This was done through an integrated design approach where public space, subsurface, and buildings were considered as a cohesive solution space by multidisciplinary design teams. The study encompassed design measures for climate adaptation, housing and social issues, and system transitions for energy, mobility, circularity, and ecology. In the Netherlands, study locations and cases were provided by the cities of Amsterdam, Maastricht, and Rotterdam, while in Flanders by Leuven, Mechelen and Oostende.

The initiative and organization for this design study were a collaboration among the Centre for Underground Construction (COB), Delft University of Technology (TU Delft), the Flemish Government (Department of Environment) and the Deltametropool Association (VDM). The urge for this study stemmed from foreseen claims on existing scarce space within dense cities due to the needs for housing, energy transition, and climate adaptation, and how this matter can be faced through a more efficient use of space. The study also encompassed the subsurface, typically regarded as terra incognita mainly seen as storage space for utilities such as sewers and cables or for transportation like metro systems and car parking. Concurrently, a Dutch governmental program for public space was initiated, aligning with the aims of the study. Cities presented issues and questions related to their locations, like the monofunctional use of space in an outdated inner-city sports park (Leuven), the potential of a heat-grid within a pre- or postwar neighborhood, also susceptible to flooding by excessive rainfall (Amsterdam, Maastricht), opportunities for circularity within a redevelopment harbor site (Oostende), the potential of a multifunctional landmark building as catalyzer for transformation of an inner-city post-industrial site (Mechelen), and the transformation potential of a large-scale traffic roundabout adjacent to a redevelopment port area and impoverished residential neighborhoods (Rotterdam). These were not presented as actual assignments for tendering or projects but as policy ideas aimed at better understanding how issues could be addressed through more efficient use of space.

For COB and the Flemish partners, the study provided an opportunity to engage with and learn from the design study and a Research-by-Design approach, which was new to them. For TU Delft, it offered an opportunity to apply and to evaluate a method for characterizing and visualizing the subsurface and to assess design proposals for locations in a more methodical manner than in previous design studies. A more formal assessment of design outcomes, resulting from various Research-by-Design approaches, should receive increased attention. As approach, a significant growth is seen in the Netherlands in spatial and urban planning and urban design over the last decade, with policymakers at various governmental levels embracing its results in policy development and programs. However, there is a lack of clear definition and documentation for these approaches, and its designs inherently involve speculation. Therefore, there is a need for a better understanding of both approach and its results to enable policy and practice to appreciate its significance and potential impact in full extent. How transparent is the process to get results? And how predictable and unambiguous are these? Especially, given the uncertainties and impacts of climate change, the multitude of system transitions, and the necessary investments to make the built environment more future proof. This understanding is also crucial for education, preparing students for their future careers and roles in the spatial domain.

1.1 Design, research, and abduction

Design has various definitions and application, encompassing a broad range of disciplines and professions involving in conceptualizing tangible objects, processes, or substances in the human-made world. In general, designers are viewed as creators, engineers as problem solvers, and researchers as discoverers. However, this distinction becomes artificial when considering the comprehensive learning cycle that embodies all these aspects. Within architecture, design and research are interrelated based on two separate determined or indefinite variables for an object and its context [2]. For instance, designing a station building at a planned location involves a determined object and context, with research informing aspects such as accessibility. This is defined as *research*

Proceedings

for design. Conversely, an old, deserted factory location could present an open-ended scenario for its future purpose. In this case design can provide insight and understanding of location's potential and alternatives. This is defined as *research by design*, characterized by an indefinite object and context. The European Association for Architectural Education (EAAE) defines *research by design* as any kind of inquiry in which design is the substantial constituent of the research process. It should lead to new insights, knowledge, practices or products which is consistent with experience in practice. Its results must be original, significant and rigorous as architectural research requires [3]. The Royal Institute of British Architects (RIBA) also refers to the same criteria that define quality for scientific research in general. These criteria address both process and output, where communication and peer review are mechanisms to assess and reflect on those criteria. The involvement of practice is seen as relevant due to its practical nature and the relationship between architectural processes, products, and performance [4].

Like these definitions, Dorst explains the notion of *abduction* and the way designers in general reason, based on the equation *WHAT (thing) x HOW (working principle) leads to VALUE (aspired)* (1), in the context of problem solving and design thinking [5]. When applied to architecture, the design and construction of a house (WHAT) to provide shelter and comfort for a family (VALUE) can benefit from archetypical designs and proven construction techniques (HOW). However, if the desired value of shelter and comfort is not for a family but for vulnerable persons who needs also care, then the WHAT would be an open question. This is defined as Abduction-1, representing traditional problem solving. In case the known working principles are strictly related to design a house or hospital, then there is also an open question for the HOW, leading to Abduction-2. This introduces two unknowns that should be resolved in parallel, requiring a novel approach due to their open and (more) complex nature. For this reason, the notion of *frame creation* is introduced, facilitating the investigation of themes related to the aspired value to discover new working principles and its application in a design which could hypothetically lead to this value.

The primary focus of the design study and its collaborating partners also extends to the public domain. Design and design thinking are recognized concepts within the realm of public administration and public policy [6]. In the early stages of this field, it was also characterized as a design discipline, with policy interventions aiming at problem solving for societal issues. However, as challenges such as climate change and migration become more complex, alongside the involvement of multiple stakeholders with diverse needs and interests, questions arise about the effectiveness of traditional policy development methods for addressing these complex, wicked, and ill-structured problems. There is a growing need for novel approaches that align with core values of public administration, including accountability, legal certainty, and predictability. Design thinking, which prioritizes societal values over mere problem identification and intervention, is increasingly seen by policy experts as a solution to the current state of policy development. In general three directions are recognized: 1) Design as optimization, as a continuation of the problem solving approach by experts for well-defined issues while considering societal impact and involving stakeholders; 2) Design as exploration, searching for creative and innovative solutions for more open issues and stimulating human-centered design thinking; 3) Design as co-creation, engaging affected actors for the definition of problems and solutions in order to learn collectively and to enlarge commitment. However, contemporary design approaches, particularly those aligned with exploration and co-creation, often raise concerns regarding effectiveness and innovativeness of resulting policies and relevant conditions. Their meaning lies more in policy definition, aiming to create a better understanding rather than improving decision-making, based on a balance of analytic rigour and societal relevance.

1.2 Research-by-Design for the built environment

When reflecting on [2], [5] and [6], a closer examination of the variables for context and value is warranted. In relation to the built environment, an object is inherently connected to a multi-actor

setting beyond its physical context, with various needs and interests addressed by policies and regulations. These are undeniably linked to the desired value(s) of these actors, whether users or clients, driven by their purposes and objectives. These latter factors represent *steering*, with value as their *outcome*. When purpose is interpreted as the (working) hypothesis stemming from the analytic and inductive exercise -by the creation of a new frame on basis of the desired value and novel working principles- then a design will not yield a binary result like false or true, as with a theory. Instead, the design process is deductive, akin to justifying a hypothesis in research, yet it is qualitative and hard to justify as the sole and righteous answer. Moreover, the design process is iterative, a facet overlooked by equation (1), next to its omission of context. The extent to which the desired value would be realized through several iterations remains uncertain, further emphasizing the distinction between design and scientific research. The latter is binary in its justification, confirming predictability and facilitating the accumulation of knowledge. In case of design, we can assess and determine to what extent the value is delivered according to its purpose.

When reconsidering aforementioned reasoning within the built environment domain, it could be formulated as follows: *PURPOSE (objectives) steers WHAT (object) x CONTEXT (plural) x HOW (working principle) leads to VALUE (outcome) (2)*. Main assumption is that the purpose is hypothetical and explicitly stated, originating from many sources: via the analysis of the values and working principles, as an idea from a single thought, as a position, or as an actual issue. The purpose may be ambiguous, open, and complex. The plural context may include physical and social, governmental, economical, financial, technological, legal, cultural, historical, and ecological aspects. Concerning the variables, the degree of abduction is higher with an additional variable, making the equation more complex as it reflects reality. In any case, for equations (1) and (2) there is no guarantee that both the analysis as inductive activity, as well as the design as deductive activity, will be appropriately and transparently executed. Scientific research has its protocols and extended review systems, alongside the developed attitudes and competences of researchers through education and training. As noted before, analytic rigour is necessary to become transparent and effective. To achieve this, a sound and clear organizational and process set-up should be in place for the execution of analytic and design activities to instill confidence in the plausibility of a design and its assumed value.

1.3 Research questions and objectives

The design study City x Space is the latest instalment in a series of design studies initially co-initiated and co-organized by the Dutch Architect Association (BNA) and TU Delft. These studies focused on exploring opportunities for the use of space at various locations considering societal and technological developments, as well the potential impact of climate change and related system transitions in energy, mobility, circularity, and ecology. The locations included station areas [7], areas adjacent to urban highways [8], potential (re)development sites [9], and social housing neighborhoods [10]. COB, comprising members from engineering firms specialized in infrastructure, water, and construction domains, was particularly interested in how spatial designers perceive the subsurface from a design perspective, and how they address issues using a Research-by-Design approach. The Flemish government also expressed interest in exploring the potential of the subsurface for functions and program beyond utilities, as well as understanding how a Research-by-Design approach could be instrumental for getting more insights in spatial related issues. As outcome of discussions among the initiators, the following central question was formulated: *How could an integrated and multifunctional use of space, with a focus on public space, subsurface and buildings in a dense urban environment, create space and added value which contribute to an attractive and future proof living environment?* This main question pertains to the how, what, context and value. The purpose stems from the interests, policies, and position of the initiators and collaborators, where the integrated and multifunctional use of space serves as the key hypothetical working principle for designing an attractive and future proof living environment, representing its aspired value.

Proceedings

Additional questions provide more direction and detail: 1) How could the (re)design of a strategic location contribute to spatial advantage, improving the living environment and strengthening resilience to climate change of a city?; 2) Which combinations of functions are desirable and favorable for a location considering societal needs and environmental conditions?; 3) How to integrate an object in an innovative way at system level and at a larger scale?; 4) How to create economical, societal, and ecological benefits by combinations of functions and spatial efficiency?; 5) How to incorporate different system transitions, flexibility, and resilience?; 6) How could an intervention for a location also contribute to area development or creating new conditions for this?; 7) Which future images, scenario's, design principles, innovations and approaches could be developed and useful for policy and practice? These questions also introduce a multitude of contexts and value related themes for frame development alongside the key hypothetical working principle.

2. METHODOLOGY

The accumulation of issues and variety of contexts reveal an open and complex situation for each study case, justifying an explorative Research-by-Design approach instead of a traditional design approach with defined variables. From a methodical perspective, the diversity of cases is relevant for comparing and understanding the relationship between the hypothetical working principle and associated design interventions, their value contributions, and conditional differences. This also provides insights into the potential for broader application and generic lessons. With its typological characterization of study cases and methodological intention on testing and analyzing the relationship between purpose and open variables, this study differs from the aforementioned design studies. It aims not only to produce future images but also to seek a better understanding of the conditions under which a Research-by-Design approach can yield plausible and explainable results based on a transparent process from a methodological viewpoint and within an urban planning and policy context.

2.1 Operationalization

The values derived from the main question were operationalized into the following main criteria: 1) Spatial advantage, 2) Environmental quality, and 3) Future proofing. The potential to realize these values was operationalized through the main criterion of 4) Realization.

This operationalization emerged from discussions among the organizers, the interpretations of case descriptions provided by the cities, and from relevant Dutch and Flemish national policies [11]. Each criterion has specific sub-criteria, like spatial efficiency, health, resiliency, etc. The criteria serve as the core of an assessment framework integrated into the process set-up (Figure 1). The operationalization process, occurring within the social context of various actors and criteria which entail a plural context, makes clear that an explicit attention for values and their origin is critical to find common ground and room for them. From a stakeholder perspective, this establishes a collaborative baseline and guides the design purpose, where values and derived criteria, along with the key hypothetical working principle, constitute a *starting frame* for designers. This provides organizers and cities the opportunity to evaluate the extent to which design proposals contribute to the desired values. The criteria are not quantitative performance indicators which is not problematic considering the purpose and nature of the design study, characterized by an open, ambiguous, and complex main question. Furthermore, the low-level of detail in the designs limits the opportunity to assess in full extent. As an ex-ante assessment, it implies a priori and fictitious contribution of design interventions, necessitating qualitative assessment from a multidisciplinary expert perspective.

2.2 Study set-up

The organizers of the design study issued an open call for participation via Dutch and Flemish architect, urbanism and spatial planner associations and networks. The study's intentions, cases,

method, and set-up were presented at a well attended information meeting, where attendees were encouraged to join as multidisciplinary design teams for specific cases. Selection criteria included motivation for the study, vision for the preferred case and method, the disciplinary composition and experience of the team, and willingness to contribute based on a fixed fee. The selection for a particular case was made by the respective city. In addition to the professional design teams, student teams from the architecture and urbanism departments of TU Delft were also involved within a curricular studio setting. Prior to commencing the design activities, three masterclasses were organized by the organizers, featuring topics and state of the art insights by scientists, policy advisors, technical experts, and designers. The first masterclass focused on spatial planning and transitions for climate adaptation, energy, and mobility. The second masterclass delved into design approaches and technical aspects related to the subsurface. The third masterclass addressed business cases involving the subsurface use of space and stakeholder approaches. These masterclasses aimed to establish a common knowledge base and provide updates for the design teams, with extra attention for the subsurface, which may be not the primary focus for spatial designers.

The applied framework for the Research-by-Design approach shows the relationship between the central question, which incorporates the design purpose for value creation, and the specific issues from the cities, represented by the local question for a strategic location (Figure 1). The design purpose functions as the *starting and reference frame* for the multidisciplinary design teams, focusing on the integrated and multifunctional use of space as the hypothetical key working principle, along with the generic values as operationalized for the assessment framework. The local question specifies the unique issues and values for the location within a local and, eventually, national policy and social context. Next to these the current

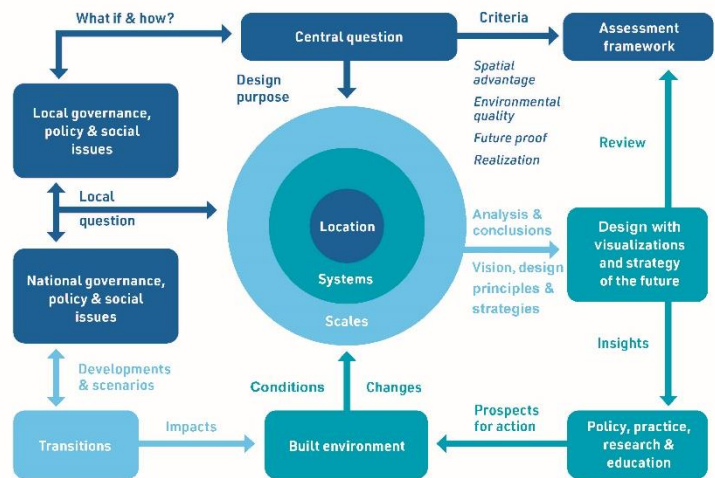

Figure 22. Framework for a set-up of a Research-by-Design approach, integrating research, design, and assessment.

conditions of a location which may already be affected by the impact of climate change and one or more transitions. The local question was discussed between city representatives and members of a design team during the first local workshop and site visit held for each location of the design study. The *what if* notion refers to the exploratory nature of the central question, its aspired values, and to the potential and uncertain impact of a multitude of transitions on the built environment and location, along with its subsequent scales and systems.

At the level of the design study, two fixed plenary meetings were scheduled for all participants. The first was dedicated to the analysis by the design teams of their case and the conclusions drawn from the inputs and location analysis. Some teams already provided a direction for further development of a vision on *what* and *how* for their location. Due to its plenary character, there was an exchange between cases and design teams, with a panel of external experts providing reflections from different perspectives. Between the first and second plenary session -for the elaborated vision and design- local workshops were planned for a more in-depth discussion involving city representatives, design teams, and in some cases, other invited actors related to the location. The second plenary meeting served as the final event where the designs and future images of the locations were presented to all involved participants. This included a strategy to connect the vision with subsequent steps or phases for interventions within a time window. Once again, city representatives and an external panel reflected

Proceedings

on the designs for the locations. A dedicated final event was organized for the student work and teams due to the curricular schedule not aligning with the design study schedule. Representatives of the cities joined this event to reflect on student's visions and designs and for its takeaway.

The subsequent phase for documentation and interpretation by the organizers and invited experts marked the conclusion of the design study. In addition, to local meetings held to inform a broader audience about the design proposals and to facilitate discussions for potential collaboration, the interpretation process followed a two-tier approach. Firstly, relevant themes were defined, experts were invited to and deepen their perspectives on these themes, which also served as a reference for assessing the designs. Secondly, the designs were assessed according to the criteria derived from the central question. The chosen themes and perspectives included integration, subsurface data and representation, urban and architectural concepts and approaches, investments and finance, spatial cohesiveness, urban value, change and steering. For the assessment according to Figure 1, design teams were requested to do a self-assessment of the extent to which their designs contributed to the main criteria through an ordinal score, supported by the interventions in their designs. Conclusions from both approaches formed the basis for fourteen generic lessons (3. Results, Table 1).

The study did not include a methodological inquiry into the extent to which cities continued with the results as part of some prospect of action for actual change related to their strategic locations.

2.3 Applied techniques

Expert sessions dedicated to the subsurface were organized by TU Delft for design teams and local experts. To assess its occupation and conditions, the System Exploration Environment and Subsurface table (SEES) was introduced [12]. This table differentiates several layers such as buildings, infrastructures, public space, and subsurface, and covers topics like civil constructions, water, energy, and subsoil. Available data about sewage pipes, heat-grids, power and data cables, foundations, constructions, water reservoirs, soil composition and condition could be categorized and be classified as dynamic or static. A completed table was translated into a visual representation through a set of plan-view and cross-section drawings prepared by TU Delft. These drawings informed design teams about the present spatial condition of the subsurface at a location, aiding them in considering for their interventions. During the analysis and design activities carried out by the design teams, a wide variety of methods and techniques were employed. Examples of these are functional and system analysis, a layer approach, a circular and flow approach, a parametric approach, and a sustainability capitals approach. The framework of Figure 1 offered designers full freedom to apply methods and techniques with which they were familiar.

3. RESULTS

The results of the design study revolve around the designs for the locations. Their potential contribution to the values was assessed by the organizers, as defined by the central question, and operationalized by the criteria. Some exemplary values and aspects are illustrated by one of the many visualizations delivered by the design teams. Additionally, the designs were scrutinized from various perspectives by experts to discern and characterize defining aspects. This all has led to fourteen lessons learned, which could be valuable for cities that have ideas or facing open, complex, and ambiguous issues concerning a location, and for designers in practice, as well for architecture and urbanism students (Table 1). The effectiveness of the applied Research-by-Design approach will be addressed in the conclusion chapter.

3.1 Addressing spatial advantage, environmental quality, and futureproofing in an integrated manner

Several designs show the opportunities that the energy transition could provide for integrating measures for climate adaptation, prioritizing pedestrians, and cyclists, and creating attractive public spaces. They address: 1) spatial advantage through the combination of mobility and energy functions, and use of the subsurface; 2) environmental quality through removing parking spaces, adding green, and providing value and usability for inhabitants; 3) future proofing through the introduction of a heat-grid, and enhancement of the resiliency of public space to heat-stress and flooding by increasing water infiltration and retention. For dense neighborhoods, a heat-grid may be the preferred system from a financial perspective, but it also opens the opportunity for a redesign of public space (Amsterdam). Similarly, less dense neighborhoods like those in Maastricht, Leuven, and Oostende, could also benefit from these combined measures achieving cost reduction. Also, the need to replace old sewage systems, as seen in Amsterdam and Maastricht, could provide an opportunity for an integrated approach. The introduction of flexible structures and the combination of functions shows potential for spatial advantages and mid- and long-term business viability (Amsterdam, Mechelen and Leuven). Moreover, novel function combinations, as part of transport and flood defense infrastructure interventions, also demonstrate potential for spatial advantages and business cases related to additional real estate (Rotterdam). The designs illustrate the relationship between public space, the subsurface, and buildings, emphasizing the need for an integrated approach to all spaces.

3.2 Assessment of technical and architectural concept

Several designs introduced new concepts for interweaving ground and subsurface level, removing the hard distinction between the upper- and underworld. This was done through the use of interconnected layers of public space (Rotterdam, Leuven, Mechelen). The use of an open casco construction for subsurface or building spaces offers flexibility for present and future functions, enhancing the designs' futureproofing and cost-benefit ratio (Amsterdam, Leuven, Mechelen). Regarding spatial cohesiveness and urban value, most designs primarily impact the immediate location. However, some designs have influence to surrounding neighborhoods by introducing complementary functions and programs such as housing, jobs, and amenities (Rotterdam, Oostende), or by establishing an ecological and utility framework (Leuven).

Figure 2. Maastricht: 'Energy boulevard' as carrier for an attractive and future proof public space [13].

Figure 3. Rotterdam: *Dike Park* with integrated water retention and utility space [14].

Figure 4. Amsterdam: modular and flexible subsurface blocks and redesigned public space [15].

Proceedings

Figure 5 and 6. Leuven: *Climate joints* connect sport park and surroundings, and integrate ecosystem services, and utilities. Cross-section of a Climate joint with integrated cycle route [16].

3.3 Design clues for realization

All designs provide clues for potential financial benefits, opposite to the costs of interventions which is pertinent for developing a business case. The design for Leuven offers ecosystem services and a flexible utility structure that reduce costs for connecting neighborhoods and maintenance while the renovation of the sport park should be covered by additional space for new functions and program. Long-term benefits could be derived by exploiters from the heat and cold storage system integrated into the climate joints. The design for Mechelen presents open and transformative spaces in their park building, potentially yielding future exploitation benefits if integrated into the business case for investments. The design team for Oostende has developed action cards for stakeholders, showcasing design interventions from a catalogue of solutions related to circular flows of water, materials, biodiversity, energy, and program. These could be instrumental in forming a coalition of relevant stakeholders to tackle the redevelopment of the port area. The designs for Rotterdam focus on the addition of real estate for housing and amenities opposite to the large investments for infrastructure. Since a dike is central for flood protection, this could give a clue for investments from the Dutch national governance. For both Amsterdam as well as Maastricht, the renewal of utilities and addition of a heat-grid are large investments with long-term benefits. Existing maintenance budgets should cover the renewal and could help to reduce costs for the heat-grid concerning opening and digging in streets and its hindrance for a lengthy period. The improvement of public space by green, water infiltration and retention could be also part of maintenance budgets or financed from climate adaptation funds in case these are available from governmental bodies.

3.4 Lessons learned

From the assessment of the designs, fourteen lessons were formulated by the organizers for an integrated and multifunctional use of space in the context of climate change and related system transitions. Clustered into three steps, these lessons offer a different direction than traditional problem solving. The equation (2) contains too many uncertain variables, whereby the challenges question the present way systems are organized and perform, while realized projects are in their infancy phase before they could become best practices or even paradigms. The eventual realization of designs as presented in this study is complex and time-consuming, as urban design and area development generally are. However, the lessons show that there are answers that could serve a broader academic and professional audience than only those involved in this Dutch and Flemish study.

Table 1. Lessons learned based on the designs and their assessment.

14 lessons for integrated and multifunctional use of space
<i>Take a different perspective</i>
1. Consider the cross-section of subsurface, public space and building as a new paradigm for integrated multifunctional use of space.
2. Consider the subsurface as a valuable building block to improve the quality of the living environment above the ground.
3. Have an eye for the larger scale and systems.
4. Look beyond the traditional land and real estate development cycle.
<i>Change one's mind</i>
5. Focus and steer based on values.
6. Design for change.
7. Make use of planned interventions in the subsurface.
8. Define an integrated business case.
<i>Act differently</i>
9. Apply Research-by-Design for exploration, idea development or the definition of plural issues where the context, conditions and impact are uncertain for the mid- and long-term.
10. Use storytelling and future images for communication with stakeholders.
11. Use storytelling and future images for communication with stakeholders.
12. Research-by-Design is not without engagement.
13. Subsurface data should be available and updated.
14. Consider how investors structure and assess costs and benefits.

4. CONCLUSIONS AND DISCUSSION

The designs show the potential for multifunctional and plural use of space for both existing and future purposes and functions within the built environment, offering a broad variety of approaches and solutions for various locations. Their potential contributions to the central question reveal similarities as indicated by the main criteria of spatial advantage, environmental quality, futureproofing, and realization. Despite the difference of visions, applied design principles and strategies, and the actual designs they all have a comparable contribution to the values. The use of a clear central question and derived criteria represents a steering force that is detached from a location's character, allowing for fresh and creative approaches with tailor-made solutions. This top-down focus on values does not hinder bottom-up inspiration and innovation.

4.1 The significance of the designs and lessons

The significance of the designs is twofold: 1) providing insight for involved cities into given issues and their translation into potential value for their location by the design; and 2) serving as study cases that lay the foundation for generic lessons for a broader audience, including policy makers, design professionals from practice, architecture and urbanism students, and scientists. A broader application of the designs is limited to similar locations and conditions which in general is unlikely. As such, the designs are not templates for reproduction due to the specificity of issues, policies, actors, and other contextual conditions. They serve more as inspiration, illustrating that the integration of functional and spatial measures can lead to cohesive and insightful designs. The lessons are more generic, with the applied visions, design principles, and strategies inspiring practitioners to consider and apply them for other locations, while informing students to expand their design toolbox. The lessons emphasize the necessity to take another look on issues, systems, and space as a first step in rethinking existing practices and approaches. Internalizing these lessons could lead to new directions in practice that develop and apply approaches contributing to a future-proof built environment.

Proceedings

Design studies like these are more grassroots initiatives that highlight the inadequacy of present sectoral approaches in addressing the challenges and issues we face. New intersectoral and interdisciplinary approaches and collaboration are needed to develop best practices that convince policy makers to join the effort. Actual realizations, however small can serve as references or catalysts when pioneering policy makers manage to overcome organizational hurdles. For practice, this presents an opportunity to develop new business and competences. For education of spatial designers, it offers the chance to prepare students for a new practice that requires a broad understanding of various systems and values, as well as competences in system and design thinking. When policy, practice, and academia engage themselves more effectively and collaboratively with the challenges facing the built environment, a growing community can develop and embrace novel approaches, methods, and strategies, ultimately contributing to a paradigm shift in the long run [17].

4.2 Research-by-Design as a transparent process for plausible outcomes

From a methodological perspective, the design study and its outcomes show that adopting a more procedural set-up to a Research-by-Design approach enhances transparency and credibility in both its process and results. This approach clarifies both the potential and limitations of what can be expected from this way of working. The scheme of Figure 1 represents a steering model primarily guided by key issues and policies, in which the central question and its values are the main steering mechanisms through the design purpose and assessment criteria. The resulting designs undergo review and reflection by experts and practitioners already during the process, aligning with the mechanisms of architectural research mentioned by the EAAE and RIBA. The assessment against the criteria encompasses both methodologically and qualitative aspects. The insights gained can inform feedback loops via intermediate structures and processes in policy, practice, education, and research. In the context of the procedural set-up and reformulated equation (2), the PURPOSE is filled-in by the central question, WHAT by the location's designs, CONTEXT by the policies, actors, systems, scales, and conditions, HOW by the visions, design principles and strategies, and VALUE by the potential contributions of the designs to the desired values within the central question. The inclusion of the context variable is evident for architecture and urban design considering the built environment, as De Jong discussed design and related research. It is also pertinent in product design, as Dorst, originating from this background, initially introduced equation (1). This broader perspective reveals complexities often overlooked when designers solely focus on the object as a *pure artefact* to design. The designs and approaches of the design teams show that there is no fixed content for the variables leading to a single answer. Different content yields different outcomes, which is not problematic if the objectives and results are recognized and appreciated by the problem owner. This is not only about its originality and significance as EAAE and RIBA have pointed out but also in its potential to be put on a policy agenda. This underscores the need for transparency and plausibility through rigorous analysis, as also noted by Van Buuren. The presented procedural set-up can ensure these qualities while enabling clients to provide guidance through defined values and maintain control over the process without interfering with the required creativity and imagination of designers.

4.3 Future research topics

The effectiveness of the applied Research-by-Design approach lies in providing insights into issues, solutions, and values related to climate change and inherent system transitions, particularly for cities in their specific locations. They must translate these insights in actionable prospects, using design as starting point for dialogue with relevant actors within their policy context. However, this design study cannot definitively determine the extent to which the designs have been or will be effective for policy development, planning, or actual change in near future. Conducted between 2021-2022, the study and its documentation occurred within a relatively brief period in the context of policy processes. For Oostende, the city commissioned the design team for further investigation aligned with their design.

COB has developed a toolbox for spatial and adaptive planning and design, including subsurface and flexible structures, along with a serious game for value determination of spatial ambitions [18]. The Flemish government communicates the environmental qualities for public space to a broad audience. The Dutch Minister of Housing and Spatial Planning employs Research by Design as an approach in general for exploratory research into spatial issues within the context of climate change and inherent system transitions. However, dedicated research is required to better understand the effectiveness of the different Research by Design approaches in driving actual change.

Another area for research is understanding the built environment through paradigms, recognizable architectural and urbanism manifestations, and data within the notion of shifting conditions as set by climate change. A framework that can detect change in the context of climate change and related system transitions could be valuable for identifying and classifying actual realizations as reference projects, informing further development toward a future-proof and attractive built environment [19]. Public space, including its subsurface, could serve as a tangible steppingstone, addressing challenges, leveraging opportunities, and embodying values. Categorizing widespread manifestations could yield a catalogue of novel and dedicated interventions within their cultural-historical architectural and urban context. When combined with open data and open-source parametric computational tools, it could enhance the rigour of analysis activities. Integrating data-driven and parametric methods and techniques into a formal Research-by-Design approach could improve transparency and plausibility.

Extended abstract

This contribution examines the current challenges faced by 20th-century Dutch housing neighborhoods. Many of these neighborhoods were developed based on modern urbanistic and architectural principles, emphasizing functionality, simplicity, and the use of innovative construction materials. They were primarily established as social housing projects outside historical centers, aiming to provide residents with improved living conditions compared to existing overcrowded and substandard housing. Today, due to subsequent developments and expansions of cities, these neighborhoods often find themselves situated close to pivotal infrastructural connections and play crucial roles in urban transformation strategies. However, despite the Netherlands' reputation for innovative solutions, several Dutch cities encounter significant difficulties in integrating climate adaptation and energy transition measures with the socio-economic issues affecting residents of these urban areas.

The most prevalent challenges relate to socio-economic disparities and different cultural backgrounds of the inhabitants, leading to social exclusion, lower educational attainment, limited opportunities, unemployment, and higher levels of poverty. Additionally, the lack of affordable housing, rising property values and rents also pose gentrification risks, threatening established communities. Integration and diversity present further challenges, necessitating strategies for social cohesion and intercultural communication. Safety concerns and inadequate public spaces further impact residents' quality of life, requiring urban design approaches that strengthen social programs, affordable housing, and public services. Simultaneously, addressing these issues must align with climate adaptation and energy transition measures. Implementing heat-resilient urban design, such as green spaces and reflective surfaces, can mitigate the urban heat island effect, improve air quality, and provide recreational areas. Sustainable water management techniques, including permeable pavements and retention ponds, reduce flood risks. Infrastructure upgrades, like retrofitting existing systems to meet new climate standards, are essential. Finally, community engagement is crucial; residents must be encouraged to participate in discussions to increase awareness and willingness to adopt climate-resilient behaviors.

To comprehensively address these challenges, a holistic, design-driven research approach is necessary. Designers, local authorities, stakeholders, community organizations, and residents must collaborate to develop and implement strategies that enhance the overall quality of life in neighborhoods, fostering more equitable and sustainable communities. Following this line of thought, this contribution seeks to elaborate on the roles of design and designers by examining relevant projects, practices, and experiences in Dutch cities. The study leverages the principles of the New European Bauhaus (NEB), aiming to bring together sustainability, aesthetics, and inclusivity as fundamental pillars for promoting the green transition throughout Europe.

Abstract

This paper introduces a data-driven approach for assessing and monitoring urban environments, building on prior typological classifications to support decision-making in various urban contexts. These environments, each distinguished by unique characteristics, collectively experience effects of climate change and transition. However, based on their levels of vulnerability and resilience, they encounter different outcomes. Such variations require targeted analyses and strategies to develop adapted solutions for the issues at hand. Our proposal introduces a computational framework encompassing three main steps, i.e., classifying urban environments based on quantifiable characteristics, pinpointing key performance indicators (KPIs) specific to each classified typology, and suggesting tailored interventions within the context of their type/class. In this paper, we discuss the role of classifying urban areas in understanding their dynamics and developmental trends based on open data. We further summarize the main steps proposed by the data-driven computational framework.

Keywords: *urban typology, open data, decision-making, urban attributes, climate change, classification.*

1. INTRODUCTION

The characteristics of urban areas are often influenced by the prevailing design philosophy and building regulation of the time, their political and social imprint and the attributes of the specific geographical location. They reflect the ideas, topologies and technologies prevalent during their planning, evident in their authentic manifestation through housing size and typology, street width and their cross-cut morphology, extent of public green spaces, distribution, and accessibility of services etc. Bearing in mind the multiple variants of urban manifestations and contexts, it is imperative to formulate customized strategies for urban regeneration that address climate neutrality and sustainability in improving living quality.

The consequences of climate change and ongoing population growth are reflected in all levels of human society. Confronting challenges through an integrated approach on the global level is manifested in the delineation of a compendium of Sustainable Development Goals (SDGs), as outlined in the United Nations' Agenda 2030 [1]. Among the 17 enumerated SDGs, Goal 11 stands as a dedicated mandate towards prospering cities and human settlements, with the overarching objective of fostering healthy living environments, liveability, and sustainability on all levels.

The computational framework outlined in this paper upgrades our previous research [2], centering on evaluating sustainability and efficiency across multiple quality dimensions of urban areas, including mobility, energy efficiency, air quality, and perceived liveability utilising open data. Taking this further, we propose the adaptive (open) data-driven methodology, suitable for neighbourhood/district spatial scale, initiating a structured approach towards the urban typology and classification of geographical units for customized assessment and analytics.

Firstly, common urban types and classification techniques are leveraged, followed by the introduction of key performance indicators (KPIs) to discern prevalent challenges and proffer corresponding solutions. We envision setting the computational framework upon different types of

data available for a specific location mostly relying on open data sources gathered either by public authorities, municipalities or open science and citizen science initiatives [3]. We propose a seamless conversion and integration of these datasets into a comprehensive set of relevant KPIs. Thus, we aim to perform both the classification and assessment of a specific environment while also suggesting optimizations towards its main designation. As part of this effort, the research envisions establishing a computational decision recommendation engine grounded in abovementioned assessment methodology and distinct urban categories.

The proposed computational framework relies on steps ranging from the identification and acquisition of relevant datasets, defining the typological classification of urban units, to the assessment of their functionalities and their optimization.

In this paper, we first overview the role of typological classification in understanding and improving urban areas through the perspective of previous studies. We continue by summarizing the main steps proposed by the data-driven computational framework ranging from the acquisition of relevant datasets and identifying the typology of the urban area at hand, to the assessment of its functionalities and their optimization. We conclude with some key reflections on current efforts and suggest avenues for future steps.

2. THE ROLE OF URBAN CLASSIFICATION: FROM OBJECT-BASED TYPOLOGIES TO MULTIVARIATE CLUSTERING

The typology analysis as a classification process and comparative examination has a long tradition in architecture and urban planning. The longstanding practice was primarily utilized as a fundamental tool for analysing buildings and urban areas (i.e. analytical typology) and became an approach towards designing and planning strategies (i.e. generative typology) [4–6]. With its roots deeply embedded in architectural history, classical typology stands out as the oldest method for classifying architectural objects, initially utilised for establishing fundamental divisions among building types by form, scale, and materials, and was often influenced by the geographical context, climate, topography etc. [7]. Rossi [4] introduced the concept of typology as the study of elements within a city and architecture that cannot be further deconstructed, a principle akin to a logical operation, enabling comparison by considering fundamental, irreducible components. He suggested focusing on the similarities of urban form exploring the morphological structures and their hierarchical organization within the urban fabric. This perspective, often referred to as typomorphological study, was principally focused on interpreting and classifying the spatial and morphological characteristics of buildings [8] gradually extending toward urban scale by exploring the connections between larger urban patterns and housing [9]. This includes examining the organization and connectivity of residential areas, districts, and other urban areas within the pronounced socio-geographical context. Urban morphological classification accentuated the study of the building block arrangements and the corresponding street grid, forming recognisable urban patterns. This was typically conducted by graphically analysing the cartographic types parallel to evolutionary characteristics [10]; i.e. the distinctive character of an urban fabric that stems directly or indirectly from the historical context of its formation [11].

The clear influence of evolutionary epochs on urban form and patterns led scholars to adopt the term "morphological period" [9,12] underscoring how the historical backdrop of an area significantly shapes urbanscape over time [4,11]. With the examination of the larger urban areas, the primary focus on form patterns progressively evolves towards a classification including utility and function. This trend became more apparent with the rise of new urban zoning paradigms, initially conceived as a strategic response to the disorders of the industrial city [13].

In recent years, a significant shift was made in the identification and classification of urban areas, particularly through mathematical, computer-based analyses and classification techniques that go

beyond the static function-form relations, capturing a multitude of factors revealing comprehensive urban dynamics. The concept of numerical taxonomy in biology [14] and the rise of mathematical multivariate morphometrics [15] quickly extended their influence on the domain of urban analytics and associated classification methodologies. This spread has been accelerated by the wealth of open-source data now accessible for automated analysis, facilitating the integration of multidimensional and problem-initiated aspects of spatial dynamics. Recent advances in urban analytics reveal the importance of using multicriteria classification and clustering techniques as a prerequisite for tailored analysis [16,17].

Dealing with large volumes of different data formats from various sources, such as remote sensors, satellites, surveys, and administrative statistical records, raises the necessity for systematic data organization, processing, and retrieval to uncover patterns, relationships, and trends that may not be apparent through individual datasets. Progress in high-resolution satellite imagery, coupled with advanced image processing algorithms, enabled the extraction of detailed spatial information relating to land cover, land use, and built-up areas [18]. The hyperspectral and LiDAR (Light Detection and Ranging) remote sensing have further enhanced the accuracy and granularity of spatial data and the potential for morphological classification driven by the machine learning algorithms, and geospatial information systems [19–22].

Furthermore, the morphometric analyses and classification in combination with socioeconomic indicators, allow for a more complex comparative approach. This is exemplified by Malah and Bahi [23], demonstrating the effectiveness of multivariate statistical techniques in assessing various aspects of urban sustainability based on the integration of five environmental indices retrieved from Landsat-8 imagery and coupled with eight general census socioeconomic indicators. Moreover, linking energy consumption to urban morphology and types as shown by Amando and Poggi [24], provides an opportunity to address climate change at the neighbourhood level. They tackled issues linked to solar energy production and consumption through the morphological categorization and analyses of urban fabric, building typologies, uses, and volumetry. Such efforts can assist in implementing necessary regulations and incentives for upgrading building inventories and plotting the city's trajectory towards higher energy efficiency standards, aligned with both present circumstances and future needs. Oliveira et al. [25] demonstrated the application of classification in domains of urban air pollution assessment and landscape metric analysis, highlighting its role in informed decision-making and cross-sectoral policy formulation. Grafius et al. [26] employed multivariate landscape metric analysis, by quantifying connectivity, fragmentation, and biodiversity. The resulting categories guide urban design, selectively focusing on three groups: green corridors, pocket parks, and multifunctional landscapes.

Since urban land-use information exhibits a robust connection with socio-economic properties and activities within urban areas, recent efforts have delved deeper by leveraging social sensing data. These comprise cell phone records and activity, social media check-ins including frequencies on points of interest, GPS trajectory information or floating car data to unveil the latent dimensions of social activities [27–33]. Based on the big-tech social platforms or mapping/navigation resources (e.g. Twitter, Instagram, Google Places, OpenStreetMap) these sources represent the new data ecosystem with rich attribute information and significant potential to uncover patterns of urban land use as well as serve as a powerful classification factor.

3. COMPUTATIONAL FRAMEWORK

The proposed computational framework is structured upon a set of steps, commencing the systematic identification and acquisition of relevant datasets. Subsequently, it entails delineating and classifying the geographical environment at hand, followed by a targeted assessment of its functionalities. This

assessment is followed by the optimization phase, wherein iterative refinement techniques are employed to enhance the said functionalities (Figure 1).

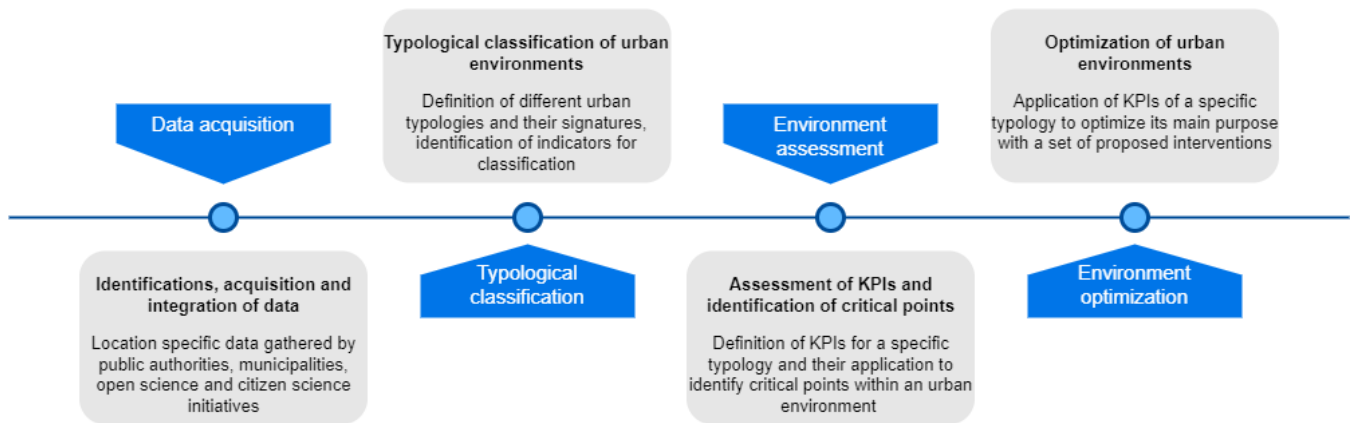

Figure 23. The proposed computational framework for classification and optimization of urban environments in the context of their typological classification. The framework consists of four steps: data acquisition, typological classification, environment classification and environment optimization.

3.1 Data Acquisition

The efficacy of computational and data-driven approaches in classifying, assessing, and optimizing specific urban environments is contingent upon the quality and spectrum of available data. A comprehensive conglomerate of datasets provides a richer understanding of the phenomena and dynamics inherent in the studied environment, enabling more accurate analysis and informed decision-making. By integrating methodically selected data sources and employing advanced analytical techniques, urban practitioners get better prospects to discern ongoing trends in urban development, identify patterns and generate tailored strategies to address complex challenges effectively. Moreover, ongoing efforts to enhance data collection methodologies and expand existing as well establish novel data repositories further augment the precision and utility of computational approaches in environmental analysis and optimization.

Data selection in this study is governed by three main criteria: a) open availability b) topic suitability and relevance, and c) spatial and temporal coverage and granularity. In the proposed computational framework two principal collections of data sources are utilized:

1. the primary (reference) datasets enable the classification of arbitrary urban areas into distinct typology classes through adaptive automated methodologies;
2. a curated array of datasets is employed for the extraction of relevant KPIs, each tailored to the specific characteristics of its corresponding urban area class.

In the first step, specific KPIs are used for the classification of the urban environment into a specific category, which is then used to select a subset of KPIs relevant only to this category.

3.2 Classification

Following the data selection criteria (open availability, topic suitability and relevance, spatial and temporal coverage, and granularity) we identified the list of datasets to implement the adaptive classification method and assessment process. Each identified class tends to represent a reference base for the semantic data layers and identification of KPIs, to support all phases of urban policy making, from designing policy frameworks and setting targets to monitoring and evaluation of trends. In our initial demonstration, we implemented the adaptive method classifying urban areas divided into 250 x 250 m and 100 x 100 m grid segments, according to their morphological and demographic

features. We approached the classification process from two main datasets: building footprints and population density. While the building footprint provides information on building tissue density, the population layer offers insight into resident density. Consequently, we were able to differentiate between low-rise and high-rise residential typologies.

a) Building footprints

Building footprints, closely resembling classical typo-morphological examination, are used to address density and build-up range, which can further inform indicators of liveability, accessibility, or land permeability [22] at the neighbourhood/district scale. In digital geometry, building footprints are typically represented by polygons, denoting the building's location, shape, dimensions, and area [34,35]. They also provide information on spatial characteristics such as distribution, floor space ratio, and the relationship between buildings and other objects (e.g., topology, orientation and proximity) [35]. The building footprints are commonly stored and displayed by vector data which allows individual features to be linked with attributes, like building height, type, use, age, occupancy etc. There are various sources for collecting building footprints from datasets such as national cadastral maps, high-resolution satellite images, and open-source projects (e.g., Open Street Map, EUBICCO [36]). For demonstration purposes we focused on Slovenia and used EUBUCCO, a scientific database of individual building footprints for 200+ million buildings across the 27 European Union countries. A 250 m x 250 m grid is initially applied to define classes based on their physical structures and contextual relationship with nearby objects. Metrics such as size, form, proximity to other buildings, and building compactness can be extracted using Momepy [37]. Momepy is an urban morphology Python library developed for OSM, enabling the creation of homogeneous categories by amalgamating neighbouring squares, thus establishing contiguous zones with analogous building compositions. Descriptive attributes such as age, height and usage are commonly additionally provided in OSM and EUBUCCO, however, these are often critically incomplete [36,38]. To address these disparities, we plan to utilize a population data source as an auxiliary tool for executing the initial classification.

b) Population density

We employed the high-resolution population density indicator to distinguish between the residential and non-residential areas and to discern the type of residential neighbourhoods accordingly (high-rise, low-rise). Several open data possibilities exist; for instance, the comprehensive open-access demographic collection WorldPop [39] covers most worldwide areas by spatial resolution of 3 arcseconds (or approx. 90 m x 65 m if demonstrated in Slovenia). In many instances, the accuracy of this population data collection can be validated (or exchanged) with comparison to national censuses at hand. Furthermore, many national authorities keep high-resolution population statistics openly available. For the demonstration purposes, we used the comparable 100 m x 100 m grid demographic data from the National Slovene Census, easily available through the geo-information portal STAGE [40], provided by the Surveying and Mapping Authority of the Republic of Slovenia and Statistical Office of the Republic of Slovenia.

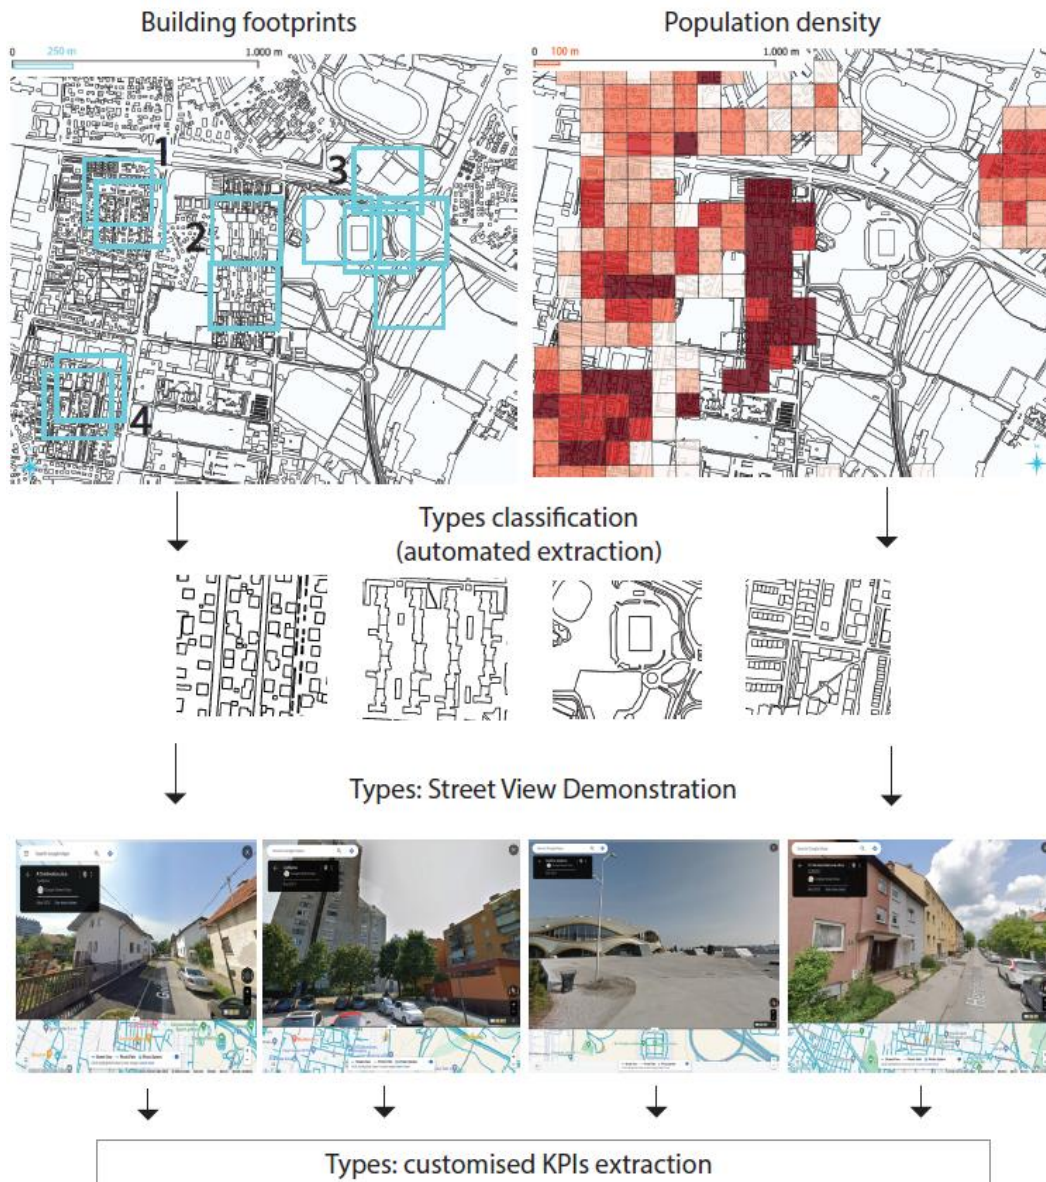

Figure 2. Proof of concept, Bežigrad, Ljubljana, Slovenia. The initial classification process is based on two data layers: building footprints and population densities (Street view demonstration by Google Street View, Google Inc., 2024).

3.3 Identification of critical points and KPIs assessment

After the main urban types (classes) have been identified, the assessment indicators can be assigned for each class. Considering the crucial characteristic of each urban type, the presumptions of potential vulnerabilities are set to extract the most relevant assessment indicators. The selected array of KPIs then allows for the identification of critical points within a particular area, comparison of akin urban types across different geographical locations, tracing trends over time periods or modelling typology-tailored predictions. Along with urban pre-classification, tailored KPI settings represent a strong decision-making mechanism. Quantitative descriptors of urban form and configuration are provided by the spatial metrics related to landscape proportions, fractal dimensions, or network density, and spatial autocorrelation measures [41]. Their practical implications address the level of urban performance, efficiency, liveability or sustainability through targeted indicators [41–43]. Also, Fleishman [44] provides a review on quantitative analysis in urban morphology that leads to

Proceedings

applications of distinct research purposes, among which are measuring the performance of urban form contributing to composite measures of sustainability, resilience, accessibility, urbanity and enabling comparison among spatial cases or predict urban growth.

In the past, numerous composed measures with KPIs have been proposed to assess the specific urban environments from different sustainability and efficiency perspectives. Some examples are KPIs to assess travel time reliability among city neighbourhoods [2] energy consumption measures for neighbourhoods and communities [45,46], or multi-scale and multi-thematic performance indicators for the assessment of nature-based solutions [47,48] among many others. Based on the characteristics related to the urban type and the presumptions of the environmental vulnerabilities supported by literature, the computational framework will automatically feature a set of KPI relevant to the chosen urban type. At this point, a secondary list of open datasets will be introduced to accomplish the assessment (e.g. Copernicus portfolio with pan-European coverage for imperviousness range, high-resolution tree-canopy cover, roof greening, or European Environmental Agency data series referring to environmental functions, services, and resources, infrastructure, or economic, social, or cultural assets in places and settings that could be adversely affected by climate hazards, including flooding, wildfires and urban heat island effects).

The framework will assess the set of these KPIs and point out the critical aspects that should be addressed in the given district.

3.4 Optimization of urban environments

After identifying critical points within an urban system, a computational framework can be deployed to pinpoint various potential interventions to enhance the system's functionalities. Integrating this recommendation engine with a simulation tool that could be used as a digital twin of the system, enables the *in silico* validation of suggested interventions to assess their impact before actual implementation. This approach allows for the evaluation of each by calculating relevant KPIs for specific scenarios, providing a measurable metric to aid decision-making.

Following the successful real-world application of an intervention, both the recommendation engine and the simulation environment will be updated with the actual assessment of indicators resulting from the intervention. This update enhances the accuracy of the recommendation engine by incorporating real outcomes, allowing it to learn from actual scenarios and progressively refine its proposals. This iterative (or potentially cyclic) process ensures continuous improvement and more effective interventions over time.

4. CONCLUSION

In formulating the envisioned methodology one of the critical junctures recognised in the research process was the selection of the most applicable dataset and indicators based on predefined constraints. The choice of data layers and indicators applied in the initial classification process significantly influences the range of classes, their mutual differentiation and how a particular spatial unit is assigned a certain urban type. Additionally, the steps of data acquisition, preprocessing, and integration across diverse formats into a cohesive system demand a significant investment of resources and time. Hence, adopting a systematic and coherent approach to data inclusion and selection becomes essential. This entails evaluating the utility and added value of envisioned datasets for classification processing, ranking them according to their role within the assessment frame as well as estimating their applicability proportionate to their availability, coverage, and processing complexity. To address this challenge, we embraced a systematic modular approach, integrating a compilation of criteria to guide our selection process effectively.

Given the importance of the EU's open data policy and the strategies towards creating shared European data space, we aim to prioritize open-source datasets, available across well-represented governmental or international repositories (e.g. Copernicus [49], European Environmental Agency

[50]), as well as community-driven and citizen science initiatives that promote participatory practices. Various citizen science projects, (e.g. Telraam [51] and sensor.community [52]) have enabled citizens to contribute data in different domains over the last decade. This involvement has resulted in enhanced availability of records on traffic, weather, or pollution, among many others, across European cities and wider. By harnessing such datasets, we can construct robust inference frameworks, that can be seamlessly applied to any arbitrarily selected location that is described with similar datasets.

Moreover, one of the important considerations in the data selection process is placed on geospatial and time-based coverage. This involves giving preference to datasets that provide extensive reach and finer resolutions in both spatial and temporal aspects. It requires evaluating factors such as data spatial granularity, and temporal frequency to enhance the accuracy of feature inventory, and thus, more detailed insight into urban trends. Wide-ranging geographical data coverage emerges as an important prearrangement, offering significant potential for conducting robust cross-regional and cross-national analyses and classification. Finally, it is important to extract potential datasets based on their relevance to the most pertinent urban issues at hand and their ability to derive meaningful indicators. Specifically, we assess how well the indicators demonstrate the complex dynamics of urban climate change and show its impact over time on overall liveability. This entails considering the dataset's capacity to address existing climate-related issues as well as its potential to discover the correlation with other phenomena.

Abstract

The contribution illustrates, through the assembly of a coherent repertoire of research-by-design activities conducted by the authors within the academic courses at the *School of Architecture, Urban Planning and Construction Engineering* (AUIC) Master degree program, and at the PhD Program *Architecture, Urban and Interior Design* (AUID) of Politecnico di Milano, a few crucial topics engaging the regeneration projects of abandoned post-industrial areas in the Milanese metropolitan context, looking towards a climate neutral scenario. The methodological approach, believed as necessary to enhance within the education paths, explores the construction of an ongoing “open glossary” of design actions for retrofitting peripheral areas that still appears as urban leftovers, due to their difficult asset of property or stakeholder and spatial lack of ecological qualities. By cataloguing and classifying the case-by-case conditions and the different design hypothesis developed by the students, a transcultural and multi-layered dimension of the possible design actions clearly emerge as shared vocabulary. The purpose is to expose and publicly discuss the possible parameters of the architectural project to tackle the challenges emerged within the context of the Green Deal and of the New European Bauhaus policies.

Keywords: *Post-industrial areas, Urban transitions, Research by design, Transcultural approach.*

1. INTRODUCTION

The New European Bauhaus Policies' Ecosystem [1,2] and its objectives broaden the spectrum of contemporary architectural design actions to new scales and horizons, with the main scope of reorienting both the cultural common ground and the economic flows towards more sustainable and inclusive growth. Specifically, its strong impulse finds a fertile field of experimentation for the architectural project when dealing with the regeneration processes of post-industrial tissues and areas, which constitute a significant challenge for contemporary urban transitions [3]. Indeed, abandoned industrial areas are often characterized by large and open-air surfaces whose contribution to sustainable reconversion must necessarily involve the dimension of publicness, and the negotiation with often an articulated panorama of stakeholders, in defining the strategic qualities of the project. It means binding together the institutional actors and the economic parties, the spatial and environmental challenges, as well as the social expectations.

For the Milanese context, the topic of balancing the relation between different parts of a continuous ongoing urban expansion it is quite relevant, mostly concerning the urban spatial qualities and the diverse social neighbors' asset. Both the Municipality [4] and the Politecnico di Milano develop since the last decades several programs to explore the possible future scenarios, with a strong accent on ecological imprint and social justice [5,6].

Moreover, starting from a more general reflection on the urgency to reconsider climate change impacts on spatial urban dimension, such explorations based on a “research-by design” approach [7] expand on an international level thanks to research platforms such as CIMATRA Consortium,

composed by several European Universities in the domain of Architecture and the Built Environment (Politecnico di Milano, Technische Universiteit Delft, Universiteit Antwerpen, Ethnicon Metsovion Polytechnion, Politechnika Warszawska, Univerza v Ljubljani).

The contribution, after presenting a brief research overview on the topics of urban design and spatial regeneration, articulates a case-by case open glossary, based on the results of academic design studios coordinated by the authors. It discusses four cases within the context of specific design actions such as: *Negotiating boundaries* (1), *Critical reuse* (2), *Fringes renewal* (3) *Reconnecting networks* (4). Finally, as provisional conclusions, a shared methodological approach within the different didactic experiences has been provided, based on two main parameters: the trans-scalarity of the design actions and its multi-layered relevance and impact.

2. AN OPEN GLOSSARY OF DESIGN ACTIONS

The last decades have been characterized by research and design experiments investigating the need to recalibrate the relationships between the suburbs' constellations, the urban fringe areas and the monofunctional tissues, with an increasingly polarized center. Some of those focus on the *mixité* for a new urban polycentrism [8], working on hybrid models to enhance the proximity between work and living areas [9], on urban porosity as a social and ecological value [10]. The scale of planning and policies meets the architectural one through a cross-gaze that requires a re-examination of the urban framework as a whole and of its concrete spatial quality, assuming the central role of the design of voids as an operational terrain. In this context, the contribution presents a case-by-case approach [11], using the didactic experiments to build an open glossary of design actions.

The glossary, which is delved into the three paragraphs below, combines the specific conditions of post-industrial contexts in the Milanese peripheries that show some shared features, – i.e. the fragmentation of land properties, the infrastructural load, the presence of abandoned or underused fabrics, the environmental criticalities – together with a specific design direction, aimed at recovering the ecological dimension in the urban fabric. The term glossary here refers to the Latin and medieval tradition of *glôssa*, not just in the original Greek meaning of language, but used to indicate a specific explanatory note placed next to a term that is difficult to understand. Therefore, within the vast disciplinary issue on the role of urban design for a just ecological transition, we wanted to carve out a narrow perspective in the methods of investigation. Indeed, the proposed glossary, breaking down the complexity of the research field *Design for Transition* [12,13], interprets the contemporary conditions of those areas through the lens of the architectural and urban project. The resulting actions are not replicable measures with standardized toolkits (often overlapping each other's), instead they present a specific design position. It involves, for example, the rethinking of thresholds as liminal spaces of negotiation and ecological encroachments within a condition of complex land ownership (The Bresso Airport and Breda Industries), or the selective reuse through demolitions and new transplants onto abandoned industrial fabrics (the Ex-Faema industry), or the conversion of infrastructural leftovers and margins into ecological networks within often disconnected urban fragments (Lambrate district).

2.1 NEGOTIATING BOUNDARIES (Fabrizia Berlingieri)

Thematic Design Studio, Architecture and Urban Design MsD, Politecnico di Milano, a.y. 2023-24; teaching staff: F. Berlingieri (coordinator), S. Lodrini, M. Manfredi; tutors: D. Fantoni, L. La Giusa, F. Monteleone.

Figure 1. *Ecological Encroachment*, axonometry and masterplan of the design proposal around the borders of Breda Factory, Bresso. Drawing by students: T. Huntingford, S. Brandner, H. Jing.

The Bresso airport, with its 94 hectares, is an aircraft and heli-surface for educational, civil rescue and private amateur flights and functions. It is part of the Parco Nord Milano and represents one of the largest reserves of underdeveloped open spaces in North Milan and in the entire metropolitan area. Its appearance dates to the First World War, when the factory of the Società Italiana Ernesto Breda Mechanical Constructions expanded its production to the military aircraft sector, thus creating the need for a nearby test runway. Along the two wars, the airport was the main air defense center in the Milan area. Nowadays the Bresso airport, despite a relatively light use, represents an endowment of great environmental value of permeable areas, meadows, and wooded surfaces, albeit within the limits defined by the ENAC rules for the operation and management of airport spaces. Its central location in the metropolitan area and the great accessibility from the city center also characterize the airport as a possible new hub dedicated to innovative flight technologies, such as urban air mobilities, automated vehicles and last-mile drone logistics. The different rules that today manage this large portion of territory, derive from an iper-fragmented land ownership, involving different actors and stakeholders in the construction of future scenarios – i.e. the two Municipalities of Bresso and Cinisello Balsamo, the Metropolitan Municipality of Milano, the Parco Nord, the Croce Rossa Italiana, among others. The area then is characterized by a strong presence of borders, fences, walls that not only define a visual labyrinth, but paradoxically does not allow publicness where the different public bodies are the main agents of change. Moreover, the location itself is at the border of the Bresso urban system on the left side and part of one of the main metropolitan ecological urban systems on the other, finally surrounded by a bundle of infrastructural networks.

The Thematic Design Studio *Infrastructure and Urban Form: The Bresso airport in the Lombardy region* considers its exceptional value regarding both the urban development potential and the need for an ecological balance. Along the course, the students faced three different steps, from site and program analysis to the design proposal. The objective, before the design proposal, was the envisioning of a *Strategic Implementation Plan*, testing a composition of several programs able to enhance the prospects for urban mobility innovation, and the environmental value with a high-quality landscape and biodiversity. This was developed according to few specific design research-actions reconsidering the airport area as: a welfare and ecological infrastructure (1), a research and educational centrality (2), an innovative air logistics and mobility hub (3), a mixed-use neighbor (4). Starting from the definition of these possible scenarios, the design proposals have been oriented to

the topic of reconnecting margins in a broader spectrum: from industry to nature, from mobility to urban environment, from land properties to public realm. The common ground of the students' design actions consists of the capacity of blending innovative functional programs together with the urgency to negotiate the boundaries between the several co-existing fragments within the large area. Boundaries become the main design focus, inverting the common sense: from separations to conveyor of new urban and social values, as the proposal *Ecological Encroach* evokes (fig.1). In this experiment the properties' borders expand to visual or physical reconnections of different programs, as in-between liminal spaces questioning the possible reversal of limits. Moreover, the principles of circular construction and reuse techniques have been applied as shared keywords for projecting the postindustrial and infrastructural site towards new coexistences.

2.2 CRITICAL REUSE (Marco Bovati)

Thematic Design Studio, Architecture-Built Environment-Interiors MsD, Politecnico di Milano, a.y. 2021-22; teaching staff: M. Bovati, M. Lavagna (coordination); tutors: S. Di Mauro, L. Fraccadori, S. Giorgi, R. Magrini, V. Panella, A. Prinzo, K. Santus, L. Simoncini.

Figure 2. The retrofitting proposal, materiality and relation with open spaces.
Drawing by students: J. Leccia, B. Neri, M.Tarchini, F. Viscomi

The Lambrate district, located in the eastern area of Milan, is about 5 km from the city centre. An ancient pre-Roman settlement conquered by the Roman legions in 222 BC, it is characterised by flat terrain that has shown a clear rural vocation since ancient times: the surrounding land was made fertile by irrigation works derived from the Lambro River, from which the neighbourhood takes its name, a waterway once navigable. Lambrate's history as an industrial settlement began in the sixteenth century; a gunpowder production site is testified in this period. Starting in 1864, the creation of the urban railway ring, which runs through the district and has a station and railway yard here, has become a separating element from the city of Milan, as well as a stimulus for the creation of a strong identity and sense of belonging, but above all, together with the presence of the watercourse, an engine for the industrial development of the neighbourhood, characterised by medium-sized and small-medium

Proceedings

manufacturing settlements. The autonomous municipality of Lambrate was subsequently annexed to the Municipality of Milan in 1923. The main industrial settlements have suffered from the general crisis in the manufacturing sector since the 1970s, resulting in the decommissioning of many production plants and the subsequent decommissioning of the railway yard. Among the most important are the following. Innocenti (later Innocenti-Maserati) was founded in the 1930s as a metalworking factory, later converted to producing automobiles and motorcycles (including, from 1947, the famous Lambretta) and was active until 1993. A residential neighbourhood and two parks now occupy the old production site. The Ex-Faema (Factory of Electro-Mechanical and Related Equipment), established in 1945, was requalified as Spazio Ventura, one of the pulsating centres of initiatives linked to Milano Design Week. After years of crisis, at the beginning of the 2000s, a process of urban regeneration linked to creative production (Creative Industries) was initiated, leading to the creation of the Lambrate Design District and inclusion in the Milano Design Week's *Fuorisalone* circuit. In this context, the realisation of the Spazio Ventura took place, acting as the engine of the neighbourhood's urban transformation. Positive aspects undoubtedly characterise this development, but according to some observers, it is still too tied to sporadic events that struggle to take root in the neighbourhood. The studio's work took as its theme the need to propose less sporadic and temporary occupations aimed at a stable urban and social rebirth of the neighbourhood. The project area is that of the Ex-Fonderia Tagliabue, founded in 1921 as an industry for producing cast iron, characterised by reinforced concrete buildings, mainly sheds. The area is located on the easternmost slope of the neighbourhood, between Oslavia Street and Sbodio Street, in a context characterised by a poor provision of public and collective spaces. After its decommissioning in the 1970s, the area was divided into two parts; since the 1990s, the predominant use has been as a warehouse, and since 2000 the site has been abandoned. The project brief required the construction of new volumes for residential use, partly in social housing, and a public and service building with a small exhibition space, a reception area and a cafeteria. The residential portion, in particular, was supposed to be characterised by a high degree of flexibility over time so that it could be transformed rapidly and with little expense, depending on the community's housing needs. Furthermore, the conservation and reuse of part of the existing buildings were required. They would be destined for artistic workshops, co-working spaces, and spaces for small businesses. The project request also included allocating part of the area to open green space and an underground parking facility.

The portion of Lambrate east of the railway is characterised by numerous disused or underutilised artisanal and industrial buildings, and the prospect of an extensive regeneration plan is the most desirable scenario. The projects, which should involve the creation of new spaces and the establishment of new functions, should be characterised by a critical reuse and/or selective demolition action, following an in-depth study of the architectural and constructive characteristics of the real estate heritage that marks out the buildings present in this area, to assess their historical value as a testimony to the neighbourhood's industrial past and to investigate their actual possibilities of reuse. Many projects have already been realised, and others are underway. However, most of them seem to be characterised by actions of mere building replacement, with little attention to the peculiar aspects of the pre-existing building heritage, often demolished hastily and uncritically. The functions realised also go in two divergent directions: standard residential construction on the one hand and places for temporary and transient events on the other. The work developed in the workshop, on the contrary, has attempted to formulate design experimentation capable of imagining flexible residences capable of accommodating different social classes and family compositions, multifunctional public spaces open to the community with several possible uses, and workspaces characterised by more stability over time, considering the combination of these functions as a factor capable of representing a significant and profound mutation in the social and economic structure of the neighborhood.

2.3 FRINGES RENEWAL (Emilia Corradi)

Fringes Renewal. Enhancing Urban and Peri-Urban Fragile Area International Workshop, AUID - Architecture Urban and Interior Design PhD Program, DASTU Politecnico di Milano, a.y. 2020-21; teaching staff: E. Corradi, C. Cozza, V. Dessì.

Figure 3. Morphological analysis of the Forlanini area. The ‘Figure Ground’ highlights the built fabric’s presence mainly at the borders of the case study area, close to the main infrastructures. On the opposite, as shown in ‘Green spaces’, the core of the area presents a variegated presence of green areas, representing the site's ecological strength. ‘Strengths’ and ‘Fragilities’ describe agricultural fields as key spaces, while a series of neglected green and low-quality spaces characterize the borders. Drawing by Phd candidates: C. Bulone, H. Dan, K. Santus

The Course addressed an investigation into the possible design tools aimed at achieving the objectives set by the New European Bauhaus and the EU Taxonomies policies and developed, together with the 36th cycle PhD AUID candidates, a series of strategies aimed at studying the role of abandoned industrial areas in the Milanese fabric as possible spaces of urban regeneration [13] aimed at restoring beauty, sustainability and sharing through a design investigation that aims to frame themes, analyzes

and projects within a strategy in tune with the challenges posed by the New European Bauhaus [14] and the EU Taxonomy [15]. Through design-driven experimentation, we wanted to identify design techniques that highlight innovative design elements and spatial organizations and investigate the inhabitants' perception of the renovated spaces. The challenge posed was to contribute to the redefinition of marginal areas of the Milanese urban fabric - Lambrate, Rogoredo, Rubattino and Ortica - areas characterized by disuse and abandonment and affected by infrastructural structures. The application of these solutions opened the possibility that they have a central role in urban and peri-urban transformations to respond both to climate change and to requests for urban regeneration in the direction of building a methodological project that can be extended and replicated to urban contexts of a similar nature. Specifically, the projects have as their starting point the construction of the cognitive and descriptive framework carried out through morphological, urban, architectural, and climatic analyses relating to the abandoned or underused areas and artefacts. This work was necessary to identify themes and components on which the project could provide range of solutions through Nature-Based Solutions (NBS). The main tools of the project were identified as urban morphology and measurement, scales and perimeters, toolkits, and nature. Compared to these tools, the projects have returned both theoretical reflections and operational strategies: observation, recognition of the different ecologies and social structures, and the relationship with the marginal fabrics led the doctoral students to work precisely on the interstitial spaces of areas in mending operations between very different urban and environmental forms and structures. Within this context, morphological analysis is used as an approach to the project, which allows the identification of urban dimensions and the construction of a design vision that includes both the abandoned space and the built environment. The morphological observation of the territory reveals a design structure that allows us to identify the area's founding elements and the unexpressed potential, underlining the importance of carefully considering the shape and physicality of the territory, especially in the face of growing climatic fragility. The project is conceived as an approach that crosses different scales, including recognizing urban fabrics and their settlement value in both built and open spaces. By reviewing the equipment and operating on targeted connection systems, it is possible to identify fragments of nature and workability and recompose the connective tissues within peri-urban areas. This theme emerges in all four projects, with different perspectives, highlighting the question of the "perimeter" of the project's scope. The proposals work coherently on the limits between areas, underlining the possibility, through adaptation processes, of rethinking urban thresholds and margins in their physical and social reimagination. The complexity of these territories, in which infrastructures play a key role in defining the borders and "perimeter" of individual areas, reveals the need to reconsider them in the spatial conditions they generate. The analysis of the project experimentation carried out by the PhD students requires some reflections necessary to orient the project actions concerning the objectives in the New European Bauhaus and the EU Taxonomy.

Addressing the issue of adapting urban space or mitigating climate change requires a systematic approach that integrates European inputs, transforming them into design actions that profoundly reflect the space issue. The technical component is certainly essential, but it is not sufficient to build the project if there is no ability to combine the technical problems and data with an aptitude for the critical analysis of urban contexts and with a vision of the city outlined through the architectural project. Only through this ability to visualize, which requires adequate training attentive to grasping data and forms that often operate on very different scales based on values and an idea of space, can we rethink these marginal areas of cities, harmoniously redefining the relationship between marginal and urban spaces.

Proceedings

2.4 RECONNECTING NETWORKS (Cassandra Cozza)

Fringes Renewal. Enhancing Urban and Peri-Urban Fragile Area International Workshop, AUID - Architecture Urban and Interior Design PhD Program, DASTU Politecnico di Milano, a.y. 2020-21; teaching staff: E. Corradi, C. Cozza, V. Dessì.

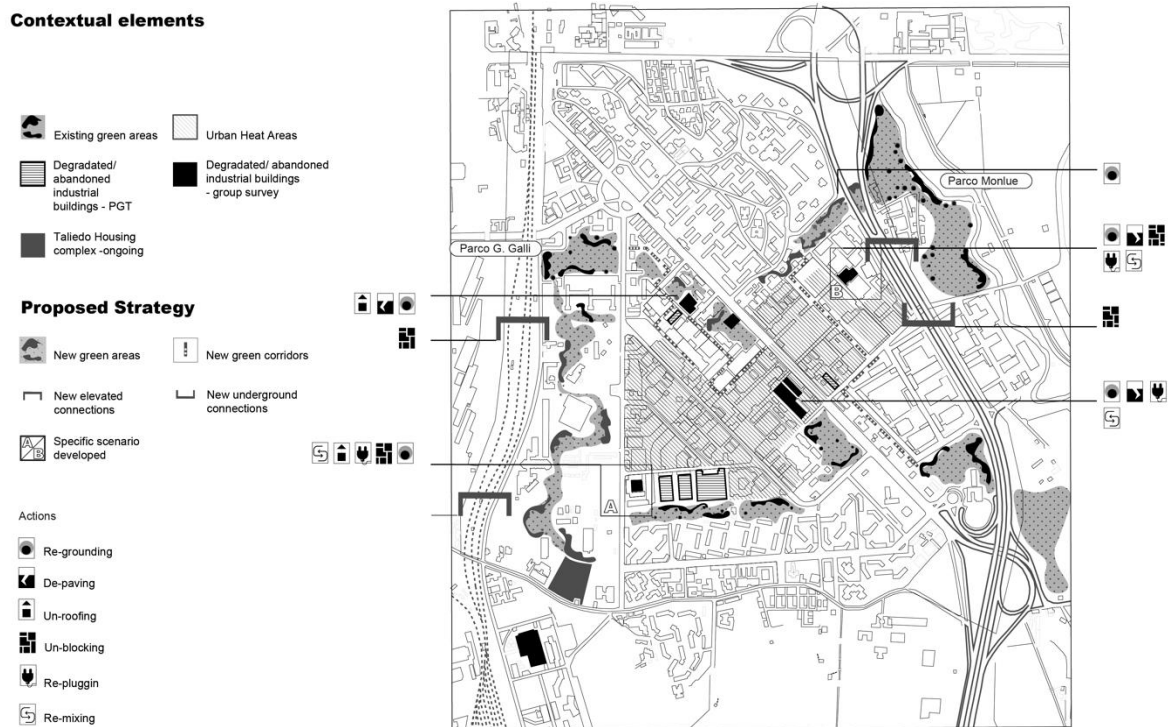

Figure 3. The masterplan shows the strategies identified to improve the porosity of the area: new open and vegetated spaces and new green and connected corridors, also made possible by the presence of aboveground and underground passages. Drawing by PhD candidates: M. Pereira, C. Cempini, P. Gamboa, V. Dall'Orto.

The Milan Eastern Fringe is a strategic resource for the spatial, ecological and social network reconnections aimed at the transition of the contemporary city toward the NEB ideals of 'beautiful, sustainable, together'. The design-driven doctoral research described in the previous section aims to establish and strengthen spatial, ecological, and social network reconnections with a multi-scale approach, from strategies to the architectural qualities of places.

The complex urban morphology of the Milan Eastern Fringe is made of urban fabrics, infrastructure, and open spaces of various typologies – part of urban, peri-urban, rural and natural domains. The developed methodology was aimed at reading and describing the common characters among the four adjacent areas of the whole fringe, reading the morphological continuities and identifying the different neighbourhoods' characters and problems to be solved. Indeed, the design actions aimed to enhance the quality of the places by spatially connecting them – both slow mobility paths and green network reconnections – and establishing new livability with climatic and social features. This fringe is characterised by various spatialities that have the potential to host significant open space enhancements in uncertain open spaces of different scales and abandoned industrial areas.

The two selected design-driven research studies described below are located in the two central adjacent areas among the four ones on the whole fringe. They are the most representative of the topics of NEB network reconnections. They are: the Southern Ortica - Forlanini Park case study, which focuses on the urban relations and reconnection both towards the city and the vast urban park; the two adjacent areas of Quartiere Forlanini – Taliedo, which proposes an urban climate and bio-climate regeneration centred on the topics of the urban climate and industrial areas abandonment.

The Southern Ortica - Forlanini Park case study investigates two main topics: spatial reconnection and green urbanism with the application of Nature-based solutions. The spatial reconnection of this area – all-around surrounded by critical infrastructures – to the adjacent neighbourhoods boosts accessibility and urban porosity. Moreover, it reestablishes the urban relationships that allow the area to be turned into the door of an important urban function, such as Parco Forlanini. Then, it operates on difficult, low-quality, neglected open spaces – mainly leftovers and passages through the limits. These are predominantly man-made environments where all future human actions should strengthen the relations between nature and architecture to trigger changes both at the local and urban scale, reimagining them in a new way combining spatial quality, environmental performance and sociality. The design actions operate directly on the ground by de-paving it, creating rain gardens, increasing the permeability of parking lots, and establishing a new relationship between the city and the environment.

The Quartiere Forlanini – Taliedo case study hosts residential and industrial fabrics; its most relevant problems are high superficial temperatures in the central industrial area and abandonment. This design experimentation works on the urban climate and bio-climate regeneration, focusing on the issue of Urban Heat Island. The proposed design actions aim at re-using and repurposing the abandoned buildings of the industrial core and the neglected open spaces and at their bioclimatic adaptation. The main design actions in the open spaces are unlocking the dense industrial area, reconnecting the network with new pedestrian and street connections, depaving and re-grounding the paving to alleviate extreme heat stress, creating new shaded public spaces, and harvesting rainwater. Moreover, the project aims to foster adaptive reuse through new mixed-use areas and services, repurposing abandoned industrial areas and buildings.

The project is a tool for urban regeneration that establishes active protection of abandoned industrial heritage, its reuse, and its renewal by managing the balance between conservation and transformation. It reactivates new life cycles for places and buildings and creates new identities by renewing the functional program and inserting innovative elements.

3. CONCLUSION

To sum up the four *lemma* of an ongoing open glossary reclaim specific design actions by:

1. Expanding borders as design potential areas, negotiating benefits and costs in periurban context of fragmented ownerships.
2. Remodeling postindustrial fabrics through critical reuse, substitutions, and graftings for energy reconversion.
3. Reconnecting architectural interstices to compose larger urban frameworks.
4. Enhancing ecological networks through NBS design for highly infrastructural areas.

On a more general level, the described didactic results show a similar approach in integrating different scales, from the geographical to the technical one of the energy building performances. This particular gaze implies a multilayer integration, where the architectural and urban design project is a systematization of environmental and cultural resources. Indeed, tackling the architectural project according to an integrated vision raises reflections on the tools to be used to operate in the historic, modern and contemporary city, in their different legacies, on the cataloguing, delimitation of spaces, elements and materials which in different roles contribute to the definition of places and their ecologies.

Abstract

The paper discusses the relationship between Milan and the second life of post-industrial areas in its metropolitan region. In fact, the relocation of the industrial belt and the modification of infrastructural frameworks have been at the center of the political and scientific debate since the end of World War II, and the general plans and talk-about projects that followed. Entailing slow and sometimes contradictory transformation processes, the gradual conversion of dismissed areas has nonetheless reshaped entire urban portions and today seems still far from conclusion. The paper selects from among the plethora of post-industrial transformations a few emblematic experiences that help to frame how Milan became a hotbed of experimentation and how the perspective and the needs of the city transformation could be addressed in the future. The outcomes discuss design challenges and themes emerging from the past and ongoing architectural projects and processes of urban transformations in post-industrial sites and reflect on the strategic way contexts, architecture, citizens, and sustainable environments can find innovative and harmonious forms of coexistence.

Keywords: *Milan, Architectural design, Urban transition, Post-industrial transformation, Resilience, Climate change.*

1. Introduction

Milan and its surrounding metropolitan area represent today the most developed financial, industrial, and technological hub in Italy, due to its strategically advantageous geographical position. Located at the core of infrastructural connections, it serves as a significant crossroads for economic and financial interests and flows.

Since the post-war period, when Milan faced the challenging task of its reconstruction, the city has been shaped by a combination of industrial growth, strategic urban planning, economic reform, ambitious regeneration projects (e.g the introduction of the P.R.U. - Programma di Ristrutturazione Urbana - by the Ministry of Public Works in the 1994, to facilitate the recovery of disused areas.), and evolving social dynamics. Collectively, these factors have contributed to the emergence of Milan as a dynamic and influential global city.

In recent years, also drawing on other urban regeneration example from across Europe, policy efforts have aimed to make Milan competitive and attractive both for residents and investments, addressing the increasingly urgent issue of environmental sustainability. Although the reactions introduced so far sometimes appear driven by neoliberal rhetoric and may not fully meet the challenge [1], the National Center for Urban Policies Studies (Centro Nazionale di Studi per le Politiche Urbane Urban@ité [2]), in the fifth annual report on cities (2020), highlighted a positive narrative emerging within Milan's urban agenda. This narrative elevates the city as a "model" of urban development capable of merging competitiveness, innovation, and inclusivity, and positioning Milan as a leading foothold of the Italian economy in Europe and also in the world [3, 4].

Over the next 10 years, the objectives of the Territorial Governance Plan (Piano di Governo del Territorio - PGT) [5] will synchronously address four major themes: the megapolis of neighborhoods, sustainable development, international aptitude, and the public city. The PGT, approved by the City Council on October 14, 2019, sets the goals for Milano 2030, including demographic, economic, and

Proceedings

tourism growth. This phase of growth is expected to continue, especially considering the Milan-Cortina 2026 Olympics. The plan's renewed vision for the city focuses especially on environment and climate change, outskirts and neighborhoods, the right to housing, and affordable rents.

The relation with the overall metropolitan area is fundamental, as it will shape the significant changes anticipated over the next decade. In fact, the Milano metropolitan region is characterized by extensive conurbations exerting real estate pressure on green areas, creating a fragmented mosaic of land hemmed in by suburban expansion, infrastructure lines, and a more limited network of post-industrial areas. Furthermore, large, disused sites have historically influenced the city's development trajectory and remain one of the critical challenges for its future, considering their potential environmental (climate change) and social (right to the city) roles.

In this context, Milano's recent urban history appears symbiotically linked to the past and future regeneration of its post-industrial sites. Thus, there is an urgent need to define a long-term strategy for the city's future, including the reuse of the large areas still available within the urban territory.

2. Literature

In Italy, since the early 1980s, the issue of the urban expansion crisis has been crucial to the debate, framed within a consolidated hierarchy based on urban densification. In 1984, Secchi in Casabella [6], observed a shift towards a progressive stop in urban growth and a gradual dispersion, which generates “new voids” in the structure. This phenomenon of abandonment creates fragmentation within the consolidated fabric, an expression not only physical but also economic. Within the disciplinary debate, observing the physiologies of a new dimension, a reflection on high-profile theory emerged through the pages of Casabella under the direction of Gregotti during those years. This reflection highlighted not only an inevitable transition from the “culture of expansion to the transformation”, but also the crisis of established planning tools [6]. The project undertakes a dominant role in the phenomena of abandonment, with the sentence “costruire nel costruito” (building within the built environment) as fundamental aspect of the future condition. Beyond reuse, every architectural operation increasingly becomes an action of partial transformation [7].

Moreover, for the past forty years, the debate on the city of Milan has focused on the major transformations of the abandoned areas within the city (industrial sites and railway yards). These sites have changed their purpose due to economic shifts. On this topic, the debate and research conducted within the Milanese School of the Politecnico di Milano have been fervent over the last years. There has been a consistent examination of ongoing processes and a questioning of both the possible strategies to adopt and the solutions to be implemented in the challenge of decisions due to political cycles, urban market dynamics, and territorial governance tools. Consequently, the scientific debate has been extensive through conferences and publications, as well as research funded by several agencies to the Polimi's departments, involving several colleagues, some of whose research will be mentioned in this paper.

3. Methodology and case studies

The paper selects from among the plethora of post-industrial transformations a few emblematic experiences which help to debate how Milan became a hotbed of experimentation and how the perspective and the needs of the city transformation could be judged and how nowadays, some of the projects can be measured with the time-critical distance.

The Bicocca district, one of the most famous completed transformations projects (1985-2005), is a representative “saga” of the sharp debate animating the transformation of post-industrial sites. The Bicocca project (Gregotti Associati & Studio Valle Architetti Associati) is one of the last points of encounter between urban planning and architectural design. Today, with the historical distance it offers significant elements of reflection on the social and climatic crisis, such as housing affordability and heat islands.

Moreover, the paper discusses two types of ongoing transformation processes affecting post-industrial sites. One regards projects born from public-private negotiations, such as the cases of Porta Vittoria, Porta Romana, Bovisa's Goccia, and the former Falck areas. The other considers the projects originated from international competitions, where the "Reinventing Cities" platform promoted by the C40 league, with its mandate to stimulate sustainable development and celebrate innovative solutions to environmental and urban challenges, plays the most significant role.

4. Selected approaches

4.1 The Bicocca transformation, a Milanese paradigm

Entering an abandoned factory, silent and devoid of workers, is always for me an experience where sadness and wonder mingle long before the promise of what will come next"⁸

The functional redevelopment project of the Bicocca area is situated in relation to the northern areas of Milan, characterized by a territory undergoing trans-scalar and functional transformations, and a symbolic landscape that signifies the union between "modernity" and "post-modernity."

At the time, the Bicocca project was, a milestone in the international disciplinary debate concerning the revitalization of disused industrial areas and a milestone in the urban history of Milano [9], which in the 1980s was countersigning internal fragmentation of the fabric due to obsolescence phenomena. (Among the major redevelopment interventions on disused areas - now either completely recovered or in the final stages of completion - are the ex Alfa Romeo Portello; ex Fina refinery in Quarto Oggiaro; ex Mechanical Workshops (O.M.) in the Bocconi area; ex T.I.B.B in Lodi; ex Ponteggi Dalmine and SCAC in Lorenteggio; ex Sieroterapico; ex Binda Paper Mills in the Navigli area; ex Carlo Erba pharmaceutical industry in Maciachini; and ex Motta confectionery industry[10]).

