with the participating students, setting the context the objectives and content of the action.
- Making contacts with the residents of the research area and, encouraging them to participate in the project. Discussing the possibility of engaging the community to involve residents as well as different associations in the creative process.
- Implementing a multicultural approach, encouraging the participation and expression of the members of the target community that coexist in the area by focusing on their different cultural approach to the site and the memory it carries.
- Raising awareness to the community about the importance of collective memory and the preservation of cultural and historical heritage through the lens of the creative process and art.

- Developing a fruitful dialogue between students and participants to recall monuments (personal/collective) related to the history of housing in Kerameikos and the wider area, the actions and experiences of residents to understand desires and needs of the community.
- Creation of multiple teams (text writing, site recording, performance event creation, performance, performance event recording-promotion).
- Identify the extent of logistical equipment needs for the implementation of the project. Sourcing logistical equipment from the University of West Attica, and funding resources through sponsorships, crowd funding or community fundraising efforts.
- Conducting archival research on photographic materials provided by residents, recording resident interviews, and personal observations through a tour of the residence and Kerameikos sites. Objects were also solicited that would function as springboards for the emergence of memories.
- Audiovisual recording (photographic and video) of the spaces, objects and narratives pushing for the preservation of cultural heritage and enhancing collective memory.
- Explaining the methods of creating works and constructions in the sites and in the wider area through educational activities and talks by artists, architects, theorists.
- Organization of experiential activities to strengthen the relationship of the body with space and memory through drama-therapeutic methods and processes.
- Realization of novel artistic and audiovisual artworks, constructions and interventions in situ. Due to the ephemeral nature of the works, an attempt was made to preserve the memory of the interventions through documentation with photographs, videos and written records.
- Organization of an art exhibition open to the public. Supervision of the installations and constructions by groups of students and residents for the safety of the works and participants.
- Promotion of the project and its results in social media, local media and cultural events, exhibitions with the active contribution of the participating groups, students and institutions (University of West Attica, Athens Festival, community groups, etc.) (Figure 21).
- Holding extensive discussions on the possibilities of long-term planning for the future of the abandoned buildings and urban areas and determining the temporary or permanent nature of the project or whether there are plans for possible reuse or redevelopment of the site.

Figure 21 Workshop in Athens Festival

4. ANALYSIS AND RESULTS

Cities inspire emotions, stories and initiatives through the experiences of their inhabitants, pushing for their improvement. Lefebvre describes the city as the scene in which all the complex interactions of everyday life take place [14]. The personal narratives and collective experiences were one of the main cores of the educational action, resulting in the emergence of the residents' relationship with their neighborhood and the wider urban space, the history of the area and their experiences that are inextricably linked to the community and the city. The participating students and artists, become virtual residents of the area by integrating their individual experiences and experiences into a

collective memory and with the ability to intervene, re-map the city and transform the space by making it familiar.

The use of abandoned buildings that carry their own history and memories that function as venues for hosting educational activities, exhibitions, performative events is a powerful tool for transforming them into living cultural cubes and focal points for the promotion of collective memory, contributing to the cultural upgrading of cities [15]. Many cities have come to promote culture and heritage as part of new reorientation strategies using cultural events in public space as a tool [16] [17]. The literature mentions cultural events, festivals and activities both as a means to enhance infrastructure investments and to improve the image of the city [18]. Their use refers to the enhancement of urban development processes and the broader transformations of cities in general [19]. A major area of both private and public investment tends to be local and regional infrastructure [20], which can help preserve and promote cultural heritage in cities, while introducing new functions to abandoned spaces or structures.

This training action is heading in this direction, highlighting and promoting cultural heritage by selecting and reusing abandoned buildings or structures. The incorporation in their design of new elements, both material and immaterial, maintains connectivity with the past and pushes towards a new contemporary concept of re-use of buildings through participatory processes. Activating them in this way encourages community participation, highlights the memory of the place and contributes to the overall well-being and the cultural and social upgrading of urban environments.

According to Knierbein et al. [21], cities can refer to human entities that have distinct personalities, with the result that the evaluation of a city is not exclusively subject to aesthetic terms, but is linked to the lifestyle, the memories evoked by the urban environment and the social trends associated with it. This view is supported by the research of Stanley Milgram and Denise Jodelet [22], which refers to a mental mapping of space that has nothing to do with the actual one. People living in a city map it by selectively identifying some elements of it as important, connecting them through their everyday experiences as well as through their social representations of the spaces they have, which may or may not be part of their everyday experience there. Space is understood as a function of the historical and social events, systems of production, recurring events and relationships of inhabitants that have developed in it, as a collective and personal experience. Moreover, Lefebvre points out the inseparable relationship between space and rhythm [23]. The recognition and understanding of space is realized through repetition and rhythm created either by natural factors (e.g. seasons), social (holidays), or personal (our breathing, our work) creating regular or irregular, slow or fast rhythms which become the means for understanding space and time.

The workshop sought tools to approach spatial experience, leading to new unconventional readings of space, strengthening collective identity and social bonds. As a result of the research, each proposed space was transformed as the main way of recalling memory, contributing to the formation of a system of interactions between individual and collective memory. The management of the image and the promotion of the identity of the city, reinforced sustainable development, giving it new perspectives. The spatial – visual art proposal functioned as a means of interaction between the participants and local residents with the space that functioned as a perceptual and compositional tool of participatory planning. The experiential experience of space, form, language and representation reconstituted the abandoned building, presenting it as a platform for performative artistic expression, bringing the participants and local residents in contact with constantly evolving techniques in the field of sound and image. The creation of the performance, which sometimes uses modern ways of digital representation, and its recording through the creation of an archive brought the participants in direct contact with the history of the place and the experiences of the inhabitants.

The photographic and video documentation of the proposal in all phases added a completely new perspective both in the field of promoting the event and in the "on-stage" coexistence of 3D and 2D space. An open, performative archive was proposed redefining the city and the human connection

Proceedings

with its history, and culture. The new proposed city archive contributed to the preservation of information so that the ephemeral, the past and the present become the future of the city and urban space becomes the place where "everything" happens, inhabits and will inhabit.

The communication of the actions of the educational workshop through the exhibition, the lectures, the discussions at the Benaki Museum, and the promotion on social media had the effect of enriching the city cell and including a wider audience by expanding the social network.

5. CONCLUSION

This paper highlights the importance of the educational process in understanding and adopting the mechanisms of activating collective memory as a synthetic tool in the creation of new hybrid spaces as palimpsests. A complex and dynamic phenomenon that requires interdisciplinary and inter-artistic perspectives and collaborations. Collective memory and art forms share a symbiotic relationship, each influencing and shaping the other. Art has a profound capacity to capture and reflect collective memories, serving as a conduit for cultural narratives, historical events and shared experiences. Collective memory provides artistic expression with a source of inspiration and subject matter.

The visual arts and the audio-visual and scenic works created were used as a medium for preserving, interpreting and transmitting collective memories among the participants. Through text, events were recorded while through visual and spatial interventions, significant moments or symbols were symbolized that echoed community stories or specific personal memories. Sound, photographic and audiovisual recordings connected fragments of memory and narratives, creating new stories and spatial relationships.

Through the above performing acts, performances, memories and narratives were reproduced in an experiential, physical and direct way, allowing the participants to delve into these emotions on a deeper level. Drawing on shared experiences and cultural references, the works explored issues of identity, space and social consciousness, encouraging dialogue and understanding between participants.

The strategy of using collective memory to redefine abandoned spaces is an important issue linked to urban development and environmental sustainability. The re-use and re-designation, of these spaces contributes to the improvement of the quality of life of the inhabitants and the development of the city.

Through the educational process, and by using new technologies and different interventions on the site, a palimpsest of virtual spaces was created that impacted on the physical ones, playing an important role in shaping collective memory. The architectural, artistic and audiovisual interventions, as well as the promotion of the actions and spaces through social media, created new ways for communities to share, preserve and reinterpret their histories, blurring the boundaries between the physical and new spatial versions, reshaping the individual and collective identities of the sites chosen for the implementation

Abstract

This paper explores the utilisation of sensory mapping techniques to enhance livable and inclusive urban environments, with a focus on revitalising neglected void spaces. It emphasises the importance of community engagement and renewal in these areas and highlights sensory mapping as a method to capture diverse experiences and insights. Drawing from interdisciplinary case studies, it illustrates how sensory experiences influence perceptions of urban spaces and contribute to a sense of belonging. The paper stresses the significance of inclusive design in shaping public spaces that accommodate individuals of all backgrounds and abilities, advocating for accessibility and consideration of marginalised groups. By synthesising theoretical insights with practical examples, it offers recommendations to promote collaboration, accessibility, and cultural sensitivity in sensory mapping projects, aiming to transform void spaces into vibrant, people-centred places.

Keywords: placemaking; sensory mapping; urban public spaces; urban void; inclusive design; resilience

1. INTRODUCTION

The urban fabric of modern cities is undergoing rapid transformation. A new perspective on urban architecture is required to meet the demands of contemporary communities. In the context of the built environment, urban voids represent a critical resource that must be effectively utilised.

In academic discourse, numerous disciplines explore the representation and experience of the built environment, providing varied perspectives on its design. Research on placemaking and the experiential decoding of urban environments examines how users' spatial self-awareness and participation influence the meaning and function of spaces.[1]

Charles Lardy (2006) [2] argues that urban environments overwhelm the senses, confining our sensory experiences to immediate surroundings and limiting our broader worldview. Therefore, spatial perception is crucial. Urban life encompasses various spatial and temporal activities that foster human interaction, with our understanding of place evolving through both material and intangible stimuli from these interactions. Truax (2001) [3] describes place perception as a form of tacit knowledge, highlighting the structural relationship between sensory environments and activities within them.