The industrial district of Pirelli's factories (at the time the second Milanese plant in addition to the one in Via Ponte Seveso, where the Pirellone is now engraved in memory) originated in 1908 in the Bicocca countryside. The first settlement, near Greco Milanese, expanded until it became an autonomous citadel of 730,000 square metres and involved the entire northern Milanese urban development. In 1983, Pirelli Industries and the municipal administration signed an allotment agreement, and in 1985, together with the Region and Province, they signed a Memorandum of Understanding to transform the site into a 'National Technology Centre'. An international competition by invitation was announced and twenty of the most important architects of the time were invited to participate: Aulenti, Aymonino, De Carlo, Gabetti, Gregotti, Piano, Rossi, Valle, Tadao Ando, Botta, Ciriani, Gehry, Meier, Solsona, Moneo, Guedes, Stirling, Hertzberger, Peichl and Ungers [11].

According to Leopoldo Pirelli's evaluation, the project was awarded in 1988 to Gregotti Associati in recognition of the expressive power of the new buildings and their ability to stitch together the surrounding urban fabric, giving it a reference point for the entire north of Milan, and contributing to a polycentric vision of Milan's metropolitan area [12, 13]. The new project aims to build a innovative "Technocity", concentrating high-tech activities, business services, research and production (headquarters of the Deutsche Bank design by architect Gino Valle, three tertiary towers and the new Siemens group headquarters), targeting the area to be a new university hub. Gregotti designed the masterplan and most of its buildings, in a mix of renovation of pre-existing buildings and new constructions [14]. Gregotti designs the district as a historical center of a diffuse periphery by now densely consolidated within an urbanized and productive countryside, also re-connecting to the memory of the old industrial settlement starting from the original grid of roads inside the factory transformed into an urban layout [15, 16]. Furthermore, it reconnects to the historical, geographical and figurative context regarding structural aspects, fully reconfiguring the stylistic aspects with buildings characterized by massive volumes [17, 18]. The layout runs parallel to the railway line over three strips and structures urban courtyard blocks with a series of public squares in sequence, connected by a central pedestrian axis. A mix of commercial functions, residences with a kindergarten and church, students' residences, an urban park (the "Cherry Hill"), CNR laboratories, the AEM, and

the Arcimboldi Theatre to the east join in the sidestreets. The Pirelli headquarters are located to the North, including the historic Arcimboldi villa and the monumental cooling tower. To the West are sports facilities also connected by pedestrian pathways to the Parco Nord [19]. Finally, the area to the North of the district is still fragmented and under construction. Although the theoretical scope of the intervention has already been mentioned, the Bicocca project remains one of Gregotti's best-known (and most debated) works from the outset. It has been criticized for the monumental character of the solutions, which oversteps the human dimension and the scale of public space, by stretching the area to the limit and depriving the district of the comfort needed to live in it. In addition, the lack of natural greenery, which is a constant problem for the city of Milan [20], and the social problem are the most debated questions.

Recently, the studio Piuarch, also students of Gregotti at the time of the Bicocca project, was 'symbolically' entrusted with the redevelopment of a portion of the district with a project called 'BiM' ("Bicocca incontra Milano", translated as Bicocca meets Milan). By 2026, an area including two of Gregotti's buildings will be redeveloped (50,000 square metres of workspace, commerce and a new multifunctional Pavilion) with a 250 million Euro budget [21]. At the center of the project is the garden space (6,000 square meters), which is intended to become the gathering point for the quarter and be livable even after working time, as part of the community that resides or only works here.

4.2. Recent emblematic projects born from public-private negotiations

In recent years, Milan has reflected on the necessity of implementing profound spatial changes, revealing the city's regenerative ambition. This capacity drives through a combination of large-scale urban transformation and infrastructural interventions, affecting large disused urban areas and facilitating molecular changes in the city's settlement and functional fabric [22]. As Bozzuto [23] highlights in the atlas, outcomes of the research project "Public City as a Laboratory of Planning: The Production of Guidelines for the Sustainable Redevelopment of Urban Peripheries" (funded by the Ministry of University in 2005), these interventions are mostly heterogeneous in terms of dimension, function, and process (project forms, implementation tools, stakeholders, actors, etc.), yet they share a common denominator becoming "significant points" for bestowing new values upon the context where they are integrated into.

Nowadays, after the large industrial areas have been completed, the railway yards (Farini; Greco-Breda; Lambrate; Porta Romana; Rogoredo; Porta Genova; San Cristoforo - a total area of more than 120 ha), the EXPO 2015 site in the North-West of Milano and the abandoned barracks system (which is an open question not only for Milano, but for almost all Italian cities) have become the focus of interest. All these plots form a widespread and fragmented system of areas, fenced and impenetrable enclaves that break up the city. They represent an unquestionable potential for multi-scaled urban transformation. Moreover, both the railway yards and the barracks are public areas but owned by an

Proceedings

agent (e.g. Ferrovie dello Stato) that however acts according to private logics and strategies, such as real estate valorization.

However, in 2008, Milan also faced the global financial crisis, which impacted the real estate market, not through price reductions but through increased timelines of contracts. Additionally, as Pasqui [24] highlights, Milan lacked an adequate urban strategy, and during the Albertini administration (2011), work was underway on a new Territorial Governance Plan (PGT – Piano di Governo del Territorio) to support a building growth strategy, which however no longer matched the current needs of the estate market.

Nevertheless, the first agreement between the Milano Municipality and Ferrovie dello Stato was initially formulated in July 2008 [25]. In 2017, a MoU was signed among the Municipality of Milan, the Lombardy Region, Ferrovie dello Stato Italiane S.p.A., FS Sistemi Urbani Srl, Rete Ferroviaria Italiana S.p.A., and the Fondo Olimpia. The project envisages the urban transformation of seven former railway yards (Scalo Farini, Scalo Greco-Breda, Scalo Lambrate, Scalo Rogoredo, Scalo Porta Romana, Scalo and Station Porta Genova, and the San Cristoforo railway areas, 1.2 million square meters) [26]. This is one of the most significant real estate operations in the coming years, thanks to the strategic locations of these areas in semi-central zones, and to provide an opportunity to mend the rift between the city center and the periphery. In return, Ferrovie dello Stato is expected to contribute to urbanization charges and to investment in a Circle Line, which should rapidly connect several zones in the city.

However, several doubts have arisen regarding this project, with divergent positions emerging both within the academic debate [27] and through the opposition of some associations such as Italia Nostra [28]. The social counterpart of the project is considered minimal relative to the value of the entire real estate operation and the increase in area value generated by their change in urban designation [29].

4.3. The “Reinventing Cities” initiative. A new model of contemporary urban transformations (ca 8.600 ch)

Inaugurating a pivotal discourse in urban studies and sustainable development, the C40 Reinventing Cities [30] initiative emerges as a seminal platform poised to redefine contemporary urban landscapes through a prism of innovation and ecological imperative. Envisioned as a catalytic mechanism to address the multifaceted challenges of urbanization, climate change, and social equity, this initiative embodies a concerted effort to reconceptualize urban development paradigms through scientific inquiry and interdisciplinary collaboration.

C40 is a global network of nearly 100 mayors from leading cities, united to combat the climate crisis and committed to diversity, equity, and inclusion in its operations and collaborations, aiming for a future where everyone can thrive. They aim to cut emissions by 50% by 2030 and limit global warming to 1.5°C, focusing on different scopes, among which building healthy, equitable, and resilient communities. C40 supports mayors through raising climate ambition with action plans and innovation, building equitable, thriving communities via global programs, engaging in international advocacy, sharing best practices in climate action, facilitating finance for green jobs and resilience projects [31].

Membership is based on performance, reviewed annually against C40’s Leadership Standards, which emphasize resilient, inclusive climate action, innovation, and global leadership.

Reinventing Cities is the competition promoted by C40 league that pursues effective strategies to field decarbonized and resilient urban regeneration across the globe, setting benchmarks in the global agenda [32]. Embracing a holistic approach, selected projects exhibit a synthesis of green infrastructure, renewable energy systems, and equitable urban design, emblematic of a nuanced understanding of the interplay between built environments and ecological systems.

At the time of writing, Reinventing Cities is running through the fourth batch of competitions in fifteen global cities: Almere, Bilbao, Bologna, Brussels, Glasgow, New York, Palermo, Renca, Rome,

San Antonio, San Francisco, São Paulo, Seattle, Venice, and Milano. In Milano, the call has been structured in two phases: PHASE I “Expression of interest” and PHASE II “Final proposals” and identifies neglected lands, vacant building, and uncertain urban situations that already expose potential for short and long term improvement, enacting solutions to the following 10 climate challenges: energy efficiency and low-emission energy, life cycle assessment and sustainable management of building materials, low emission mobility, resilience and climate adaptation, ecological services for the territory and green jobs, sustainable management of water resources sustainable waste management, biodiversity, urban reforestation and agriculture, inclusive actions, social benefits and community engagement, and innovative architecture and urban design.

As readable from the municipality’s webpage [33], in 2017, 2019, and 2022, the City of Milano took part in the initiative with a selection of properties partly owned by the municipality and partly stewarded by other companies. In the first edition in 2017, five sites were offered. Four, Doria, Serious, Scuderie de Montel, Gorla Market, owned by the city and one, Scalo Greco Breda, owned by Ferrovie dello Stato Italiane SpA (FS) and FS Sistemi Urbani SRL (FSSU). The competition addressed 8,4 hectares of land, received more than 40 expressions of interest, 13 of whose were admitted to the second phase, 8 selected for the final stage, and 4 were awarded: all the sites but Gorla Market.

Figure 2. The design sites of the first (sx) and second (dx) edition of Reinventing Cities in Milan (source: <https://www.c40reinventingcities.org>, graphic elaboration by G.S.)

In the second edition in 2019, seven sites were put out for tender. Five were owned by the city: Piazzale Loreto (“Loreto”); PA3 Viale Molise ex-Slaughterhouse (“Ex-Slaughterhouse”); Palazzine Liberty; ERS Area Crescenzago (“Crescenzago”); and Section A of the Monti Sabini PII (“Monti Sabini”). One, “Bovisa Node”, owned by the Municipality of Milan in partnership with Ferrovienord Spa, involving areas near the Bovisa FNM station. One, the former Lambrate railway yard (“Lambrate”), owned by Ferrovie dello Stato Italiane SpA (FS) and FS Sistemi Urbani SRL (FSSU) is part of a broader program agreement for redeveloping Milan’s railway yards, signed on June 23, 2017. The call covered 42 hectares, more than 60 manifestations of interest, 27 of which were admitted to the second phase, with 13 finalists, and 5 awarded (Ex Macello, Scalo Lambrate, Crescenzago, Nodo Bovisa, Piazzale Loreto) (Figure 2)

In the third edition in 2022, the topic got closer to housing affordability and right to the city issues, epitomized by the new slogan “Reinventing Home.” Six sites were offered. Four, “Zama Salamone,” “Martesana,” “Bovisasca,” and “Certosa 186,” are owned by the city; one, “Pitagora,” provided through a partnership with MM Spa on land co-owned with the Municipality of Milan, and one, “Abbiategrasso,” in partnership with Aler Milano, which provided an area over which it holds surface rights. The competitions addressed 4,6 hectares of land, and 9 proposals were invited for the final

Proceedings

stage. While the results are still to be officialized, the third edition of Milan's Reinventing Cities appears less successful than the previous two.

Figure 3. The design sites of the third (sx) and fourth (dx) edition of Reinventing Cities in Milan (source: <https://www.c40reinventingcities.org>, graphic elaboration by G.S.)

The fourth edition was launched in 2024, when the Municipality of Milan selected the school located at via Zama 23 as the testbed or innovative design solutions. Having one sole site may suggest that the attention on the overall initiative is decreasing in the Milanese environment, posing questions on how to reboot a widespread interest from different stakeholders (Figure).

Figure 4. Iconic images of the awarded projects from the Reinventing Cities initiative (source: <https://www.c40reinventingcities.org/en/professionals/winning-projects/filter-milan/>)

Up to date, Milan can praise 9 awarded proposals (Figure 4), with projects various in size, type, functional program, contextual conditions, and design attitudes. These ventures are conversely accumulated by transdisciplinary synergic approaches, sustainable objectives, and public-private cooperation (Table 2). Witnessing the growing role played by C40 initiatives, Reinventing Cities has recently been launched also at students' level competitions. Up to now, Milan has awarded one project "Flyover Corvetto"[34] and at the time of writing no open calls appear available.

5. Discussion and conclusion

The paper has introduced design challenges and key issues related to a selection of transformations that have reshaped, or are still on design phases, the connotates of Milan. The results suggest that the post-industrial conversion, beyond a process not yet exhausted after several decades, is still the prominent testbed for sustainable-oriented architectural and urban projects. The examples of Bicocca

Proceedings

District conversion and the coeval season of an unclear public-private partnerships urban projects unveil the gradual retreat of the public initiative in Milan's governance and transformative trajectory. Despite increasing heteronomous forces, the role of the architectural project as a design-driven agent of transformation, when supported by adequate urban governance, has already been acknowledged as pivotal in times of complex and uncertain transitions [35]. Strippoli, for instance, has emphasized how the architectural project is called time by time to reinvent its implementation tactics while keeping core strategic values of sustainability and inclusivity beyond aesthetics and functionality [36]. The C40 Reinventing Cities program was built on similar pillars: localized actions addressing global challenges.

However, evidence shows that the primary trend embodies a slow but inexorable weakening of public governance, accompanied by the so-called *de-regulation*, in favor of an increasing incisiveness of private initiative. Fostered by the privatization of basic welfare, such as transportation, social housing, or leisure, the market's dynamics have taken over the delivery of public services, triggering widespread phenomena of commodification that have also impacted architectural production. Many buildings designed for collective use have bargained their civic meaning with the flavor of fancy international styles, generating urban icons and simulacra that respond more to consumption logic than collective inhabiting. The urban transformations selected here represent this historical phenomenon well. Even the C40 Reinventing Cities initiative, inaugurated under the auspices of a new shared awareness and sensitivity towards sustainable themes, appears to have consistently shrunk over the last years, suggesting that private investments have re-oriented their focus on probably more remunerable enterprises. As the object of permanent negotiations between public and private actors, Milanese post-industrial or abandoned areas will struggle to counteract capitalistic mechanisms.

However, the high land values inevitably drive the market towards profitable logic. Considering what happened to the agricultural fields of Expo 2015, where the transition to the MIND (Milan Innovation District) aims to become a cathedral of research and innovation. The goal, in theory, is to transform the area with hundreds of enterprises and thousands of people who, using existing structures in a circular economy perspective, will begin to populate this city of the future. Yet, where one of Europe's largest linear parks was supposed to begin as a legacy, a multi-million real estate deal took place. This deal was secured by the Australian real estate giant Lendlease, which, together with Arexpo (a majority-public company), developed the project through a partnership between public entities (Galeazzi Hospital, Human Technopole Foundation, and the University of Milan) and private interests (including major pharmaceutical giants and multinational corporations allocated an area of 475,000 square meters)[37].

According to the circular logic the project for the Olympic Village in Porta Romana [38] (190,000 square meters) should be include its future transformation. The Porta Romana area, on the outskirts of Municipality 5, has long been a barrier and fracture between the North, with a consolidated residential city, and the South area, which in the recent years has experienced significant propulsion towards redevelopment thanks to the establishment of important tertiary and cultural functions such as Fondazione Prada and Symbiosis. The redevelopment of the Porta Romana rail yard, awarded to the Porta Romana Fund managed by COIMA, Covivio, Prada Holding, and the COIMA ESG City Impact Fund, has involved some of the most prominent international architectural firms for both the masterplan and the Olympic Village project. The overall objectives are intended to align with those of the EU ecological transition and the National Recovery and Resilience Plan (PNRR). Additionally, the project proposal has been reviewed through several consultations with citizens. The post-Olympics phase is also included in the initial design of the entire neighborhood, which is envisioned to have a mixed cultural/university vocation, with student housing solutions and a focus on open spaces as biodiverse meeting places for the entire city.

In this regard, the programme envisaged in the PoliMi work package of the Cimatra consortium can offer a valuable opportunity to shift the focus to post-industrial sites that are still highly valued but

are nevertheless on the outermost fringes of the city, i.e. in the urban conurbation of the extended metropolitan area. Even in these former rural areas, first industrial decentralisation and then residential pressure has generated an increasing contraction of vacant spaces. Nowadays, where even the industrial sectors have entered a crisis and have further decentralised, it remains to be clarified which tools and design solutions can be implemented.

Especially in these areas, the lower pressure of private contracts can lead to virtuous public-private synergies that can more effectively rebalance socio-economic inequalities and, at the same time, tackle the uncertain challenges of fast-changing climate change. Local governments and development agencies' attention to suburban areas may represent an interesting opportunity to counteract urban gentrification, rebalance the provision of services, and requalify degraded peripheries [39].

The challenge for the Milanese metropolitan area is to achieve territorial cohesion, trying to design a new structure for the fragmented and widespread city, reinforcing the polycentrism of the urban region, encouraging the recognition of inter-municipal aggregations which are able to get involved in municipalities, in which to seek complementarity, integration of the service system, and identity.

Extended abstract

The article talks about the challenges related to shaping public spaces in suburban areas of large cities, the so-called Eastern Bloc, on the Polish example. At the beginning, the article is focused on the characteristic features of the development of post-socialist cities, which are confronted with challenges in the cultural, energy, operational areas and the effects that result from the change of the political system. This is an attempt to systematize the typological phases of transformed large cities in relation to the Polish case – Warsaw. These cases show that they are distinctive, especially in relation to the development trends of the suburban sprawl. The change of political system that took place in Poland in 1989 initiated a new era of urban development. Local governments looking for effects as the first consequence of the political system uncritically accepted the conditions of new investors who invested in their cities, which brought far-reaching social and, above all, functional and spatial outcomes. The legal system in Poland was not equipped with adequate tools, which further deepened the spatial chaos. Large post-socialist cities, were subordinated to the dictates of the market, unavailable in the unplanned development of the suburbs. To this day, we are still in the process of urbanization of Polish cities, which has taken a pathological form, especially where land and former agricultural divisions have determined a new urban structure.

In all this, it concerns the chronic inhibitions of public space, towards which social expectations are growing. This aspect of culture in relation to public space is also available to the other post-socialist countries. The article presents a public space structure in the selected communes of the southern part of the Warsaw agglomeration, due to its use after 1989. The background for the research was also related to the social background for the changes occurring, and it is additionally interesting to note how the issues of public space have changed over the last post-socialist solution to urban development. In socialist times, it was treated as a domain of public, and there was no grassroots involvement in its shaping. After the political transformation, public space was perceived as nobody's property, with the expectation, being a remnant of the old system, that the authorities were responsible for it. Only recent years have shown the emerging readiness to co-decide and co-responsibility for space, but this situation mainly concerns the inhabitants of large cities. It will also be interesting to study what role a public space begins to play in places where there is no traditionally understood public space.

The conclusion of the article is a diagnosis of the condition of public spaces and their shortcomings, as well as an assessment of the possibilities of creating systemic solutions in this area, which are a response to contemporary civilization challenges, including climatic, technological and social ones.

Extended abstract

Back in 1974, C. A. Doxiadis finalized the manuscript of his last book, “Ecology and Ekistics”, one that would be published, a short time following his death and edited by the renowned Gerald Dix. This text, although it has not, until recently, been situated at the epicenter of doxiadic studies, proposes a comprehensive reconstruction of Ekistics as the science of Human Settlement in the light of the most primary parameter in their historical evolution, that being Nature. In the light of the current international debate on sustainable cities and architecture, the paper proposes and calls for a double reading based on the following axes. a. How did the concept of nature function as a paradigm for the constitution of the Ekistics? b. In what ways did the ecological reconceptualization of architecture and planning function, itself, as a source of later institutional and scientific developments, such as UN HABITAT, contemporary methodologies and technological frameworks, like Ecological Urbanism, GIS and geo-informatics et.al.?

The rise of the discourse on Sustainable Development and the UN SDG 17 goals, could provide with appears as a necessary reference to this discussion. Could it be hypothesised that Doxiadis iterated the presuppositions for such an ecumenical and compositional, dynamic approach? By referring, himself, to the example of Patmos, and comparing it to larger scale case studies, such as the Attica Peninsula in continental Greece, he grasps the opportunity to explain his concept of the “global ecological balance goals”. His holistic study of both its monumental and natural assets could be almost straightforwardly make sense within the contemporary definitions of ‘UNESCO cultural landscapes’, their sustainable management and the “balance between preservation and change”. Doxiadis is pioneering in both his systemic approach and his coining of a series of neologisms.

This has been a characteristic of his epistemological thinking already since the Delos symposia and the schematisation of the Human-Nature-Society-Shells-Networks diagram. Ekistics are not a sheerly taxonomic and descriptive analytical science. It may be mainly understood as an adaptive theoretical body allowing for a clear view of complex phenomena far exceeding the potential of deterministic positivist approaches. Still, a closer look at the historical evolution of Ekistics may shed light on important points of rupture, regarding its main epistemic hypotheses. To give but one example, it has been often criticised for its incapacity to cater for the political aspects of spatial ecumenical governance. At the same time, Ekistics seem to be modelling space, in all its scales, in the same way and without any direct concern for what today stands out as a crucial aspect, that of the ‘in-between’. This paper invests in Ekistics’ capacity to constantly reframe its elements and the relations between them. Doxiadis’ words may serve as an epilogue to his multifaceted experience and as a prologue for future action: ‘Our task is to define the system of life expressed by human settlements so clearly that it can contain every part, aspect, expression of opinion, known or unknown, foreseen or unforeseen. Once defined, our task is then to learn to control this system wisely for the sake of mankind.’ The task of reinterpreting and reframing this rhetorical iteration today is in ‘intensive’ limbo.

Planning the Human Habitat – The Foundation of Contemporary Ecological Urbanism on C.A. Doxiadis' Ekistics

V. Bekiaridis

PhD Candidate, CRISIS Lab, Department of Architecture, University of Ioannina, Greece

*Corresponding author: E-mail: v.bekiaridis@uoi.gr

Extended abstract

This paper delves into the institutionalization of *ekistics*, the study of human settlements devised by C.A. Doxiadis, navigating the transformative journey from early urban planners to a more inclusive, diversified and “natural” approach. Against a backdrop of a century marked by population growth, widespread urbanization, and diminishing natural resources, the urban planning landscape witnessed a paradigm shift. From being predominantly, the domain of city-builders, planning now involves a multitude of contributors, including social theorists, scientific consultants, administrative committees, and the ordinary citizens affected by planning decisions. As globalization heightened the need for universally applicable planning methods, the institutionalization of principles became a defining feature by the late 20th century. City-building expanded extensively in response to the demand for larger urban environments, yet the surge in urban populations highlighted the pivotal role of those who inhabit these spaces. The act of dwelling emerged as a determinant factor in the evolution of cities, guided by the influence of habitat culture emphasizing the construction of living spaces.

The concept of *habitat*, over seven decades, has served as both a theory of habitation and an effort to formalize its manifestations, underscoring the importance of context and the link between individuals and their living spaces. Through the pioneering work of Doxiadis, this term has left an indelible mark on space planning, emphasizing the social conditions of habitation. The collective nature of human habitats, akin to living organisms in the natural environment, evolves alongside advancements in technology that enhance social links. Furthermore, the doxiadic concept of *kinetic fields* focused on the interactions between human movement and the city's organization, again drawing on the complex relationship of individuals with their urban environment and nature.

Over the past decades, various intersecting and overlapping theories have built on these foundations – from sustainable and resilient urbanism that promote social equity and provisions against climate change, to Timothy Beatley's green or *biophilic* urbanism that actively incorporates natural elements into urban design and models urban environments on regenerative ecosystems. Currently it is the city, as the most adaptive habitat, that reflects attempts to reconcile man with nature – but sustainability hinges not only on external factors but also on the forces inhabiting it. This paper links the evolution and establishment of *ekistics* through international conferences and policy shifts, with the contemporary search for a framework for implementing more ecologically sustainable cities in the face of global urbanization and environmental challenges.

The historiography of a Biological or Ecological urbanism?

V. Tsesmetzis

PhD Candidate, Department of Architecture, School of Engineering, University of Ioannina, Greece

*Corresponding author: E-mail: v.tsesme@uoi.gr, Tel +30 6936793746

Extended abstract

Man made structures have originally been seen throughout history as an attempt to control the physical environment in a way to express human needs. But scaling in cities through the centuries has caused an unexpected consequence, the need of a diversified approach, that of not only satisfying human needs in a hostile environment but the need of a controlled flow of natural resources, such as fresh air and water, livestock and most importantly the re-introduction of controlled nature in the city, like a domesticated landscape.

While the progressive new world strived to re-engineer society as a whole, with its most prominent tool, the institution of enlightenment science, thinkers could not but try to apply in the same spirit a new paradigm of city planning.

Through the middle of the 20th century and after a complete application of the aforementioned biological interpretations of biological processes through simplification and systematization of human processes, followed a second wave of thought, that of dynamic systems and the analysis of complex phenomena.

This paper aims to create a theoretical framework of key theoretical phases of urban planning theory and create a cartography of key movements and representatives of them, concluding to the contemporary discourse.

Architects and urban planners today are turning their interest towards sustainability, climate issues and social and economic resilience. In spite of individual intentions of academics and professionals there has not been a satisfactory update in architectural education not to mention the distancing of urban planning education from a wide ranging knowledge base such as in the architectural context.

A final statement of the paper will include the expanding scientific landscape of spatial sciences proclaiming to have the solutions of the contemporary urban condition and human settlements in general.

Keywords: *Historiography of Urbanism, Biological Urbanism, Ecological Urbanism, Ekistics*

1. INTRODUCTION: A 19TH CENTURY PREHISTORY OF URBAN PLANNING

Human settlements have always been the incubators of civilizations. Throughout the centuries, different civilizations managed to evolve and increase their capacity of maintaining human life in increasing numbers. So, cities following this progress of humanity tested in every step the basic framework of infrastructure available at the time and accordingly tested by trial-and-error new ways of handling spatial and infrastructural problems. As numbers in term of populations, densities and pollution etc. increased in exponential rate, we can witness the uprising of urban theories, as systematic efforts to establish new manners of organisation.

As we already know from history the fundamental prism in the creation of urban theories has always been political. Political organization is in the core of societal organization and urban function. From the very beginning of urban theories from the First Socialists such as Charles Fourier and Garnier have tried to theorise on a perfect societal function where the paradigm of the organic city of the past used only as the reference on mean of production, functions, and familiar spatial scales so the new experimental cities could be familiar to the new inhabitants. As a parallel phenomenon with the exploration of urban alternatives we have witnessed a silent sabotage of social change by the scope

Proceedings

of the International Conference on Changing Cities VI:
Spatial, Design, Landscape, Heritage & Socio-economic Dimensions

ISSN: 2654-0460
ISBN: 978-618-5765-02-6

that urban planning works as a tool in favour of the ones in power and cannot bring by even the improvement of human life the true radical change of society.

Another story in the aesthetic universe of urban space has developed in history. That is two opposite approaches in the image of the city and going along the image of nature through the eye of the urban dweller. On the one side we have the polemic position of organisation and systemisation of society and as a reflection of that a very geometric unified and integrated urban environment. This environment must present the dominance of man-made structure versus the chaos of nature and by that means we observe the reintroduction of “green spaces” in the city as merely the quantitative amount of vegetation for fresh air or even worse the presence of nature as a domesticated object.

The other aesthetic order of city making is that of the romanticism of organic processes in city creation such as the medieval heritage of the cities that so beautifully Camilo Sitte analyzed but also translated as a synthetic tool for urban planning. Accordingly, nature is reflected similarly in this romanticist approach as a space with extravagant properties that exceed functionalism and enter to the area of connection with metaphysical schools of thought [1].

Concluding on this short introduction as we can notice, we see the influence of the two main philosophical schools of thought projecting in the urban space, Realism, and Idealism. As we will continue our research we will utilize this important observation for future connections of historical expressions in urban planning, where the aforementioned purity of intentions changes and we can see hybrid approaches in lets say modernity and organicism, as engineered naturalism and ecology of non-design.

2. PATRICK GEDDES: THE BIRTH OF BIOLOGICAL URBANISM

Beyond the above epistemological battle of implementing the principles of enlightenment or other principles of the anthropology of the western civilization, a different approach in urban thinking occurred, caused by the great impact of a new science being developed in the end of the 19th century. The thoughts of Charles Darwin’s about Evolutionary theory and the unraveling of the orders or mechanics that govern our cosmos could not dismiss Biology having a great influence in bringing solutions in the destabilization of the urban environment caused by increasing numbers and a technological shift.

Geddes being a Biologist studied the city in a very different way, which we can argue include and combine axioms from both sides of the opposing views mentioned above. Without dismissing the scientific tools to act on the city and the modernist methods to develop new strategies for urban development, Geddes argued for the city as a specialized organ for social transmission. In that way he connects the modernistic reductionist abstraction of city as an organ with a very fundamental factor of city making supported by the culturalists of the past, which is cultural heritage. This is more obvious while he describes the city as the embodiment of the cultural heritage of larger units and the transmitter of it, to societies and individuals.

Without getting too deep in the work of P. Geddes we can make a fundamental observation in the context of this paper, that the conception of Biological Urbanism by Geddes pushed forward the overall discourse of urban theory as it reached new levers of grasping the elusive and diverse phenomenon of the city, but fell in the trap of reductionism, being completely natural for the technological status of the time, by resorting to biological metaphors [2].

3. PLANNING AND NON-PLANNING. A 20TH CENTURY DISCOURSE

One of the many changes we experienced in the 20th century in the science of urban planning had as its main instigator not an urban planner but the economist Friedrich Hayek. In his book *The Road to Serfdom*, Hayek develops his liberal positions based on the basic finding that fascism was a capitalist reaction to socialism. In this book he specifically mentions that socialist or state-driven

urban planning belongs to an era of "passion for conscious control of everything". The author criticizes in his book the assumption that a democratic society must necessarily be based on pre-decided - planned principles. Hayek contrasted the planned structure of socialist states with the spontaneous expression of free economies, characterizing them as an unplanned coordination that results when individuals are allowed to pursue their own self-interest and trade more freely. This polemic aimed to emphasize a radical relationship where only a liberal society can be democratic because it does not limit individual freedoms and on the other hand any other form of central state whether right or left leads with mathematical precision to totalitarianism. In contrast to Hayek, John Maynard Keynes believed that government intervention could balance the capitalist market. These two approaches to this day remain relevant and unfortunately with the course of market deregulation we observe the "scientific" documentation of neoliberalism with the reinstatement of Hayek's work.

Accordingly, in the field of art and architecture appeared the current of New Brutalism (New Brutalists) and the Independent Group (Independent Group) part of which consisted of the Smithsons, Paolozzi, Hamilton, McHale and Reyner Banham. This generation turned away from the Bauhaus vision of the overall work of art (Gesamtkunstwerk) and turned to the unplanned every day and fragmented environment, especially the urban environment which brings together and in unplanned relationships heterogeneous elements. In 1969 the group of Banham, Barker, Hall and Price published the manifesto entitled "Non-Plan: An Experiment in Freedom" where they defined Non-plan as the liberation from regulation to promote spontaneous urban development. More specifically, they argue that the notion that the urban planner has the right to define what is right is an antiquated idea from the age of left-wing collectives and has been abandoned.

At the limits of the unplanned and free initiative of the development of the city, other recognized authors moved in a different way. Jacobs with her book *The Death and Life of Great American Cities* directs her polemic against centrally controlled urban planning and large projects in the city through the dichotomy of hierarchical and emergent planning (top-down, bottom-up). Accordingly, Venturi with his book *Learning from Las Vegas*, which is par excellence the manifesto of postmodernism, advises young architects to escape from the orthodoxy and purity of modernism and to start observing the existing heterogeneous and rich environment of the city so that they can enrich it and not to sterilize it [3].

Unfortunately, the above positions along with many others in the 70s and 80s made a terrible attack on the schools of urban planning and forced them in many cases to either close or be transferred from the Architecture schools to those of organization and administration. At the end of the century, several attempts were made to counter the neoliberal dominance of Non-planning with the aim of regaining confidence in large urban interventions. The emerging environmental movement and awareness of the planetary consequences of climate change play a catalytic role in this new venture.

4. C.A. DOXIADIS: THE FOREFATHER OF ECOLOGICAL URBANISM

As mentioned above, man throughout the evolution of civilization had an "aggressive" attitude against the wild environment in order to ensure his survival. The intensity of the human presence in space increases exponentially from the industrial revolution onwards, and consequently this data reveals the inability of the human factor to initially perceive the finiteness of resources but also the resilience of natural systems to withstand a continuous burden of their carrying capacity and their degree of feedback. On the other hand, we have a huge urbanization process at the global level with consequences such as the change of the scale of the city as well as the change of urban-rural relations. The science of Ekistics proposed by C.A. Doxiadis, is a comprehensive theory of human settlements and as such may be one of the few or even the only one with such a degree of scientific proficiency, research completeness and extent at all scales and perspectives.

Proceedings

Doxiadis in his book *Ecology and Ekistics* is certain that we are in the middle of an ecological crisis and that we still have not developed the tools to deal with it, although Ecology as a foundation of the study of natural history goes back to Aristotle. He sees the two sciences as complementary, Ecology as the one that deals with the relationships of all living organisms with the environment and Housing as the science of human settlements which are the spatial structures made by man for man.

Ekistics was coined by C.A. Doxiadis and was used for the first time as a term in his lectures at NTUA in 1942. It perceives human settlements as living organisms that have their own laws, and through the study of the evolution of human settlements from the earliest phase up to the present, develops an interdisciplinary approach to solving their problems through the recording and systematization of the fundamental principles that govern them. More specifically, Doxiadis states that for the planning of future cities and more generally of the future of human habitation, we must understand the chronological evolution as well as the variety of human dwellings to date.

We need a unifying interdisciplinarity and not just a relational one, because the object of research is composed in a unit and can only be treated as such. In his book *Ekistics, an introduction to the science of human settlements*, Doxiadis describes Ekistics as the initiative to undertake an adequate conception and testing of the data, concepts and ideas related to human settlements, and the attempt to re-approach all of the principles and theories connected with Ekistics, leading to a new science. The creation of such a science, according to Doxiadis, must be carried out in a systematic way, because without objectivity and a systematic approach that defines goals, criteria and methods, it will be impossible to achieve coordination of related knowledge, much less the coordination of ideas that they can lead to the arrests that will direct growth.

In relation to Ecology, Doxiadis identifies the common goal of Ecology and Ekistics, which is the Global Ecological Balance. Considering the course of population growth steadily upward and parallel to the evolution of technology, the world population will at some point reach a size that will test the very ability of the earth's ecosystem to support it but will also endanger the quality of life of the people.

GEB is derived from predicting the maximum carrying capacity of the global ecosystem to sustain the human population as resources. The subject is then analyzed in the distribution of human activity and the protection of the delicate issues that touch the extremes. relationships between global energy flows and endangered species. Accordingly, human activity must be spatially coordinated so that valuable ecosystems survive and are not replaced by even highly profitable and intelligent human interventions.

Doxiadis states that we need four basic categories of land:

- Naturareas - Areas of nature where the main intention is to preserve the natural wealth
- Cultivareas – Areas of crops and livestock
- Anthropoareas – Areas for people where the main objective is to meet vital needs, and is not limited to the built space that is a part of human needs
- Industrareas – Industrial and mining areas

The four categories are historical stages in the evolution of our societies from prehistory to the present day and we must maintain continuity with them. A basic problem of governance is the horizontal separation of the overall unity of the lifestyles of the categories which breaks the wholes into ministries and does not deal with the problems as a whole.

These zones occupy a percentage of one hundred in the coverage of the earth's surface depending on the geomorphological peculiarities of the regions. Something that is essential in achieving Global Ecological Balance is the balanced distribution of zones and states so that societies can ensure access to and performance of their natural resources. For this reason, this conceptual scheme must be applied at all levels of the residential logarithmic scale up to the micro-level of the neighborhood. So, achieving global ecological balance depends on maintaining ecological balances at lower levels.

Proceedings

In this way we will be able to evaluate conflicting interests of different levels, such as industrial or infrastructure development issues in relation to local and sensitive formations. The field in which Housing develops is that of the Anthropocosmos where it is part of the Biosphere and describes not only the areas of human activity but also the dynamic flows and functions. The Anthropocosmos is a fundamental framework for human survival on earth and the need to preserve it for future generations is imperative [4].

Doxiadis' work on Ekistics was literally a undertaking of the big, until today unanswered questions of sustainability along with development and making the connection of micro and macro matters. This leap of faith in the resolution of all problems by a new scientific field, even today after almost 70 years from its conception, brings agony and stress. If we can make a small critique to a such commendable and noble work, it is that in the need to cover that big research area Doxiadis gave a lot of support to systemization processes for model creation and finally articulation of a general theory, that lost in a big extent very easily its credibility while at the late 20th century all of the academia of the social sciences had been punished by the wrong doings of modeling society.

5. ENTERING THE 21ST CENTURY: LANDSCAPE, ECOLOGICAL & INFRASTRUCTURAL URBANISM

Since the mid-1990s, the environmental awareness of many architects and scientists in the field, who until recently may have also been involved in landscape architecture, and of course were limited to micro-scales in agricultural methods and practices with an aesthetic approach, together with the emerging field of urban ecology they formed the term of Landscape Urbanism. Landscape Urbanism is a planning theory and its actual applications in space are very few. As an evolution of the term, Ecological Urbanism was later promoted as a more interdisciplinary approach to planning beyond the Geographical and Architectural spectrum. This path of thought ends in a very interesting thread of Urban Planning as Infrastructure, where the previous ecosystem approach remains, but without the "green" envelope of Ecology. As a basic concept we can argue that it stands on a strong meta-aesthetic approach on matter through the treatment of everything as infrastructures or as factors that support systems of life, organic or artificial, in a similar manner.

Landscape urbanism is the term mainly attributed to Charles Waldheim, who as a student studied and followed the development of Landscape architecture. One of his teachers, James Corner typically mentions that the question of landscape is not of interest to us today for vegetation, relief and earthworks within Architecture and Urban planning schools but because the term also provides a deep reflection on the conceptual dimension of the landscape, for its ability to approach the various places, soils, ecosystems, networks and infrastructures and to organize large urban areas. He continues in his description by emphasizing that at an organizational level it must include the dynamic changes of ecosystems and tend to a "loose" urban planning in terms of definition and canonical orders, that can withstand the real complexity of cities in its structures. It is also important to mention that Landscape Urbanism places special emphasis on processes and this does not work in competition with the composition but as a complement to a proposal that takes into account the intense dynamics but also the invisible factors of the environment of intervention [5].

Landscape Urbanism is both an instigator and an accelerator and does not aim at the development of a formal proposal, but rather proposals on the public processes that planning and future appropriations produce. Waldheim himself considers that through the criticism of the scientific and professional commitment of traditional urbanism, Landscape Urbanism emerged and is an alternative proposal to New Urbanism movement. He considers that one of the characteristics that differentiates Landscape Urbanism from Landscape Architecture is interdisciplinarity and that Urban design has great difficulty in relating even to the other scales of planning, let alone to other sciences.

Ecological Urbanism on the other hand aims to develop theory and practices that emulate the insights of ecology and other environmental disciplines such as climatology, hydrology, geography, etc. Ecological Urbanism elaborates the future of cities and their planning and offers a framework for interventions on the problems that threaten humanity, such as climate change, rising waters, dwindling reserves of liquid fuels, increasing energy consumption, as well as meeting people's need for care, safety and justice. We can say that Ecological Urbanism is not an Architectural or Urban Planning movement, although since the 60s a multitude of "movements" have appeared such as Ecological design, Environmental art, Landscape design, Sustainable design, Green architecture and so on.

An important contribution to the development of these approaches was the study of the urban environment by ecologists and climatologists where they essentially highlighted the city's ecological status and, by extension, urban planning as a process and not as a final state. Ecological urbanism is differentiated from Landscape Urbanism by commenting that the latter, although not superficial as an approach, insists on the synthetic side of architects and the scale and articulation of urban design, staying in an approach of the urban space as a relief, while Ecological Urbanism aims at a direct effort to highlight ecologies, habitats and inductively explore catalytic factors of design strategies, not caring about the size of the intervention neither the exact tectonic articulation but about the relationships and thus it spreads on all its possible scales.

Stan Allen is one of the main, if not the only, exponents of the term Landscape as Infrastructure. It is a term that aims to transcend stylistic, morphological issues and anchorages and will provide a new model for action as well as push architecture to once again be able to define the future of the city. In the last two decades, avant-garde architecture has sought a biological transfer of its paradigm, trying to make it more fluid, adaptable and responsive to change. New computing technologies were used to sculpt biological forms through diagrammatic forces called biomimicry. According to Allen, we have passed the stage of biomorphism of the 1950s and 1960s, of imitating forms of nature, but as modeling the natural processes of morphogenesis. The result of this effort, although ambitious and exciting, is limited to ceasing to be dynamic as in simulations and to negate itself by "freezing" in a frame of this dynamism.

An opposing trend is that which does not aim at the biology of an organism, but at the collective behavior of ecological systems as models for cities, buildings and landscapes.

"Architecture is placed between the Biological and the Geological, it is much slower than living organisms but also much faster than the geological formations that surround us."

At this confluence of species and environment, the concepts of ecology and landscape offer more than an architecture or urbanism of frozen biodynamic form. The environment and organisms develop an integral vehicle of parallel development at all scales from micro to macro, and the issue for us is whether we can manage the complexity and the absence of boundaries. In the redefinition of Landscape Urbanism, which has been the catalyst in opening the dialogue of the last decades, placing the concept of infrastructure as central, offers a guide into the complexity of urban systems where planning is of particular importance. No one disputes the need for planning in urban infrastructure. What we need, according to Allen, is a new mindset that will be able to view infrastructure design not as an exercise in minimally necessary engineering standards, but as capable, catalytically, of energizing complex and unpredictable urban effects beyond its designed capacities.[6].

Urban planning as Infrastructure understands architecture as a material practice, as an activity that works within and with the multitude of systems and agents, and not necessarily with central argument or deterministic end product. It is an architecture dedicated to solid proposals and realistic implementation strategies, not detached criticism. It is a way of working on large scales and escaping the usual notions of master plan, and the Ego of an architect. Finally, urban planning as an

infrastructure marks the return to the effectiveness of architecture and not the imperative of a representation of it.

The big issue we are facing as Architects and Urban Planners today, if we suppose we share the same interests, is not the existence or not of powerful and important theories of urbanism, but the actual role as experts to consult policy makers and other to change their ways.

URBAN ECOLOGY: A 21ST CENTURY DISCOURSE

Ecology is also a humanitarian science. There are many practical applications of ecology in conservation biology, wetland management, natural resource management (agroecology, agriculture, forestry, agroforestry, fisheries), city planning (urban ecology), community health, economics, basic and applied science, and human social interaction (human ecology).

According to Sukopp & Wittig the term 'urban ecology' can be defined in two ways. Within the natural sciences, urban ecology addresses biological patterns and related environmental processes in urban areas, as a branch of biology and ecology. In this sense, urban ecology seeks to analyze the relationships between plant and animal populations and their communities, as well as their relationships with environmental factors including human influence. In this respect, research is not limited to anthropocentric assessments. However, the second, complementary, definition implies the anthropocentric approach.

Here, urban ecology is understood as an interdisciplinary approach to the improvement of living conditions for the human population in cities, referring to the ecological functions of urban habitats or ecosystems for people, and therefore includes the social and especially the planning sciences. From an even broader perspective, cities can be seen as emergent local-scale phenomena, dynamic interactions between socio-economic and biophysical forces.

These are the two complex ecological entities that have their own unique and internal rules of behavior, growth and evolution, and significant global ecological influence. Urban ecology is the study of ecosystems that include people living in cities and urban landscapes. It investigates ecosystem functions closely related to patterns of urban development [7]. Urban ecology is an interdisciplinary field that supports societies' efforts to become more sustainable. It has deep roots in many scientific disciplines including geography, sociology, urban planning, landscape architecture, engineering, economics, anthropology, climatology, public health and ecology. Because of its interdisciplinary nature and particular focus on humans and natural systems within urbanized areas, urban ecology has been variously used to describe the study of humans in the city, nature in cities, and human-nature relationships [8] In the literature, urban ecology has gone through two stages of development and now a third is proposed, with each transition being a disciplinary paradigm shift.

Ecology in the city

The initial phase is that of urban ecology within the city. Urban ecology targets terrestrial and aquatic patches within cities, suburbs and non-urban environments. In this example, ecologists specializing in biology study the habitats and ecosystems known to them that are in an urban or urbanizing environment. Urban wildlife ecology was a key contribution to the development of ecology within the city. This example reinforced the desire to develop habitats and wetlands or protect them within the urban environment and to a large extent defined urban planning directions [9] by introducing green and water lands for citizens and to a lesser extent the urging green facades and roofs.

Ecology of the city

The second paradigm, that of Ecology of the city, was recognized in the late 1990s [10] and moves beyond the proportional approach of sections within the city. This paradigm requires two approaches, firstly a thorough search for parts and habitats that are not dominated by non-human organisms, and secondly it requires a thorough understanding of how social and socially determined human activities affect even the analog environments studied by the ecologists of the first paradigm. This approach

Proceedings

intersects with a variety of social sciences, such as geography, economics and urban planning for example. The field of interdisciplinary collaborations also extends to engineers, scientists specializing in complex systems, and other science and technology disciplines [11]. The distinction of the relationships of the two paradigms within the urban systems was promoted to clarify the existence and presence of bio-ecological processes and structures, visible and invisible. More specifically, the contemporary approach to city ecology maintains a perspective based on process and ecosystem ecology. Although the two examples seem opposite, the truth is that one works (within) included in the second (of).

Ecology for the city

The paradigm evolved from the first two, in the context of linking ecological science with civic processes (12). Urban ecology deals with the human quality of life, the sustainability of the urban environment, the biological diversity of cities but above all, it recognizes the legitimacy of both clean and use-driven research. The core of the ecology paradigm for the city is that it takes an active role in shaping the city “from knowledge to action”. It perceives the urban ecosystem as a social-ecological system in which scientific knowledge is integrated into decision-making and in general into all processes. Finally, ecology for the city also includes and needs the support of the two previous examples, but in contrast to them it can connect the conclusions of urban ecology with the normative goals of environmental integrity, social justice and economic sustainability through the context it provides.

As we can observe Urban Ecology is following a techno-political path into establishing an implementational role in Planning, and not just analytic. Urban ecology as we can observe, is beginning to stand out as a scientific field, creating new processes for planning in a similar manner as regional planning acted in the 20th century, maybe questioning the importance of Urban Planning as the fundamental science for shaping cities. On the contrary Urban Ecology could strengthen connection between Ecology and Urbanism (Ekistics) and as so there should be stronger initiatives for the establishment of a common knowledge.

5. CONCLUSIONS

The science of Urban planning is facing a very important epistemological challenge. First to find ways to reconnect with its historical past of urban thinking. We have witnessed internationally the schism of Architecture and Urban planning, and a fragmentation of common knowledge between disciplines that in the past used to be one. Secondly to create new unifying powers that will bring together a common body of knowledge to the broader scientific field. As we mentioned above, new sciences appear and are capable of expanding their knowledge in to fields of other sciences. This epistemological phenomenon, calls for an opposite process that that of the enlightenment, that could be described as the separation of scientific fields as clear territories of knowledge. Urban planning should, following the paradigm of ecological science, climb and pursue a leading role in the contextualization of knowledge on human settlements.

Abstract

Design in Architecture is typically inspired by an anthropocentric character, which is projected onto the place where it is applied. The purpose of this research is to highlight a more holistic approach to urban design planning, where the interaction between individuals and their environment is carefully considered through a balanced evaluation of anthropocentric factors and those dictated by natural and ecosystemic processes. With the advent of new computational tools, it has been possible to anticipate solutions that effectively achieve this objective. By analyzing the dynamic relationships that unfold between humans and the natural element in each of its manifestations, the produced system allows to integrate human/nature's principles related to sustainability. The architect's updated toolset goes beyond mere representations and emerge as a comprehensive means by which to explore human-nature relationship in every design phase.

Keywords: *sustainable urbanism; traditional settlements; expansion; human/nature integration; topology*

1. INTRODUCTION

The research delves into a system for the development of existing settlements that is rooted in the logic of organization of the broader natural system. The approach responds to a search for optimal harmonization and coexistence of settlements with the environment, while maintaining compatibility and avoiding adverse effects such as permanent alterations and human-made disasters. Further, solutions are sought, where human-centered priorities go hand in hand with the dynamic character of the landscape and the overall place, leading to more sustainable outcomes. Therefore, a holistic system is proposed, applicable at an urban scale, taking into account all factors and configurations that influence decision-making in spatial design. The system evolves dynamically to anticipate and adapt to future needs and situations that may arise. The process benefits from the use of advanced computational technologies, particularly dynamic simulation tools, as the latter have advanced to handle complex tasks and diverse data inputs. In particular, these tools enable designers to overcome limitations associated with conventional Cartesian system, transforming the dynamics of nature into flexible man-made organizational structures.

Zagori region of Ioannina, and specifically the settlements located along the edge of the Vikos Gorge, were chosen as the case study area. The reasons these settlements were selected are due to two main factors. Firstly, the peculiarity of the landscape. The Gorge of Vikos has been characterized as the deepest canyon in the world in terms of vertical development to opening ratio. The second reason lies in the strong traditional character of the villages in this region and their well-defined boundaries. Throughout the years, the specific villages have undergone significant changes, which, can be categorized into three distinct periods spanning from 1960 to the present day. By analyzing these changes, the data files of the variables of the new system will be created, which are related to both human activity and the landscape itself. Additionally, we can distinguish extraneous variables, which

Proceedings

are not completely controllable, but have the potential to influence the results of the study. Capturing these elements necessitates the use of dynamic data management software to adequately support the level of complexity required by the challenges, subject matter and objectives of this research.

The paper introduces an initial version of the system, based on the data available, in order to tailor it to different settlements that meet the specified criteria. The current method proposes a more environmentally conscious approach to planning at the urban scale, guided by the harmonious relationship between humans and nature alliance in order to define and achieve desired objectives.

2. CASE STUDY AREA ANALYSIS: THE EXAMPLE OF VIKOS'S GORGE

A residential complex undergoes constant changes driven by dynamic variables that define its characteristics. The primary objective is to thoroughly analyze and comprehend these changes, transforming them into a structural system of variables, where they will be more manageable. The key categories of these variables may be attributed to landscape and human activity. The landscape remains relatively stable over time, with minimal changes observed during the study period, while human activity emerges as a more dynamic and influential factor.

Starting with the location of the settlements, the Gorge of Vikos serves as a prominent geographical reference point. The Gorge of Vikos is located in the region of Zagori, in the northern part of the Pindos Mountain range, about thirty kilometers north of Ioannina, the nearest city. The area's highest point, Tymfi's peak of Gamila, stands at an impressive height of 2,497m. The Gorge boasts a maximum depth and opening of 1,144m, and 2,420m, respectively, resulting in a depth/aperture ratio of 0.76. The Voidomatis River traverses the Gorge, spanning a total length of 15 kilometers and covering a catchment area of 384 square kilometers. *"The terrain surrounding the area is characterized by uplifted topography, featuring numerous narrow V-shaped valleys"* (TELBISZ, et al. 2019). Nature offers a multitude of benefits for humanity that can be utilized in a variety of ways. Despite its challenging landscape, the area offers a unique environment with limited exploitation opportunities, including minimal arable land, challenging access to water sources, and steep terrain slopes. However, the distinctive features contribute to the development of a diverse ecosystem, hosting rare and endemic species, along with a wide variety of thriving herbs. The area is rich in cultural heritage, with a history that dates back centuries, leaving a lasting impact on the region. Vikos' Gorge strong cultural identity is evident in its traditions and customs, making it a significant part of Greece's historical narrative.

Figure 25 Aerial photo: Wider view of Vikos’s Gorge and the settlements around it

The intricate terrain has significantly shaped the features and morphology of the settlements. Zagori comprised of 46 settlements, informally categorized into Western, Central and Eastern Zagori. The focus of this research is on the settlements located in central Zagori, situated on the periphery of the Vikos’s Gorge. Specifically, the settlements of Vradeto, Kapesovo, Monodendri and Vitsa are examined (Figure 1). As time progresses, these locations also experience transformations, forming a continuous evolution that allows for the observation of distinct moments in their development.

Figure 26 Schematic section (North-South) Position of Monodendri village in relation to Vikos’s Gorge

Figure 27 Schematic section (West-East) Position of Monodendri village in relation to Vikos’s Gorge

These four settlements can be divided into two groups based on their location and their connection to Vikos's Gorge. Kapesovo and Vradeto are situated on the eastern side, while Monodendri and Vitsa are located on the western side. Access to these settlements is primarily provided by a carriage road, which is divided into two main sections with various branches. Each settlement is connected individually by paths, enhancing their accessibility and connectivity.

The relationship between human activity and the development of settlements will be examined across three distinct time periods, each influenced by the prevailing political-economic context of the era. The initial period and the starting point of the study is the 1960s, a pivotal decade following the aftermath of the World War II. During this time, agricultural and economic endeavors began to take root in the region, with the lands surrounding settlements utilized primarily for animal husbandry. "7,000 acres of land surround Kapesovo and 8,500 acres are within a few hours' walking distance... Livestock farming provides the village with a slightly better income than crop income (16% of total village income, compared to 15.2% of agriculture)". (Baud-Bovy & Papageorgiou, etc.). According to demographic data of that period, the permanent population of the wider Zagori region totals 8,977 inhabitants. When broken down by settlement, Vitsa is home to 485 individuals, Vradeto to 315, Kapesovo to 197, and Monodendri to 244, resulting in a combined population of 1,241 across the four villages.

The second period of study focuses on the 1990s, a decade marked by significant urbanization trends in the area. The gradual shift from small settlements to larger urban centers, created stark contrasts within the study area. Concurrently, there was a noticeable rise in tourist activity, which began to shape the region's dynamics. The population of the settlements, during this period, totaled 382 inhabitants in Vitsa, 129 in Vradeto, 122 in Kapesovo and 212 in Monodendri, amounting to 845 inhabitants in total, representing a 32% decrease.

Moving on to the third period of interest, in the research, the 2020s, it is observed a landscape where permanent residents are scarce, yet construction activity is on the rise as tourists comes to fill the vacancies. The total population in the area stands at 267 residents, with 82 in Vitsa, 22 in Vradeto, 30 in Kapesovo and 133 in Monodendri, reflecting a 68% decrease in population.

"The people of Zagori are generally skilled, active and engaged in commercial activities. We find rich merchants in Kapesovo and Veija who have trading houses in Vienna, Moscow, Breslau. in Leipzig and Amsterdam. Most of these big traders are getting rich in Germany." (Baud-Bovy & Papageorgiou, etc.). The occupation of the inhabitants in trade, brought about economic prosperity and subsequent development in the region. The architecture of Zagori reflects its economic standing, with elaborate houses that are product of the unique terrain. The morphology of buildings is a consequence of the specific terrain, in which they are situated, although it may not be entirely unique. The use of stone and wood in construction, coupled with the cold climate and rugged landscape, which implies both intense shading and protection from the winds, resulted in buildings characterized by simplicity, geometric shapes and limited openings. The roofs, typically square with slate coverings, are a common feature in this region and can be found in various parts of Greece and Balkans. It is worth noting that this architectural typology may be attributed to the prevalence of builders in Epirus, who often sought work in the Balkans during the winter months. This migration pattern likely influenced the architectural styles seen in both regions.

3. DEVELOPING RELATIONSHIPS AND THEIR ASSOCIATED VARIABLES: FROM ABSTRACT TO DIAGRAM TO DYNAMIC TO PARAMETRIC

“To abstract means to take away, to isolate, to remove”, (Cache, 1995)

In order to grasp the necessity of a comprehensive system, it is imperative to delve into the concept of "abstraction". This concept is prevalent across various disciplines, including Art. Generally speaking, abstraction involves isolating the fundamental characteristics of a set. By abstracting the core essence of a subject, without imparting morphological or other details, a universal framework is established that allows for diverse interpretations based on the observer and the broader context in which she/he exists. Abstraction invokes conceptual approaches related to use of diagrams. Diagrams operate on a similar principle. The act of extracting certain features and transforming them into dynamic variables makes the diagram a flexible device adaptable to various models. This flexibility increases the diagram's utility and relevance to multiple scenarios, expressed as continuous changes of the dynamic models.

Figure 28 Diagrams of dynamic movement

In the field of Architecture, the advancement of digital computing has revolutionized the production of dynamic models, enhancing the interpretation of data. "Coming from the mechanical industry, computational drafting tools have their origins in the post-war research projects of American universities, most notably the MIT. As is the case with many other appropriated technologies, their diffusion had to wait many years", (Echenagucia, May 6, 2014). Since the mid-90s, digital computing has played an increasingly significant role in Architectural design. Initially, its primary function was procedural, focused on accurately representing and describing designs through two-dimensional and three-dimensional visualization. Digital media, which originally developed for entertainment graphics, found valuable application in the field of Architecture.

The incorporation of a multi-parameter logic in the design process is crucial for accurately defining and solving problems. This logic involves describing elements through parameters and variables, where any alteration in these elements directly impacts the final outcome. The advancement of digital technologies has led to the widespread adoption of integrated parametric methods in design. The primary objective is to discover innovative organizational structures and morphologies by leveraging the experimental capabilities of digital computing tools. According to P. Schumacher, parametric design represents the culmination of a contemporary mindset, harnessing computational power to its fullest extent. Despite what is widely believed, parametric design is not an outgrowth of modern digital design media. While parameters are now expressed digitally, they are fundamentally rooted in physical elements, such as the climate, human movement and structural functionality. In smaller scale areas, like the traditional villages of Epirus, these elements are inherently integrated into the design and construction process. It is observed, however, that there is a noticeable lack of evolution in these practices despite the introduction of new technological innovations in design. The integration of parametric design principles is essential for pushing the boundaries of architectural innovation and responding effectively to the challenges of a rapidly evolving world. As it is suggested, the use of

Proceedings

advanced methods and the respective computational techniques in this present case will allow to fully leverage the potential of parametric thinking in creating efficient design schemes for sustainable integration into the rich environmental and cultural context of the greater Zagori region.

Upon comparison of the different time periods being discussed concerning the Zagori region, since 1960, there has been a noticeable shift in population movement, from small settlements to larger urban centers. Prior to that period, the primary force (in other words, magnitude) keeping inhabitants in villages was security, which was directly linked to the challenging terrain of the area. Land served as a pivotal point for the development of settlements during this time. The unique topography of the region has gradually led to a decline in the population (permanent residents), while simultaneously is contributing to an increase in tourism (periodic residents). By 1990, the trend of permanent population migration towards urban centers continued, while the emergence of tourism caused to create new poles of attraction towards the settlements in the opposite direction. As of 2020, the “force” of tourism, based on the topography is on the rise, while, the development of the internet and the growing trend of remote work are contributing to this growth. It becomes evident that when services are not a primary draw for an urban center, their impact on the human flow diminishes. Additionally, the growth of tourism has spurred improvement in infrastructure, particularly in healthcare and education, fostering a sustainable return of permanent residents.

The development of tourism, closely tied to the landscape, serves as a point of attraction for human activity. However, it is acknowledged nowadays that excessive and rapid population growth can have detrimental effects on the natural ecosystem and the environment. Factors such as water purity, soil quality, wildlife populations and fire risk are all susceptible to the impacts of increased human presence, particularly tourist. The intricate relationship between nature and tourism is affected both by the volume of tourists in the given area and by the duration of their stay. So, the dynamics of a variable such as the flow of people in a settlement brings about changes in a set of other factors as well as problems that may arise over time.

The development of a road network is contingent upon various factors, including the location of settlements and unique characteristics, such as geomorphology and soil composition. The main objective of a road network is to provide access to different areas, but the method of connection is heavily affected by the landscape (terrain), particularly the steep gradients that need to be integrated into the network design. Key variables that impact the final design of the network include the slope of the road, its width, the minimum distance required for travel, the stability of the ground and the presence of obstacles. These factors interact to shape both primary and secondary roads, with the importance of each variable shifting depending on the specific circumstances. In the recent years, tourism has emerged as a significant factor that affects road networks, with new routes being established or existing ones being upgraded to accommodate visitors. The length of these routes is not solely determined by speed and efficiency, but also by the experiential connection they offer to nature and the surrounding landscape. In essence, the design and development of a road network is a complex process that requires careful consideration of various factors, with the ultimate goal of providing efficient access while enhancing the overall experience for travelers. Another relationship coming to light is the correlation between the morphology of roads and rivers. The flow generated by the momentum of the waters is influenced by similar factors that shape the course of a route. The form of a road often mimics the natural curves of a river, as both are designed to navigate efficiently through the landscape. Other factors such as obstacles and ground deformation have a decisive role in the morphology of roads and alike of rivers, since the most sustainable solution would be to adjust. Another notable aspect, a consequence of the area's rich history, is the presence of a significant number of historical monuments and traditional bridges. The stone bridges, constructed during the 18th and 19th centuries, served the purpose of connecting several villages that were previously inaccessible due to the rugged terrain. However, the construction of these bridges was a complex process influenced by various factors. On the one hand there is the landscape and the human movement towards settlements, as it offers access and bypass obstacles. On the other hand, there is the residents' expertise as skilled builders, demonstrating their developed skills. Their craftsmanship and dedication to their craft are evident in the lasting legacy of these historical monuments. In the present period, these bridges and historical monuments continue to play a significant role in the development of tourism in the area. While their functional purpose may have diminished over time, the experiential value they offer to visitors leads to the present growth of tourism.

By delving deeper into the analysis of internal forces and variables while adjusting the scale, the attention can shift towards the architecture of the settlements in Zagori. These settlements create an autonomous system that is shaped by a combination of internal dynamics and external pressures. *"If we wish to define architecture as an operation on space, we must then define the nature of this space more precisely"* (Cache, 1995). Architecture is the process of designing and organizing space in a way that is functional, aesthetic and meaningful. *"On the outside the vector indicated the site as an eminence in order to determine a territorial identity; on the inside the vector is this object opposite which one must position oneself to determine a sexual identity"*, (Cache 1995). In this context, a "vector" can be identified as a force that molds the identity of a space or an individual within that space. The built is the combination of the forces exerted on it, either by the environment, or by the user. The built can initially be treated as an object, which receives forces, but at a second level it turns

into a dynamic object, where the same forces interact with the environment. The factors that influence the interaction between two variables can be categorized as either endogenous or exogenous. Endogenous factors refer to internal changes that can be caused to a unit, such as the user property and scale. On the other hand, exogenous factors include external elements like gravity, weather conditions and terrain (Figure 5 & 6). The environment can be defined as a constant with limited changes, while the user is a variable with a broader range of values, including property, length of stay and age. So, in a system of continuous changes, one can observe how external geography impacts internal morphology. In the example of Gorge of Vikos, the forces of the location have influenced the formation of settlements with distinct characteristics. The narrow internal networks of routes contribute to high-density settlements, with arable lands surrounding them. The soil quality dictates different agricultural activities, while rocky surfaces present challenges and opportunities for development.

Figure 31 Diagrammatic section (West-East) of the settlements of Monodendri (Left) and Kapesovo (Right) and the external forces they receive

Figure 30 Diagrammatic representation of the internal changes of a unit

Regarding the building units, specifically the residences, we identify respectively internal and external forces from which the morphological and design choices derive. In terms of the environment, the way buildings are constructed is a consequence of the terrain. The materials used, such as stone, come from the Zagori area. They are carefully selected to provide protection from harsh weather conditions, especially during winter months, while also ensuring the buildings are not affected by the flows of the streams formed by the rainfall. The residents themselves can be added to the internal factors shaping the morphology of the buildings. Historically, there has been a gradual evolution in the design of residences, with three main typologies emerging based on the needs and the economic situation of the residents. However, from the 20th century onwards and especially during the last most recent period, the process of evolution of typologies has changed, reflecting changes in the qualities and needs of the residents. In appreciation of the past, there has been a strong connection between the dwelling and the inhabitant, with the building typologically adapting to the individual's qualities and needs. However, this bond progressively changes course with the inhabitant appearing to adapt more to the shell, which now tends to remain essentially unchanged especially in cases where traditional architectural style is preserved.

4. CONCLUSION

It has been noted that certain elements may initially appear to be independent of one another or the relationship between them may not be immediately apparent. However, upon closer analysis of their characteristics and a broader understanding of the overall system, deeper relationships between them can be identified. This observation allows for the linking of spatial elements and qualities as related variables within a larger system model. It is important to note that such a model, which incorporates these relationships, cannot be considered an absolute or closed one, due to the nature of the data involved being mostly negotiable. This means that due to its special nature, the data used in this approach cannot be precisely analyzed or quantified, nor can it be clearly defined. These data are referred to as “fuzzy” data (Ζαβολέας 2023). The goal, therefore, is to develop an approximate method that utilizes variables, constants and relationships derived from the analysis of the study area, to create a predictive model. This model aims to propose a holistic integration of residential complexes into their surrounding environment. The example of the Gorge of Vikos serves as an initial case study in the development and application of such a model, particularly in urban areas that display similar characteristics. This model has the potential to be adapted for use in other areas, providing valuable insights for planning decisions across various scales.

Extended abstract

K. Doxiadis believed that when integrated with nature, society, physical structures (shells), and networks, human presence could ensure the city's harmonious operation. In *Ecology and Ekistics* he called for action, based on a systematic analysis of a set of problems, the concept of nature functioning as a paradigm for the reconstitution of *Ekistics*. In the same way nature could recompose the theory of *Ekistics*, in the light of the current international debate –political, social, technical, economical- on sustainability, architectural education is challenged and reconfigured under this prism. The *science of human settlements* has an inherent connection with the question of housing. The orientation towards approaches tackling ecology via adaptability, resilience, inclusivity a.o., redefine both the frameworks and methodologies of housing typology and its spatial characteristics. Even if parameters related to ecology are part of the guiding directions but also of the briefs used in the architectural education at a theoretical and synthetic level, they could be re-read under this prism, shedding light to a potential application of Doxiadis principles to today's architectural teaching methods and tools. This article proposes to explore the possibilities of these principles informing the typology of housing within architectural education, both in design studio and theoretical courses, in order to serve as conceptual, organizational and methodological tool that promote experiential learning. In other words, the article seeks to understand how a possible integration of Doxiadis principles as derived from the *Ecology and Ekistics*, in the educational process of architectural design and theory, could affect the compositional and interpretative approach to housing typologies, participating on students' spatial thinking as well. To approach this question, the five principles of *Ekistics* and the categories of human settlements are applied in current briefs on housing typology. With an insight on ecology, the codification of Doxiadis theory into concepts, terms and parameters is related to the key concepts and topics of the corpus chosen. The correlations and analogies derived serve as a material for systematization. By redefining and reorganizing the briefs based on the relational structures governing *Ekistics*, we intend to propose a re-evaluation of the compositional and theoretical approach of architectural education towards the integration of a thorough conceptual, functional, technical and sociocultural approach of nature and ecology. The aim of the analysis and interpretation proposed is to study the formation and evolvement of the housing design process carried out, through a pedagogical point of view, within the framework of the ecological reconceptualization of architecture. Moreover, the ways the experience can be transformed into spatial perception, through critical and inquisitive spirit, are investigated.

Keywords: architectural education; design process; housing typology; sustainable architecture; ecology

1. INTRODUCTION

In recent years, there have been significant discussions and debates on the need to transform and rethink architectural education. Several key themes and proposals have emerged in response to the evolving needs of society, advancements in technology, and shifts in architectural practice, all through the lens of ecology and the environmental crisis. Within these discussions, critical pedagogy and experiential learning have been introduced as important methodologies, as they are regarded to be vital in architectural education, particularly in the exploration of housing typology. What is the role of students' cognitive experience of habitation and domestic spaces in the process of architectural design and in what ways does this experience define the development of their own architectural identity?

Doxiadis' theories present human settlements as living organisms that can evolve: anthropos can employ the ideas derived from his theories to direct this development and ensure a better living environment [1]. This paper aims to explore the role of experiential learning in architectural design studio, particularly on the theme of residential design projects, with the introduction of Doxiadis' theories on human settlements as a methodological tool to analyse the transformative process that takes place in architectural education on the exploration on this specific typology. How can one use Doxiadis' theories and concepts to comprehend housing typology strategies? In what ways could ecology be involved in this process?

2. DOXIADIS' EKISTICS & ECOLOGY: APPLICATIONS ON CONTEMPORARY BUILT ENVIRONMENT

Human settlements are the territorial arrangements made by Anthropos for his own benefit and welfare. They are the results of human action and their goal is human survival, an easier and better life; happiness and safety (as Aristotle demanded); and opportunities for human development. [2]

How can we, as designers, achieve urban environments that respect human dimensions and our communities? The theory of *Ekistics* (1970) by Constantinos Doxiadis focused on the analysis of human settlements, aiming at a balance between man and his (artificial) surroundings. The five pillars of human existence — nature, humans, society, shells (buildings), and networks — served as the foundation of his study and formed a methodological tool to analyse habitation. As key elements of human existence and behaviour, these components are subject to examination from the perspectives of politics, society, technology, culture, and economy, offering multiple layers of interpretation.

One basic component of human life is the need of people to maximize their possible contacts. Doxiadis' theory's first principle addresses the necessity for people to interact more with their environment and with other people. This can be seen as a realistic interpretation of each person's right to personal freedom and the reason why humans want to control their surroundings. The second principle relates to the fact that people want to use as little energy, time, and money as possible to achieve their present and future objectives. For instance, people usually choose the simplest path when faced with a physical obstacle, such as a mountain. Maximizing the protective area in which people live, whether permanently or temporarily, at any time and place, is the focus of the third principle: humans need a shelter from heat, noise, and other distractions, a shelter that can make their life comfortable. The fourth principle deals with how human connection with the environment is organized and optimized. This includes interactions with other people (society), buildings of all kinds, networks (such as telecommunications and roadways), and the natural world. This type of structure, which encompasses both organic, daily functions and aesthetics, is essential to preserving order in human existence. According to the fifth principle, man organises his settlements to achieve the best possible synthesis of the preceding four principles; nevertheless, this synthesis is dependent on a number of variables, including time and space, the actual world, and man's capacity for synthesis. "Successful human settlements" can be defined as such when this is achieved through a planning that maximizes the number of possible contacts (first principle), minimizes the energy used (second

principle), permits separation from others (third principle), and creates the desired relationship with the environment (fourth principle). [3]

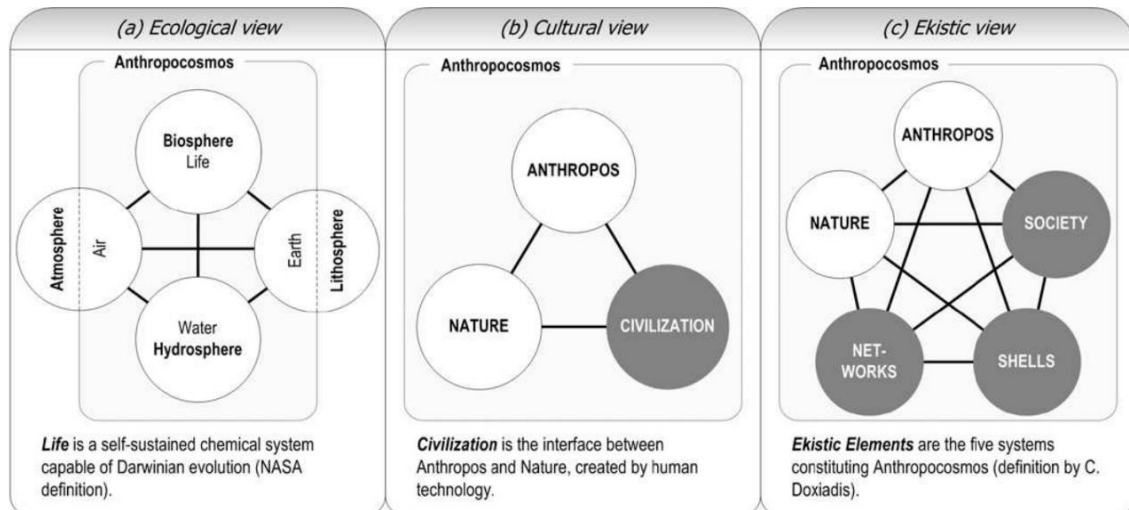

Figure 32. Ecological, cultural and ekistic view of Anthropocosmos. (source: Pertsemliadis, 2007)

Ecology: Branch of biology dealing with the mutual relations of living organisms and their surroundings; their habits, modes of life, populations, etc: human ecology, study of interaction of persons with their environment, their spatial distribution in relation to material and social cases and effects. [4]

In the study of *Ecology & Ekistics* in 1977, the ideas analysed in *Ekistics* are approached through the lens of ecology as interpreted by Doxiadis. He discusses the achievement of a global ecological balance that will support the optimal development of humanity and analyses the ecological system focusing on its five ekistic elements: nature, Anthropos (humankind that is), society, shells and networks. This book, although not central in Doxiadis studies until recently, offers a thorough reimagining of *Ekistics*, emphasizing Nature as a fundamental factor in their historical development. *There is only one way to get out of the confusion and achieve the balance we need: we must clarify our intentions by defining and establishing types of spatial areas necessary for the survival of humans and their ecology.* [5]

Ecology and Ekistics calls for action grounded in a systematic analysis of specific problems. For issues arising from the growing degradation and pollution of the natural environment, it advocates for the international adoption of a universal classification code, along with a code of conduct for each zone. [6]

Specifically, Doxiadis proposed four basic types of areas, or ‘ecological types of space’, differentiated by use: the naturareas, the cultivareas, the anthropareas and the industrareas, each of them subdivided into defined zones with different characteristics. [7]

Of the many disciplines related to nature, ecology is to Doxiadis the closest to current needs, making it the chosen field for connection to *ekistics*. This effort attempts to integrate and relate disciplines, technologies, and sciences with all aspects of human settlements to better understand the world of humans. [8]

With current global discussions on sustainable cities and architecture Doxiadis' concluding thoughts highlight the importance of understanding and managing the system of human settlements for humanity's benefit. A consideration that arises concern the possible applications of this research on the contemporary built environment and the ongoing research on this direction.

On a worldwide level, while interconnecting local and global environmental issues, the United Nations Human Settlements Programme (UN-Habitat) aims to integrate environmental considerations into urban policymaking, addressing housing as well. At the same time, an essential

feature of ecological urbanism is acknowledging of the wide-ranging impact of ecology, which expands beyond the urban area. *The city, for all its importance, can no longer be thought of only as a physical artifact; instead, we must be aware of the dynamic relationships, both visible and invisible, that exist among the various domains of a larger terrain of urban as well as rural ecologies.* [9]

3. THE HOME AS ARCHITECTURAL TYPOLOGY: EXPERIENCE, SPACE, EVOLUTION

Shells: All types of structures used by anthropos for living in or for the accommodation of animals, machinery, produce, manufacturing, etc.; the structures within which and by which mankind lives and carries out his different functions; the structures that cover ekistic functions: one of the five ekistic elements.

House, housegroup: These terms, replacing the terms 'dwelling', and 'dwelling group' formerly used, correspond to ekistic Unites 3 and 4, with a population of 5 and 35 people respectively. Housegroup corresponds to community class 1.

Room: Ekistic Unit 2, with a population of 2 [10] [11]

From the early days of human civilization, as Stoneham and Smith [12] state, any form of built, enclosed space, provided a sense of security and protection for its users. Residential areas acquired specific spatial qualities as mankind evolved and arranged itself into permanent communities according to location. These characteristics varied depending on several aspects, including religion, climate, socioeconomic factors etc.

The space that one calls "home" reflects and shapes one's identity, serving as an extension of the self and a canvas for self-expression.-At the same time, the experience of being at "home" fosters a sense of belonging and rootedness within a community or social group. It is a place where individuals feel accepted, understood, and connected to others, forming bonds with family members, neighbours, and broader social networks.

David Benjamin described "home" as: *(The home is) that spatially localized, temporally defined, significant and autonomous physical frame and conceptual system for the ordering, transformation and interpretation of the physical and abstract aspects of domestic daily life at several simultaneous spatio-temporal scales, normally activated by the connection to a person or community such as a nuclear family.* [13]

While the psychological definition of home emphasizes the emotional, social, and symbolic dimensions of residential spaces, their architectural characteristics focus on the physical and spatial attributes that shape the built environment and provide shelter and accommodation for individuals or families.

Over human history, there has been a direct correlation between the spatial characteristics of "home" and the development of society. The relationship between social factors and residential space organisation is very strong, and the changes in the latter clearly reflect shifts in society institutions, cultural norms, and technology developments, as well as the rising role of sustainability.

An interesting example can be found on the transition from the typical Athenian house (Athens, Greece) to the architectural archetype of polykatoikia.

Until the early 20th century, each household in the area of Athens occupied its own space, but were organized in groups around a courtyard, which served as a strong gathering place for informal interactions between the residents for daily activities by offering opportunities for socialising, recreation, and household activities. Although the common areas were shared by all members of the households, they also provided some privacy and isolation from the public realm. Such a spatial organization promoted social interactions and close-knit family ties. The houses were organized in one or two-storeys, with the upper floor to be equipped with a glass facade element [14]. This arrangement of Athenian houses was reminiscent of the ancient typology of residential areas and the idea of atrium and peristylion. According to Theocharopoulou, A. Konstantinidis, a prominent name

Proceedings

of greek 20th century architecture, who studied in detail these houses, stated that there is a direct link and sequence between ancient domestic architecture and “old” (referring to pre-revolutionary period) athenian houses’ typology. [15]

In contrast, the polykatoikia represents a significant architectural and social shift. Polykatoikia, which emerged in the 1930s, expanded swiftly during the 1960s and 1970s, and currently has a prominent position in the city's urban identity. This architectural model was closely linked to the rapid urbanization of Athens metropolitan area. The term “polykatoikia” stands for the small-scale, multi-storey apartment building, and ultimately refers to a method for constructing and disposing multiple housing units and apartments within a single plot of land. [16]

Polykatoikia apartments was originally planned to enhance a sense of connectivity among residents, as multiple households shared common areas such as stairwells, lobbies, and courtyards, and this organization ideally would encourage social interaction and neighbourly relationships, albeit within the confines of a more structured and organized environment compared to the informal interactions of typical Athenian houses. But, as this housing model expanded within Athens, it turned out that it did not aspire the sense of collectivity as originally planned. [17]

The Blue polikatoikia in Exarcheia area is a characteristic example of the previous statement. In its original design and first period of habitation, on the top level, there was a large space for social interaction of the building’s residents, which promoted the sense of neighbourhood, the ‘enteftkirion’. This space offered to its users a chance for rest, peace, tranquillity, unobscured city views and an opportunity to socialize with the rest of the polykatoikia’s inhabitants. Unfortunately, enteftkirion did not last for long – this and other spaces designed for communal use, were transformed into small apartments.[18]

The polykatoikia enhanced the sense of individuality within residents and the need for privacy, as it featured a vertical layout, with multiple floors housing separate apartments. Each apartment had its own self-contained living spaces, including bedrooms, bathrooms, and kitchens, providing a greater degree of spatial separation and privacy between individual households, when compared to the typical Athenian house. [19] Polykatoikia contributed, along other social factors to the increasing privatization of domestic space.[20]

Overall, both housing types served as reflections of their respective societal contexts: the typical (pre-revolutionary) Athenian house represented a more traditional and informally communal form of domesticity and the polykatoikia symbolized a shift towards modernization, urbanization and increased population density with less communal, vertically integrated forms of urban living. The architectural transition from the typical Athenian house to the polykatoikia apartment reflects a complex interplay of social, economic, and cultural factors shaping urban life in Greece over time.

4. HOUSING TYPOLOGY IN ARCHITECTURAL EDUCATION: EXPERIENTIAL LEARNING AND THE TRANSFORMATIVE PROCESS

The introduction of housing design projects in the architectural design studio has a distinctive difference in comparison to all other categories of projects: each student is, by default, carrying specific ideas and spatial experience from their own domestic environments. [21] It can be regarded as a dichotomous issue, as, according to Czafik, Puškár, Vráblová & Bacová “it reflects individualism and, at the same time, manifests contemporary architectural shaping”. [22]

Given the above-mentioned statement, residential design projects in architectural studio form an ideal case for the application of experiential learning theory. ELT, as widely known, was analyzed by Kolb and other scholars (John Dewey, Kurt Lewin, Jean Piaget, William James, Carl Jung, Paulo Freire, Carl Rogers and others) who gave experience a central role in their theories of human learning and development—notably—to develop a holistic model of the experiential learning process and a multilinear model of adult development. [23]

According to ELT, learning is defined as “the process whereby knowledge is created through the transformation of experience. Knowledge results from the combination of grasping and transforming experience” (Kolb, 1984: 41) [24]. The ELT model portrays two dialectically related modes of grasping experience— Concrete Experience (CE) and Abstract Conceptualization (AC)—and two dialectically related modes of transforming experience—Reflective Observation (RO) and Active Experimentation (AE). Experiential learning is a process of constructing knowledge that involves a creative tension among the four learning modes that is responsive to contextual demands. This process is portrayed as an idealized learning cycle or spiral where the learner “touches all the bases”— experiencing, reflecting, thinking, and acting—in a recursive process that is responsive to the learning situation and what is being learned. [25]

Through experiential learning, the students undergo a transformative process, by using their concrete experience of own residential spaces as a basis to observe and experiment on their educational projects in the architectural design studio, by integrating spatial principles on functionality, layout and user experience.

According to Mezirow, transformative learning is “the social process of construing and appropriating a new or revised interpretation of the meaning of one’s experience as a guide to action.” [26]

The architectural studios and the way they operate can be classified in both the areas of pedagogy and andragogy. [27] Pedagogy, as Winter at al, describe it, is a content model of teaching, where the transmission of information and skills, predetermined by the teacher, is focused on filling perceived deficits in students’ knowledge and comprehension.[28]

Andragogy, on the other hand, describes the process of learning as a transaction between the teacher and the learner, in which the needs of the learners are addressed as teachers facilitate the process of content acquisition by providing leads to other content resources. [29]

This is achieved by the teacher facilitating experiences through which the topic, or what is being learnt, can be directly related to learners' own life experiences. [30]

Taking into account the distinctive characteristics of architectural design studio and its interactive, dialectic nature between the tutor and the student, the educational process can also be classified under the term of “critical pedagogy”, which, according to A. Salama: *aims at reconfiguring the traditional student/ teacher relationship, where the teacher is the active agent—the knowledge provider—and the students are the passive recipients of the teacher's knowledge. Grounded on the experiences of both students and teachers, new knowledge is produced through the dialogical process of learning.*

[31] This new knowledge, derived from the students’ and tutors’ experience from their own domestic spatial cognition, combined with tutors’ knowledge of compositional principles as per bibliography, empirical professional experience and curricula, is the main hypothesis of this article. How can this process of learning be mapped and facilitated, using *Ekistics*’ principles on human settlements as a methodological tool?

5. DOXIADIS’ EKISTICS AND ECOLOGY AS A METHODOLOGICAL TOOL IN THE HOUSING DESIGN STUDIO

In order to approach the issues raised, an empirical process will concentrate on a series of workshops conducted within the architectural design studio, aimed at exploring the connections between design process, housing typology, the theory of *Ekistics* as well as *Ecology and Ekistics*.

A first workshop tool place with the participation of Year 1 and Year 2 students of BArch (Hons) Architecture program (Metropolitan College in collaboration with Oxford Brookes University). This workshop introduced Doxiadis' theories to the students and highlighted key concepts of architectural composition by relating through keywords the principles of *human settlements* to the idea of habitation. The objective was to document each student's understanding of the habitation experience by linking it to specific phrases that encompass the essence of feeling at home. Simultaneously, students used these keywords to describe the spatial qualities related to housing typology in their

Proceedings

current architectural design project. Diagrams and word clouds served as tools to record and convey the findings of the experiment.

More specifically, the questionnaire [Appendix 1] aimed to highlight correlations concerning the development and exploration of housing typology, as studied in the studio course of Architectural Design, between the theoretical principles of *Ekistics* by C. Doxiadis and the design process elaborated. In this questionnaire, students were asked to associate spaces with keywords deriving from the interpretation of each of the five principles of *Ekistics* regarding the relationship between humans and the organization of space.

The students of the 2nd and 3rd year were asked to reflect on the spaces that have impressed them, identifying them experientially as strongly connected with the meaning of ‘home’, today or in the past (a). They were also asked to consider the residence(s) they have designed in their current proposal for the architectural design course (b). During this process, they were provided five keywords for each principle, to align with the relative spaces in (a) and (b) case.

<i>Doxiadis principles</i>								
	<i>keywords</i>							
1 st principle	contact	interaction	socialization	transition	threshold			
2 nd principle	distance	functionality	sustainability	economy	access	circulation	movement	
3 rd principle	safety	shell	familiar	protection	privacy	comfort		
4 th principle	system	network	connection	society	nature	community	order	organisation
5 th principle	sustainability	development	Harmony	Balance	symbiosis			

Table 3 Attribution of keywords to each Doxiadis principle, deriving from the interpretation of its notions and concepts

The collection of the results was interpreted and classified as follows, demonstrating the keywords most used for the description of the students’ own perception of the habitation experience, thus linked to the idea of *home* (a – circle at left), the keywords mostly associated with the students’ proposed perception of the habitation experience, thus linked to the design project (b – circle at right) and the ones intersecting both categories, thus representing the common ground.

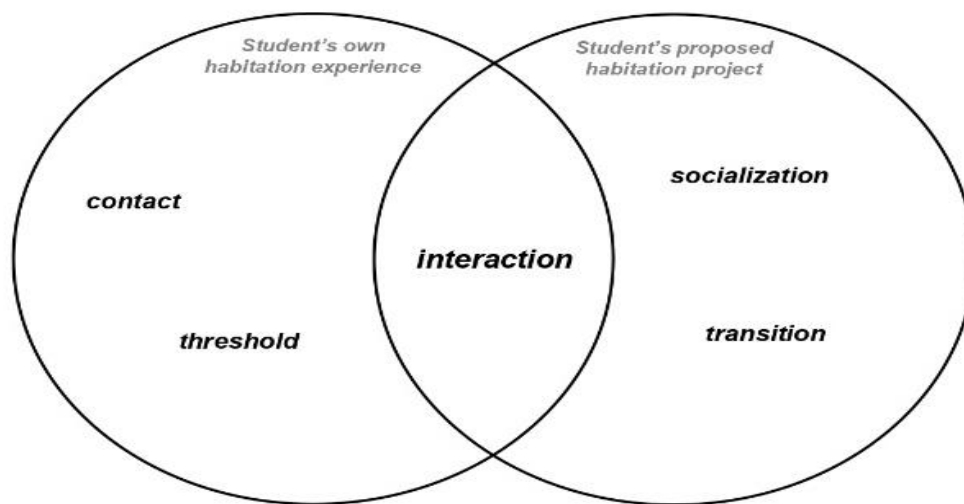

Figure 33. First principle: maximization of man’s potential contacts with the elements of nature, with other people, and with the works of man. Proposed keywords: contact, interaction, socialization, transition, threshold. (source: authors)

The keywords *contact*, *interaction*, *socialization*, *transition*, *threshold* interpreted Doxiadis first principle. According to the students the common ground that relates the perception of the habitation experience of their personal notion of home and the one of the proposed housing design project is the keyword *interaction*. For the second principle, among the keywords *distance*, *functionality*, *sustainability*, *economy*, *access*, *circulation*, *movement*; according to the students the common ground that relates the perception of the habitation experience of their personal notion of home and the one of the proposed housing design project is the keywords *circulation* and *distance*.