The senses are essential for navigating urban landscapes, enabling experiences of public spaces and the built environment through visual, olfactory, auditory, tactile, and cognitive perceptions. This underscores the importance of research into the multidimensional mapping of urban landscapes, where users' senses mediate their understanding of spatial concepts, usage patterns, and design flaws. The sense of place represents an individual's emotional bond with their surroundings, shaped by their perception of specific environments [4]. "Place" carries deeper significance and imparts a sense of identity, unlike "space," which is a mere spatial dimension. Urban areas become meaningful places through repeated visitation and user attachment, transforming them into venues for positive

ISSN: 2654-0460

ISBN: 978-618-5765-02-6

interaction and embodying the essence of "public place." This sense of place enhances personal identity and elevates the city's appeal and significance for its residents and society.

Recent studies on urban public spaces have largely focused on piazzas and nodes, often neglecting urban voids and leftover spaces, and their potential utility. Urban voids, emerge unintentionally during multiple project developments, resulting in vacant and uninhabited spaces. These voids can be repurposed and managed to enhance urban environments, particularly in developing countries, fulfilling users' needs for valuable and aesthetically pleasing spaces.

This paper reviews urban voids and their impact on cities, aiming to understand their significance in social, economic, and environmental aspects. It highlights how these voids currently affect a city's image and proposes strategies to reimagine public spaces. Sensory mapping is emphasized as key to creating inclusive and vibrant environments, challenging traditional placemaking methods. The paper advocates for integrating sensory experiences, technology, physical features, community cohesion, and public health in urban design.

2. UNDERSTANDING URBAN VOIDS AND THE SIGNIFICANCE OF REPURPOSING

Urban voids are a complex and multifaceted concept in urban planning and design, encompassing a range of spaces defined by their lack of functional, social, or aesthetic integration into the urban fabric. The term "urban void" can often be confused with similar terms such as unoccupied areas, vague land, and abandoned land, due to their overlapping characteristics related to formation, history, and development potential. In the context of this research, urban voids are understood as spaces characterized by an absence of function, human activity, and aesthetic value within the urban setting. These voids disrupt the continuity of the urban tissue, creating physical and perceptual gaps that can be either publicly or privately owned. These vacancies are often the result of neglect and abandonment.

Trancik [5] identifies urban voids as negative spaces that lack human interaction. The absence of human activity in these spaces categorises them as voids. While, Lynch [6] describes urban voids as neglected, useless, and empty areas, often referred to as waste zones. These voids are generated by permanent structures such as highways, railways, and bridges. Lynch, also argues that these spaces have potential and should be repurposed to meet the evolving needs of the city and its inhabitants.

Urban voids contribute to the fragmentation of city spaces, creating barriers between neighbourhoods and hindering pedestrian movement. Transforming these spaces into public realms can bridge these gaps, fostering greater connectivity and coherence within the urban fabric. By establishing pedestrian-friendly pathways, verdant corridors, and cultural nodes, cities can enhance mobility and facilitate social interactions, thereby cultivating a more integrated and cohesive urban environment. [7]

Reimagined urban voids can become inclusive public spaces that cater to diverse populations. Traditional public spaces often serve specific demographics or activities, potentially excluding various community members. In contrast, repurposed voids offer versatile settings that can accommodate a range of cultural expressions and recreational activities. Community gardens, outdoor art exhibitions, and temporary markets are just a few examples of how these spaces can serve diverse needs and preferences, fostering a sense of belonging and social solidarity among residents. [9]

Transforming urban voids into green spaces boosts environmental sustainability and urban resilience by integrating green infrastructure like pocket parks, rain gardens, and urban forests. This approach enhances biodiversity, mitigates urban heat island effects, improves air quality, and manages stormwater runoff through sustainable designs such as permeable surfaces and rainwater harvesting. Redeveloping these spaces helps cities adapt to climate change, attracts investment, stimulates local economies, and creates jobs. Revitalizing underutilized spaces rejuvenates neighbourhoods, attracts businesses and residents, and enhances cultural and recreational amenities, boosting the city's cultural capital and local business revenue. Successful transformation requires collaboration among city planners, architects, developers, and community stakeholders, ensuring projects align with residents'

needs through participatory design, feasibility studies, and secured funding, leading to dynamic and resilient urban environments.

3. THE NEED FOR NEW LIVABLE AND INCLUSIVE PUBLIC SPACES

Contemporary urban life pulsates with the vitality of public spaces, which serve as embodiments of societal values and collective identity. These spaces, far from being mere physical entities, are vibrant arenas where diverse interactions converge, echoing the ethos of coexistence. In today's fast-paced, interconnected world, the imperative for new, liveable, and inclusive public spaces is pressing.

Liveability in public spaces transcends mere functionality; it encapsulates the holistic well-being of individuals and communities. Human-centric design fosters a sense of belonging and facilitates diverse activities catering to various needs [10]. Inclusive design, going beyond physical accessibility, embraces diversity in cultural, socioeconomic, and generational aspects. A truly inclusive public space is where everyone feels welcome, regardless of background or ability.

The necessity for new public spaces arises from the evolving dynamics of urbanisation and technological progress. As cities expand in population and density, the demand for communal areas to counter urban sprawl's alienating effects becomes paramount. These spaces serve as connective nodes, bridging virtual interactions with tangible experiences and fostering dialogue and collective action. [10]

However, creating such spaces poses challenges, requiring a shift in urban planning priorities towards community well-being over commercial interests. Innovative design and governance approaches empowering local stakeholders are essential, along with a re-evaluation of existing norms perpetuating exclusion and inequality.

Ultimately, the call for new liveable and inclusive public spaces transcends convenience, representing a moral and existential imperative. It is about reclaiming human essence – to connect, belong, and thrive in shared environments. As society stands on the cusp of rapid urbanisation and transformation, redefining public spaces to reflect inclusivity and the richness of human experience becomes paramount.

4. SENSORY MAPPING: THE CONCEPT AND APPLICATION

Sensory mapping offers a promising approach to understanding the complex and dynamic interactions between people and the built environment. By considering the multisensory experiences of users, sensory mapping enables designers and planners to gain insights into how people perceive, navigate, and interact with urban spaces. Through the systematic collection and analysis of sensory data, sensory mapping identifies opportunities for intervention and improvement, ultimately contributing to more responsive, engaging, and inclusive public realms. Therefore, the sense of place arises from environmental design features and activities, alongside the subjective significance individuals attribute to them. [11]

The paradigm of Sensory Urbanism explores individuals' sensory perceptions and interpretations within their local environments, emphasizing the pivotal role of sensory stimuli in shaping and influencing urban experiences. Various theories and methodologies have been devised to delineate the parameters of sensory experiences and methods for their documentation. Kevin Lynch (1960) posited that individuals construct mental representations of urban elements to comprehend and navigate their surroundings. Sensory mapping augments this comprehension by integrating urban and environmental analyses with resident feedback. These mappings include visual, auditory, olfactory, and tactile dimensions, collectively enriching our understanding of urban spaces and potentially fostering enhanced practices in urban regeneration. [12]

Visual mapping delineates parameters of visual comfort, encompassing preferences for vistas, appropriate illumination levels, and minimization of glare. Sound mapping, conversely, digitally represents sonic environments, termed soundscapes, which encapsulate the auditory ambiance of

specific locales. Additionally, olfactory mapping attends to the unique olfactory signatures of urban areas, amalgamating scents from diverse sources such as street markets, eateries, vehicular emissions, and human perfumes. Texture mapping identifies the material compositions within urban landscapes, correlating with thermal comfort, visual aesthetics, and energy efficiency considerations. These maps serve as instrumental tools in the realm of comfort analysis and urban planning, potentially catalysing the emergence of sensory-oriented placemaking methodologies.

Furthermore, the evaluation of placemaking initiatives necessitates consideration of users' subjective experiences, memories, and emotional responses. Such considerations underscore the transformative impact of urban development not only on physical and economic landscapes but also on the somatic and experiential realms, profoundly influencing individuals' attachments to place. [13]. As elucidated, human sensory faculties profoundly shape perceptual experiences, rendering sensory placemaking a pivotal avenue for redefining urban evaluation paradigms. By incorporating users' multifaceted sensory encounters into placemaking endeavours, a more nuanced understanding of urban spaces can be attained, fostering inclusive and enriching environments conducive to diverse wayfinding experiences.

The diagram below captures the relationships and key points from the narrative about the importance and characteristics of new, liveable, and inclusive public spaces in the context of contemporary urban life & sensory mapping:

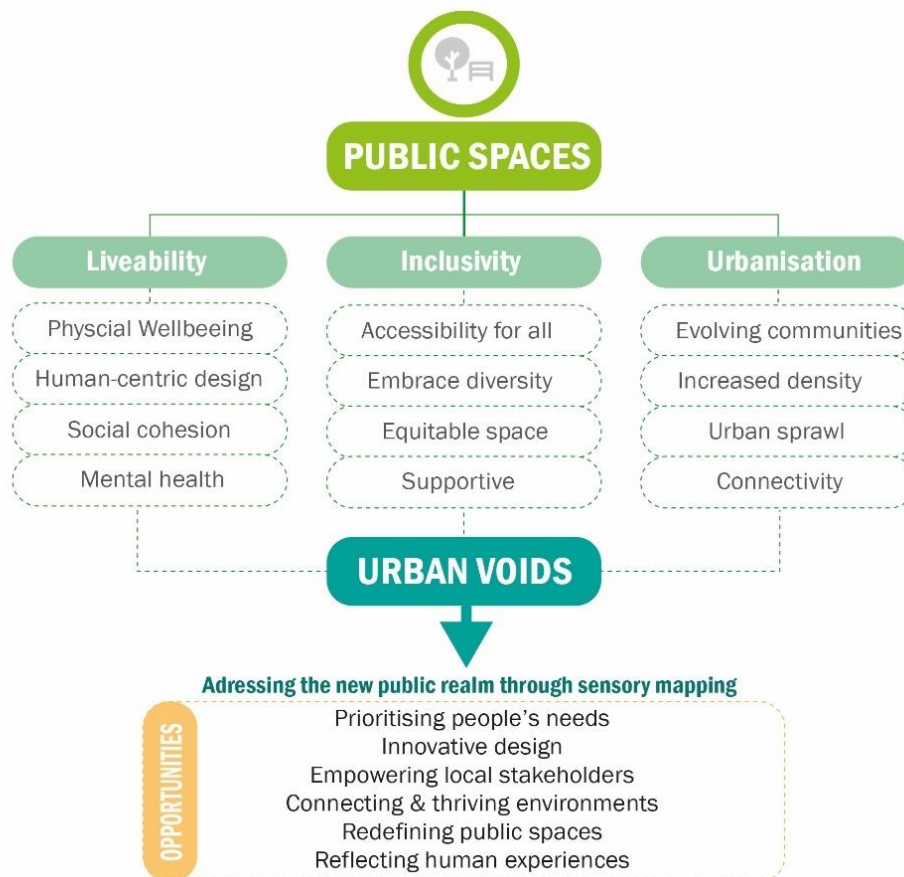

Figure 1. Inception diagram to investigate the key attributes to the new public spaces

5. CASE STUDY – TRANSFORMATIVE INTERVENTIONS IN URBAN VOIDS

Numerous examples illustrate the transformative potential of sensory-driven interventions in urban voids. To illustrate the application of sensory mapping principles in urban planning practice, this section presents one key case study that showcase successful examples of creating liveable and

inclusive public spaces in redundant urban voids, and how the principles described above has been achieved.

High Line Park, New York City:

Figure 2. Joel Steinfeld’s most iconic shot of the High Line, looking east along 30th St. A railroad artefact, May 2001 (Photo by Joel Steinfeld [Historical | The High Line](#))

Figure 3. Repurposed High Line in New York City, creating one of the most vibrant and successful public realms in the city (source: google)

The High Line Park is a renowned example of adaptive reuse, transforming a disused elevated railway into a vibrant linear park that spans the west side of Manhattan. Through careful planning and design, the park incorporates elements of nature, culture, and art to create a unique sensory experience for visitors. The integration of native plantings, public art installations, and panoramic views of the city skyline contributes to the park's appeal as a destination for leisure and recreation, while fostering social interaction and community engagement. The High has significantly enhanced inclusivity, liveability, and urban form. This elevated park, which stretches for 1.45 miles along the west side of Manhattan, was transformed from a disused railway line into a vibrant public space.

Here are the key achievements, described in Figure 1, in these areas:

Inclusivity

The High Line has succeeded in fostering inclusivity by creating a public space that is accessible to all. Its design incorporates numerous features to accommodate individuals with disabilities, including elevators, ramps, and smooth pathways. The park's programming, which includes cultural events, educational programs, and community gatherings, is designed to engage a diverse audience. By offering free access and activities, the High Line ensures that people from various socioeconomic backgrounds can enjoy its amenities. This inclusivity is further supported by the Friends of the High Line organization, which actively works to involve local communities and address their needs.

Liveability

In terms of liveability, the High Line has dramatically improved the quality of life in its surrounding neighbourhoods. It provides a green oasis in the dense urban environment of Manhattan, offering a place for relaxation, exercise, and social interaction. The park's lush plantings, scenic views, and artistic installations create a serene atmosphere that contrasts with the bustling city below. This transformation has not only enhanced the physical health of residents by promoting outdoor activities but also contributed to their mental well-being by providing a space for tranquillity and reflection. Additionally, the High Line has spurred economic development, attracting new businesses, restaurants, and housing developments, which has revitalized the area and created jobs.

Proceedings

Urban Form

From an urban form perspective, the High Line represents a visionary approach to adaptive reuse and sustainable urban planning. By repurposing an obsolete railway into a dynamic public space, the project preserves historical infrastructure while giving it new life. The elevated nature of the park offers a unique vantage point to experience the city, fostering a stronger connection between people and their urban environment. The design seamlessly integrates with the surrounding architecture, encouraging pedestrian movement and connectivity within the city. The success of the High Line has inspired similar projects worldwide, demonstrating the potential for innovative urban design to transform neglected spaces into valuable community assets.

In conclusion, the High Line stands as a testament to how thoughtful urban design can promote inclusivity, enhance liveability, and reshape urban form. Its success has not only improved the lives of New Yorkers but also set a benchmark for cities globally seeking to create more inclusive and liveable urban environments.

6. CHALLENGES & OPPORTUNITIES

The concept of creating liveable and inclusive urban voids holds significant promise, yet it also presents a myriad of challenges that must be addressed to fully realize its potential. These challenges include:

- Limited resources and funding for urban redevelopment projects.
- Conflicting interests and priorities among different stakeholders.
- Regulatory barriers and bureaucratic hurdles that impede the implementation of innovative ideas.
- Socioeconomic disparities that may exacerbate inequalities in access to public spaces.
- Resistance to change from established norms and conventions in urban planning practice.

However, these challenges also present opportunities for creativity, innovation, and collaboration. By engaging with local communities, leveraging public-private partnerships, and harnessing the power of technology, cities can overcome these obstacles. Such efforts can pave the way for more inclusive and resilient urban environments.

7.1 The Significance of Sensory Mapping to repurpose the urban voids:

Human perception of the environment is inherently multisensory, involving the integration of visual, auditory, olfactory, tactile, and even gustatory stimuli. Each sensory modality contributes to our overall experience of space, influencing our emotions, behaviours, and sense of belonging. Therefore, to truly understand urban voids and their potential, it is essential to consider the full spectrum of sensory experiences that they afford.

Sensory mapping provides a holistic approach to consider the sensory experiences of people within the built environment. By mapping various sensory stimuli present in urban spaces, we can gain insights into how people interact with their surroundings and how these interactions influence their well-being and quality of life.

Sensory mapping can allow us to identify opportunities to enhance the sensory qualities of urban spaces, thereby creating more engaging and inclusive environments. By incorporating elements such as greenery, public art, lighting, and street furniture, planners can design multi-sensory experiences that stimulate the senses and foster a sense of place and belonging.

Moreover, sensory mapping can help identify areas of concern, such as noise pollution, air quality issues, or lack of accessibility, enabling planners to address these challenges and improve the overall liveability of urban environments. By prioritising sensory experiences in urban planning processes, cities can create spaces that cater to the diverse needs of their inhabitants and promote social cohesion and well-being.

Proceedings

- Establishing the strategies for Creating Liveable and Inclusive Urban Voids:

As we contemplate the future, a pertinent query emerges: How can the user-centric approach continue to fulfil the expectations and demands of local communities amidst evolving urban complexities? Illustrated below is a foundational list of strategies pertaining to sensory placemaking, outlining seven core attributes that underpin and contribute to the vision of creating new public realm. These attributes encompass the physical milieu, aspects of health and well-being, community involvement, the integration of smart technologies, and the perceptible environment. The strategies below aim to establish the key drivers to transform urban voids into vibrant and inclusive public realms, we can employ a range of strategies informed by sensory mapping principles. These strategies aim to enhance the sensory qualities of urban spaces while addressing the diverse needs and preferences of urban populations and include:

- Inclusive Design Strategies

Incorporating principles of universal design ensures that public spaces are accessible and accommodating to people of all ages, abilities, and backgrounds, thus fostering inclusivity. Key strategies involve eliminating physical barriers, enhancing navigation, offering inclusive seating arrangements, and accommodating diverse sensory preferences. Prioritising these inclusive approaches can significantly enhance residents' quality of life, promote social interaction and community engagement, and cultivate a sense of belonging. This holistic approach to urban design aims to create equitable, enjoyable, and empowering spaces for all users, recognizing and addressing diverse needs to ensure dignified experiences for everyone.

- Incorporating Nature and Green Spaces

Greenery significantly enhances the sensory experience of urban environments by providing visual appeal, improving air quality, and promoting mental well-being. Integrating parks, gardens, and green spaces into urban voids can create oases of tranquillity amidst the city's hustle and bustle. These green spaces offer recreational and relaxation opportunities and serve as habitats for biodiversity, contributing to the ecological resilience of urban ecosystems. [14]

- Fostering Cultural Identity and Diversity

Urban voids offer opportunities to celebrate the cultural heritage and diversity of urban communities. Incorporating elements of local culture, history, and tradition into public space design can create inclusive environments that reflect the community's unique identity. Public art installations, cultural festivals, and heritage trails can foster a sense of pride and belonging among residents while promoting intercultural dialogue and understanding.

- Promoting Safety and Security

Safety is critical in creating inclusive urban voids, especially in areas perceived as unsafe or undesirable. Planners can address safety concerns through improved lighting, surveillance cameras, and active programming of public spaces. By fostering a sense of security, cities can encourage greater utilization of urban voids by residents and visitors, thereby activating these spaces and enhancing their vibrancy.

- Integrating Technology and Innovation

Advances in technology offer new opportunities to enhance the sensory experience of urban environments [15]. Planners can leverage digital tools such as augmented reality, interactive displays, and mobile applications to create immersive experiences that engage the senses and encourage exploration and discovery. Additionally, incorporating sustainable technologies such as green infrastructure, renewable energy, and smart lighting systems can reduce the environmental impact of urban development while enhancing inhabitants' quality of life.

- Promote health and wellbeing

Promoting health and well-being when considering new public realms in cities is crucial, and sensory mapping plays a pivotal role in this process. By understanding how different environments affect

people's moods and behaviours, planners can create more inclusive, accessible, and enjoyable spaces. This approach can reduce stress, promote physical activity, and foster social interactions, contributing to overall public health. Sensory mapping helps identify and mitigate potential negative sensory impacts, such as excessive noise or pollution, ensuring that urban environments are both pleasant and conducive to well-being.

• Creating city memories

In urban environments, lasting memories are crafted through intentional urban design, where each aspect, from architecture to public spaces, shapes experiences. A city's design should seamlessly blend aesthetics with functionality, inviting exploration, interaction, and contemplation [16]. Iconic landmarks serve as focal points, while more intimate spaces like foster social connections and personal moments. Thoughtful design also weaves in the city's story through art, history, and culture, imparting a sense of place and identity. Sustainable practices ensure these memories endure for future generations, maintaining the city's vibrancy and relevance. Ultimately, a well-designed city becomes a canvas for human experience, where every element contributes to a tapestry of enduring memories that reflect its unique character and spirit.

By implementing these strategies, we can transform underutilised spaces into dynamic, inclusive, and sensory-rich public realms that cater to diverse urban populations. The diagram below has been developed as a starting point of establishing strategies for repurposing the urban voids through sensory mapping. Each strategy contributes to the overarching goal of transforming urban voids into vibrant and inclusive public realms.