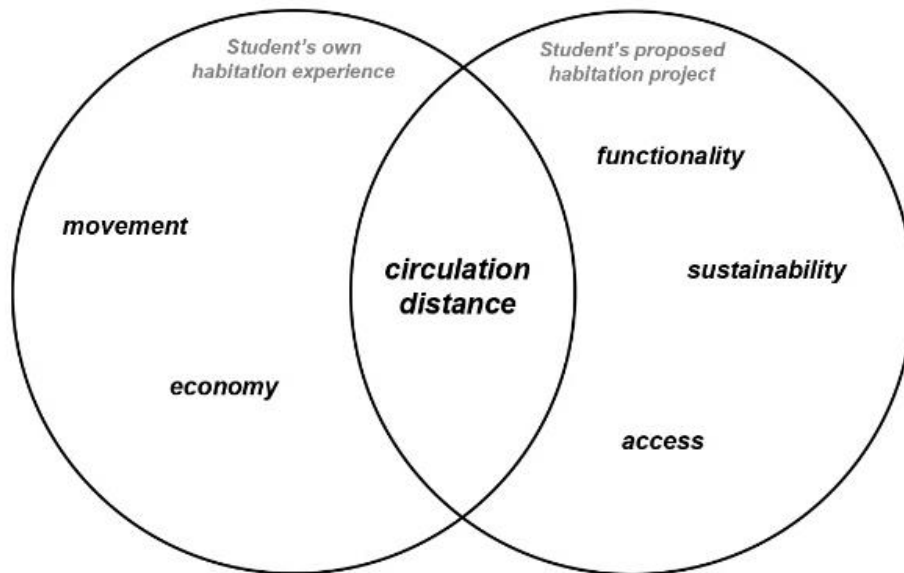

Figure 34. Second principle: minimization of the effort required for the achievement of man's actual and potential contacts. Proposed keywords: distance, functionality, sustainability, economy, access, circulation, movement (source: authors)

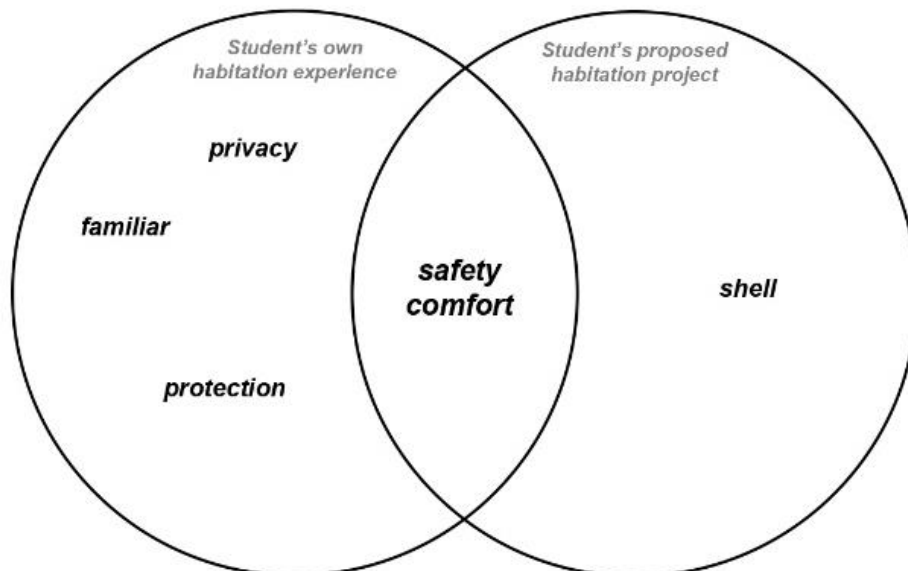

Figure 35. Third principle: optimization of man's protective space. Proposed keywords: safety, shell, familiar, protection, privacy, comfort. (source: authors)

The keywords *safety, shell, familiar, protection, privacy, confort* interpreted Doxiadis third principle. According to the students the common ground that relates the perception of the habitation experience of their personal notion of home and the one of the proposed housing design project is the keywords *safety* and *confort*. For the fourth principle, among the keywords *system, network, connection, society, nature, community, order, organisation*; according to the students the common ground that relates the perception of the habitation experience of their personal notion of home and the one of the proposed housing design project is the keywords *nature, community* and *organisation*.

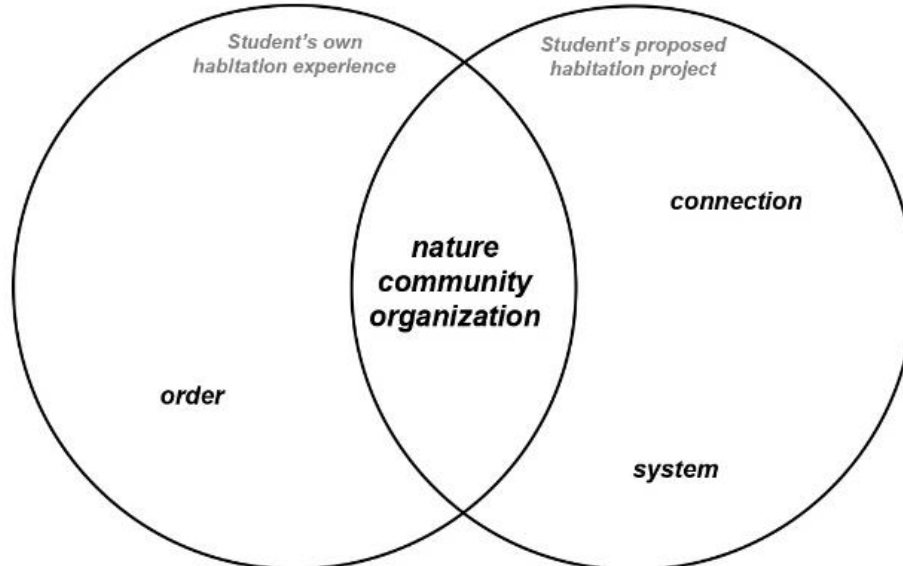

Figure 36. Fourth principle: optimization of the quality of man's relationship with his environment, which consists of nature, society, shells and networks. Proposed keywords: system, network, connection, society, nature, community, order, organisation. (source: authors)

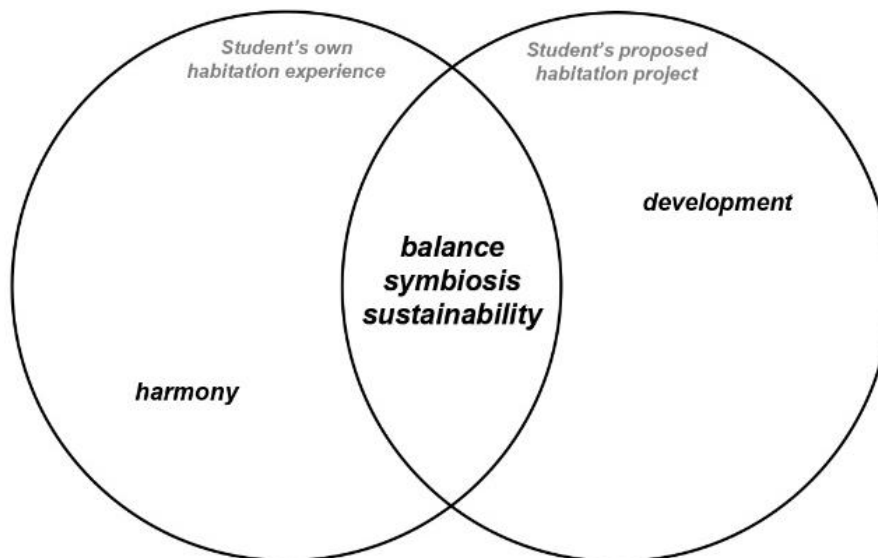

Figure 37. Fifth principle: man organizes his settlements in an attempt to achieve an optimum synthesis of the other four principles. Proposed keywords: sustainability, development, harmony, balance, symbiosis. (source: authors)

Finally, as far as the fifth principle is concerned, interpreted with the keywords *sustainability, development, harmony, balance, symbiosis*, the students chose as common ground between their proper perception of the notion of home, and the experience of housing as designed in their project, the keywords *balance, symbiosis, sustainability*.

The aforementioned paradigm demonstrate elements to be considered when integrating ecological issues, initially linked to *Ecology and Ekistics*, as a methodological tool in housing design studios: combining scientific knowledge with empirical analysis, including experimental processes; applying theoretical concepts in practical design scenarios and vice versa, interrogating housing on different scales and considering the micro and macro impacts it conveys, encouraging an interdisciplinary approach while acknowledging the complexity of the relations between the natural and artificial systems. Integrating the study of ecology into educational programs could enrich the design process activity. In link with Doxiadis diagrams overlapping layers and fields of concepts and disciplines in a broader system including ecology and *ekistics*, it is intended to extend this first step of the inquiry within workshops that will be followed. Using as keywords concepts chosen meticulously from the glossary of *Ecology and Ekistics* it is aimed to figure the ways those notions refer to spaces within the home, and, further, to identify which are those spaces.

Figure 38. Overlapping fields and layers of knowledge in Doxiadis research. (source: Pertsemlidis, C. 2007)

All those who are studying architecture, planning, economics and other subjects concerned with humans and their settlements should also be required to study basic ecology. Similarly, those studying ecology, geography, and related disciplines should be required to learn about the elements of ekistics. In this way we will help to establish firm connections between disciplines and attract to this area of activity those few young minds interested in inter-disciplinary innovation. [32]

6. CONCLUSION

Critical pedagogy and experiential learning are essential components of architectural education, particularly in the exploration of housing typology. By promoting critical thinking, social justice, and hands-on experience, they prepare students to address the complex challenges of housing design with creativity, empathy, and a commitment to positive social change.

The main hypothesis of the research analysed above, is the integration of *Ecology and Ekistics* theory within architectural education, particularly on the theme of housing, to promote experiential learning in architectural design studio and explore new practices within the education of aspiring architects. In the steps to follow, this research will be expanded with additional workshops, using the terms used in the glossary included in *Ecology and Ekistics* as keywords connected with domestic spaces and experience. In this way, the ways in which these notions and concepts relate to different spaces within

the home will be explored, leading to a further identification of those spaces. The main aim of the research is to propose a new methodology for architectural design studio, particularly on the typology of housing, for the investigation of spatial qualities and correlations that includes the theoretical principles of *Ekistics* in general and *Ecology and Ekistics* where applied.

APPENDIX 1

Ekistics, the Science of Human Settlements, C.A.Doxiadis, 1970

Five principles of Constantinos Doxiadis on the relationship between man and the organization of space

1. The first principle is **maximization of man's potential contacts with the elements of nature** (such as water and trees), with other people, and with the works of man (such as buildings and roads).

Key words: contact, interaction, socialization, transition, threshold

2. The second principle is **minimization of the effort required for the achievement of man's actual and potential contacts**. He always gives his structures the shape, or selects the route, that requires the minimum effort, no matter whether he is dealing with the floor of a room, which he tends to make horizontal, or with the creation of a highway.

Key words: distance, functionality, sustainability, economy, access, circulation, movement

3. The third principle is **optimization of man's protective space**, which means the selection of such a distance from other persons, animals, or objects that he can keep his contacts with them (first principle) without any kind of sensory or psychological discomfort.

Key words: safety, shell, familiar, protection, privacy, comfort

4. The fourth principle is **optimization of the quality of man's relationship with his environment**, which consists of nature, society, shells (buildings and houses of all sorts), and networks (ranging from roads to telecommunications). This is the principle that leads to order, physiological and aesthetic, and that influences architecture and, in many respects, art.

Key words: system, network, connection, society, nature, community, order, organization

5. In the fifth principle, man organizes his settlements in an **attempt to achieve an optimum synthesis of the other four principles**, and this optimization is dependent on time and space, on actual conditions, and on man's ability to create a synthesis.

Key words: sustainability, development, harmony, balance, symbiosis

Questionnaire in the context of scientific research entitled as:

The application of the principles of Ekistics (C.Doxiadis, 1970) in architectural education, focusing on the typology of housing

Date: April 2024

Year of study: 1st/2nd

The present research seeks to highlight correlations between the theoretical principles of Doxiadis' Ekistics and the process of architectural design. These correlations concern specifically the development and exploration of housing typology as studied in architectural education, especially in the Architectural Design studio

In this questionnaire, you need to associate the **spaces** with **keywords**.

With which spaces:

(a) **your house** as you have experienced it (the space mostly associated to the meaning of home, now or in the past)

(b) **in the housing areas in your current Arch. Design proposal**

would the following keywords correspond to each of C. Doxiadis' five principles concerning the relationship between man and the organization of space?

Principle 1: maximization of man's potential contacts with the elements of nature

Key words: *contact, interaction, socialisation, transition, threshold*

(a)

(b)

Principle 2: minimization of the effort required for the achievement of man's actual and potential contacts

Key words: *distance, functionality, sustainability, economy, access, circulation, movement*

(a)

(b)

Principle 3: optimization of man's protective space

Key words: *safety, shell, familiar, protection, privacy, comfort*

(a)

(b)

Principle 4: optimization of the quality of man's relationship with his environment

Key words: *system, network, connection, society, nature, community, order, organization*

(a)

(b)

Principle 5: attempt to achieve an optimum synthesis of the other four principles

Key words: *sustainability, development, harmony, balance, symbiosis*

(a)

(b)

Doxiadis' Ekistics as a legacy on Arab urbanism and beyond; The Softscapes and Hardscapes of Modernity

A. Kyriazis

Associate Professor of Architecture and Urbanism, Department of Architecture and Design,
Abu Dhabi University, United Arab Emirates

Corresponding author: E-mail: apostolos.kyriazis@adu.ac.ae, Tel +971526747096

Extended abstract

It was in 2017, at the aftermath of The United Nations Habitat III Conference on housing and sustainable urban development in Quito Ecuador and the New Urban Agenda, when Saskia Sassen, Ricky Burdett and Richard Sennett manifested a new, open-ended, inclusive urbanism, while cynically launching a polemic against the role of the modernist urban planning approaches on shaping today's urban condition. Whilst a great volume of literature has repeatedly elaborated on the issue ever since and various architectural theories have evolved as a response to modernism's most radical teachings, one could argue that modernism is not the sole culprit and that other schools and forces that followed have contributed equally or more so. Furthermore, such an accusation should apply to modernism's full width and breadth of expressers, sub-currents, variations, tools and contexts.

The theoretical and applied work of Konstantinos Doxiadis, an arguably dominant figure of that era, could serve as a vantage point of such an examination. Ekistics, his scientific approach on human settlements, is deterministic enough to express both the modernist "machine" and its global configuration. However, the roles and position of Anthropos and the society are interestingly contrasting the more rigid Charter of Athens. Similarly, his geography of projects spans across most continents, but it is in the Middle East and the Gulf region in particular that the spatial manifestation of his ideas shows the clearest, due to the "tabula rasa" urbanism that thrived under the petroleum concessions of the mid-century. However, even though Doxiadis was offered the means, power and space to implement his Laplacian modernism, he displayed a remarkable resistance and respect to the human scale, the local context and the right to the city.

The aforementioned controversies are indicative of the overall debate on modernism's impact on the contemporary urban condition. They consist the already familiar "hardscape" – the more rigid, purist and harshly criticised expression of modernism, but also a more elusive and context-sensitive "softscape". This paper attempts to showcase Doxiadis' approaches and methods on several key projects in the Gulf region, thus arguing in favour of partially lifting responsibility off towards other theoretical and implementation approaches that followed ever since. His human-centered advocacy has left its stamp towards a more socially cohesive urban planning that have in-formed numerous sustainability manuals and rating systems, such as Abu Dhabi's "Estidama".

Extended abstract

In this day and age, as well as the societies we have created, have begun to swell to a suffocating degree regarding the quality of life in cities. Today, more than ever, it is imperative to integrate urban ecology into the management of cities, in order to change the quality of life of people living in small and large societies. The imperatives for improving the quality of life can be found in a total analysis of city structures where, among others, Doxiadis has also spoken and developed the science of Ekistics. This paper has to do with the science of Ekistics which was created by Doxiadis through his study of human behaviors in human settlements, small and large communities and their creation through parameters such as geography, human psychology, the ecology of cities and culture. In order to understand the Units, Elements and Ekistics Disciplines, an analysis must be done in a Geographical Information Systems environment, because we are referring to geographic data. The units that Doxiadis integrates the science of Residential science into the field of sciences, start from the unit of man (anthropos), mediated by an average human community and end in Doxiadis' vision of a single community of people called Ecumenopolis. For the above units the geographic data in a G.I.S environment. they give the raw data for analysis through the information contained in it. The important thing about these geographical data is found in the detail of the analysis (L.O.D.). When we talk about a small city community or a neighborhood there is a diametric difference compared to a Metropolis. The information embedded in geographic data may vary from unit to unit. In addition to the primary data for the analysis, the elements that embedded human communities such as nature, society, transport networks etc. are also integrated, but also the parameters that influence the analysis such as social, technological, economic, cultural etc. parameters. Through these 3 different groups of data and parameters Doxiadis in his analysis tried to integrate them into a holistic methodology for predicting human societies in transition for a single city "Ecumenopolis". For all of the above in this text, an attempt will be made to integrate them into the science of Geoinformatics, where the individual units, elements and disciplines will be developed with examples from the scientific community and procedures and further analysis of them will be made. Geographical Information Systems, Remote Sensing or Photogrammetry will join the discussion on the analysis of the various data, in a branch of universal management of modern cities, but also of the predictions of the Doxiadis' vision for the Ecumenopolis.

Keywords: *ekistics, spatial analysis, geoinformatics, urban ecology, Ecumenopolis*

1. INTRODUCTION

Doxiadis' work in the fields of urban transformation and architecture is vast and continues to be studied for years after his death. On his way, Doxiadis for the interpretation of the city and the elements that define and make it up, created the science of Ekistics where he systematically studies human settlements. '*Ekistics begins with the premise that human settlements are susceptible to systematic research*' he says characteristically and continues in his texts on the study of human settlements and how to create a system / city that respects human, history and dimensions in order to be sustainable. For this study of the settlements where people live, the study of a wider spectrum of

Proceedings

the human environment is also needed, such as nature, society, man, buildings and networks, which can be studied in many ways, such as, economic, social, political, technological and cultural [1]. Now the planet is saturated and according to the predictions it continues at the same and greater pace, the need to manage this saturation through sustainable solutions for cities and people. Human needs are increased, as a result of which changes are evident and the tendency to concentrate people in large urban centers creates predictions which are not so utopian, these predictions are the Ecomenopolis of Doxiadis [2]. Following Doxiadis's study on Ekistics, he studied the dynamics of a hypothesis - theory of a city that would gather the people of the earth, the so-called Ecumenopolis. This city refers to the planetary level and is a single and continuous city which was the evolution of megacities and the trend of human settlements towards urbanization. In the study of Settlement we must move from a small scale to a larger one in order to study the whole spectrum of human settlements. As a smaller scale of study we consider human and end up with the single city of Doxiadis' Ekoumenopolis [3]. However, these elements by themselves do not have any coherence if we do not also study the influencing factors according to the conditions they choose each time. For this particular study, they could not but play a special role in G.I.S., through which the spatial data (units) will interact with the analysis of the elements (elements and disciplines), with various methods of spatial analysis of human settlements. For the study of this scale of Doxiadis (from human to Ecumenopolis) categories are mediated which differ from each other in terms of the approach but also the level of detail of the data and those produced from them. However, in order to be able to study the units, elements and disciplines, an analysis and recording of these and the methods of analysis must first be done.

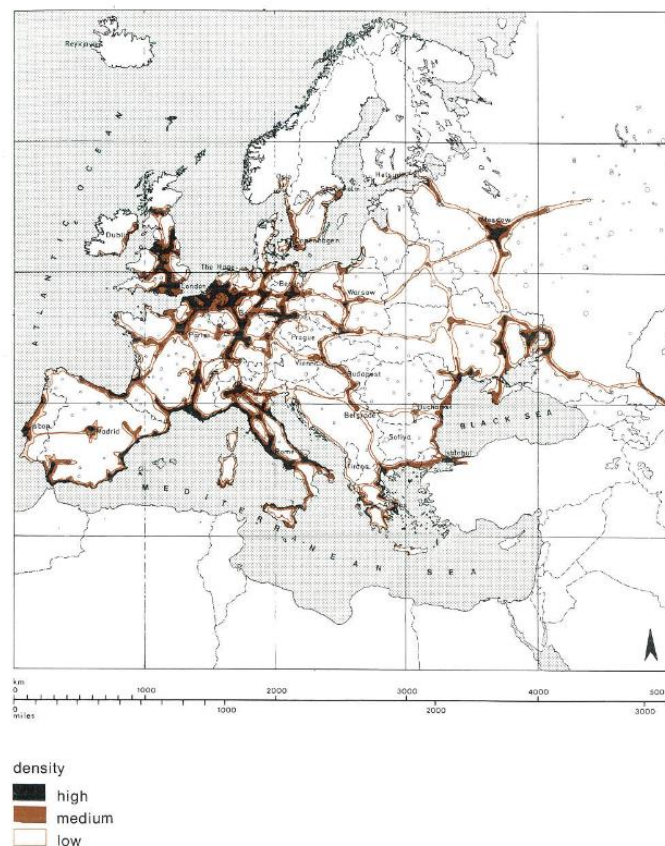

Figure 1. Map of Ecumenopolis in Europe, the habitation evolution in 2100 Source: (Constantinos A. Doxiadis, 1974, p. 371: 147 fig.

2. UNITS

In the book *Ecumenopolis* by Doxiadis we have the 15 categories, where we gradually move from a level of detail of the human being as a unit to the single future hypothetical city which will gather all people together. The intermediate categories concern small groups of people (neighborhoods), large cities where more people gather, metropolises which are a station in the network and finally we end up in the *Ecumenopolis*. All these categories have a geographical aspect as well as information technology depending on the elements that make them up, with the result that each one has a different level of detail. The level of detail (L.O.D.) for each category is different due to the nature of the log data. From the first category which refers to human we could say that the recording method is completely different in relation to a Metropolis without meaning that there is no coherence and connection of human with the other categories, because man is the one who constitutes part but also has created the communities through cultural, political and other characteristics. The first 2 categories (human and room) and perhaps the third one the house we would say have a similarity in the level of detail of the recording, the method in which we collect information about these categories is mainly the statistical recordings, as applied by the statistical services around the world. For example, the population census in Greece is carried out every 10 years and information is collected, through questionnaires and personal interviews, about the person and his family and the place where they live, as well as information about the income of each household [4]. Doxiadis had in the past tried to "record" in his own way with personal interviews in 18 Athenian neighborhoods, with which research on the inhabitants of Athens he tried to record and measure their adaptation to the emerging rhythm and spaces of the post-war city. The program was called (human community)[5]. Continuing from the first 3 categories, which are more or less statistical-census records, we move to 4 categories that are similar in terms of data recording and collection. From the house to the neighborhood we could say that there are similarities, due to the fact that the house is also part of the neighborhood. The spatial registration of these categories can be performed with Photogrammetric procedures, where through a number of photographs the three-dimensional reconstruction of the study area is made with geometric characteristics with the possibility of extracting the outline of the buildings. In the paper by (Mayank Sharma, Rahul Dev Garg) extracted from photogrammetric data (point cloud) the footprints of the buildings at Indian Institute of Technology (IIT) Roorkee, Uttarakhand, in an automatic way through algorithms and thus created the backgrounds for a "neighborhood" [6]. The above process of creating a background with the elements of the buildings is said to take precedence over the inventory of the previous categories (human, room), because through the elements of the buildings which act as a background to select the houses for collecting information from the people who staff them in order to have records at the neighborhood level from the statistical services. Then we will move on to something bigger, in the city and small town category, where the process of collecting information through a drone to create 3D information is quite difficult due to the area it occupies, for this reason the recording of information in such areas is common be performed by manned aircraft carrying either a camera or a lidar sensor. Procedures for extracting building information from lidar sensor recordings are often applied to such city sizes and the data are reliable. The data to be processed are also point clouds but with a different creation process, just as the characteristics of the points have information through which the classification of the points concerning the buildings in relation to other categories (vegetation, cables, etc.) is done by automatic procedures [7]. The recording processes of urban areas to extract the building stock can reach the city category due to the fact that in larger urban environments the data will be huge and the computing power will be required to be greater, but this is not a rule because it is common to happen, but the segmentation of a megacity or a metropolis into smaller pieces of recording and processing also helps control errors. The 4 categories of the metropolis and megalopolis can be seen in a larger spectrum of analysis and extraction of information. Data can be extracted from these categories one of Remote Sensing of the area occupied by the built environment in urban areas in order to analyze neighboring

cities and how they spread and develop in space over time. In the metropolis of Hangzhou, China, researchers through remote sensing data identified the built environment between the years 1991 – 2014 through multispectral images from the Landsat satellite [8]. In this way we can have in our hands at a planetary level the structured and unstructured environment in a depth of time from 1985 to the present day. In the last category of the Eperopolis and the Ecumenopolis, no record could be made with spatial data because they are stochastic plans for the development of the single city envisioned by Doxiadis, but the above data from man to the megapolis and the possibility of a historical background either from multispectral data or from historical evidence of the evolution of cities, this vision can be given the possibility to be studied with precise spatial and informational data.

Figure 2. Doxiadis' units and gis analysis

All the above mentioned in the Doxiadis units can be integrated into a single base where one will interact with the other in a gis environment. The level of detail of each category is evident in the text above, from the man in the big city we have a detail which differs greatly, because the data collection process also differs but in between categories.

3. ELEMENTS

The Elements that Doxiadis refers to in his book Ekumenopolis could be said to be something like a record of the elements that a city has but also the basic characteristics of the analysis of the above spatial data units. They are tangible features with a geographic background and obvious metrics of analysis, they are features that are a key ingredient to structure an urban fabric. Data such as infrastructure, nature and man are the ones that in the analyzes through gis have obvious characteristics and are shaped over time because they are a basic component of the functioning of human societies. In this category we have more of the organization of cities and the structures that make them up. In the foreground comes nature, both the natural environment and the built environment itself within the city, which also refers to those elements that human has contributed to shape the environment - nature in which he lives. In this category the analysis automatically switches to the characteristics of landuse & lancover. The category landuse as data are the areas in which man applies particular uses to his benefit. They are areas where anthropogenic activity forms areas with various characteristics. The specific categories are the ones where we can have information about human activity but also the spatial / geographical boundaries in which each category is surrounded.

Proceedings

The landcover data category has more natural characteristics and refers to the covers that either man or nature has shaped [9]. In Siliguri region researchers applied analysis through remote sensing data to find suitable area for development of new urban area due to the problem of overpopulation. Data such as landuse & landcover were in the foreground due to the type of data referred to the surface category of the study area and through multi-tiered analyzes with other data such as elevation gradients but also features such as infrastructure were integrated into a gis environment to find these areas [10]. The next category could be said to be similar to the human category from the units due to the fact that the data in this category refers to the collection of data on human habits from interviews and recording them. Analyzes such as population density generated in a GIS environment can provide information on the concentration of people in an area [10]. Also, information such as ownership status is what organizes an area, with ownership and commons and utilities creating the quality characteristics of a city and driving decisions about a sustainable city. Public and shared buildings as well as commercial or other buildings in which there is a large concentration every day must also be studied. The suitability of an area for the reconstruction of such a building or the study of the existing ones is important for the structure and evolution of the city and is applied in a gis environment, due to the fact that from there we can apply tools such as kernel density which analyzes the characteristics of the input data with the neighboring similar features and accordingly the analysis determines the appropriate positions [11]. Next, one of the most important categories of data is transportation networks or other networks that play a role in shaping cities. In his publication Aleksandar Valjarevic studied the infrastructures of the networks (road, rail and ports) of Europe and through the analysis in a gis environment he identified the connectivity, mobility, availability, centrality and how these networks can and interact - they are connected to each other like tissue [12]. Finally, All of the above are what shape the next category "society" as a living organism with such elements that make it up and shape it over time the communities of people around the world..

	Elements	Data	Method	Analysis and Results
A	nature	Landuse/Landcover	G.I.S. / Remote Sensing	Multispectral data and Multispectral analysis
B	anthropos	Population, Labor force, Householders	G.I.S.	Population Density
C	society	Society Organization	G.I.S.	Society Organization analysis through G.I.S.
D	shells	Public benefits buildings, Commercial Centers, Industry Spaces	G.I.S.	Business analysis
E	networks	Road, Rail, Airline and Marine Network, Commercial Network	G.I.S.	Network Analysis

Figure 3. Doxiadis' Elements and gis analysis

4. DISCIPLINES

The Disciplines category, in turn, has characteristics that can be integrated into analyzes through gis. However, the specific category differs from the previous element in terms of the nature of the data, because in this category we are talking more about intangible characteristics. Characteristics which are formed by humans and the conditions in which they live in urban and other areas. These criteria do not have such obvious characteristics and are not as controlled by the respective researchers due to the fact that some of them have multiple interpretations, but this does not mean that they do not have a constant and a base. The first category to be analyzed is the economic characteristics for which the sources of data collection are the statistical authorities which, through the census, record economic data as well as the economic services of the states. An example of a study of economic characteristics at the level of analysis in a gis environment is the study in the territory of China where researchers studied the country's gdp and through various statistical models from machine learning algorithms in geographical backgrounds of the borders of the country's regions and cities. The sciences of statistics and GIS interact in such with the aim of qualitative results through interdisciplinary [13]. A category that is largely difficult to calculate and measure is the social category and it is difficult to calculate characteristics related to equality and equity. Inequalities are characteristics that are scattered in human societies and their calculation and their study in gis environments is a problem due to the nature of these data, but it is a regulatory factor in the study of neighborhoods and cities [14]. The next category is a station in human societies because through it the societies themselves are changed by specific decisions. The urban planning of cities has a political connotation because the respective governments, whether local or the central governments of the countries, are the ones who shape the cities [15]. The category of technology is necessary in the study because from there we have the current of the development of modern societies. In the study of Ekistics and the Ecumenopolis, the technological sector is a key component of the concentration of human resources, and this seems to have been happening in countries around the world for 150 years. Finally, the culture carried by the peoples of the earth throughout the centuries and is the one they carry to this day. The recording of this culture as well as the preservation is necessary to be recorded in such a way that not only will there be a historical background of recording but will help to preserve and spread it as well as to chart the course of modern societies. In the Nanjing region, Zhifeng Jiang applied a research on the cultural points of the region and studied the dynamics within a GIS environment and the accessibility of these points with other spatial analysis data [16].

Disciplines	Data	Method	Analysis and Result
I economic	Gross Domestic Product Country Level, Gross Domestic Product per Capita	Data analysis & G.I.S.	Choropleth map
II social	Social Divisions, Equality and Equity, Social Formation	Data analysis & G.I.S.	Thematic map
III political	Urban Planning, Wars	Data analysis & G.I.S.	Thematic map
IV technological	Accelerating change	Data analysis	Thematic map
V culture	Cultural Dynamics per Country	Data analysis & G.I.S.	Thematic map

Figure 4. Doxiadis' Disciplines and gis analysis

5. CONCLUSION

The above analysis of the elements (units, elements and disciplines) of the science of Ekistics helps us to understand the way of the nature of these elements and through analysis in a GIS environment, how it can work. From the human data records in Ecumenopolis as well as the analyzes of the tangible (elements) and the intangibles (disciplines) characteristics, researchers can have in their hands "tools" for the purpose of managing cities through GIS, but the engraving. path for a better sustainable city. The science of Ekistics by Doxiadis, in a way, we could say that it was shaped to be analyzed through GIS systems, although it had been created by it before the application of GIS came to the fore for the study of the city.

Abstract

Doxiadis' theory of Ekistics evaluates human settlements and their evolution. A "successful human settlement" achieves a balance between human beings and their built environment. The metropolitan areas of the second half of the 20th century had grown beyond the area of daily interaction; therefore, defined and comprehensible natural and built environments became necessary. This paper proposes a reading of planned post-war modern satellite towns as alternatives in terms of daily use and networking in terms of Doxiadis' theories. Indeed, many examples, based on various western models, to which Doxiadis' ideas were also directly related, tried to recreate positive personal experience and social and natural interaction in designed spaces and places.

Istanbul was already a large city by 1950, with a population exceeding 1 million. A municipal survey in 1953 put the lack of housing in the city at 30-40 thousand units. Housing projects of this period created new living places within the settlement areas or on their periphery along the proposed development axes to the north, west and southeast. The projects considered in this context are Levent Phases I-III (Kemal Ahmet Aru and Rebiî Gorbon, 1947-1956, 977 units), Levent Phase IV (Kemal Ahmet Aru, 1954-1956, 373 units), Atatürk Boulevard Block Apartment (Istanbul Municipality and T. Emlak Kredi Bank project offices, 1954-1956, 90 units), Ataköy Phases I-II (Ertuğrul Menteşe and the Baruthane Project Office, 1957-1964, 1514 units) and Hukukçular Block Apartment (Haluk Baysal and Melih Birsal, 1962, 66 units). While the block apartments followed Le Corbusier's *Unité d'Habitation* principle, Levent Phases I-III was a late garden city, and Levent Phase IV and Ataköy Phases I-II were new-towns. All except for the Atatürk Boulevard Block Apartment were located on the urban periphery along the development axes.

If these projects are considered in the light of Doxiadis' five principles of Ekistics, (a) maximizing the habitants' contacts with nature, people and built environment, and (b) minimizing the effort required for this, (c) optimizing the habitants' protective space and (d) the quality of their contacts, and (e) achieving an optimum synthesis of these principles, they may be considered attempts to create positive human settlements within a larger chaotic city. They became cases that may be considered in terms of Doxiadis' *Entopia*, meaning "place that is practicable, that can exist". Indeed, the inclusion of commercial-service, social, cultural-educational and natural-recreational spaces and places integrated within the projects as well as the quality of the built environment and circulation patterns, derived from former concepts of modern urban planning, made them so. The projects also present ecological urban landscapes for their inhabitants. Their sustained desirability in today's Istanbul, a *Dynapolis* and almost an *Ecumenopolis* in Doxiadis' terms, indicates that positive and livable environments were created.

Keywords: *Ekistics; post-war modernism; housing; satellite towns; Istanbul.*

1. INTRODUCTION

Constantinos A. Doxiadis, a visionary architect and planner, studied human settlements of almost all periods in order to develop his theory of Ekistics. He published these during the transformation period from Modernism to Postmodernism. Indeed, his ideas were related to modern urbanism but they were also instrumental in shaping postmodern approaches. This paper aims to evaluate post-war modern satellite towns and housing estates in Istanbul in relation with the theories Doxiadis published right afterwards, thus, discussing correlations between modernism and his theories in terms of positive living environments while considering their sustainability in the contemporary urban environment. Istanbul was already a large city by 1950, with a population exceeding 1 million, 70% of which lived in the Historic Peninsula, Kadıköy and Üsküdar. The new urban development axes on the European side were proposed along the Marmara shore to the west and along and behind the Bosphorus shore to the north, enlarging the urban area with extended arms and filling some of the vacant zones between the center and the peripheral settlements [1] (Figure 1). These axes were supported by new means of transportation, such as suburban railways and new motorways. A municipal survey dated 1953 put the lack of housing in the city at 30-40 thousand units. Housing projects of this period created new living places within the settlement areas or on their periphery along these axes. The examples chosen in this context are dated to 1947-1964, and were designed by prominent architects of the period; they still retain their importance as housing estates in the architecture in Turkey.

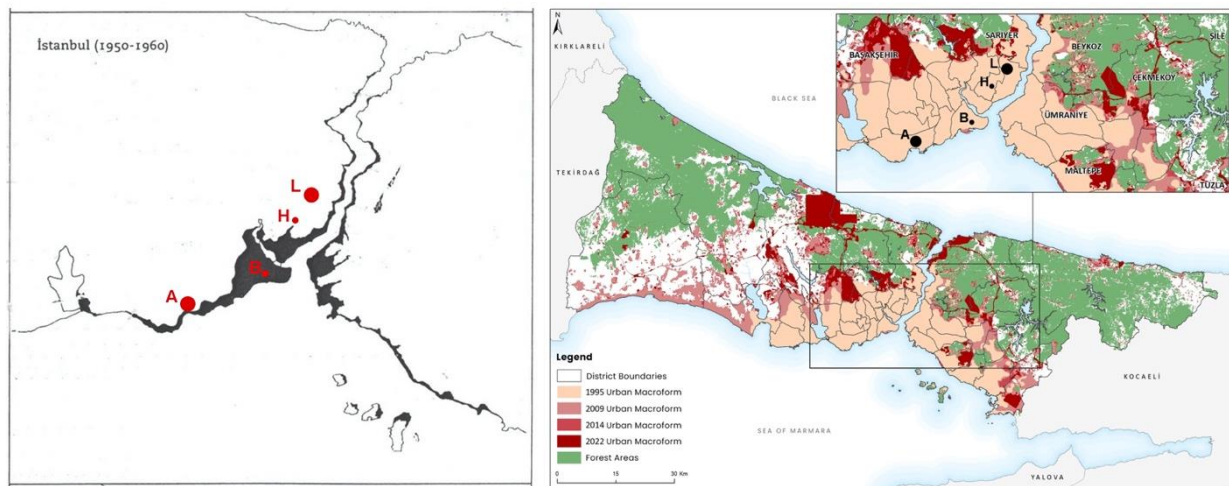

Figure 1. The locations of the case studies in 1950-1960s (left) [1] and present (right) [2] Istanbul urban macroform (A-Ataköy, B-Atatürk Boulevard Block Apartment, H-Hukukçular Block Apartment, L-Levent).

2. SPIRIT OF DOXIADIS IN URBANISM & PERI-URBAN THEORIES

Doxiadis [3] defined Ekistics as “the science of human settlements”. His pragmatic, objective and rational approach derived principles from an evaluation of past examples, and provided projections for the future: The settlement designs, “the city of optimum size, that is, a city which respects human dimensions”, should (a) maximize the habitants’ potential contacts with nature, other people, and the built environment; (b) minimize the effort required for the achievement of the habitants’ actual and potential contacts; (c) optimize the habitants’ protective space (“the selection of such a distance ... [to] keep [their] contacts ... without any kind of sensory or psychological discomfort”); (d) optimize the quality of the habitants’ relationship with his environment (nature, society, shells) and networks; and (e) attempt to achieve an optimum synthesis of the other four principles, “depending on time and space, actual conditions, and [their] ability to create a synthesis”. The natural environment plays an important role in this context [4: 20-37]: “naturareas”, “cultivareas”, “anthropareas” and

“industrareas” need to co-exist in harmony. The inevitable Ecumenopolis should have a global balance with the Ecumenokepos (Figure 2).

Figure 2. Ecumenopolis 2060, C. A. Doxiadis, 1967 (© Constantinos and Emma Doxiadis Foundation).

In *Between Dystopia and Utopia* Doxiadis [5] proposes a solution to the dichotomy through Entopia, meaning “place that is practicable, that can exist”: “The present city – without reason, without dream – leads to dystopia and disaster. Utopias – without reason, with dream – cannot get us out of the impasse. There is only one road left – *with reason and with dream* – which should take us out of the bad place into a good place, which is not out of place, but in place – an entopia.” Thus, Entopia could become a useful tool in assessing positive living environments in urban context.

Attributing the entity to be an architectural design without standing resilient to time is unfair. Yet, the timelessness of a design proves itself with its positive potential, ready to be reformed and existing in future urban formations. Understanding Doxiadis’ Entopia as giving the character of a place in the practice of time lies on the macro form strategies in urbanism and its engagement of peri-urbanism. Early designers deemed the environment limitless to settle in and built timeless masterpieces under the hegemony of the human self. Urban expansion tightened the geographic environment. Lived-in geographies have been expanding at the outside edge of the urban fringe. Settlements have accumulated, and there could be no absolute place to stay as a peri-urban settlement forever on the outskirts of the cities.

Ancient Greeks used biological analogies for the development of urban macro forms. Aristotle stated, “ten citizens do not make a polis, while with 10,000 is a polis no longer”. Plato calculated the ideal population size to be 5,040, using mathematical theory, while Hippodamus identified populations in geometrical terms, dividing the land into three distinct zones: public, private and sacred [6: 54]. Doxiadis argues that the Greeks “employed a uniform system in the disposition of buildings in space that was based on principles of human cognition” with variations based on mathematical and geometrical formulae, which “represents a general theory of spatial organization – a theory of city planning” [7]. These considerations opened the way to his principles of Ekistics based on human interaction with nature.

Romans had a similar metaphoric approach when they settled Istanbul. They sustained the isomorphic geographical relation between Rome and Constantinople or “New Rome” on the mythical topographical formation of seven hills. So, the city had an opportunity for a revival, replicating the physical setting of Rome: “No longer are we cultivating more territory within our walls than we

inhabit; the beauty of the city is not as heretofore scattered over it in patches but covers its whole area like a robe woven to the very fringe.” [6: 90, quoting Themistius, *Oratio XVII*].

Pre-modern urban geographers worked on the theories to create bonds between urban and town planning zones, dealing with the effects of the Industrial Revolution. Ebenezer Howard visited Chicago before publishing *Garden Cities of To-Morrow*, and experienced the frightening congestion: “These crowded cities have done their work; they were the best which a society largely based on selfishness and rapacity could construct, but they are in the nature of things entirely unadapted for a society in which the social side of our nature is demanding a larger share of recognition” [8: 38, quoting Howard, 1902: 50-57]. The public demand for decentralization boosted the suburbia and created considerable pressure on peri-urban formations as a result of the rising congestion in the city centre while the development of motorized transportation and private car ownership aided it.

The term Satellite City was first used in 1915 by Graham Taylor [9] to identify the industrial suburbs, which were differentiated from a suburb by having a centre and being not only a housing settlement. The peri-urban settlements in Istanbul are different in practice from their European/American counterparts with a rapidly urbanized distinctive metropolitan macroform, being not strictly suburbs or satellite towns in definition.

Walter Christaller’s Central-Place Theory [10] was a comprehensive design approach, bridging modern urban planning to handle the peri-urban formations with the central places while focusing the multi-central development strategies through practical human habitat. He generated a complete urban macro-form theory by concentrating on marketing, transport, and administrative principles in the unavertable expansion of the urban environment, thus, similar to Doxiadis in terms of human interaction. In 1964, Melvin Webber proposed a critique of Non-places of the modern urban realm, stating that “spatial distribution is not crucial determinant of membership in these professional societies, but interaction is” [11: 110]. The obsession of metropolitan planners with place is meaningless because central places may change, vary and lose their identical attributes [11: 137]: “For it is interaction, not place that is the essence of the city and of city life... it is now becoming apparent that it is the accessibility rather than the propinquity aspect of ‘place’ that is the necessary condition” [11: 147, 109]. Geographers also questioned the limits of the urban environment through the environmental affordances from an ecological perspective [12]. Even so, no limits in urbanism caused by the seduction of place [13] have not already been bringing distinct peri-urban areas that could be in practice. Doxiadis’ Ekistics also followed and addressed similar concerns.

The so-called death of peri-urbanism reveals the sprawling, growing *metamorphoses* [14] like parasitic organisms, occupying the territory with an uncontrolled desire to build via an unstoppable, uncontrollable understanding of the relationship through the theoretical framework under complexity in urbanism. Former peri-urban settlements have become congested and urban due to ever-continuous development (Figure 1) although they may retain their intrinsic Ekistic and Entopic value as a finished and limited urban form. Unfortunately, this does not mean that intrinsic transformations could take place in the future as illustrated by threats, which do not consider these settlements worthy of preservation. On the other hand, we are yet far behind the Ecumenical World (Figure 2). Ecumenopolis is not the end of peri-urban theories. Peri-urban areas still have the clues of the development strategies as positive living environments in urbanism and are also dedicated lands for architectural praxis like Entopia.

3. CASE STUDIES: POST-WAR SATELLITE TOWNS AND HOUSING ESTATES IN ISTANBUL, TURKEY (1947-1964)

The projects considered in this context chronologically are Levent Phases I-III (Kemal Ahmet Aru, Rebi Gorbun, Hakkı Uras, 1947-1957, 977 units), Levent Phase IV (Kemal Ahmet Aru, 1954-1956, 373 units), Atatürk Boulevard Block Apartment (Istanbul Municipality and T. Emlak Kredi Bank Project Office, 1954-1956, 90 units), Ataköy Phases I-II (Baruthane Project Office, dir. Ertuğrul

Menteşe, 1957-1964, 1514 units) and Hukukçular Block Apartment (Haluk Baysal, Melih Birsal, 1962, 66 units), supplying about 10% of the housing lack in Istanbul. While the block apartments followed Le Corbusier's *Unité d'Habitation* principle, Levent Phases I-III was a late garden city, developed on the principles of Henri Prost's Istanbul Master Plan (1943-1953), and Levent Phase IV and Ataköy Phases I-II were new-towns. All except for the Atatürk Boulevard Block Apartment were located on the urban periphery along the development axes. It must also be noted that all the projects are related to T. Emlak Kredi Bank, which was the main developer and financier of housing in Turkey in this period [1, 15]. It is estimated that the bank produced and/or financed the production of 300,000 houses in Turkey between 1963 and 1973, totaling about 1/2 of the housing lack in the country.

3.1 Levent Phases I-III (Kemal Ahmet Aru, Rebii Gorbon, Hakkı Uras, 1947-1957)

Kemal Ahmet Aru was the most influential planner and architect for housing estates in the 1950s [1]. The suburban "garden cities" became an alternative to over-crowded traditional urban housing areas with the development of liberal economic policies. As a new development area, Levent was designed with its localized urban plans and infrastructure and did not receive planning, financing or construction subsidies from the state or municipalities. Levent Phases I-III was a garden city, and one of the earliest and largest projects of T. Emlak Kredi Bank in Istanbul with more than 1,000 units [15]. Koşuyolu Housing Estate (Kemal Ahmet Aru and Rebii Gorbon, 1948-1954, 519 units) was a similar project on the Asian side [16].

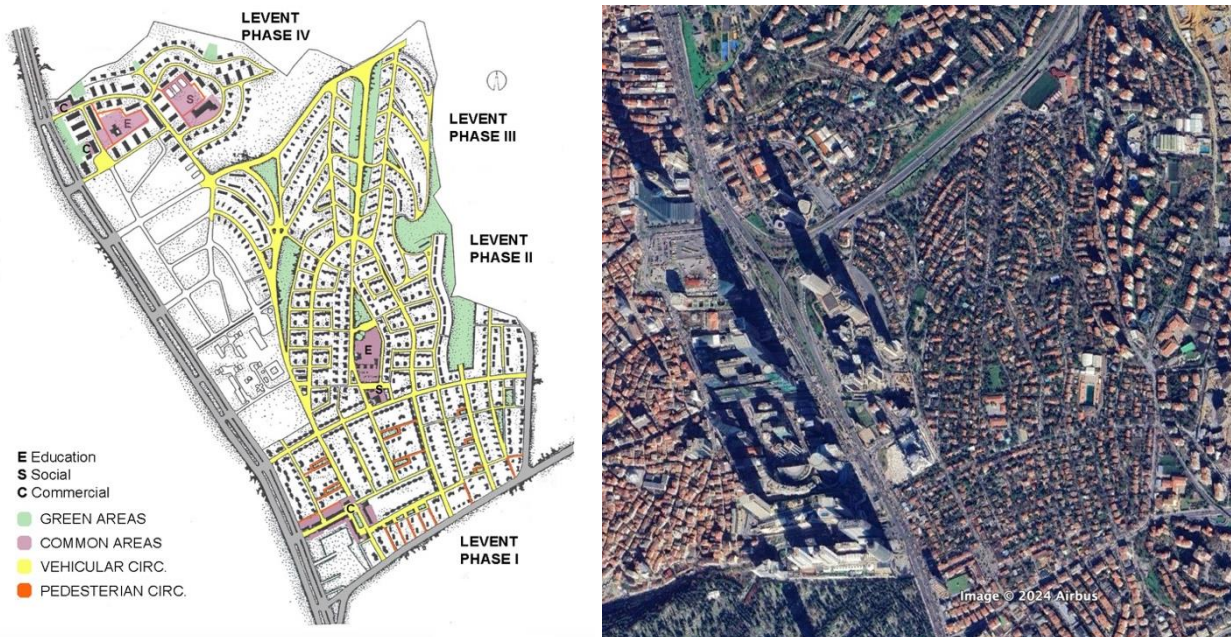

Figure 3. The original layout of Levent Phases I-IV (left; plan from the T. Emlak Kredi Bank Archive, with zoning marked by the authors) and the current aerial view of the area (right; GoogleEarth image, 9 February 2024, altitude 2.65km).

Settlement principles focused on changing the original topography as little as possible without major excavation and landfilling, segregating pedestrian and vehicular circulation, creating architectural variations and locating the houses in different relationships with the roads against monotony (Figure 3) [17]. The public green areas were located at the centers and between the units in addition to private gardens. The common areas included schools, commercial and social areas and other services. The population density was 66, 60 and 95 people per hectare and the built area density was 13, 13 and 19m² per hectare for phases I-III. 37 different types of houses were designed for Phase I alone, and

Proceedings

ISBN: 978-618-5765-02-6

12 different types were built, of which 7 were single houses, 3 were twins and 2 were rowhouses; 6 of the 7 single house types were single-storey and the rest had two storeys [17] (Figure 4). There were mixed-use double-storey rowhouses with shops on the ground floor in the commercial area. The settlement design aimed at a new neighborhood type, interacting within and with the rest of the city in a natural environment. Today the simultaneous transformation of the area into the central business district has changed the near built environment into a crowded high-rise typology and effected residential use, introducing commercial uses although the green layout is preserved inside the area (Figures 3 and 4).

Figure 4. Levent Phases I-III in 1952 (left; Aru and Gorbon, 1952) and in 2012 (right; Nilüfer Baturayoğlu Yöney).

Figure 5. Levent Phase IV, view from Büyükdere Street, orthographic drawing of the design project (left; Bedri Kökten, 1956) [18] and photograph (right; 1957) [1].

3.2 Levent Phase IV (Kemal Ahmet Aru, 1954-1956)

While the construction of Phase II was continuing, Aru began designing Phase IV as a “new-town” with high-rise multi-unit apartments as well as single house types. The layout characteristics and infrastructure followed that of the earlier phases; the segregation of vehicular and pedestrian traffic was better regulated as parking lots were defined for the blocks, and commercial and socio-cultural uses were integrated into the ground and roof levels (Figure 3). All the open spaces, except for the private gardens of the single houses were public. The population density was 79 people and the built area density 16m² per hectare [17]. 18 different types of buildings were designed and repeated 1 to 16 times: Blocks had external corridors or *punkt* with one or more entrances; the flats ranged between 1+1 and 4+1, and 68 to 270m², and there were 4 types of single houses and 2 types of rowhouses [1, 18]. These were intended at providing a wide range of flexibility for housing many different types of families as well as creating architectural variations in the built environment (Figure 5).

Proceedings

3.3 Atatürk Boulevard Block Apartment (Istanbul Municipality and T. Emlak Kredi Bank Project Office, 1954-1956)

This is a megablock, located on Atatürk Boulevard in the Historic Peninsula, one of the main urban axes designed according to the Prost Plan. The ground floors were designed as a pass-through commercial street with access to the upper floors and the roof level had social common spaces and services with integrated green spaces in the dense urban environment (Figure 6). Although commercial use at ground floors of residential buildings along main street were common, more complex functional integration similar to this case was an architectural approach of the period that could be seen in other examples, including Levent Phase IV and Hukukçular Block Apartment discussed in this paper. The 1650m² plot was built-up completely reaching c. 15.000m² at 8-9 levels with one bank branch, 35 shops and 90 3+1 apartments of two different types, 110 and 140m² [19].

Figure 7. Ataköy, conceptual illustration, 1958 [21: cover].

3.4 Ataköy Phases I-II (Baruthane Project Office, dir. Ertuğrul Mentеше, 1957-1964)

Ataköy was a new-town morphology satellite settlement on the western development axis of Istanbul along the Marmara shore, also designed and implemented by T. Emlak Kredi Bank. Phases I and II included 90 blocks, 2-13 storeys high with 1514 apartments in 16 different types, ranging between 2+1 and 7+1 configurations and 93-248m² [20]. Luigi Piccinato consulted on the initial planning and layout. Similar to Levent Phase IV, all open spaces were public and interconnected as most block types were raised on pilotis (Figure 7); Condominium Ownership Act (1965) enabled this process. Commercial functions were separated as zones, and the flat roofs with pergolas provided social common spaces; two primary schools and recreational beach facilities. The zones around the blocks are for pedestrian circulation only with vehicular access to parking lots from the circulating main streets (Figure 8). The estate became a resort/waterfront settlement integrated with the city (Figure 9). The beach fell out of use due to marine pollution in the 1980s, and a shopping mall and marina replaced it whereas the motels and camping also along the shore were torn down in 2008 to be replaced with high-rise development, ending the relationship of the estate with the sea. However, the housing estate remains to be the least dense area in Istanbul's urban morphology.

3.5 Hukukçular Block Apartment (Haluk Baysal, Melih Birsal, 1962)

Designed as a megablock in the then almost rural Mecidiyeköy district, the twelve-storey building derives its inspiration from Le Corbusier's *Unité d'Habitation* [23]. The two-storey commercial section at the ground floor level included shops, a social club and main entrance to the apartments as well as gardens and terraces. The basement had a parking lot and services with open gardens. Further common functions were located at the roof level, including social halls, a youth club, a kindergarten and playground with open terraces and gardens (Figure 10). All functions were defined considering the needs of the users. There were three different types of units with 3+1 configurations, 12 simplexes, 30 duplexes and 24 semi-duplexes, totaling 66, and ranging between 117-151m². The flats opened to the environment and views of the city and the Bosphorus with integrated balconies.

4. CONCLUSION

Like many other post-war housing estates, these projects were based on concepts, derived from former modern urban planning and architectural design, as Doxiadis' theories were. If considered in the light of Doxiadis' five principles of Ekistics, (a) maximizing the habitants' contacts with nature, people and built environment, and (b) minimizing the effort required for this, (c) optimizing the habitants' protective space and (d) the quality of their contacts, and (e) achieving an optimum synthesis of these principles, they may be considered attempts to create positive human settlements. They became Entopias, "places that is practicable, that can exist" within an ever-growing chaotic city. The inclusion of commercial-service, social, cultural-educational and natural-recreational spaces and places integrated within the projects as well as the quality and variety of the built environment, and infrastructure and circulation patterns created estates with centers in different sizes, presenting their inhabitants with ecological landscapes. However, the naturareas are all domesticated in the urban environment. They are no longer peripheral settlements, and their desirability has increased in today's Istanbul, a Dynapolis and almost an Ecumenopolis in Doxiadis' terms, indicating that the positive and livable environments created are now more valuable. However, rising land values threaten them with denser development while their heritage status is being debated against economic considerations.

Extended abstract

The financial crisis in Greece has necessitated reforms in the planning framework, with a focus on promoting economic growth. The primary axes of reforms were to facilitate strategic investments, along with introducing new tools in the urban planning process, specifically the Special Urban Plans (SUPs). The complex and novel elements of SUPs, related to urban development, have thus far prevented firm conclusions about the impact of the changes it will bring to urban space. Questions arise: Is the new framework as flexible and effective to facilitate urban development as it was intended? Do SUPs foster the engagement of all interested actors/stakeholders? In what terms is the quality of urban planning and design integrated into the governance process? To what extent has the SUP been advanced as a tool to establish a new urban design culture?

In Greece, it is observed that urban planning processes remain obscure while the public and involved stakeholders are not adequately informed or trained to easily understand the recent changes in the official planning framework and its impact on urban life. However, there's an increasing availability of technological and participatory tools that significantly aid in bridging this gap. Consequently, evolutions in spatial issues do not align with the local and community needs, putting at stake the sustainability of cities to the detriment of development and investments, as well.

The purpose of this paper is to highlight, through the perspective of different publics and specialists in planning, the issues of governance in urban design and planning within the context of the development and promotion of SUPs, focusing on the promoted SUPs in Thessaloniki, city of almost a million inhabitants and second in the national spatial hierarchy. Thessaloniki was the first city in Greece, where SUPs have been widely applied to implement urban development projects and serve as an example for both the reformed urban planning processes to be followed and the development to be pursued. SUPs in the case of Thessaloniki have been identified as development frameworks or aimed at modifying existing urban configurations. Following extensive empirical investigation, the evolution of SUPs in Thessaloniki (formal and informal tools, design governance, stakeholders, etc.) is documented and examined emphasizing weaknesses and shortcomings in terms of their efficiency, effectiveness, and credibility in improving and integrating urban planning and design qualities at all scales of Metropolitan Thessaloniki. A structured questionnaire was also developed as a research tool, addressing the relationship between different publics (laypeople, experts, etc.) and urban planning and design practices, the SUP itself as a tool, the role of visual representations, and the role of public consultation.

Thus, the paper sheds light on the intricate challenges and opportunities presented by the analysis of forwarding the numerous SUPs in the case of Thessaloniki and enhances the importance of engaging not only technical aspects but also broader governance issues, fostering a comprehensive approach towards sustainable and inclusive urban development.

Abstract

In the 1980s, Sikhs migrated to the Pontine Plain from Punjab, one of the wealthiest and most fertile regions of the Indian subcontinent. To the Sikh migrants, the Pontine Plain was not just a foreign land but a place that echoed their homeland's rural character and physical features. Sikh settled between Latina, Pontinia, Aprilia, Bella Farnia, Sabaudia, Borgo Hermada, San Felice al Circeo, Terracina, and Fondi, transforming many former farm sheds into places of worship, social gatherings, and political discussions. According to estimates, in 2018, around 11,000 Sikhs lived in the Pontine Plain. However, the actual number may be more than twice as high. This Sikh community is considered the second-largest in Europe. Based on research carried out by C. Pallini for the EU-funded project Modscapes and ongoing work by D. Bose for his MA thesis, this paper explores the settlement patterns of the Sikhs, arguing that their settlement might provide an asset for the future, taking into account the challenge of climate change.

Keywords: Sikh settlement; Pontine Plain; public space; urban-rural continuum; climate change.

1. INTRODUCTION (Punjab and the Pontine Plain present some similarities)

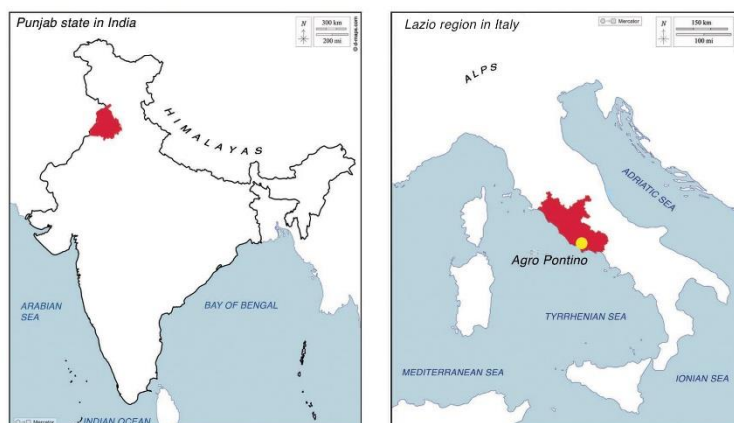

Figure 1. Punjab state in India and Agro Pontino in Lazio region (Italy)

Punjab is a region in northwestern India. Its name translates into “land of five rivers,” namely the Jhelum, Chenab, Ravi, Beas, and Sutlej, which belong to the Indus basin. These rivers, unsuitable for navigation, have been extensively used for irrigation, and many canals have been cut from them. Historically, Punjab has long served as a gateway to the West. The province gained autonomy in 1937. The separation of Pakistan from India in 1947 resulted in the division into East and West Punjab, with Hindu and Muslim minorities. This division led to violence and the mass movement of about 10 million people. In Indian Punjab, rural development took priority. To irrigate 370,000 acres, the multi-purpose Bhakra-Nangal project was implemented. By 1955, 677 miles of main and 3,958 miles of secondary canals had been built, leading to the irrigation of one million acres. Upon completion of the project, 6.5 million acres were reclaimed [1]. The landscape of Punjab continued

Proceedings

to change during the Green Revolution of the 1960s, when mechanised pumps, fertilisers, and various high-yield crops brought about great agricultural prosperity and a dense framework of small and medium-sized villages linked by water networks. These dense Sikh villages sharing distinguishing physical connotations in the local language are called *pinds*. Scattered in the vast agricultural areas of Punjab, *pinds* are tightly packed settlements hosting from 1000 to 5000 people who cultivate small plots of land watered by canals and irrigation pipes. Some *pinds* have a Gurudwara temple associated with a sacred pond (*sarovar*). *Pinds* foster a strong community identity by often organising wrestling matches (*kushti*) in the traditional gymnasium (*akhara*). They are usually associated with a larger open space for seasonal fairs (*mela*) or the weekly vegetable market (*haat*). These open spaces are also multifunctional, used for sports like *kabaddi* (a contact team sport dating back to ancient India) and cricket. The houses, generally one to four stories high, can be made of mud and straw (*kutchra*) or designed to be solid and permanent (*pucca*). The roads may be metalled or unmetalled. *Pinds* have a specific Sikh or Punjabi genius loci with a celebratory, energetic and warm feeling connected with the agricultural land, ecology, cattle and community life. The festivals, food culture and dances like *Bhangra* and *Gidda* often create an intense experience of the Sikh countryside. The *pinds* are rich in art, culture, crafts and gastronomic delights, which usually find access to the urban population moving on the highways through traditional highway restaurants (*dhabas*).

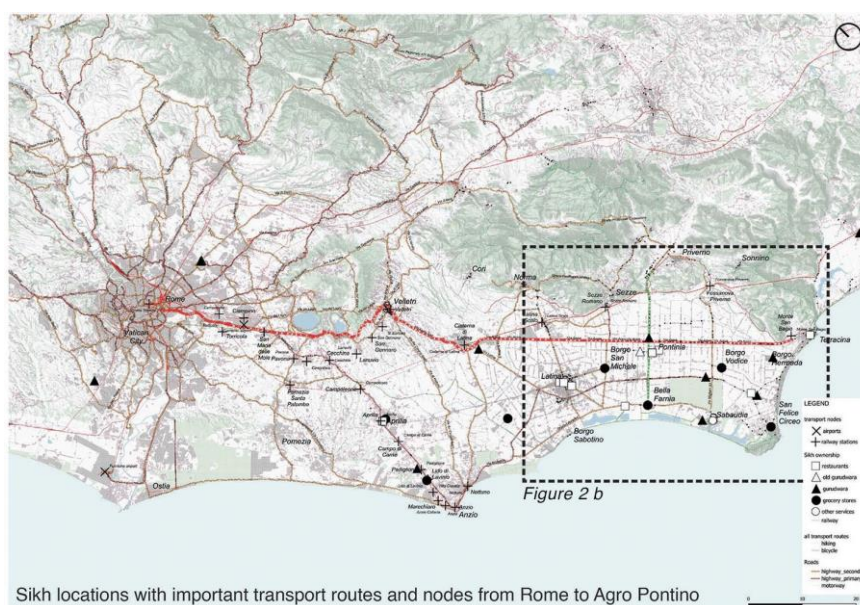

Figure 2a. Locations of Sikh owned public facilities in relation with transport routes and nodes from Rome to Agro Pontino

The Pontine Plain, stretching southeast of Rome between the Lepini Mountains and a belt of coastal dunes, underwent similar changes a few decades earlier. Attempts at its drainage date back to the Romans and were repeated various times without much success. Countless travellers described the Pontine Marshes as alternating swamps with thick woods and dry areas, populated by hunters, harvesters, herds of cows, buffaloes, and sheep or planted with wheat and maize. The region was a pestilential place of torment in the heat of summer, but it became a sea of flowers in May and June. The Appian Way in ruins provided an open-air museum for lovers of antiquity. Reclamation was finally achieved under the Fascist government between 1930 and 1934, resulting in a modernist rural landscape featuring three new towns — Littoria (1932), Sabaudia (1933), and Pontinia (1935) — and a system of rural service villages hinged on a new road network [2]. Most settlers came from the then-poor and overcrowded regions of Veneto, Friuli, and Emilia. They received arable land, a house with

stables, animals, and tools. Their debt was to be gradually paid off by transferring agricultural production to the state. Newly established villages initially acted as logistic centres for reclamation workers and later as connecting centres between the various farms. They comprised a school, a small church, storage, shops, and offices providing for the settler's needs. Many scholars from various disciplines, particularly architecture and town planning, have repeatedly extolled the resulting built environment, combining classicism, rationalism or even picturesque [3]. After the Second World War, when the Pontine Plain was integrated into the areas supported by the Development Fund for the South of Italy (Cassa del Mezzogiorno) [4], considerable labour availability favoured the establishment of chemical, food, and pharmaceutical industries which, in the 1970s and 1980s, attracted many immigrants, mainly from Abruzzo, Campania, and Sicily. In the early 1980s, the first Sikhs turned the Pontine Plain into an international demo-sociological case study. Sikhs settled in the Pontine Plain because of its agricultural character, similar to their places of origin in India. Sikhs are a religious group that broke away from Hinduism in Punjab in the late 15th century, following Gurū Nānak. They are the predominant ethno-religious group in Punjab. Since the late 19th century, many emigrated to Western countries, primarily the United States, Canada, Australia, New Zealand, and the United Kingdom. Sikhism gained momentum during India's general awakening, accounting for millions of followers worldwide. Their skills in agriculture made it easier for them to find an occupation, which also explains why they chose to migrate to a rural area rather than a city [2].

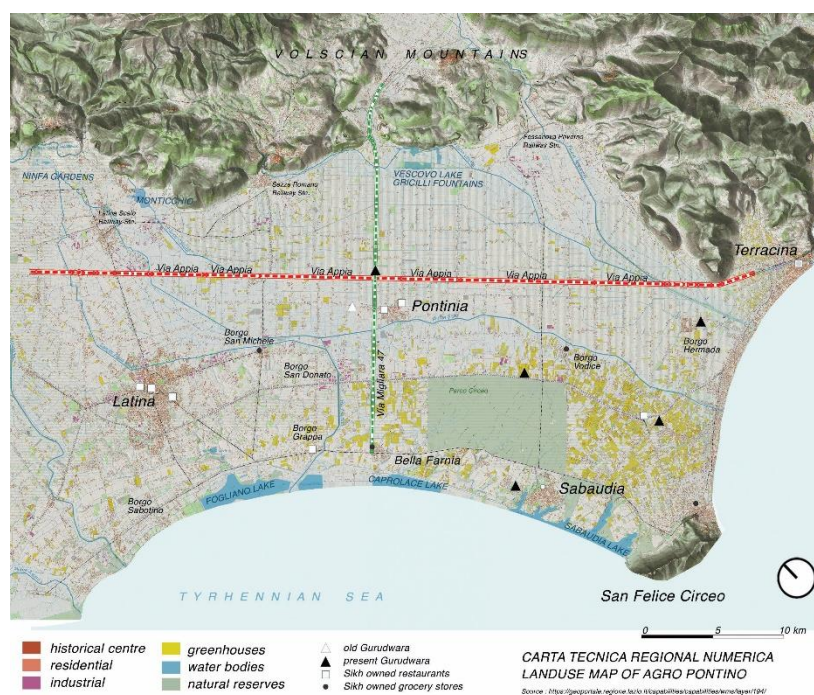

Figure 2b. Sikh Gurudwaras and other facilities on Regional technical landuse map (CTRN) (WMS metadata source : <https://geoportale.regione.lazio.it/capabilities/capabilities/wms/layer/959/>)

In the eyes of the Sikhs, the flat Pontine Plain resembles Punjab's agricultural landscape with year-round crops, small settlements, and an extensive canal system. Somehow, the presence of the Volscian mountains reminds the Shiwalik Himalayas rising above the northern edges of Punjab. The settlement pattern of the Pontine Plain features three towns — Latina, Pontinia, Sabaudia — and a regular grid of roads (Migliare) is similar to the territorial grid surrounding Chandigarh. When planning the capital of Punjab, Le Corbusier was very careful to frame fine views of the Shiwalik mountains as a backdrop to the flat lake. Similarly, Pontinia's and Sabaudia's main roads frame the views of the mountains which Sikhs crossing the plain perceive on a daily basis.

2. THE SIKH PRESENCE IN THE PONTINE PLAIN

Currently, Italy has the second-largest concentration of Sikhs after the UK. They arrived in the 1980s, settling in the Po Valley in northern Italy and the Pontine Plain south of Rome. Since the very beginning, when their extensive migration was partly due to political reasons, they were looking for work in the agricultural sector. Afterwards, their migration was also influenced by increasing globalisation trends: Punjab's overpopulation was somewhat complementary to depopulation in Italy despite a prosperous agricultural sector.

In the 1980s, the number of Sikhs in the Pontine Plain soon rose to 7,000, mainly in Aprilia, Cisterna, Pontinia, Sabaudia, Terracina, and Fondi. In the 1980s, Sikhs concentrated in Bella Farnia (Latina), which they called *pind* (village) or "Little India." There they found a refuge upon arrival, a haven in an unfamiliar land, and a place to establish new roots.

Bella Farnia is a hamlet (*frazione*) of Sabaudia spread over 0.85 km². The 2011 census registered a population of 1002 people, doubling from 458 in 2001. According to the 2013 registry data of Sabaudia municipality, 86% of the population of Bella Farnia were Indians (Sikhs) [5].

The housing complex of Bella Farnia Mare, derived from a parcelling plan started in the early 1980s and never fully completed, hosts the largest concentration of Indian immigrants in the Pontine Plain. This complex, particularly the plots where single villas were built, is still partly owned by Italians. The remaining parcels belong to the Sikh community which is bringing the neighborhood back to life.

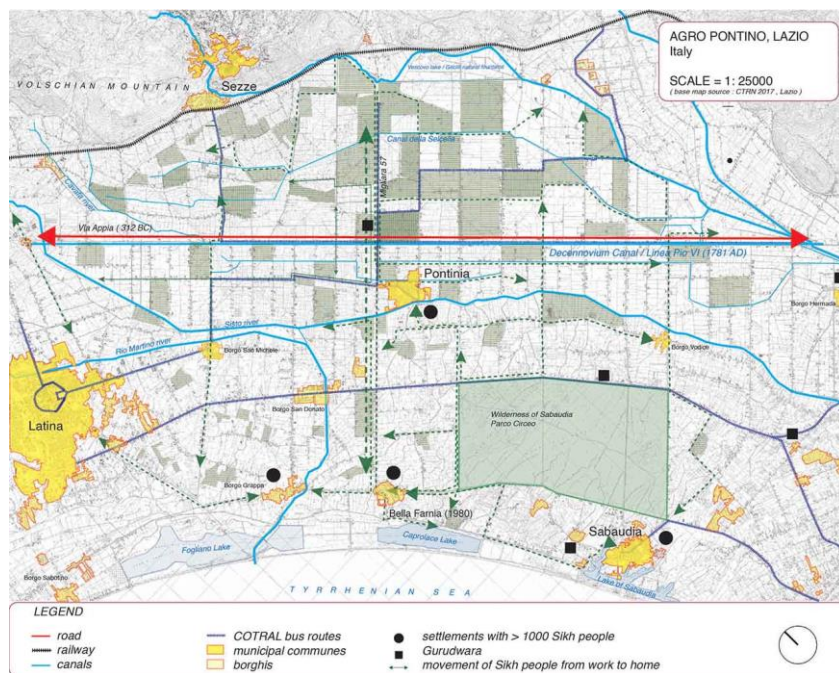

Figure 3 a. Sikh locations and movement patterns in Agro Pontino

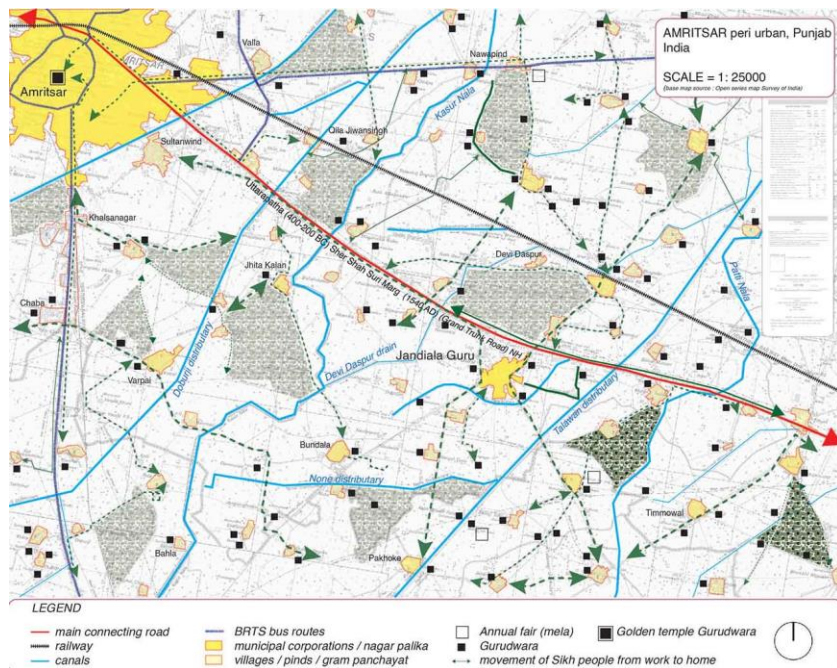

Figure 3 b. Sikh locations and movement patterns in Punjab, India

Bella Farnia is located in a privileged landscape position between Fogliano and Caprolace Lakes near Circeo National Park, just 3.5 km away from the sea. It was initially designed as a seaside resort featuring various types of houses. Unfortunately, most of the houses were not sold and remained unoccupied. However, the low cost of rental and purchase made it an attractive economic opportunity for the Sikhs who arrived in the 1980s. This was just when the Bella Farnia Mare project had failed. Bella Farnia Mare shows the clash between the rural economy and tourism, with income and the market being the deciding factor. As per Sabaudia's registry data, the Sikhs occupied the smaller villas, which are two to three floors, with a utilisation rate of 134% to 251%, which signifies a highly crowded living condition.

For about twenty years, however, the Sikh community has remained almost entirely unknown. Currently, they represent the Pontine Plain's first largest foreign community. According to ISTAT data, their numbers are second only to Romanians. They are more prosperous agriculture, manufacturing, and public service professionals.

Bella Farnia is now an entirely self-organised village where many Sikh Indians live. More recently, many families moved to the smaller (former) rural service villages like Borgo Grappa and San Donato. Borgo Grappa was established in 1929 for workers constructing the Littoral road. San Donato was built at the intersection of two reclamation roads between 1933 and 1934.

The number of Sikhs is ever-increasing as more younger men find stable employment in agriculture while the elderly try to set up their small businesses after working as farmers for ten or twenty years. Sikh men tend to a specific economic cycle: they accumulate capital and skills, start a family, and transition to other activities. Yet, when individuals and communities purchase commercial and residential land, it reflects their capital accumulation. This is especially evident when they buy properties for business purposes, such as restaurants. Sikhs are becoming increasingly visible in both the social and cultural spheres and residential and commercial land use. They organise Sikh festivals and celebrate the birthday of Gurū Nānak and Baisakhi, the Sikh New Year. Most recently, the community purchased land for building a Gurudwara temple, which welcomes all visitors as long as they cover their heads. Elsewhere, the gurdwaras have proven essential for diasporic consciousness and cultural production, allowing Sikhs to move beyond the initial stages of invisibility [6]. Despite these social and economic changes, territorial policies remain stagnant [2].

Sikh migrants manifested and moulded their cultural identity by adapting to the Pontine landscape while creating a community of amiable, diligent, selfless, and peaceful caretakers of the land. Statistical data show that their connection with the former new towns and service villages is vital, [7] As of 2022, the population of Latina was 127,719, showing a decline of 0.11% from the previous year [8]. According to the latest ISTAT data, 55,446 foreigners have registered in the province of Latina. In 2023, 12,030 new arrivals were recorded, making up 9.4% of the total population. Of the total number of foreign arrivals in Latina province in 2023, 11.9% were Indians, mainly Sikhs. They comprised 964 males and 465 females who arrived in 2023 [9]. After settling in the Pontine Plain, Sikhs try to obtain Italian citizenship. Since many have already acquired it, the foreigners' figures do not represent the Sikh community. In 2021, 1364 Sikhs got Italian citizenship, accounting for 11.85% of the foreign population and 1.07% of the total population in the Latina province, including Pontinia, Sabaudia, Terracina and the entire plain [10]. The official figures report 30,000 Sikhs in the Pontine Plain, but the exact number is estimated to be significantly higher. Out of them, 12,000 reside in Sabaudia [2].

Anyone reaching Latina, much less Pontinia or Sabaudia, realises that the new towns built by Mussolini in the 1930s have changed and expanded well beyond their original layout. Yet, the countryside is still characterised by many distinguishing features acquired over time.

The Appian Way runs parallel to the Linea Canal, perpendicular to a regular system of roads and drains (*migliare*) set one mile apart. This grid forms the backbone of the territorial palimpsests established in the late 18th century and extended in the 1930s.

Over the last decades, Sikhs have navigated this territorial palimpsest. Initially, they were considered a community "of arms" (*di sole braccia*). As their population increased and settled, their "arms" have contributed to re-shaping the region.

Primarily concentrated in the rural service villages around Pontinia, Latina, and Sabaudia, The Sikhs utilised existing farms and greenhouses for their daily activities, including work and leisure. Exploring their living and working practices, we realise the importance of ecological artefacts that serve as the primary connection between people and their natural surroundings. These artefacts play an essential role in the migration history of a community trying to find meaning and a sense of belonging in a foreign territory. Every day, they leave their imprints, which can be difficult to express using urban design or territorial mapping tools. This kind of resignification of the territory goes well beyond the rural-urban dichotomy, showing that taking roots for a foreign community may be embedded in a natural and rural environment.

3. GLOBAL COUNTRYSIDE AS A SPACE OF NEGOTIATION

Sikh migrants generated new settlement patterns in the Pontine Plain, involving negotiation processes, which the globalisation literature may partly explain. Geographer Michael Woods coined the term "global countryside" to highlight the interconnectedness of rural areas worldwide where primary and secondary economic activities are centred around producing and transporting agricultural products to consumers, often through extensive commodity networks, which are also essential for those who live and work in the rural areas concerned. Somehow, migration and globalisation are rooted in the complexities of the global countryside, yet the effects of globalisation on rural areas may vary significantly from region to region [11]. The global countryside is rapidly changing, especially in India, where over 60% of the population is rural (Punjab has a rural population of 62%). A more anthropological approach can also help understand how Sikhs viewed (and view) their presence in a new territory. Identity plays a crucial role in a globalised world, particularly for migrating diaspora communities who seek to define their citizenship and sense of belonging in a complex and heterogeneous context. According to anthropologist Arjun Appadurai, migrant communities live in the tension between cultural homogenisation and cultural heterogenisation, fearing cultural absorption, mainly when arriving in a well-established territory [12]. In the case of

Proceedings

Sikhs, they have to deal not only with a country extremely rich in history and heritage like Italy but also with the solid modernist imprint embedded in the towns and villages of the Pontine Plain.

The Pontine Plain has experienced multiple waves of migration from other regions of Italy. However, Sikhs, who have migrated from a distant region and have a culture that is very different from any Mediterranean culture, have found it more critical to maintain homogeneity among themselves. This has resulted in fewer opportunities for integration.

In the public Italian discourse in mass media at a local and national level, Sikhs are generally considered a supportive and cohesive community of excellent and pacific workers immersed in a religious dimension of life [13]. Even if in the Indian subcontinent, Sikhs have lived in conflict and religious tension for over four centuries, in the Pontine Plain, they have maintained the image of a peaceful, hardworking, friendly and open community accepting the hardships of daily work in the fields. The memory of Mahatma Gandhi and his life based on “non-violence” and of Mother Teresa’s actions foster the definition of a positive and homogeneous community, where internal religious and cultural distinctions are played down [13].

As the Sikhs first established themselves economically and later built their community while negotiating with Italian partners, they created a new settlement pattern regarding physical and social infrastructure. Weber sought a city that combined conditions and dynamics, forcing residents and leaders into creative, innovative responses and adaptations [14]. These adaptations occur on both sides, the Sikh community and the Italian administration, resulting in a certain degree of embeddedness of all people on the territory, adding the human factor to the traditional physical layers of hydrology, ecology, and built environment. Instead, embeddedness is in particular conditions, opportunities, constraints, needs, interactions, contestations, and interests [15].

4. MAPPING SIKH CITY IN THE MAKING

Specific aspects of this trans-continental rural-urban and urban-rural migration between Punjab and Agro Pontino deserve our attention. The phrase “Sikh City” in the title of this paper refers to the areas where Sikhs reside and work, as well as the broader set of reference points that demonstrate a novel approach to living in the plain through negotiation and a unique way of practising the Pontine landscape. The subsequent arrival of Sikh migrant farmers and their consolidation into a community helped them establish themselves as Italian citizens, opening up new opportunities for land ownership and use of agricultural land.

News reports and discussions with local people show a persisting degree of invisibility of Sikh migrants. The first generation tended to live “encapsulated” in the community, at least in everyday social and working life. Italians perceived this behaviour as a non-threatening sign that the newcomers were devoted to hard work and spiritual life [13]. However, this invisibility should not be mistaken for complete obscurity but rather a visibility within the community. When travelling by bus from Latina to Pontinia or waiting at the railway stations of Latina Scalo, Sezze, and Priveno, or taking a walk in Pontinia we come across Sikh men with a turban and their families in Indian clothes, occupied with their daily activities. Sikhs become visible in public spaces during special occasions, such as Vaisakhi celebrations and Nagar Kirtan [13]. Driving along the Migliare roads, one can see the daily commute of Sikh men biking long distances from their homes in locations like Bella Farnia to the northeast of the plain, where most fields and farms are located. They move from the higher southwestern areas along the Fiume Sisto river, geologically called the “marine terraces”, about 12-30 metres above sea level, towards the lowland lying 1 to 2 metres below sea level, corresponding to the permanent swamp of the Pontine Marshes. Bella Farnia is a place commonly known as “Little India” as indicated by a road sign, while locals refer to it as *pind*. The densely populated area is characterized by the strategic use of public spaces for playing cricket or taking a stroll after a long day of work in the fields, reminiscent of a typical village in Punjab. At Bella Farnia the ‘*pind*’ translates in physical terms, with high-density living, using open areas for sports and owning

Proceedings

restaurant business as well as in intangible terms of identity, community, celebration and belongingness.

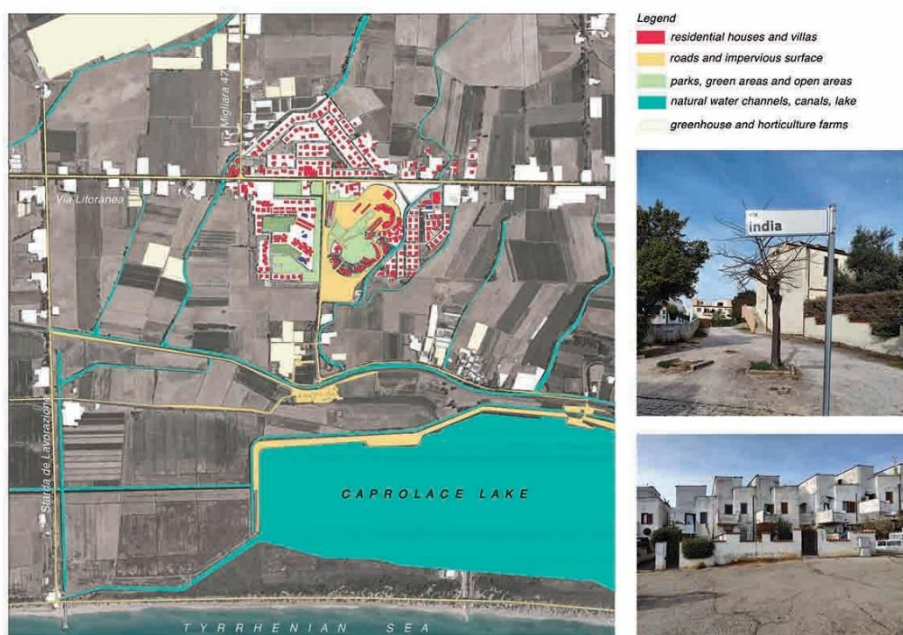

Figure 4. Map of Bella Farnia **Figure 4a.** Street named “Via India” at the central core of Bella Farnia **Figure 4b.** houses used by Sikhs as residential buildings in Bella Farnia

Using GIS statistical and analytical cartography, we tried to map how these dynamics impacted the territory and how the former new towns and service villages are evolving. Over the last 10 years, the land-use change in Italy has been mapped using CLC (CORINE Land Cover) which shows some land-use changes in the Pontine Plain from 1990 to 2012.

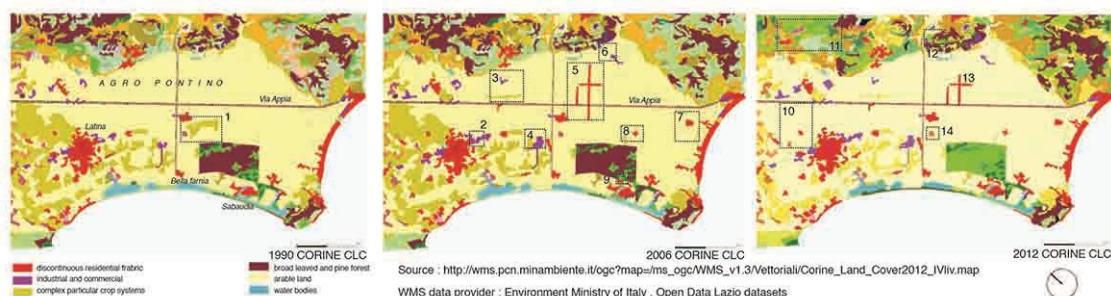

Figure 5. CORINE CLC land use classification from 1990 to 2012.

We can synthesise the following observations :

1. complex crop system along fiume Sisto near Pontinia disappears from 1990-2006;
2. discontinuous residential fabric fuses with industrial landuse in Eastern part of Latina city;
3. new industrial area near Sezze Romano railway station is visible with a new complex crop system towards Via Appia;
4. Borgo San Donato industrial area expands with new discontinuous residential fabric;
5. a new linear discontinuous residential fabric is visible at Via Migliara 50 x Strada del Quartaccio junction that is a unit Migliara segment North of Messa/Ad Media Roman ruins on Via Appia;
6. Mazzocchio I and Mazzocchio II industrial areas are visible near Fossanova railway station;

 ISBN: 978-618-5765-02-6

7. Borgo Hermada shows up as a discontinuous residential fabric along with a strip of complex crop system;
8. Borgo Vodice shows up as discontinuous residential fabric;
9. discontinuous residential fabric of Sabaudia expands North Eastward towards Parco Circeo
10. complex crop system landuse, North of Latina disappears to be replaced by arable land;
11. broad leaved trees and pine forests in Volscian mountains between Sermonetta, Bassiano and Sezze disappear;
12. broad leaves forests increase at the foothills of mountains near Ceriara and Priverno;
13. discontinuous residential fabric at the Via Migliara 50x Strada del Quartaccio junction shrinks;
14. a new vineyard shows up South West of Pontinia;

The OSM service mapping on GIS for popular public services was also used to map amenities owned by Sikhs. The time travel plugin of QGIS was used to generate isochrones maps for 30 minutes bicycle path from important travel zones and 30 minutes pedestrian accessibility zone for Bella Farnia. On-the-spot investigation and interviews with Sikhs and local stakeholders, however, were equally fundamental. Cross-referencing these data shows that the Sikhs found a new way to inhabit the plain beyond the rural-urban dichotomy. Moving daily between the fields and the villages of the plain, they established relationships with Italians and other migrants. While using existing facilities, they also identified new reference points based on the symbolism they attach to physical features. These reference points involve territorial artefacts such as the Appian Way, Fascist landmarks such as piazza, water towers (pani tanki), church as girja (Punjabi), water bodies and water-pumping plants, gardens and groves. Some reference points are fixed, while others, such as the Gurudwara, move over time. The relationship between topography and mobility infrastructure explains the selection of sites for the Gurudwara.