Figure 4. Inception diagram to investigate the key strategies to establish inclusive and liveable public realm

7. CONCLUSION

In the journey to reimagine urban voids, sensory mapping emerges as a pivotal tool, unlocking the potential to transform neglected or underutilised areas into vibrant, inclusive public spaces. The process of sensory mapping, which considers the multisensory experiences of urban users, provides

Proceedings

a framework for designing environments that are not only functional but also responsive to the diverse needs and preferences of the users. For urban policymakers and practitioners, sensory mapping in combination with the strategies described above, could provide a robust tool to guide decision-making processes. This method can be instrumental in prioritising investments, evaluating the effectiveness of interventions, and ensuring that urban development is both equitable and inclusive. By embedding sensory considerations into urban planning policies and guidelines, cities can move towards a more holistic approach to development. The realisation of inclusive and sensory-rich cities is a collective endeavour, demanding active participation from a wide array of stakeholders, including government agencies, urban developers, designers, researchers, and community members. This collaborative approach ensures that the diverse voices and experiences of all urban users are heard and integrated into the planning and design processes. By embracing participatory methods, universal design principles, and leveraging innovative technologies, cities can fully utilise the potential of sensory mapping. Such efforts will lead to the creation of public spaces that are not only vibrant and welcoming but also universally accessible, setting the stage for urban environments that truly serve the needs of all their inhabitants. In conclusion, sensory mapping is more than just a design tool—it is a philosophy that champions the creation of urban spaces that are inclusive, equitable, and alive with the sensory experiences of their users. As cities around the world strive to become more sustainable and resilient, integrating sensory mapping into urban planning represents a significant step towards achieving these goals. By doing so, we can ensure that our urban environments are not just places to live, but places to thrive, fostering a sense of belonging and well-being for all.

Abstract

The purpose of this article is to explore the connection between biomaterials and technology in Architectural construction, as a process that can lead to a more effective design, regarding the reduction and response to the dramatic effects of climate change. It aims to learn from the principles of the circular economy and integrate these learnings into the development of structures to understand the importance and impact that their implementation can have in achieving the goals of the 2030 agenda, as they relate to the decarbonization of architectural constructions. The methodology followed is the investigation of the problem through analytical bibliographic research and other evidence as well as the study of four case studies, to evaluate the application of such an approach in contemporary and future Architectural design, to achieve the eleventh goal of sustainable development of U.N. that urges us to create cities that are resilient and sustainable, free from poverty and exclusion. In conclusion, proposals are formulated for current and future constructions, regarding the contribution of these strategies to climate change mitigation and adaptation to its effects.

Keywords: biomaterials, circular economy, modern manufacturing technologies, bio-mimicry, UN sustainable development goals.

1. INTRODUCTION

Around 37% of energy and process-related CO₂ emissions and more than 34% of global energy demand are attributed to the buildings sector, which includes energy used for building, heating, cooling, and lighting homes and businesses as well as the appliances and equipment installed in them, according to the United Nations.[1]

The Intergovernmental Panel on Climate Change (IPCC) claims that energy-efficient building and construction policies can help lift 2.8 billion people out of energy poverty in developing nations by reducing greenhouse gas (GHG) emissions by up to 90% in developed nations [2] and up to 80% in developing nations. Nevertheless, the industry is still not on schedule to realize its full mitigation potential because half of the structures will still need to be constructed by 2050. [3]

The lengthy lifetime of building appliances, HVAC systems, and other structures means that choices made today about purchase and design will influence energy use for many years. In the ensuing decades, buildings' influence on the climate is probably going to grow. Future construction will need to be more resilient to natural disasters and decarbonized throughout their lives. [4]

Many governments have committed to initiatives like the UN Paris Agreement and the EU's goal of becoming carbon neutral by 2050, and they have increased their efforts to lessen the impact of building construction on the environment. To achieve this, construction procedures must be approached in a circular rather than a linear manner, allowing for the reduction of carbon emissions throughout a building's life cycle.

Is it possible for a bio-based economy to meet the demands of increasing urbanization while lowering the carbon footprint of infrastructure? What is the scope of innovative manufacturing using various

technologies, and which technologies should be used? The eleventh UN target for sustainable development can be accomplished in this situation.

In this article, we recommend using the following strategies to achieve global decarbonization solutions: a. the biomimicry paradigm; b. the use of agricultural waste and recycled materials; c. the integration of nature into urban environments; and d. resource optimization, such as the use of 3D printing technologies to create concrete with low carbon emissions. Consequently, four case studies related to sub-goals 11.1, 11.7, and 11.10 of the UN's eleventh goal—among the seventeen sustainable development goals—are provided. In particular, goal 11.1 states that by 2030, everyone should have access to essential amenities, safe, affordable housing, and slum upgrading. Furthermore, sub-goal 11.10 calls for our cooperation in providing less developed nations with the financial and technical means necessary to construct sturdy, long-lasting structures out of locally available materials. Last but not least, target 11.7 exhorts us to ensure that everyone has access to secure, welcoming, and accessible green and public places by 2030.

2. CASE STUDIES

2.1 The Biomimicry paradigm

Figure 1, 2, 3 from left to right, “The Agri-voltaic Pavilion”, [RB](#) [5]

A method for conserving energy is biomimicry. Architect Pawlyn asserts that there are numerous benefits to studying the assembly of materials in biology, including low-energy production using locally accessible materials, the lack of bio-accumulative accumulative and persistent toxins, and closed-loop interconnections that allow for the reuse of everything. We then provide creative carbon sequestration structures that illustrate the dynamics of the biomimetic paradigm.

According to architect Jenny Sabin, the demand for cooperative material solutions stems from the sustainability and climate issue, which has led to the creation of a new research model. He views nature as a design metaphor and has developed a generative design process. Research does not translate what may be considered an aesthetic form; rather, it aims to understand the behaviors and processes that regulate these systems. How might buildings and their interconnected material systems behave more like creatures that react and adapt to local contexts? is one of the main issues that drives her research.

Based on the biomimetic paradigm, as depicted in Figures 1,2,3, a project was developed that innovates the design and engineering of Building Integrated Photovoltaics (BIPV) through computational design and 3D printing to create highly customized non-standard filters and panels that result in site-specific non-mechanical tracking solar collection systems. The project is a collaboration between the Sabin Lab at the College of Architecture, Art, and Design at Cornell University and the DEfECT Lab at Arizona State University. Biological adaptations, such as heliotropic mechanisms in sunflowers and light-scattering structures in Lithops plants, provide a starting point for the investigation of non-conventional panel layouts that enhance energy conversion efficiency.

Following solar path data, the suggested method eliminates 30% of copper cable and the usual 50% extra structural metal per module, resulting in a 15% reduction in carbon intensity for a southwest installation. Consequently, the Agri-voltaic Pavilion showcases the potential of sustainable design for a resilient land-use model that offers an integrated approach to food, energy, and water by demonstrating the first adaptable system with exceptionally low greenhouse gas emissions.[6]

- **Sustainable 3D printing Constructions from agricultural waste.**

Figure 4: left: coconut panel **Figure 5:** right: agricultural by-products, <https://shorturl.at/dOTZ3> [7]

In line with UN Sustainable Development Goal 11.10, which calls for financial and technical support to less developed nations so they can construct long-lasting, sustainable structures out of local resources, this article recommends as best practice the use of biomaterials made from recycled agricultural waste [8]

A case study on bio-based post-agricultural waste materials and sustainable construction techniques is offered in this context. Getting rid of agricultural waste is a big problem in many nations. The agriculture sector may find a solution to this problem by turning this waste into construction materials, which would have a beneficial environmental impact and provide a clean building material that could be fully recycled back into the ground. The example we shall present, as depicted in Figures 4 and 5, relates to the fundamental elements of floodwater retention, which are rice and coconut bark. applied to the Efua Sutherland Park bioswale project in Accra, Ghana. Additionally, we will demonstrate how to make brickwork using a treatment of moringa bark. There are often technical concerns about scalability, industrial production, standardization, fire safety, and mechanical strength when working with agricultural waste and bio-based materials. From the standpoint of developing regions in West Africa, this data was thoroughly examined by Willow Technologies, a sustainable material and building technology company founded in 2017 to promote research and development of biological, agricultural by-products in building technologies, led by Ghanaian-Filipina architect Mae-Ling Lokko.

Mae-Ling Lokko's practice has been able to explore and document the material character of various crops, their potential by-products, local transformation techniques, and the prospect and challenges of their extensibility as building materials through extensive work with coconuts, moringa, rice, and other indigenous crops. Mae-ling asserts that increasing demand for agro-based materials via

knowledge and education about them is a prerequisite for achieving the scalability of these materials. This was the basic concept driving Willow Technology's investigation into the utilization of rice, coconuts, and moringa agricultural by-products in a nation where the introduction and promotion of foreign hybrid foods was steadily decreasing the commercialization of native species.

The study topic "How to induce demand and productive use of indigenous crops and agricultural by-products in Ghana" arose from the fact that the crop could only produce enough by-products through practice to be scaled up into construction materials. Willow accelerates the research and development of low-carbon solutions across all industries by collaborating with entrepreneurs, government agencies, private foundations, and local and international partners.[9]

In Ghana and Senegal, Willow is in charge of the creation and research of the carbon life cycle of building materials for all residential building sectors. Willow collaborated with the Roads Research Institute, the Ghana Council for Scientific and Industrial Research on Buildings, Worofila, and AARBMN in Senegal for each country's case study. Together, they evaluated and contrasted the carbon footprint of conventional materials from their initial construction to their end of life with that of low-carbon alternatives. In response to a request for COP27 (the 27th United Nations Climate Change Conference (UNFCCC), that was realised in Sharm el-Sheikh, Egypt, November 6–18, 2022), Willow used rice and coconut husks as essential elements of flooding and water retention in the 'bioswale' project at 'Efua Sutherland' Park in Accra, Ghana. In collaboration with renowned African chef Selassie Atadika, Willow and the Midunu Institute procured 126 bags of rice from Africa Rice via the World Crop Trust, which were then incorporated as green infrastructure in a section of the park that is vulnerable to flooding. To slow down the water, the project entailed creating and constructing a bioswale and planting flood-resistant rice with other native species.

There may be more opportunities for by-products with broader uses due to the strong demand for regional food items. Willow Technology's investigation into by-products from "moringa," a popular tree in Ghana that is frequently used for tea, oil, herbs, and medical purposes, is proof of this. Press powder is a byproduct that is left over after moringa oil is extracted. This flour-like material aids in the accumulation and sedimentation of heavy metals and other harmful elements in wastewater, making it useful for treating toxic sewage. The moringa research and design from Willow Technologies was used by Global Mamas, a network of women-owned home-based batik dyeing businesses, to treat textile effluent. This method made their effluent less harmful than EPA standards in a proof-of-concept project, allowing it to be safely dumped into municipal sewer systems. Additionally, the process leftovers provide a sludge that can be utilized to create compacted earth masonry.

According to Willow Technologies, creating a new distributed production infrastructure for distributed biomass from the food, building, and agricultural cycles is the key to increasing the number of farming byproducts. According to Lokko, the first step in cutting production costs is to bridge the gap between the collection of agro-waste and its quality control by creating accessible production techniques. These concepts are best illustrated by the company's early use of coconut husks as a building material. Their initiatives were a reaction to Ghana's coconut boom, which resulted in traders disposing of tons of husks on the side of the road because there were no proper disposal facilities. For these projects, they gathered these husks from traders; nevertheless, their goal is to create a dispersed system of small-scale milling machines in particular areas of the city, enabling coconut vendors to process their husks and receive payment. To produce material, the husks are diced into light, fluffy, dried fibers that are easier to handle. Compared to immature coconuts from other worldwide producers, native mature coconuts from Ghana have a higher lignin concentration, which offers them a structural edge for possible usage in construction products like medium and high-density fiberboard. Using heat compression techniques and bio-based adhesives, Lokko's practice has harnessed this bark material to create low-carbon, non-toxic fiberboard. Insulation is typically the quickest application for these materials in buildings. However, no one is interested in them or is

Proceedings

prepared to pay a premium price if you conceal them behind a wall, according to Mae-Ling. He continues, saying that design plays a significant influence in changing cultural perspectives. "I think there is a missed opportunity to capture their true value as strong, breathable building skins, partitions, and furniture, which has the potential to attract people to adopt them," he says. Using the form, texture, color, and surface patterns of these panels, this method was also applied to the usage of coconut husk boards in projects, enhancing the mechanical, acoustic, or thermal performance of the item showcased in projects like the Yale CEA Nairobi Ecological Pavilion and exhibitions at the Museum of the Future in Dubai [10]

The Ghanaian architect argues that not all architectural materials should be considered everlasting and that we should reevaluate each material's performance metrics and value for maintenance. By coating such bio-based materials, the likelihood that their distinct hygrothermal characteristics may impact interior comfort is greatly diminished. In hot, humid tropical regions, these material behaviors—which involve absorbing and storing moisture in the late evening and early morning and releasing it during the day—are significant passive cooling technologies. When comparing the general characteristics of bio-based products, it can be seen that these materials are crucial in utilizing the plentiful local resources and lowering carbon emissions during the construction, operation, and eventual demolition of buildings. Building relationships between players in agriculture and construction is necessary to maximize these resources and assist in the upskilling of local experts and craftspeople so they can contribute to a flourishing bio-economy. However, governments will also need to encourage and promote these collaborations, drive market demand, and take a proactive role in national and regional policy [11]

- **Solutions incorporating nature in urban environments**

Figure 6. Bioactive green wall, <https://shorturl.at/rsuOS> [12]

Target 11.7 of the UN's Sustainable Development Goals calls for ensuring that everyone will have access to secure, inclusive, and accessible green and public places by 2030. [13]

Green wall solutions are essential to the search for more sustainable buildings made of long-lasting materials with lower environmental impact, better financial performance, and circularity. They also help to mitigate the heat island effect that occurs in large urban centers. "Bioconcrete" is a new substance that was developed in response to the rising global CO₂ emissions caused by the production of concrete. It is a type of self-healing concrete that has bio cement—an environmentally friendly main ingredient—added to it. This substance is only active when there is water present; it can lie dormant for many years. Thus, in contemporary culture, bio cement—bio concrete—produced via MICP (biomineralization/bio precipitation) may be a good substitute for ecologically friendly building materials [14]

Bio-Active Concrete from Holcim, a multipurpose material that was used during the German Design Week in the Netherlands in 2021 by the architectural firm Bouw & Infra, is an example of this self-healing building material. As shown in Figure 6, Holcim's innovative green wall consists of two surfaces: a layer of structural concrete and a porous concrete that allows plants and seeds to grow. The solution is easily expandable for both residential and infrastructure applications because it is composed of precast concrete parts. By functioning as a biofilter, it controls the building's temperature and lessens the impact of the heat island. In addition, it helps preserve rainwater, enhances biodiversity, and lessens noise pollution by absorbing sound [15]

Additionally, as shown in Figures 7, 8, and 9, the bioactive wall of eco-concrete is a construction that grows naturally, attracting lichens, moss, endolithic algae, and attached plants. It doesn't require intricate soil systems to create wet niches that support vegetation because of its high porosity and complexity. For increased green coverage, bioactive wall features with planting pockets are a great option for facades. The Bio Active wall tile's proportions can be changed to meet the needs of every project. The project's unique structural and biological requirements determine the precise concrete matrix that is used for casting.[16]

Figure 7. Bioactive wall

Figure 8. Standard tile

Figure 9: Pocket tile

Moreover, Chris Allison, the founder of City Forest, a group of horticulturists, designers, and engineers dedicated to creating sustainable plant systems, created the superb and cutting-edge seven-layer vertical garden system, as depicted in figures 10 and 11, known as the Bioactive Wall, which permits plant roots to spread freely. This green wall technology produces an almost natural environment by allowing plants to grow along and through the construction. Plant spores, from lichens to ferns, can organically proliferate on the wall in this way. Fundamentally innovative, the Bioactive Wall promotes sustainability by requiring less water, upkeep, space, weight, and plastic. Water conservation can be achieved by eschewing the application of conventional green wall

methods. The Bioactive Wall works to moisten the plants' surface and then take moisture from it, eliminating the need for water to drop from pot to pot and effectively wasting water.

Figure 10, left. Interior space, **Figure 11**, right. Exterior space, <https://www.cityforest.com.au/bioactive-wall> [17]

Using as much recyclable material as feasible, garden systems cool our sweltering cities while removing CO₂ from the environment. This implies that we intentionally select aluminum parts made from waste materials, such as drink containers when constructing our garden systems. Furthermore, the walls' bio felt is composed of recycled materials, preventing microplastics from entering rivers and the food chain [17]

2.4 3D-printed low-carbon concrete.

By tying in the eleventh sustainable development objective of the United Nations with the several ways to accomplish CO₂-free architecture, we selected strategies that support energy efficiency and reconstruction with new technology while also favorably impacting environmental sustainability. More specifically, the UN's sustainable development target 11.1 states that the objective is to guarantee everyone's access to appropriate, safe, affordable housing and the renovation of slums until 2030 [18]

Low-carbon concrete solutions combined with 3D printing technology offer a tremendous potential to decarbonize buildings and achieve speed and economy in construction, ensuring that everyone has access to secure and cheap housing. This kind of concrete can be used in circular construction because it is entirely recyclable and produced locally. They combine a low carbon footprint with circular benefits by incorporating recovered trash from construction and demolition projects. By using them, CO₂ emissions can be decreased from the market reference by at least 30%. They may be pumped and used like regular concrete to finish their life cycle, making them simple to use as well. Among other things, they can be used for roads, pavements, walls, beams, columns, and foundations. Concrete 3D printing, as shown in Figures 12 and 13, is a rapidly developing technology that has the potential to fill infrastructure gaps globally by enhancing performance and facilitating more effective construction. Buildings made with 3D printing are more resource-efficient, require less intricate structures, and maximize material utilization [19]

Figure 12, left. Print ten housing units in Kenya, <https://shorturl.at/sEQRZ> [20]

Figure 13, right. [Advanced Mortars for 3D Printing.](#), 30/12/2023

To expedite the building of large-scale projects, sophisticated mortars for 3D printing have also been created in the cement sector. These solutions' benefits allow for up to a 50% decrease in project materials without sacrificing project performance. Large-scale projects can be completed more quickly thanks to sophisticated mortars that optimize material usage and reduce errors on construction sites 3D printing only uses the resources required for construction. [21]

3. DISCUSSION AND CONCLUSIONS

Many building materials have an adverse influence on the environment when we take into account the human activities necessary to create our urban surroundings. To obtain raw minerals, mining is typically required. The utilization of mining minerals affects the world's natural systems. The mined materials used to produce common building materials, such as minerals, sand, gravel, crushed stone, cement, etc., are non-renewable resources because their formation is dependent on long-term natural ecological products and services, like natural sedimentary cycles. These materials are used to make steel, aluminum, concrete, glass, and other materials. According to Keena and Dyson (2017), these cycles can endure for thousands or even millions of years.[22]

The depletion of non-renewable mineral resources is the foundation for the manufacture of basic building materials. In addition to raw materials, the human race depends on the world's ecological systems for other ecosystem services including air pollution, which is frequently linked to the building and manufacturing of building materials. For instance, producing cement, one of the primary ingredients of concrete releases a lot of CO₂, therefore the environment is crucial to the making of concrete in absorbing and reducing the pollution brought on by CO₂ emissions. On the other hand, bio-renewable materials, including agricultural byproducts, can sequester CO₂ throughout their existence and have low-carbon production techniques. Therefore, many biomaterials are carbon neutral or carbon negative when looking at life cycle analysis. Renewable biological resources derived from plants, as well as waste (food) streams, are rich in several important components, including cellulose, proteins, and carbohydrates.