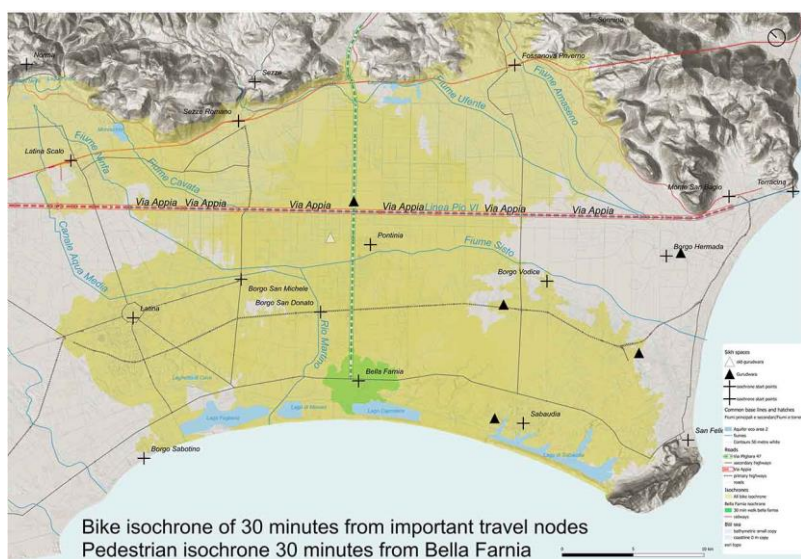

Figure 6a. GIS analytical cartography of isochrones of 30 minutes showing accessibility by bike (in yellow) from main transport nodes and by walking (in green) from Bella Farnia

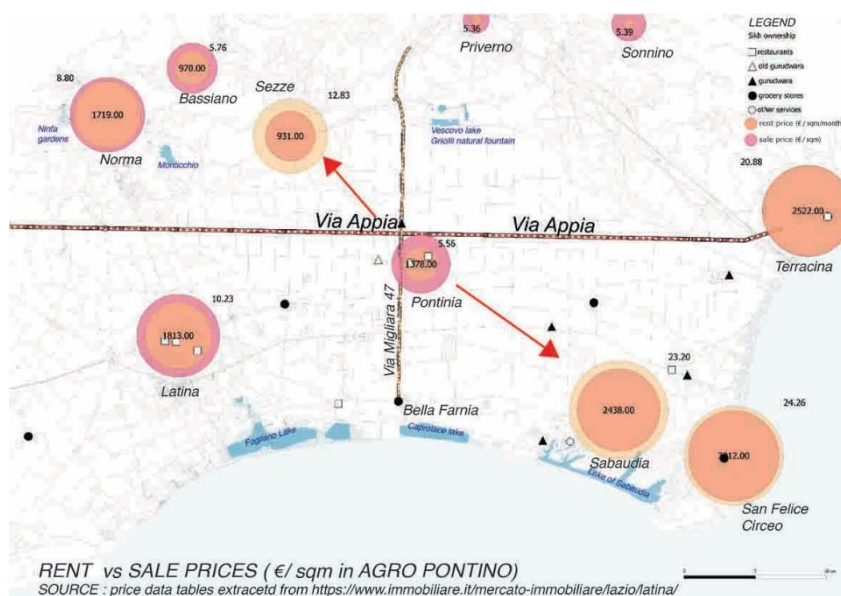

Figure 6b. GIS statistical cartography of property renting and sale prices for the year 2023 as extracted from real estate website : <https://www.immobiliare.it/mercato-immobiliare/lazio/latina/>

The presence of the Gurudwara is related to the lowest sale price in Pontinia as compared to Latina, Sabaudia and Terracina. We compared the property prices around Agro Pontino from a popular real estate company website "immobiliare.it" and mapped on GIS. At the same time, we observed that, Sabaudia and Sezze has a comparative sale price lower than comparative rent price . The presence of a highest number of Sikhs in Pontinia and a new Gurudwara which the Sikhs community built after buying the existing property near Via Appia and Via Migliara 47 junction corresponds with the property price mapping.

4.1 The Gurudwara as a genius loci

Since the 1980s, subsequent waves of Sikhs travelled over 6,000 km from Punjab to reach Italy, bringing knowledge of their homeland and establishing new social networks while working and expanding their families in Italy. In this process, many individuals became heads of a family and set up a business, thus creating a new social body evolving in the space. Until the end of the 1990s, Sikh migration remained predominantly male [6]. Gurudwaras initially emerged as spaces of male hierarchical sociability, where unique power relations within and beyond the community were negotiated and contested [6].

Figure 7. Golden Temple in Amritsar, India, the most sacred Gurudwara temple for Sikhs
 (Source : https://commons.wikimedia.org/wiki/File:Golden_temple_aerial_shot_in_Amritsar.jpg)

Proceedings

The Sikh identity remains with each migrant not only through his beliefs and ideals but also his work ethic and decisions regarding marriage and family, which later helps him build a Sikh community centred around shared well-being and work-related networks, many of them centred around the Gurudwara. As in their homeland, Gurudwaras are conceived as sites of spirituality and for transmitting Sikh principles, yet they also contribute to enhancing community wellbeing and development [6]. The working Sikh youth, the Sikh man with a family, the Sikh wife, an elderly Sikh lady, or the Sikh children, everyone finds a relational genius loci from their deterritorialised context in the space of the Gurudwara which initially hides its form in old warehouses, but later takes shape out of dedicated space in the countryside surrounded by agricultural fields, negotiating with Appian Way and Migliara 47 and creating microcosm landscape around it.

The earlier Gurudwara and Gurughar (smaller versions of Gurudwara) were located in warehouses between Latina and Sabaudia. They changed their place, until the Sikhs pooled money to buy a land near the intersection of Via Appia and Via Migliara 47 for a permanent Gurudwara. The new location is surrounded by a row of villas along the Migliara and one can see the canopy pines of Via Appia extending across to the horizon. The Gurudwara is surrounded by a vastness of green agricultural field. It has its own parking space for cars, garden, a small water body (nascent *sarovar*), kitchen, dining (for *langar*) and praying hall that doubles as a community gathering and school for Sikh children to learn their native language Gurmukhi.

Figure 8. Gurudwaras in Borgo Hermada, near Borgo Vodice and in Terracina in Agro Pontino

The openness around the Gurudwara and its direct contact with the agricultural fields and landscape around is unique and lets the tired Sikh workers find spiritual peace and community support on Sundays. It is also the place where Sikh women come with their children and organize various cultural events.

The Gurudwara as a new location of socialization and land ownership is starkly different from the historic center of Pontinia, where the view and landscape is framed and controlled by the axes, material and monumentality of the planners of ONC.

4.2 Nagar Kirtan (processional parades)

The largely invisible Sikh community working hard in farms and greenhouses find sporadic visibility during their festivals, such as the birthday of Gurū Nānak (*Guruparb*) and Gurū Gobind, the first and tenth Gurūs of Sikhs celebrated with great enthusiasm. The Sikh New Year *Baisakhi* in mid-April is also a time of community congregation and celebration. These festivals are an occasion for Sikhs to organise processional parades around Pontinia called the Nagar Kirtan. *Nagar* means town, and *Kirtan* means singing divine hymns of the Gurū. The *Nagar Kirtan* is often associated with an initiation by *Prabhat pheri* (morning rounds) by a smaller group of Sikhs. Later in the day, the Nagar

Proceedings

kirtan is a grander form of celebration. During *Nagar Kirtan*, Sikh men carry their holy book Gurū Granth Sahib, an embodiment of their living Gurū in a vehicle tableau. The procession is led by holy men or priests dressed in saffron or blue, often carrying *khanda* (swords) that mark the valour of the Sikh community. The procession is followed by all Sikh people, men, women and children. Some of them perform martial arts and *gatka*. The mayors of Pontinia, Latina, Sabaudia and local Italians also attend the festivals, which have now become a significant cultural event for Agro Pontino. The interaction with global networks may transform traditional practices and systems, but the result is frequently not standardisation but the production of ‘localised hybridity’ [16]. Some years the Nagar Kirtan procession reaches one km of colourful people singing hymns and expressing their happiness. They generally start at the respective Gurudwara and continue to the nearest Piazza at the centre of Pontinia and Sabaudia. Significantly, the Nagar Kirtan originates in a Sikh gurudwara in the countryside and terminates in a 1930s Italian square. This mobile genius locus is notable in its ephemeral process that takes the primary votive artefact of a Gurudwara along a mobility infrastructure to the centre of a modernist urban artefact, the main square of Pontinia. In this process, which might last four to six hours following a certain route, the spatial dynamics of the people might vary with changing cultural activities like hymns, slogans, music, and martial arts. Towards the end, people greet each other on reaching the square, and spend leisure time, often accompanied by a community food service or ‘*langar*.’

4.3 ‘Langar’ Community Kitchen and ‘Bhangra’ Dance

The langar, as one of the important Sikh social activities, has a direct relationship with the Sikh agricultural history, which finds easy continuity in the Pontine Plain. *Langar* is a community kitchen associated with permanence in a Gurudwara and ephemerality in the case of Sikh religious festivals. The Golden Temple in Amritsar has the world’s largest community kitchen, serving over 50,000 meals daily. The Gurudwara on the outskirts of Pontinia, Sabaudia, and Terracina all have an attached community kitchen facility for language service. The langar services in the Gurudwaras are periodic, unlike the Golden temple’s daily services. During the langar service, first the vegetables and cooking ingredients are brought and stored. Then, through volunteer Sikh men and women, the food items are washed and prepared in the Gurudwara premises as a collective activity. Then, the food is cooked in large pots. The food items are always lacto-vegetarian as per the Sikh religious principles. The principle of preparing langar food with the community is called *sewa* or selfless service. Later, the prepared food is served to everyone as they sit on the floor in rows and respectfully consume it. The langar breaks social barriers and provides a socio-religious platform promoting the equality of all humans. Langars are open to all religious faiths and all social classes. As a community kitchen, the langar is also served in temporary structures during festivals in urban centres when the Sikhs mobilise their volunteers to provide food. This creates a social and spatial unit among travelling Sikhs who link agricultural produce and food service in both the city centre and the countryside.

The Sikhs in Agro Pontino are also active in preserving and promoting their traditional dance, *Bhangra*. They formed the Sikh dance company Bhangra Boys and performed across dance festivals in Italy. Bhangra is a dance originating from the Sikh countryside in Punjab and has diverse themes related to love, life, friendship, family, valour, and patriotism. The Bhangra Boys in Agro Pontino performed at festivals in Latina and Festival dell’Oriente in North Italy. They also organise dance workshops for everyone. *Bhangra* is used as a tactical tool to showcase Sikh culture and use different spaces in the city and countryside to mark the presence of Sikh identity.

4.4 Planting Trees to make Sikh Sacred Groves in a public park

Sikhism embodies a considerable amount of reference and reverence to nature, mostly depicted in the hymns and verses of their holy book the Gurū Granth Sahib. They have a memory of sacred and monumental trees spread across the landscape of Punjab where the Gurūs gave sermons. There are

14 species of trees mentioned in their Holy Book, like Mango, Neem, Date palm, Berries, and Sandalwood. It is considered a sacred act (daan) to donate and plant trees. In 2020 the Sikhs donated 550 trees to mark the 550th birth anniversary of Gurū Nānak. It was part of the global Eco Sikh project that has targeted climate change through ecological stewardship by planting 1 million trees around the world. The Parco San Marco, Piazza Alpi, and green areas near Cepla cooperative in Viale Le Corbusier. Green Oasis Susetta Guerrini in Latina was the location where the trees were planted. The Sentiero Gurū Nānak was part of this landscape project carried out with the Latina Municipality and the studio Sand and Birch.

These ecological tools for a sustainable future used by the Sikhs are not only physical infrastructure but hold spiritual and cultural meaning for belongingness in the Pontine Plain. They bring a new ecological genius loci embedded in the culture and spiritual tradition of Sikhs creating new openings in the fascist urban plan of Latina.

CONCLUSION

When we refer to Sikh City as opposed to Latina, we evoke precisely this bottom-up process which is singular and universal simultaneously. Aldo Rossi considered the “*centro storico*” as the genius loci of Italian cities. The cities of the Pontine Plain share a similar character, originally dictated by the central state, and following a similar programme. According to ONC official Ugo Todaro (1937), the embryo of a reclamation town was to be a square with a mountain or sea view, big enough to accommodate the population of the entire municipal area. Architects were to create a scenic effect and a stylistic code in the first geometric void, where there should be no lack of state-sponsored buildings representing the social order enforced by the new political course.

Victor Turner, a British cultural anthropologist, believed that transitions between times, statuses, and places were experiences that created meaning [17]. The life journey of the Sikh man adds meaning to the territory through the networks and agencies he builds during his lifetime, which can range from community brotherhood to friendship, family, employer relationships, and business partners. This process transforms a migrant individual into a member of a community and an agent of territorial change. Using Gurudwara as travelling genius loci both from their place of origin to the Pontine Plain and around different locations in the plain, the Sikhs took root overcoming their deterritorialised condition. In the Pontine Plain, the Sikh presence has brought back the emphasis on the identity traits of the countryside rather than the cities, thus picking up the thread of a very long history to build a possible future.

Chronicle of peri-urban (mis)governance: values and defense of the territory vs. governance vacuum and institutional incompetence. The case of the *Vega Sur* of Granada (Spain).

J.L. Rivas-Navarro^{1*}, B. Bravo-Rodríguez¹

¹ Department of Urban and Regional Planning, School of Architecture, University of Granada, Spain

*Corresponding author: E-mail: juanluisrivas@ugr.es, Tel +34 646218357

Extended abstract

It begins with an explanation of the Spanish case in terms of governance and participation, outlining the reasons for an unequal culture of urban planning as a venue for collaborative decision making. This structural imbalance is related to the territories' centrality and urbanity, as well as the transfer of urban planning powers to the autonomous regions. This implies a significant difference between the various regions of the state in terms of democratic principles regarded to be necessary in the planning processes.

Granada is an example of contemporary metropolitan construction, with half a million inhabitants distributed in more than thirty functionally dependent municipalities. The geographical support is a geographical depression of the Quaternary period, vertebrate by the Genil river basin, and that originated an agricultural area of exceptional environmental, historical, and ethnological value, from the Roman and Arab times, through the flourishing of the early twentieth century and current role. All this forms a central identity landscape to understand today the whole territory of "the extended Granada". The urbanization pressure of the second half of the 20th century, the increasing metropolitan mobility, and the lack of control of the administrations of these growths by polarization, have been segmenting the agrological matrix that today is more threatened and fragile than ever. The safeguarding initiatives of civil society, very meritorious and intense in recent decades, contrasts with urban development projects of all kinds -most of municipal initiative-, which fall on the peri urban space without transparent or participatory processes. The intermunicipal situation of this territory is the perfect excuse for the neglect in its management and planning, unprotecting its watercourses, its historical paths and its special areas such as the *Vega Sur*, which are increasingly abandoned and disconnected from the urban and geographical support to which they have always been linked.

The presentation will try to expose the current situation, drawing the diagram of a territorial (dis)governance that only has civil society as an actor aware of its special landscape value and economic potential in an essential scenario of greater sustainability and the fight against climate change. The conclusions will be drawn from the contrast between this reality and certain positive examples of the area itself and other experiences in assimilable peri-urban spaces in other contexts, such as the case of *Els Rajolars*, in Oliva (Valencia), within the framework of the European architecture competition *European 15* and its subsequent implementation.

Extended abstract

Urban design governance makes use of acupunctural interventions as means and processes of designing the built environment. The focus of this method, in particular, is on the quick and effective use of the so called “soft powers” and “allied financial mechanisms” to influence design quality and political impact, with the latter being particularly inclined towards confined scales of intervention due to the limited time and resources of each political mandate.

This article traces the scope, and confronts the effectiveness of the approach vis-a-vis other formal and informal (non-regulatory) urban governance tools that governments, municipalities and others policy makers have at their disposal, taking Tirana as a case study.

The article places such tools within a critical analytical framework discussing the success factors for an effective urban design governance.

This article looks into the case of “Urban design governance” of Tirana as a city emerging from a communist past and eager to get itself a new (European) identity. The design practices adopted in this place-making process are closely examined paying particular attention to the participatory aspect and the extent to which citizen engagement is ensured.

Discussing the planning policy gap in the development of tall buildings in Greece

G. Gemenetzi

Department of Planning and Regional Development, School of Engineering, University of Thessaly, Volos, Greece

Corresponding author: E-mail: ggemenetzi@uth.gr, Tel +30 2421074477

Extended abstract

Nowadays tall or high-rise buildings have become a form of ‘urban habitat’ and not just a symbol of the city’s power. Their role as essential urban infrastructure comes increasingly to the forefront, as European policies for urban planning (such as compact city, 15-minute city, energy-efficient city, increased walkability) push to higher densities that are related to vertical urbanism. However, many European countries and cities (re)consider the development of tall buildings with more scepticism than in the past. Despite the fact that many cities, especially in the Northwestern Europe, have developed policies for interweaving tall buildings into the urban fabric, having taken into account the townscape, the skyline, the sightlines, vistas and views they often experienced a reaction against the construction of tall buildings. This reaction was mainly related to the conservation of historic urban centres and the city’s skyline as part of the cultural heritage and the urban landscape (cityscape). In addition to that, high-rise urbanism has aggregated spatial and social impacts on a) the city/metropolitan level and b) urban life, which are tended to be neglected by policy makers. For example, the fragmentation of cities into soaring towers may lead to the loss of any sense of neighbourhood context or community, create sharp disjunctions and a non-conscious urban space. Taking into account that individuals and institutions reclaim their built environment and put greater emphasis on sustainable development, the relationship of tall buildings with the human scale and the quality of life offered around and between tall buildings becomes an issue of crucial importance for successful city planning, public realm and creation of cohesive and attractive at eye-level cityscapes. These challenges become more urgent to be confronted within the Mediterranean European city, many of which have no or very limited policies regarding the development of high-rise buildings. In Greece the lack of policies for the allocation and development of tall buildings paves the way for radical urban and social transformations and highlights the need to formulate a comprehensive planning policy framework that addresses the challenges for the integration of tall buildings into the social and urban realm. Tall buildings developments are going to have both a sound impact on Greek city and neighbourhood level; in particular, on skyline, urban landscape, urban microclimate and social life. The current paper discusses the planning policy gap in Greece and gives implications for the formulation of an urban planning and design policy framework for tall buildings development.

Extended abstract

As a particular geo-political mosaic, the Mediterranean region continues to be an important and intriguing context, functioning as a notional buffer or “transition zone” (Chiodelli, 2021) between the global North and South. It may be articulated as an epistemological terrain in which the *South and South-Eastern European* peripheral countries are able to be placed. It is also arguably an ideal territory for studying the complex interplay of informal and clientelist planning procedures and high homeownership rates that produce particular patterns of residential settlements (Allen et al., 2004; Leontidou, 1990). Furthermore, within this highly variegated region, lies the challenge of applying Western urban theory to societies with different socio-political systems. Specifically, the urbanisation processes in Cyprus make a particularly interesting case study in order to analyse the concepts of urbanisation in the region’s mixed geo-political, cultural and economic relations. This paper explores the notion of “territory based urban governance” (Schindler, 2015, p. 10) through the contextualisation of planning procedures related to the co-production and transformation of land in Cyprus.

The hybrid relationship between formal and informal practices in urban governance and social institutions have been fundamental in the parcellation and development of land for homeownership. The dominance of the private real estate sector, land speculation on the fringes of cities and the supporting role of an enabling/clientelist state, are brought into relief with the aim of contributing to critical urban theory in the wider European peripheral region. The methods used combine an analysis of theoretical papers, newspaper articles, housing and planning policy with empirical data of the morphological patterns and visual characteristics of the urban-rural continuum of Cyprus.

Key findings indicate that the relationship between clientelist and territory-based forms of urban governance have resulted in a patchwork of suburban (or peri-urban) environments characterised by the juxtaposition of oversupply of residential land and undersupply of affordable housing. Rather than outright formal planning policy, the combination of mechanisms for boosting land value, the historic evolution of clientelism and formal-informal interactions and negotiations that govern land development, have had a greater impact on the transformation of urbanizing areas.

Extended abstract

Traditionally, heritage has been viewed as a “passive victim” of rapid urbanization, facing threats to its survival rather than being recognized for its potential to actively contribute to the sustainable development of cities. In addition to that, it is a fact that when cultural tangible heritage protection is not prioritized in agendas, “the availability of resources (economic, technical or human) allocated to conservation efforts may be compromised, which could result in neglect or abandonment of cultural assets”¹, despite the fact that cities could benefit from the protection of its heritage. It is well known that conserving historic buildings provides significant economic, cultural and social benefits.²

Within this context, it is necessary to redefine how cultural heritage nowadays is understood and which role could play for the city’s resilience. At that point, it is necessary to refer to the 2004 Agenda 21 for Culture, concerning the understanding of culture as a fundamental dimension in sustainable development, but also to the 2030 Agenda for Sustainable Development and in particular Target 11.4 concerning the efforts to protect and safeguard the world’s cultural heritage in order for making cities and human settlements inclusive, safe resilient and sustainable.

Moreover, the complexity surrounding heritage should therefore compel society to engage in its holistic management rather than to conserve only specific structures, as happened in the past.³

So, in this framework, and by having in mind on the one hand that “heritage is dynamic, as it links the past, the present and the future⁴” and on the other hand that heritage protects and enhances collective historical memory, the paper presents two recent research programs, concerning on the regeneration, revitalization and integration of architectural heritage of tobacco warehouses in the contemporary urban environment of three different cities of northern Greece: Drama, Kavala and Xanthi.

By analyzing two tobacco warehouses as case studies, the basic project aim was to include all the necessary stages - from documentation to restoration of good practices - in order for the buildings to be integrated into the urban fabric, as well as the whole socioeconomic city network.

Keywords: *cultural heritage; urban regeneration; urban resilience; tobacco warehouses; sustainability.*

Abstract

The proposed paper discusses the evolution and changes in time of the lakeside front of Lake Pamvotis in Ioannina in northwestern Greece, from the time of the creation of the lake until the present day. The current study examines the development of the lakeside area over time, its division into public and private areas and the reasons that led to this fragmentation. It presents the particular urban qualities of lakeside fronts and areas that have developed on the shores of lakes both in Greece and in neighbouring Balkan and European countries.

The evolution of the development of the city's lakefront is documented and studied, the causes that contributed to these changes are investigated and the possible future changes that may result from continuous human interventions are assessed. The boundary situation between the undeveloped natural landscape and the fragile lake ecosystem is examined and studied in relation to the built landscape of the lakeside urban fabric.

The phases of development of the urban fabric of the city and the location of individual activities in relation to Lake Pamvotis are studied. With regard to the lake, its topography and the catchment areas it contains are examined, as it is protected under European regulations.

For this research, historical data (maps, photographs, etc.) and studies that have been carried out over time for Lake Pamvotis are used. The form of the lake front, as influenced by mainly human interventions in four distinct periods, is studied.

The most significant changes in the lake front occur from 1959 onwards, when major technical flood protection works of the basin and land reclamation for the needs of agriculture and livestock farming in the area were carried out, which dramatically reduced the perimeter and the total area of the lake.

The rapid development of the city since 1980 and afterwards, as the city is the economic, cultural and administrative center of northwestern Greece, resulted in a large increase in the population of the city and the settlements along the lake. This, combined with the particular natural beauty of the lakeside area, has resulted in the development and creation of luxury housing, leisure and entertainment areas, sports and hotel facilities on the available areas of the city's lakeside front. In other words, there are urban qualities that are not found in other areas of the city.

The present paper approaches the development of the lakeside area as it has evolved to date, the residential development that has followed, and seeks and draws conclusions about the current form of the area in relation to the rest of the city's residential development.

Keywords: *urban qualities, lake, lakefront, Ioannina, Lake Pamvotis.*

1. INTRODUCTION

All major European cities have historically been located and developed in areas adjacent to rivers and lakes, because lakes and rivers provide a special environment for the development of cities and settlements. This occurs as they facilitate various human activities: they provide water for energy production and agricultural land for the production of food, and they also facilitate trade through transport.

The water quality of rivers and lakes deteriorated after the 19th century due to the increasing number of settlements that developed on their banks and industries that discharged untreated sewage. In addition, human interventions modified the river and lake banks due to urban development, the

construction of facilities to serve the shipping industry and the construction of anti-flooding structures. [1]

The present study focuses on the evolution over time of the lake front of Lake Pamvotis, on the western shores where the city of Ioannina in Greece is developed. It divides the lakeside area into public and private areas, the reasons that led to this fragmentation, and presents the particular urban qualities of lakeside fronts and areas that have developed on the shores of lakes both in Greece and in neighbouring Balkan and European countries.

The evolution of the city's development in relation to Lake Pamvotis from the time of its creation to the present day is recorded and studied, and the possible future changes that may result from continuous human interventions are explored and assessed. The boundary situation between the undeveloped natural landscape and the sensitive lake ecosystem in relation to the built landscape of the lakeside urban fabric is examined and studied.

By studying examples of lakeside fronts in Greece, Europe and the Balkans, it was found that in all cases lakes are created due to the particular morphology of the terrain of a region, where a basin is surrounded by mountainous areas and at its lowest point the rainwater is "trapped" with no escape route. The selected lakes vary in size, but have several characteristics in common. After research and assessment, it is observed that the urban qualities identified and developed next to the ponds have some common characteristics not found in other urban environments.

In particular:

- Similar conditions are created for the urban development of settlements as, due to the mountainous terrain of these areas, there is limited space available for the expansion of urban borders.
- The lakes function as natural receptors of a network of streams with a high drainage capacity of rainwater, which erode the mountainous soils, carry away sediment and create siltation in the lake area and its banks, resulting in a change in both their capacity and their natural contours over time. The siltation reduces the capacity of the lakes and causes flooding of the lakeside areas. The land resulting from the siltation of lakes is also an attractive area for urban expansion.
- Areas around the lakes are used as agricultural land, due to the existence of water for their irrigation
- Human activities affect the sensitive ecosystems of the lakes (water pollution from waste, pesticides, etc.)
- Some cities include historic castles and settlements
- The special natural environment of the lakes' shoreline increases the demand for the creation of recreational areas for urban residents (creation of squares, parks, hiking and cycling trails, etc.)
- Tourism is growing and spaces are being targeted for the creation of tourist facilities
- Lakes are usually home to a large number of rare plants and birds and many other living organisms and are therefore protected areas under European regulations.

2. HISTORICAL DEVELOPMENT OF THE LAKESIDE FRONT OF THE LAKE PAMVOTIS

In the following chapter the development of the lakeside front of the Lake Pamvotis in Ioannina is recorded, categorized and described in various periods of time. The selection of the periods was based on the main human interventions on the lake front, which led to its present form.

2.1 First period: From the creation of the lake to 1900

Ecological balance established in Lake Pamvotis

Lake Pamvotis is considered one of the oldest lakes in the world and its age is estimated at about 7 million years. [2]

Lake Pamvotis in the area of Perama communicated through a narrow strip of water with the adjacent Lake Lapsista. Lake Lapsista occupied an area of 40 km² and had a depth of 1-3m. [3], while Lake Pamvotis covered an area of 23.8 km² [4] and had a maximum depth of 8m. [5]. The two lakes formed a single network of lakes and, through the sinkholes at Rodotopi, the lake ecosystem communicated with the river Kalamas and the sea and for centuries ensured the flood protection of the basin.

On the southeastern side of the lake are the areas that were flooded and through other sinkholes were drained to the Louros River. [4, 5]

During this period, the lakeside front had a longer length, while the urban fabric of the city of Ioannina is in contact with the lakeside front only in the area of the historic castle of Ioannina.

Figure 39. The original shape of the lake front of Lake Pamvotis and Lake Lapsista, as well as the areas on the southeastern side of the basin that were flooded.

2.2 Second period: From 1900 to 1959

During this period, the mild utilization of the lake continues to meet the needs of society, such as fishing, hunting and irrigation (e.g. vegetable garden area).

The figures below show the catchments and streams feeding Lake Pamvotis as well as its location in the basin and sections of the lake. It can be seen from the drawings that the lake is located at the lowest point of the basin. Due to the morphology of the terrain of the basin and the fact that the lake and the mountains are natural boundaries, the city of Ioannina is forced to develop on the north-south axis and parallel to the western shore of Lake Pamvotis and in contact with the historic castle of the city.

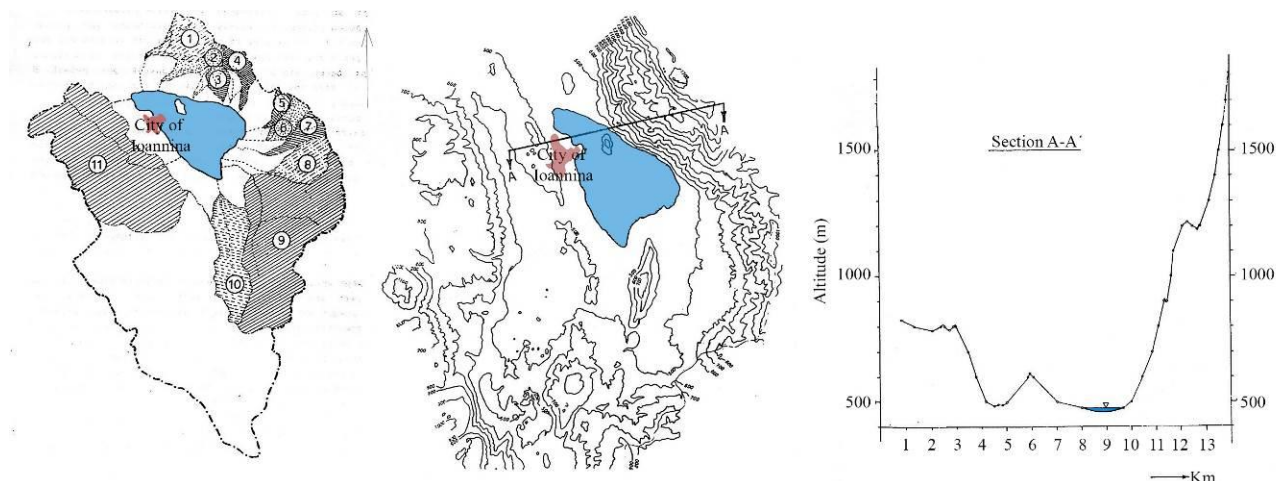

Figure 40. The figures show the catchments and streams that feed Lake Pamvotis, the location of the lake and its section. [5]

Also, due to the high altitude of the mountains, sediment and mountain streams end up in the lake, creating siltation and reducing the size of the lake.

From the Historical Archive of the Municipality of Ioannina, copies of maps drawn in the early 19th century were obtained and constitute historical sources. The following maps show that the historic castle and the areas of the vegetable gardens are developed on the coastal front of the city of Ioannina. [6]

The map of the approved town plan of 1915 and the map of Melirritos in 1919 show the desire to exploit the public space in contact with the lake and around the historic castle of the town, the creation of streets and green spaces, the placement of a row of trees along the road, the integration with the vegetable gardens in the area of Matsika and the partial urbanization of the area of Matsika in contact to the lake.

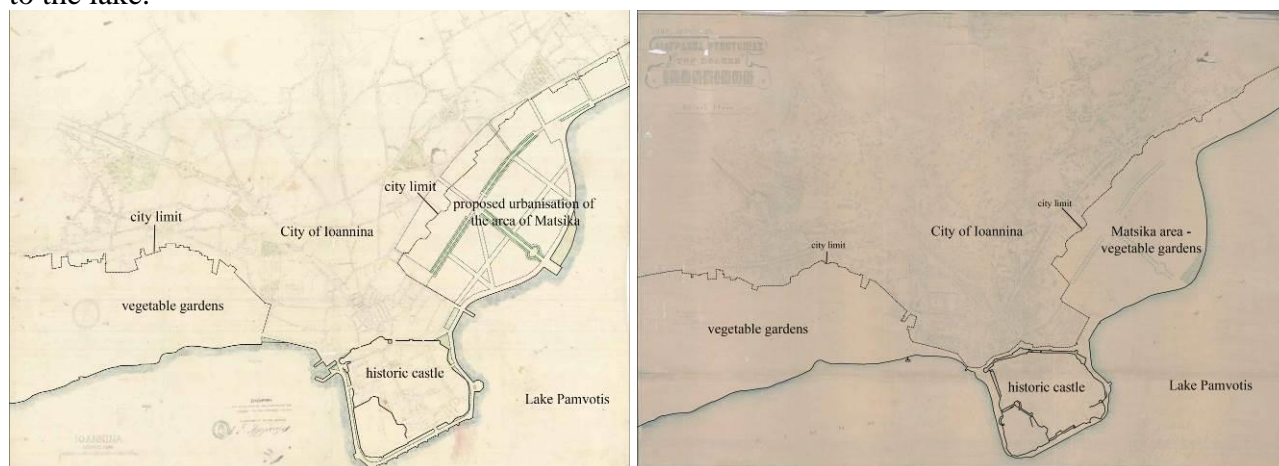

Figure 41. The map of the approved town plan of 1915 and the map of Melirritos in 1919 for the development of the lakeside front of Ioannina

Four years after the approval of the 1915 plan, the government of Eleftherios Venizelos assigned Ernest Hébrard to design the urban plan of the city of Ioannina in 1919. [7]

Ernest Hébrard foresees economic and political development of the city, as there are embassies of foreign countries, and even plans a tramway, seeing the city's development path towards the current district of Anatoli - due to the morphology of the basin. The city's vegetable gardens on the lakeside front are mapped and preserved, and there is provision for integrating these spaces with other public areas, such as squares and parks, within the city. Furthermore, Hébrard plans an industrial area in contact with the lake after the vegetable gardens towards the district of Anatoli.

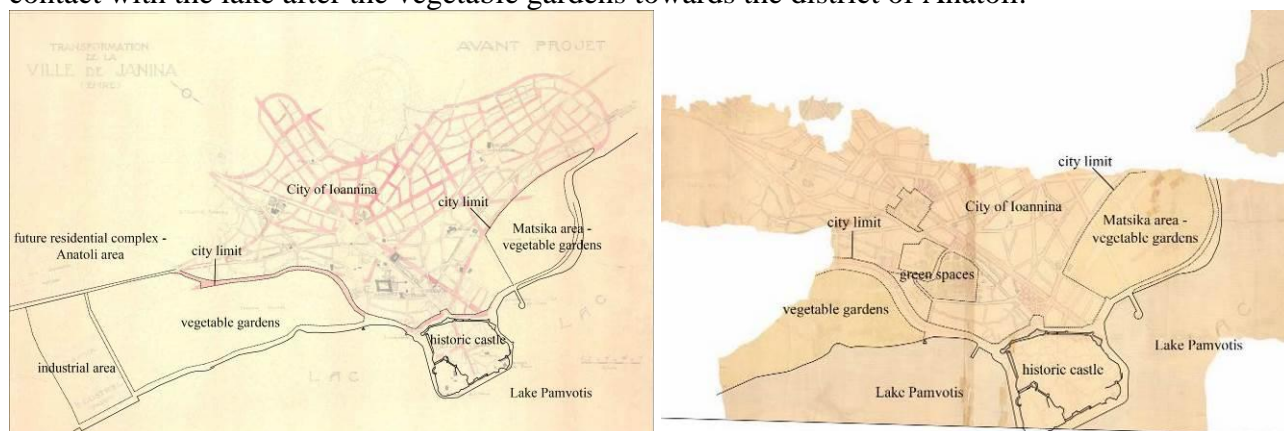

Figure 42. Ernest Hébrard maps for the development of the lakeside front of the city of Ioannina

During this period after the Asia Minor catastrophe, part of the public space was granted by the State for the refugees' residences on the lakeside front and at a short distance from Lake Pamvotis, in the areas of Matsika and Anatoli. [8]

Figure 43. From the aerial photograph of 1945 it is observed that the urban fabric of the city of Ioannina is in contact with the lake front only in the area of the castle of Ioannina. The other settlements that are created are located at a distance from the lake front. [9]

2.3 Third period: From 1959 to 1980

Major engineering works disrupt the ecosystem of the lake

During this period, a series of major technical flood protection and land reclamation projects were completed, which irreversibly changed the boundary line and the balance of the lake ecosystem of Lake Pamvotis [4, 5].

Within a program for the strengthening of agriculture and livestock farming of the rural population of the basin, the following were carried out:

1. The construction of embankment dams in the districts of Perama and Anatoli-Katsika for the drainage of Lake Lapsista in 1959 [10] and the creation of arable land which was granted to the rural population of the city.
2. The construction of a dam in Perama for flood protection of the basin, which determines the maximum elevation of the lake level and - through the Lapsistas ditch - channels the flood waters to the river Kalamas.
3. The reclamation works that ensured the irrigation of these fields by the waters of Lake Pamvotis - as continues today. These works transformed the lake from a free natural ecosystem into an irrigation tool (a large storage reservoir) and a tool for the exploitation of agricultural land in the basin, resulting from the draining of the marshes of Lapsista, etc., as mentioned above.

The interventions on the lakefront were made because of economic development, political will and the safety of the residents. [11]

However, while these interventions were initially made with good intentions, such as draining the marshes to improve the lives of the inhabitants of the city and the lakeside settlements, creating areas for agricultural exploitation and livelihood of the local rural population, etc., they ended up having negative to dramatic long-term impacts on the lake ecosystem. The uncontrolled use of chemicals and other waste on agricultural land has degraded the quality of the lake's water.

In addition, the construction of these projects has cut off the supply of clean water to the lake from important sources, resulting in a dramatic deterioration in the quality of its waters and the quality of life of the organisms endemic to the lake.

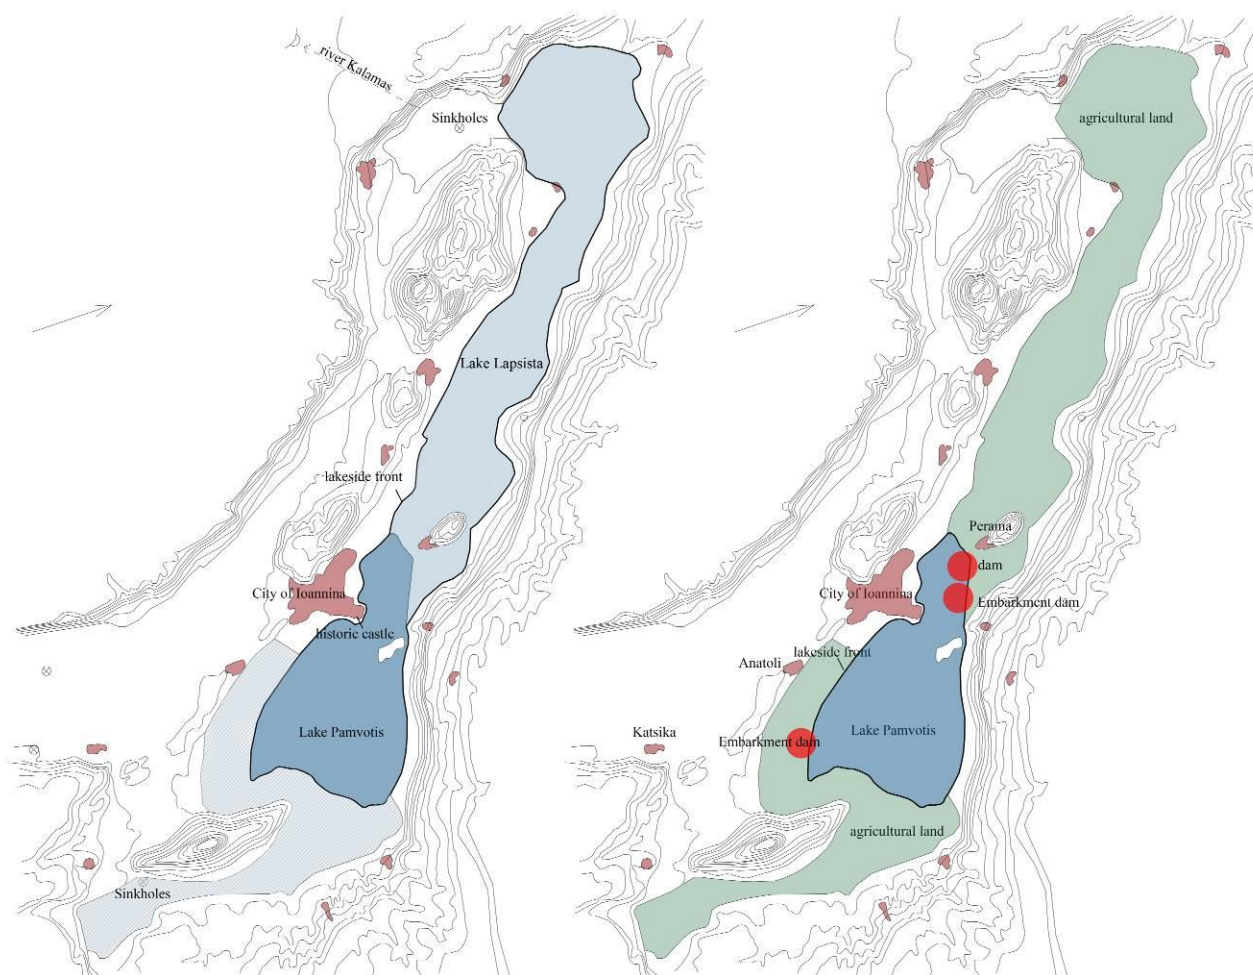

Figure 44. The figure shows the original shape of Lake Pamvotis and its connection with Lake Lapsista as well as the final shape of the lake with the interventions that have changed the boundary line of the lake front.

After the construction of major flood protection and land reclamation works, the size of Lake Pamvotis is reduced to 22.8 km² [12]. The total length of the lakeside front of Lake Pamvotis today is approximately 24km.

Interventions have been made in the lakeside area with the aim of shaping the public space and creating the lakeside front, with rows of trees, squares, roads, parks, etc. The lake front which was developed covers about half of the perimeter of Lake Pamvotis. On this side of the shore, in contact with the urban fabric of the city of Ioannina, the biggest interventions that change the lake's boundary line are located.

At the same time, the city is experiencing rapid growth. The University with the University Hospital, the increase of economic activities in the region, the opening of the border with Albania made the city an administrative, economic and cultural center of the wider region of north-western Greece. This resulted in a large increase in the city's population and an explosion of building activity.

Outside the city, all the large settlements of the basin (Anatoli, Perama, Katsika, etc.) developed. The town expanded towards the settlements and towards the shores of Lake Pamvotis and absorbed the arable land.

The major residential development on the lake front is observed on the western side of the lake within the boundaries of the residential fabric of the city of Ioannina and the settlement of Anatoli. This particular residential development is not found in the other parts of the lake.

The rest of the perimeter of the lake is not in a similar situation and the lakeside sections do not show any changes, as they retain their original character as wetlands or arable agricultural land.

2.4 Fourth period: From 1980 to the present day

Lake Pamvotis is part of the European network of protected areas Natura 2000 [13]. However, multiple human activities and the city's large-scale residential development have resulted in pollution of the lake's waters, which has endangered its sensitive ecosystem.

Studies were carried out by various scientific bodies and techniques were applied to help revitalize the lake. The completion of the biological treatment of the city was crucial to its preservation.

In general, the benefits that can accrue to lakeside cities from improving the urban water environment include:

1. Creating opportunities for access to the natural environment, providing new open spaces for amenities and recreation, and green networks for wildlife and people,
2. reducing the heat island effect,
3. reducing urban water pollution by incorporating sustainable drainage systems and restoring contaminated land; and
4. enhancing biodiversity

Achieving these benefits can have wider socio-economic consequences, as restored urban water bodies create an attractive environment that encourages recreation, creates open spaces and a more natural landscape, enhances the physical and mental health of residents, encourages business investment and tourism, increases property values but most importantly because it can lead to the sustainable development of cities. [1]

At the same time, the city of Ioannina is a regional and inter-regional development center and a hub of trans-European road networks.

Due to its historical and cultural value and the particular natural beauty of the city and the areas it is adjacent to, the city is experiencing a population explosion and a rapid increase in tourism. In the 1921 census the population of the Municipality of Ioannina was 20,765 inhabitants, in the 1961 census (the period when the major technical flood protection works of the basin and land reclamation works were carried out) the population was 34,997 inhabitants, while in the last census of 2021 the population rises to 113,978 inhabitants. [14]

In recent years there has been a strong movement of the city's residents for recreational purposes towards the lake front. Hiking trails by the lake are a daily habit of a large number of town residents. Visiting the cafes and restaurants that have been established have moved the recreational center of the town to the lake area. Large sports facilities (sports fields for various sports, indoor sports facilities, swimming pool, etc.) in the Limnopoula and Anatoli areas are a daily gathering point for a large number of citizens. Also the recently constructed Mavili Square, small theatre in the area of Skala and the cultural area created after the development of the site of the old slaughterhouses of the city host numerous events organized throughout the year, with a huge increase in human flows to the lake front. The lake is now an integral part of the daily life of the city's residents.

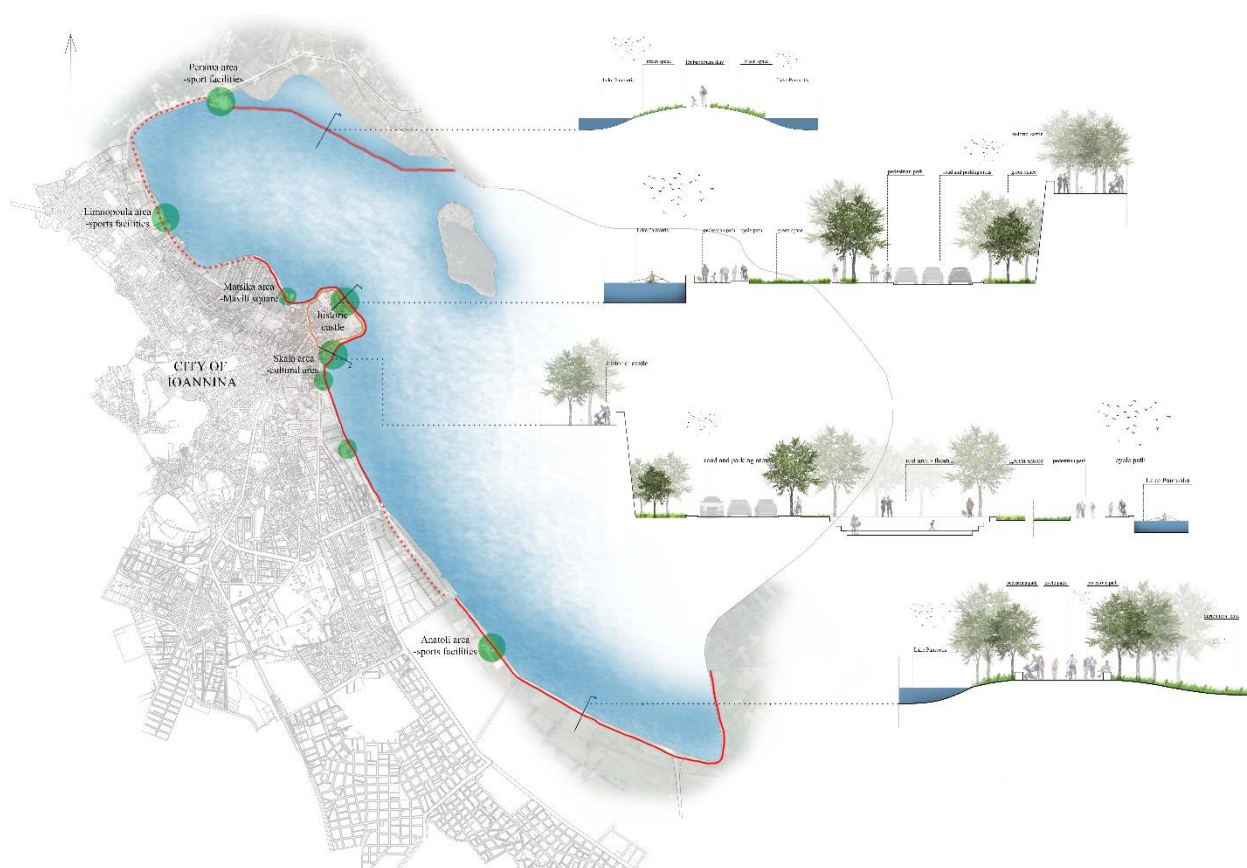

Figure 45. The figure shows the interventions on the lake front of Ioannina. The continuous line shows the existing walking and cycling route, while the dotted line shows the intention for a future connecting route. The rest of the lake front has not been affected.

There is an increasing need to make use of the few public spaces available, in particular the lakeside frontage, by creating parks, squares, hiking and cycling trails, etc. The agricultural land along the shore is the only one available, which of course has the exceptional privilege of being of particular natural beauty due to its proximity to the magnificent natural landscape of the lake. The lakeside front is being compressed residentially due to its special natural beauty - it is a first choice for development and creation of housing, leisure and entertainment facilities (cafes, restaurants, sports and recreational facilities) and many hotel units.

The economic growth of the city and the increased real estate prices are creating high pressure on the management of the land around Lake Pamvotis leading to the issue of changing the boundary of the lake.

However, human interventions over time have significantly affected the sensitive ecosystem of the lake and restrictive and other measures should be taken immediately to save the lake.

4. CONCLUSION

The human interventions that have been made over time on the lakeside front of Lake Pamvotis in Ioannina have dramatic consequences on the shape of the lake and the quality of its waters. The conversion of parts of the public lakeside area to private through concessions from the state to meet the needs of refugee housing and farms has led to claims for residential development in these areas. The economic, administrative and cultural development of the city resulted in the construction of numerous sports, cultural facilities and subsequently tourist facilities to meet the needs arising from

the large tourist development of the city and nearby settlements. This resulted in the creation of urban qualities that are not found in this form in the rest of the urban fabric of the city of Ioannina. Uncontrolled residential development is a burden on the sensitive ecosystem of the lake and there is an immediate need to establish a framework that defines land use throughout the lake front to protect the sensitive ecosystem, which is protected by European NATURA regulations.

Reshaping the industrial urban landscape: an innovative approach or a means to gentrification?

V. Toura

Corresponding author: E-mail: valiatoura@gmail.com, Tel +33 (0) 782589025

Abstract

The paper questions the meaning of preservation of industrial remnants in former industrial cities. Isolated buildings as factories and abandoned infrastructure and equipment dated on the industrial era are often demolished in favor of contemporary buildings which seem to better correspond to contemporary aesthetics. The concept of industrial heritage is changing with the emergence of Critical Heritage Studies which consider heritage as an evolutionary process that responds to the needs of contemporary societies in terms of sustainable development, economy, or culture.

The two case studies of the paper are considered as exemplary models of architectural and urban design forms in former industrial cities. On the one hand we have the reconversion project Ile-de-Nantes, a brownfield within the former industrial city of Nantes, a city with a significant industrial heritage. On the other hand, we have the reconversion project Docks-de-Seine, a brownfield located in the city of Saint-Ouen in the outskirts of Paris, a city characterized in the last 20 years by its urban transformations (spatial, economic, social), in which industrial activities have never ceased to exist. The study and comparison of the two case studies revealed the risk of gentrification in former industrial cities as their working-class identity changes due to the arrival of executives and the rejection towards the cities' periphery of the modest socio-professional categories. We must also note the high cost of such operations, even in the case of large, deindustrialized cities, because the financing of such projects requires significant economic funds, at the risk of disfavoring other municipal actions.

Keywords: industrial heritage, urban regeneration, cultural identity, gentrification, France.

1. INTRODUCTION

Former industrial cities are characterised after their deindustrialization by the presence on their urban fabric of remnants of their industrial past such as buildings, infrastructure and equipment reflecting industrial activities of previous decades. The question of reintegration of these elements to the urban fabric and the consequent transformation of the former industrial landscape are primarily based on urban regeneration programs and on the social, economic and environmental reactivation of the deindustrialized sites [1]. These programs usually involve the conservation of industrial buildings as a measure of preservation of local history and collective memory of the living and working conditions of former industrial workers [2]. At the same time, we observe in several cases of urban regeneration programs in deindustrialized cities conflicts of interest between the procedures of heritage making and neoliberal urban development practices in architecture and urban design which lead to the demolition of infrastructure and equipment dated on the industrial era and the consequent construction of contemporary buildings by star architects which seem to better correspond to users' needs and contemporary aesthetics [3]. The decision to preserve or not preserve the places of industrial production is not neutral, according to French researcher Vincent Veschambre [4] and it depends on the decisions of the municipalities of deindustrialized cities and project managers of urban regeneration projects on the ways in which architectural and urban design is supposed to face the consequences of deindustrialization (social and economic decline) [5].

Proceedings

of the International Conference on **Changing Cities VI:**
Spatial, Design, Landscape, Heritage & Socio-economic Dimensions
Rhodes Island, Greece • June 24-28, 2024
ISSN: 2654-0460
ISBN: 978-618-5765-02-6

The question of preservation of industrial heritage and its reintegration to the urban fabric is based on the principle of conservation of historical urban forms as well as a reminiscence of the social character of the architectural design of the buildings of these areas, especially of the industrial workers' houses [6]. In France, Robert and Reichen, propose new forms and uses for the old industrial buildings such as industrial museums and houses based on the principles of circular economy (recycle of buildings) and preservation of urban heritage [7]. In Great Britain the urban fabric of former industrial cities that were highly urbanized such as Liverpool and Manchester retained its centralities from the industrial era as a result of the strategic relay points of trade routes [8]. Even though the media highlight the clash between different values and meanings (on one hand the conservation of cities' past that no longer exists and on the other hand the cities' future based on new forms of architecture and economic activities), we must underline that there is a different approach in the content of urban regeneration/renewal programs. This means that decision-makers (local elected officials, developers, urban planners, architects) choose either to restore and reuse old industrial buildings or to demolish them in order to transform the industrial urban landscape [9].

2. HOW TO RESHAPE THE INDUSTRIAL URBAN LANDSCAPE? INTRODUCING THE CONCEPT OF CRITICAL HERITAGE STUDIES

The concept of industrial heritage is changing with the emergence of Critical Heritage Studies which consider the conservation of industrial heritage as an evolutionary process that responds to the needs of contemporary societies in terms of sustainable development, economy, or culture [10]. This practically means that the appearance of preoccupations since the 1980s at international level about social, economic, and environmental sustainability of cities, creates new challenges for the preservation of industrial heritage as the industrial buildings can be restored and reused in order to have a second life for example as housing units and cultural spaces [11]. We must also underline the fact that many reconversion projects of industrial brownfields contribute to boost social actions and environmental responsibility in architecture and urban design [12] such as the case study of the urban regeneration project Ile-de-Nantes in France.

In this context the principal hypothesis of the paper is to consider that the preservation of architectural and urban design forms in former industrial areas can lead to the reshape of the industrial urban landscape and to the conservation of essential meanings in architecture and urban design as a means against a possible gentrification scenario. Through a critical examination of the procedures of preservation of industrial heritage in programs of urban regeneration in deindustrialized cities, which are often characterized by neoliberal practices, the objective of the paper is to question the policies and tools which seem to contribute to the transformation of deindustrialized territories. At the same time the paper will investigate the ways in which a balance in city planning could be achieved between the construction of new contemporary buildings and the conservation and reuse of industrial buildings. In order to respond to the main hypothesis of the paper we used data (interviews, socio-economic elements) collected from two programs of industrial reconversion in France which highlight the context of preservation of industrial heritage and the risks of gentrification.

3. REUSE, RESHAPE, TRANSFORM THE INDUSTRIAL URBAN LANDSCAPE OF FRENCH DEINDUSTRIALIZED CITIES

The two case studies of the paper are considered as exemplary models of architectural and urban design forms in former industrial cities as they allow the dialogue between buildings, equipment, and infrastructure of different eras (industrial, contemporary). On the one hand we have the reconversion project Ile-de-Nantes, a brownfield within the former industrial city of Nantes at the west of France, a city with a significant industrial heritage. The project functions as a vector for the development of new architectural forms in public buildings (for example the local courthouse). On the other hand, we have the reconversion project Docks-de-Seine, a brownfield located in the city of Saint-Ouen in the

north suburbs of Paris, a city characterized in the last 20 years by its urban transformations (spatial, economic, social), in which industrial activities have never ceased to exist. The project functions (as the first case study in Nantes) as a vector for the development of new architectural forms in office buildings (for example the buildings of Alstom).

The study and comparison of the two case studies revealed the risk of gentrification in former industrial cities and the swift to different values and meanings in architecture closer to a more productive dimension due to the design of public and commercial buildings by star architects, the limited number of social housing units and the uses of the former industrial buildings. The results of this trend are the arrival of executives in deindustrialized areas and the rejection towards the cities' periphery of the modest socio-professional categories.

Total	34466	36060
Craftsmen, tradesmen, businessmen	1912	1969
Senior managers and professional occupations	11353	13489
Intermediate professions	8829	8623
Employees	6801	6807
Industrial workers	5571	5115

Table 2. Number of working positions in Saint-Ouen, *INSEE and City of Saint-Ouen* (2018). It is interesting to compare the numbers of senior managers and intermediate professions to the number of industrial workers, in order to understand the swift to a different economic model.

3.1 The Ile-de-Nantes project: regeneration based on the local sources.

In 1987 the Bougainville, is the last ship constructed in the shipyards located at the west of the industrial site of Ile-de-Nantes. After a prosperous industrial era, only brownfields remain on this site. The future of the territory was part of the debates during the municipal elections in Nantes in 1989. During the 1990s the team led by Jean-Marc Ayrault launched a period of reflections on the future of the site which embodies both the preservation of its industrial past and the solving of social problems linked to the closure of shipyards, as well as the possibility of reactivation and regeneration of the site. The idea of transformation of the entire territory, uniting its three parts in a dynamic way, emerges. The desire of the municipal team for an extension of the historic center of Nantes towards the site of Ile-de-Nantes is shown by the proposal of the city to the French government in 1996 to

construct on the site the new City Courthouse. To formulate the project the Municipality launched a contract in 1998.

The Atelier de l'Ile-de-Nantes, a team of architects, urban planners and landscape architects led by the architectural studio of Alexandre Chemetoff, was the first to be selected in order to implement the strategy and political ambitions of the municipal team. The first phase of studies, which lasted ten years (2000-2010), resulted in the desire to reconsider the island as a whole and to define an urban regeneration project adapted to the new economic, environmental, and social challenges without denying the local urban history that has shaped its territory. In this context several industrial buildings were preserved especially on the site of the former shipyards and were reused as museums and exposition spaces.

During the ten years of project management by the team of Alexander Chemetoff we can see his vision for the regeneration of the site through small-scale urban projects concerning the site's public spaces and buildings. These include: the Schoelcher footbridge built in 2001, a pedestrian bridge that connects the historical center of Nantes to the site, the Boulevard De Gaulle built in 2007 that connects the north and south part of the site and the Quai des Antilles built in 2007 which echoes the industrial and port memory of Ile-de-Nantes. We should note the will of the Municipality of Nantes and the team of project management to create an urban project whose design is linked to territorial experiments. In fact, the Guide Plan, a design method proposed by the team of Alexander Chemetoff for the urban regeneration project of Ile-de-Nantes based on a reconfiguration of the site's public spaces, provides broad guidelines for the development of the urban regeneration project which allow the preservation of the industrial heritage in the redevelopment of the different site sectors.

The turning point towards more neoliberal practices in architectural and urban design forms is the construction on the site of Ile-de-Nantes in 2008 of the Beaulieu Commercial Center and Nantes School of Architecture in 2009 which will give a new vision for the resilience of the site based on cultural and commercial activities. The later construction of the University hospital center of Nantes on the site of Ile-de-Nantes is based on the same principle which underlines the importance of big infrastructure and equipment in order to achieve urban resilience. Besides this vision towards a productive dimension in architectural and urban design we must underline the risk of gentrification as we have seen previously in the Table 1 which shows a swift towards tertiary activities.

The restoration of the link between the territory and its industrial past through the redevelopment of the quays and banks, which was part of the strategy of the Chemetoff team, is pursued during the project management led by the team Smets and Depuydt (2010-2017). During this phase of the project the banks of the Loire River are transformed into places for walking and leisure. The study of site's landscape relief is also based on other founding elements of the site's urban history, such as the railway infrastructure, which is integrated into the site's regeneration project in order to play a new role.

In this second operational period of the project, we can see the will of the management team and the Municipality of Nantes to continue the redevelopment processes, begun by the previous management team. On the other hand, it should be noted the different policies for the preservation of industrial heritage during this phase of the project which are not based on the rehabilitation of the industrial buildings of the site but on the inscription of traces of the industrial past in a system of parks that unite the various neighbourhoods of the site. In addition, it can be noted that the Transformations Plan, a design method proposed by the team Smets and Depuydt based on the study of the landscape's relief, is an operational document that provides broad guidelines for the development of the project, as was done previously by the Guide Plan of the team Chemetoff. We can therefore see a local urban planning approach (*urbanisme à la nantaise*) that highlights territorial experiments in architectural and urban design which allows a balance in city planning through the construction of new contemporary buildings and the conservation and reuse of industrial buildings. However, it should be mentioned that the construction of big infrastructure and equipment on the site such as the University

Proceedings

Hospital and the City Courthouse, as well as the creation of neighbourhoods that promote commercial and cultural activities, have modified the social character of the project. The shift to different values and meanings in architecture closer to a more productive dimension is evident and has as a result the arrival of executives and entrepreneurs and the increase of rentals and property sale prices.

3.2 The Docks-de-Seine project: regeneration based on a national program for the reactivation of wastelands (*friches*).

The willing of a group of industrialists to create an outer harbour downstream in Saint-Ouen near the Paris Metropolis has contributed to the economic attractiveness of the city and its surroundings with the arrival of internationally renowned companies and many state-owned enterprises. The departure of the industries gradually changed the face of the district of the Docks-de-Seine. At the beginning of 2000 (departure of Total in 2003 and Alstom in 2004), discussions began at municipal level in order to give new functions to the Docks site while preserving its industrial heritage. This objective was interpreted by the Municipality of Saint-Ouen and the project management team as the need to connect the city center of Saint-Ouen to the industrial remnants of the site in order to offer to the Docks new development perspectives. The goal of the Municipality of Saint-Ouen and the developers is to transform the industrial site into a mixed-use sustainable neighbourhood (*écoquartier* in French) an urban planning practice already used in other French cities, with the reuse of former industrial buildings and the maintenance and development of important metropolitan facilities on the site (energy pole of Saint-Ouen). The project management team selected is led by Makan Rafatdjou (architect) and is consisted by urban planning and landscape agencies (Agence Reichen & Robert & Associés, Olga Tarraso, Hélène Saudecerre, Peria & Pena, Coup d'Eclat, Beri, Ter Agency). The development of the urban regeneration project of the Docks-de-Seine began in 2007 with the creation of the ZAC of the Docks (Urban Development Zone).

The realization of the development project is the result of two factors. On the one hand, the creation of the ZAC, result of a reflection carried out by the Municipality of Saint-Ouen for the transformation of its territory. On the other hand, the announcement of Total in March 2003 of the closure of its factory at the east part of the site of the Docks, resulted in the lifting of the Seveso perimeter (industrial sector with a risk of major accidents) and in the first urban planning projects for the site's redevelopment in 2004 as part of the local PADD (Planning and Sustainable Development Framework). According to the PADD the site of the Docks will be part of an urban regeneration program that includes all city's brownfields while at the same time its urban regeneration program is in line with the Municipality's strategy to preserve and demonstrate its industrial fabric through the rehabilitation and reuse of former industrial buildings.

The purchase of 18.8 ha of the site of the Docks by the French real estate group Nexity in March 2004 (initially they belonged to the French enterprise Alstom) shows the differentiation of the project from other sustainable neighbourhoods in France, because in this case we can find a private company among the team of developers of the urban regeneration project. This vision to include private companies in the development of the site is described in the 2008 PLU (Local Urban Planning Plan) as a strategy that aims to attract private investors who in turn will contribute to new forms of architectural and urban design as well as to economic resilience.

The strategy of the Municipality to attract private companies for the funding of the project of the Docks-de-Seine led to a shift from industrial activities to tertiary ones, to the demolition of industrial buildings in order to construct new buildings in the perimeter that belongs to Nexity as well as to a change of the socio-professional status of the city's inhabitants as we have seen in previous part of the paper. The construction of office buildings on the site of the Docks is also linked to the previous construction of office buildings to the nearby Victor Hugo neighbourhood in which former industrial buildings were demolished.

Proceedings

The real estate developer Nexity is looking to develop a policy of co-creation of the territory and collaboration in the processes of urban regeneration. Through its role as a contracting authority, it seizes to guarantee opportunities for the group's real estate development subsidiaries and companies. What we should note from Nexity's speech is its ambition to be directly involved in urban regeneration projects, as is the case of the Docks-de-Seine. In this context, Nexity tries to assume the financing of the whole urban regeneration project (buildings, equipment, infrastructure) and become a contracting authority through the purchase of the industrial land. We should also mention the swift to the values and meanings in the architectural design of social housing in an industrial area as the prices of Nexity's housing are higher compared to the ones of other companies. A tripartite agreement between the Municipality of Saint-Ouen, Séquano Aménagement and Nexity was concluded in 2009, before being revised in 2012, in order to guarantee the project management of the ZAC of the Docks. The agreement signed between the Municipality of Saint-Ouen, Séquano Aménagement (project's contractor) and Nexity seems to have slowed down the ambitions of Nexity to develop and commercialize the Dhalenne sector and thus profoundly change its working-class character in architectural and urban design forms. However, its involvement in the urban regeneration project of the Docks, following the purchase of land by the Alstom group, attracted several investors interested in tertiary activities and led to the demolition of industrial buildings even though certain buildings such as the Hall Alstom were preserved and restored. These activities change the meaning of urban resilience in industrial areas as the social character of the Docks project (a project for all, especially low-income families, and immigrants) is confronted with a productive dimension in architectural design and with the gentrification processes already observed in Saint-Ouen and in other municipalities of the Ile-de-France region.

4. CONCLUSION

The issue of preserving the industrial urban heritage, which is often cited by stakeholders as a good practice regarding the subject of urban regeneration of industrial brownfields, has also its contradictions according to the two parameters of preservation of industrial heritage (preservation of the built heritage, preservation of the social fabric). It is evident from the previous analysis of the context of the two regeneration programs that the working-class character of former industrial districts no longer exists with the arrival of executives in these territories. Despite the replacement of industrial activities by tertiary ones, traces of the industrial past are still present on both sites (we can note the rehabilitation of old industrial buildings in the Ile-de-Nantes project and the continuous presence of industrial activities on the site of Docks-de-Seine). The preservation of industrial heritage of the two sites goes beyond the rehabilitation of certain industrial buildings and also includes the creation of industrial museums, publications, and exhibitions regarding the places of industrial production and the living conditions of former industrial workers, as well as guided tours of industrial monuments. Therefore, it can be seen, that the industrial heritage contributes to the urban resilience of the two cities with the preservation of architectural and urban design forms while at the same time it offers the possibility of a collaborative economy with the direct participation of local communities in the planning processes of their living environments.

5. DISCUSSION

To go further on the subject of urban regeneration of industrial brownfields and their development in a resilient and beneficiary way for the local communities, we should underline the link between the location of brownfields (inside or on the outskirts of cities), the architectural and urban design forms of the industrial era (factories, small industrial units, social housing, administration offices) and the policies and obstacles for their reconversion. Brownfield sites on the outskirts of large cities are part of urban expansion dynamics in order to respond to the need for new housing that is less expensive to the real estate prices in central districts. Real estate prices in peripheral neighbourhoods have increased over time and have led to a change in the identity of these neighbourhoods, which are no longer working-class neighbourhoods but rather gentrified places. Brownfield sites inside cities

centers are part of urban regeneration programs which include the reuse and reconversion of industrial infrastructure and the creation of public spaces on these sites.

These urban regeneration programs often include the construction of new residential buildings whose real estate prices are the same to those in other central city neighbourhoods. The socio-economic identity of central city districts has changed, as has done that of the peripheral districts, with the arrival of executives, which in turn led to the gentrification of working-class neighbourhoods and the rejection of modest socio-professional categories to the periphery of cities. At the same time many industrial buildings were demolished in order to construct new commercial and office buildings. Can we continue to talk about the industrial urban landscape in the context of the gentrified city? Policies such as the reuse of industrial buildings as social housing, property prices' controls and equal access to housing could reverse this trend. However, we must ask ourselves under what conditions are such policies possible while maintaining the industrial and popular character of these sites?

The local political and social context plays a major role in making decisions about the content of brownfield conversion programs. All cities do not have the means to take such operations, either because they lack funding or because they are in economic decline. Voluntarism and political stability at local level (we should mention that the reconversion programs last for several years and the continuity of local policies is a strong point for their implementation), the active associative network (both architectural associations and inhabitants and activists) and the favourable financing conditions (public-private partnership, public funds, European Union funds in the case of member countries) make these policies possible and at the same time differentiate them according to the challenges and orientations determined by the different actors. In addition, we should note that a certain number of cities, especially at European level, find the opportunity to finance such operations through the organisation of sporting (for example the Olympic Games in London in 2012 where the Olympic Village was built on an industrial brownfield on the outskirts of the city) or cultural events (such is the case of the European Capital of Culture in which the host city is often a deindustrialized one and industrial buildings are reconverted and reused for cultural activities). We could, therefore, underline the exceptional conditions and means (financing, media coverage) that lead to the realization of this type of operations.

We should also note the confrontation between the concepts and forms of regeneration in the processes of transformation of the industrial urban landscape. In several cases they are based on low-cost practices such as the reuse of existing buildings. In other cases, especially those of large-scale urban regeneration operations, the cost is high as it usually involves the demolition of existing buildings and the construction of new ones. The financing of such projects requires large amounts of capital, at the risk of disadvantaging other municipal policies (health, education, housing). We can see therefore that a balanced transformation of the industrial urban landscape could be achieved through a multiform regeneration program that involves the construction of small-scale contemporary buildings and the conservation and reuse of industrial buildings.

Abstract

In Mycenae, and its neighbouring Fichti, the threshold between myth and history, the utopia of vacation and the reality of contemporary daily life, the landscape is overrun with spatial folds (plis) that represent different temporalities: zones where time expands or becomes suspended. Mycenae's Tourist Pavilion and the old railway station in Fichti are two such zones. Located on the plain of Argolis, Peloponnese, near the World Heritage archaeological site of Mycenae, the two buildings used to be nodes of wider networks. The old station, part of the railway network of the Peloponnese region, is a prime example of industrial architecture in Greece. The Tourist Pavilion, completed in 1951 to the designs of modernist architect Kimon Laskaris, formed an early addition to the Xenia network, the post-war tourism development programme run by the Greek National Tourism Organisation (GNTO). The programme aimed at the improvement of Greece's run-down tourist infrastructure and the modernisation of local communities. The pavilion was a small-scale intervention in a sensitive natural landscape, servicing visitors to the adjacent archaeological site and rendering Argolis a potent tourist destination. However, the transformation of the economy and the structural changes of the tourism industry that have been taking place since the turn of the century, rendered part of the cultural and tourism network of Argolis inactive, leaving the pavilion and the station without a designated function. Moreover, the lack of facilities and infrastructure in both Fichti and contemporary Mycenae and the changes in transportation transformed the visit to the archaeological site of Mycenae into a short and fleeting experience, depriving the two settlements of an active role. *Pavillon abandonné* workshop (2022), organised by a consortium of Greek university departments and faculties, under the umbrella of the *Fichti Art Festival*, aimed at the pavilion's documentation through archival material and the reactivation of local collective memory. The workshop aimed at reinstating the pavilion as a node of a re-imagined local cultural network. In 2023, *Pavillon relancé* workshop temporarily revived the pavilion through curated actions and performances with a strong, yet temporary, spatial imprint. The ultimate goal of this work in progress is the adaptive reuse of the pavilion and the old railway station, by integrating them into a new cultural and tourist network that will lead to their local reactivation and sustainable development and sustain a new identity for the two landmarks with a wider social impact.

Keywords: *Xenia pavilion; collective memory; network; community reactivation; Mycenae*

1. INTRODUCTION

Contemporary socio-economic conditions and demographic shifts, as well as transformations in transport and tourist culture that have been taking place in Greece since the turn of the century, have

Proceedings

of the International Conference on **Changing Cities VI:**

Spatial, Design, Landscape, Heritage & Socio-economic Dimensions

Rhodes Island, Greece • June 24-28, 2024

ISSN: 2654-0460

ISBN: 978-618-5765-02-6

led to the gradual neutralisation of part of the state's infrastructure that was scattered across the Greek periphery. Mycenae's Tourist Pavilion and its neighbouring old railway station in Fichti, both located near the World Heritage archaeological site of Mycenae, are two such cases. The two buildings used to be nodes of wider networks; the old station, a prime example of the 19th-century industrial architecture in Greece that has been recognized as a "work of art of buildings that need special state protection", was part of the railway network of the Peloponnese region, while the Tourist Pavilion formed an early addition to the Xenia network, the post-war tourism development programme run by the Greek National Tourism Organisation (GNTO). Mass tourism and the consequent transformations of vacations have turned the visit to the archaeological site of Mycenae into a short and fleeting experience, depriving the two settlements of an active role in the tourist market and creating a community weakened by these losses, that is now trying to adaptively reuse its abandoned infrastructure for the benefit of its citizens.

Fichti Art [1], an annual festival launched in 2021, is an initiative based on the transformative potential of ephemeral actions and aligned to a bottom-up awareness of the value of historical-cultural assets as a common/shared good. Through the development of collaborative creative activities centered around the two abandoned historic buildings, the festival aims at their reuse and reappropriation by the local and/or wider community. Under the auspices of *Fichti Art* festival, the two Experiential Learning Workshops of Architectural & Artistic Investigation, *Pavillon abandonné* (2022) and *Pavillon relancé* (2023), inspired by relevant archival material and oral testimonies, temporarily revived and reactivated the Tourist Pavilion for the duration of the festival. Based on this experience, the paper aims to stimulate a discussion on the role of the creative mediation of collective memory in temporary interventions in neglected historic buildings and their connection to current issues of cultural identity, resilience, adaptation and sustainable development.

2. CULTURAL HERITAGE, MEMORY AND TEMPORARY CREATIVE RE-ACTIVATION

Globalisation, improvements in transport and telecommunications technology, social changes, and cultural uniformity, have raised concerns about a homogenised world, redrawing the attention of scholars/researchers on the cultural identity of contemporary societies. Cultural heritage, as a bridge of communication between past, present and future, plays a crucial role in the formation and maintenance of collective memory and cultural identity. The document *Culture 21: Actions* recognises cultural heritage - in all its multiple forms, from memories to landscapes - as "a resource for the construction of the identities of people and communities" which is in constant evolution, like "something that is alive" [2]. Viejo-Rose (2015) [3], drawing both on the neuroscientific perspective that memory is a process of construction, of remembering the past and imagining the future, and on the fundamental dynamics of heritage, such as interpretation, reproduction, narrative and imagination - especially as a process of meaning-making - foregrounds the point of convergence of memory and heritage. Although she refers to heritage sites as "anchors, fixing narratives of memory and history, identity and belonging, to places and people" (3: 10), she indicates the mutability of their interpretation and understanding, highlighting their potential to create links with the past and references for the future. Additionally, Assmann (1995) [4] argues that cultural memory is a storehouse of knowledge from which a community draws its sense of unity and identity, and, it is that "need for identity" which controls access to and transmission of this knowledge. He also states that although cultural memory is fixed in immovable figures, it operates through reconstruction, thus, it always relates knowledge to the present contemporary context. This is achieved through various ways such as critique, appropriation, preservation or transformation. Therefore, the appropriation of heritage through transformation and reuse reconstructs memory and creates opportunities for the continuity and development of communities, while creating possibilities for new memories and heritage [5].

At the same time, the identification of cultural heritage as a critical factor for sustainable development [6, 7], as well as the growing demographic, economic and environmental issues that have limited the opportunities for new construction, leading to the implementation of circular economy models for urban policies, have increasingly directed the attention of academics, architects and policymakers to new challenges related to the adaptive reuse of existing historic buildings in order to ensure their long life-cycle and sustainability. Architectural heritage is a “non-renewable resource” [6] and susceptible to abandonment. Vacant historic buildings are at great risk of damage and decay and, according to English Heritage [8], the best strategy to protect them is to keep them occupied. Taking into account that top-down policies for permanent reuse take a long time to be implemented, temporary adaptive reuse may act as an *incubator* for historic buildings complementing the traditional role of preservation. In recent years, many international bottom-up initiatives have temporarily reactivated disused or underused historic buildings, aiming to reclaim missing value and augment heritage sites, by providing new memories, raising awareness and reconnecting communities with their historical past. Such collaborative actions in line with the eleventh article of the 2005 *Council of Europe Convention on the value of cultural heritage for society* [9], which encourages voluntary initiatives that complement the role of public authorities, can enhance social cohesion, reduce environmental degradation and stimulate urban regeneration [10]. Creative re-activation actions, often led by local groups, individuals or organisations usually use the abandoned cultural scene as a platform to influence, inspire and activate communities, through interdisciplinary collaborations and public participation, towards cultural heritage conservation, preservation and adaptive reuse. The possibilities for such appropriation and temporary reuse of historic buildings, based on cultural memory and identity, are discussed in three characteristic case studies.

The rapidly changing urban environment of Berlin's inner city in the years following the fall of the Wall transformed the new capital of Germany into an experimental hub for the temporary reuse of its countless vacant buildings, providing useful insights into the preservation of historic buildings through creative reuse and public participation. *Kunsthau Tacheles* (Art House Tacheles) in the Mitte district of former East Berlin is such a case. The five-story building first opened in 1909 as one of the largest department stores of Berlin at the time. After 1928, it accommodated a variety of uses, such as travel agency, office space by the National Socialists, professional school, and movie theatre. During World War II it was moderately damaged, while in the early 1980s, a part of it was demolished in order to free space for a new urban development. The demolition of the remaining part, planned in 1990, was prevented by a group of local artists from both former parts of Germany. This historic cultural squat achieved to reverse the planned demolition - in collaboration with experts that verified its good structural condition - as well as to unearth the historic background and to register the building in the city's long list of monuments [11]. During the twenty-three years of the occupation, the building was open to the public, offering workshop and exhibition spaces, a cinema, a theatre and other facilities. In 2000, when Berlin was undergoing major urban revitalisation projects and was focused on spectacular cultural facilities, *Tacheles*, gained great local and international attention and became a landmark of Berlin's dynamic cultural scene [12]. The global financial crisis that followed and the change of ownership led to the artists' permanent eviction in 2013. Today the building accommodates a photography museum (*Fotografiska Berlin*) and cultural space and is part of a large-scale redevelopment designed by Herzog & de Meuron. Although the project aimed to restore the site's historic significance by developing a new urban narrative that incorporates its historical footprints, the result lost the social and collective spirit that pervaded the site after the fall of the Berlin Wall.

The war material factory *Braço de Prata*, located at the eastern part of Lisbon, is a case where bottom-up processes sometimes oppose to top-down processes that are oriented towards the international market and often tend to the homogenisation of the heritage, material and symbolic space [13]. The factory was built at the beginning of the 20th century on the military arsenal site, employed 12.000 workers and closed in 1998. At the same time, the realisation of the World Expo in this part of the

Proceedings

of the International Conference on **Changing Cities VI:**
Spatial, Design, Landscape, Heritage & Socio-economic Dimensions
Rhodes Island, Greece • June 24-28, 2024
ISSN: 2654-0460
ISBN: 978-618-5765-02-6

city triggered the transformation processes of the post-industrial zones of eastern Lisbon, influencing their cultural meaning and spatial perception. Thus, this post-industrial working-class neighbourhood attracted the interest of investors, and the vast spaces of the former factory were designated for the construction of a series of emblematic buildings, bringing about a novel lifestyle that in no way echoed area's former character. The factory's administrative building, a 19th century mansion, was planned to serve as a sales pavilion for the luxury residential complex, *Prata Living Concept*, which is near completion. When the construction of the building was suspended, due to a dead-end phase, the philosopher Nuno Nabais suggested its reactivation as a cultural space, obtaining free use in exchange for its maintenance. Thus, in 2007, the *Fábrica de Braço de Prata* re-opened its doors, this time for the public, offering a reading space, two bookshops, art galleries, bars and a rich cultural program, transforming the disused building into a vibrant and dynamic cultural venue, renowned across borders [14]. The principle of minimal intervention and reversibility, dictated by the ephemeral nature of the project, and the habitation scenarios, led to the adaptive reuse of the site in a harmonious coexistence with its industrial essence. In 2008, following the bankruptcy of the owners, the initial concession agreement was annulled and the *Fábrica* continued to operate illegally ever since. However, the Lisbon City Council embraced this project acknowledging its potential for change and creativity, despite its questionable legal status. Given the sweeping changes in the urban, social and financial fabric of the area, this place bears testament to Lisbon's twinkling spirit of resilience.

The reactivation and reuse of historic and abandoned buildings have also been the focus of ephemeral or recurrent actions. *Budapest100* is an annual two-day community festival that unveils and celebrates the built heritage of the city. The project aims to draw attention to the value and history of local architecture (irrespective of their legal protection status). Through guided visits, exhibitions and shared stories narrated by local residents and qualified professionals (architects, urbanists and researchers), the festival aims to keep the past of these buildings alive in the collective memory and to establish a connection between heritage and community. This community festival inspired self-organised actions, resulting in restorations, renovations and minor architectural interventions in some buildings. *Budapest100* also attracted the attention of tourists, local businesses and municipalities, establishing a platform for common dialogue on issues related to the city and its citizens, and encouraging decision-making processes at municipal and urban planning levels.

The above-mentioned cases emphasize the role of temporary reuse in reclaiming abandoned historic buildings as a common good, protecting them from decay at low cost, which can be interpreted as a strategic approach towards sustainability. All initiatives succeeded in attracting the attention of the public authorities while capturing the imagination of local communities. In the case of *Kunsthau Tacheles*, this led to its conservation and, finally, to its permanent reuse, while the success of the *Fábrica de Braço de Prata* lies in the fact that it has modified, so far, the initial intended plan, which can be attributed to its sensitive integration into the industrial fabric, carried out with great respect for the memory of the place; the building itself and its former use, and the life of the working-class that depended on it [13]. All cases, capitalising on the concepts and resources of heritage and memory, reconnected communities with their historical past, raised awareness both in local communities and a wider audience and offered opportunities for creating new memories and heritage through shared experiences.

3. ABANDONED HERITAGE: THE TOURIST PAVILION OF MYCENAE

The long-abandoned Mycenae Tourist Pavilion is a typical architectural example of the GNTO's post-war programme that aimed at the improvement and modernisation of Greece's run-down tourist infrastructure. It was completed in 1951 to the designs of modernist architect Kimon Laskaris, in order to render Argolis as a potent tourist destination. The pavilion was expected to function as a crucial node - servicing the nearby World Heritage archaeological site of Mycenae - of an integrated network of modern facilities that included the Tourist Pavilion of Epidaurus (1950) and the

Proceedings

conversion of the fortress of Bourtzi into a guesthouse (1951), both designed by Laskaris, the hotel Xenia Amfitryon (1951 & 1956), designed by Kleon Krantonellis, the hotel Xenia Acronafplia (1958) and the organised beach of Arvanitia (1962), designed by Ioannis Triantafyllidis and, later, the Nafplia Palace (1970-1975), designed by Thymios Papagiannis. These facilities, built on natural sites of outstanding beauty and/or into major archaeological sites, were to form the core of the country's emerging tourism industry, attracting visitors from Greece and abroad. At the same time, the overtly modern architecture of the GNTO's tourist facilities served as a vehicle for ushering Greece's remote communities to modernity [15].

The Mycenae Tourist Pavilion, located to the south of the prehistoric archaeological site and at a short distance from the contemporary village of Mycenae, on a natural hill with unobstructed views of the plain of Argolis, is a discreet, single-storey construction of square plan (approximately 420m²), with a small semi-underground space (around 150m²) with four rooms designated for the employees. It accommodates a 'T' shaped restaurant that extends across the building, leading to a south-facing porch and to a north-facing elevated atrium, due to the slope. The flat roof, yielding panoramic views, is accessible via an external, built-in staircase. The floorplan evokes traditional typologies of enclosure around a central courtyard that may be found throughout the Mediterranean, with additional, subtle references to the formal attributes of the Mycenaean *megaron*. The richly textured facades with the extruded mortar joints animate the thick stone walls in the changing light, mitigate the severity and austerity of the single, solid mass. Consistent with the GNTO's policy for small-scale spatial interventions that harmonise with the surrounding landscape, the design of the pavilion distinguishes itself for its gentle geometry and its tempered modernism. The *pièce de résistance* of the restaurant's decoration was a now-lost large-scale portable fresco by artist Nikos Nikolaou - with prehistoric iconography rendered in a modern style - hanging over the fireplace [16] (Figure 1).

Sotiriou (2016) *Mycenae tourist pavilion*

The final synthesis - like most of the state-run tourist facilities of the era - can be characterised as an example of an early 1950s attempt at total design, since it involved many interlocking levels of spatial intervention, such as the organic integration of the pavilion into a dynamic network of distant tourist facilities, its placement in a sensitive historic and natural environment, the design of a well-functioning restaurant, the synergy of art and architecture, and, finally, the design of furniture and other fixtures in accordance to the overall visual identity of the Xenia network. The pavilion operated all year round and provided a popular venue for a wide range of activities for both tourists and locals. In addition to its basic function as a café-restaurant, it provided a suitable setting for events and celebrations - on occasion attracting audiences of up to a hundred people - and, on special functions,

Proceedings

according to local narratives, its few rooms hosted eminent personalities. The tourist pavilion remained popular until the early 1990s when the property lease expired and the building was abandoned. This happened at a time when the ascetic design and vacation philosophy promoted by the Xenia programme began to fade out of fashion and a new model of leisure was emerging both in Greece and abroad [17]. At the same time, this was a transitional period for the GNTO, which now focused on promoting tourism in Greece, thus abandoning its ambitious, multifaceted construction programme of the previous decades [15]. Furthermore, despite their architectural qualities, the fact that GNTO tourism facilities were unable to adapt to the new energy performance and seismic safety measures and regulations made their rehabilitation and retrofitting particularly demanding. The Mycenae Tourist Pavilion is comparably in good condition, despite the vandalism it has suffered during its long neglect (**Figure 2**).

Figure 2. Mycenae Tourist Pavilion, current condition (a) South facade | photo: Authors, 2023
(b) Main hall | photo: Authors, 2023

To manage and exploit the properties owned by the GNTO, *Hellenic Tourist Properties SA* was established in 1998. In the years that followed, and in particular since 2001, every exploratory proposal aiming to reactivate and develop the site, most recently in 2010 with a feasibility study by the then Municipality of Mycenae, came to a dead end for various reasons. In December 2010, the ownership of the property was transferred to the present-day *Hellenic Organisation of Cultural Resources Development (HOCRED)*, operating under the supervision of the Ministry of Culture and Sports. Since then, no action has been taken, while, at the same time, due to its omission from the first documentation of the historic Xenia network, the official listed status of the building as a monument of cultural heritage is still pending.

However, despite its long abandonment and worn-out condition, the pavilion is still attractive; summer travelers with their motorhomes find a cool shelter for an overnight stay in its lush and onerous landscape while groups of local youths appropriate it for fleeting moments of escape. According to oral testimonies, it has also served as the natural setting for a modern/contemporary play, but this has not been verified. The Mycenae Tourist Pavilion, entangled in bureaucracy and state inertia, fading in the memories of the community, and condemned to the ravages of time, waits for its reactivation in the contemporary daily life of the community through a coherent long-term strategy for its adaptive reuse that will lead to its reconnection with the place and essentially to its sustainability.