A novel biorefinery is being developed at Wageningen University & Research to utilize all of these components. The goal is to employ them as much as possible in food, materials, chemicals, and animal feed. Finally, we also take into account if a tiny portion can still be used to produce biofuels for heavy-duty vehicles. Opportunities are created by Wageningen University & Research to fully utilize biomass while preserving the quality of the soil. For instance, we can use the stalks of corn in addition to the cob since they contain essential components that can be used to make plastics. To establish a circular bio-based economy, Wageningen University & Research has adopted this strategy, utilizing our knowledge in biorefinery technologies, crop cultivation, bio-based product creation, and economic models.[23]

Using renewable resources from agricultural waste is a beneficial practice in current studies on sustainable construction methods, according to researcher Mae-Ling Lokko, an assistant professor at Yale University, discussing the energy and carbon life cycle of materials. Lokko 2016 [24], Lokko et al. 2016 [25], and Lokko and Rempel 2018 [26], the researcher's papers, indicate that raw materials for the building industry can be crucial in "closing" material life cycle gaps in the global economy. Throughout the building's life cycle, the application of bio binders to produce a variety of low-to high-density agro-waste-based materials has shown advantages for enhancing energy efficiency and air quality. The materials' ability to function as an inherent evaporative cooling material in humidity management systems and technologies is demonstrated by their hygienic and thermal performance. Compressed coconut fiberboard's mechanical strength can rival that of reconstituted wood material technologies on the market, which creates opportunities for applications related to indoor air quality and acoustics. One such application is as a plasterboard substitute spacer.

The same researcher used life cycle assessment (LCA) to compare three wall assemblies made of locally available bio-based materials in Montreal, Kenya, and Accra, Ghana, against a traditional construction that uses plasterboard and Rockwool insulation. The results of the comparison, published in a recent article, showed that all bio-based material alternatives had lower life cycle impacts per functional unit than traditional construction. It has also been demonstrated that DfD (design by disassembly) techniques lead to effect reductions of between 10% and 50%. The findings for the two African nations demonstrate a substantial possibility for future decarbonization, despite a strong reliance on the source of power used for building.[27]

Resurrecting bio-architecture as an alternative to other construction processes is the result of the present trend toward sustainable building construction and growing environmental awareness. Because biomaterials are renewable, their primary benefit is their little environmental impact. It can also be processed with basic tools. Biomaterials enable quick installation and prefabrication. As a result, biomaterials are now referred to as the "building materials of the twenty-first century" since they are seen as an appealing substitute for many conventional building solutions. Biomaterials mitigate emissions from other materials because they can efficiently sequester carbon. There are several opportunities that biomaterials bring to the built environment. From the perspectives of the environment, economy, society, and human health and well-being, biomaterials provide a comprehensive strategy with the ability to mitigate various effects at each stage of the building's life cycle. These kinds of solutions move us one step closer to our nature strategy and our objective of greening cities. By creating this nature-based strategy, we will contribute to creating a future that benefits both people and the environment.

Abstract

The paper discusses the challenges of climate adaptation of public spaces in the context of Southeastern Mediterranean Urbanism from an urban design perspective drawing on the experience of Greece. It begins by highlighting the defining characteristics of the particular tradition of urbanism that has evolved in the region. Climate adaptation of public spaces in the context of Southeastern European Urbanism is seen as having a double scope. On the one hand restoring deficiencies and enhancing urbanity in areas compromised by problematic urban structure and low-quality public realm and on the other hand introducing nature-based solutions through strategically devised urban interventions. The paper explores this potential by examining three characteristic design case studies in the metropolitan area of Athens. Analysis concludes that cities and coastal areas in the South-Eastern Mediterranean are in dire need of restoring urbanity in balance with nature and eco-systemic processes. Climate change pushes for a new orientation and design priorities such as heat relief, better use of unutilized and abandoned green infrastructures and recuperating the coastline as public space. Understanding the context of local urbanism is key to unlocking solutions for climate mitigation and adaptation of urban public spaces. Meanwhile, Research by Design provides the analytical tool for investigating and framing strategic urban interventions.

Keywords: *Mediterranean urbanism, climate adaptation, retrofitting urban interventions*

1. INTRODUCTION

Responding to the consequences of climate change is by now a widely debated topic among various policy communities, such as politicians, legislators, urban planners and environmentalists, and, not to omit, a central theme of many European policies and programs, starting with the European Green Deal and the New European Bauhaus. This paper addresses the question of climate adaptation from the angle of urban design, drawing more specifically on the concept of ‘Urbanism’ as an analytical tool and ‘Research by Design’ as a broader methodological track for dealing with urban problematics. Their value in devising urban design approaches for climate adaptation of public spaces is explored here.

Under the term *Research by Design*, we refer to the growing significance of the type of investigatory analysis of the city and urban space through drawings and visualization of data that is typically undertaken in schools of architecture and some architectural practices as a starting phase but also a methodological approach towards carrying out urban design. More recently, Research by Design has been recognized as a valid framework for conducting PhD related research in accredited academic programs of architectural and urban design, while a definition of Architectural Research which encompasses RbD is acknowledged in the Charter of the European Association of Architectural Education [1]. Going beyond official formulations, one could argue that research by design rests on the long tradition of architectural thinking about the city that has been nurtured over the years in-between theory, practice and research which involves meticulous identification of the terrain, critical inquiry, and devising of innovative synthetic solutions that go beyond the mere transposing of social and political agendas onto space. This tradition is certainly associated with the practice of urbanism.

Under the term *Urbanism* we refer to the holistic approach to planning and design of urban space which originated in the 19th century European city, also transplanted overseas, that encompasses merged planning and design preoccupations, such as land use, real estate and regulation, urban form, circulation and infrastructure along with ecological aspects into complete artefacts and can be summarized as ‘the art of building cities’ [2]. Among the products of the practice of urbanism are included some of the most iconic and resilient historical districts of European and American cities.

Proceedings

of the International Conference on **Changing Cities VI:**
Spatial, Design, Landscape, Heritage & Socio-economic Dimensions
Rhodes Island, Greece • June 24-28, 2024
ISSN: 2654-0460
ISBN: 978-618-5765-02-6

Whereas urbanism has evolved since the 19th and early 20th century obviously along with the evolution of dominant ideas about city planning, so that the contemporary connotations of the term deviate from the original context of civic architecture and design, what remains as its legacy for urban research, is the emphasis on typologies, urban form and the unitary approach in linking spatial-technical with socio-ecological dimensions of the built environment. Perhaps it is not accidental that contemporary supporters of the movement of New Urbanism in the US argue that it is by definition ecological, sustainable and climate resilient contrary to the assumptions of its opponents [3]. Consequently, the argument made in the paper is that it is not possible to devise fitting design solutions for climate adaptation of public spaces without a solid understanding of the local context of urbanism. Inversely, the systematic study of local urbanism and the way that it has responded to resilience challenges in the past, can provide valuable hints on how to address contemporary problems, such as climate adaptation [4]. And, coming back to the previous point, Research by Design can provide the analytical means on how to uncover these hidden qualities and operationalize them into a design intervention scenario.

This paper builds on the experience of participation in the research network CIMATRA (City Making in Times of Transition) that was formed in 2018 among six European schools of Architecture with the aim to study via research by design the necessary design transitions in different urban environments in response to changing climatic conditions. In the rest of the paper, we present how this research scope unfolds in the case of Greece. First, we provide a brief background on the particularities of Greek Urbanism with regard to climate related challenges drawing on academic literature and recent developments. Following from there, we explore the potential of research by design to respond to these challenges in three characteristic case studies, namely design for heat relief in a densely built central district, retrofitting of a modernist university campus on the urban fringe and recuperating the urban waterfront as public space. The design research in all three cases was carried out at the School of Architecture NTUA in the period 2022-2024. In the last part of the paper, we discuss the findings and return to the main research question about how architectural thinking for the city can contribute to ongoing discussions about climate adaptation of urban public space.

2. CLIMATE CHALLENGES OF SOUTH-EASTERN MEDITERRANEAN URBANISM

The distinct path of Greek Urbanism was analyzed most characteristically by Greek Geographer Lila Leontidou in her ‘Mediterranean City thesis’ [5]. Leontidou looked into the similarities across Southern European cities and their notable differences from the industrialized North, manifested in a number of aspects, such as the spontaneous character of urban development and tolerance of informal practices, the importance of family strategies for housing provision that are associated with widespread practice of self-housing and self-employment [6] and the weak character of welfare provisions. This model of urbanism has been associated with specific typological and urbanistic traits, most notably the small scale of plots, high density of urban development with few open and green spaces, the uniformity of structures and mixity of land use inside dense urban areas [7]. Linking the socioeconomic analysis of Leontidou about Southern European cities with urbanistic and typological characteristics of spontaneous post war urban development shared among countries such as Greece, Cyprus, parts of Turkey and Albania, we arrive at a tentative definition of Southeastern Mediterranean Urbanism.

Climate resilient responses were ‘built in’ into the model of the ‘Mediterranean City’ early on through the development of areas with second homes next to the sea in vicinity to main urban centres, which enabled urban residents to escape the city during the hot summer months. This was facilitated by the relatively easy access to land and favourable conditions for home-ownership seen also as family investment, a practice that spread across a wide spectrum of social classes and incomes [8]. Typically, the model was supported by the context of extended family structure which facilitated flexible arrangements, such as grandparents and relatives keeping the children over the entire three months of the school break in the summer house while parents stayed in the city or commuted to work. The expression *paratherizo* [passing the summer], (*veranear* in Spanish) most accurately captures this widely spread social practice in South Europe. Its spatial manifestation is associated with the typical low-density sprawl that characterizes the majority of coastal development in the periphery of large metropolitan conurbations of Athens and Thessaloniki but also elsewhere.