4. THE WORKSHOP EXPERIENCE: TOWARDS THE TEMPORARY REACTIVATION OF THE PAVILION

To this end, two art and architecture workshops were designed and organised by our team in the context of the second (2022) and the third (2023) *Fichti Art* festivals that took place in Mycenae and the nearby village of Fichti. They were populated by faculty and students from the following

Proceedings

academic institutions: Department of Architecture, Aristotle University of Thessaloniki; Department of Interior Design, International Hellenic University; School of Humanities and School of Applied Arts and Sustainable Design, Hellenic Open University. Both workshops were organised as a reflection on the aforementioned case-studies, where the temporary reactivation of architectural heritage increased public scrutiny over the fate of endangered buildings and ultimately led to their restoration and reuse. The workshops aimed at raising awareness both in the local community and a wider - though specialised - audience, comprising architects and artists, about current aspects of cultural heritage and identity reclamation, through the creative mediation of cultural memory. The short-term goal of the workshop was different each year, and so were the actions-events that took place. These are briefly discussed in the following sub-sections.

4.1 Pavillon Abandonné - Experiential Learning Workshop of Architectural & Artistic Investigation - Mycenae 26/07- 01/08 2022

The first workshop had multiple aims. In particular, it utilised the material/spatial trace of the decommissioned tourist pavilion as a vehicle for renegotiating lived or even imagined experiences and reactivating local memory. In the context of this workshop, students formulated policy pilots and devised conceptual protocols for the critical reactivation of collective memory and the reintegration of the tourist pavilion in the contemporary life of the local community. More specifically, students engaged in three successive but interconnected stages of reflection that included: a) memory mapping, b) spatial experience mapping and c) transcribing lived memory and experience into spatial imprints. The first goal of this workshop involved aspects of memory mapping and documentation of the vandalised pavilion. After its abandonment, all furniture and equipment was removed, including the fresco that adorned the wall above the fireplace. During the first stage of the workshop the collection of archival material provided information about the history and the operation of the pavilion. This material, although limited, offered great insights into its routines. In addition, the pavilion was mapped using photographic, video and architectural drawing techniques, leading to the thorough updating of the official blueprints of the building. During this phase, the kaleidoscopic recording of the local community's living memories and experiences was also pursued through (a) the collection of personal mementoes (i.e. family photographs, etc.), as testimonies of their relations with the tourist pavilion, and (b) the recording of interviews, in the vein of a typical oral history project, with a view to develop a dynamic cultural memory archive and to explore the potential for the adaptive reuse of the pavilion. Oral narrations pointed out the problems, needs, objectives and aspirations of the community. Collecting all this information and documenting the pavilion in as much detail as possible will serve as an important basis for our preliminary restoration and reuse feasibility study, i.e. the main focus of our next workshop.

This phase also involved the multimodal and multimedia mapping of the experience of walking through the site via the creative documentation of various trails, designating the tourist pavilion as a crucial reference point. Using a common/free mapping tool (i.e. Google Earth), many official/public and unofficial/private landmarks of the region, including the tourist pavilion, were introduced into a common, annotated cultural database as pins on a user-friendly, interactive digital map of the wider area. Different types of pins corresponded to different kinds of monuments (i.e. natural, cultural, historic, etc.). Utilizing the abandoned railway station in Fichti as a starting point and the archaeological site of Mycenae as the final destination, and vice versa, the mapping tool calculated different routes, based on the preferences of the user, where the tourist pavilion served as an important stop, thus reinstating it as a node of a re-imagined local cultural 4km-wide network (**Figure 3**). The tool would calculate mono or multi-thematic walks (i.e. nature, culture, history, etc.), e.g., combining pre-historic burial sites with the happenings organized by the *Fichti Art* festival. The final deliverable, the interactive map, was presented to the local community in situ, during the festival, provided a

platform for the dissemination of our work and functioned as a *digital diary* that may be used as a guide for future workshops and, most crucially, by the local community for memory reactivation.

Figure 3. Experiential Learning Workshop of Architectural & Artistic Investigation (a) The re-imagined local cultural network | image: Authors, 2022 (b) Main hall | photo: Authors, 2023

4.2 *Pavillon Relancé* - Experiential Learning Workshop of Architectural & Artistic Investigation - Mycenae 24-31/06/2023

The experiential architecture and art workshop *Pavillon Relancé* furthered the explorative framework and extended the ambitions of the previous workshop (*Pavillon Abandonné*). In particular, it sought to reactivate the living memory of the Mycenae Tourist Pavilion through targeted actions, inspired by the history and the architectural qualities of the building. The content of these actions was the objective of working groups comprising architects and artists. Archival material collected and interviews conducted during our previous workshop provided a sound foundation for the speculative investigation into the different habitation scenarios of the tourist pavilion. In an effort to convey a sense of function and scale, we created luminous traces of the original furniture and prop layout on the pavilion's ceramic tile floor, identified through research, while original light features were installed along the main longitudinal wall. In addition, the main hall, namely the café/restaurant and the outdoor serving area, were partly re-furnished with the vital contribution of the local community. To recall its former glory and to highlight its neglect, archival photographs of the pavilion's former condition were also put on display at selected locations. This also provided a way to juxtapose our installations against printed testimonials of the pavilion's original atmosphere. Additionally, to enhance the feeling of place, the team studied the soundscape of the site and designed a new soundscape - a speculative investigation into the original sounds that corresponded to the years of its heyday - as an important environmental element that provided opportunity for reflection. At the same time, artists from the Department of Fine and Applied Arts of the University of Western Macedonia captured the special atmosphere of the derelict pavilion, reflecting on its relationship with the surrounding area and the topography of the Argolic field through installations in the atrium, the kitchen and other areas. This curated 'revival' of the pavilion (**Figure 3**) served as the dynamic backdrop for a spontaneous event that took place in its courtyard on the closing day of the festival. It offered our guests a unique opportunity to experience this long-disused and depreciated edifice as a temporary artistic event, while showcasing the extreme potential that lies in its future spatial reappropriation through the transformative practices of remembrance.

5. CONCLUSION- FUTURE CHALLENGES: HERITAGE AND ADAPTIVE REUSE

This paper demonstrates how the mediation of collective memory is being used in temporary creative practices that re-imagine historic buildings as *social condensers*, connecting the public to their historical past, both recent and distant, while creating new, contemporary memories by inspiring the community to engage in the co-evolution of its architectural heritage. Such approaches, it is argued, bring together the social, creative and scientific capital of the community and act as a lever to activate not only residents but also stakeholders and policymakers towards seeking solutions for the viability of endangered historic buildings. However, the case of *Kunsthau Tacheles* is a reminder of the susceptibility of abandoned heritage to political and bureaucratic intrigue, both past and contemporary, that offers overly reductive, simplistic interpretations of cultural and collective memory, rendering it into instrumentalised and marketable narratives, driven by international trends and therefore not adapted to the memory and identity of the place.

Argolis, an area that in the recent past spearheaded Greece's bid for a thriving tourism market, is a par excellence example of a place that seeks to adaptively reuse its disused tourism infrastructure for the benefit of its citizens. Our experience with the two workshops provided us with a valuable opportunity to document the Mycenae Tourist Pavilion through an exploration of its multiple interactions with the surrounding environment and the locals, both in the physical space of their daily routines and in their memories. The exploitation of these outputs in the temporary re-activation of the pavilion constitutes a critical contribution to the discussion of the notion of collective creativity. Moreover, this active and interactive approach led to the revival of local memories and functioned as a kind of maieutic process that enriched our research. Future actions anticipate the active involvement of the local community and various stakeholders (e.g. the local authorities, the local ephorate of antiquities, local arts and culture societies, etc.) with the aim of exploiting the site's capacity to host architectural and artistic events, i.e. a reactivation of the tourist pavilion of Mycenae and its experimental integration into the local network of existing cultural sites and routes. Finally, the ultimate goal of the project is the development of adaptive design proposals based on the needs of the local community, the potential of the site and the requirements of the spatial context. Ultimately, the paper discusses a realistic and coherent long-term approach in the building of cultural identities and sustainable communities that assesses the complex and multilayered connections of the place and values the role of cultural and collective memory in the adaptive reuse of heritage.

Protection or Isolation Boundaries? Designating the cultural heritage in a Greek contemporary city

Extended abstract

Protection boundaries are always a point of concern in every restoration and designation project on archaeological sites, architectural ensembles and monuments. Architects' desire for appropriate integration of the monuments in the daily life of citizens as part of Greek contemporary cities' public space contradicts the regulatory framework promoted by the ephorates managing our cultural heritage. Restoration of monuments within urban areas in Greece is not usually accompanied by a corresponding procedure for integration and restoration of the relation that these buildings had with the rest of the city and citizens in the past. On the contrary, in the majority of restoration and projects, distinct and impassable boundaries are intentionally emplaced between the monument and the city. Boundaries' The form of these boundaries usually goes beyond the one of a simple fence and is emphasized through its architectural design, the choice of plantings and other configurations. Such boundaries are proposed and constructed both in the surrounding area of detached monuments and in restored complexes, even of the newest architectural heritage, such as in industrial complexes and complexes of educational buildings among others. Examining the issue of the boundaries through urban plans of Greek cities, mainly in northern Greece, since the beginning of the 20th century, the difference is identified, in the way important landmarks were integrated and opened to the city and citizens in the past. Main roads and road network organization of the cities were performed in a way that allowed monuments to be featured and to ensure suitable viewing conditions. A typical example is the city of Thessaloniki where, in Hebrard's plan for the reconstruction of the city's stunned zone, the landmarks consist of points of a cultural heritage network, on which the new urban plan was articulated. On the contrary, in Greek contemporary cities in an attempt to over-protect the monuments, this relation has changed and often the boundaries proposed to protect the monuments eventually lead to their isolation from the city, also degrading their image. At the same time, this isolated zone on the perimeter of the monuments often offers the right conditions for the action of fringe groups, turning the area into a ghetto. Through the presentation of the above-mentioned issues, regarding the necessity or not of the boundaries between the monuments and the city, the form they usually take in Greek contemporary cities and the presentation of different alternatives, a concern for the improvement of the form of the boundaries in a way that protection and real monuments' designation and integration co-exists, will arise.

Abstract

The present paper delineates the chronological evolution of Kavala as a tobacco city, spanning from its prosperous era in tobacco production to the gradual fading of its tobacco identity. It highlights the alterations in the urban fabric that have steered the city towards its present condition within a socio – economic context. Kavala, situated in Northern Greece, boasts a deep – rooted history entwined with tobacco production. Positioned within Eastern Macedonia and Thrace, an administrative region in the northeastern part of Greece, Kavala functions as one of its principal seaports.

Due to its advantageous seaport location and favorable climate and soil conditions, the city has a historical tie to tobacco cultivation dating back to the late 19th century. By the early 20th century, it had risen as a significant tobacco center, marked by the construction of tobacco warehouses dedicated to processing, production and trade. The surge in tobacco production attracted international investors to the city, particularly during the first half of the 20th century. This influx was accompanied by the affections of European urban models, that led to modernization and development of the town.

The infusion of wealth from the tobacco trade spurred economic prosperity in the city, propelling its urban advancement. Tobacco merchants funded the construction of tobacco warehouses and commercial structures, while grand mansions and infrastructure projects were undertaken to meet the demands of the burgeoning industry. The cityscape underwent a significant transformation with the erection of new buildings, influenced by emerging urban models, as well as the establishment of trading centers, all of which became integral parts of the urban fabric. This metamorphosis was accompanied by the migration and temporary relocation of populations seeking employment opportunities and goods, leading to further changes within the city.

Under such conditions, Kavala emerged as a primary tobacco - centric urban hub, especially during the first half of the 20th century, being called as ‘Mecca of tobacco’. This designation fueled economic growth, fostering job creation and bolstering local revenue streams. It further brought about social changes, facilitated by the influx of migrants seeking opportunities, thereby fostering cultural diversity and demographic changes. However, the city began to shift away from its tobacco – centric identity in the latter half of the 20th century, mostly because of the ongoing construction activities during that time. These transformations altered the city’s profile, leading to the gradual fading of its tobacco identity alongside a rapid overhaul of the urban landscape.

Keywords: *tobacco, tobacco city, urban evolution, socio-economic implications, Kavala*

1. INTRODUCTION

Tobacco originated in North America, with its earliest mentions in Europe dating back to the 16th century. It was officially introduced to Europe from America, with the first tobacco crops being cultivated in Portugal, Spain and France [1]. In Greece, tobacco cultivation appears in the early 17th century, preceding the establishment of the modern Greek state. The importation of tobacco is believed to have initially occurred in Thessaloniki. Presently, Greece ranks second globally in oriental tobacco production and is one of the eight countries holding the 99% of tobacco production in the European Union, alongside Italy, Spain, Croatia, Bulgaria, Poland, Hungary and France [2]. The country boasts a rich history in tobacco cultivation.

Within Greece, Eastern Macedonia and Thrace stands out as the leading region in tobacco production, believed to be the area where its cultivation first began. It is widely regarded as one of the most significant areas globally for producing top-quality tobacco for cigarettes alongside Smyrna-Sampsouda and Bafra on the southern coast of the Black Sea [3]. The fact that tobacco cultivation and processing in Macedonia and Thrace is included in Greece's National Inventory of Intangible Cultural Heritage, under the title: "The cultivation and processing of Oriental Tobacco in Macedonia and Thrace" [4], demonstrates its cultural importance. Situated in the south-western part of Eastern Macedonia and Thrace, Kavala boasts a rich history in tobacco cultivation, production and trade.

During the 20th century, Kavala earned the titles 'Mecca of tobacco' and 'Tobacco City of the Balkans' [5], because of its strategic geographical location, favourable climate and soil conditions and its prominent seaport, which facilitated the transportation of tobacco. These factors stimulated city's economy and led to rapid population growth, industrial development, and craftsmanship, fundamentally altering its profile. During this period of prosperity, the city acquired a diverse cultural identity. These changes significantly influenced its socio – economic condition, as indicated by the altering urban environment. Kavala experienced peak prosperity during the early 20th century tobacco boom, followed by a gradual decline in the tobacco industry during the latter half of the century.

2. HISTORICAL TOBACCO TRACES

Tobacco industry first appeared in Kavala prior to the Greek War of Independence of 1821 [5]. The emergence of tobacco warehouses followed after 1864, primarily located in the coastal area of the city to capitalize on its seaport, facilitating the transportation of tobacco products to and from the harbor for international imports and exports [6]. By 1838, seven tobacco companies had been established in the city, specializing in the production, processing and trade of tobacco [7].

The growth of the tobacco industry in Kavala begun to accelerate towards the end of the 19th century, particularly from the 1860s onwards, aligning with the establishment of tobacco subsidiaries headquartered in New York, Cairo, London and other major cities [7]. Skilled workers from Turkey and Alexandria arrived in 1880s, specializing in cigarette rolling to ensure an optimal smoking experience [8]. In 1883, a tobacco tax was introduced, followed by the importation of the first cigarette production machines a year later [1]. By the end of the 19th century, tobacco had emerged as a significant crop in the city, strengthening the local economy and providing livelihoods for many residents.

2.1. The 20th century tobacco boom

The first half of the 20th century is characterised by a substantial expansion of the tobacco industry. By 1900, the largest portion of tobacco trade was dominated by Jewish – owned companies, such as the Commercial Company and Oriental Tobacco. These companies were responsible for exporting 70% of the tobacco produced in the regions of Kavala, Xanthi and Drama in Eastern Macedonia and Thrace, as well as Serres in the Central Macedonia Region [6].

Several factors contributed to the significant growth of the tobacco industry in the city, including its strategic location and port, as previously mentioned, along with the cultivation of a specific type of tobacco known as ‘Basma’, a variety of Greek oriental tobacco. Basma, as all Greek oriental types of tobacco, is renowned for its exceptional flavour and high quality, attributed to the geological composition of the soil, favourable climate conditions, and extensive expertise in its processing gained from a long tradition of cultivation [9]. This superior aromatic tobacco, garnered considerable demand in European markets.

As depicted in the table provided [Fig. 1], Kavala emerged as a leading commercial tobacco processing centre in the early 20th century. Between 1925/29 and extended until 1945/54, Kavala held the highest percentage of tobacco processing businesses, while Xanthi experienced a consistent decline. Following 1955/64, Kavala also witnessed a downturn, contrasting Thessaloniki’s trajectory. Utilizing its port, the city emerged as the primary tobacco hub for tobacco exports in Europe, solidifying its status as a pivotal centre of economic activity until 1950s.

Figure 1. The primary commercial tobacco processing centres from 1925 to 1984 in Greece [10].

This phenomenon not only enhanced its tobacco revenues but also solidified its reputation as a tobacco processing centre. The economic prosperity fuelled by the tobacco trade prompted the construction of the warehouses, initially smaller during the early stages of tobacco cultivation and expanding significantly during the tobacco boom period.

2.2. Tobacco constructions

Tobacco gained popularity in Greece from the mid-18th century, with small tobacco shops being established in bustling markets and residential neighbourhoods to cater to smokers. As the cigarette industry evolved, the demand of processing, storing and selling tobacco grew. Consequently, tobacco warehouses were constructed serving as one of the most notable remnants of Kavala’s tobacco heritage. These remarkable buildings, erected during the late 19th and early 20th centuries, served as storage and processing centres for the abundant volumes of tobacco leaves harvest in the region.

In the early stages, tobacco was stored in small single – storey buildings or in the ground floor and basements of the merchant’s homes. By the end of the 19th century, two – storey tobacco warehouses with load – bearing stone construction and internal wooden beams, covered with Byzantine-tile roofs. On the first floor, tobacco leaves were placed on wooden racks to protect them from moisture, with smaller openings along the perimeter for ventilation and sun protection. The second floor was dedicated to tobacco processing, featuring larger openings for natural light [1]. Gradually, larger

warehouses were constructed due to the growth of tobacco trading. Some used international materials like stone and wood, while others incorporated neoclassical and eclectic elements. These buildings confirm the tobacco industry's prosperity and significance during its peak.

As mentioned earlier, the warehouses were initially concentrated in the coastal area, but gradually expanded throughout the entire city. Some warehouses formed clusters, often owned by the same trader and sometimes connected via small metal bridges, while others stood alone, scattered across the cityscape in various locations. In addition to the warehouses, small tobacco shops were dispersed throughout the city for the sale of cigarettes and other tobacco products.

Apart from storage, production and sales, preservation offices were established in Kavala, Volos, Thessaloniki and Agrinio in 1925. These offices were consolidated into a single administrative entity in 1942, known as the Autonomous Organization for the Protection of Greek Tobacco [11]. In 1957, it was renamed the National Tobacco Organization (EOK). The organization, established to safeguard the tobacco industry, had its headquarters on Palaiologou Street in the city centre of Kavala, originally purchased by the Swedish Tobacco Monopoly [12]. The EOK warehouse was designed by the renowned architect Leandros I. Zoidis and constructed in 1958 (completion of the first phase), with completion in 1960 (second phase) [13].

The construction of new buildings and the adaptation of existing ones for tobacco – related purposes, including warehouses, shops and organizations/services, prompted the development of new infrastructure, such as widened roads. This also facilitated the acquisition and expansion of equipment and general facilities to support business growth. These factors resulted in substantial changes in the cityscape during that era, which continued to evolve over time.

3. CITY TRANSFORMATIONS & SOCIO – ECONOMIC IMPACTS

The history of Kavala is rich with diverse cultural influences and economic developments. Particularly, from the late 19th century onwards, the tobacco trade emerged as the city's defining attribute. During the same period, smoking habits underwent changes, with traditional practices such as chewing tobacco or nasal inhalation gradually being supplanted by rolling cigarettes, while hookahs and pipes fell out of favour [14]. By the turn of the 20th century, Kavala had already established itself as a significant hub for the tobacco industry, attracting substantial migration to the city both in search of employment opportunities and as consumers seeking tobacco products. This is evidenced by the employment of 6.000 workers by three major tobacco companies in their numerous warehouses at the beginning of the 20th century [7], with the number of tobacco workers increasing to 14.000 by 1930 [15].

The flourishing tobacco industry attracted a sizable labour force, resulting in notable demographic shifts in the city. The influx of workers from various regions enriched the city's demographic diversity and cultural vitality. Employment within the tobacco sector provided steady livelihoods for numerous families, thus improving their living standards. Until the 1950s, a significant expansion was observed in the number of tobacco workers. During this period, tobacco cultivation occupied 50% of Greece's total cultivated area, providing employment for approximately 200.000 households and creating additional jobs for 18.390 tobacco employers. Kavala had the highest number of employers, exceeding even Thessaloniki, with 7.693 and 5.082 tobacco workers, respectively [16].

Under these circumstances, coinciding with the influx of migrants, the city experienced gradual expansion. Specifically, in 1923, Kavala comprised five primary districts, as depicted in the map provided [Fig. 2]. Within the old city of Kavala, there were three Muslim districts- Kadi Ahmed Efendi, Huseyin Bey and Halil Pasa-, one Christian district, Panagia region and the central area known as 'Ibrahim Pasa'. In the eastern part of the town, three Muslim districts - Hamidiye, Selimiye and Yeni Mahalle- were present. Progressing westward, the districts have a multicultural profile, designated as Gomlek Dere, Kucuk Mahale, the Jewish District and the new central areas of the city.

In the northern part of the city, the districts were the Saint Paul and Caylar. Lastly, in the western part of the city, the districts were the Saint John and even further west, Kuguk Orman.

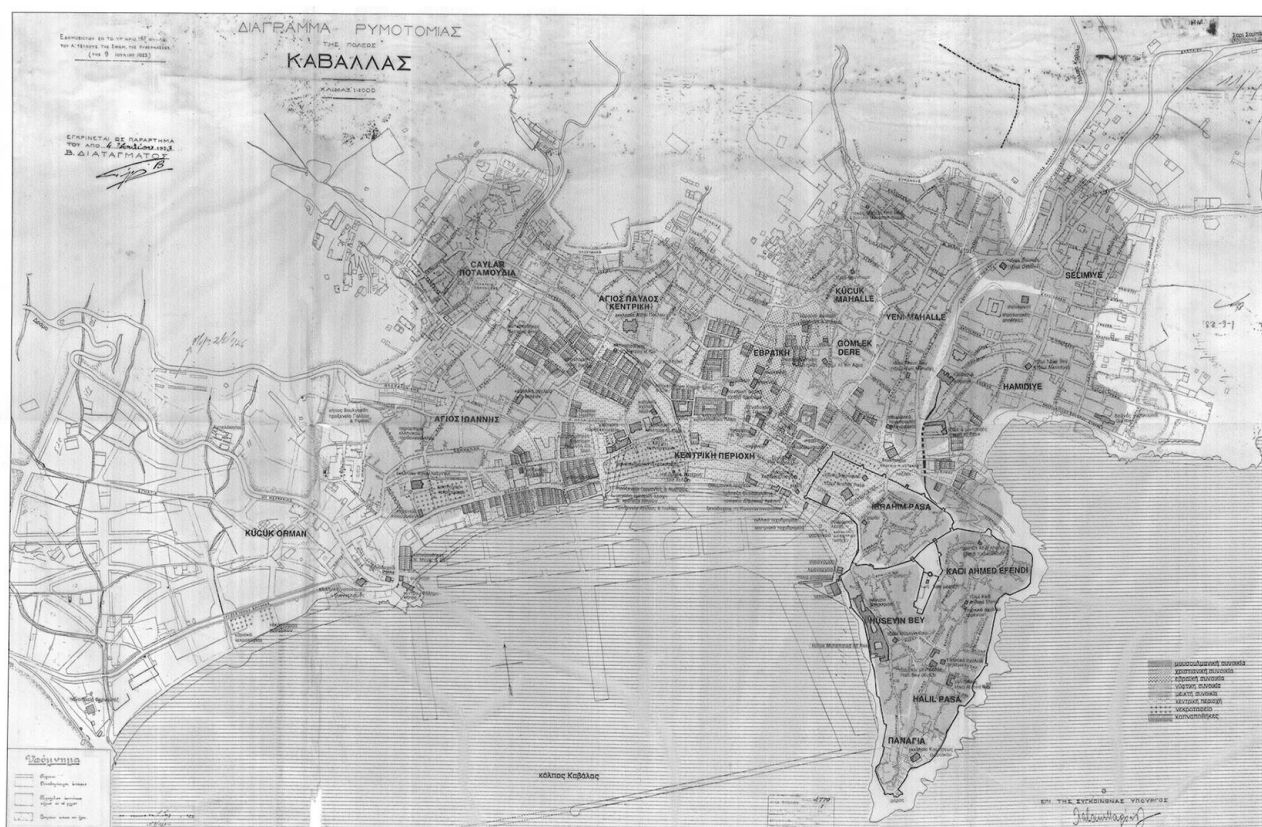

Figure 2. City Layout Plan, 1923 [17].

Based on the provided information, the cityscape during this period reflects a rich tapestry of multicultural elements. The eastern part of the city was predominantly inhabited by the Muslim community, while the northern and some of the western districts, surrounding the city centre, were populated by Christians. In the old city of Kavala, named as Panagia, there was a mix of Muslim and Christian populations, alongside a diverse central area. Moving from the western to the central part of the city, a fusion of cultures could be observed, including Jewish, Muslim and Christian inhabitants. The western part of Kavala seems to have been a Muslim district as well.

During this time, the city's population profile comprised Turks/Muslims, Jews, a few Greek Orthodox families and a small number of Armenians. Additionally, by 1910, the Bank of Athens, Bank of Thessalonica, Imperial Ottoman Bank and several independent bankers (including Benveniste M., Kolokithas M., Proropapas G. D., Herzog M. et Cie and Sarikas Zisis P.) were functioning in the city [15].

The city underwent significant changes by the establishment of the refugees and the overall development of the tobacco production that led to its economic advancement. The refugees in Eastern Macedonia and Thrace the year 1923 were 80.691 [18] while Kavala in 1928 had 56,90 % refugees of the city's overall population [19]. The first initiatives to manage the influx of refugees in the city, were launched in 1923 by the newly established Refugee Relief Fund, under the auspices of the Local Council for Refugee Welfare and Housing. During this initial phase, constrained by urgent needs and limited financial resources, the authorities opted for temporary and short-term construction solutions [20]. Consequently, a total of 1.975 houses, mosques and institutions were allocated for the resettlement of refugees [20].

Proceedings

Before 1924, in the Kuguk Orman, the Hamidiye and the Selimiye neighborhoods and on exchangeable properties, a total of around 213 residencies and 253 single – room, one – storey shanties were built. These structures primarily utilized stone for foundations, wooden superstructures and roofs made of tap paper. However, following 1924, the government shifted towards a more comprehensive approach to address the refugee issue by constructing multi-storey buildings [20].

Within this context, two refugee settlements were established in the undeveloped western and eastern regions of the city, known as ‘Chilia’ and ‘Pentakosia’, reflecting the number of the families to be resettled (1000 and 500 respectively). The former was situated in the Kuguk Orman district, while the latter was located in the Hamidiye region.

Furthermore, alongside the population shifts resulting from refugee influx and tobacco labour, the broader movement of people from both Greece and abroad, mainly for investments in the tobacco industry and for tourism purposes to explore the ‘Mecca of tobacco’ and acquire the exceptional tobacco available in this multicultural city, would reshape Kavala by modifying its social composition.

During the tobacco era, the city was completely centred around tobacco at all levels, a characteristic evident in every aspect of its landscape. Residents witnessed tobacco activity throughout their daily lives, with tobacco trucks loading and unloading products at warehouses and transporting them to the port. Smoking was widespread across the city, and shops specialized in selling tobacco products flourished. Tobacco warehouses multiplied across the cityscape, driven by its significance in the local economy. Visitors arrived in the city as customers in order to purchase the finest tobacco products from the ‘Mecca of tobacco’ of that period. Additionally, various amenities such as restaurants, hammam baths, hotels, and other facilities experienced development during this time [21], primarily driven by a combination of factors including the multicultural environment, the tourist appeal arising from Kavala’s tobacco-centric identity, and its overall economic prosperity.

Therefore, the accumulation of wealth and industrial activity in Kavala, gave rise to a thriving middle class. The city’s cultural and political landscape was further complemented by the establishment of educational institutions, cultural groups and political movements. Types of tobacco clubs formed by the communities, including the Grand Commercial Club and the Tobacco Workers Club [21] and subsequently this role of the worker’s organizations led to the establishment of larger political movements. This development, in turn, caused a series of significant strikes in the city. The socio-economic profile underwent transformation, with progress facilitated by the tobacco industry contributing to a vibrant urban community.

While tobacco remained the fundamental element of Kavala’s economy, the wealth it generated enabled diversification. Entrepreneurs began investing in sectors such as shipping, commerce and subsequently tourism, thereby establishing a more resilient economic foundation for the city. This stability played a crucial role in mitigating the impacts of fluctuations in the global tobacco market. During that period, the city could be aptly described as a kinetic city rather than a static one, signifying a city characterized by motion and activity, where buildings and infrastructure supported the functions of construction and residents’ lives. Consequently, the prosperity stemming from the tobacco trade fostered urban development in Kavala, resulting in the emergence of new neighbourhoods, structures and infrastructure, ultimately contributing to the city’s expansion. The cityscape during this period evolved to accommodate a growing and economically active population.

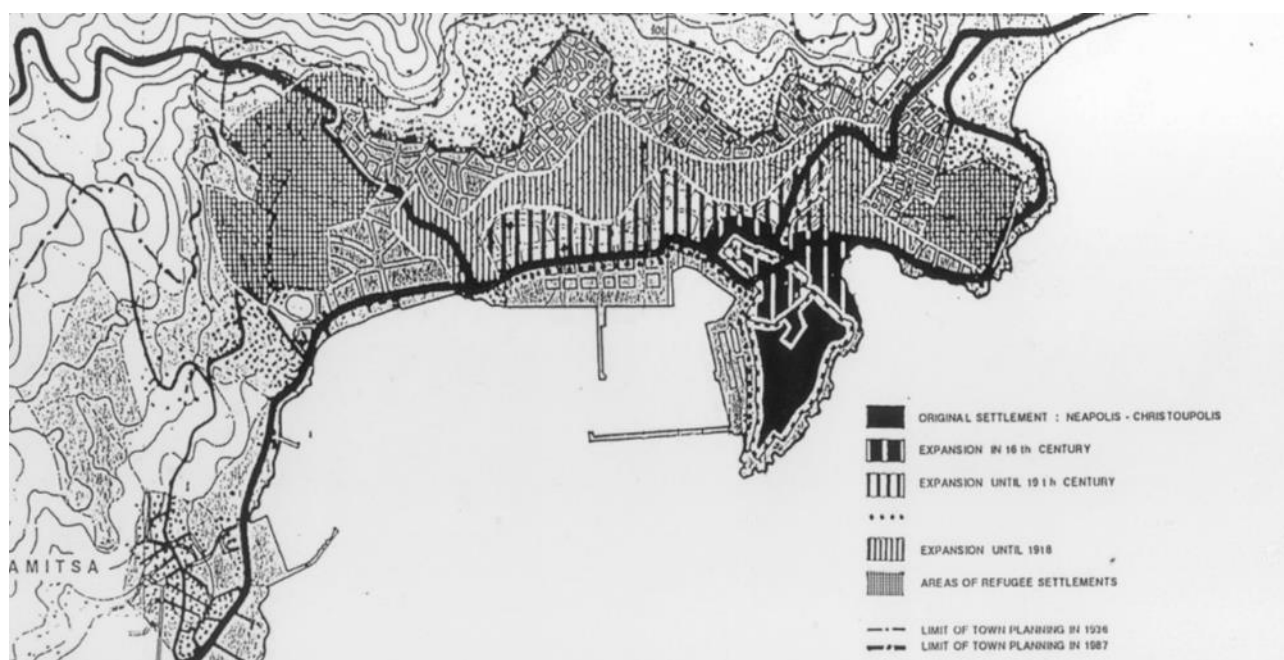

Figure 3. Evolution over time and stages of the development of Kavala [15].

The map [Fig.3] displays the evolution of Kavala’s cityscape over time. Prior to the 19th century, the city predominantly expanded around the walls of the Panagia region (now known as the old city of Kavala), with limited expansion along the central coastal area. Subsequently, until 1918, the city’s growth extended northward and slightly to the east and the west. The most significant changes occurred with the establishment of refugee settlements, as mentioned earlier, and the influx of tobacco workers which shaped Kavala closer to its current form. Substantial transformations occurred in the following decades, particularly in the 1960s and 1970s, characterized by extensive construction activities that transformed it into a ‘concrete city’.

These constructions were built using manufacturing techniques that departed from the architectural and decorative norms previously dominant in the region [22]. They profoundly impacted the city’s architectural landscape. Not only did the introduction of vertical multi – storey structures changed the general characteristics of the city by altering its skyline but it also significantly influenced the tobacco heritage and the overall profile of the city. This shift marked a transition from a tobacco – centric city to a standard Greek mid – sized city. Subsequently, a downward trend occurred, especially after the mid – 70s, as the industry shift to marble production, textiles and tourism. The last two tobacco warehouses were constructed in the 1990s, while during the same period (1992), approximately 1.500 workers remained employed in the city [15].

The changes in Kavala’s districts from the beginning of the 20th century to the present can be observed in the map below [Fig. 4], in contrast with the map that illustrates the old districts [Fig.2]. The correspondences between the neighbourhoods in 1923 and now are generally as follows (old district’s name – newer district’s name): Selimiye-Perigiali, Hamidiye – Pentakosia & Agia Barbara, Kadi Ahmed Efendi & Halil Pasa & Huseyin Bey & Panagia Region – Panagia, Ibrahim Pasa & part of the central city – Agios Nikolaos, Yeni Mahalle – Agios Athanasios & Sougelo, Kucuk Mahalle – Horafa, Complek Dere & Jewish District – Saint George, Part of the Jewish District – Saint Elias, Saint Paul and the central area of the city are the same, Caylar – Lazeika & Part of Potamoudia District, Saint John – Dexameni & Saint John, Kucuk Orman – Vyronas and the region that the city centre is located, remains the same.

The comparison between the 1923 and the present not only highlights significant changes in the city’s expansion due to the establishment of refugees, the tobacco trade and the ongoing construction in the

Proceedings

1960s and 1970s, but also indicates the decline of its multicultural and tobacco identity. The renaming of districts reflects alterations in the cultural and overall profile of the city. While Panagia remains a district with the fewest modifications, along with the city centre, all other neighbourhoods have undergone resettlement.

Figure 4. The districts of Kavala today [Google earth self – processing image| 23].

The aforementioned transformations are additionally amplified by the dispersion of tobacco warehouses throughout the Kavala landscape over time, serving as significant heritage landmarks. Initially, there were 144 tobacco warehouses in the city, but today only 49 remain [12]. In the early 20th century, these warehouses were distributed throughout the city, with clusters observed in the coastal area, the city centre and the northern part of the city centre, while others were scattered across the cityscape [Fig. 5]. However, today, many of the warehouses in the coastal area and elsewhere in the urban fabric have been demolished and replaced by newer constructions.

Fig. 5. Tobacco warehouses in Kavala during the beginning of 20th century compared to their current state [21]

Important tobacco buildings, primarily Tobacco Organizations, played a significant role to the city, due to their function and use. These buildings were distinct from typical storage facilities because of

their hosting administrative offices, public services and else (that are related with tobacco), attracting a different demographic profile beyond just tobacco workers. One of the most notable buildings from both past and present is the National Tobacco Organization building. It now hosts the Tobacco Museum of Kavala in the ground floor and some administrative offices in the upper floors. Located in the city's central region, its distinctive architecture and current use as a museum make it a significant landmark.

In addition, other former warehouses have been repurposed. The Reggie Shopping Mall, the Municipal Tobacco Warehouse (now a cultural venue), and some entertainment centres and bars have all found new uses. However, most of the remaining buildings have been abandoned and face demolition, reflecting the overall decline of the tobacco industry in the region. Today, only one active enterprise and its possible subsidiaries remain.

Hence, some limited efforts are being made to repurpose and restore the warehouses. The Institute of Social Movements and Tobacco History plays a crucial role in these endeavours. Established with a mission to preserve and enhance the tobacco heritage, the Institute organizes a variety of events, conferences and festivals dedicated to tobacco cultural heritage. These activities highlight the historical significance of tobacco and foster community engagement and awareness.

4. CONCLUSION

In conclusion, tobacco heritage has left its traces in Kavala, mostly through the existence of tobacco warehouses scattered throughout the cityscape. Urban transformations have had significant socio – economic impacts, reshaping the physical environment and influencing social and economic dimensions. The rejuvenation of urban areas, infrastructure development, and new economic opportunities created a vibrant environment during the tobacco era.

Kavala's tobacco history began in the 19th century, flourished in the early 20th century and declined in the latter half of the century. Expansion was driven by refugee mobility, migration of tobacco workers, construction of warehouses and international investments. However, urban changes and socio-economic shifts led to the gradual disappearance of most tobacco warehouses and a reduced influence of the tobacco industry in city's identity.

Despite this decline, Kavala's rich tobacco history remains a crucial part of its cultural heritage, while physical traces may fade. The industry's impact endures, contributing to the city's unique identity. Embracing its heritage, while adapting to economic changes, Kavala can preserve its legacy and continue to develop as a dynamic urban centre with a rich historical background.

Extended abstract

In the ever-evolving landscape of urban development, the preservation of architectural and industrial heritage stands as a testament to collective history and identity. Within this context, Greek cities harbour a distinctive legacy in the form of tobacco warehouses, once vibrant symbols of economic prosperity and industrial prowess. As we navigate the challenges posed by climate change, these historic structures face the dual imperatives of preservation and adaptation.

This paper delves into the development of a methodology via the intersection of architectural and industrial heritage preservation, meticulous documentation practices, and the transformative potential of urban regeneration. The research subject consists of tobacco warehouses of the Hellenic Tobacco Organization (HTO) in Eastern Macedonia and Thrace, which are attributed to the architect L. Zoidis. As a result of his studies in Berlin, L. Zoidis has developed an ideal organizational building model based on a thorough analysis of tobacco warehouse types, including the completeness of the building program, the distribution of individual uses on each floor, as well as the integration of the high-rise buildings into the urban environment. The specific model appears to have been applied with minimal variations to all twelve tobacco warehouses designed by the architect and associated with his work for the Hellenic Tobacco Organization. Three of these buildings are examined in this case study: a. that of Kavala, which is currently being studied within a Research Program of the Department of Architecture at Democritus University of Thrace, b. that of Xanthi, which has been the subject of diploma theses (Department of Architecture at DUTH) based on its location and ease of access, and c. that of Drama, as the only of these buildings that is protected and declared as historic monument. Focusing on the adaptive reuse of tobacco warehouses in these Greek cities, it explores strategies that not only safeguard the cultural significance of these structures but also contribute to sustainable urban futures. The juxtaposition of heritage preservation, thorough documentation, and innovative urban regeneration emerge as a dynamic framework for cultivating resilience in the face of contemporary challenges, ultimately weaving a narrative that harmonizes the past with the imperatives of the future.

Tobacco identity of Kavala: an urban landscape in transition

Abstract

The existence of cultural heritage can enhance a city's sense of local identity, in a period of increasing competition between cities and a "reinterpretation" of the relationship between globalization and localism.

Kavala was known as a tobacco export port since the 18th century. However, intense building activity took place after 1866, with the construction of the first tobacco warehouses outside the walls surrounding the old city, in the area that later became the city center. At the end of the 19th century, the urban image of the Ottoman Empire's cities reflected the social, economic, and spatial characteristics of its industrial identity, while the economic boom led to significant urban transformations. The economic growth that occurs with the emergence of the urban class - made up of wealthy tobacco merchants, other merchants, and professionals (Christians and Jews in the vast majority), European merchants, representatives of foreign trading houses and consuls - is accompanied by demographic growth as new populations arrive to engage in tobacco processing and the construction of new buildings.

The urban landscape is therefore identified with the tobacco physiognomy of the city, as there are about 172 tobacco warehouse buildings. Moreover, the evolution of the city's tobacco identity over time influences both its social and urban transformations.

Today, most of the buildings are abandoned, while there are scattered some that are operating with new uses, whether the shells have been restored or not. Some efforts are being made, but they are piecemeal moves rather than a comprehensive initiative. Regardless of the existing institutional framework or sophisticated and adapted restoration techniques, it is equally important that the local community should recognize the importance of tobacco warehouses to the city on multiple levels. From that of collective memory, to that of the morphology and function of the urban fabric. From that of the historical identity of the place to that of its contemporary development identity.

The issue of tobacco warehouses, like many issues of collective identity and the perspective of cities, cannot be left unchecked to the market forces, because it cannot, by its nature, assume a coordinating role for the overall perspective of a place. A policy is therefore needed that takes a strategic approach to urban development, specifies the functions and role of tobacco warehouses in the urban landscape and, lastly, extends to urban planning and urban design. This policy should be accompanied by the development of a methodology for the process of restoring and re-using buildings.

Keywords: *cultural identity, urban collective memory, city in transition, tobacco warehouses, Spatial transformations.*

1. INTRODUCTION

This paper focuses on the contribution of a city's cultural heritage to the enhancement of its local identity and image, as a sustainable mechanism for development and urban regeneration. The case of Kavala represents a Greek city with a strong architectural and cultural heritage focused on the processing and international trading of tobacco from the mid-19th to mid-20th century [1,2], offering today a unique opportunity for its exploitation to cope with the contemporary needs of a city. The exploration of the role of a city's cultural heritage would be a trigger for utilizing the results of the

present study in any similar case of a city internationally that presents similar needs and opportunities to highlight its locality.

The case of Kavala, in terms of cultural heritage, focuses on its tobacco history and identity, which today is evident in a series of buildings of particular architectural beauty. These buildings, which were once used as offices and warehouses for tobacco processing and marketing, occupy a large part of the urban fabric of the city, although most of them are now abandoned, and have the necessary symbolic size to form the core of the city's image and identity [3,4].

The sense of cultural alienation and economic competition among cities makes the dynamics of the local identity and image of a region the only counterweight to these international pressures. This conclusion is evidenced by the fact that many cities worldwide are reorganising and reconstructing their images to make themselves more appealing in order to attract tourists, conferences, sporting events, investors, etc. [5].

In particular, in the city of Kavala there are numerous industrial buildings, especially tobacco warehouses, which need to be preserved and reused in order to enhance the unique character of the city. Until the 1950s, the tobacco warehouses were the main element shaping the urban landscape of the city. They were multi-storey buildings and building complexes of a large scale and of architectural importance, with the possibility of flexibility in their interiors [6]. The modern and radical changes in tobacco processing and marketing have rendered them out of functional use, with parallel high costs of maintenance and upkeep. For this reason, combined with the inadequate institutional framework regarding the preservation of modern architectural heritage and the absence of both policies and political will in the 1970s and 1980s, many of them were demolished and replaced by modern buildings. The contemporary challenge is to adopt an integrated and sustainable management strategy of an urban landscape in transition in the context of the new European Bauhaus and the European Green Deal.

2. EVOLUTION OF THE TOBACCO IDENTITY OF THE CITY OF KAVALA

2.1 Kavala as "tobacco city"

Kavala was known as a tobacco export port since the 18th century. However, intense building activity occurred after 1866, with the construction of the first tobacco warehouses and the church of Agios Ioannis, outside the walls surrounding the old town, in the area that later became the city center. This activity coincided with Turkey's new 1864 'Roads and Building Regulations' (Tanzimat). This regulation stipulated urban planning rules for residential areas, the drawing up of new town plans and an increase in the permitted height, which had previously been limited to 7 meters for Christians. This amendment made it possible to build tobacco warehouses on a massive scale and in an area that represented the first major expansion of the town. This expansion was approved by a firman of the Sultan, but the date and other relevant information has not been found. Immediately after the approval of Kavala's expansion, tobacco warehouses, tobacco factories, company offices, bank shops and residences of tobacco merchants, bankers and diplomats began to be constructed at a rapid pace. As there were no size restrictions, the new buildings were usually large enough to provide adequate storage space for tobacco or to provide adequate working space for numerous tobacco workers. Indicative of the size is that at the beginning of the 20th century, three large tobacco companies employed 6,000 people as workforce [7].

Towards the end of the 19th century, this new part of the city presented a modern and luxurious urban landscape. Most structures were built semi-circularly around the coastal zone, with tobacco warehouses usually on the coastal zone and offices, banks and residences gradually spreading inland. These structures largely expressed the architectural style of their owners' countries of origin or of the architects who designed them. Neoclassical, eclectic, baroque and Ottoman-influenced buildings, etc., coexisted in a cosmopolitan environment [8].

The first new district to be established outside the walls was that of St. John, with an Orthodox church of the same name, Christian, Muslim and Jewish schools, as well as hotels, baths and restaurants. The present-day districts of St. Paul and St. George concentrated the poorer residences of tobacco workers, also multi-ethnic in composition (Christians, Muslims and Jews), but without basic social infrastructure [9].

With the arrival of the refugees of the Asia Minor catastrophe, the population of the city increased from about 23,000 (1920) to 39,980 (1924) and to 50,065 (1928). The refugees settled around and outside the central zone of the city, occupying the barren hills that were owned by the State. The first city plan of Kavala, which mainly focused on the central area, was drawn up in 1929 by the Russian sub-engineer Rudometov, on an area of 4,500 acres. At the same time, the construction of the new port of Kavala began with silting up and extending the onshore coastal zone. The construction of the harbor project, which began in 1929, was completed in the 1960s. From the 1920s until 1936, the tobacco processing industry, with its abundance of low-cost labor and the flourishing tobacco trade, made impressive profits, and the tobacco workers' movement also thrived [10].

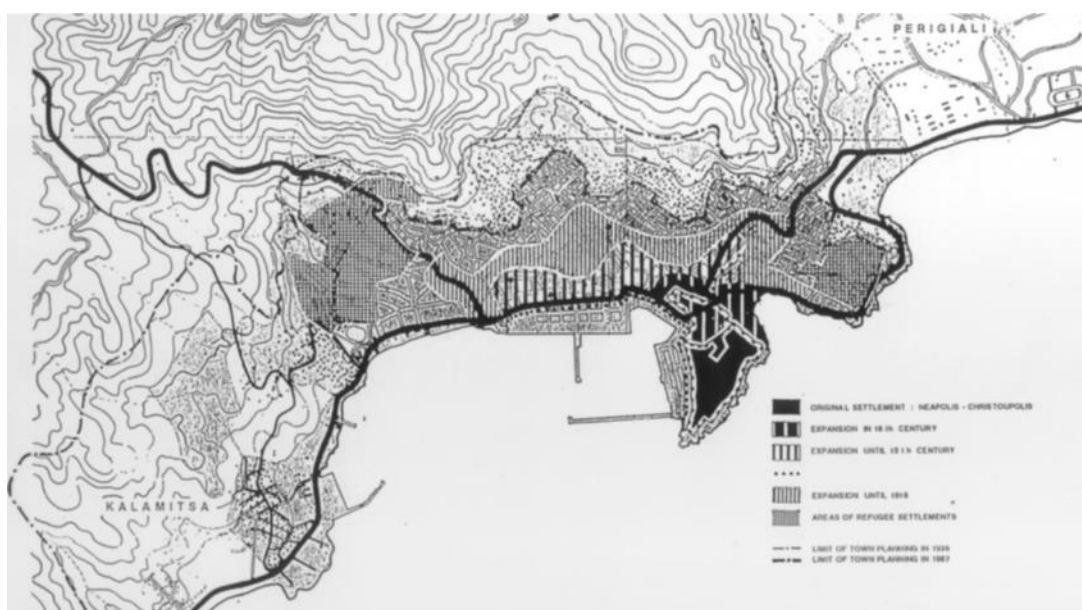

Figure 46: Gradual expansion of the city of Kavala [11]

Tobacco production and trade formed the economic and general development basis of Eastern Macedonia and Thrace from the 19th to the mid-20th century. The main export trade to Europe took place through the port of Kavala and the city was already the home of many consulates serving the trading houses. The rapid development of the tobacco trade made Kavala the first export port of Macedonia in the three years 1909 - 1912 with four times more exports than Thessaloniki [12, 13].

The commercial processing of tobacco is carried out exclusively in the tobacco warehouse complexes, which belong to the category of industrial buildings as they were constructed to accommodate the industrial production of the time. The accurate and uninterrupted processing of tobacco was inextricably linked to the premises and the specific characteristics of the tobacco warehouses and dictated the functional and morphological layout of the buildings [14].

The emergence of tobacco warehouses in the urban fabric of the city was a dominant image for several decades. However, the gradual decline in the production and trade of tobacco resulted in these buildings being left unused, constituting an important building stock, which remains unexploited in the urban landscape until today [15, 16, 17].

Proceedings

2.2 Urban and social transformations in the city of Kavala during the period of prosperity

Until the middle of the 19th century, Kavala was a small town built on a peninsula, surrounded by a Byzantine wall. Its population consisted of Turks, Jews, a few Greek Orthodox families and a few Armenians. There were five districts in the city, three of which were inhabited by Muslims, one by Christian Greeks and one, which was the commercial area, inhabited by Jews. The wall was the boundary of the city beyond which, industrial construction was prohibited. Tobacco processing took place in workers' houses and small buildings, most of which were owned by Ottomans who rented them to non-Muslim workers. The houses of Muslims were differentiated from non-Muslims by allowing them to have two or even three floors, while the houses of non-Muslims were allowed to be developed on only one floor. This differentiation was in accordance with the building regulations that existed before the Tanzimat Reforms [18, 19].

At the end of the 19th century, the urban pattern of the cities of Eastern Macedonia and Thrace reflected the social, economic and spatial characteristics of its industrial identity, while economic boom led to significant urban transformations. In the 19th century, and especially in the context of the reforms and modernization of the Ottoman state, those who mainly controlled the shipping, trade and economic traffic of the Ottoman Empire, in the ports of Istanbul and other smaller ports in the periphery, were Greeks and Jews, who foresaw the future value of the tobacco product [20]. Thus, the profession of the "Tutunji", i.e. tobacco merchant, was created first in Constantinople and then in the other ports and tobacco centres.

In Eastern Macedonia and Thrace, apart from Greeks and Jews, some Ottomans and Armenians were also involved in the tobacco trade. These were the main actors of the commercial activity, who contributed significantly to the spread of the tobacco trade and its establishment in the world market, since they were not limited to the regions where they were based but expanded to many countries in Europe and in the Mediterranean. The multiculturalism of the tobacco trade in its early years of prosperity is reflected in the names of the local traders and the impressive buildings they constructed. While the first tobacco trading companies were owned by Ottomans, Armenians, Jews and Greeks, eventually there was a dynamic entry into the - until then - mainly local market by powerful companies and firms from several other European countries. It is characteristic that by 1880 all major European countries had established their consulates in the city of Kavala [21]. Until the beginning of 20th century, foreign companies that settled in the region dominated the tobacco trade and controlled exports to the global market [22]. At the same time, in 1910, the Bank of Athens, the Bank of Thessaloniki, the Imperial Ottoman Bank, and several independent bankers (Benveniste M., Kolokythas M., Protopapas GD, Herzog M. and Sarikas Zisis P.) were all operating in Kavala [23]. The economic prosperity that comes with the emergence of the urban class - consisting of wealthy tobacco merchants, other professionals (Christians and Jews in the vast majority), representatives of foreign trading houses and consuls - is accompanied by demographic growth as new populations arrive in the city to occupy themselves with the tobacco industry and the construction of new buildings. New districts were developed, extending the boundaries of the city, and new buildings were constructed, introducing to the city the flavor of western and eclectic architecture, whether they were residential, public and communal mansions or industrial and commercial buildings. The function of temporary accommodation at this time was served by the hania, the majority of which were built between 1870 and 1910. At the end of the 19th and until the beginning of the 20th century, Kavala had 20,000 inhabitants [24].

At least half of the population of the city dwellers were tobacco workers, whose families constituted the working class. The figures quoted at the beginning of the 20th century are typical. In Kavala, 14,000 people were employed, of whom approximately 6,000 worked for the three largest tobacco companies in the city (Commercial, Hertzog and ATC) [25].

Many of the workers came from the rural hinterland, who after the end of the tobacco season (which lasted from May to October) returned to their villages and worked in the fields. The tobacco workers constituted a multicultural social class, which was very much alive in the daily life of the city, despite the difficult conditions under which they carried out their labor (long working hours, wages inversely proportional to the working hours, seasonal occupation and unhealthy due to the dust, humidity and heat). Regardless of the ethnic group to which they belonged, they developed strong trade union activity and contributed significantly to the trade union movement, with common struggles for better working conditions, wages and equality as early as the end of the 19th century [26].

At the end of the 19th century, the image of the urban landscape reflected the social, economic and spatial characteristics of its industrial identity, while the economic boom led to significant urban transformations.

After the 1860s Kavala was established as the most important port for the export of tobacco in the region. Until then, processing in the small buildings within the walls could not meet the growing demand, so requests to the Sultan for more and more suitable places for tobacco storage and processing became pressing [27].

Several travelers in the area point out the striking contrast in the city images of the two areas: the parts of Kavala inside and outside the walls. The inside of the walls, inhabited mainly by Muslims, consisting of the historical part of the city, still had the image of a poor, dark, dirty and 'depressing' urban environment, with wooden houses, and narrow muddy streets. In contrast to the above, the new part of the city, outside the walls, was a modern urban area, inhabited by Christian Greeks and Jews, with stone-built structures, new architecture and obvious wealth. It hosted a variety of economic and social functions and the city's image was 'European'. The new structures reflected to a high degree the architectural standards of their owners' origins [28].

Figure 47: Panoramic view of Kavala to the east, at the end of the 19th century [29]

The western quarter is inhabited by Christian Greeks, while the eastern quarter is inhabited by Muslims. The small community of the Jewish population, which had settled in the city, was located in the area between the springs of Aghia Varvara and the commercial city center. In the southern part of the urban fabric, around the springs of Aghia Barbara, the buildings of the tobacco warehouses and the recreational areas of the city's inhabitants were situated [30].

Finally, as mentioned in a previous paragraph, the city of Kavala received many refugees (about 20,000) and almost doubled its population to 50,000 inhabitants in 1930. Most of them inhabited areas outside and around the existing urban fabric, occupying the sterile hills that were publicly owned. Others settled in four refugee neighborhoods (Pentakosia, Chilia, Byron, Dexameni), built

Proceedings

partly by the Greek State and partly by the refugees themselves, and some of them were housed in the old residences of their former Ottoman owners. The city expanded rapidly and in an uncontrolled manner. Illegal construction in public spaces on the hills surrounding Kavala formed a new urban zone, the "Perigram" ("Surrounding Zone"), with an area almost equal to the "institutionalized" area of the City Plan. The growth of the city's population during this period is reflected in the population of tobacco workers, which in 1930 reached 14,000 [31].

2.3 Spatial footprint of tobacco identity in the urban fabric

The numerous tobacco warehouse complexes in the city of Kavala initially formed separate districts, in which the choice of their location was not accidental, while at the same time their contribution to the urban development of the city was catalytic. Moreover, apart from the scale, which clearly differentiates these areas from the rest of the urban fabric, the tobacco warehouse buildings introduce the European architectural standards of the time to the area. By the early 1920s, it is estimated that 156 buildings of different sizes and types existed and were in full operation in Kavala as tobacco warehouses [32].

Figure 48: Tobacco warehouses in the city of Kavala in the late 19th and in the beginning of the 20th century [33]

The process of construction and establishment of most of the tobacco warehouse complexes in Kavala lasted from 1860 until 1930. It is located in the first extensions outside the city walls, in the district of Agios Ioannis, near the beach, but also scattered outside the boundaries of the fortified core. Initially they were significantly distant from all the functions of the city, but gradually the gaps in the urban fabric were filled with supporting uses due to the needs that developed (tobacco workers' residences, tobacco merchants' urban estates, commercial uses, temporary catering facilities - hania). In these areas, it appears that a town plan was drawn up from the outset in accordance with the new Ottoman town planning regulations of 1882. A Hippodamian plan (rectangular canvas) with large building blocks and relatively wide streets, which allowed the construction of several large-scale industrial buildings. The sizes and building solutions are related to the intended functionality of the buildings in terms of product storage and processing. These areas offered abundant and affordable land, as they were located outside the urban fabric, which meant that they could allow the concentration of a number of large plants. Such concentration was a prerequisite for security conditions, but above all for effective control of smuggling [34, 35].

Another important parameter was the working conditions prevailing in these spatial units. The district of Agios Ioannis, the Central Quarter and the one of Soujolou were characterized by their proximity to the sea, but also by the fact that streams crossed them, which flowed into the sea. These unhealthy conditions for housing were favorable for the storage and processing of tobacco, as they ensured

consistently high levels of humidity. They also favored the construction of semi-subterranean rooms, which were essential for processing and storing the product. The sites also had other advantages. Some of the tobacco warehouse complexes formed the entire coastal front until the middle of the 20th century, while their concentration in the coastal area and their development around the new commercial center of the city facilitated the transport of tobacco by barges or carts to the port [36].

3. URBAN LANDSCAPE IN TRANSITION

The effort to reduce the cost of tobacco processing, combined with the evolution of technology in the industry, resulted in the gradual replacement of all traditional activities with modern facilities [37]. Following the entire mechanisation of the production line, an attempt was made to adapt the existing tobacco warehouses to the new technological requirements, given that they were very flexible in terms of typology and structure to accommodate new devices per level. After 1950, modern buildings were also constructed to meet the current demands of tobacco production, while the historic industrial buildings were used for a short period of time for the storage of tobacco bundles [38].

Figure 49: Extract from a topographical map of Kavala of 1939 [39]

Over time, the need for modern facilities, and especially the escalating crisis in the tobacco industry, led to most of them being underused or abandoned, while after 1974 a significant number of them were sacrificed on the altar of building capital and the rent system. The above map indicates the tobacco warehouse complexes. The surviving tobacco warehouses are marked in dark blue and those that no longer exist are marked in cyan.

As a result of this process, only 48 complexes are currently identified in Kavala, with most of them being abandoned, while at the same time, there are industrial buildings scattered throughout the city that are in operation with new uses, whether the shells have been restored or not. Even though some efforts have been made, they are fragmentary moves rather than a comprehensive initiative. Regardless of the institutional framework or the sophisticated and specialized restoration techniques, it is equally important for the local community to recognize the importance of the tobacco warehouses

for the city: from that of collective memory, to that of the morphology and function of the urban fabric [40].

Figure 50: View of abandoned tobacco warehouses [41]

The central area of the out-of-core area of the city until the 1950s retained a highly aesthetic characteristic set of urban and productive shells. The deterioration in the decades that followed has been significant and today only relatively small, discontinuous groups or individual buildings survive, many of which are listed. In some cases, inactive shells of productive activities and buildings of other civic functions have been allocated to uses that also incorporate them into the current function of the town. The historic and business center of the city is an area of special cultural character, as there are numerous historic, architectural and industrial buildings on its boundaries which require protection and enhancement. However, most of the buildings of traditional architecture have been abandoned and only in recent years there has been an attempt to restore and reuse some of them, either by the municipality or by private individuals. In addition, there are several remarkable buildings in the area that the Ministry of Culture has designated as 'Historical Monuments of Conservation' or 'Works of Art' under Law 3028/2002 [42].

These structures constitute a complex that enclosed the tobacco warehouse zone or penetrated in clusters in the central area of the city. The architecture of these buildings generally ignored the tradition of the buildings of the old town and followed western models with the manifestation of a peculiar eclecticism, influenced both by various architectural trends of the era and by historical architectural memories of the past and echoes of neoclassicism.

Proceedings

Several buildings of this classification, such as most of the buildings on Cyprus Street, belong to public institutions and are presumably not in jeopardy. However, many of the buildings of this category scattered throughout the residential area have been demolished or are in danger of being lost due to lack of maintenance, even if they are protected by a declaration of conservation.

4. CHALLENGES AND PERSPECTIVES

The issue of tobacco warehouses, like many issues of collective identity and cities' perspectives, cannot be left uncontrolled to the forces of the market, because it cannot, by nature, adopt a coordinating role for the overall vision of a place and for the common good. Especially when real estate is reduced to the usual practices of commercial building, without any alternative strategy. It turns out, therefore, that the issue ultimately transcends urban policies and technical methodologies and reaches into contemporary aspects of urban development and urban management and governance. A management whose most important elements are the participatory processes, the civil engagement and the activation of local potential in the direction of a holistic development planning.

In any case, it is more crucial than ever that a process of overall policy redefinition should be undertaken, both for the tobacco warehouse district and for all the complexes scattered around the city. A policy that must extend from a strategic approach to urban development, to urban planning and design, and must be completed by the establishment of a methodology for the process of restoring and re-using such buildings [44].

Moreover, the existence of cultural heritage can strengthen the sense of local identity of a place, in a period of increasing competition between cities and the 'reinterpretation' of the relationship between globalization and localism ('glocalization') [45, 46, 47].

According to the land use planning of the Municipality of Kavala, 83.5% of the tobacco warehouse buildings are in areas with central function uses: 76% in the City Centre and 7.5% in areas with Local Centre use. 9% of the cases are found in Residential areas and 4.5% in Urban Green/Open Space areas. Finally, 3% falls within Cultural Functions areas. Accordingly, based on the current Urban Plan of Kavala (Government Gazette 68/D/1980) and its amendments, 21% of the buildings are urbanized and the relevant properties are subject to expropriation.

Recognizing the dynamics and the importance of the preservation of the industrial heritage and the reuse of the abundant building stock, the current Master Plan of the Municipality of Kavala, defines the Tobacco Warehouse Area around the Labor Center as an Urban Regeneration Area with guidelines for the reuse of the inactive shells of the tobacco warehouses, the safeguarding of the existing public spaces, the protection and promotion of the historical elements of the area, the upgrading of the quality of the built environment and the tackling of the deficiencies in infrastructure. This redevelopment area includes 62% of the Tobacco Warehouses cases.

5. CONCLUSIONS

In accordance with the new trends and conditions of urban development, residents, economic stakeholders and institutionalized authorities within a city should act and make decisions that regulate the urban environment. It is therefore necessary to exploit the historical, cultural and architectural heritage of a place through a modern model of urban sustainability, involving integrated urban approaches and participatory processes to enhance the image of a place and to shape its identity.

The tobacco warehouses of Kavala are the buildings that are of particular importance because they are an integral part of the tobacco identity of the city. They are also valuable because they mark the beginning of the city's architectural and urban development and because they highlight the multicultural character of the city during the 'Golden Age of Tobacco' and earlier. It is of particular interest to investigate how this diversity was 'absorbed' and integrated without changing the cultural and social heritage of the city.

The Tobacco Warehouses are partly monuments of industrial/cultural heritage and elements of the city's identity and on the other hand, they are private properties with potential for economic exploitation, making their promotion and exploitation a very complex but also multifaceted process. As the tobacco warehouses are a special architectural and historical feature of the city, which characterizes its identity, it is vital to be promoted and reused, integrating them into the urban structure and function of the city. The integration of Kavala's tobacco identity into a bottom-up model of urban regeneration will help to strengthen the dynamics and development process not only of the city in discussion, but also of any other city with an extensive cultural heritage.

The existence of this industrial cultural ensemble that can enhance the sense of local identity of the region, combined with the utilization of existing urban voids, is an important development potential to be explored, especially in view of the increasing competition among cities today.

Extended abstract

This paper focuses on local participatory planning processes in two cities, Kavala and Kalamata, which have varying expertise in this domain. The municipality of Kavala has had a long-term citizen participation strategy emphasizing issues of planning and urban mobility, whilst the municipality of Kalamata recently stepped up its efforts with a group of citizen-expert moderators co-drafting the city's climate neutrality contract, as part of the relevant EU Horizon mission for climate neutral and smart cities. In line with current principles and trends in urban planning, such as the introduction of the 15-minute city model and strategies of climate mitigation actions at local and neighborhood level are crucial and must involve interacting and co-creating with residents and local actors to define their needs.

Drawing from the experience of intensive local and neighborhood participation actions organized in the two cities in the period 2023-2024 as part of an EC-funded World Bank project, the present research discusses the methods employed to identify and connect key local stakeholders and to engage the local community in the participatory activity, which was targeted on specific groups (residents, entrepreneurs, students, public bodies etc.). The success of processes in both familiar and inexperienced audiences is then evaluated.

The engagement strategy of local stakeholders should take into consideration the diversity of stakeholders and the conflicts of interests, concerns, and perspectives. The engagement strategy should also focus on dialogue-oriented planning processes to ensure that the project is inclusive and participatory. The outcome of the qualitative findings, as well as a preliminary definition of emerging issues in the development of neighborhood action plans have also been studied. The central issues of significant importance were coastal (waterfront) regeneration and sustainable urban mobility and accessibility, since they are related to specific technical and policy requirements.

The results highlight the importance of participatory planning processes and consultation in urban planning and design. Another issue highlighted by this research is the high degree of social appointment of a project when local society has participated in the design or/and implementation processes. The methodological and theoretical lessons learned from these pilot case studies enhance the value of participatory planning with regards especially to (a) rapid interventions, adaptation, and mitigation actions that cities are going to undertake under climate and green transition imperatives; and (b) increasing civic engagement in strategic and public funded interventions such as those supported by EU regional policy.

The set of participatory actions discussed in this paper were carried out in the context of the World Bank Technical Assistance Facility entitled "Greece Sustainable Cities and Regions Through Integrated Territorial Investments", and funded by the European Commission's DG Regio. They aimed to support Kavala, Larisa, Heraklion, and Kalamata in using practical methods to improve strategic processes and plans, as well as design and implement projects for sustainable urban development. One of the key deliverables were Participatory Neighborhood Planning Processes in Three Medium-Sized Cities in Greece (Kavala, Heraklion, and Kalamata). The primary goal has been the support of three Greek cities in the development of neighborhood visions and action plans, the

Extended abstract

Following the end of WWI and the dissolution of the Ottoman Empire, Greece with the aim of protecting the national minority, participated with other European powers in the occupation of territories in Asia Minor (1919-1922). After the change in the policy of the Great Powers, Greece abandoned these lands, resulting in the destruction of Asia Minor and the exchange of populations, in accordance with the Treaty of Lausanne (1923), that settled the differences in the area. The refugee flow towards Greece, which had already started before these events, was significantly increased, and concluded with the mandatory exchange of populations between Greece and Turkey. The issue of housing the displaced population, hailing from Asia Minor, Eastern Thrace, and Pontus, emerged as a major concern for the government at the time. Under the auspices of the League of Nations, permanent accommodation was provided through the Refugee Settlement Commission (RSC). Urban refugee settlements were established throughout the country introducing not only the urban planning trends of the late 19th and early 20th c., in some cases associated with the Garden City movement, but also the concept of social housing. This study explores, with the city of Xanthi as a key case study, the intricate relationship between architectural heritage, collective memory, and the urban landscape, focusing on the significant impact of historic refugee settlements on shaping the identity of modern Greek cities, and indicates the diversity of the development between large urban centers and small towns of northern Greece.

Architectural conservation forms a central issue in this research, elucidating how the preservation of these areas and their uniqueness, contributes to the safeguarding of Greece's architectural heritage. The concept of collective memory intertwined with community identity, is also addressed by identifying urban refugee settlements, as tangible manifestations of historical events and vital repositories of shared experiences, embedded with layers of cultural significance and social narratives. Through empirical evidence and embracing the Historic Urban Landscape (HUL) approach, it illustrates how the preservation of historic refugee settlements may not only maintain architectural authenticity, but also become a catalyst for community cohesion.

Legal and ethical considerations, including frameworks and regulations, are discussed to highlight the complexities and responsibilities associated with preserving historic locations and buildings outside protection zones, threatened by the phenomenon of intense urbanization, taking into consideration a) the urban patterns, b) the form and appearance of the buildings, c) the relationship between the urban area and its surroundings, d) the various functions that the area has acquired over time and e) the cultural traditions, techniques and everything that contributes to the identity of a place. Finally, the paper underscores the importance of recognizing and preserving these invaluable aspects of tangible and intangible cultural heritage, within the contemporary urban context and aims to contribute to a nuanced understanding of the inherent challenges and opportunities.

Abstract

“Composition” is a term intensively applied in architectural and space design approaches, insisting on the formation of expressive graphic systems, of “languages” that may depict space formations. In the case of the proposed intervention to the Pikrodafni stream the project refers to an extensive reform of the natural earth bas-relief, in favor of the waterscape resilience and the prevention of possible floods. In the case of a second project, which we shall also present, that of the intervention to the wetland area of the municipality of Oropos, in Attika near Athens, the proposed architectural composition principally refers to the design of an environmentally friendly network of constructions hovering over the natural bas relief. It refers to a network of wooden visiting platforms, birdwatching wooden towers and hiding walls, and reception and information structures for visitors. Nevertheless, the proposed project if ever materialized, would have no interest without the safeguard of the existing waterscape formation, without an intervention to the linear coastal zone between the wetland and the sea, which would ensure the existing waterscape resilience. In both cases, the projects to be presented attempt to form compositional design “languages”, correlating the natural earth bas-relief, and the contours of the streambed or the wetland basin, with plantation interventions and hard landscape structures, and finally with the water’s substance. It is in this context, of intervention to natural waterscape receptors that we use the metaphor of Narcissus. Ecosophic communities, compared to the hero of the ancient legend, are looking at the waterscape surfaces. There the mirroring of their own cultural capacity may be produced, an ecologically oriented reflection of culture amalgamated to the primordial substance of water.

Keywords: Waterscape resilience; waterscape design; urban landscape porosity; water networks.

1. INTRODUCTION: NARCISSUS SEDUCTIVE MIRAGE ON THE WATER, A LEGENDARY METAPHOR AND A CONTEMPORARY DESIRE

According to the ancient legend of Narcissus [1], a legend fascinating intellectuals and artists from antiquity till the period of modern surrealism (Figure 1) [2], the hero of the narration was an adolescent of incomparable beauty. Looking at his mirrored image on the water, he fell in love with it, without realizing that the object of his desire was his own self. He tried again and again to come in contact with his supposed lover, and as he continuously failed, he died, sunk in despair and sorrow. We have just referred to the illusionary conception of the water, presenting it as a substance of reference for positive imagination or deluging terror... It is in this context that we associate water through the ancient legend of Narcissus – a material surface whereon our cultural image may be mirrored in a seductive reflection or be liquefied in a destructive way. It is in this context that we shall continue our presentation, by describing our desire for landscape intervention, our desire to design waterscape entities trying to offer them positive qualities, in association with urban or peri-urban environments and fascinating visiting itineraries.

2. NARCISSUS IN ATTICA: THE WATERSCAPE “POROSITY” OF THE ATHENIAN URBAN TERRITORY

It was in 2010 that a research program, intending to investigate the general regeneration approach of the metropolitan area of Athens and Piraeus, was set forth by the Ministry of Environment [3]. In the context of the previous program, the author of this article insisted on the concept of “porosity” as a description of the correlation between public open-air urban spaces and built urban areas. Moreover, the previous reference to the urban porosity attempted to go further and investigate the natural environmental porosity of the city, the correlation of the urban context with green spaces and furthermore with the network of rivers and streams of the metropolitan area, still perceptible or covered and effaced from the urban surface. An important mapping result was produced, a fascinating depiction of possible waterlines, of a water network invigorating the “wet dreams” of our ecological desires.

In correlation to such an approach, we decided to investigate, through our academic lessons, in the School of Architecture N.T.U.A., a paradigmatic case, the rehabilitation of the important stream of Pikrodafni (Figure 2), the third more important route of water in the territory of the basin of Athens, after Kifissos and Ilissos rivers. Our design approach tried to associate a hydrological and hydromechanical understanding, with an extended landscape architecture proposal and an urban design approach, insisting on the amelioration of the streambed through natural material remedy, and implementing furthermore the extended use of the plantation. The central idea of the approach, applied in the context of a diploma thesis in the School of Architecture N.T.U.A. [4], had to do with the didactic concept accepting that natural landscape entities could be designed and “composed”, “con-posed”, organized as compound spatial structures, according to principles of appropriate natural “function”, possessing in the same time aesthetic “compositional” value [5, 6, 7].

Figure 2: Pikrodafni stream in the context of the Athenian basin.

3. RE-HABILITATION OF THE IMPORTANT STREAM OF PIKRODAFNI, IN THE METROPOLITAN PERIPHERY OF ATHENS: AN EXAMPLE OF WATERSCAPE COMPOSITIONAL APPROACH

“Composition” is a term intensively applied in architectural and space design approaches, insisting on the formation of expressive graphic systems, of “languages” that may depict space formations. Analyzing the etymology of the term, we may moreover comment that literary it refers to the coexistence of different elements in a spatial place context. In our paradigms, compositional proposals refer to the correlation of different elements. In the case of the proposed intervention to the Pikrodafni stream the project refers to an extensive reform of the natural earth bas-relief in favor of the waterscape resilience and the prevention of possible floods.

3.1 Pikrodafni stream: hydrological intervention and the redesign of the streambed as a central compositional approach of the proposed waterscape

It was in the previous context that the design approach of the Pikrodafni stream firstly regarded the hydrological reform of the bed of the stream, as the initial condition pre-regulating the other compositional decisions. The bed was partly reorganized, trying to keep and augment its curvilinear

schematization, in a way that the length of it would be expanded and the speed of the water movement could be retarded (Figure 3).

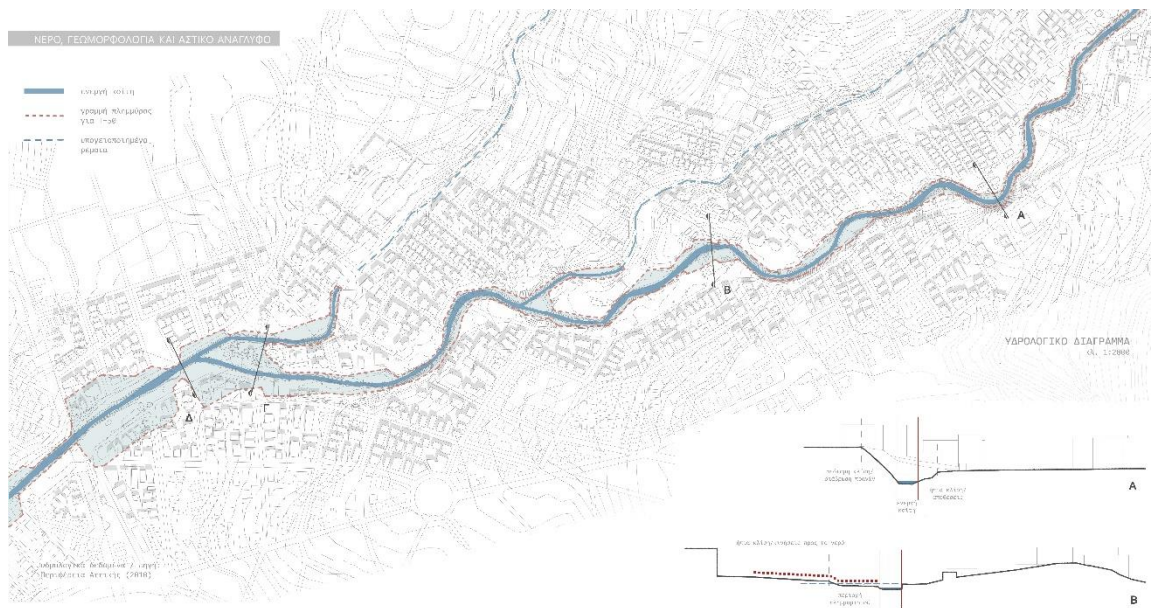

Figure 3: Pikrodafni stream; its curvilinear waterbed and the focal places (in azure color), where a possible flood could decompress.

Moreover, extended space was provided at focal places of this curvilinear bed, in such a way that a possible future flood could easily decompress without delusive results for the surrounding urban territory. In addition, the banks of the stream were proposed to be reformed naturally, through the enforcement of them with wooden implants and vegetal formations, without the use of concrete. ‘Composition’ as used in architectural and urban design, was thus oriented towards the reorganization of the natural formation of the water environment: of its hydromechanics and the need to facilitate natural interactions, between water and its surrounding earth substratum. Narcissus looked at the surface of the Pikrodafni stream. There, his own human-centered image disappeared, it was liquefied and replaced by the choice of a *More than Human* [8] orientation, towards a nature-centered symbiosis.

3.2 Pikrodafni stream: waterscape intervention in correlation to the surrounding urban scape plantation

The second central idea of landscape composition, proposed for the Pikrodafni stream, refers to the extended use of the plantation as a means for the revitalization of the zones spread on both sides of the waterbed. An enlarged “water and green corridor” was thus proposed, comprising the main waterbed, the active branches of it and the lateral planted zones, expecting to radically reform the densely built context of the city. In addition, we must explain that the plantation was used, in a way analogous to that of the composition of building or hardscape urban formations. Plantation was thus used as a composition means, which may offer different formal schemes (Figure 4), of differentiated volumes and colors and surely of differentiated natural substances [9: 256-260].

Figure 4: Pikrodafni stream; composition of its waterbed zone with the extended plantation, proposed to be reformed, areas on the lateral zones of the stream.

4. A SECOND WATERSCAPE COMPOSITIONAL APPROACH: AN INTERVENTION PROPOSAL AT THE OROPOS WETLAND, IN ATTICA GREECE

In the case of a second project, which we shall also present, that of the intervention to the wetland area of the municipality of Oropos, in Attika near Athens, the proposed architectural composition principally refers to the design of an environmentally friendly network of constructions hovering over the natural bas relief. It refers to a network of wooden visiting platforms, birdwatching wooden towers and hiding walls, and reception and information structures for visitors. Nevertheless, the proposed project if ever materialized, would have no interest without the safeguard of the existing waterscape formation, without an intervention to the linear coastal zone between the wetland and the sea and an intervention assuring the existing waterscape resilience.

Figure 5: Oropos wetland; its correlation with the built area, on the back and South Euboean Gulf on the front. A thin linear barrier partly separates the wetland basin from the sea. The red line describes the wooden corridor, created over the water to facilitate the circulation of the visitors, while the red dots on it refer to wooden premises providing reception and information complexes (at both edges of the red line), or to wooden bird-watching walls and towers (at focal points across the red line).

4.1 Oropos wetland: a valuable ecosystem on the south coast of Euboean Gulf in Attica, near Athens

Oropos wetland is located on the outskirts of Skala Oropou, a seaside town on the south coast of the South Euboean Gulf, situated near the mouth of Asopos River. It is formed as a result of the mixture of the river’s water with the sea, separated from the gulf by a thin linear barrier island. The sea is thus penetrating the interior of the wetland without, nevertheless, completely changing the aquatic substance of the river water surfacing at the coastal zone. A distinct valuable ecosystem is thus produced, a charismatic natural habitat where migratory birds may rest and nest, during their seasonal voyages over the Greek mainland. As a consequence of the previous important ecological identity, Oropos wetland was developed into a visiting place of a high international profile for bird-watching groups, facilitated for their approach by the vicinity of the place to Athens.

Figure 6: Wooden structures facilitating the reception and circulation of visitors, in Oropos wetland. 3D description of the reception and information booths for the visitors - in both images, the wooden corridors and the bird-watching wooden walls are presented.

4.2 Oropos wetland: safeguarding the wetland from the invasion of salty water and land grabbing.

It was because of the high ecological importance of Oropos wetland and its equally high esteem as a bird-watching destination that the intervention presented was decided by the municipality of Oropos, in 2010, and the corresponding project was assigned to a group of architects, civil engineers and environmentalists. The central idea of the project had to do with the safeguarding of the wetland, which was largely diminished during the last fifty years as the result of the extension of the housing

territory of Oropos municipality. In the context of a distorted idea of development, housing construction was considered as matter of higher importance than the natural resilience of the pre-existing landscape. Parts of the wetland were gradually dried out and a continuous building pressure exerted on the natural substratum of the broader territory of the mouth of the Asopos River.

We shall not extend our description on the subject of the extreme pollution of Asopos, as a result of the industrial chemical waste. We shall limit our comments on our principal object of interest, concerning the wetland itself. In this context, of the safeguard of the wetland, the project proposed an earth barrier, a mound, between the wetland and the peripheral road of the housing territory, thus repulsing the illegal pressure of land grabbing. A second proposal referred to the need for the restoration and enforcement of the thin linear barrier separating the sea from the wetland basin; otherwise, the salty sea water would largely invade its interior and destroy the hybrid ecosystemic condition, disequilibrate the degree of the higher salt tolerance, the “halotolerance” that permits to the halophytic vegetation to grow. As halophytic vegetation, or “halophytes” (a term derived from Ancient Greek ἅλας – halas, “salt” and φυτόν – phytón, “plant”), we describe the vegetation of salt-tolerant plants that cover nowadays the larger part of the wetland and create the nesting environment of the migratory birds.

4.3 Oropos wetland: composing a system of wooden structures facilitating the reception and circulation of visitors.

The final aim of the project presented was, nevertheless, the promotion of the Oropos wetland as a precious ecological paradigm that has not only to be preserved but, furthermore, to be promoted as a landscape of didactic ecosophic value. The vicinity of the wetland to the larger urban territory of Greece (the Athenian metropolitan area) could guarantee the facility of the visitors’ approach, for natives or bird-watching tourists, facilitating in addition the environmentally focused excursions of the Greek elementary and high schools. Such publicity, if rationally regulated, could assure the survival of the wetland and the advancement of Oropos as an exemplary environmentally friendly municipality, and would strengthen, in addition, the governmental interest in the preservation of the environmental reserve.

In association with the previous targets, the project proposes a system of wooden structures, organizing the visiting navigation in the interior of the marsh. Two complexes for the reception and information of the visitors were designed, at the opposite ends of the suggested itinerary. Then a wooden circulation corridor was added, connecting the two reception and information complexes. It would permit the visitors to walk, even if the water would rise above the height of the possible walkable areas. Across the corridor, at different points of it, bird-watching walls and towers were also proposed.

It is important to repeat that the principal material of all previously described constructions is wood and that all of them would be founded on wooden pegs and they would, if needed, be removed [9: 552-556].

5. CONCLUSIVE REMARK: NARCISSUS MUST BE ABSORBED BY HIS CULTURAL, WATER FANTASIES

Narcissus looked on the water surface, of Pikrodafni stream and Oropos wetland and fascinated by his ecosophic, environmentally friendly identity. His new cultural water fantasies transformed his human centred, “narcissistic”, egocentric, self-absorbed mentality towards a radical ecological behaviour. According to Félix Guattari’s *Three Ecologies* [10] scheme, ecology has to be natural, social and mental at the same time, in order to be successful. Our projects had thus to propose not solely material landscape interventions but present, moreover, didactic cultural examples: didactic examples introduced in the courses of the School of Architecture N.T.U.A., as well as in the experience of the Oropos wetland visitors.

Acknowledgments

The two projects presented would not be realized without:

- The dedication of the students’ team of A. Androulakakis and A. Tzanavara, in the first project of “Pikrodafni stream intervention”, and the didactic collaboration of Prof. M. Markou.
- The design effort of “Arsis Architects” (A. Chelidoni, S. Bakopanou, K. Moraitis, D. Ververis) in collaboration with “KOMETKA Arch” (A. Androulakakis, Ch. Kontolepha, A. Tzanavara), in the second project for the “Oropos wetland intervention.” Participation of the Civil Engineer Prof. E. Tsakanika, the landscape architect N. Giorgi and the environmentalist E. Lagadinou.

Revisiting the public perceptions of water infrastructure landscapes under contemporary landscape changes

R. Ioannidis¹*, K. Moraitis²

¹ Postdoctoral Researcher, School of Rural, School of Architecture, National Technical University of Athens, Greece

Extended abstract

The impacts of infrastructure projects on landscape has been an increasing concern for public opinion over the last two decades, both in Greece and globally. The main origin for this has been the renewable energy transition and in particular the integration, or lack thereof, of wind and solar photovoltaic projects on landscapes. Public opposition movements have stressed the potential effects of such works on the natural, cultural and aesthetic character of landscapes. At the same time, however, the discussed concern has led to the emergence of an important, yet formerly overlooked, characteristic of water infrastructure: the characteristic of landscape and architectural adaptability. The first observation of this was made during a comparison of renewable energy technologies in terms of their landscape impacts and in particular the comparison of wind and solar works with hydroelectric dams. Broadening this investigation it was recognized that the same characteristic of positive landscape contribution could also be identified for dams of other types, their water reservoirs and their appurtenant works. Water infrastructure is therefore highlighted as one of the few types of infrastructure that can have a measurable positive contribution to landscapes, a contribution that is all the more important in the context of the current landscape-related upheaval.

At a scientific level, the potential positive contribution of dams to the landscape is related both to the creation of artificial lakes, which are a naturalistic alteration of the landscape, but also to the amenability of dams and their accompanying works to architectural treatment. This paper analyses these characteristics of dams in technical and social terms. Particular emphasis is given in quantifying and analyzing the origins of positive landscape perceptions of water infrastructure. In this regard, we utilize geotagged data, crowdsourcing and an extensive literature review. The research also presents the comparison between the impacts of the main renewable energy projects on the landscape, which acted as the origin of the further research on water infrastructure. Measurable indicators of land use, visibility and public perception of the different technologies are analyzed to this aim, in a comparison that includes hydroelectric, wind and photovoltaic projects. After identifying the importance of hydroelectric dams, as renewable energy works, for the landscape, an overview of best international practices in their architectural design and an analysis of the relevant perspectives for Greece is also presented. Finally, the conclusions of the work are broadened to all major water infrastructure including dams, reservoirs and appurtenant hydraulic structure, meanwhile proposing ways to further utilize their landscape and architectural advantages and overall contributing to more positive landscape perceptions of infrastructure.

Abstract

Addressing the issue of sensitive, integrated and contextually responsive architecture, the question of how we can utilize the potential and draw inspiration from the unique character of a specific location arises.

This paper aims to promote a project-oriented approach to context interpretation, place intervention and translation of its identity into an architectural proposal. Through an extensive analytical procedure, it intends to provide some initial answers to the question stated above via a case study focused on a developmental vision for Messolonghi. A city with a unique spirit structured around its strongest spatial feature – the surrounding lagoon.

Messolonghi is located in the Aetolia-Acarnania region of Greece and is charged with an immense international historical influence, folklore identity and environmental value. The Messolonghi lagoon complex – that has acted as a reference point for every aspect of its identity through the years – is protected under the Ramsar Convention as well as the Natura 2000 due to its great biodiversity.

The proposal aims to incorporate the 4 broader themes that shape the *genius loci* of the city – natural environment, productive identity, historical value and intellectual identity – into a single route/a circular path, while simultaneously activating the area around the Kleisova Lagoon (placement of pavilions on selected points). The main objective is a mild, sustainable, and easily reversible intervention, that attempts to improve on shortcomings and bring the spirit of the area to light, without undermining its future.

In this framework, apart from presenting a systematic approach to such a goal, the paper introduces an innovative synthetic tool – a modular system that can be restructured in order to provide suitable variations, the uniformity of the proposal and its integration into the waterscape of the lagoon.

The idea is based on the analysis of the 4 themes stated above and the interpretation of the local architectural vocabulary. Taking as a starting point the traditional timber dwelling – the “pelada” of Messolonghi, – the main elements that characterize its identity constitute the components of the system and are recomposed accordingly, to create a modern version in analogy with the original. In this endeavor, the synthetic composition and structural concept were developed simultaneously, to design a timber frame that combines references with flexibility.