Recent studies on the evolution of the development path of Greek cities and the relevance of the ‘Mediterranean City’ thesis [9] have shown that Southern European cities have evolved as a

consequence of social and economic change brought by globalization, the effect of tourism and real estate but also economic crisis and austerity related reforms that eroded some of their inherited resilience characteristics. In this new context climate change bears multiple new challenges. Most notably the urban overheating in the dense urban districts aggravated the living conditions in central urban areas considering also the low construction quality of *polykatoikia*, the typical` condominium housing stock, that makes them particularly vulnerable to the new conditions [10]. Meanwhile, the rising housing maintenance and transport associated costs, the abandonment of the traditional family model also due to demographic changes, as well as increased property taxes, make it now much less affordable to the vast majority to perform this dual living in the summer months. Last but not least, year-long underinvestment of public infrastructures, the so-called infrastructure gap, due to lack of value capture mechanisms [11], negligence of adoption of nature-based solutions and poor management of peri-urban forests make the urban environment and landscape more vulnerable to increased risks of wild fires and sudden floods, like the ones experienced in Greece in the summer of 2023. Also, they provide little possibilities for recreative and relief infrastructures, such urban parks, green corridors and promenades, easy access to nature and the coastline where urban residents can find refuge to.

In the following section we elaborate on three investigations for design transitions of urban public spaces in response to the shifting conditions in the context of Southeastern Mediterranean Urbanism.

3. DELVING INTO THE HADRIAN AQUEDUCT TO DESIGN FOR HEAT RELIEF IN CENTRAL ATHENS

The first investigation involves the activation of an antique Roman aqueduct as tool to generate a pole of urbanity and heat relief based on the principle of the 15min city [12] in the dense urban district of Ampelokipoi, one of the most vulnerable neighbourhoods of central Athens. It has been the topic of an urban design studio led by the author at the School of Architecture NTUA in Spring 2023 in collaboration with Athens Water Supply and Sewerage Company that assisted in providing material, expertise and offering feedback along the design process.

Eleni Myrivili, the first appointed heat officer of Athens Municipality commented in the NYC in 2022 about the dangers of rising heat waves in Athens as follows: “*Without action, the future for Athens would be bleak and airless. The capital would become more of an urban heat island with empty squares and cafes, fewer tourists and an exodus of residents who have the means and opportunities to live elsewhere*” [13].

The Hadrian Aqueduct is an underground urban infrastructure of the antiquity, one of the largest of its kind, which was built in 140 AC by Emperor Hadrian with the aim to water supply the city of Athens. It collects water along a course of 23.5km, a territory which today transcends nine municipalities that form part of the wider Athens dense urban area. The aqueduct fell out of use during the period of Ottoman rule but has been repaired and put back into use in the 19th century to water supply the newly founded capital of the modern Greek state in 1871 [14]. Despite being replaced by more modern infrastructure since the beginning of the 20th century, the aqueduct remains alive still today transporting enough cool water to meet the daily needs of a city of 10.000 inhabitants from the foothills of Mount Parnes to the centre of Athens where it is dumped into the sewer system because we are not prepared to use it differently. In 2021 an initiative to channel European funds for reconnecting the aqueduct with the city was launched by the Region of Attica in the form of an Integrated Territorial Investment (ITI) [15].

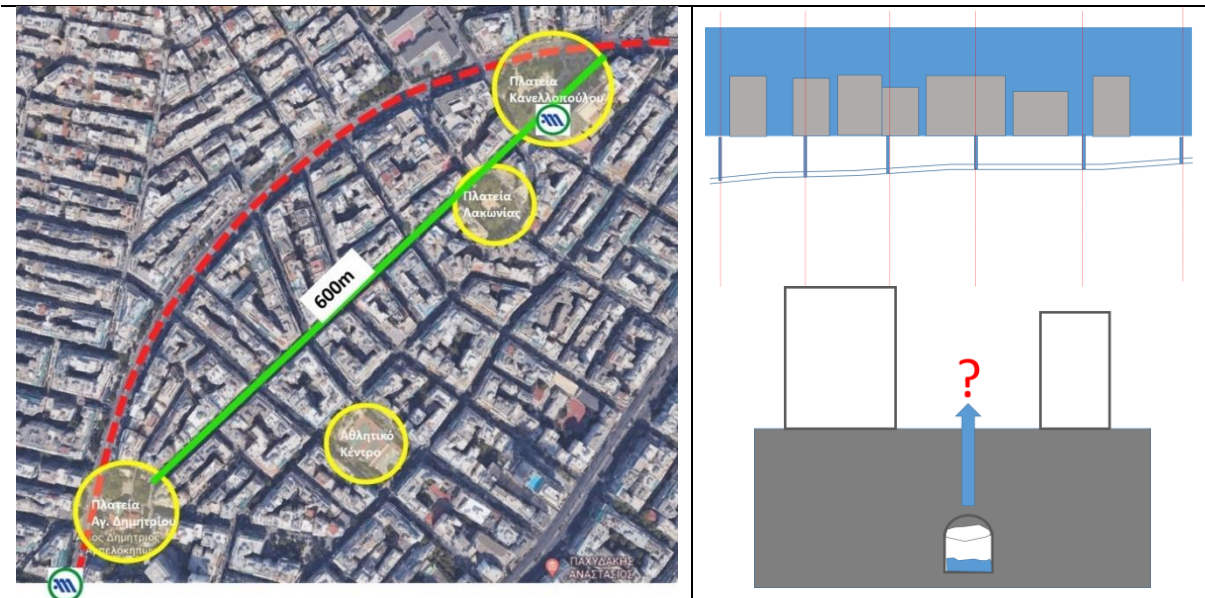

Figure 1: Exploring the resurfacing of the Hadrian Aqueduct along Louise Riancour Street in the central district of Ampelokipoi

In this context the studio aimed to investigate how this goal could be pursued by means of research by design. The studio focused on Ampelokipoi, a densely built mixed use residential district in central Athens on the grounds of it being one of the five most vulnerable neighborhoods to heat based on a combination of socioeconomic and environmental criteria [16]. Meanwhile, in Ampelokipoi, the trajectory of the aqueduct aligns over a distance of 600m with a wide local road (Louise Riancour) that has the potential to become a neighbourhood centre.

The aim of the course has been to bring into focus the presence of the Hadrian Aqueduct and redesign the axis of Louise Riancour Street as a public promenade zone and refuge for heat relief, while also addressing concerns of restituting typological order and enhancing urbanity. More specifically the questions addressed by the studio were the following:

- How can the presence of the aqueduct have an impact on the surface and give a new identity to the neighbourhood?
- How can the redesign of the street have a transformative effect promoting the principle of the 15 min city?
- How can the water of the aqueduct be used to improve climatic conditions and cooling of the area?

The study was organized in three stages. The first stage involved design investigations that focused on the element of water in the city and the design of water features with reference to the history of the Aqueduct in combination with readings of the site's urbanistic characteristics and identifying the parameters that inhibit typological coherence and unity. The second stage involved formulating a schematic design proposal for the redefinition of the axis according to a chosen theme and typological order, making note of the presence of the Aqueduct in the surface and addressing issues of accessibility, program and ecological design of public spaces. The last stage involved elaboration of specific design interventions and landscaping.

Figure 2: Final results of the urban design studio for the adaptation of Louise Riancour Street as promenade and heat relief zone (studio leader: Athanasios Pagonis)

4. RETROFITTING THE UNIVERSITY CAMPUS

The second investigation deals with the retrofitting of idle green spaces of Athens university campuses to become more climate resilient, while enhancing their transformation into valuable public spaces by removing external and internal fences, redesigning accessibility and enhancing ecological landscape design through nature-based solutions.

Alexandra den Heijer, a professor of Public Real Estate at TU Delft and expert on the planning of university campuses who advises governments on how to make optimal decisions on the use of public facilities has included in her PhD propositions the need to transform the university campus, by “doing more with less” pointing out also that “the ideal campus of the future is a city” [17].

In the era of climate change and overheating, peri-urban green spaces have become increasingly important as spaces where the urban population can find refuge in the hot days and various functions -from walking and cycling to sports and recreation- can be hosted. Often however, peri-urban green spaces fail to fulfil their expected role because they are either compromised or occupied by other uses. This is the case of the campuses of the two main universities of Athens that were constructed on greenfield sites at the foot of Hymettus Mountain in the 1960s moving out of the centre in search of available space for their expanding facilities. It was the period of decentralization supported by the ascent of the automobile as basic means of transport, so the campuses were proudly designed with modernist urban design principles and brutalist architecture and aesthetics. Fortunately, the planting of trees enhanced forestation of the sites at a time when ecological concerns were not a priority. Today the campuses along with adjacent public institutional uses represent the only remaining green corridors that connect the city with Hymettus Mountain amid a ‘sea of concrete’. The government has recognized their ecological value by designating the area a metropolitan park and drafting a masterplan [18]. However, since that time little actions have taken place to make this plan a reality. In the largest part the institutional uses remain fenced and disconnected with problematic accessibility even though there is strong evidence that a large number of people are informally using the facilities for recreation, sports and walking.

Figure 3: The NTUA Campus in the district of Zografou forms part of Goudi Metropolitan Park but only in paper. To what extent is the crisis of the Greek University Campus attributed also to urbanistic parameters and disconnection from the urban tissue besides lack of maintenance and underinvestment?

The aim of the urban design studio led by the author in the Fall of 2023 was to reverse the existing sense of abandonment and uninviting urban environment through redefining basic operating principles of the NTUA University Campus. In particular: promoting walkability, creating an attractive landscape setting through introduction of nature-based solutions and renegotiating the relationship between the campus and the city and the range of services offered. Each student team was invited to address the aspect of climate adaptation in one of the three proposed sub-areas of intervention as follows:

- How can we re-imagine the heart of the Campus as a combination of open-air and communal functions (library, restaurants, cafes) in direct contact with surrounding educational buildings?
- How would you redesign the area of the new student residences as a pleasant and sheltered environment for collective living?
- Is it possible to stitch anew the campus with the surrounding urban grid and transform the present property boundary into a lively urban interface?

Studio work was organized in three stages. The first stage involved design investigations that focused on mapping the intertwining of formal and informal ways of learning that take place across different spaces along with site recognition and study of different typologies of Campus organization. The second stage involved formulation of a spatial and programmatic intervention strategy taking into consideration climate adaptation parameters, such as walkability and landscape rehabilitation. The last stage involved elaboration of specific design proposals for the configuration of outdoor public spaces and communal building infrastructures in the envisaged new setting.