The 7 typologies of pavilions that were studied (bird observatory, viewing pavilion, historical identity pavilion, auxiliary bathing facilities, accommodation pavilion, productive identity pavilion, and service station), constitute 7 possible combinations, that were considered to serve the purpose of a complete and integrated proposal. Thus, the intervention has an experimental character with adaptability and flexibility of possibilities, providing a pilot proposal for the management of the site. Such a proposal constitutes an example of a way to create sensitive architectural interventions, suitable for their context, contemporary in their design, while responding to historical and cultural precedents.

Proceedings

During a time of rising mass-production in the fields of design, a shift towards more sustainable and culturally sensitive approaches is of outmost importance for achieving a meaningful and responsive architecture that is deeply inspired and rooted in its context.

Keywords: *Messolonghi; Genius Loci; place identity; sensitive architecture; modular system*

1. INTRODUCTION

In the realm of architecture, the pursuit of sensitivity, integration, and contextual responsiveness stands as a paramount challenge. The systemic approach of spatially invasive and environmentally hostile design of the past century is starting to get replaced with practices that harmonize with the environment, respect, and honor the cultural tapestry of a place.

Within this perspective, the Latin term *genius loci* – the spirit of a place, encapsulates the unique character or essence of a specific location, shaped by its physical, cultural, and historical context. When applied to architecture, this principle may assist in harmonizing it with the existing environment, contributing to more responsive designs, deeply rooted in the fabric of their surroundings – to “*landscapes of pleasure*”.

The confluence of this philosophy with the distinctive character and energy of a waterscape, inevitably alters the area's genius loci. As mentioned in the abstract of the session, the allure of water transcends mere aesthetics, encompassing cultural and political significance across coastal landscapes and terrestrial surroundings alike. While exploring the interplay between cities and water bodies, it becomes evident that their association is not merely functional but deeply ingrained in their identity. Such an example is Messolonghi. A city charged with an immense international historical influence, folklore identity and environmental value, structured around its strongest natural spatial feature – the waterscape of the surrounding lagoon. “*You sigh, my heart, the same sigh: To live there again, Where the sea is shallow and tame, where the sea is vast and wide*” writes the notable Greek poet Kostis Palamas for the Mesolonghi – his birthplace – and the lagoon. And through his lyrics we can feel it: the lagoon is not merely IN Messolonghi, but it IS Messolonghi. It constitutes a reference point for every aspect of its identity.

In respect with the above, the structure of the diverse components comprising the city and its surrounding environment will be analyzed. The examination will highlight historical and socio-spatial features that contribute to the unique essence of the locale, with particular focus on the prominent water-centric attributes of the area. The paper will focus on the methodology of dealing with the research and design of a contextually responsive proposal in an existing, sensitive environment by presenting as a case study an architectural project managing the area around the Kleisova lagoon in Mesolonghi.

Figure 1. Drone images from the city of Messolonghi and the surrounding Lagoon (Messolonghi by Locals archives).

2. THE IDENTITY OF A PLACE

The concept of place is complex and multifaceted, encompassing both qualitative and spatial features. Understanding a place requires examining these various dimensions, which interact to create its unique identity.

Qualitative features are the non-physical, intangible aspects that contribute to a place’s identity. Such features are often subjective and shaped by human experience, cultural values, practices, and social

dynamics. They include cultural identity, historical context, social dynamics (behaviors, interactions, and community practices of residents), emotional and psychological associations, symbolism and meaning (often reflected in art, literature and media), community practices and intangible heritage (religious beliefs, spiritual practices, and culinary traditions).

Spatial features are the physical, tangible elements that define the layout, structure, and environment of a place. These features are crucial in shaping its functionality, appearance, and organization. They include the geography and natural environment, the urban and architectural design, land uses and zoning, transportation and connectivity, spatial organization and infrastructure and utilities.

Most of these features are shaped by the passage of time and the evolution of human civilization, environmental changes, technological advancements, economic development, and other factors. Consequently, the identity of a place is dynamic and constantly evolving, reflecting the continuous changes in human societies. This transformation highlights a place's adaptability and resilience to both internal and external influences.

Thus, to read a place is to interpret and deeply understand its various layers and elements, integrating both qualitative and spatial perspectives. This involves using maps and diagrams to display and analyze geographic, demographic, and qualitative data, consulting historical records and archives to understand the historical evolution of the place, and employing ethnographic methods such as observations, interviews, and surveys to gather qualitative data on residents' experiences and perspectives. Visual documentation, such as photographs and videos, captures the physical and social environment, while studying art, architecture, and literature helps to grasp the symbolic meanings and cultural expressions associated with the place.

This holistic approach, as outlined in Christian Norberg-Schulz's book "Genius Loci: Towards a Phenomenology of Architecture" (1980), defines the essence of a place through the concept of *genius loci*. It encapsulates all physical and symbolic values inherent in both nature and the human environment. By applying this type of methodology in Messolonghi, it is possible to develop a nuanced appreciation of the place, ensuring any intervention is sensitive to its unique identity and evolving nature.

3. DRAWING INSPIRATION & AREA ANALYSIS: MESOLONGHI

Messolonghi is located in the Aetolia-Acarnania region of Greece and is charged with an immense international historical influence, folklore identity and environmental value. The tranquil beauty of the wetland that surrounds it evokes a sense of peace that has served as a wellspring of inspiration and empowerment through time. Messolonghi's history bears witness to the lagoon's pivotal role, from its involvement in the Hellenic Revolutionary War of 1821 to its enduring influence on poets and artists on a national and international level.

3.1 Understanding Messolonghi – Four Themes of Inspiration

Being captivated by the unique potential and character of Messolonghi, the team's desire to bring its spirit to life again, became the project's goal. Thus, personal exploration led to the identification of the four broader themes that shape the *genius loci* of the city, to be used as a guiding tool to further analyze the area and, later, formulate the proposal. These themes are the significantly important natural environment, the distinctive productive identity, the highly significant historical value, and the intellectual identity of the site.

Concerning the natural environment, the Messolonghi Lagoon Complex is the largest in Greece. The area in its entirety is a waterscape of international importance that is included in the Natura 2000 network and protected by the Ramsar Convention. The Lagoon's unique ecosystem hosts a wide range of flora, fauna, and fish fauna.

The abundance of natural resources allowed the development of fishing and trade along with the extensive establishment of salt flats in the area. For these reasons, the ecosystem of Messolonghi

dictated the development of unique techniques, in the fields of architecture, collective fishing, and salt production. Over the centuries, the method of exploitation of the lagoon has remained unchanged with traditional fishing techniques and tools being inextricably linked and adapted to the ecology of the area. The traditional dwellings and construction techniques were also in connection to fishing – *a pilled timber hut, the “pelada” of Messolonghi acted as the residence of working fishermen.* Moreover, the abundance of salt due to the salt flats has had a direct impact on culinary tradition. Apart from the extensive consumption of salted fish, the most typical product produced in the area is the famous Messolonghi roe – the country's only PDO fishery product also known as the caviar of Greece.

Figure 2. Traditional fishing and dwelling techniques, Messolonghi roe and salt gathering (from left to right Paliouras, 2009. Mpada, 2004. Paliouras, 2009. Mpada, 2004. Artikos, 2010. Kordosis, 2022).

Even more significantly, Messolonghi holds a profound historical importance on a global scale. Even before the 19th century, due to its vicinity to the lagoons, the city possessed great naval power, that was in fact comparable to the biggest European countries in the field, and internationally recognized for its maritime trading. This relationship with water proved to be vital also in its involvement during the Greek War of Independence, when the city emerged as a powerful symbol of defiance against Ottoman rule, reaching the pinnacle of its significance. The town endured several sieges, notably in 1822-1826, where its people, despite suffering immense hardship, bravely withstood overwhelming adversities. In the final siege, their heroic sacrifice during the events of what is called today “the Exodus of Messolonghi” reverberated beyond Greek borders becoming a rallying cry for Greek independence and inspiring artists and intellectuals worldwide. To this day, Messolonghi stands as a symbol of physical and spiritual liberty, integrity and resilience.

Figure 3. Greece on the Ruins of Missolonghi by Eugene Delacroix (<https://www.eugenedelacroix.com/greece-on-the-ruins-of-missolonghi.jsp>).

Lastly, the intellectual identity of Messolonghi is simultaneously determined by the geophysical characteristics of the landscape, the dynamic presence of the fishing culture, and the historical pride that were mentioned above. The investment of accumulated wealth that came from the city’s naval power and merchant shipping in earlier centuries, led to the emergence of a social class, bringing about a remarkable intellectual movement that is strongly reflected in education and culture in general. With its heroic resistance, Messolonghi touched a large number of intellectuals around the world – such as the philhellene and English poet Lord Byron – and traveled through Greek and

international literature, securing its timelessness. Apart from being the city of immortal heroes, Messolonghi is also the city of 5 Prime Ministers and some of the country’s leading poets.

3.2 From selecting the area of intervention to site analysis

Examining the city through the lens of the four axes highlighted a concept echoed in Kostis Palamas's poem. The prominent role of water emerges as a commonality making the waterscape of the lagoon the unifying element among the various facets of Messolonghi’s identity.

In light of this realization, the decision was made to focus on the Kleisova Lagoon, the part of the lagoon complex that has an immediate connection with the city. Initially intending to concentrate solely on the the coastal segment adjacent to the lagoon – the road and the beach of Turlida – an extension of the study area was decided, to include its entire perimeter (approx. 25km) and allow for its activation and reintegration to the life of locals and visitors alike.

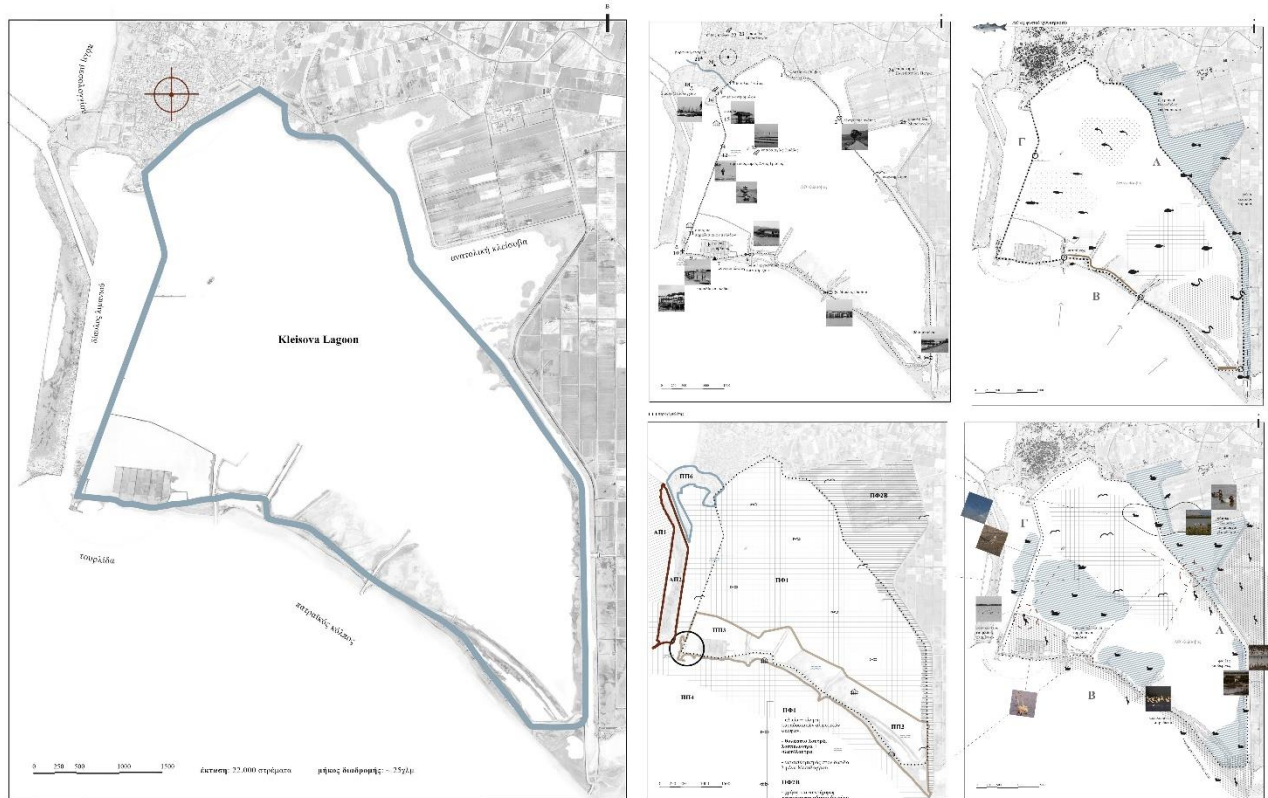

Figure 4. The area of intervention (marked with blue) and examples of area analysis through mapping (landmarks, fish fauna distribution, permissible actions, and bird fauna distribution).

Subsequently, a focused field survey was performed to identify suitable sites for an intervention proposal and understand the unique characteristics of the site. This research involved extensive mapping of various aspects such as land uses, distribution of fish, bird fauna and flora, zones of permissible actions as dictated by the environmental legislation, landmarks and prevalent activities performed in the area. As a result, the perimeter of the lagoon was separated into three distinct sections with different spatial characteristics and varying levels accessibility, traffic, and community engagement. This segmentation paved the way for tailored strategies to manage the area in accordance with its respective capacities, challenges, and opportunities.

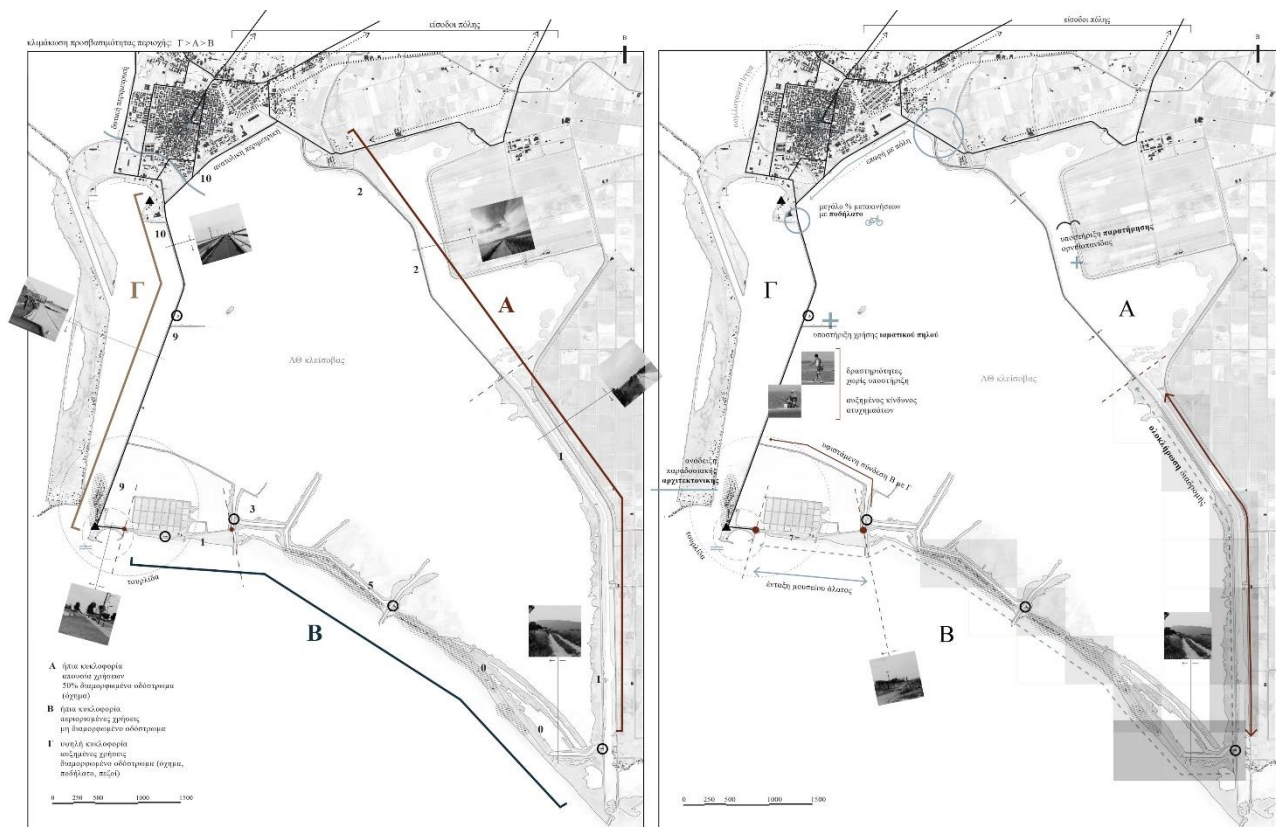

Figure 5. Map for the separation of the area into 3 sections A, B, Γ (left) and map of challenges and opportunities that will later lead to the masterplan (right).

4. ANALYSIS OF THE PROPOSAL AS A CASE STUDY

Recognizing the rich cultural and environmental heritage of Messolonghi and the ecological significance of Kleisova, the primary objective was a subtle, adaptable, and reversible intervention that addresses existing challenges while illuminating the area's unique character. In this context, the proposal aims to incorporate the 4 broader themes that shape the *genius loci* of the city (natural environment, productive identity, historical value and intellectual identity) into a single route/a circular path. By highlighting local identity, it seeks to enhance the region's appeal without compromising its long-term viability.

The two-tiered approach outlined in the proposal addresses both practical and aesthetic aspects of development. The first level focuses on improving connectivity along the perimeter road, ensuring equitable access to different parts of the area. The second level involves the strategic placement of pavilions in selected points around the lagoon, providing visitors with educational and recreational opportunities while harmonizing with the natural landscape. The designed pavilions are divided into 7 different typologies – bird observatory, viewing pavilion, historical identity pavilion, auxiliary bathing facilities, accommodation pavilion, productive identity pavilion, and service station – which, depending on the case, are repeated in different locations around the perimeter of Kleisova.

Overall, the proposal represents a holistic approach, considering both practical needs and cultural/environmental sensitivities. It seeks to leverage the unique assets of the area to create a sustainable and appealing destination for residents and visitors alike.

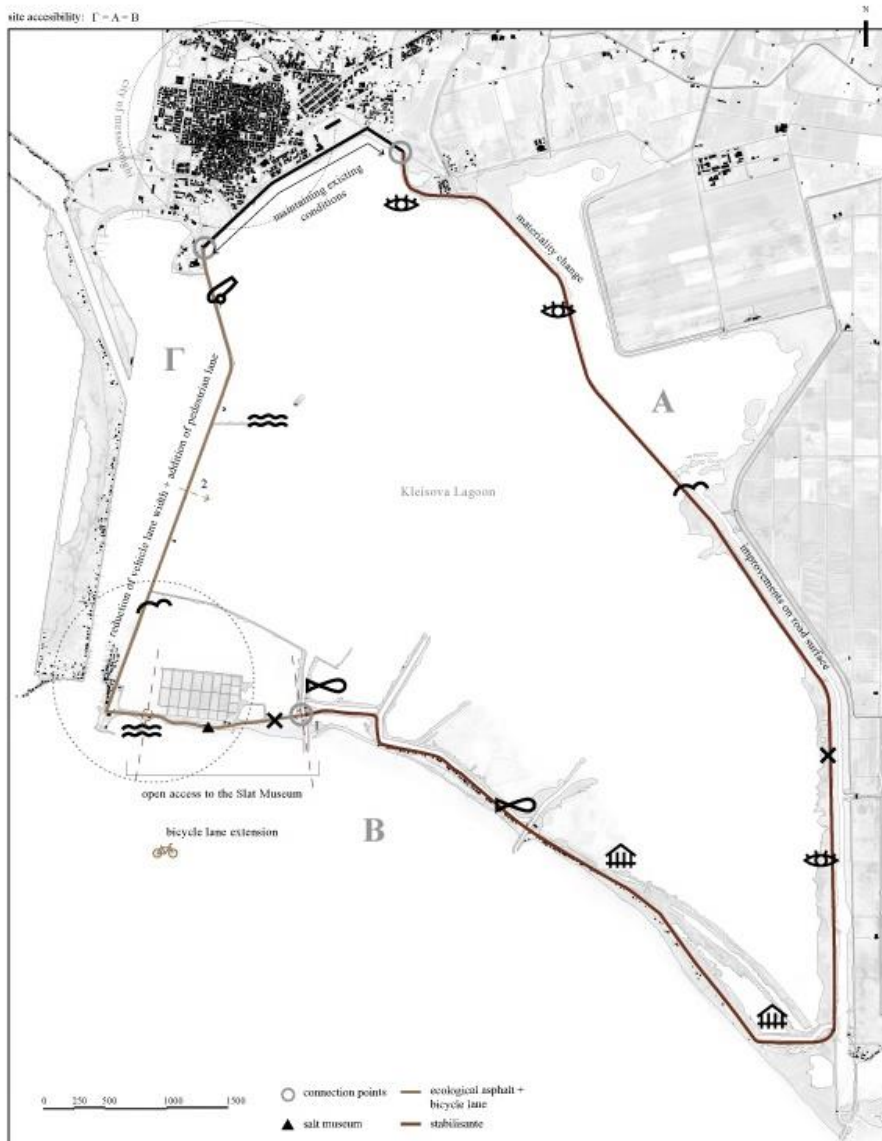

Figure 6. Masterplan of intervention.

4.1 Methodology and Context interpretation

The primary goal of the design process was to consistently refer to the findings and insights gleaned from research, allowing them to guide each decision and action. Therefore, every step taken, and choice made was based on the results of the area analysis.

Concentrating on the second level of intervention, the selection of content and functions for each pavilion was determined by considering the four themes of Messolonghi's identity, conducting literature research, interviewing and consulting local authorities.

Additionally, the specific locations for each pavilion were determined through a synthesis of all the mapping data generated during the site analysis, supplemented by individual field surveys for each designated point. For instance, the bird observatory was strategically situated in areas with a notable concentration of bird fauna (as highlighted in the bird fauna map) while also offering extensive visual coverage of the lagoon. Similarly, the history pavilion was positioned in close proximity to the town of Messolonghi and two sites of significant historical events during the revolution (as depicted in the landmarks map). As for the productive identity pavilion, its placement was guided by proximity to fish barriers and existing hatcheries, as indicated in the fish fauna map.

Proceedings

For the composition of the pavilions, the concept design prioritized the development of an innovative synthetic tool – an adaptable, flexible modular system that could be restructured and recomposed to produce buildings of different shape, type and use. This approach was intended to address the distinct needs of each typology and provide suitable variations while maintaining a cohesive aesthetic along the route. Additionally, adherence to the prevailing legislative framework, which stipulates the use of lightweight construction techniques rooted in traditional regional practices, was deemed essential to ensure seamless integration with the surrounding landscape.

Having in mind the above, drawing upon references from the traditional dwelling emerged as the most fitting strategy, not only offering a structure that harmonizes with the delicate environment of the lagoon, but it responding to the local heritage.

4.2 The traditional dwelling – the *pelada* of Messolonghi

Part of Messolonghi’s rich traditions related to the fishing culture was the development of traditional dwelling techniques inextricably linked and adapted to the ecology of the area. The “*pelades*” of Messolonghi, situated around the lagoon, served as homes for fishermen plying their trade in its waters. These structures are constructed as timber huts on poles, elevated above the water on a foundation of poles (timber originally, now of concrete), in a 50x50cm grid, ~10-20cm in diameter with a total length of around 2.50m. As a measure against fluctuations in water levels due to tides, a distance of about 1.00m existed between the water level and the floor of the building. Upon these poles, beams measuring 8-10cm were positioned crosswise to support the floor. The typical roof of the *pelada* was double pitched, reaching a height of approximately 3.0m from the floor, and housed also a peripheral corridor known as the “*lotza*,” which maintained an opening allowing the fishing boat to enter the structure. The wall structure was made of timber too. Materials for construction were sourced from the surrounding environment, with chestnut or cypress wood commonly used for the structural framework, while reed, water cane, rushes, and seaweed for the filling and the covering of the walls.

Today, the *pelades* have taken the form of holiday summer homes for the locals and have been renovated to meet modern needs, while maintaining some of their traditional character. Although their number has decreased significantly compared to the past, there are still some actively used by local fishermen. Examples of modern materials incorporated in their construction is the use of concrete for the formation of the poles and the use of tin metal sheets for the covering of the roof.

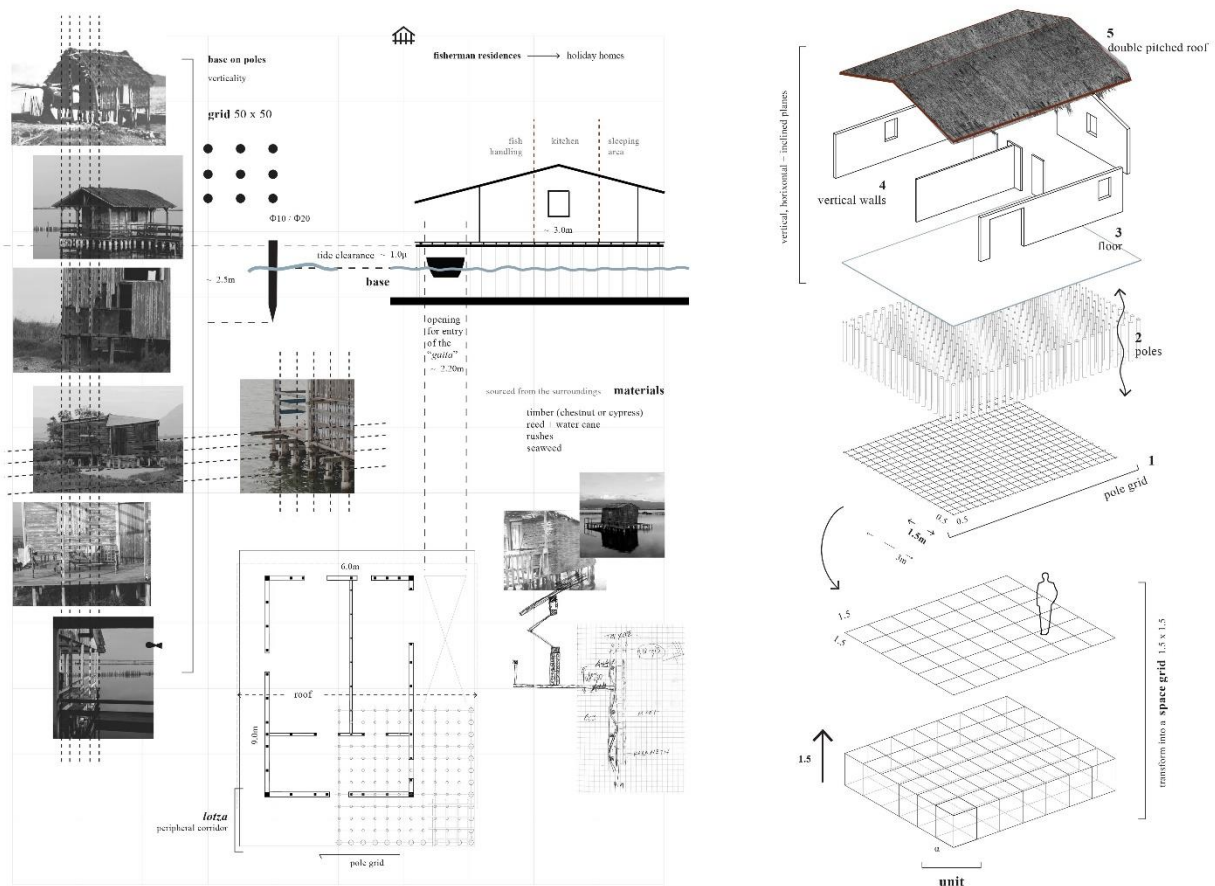

Figure 7. Analysis of the traditional *pelada* of Messolonghi and deconstruction to its defining elements to acquire the unit of the modular system.

4.3. The Modular System: an innovative synthetic tool

In an effort to interpret the local architectural vocabulary, the deconstruction of *pelada* of Messolonghi into its defining elements provided the components of the system that was searched for in concept design. Elements such as the double-pitched roof, vertical walls, floor, poles and the 50x50cm construction grid were isolated and recomposed to form a contemporary iteration, paying homage to the original *pelada* while incorporating modern touches.

Recognizing the grid of the poles as a crucial feature of the construction, it was then adapted to a habitable size of 1.5x1.5m and transformed into a space grid. This space grid serves as the fundamental unit of the system and can be multiplied to create various forms and structures tailored to specific requirements. The design vocabulary also includes vertical, horizontal, and inclined planes, which are freely positioned within the rigid space grid to accommodate diverse uses, needs, and spatial qualities.

Figure 8. System Vocabulary: Unit (α), multiplication and divisions and horizontal, vertical and inclined planes

This modular approach allows for numerous compositional possibilities while ensuring cohesion among the different pavilions. The 7 typologies that emerge constitute 7 snapshots or possible combinations, that were considered to serve the purpose of a complete and integrated proposal. Thus, the intervention has an experimental character and a flexibility on possibilities, providing a pilot proposal for the management of the site.

In this endeavour, the synthetic composition and structural concept were developed simultaneously, to design a timber frame that balances historical references with adaptability, flexibility and landscape integration. Timber beams and posts materialize the space grid that derived from multiplying the base unit. The posts are extended, where necessary, becoming the poles for the foundation of the buildings, either in the ground, or the water leaving the environment almost intact, since minimal interventions are required for the proposed constructions.

Figure 9. The Modular System: Synthetic principle (left) and constructive principle (right).

In all the proposed pavilions, there is an emphasis on the vertical axis. In forming the facades and providing support to the timber frame, a grid subdivision of 50x50cm was used. The vertical timber elements as if they were growing organically from the ground are mirroring the vegetative forms found throughout the landscape, including fishermen's dams and natural reedbeds. The natural aesthetic is further accentuated by the use of uneven timber blinds, strategically placed around the

Proceedings

structures. These blinds are arranged in clusters of varying distance between the posts, offering shading and additional privacy where needed.

4.4 The pavilions

The bird observatory is developed vertically, supporting the supervision of the area from above and facilitating birdwatching. The space is organized into successive levels around the core of the structure, creating a path culminating in an upper "balcony." The subdivisions of the grid become denser on the sides of ornithological interest, forming two more "closed" facades as observation walls. The entry axis remains open, allowing for an extensive view of the landscape. An intermediate level is designed with seating, framing the view through a wooden structure. ***In the reed area, the structure is designed so that the planting extends in the interior, attempting a direct dialogue with the natural environment.***

Figure 10. The bird observatory.

The viewing pavilion is designed as a stop for visitors to pause and absorb the beauty of the surrounding landscape. The incorporation of QR codes adds a layer of depth to the experience, allowing visitors to engage with literary and poetry works written or inspired by Messolonghi. The experience of reading the texts allows visitors to emotionally and globally connect with the scenery providing a transcendental sense of the landscape. Similar to the observatory, the pavilion features different levels, offering opportunities for rest and contemplation, ***enabling visitors to appreciate the landscape from multiple perspectives.***

Figure 11. The viewing pavilion.

The history pavilion is designed as a historical journey with successive levels and alternating covered and open spaces. As visitors progress through the pavilion's multiple levels, they experience a dynamic narrative, from the pre-revolution era to the Exodus of 1826 and the events that followed. The spatial layout mirrors historical context, with each level representing a different phase of Messolonghi's history. Unlike the other pavilions, it features a recessed enclosed cube symbolizing the tumultuous events during the Greek War of Independence. *At the heart of the cube lies a void, establishing a direct connection with the water and symbolizing the pivotal role it played in shaping the city's destiny.* As visitors ascend to the upper level, they reach the climax of their journey, experiencing a sense of liberation and panoramic views of the surrounding landscape. A literal "exit" from the cube, as an allegorical reference to the heroic Exodus. The descent to the final section of the pavilion explores the aftermath of historical events.

Figure 12. The history pavilion.

The accommodation pavilion supports overnight stays in a camping-style setting for nature enthusiasts, students, academics, and observers alike. The unit includes 2 sleeping areas, auxiliary

facilities, and common areas. At the entrance, it features a gap in the grid for the passage of the traditional fishing boat, yet another reference to the traditional fisherman dwelling. **At the center of the structure, an internal water core is created, providing a breath of fresh air and a connection with the aquatic element.**

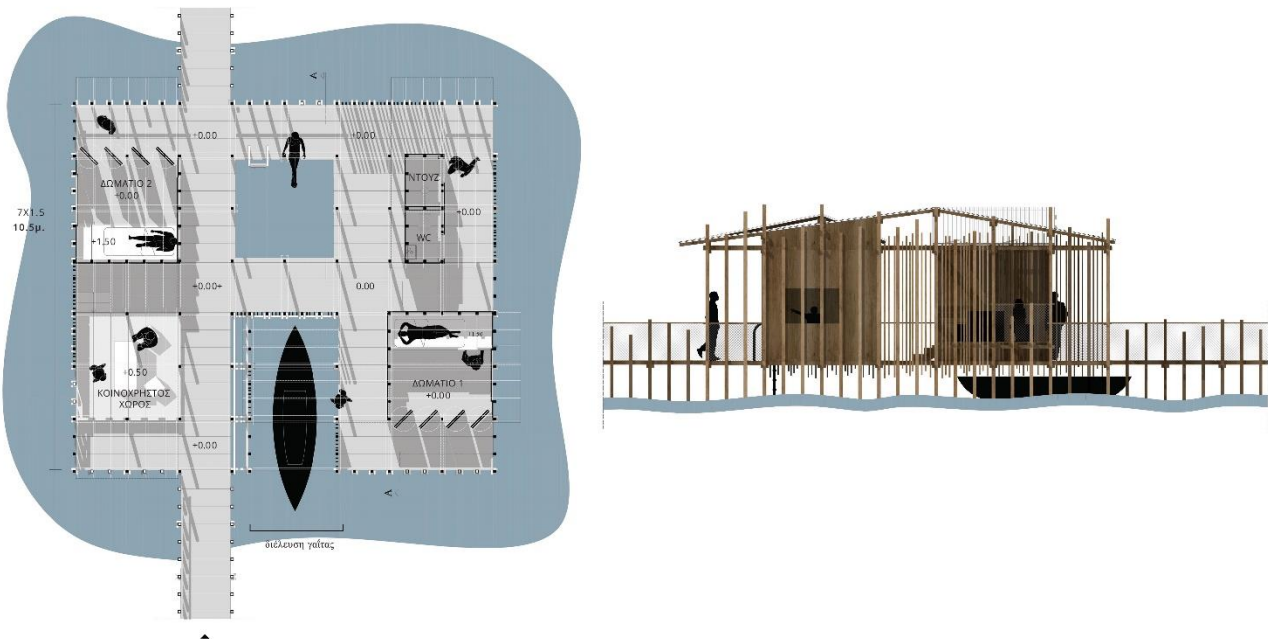

Figure 13. The accommodation pavilion.

The auxiliary bathing facilities offer basic amenities to serve beachgoers, as stated in relevant legislation. The layout of the pavilion is divided both literally and functionally by the entrance axis into two sections. On the left side, all the facilities such as toilets, changing rooms, showers, and lockers are found. Meanwhile, the right side features levels at different heights, serving as relaxation and sunbathing areas, some of which are covered by the double pitched roof, while others are not. **In the centre, there is a water core for swimmers, making the aquatic element an integral part of the pavilion.**

Figure 14. The auxiliary bathing facilities.

The production identity pavilion stands adjacent to the bustling activity of local fish weirs, offering insights into traditional fishing practices and the life of fishermen. Divided into two sections, it in

meant to educate visitors about both fishing techniques and the production of roe. With its open-plan layout, the pavilion encourages a seamless flow of exploration, allowing visitors to engage with informational exhibits and demonstrations. *Again, a gap in the structure pays homage to the traditional pelada.*

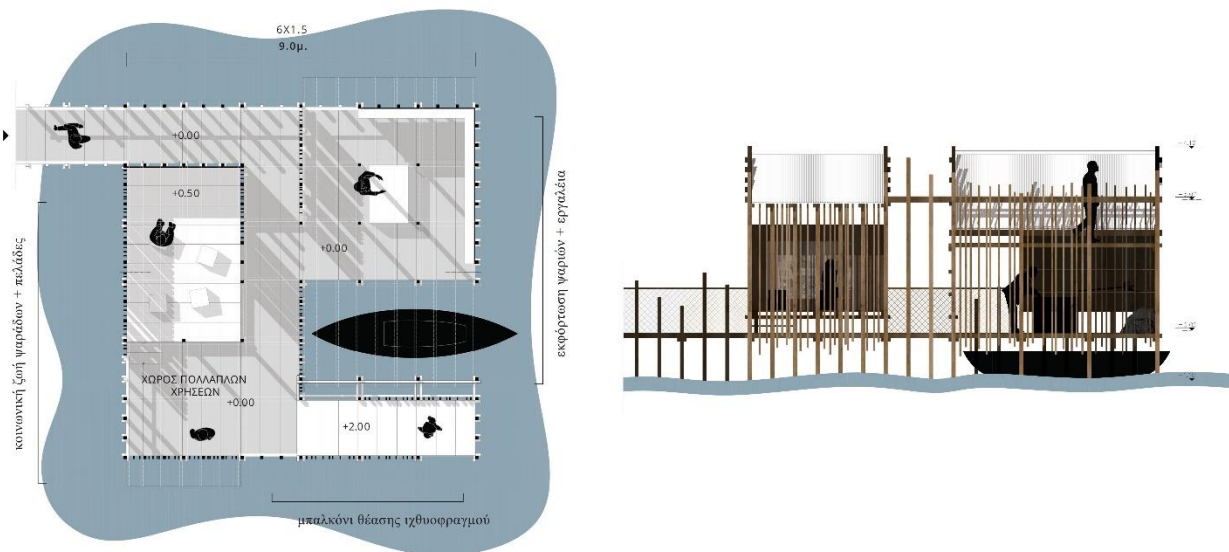

Figure 15. The production identity pavilion.

Lastly, the service station is separated in two units positioned on either side of the road. On the left side of the structure, there's a refreshment area, featuring a sheltered vending machine and outdoor seating. On the right side, restrooms facilities are located.

Figure 16. The service station.

4.5 Structural System

The studied typologies feature timber structures on poles that reference the traditional *pelada* while incorporating flexibility, adaptability, reversibility, and landscape integration. Timber, being a sustainable and natural material offers many advantages in terms of its environmental footprint (negative carbon dioxide emissions, minimal embodied energy, and ease of recycling and reuse). In keeping with the principles of gentle and reversible interventions, timber structures designed accordingly from the beginning, can be disassembled and reassembled, or their components can be recycled and reused in other constructions.

Proceedings

In designing and selecting the specific structural system, the economy of construction was an issue of high consideration (low cost, easy and quick construction procedure). The structures obey the main principles of ADISA (Assembly for Disassembly), while the dense arrangement of the columns due to a specific grid allows the use of small cross-sections which can be easily found in the market. Metal bolts are used to connect the beams with the columns, creating a typical joint that is easy to assemble and disassemble. In all timber elements, natural durable species of wood is proposed (chestnut or cypress wood), echoing the same materials found in the *pelades*.

Figure 17. Axonometric views of the pavilion models (from left to right: bird observatory, viewing pavilion and on the bottom the auxiliary bathing facilities).

More specifically, in the vertical dimension, the pillars-poles are arranged according to a construction grid of 50 to 150 cm and at their lower part are connected to screw-shaped metal galvanized poles, specially treated for water conditions. This solution was chosen over conventional concrete poles for their reusability. Horizontally, all beams are double on the interior of the buildings, facilitating a connection to the posts without any metal plates (timber-to-timber connection with a metal bolt). On

the exterior, the beams are single in order to maintain the continuity of the vertical elements of the facade. This deliberate choice serves as a key architectural element, referencing the verticality of the surrounding landscape. The roof covering consists of galvanized tin corrugated metal sheets (a reference tying together the old and the new *pelades*), laid over plywood sheathing which is used also for the flooring. Finally, in areas of the structure requiring protection from falling, timber railings are reinforced with netting, are serving as an additional nod to the fishing tradition.

Figure 18. Typical axonometric sections of the structural system of the pavilions.

5. CONCLUSIONS

Contemporary architecture is moving away from the invasive and environmentally hostile designs of the past century towards approaches that harmonize with the environment and honour the cultural and historical context of a place. The concept of *genius loci*, or the spirit of a place, is crucial in achieving this harmony. It helps in creating architectural designs that are responsive to and integrated with the unique physical, cultural, and historical aspects of their surroundings. ***More specifically, waterscapes significantly influence the genius loci of an area. Their appeal goes beyond aesthetics, playing a vital cultural and political role in defining the identity of coastal and earthly landscapes. Messolonghi emerges as a prime example of a city where the waterscape, specifically the lagoon, is integral to its identity. The lagoon is not just a feature of the city but embodies its essence, influencing every aspect of its character.***

This paper intended to analyse the diverse components that comprise the city and its surrounding environment, focusing on historical and socio-spatial features that contribute to its unique essence.

In conclusion, the paper underscores the importance of contextually responsive architecture by proposing a project-oriented approach to the methodology of reading, interpreting, and intervening in the identity of a specific location. Through a detailed analysis and case study in Messolonghi, the proposal integrates physical, productive, historical, and intellectual themes into a sustainable and reversible intervention that respects and enhances the local spirit. The innovative modular system introduced provides a flexible and uniform solution that harmonizes modern design with traditional

architectural elements. By creating seven typologies of pavilions, the proposal offers an experimental and versatile approach to site management.

This work exemplifies the potential of sensitive architectural interventions that are sustainable, culturally attuned, and deeply rooted in their unique contexts, encouraging a shift away from mass-production towards more meaningful and responsive design practices.

An additional conclusive comment: Neither architectural function and construction, nor symbolic architectural references may be neutral to the landscape context, to their natural environment and to their cultural landscape references as well.

Abstract

Contemporary ecological theories reinforce the philosophical context of the twenty-first century with the Anthropocene theory, in which man is defined as the most important influencing factor of territorial transformations. The human-nature dichotomy is critically analysed as the formations of aquatic and terrestrial landscapes are interpreted as an extension of corporeal anthropogenic actions (Crutzen, 2007). The current study attempts to investigate the forces exerted on aquatic landscapes alongside the reading of corporeal expressions of eroticism as interrelated phenomena shaping dynamic cultural and territorial assemblages.

The research proceeds from the analysis of the narrative of Cretan folklore that refers to the metaphysical parameters of the creation of Lake Kournas in the prefecture of Chania, Crete. Attributes of erotic desire and bodily freedom are interwoven with the expansion of territorial boundaries, as a natural quality that characterizes water flows, in an attempt to meta-narrate the myth through conceptual approaches to landscape, body and eroticism.

The second section introduces the issue of the restriction of seascapes-ecosystems as a consequence of the expansive practices of the development of modernity alongside the limitation of sexual expression. Instrumented by the concept of double-articulation, de-territorialization - re-territorialization, a comparison is made between the characteristics underlying deep sea mining practices and the rational formalization of erotic desire. The ocean depths are undefined, unexplored landscapes, as amorphous as the space produced by the attraction between bodies, the space that tends to be shaped by erotic desire.

Keywords: *aquatic landscapes; corporeal expressions; eroticism; erotic desire; double-articulation; deep sea mining;*

1. INTRODUCTION

The narratives of Greek folklore, as well as mythology, incorporate a variety of cultural and territorial coordinates as well as multidimensional approximations of geological transformations. As an assemblage of metaphors, myth constitutes a mutable space of constant conceptualization, raising questions about the boundaries set by symbolic systems.

2. RE-SHAPING KOURNA'S LAKE MYTH

The verbal narrative related to Lake Kournas describes the adulthood period of a resident of the settlement, during which she turns into an object of erotic desire. Helping her father out with the farming labour, the narrative climaxes as he approaches her sexually and threateningly one day while she was brushing her hair. In her attempt to escape, she invokes to water deities to transform her into liquid, shouting "Voula and Voulolimna, and I haunt the lake." Her hair is transformed into meandering river flows, the material boundaries of her body are ripped open, the waters that pour inexhaustibly from within flood the valley and crush the settlement, composing the body of the lake. The viciousness of this bodily transformation constitutes a metaphor for the assertion of somatic freedom intertwined with the urge to redefine erotic desire. The thresholds of the female body of the myth are interpreted as the contours of erotic desire shaped by the social context of the time. At the

Proceedings

same time, water, as the ruling force of this liberation, acts as a unifying factor of the inorganic and organic forms of the landscape. The clearly defined agricultural lands and buildings of the settlement are transformed into a dynamically shifting landscape capable of embodying the complexity of its coordinates, a landscape in constant motion. The merging of water with the body softens the edges of the skin, revealing its capacity to expand and connect with other bodies,

“Skin is our border with the world, but it is a leaking boundary. [...] Our bodies do not end with our skin, just as islands do not end with the outer perimeter of the land.” (Johnson, 2022: 5)

The recontextualization of the myth creates grounds for reconsidering issues that arise in the present geological era, which are related to the limitation of aquatic landscapes.

3. READING FLOWS, FROM OCEANIC TO EROTIC SPACE

In the post-industrial period (after the 19th century) geological changes are characterised by a Great Acceleration (Crutzen, 2007), as the needs of human habitation increase. A wide range of cartography, depicts waterscapes as an inversion of the terrestrial terrain, with a lack of mobility. Rivers, lakes and seas are presented as forms completely controlled by contours, engravings inscribed as other urban planning grid lines. The one-dimensional blue entity that represents the aquatic landscapes constitutes an articulation of this 'other', a form of geopolitics whose main focus is the study of the planetary landscape as a mechanism of economic development of globalized capitalism (Latour, 2017: 40).

Ecological degradation, based on the ecosophical view of the philosopher Felix Guattari, constitutes an interconnection of three interlinked ecologies: mental, social, and environmental. In this context, the deterministic approach to territories by the practices of modernity is intertwined with the rational determinations of cultural elements, a condition that affects erotic desire as a factor in shaping subjectivity. Guattari, in collaboration with Gilles Deleuze in the text *A Thousand Plateaus*, develops the theory of the double articulation, de-territorialization - re-territorialization, as a method of analysis of multiple phenomena, biological, geological, social and psychological. Based on Deleuze Guattari's theory, capitalist practices develop through the territorialization of the entities that coexist in the planetary landscape and the social realm, constructing solid and invariable subjectivities. Territorialized geological analyses compose the vision of totally controlled geographical areas, expressing stability and order as the basic principles of globalized capitalism. At the same time, this practice produces distinct and stable social structures, which are related to erotic desire, composing roles and norms that regulate social expression. At the opposite end of this categorization, double articulation refers to a constant movement between the undoing of existing structures and their reconceptualization, creating new structures, a productive process that can be observed in all entities and systems on earth.

The endless practices of mineral extraction are rapidly highlighting the exhaustible limit of energy reserves, while the rhetoric that is being developed is constructing the argument of the expansion of depleting landscapes as an unavoidable condition of human survival. In particular, the case of Deep Sea Mining [DSM] emerges as a new "blue economy" (Childs, 2022: 1), maintaining the central pillars of the pre-existing "green economy." The key difference between the two conditions can be found in the ecosystems referred to and the way they are presented in scientific studies. DSM is applied on the seabed, a landscape distanced from human habitation. However, descriptions of this system follow a direction of technomorphism and anthropocentric storytelling by identifying it as a place where nature 'appears inactive: ready to be sliced and packed for extraction' (A. Tsing 2003: 5100). The complexity that characterises assemblages at these depths is altered through the incorporation of homogeneous categories into their descriptions. The purpose of these descriptions is to territorialize the assets of these assemblages, considering the seabed as a resource-generating industry.

«the geological vitality of the seabed and its unfamiliar attitude towards human experience open up a very specific set of challenges to the imperatives of capital accumulation.» (Childs, 2022 :1)

Proceedings

Beyond anthropocentric narratives, the seabed constitutes a complex synthesis of biotic and non-biotic dynamic systems, in which the influences of urban landscapes are registered.

«Regulations for deep-sea mining require protected recovery areas to be created next to the mining areas. The environmental impact is supposed to remain local. The boundaries are clearly defined. But the impacts of mining move with water currents and sediment displacement, and the organisms are part of a larger, deeply interconnected ecosystem». (Hessler, 2022: 3)

According to Deleuze & Guattari's theory, the seabed is an assemblage, with the internal forces pushing it into constant transformations. Similar qualities are observed in the erotic space, as described by the classicist poet Anne Carson. To Carson, eros is a synergy of three entities, the lover, the beloved and the difference between them. This in-between, which she defines as absence, is the space where desire evolves. It is the space that evokes love as "postponed, defiant, obstructed, hungry, organized around a radiant absence" (Carson, 1988: 166). A space undefined and ever-changing that maintains the differences of each body encapsulated in it, while enhancing the difference of their behaviors.

The erotic desire for Carson is reinforced through multiple de- and re-territorializations, while at the same time maintaining the interlude of the double articulation, constantly producing multiple differences. This condition expands the boundaries of the erotic, allowing it to occur in encounters between human and non-human bodies, land and water, as well as on a planetary scale. The explicit definitions of erotic and oceanic space, as an outgrowth of the distancing from alterity in the post-colonial era, prevents this openness of erotic desire, as the material and immaterial meanings produced in these spaces pose a threat to the maintenance of order and homogeneity in globalized capitalism.

Returning to the reading of the Lake Kournas myth, water, in the form of bodily fluids excreted, is observed as a unifying factor with the surrounding entities of the landscape. The young girl of the narrative is becoming a lover, while the figure of the lake conveys the notion of beloved. The process of transformation of one body into another is what Carson defines as the reaching of erotic desire, a condition of mutually transgressing the boundaries between all the actors of the assemblage, but at the same time maintaining their differences. As the thinker Stephanie Hessler states in her book *Erotic Ocean*,

“Eros makes my desire to dissolve my boundaries, but at the same time it depends on those very boundaries and the realization that my boundaries will never be completely dissolved.”

As you can see, the survival of the human species is directly dependent on the survival of marine ecosystems. Distancing oneself from the seabed expands the ambiguity of this in-between of absence, intensifying erotic desire, what Stephani Hessler calls "oceanic eroticism".

“An oceanic eroticism can bring us closer to bodies, including bodies of water. My desire for the ocean knows that I can never fully grasp it and that its edges shift, like those of the shallow ones. But eroticism does not need to know a finite body to desire.”

It is the same erotic absence that creates a new ground of associations of human bodies with the many different entities that constitute the ocean, as opposed to the approaching of these bodies through the consumerist associations of an imperialist policy.

“Other bodies pass through me, but where I long to be one with the ocean, we remain separate. This erotic absence marks the unique relationship between me and the many bodies that make up the ocean. At the same time that I am being squeezed into it, the ocean is being squeezed into me.” (Stephanie Hessler, 2022: 7)

Katsanevakis E., (2024), *Garden of Hydro-Eroticism*, Mixed Media

3. CONCLUSION

According to the new Materialism, water and the body as materials are not inert substances, but rather spaces of vivid operations where meanings are assembled with material dynamics (Iovino, 2005: 16). Matter has agency and is imbued with meanings, thus each material formation constitutes a narrative landscape, and therefore can be subject to critical investigation of its interactions, its position in a world full of both expressive and narrative forces. The preservation of these in-between spaces, the erotic and the ocean floor, constitutes a practice that goes against the imperatives of modernity, in the attempt of a perpetual creation of differences, meanings and narratives. Such a method, applied to the study of multiple phenomena occurring in the planetary landscape, is capable of restoring the multiplicity of our associations with other bodies. To synthesize an expanded narrative of coexistence with otherness.

Abstract

Extending my focus on waterfront urbanization from past Changing-Cities participations, here our projectile for Chalon Sur Saône (central-eastern France) studies the objective of ‘domesticating’ an infrastructural node experientially, as to regain an environmentally operative riverside landscape. The industrial *Port Nord* site lies in close proximity to the historic urban nucleus, offering a unique case for applying broader regeneration strategies over multiple phases of intervention.

“Constructed Wetlands” explore the presence of freshwater from adjacent ponds and Saône riverbed, as well as excessive rainwater runoff from extended roof-scapes on-site. Implementing new ‘zones’ as man-made water flow networks, is prioritized here under the intention to eventually re-develop land and soil for taller vegetation while recovering ground toxicity hotspots. Main conceptual attribute is thus an incorporation and re-evaluation of organizational patterns originating from cargo handling processes into formal derivatives.

Here, infrastructural operation protocols become transposed as re-elaborated strata of intellectual potential. Most representative feature addressing this directive, the semi-elevated scheme of re-configurable cargo-containers, is re-imagined as residential shelf-system. Mobilization patterns and cross-connectivity between lake-edge and riverbank become primary elements of visual directionality. Notions of mobilization, impermanence and a furtive pledge of recovering the formerly rural site to a previous stage of natural existence, formulate urbanization dynamics. And yet, the visual manifestation of an industrial port is not simply its established and past memory on-site, but also the present – and potentially future – status. At all phases of re-development, from the least densified nascent stages already, the cargo harbor would still be fully operable, regardless if the river frontage would eventually be overtaken by housing and urbanist vibes – even if stockyards would transform from hard-paved expanses to soft-scape.

The *Port Nord* urbanization scheme was developed as an international competition scheme in collaboration with colleagues Lucas Correa (Ecuador) and Peter Glasson (USA) during their student years with my team-leadership and was recognized as pre-selected among almost one hundred entries, while this text was written by the author.

Keywords: *riverfront landscape, phased brownfield urbanization, waterfront regeneration.*

1. INTRODUCTION & PLACEMENT: ORGANIZATIONAL PROTOCOLS

This formerly European 8 competition site in central France is located at the outskirts of the historic city of Chalon sur Saône. The intervention area, *Port Nord*, is a typical central-European no-man’s-land waterfront, a derelict logistics sector appropriated by industrial activities and transportation circuits; a territory hostile to human habitation amidst a surrounding antithetical context of physical beauty. The experiential objective of domesticating and inhabiting the industrial port and regaining a riverside environment is achieved through multiple layers of intervention as outlined in this outset and analyzed minutely in following paragraphs. The main tectonic approach establishes clear associations and visual references to harbor life. All operating and re-used – currently abandoned – gantries and cranes, industrial warehouses, and silos – preserved and renovated to work as large-span enclosed venues – keep a visual lineage with the previous state of existence on-site.

Figure 1. Chalon sur Saône, intervention area, *Port Nord*, with phased master-planning scheme.

Concrete cubical blocks become a primary landscape element allowing for a range of experiential feats: combining hard-paved river edge with elevated metallic tectonic forms generates a context for the ‘harboring flaneur’ through the seemingly randomized block-scape. The generated broken, or defragmented, river edge becomes exploratory for non-cargo activities. Offering a mutable environment for direct individual interaction with the waterfront this segmentation responds to practical issues of extreme water level fluctuation. This man-made river edge may be reborn daily in response to volumes of high-current water coverage thus allowing variable projections over the water surface. Long-term erosive sculpturing by the fast-moving waters of Saône ensures here for additional effects: varying water sounds, waves crushing onto the blocks, small boats or canoes discovering quasi-naturalistic havens safe from the current and accessible by the more adventurous pedestrians. The artificiality of this hardscape keeps clear the connotations of a harbor edge.

2. NAVIGATIONAL PATTERNS AND AQUATIC FORA

Mobilization patterns and cross-connectivity between the lake edge and the riverbank becomes a primary element of visual directionality. “Randomly” positioned cross-routes, thinned strips of landscape along straight lines connect the river to the lake, providing a sense of visual clarity and control for the newcomer [user, dweller or tourist]. Even from the ground level and at any time, and any point, there is a sense of total overview of the circulation options, the potential destination points, and the intriguing urban moments.

The series of warehouses and silos at the edge of the site towards the bridge will be preserved as to accommodate cultural events and community needs at large; such as the boat transportation node, a low-profile ferry terminal, an info center, along with a plain foyer-type space, or communal gathering spaces for athletic groups [cyclists, runners, water sports addicts, etc.], and perhaps basic services [post, bank, etc.]. There was a clear intention to avoid the implementation of “design object” buildings along the harbor lines. Such a particular design approach was judged as outdated and banal [a designer

Proceedings

trying to design disparate building forms]. The choice for the re-use of the existing buildings reinforces the inhabited port effect, saving resources [financial and material] while allowing the overall urban scale proposal to read as a strategic plan rather than as a fragmentary design exercise in formal hedonism.

The notions of mobilization, of impermanence and the secret promise of recovering the site to a previous stage of natural existence, form the dynamics of the project. On one hand the attempt for an exhilarating visual imagery is obvious, on the other hand the site is treated with great sensitivity at an environmental level, dealing with aspects of sustainability and recovery that have been of great importance in the development agendas of local authorities. Chalon sur Saône has demonstrated a significant record of attention to environmental issues, and the Port Nord site becomes the ultimate epicenter sampling the future of the city.

3. ENVIRONMENTAL SAMPLING – SECTIONAL FLUX

Clarity of organization was central for site planning. Landscape horizontality is accentuated with the straightforward placement, parallel to riverbanks, of strips representing isolated aggregates. From the lake towards the river, the natural [in recovery] landscape, is progressively transformed to man-made green patterns, and then becomes a tectonic, solid, hard-scaped zone by the riverfront. A visually fascinating spectrum of landscaping types combines what one would call odd juxtapositions: corn crops, biological agriculture, communal gardens, forest strips, hedge/park zone. This uncanny coexistence of the above entities is conceptually interwoven through the soil sustainability goals. A primary landscape pattern of parallel strips of diversified vegetation densities acts as a tight environmental infrastructure, a steady and strong condition of reference, a striated plateau upon which the more point-like or line-like urban relations occur.

The current height of the concrete wharves forbids any interaction with the river water at a pedestrian level and forbids the accommodation of small boats used for transit to downtown, for small cruise-ships, or medium-size private vessels. Reflecting the concept of defragmentation / decompression, the uniform artificial plinth of the wharves is broken down into individual rectangular solid blocks organized in an orthogonal system for placement [in plan] and varying in height in section. A gradual randomized stepping configuration emerges, as a challenging landscape feature, inviting the pedestrian urbanites to walk from one block to the next, allowing contact with a water in a variety of ways: feet splashing in the water, to diving, fishing, swimming etc.

Relation of these individual platforms to the water and pedestrian contact with the river is in a state of constant flux, depending on the water level and the season. In this way, the issue of the fluctuating water level is no more an inconvenient factor of unpredictability, but transforms into a parameter of mobilization, of constant reconfiguration of the waterfront, with some blocks being for periods of time underwater and during other seasons above water.

A sense of personalization immediately emerges, as dwellers, visitors or urbanites are potentially expected to develop emotional preferences with individual segments/concrete blocks, reinforcing a sense of personal identification with the waterfront.

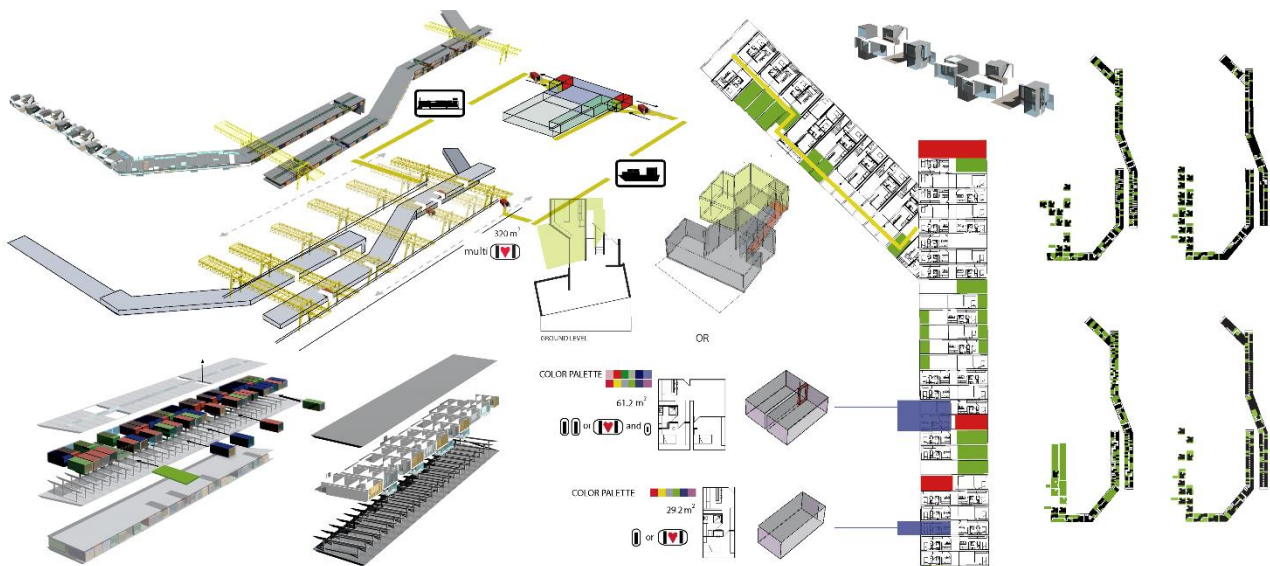

Figure 2. Movement and place-making of high dynamism are defined through surfaces or axes.

The concept of braking down wharves into segments with randomized sectional configuration relates further with the accommodation of smaller boats and medium-size vessels. By eroding the current, highly linear and austere artificial edge, individual smaller canals emerge, controlling the issue of high current of the water, and allowing smaller boats to tie up to the shore, and engage visually into the energized waterfront environment.

This multiplicity of interaction levels with the water relates to the common French strategy of having two riverfront conditions: a lower bank for strolling, allowing direct contact with the water, and a second upper edge, at the city level, dealing with extreme flooding scenaria. The condition is common in Paris, with a more serene and pedestrian-oriented riverbank and an upper bank, responding to the urban energies of the city.

4. MARITIME HYDRO-SCAPE: HYDRA-CITY: HYDRO-POWER

Water current high of the becomes a fascinating feature, promising on one hand a constantly active water edge, with waves eating up the solid blocks, generating an environment that addresses all senses: sound [water hitting the concrete blocks], smell [moisture and evaporating water], vision [a lively artificial beach condition]. Because of the high current, water can circulate and renew within deeper canals/patches/recesses that eat up into the land generating more isolated water hubs.

The new urban amalgam is generated by merging the concept of the paved urban plaza with the waterfront condition. This landscape is expected to act as a very desirable destination allowing a number of sports activities to find departure/arrival hubs. From water ski, rowing, or even surfing to swimming, fishing, diving, the urban zone is expected to trigger the interests of everyone by focusing on physical activity beyond age barriers. Diverse zones for everyone are included: bathing/swimming for the elderly, extreme sports for the youngsters, and for the family-oriented a water educational locus allowing the kids to familiarize themselves with water experience.

A potential incorporation of hydraulic energy-producing devices becomes a more practical way of utilizing the high current. This strategy responds to the high-levels of environmental consciousness of the city, and belongs to the sampling of environmental strategies that animates the site, promoting an educational agenda that focuses on urban ecology. [introducing more energy production strategies on-site].

Figure 3. Cranes and stepping blocks emanate a sense of stage-like theatricality, an urban forum.

5. CONTEXTUALIZED PHASING VS. ADAPTIVE TYPOLOGIZING

It is expected that the proposal will operate well even with the lowest of building density. In effect, the landscape and site concepts could work even with no new buildings. Beyond this assumption, a number of density patterns have been considered through a timeline.

Phase A: The existing gantry is used as a suspension device for an ultra-long housing strip, elevated from the ground, and supported on pilotis in one end, while turning vertically to merge into the ground at the other end. Beyond the pilotis the strip extends across the site, reaching the flood-plane, where it turns again parallel to the riverbanks, defining a dispersed development. The housing strip structure, typologies and attributes are defined separately in individual paragraphs.

Phase B: A new gantry is installed on-site, regaining the status of an operating cargo port. The primary function of the gantry is to move, relocate and position housing units along linear elevated strips that develop along the river frontage. A C-shaped waterfront development defines the site, expecting further infill growth.

Phase C: More perpendicular strips of housing develop, not associated with gantries at this stage. The typology of the habitable elevated strip becomes a primary tectonic feature of the site. These are potentially overlapping with the earlier strips, and merge with the ground. The trusses turn vertically to stop on the ground in many cases. In parallel to the continuous strengthening and growth of the streets, it is expected that a second urban zone will grow in parallel to the river, focusing on services, always associated with the immediately adjacent landscaped strips, and conforming to the transverse connectors. The potential of the urban boulevard gains strength at this third stage where businesses and professional space starts to be at higher demand.

The existing gantry is utilized as a bridging structural device that supports single-storied strips of housing through suspension. The existing gantry is expected to stay out of its original use and will be permanently attached to the ground. Through simple structural reconfigurations, the gantry will serve as main structural member of the underlying yet airborne housing strips. This incorporation of the harbor infrastructure into the housing scheme accentuates the attention and the overall focus on maritime identity, on post-industrial housing prototypes concepts.

Through the utilization of the existing gantry we were able to implement an abstract concept that would otherwise seem unrealizable: a hovering, elongated, segmented strip with slight kinks along its length in section and in plan, finds now an ideal support element: the gantry, re-emerging as an external structural skeleton is clearly of different [utilitarian] nature than the slick housing strip, therefore does not impose the problem of spoiling the linearity of the airborne housing bar.

Simply put, the same exact infrastructure that was fully dedicated to logistics in a non-habitational enclave, the industrial port, reflecting insofar notions of blunt utilization of environmental resources, can now fully service the direct needs of human habitation in a highly vibrant environment. The

container port infrastructure offers this way a lot more than a simply symbolic presence connoting the past. It embodies a sense of energetic continuity with the history of Port Nord even if there is a clear transformation of the organizational basis and of the functions incorporated.

Figure 4. Ground horizontality and elevated steel ribbons generate a certain sense of enclosure.

6. RIVERFRONT PROMENADE ACCESSIBILITY ARCHETYPES

The structural system accommodating housing strips is absolutely straightforward. A common vierendeel [4-meter-tall rectangular cage] truss allows, in cross-section, its horizontal members to extend on either side, cantilevering outwards. This truss spans from the gantry to support points connected to the ground on either end. Linear members composing the vierendeel truss are welded rectangular-section steel tubes. The horizontal surfaces of the truss are clad in steel plate, similarly to the decking concept of a boat. It is expected that the truss will be constructed in nearby shipyards and will be moved and finally welded on-site. The final cross-section is a hybrid prototype utilizing the strengths of a vierendeel truss and the lateral rigidity of a sandwich structure. The symmetrical cantilever on either side of the cross-section allows three zones to occur: thinner linear bands on either end of the structure can be utilized as circulation corridors or as private semi-outdoor shaded zone on the opposite side, the equivalent of balconies or verandas. The central zone is wider and acts as the main spatial entity that accommodates the housing units. In effect, there is a constant flux in the configuration of these spaces, and not an imposed linear holistic order. In that sense, any kind of mixture of public-use and private spaces, pulled and pushed asymmetrically in cross-section, are welcome in this configuration. It is expected that this integral organization will be in a state of constant flux responding to probabilities and statistics of real estate dynamics.

The most accentuated [visually] structural node for the elongated strips is clearly the gantry juncture, however, the other support points are equally intriguing and responsive at an urban scale. On its end, the steel-plated strip folds vertically and merges with the ground, providing a vertical circulation node. This is a major access point and simultaneously a pin-point for development and visual reference on the ground level. Towards the other side, the steel-plated strip turns in section and in plan, becoming a ramping feature, accommodating a stepping housing configuration [refer to housing analysis]. At the end of the ramp, the strip becomes again parallel to the ground [horizontal in section] and is supported by a forest of randomized columns, forming a linearly developing piloti. The pilotis become major landscape features, as the strongest shaded surfaces, accommodating functions that range from parking to ephemeral markets, to pick-nick spots etc.

Sets of outdoor stairs are embedded within the section of the gantry vertical lattice frame supports as fire egress. Occupants can be moved onto the roof of the housing strip, outdoors, and may use the ramping surfaces to evacuate the structure. The cross-sectional exposure on both sides and the linearity of the strips helps to identify and resolve fire emergencies before a larger portion of the structure gets affected.

Greatest component of the fire egress system is that the moving [new] gantry is by default the most powerful component for the resolution of fire emergency cases. The gantry serves as a giant fire extinguisher moving along the frontage of the strip and operating in all [x,y,z] axes, exactly in the same way it circulates housing units or products. Through catwalk corridors embedded within the horizontal portion of the filigree frame, and stairs within the vertical sides of the steel portal, people can be moved from any portion of the housing strips to the ground.

The ramping portions of the housing strips have a very gentle slope of 2.5% allowing convenient cargo, elderly and disabled circulation. All ages and health groups have equal rights of access and above all, equal experiential patterns of mobility. The full length of all housing strips is fully accessible by people on wheelchairs. Elevators are offered at the ends of the strips for circulation at a faster pace.

7. PROGRAMMATIC MOBILIZATION + APART-MENTALITY

Housing strips mutate progressively covering a full spectrum of housing typologies: prefabricated removable units fit for social housing allocated to persons or families of lower income for limited periods of time -therefore reconfigurable; permanently embedded units along the second segment of the strips [the ramping portion]; a rowhouse sector that stands on pilotis -establishing a first contact with the ground; a progressively semi-detached system that brakes perpendicularly the continuity of the long strip introducing voids; a detached housing zone responding to the boundaries of the original strip; then finally a morphed, complex series of buildings celebrating formalism; arriving progressively through height increase to a potentially commercial entity -of detached taller buildings. If the first reference to the industrial container port [the previous function] is evidenced through the incorporation of the existing crane to the structural concept then the second reference goes full speed: a new, fully operable crane is actually introduced, receiving prefabricated units by boat or railway [fully customizable during production] similar to shipping containers. The units are inserted by the gantry onto the elevated housing strips [the shelving system]. The units enjoy a very privileged elevated overview of the river and a variety of public use spaces on the strip. The concept is one of a linear arrangement that almost randomly fluctuates in section and varies in occupant density for different periods. This arrangement, detached from the ground, enjoys the advantages of an apartment tower configuration becoming an organizational device for a number of typologically differentiated housing entities.

A clear distinction between renter vs. Bbuyers and their relation to the site is articulated through the arrangement of highly mobile housing units away from the natural ground, and in distance from the detached housing. The nature of this forefront housing arrangement and the mobilized container strips allow for short-term occupancy by tourists and other non-permanent groups. The distinction between social housing and hotel-style accommodation merges here into one entity, allowing for intricate dynamics between members of radically differentiated social and economic standing. The wealthier leisure visitors, tourists and jet-set nomads mingle with the socially assisted locals, re-negotiating social barriers.

8. SHIPPING LANDSCAPE: BOULEVARDS, STRIP GRADATION & SLOPING CONDOS

The shipping container form appears as a series of types and becomes the prototype for enclosed spaces developed on-site. A system of distributed semi-mobile vendors [refreshments, light food and café bars] is accommodated in reformed containers servicing visitors, athletes, dwellers, tourists, right in the outdoors. There is a level of elitism that characterizes a great number of shipping container projects in the recent age, however our project is differentiated in a straightforward way: the notion of the industrial port is not simply a past memory but is at the same time the presence. The industrial port is still fully operable, regardless if the river frontage has been overtaken by housing: containers

can still be unloaded from the ships and delivered to trucks, even if the stockyards have transformed from hard-paved expansions to a green landscape.

Knowing that there would be high demand for the high-view apartments, a second, less frontal section of the strips is occupied by structures of a beach-house feel. Housing structures are permanently embedded into the mega structure characterized by the hybrid vierendeel system and feature more luxurious interiors. Combining aspects of outdoor and leisurely living, the tilted rowhouses feature private patios and open atria-courts. The composite welded steel roof plate is punctured to allow for sunlight to enter through. The puncturing occurs between the main structural ribs, not affecting the structural coherence of the cyclopean girder.

Similarly, the puncturing occurs on the floor plate, with small rooms occurring on a lower level, hanging below the main structure. Such bays of upward and downward protrusion are set side by side, reforming the rigid archetypal form of the container parallelepiped and exploring the sectional properties of the slope. The sectional complexity becomes a celebrated feature, suggesting the consequent further dissolution of the solid linear forms.

Beyond the ferrous gantries, the metal mega-strips find their second structural support zone on pilotis that keep the vierendeel truss approximately 4 meters above ground for a linear segment. The loads are transferred to the ground through a randomized forest of columns. This means that the upper plate of the structure becomes redundant. Progressively the roof plate is punctured away and the new structural system is “a plate on stilts”, holding a more diverse series of housing units on top. The continuity starts to erode in a sectional manner too, therefore gaps can be seen in the rowhouses series [because of the missing roof slab].

At the pilotis end, the rowhouse system brakes further and finally the detached housing takes over as a deposited series of fragments, remnants of the deteriorating steel strips on-ground. This becomes the normative pattern that allows more solid relations to occur with the adjacent spaces, enabling the development of urbanized streets and normative urbanism. The car streets front these housing and mixed-use sectors. This is the city-as-we-know-it sector that can allow for significant growth during consecutive development phases. The on-ground building lines mutate from the more conventional single-family maisonettes to more challenging building shapes that defy the already dissolved steel strip layout. As the building density and proximity lessens, a progressive change of function is anticipated, with the building typologies morphing progressively into gradually taller, volumetrically simplified structures for commercial use, offices, stores.

Two parallel roads [for private vehicle use] are introduced along the site, merging only at the two ends of the Port Nord study site, generating a clear axis of street-side urban growth. This growth is anticipated in consecutive development phases. The traffic flow smoothly merges with the newly introduced North-South axis road that connects to the north end beyond the lake. The width of the road and the conditions established at the Port Nord site formulate possibilities for intense street-side activity, fostering the evolution of an urban boulevard rather than a mere connection road or a motorway.

Main accomplishment of the urban plan is the definition of an exciting destination zone triggering movement along the north-south axis, generating a flow of people coming from the north towards the site and an uninhibited, flawless connection to the city center through multiple means of transportation: from the ferry transit, to private car routes, to cycling and pedestrian or horse-riding networks, buses, or small train [tram or trains on wheels] networks. In this sense, ensuring that the two ends of the north-south axis are strongly defined, residential in the north and leisure, landscape/mixed-use in the south [our site], the potential of progressive densification of the in-between strip can be strong, particularly because the landscape characteristics of the north-south strip of land between Saône and the lake reservoir will appear equally strong.

9. CONSTRUCTED WETLANDS: SOIL RECOVERY AND DECOMPRESSION

The industrial use of the site almost confirms the existence of soil pollution at a certain degree and perhaps toxicity hotspots. This is only a speculation relating to the nature of the cargo circulated on-site in the past. The strategic brief of the proposal includes a certain number of strategies tackling such environmental issues.

The site has been heavily paved for extended periods of time, and this fact translates into poor soil quality after demolition. The process of recovering and decompressing the densely packed soil is gradual, if implemented through natural [slower] processes. The easy solution of bringing in new soil is regarded as essentially anti-sustainable, as this soil would need to be scraped from another natural site [disturbed at a great degree] and transferred egotistically into the Port Nord site. This was not a desirable option. Instead, the slow process of regaining the soil quality could include the cultivation of low vegetation that in progressive years would enrich the soil ingredients. A series of strategies is analyzed here.

Water presence, from both river and lake, and ample water run from extended roof slopes offer the possibility to implement a zone for artificially developed wetlands, with the intention to develop eventually land that can be used for larger vegetation.

In relation to the potential creation of constructed wetlands and perhaps in a more simplistic and immediately effective vision for the site, the project suggests the creation of a demonstration site for water cleansing processes. Water can be progressively filtered and directed to the river through a series of retaining ponds. The visual effect of the process is embodied into the landscape concept.

The potential use of corn crops on-site as a demonstration feature for the production of biofuel, [ethanol as an alternative energy source allowing a certain off-grid energy capability] offers visually a desirable landscape effect. Rural life enters the urban environment in close proximity with high-density off-ground development.

For immediate development, only a small portion of the site is planned to accept new and healthy soil so that faster-pace landscape effects start to emerge. For the greater portion of the site the strategy is to recover the existing soil, as a statement of true dedication to the locality and to non-commodified understandings of quality of life. The promise of showcasing organic agriculture on-site, and the scenario of self-sustainable food resources becomes another striking landscape feature.

Acknowledging the possibility of polluted or intoxicated soil on-site, we propose the enclosure of toxic hotspots in paved areas. This strategy prevents in a rough way the transmission of pollutants to neighboring soil and water through encapsulation. This is a short-term effect enabling the immediate use of the site. At a later stage the method can be re-examined to give way to more sustainable recovery strategies. These areas are paved and enclosed with concrete at a great depth vertically and horizontally. For our landscape proposal, these are potential areas for the creation of small artificial mounds using the randomized stepping pattern of concrete blocks that is [as aforementioned] also implemented on the riverfront. These spots are expected to function as primary destination areas for several leisure activities, pick nicks, readings, sunbathing, etc. enjoying a more elevated view of adjacent natural features.

It is expected that demolition waste will be recycled, cleansed from pollutants, and potentially recovered for use on-site. The large surfaces of concrete paving, the existing buildings and structures, can be re-used for the development of the artificial mounds as aforementioned.

The constructed edge of the water remains largely tectonic with hardscapes allowing increased public pedestrian circulation. The zone close to the water remains largely open with no building footprints. A very thin circulation tower leads to the elevated housing enclave. This tower along with the pilotis of the steel airborne housing strips, are the primary visual elements. The colossal portals of the gantries and cranes define framed views. The hardscaped river-side walk is at a great extend shaded by the large volume of housing hovering above.

Proceedings

10. HARBORING CAR-BAN-ITIES: CITY-CENTER CONNECTIVITY

As demonstrated in the city-scale diagrams and partially in the site plan, a network of roads is reinforced to support mobility patterns towards the Port Nord site. Ranging from car traffic to public transit systems, boat transportation and linear sports networks, the connection promise between our site and the city is strengthened. Of particular interest is the proposal to continue the waterfront roads from the Chalon City Center under the motorway bridge, and into our site, creating a reformed roundabout that closes the loop of primary circulation from the city.

This title is a leptic play between Ban-ning the Car [Car-Ban-ity] and the word Urbanity. The competition brief states strongly the intention to reduce the use of the car and promote alternative networks and patterns of mobility. The proposal clearly gives attention to the moderated inclusion of automotive circulation, avoiding utopian chimeras and ensuring a coherently and densely organized network of alternative urban or landscape elements to organize the living experience. The common cliché of setting street pattern design as the foremost regulatory tool for urban planning is here rejected. Urban design is not traffic engineering, and the experiential qualities focus instead on uncommon sets of relations between the natural or the man-made landscape.

A stretched round-about configuration would hug the site of the soon-to-be-built bowling center. This in-between zone screens partially the rough automotive bridge, by extending the parking facilities of the bowling center, becoming the primary automotive drop-off area. This feature suggests the use of other means of transportation through a series of closely spaced individual destinations, and above all, reinforces walking along and across the riverside promenade.

Large and singular car parking areas worsen the visual effect of countless automobiles dominating the landscape. We propose a main drop-off center close to the bowling center, however; there is provision for a tight network of smaller parking areas, or side-street parking, potentially to be implemented in following stages of urban growth. The creation of green transportation interchange nodes, with bicycle parking, car parking, bus or tram stops, combining with small retail options and café or brasseries, ensures a network of lively point-like areas of relative concentricity. These nodes are located at the piloti areas supporting the large steel housing wings. For the first phase of the development, this intricate small retail network can be adequately compensated by a light and mutable network of vendors using container like units.

Territorial planning around water: a path to the development of living spaces

Extended abstract

This paper seeks to assess both the importance and the feasibility of one of the main aims of the national development plan (NDP) of our actual Colombian government, which is *The territorial planning around water* as an strategy to face climate change and, warranty the life conditions not only of vulnerable communities but of the whole population urban and rural. For such an aim, the NDP states that: It seeks a change in territorial planning and development, where the protection of environmental determinants and areas of special interest to guarantee the right to food are central objectives [...] (Law 2294/2023, art. 3).

Water, it's well known, is one of the most important sources of life. For the UN, a person would need between 20 to 50 liters of water as a daily base consumption. It is estimated that worldwide 1.1 billion people don't have access to drinking water and nearly 1.7 billion are not able to access to essential sanitation services and facilities. Such a situation leads to several diseases as diarrhoea in developing countries, one of the main causes of child mortality.

In Colombia, there is in average an availability of 43.000 m³ of water per person per year. That means 7.6 times higher than the global average. However, only 73% of population at national level have access to managed water supply and only 40% in rural areas.

Whilst worldwide urban population has reached 56% of total population, in Colombia, urban population represents 77,1%. It is worthy to remember, that water source for urban areas depends on aquifer reserves resting in the countryside. So, the relationship between how water resources are managing, how the environment where such sources are located are protected and, how urban and territorial planning as whole is undertaken in order to ensure that water supply can be sustained and accessible are maybe the main challenges that societies face even more given that change climate is underway.

Climate change demands building up resilience cities based on “the conservation, protection of the environment and ecosystems, the water cycle, natural resources, prevention of threats and disaster risks, climate change management and food sovereignty” as mentioned in the NDP (art. 10). In that sense, urban planning must seek to create spaces that guarantee human life as well the life of every species.

Extended abstract

‘... Ἐφύραν Ὠκεανοῦ θυγατέρα οἰκῆσαι πρῶτον ἐν τῇ γῆ ταύτῃ...’ (Pausanias Description of Greece: Corinth' (1.1)) ...Ephyra, daughter of Oceanus first inhabited this land....

Everything originated from the sea and Corinth, the city of two seas, the Corinthian and Saronic gulf, owes its genesis to the sea. Its two ports, Lechaion and Kenchrees, played a decisive role in this exogenous dynamic. Lechaion, as the port on the Corinthian gulf, with its west orientation and being axially connected to the city, was its most important port.

Architectural design that harvests its tools from place itself, by analyzing and experiencing it and is born out of it, offering the sophisticated effect of architecture on it, has been the aim of the present paper.

Especially, this paper aims to promote a project-oriented approach to context interpretation, place intervention and translation of its identity into an architectural proposal. Through an extensive analytical procedure, it intends to provide some initial answers to the question stated above, via a case study focused on the archaeological site of Lechaion Ancient Harbor which is, at the same time, an important water landscape ecosystem, which in now days act as a biotope.

The fact that in its present state, the ancient port of Lechaion comprises of a fenced space, to which the public doesn't have access, introduces the question whether the ancient port can become a "place" today, i.e. part of the social and cultural life of the city, but also an international archaeological destination, part of the network of important archaeological sites of the wider area of Corinth, also important spatial organization for the history of the Mediterranean, considering the acropolis (Acrocorinth), the city (Ancient Corinth) and the two ports of the ancient city of Corinth (Lechaion and Kenchrees).

In order to answer the question, it was considered important to search for the principles that constituted the ancient port as a "place" in the past.

Specifically, the redefinition of place proposed, is based on a process of deep understanding and investigation of all the elements of the historical and archaeological tracing that constituted it.

Also, reference was made to the abandonment of the port in recent years and its evolution into a place where this time its appropriation did not concern people but birds and the ecosystem that developed as a whole. Thus, the analysis of the elements of the habitat followed, examining the second status of Lechaion as a place today, as a biotope.

The study of the historical reports about Lechaion, the archaeological findings and the theories of the various local researchers through time, constitute the tracking method in order to create a comprehensive perception of the location, formulate personal speculations through cartographic observation and synthesize through the set of documents the historical course of the port from prehistoric times to the building of the new city of Corinth.

In this case, the aim was to compose an experiential experience of the place of how it was in the past, in a context of synthesis of traces and elements that determined its formation intangible and material, but also an environmental walk of correlation with the natural landscape and the life of the ecosystem. All those data, as well as its current appropriation by birds as habitats, gives birth to architectural creation from the small scale of basic decisions on the organization of the greater area, to the urban scale of the ancient port, at the scale of landscape design, by plotting the route, the local planning and

the birth of the unit as the architectural jargon of composition in all planning scales, for small semi open-air structures and for building units.

The composition is based on three typologies, the stasis, the node and the observatory, which create the routes proposed, some points of interest, were selected as parts of this route that come to complement its design and the experience of touring the ancient harbor.

Also, the materials used are consistent with respect to the ecosystem and the natural palette of the landscape, the use of planting as an element that was spatially analyzed and shaped the architectural solution proposed was decisive.

Listening to the landscape, deeply understanding the way in which the place was formed, walking mentally and perceptibly on the traces of the past and giving value to the life that appropriates it in the present are the pillars of an architecture that can regenerate a place, redefine it in the present for the future, while carrying its spirit, what characterizes it and makes it unique compared to any other place in the world.

This kind of approach can play a significant role in creating sensitive architectural interventions, suitable for their context, contemporary in their design, while responding to historical precedents.

It can establish a methodological tool, as a link between the fields of architecture, nature and archaeology, which in more ways than one has a lot in common.

In a time of increased awareness on issues of sustainability and heritage, the preservation of architectural landmarks of historical significance and of the biotopes which are protecting the environmental balance of our planet is of major importance.

Extended abstract

In Greece, marine and coastal ecosystems in coastal and insular areas' are unique and imbued with significant sociocultural values. These ecosystems support recreational activities essential for the well-being and cultural identity of local communities and, thereby **necessitating a comprehensive method for their assessment and conservation**. Traditional approaches to valuing ecosystem services have primarily focused on biophysical and economic aspects, often overlooking communities' profound sociocultural connections with their natural surroundings. Recognizing this gap, our study introduces a novel methodology that holistically integrates the sociocultural values alongside the physical and biological contributions of coastal and insular areas' coastal and marine ecosystems. The paper investigates two pilot cases: (a) the island cluster of South Dodecanese islands/eastern Crete and (b) the coastal area of west Pagasitikos Gulf in Magnesia, introducing a specific methodology for coastal and maritime planning of cultural heritage. The main objective is to create a valuable tool for identifying and mapping various distinctive clusters of cultural heritage, designing data, and using user-friendly geo-technology tools to facilitate local-scale, detailed analyses of recreational ecosystem services.

This approach is pivotal for MSP, which seeks to balance various interests and uses of marine spaces in sustainable ways that benefit all stakeholders. By incorporating sociocultural values, our method enriches the MSP process, ensuring that decisions reflect the multifaceted nature of ecosystem services and their importance to local communities. Integrating socio-cultural values represents a significant advancement in ecosystem service assessment, offering a more nuanced understanding of the benefits of these natural environments. This is particularly relevant for coastal and insular areas, where the cultural heritage and natural landscapes are closely intertwined, and sustainable management practices are critical for preserving this unique interconnection. To further enhance the efficacy and impact of our approach, we propose the establishment of a community of practice for each case study area and then on a national level. This initiative aims to gather a network of local stakeholders, experts, and practitioners who share a commitment to the sustainable management and conservation of these ecosystems. Through regular interactions and knowledge exchange, these communities of practice will foster collaborative learning, enable the sharing of innovative solutions, and enhance the collective ability to address conservation challenges. This inclusion amplifies the study's practical applications and reinforces the significance of engaging local communities recognizing that the sociocultural values of ecosystems are best understood and preserved through the active involvement of those who live closest to them.

Our contribution to the field of MSP through this practical tool for evaluating recreational ecosystem services emphasizes the critical role of sociocultural factors. It aids in informed decision-making for sustainable management and highlights the necessity to preserve coastal regions' unique sociocultural and natural heritage. The methodology has the potential to be adapted and applied in other contexts, offering a valuable resource for the conservation and sustainable development of coastal ecosystems. This expanded overview underscores the importance of our study's innovative approach in advancing the conservation and sustainable management of coastal ecosystems, focusing on the rich sociocultural and natural heritage of coastal and insular areas.

Extended Abstract

Coastal and maritime cultural heritage in Greece often appears as under-exploited pieces of heritage due to basic weaknesses such as

1. dispersed locations of cultural heritage sites with low level of accessibility for both visitors and local communities;
2. non-involvement of local society and professional associations related to tourism, in the decision making and management of cultural heritage;
3. the absence of a decentralized local governance model and monitoring mechanisms for cultural heritage, as well as overlapping of responsibilities among authorities in terms of both planning and management for heritage enhancement.

This paper deals with strategic planning and social management of zones of coastal and maritime cultural heritage, both built and non-material, that are characterised by dispersed and non-accessible cultural sites, thus, remaining mainly unexploited for tourism development and non-integrated into residents' everyday life. The research focuses on

1. *how the creation of local social networks and societal participation processes* in decision making and management of cultural heritage, and

2. *smart solutions by means of strategic spatial and maritime planning and soft projects*, that may fundamentally reinforce the enhancement of dispersed cultural heritage sites by creating integrated large cultural clusters and networks of cultural sites; and in these ways, promoting tourism and economic development of the area in agreement with stakeholders in the local society. The paper presents the research outcome on the significant zone of coastal and maritime cultural heritage in West Parasitic Gulf, Magnesia, Greece. More specifically, it portrays (i) the creation of a social network for cultural heritage management in West Pagasitic; (ii) a strategic plan with proposed soft projects connecting the dispersed cultural sites in West Pagasitic as well as minor hard projects for integrating cultural heritage into the residents' everyday life; and (iii) the consultation processes adopted in the research as well as the Participatory Lab realised for the evaluation of the proposed projects by social stakeholders.

This research is part of the ongoing research project "*Developing an Observation Network for Maritime Cultural Heritage (MCH/UCH) in Greece*" - acronym HER-Sea -financed by ELIDEK, and realised with the collaboration of three academic institutions: Panteion University as Leader, University of Thessaly and University of The Aegean as partners. HER-Sea investigates two pilot research zones: (a) south Dodecanese islands/eastern Crete and (b) west Parasitic Gulf.

Abstract

The article considers soundscapes as part of the territorial (including cultural) capital of a city or territory. It highlights, through a territorial approach, the role of soundscapes for shaping the evolving contemporary urbanism, going beyond the attenuation of ambient noise and beyond quietness, considering the quality of the sound environment as a key factor of the attractiveness of a city or neighborhood. Several examples of cities and neighborhoods (eco-neighborhoods) that have incorporated sound design into a global vision of urban quality, often including conservation and promotion of their cultural capital, are presented. The article links soundscapes with the concept of the frugal city, which goes beyond a sustainable city, supporting a dynamic and active approach in producing sound-related satisfactions to serve citizens. Through this research, it is evident that soundscapes, as intangible cultural assets, can play a significant role in dynamic and innovative urban strategies. These strategies are based on providing various satisfactions to citizens while minimizing the use of material resources. This allows society to create a sense of place and positive spatial imaginaries, enabling creativity and frugality simultaneously, with promising prospects for the entire economy.

Keywords: *Soundscapes; territorial capital; cultural capital; intangible cultural heritage; attractiveness; sustainability; frugality*

1. Introduction

Cities and territories are undergoing constant transformation due to population growth leading to rapid urbanization and urban sprawl [1]. Despite the global efforts towards circular economy [2], nature-based solutions [3], smart city initiatives [4], the adoption of the Agenda for Sustainable Development (17 SDGs) [5] and especially Goal 11 [6] towards inclusive, safe, resilient, and sustainable cities, several environmental pressures continue to impact the quality of life for urban residents [7]. Environmental noise in urban areas may be thought as a byproduct of growth [8] as various activities related to the pursuit of economic gain—such as commerce, construction, and infrastructure maintenance—often result in this auditory disturbance. The effects of noise on physical and mental health of individuals [9] should not be overlooked and territorial strategies towards its management are crucial [10–12].

Paradoxically, a noisy environment is sometimes synonymous with a highly productive, economically rising society that promotes progress, including industrial and recreational activities, at the expense of quietness and liveliness. In this case, quietness is misunderstood as the result of a dormant way of living in an economically declining society [13]. In reality, environmental noise is

considered an important factor and one of the main causes of urban deprivation and economic decline, affecting property values in certain residential areas [14].

A large part of European population suffers daily from too high and unacceptable noise levels [15]. Noise can seriously affect the quality of life and lead to annoyance, sleep disorders and adverse health effects [9]. By extension, the social and economic impacts are also serious, regarding productivity as well as the property values of the affected areas. Analyses of environmental inequalities show that across the whole urban territory, income is a robust interpreter for noise exposure [16]. Several studies have also observed positive associations between road-traffic noise and deprivation [17,18]. Dale et al. [19] identified a clear deficiency of environmental equity on the Island of Montreal. Their research indicated that disadvantaged groups bear a double burden of higher exposure to noise and low-income status. Their findings showed that noise exposure was strongly correlated with socio-economic indicators, such as median household income, percentage of people who live in non-affordable housing -spending over 30% of their income on housing-, percentage of people below the low-income line and with a social deprivation index combining several socio-economic variables. Similar outcomes are identified by Nega et al. [20] associating noise levels and household income, median household value, the proportion of non-white residents, and the percentage of young population. Another research outcome is the positive association between depressed mood and high road traffic noise exposure in residential settings which is besides happening for all urban citizens independently from ethnic minority or socioeconomic status [21].

An additional effect of environmental noise is the decline of land and property values. In Switzerland, it was found that almost 60% of the calculated costs of noise (more than 1 billion Swiss francs per year) correspond to losses of property value, caused primarily by the dominant traffic noise. Buildings exposed to excessive noise levels have lower rent or sale prices compared with those located in quiet areas. To this end, methods have been developed (e.g by the Zurich Cantonal Bank, ZKB) to accurately calculate the depreciation of real estate properties for rent or sale, caused by noise. The ZKB study indicates that the effects on property values differ based on the type of noise and the type of property. Noise has a greater impact on the segment of property than on the rental sector, and rail noise causes higher price drops in the rental segment compared to traffic noise. According to the same study, each decibel above the threshold of 40 dB at night or 50 dB during the day is reflected in the following price drop (Table 1).

Table 1. Impacts of noise on property values, Source: Zurich Cantonal Bank

	Location	Property
Road traffic	-0.19%	-0.59%
Rail traffic	-0.26%	-0.47%
Air traffic	-0.11%	No dat

Under the novel standardization of the soundscape [22], sounds are considered to be a resource and not a waste [23]. Moscoso et al. 2018 [24] proved that soundscapes directly influence human wellbeing and highlight the necessity for further research about the kind of sounds that promote a healthier environment. However, the quality of the sound environment can now become a factor in assessing the living conditions of urban populations. It is even recognized, especially through the concept of « soundscape » as an asset in terms of attractiveness of a city or region [25]. If noise reduction can represent a cost, the quality of the sound environment or in other words a high-quality soundscape can represent a value. Consequently, a strategy to enhance urban living and create satisfactions can be centered on providing positive soundscapes. This approach could challenge the

foundational assumption of political economy that suggests satisfaction is primarily driven by wealth creation.

The goal of this research article is two-fold: first, to examine soundscape from a human perspective and the related concept of “quiet areas”, using the case-study of the city of Mytilene, in Greece. Secondly, to go beyond quietness, exploring the quality of soundscape as a *territorial asset*, often part of the intangible cultural heritage of a city or region and shaping factor of a continuously evolving sustainable and emotional urbanism.

2. Materials and Methods

In order to reach the above goals, the following steps were followed: An inventory of cities and neighborhoods that have managed to make themselves attractive and regain positive cultural and economic dynamics through the improvement of the sound environment. Identification of projects that have explored holistic ways to include sound planning and soundscapes in urban planning.

3. Results

3.1. Experiences of neighborhoods, cities and territories

Many cities worked methodically utilizing sound as a musical satisfaction which can be translated into "soundscape", thus achieving attractiveness and regaining positive cultural and economic dynamics. For example, in the city of Porto (Portugal) the project **Porto Sonoro** involved the creation of a digital database dedicated to collecting, organizing and transforming urban sounds. The project aimed at reflecting the sound identity of the city through the articulation of documentary, analytical and social objectives with artistic transformations of sound contents [26]. Another example of the potential impact of positive soundscapes in urban planning is the sound event realized in real time in Brighton called "**Sounding Brighton**" during which it has been documented that the crowds in the streets were comforted and altered their behavior once they were exposed to musical sounds of outstanding artistic value, during a “white night”. The project [27] has attempted to evaluate how ambient soundscapes could act as a remedy to the culture "Saturday night for drinking" observed on the most dangerous streets of the city of Brighton. Additionally, the FP7 **SONORUS** project funded by the EC [28] explored holistic ways to include sound in urban planning, revealing also the need to raise awareness and carry out training of the future “urban sound planner”.

The evidence on the negative effects of noise on human and environmental health are increasing [29,30] highlighting the need to manage this pressure. Amongst the efforts of dealing with this pollutant was the publication of END (Environmental Noise Directive) [31]. Apart from the prompt to create strategic noise maps, a solution to the noise problem was the introduction of quiet areas in agglomerations. Urban quiet areas are defined as “*areas delimited by the competent authority that are not exposed to a specific noise indicator value set by the member state*”. Numerous efforts have been conducted in order to identify urban quiet areas. Notably, the **QUADMAP project** (QUIet Areas Definition and Management in Action Plans) [11] offered a methodology to identify them utilizing a set of objective and subjective metrics. Other efforts incorporated additional acoustical aspects of the sound environment by including the acoustic biodiversity indices in the list of quiet area criteria. Particularly, the **SALVE project** proposed a method to identify urban quiet areas in Germany utilizing criteria for human health and the promotion of healthy acoustic environments [32,33]. Finally, using a mixed method approach, the quiet areas of Mytilene (Lesvos Island, Greece) have been identified [34]. The realization that the concept of quietness regards issues beyond the increased noise levels [8,35] has led to the establishment of the soundscape approach that focuses on the description of the sound environment using soundscape descriptors rather than a strict quantification using decibels [36]. The recently published ISO standard on soundscape assessment focuses on the perceived affective quality of sound environments focusing on the perceptual aspects of pleasantness and eventfulness [22]. Nevertheless, the need to apply an engineering approach in sound planning in

Proceedings

of the International Conference on **Changing Cities VI**:
Spatial, Design, Landscape, Heritage & Socio-economic Dimensions
Rhodes Island, Greece • June 24-28, 2024
ISSN: 2654-0460
ISBN: 978-618-5765-02-6

order to allow the predictiveness of soundscapes, led to the **SSID project** [37] aiming towards the establishment of soundscape indices. The specific novel initiative has altered the way that sound environments are being assessed.

It is evident that the above projects portray different views on issues of noise, quietness, satisfaction, and environmental health. It is undeniable that these different approaches aim towards healthy urban sound environments, but in some cases the co-benefit of environmental sustainability is absent and considered to be a missed opportunity [13]. In table 2 the contribution of the selected projects on the basic sound planning criteria: music satisfaction, noise mitigation, perceived affective quality and environmental sustainability are reported.

Table 2. Selected project contribution on sound planning criteria

Project	Music satisfaction	Noise mitigation	Perceived affective quality	Environmental sustainability
Porto Sonoro	✓			
Sounding Brighton	✓			
SONORUS	✓		✓	
QUADMAP		✓	✓	
SALVE		✓	✓	✓
SSID		✓	✓	

It is thus evident that sound planning, and design has a role to play in urban planning. Rather than considering negative aspects in terms of noise annoyance, planners and sound artists should positively contribute to improving the sound environment of the city giving equal importance to all sound planning criteria. Furthermore, the sound environment is dynamic and is not characterized by inertia; it can be altered, improved, shaped, re-created and designed, so as to provide satisfaction to the citizens.

3.2 Soundscapes as part of cultural capital of cities and territories

The sounds are part of the ingredients of towns and territories, their sensory landscape and their identity. They are urban or territorial markers, like the landscape. The relationship between soundscape, intangible heritage and attractiveness was however largely unexplored, so far. However, in recent years heritage and identity character of ambiances and urban soundscapes begins to become acknowledged.

An example is undoubtedly the inscription of the Jemaa El-Fna square on the Representative List of the Intangible Cultural Heritage of Humanity in 2008 [38], which introduced or encouraged a new registry of heritage based on the consideration of oral expressions as they are unfolded in the urban space. This place, situated at the entrance of the Medina, represents a unique concentration of popular Moroccan cultural traditions performed through musical, religious and artistic expressions. The triangular square, which is delimited by restaurants, stands and public buildings, provides everyday commercial events and various entertainment rituals and is a meeting point for the local population, tourists and visitors. Through day and night, a variety of services are offered, such as dental care, traditional medicine, fortune-telling, preaching, and henna tattooing; water-carrying, fruit and traditional food may be bought. In addition, one can enjoy many performances by storytellers, poets, snake-charmers, Berber musicians (mazighen), Gnaoua dancers and senthir (hajouj) players. The oral expressions would be continually renewed by bards (imayazen), who used to travel through Berber territories. They continue to combine speech and gesture to teach, entertain and charm the audience.

Adapting their art to contemporary contexts, they now improvise on an outline of an ancient text, making their recital accessible to a wider audience. While Jemaa el-Fna Square enjoys great popularity, the cultural practices may suffer acculturation, also caused by widespread tourism.

Another example is safeguarding of cowbells in Portugal that have contributed to the creation of soundscapes in the Portuguese countryside, a sort of "voice of fields" throughout 2000 years. The Portuguese cowbell is an idiophone percussion instrument that creates a characteristic sound landscape in the countryside. From the operational point of view, the neighborhood scale [39] seems particularly relevant to take into account these expectations. In this context, eco-neighborhoods, in which the issues of well-being, health and attractiveness are central, present particularly exciting opportunities.

Besides, one of the most recent definitions set for "soundscape" is the compilation of biological, geophysical and anthropogenic sounds that derive from a landscape, and which vary over space and time, echoing important ecosystem processes and human activities [40]. Other considerations of Soundscapes view them as a group of immaterial resources that are ecologically, culturally and economically valuable [41]. Research on the visual qualities of a landscape demonstrates the strong connections between sense of place and sound. In cultural landscapes, the soundscape is the result of mutual progress between human culture and natural processes [42]. Sounds are considered essential factors of place making. Therefore, cultural soundscapes should be protected and preserved as cultural heritage.

4. Discussion

What is important in the design of any strategy for the development of territorial attractiveness is the combination of the two aspects of territorial attractiveness, namely of supply and demand through the development of the assets of the region in relation to the quantities requested as part of an integrated spatial strategy that will support: (a) the emergence of different forms of territorial capital through tangible and intangible interventions; b) enhancing the institutional partners and various stakeholders in the region, for example by using territorial marketing policies (place marketing) designed for a specific audience. It is widely acknowledged that during this crisis period, it is necessary to recognize the importance of territorial capital as part of a strategy to mobilize and exploit regional assets in relation to specific audiences.

Thanks to the concept of the "soundscape" invented by Schafer, numerous research has been conducted, thus creating an important space for interdisciplinary and multidisciplinary meetings and exchanges. Several disciplines are concerned: sound ecology, acoustics, psychology, musicology, sociology, geography, architecture, urbanism, etc. These strong multidisciplinary and transdisciplinary were also apparent at the international event "ECHOPOLIS 2013" entitled "Sounds, noise and music to reinvent the city and the eco-neighborhoods" which set itself the goal of educating planners and developers about the concept of soundscape and its role in spatial planning.

In contemporary times, the landscape has evolved in a concept that evokes the sensitive relationship of society to its living environment; it is no longer merely a support or a view. Similarly, the soundscape should no longer be reduced to its remarkable aspect to be protected or its musical essence, but it must be recognized through its societal and economic dimensions [43].

5. Conclusions

The position of the authorities in the field of environmental noise has been, so far, to reduce the sound levels of the main sources of noise and to set limits that should not be exceeded in some areas affected by strong noise to reduce the exposure of residents. Nevertheless, to answer primarily to citizens and to the challenges linked with attractiveness of cities and territories in times of economic and urban crisis, planners should go beyond the quantitative aspect of noise, integrate the issue of sound quality

in any urban or territorial development project and consider noise not as "waste" but as a local "resource" (see COST Action TD0804) and the soundscape as a decisive value of local wealth.

Abstract

Imagination is an uncontrollable and essential aspect of life, as Andrei Tarkovsky aptly emphasizes. From the time of the Oracle of Delphi to Plato's ideal cities, our imagination has allowed us to envision the future of our urban environments. Although it has been viewed both as a source of deception and a powerful catalyst for change, imagination remains central to our understanding of reality. This article delves into the role of imagination and spatial imaginaries in design, drawing insights from seminal works in the field.

The concept of the social imaginary, rooted in the philosophies of Hegel and Durkheim, has recently been applied to understanding contemporary societies. Popularized in the 1950s by Charles Wright Mills and Cornelius Castoriadis, the social imaginary refers to the collective consciousness that shapes social structures and practices.

The core idea is that integrating imaginative and cultural elements into urban planning can significantly enhance the resilience of cities. By merging cultural heritage with social imaginaries, societies can create environments that are both sustainable and resilient. This study provides a perspective on developing dynamic and cohesive urban landscapes by leveraging imagination, cultural heritage, and social construction

Keywords: *symbolic construction, social organization, imaginary systems, urban resilience, territorial resilience, cultural heritage, urban planning, social imaginary meanings.*

1. INTRODUCTION

The concept of territorial resilience is of paramount importance today due to the numerous challenges that cities and regions face, such as environmental disasters, social inequalities, and cultural changes. This study explores the role of imagination and symbolic structures in strengthening the resilience of cities and regions by combining theoretical frameworks and practical observations. It specifically focuses on the theories of social imagination by Cornelius Castoriadis and cultural heritage by Pierre Bourdieu, emphasizing imagination as a catalyst for innovation and cultural heritage as a foundation for social cohesion [7-4].

Castoriadis' concept of social imagination refers to the capacity of societies to create and transform institutional and cultural realities. This idea is vital for understanding social change and for developing new forms of social organization that can address contemporary challenges [7]. Bourdieu's analysis of cultural heritage includes the material and intangible cultural assets passed down through generations, which shape the identity and values of a society [4].

This study presents initial findings from a literature review on notable cities such as Barcelona, Kyoto, and New York, illustrating how the integration of imaginative and symbolic elements in urban planning can foster resilient and adaptive urban environments. From Plato's era to the present,

Proceedings

imagination has played a crucial role in envisioning and shaping cities [13-7]. Symbolic structures and cultural heritage contribute to social stability and identity, enhancing the resilience of cities [9-4].

In conclusion, the combined application of these theories proposes a holistic approach to urban design. Resilience can be achieved through the strategic use of cultural and imaginative elements, creating sustainable urban environments that reflect the collective human spirit and aspirations. This approach offers a comprehensive perspective for developing dynamic and resilient cities.

2. METHODOLOGY

The process of verifying the hypothesis that integrating imaginary, symbolic structures, and cultural elements into urban planning enhances the resilience of cities involves several stages. First, the hypothesis is formulated, and a comprehensive literature review is conducted on seminal works in sociology, anthropology, philosophy, and urban planning. Next, the concepts of imagination, cultural heritage, and resilience are analyzed, contrasting their characteristics as design tools. Following this, theoretical outcomes are examined in real-world cities, identifying their impacts on the social and spatial fabric. Finally, the hypothesis is either confirmed or refuted based on the findings.

3. LOGICAL ANALYSIS OF KEY CONCEPTS

3.1. Imagination and Social Imagination

Imagination is a fundamental human trait that enables individuals to envision and create new realities. Philosophers like Aristotle have long examined the role of imagination in human thought and cultural development [3]. According to Aristotle, imagination is a function of the soul that links sensory perception with intellect. This understanding is crucial for exploring how imagination enhances urban resilience through symbolic and imaginary structures in city planning [17].

Aristotle distinguished between two types of imagination: aesthetic and logical. Aesthetic imagination relates to the senses and influences memory and dreams, while logical imagination connects to intellect and decision-making. Imagination motivates people towards specific actions by making objects appear desirable or pleasurable.

Cornelius Castoriadis expands this discussion with the concept of social imagination, describing it as the collective ability of societies to create and reshape their institutional and cultural realities [7]. Social imagination is the source of creating institutions and social forms, enabling societal autonomy [7]. For example, the establishment of democratic institutions can be seen as a product of social imagination.

Castoriadis's notion of social imagination provides a theoretical framework for understanding the role of imagination and symbolic structures in society [7]. A society's capacity to imagine and create new social organizations is critical for its survival and adaptation to new challenges [7].

Benedict Anderson's concept of "imagined communities" adds another layer to the understanding of imagination. In his work "Imagined Communities," Anderson explores how communities are formed through shared imaginary constructs, such as national identities [1]. These imagined communities allow individuals to feel connected to others through common narratives [1]. For instance, national holidays and symbols can foster a sense of unity among citizens.

Spatial images, or the perceptions and representations of space, play a crucial role in shaping these imagined communities [19]. Tools like maps, censuses, and museums help reinforce national identities [1]. This analysis has important implications for understanding spatial images and territorial resilience [19]

Charles Taylor, in his analysis of modern social imaginations, highlights the importance of collective images and meanings in the functioning of contemporary societies [32]. Social imaginations are

shaped and perpetuated through interaction and shared understanding among individuals within a society [32].

In summary, these theories emphasize the significance of imagination and social imagination in shaping and enhancing the resilience of societies [3]. Imagination is a collective tool that allows societies to create and recreate their realities, adapt to challenges, and achieve sustainability and resilience [32]. For instance, envisioning sustainable urban environments can lead to innovative solutions to climate change.

3.2. Cultural Heritage and Symbolic Structures

Cultural heritage and symbolic structures are crucial for understanding and enhancing the social cohesion and resilience of communities. Cultural heritage includes both tangible and intangible assets passed down through generations, shaping the identity and values of a society. Pierre Bourdieu, in "Distinction: A Social Critique of the Judgement of Taste," explores cultural capital, highlighting that cultural heritage not only preserves tradition but also acts as a means of social distinction and power. Cultural capital consists of knowledge, education, skills, and cultural practices held by individuals and groups, playing a key role in shaping social order and mobility [4].

Bourdieu's theory emphasizes how cultural capital, which encompasses the knowledge, skills, and practices acquired through socialization, influences social mobility and success [4]. This theory is linked to spatial images and territorial resilience, providing insight into how social and cultural structures affect community resilience.

Cultural capital is defined by Bourdieu as a collection of symbolic and material resources acquired through social inheritance that shape individuals' dispositions to understand and attribute meaning to the world [4]. Spatial images, or representations of space, are directly influenced by cultural capital. For example, maps, architectural works, and urban landscapes function as symbols that reinforce social cohesion and community identity.

Cultural representations of a city or region through art or media can enhance the sense of belonging and create a shared vision for the community. This shared vision, based on cultural traditions and common values, strengthens social cohesion and territorial resilience.

Territorial resilience refers to the ability of an area to withstand and recover from crises and changes while maintaining its social structure and identity [1]. Cultural capital is crucial in this process, as cultural values and social practices embedded in spatial images help build resilient communities. Education is vital in this regard, as it enables individuals to acquire the cultural capital needed to understand and address the challenges facing their space and community. A community's ability to adapt and recover from crises depends significantly on the education and social mobility of its members.

Consider cities like Barcelona, renowned for its architectural monuments, and New York, celebrated for its multiculturalism. These cities invest in education and promote cultural heritage, thereby enhancing their resilience. They create environments where residents feel connected and supportive of the community, improving their ability to handle changes.

Bourdieu's theory of cultural capital provides a valuable framework for understanding the mechanisms that shape social structure and community resilience. By reinforcing cultural values and social cohesion, communities can effectively confront challenges and preserve their identity. Integrating these elements strategically into urban planning can lead to sustainable and resilient environments that reflect the collective aspirations and cultural heritage of societies.

3.3. Urban and Territorial Resilience

Urban and territorial resilience refers to the ability of cities and regions to adapt, recover, and thrive despite facing challenges and disruptions. This concept goes beyond just natural disasters to include social, economic, and cultural aspects.

Jane Jacobs, in her influential book "The Death and Life of Great American Cities," argues that the vitality of cities depends on the dynamism and diversity of their communities. She highlights the importance of "eyes on the street" and vibrant neighborhoods, asserting that social interaction and local self-management are crucial for urban resilience. When different land uses coexist and residents actively participate, it strengthens social cohesion and enhances communities' ability to tackle challenges [16].

David Harvey, in "Social Justice and the City," introduces the idea of the right to the city. He argues that urban resilience must include social justice and equal access to urban resources. According to Harvey, cities should be designed with social inclusion and economic equality in mind, ensuring all residents can participate in and benefit from urban development. For instance, accessible public transportation and affordable housing can significantly contribute to urban resilience by promoting social equity [14].

Jacobs also stresses the importance of "mixed-use" development, where various activities occur in the same area, fostering economic and social vitality. This variety helps prevent monotony and social isolation, thereby strengthening the city's resilience. These ideas are linked to "spatial resilience," where thoughtful design and management of urban spaces encourage social cohesion and adaptability to changes.

Harvey examines how the spatial organization of cities affects and is affected by social processes. He suggests that the layout of urban spaces can either exacerbate or alleviate social inequalities. Spatial awareness is crucial in shaping social justice, and integrating sociological and geographical analyses is essential for understanding urban issues.

C.S. Holling's concept of ecosystem resilience offers a theoretical framework that can be applied to urban resilience. He defines resilience as the capacity of a system to absorb disturbances and maintain its core functions and structures [15]. For cities, this means being able to absorb and adapt to various changes, whether environmental, economic, or social.

Holling's concept of ecological resilience emphasizes the importance of diversity and heterogeneity in a system. Diversity allows a system to adapt to different situations and recover from disturbances. This principle can be applied to cities, where diverse economic activities, social diversity, and varied infrastructure enhance resilience. For example, a city with a mix of industries is less likely to suffer economically if one sector declines.

Consider the examples of Barcelona and New York. Barcelona invests in education and celebrates its architectural heritage, while New York thrives on its multiculturalism. These cities create environments where residents feel connected and supportive of their community, improving their ability to cope with changes and challenges.

In summary, urban and territorial resilience requires an interdisciplinary approach that combines social sciences, economics, architecture, and ecology. By strategically integrating these elements, cities can create sustainable, resilient environments capable of adapting and thriving despite the modern world's challenges. This comprehensive approach ensures that cities not only survive but also flourish, benefiting all their residents.

4. CATEGORIZATION AND CLASSIFICATION OF THE BIBLIOGRAPHY

4.1. Historical Development of Imagination in Urban Planning

Imagination in urban planning has profoundly influenced the way societies envision and manage their urban spaces, tracing back through human history and philosophical thought. From antiquity to modern urban design, imagination has been pivotal in shaping cities and communities.

One of the earliest instances of imagination in urban planning is found in Plato's "Republic." Here, Plato envisions an ideal city-state where justice, harmony, and happiness are achieved through a meticulously structured social and political organization [25]. His vision extends beyond the mere layout of an ideal state to a comprehensive framework for human relations and societal structures. During the Renaissance, imagination became a central element in urban design once again. Thomas More's "Utopia" presents a visionary society with advanced ideas on social justice and urban management. These utopian concepts significantly influenced Renaissance urban planners and architects, who employed imagination to design cities that embodied principles of harmony, aesthetics, and functionality [22].

The 19th and 20th centuries saw imagination in urban planning take on new dimensions with the advent of industrialization and technological advancement. Architects like Le Corbusier and Frank Lloyd Wright introduced futuristic visions of cities as machines for improving human life [18].

In "Ville Radieuse," Le Corbusier envisions cities characterized by towering buildings, expansive streets, and green spaces designed to promote the health and well-being of their inhabitants. These visionary ideas profoundly influenced modern urban planning and city development throughout the 20th century.

In contemporary urban planning, imagination continues to be a crucial component, now approached with greater interdisciplinarity. Cornelius Castoriadis' concept of "social imagination" emphasizes the collective capacity to create and recreate institutional and cultural realities, facilitating societal adaptation and transformation [7]. This notion underscores the importance of collective imagination in shaping social and urban structures.

The evolving perceptions of imagination and social imagination reflect the changing priorities and needs of societies over time. From Plato's ideal city-state to Le Corbusier's futuristic visions and Castoriadis' social imagination, the role of imagination has continuously adapted to address the challenges and opportunities of each era.

Today, urban planning integrates cultural heritage, social justice, and sustainability. This comprehensive approach allows for the creation of resilient and sustainable cities that reflect the collective aspirations of their inhabitants. Modern cities like Copenhagen and Amsterdam exemplify this integration, with urban policies that promote environmental sustainability and social cohesion. In conclusion, the historical development of imagination in urban planning illustrates how societies have harnessed imagination to envision and create improved urban spaces. As a powerful agent of change and adaptation, imagination remains essential for developing resilient and sustainable cities capable of meeting contemporary challenges.

4.2. Theories of Social Organization and Symbolic Structures

Symbolic structures, encompassing symbols, rituals, myths, and cultural narratives, are foundational to social cohesion and resilience. Émile Durkheim, in his seminal work "The Elementary Forms of Religious Life," posits that symbolic structures forge shared values and beliefs, uniting individuals into a cohesive community. This collective consciousness fosters a profound sense of belonging.

Pierre Bourdieu, in "Distinction: A Social Critique of the Judgement of Taste," examines how cultural capital shapes social organization and power dynamics, often perpetuating social inequalities. To enhance urban resilience, it is imperative to ensure the equitable distribution of cultural capital, thereby promoting social inclusion.

Clifford Geertz, in "The Interpretation of Cultures," highlights the role of cultural narratives and symbols in shaping societal understanding and reinforcing social cohesion through shared perceptions and values.

Incorporating cultural elements into urban design, such as monuments, squares, and public spaces, significantly enhances the social cohesion and resilience of cities. Cultural heritage, including

historical buildings and traditional neighborhoods, plays a crucial role in preserving collective memory and reinforcing local identity.

Examples such as the restoration of historic city centers and the development of public parks that celebrate cultural diversity demonstrate how urban design can foster social justice and equitable resource access. These public spaces act as communal assets, promoting social interaction and a sense of community.

The complexity of integrating cultural elements into urban environments necessitates collaboration among architects, urban planners, sociologists, and anthropologists. Community participation in the design process ensures that symbolic structures genuinely reflect the values and aspirations of residents, thereby enhancing the resilience and sustainability of urban settings.

In conclusion, the theories of Durkheim, Bourdieu, and Geertz underscore the critical importance of symbolic structures in fostering social cohesion and resilience. Urban design that thoughtfully incorporates these structures can create cities capable of withstanding modern challenges and flourishing as vibrant communities with strong identities and rich collective memories.

5. SYSTEMATIC PROCESSING AND SYNTHESIS OF LITERATURE

5.1. Synthesis of Theories

The systematic analysis and synthesis of the theories of imagination and cultural heritage reveal their deep connection to urban resilience. Imagination, as a tool for envisioning and creating, and cultural heritage, as a repository of collective memory and identity, are pivotal in shaping resilient and sustainable cities.

Connecting these theories with urban resilience in iconic cities provides a critical analysis of each theory's contributions. The theory of imagination, developed by thinkers like Cornelius Castoriadis, highlights the importance of collective imagination in shaping social and urban structures. Imagination fosters the envisioning of new possibilities and the development of innovative solutions to urban challenges. The capacity of communities to imagine diverse futures is crucial for their adaptability and resilience [7]. Additionally, social imagination supports collective action and participation, enhancing social cohesion and community spirit. In Barcelona, social imagination has led to numerous public spaces and initiatives promoting inclusivity and social cohesion. However, the theory of imagination can sometimes be seen as abstract and challenging to apply without specific frameworks and tools.

Cultural heritage provides a stable foundation for strengthening social cohesion and identity. Preserving cultural elements bridges the past and present, fostering a sense of continuity and stability essential for community resilience. Moreover, cultural heritage reinforces local identity and a sense of belonging, promoting social solidarity and collective action [21]. For instance, the preservation of historical buildings and traditional neighborhoods in Prague enhances collective memory and local identity. Nevertheless, focusing solely on cultural heritage can lead to stagnation and hinder innovation if not combined with imagination and adaptability [14].

Synthesizing the theories of imagination and cultural heritage offers a comprehensive approach to understanding and enhancing urban resilience. Imagination drives innovation and adaptability, while cultural heritage bolsters social cohesion and collective identity. Together, these theories form a robust framework for creating sustainable and resilient cities capable of meeting contemporary challenges.

By integrating the creative potential of imagination with the stabilizing force of cultural heritage, cities can foster environments that are both innovative and rooted in a strong sense of identity. This dual approach ensures that urban areas are not only able to adapt to change but also retain their unique cultural essence, thereby enhancing overall resilience.

5.2. Reading Theories in Emblematic Characteristic Cities

The synthesis of fantasy theories and cultural heritage reveals their close connection to urban resilience. Fantasy, as a means of vision and creation, and cultural heritage, as a carrier of collective memory and identity, play a crucial role in shaping resilient and sustainable cities.

Barcelona is a characteristic example of a city that has incorporated imaginative and symbolic structures into its urban design. The work of Antoni Gaudí, such as the Sagrada Família and Park Güell, contains imaginative and symbolic elements that reflect the city's cultural heritage. These works attract tourists and enhance the local identity and pride of residents, promoting social cohesion and the city's resilience [28].

The city of Kyoto has managed to maintain and incorporate traditional elements into modern urban design. Temples, gardens, and traditional wooden houses enhance the social cohesion and cultural identity of the city. These elements create a sense of continuity and stability, contributing to the city's resilience [30].

New York City has also incorporated imaginative and symbolic structures, such as Central Park, the Empire State Building, and the Brooklyn Bridge. These symbols of urban identity and cultural heritage promote social cohesion and a sense of belonging, while providing spaces for recreation and social interaction [20].

The integration of imaginative and symbolic structures in urban design has significant impacts on the resilience of cities:

Enhancing Social Cohesion: Symbolic structures and imaginative elements create common references and values for residents. This strengthens the sense of belonging and identity, making communities more cohesive and resilient to social and economic disruptions.

Promoting Cultural Identity: Integrating cultural heritage into urban design helps preserve and promote the cultural identity of a city. It enhances local pride and cultural awareness, creating a stable and cohesive social environment [21].

Economic Development and Tourism: Imaginative and symbolic structures attract tourists and investments. Tourism and cultural activities create jobs and incomes, boosting the city's economic resilience (Richards, 1996).

Psychological and Social Well-being: Symbolic structures and cultural spaces offer places for social interaction and recreation, enhancing residents' psychological and social well-being. These spaces serve as refuges in times of crisis, providing safety and stability [24].

Environmental Resilience: Green spaces, like Central Park, provide ecosystem services such as temperature reduction, air quality improvement, and water management, enhancing the city's resilience to climate change [27].

In conclusion, the integration of imaginative and symbolic structures into urban design has positive impacts on city resilience. Cities like Barcelona, Kyoto, and New York show that these structures enhance social cohesion, promote cultural identity, support economic development, and improve the psychological and social well-being of residents. These practices create resilient and sustainable cities capable of facing the challenges of the modern world.

6. CONCLUSIONS AND RECOMMENDATIONS

6.1. Verification of the Hypothesis

This study examined the relationship between imaginary and symbolic structures and urban and territorial resilience. By reviewing literature and analyzing case studies from iconic cities, we tested the hypothesis that fostering these structures can enhance urban resilience.

The literature review underscores the profound impact of imagination and cultural heritage on urban planning and resilience. The theory of imagination, notably developed by Cornelius Castoriadis, highlights the role of collective imagination in shaping social and urban frameworks. Imagination

fosters innovation and adaptability, enabling communities to envision new possibilities and develop creative solutions to urban challenges [7].

Similarly, the theory of cultural heritage, advocated by scholars like Pierre Bourdieu and Edward Said, emphasizes the importance of integrating cultural elements into urban planning. Cultural heritage enhances social cohesion and identity, providing a sense of continuity and stability that bolsters urban resilience [4-29].

Iconic cities such as Barcelona, Kyoto, New York, and Athens illustrate the successful integration of imaginary and symbolic structures into urban planning. These cities show that incorporating cultural elements can enhance social cohesion, promote cultural identity, support economic development, and improve residents' well-being [28-30-20].

Our findings confirm the hypothesis: cultivating imaginary and symbolic structures significantly enhances urban and regional resilience. Theoretical and empirical evidence demonstrates that these structures are crucial in building resilient urban environments.

Imagination and cultural heritage offer pathways to creating sustainable and resilient cities. Imagination drives innovation and adaptability, while cultural heritage fosters social cohesion and collective identity. When strategically integrated into urban planning, these elements help cities meet contemporary challenges and thrive despite adversities [26-24-27].

In summary, our hypothesis is validated, showing that fostering imaginary and symbolic structures is essential for enhancing urban resilience. This study provides valuable insights and practical recommendations for urban planners, policymakers, and communities aiming to build sustainable and resilient cities for the future.

6.2. Recommendations for Further Research

The examination of imaginary and symbolic structures in urban design and city resilience uncovers critical dimensions and gaps that necessitate further investigation. This section outlines key areas for future research.

While qualitative studies offer valuable insights, there is a significant need for the quantitative evaluation of the effects of imaginary and symbolic structures on urban resilience. Future research should prioritize the collection and analysis of quantitative data to measure their impacts on social cohesion, economic development, and environmental sustainability. For instance, studies could explore how specific urban interventions influence community bonding and economic activities over time [5].

Furthermore, it is essential to explore how these structures contribute to social justice and equity. In highly unequal cities, understanding the role of cultural initiatives in promoting social inclusion and reducing disparities is crucial. Research should investigate how cultural projects can bridge gaps between different social groups and enhance equitable access to urban resources [14].

Comparative studies across various cultural and geographical contexts can offer valuable insights into the transfer and adaptation of best practices. By examining how different cities incorporate and benefit from these structures, researchers can identify culturally sensitive strategies that enhance urban resilience. For example, comparing cities with diverse cultural backgrounds can reveal unique approaches to integrating symbolic structures into urban planning [11].

The advent of digital technology presents new opportunities to strengthen imaginary and symbolic structures. Future research could examine how virtual and augmented reality technologies promote cultural heritage and foster social cohesion. Case studies of cities utilizing these technologies can highlight innovative ways to engage communities and preserve cultural narratives [12].

Lastly, long-term studies and ongoing monitoring of the impacts of these structures are vital. Establishing robust monitoring mechanisms to track changes over time can provide invaluable data

for refining and improving urban resilience strategies. Longitudinal studies that follow the evolution of urban projects can offer deeper insights into their sustained impacts [31].

In conclusion, focusing on quantitative assessment, social justice, comparative studies, digital technology, and long-term monitoring can significantly contribute to the development of sustainable and resilient cities. By addressing these areas, future research can provide a more comprehensive understanding of how imaginary and symbolic structures influence urban resilience.

Harnessing local resources for resilient communities: Urban heritage and creative tourism in peripheral areas

D. Asimiadis^{1*}, A. Manglis¹, P. Raxis¹

¹Atlantis Research

*Corresponding author: E-mail: asimiadis@atlantisresearch.gr, Tel +30 2310 531000

Abstract

This article examines the significance of local resources in building resilient communities, both in urban and peripheral/rural settings. It is inspired by the work being carried out in the framework of the TOURAL project, funded by the European Union through the Horizon Europe programme.

The concept of resilience is becoming increasingly crucial as communities face growing challenges, such as natural disasters, climate change, and economic hardships. Leveraging local resources, such as urban heritage and the potential for cultural and creative tourism, can play a pivotal role in strengthening the resilience of these communities. Urban heritage encompasses the tangible and intangible elements that bear witness to the history and culture of a place. It may include monuments, historic buildings, archaeological sites, traditional arts and customs. Leveraging urban heritage can contribute to resilience in several ways:

1. **Enhancing a sense of belonging:** Connecting with urban heritage can strengthen residents' sense of belonging, leading to increased social cohesion and solidarity.
2. **Providing tangible assets:** Urban and rural heritage can serve as a source of income and employment, particularly through tourism.
3. **Offering historical knowledge:** Understanding a region's past can aid in better comprehending current challenges and developing effective strategies for the future.
4. Cultural and creative tourism focuses on experiencing the culture and creativity of a place. It may involve visiting museums, galleries, historic sites, festivals, and other cultural events. Developing cultural and creative tourism in peripheral areas can offer the following benefits:
5. **Job and income creation:** Tourism can be a significant source of income for local communities, especially in rural areas with limited economic opportunities.
6. **Preserving cultural heritage:** Tourism can contribute to the preservation of a region's cultural heritage by attracting resources for the restoration and utilization of historic monuments and sites.
7. **Promoting sustainable development:** Sustainable tourism can help protect the environment and strengthen local economies.
8. Harnessing local resources, such as urban and rural heritage and the potential for cultural and creative tourism, can significantly contribute to building resilient communities. By fostering a sense of belonging, providing tangible assets, offering historical knowledge, and promoting sustainable development, these resources can empower communities to face challenges and thrive in a rapidly changing world.

Keywords: *resilience; urban heritage; cultural & creative tourism; sustainable development; TOURAL.*

1. INTRODUCTION

Many rural and remote areas are heavily reliant on traditional agriculture, livestock farming, and forestry for their livelihoods. This overdependence often leads to a noticeable decline in the standard of living for their inhabitants. These regions are particularly vulnerable to fluctuations in economic and political conditions, while the agriculture sector itself offers limited job opportunities. This situation significantly increases the prevalence of unemployment and poverty, widening the development gap between these regions and urban areas, and exacerbating social inequalities. However, these same areas often possess untapped potential for tourism development, offering a multitude of benefits that can permeate various aspects of life. Economic growth stands as the most compelling incentive for pursuing tourism development in these regions. By harnessing their unique tourism potential, these areas can create a surge of new business opportunities and employment prospects. This, in turn, will lead to an increase in residents' income, significantly boosting the local economy. Consequently, this economic revitalization will help to reduce social inequalities, which are typically more pronounced in regions with weak economies [1].

The allure of tourism, with its promise of economic prosperity and cultural exchange, is undeniable. However, beneath the surface of this seemingly golden opportunity lies a potential quagmire of challenges that, if left unaddressed, could unravel the very fabric of the destinations it seeks to promote. The decision to embrace tourist exploitation, while presenting a tempting avenue for economic growth, must be tempered with a keen understanding of the environmental and cultural ramifications that could ensue if not carefully managed. The environmental impact of unfettered tourism cannot be overstated. The influx of visitors, each with their unique needs and habits, places an immense strain on the delicate ecosystems that form the very foundation of these destinations. Natural habitats are encroached upon, pristine landscapes scarred, and precious resources depleted to accommodate the demands of this burgeoning industry. The consequences of such exploitation are far-reaching, leading to soil erosion, water pollution, and a decline in biodiversity. The cultural fabric of these destinations is equally vulnerable to the homogenizing forces of mass tourism. As droves of visitors, often unaware of local customs and traditions, descend upon these communities, their presence can lead to a dilution of cultural identity. [2]

The authenticity of local practices and traditions may be compromised, replaced by superficial representations tailored to cater to tourist expectations. This erosion of cultural heritage can sever the deep connection between communities and their ancestral roots, threatening the very essence of what makes these destinations unique. The specter of pollution looms large as a consequence of unchecked tourist exploitation. The sheer volume of waste generated by visitors, coupled with the increased demand for energy and resources, places an unsustainable burden on the environment. Untreated wastewater, overflowing landfills, and air pollution from vehicles and industrial activities can wreak havoc on the delicate balance of these ecosystems. The pristine beauty that once drew visitors may become a distant memory, replaced by a polluted landscape that repels rather than attracts. In order to reap the economic benefits of tourism without succumbing to its detrimental effects, a paradigm shift is essential. Destinations must adopt a holistic approach to development, one that prioritizes sustainability and environmental protection [3].

This requires a concerted effort from governments, tourism agencies, local communities, and individual visitors. Governments must implement stringent regulations to minimize the environmental impact of tourism. This includes enforcing strict waste management protocols, promoting renewable energy sources, and preserving natural habitats. Tourism agencies must prioritize responsible tourism practices, educating visitors about local customs and traditions while encouraging them to minimize their environmental footprint. Local communities must play a central role in shaping the tourism narrative, ensuring that their cultural heritage is not exploited but rather celebrated [4].

This involves showcasing authentic traditions, engaging visitors in meaningful cultural exchanges, and fostering a sense of mutual respect and understanding. Individual visitors must take responsibility for their actions, making informed choices that minimize their environmental impact and respect local cultures. This includes choosing sustainable travel options, reducing waste generation, and respecting local customs and traditions. By embracing a collaborative approach that prioritizes sustainability and cultural sensitivity, destinations can navigate the double-edged sword of tourist exploitation, reaping the economic rewards while preserving the very essence that makes them unique and worth visiting. Only through responsible tourism practices can we ensure that these destinations remain havens of natural beauty and cultural richness, not just for the present but for generations to come [5].

It is therefore necessary to implement an alternative tourism model which will focus on cultural and creative tourism in remote areas which remain untapped, displaying in this way their special characteristics, without undergoing any alteration, in order to strengthen the economy as well as the sustainable development in these areas. The TOURAL project is set to address the above challenge with its multidimensional approach and its integrated development plan; aiming at the combination of regional economic development and financial resilience, while respecting all the regional characteristics and leveraging regional strengths.

2. A CULTURAL AND CREATIVE TOURISM RENAISSANCE

Cultural and creative tourism has emerged as a dynamic force within the global tourism industry, offering travelers immersive experiences that connect them to the heart and soul of a destination, its culture, arts, and heritage. This unique form of tourism fosters a multitude of benefits for both host communities and visitors [6].

For destinations, cultural and creative tourism fosters diversification within their tourism offerings, attracting new market segments of travelers. This diversification invigorates the local economy through increased visitor spending and generates new employment opportunities. It strengthens local identity and fosters a sense of pride within communities. Cultural and creative tourism also promotes social cohesion by encouraging interaction between visitors and residents, fostering a deeper understanding and appreciation for each other's cultures. Most importantly, it serves as a powerful tool for safeguarding cultural heritage by raising awareness and appreciation for traditional practices and historic sites. For visitors, cultural and creative tourism unlocks a treasure trove of unique experiences. They gain the opportunity to engage with the authentic culture of a place, immersing themselves in its rich history and traditions [7].

This engagement can take many forms, from attending vibrant artistic performances to participating in traditional workshops that allow them to learn firsthand from local artisans. Through these immersive experiences, travelers broaden their horizons, develop critical thinking skills, cultivate empathy, and build bridges of understanding with cultures distinct from their own [8].

However, developing cultural and creative tourism is not without its challenges. One of the most critical concerns is ensuring the authenticity of the experiences offered. It is imperative that these experiences are genuine and not merely contrived attractions catering solely to tourists. Achieving authenticity necessitates close collaboration with local communities and a deep respect for their cultural heritage. Inauthentic experiences risk transforming into superficial attractions that fail to capture the essence of a place and its culture, leading to disillusionment among visitors who may feel misled. Moreover, inauthentic experiences can contribute to the erosion of cultural heritage and traditions, prioritizing commercial interests over the preservation of local practices and knowledge.

To safeguard authenticity, fostering genuine connections with local communities is paramount. This involves engaging with them throughout the planning, development, and implementation of tourism initiatives. By actively involving residents in the process, their insights, perspectives, and expertise can be incorporated, ensuring that the experiences offered are rooted in their culture and traditions. Furthermore, demonstrating respect for cultural heritage is essential. This entails understanding and

appreciating the historical, artistic, and traditional significance of a place. It also involves ensuring that tourism activities do not cause harm or disrespect to cultural sites, artifacts, or practices. By prioritizing cultural sensitivity, destinations can preserve their unique heritage while simultaneously sharing it with visitors in a meaningful way [9].

Another challenge lies in ensuring the sustainable development of cultural and creative tourism. Striking a balance between promoting tourism and safeguarding the environment, cultural heritage, and the well-being of local communities is paramount.

Environmental sustainability is of utmost importance. Cultural and creative tourism initiatives must be designed and implemented in a manner that minimizes negative impacts on the environment. This includes reducing carbon emissions, conserving natural resources, and adopting eco-friendly practices. By prioritizing environmental sustainability, destinations can protect their natural beauty and ensure that future generations can continue to enjoy the unique ecosystems that attract visitors.[10]

Cultural heritage sustainability is equally crucial. Cultural and creative tourism should not come at the expense of a destination's cultural heritage. Instead, it should serve as a tool for preserving and promoting local traditions, practices, and historic sites. This requires careful planning and management of tourism activities to ensure that they do not cause damage or disrespect to cultural heritage. By safeguarding cultural heritage, destinations can protect their identity and strengthen their sense of place.

Ensuring the fair distribution of tourism development benefits to local communities is another critical aspect of sustainability. Tourism growth should not exacerbate existing inequalities or marginalize residents. Instead, it should provide opportunities for economic empowerment, job creation, and community development. This involves engaging local communities in tourism planning and decision-making processes, ensuring that they have a stake in the industry and benefit from its growth. By promoting equitable distribution of benefits, destinations can foster social cohesion and ensure that tourism contributes to sustainable community development [11].

Promoting cultural and creative tourism effectively also presents challenges. This form of tourism is often less well-known compared to traditional beach or city tourism, making it harder to reach the right target audience. Targeted communication and marketing strategies are essential to highlight the unique experiences and offerings of each destination. This includes utilizing digital platforms, collaborating with travel influencers, and engaging in niche marketing campaigns that appeal to specific traveler segments. By effectively promoting their cultural and creative assets, destinations can attract visitors seeking authentic and enriching travel experiences.

Overall, cultural and creative tourism presents a dynamic and multifaceted approach to travel, fostering economic and social benefits for both destinations and visitors. As this segment of the tourism industry continues to flourish, it offers a promising path for promoting cultural exchange, fostering understanding, and enriching the travel experience for all. Addressing the challenges that arise is essential for the healthy development of this type of tourism and for maximizing its benefits for all. Cultural and creative tourism, when approached thoughtfully and responsibly, presents a powerful force for positive change. By overcoming the challenges discussed, destinations can cultivate a thriving tourism sector that fosters economic prosperity, social cohesion, and cross-cultural understanding on a global scale [12].

3. THE TOURAL PROJECT APPROACH AND MULTIDIMENSIONAL MODEL

Scattered across the vibrant tapestry of Europe's landscapes lie vast swathes of rural and remote regions, each brimming with potential waiting to be unleashed. These areas, steeped in the traditions of agriculture, forestry, and farming that have shaped their identities for generations, now confront the pressing need to diversify their economies and forge a path towards sustainable growth. In this context, TOURAL proposes a transformative model that harnesses the potent force of cultural and

creative tourism to revitalize these very regions, by bringing to light hidden landmarks through offering immersive experiences.

TOURAL's vision is to unlock the potential of cultural and creative tourism, fostering a new kind of travel experience that goes beyond the superficial. By promoting artistic expression, traditional crafts, and vibrant cultural events, TOURAL aims to weave a new thread into the economic tapestry of these rural regions. This approach not only fosters economic diversification but also fosters a sense of pride and ownership within local communities [13].

As visitors become active participants in cultural experiences, they become stewards of these traditions, ensuring their preservation for generations to come. Furthermore, TOURAL recognizes the importance of sustainable practices. Responsible tourism, which minimizes environmental impact and celebrates the natural beauty of these regions, lies at the heart of the project. Imagine visitors exploring breathtaking landscapes on foot or bicycle, savoring locally sourced cuisine, and immersing themselves in the breathtaking biodiversity that defines these areas. This responsible approach ensures that tourism becomes a force for good, protecting the very resources that make these rural regions so special. By harnessing the power of cultural and creative tourism, TOURAL aspires to breathe new life into Europe's rural and remote areas. The project is not just about economic growth; it's about creating a future where these regions can thrive, their unique cultures celebrated, and their natural beauty preserved for all to experience.

Leveraging a comprehensive understanding of the inherent challenges and burgeoning opportunities within rural and remote regions, TOURAL champions a multifaceted approach to tourism development. This innovative framework transcends the limitations of traditional models, embracing a diverse spectrum of complementary tourism verticals and niche sectors. The project encompasses a captivating range of experiences, from underwater cultural and natural heritage exploration to the vibrant tapestry of cultural and creative tourism [14].

One pillar of TOURAL's approach is underwater cultural and natural heritage tourism. Imagine submerging oneself in the sea-waters surrounding these regions, where shipwrecks whisper tales of forgotten voyages and vibrant coral reefs teem with life. This immersive experience fosters a unique perspective on the region's historical and ecological spectrum, fostering a deeper appreciation for its past and present.

TOURAL extends its reach beyond the aquatic realm, delving into the heart of these regions to promote cultural and creative tourism. This facet of the project celebrates the artistic soul of local communities, fostering rich visitor engagement. Envision visitors acquiring the art of pottery, a tradition passed down through generations, or participating in vibrant music festivals that showcase the region's unique artistic talent. Immersion in traditional dance performances becomes a captivating journey through the region's cultural memory, fostering a profound understanding and appreciation for the distinctive cultural tapestry woven into the fabric of these places. Furthermore, TOURAL recognizes the intellectual curiosity that motivates many travelers. Cultural science tourism is embraced, offering opportunities to delve into the scientific wonders that define these regions. This could involve exploring archaeological sites that unveil the secrets of bygone eras, participating in workshops that illuminate the fascinating ecosystems, or embarking on guided tours led by local experts who share their profound knowledge of the region's natural world.

Finally, TOURAL acknowledges the growing segment of mature travelers seeking enriching experiences. The project incorporates silver tourism, catering specifically to this demographic by offering experiences tailored to their interests and needs. Imagine senior travelers exploring historical sites at a leisurely pace, participating in wellness workshops that draw inspiration from local traditions, or attending cultural events that celebrate the wisdom and heritage of these regions.

By embracing the above multi-dimensional approach, TOURAL ensures a captivating and diverse tourism landscape for revitalized rural and remote areas. It caters to a wide range of interests, fosters cultural appreciation, and celebrates the unique character of each region.

Proceedings

TOURAL's sustainability of results and impact hinges on its unwavering commitment to participatory principles. By actively engaging local stakeholders, including communities, businesses, and government entities, TOURAL's tourism development approach aligns with the aspirations and needs of those who call these regions home. This collaborative approach fosters a sense of ownership and empowerment, ensuring that tourism benefits are shared equitably. Sustainability is not an afterthought in TOURAL; it is the very foundation upon which the project is built. Recognizing the delicate balance between tourism development and environmental preservation, TOURAL promotes responsible tourism practices that minimize environmental impact and protect the rich cultural heritage of rural areas.

Through its multifaceted approach, TOURAL aims to achieve a transformative impact on rural and remote areas, unlocking their potential as vibrant destinations for cultural and creative tourism. By fostering economic diversification, promoting sustainable practices, and empowering local communities, TOURAL paves the way for a renaissance of rural tourism, breathing new life into these often-overlooked gems of Europe. The expected results of TOURAL will not only revitalize rural economies and preserve cultural heritage but also serve as a model for sustainable and inclusive tourism development worldwide. As the project unfolds, it is poised to inspire and empower communities across the globe, demonstrating the transformative power of cultural and creative tourism in shaping a more resilient and equitable future.

4. TOURAL EXPECTED RESULTS

TOURAL focuses on developing innovative cultural and creative tourism experiences. These include unique offerings such as underwater heritage trails, cultural science festivals, and silver tourism packages aimed at senior travelers. Additionally, the project seeks to improve the accessibility and quality of existing tourism offerings through renovations of cultural sites, training for tourism providers, and the development of new marketing instruments. Promotion of rural and remote destinations is another critical component to attract more visitors and showcase their unique attractions.

An interactive online platform will serve as a hub for tourism stakeholders to share information, collaborate on projects, and access valuable resources. This fosters a community-driven approach to tourism development, ensuring that all parties can contribute to and benefit from shared knowledge and initiatives. For tourists, a mobile App will offer a seamless way to discover and enjoy local experiences, plan their trips, and access real-time information. This App will be designed to enhance the tourist experience by providing convenient access to a variety of activities thus ensuring up-to-date information.

The TOURAL model is designed to be replicable and sustainable, emphasizing multi-dimensionality, participation, and integration. It provides a set of guidelines and best practices for stakeholders involved in cultural and creative tourism development. In addition, to support data-driven decision-making, an AI-powered data analytics dashboard will provide valuable insights into regional tourism trends and outcomes, helping stakeholders to improve the tourism growth balance between urban and rural areas, making informed decisions that promote sustainable tourism practices.

Beyond these immediate goals, the TOURAL project aims to contribute significantly to the increased economic growth and creation of job vacancies in rural and remote areas, to strengthen local communities, and improve the quality of life. By fostering more sustainable tourism practices that respect the environment and local cultures, TOURAL sets a new standard for tourism development.

5. CONCLUSION

Cultural and creative tourism, when embraced thoughtfully and responsibly, presents a transformative force for positive change within the global tourism landscape. By effectively addressing the challenges discussed above, destinations can cultivate a thriving tourism sector that fosters not only

economic prosperity but also social cohesion, cross-cultural understanding, and environmental sustainability on a global scale.

Empowered Local Communities. Sustainable cultural and creative tourism ensures that residents are active participants in and beneficiaries of tourism development. This fosters a sense of ownership among local community members and encourages investment in cultural preservation efforts. When local communities are actively involved in planning and decision-making processes, their unique knowledge, traditions, and perspectives become the foundation for authentic and enriching tourism experiences. This, in turn, fosters a sense of pride in cultural identity and strengthens community bonds.

Economic Diversification and Resilience. Cultural and creative tourism when combined with new and diverse market segments such as underwater cultural & nature heritage tourism, cultural science and silver tourism; reduces reliance on traditional tourism models. This diversification strengthens the local economy by creating new job opportunities in areas such as cultural heritage preservation, artisanal crafts, and creative experiences. Increased visitor spending also benefits local businesses, restaurants, and accommodations, contributing to a more resilient and vibrant economic landscape.

Cultural Preservation and Transmission. Sustainable cultural and creative tourism prioritizes the responsible presentation and celebration of local traditions and heritage. By ensuring that tourism activities are respectful and sensitive, destinations promote the continuation and transmission of knowledge and practices to future generations. This can also lead to increased local appreciation for cultural heritage, fostering a deeper sense of connection to the past.

Social Cohesion, Understanding, and Global Citizenship. Cultural and creative tourism fosters genuine connections and understanding between visitors and residents. By engaging with different cultures and traditions, visitors develop empathy and a broader perspective on the world around them. This breaks down stereotypes, promotes cross-cultural dialogue, and fosters a sense of global citizenship. Breaking down barriers and building bridges of understanding between diverse cultures contributes to a more peaceful and interconnected world.

Environmental Sustainability and Long-Term Viability. A commitment to environmental sustainability ensures the long-term viability of cultural and creative tourism destinations. This involves adopting eco-friendly practices, reducing carbon emissions, conserving natural resources, and minimizing negative environmental impacts. By protecting their natural beauty and ecosystems, destinations can attract environmentally conscious travelers while safeguarding the very resources that contribute to their cultural richness and appeal.

In conclusion, cultural and creative tourism, when approached thoughtfully and responsibly, offers a transformative approach to travel that benefits not only the destinations themselves but also the individuals who visit them. By addressing the challenges and embracing the opportunities, destinations can harness the power of cultural and creative tourism to create a more inclusive, sustainable, and enriching experience for all. As cultural and creative tourism continues to evolve, it has the potential to become a cornerstone of a more interconnected, sustainable, and culturally diverse future for travel. It is a force that can bring people together, foster understanding, and promote appreciation for the rich tapestry of human cultures around the world.

Extended abstract

Public spaces are basic urban elements that have been shaped through the centuries with principles guided by different economic, social, political, and religious conditions. Public spaces constitute an important element of the city's system and consequently of urban resilience. The development of resilient public spaces should promote the interconnection of the public spaces physical and social dimension. The allocation of public spaces, their relation and proximity with the rest functions of the city, their accessibility, their green surfaces and other qualitative features, and their digital elements constitute critical parameters.

The current paper aims to analyze the resilience of public spaces in a typical Greek middle-sized city, the city of Chania. Based on a methodology that evaluates

- access: finding your way and getting about.
- use: what activities and opportunities the space has to offer.
- other people: how the space caters for different needs
- maintenance: how clean and cared for the space is.
- environment: how safe and comfortable the space is
- design and appearance: what the space looks like and what it's made from
- community: how important the space is to local people – you: how the space makes you feel, it analyzes the public spaces of the city with quantitative and qualitative data.

Research proceeds to the categorization of public spaces according to their resilience and proposes strategies that can strengthen their role in city's function.

Extended abstract

Contemporary urban challenges, such as those posed by climate change and the growing global population, have accelerated the discussion over the shift to urban sustainability and resilience. Technological innovation, social know-how, behavioral changes, and the effective utilization of urban space are all suggested as means to achieve this goal. In recent years, governance has emerged as a necessary component of urban sustainability and resilience. This perspective involves new forms of communication and decision-making, alliances and partnerships between public, private and social actors, and novel institutional structures, networks and representation. In this context, there is a growing recognition among scholars, policymakers, and professionals of the significance of utilizing innovative governance tools in effectively managing and transitioning towards sustainable and resilient systems. One such tool is the Living Lab (LL), which functions as a governance structure to organize, facilitate and provide an environment for exchange, cooperation and accountability in decision-making.

The objective of this paper is to provide some highlights on the overall concept of the Living Lab and its utilization as a governance tool within the project “Institutionalized Integrated Sustainable Energy and Climate Action Plans – 2ISECAP” (Horizon 2020). The project aims to address local energy transition by enhancing the performance of Sustainable Energy and Climate Action Plans’ (SECAP) development and implementation process. Six pioneering European municipalities of different sizes and types and with different socio-economic, geographical and economic settings are involved in 2ISECAP. These are: Karditsa – Greece, Leon – Spain, Ljutomer – Slovenia, Padova – Italy, Tartu – Estonia and Thun – Switzerland. Within each Municipality, a LL has been organized to support the development and enhancement of integrated sustainable energy policies. The LL concept has been chosen to serve as a platform that: i) encourages public administration of all levels to evolve from its silo-based working culture to a participatory, cross-departmental and multilevel way of working, ii) enables a citizens-driven, private party included and facilitator-based co-creation process to identify local/ regional visions and planning priorities, iii) supports the development of sustainable relationships between actors through engagement and trust creation, iv) facilitates the exchange of know-how, the spanning of knowledge and experiential learning, and promotes innovative thinking. LLs mobilise existing innovation tools or develop new ones, as examined in this paper.

Overall, it is argued that Living Labs enable the development and experimentation of innovative concepts, tools and products and help build the institutional, technical and financial capacities needed to implement plans, as well as to be flexible and adapt to change and pressures, key elements towards urban resilience.

Building simply: A resilient approach to sustainable urban living amid climate change challenges

A. Niemann

Senior Researcher, School of Engineering and Design, Technical University of Munich, Germany
Corresponding author: E-mail: anne.niemann@tum.de, Tel +49 179 7048433

Extended abstract

As urban overheating is becoming an increasingly pressing concern due to climate change, it is important to develop robust concepts that address thermal insulation in summer. The 'Building Simply' concept, developed at the Technical University of Munich, offers a potential solution by creating a constant indoor climate without relying on technical systems such as air conditioning. The approach includes large storage masses, a balanced window-to-room area ratio, and efficient window ventilation. Sun protection was deliberately excluded due to frequent misuse by users. The primary objective of this study was to determine whether the simplified design of the three houses, aligned with the 'Building Simply' concept, results in an acceptable temperature perception among residents. A combination of semi-structured questionnaires, guided interviews, measurements, and on-site observations was used to analyze user acceptance and identify potential resistance to resilient buildings. The summer temperatures in the houses were generally moderate, although there were instances of localized overheating in specific areas. Although temperatures were slightly above the standard comfort range, most residents found them acceptable. The impact of the environment – specifically, shade from trees or nearby buildings – had a notable impact on well-being. The lack of external solar shading was found to be effective in terms of average temperature and overall user satisfaction. Although manually operated external solar shading could improve user comfort, it was considered unnecessary for the proper functioning of the houses. Night-time ventilation is an important factor in regulating temperature, but it can be hindered by ambient noise and lack of understanding among users. The study showed that the construction is robust, with some test subjects choosing not to use regulating measures such as curtains or fans. The implementation of the 'Building Simply' concept demonstrates that a focus on resource-efficient and low-tech buildings is ecologically sensible and well-received by users. The moderate summer temperatures were perceived as pleasant by residents, affirming the success of the resilient building concept, despite localized overheating. The study highlights the impact of surroundings on resident well-being and emphasizes the importance of holistic planning that considers both the building and its surrounding infrastructure. Further research should explore broader applications of the 'Building Simply' concept in diverse urban settings, particularly in light of the escalating urban overheating problem. Investigating the scalability and adaptability of the concept to different climate zones and architectural styles would provide valuable insights. Furthermore, assessing the long-term energy efficiency and ecological impact of such constructions over extended periods is essential for validating the sustainability of the approach. Future research could explore the integration of smart technologies to improve user comfort and energy management while maintaining the low-tech nature of the concept. By addressing these aspects, the 'Building Simply' concept could make a significant contribution to the development of resilient and environmentally conscious urban spaces.

Extended abstract

The local cultural sector, like others, has been hard hit by Covid-19, but with particular acuity due to its non-essential status in the fight against the pandemic and that could have provoked gatherings outside homes. At the same time, the cultural sector has continued to reflect on the ecological impact of its activities.

Archives, visual arts, libraries, museums, heritage, cinemas and theatres, etc. have all come to a standstill, while digital services accessible from the home have been in great demand, accelerating their development and, in some cases, their hold on society. The first-mentioned areas of activity have received varying degrees of support depending on the country, sometimes with direct or indirect aid to artists and cultural professionals. They have also made greater use, or for the first time, of remote diffusion methods, which may continue after Covid-19. The return to cultural venues has been gradual, but with often lower attendance up to 2023 than in the year preceding Covid-19.

As far as climate change is concerned, over the last ten years or so some festivals have sought to limit carbon consumption in terms of short supply chains based on circular economy, waste management and ecological transport, for example by carpooling and the train, but overall festivals are still very polluting because of the large number of artists and audiences they welcome from all over France and the world. Cultural establishments have also recently been looking at their carbon consumption, sometimes voluntarily but also under the impetus of State and local authority subsidies.

The aim of this paper is to show the nature of the environmental, economic, social and technological changes underway in the cultural sector for sustainable territorial resilience, but also to raise the question of how to support and encourage possible changes based on studies and examples. Our research into the effects of the Covid-19 in Reims and the surrounding area, using questionnaires and interviews with cultural players, highlighted the heavy dependence of French cultural structures, artists and professionals on public subsidies and fossil energies, and suggests ways forward.

Housing as a site of everyday practices of resilience: the case of Um-Al-Sharayet neighborhood-Ramallah/ Al-Bireh- Palestine

S. Awad

Assistant Professor, Department of Architectural Engineering and Urban Planning, Faculty of Engineering and Technology,
Birzeit University, Palestine

Corresponding author: E-mail: sqasem@birzeit.edu, Tel +970 2982119

Extended abstract

This research investigates the Post-Oslo urban developments in Ramallah / Al -Bireh in Palestine amidst major neoliberal urban restructuring and the Israeli occupation land grab and mobility control. According to Taraki, the establishment of the PA after the Oslo Accords in 1993 marks the transformation of Ramallah/Al-Bireh from small villages in the early 20th century to a central city (Taraki, 2008). Taraki explained that the imposed spatial regime that the Oslo Accords produced has enclaved the city of Ramallah/Al-Bireh, separating it from other Palestinian cities (Taraki, 2008).

Within these urban socio-political and economic transformations the Palestinians are struggling to create their own state, apparently new architectural forms and meanings appeared in response to these changes. Impressively Ramallah / Al-Bireh represents an ideal case that reflects the Israeli occupation spatial control and the neoliberal forces impacts on the city; the research is investigating Um- Al -Sharayet neighborhood which is considered a facet of post-Oslo rapid urbanization in the Palestinian urban context.

Accordingly, the study draws on ethnographic research to tackle the everyday practices of the residents in Um-Al-Sharayet neighborhood in order to understand the their experience of the neighborhood and the adaptation strategies and the tactics they developed to cope with the political, and socio-economic transformations. Based on Lefebvre various kinds of space for everyday discourse, such as street corners, market places, shopping centers and so on, are considered as organized codes which are part of the interaction between 'subjects' and their space and surroundings. These codes construct the spatial system of the space (Lefebvre, 1991 [1974], p.16). The research fieldwork combined observation and recording of field notes; interviews with residents; taking photographs; and the collection of documents, archival, and online materials. The research contributes to revealing how resilience practices are sustained in everyday housing contexts.

Disaster risk reduction planning for people with disabilities: case study on the city of Kalamata (Greece)

E. Bitsani¹, I. Thymi^{2,*}, G. Marava²

¹Professor, University of Peloponnese, Kalamata, ²Phd Candidate University of Peloponnese, Kalamata

*Corresponding author: E-mail: g.marava@go.uop.gr

Extended abstract

The literature suggests that individuals with disabilities, who constitute 16% of the world's population, are more vulnerable during natural hazards, climate-induced disasters and global health emergencies, as they are disproportionately affected due to various reasons. The Sendai Framework for Disaster Risk Reduction 2015-2030 acknowledges persons with disabilities as contributing stakeholders and emphasizes the need for their inclusion in all DRR policies and practices. However, emergency planning often represents this group inadequately, with limited training and awareness among emergency managers. Researchers acknowledge that disaster planning for people with disabilities is a complex and multifaceted issue that requires a “whole community” approach, involving families, clinicians and public authorities.

Given the increasing number of disasters due to climate change, the problem must be addressed as soon as possible. In Greece there have been recently legislative initiatives that prioritize the issue, although there are lot of implementation problems due to long-standing pathogenesis of Greek administration system, especially in the local level, but there is not enough research in the field.

In this research is presented the case - study of Kalamata, a city in southern Greece in DRR planning. Specifically, using the questionnaire of UNDDR, in order to understand the progress made in disability inclusion in DRR, the survey gave a numeric estimation of Kalamata's population with disabilities, and the types of disabilities present. Moreover, showed that there is an adequate knowledge of exposure to natural hazards. On the preparedness level, the survey confirmed the lack of personal preparedness plans, as well as lack of awareness in the local DRR plan. On the willingness to be involved in planning processes there was a vast majority in favor.

The basic outcome of this survey is that it is of utmost need a campaign for awareness raising of the population.

Unraveling the Dynamics of Climate Resilience at the Neighborhood Level: An Actor-Network Theory Approach

D. Can

Research Assistant, Middle East Technical University, Department of City and Regional Planning, Turkey
Corresponding author: E-mail: denizcan2805@gmail.com, Tel +90 5375109610

Extended abstract

In recent years, the imperative to enhance climate resilience at the local level has gained significant attention, with a growing recognition of the critical role of neighborhoods and frontline actors in confronting climate change impacts. This paper adopts Actor-Network Theory (ANT) framework to elucidate the complex network of actors and interactions involved in shaping climate resilience strategies, policies, implications and their outcomes at the neighborhood level. Drawing on empirical data from diverse urban neighborhoods, this study employs ANT as a methodological tool to unravel the intricate web of relationships among human and non-human actors, institutions, and socio-technical systems that influence the development and implementation of climate resilience strategies. By analysig these actor-networks, the research seeks to investigate the mechanisms, challenges, and opportunities for achieving climate resilience in neighborhood contexts.

Key components of the analysis include actor mapping, – i.e., the study systematically maps the heterogeneous array of actors involved in climate resilience efforts at the neighborhood level, ranging from residents, community organizations, and local government agencies to infrastructure systems, ecological features, and technological artifacts, their relations with each other, collaboration and cooperation. Following the identification and classification of these actors, this study highlights the diverse interests, motivations, and capacities that shape resilience outcomes. Additionally, network analysis techniques are applied to characterize the patterns of interaction, collaboration, and influence within and across actor-networks, shedding light on the flow of resources, information, and power dynamics that shape decision-making processes and governance structures related to climate resilience in neighborhoods. Emphasizing the intertwined nature of social and technical dimensions, the study investigates how socio-technical systems, such as green infrastructure, smart technologies, and community-based initiatives, mediate and shape climate resilience outcomes. By examining the roles and interactions of human and non-human actors within these systems, the research highlights the socio-technical dynamics that underpin neighborhood-level resilience strategies. The findings of this study have significant implications for policy, strategy and governance interventions aimed at enhancing climate resilience in neighborhoods, because they highlight key actors, relationships, and leverage points within actor-networks. Designs and implementations of targeted policies, programs, and interventions to foster more adaptive, inclusive, and sustainable approaches to climate resilience are suggested at neighborhood level according to the inferences of actor network analysis. By employing ANT approach, this paper contributes in advancing theoretical and methodological understandings of climate resilience at the neighborhood level, offering practical insights and recommendations for urban climate policies to foster more resilient urban neighborhoods in the face of climate change.

Extended abstract

Over the past decades, the amount of people that migrate to cities has rapidly increased, in pursuit of job opportunities and variety of choices when it comes to both entertainment and cultural amenities. As a result, individuals have changed their way of life, spending more hours in indoor spaces neglecting the outdoor places and activities. Urbanization has been a central concern by a variety of health and environmental experts, raising alarming questions for issues related to thermal evaluation of outdoor spaces but also the implementation of measures to encourage their utilization. Thermal assessment in outdoor spaces, and especially those in University campuses all over the world, has been vital for maintaining not only a healthy and environmentally friendly scene for both students and university staff, but also a more sustainable way of living. Due to radically different lifestyle in the last decade, with technology covering the biggest part of an individual's, everyday life, and especially a student's everyday life, it is considered of vital importance to try to make outdoor spaces more accessible and comfortable, so that individuals have a more balanced way of living and a deeper connection to nature, and they are also able not to misuse the various energy sources currently over-exploited.

This research is based on the case study of outdoor spaces at the campus of the School of Engineering, Democritus University of Thrace, located at the city of Xanthi, North-East Greece. It focuses on the evaluation of outdoor thermal comfort and microclimatic factors that affect it. The research was carried out with site monitoring of microclimate and thermal comfort parameters and thermal comfort evaluation by users of the site.

Measurements lasted 13 days, covering mostly June 2023, during the hours of 11:00 am to 14:00 pm, when the use-density of outdoor spaces by students and staff members is usually very high during these hours. The measurements took place with a portable weather station measuring air temperature, radiant temperature, and wind speed. A survey of a total of 252 questionnaires was carried out; and questionnaires were classified according to date and time of response.

The Actual Sensation Vote (ASV) and Thermal Sensation Vote (TSV) were statistically analyzed, using T-test function, F function and Pearson correlation. The analysis pointed a very low correlation in terms of microclimatic data, with air temperature having the highest predominance. The latter appears to be the major environmental factor that most influences people's thermal sensation and comfort, since it can well predict with greater validity both indicators. In general, the assessment of the thermal comfort of the outdoor spaces was satisfactory, and in line with the conclusions of other research publications.

Keywords: *thermal sensation, outdoor thermal comfort, university campus outdoor thermal comfort*

How Does Plant Taxonomic Choice Affect Building Cooling?

P. Kunasingam^{1*}, A. Clayden¹, R. Cameron¹

¹ Department of Landscape Architecture, University of Sheffield, UK

*Corresponding Author: E-mail: pkunasingam1@sheffield.ac.uk, Tel +44 114 222 0614

Extended Abstract

Urban green infrastructure represents a nature-based approach to mitigate urban heat islands, improve energy efficiency, and enhance human thermal comfort. All factors linked to a changing climate. Among various urban greening strategies, vertical greening systems (green walls and green façades) have gained popularity due to the densification of city landscapes, and the fact that these interventions take up little space. Vegetation on buildings cools the surface facades of the building and thus interior temperatures, reducing the reliance on energy-intensive artificial air-conditioning during summer. Plants confer a cooling effect on buildings through shading, evapotranspiration, and depending on foliar characteristics through the albedo effect (i.e., reflection of light). Selecting appropriate plant taxa would appear important in maximizing the thermal benefits of vertical greenery. However, there is limited information available on how the taxonomic choice of plants influences wall cooling. Thus, this paper investigates wall cooling capacities across different plant taxa in a temperate climate (UK). The aim of this study was to identify plant species that effectively cool the building surface across a range of ambient temperatures and investigate the correlation between wall cooling and key plant traits. Wall temperature behind 24 different taxa were monitored using thermocouples attached on individual panels, and the recorded data were compared against a control wall panel. Analysis was conducted on cooling differentials (the difference in temperature between the control panels and those behind the plants) across different summer weather conditions. Results showed that plants provided cooling capacity under all summer day-time conditions, but the cooling capacity increased as ambient temperatures rose, i.e., the differentials in temperatures were greatest under the warmest days, and when solar intensity was at its highest. On the warmest days wall panels behind plants could be 26°C cooler than wall panels without screening. Plant taxonomic choice was important in optimising the cooling effect, but notably, the taxon that provided the greatest cooling to the wall could change as ambient conditions themselves changed. As the temperature of the bare wall panel rose from 35°C to 45°C and then 55°C, the taxa that optimised cooling were *Lonicera*, *Hebe* and *Hedera*, respectively. In essence, plant genotypes that cool best under moderately warm conditions, are not necessarily the same as those that provide maximum cooling under the hottest conditions. Thus, there appear to be relations between plant traits and the conditions plants find themselves in, and their capacity to cool the environment around them. Further analysis suggested that maximising the amount of leaf area in front of the wall panel (greater shading) could partially explain the cooling effect of different plant taxa (especially under the warmest conditions), but otherwise cooling was not clearly linked to other traits such as foliage colour, leaf morphology or leaf texture. Overall, the data supports the notion that plants provide significant cooling to a building façade, but in practice, a mixed plant community may be preferred to a single-taxa ‘mono-culture’, due to this providing a greater array of cooling mechanism, across a range of different environmental conditions.

Green Management and Environmental Planning in Greek Forest Services

A. Liaskopoulou^{1*}, I. Papadopoulos¹

¹ Department of Forestry, Wood Sciences & Design – University of Thessaly, Greece

*Corresponding author: E-mail: aliaskop@uth.gr, Tel +30 697 6579470

Abstract

This study investigates the effect of Green Management on the operation of the Forestry Service (FS) and its strategic planning for the protection of the environment. The Environmental Planning as a forest strategy, is an obligation and basic mission of the Forestry Services (F.S.), as the majority of Greek Forests are public. The main purpose of the research is to highlight the knowledge of the importance of green management among FS executives, answering to the questions of the research about green management, organizational culture, employee behavior and their degree of satisfaction, as well as the creation of a positive psychological climate in the FS for the effective implementation of environmentally sustainable policies.

To conduct the research, a specially structured questionnaire was drawn up based on the literature review and was distributed to all executives of the regional and central F.S. of Greece. In total we have 232 fully answered questionnaires from all over Greek territory. The questionnaires were collected from September 2023 to February 2024. Most questionnaires were completed electronically through the Google Form platform, and some were required to be sent by post or by visiting the local F.S. The results were processed with the help of the IBM SPSS 26 statistical package.

The analysis of the results highlighted the relationship between the culture of the organization and the employee, as well as the connection between green management and job satisfaction, as the executives of F.S. seemed to accept this interaction to a very large extent.

In addition, it emerges that the behavior of employees in F.S. is largely linked to and influenced by its organizational culture which refers to employee values, beliefs and behaviours, such as: individual green values, green behavior and competence, green commitment, commitment, work performance and well-being, which mutually influence each other to a greater or lesser extent.

In addition, the individual values of the employees of F.S. have positive effects on employees' workplace, while employees' evaluation of their job characteristics is a critical factor influencing their work behavior.

Based on the results of the research, it is proven that Green Management is a fundamental strategic plan that improves the environmental performance of organizations, but also plays a vital role in improving the quality of some employees' work criteria, such as job satisfaction and psychological climate of the Forest Service of the country.

Keywords: *Green Management, Environmental Planning, Digital Transformation, Forest Service, Green GAP, Forestry Strategy*

1. INTRODUCTION

The recent interest about the worldwide environmental mindset has arisen from specific circumstances to combat climate change, [1-2].

The sustainable development requires the conservation of natural resources and the respect for human rights. Under the current situation, organizations and services also need to find ways and techniques to deal with reducing their ecological footprints and develop a relevant mindset. The successful implementation of these sustainable corporate strategies within an agency requires both strong leadership and specific processes [3-4]

Proceedings

The integration of the term "green" in the strategy of services and organizations opens new ways in their development, however it is still requested [5-7].

In this way [8], the marketing, the IT and the finance combined with the core object of each organization, work together harmoniously to promote a positive joint effort and all these are coordinated by the human resources management department or by the heads of departments and services. Undoubtedly, the employee of Forest Service (FS), due to the nature of the subject matter, show or should show a special interest in environmental issues and therefore form opinions on how to deal with any environmental risks.

The European Union encourages the education and training sector as a prerequisite of Green Management to take action to contribute to the green transition and to strengthen social responsibility [9].

Afedzie et al [10] defines Green Management as the action which continuously promotes the cause of environmental management, such as the management of personal responsibility(?) for environmental activities and biodiversity conservation.

Green Management, which focuses on human resources, is based on practices related to environmental sustainability through the creation of "green" employees who can recognize and value the organization's environmental initiatives. It focuses on green selection and recruitment, green training and development, green performance, management and evaluation, green payment and reward system that expands the organization.

Organizational culture refers to values, beliefs, and behaviors of employees in the organization [11], [12]. According to the above, Green Management is defined as the implementation of practices that focus on environmental sustainability through the creation of green employees, who are able to recognize and appreciate the organization's environmental initiatives. It focuses on green selection and recruitment, green training and development, green performance, management and evaluation and of course green reward system [13].

Green Management is not only a fundamental strategic plan that improves the environmental performance of organizations, but also plays a vital role in improving the quality of some employee work criteria, such as job satisfaction [14-17]. Research shows that employees' evaluation of their job characteristics is a critical factor influencing their work behavior [18], [13]. Specifically, several job characteristics including pride, participation, recognition, self-actualization, advancement, justice, can influence the way that employees perceive their work and their satisfaction [19-24].

Therefore, organizations can use green management to effectively implement environmentally sustainable policies [25]. During recruitment and selection activities, the organization can include environmentally friendly hiring criteria, and communicate environmentally friendly commitments to applicants and give priority to applicants who have had experience in environmentally friendly activities. There will also be reward practices for green work performance. It is necessary to have training programs that develop environmental awareness, attitudes, skills and knowledge [26-28].

2. THE RESEARCH OBJECTIVE

The main purpose of this research was to investigate the perceptions and beliefs of Forest Service's executives regarding Green Management and its reflection in their Services. The central hypothesis of the research was that the majority of Forest Service's employees are still unaware of the importance of Green Management. The research questions of the survey were posed as follows:

- 1st research question: Are employee values, beliefs and behaviors, like the organizational culture of the Forest Service, related to each other and with the green management?
- 2nd research question: Are employees' behavior related to the culture of the Forest Service?
- 3rd research question: Is green management related to Forest Service employee's satisfaction?

- 4th research question: Can green management create a positive psychological climate in the Forest Service for the effective implementation of environmentally sustainable policies?

3. METHODOLOGY

A primary pilot qualitative and quantitative survey has been carried out among senior officials of the Central Forestry Departments of the Policy Implementation and Inspection of Greece (Table 1), in order to reflect the reality of the current situation and to make the final formulation of the questionnaire, so that it is comprehensible to the whole sample. This group (focus group) of the qualitative research presents common characteristics and knowledge related to the title of the present research, but they do not know each other. In this way, the detection of whether the basic concepts of Green Management are clear, was achieved.

During the next period, some questions were designed based on the Maturity Model [29-31] to collect the data required for further research. Before creating the final Likert-type questions, a platform was used to define the maturity model of the respondents of the original survey. The mendix platform (<https://www.mendix.com/>) was used to position the questions in such a way that they could be piloted by the first respondents. Most of the questions in the questionnaire were closed, of the following type: ranking, dichotomous, Likert scale, multiple choice. The Likert scale questions were structured in 5 levels, where: 1 corresponded to the upper level and is the most ambitious level, which is a trigger for long-term planning, 2 as the level of cooperation in a positive direction regarding the requested issues, 3 as the established base, 4 as the level where the services are, which are progressively starting and changing and as 5 those that are now emerging in the demands of a human resources administration in line with the green data. In several cases it was necessary to repeat the electronic sending of the questionnaire or to use multiple distribution channels.

Table 1. Forestry Services by Region that participated in the survey

District	N.	Percentage %
Thessaly	77	33.2
Stereia Ellada	36	15.5
Central Macedonia	29	12.5
Attiki	23	9.9
Peloponnese	21	9.1
Creta	16	6.9
West Macedonia	9	3.9
Epirus	8	3.4
North Aegean	6	2.6
East Macedonia - Thrace	4	1.7
Ionia Island	2	0.9
West Greece	1	0.4
TOTAL	232	100.0

Finally, the sample of the research amounted to 232 forest employees from all the Regions of the Country, with their demographic characteristics, as shown in Table 2, i.e. approximately 20% of the total population of 1.160 forest employees to whom the link of the specific questionnaire was sent by email. The survey's data collection took place in May-June 2023. There was a first phase of a pilot survey with four (4) respondents where some ambiguities were settled. After the collection of the questionnaires of the sample, the statistical processing of the research data followed with the program IBM SPSS Statistics, ver. 29 [32].

		Phd	4,7
Age	Percentage %	Work Experience	Percentage %
≤25	0.9	<1 year	14.2%
26-35	4.3	1-5 years	19.0%
36-45	17.2	6-10 years	10.8%
46-55	47.4	11-15 years	14.7%
55-65	27.6	16-20 years	10.8%
>65	2.6	>20 years	30.6%

4. RESULTS

In this research, as can be seen from Table 2, forestry employees who took part, work in various positions with an average of 20 years of service, while the percentage of those with more than 20 years of service amounted to 30.6% of all of them.

Regarding the basic hypothesis of the survey, which is that the majority of forest employees do not know Green Management, it is verified because the 54.6% of them stated that they do not know it. The knowledge or not about green management is independent of gender and level of education, but is related to age, as the age groups between 26-45 years know better about green management ($X^2 = 11.093$, for $\alpha < 0.05$) and thus the central hypothesis of the research is verified.

Those who know green management associate it most with practices to save from global warming and the depletion of natural resources at a rate of 45.7%, but also with digitalization at a rate of 42.2%, which it makes necessary for a green transition.

Regarding the area of human resource management of an organization, respondents answered that it is related to the factors (Table 3) of green selection and staff recruitment (2.89) and green reward system (2.83), while in a smaller degree concerns green education and development (2.19), where 1=very much and 5=not at all. These results confirm previous research [13].

Table 3. Green Management Human Resources in the organization

	N	Minimum	Maximum	Mean	Std. Deviation
Green education and development	232	1	5	2,28	1,136
Green work performance	232	1	5	2,41	1,033
Management and evaluation	232	1	5	2,47	1,027
green reward system	232	1	5	2,83	1,130
Green staff selection and recruitment	232	1	5	2,89	1,233

Most of the respondents strongly associate the implementation of Green Management in the Forest Service with personal factors, as shown in Table 4, (where: 1=very much and 5=not at all), as respondents associate green management with individual green values (2.38) and green behavior (2.43) and less with the sense of ownership (3.27).

Based on the results of the Pearson correlation (r), the two-way significance test certifies that the correlation between the following variables is positive and statistically significant at the $\alpha=0.001$ significance level, namely:

1. Individual green values are strongly positively related to green behavior ($r = 0.847^{**}$, $df=232$, $p<0.001$), that is mean, if they have in a strong level green values, they have a truly green behavior.
2. Green behavior is strongly positively related to green ability ($r =0.799^{**}$, $df=232$, $p<0.001$), that is, green behavior manifests to a greater extent the green abilities for executives' actions.
3. Green competence is strongly positively related to green commitment ($r = 0.704^{**}$, $df=232$, $p<0.001$), that is, executives' green competence shows a much greater commitment to the green actions.
4. Job satisfaction is strongly positively related to loyalty ($r =0.703^{**}$, $df=232$, $p<0.001$), i.e. when employees are satisfied with their Service, this affects their loyalty to it to a greater extent.
5. Work performance is strongly positively related to wellness ($r =0.671^{**}$, $df=232$, $p<0.001$), i.e. for greater work performance there should be greater employee well-being.