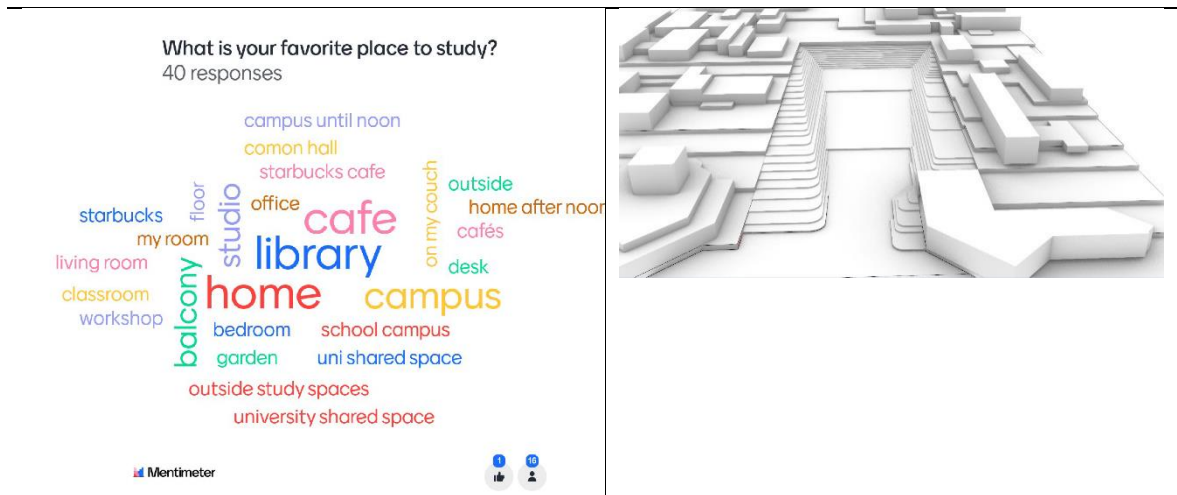

Figure 4: Interim results of the urban design studio for the retrofitting of NTUA University Campus (Studio Leader: Athanasios Pagonis)

5. RECUPERATING THE COASTLINE OF ATHENS AS PUBLIC SPACE

The third investigation deals with the redefinition of the relationship between the city and the sea in a context of shifting climatic conditions and the possibility of recuperating the coastline of Athens as public space [4]. Since the hosting of the Olympic Games of 2004 but particularly after 2015, a clear shift is noted in the dynamics of urban development of Athens towards the sea associated with public and private real estate investments, particularly the Stavros Niarchos Cultural Centre in Faleron and the development of the former airport of Ellinikon [19]. The increase of the permanent population as well as the demand for recreational services has born a significant load on the communal infrastructures and available public space in the coastal municipalities of the Athenian Riviera [20]. Combined with the shifting climatic conditions, this has pushed residents and an increasing number of daily visitors towards the seaside. In the era of the climate crisis, the beach becomes thus a new public space, a large open access urban infrastructure capable of hosting a program of activities which exceeds substantially the traditional perceptions of the Riviera: work, play, recreation, sports and exercise, improvised private and public events unfold almost on a 24hour basis and at much higher frequency. But how prepared is the Athenian coastline to accommodate these new requirements? This programmatic intensity puts a new pressure on a resource that has been up to now a residual space fragmented between various jurisdictions and subject to incremental and provisional interventions. In 2021 the Public Real Estate Fund (TAIPED) which manages the coastal land has announced its plan to create a continuous public pedestrian and cycling route, 6m wide, along the entire coastline of Athens over a distance of 22km from Faleron up to Vouliagmeni [21]. A positive initiative, but how will it play out with the existing situation in the terrain and how can we ensure that it will have a transformative effect towards the desired direction of climate adaptation?

Figure 5: Views of the study area of the beach of Glyfada with the characteristic promontories of portual facilities. The area has been divided into 9 segments with students working in parallel but coordinated investigations.

The investigation of climate adaptation interventions along the coastline and the new role of the beach as public space has been the subject of the urban design studio in the Spring of 2024 focusing on the area of Glyfada. The beach of Glyfada, a longitudinal zone of 3 km is the only outlet to the sea of a large Municipality which in recent years has emerged as the main service centre of Southern Athens. The zone is ‘sandwiched’ in-between large private real estate investments developed on former state land that has been privatized as part of the bail out agreement of Greece since 2018. The urban waterfront forms the inner ring of a system of broad axes leading to the sea interrupted by the coastal avenue (Poseidonos). This limited coastal zone is further fragmented by the presence of four small portual facilities of varying character, fishing boats, nautical vessels and private yachts that disrupt physical and perceptual continuity. Despite the fragmentation of the beach however, these interstices of unutilized land which penetrate the sea represent also opportunities for the creation of valuable green spaces due to the privileged views to the sea and the city that they offer.

The following goals were set for the design studio:

1. Reorganize the waterfront to accommodate the passing of the pedestrian-cycling corridor and to create cool and shaded rest areas.
2. Retrofit vehicular circulation and parking as well as the tramway so that they do not inhibit walkability.
3. Reinvent a new landscape identity attractive and welcoming to all types of users.
4. Restore beaches and marine facilities and renegotiate the boundary between land and sea.

The studio work was structured as follows: The study area was divided into nine segments that were allocated to different teams of students, each working on their designated site but in a collaborative way without predefined masterplan but with obligation to stitch their proposals with those of neighbouring teams. Design investigations were centered around the construction of two large physical models of the entire site in a collective way based on uniform specifications corresponding

Proceedings

to two different stages of work. In the first stage the design investigations were carried out in scale 1:666 corresponding to identification of terrain and key locational and programmatic decisions, whereas in the second stage the investigations deepened into scale 1:333 corresponding to design development.

Figure 6: Interim results of first stage investigations in Glyfada urban design studio (Studio Leaders: Athanasios Pagonis & Tilemachos Andrianopoulos).

6. DISCUSSION

The paper presented three different cases of research by design investigations for climate adaptation of public spaces in the context of Southeastern Mediterranean Urbanism located in Athens. The design investigations were carried out in the context of master's level studios held at the School of Architecture NTUA. The Hadrian Aqueduct project explored the potential of climate adaptation in the case of the dense central area with a double scope, on the one hand creating a refuge for heat relief and promoting the concept of the 15min city at neighbourhood level and on the other hand restituting coherence and typological order in an urban environment with compromised built form. The studio revealed that retrofitting existing urban space for pedestrians rather than cars and introducing micro-climate improving design can bear a transformative effect. The University Campus project explored the possibility of turning idle outdoor spaces of public ownership within fenced institutional compounds into valuable green spaces offering comfortable climatic conditions to their users but also nearby residents. The project revealed that urbanistic problems deriving from isolation can be resolved by removing boundaries and enabling the dual condition of 'the city in the campus and the campus in the city' to evolve'. Also, that there is significant ground to reconstitute the urbanity of university life in a new context of a climatically resilient environment that both nourishes and benefits from restored ecological functions. The Glyfada beach project explored the potential of the coastline of Athens to become an open access public infrastructure capable to respond to the increased needs of permanent residents and daily visitors for cooling and recreation as part of their daily routines and itineraries. The project interim results already reveal an enormous potential for the coastline to

become an attractive, climate resilient but also inclusive territory of high capacity provided that it is treated in an integrated way and individual requirements are disciplined by the respect to common principles and collective interest.

Coming back to the main research question of the paper the analysis of the case studies revealed that there is a great scope of work in retrofitting the existing urban environment of the Mediterranean City towards meeting the goals of mitigation and adaptation. Design goals have always to be framed within a solid understanding of the local context of urbanism. Questioning the existing urban condition and not taking it for granted through an investigative urban design has the capacity to deliver innovative findings on how design transitions can be set forth.

Abstract

The paper discusses the necessary integrated approaches and design actions aimed at fostering a future-proof built environment through the (re)design, retrofitting, and transformation of public spaces into sustainable, resilient, inclusive, and attractive areas for inhabitants and visitors. It emphasizes the importance of adapting to and mitigating the effects of climate change, as well as addressing spatial advantage and quality, social well-being, and ecological balance. Can we leverage climate adaptation and the urge for the energy and mobility transition as catalysts for spatial transformation to benefit inhabitants? Can this lead to improving attractiveness and use of public space within their neighbourhood? Can design thinking, with a focus on societal values, overcome governance's preoccupation with costs?

The City x Space design study demonstrate that an integrated design approach from different perspectives and disciplines can tackle the multitude of transitions in diverse urban settings, with public space -including its subsurface- playing a pivotal role in improvement or even transformation. Six design cases in different Dutch and Flemish cities, spanning historical, post-war reconstruction, and post-industrial contexts, showcase tailored solutions that contribute significantly to creating a more attractive and inviting future-proof built environment. The combination of a more formal set-up, a clear *Research-by-Design* approach with included assessment criteria, and the involvement of multidisciplinary design teams from practice provides both directions from a policy perspective and freedom from a design viewpoint to explore and envision plausible futures for selected locations.

The main conclusion is that policy makers, architects, urban designers, and landscape architects must deal with new and shifting conditions with a focus on societal, spatial, and ecological values. For policy makers, it is relevant to translate insights from designs produced by *Research-by-Design* into their policy processes for developing a prospect for action. Both professional practices and education need to foster innovative and interdisciplinary design strategies in a more holistic and integrative approach within their cultural-historical architectural and urban contexts. For both current and future spatial designers, the task -but above all the opportunity- is to position themselves more as integrators and agents of change contributing to a paradigm shift that can drive tangible adaptation and improvement in our living environment at the local scale.

Keywords: *built environment, public space, climate change, shifting conditions, paradigm shift, holistic and integrative approaches, research by design, design actions, multidisciplinary collaboration.*

1. INTRODUCTION

This paper presents the results of the design study *City x Space* (Stad x Ruimte) conducted in the Netherlands and Flanders in 2021 and reflects on the effectiveness of the *Research-by-Design* approach facilitated by the initiators. The design study explored the potential of multifunctional and plural use of space for existing and future purposes and functions within the built environment [1].