Based on the above, answers are given to the 1st research question.

Table 4. Green Management Human Resources and employee in Forest Service.

	N	Min.	Max.	Mean	Std. Deviation
Individual Green Values	232	1	5	2.38	1.062
Green Behavior	232	1	5	2.43	1.103
Positive image of the organisation	232	1	5	2.52	0.998
Green Ability	232	1	5	2.63	0.990
Job satisfaction	232	1	5	2.66	0.962
Wellness	232	1	5	2.66	1.101
Green Commitment	232	1	5	2.69	1.011
Work performance	232	1	5	2.76	0.953
Loyalty	232	1	5	2.84	0.983
A sense of ownership	232	1	5	3.27	1.061

8. Loyalty	.477 ^{**}	.539 ^{**}	.610 ^{**}	.507 ^{**}	.461 ^{**}	.399 ^{**}	.703^{**}	1	.625 ^{**}	.579 ^{**}
9. Work performance	.427 ^{**}	.526 ^{**}	.603 ^{**}	.578 ^{**}	.504 ^{**}	.402 ^{**}	.658 ^{**}	.625 ^{**}	1	.671 ^{**}
10. Wellness	.439 ^{**}	.498 ^{**}	.543 ^{**}	.554 ^{**}	.397 ^{**}	.353 ^{**}	.567 ^{**}	.579 ^{**}	.671^{**}	1

The 55.6% of Forest Service's executives of the survey agree that employee's behavior is related to Forest Service's culture (2nd research question), with 33.6% expressing a neutral opinion and 10.8% disagreeing (Fig. 1). The crosstabulation analysis showed that this opinion is independent of gender, level of education and age, but depends on the region in which they work ($X^2=76.673$, $df=42$, $a<0.05$), with the regions of Eastern Macedonia-Thrace, of Western Macedonia and Central Macedonia, expressing themselves more positively in the above question.

Figure 1. Employee behaviors are related to the culture of the Forest Service

Regarding the relationship between Green Management and the employee's personal culture, it is proven from the data in Table 6 that they are highly correlated (2.36). Most respondents state that there is a connection between individual values and Forest Service's values at a rate of 48.0% so it has positive effects on employees' workplace (Question 1 of Table 6), as well as what green management can affect workplace outcomes of employees through the work climate in the Forestry Service at a rate of 35.7% (Question 2 of Table 6).

Regarding the 3rd research question, it appears that green management can satisfy Forest Service's employees at a rate of 42.6% (Question 3 of Table 6), with men being more positive than women, as well as the youngsters' satisfaction (26 - 45 years old) and those with doctoral studies being more optimistic and positive. The crosstabulation analysis showed that this question is statistically independent of the respondents' characteristics.

According to question 6 of Table 6 it is shown that green management will create a positive psychological climate in the Forestry Service for the effective implementation of environmentally sustainable policies at a rate of 41.4% (4th research question). Those over the age of 45 are hopeful that this will happen as until now, based on their experience, they are disappointed with the existing climate of the Forest Service and have begun to trust the prospect of implementing green management in their Service. The X^2 test showed that this opinion is independent of gender and level of education, but is statistically significantly related to the region in which the respondents work ($X^2=70.897$, $df=44$, $a<0.01$), with the regions of Eastern Macedonia-Thrace, of Western Macedonia, Northern Aegean and Crete, to express themselves more positively in the above question.

Table 6. Green Management Human Resources and culture of organization (1=Very much..... 5=Not at all)

	N	Mean	Std. Deviation	Πάρα πολύ	Πολύ	Μέτρια	Λίγο	Καθόλου
1The congruence between individual values and the values of the Forest Service, has positive effects in the workplace of the employees.	232	2.36	0.965	12.5%	34.5%	30.2%	16.8%	6.0%
2. Green management can affect employee workplace outcomes through work climate in the Forest Service	232	2.66	0.959	7.3%	28.4%	37.9%	19.0%	7.3%
3. Green human resource management can satisfy Forest Service employees	232	2.66	0.939	11.6%	31.0%	40.5%	13.8%	3.0%
4. Practices in a green human resource management transition affect Forest Service performance through impact on employee workplace behavior	232	2.69	1.080	17.7%	44.4%	24.1%	12.1%	1.7%
5. Practices in a green human resource management transition affect Forest Service performance through impact on employee workplace behavior	232	2.77	1.027	8.2%	37.5%	38.4%	11.6%	4.3%
6. Green Management characteristics and practices determine the behavior of Forest Service employees	232	2.91	1.028	9.1%	32.3%	38.8%	12.5%	7.3%

5. CONCLUSION

From the presentation of the results, it appears that most forest officials do not know Green Management, while it is interesting that they associate it with the digitalization of the processes and organizational functions of the Forestry Service, which leads to a successful green transition that opens new paths of their development [5], [6] which is the objective of the European Green Deal.

Regarding the research hypotheses where the relationship between the culture of the organization and the culture of employee was analyzed, as well as the connection of Green Management with job satisfaction, it seems that forest employees accept this interaction to a very large extent. After all, according to previous researches [19], [18], [23], and [13], certain job characteristics can affect employees' satisfaction with their Service.

The behavior of employees in F.S., is largely connected and influenced by its organizational culture which refers to the values, beliefs, and behaviors of its employees according to the researchers [11], [12].

In addition, the individual values of the employees of F.S. have positive effects on employees' workplace, while employees' evaluation of their job characteristics is a critical factor influencing their work behavior.

Based on the results of the research, it is proven that Green Management is a fundamental strategic plan that improves the environmental performance of organizations, but also plays a vital role in improving the quality of some employees' work criteria, such as job satisfaction and psychological climate, [14], [15], [17], so it can be applied to the Forest Service of the country.

Proceedings

Another key conclusion of this research is that the 84% of the staff of Forestry Services in Greece have ages between 46-65, and it is deemed imperative to renew the staff with capable people who will have the green culture needed to be able to lead F.S. in a proper green transition. Further research will be carried out in all the Forestry Services of the Country and will concern beyond Green Management and the digitization of forestry processes, with the main objective of how much these would serve the green growth but also the study of the green gap within the Forestry Service with an emphasis on the distance between the stated importance of environmental protection and actual behavior, in order to help the environment, as well as the lack of communication of goals within the Forest Service between employees and executives.

Abstract

SEA (Strategic Environmental Assessment) for more than 20 years represents adequate controlling mechanism in urban planning. SEA is an instrument for evaluation of potential negative repercussions of urban development on environmental protection and human well-being and the determination of measures to prevent, minimize, mitigate, remediate or compensate harmful impacts on the environment and human health that certain activities in the environment can cause. Methodology of SEA aims to assess certain impacts that minor or major urban development could have on environmental quality and quality of life, as well as cultural and natural heritage and biodiversity. However, new environmentally-related problems have risen in the past 10 years, mainly oriented towards climate change, which represents a new unknown variable in the urban planning equation. It is of the utmost importance to observe and analyze how these climate-related circumstances reflect on urban development and how urban development affects climate change, on the other hand.

SEA has a new assignment to prepare a new set of goals and indicators that include climate-related issues and to evaluate its potential impacts on the environment.

Planning of urban development in uncertain conditions such as climate-sensitive environment must have large number of supported mechanisms. One of them is SEA, whose role is to define potential measures for overcoming climate change problems, through adaptation and mitigation guidance.

Aim of the SEA is first to identify all the goals and indicators (including those for climate adaptation and mitigation), and afterwards to evaluate urban planning solutions through MCDA (Multi Criteria Decision Analysis). Based on the expert's evaluation, SEA is proposing measures for transcending, neutralizing or decreasing all of the potential negative repercussions on the environment. Measures for climate adaptation and climate mitigation, in today's circumstances, represent the most important item in the recommendations, and the adequate placement of these measures has far-reaching consequences.

Based on the analysis of Action plans for mitigation and adaptation with SEA for two Serbian cities (Užice and Smederevo), this paper will present the importance of SEA not only as a controlling instrument, but also as a necessary pre-condition in all of the analysis conducted in urban planning.

This paper will give brief analysis and introduction of climate-related goals and indicators within SEA, process of evaluation of potential impact of urban development on those parameters, as well as proposal for measures for adaptation and mitigation. SEA can anticipate all of the planning solutions whose realization could have significant negative impact or cause serious conflicts in space in terms of climate change, and propose measures for its neutralization or reduction.

Keywords: SEA, urban planning, climate change adaptation, climate change mitigation, Serbian cities

1. INTRODUCTION

Climate change represents one of the most important challenges and huge urban development obstacles of the 21st century, profoundly impacting ecosystems, natural and cultural assets, societies, and economies on the world level. As global temperatures rise and extreme weather events become

more frequent and severe, the imperative for proactive adaptation and mitigation strategies in the urban areas intensifies. In this context, Strategic Environmental Assessment (SEA) emerges as a crucial tool and instrument for integrating environmental considerations into decision-making processes in urban planning, particularly within the framework of climate change adaptation and mitigation.

SEA, as a systematic, environmentally-based and participatory process, holds significant potential for enhancing the resilience of human and ecological systems to climate change impacts. By systematically evaluating the environmental consequences of proposed policies, plans, and programs, SEA enables stakeholders to identify and address potential risks, trade-offs, and synergies early in the decision-making process, and also enables perception of cumulative and synergetic effects of planning. Through its proactive approach, SEA facilitates the integration of climate change considerations into development initiatives, fostering more sustainable and climate-resilient urban planning solutions.

SEA is an instrument for evaluation of potential negative repercussions of urban development on environmental protection and human well-being and the determination of measures to prevent, minimise, mitigate, remediate or compensate for harmful impacts on the environment and human health that certain activities in the environment can cause. Methodology of SEA aims to assess certain impacts that minor or major urban development could have on environmental quality and quality of life, as well as cultural and natural heritage and biodiversity.

SEA makes a critical consideration of the environmental impact of all the foreseen activities, after which a decision is made whether to proceed with the implementation of those activities and under what conditions, or to abandon the planned activities.

Climate change problems have opened a new research field within standard multicriteria analysis in SEA, bringing new parameters in the environmental equation.

This paper explores the integrated role of SEA in advancing climate change adaptation and mitigation efforts, by integrating social-economic context and bio-physical segments of the environment into evaluation. Also, it represents instruments that can help to integrate the goals and principles of sustainable development in the decision-making process in urban planning, taking into account the need to avoid or limit negative impacts on the environment, health and socio-economic status of the population.

The importance of SEA is reflected in the fact that:

1. includes the aspect of sustainable development and response to climate change by addressing the causes of environmental problems at their source,
2. addresses issues and impacts of wider importance, which cannot be divided into projects, for example – cumulative, synergistic and social effects,
3. helps to check the feasibility of different variants of development concepts,
4. avoids the limitations that appear when the environmental impact assessment of an already defined project is carried out.
5. ensures the locational compatibility of the planned solutions from the environmental aspect,
6. determines the appropriate context for impact analysis of specific projects, including prior identification of issues and impacts that merit more detailed investigation, etc.

By synthesizing existing knowledge and highlighting best practices in Serbia through already adopted SEA (analysis of Action plans for mitigation and adaptation with SEA for two Serbian cities - Užice and Smederevo) [1], [2], this paper will present the importance of SEA not only as a controlling instrument, but also as a necessary pre-condition in all of the analysis conducted in urban planning. This paper will give brief analysis and introduction of climate-related goals and indicators within SEA, process of evaluation of potential impact of urban development on those parameters, as well as proposal for measures for adaptation and mitigation. SEA can anticipate all of the planning solutions

whose realization could have significant negative impact or cause serious conflicts in space in terms of climate change, and propose measures for its neutralization or reduction.

This paper also aims to inform policymakers and researchers about the potential benefits and challenges associated with integrating SEA into climate change adaptation and mitigation strategies and/or action plans [3], [4], [5]. By recognizing SEA as a critical enabler of climate resilience, more informed, inclusive, and effective approaches in urban planning could be achieved to addressing the complex challenges posed by climate change in the 21st century.

2. MATERIALS AND METHODS

In the past 15 years, CO₂ emission is rapidly increasing worldwide. Countries are striving to achieve goals set through Kyoto protocol in 1998 to the Paris Agreement in 2015 and COP 28 in Dubai, in terms of holding the increase in the global average temperature to well below 2°C above pre-industrial levels” and pursue efforts “to limit the temperature increase to 1.5°C above pre-industrial levels” [6], [7]. But the main problem is the fact that sometimes national and regional targets are not well coordinated with the international aims and goals, and are not evaluated through SEA in order to meet emission reduction obligations falling on the transport, energy, housing, agriculture, and forestry sectors [8].

Reducing the proportion and volume of greenhouse gas (GHG) emissions is crucial for mitigating the impact of human activities on climate change. GHGs, such as carbon dioxide, are the primary contributors to climate warming. Low-carbon development entails minimizing the release of carbon dioxide and other GHGs during economic advancement. Within this framework, adopting a new development model becomes imperative to address the adverse effects of carbon-based energy usage on climate warming. Such a model represents a positive progression, facilitating the transition from an era reliant on high-carbon energy to one characterized by low-carbon alternatives (Yong, et al., 2021). But, for designing and planning new urban development based on the risks of climate change has many obstacles which should be resolved by the implementation of multicriteria analysis of planning activities through SEA.

Serbia, as all of the other countries in Europe has severe problems with climate change adaptation and mitigation in the past 10 years. According to the vulnerability index developed by the University of Notre Dame, Serbia is ranked as 86. vulnerable country in the world and is the most vulnerable country in Europe [9]. This index includes a whole range of indicators, from the concentration of the urban population and preparedness for natural disasters to the availability of water and agricultural capacities. At the same time, Serbia is located in a territory called the "hot spot" of climate change: the increase in average temperature here is higher than the world average, and the incidence of extreme events such as droughts and intense precipitation is also higher. But this country, in which the ten warmest years from 1951 to the present day occurred after 2000, in which every year we record various unpleasant records in terms of temperature and precipitation, and which in the technological capacities of agriculture is in the rank of agriculturally impoverished countries such as are Afghanistan or Kenya - it is also one of the slowest in Europe when it comes to adopting basic strategic documents in the fight against climate change and its consequences [10].

However, the majority of Serbia's strategic and urban planning and design often overlooks the principles of low-carbon development and lacks effective assessment criteria and tools. Consequently, there is a deficiency in effective strategies and tools to incorporate low-carbon development objectives into the policymaking and decision-making processes, and to shift low-carbon development from mere policy into a guiding principle for social and economic endeavours.

Also, by the Paris Agreement, the Republic of Serbia has committed to reducing GHG emissions by 9.8% by 2030 compared to emissions in 1990. Serbia is also among the few countries that have emphasized the necessity of reducing risks, damages and losses from natural disasters and natural disasters. The Paris Agreement also defines requirements regarding adaptation to changed climate

conditions, financing, development and transfer of technologies for the period from 2021. It also calls for an increase in the ambition to reduce GHG emissions, which the states will submit to the secretariat of the Convention during 2020, emphasizing the establishment of a monitoring and reporting system as a key element to confirm the achievement of the goals to which the state has committed itself (in the case of the Republic of Serbia, a 9.8% reduction in emissions GHG).

In addition to the obligations that the Republic of Serbia has under the Convention and the Agreement, as a candidate country for EU membership, it also has certain obligations from the aspect of harmonizing national and EU legislation. Part of these obligations, especially in the areas leading to the reduction of GHG emissions, derives from membership in the Energy Community Agreement (EnZ). These obligations are significantly increased with the EU Green Deal, with which the EC showed a tendency to establish a carbon-neutral European continent by 2050.

Commitments from Paris agreement also obliged Serbian government to adopt strategies for the climate change mitigation and adaptation strategies and action plans on the national and local levels. Both strategies and action plans have to be followed by strategic environmental assessments.

Serbia has adopted Climate strategy/Low Carbon development strategy for period 2023-2030 with projection to 2050. with SEA in 2023 [11]. This document represents umbrella strategy for all action plans and strategies for the local self-government units in Serbia.

2.1. Pilot areas

Research into climate changes in Serbia is of particular importance considering its position between Mediterranean and continental climate conditions. A significant increase in air temperature in Serbia was observed in the 90s of the last centuries at most meteorological stations.

The duration of heat waves and their frequency are particularly important in the analysis of the risk of high temperatures and the threat to the eco-system, economy and human health. On average for the last 10 years, there were more than 20 days of heat waves in one year. An increase of more than 30 days was observed in western and central Serbia. In the period 2008-2017, the average number of extreme heat waves increased by 2-3 per year compared to the reference period, with the highest frequency of occurrence in western and southwestern Serbia, where the increase is over 4.

In Serbia, there has been an increase in the intensity of heavy rainfall, with more pronounced changes during the last decade. The number of days with very heavy precipitation has increased by 1-2 times on average. However, the frequency of more extreme weather events, days with precipitation over 40 mm, in certain parts of Serbia increased by more than 5 times compared to the reference period. During the year, the maximum daily values of eight-hour accumulated precipitation increased in most parts of the country by over 5% (in some parts even over 10%).

Having in mind all the changes in climate parameters, Serbia has started to developing local action plans for climate change adaptation and mitigation, in accordance with the national strategy.

The "Cities and Climate Change" program, implemented by the Ministry of Environmental Protection and financed by the French Development Agency, supported the Government of Serbia in its efforts for more sustainable green growth and urban development. This program, which began with the entry into force of the Law on Climate Change ("Official Gazette of RS" No. 26/2021) [11], aims to strengthen initiatives for adaptation and mitigation of climate change at the national and local level in Serbia. The first two pilot areas where action plans were developed were the city of Smederevo (climate adaptation plan) and the city of Užice (climate mitigation plan) [1], [2].

City of Smederevo is located in Podunavlje District in eastern Serbia. The is bordered by the Danube river on the north, the Velika Morava River on the east, and the Sumadija hills to the south and west. It is located at the intersection of the Pan-European Railway, the international E-75 highway Corridor 10 (connecting Budapest, Belgrade, Nis, Thessalonica, and Athens) and on the most attractive part of the Danube riverbank: the international Corridor 7. Smederevo is known as a large industrial centre. The industrial plants present in the city and its outskirts generate significant impacts on resource

Proceedings

consumption (water and electricity consumption), and water and air quality. Since 2011, the air of the Smederevo agglomeration constantly belongs to the III category “excessively polluted air”, and concerns are raised about the quality of the Danube river, following excessive discharge from industrial plants directly into the watercourse. In addition to direct human impacts cause by the economic activities, Smederevo is affected to impacts of climate change and related increasing weather extremes and disasters like heated waves, droughts, high precipitation, landslides, fires, etc. For the purpose of Climate Adaptation plan of Smederevo, several analysis and predictions have been conducted, namely: future temperature and precipitation change, future change of relevant climate indices, as well as local vulnerability of population, urban services and infrastructure, social infrastructure, economy, water resources and quality, agriculture, forests, ecosystems and biodiversity. Near past climatic vulnerability was defined through all of these factors.

		VULNERABILITY						
		Temperature Change	Heat wave	Extreme cold	Drought	Precipitation Regime Change	Floods	Storms
Urban services								
Built Environment								
	Housing /Building stock	Low	Medium	Medium	Low	High	Very high	Medium
	Urban functionality	Low	Medium	Low	Low	High	Very high	Medium
Urban Infrastructure								
	Transport	Low	Low	Low	Low	Medium	High	Medium
	Electricity and heat supply	Medium	Medium	Medium	Low	Medium	Medium	Medium
	Water supply, wastewater management, drainage and flood protection	High	Very high	Very high	Medium	Very high	Very High	Medium

		Medium	Medium	Medium	Low	Medium	Medium	Medium
Urban Green Areas								
		Medium	High	High	High	Medium	Medium	High

Table 1. Near past climatic vulnerability of Smederevo (urban parameters)

Source: [1]

On the other hand, city of Užice is located in Western Serbia, close to the border with Bosnia and Herzegovina, about 180 km southwest from Belgrade. Užice is the administrative centre of Zlatibor district, and it is a cultural, social and economic centre of south-west Serbia. The industrialization and urbanization of Užice after the Second World War increased levels of pollutant emissions from all sources and contributed to pollution and environmental degradation. The increase in air and water pollution was caused by outdated technologies in industry, poor plant maintenance, and poor quality energy sources, outdated vehicle fleet in traffic, stagnation in the development of infrastructure, extensive illegal construction, poor solid waste management and other problems. Air quality in Užice has been monitored for more than 20 years. Its specific location in Đetinja valley, surrounded by mountains on all sides is causing severe air pollution for almost 30 years. For the preparation of the Climate Change Mitigation Plan in Užice, an inventory of greenhouse gas emissions was prepared at the city level, using 2019 as the base year. This inventory complies with the Global Protocol for Community-Based Greenhouse Gas Inventories (GPC). The GPC standard was developed by C40, the World Resources Institute and ICLEI. It offers a robust framework, which ensures consistent and transparent measurement and reporting of GHG emissions at the city level, in accordance with internationally recognized GHG accounting principles.

Proceedings

So far, the impact of burning fossil fuels in boiler rooms for district heating, the consumption of other fossil fuels in public buildings and the burning of natural gas in individual boiler rooms in the residential and commercial sectors located within the City has been quantified.

Sector	Total by scope (tCO ₂ e)				Total by city induced reporting level (tCO ₂ e)		Biogenic Emissions (tCO ₂ e b)

2.2. MCDA analysis for Action plans – used methodology

Action plans for adaptation and mitigation in cities of Smederevo and Užice demanded realization of strategic environmental assessment, not only by the force of law, but also because SEA is a instrument for timely and systematic consideration of possible environmental impacts at the level of strategic decision-making on plans and programs, respecting the principles of sustainable development. The most common expert methods used in the practice of strategic assessment are checklists and questionnaires, matrices, multicriteria analysis, spatial analysis, SWOT analysis, Delphi method, environmental capacity assessment, cause-and-effect chain analysis, vulnerability assessment , risk assessment, etc. As a result of the application of any method, matrices and graphs appear that examine the changes in space and environment that would be implied by the implementation of the plan and the selected variants [4]. Charts and matrices are formed by establishing the relationship between plan objectives, plan solutions and strategic assessment objectives with associated indicators [4], [5].

Methodology used within these SEAs was introduced within scientific project of Institute of Architecture and Urban&Spatial planning of Serbia "Methods for strategic environmental assessment in planning the spatial development of lignite basins", and patented by the name „Methodology for SEA plans, programs and strategies on the environment - method of multi-criteria evaluation" authored by Dr. Božidar Stojanović, Dr. Boško Josimović and Dr. Tamara Maričić, registered within The Intellectual Property Office of the Republic of Serbia N° A-336/2021. In preparation of the strategic environmental assessment for the action plans of adaptation and mitigation, a model of multi-criteria qualitative expert evaluation of planning solutions (strategic goals of the Action Plan) was applied in relation to the defined special goals of the strategic assessment and associated indicators of sustainable development. The method of displaying possible impacts using graphs enables a clear insight into the positive and negative impacts of each individual planning solution, which is of particular importance in the context of the participation of interested authorities, organizations and the public. The applied methodology is based on the qualitative evaluation of the environment in the planning area, and its immediate and wider environment, which served as a basis for the valorisation of the space for further sustainable development and planning. In terms of general methodological principles, the strategic environmental assessment has identified: baseline scenario

Proceedings

and assessment of the current state of the environment, qualitative and quantitative assessment of possible impacts that planned activities can have on basic environmental parameters, and in conclusion - proposal of measures for improvement of environmental parameters and monitoring measures. There are several important criteria that have to be taken into account within MCDA analysis for assessment of the plans concerning climate change adaptation and mitigation (given within table 2,3,4)

Size of impact	Label	Description
Critical	- 3	It overloads the capacity of the space
Bigger	- 2	It damages the environment to a greater extent
Smaller	- 1	It damages the environment to a lesser extent
No impact	0	No impact on the environment
Positive	+ 1	Less positive changes in the environment
Favorable	+ 2	Favorable changes in the quality of the environment
Very favorable	+ 3	Changes significantly improve the quality of life

Table 3 . Criteria for evaluating the size of the impact

Significance of influence	Label	Description
Regional	R	Possible regional impact
Municipal	C	Possible impact on the City area
Local	L	Possible influence of local character

Table 4. Criteria for evaluating the spatial scales of possible impacts

Probability	Label	Description
100%	S	Certain impact
more than 50%	V	Impact likely to be happen
less than 50%	M	Possible impact

Table 3.3 . Impact Probability Rating Scale

Based on these criteria, as well as on proposed general and specific objectives and indicators of SEA (Protection and preservation of water quality, Reduce the level of harmful substances in the air, Protection and sustainable use of agricultural land, Protection and preservation of natural assets of biodiversity and geodiversity, Protection of population and human health, Protection of cultural heritage and Socio-economic development with associated indicators), planning activities have been evaluated within MCDA – expert evaluation.

3. RESULTS

3.1. SEA Smederevo

A local climate change adaptation plan seeks to proactively prepare the city for both the negative impacts (thus reducing the adverse outcomes of climate change) and, at the same time, explore the potential opportunities that will occur as a result of changed climatic conditions. It is important to understand that successful adaptation does not mean that negative impacts caused by climate change will not occur, but that they will be less severe than in the case that no adaptation to climate change has been implemented. Since the Action plan has proposed several strategic goals (Strengthening the resilience of public health services and infrastructure to changing climatic conditions, Urban planning and construction based on the vulnerability of urban space from the harmful effects of changed climatic conditions, Protection against the harmful effects of water, Providing sufficient amounts of water, Encouraging and promoting good agricultural practices that reduce the vulnerability of agricultural production to changed climatic conditions, Encouraging and promoting good agricultural practices that reduce the vulnerability of agricultural production to changed climatic conditions, Development of urban green infrastructure, Strengthening the institutional, managerial and financial

capacities of the local self-government of Smederevo and the local community for adapting to the changed climatic conditions), the aim of the SEA was to evaluate any potential negative impact that these goals could have on the environment and climate. Evaluation was conducted through matrices that combine the impact strength with the possibilities of their occurrence as well as the probability of the impact, provided in the table 6.

Adaptation measure	The rank of influence in relation to the objectives of the SEA									Impact rationale	
	1	2	3	4	5	6	7	8	9		
Reducing the impact of heat load due to the effects of weather extremes on public health		+1LMD				+3CSD		+3CSD			This adaptation measure can show low positive possible long term impact on reducing the populations' exposure to harmful substances from the air and higher positive impact on the city level to protection and preservation of human health, quality of life and improvement of information as well as on accident protection
Strengthening existing and developing and implementing new services in the health system of Smederevo						+3CSD					Greater long-term positive impacts of the city character on the protection and preservation of human health quality of life and improvement of information

Table 6. Example of evaluation of two adaptation goals within matrix

Source: [1]

Having in mind all of the evaluated impacts of adaptation measures on the environment and elements of sustainable development, it can be concluded that the negative impacts are almost non-existent and may appear only in the area of urban design. Even in that case and for that adaptation measure, the possibility of a negative impact is very low, taking into account that during the adaptation of the buildings, all precautionary measures will be taken into account for the possible impact of the adaptation on cultural and historical assets. On the contrary, all other planned activities will have strong positive impacts of a local and/or city character on the improvement of ecological condition of the city, as well as human health and well-being. All the above statements are expected considering the concept of the Action Plan, which is based precisely on the protection of space and the preservation and improvement of the quality of the environment and citizens' health.

3.2. SEA Užice

The Climate Change Mitigation Action Plan for Užice provides the Inventory of GHG emissions for the City of Užice, with GPC methodology, emissions calculation, calculations by GHG emission sources and GHG inventory for the City of Užice. Action plans represents the method of "how the city will meet its commitment to address climate change". Action plan has identified the sectors that emit the most GHG emissions (GHG Inventory), the goal to ensure a more emission-neutral city and developed a pathway to achieving these goals through mitigation actions. Similar as the Action plan for Smederevo, this action plan has proposed mitigation goals (Energy efficiency measures in public buildings, Renewable energy, Improvement of the district heating system, Development of active mobility, Promoting recycling, Spreading public awareness) which were evaluated through proposed goals of SEA. Withing MCDA all those goals where assessed and the results were elaborated in the matrix (Table 7).

Planning solutions	The rank of influence in relation to the objectives of the SEA									Impact rationale	
	1	2	3	4	5	6	7	8	9		
Reconstruction and improvement of energy efficiency		+3LSD			+1LMD	+3LSD	-1LMD			+1LMD	Greater positive impacts of a local nature on reducing the population's exposure to harmful substances from the air are possible, as well as certain greater impacts at the local level on the protection of the population and the preservation of human health and the improvement of information about environmental protection. In addition, minor negative long-term impacts of a local type on the preservation of cultural heritage are also possible due to potential interventions on the facades of buildings.
Thermal insulation of public buildings						+3LSD	-1LMD			+3LMD	Greater long-term positive impacts of the local character on the protection and preservation of human health and smaller negative long-term impacts of the local character on the preservation of cultural heritage due to potential interventions on the facades of buildings are expected. A special contribution relates to the creation of conditions for the economic development of the entire city area

Table 7. Example of evaluation of two mitigation goals within matrix

Source: [2]

Summarizing the impact of the plan on the environment and elements of sustainable development, it can be concluded that the negative impacts are extremely few and that they occur only in activities related to the reconstruction and improvement of energy efficiency and thermal insulation of public buildings. These activities may have less negative long-term impacts of a local type on the preservation of cultural heritage due to potential interventions on the facades of buildings, which can be reduced or neutralized by careful design and installation of insulation on public buildings and compliance with the conditions of the competent institutes for the protection of cultural monuments. Climate change mitigation measures and monitoring were proposed based on the results of the evaluation of planned activities in order to improve current state of climate factors in Serbia. Measures were divided and oriented towards protection of air quality, noise, water, soil and life and health of the citizens.

4. CONCLUSION

Integrating Sustainable Environmental Assessment (SEA) into urban planning represents powerful tool for confronting climate change challenges in urban spaces. By systematically assessing environmental impacts and considering climate adaptation and mitigation measures from the planning stage, SEA facilitates the creation of resilient and sustainable cities. Through SEA, urban planners can identify opportunities to enhance green infrastructure, reduce emissions, and promote sustainable development, ultimately fostering livable and climate-resilient urban environments for present and future generations. However, effective implementation requires collaboration among stakeholders, robust data collection, and ongoing monitoring and evaluation to ensure that urban spaces truly adapt and mitigate the effects of climate change. At the local level, the development of SEA will help local authorities to: integrate climate issues and challenges in relation to their future development plans (spatial plan, socio-economic profile), gain awareness of how climate change can affect their territory, define a path that supports climate transition by focusing on either adaptation measures or mitigation measures, link this ambition with actions (soft or hard) that should be implemented in the short and medium term, and determine the priorities of actions for planning future investments at the local level. Smederevo and Užice specialized technical assistance aimed at identifying priority needs and projects for climate change adaptation and mitigation. Developing local climate action plans will not only enhance environmental quality and optimize natural resource usage but also consider the unique urban and socio-economic characteristics of these cities/municipalities. The formulation of these plans presents an opportunity for local governments in Serbia, alongside their stakeholders and communities, to take ownership in defining and implementing local strategies for climate change adaptation. It provides cities with a chance to address climate-related challenges and chart their course towards ecological and climate resilience, benefiting not only the cities themselves but society at

Proceedings

large. Additionally, this effort will bolster the contribution of Serbian cities to both the national climate change agenda and the broader green agenda.

Abstract

Climate change has a significant impact on the urban built environment, in view of both the increased probability of dealing with extreme weather effects but also in terms of outdoor and indoor thermal comfort conditions as well as the energy behavior of urban building stocks. Hence, climate change may lead to a slight reduction in heating energy requirements of buildings but, as the literature indicates, it can severely exacerbate cooling energy needs, influencing peak energy demand, energy generation and energy supply. In this context, this paper reports on the initial stages of the Re.Nature Cities research project, namely the assessment of the microclimatic conditions prevailing in two urban districts in the city of Athens, on the basis of current and estimated climate change conditions. The results indicate a significant increase in air Temperature by approximately 10%, for the period 2040-2060, which stabilizes towards the end of the 21st century (2080-2099), with an average Tair rise up to 2%.

Keywords: urban microclimate; ENVI-met; dynamic microclimate simulation; vegetation; NBS.

1. INTRODUCTION

Due to the ever-growing rates of urbanization, at least 55% of the global population resides in urban areas, with the United Nations predicting that this percentage will reach 68% by 2050 (UN, 2018). In Europe, in particular, this value is expected to reach 80% within the same timeframe (EC, 2020), (UN-Habitat, n.d.). Furthermore, considering both global warming due to climate change and the development of urban heat island (UHI) effect (Kolokotsa, et al., 2022), cities suffer the most from an ever-growing rise of temperatures, especially in the summer. In the case of Europe, the Mediterranean region presents the greatest level of vulnerability due to the local climatic conditions as well as the cities' morphology. Dense construction, impervious materials, limited evapotranspiration potential due to absence of natural elements as well as the intense human activity exacerbate the impacts of climate change and intensify UHI effect (Taha, 2004), further increasing the air temperature and resulting to high energy demand for cooling. Given the fact that this energy is covered by electricity that is mostly generated by fossil fuels, the result is a high amount of greenhouse gas (GHG) emissions that have an adverse effect on the atmosphere and climate. Cities are particularly susceptible to the impacts of climate change, due to incoherent and compact spatial design, which lead to (i) a limited capacity of dense urban communities for the development of holistic mitigation strategies, (ii) poor living conditions and (iii) to increased vulnerability of cities to extreme weather events (IPCC, 2022). Nevertheless, cities present the greatest improvement potential as well; thus, local authorities are more efficient in implementing mitigation measures, especially when aligned with other bodies at national and regional level. Hence, bottom-up approaches, based on extrapolated analyses from neighborhood -, to city -, to regional - scale, enables the targeted development of holistic, tailor-cut action plans and policies, whilst ensuring their efficient

Proceedings

ISBN: 978-618-5765-02-6

implementation. These concepts allow for enhanced positive outcomes on a larger scale of influence, resulting in higher measured impacts. Against this background, over the past two decades, cities have been surpassing ambitions to achieve sustainability goals, while the IPCC warns that existing national contributions are insufficient (EC, n.d.). In addition, the ever-growing urbanization and climate change will continue to increase in the future, leading to severe impacts in urban areas. Hence, the dedicated analysis of existing climatic conditions and future projections in urban environments is of vital importance so as to understand and predict the impacts of climate change, enabling the design of holistic solutions for the development and monitoring of mitigation and adaptation strategies.

The impact of climate change can be assessed based on the future projection, developed by the United Nation in the Third Assessment Report (IPCC, 2001). This projection, expressed in specific forecasting scenarios, known as Representative Concentration Pathways (RCPs), outline different trajectories of greenhouse gas emissions and their potential impacts on the climate system. RCPs range from lower emission scenarios, such as RCP2.6, involving significant reductions in emissions, to moderate scenarios like RCP4.5. The latter represents a moderate emissions pathway, with greenhouse gas concentrations stabilizing by the end of the 21st century. RCPs also include higher emission scenarios like RCP8.5, where emissions continue to rise rapidly throughout the 21st century. Each RCP provides valuable insights into potential future climate conditions, supporting policymakers and researchers to better assess the range of mitigation and adaptation potential and plan sustainable strategies.

In this context, the aim of this study is to evaluate the impacts of climate change on two typical urban districts in the city of Athens, analyze the changes affecting the urban microclimate and produce data as well as conclusions that will serve as a basis for the Re.Nature Cities research project. The selection of the study areas, based on the LCZ classification, further contributes to the understanding of how urban morphology affects microclimate under different climatic conditions. Hence, the study examines the potential for implementing these results in other areas with similar morphological and climatic characteristics to better assess the impact of climate change in urban built environments.

2. MATERIALS AND METHODS

The methodology includes the assessment of the microclimate of two study areas under the current and future climatic conditions with the use of ENVI-met tool. The process involves three main steps: first, the identification of the target areas to ensure a focused analysis; secondly, the generation of the climatic data based on the areas' specific locations for the current conditions and the future projection of climate change and finally, simulations within the 3D environment of the ENVI-met microclimate model.

2.1 Microclimate assessment tool: ENVI-met

For the assessment of the microclimatic conditions of the selected areas, ENVI-met V.5 was used that simulates the interactions between the atmosphere, the surface and the vegetation. ENVI-met is a three-dimensional, non-hydrostatic, prognostic model that simulates surface-plant-air interactions based on fundamental laws of fluid dynamics and thermodynamics with a typical resolution of 0.5 m in space and 1-5 sec. in time (ENVI-met, 2024) (Bruce & Fler, 1998). ENVI-met has been validated with field experimental measurements by several researchers (Tsoka, Tsikaloudaki, & Theodosiou, Analyzing the ENVI-met microclimate model's performance and assessing cool materials and urban vegetation applications—A review, 2018); Existing deviations between measured and calculated data are a result of a) the model's simplification of specific parameters and calculations such as the static cloud coverage and wind speed, and b) user's input simplifications such as the selection of one typical tree type, SR overestimation or the obtain of weather data by nearby stations and not from the specific weather location (2021) (2023).

2.2 Study areas

The study areas are located in the city of Athens, Greece. The climate of the city is Mediterranean (Köppen climate classification: Csa), generally characterized by hot, dry summers, mild, wet winters and evenly distributed rainfall throughout the year. During the winter months, the average daily temperatures close to 9.03 °C with the coldest month being January. In summer, the mean high and low Tair values are between 31.83 °C and 21.27 °C respectively, with the recorded maximum air temperatures of the last decades rarely exceeding 40 °C. July is the warmest month of the year with Tair averages of 27.7 °C (Climate Data, 2024). The selection of the areas was made on the basis of the Local Climate Zones (LCZ) classification of Agathangelidis, Cartalis and Santamouris (2020) and the main selection criteria included the existing vegetation, the topography and the streets' orientation. The two selected areas represent typical samples of LCZ2 and LCZ3 classes, characterized by limited vegetated areas, narrow streets adjacent to a crowded highway and densely built environment with adjacent multifamily buildings. Both areas have uniform flat topography and orthogonal street and building block organization to ensure optimal adaptation to the 3D environment of the assessment tool and minimal deviations during their standardization. The existing vegetation is limited to sparse low vegetation and small to medium trees across sidewalks, with the predominant species being bitter orange trees. The investigated sites are the same size, 200x150m (30,000 m²) and represent different geometrical and morphological characteristics (i.e., building surface density, height/width ratio (H/W) of the street canyons, etc.) which correspond to the LCZ2 and LCZ3 categories. For the sake of clarity, each area is named after its classification, LCZ2 and LCZ3 (see Figures 1, 2)

Figure 52 LCZ2 study area and its location in the greater city center of Athens

2.3 Definition of simulation days and climatic data generation

Due to the high temporal resolution of microclimate analysis, simulations are generally conducted on a daily basis; this study focused on the summer period, when the impacts of climate change in the studied areas are at their peak. The simulations took place on a typical summer day, for the month of July and for a reference period 1980-2000 (Scenario 1) and future periods 2040-2060 (Scenario 2), 2080-2099 (Scenario 3). The climatic parameters were derived by Velikou (2021) and include high-resolution climatic data, issued by the up-to-date, dynamic regional climate model RegCM4.

Figure 3 Tair evolution for the typical summer day for the reference (Scenario 1) and the 2 future periods (Scenario 2 & Scenario 3), for the LCZ2 case study area

Figure 4 Tair evolution for the typical summer day for the reference (Scenario 1) and the 2 future periods (Scenario 2 & Scenario 3), for the LCZ3 case study area

For future projections the model is using RCP4.5 scenario corresponding to an intermediate pathway with no exceedance of radiative forcing at a stabilizations level of ~ 4.5 W/m². The main physics configurations of the model are described in detail in the study of Velikou et al. (2019). For the purposes of this study, three meteorological parameters are utilized for two selected grid points (the closest to the examined case study areas). The data includes air temperature (°C), relative humidity (%) and wind speed (m/s). The output weather files have a 3-hour temporal resolution. Additionally, the 3-hourly mean data over each 20-year period are calculated and based on the latter output, the typical simulation days are defined. These parameters will comprise the input boundary conditions for the ENVI-met microclimate simulations and will be incorporated within the model through the simple forcing model. The Tair evolution during the typical July day for the reference and the future periods, for both study areas, that have been used as an input boundary condition in the ENVI-met microclimate simulations is shown in Figure 3 and Figure 4.

2.4 Modeling description

For setting up the area in the three-dimensional space of ENVI-met, the basic morphological parameters were defined including building heights, environmental materials, their thermophysical characteristics, area dimensions, cell sizes, etc. The selected sites were adjusted to a standard area of 200x150m accounting for a total surface area of 30.000 m². Based on each areas' footprint, as retrieved from Google Earth. The areas were normalized into an orthonormal grid, with the width of the roads ranging between 7.5 to 10, including sidewalks. The floor height of the ground floor is 4 m.

and of a typical floor 3 m. Existing floor setbacks on higher building floors, as well as staircase upper edge rooms on the roofs were also considered. For the x and y axis a resolution of 2,5 m. was selected, and the model was created on the basis of 60x80 grids. On the z axis, the number of cells was set to 20 with a 3 m. resolution. Six nesting grids were assigned to the model, that surround the main area to reduce the boundary effects and assure the model’s stability. The assigned material of nesting grids is asphalt road, as a most representative material found in the main area. 5 and Figure include the buildings elements, position of trees and numbering of the street canyons. The simulation configuration inputs are included in Table . The physical properties of the materials and ground surfaces and the assigned construction and soil profiles are presented in Table . The materials’ values reflect the construction period of the buildings, dated between 1970-1980.

The geometry and foliage characteristics of the modeled plants are designed in ENVI-met’s “Albero” tool. For this study, Citrus Aurantium (bitter orange) evergreen tree species was selected as the main tree type for both study areas. LAD value was defined as 2 m²/m³ to correspond to the tree’s dense crown. The tree height is 4.5 m. and the crown diameter 3 m. These values correspond to mature trees based on field study and relevant measurements that are reported in the existing literature (Tsoka, Evaluating the Impact of Urban Microclimate on Buildings’ Heating and Cooling Energy Demand Using a Co-Simulation Approach, 2023). Finally, the model initialization parameters are included in Table .

3. RESULTS – DISCUSSION

The research focuses on the hottest summer period, when the effects of rising temperatures are most evident. The examined climatic parameters involve air temperature (T_{air}), mean radiant temperature (T_{mrt}) and surface temperature (T_{surf}). Here, T_{air} maps at a height of 1.5m above ground level are presented to assess the impacts at the level where human activity develops. The projected T_{air} , during noon (12:00) and afternoon (18:00), for LCZ2 and LCZ3, for Scenario 1, 2 and 3 (i.e. reference and the 2 future periods), is presented in Figure 9 to Figure 10. Based on the results, the average temperature across the entire LCZ2 area during midday ranges from 27.37°C to 33.91°C. The highest temperatures are found in unshaded areas, specifically in canyon 1 (refer to Figure 5), crossing transversely the area with a N-S orientation. In the afternoon, at 18:00, the average T_{air} drops significantly, with a decrease of 7.48°C compared to noon. The lowest value is 24.72°C and the highest at 26.42°C. The central street cools relatively quickly in the afternoon, given the dominant wind speed being North. Higher afternoon temperatures persist in street canyons 2 and 3, oriented towards E-W, that benefit less from natural ventilation. Temperatures in the enclosed backyards of the building blocks remain lower than average throughout the day, likely due to the intense shading from surrounding buildings that block large amounts of solar radiation from insert.

Similarly, in LCZ3 for the reference period (1980-2000), an analogous temperature pattern is observed, with the highest temperatures in streets 3 and 2, which have a NS orientation receiving higher amounts of solar radiation during the sun's peak position. The average temperature of the area

Proceedings

at midday is 28.7°C, with the maximum reaching 31.07°C. LCZ3 is slightly cooler than LCZ2 (by 2.11°C on average), primarily due to (i) the local climatic variations of the areas, as calculated by Velikou [16], (ii) the increase vegetation cover in LCZ3 that shades larger portion of the ground surfaces and cools the area through evapotranspiration, (iii) the lower building heights allowing the wind to insert the lower layers of the area and enhance natural ventilation. In the afternoon Tair values vary between 25.39°C and 27.07°C. In both cases, air temperature at midday shows higher variability compared to the afternoon, where temperature distribution is more uniform. The temperature range at noon exhibits a larger spread compared to 18:00 pm, suggesting greater variability and the possibility of more extreme conditions during the midday period.

Looking ahead to future projections, both scenarios forecast a substantial rise in temperatures between 2040 and 2060 (Scenario 2). However, the rate of increase is expected to decelerate during the period from 2080 to 2099, aligning with the RCP4.5 scenario. In the case of LCZ2, the average temperature ranges between 29.84°C (+2.46°C) and 36.69°C (+2.76°C) at midday and between 27.26°C (+2.53°C) and 29.29°C (+2.87°C) in the afternoon. Similarly, in LCZ3, midday temperatures range between 28.62°C (+2.52°C) and 33.53°C (+2.46°C), and afternoon temperatures range between 28.06°C (+2.67°C) and 29.71°C (+2.64°C). The average temperature increase in both cases reaches approximately 10%.

For the third period, 2080-2099 (Scenario 3), at midday, the average temperature ranges between 30.09°C (+0.25°C) and 36.97°C (+0.28°C) for LCZ2 and between 29.07°C (+0.45°C) and 34.04°C (+0.50°C) for LCZ3. In the afternoon, these values range between 27.58°C (+0.32°C) and 29.64°C (+0.35°C) for LCZ2 and between 28.52°C (+0.47°C) and 30.16°C (+0.45°C) for LCZ3. The average temperature increase in both cases does not exceed 2%, with the temperature rise stabilizing by the end of 21st century.

The analysis of the results also indicated that the Mean Radiant Temperature (Tmrt), remains high during noon and afternoon hours in both areas. A significant reduction is only observed in areas with vegetation cover and shaded locations. The existing trees, due to their limited number and size, fail to reduce Tmrt values beyond the area covered by their crowns. In certain areas, particularly along streets 2, 3, and 4 in LCZ2, and street 1 in LCZ3, temperatures can reach as high as 70°C, especially where vegetation is scarce or non-existent. In the remaining streets canyons, the cooling impact of trees is negligible.

During the afternoon, the mean radiant temperature (Tmrt) stays relatively high due to the urban heat island (UHI) effect and the high thermal mass of urban materials. These materials absorb heat throughout the day and release it back into the surroundings in the late evening. Future projections indicate that average Tmrt values are expected to rise by 9% in LCZ2 and 7% in LCZ3. Additionally, the range of Tmrt values decreases in Scenarios 2 and 3, suggesting that higher temperatures will affect a larger portion of the areas rather than being isolated occurrences. Finally, ground surface temperature exhibits a similar trend to Tmrt. The study of the areas in vertical sections highlights the extent of the phenomenon at higher elevations within the city. As shown in Figure 11, the temperature increase in LCZ2 affects both the ground level and upper levels where buildings are present, extending 12 meters beyond the highest built volume. The highest intensity of the temperature rise is observed at the lower level, accompanied by high surface temperatures and high Tmrt values. Similar findings are observed in LCZ3.

4. CONCLUSION

The study aimed to quantify the impact of climate change on the urban environment by analyzing two areas in Athens using the RCP4.5 projection. The initial results indicated that existing vegetation did not significantly improve air temperature, but streets with tree plantings showed lower T_{mrt} and T_{surf} values, as expected. The study reaffirmed the importance of trees in improving microclimates, with their influence remaining significant in future projection scenarios. The highest rise in air temperature was observed in Scenario 2 (2040-2060), where the air temperature increase exceeded 10%. Area LCZ2 showed slightly higher temperatures during midday compared to LCZ3, suggesting an influence of denser urban structure, lower SVF, and less vegetation. By the end of the 21st century (Scenario 3), the air temperature rise continued at a lower rate of 2%. Overall, predicted climate change will impact urban areas by increasing air temperature and deteriorating human thermal comfort. This study offers a preliminary assessment of climate change's impact on the urban environment and is an early component of the Re.Nature research project. Moving forward, the researchers plan to analyze data from extreme weather days in addition to typical day simulations to gain a more comprehensive understanding of climate variability. Furthermore, they will explore a more pessimistic RCP scenario and assess its effects on the areas to develop a more objective perspective on the challenges cities may encounter by the end of the 21st century.

The research project is implemented in the framework of H.F.R.I call “Basic research Financing (Horizontal support of all Sciences)” under the National Recovery and Resilience Plan “Greece 2.0” funded by the European Union – NextGenerationEU (H.F.R.I. Project Number:15566).

Extended abstract

Across Europe, several thermal towns established in the nineteenth-century have faced a profound crisis in recent decades due to shifts in tourist demand and the difficulty of renewing a well-established touristic model. Montecatini Terme in Italy is a case in point: its tradition of diuretic waters dates back to the Middle Ages, and the city boasts a rich system of thermal facilities built in the early 1900s of exceptional historical and artistic value. In 2021, the city was declared a UNESCO World Heritage site within the "Great Spa Towns of Europe" network. Montecatini's peculiarity lies in its thermal structures being located within a park (the Terme Park), which has always played a significant role in the city's tourism. Due to a decline in thermal tourism for medical purposes, the city has gradually reduced its economic impact. Currently, the thermal system is fragmented among various owners (the municipality, the thermal company, and other private entities) and only partially operational, with several facilities closed and abandoned. Similarly, the park is now partially fenced and inaccessible due to a lack of maintenance.

The city is in the process of developing a new Tourism Strategic Plan aimed at reconfiguring it as a "wellness city". Following the guidelines outlined in the plan, the Terme Park assumes a new centrality within the urban context. This contribution presents the outcomes of preliminary research and conceptual design work to redefine the park's role in the system and reorganize its uses and functions. The goal is to translate the general directions of the new Tourism Strategic Plan into a design proposal, developing specific aspects such as greenery, water, and biodiversity as catalysts for the renewal of Montecatini's tourist proposal. The project acknowledges the rediscovery of the value of self-care, stemming from the pandemic, and adopts a holistic approach to urban design for well-being. The proposal aims to enhance the park's capacity to provide Ecosystem Benefits within the urban context while simultaneously proposing a sustainable transformation model, also from an economic perspective.

The park's refunctionalization focuses on three key elements: nature, art, and water. The aim is to enhance and increase the natural heritage of the area, creating thematic areas and structuring botanical paths for biodiversity. Furthermore, Montecatini's rich artistic tradition, tied to names like Joan Mirò, has inspired a new narrative. In this scenario, water, a protagonist in the city's history, regains a new centrality. In conclusion, the case of Montecatini represents an interesting case for other spa cities facing similar challenges and serves as a reference for the redevelopment of urban green spaces.

Extended abstract

Inequality is an interdisciplinary concept given that it is realized in the interwoven fields of economy, society, and politics. Even though an unanimously holistic definition is still missing, inequality denotes: (a) the unequal distribution of income or / and the unequal distribution of wealth (economic inequality); (b) the lack of equality of outcome or / and the lack of equality in access to opportunity (social inequality); and (c) the unequal participation in the political process (political inequality). Evidently, a plethora of pre-market, in-market, and post-market inequality drivers operate simultaneously as it became widely understood that inequality is not only the result of “efforts” but also the result of “circumstances”. The latter are out of individuals’ control, whereas the former are affected by individuals. In fact, “efforts” may provide a reflection of “circumstances”. Pre-market drivers may encapsulate in “the level-the-playing-field principle” and refer to initial conditions, in-market drivers may encapsulate in “the during-the-process-competition”, and post-market drivers may encapsulate in “the nondiscrimination principle”.

Inequality has been a long-standing issue, providing a terrain of theoretical and empirical discussions and debates, in both academia and policy making. Though malleable – meaning different things to different people and in different contexts – the concept and the phenomenon of inequality encompasses discrete, yet overlapping and interrelated, types. Considering that a complex set of theoretical propositions, ideological preoccupations, and institutional arrangements are confronted with the hard evidence of frequent market and policy failures, understanding the relations among the types of inequality is, apparently, an extremely important task that may provide valuable insight both to academic theory and to policymaking. This is especially so in the light of the paradigm shift that is taking place, most emphatically in Europe, as inequality is perceived not only as a problem of (re-)distribution but also as a problem of processes.

The paper consolidates discrete (unconnected) strands of literature that revolve on the concept of inequality. Overcoming the existing fragmented approaches of the various disciplines of inequality, the paper provides a comprehensive understanding of the interplay among different drivers and types of inequality, in the light of the global mega-trends, and, overall, addresses the need for a holistic understanding of the concept. Providing a state-of-the-art understanding of the concept of inequality, the paper paves the way to the identification of path-dependent (or cumulative causation) processes that cause multiple drivers and types of inequality not only to coexist but also to reinforce each other, within and between different social groups and spatial entities.

*Corresponding author: e-mail: saratsis@uth.gr, Tel +30 2421074462

Extended abstract

In this paper we examine the way that many types of inequalities are related with urban conditions. We rely on an experts' questionnaire conducted during an ongoing "Horizon Europe" research project on inequalities.

Given the wide spectrum of the notion of inequalities it is important to understand the complexity of the phenomena and its social and spatial dimensions. By doing so, we are able to identify the best solutions to deal with the phenomenon considering that the already implemented policies did not always have the desired effect on inequalities.

At first, questions regarding the various dimensions of inequalities are presented with focus on those relevant to urban areas. We acknowledge that many dimensions are shaped by the wider socioeconomic conditions in a country, but as the results indicated, the urban environment acquires a mediating role in augmenting or attenuating them.

Second, factors that may increase inequalities at the sub-national level, i.e. among regions and cities, are presented and evaluated according to their importance.

Finally, policies that have the best impact on reducing inequalities are discussed having in mind that in many cases these policies are implemented in local or regional scale, and by definition they have a clear urban dimension.

The paper concludes with deeper research and policy recommendations.

Regional business cycles synchronization and regional inequality in the EU

D. Kallioras^{1*}, G. Petrakos¹ and M. Tsiapa¹

¹ Professor of Economic and Regional Development, Department of Planning and Regional Development, University of Thessaly, Greece

*Corresponding author: E-mail: dkallior@uth.gr, Tel +30 2421074484

Extended abstract

Against the backdrop of the EU economic integration process, the paper focuses on business cycles. Particularly, the paper examines the impact of the evolution and the synchronization of regional business cycles on the evolution of regional inequalities in the EU. Both topics are crucially important. On the one hand, the relation between the evolution of regional business cycles and the evolution of regional inequalities is going to reveal whether (and to what extent) the latter follows a pro-cyclical or a counter-cyclical pattern. The pro-cyclical pattern indicates that growth poles (i.e., metropolitan and dynamic regions) are more likely to be positively affected than the rest of the regions in periods of expansion and, correspondingly, are more likely to be negatively affected in periods of contraction. On the other hand, the relation between the synchronization of regional business cycles and the evolution of regional inequalities is going to reveal whether (and to what extent) sectoral shocks are distributed evenly or unevenly within the integrated economic space. An even distribution indicates the smooth functioning of the economic union. Business cycles are defined as “a type of fluctuation found in the aggregate economic activity of nations that organize their work mainly in business enterprises”. Ergo, business cycles refer to the concerted cyclical upswings and downswings that characterize a span of macroeconomic variables - the most notable one is real GDP – and aggregate economic activity, in general. Typically, business cycles consist of a quartet of recurrent, but not periodic, stages: (a) expansion; (b) crisis; (c) recession; and (d) recovery. Apparently, the notion of business cycles is not compatible with the neoclassical understanding of the (spatial) economy, which operates always in equilibrium and the only variations from a steady-state growth path may be arising from random or external shocks. The analysis of the paper refers to 242 EU NUTS II regions and covers the period 1990-2020. Using sound and rigorous methods of empirical analysis, the paper presents clear-cut empirical evidence that shed light on academic theory and provide valuable insight to policy making.

Extended abstract

The article presents research on the potential of integrated development in tourism and the protection of cultural values of the cross-border regions of Poland and Ukraine. The scope of the study is selected areas of Podkarpacie, the Outer Western Carpathians, and the Outer Eastern Carpathians. The Carpathians are located in the heart of Europe, a crucial part of the ecological, economic, cultural, recreational, and habitat environments shared by many of its countries.

The research aims to determine places with a functional need and general infrastructural possibility of locating new border crossings and determining directions of activities in integrating cross-border regions. The authors attempt to analyze transport, functional-tourist, natural, landscape, social, cultural, and recreational connections. The research spatial axis is the border, and the central point is the southernmost border crossing Krościenko - Smolnica. A location map of the research area was prepared as part of the graphic studies, considering large cities such as Lviv and Rzeszow and medium-sized ones to facilitate spatial reference. Then, a recreational and tourist infrastructure analysis and the generalized location of the concentration of accommodation facilities were prepared. A road and transport analysis assumed a one-hour travel distance from the border, emphasizing tourist attractions and the Polish-Ukrainian border crossings. Archival pre-war road, railway, and tourist maps were also examined, historically showing this area without a border with the no longer present part of the former road network crossing it.

The conclusions illustrate the directions of suggested actions to increase the potential and integrate cross-border areas, considering their tourism potential, recreational infrastructure, natural resources, biodiversity, cultural heritage, ecological stability, standard guidelines for nature protection, landscape, and sustainable development. New transport and recreation axes create an opportunity for new structures of recreational facilities that will allow for more excellent preservation of natural landscapes, blue-green infrastructure connections, and the authenticity of traditional settlements while using space for recreational purposes. New road and pedestrian crossings between Ukraine and Poland could provide an impulse for the border regions' sustainable economic and social development. The Carpathian region needs to develop concepts and strategies for developing territories and general plans for recreational and tourist areas.

Keywords: *cross-border regions, tourism, Polish-Ukrainian borderland, Carpathians*

Social Exclusion and New Spatial Inequalities: The Case of Palermo in Italy

V. Todaro¹, F. Lo Piccolo², S. Siringo^{3*}

Extended abstract

The increase and diversification of levels and forms of poverty (absolute and relative poverty, energy poverty, educational poverty, mobility poverty) have considerably broadened the area of vulnerability of a considerable segment of European citizens in the last decade, especially in the most economically disadvantaged regions. This phenomenon has not only generated marginalisation and social exclusion, but has had significant repercussions on the spatial configuration of cities, with inadequate responses from institutional policies. In the urban contexts of Southern Europe, in particular, critical issues manifest themselves through housing deprivation, difficulties in accessing public services, mobility poverty and structural weakness of urban policies.

This paper aims to address new forms of poverty, marginalisation and social exclusion in Southern European cities, focusing on the examination of new socio-spatial inequalities. A central question is: what are the new spatial boundaries of socio-economic inequalities in Southern European cities? This implies the need to recognise and map these inequalities, not only to understand their extent, but also to inform more effective urban policies.

The chosen case study is the city of Palermo, Italy, which will provide a detailed analysis of local dynamics. The paper proposes to use new socio-spatial indicators, both quantitative and qualitative, and innovative interpretative tools, such as digital and social co-production tools, to recognise and map these new spatial geographies.

Expected outcomes include the creation of new analytical-interpretive frameworks, through the conceptualisation and mapping of emerging socio-spatial inequalities. This will provide a crucial foundation for the development of more targeted urban policies sensitive to the specific socio-economic challenges of Southern European cities. The multidisciplinary approach and the use of innovative tools will provide a deeper understanding of local dynamics, facilitating the implementation of tailor-made solutions that can improve the quality of life and promote social inclusion in these urban communities.

Keywords: *Social Exclusion; Spatial Inequalities; Urban policies; Palermo*

The spaces of productive micro-districts: an asset available for adaptive projects?

M. F. Felloni

CCRR-Lab - Climate Change Risk and Resilience Lab, Department of Architecture and Urban Studies,
Politecnico di Milano, Italy

Corresponding author: E-mail: mariafiorella.felloni@polimi.it

Extended abstract

This paper deals with the adaptive regeneration of productive areas and is a reflection supported by the outcomes of the recent experience in the research project “Productive Areas, Pro-Adaptive Areas” (AP+A) (<https://www.areeproadattive.polimi.it>) conducted by the Department of Architecture and Urban Studies of the Polytechnic of Milan and funded by the Ministry of Ecological Transition (MiTE). The project carried out activities to spread the culture of sustainability and promote projects and actions for climate change mitigation and adaptation. It has made it possible to propose and test innovations for the adaptive regeneration of strategic areas for coping with the climate crisis, which, like productive areas, have received little attention in the history of urban planning since the Second World War. The main actions involved building climate knowledge at the micro-scale, raising awareness and involvement of the local business community and stakeholders, co-designing adaptive solutions, and developing specific urban planning and governance tools.

The research area was the Metropolitan City of Milan, with two pilot municipalities in the north-west and south-west. A territory in which productive areas contribute to a significant extent to determining critical phenomena such as heat islands, inefficiency of surface drainage, poor quality of open spaces, of public and public-private thresholds, in general, of urban habitability.

These are areas with highly impermeable soils, little vegetation, buildings of poor construction and urban quality, and low energy efficiency. The overall picture is one of a territory dotted with widespread micro-production areas, now integrated into the urban landscape. This spatial connotation, the result of functionalist urban planning since the Second World War, has helped to promote the idea of *adaptive productive micro-districts* and a model of *productive urban district governance* that aims to encourage stable, direct, and organised interaction between private and public bodies to carry out regeneration projects.

At the same time as the research was carried out, both the Metropolitan City and the two pilot municipalities developed new tools for territorial governance, the Metropolitan Territorial Plan, and the Municipal Urban Plan, respectively.

This fortunate circumstance was an important opportunity for further theoretical reflection and to explore and establish real implementation prospects for the proposed solutions. In the case of one municipality, the engagement and co-planning activities were part of the participatory process of the urban plan, and the adaptive solutions were classified according to a performance model that will be used, albeit in an experimental form, in the preliminary study phases for the approval of projects and possible bonuses for private interventions.

The idea of adaptive, productive micro-districts, supported by specific district governance, remains, for the time being, a proposal appreciated by public and private actors.

Keywords: *productive areas; adaptive urban planning; adaptive performance; Metropolitan City of Milan*

Business analysis: Citizen Science verge inventory and management in urbanized Flanders

V. Strosse

Researcher, Department of the Environment, Flanders, Belgium

Corresponding author: E-mail: Veerle.strosse@vlaanderen.be, Tel +32 474 59 11 27

Abstract

Verges form an important part of the green-blue veins of urbanized Flanders, which can be considered as one large city. They play an important role in relation to climate change, numerous ecosystem services, and genetic diversity to combat pests. Green-blue permeation, including road verges, forms the foundation of resilient cities.

There is a need for a uniform inventory of Flemish verges and their quality for all of Flanders. Through this overview, we know which verge location needs to be actively addressed, for example through adapted verge management. Currently, there are numerous verge inventories, which however all are conducted in very different methods. This research builds on a previous study on Flemish verges that developed a scoring system for the verges and carried out an initial integration of existing verge inventories. With this current research, carried out on behalf of the Flemish Department of Environment, we want to get a more detailed view of the quality of the Flemish verges using a scoring system. We want to do this through Citizen Science and at the same time raise awareness about the importance of biodiverse verges. In this study, we carried out a business analysis, in preparation for an app that will be developed in the context of the Citizen Science project. All stakeholders were surveyed using different research techniques, and a communication strategy for the end users was defined. To confirm the viability of this approach, we developed a proof of concept in the validation phase, containing a solution for technical issues. The analysis found that the app ideally targets two audiences: nature lovers without and with species knowledge. The proof of concept showed that essential functionalities include location determination, registration of flora and fauna, photographic documentation, date and time registration, and space for user notes. For the communication strategy, we recommend a broad approach, aimed at nature lovers and various groups who often seek out nature. The communication should share facts about biodiversity in Flemish verges and the launch of the app is best supported by both traditional media and digital marketing.

The results and recommendations of this research allow us to continue with the development of the app for the Citizen Science project for verge inventory. This will ultimately not only lead to a uniform verge inventory, where data exchange is possible, but also to more support in relation to the importance of verges, as part of the green-blue veins in urbanized Flanders. And in this way, this research contributes to a more resilient Flanders.

Keywords: *verges, business analysis, Citizen Science, green-blue veins of Flanders*

1. INTRODUCTION

Verges collectively constitute a fundamental component of the ecological structure and the green-blue network within the landscape. Beyond their importance for biodiversity, these verges - as an essential part of the green-blue veining - play a crucial role in mitigating climate change, delivering ecosystem services, and preserving genetic diversity. In urbanized Flanders, they serve as essential buffers against the urban heat island effect, providing necessary cooling. However, biodiversity in Flanders faces significant challenges due to various factors, including environmental pollution, land use expansion, spatial fragmentation, barriers, monocultures, and pesticide usage. Addressing these

of the International Conference on **Changing Cities VI:**

Spatial, Design, Landscape, Heritage & Socio-economic Dimensions

Rhodes Island, Greece • June 24-28, 2024

ISSN: 2654-0460

ISBN: 978-618-5765-02-6

issues is critical for maintaining ecological balance. There is a need for a uniform inventory of Flemish verges and their quality for all of Flanders. Through this overview, we know which verge location needs to be actively addressed, for example through adapted verge management. We achieve this by deriving a comprehensive scoring system and visualizing this information on maps in the study of 2022, namely ‘Onderzoek Vlaamse bermen en onmiddellijke omgeving in het kader van groenblauwe netwerken en de afname van biodiversiteit’ [Investigation of Flemish Roadside Verges and Immediate Surroundings in the Context of Green-Blue Networks and Biodiversity Decline] [1].

Understanding the biodiversity status of the verges informs optimal verge management strategies based on their respective scores. Currently, there are numerous verge inventories, but they were all conducted in very different methods. There is a need for a standardized verge inventory to enable data exchange and comparison across different verges. Building upon the above-mentioned first verge study [1], we propose data collection through a Citizen Science project. An accompanying mobile application will facilitate data gathering. Additionally, the Citizen Science initiative will raise awareness about the importance of roadside verges.

This article also discusses the business analysis carried out in the context of the preparation of the app development and outlines the communication strategy associated with the proposed app, as described in the report of 2024, ‘Business analyse: Citizen Science Bermininventarisatie en -beheer’ [Business analysis: Citizen Science Roadside Inventory and Management] [2].

2. FIRST STEPS TO INTEGRATION OF ROADSIDE INVENTORY

Two studies have already been conducted on this topic. In the first study [1], the need for a comprehensive overview of Flemish road verges was highlighted. However, to gain insight into the quality of these verges, a robust inventory methodology (via Citizen Science) with data collection in a reliable database and an ecological score are essential requirements.

This first study on verges [1] consists of three parts: integrating existing roadside inventories, setting up a scoring system and initiating a Citizen Science study.

Firstly, data from existing inventories provided by the Flemish Waterway Authority (Vlaamse Waterweg nv) and the Agency for Roads and Traffic (Agentschap voor Wegen en Verkeer) were analysed. A high-performance relational (geo) data model was developed to seamlessly integrate existing databases containing information about these verges without any data loss.

Second, to assess the quality of the verges, a dual scoring system was devised based on landscape-ecological and biotic values. The landscape-ecological value, with a score from 1 till 10, considers the verge’s proximity to legally protected natural areas (such as nature reserves) and watercourses. In the figure below (Figure 1), this scoring system with landscape-ecological value has been applied to the verges in Flanders.

Figure 1. Landscape-ecological score of the roadsides (Anteagroup & Natuurpunt, 2022)

Additionally, the score considers adjacent land use, exposure, and slope (Figure 2). The biotic score relies on verge characterization and the presence of red-listed species (both fauna and flora) and has a score from 1 till 20.

Figure 2. Biotic score of the roadsides (Anteagroup & Natuurpunt, 2022)

This first study also serves as a stepping stone toward a Citizen Science project. It identifies success and failure factors based on known Citizen Science projects and outlines an action plan for the Citizen Science initiative, leveraging the established database.

In the policy recommendations emphasis is placed on expanding the database. This expansion would involve local managers in verge maintenance and allow for the derivation of baseline data and trends

to inform management tips. Expert assessment remains crucial for establishing effective management practices (e.g., practical considerations)."

Furthermore, it is emphasized that a sufficiently robust communication component (with targeted awareness and motivation) needs to be established to engage administrators, associations, etc. In terms of the follow-up process, it is indicated that it is crucial that the various stakeholders and developers work together to actively utilize the results of this study.

The current research builds on the preliminary investigation and focuses extensively on stakeholder mapping and surveys. In addition, the Citizen Science project was further developed into a proof of concept.

3. NEXT STEPS – RESEARCH QUESTIONS

The second study on verges [2] presents the results of the business analysis for the development of an app for a Citizen Science project on verge management and inventory. The analysis includes a definition of the goals, a thorough investigation, an internal and joint brainstorming, an elaboration of a proof of concept and advice on a matching communication strategy. The main findings indicate that the app would be optimally aimed at both nature lovers with and without knowledge of plant species. Through features such as location tracking, flora and fauna registration, photographic documentation and user notes, the app has the potential to deliver significant added value to existing verge management in Flanders.

Thus, the main objectives of this business analysis are the following: a stakeholder mapping, the realisation of a proof of concept and a communication strategy.

For the business analysis of the application, the following research questions were asked (objectives).

- Who owns the app?
- What functionalities should the app have?
- What data should the app record?
- How is app management organized?
- How is data entered into the app?
- Who processes the data and how is it handled?
- What will be the cost of the app, including app management and processing the data entered in the application?

In line with this, the following questions must be answered when providing advice regarding the communication strategy:

1. What is the target audience?
2. Which content needs to be communicated?
3. How will the app be launched (via which tools, which media)?
4. How will further guidance and follow-up occur after the app's launch?

This part of the paper includes objectives with the research questions. In the following, the methods to answer these questions will be briefly described.

4. NEXT STEPS - METHOD AND RESULTS

Stakeholder consultation

An extensive stakeholder analysis examined and surveyed the key stakeholders for roadside research and roadside management. This ultimately resulted in an overview.

The stakeholder mapping related to roadside inventory and management identifies the various stakeholders, including their shortcomings, obstacles, and gains. It also assesses the available knowledge about these stakeholders and identifies any missing information.

During flow workshops with different stakeholders, the research maps both the current (as-is) and desired (to-be) flow. In this research, we meticulously go through all the steps of the various processes

involved in inventorizing (and sometimes managing) roadside areas. The outcome is a business process map that captures the different flows resulting from the research.

Additionally, the research conducts interviews with users (traditional observers, novice volunteers, average citizens, schools, municipalities, etc.) to understand their needs, desires, and current customer journey. The investigation specifically examines their existing interactions with government initiatives and identifies their main motivations and obstacles, aiming to address the latter.

Using all the gathered information, the research creates several personas and customer journey maps. The personas (four types: volunteers with extensive natural knowledge, volunteers with limited natural knowledge, volunteers with no natural knowledge, and biology teachers) focus on the different stakeholders, their needs, desires, and frustrations. The customer journey map highlights the processes and how stakeholders navigate them, including where they seek information, through which channels and which other target groups they interact with. A customer journey reflects the context and behaviour of an individual within a user group, describing both the current state (as-is) and a potential future state (to-be).

In this section, we will briefly describe the main conclusions of this research phase:

- **Project Objective Clarity:** It is crucial to define the project's objective precisely. This research identifies issues related to awareness among citizens and challenges in monitoring, knowledge, and communication within institutions and municipalities regarding roadside management. If the goal is to accurately inventorize road verges, multiple parameters must be considered, with a focus on naturalists as primary users. However, if the aim is to raise awareness and sensitize the public, fewer parameters are necessary, allowing for a broader audience reach.
- **Tailoring Content for Different Audiences:** As mentioned in the previous study (Heylen et al., 2022), content alignment with various target groups is essential. For instance, when communicating information within the tool to (novice) volunteers or young individuals, we need an approach that is easy to understand. Since knowledge is essential for plant recognition and effective inventorizing, the provided information should be clear and visually presented. Additionally, the application may benefit from training sessions or informational meetings. On the other hand, for experts, the application should not be overly simplified. Their expertise warrants efficient execution of tasks and input to optimize roadside management.
- **Ensuring Data Quality:** To maintain high-quality input data, consideration should be given to methods for error checking and prevention of misuse. Allocating limited additional resources or time to monitor and address erroneous or incomplete inventory data within the Citizen Science project is crucial.

Proof of concept

In this phase, a prototype of the concept was developed to validate the technical feasibility or report any remaining limitations. The focus and content of this prototype are based on the findings from the research phase.

At the start of the proof of concept (POC), two possible tracks were identified based on the research conducted by Heylen et al (2022) [1]. The first track involved creating an entirely new application, while the second track aimed to develop an app connected to [waarnemingen.be](https://www.waarnemingen.be). Both tracks were carefully analysed, with extensive research to map out the specific advantages and disadvantages of each approach. The findings of this research can be found below.

The first track, focused on developing a completely new app, is characterized by several notable benefits. A crucial advantage is the ability to have full control over both the design and functionalities of the app. This allows the development team to tailor the application precisely to specific needs and objectives. However, these advantages are offset by some drawbacks, including higher development costs and a longer development timeline.

Proceedings

On the other hand, the second track, focused on developing an app connected to waarnemingen.be, also presents an interesting set of advantages and challenges. A significant advantage of this approach is the ability to leverage an existing platform with an established user base. This can result in lower development costs and an accelerated implementation timeline, as building upon an existing infrastructure is feasible. Furthermore, the benefit of having pre-existing data and functionalities provides a solid foundation for further development. However, the reduced level of control over app functionalities, compared to the first track, is considered a drawback. Additionally, there is a need to consider the dependency on the external platform and the inherent limitations it brings. This includes constraints on customization and integration, which are crucial factors in decision-making during the development process.

The research questions from part 2 of this paper and their corresponding answers are concisely presented in Table 1 below.

Table 1. Research questions and answers derived from the research.

Who owns the app?	The entity responsible for the app is the Flemish Environmental Assessment Agency (owner)
What functionalities should the app have?	1. Location tracking, 2. Registration of flora and fauna, 3. Photographic documentation, 4. Date and time registration, 5. User Notes
What data should the app record?	1. Location, 2. Type of observation (flora and fauna), 3. Description, 4. Date and time, 5. Additional Notes
How is app management be organized?	The technical party that develops the app is responsible for the management of both the app and the associated data.
How is data intered into the app?	(1) automation through existing systems, (2) user input, (3) validation and quality control.
Who processes the data and how is it processed?	Since the technical party chosen for the development of the app is in charge of the processing of the data, this responsibility includes a thorough series of steps aimed at ensuring the secure, organized, and easily accessible storage of the data received: (1) processing for secure storage, (2) rapid search and geolocation, (3) data analysis and reporting. This comprehensive approach to data processing by the technical party guarantees secure storage of the data lays the foundation for a quick and effective use of this data to identify valuable insights and trends. The stored data is considered a static entity, and a dynamic resource that contributes to the app's success in understanding and conserving biodiversity.
What will be the cost of the app, including app management and processing the data entered in the app?	(1) development costs, (2) management fees

Figure 3 provides a simplified representation of a possible look of the app. However, the app needs further development in a follow-up study.

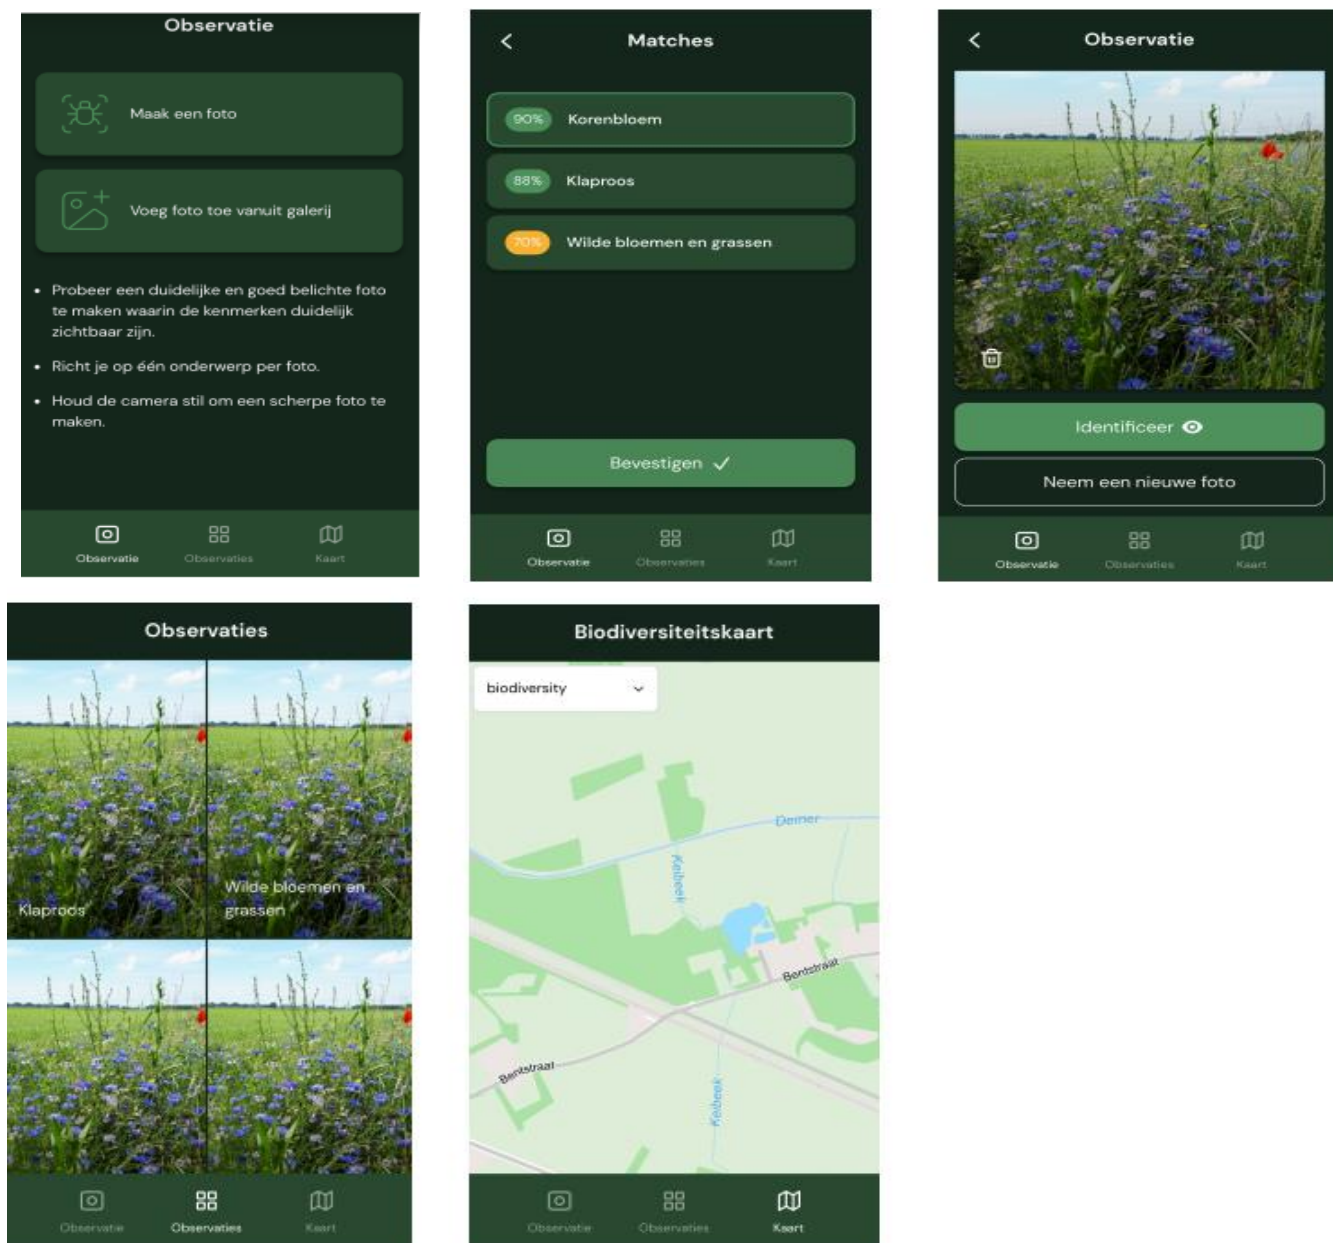

Figure 3. Proof of concept of the application (Wisemen, 2024)

Communication strategy

The research questions in order to communication (cfr. part 2 of this paper) and their corresponding answers are concisely presented in Table 2 below.

Table 2. Research questions and answers in order to communication, derived from the research.

<p>What is the target audience?</p>	<p>Nature lovers, groups that often seek out nature. Reaching individuals with marketing is fine, but also: the wider the participating audience, the better.</p>
-------------------------------------	---

Which content needs to be communicated?	(1) Information about the verges, (2) Brand story, which consists of three parts: status quo, conflict, resolution, (3) Creating content categories (e.g. roadside hero), which has the following benefits: targeted communication and recognizability.
How will the app be launched (via which tools, which media)?	Balance between traditional media and digital marketing (each with advantages and disadvantages), launch event, PR as a cost-efficient tool, App Store Optimization (ASO) and Search Engine Optimization (SEO), Email marketing, Influencer marketing, Boost your app with reviews, measure and adjust goals.
How will further guidance and follow-up occur after the app's launch?	App Store Optimization (ASO) and Search Engine Optimization (SEO) is important to increase the app's visibility on different platforms. Email marketing is recommended for activating existing users and using the network of stakeholders. Influencer marketing with influencers in environmental and nature-related domains can increase brand awareness. The importance of positive reviews and effectively measuring and adjusting goals using collected data is emphasized for long-term success.

5. CONCLUSION

Preparatory steps were taken in the previous studies [1] and [2] to develop an app for the Citizen Science Project. In the business analysis, all kinds of questions are answered about the app and a proof of concept is made that can be tested by the partners of this research. A communication strategy has been developed in parallel. The answers to all these questions form a preparation for the next phase, so that we can immediately proceed to the development of the app needed for the Citizen Science project. Undoubtedly, additional questions will arise and will have to be investigated during the development of the app. Based on the proposed communication strategy, the next step is to proceed with a broad communication of the project.

The Citizen Science project for verge inventory will ultimately not only lead to a uniform verge inventory, but also to more support in relation to the importance of verges, as part of the green-blue veins in urbanized Flanders. In this way, this research contributes to a more resilient Flanders with more resilient cities. The results can also form an important approach for environmental urban planning, which will become increasingly important, given the impending climate effects.

The Masking of Inequities in Naples: Constructing the Invisibility of the Poor since the 19th Century

C. Ignaccolo

Department of Urban Studies and Planning, School of Architecture and Planning
Massachusetts Institute of Technology (MIT), USA

Corresponding author: E-mail: carmeloi@mit.edu, Tel +1 6463398231

Extended abstract

Urban incisions—characterized by wide linear demolitions and boulevard-shaped reconstructions—have profoundly reconfigured the physical and socio-economic landscapes of cities since the 19th century. Comprehending the enduring repercussions of these often-contested interventions poses a challenging task due to the intricate choreography of institutional actors, the scarcity of longitudinal spatial datasets, and methodological shortcomings in planning history.

This paper addresses these challenges by advancing a spatial history investigation of the enduring legacy of the late-19th-century urban incision (*Rettifilo*) bisecting Naples' water-facing neighborhoods. It employs computational humanities and historical GIS techniques to shed light on the design politics of masking the urban poor and on the spatial inheritance of social exclusion in the spaces behind Naples' 2Km-long boulevard. In this paper, I use archival administrative documents, extract urban morphology metrics from historical maps, and mine data from longitudinal socio-economic records.

This research provides empirical evidence of how Naples' urban incision masked and isolated vulnerable communities and neighborhoods with precarious living conditions. It demonstrates that promised gains in public space coverage were never realized, overcrowding persisted in less visible areas, and topography was manipulated to eliminate previously-available ground-level affordable housing. Most importantly, this research exposes enduring inequalities resulting from centuries-old design interventions in contemporary communities, revealing the connection between forms of linear development and socio-economic exclusion.

Extended abstract

The proposed study delves on the challenge of providing affordable housing at the neighborhood or district scale. Affordability is examined as part of a broader mandate for sustainable urban development that examines aspects of reducing housing prices through compactness in design, while at the same time making a case against energy poverty. In this latter aspect of neighborhood design, housing block layout is based on prior work done on optimizing building massing outlay to take advantage of harnessing the potential of solar energy. Insolation is examined in the context of photovoltaic and solar thermal systems that may be located on roofs and building envelopes, as part of integrated design approaches and alongside complementary passive design strategies. The geographic context of this examination is the island of Cyprus and its two major cities on Nicosia, the center of government and Limassol incorporating the main seaport. In the first instance the site for this pilot proposal is an exurban location just beyond the city's western suburbs, whereas in the latter case the site investigated lies on the fringe of the northern outer suburbs. In both instances the land is owned by the Cyprus Land Development Corporation, the republic's main provider of socially minded and driven housing, which has a special interest in solutions that decrease real estate asset prices and increase energy savings with regards to winter heating and summer cooling. The work briefly examines some relevant literature, learns from appropriate precedents, and it references and analyzes comparable case studies. The aim of this approach is to subsequently devise masterplan proposals that adhere to the stated goals and are enabled by standardization of lot sized and built components at the district scale and by the use of an infrastructural kit-of-parts for the accessorization of neighborhood amenities and services. The proposed study concludes with a presentation of masterplans at these two locations and with a brief critical positioning of a procedural roadmap that made use of participatory and co-creative urban design practices.

Keywords: *Socially-minded housing; energy poverty; compact development; passive design; co-design.*

1. INTRODUCTION

The current research project between the Cyprus Land Development Corporation (CLDC) and the Department of Architecture of the University of Cyprus concerns the development of innovative planning for the residential development of the Organization's plots in the areas of Kokkinotrimithia and Polemidia, 274,000 sq.m. and 128,000 sq.m., respectively. The two regions present particularly different geographical, urban planning and topographical data and therefore each region is analyzed separately. Analysis that will form the pillars of study and planning, of interest being the fact that the areas of Kokkinotrimithia and Polemidia negotiate the urban-rural fringe, i.e. an extensive area, involving on the one hand the urban condition, including the nearest urban centers, and on the other hand, the rural areas and the related settlements of the nearest communities. Also, a decisive planning

Proceedings

of the International Conference on **Changing Cities VI:**

Spatial, Design, Landscape, Heritage & Socio-economic Dimensions

Rhodes Island, Greece • June 24-28, 2024

ISSN: 2654-0460

ISBN: 978-618-5765-02-6

factor is the large size of the available lots, as this makes them suitable for integrated and unified planning of self-sufficient settlements with a special identity that will ensure a harmonious and sustainable coexistence with the existing neighboring and future communities. On this basis, a common development vision for both areas is the proposal of a new and sustainable development plan based on international standards of eco-neighborhoods with the main aim of creating a new standard of affordable housing.

1.1 A new Identity for CLDC

The design of eco-neighborhoods is guided by ecologically responsible development principles concerning the design quality of public spaces and the quality of social life. At the same time, it must be shielded from threats (e.g. climate change, difficulties in acquiring housing). Neighborhoods intended primarily for the purpose of affordable housing must be the basis for continued social and economic sustainability, which is achieved by the interconnection of five pillars, taking into account the scale, organizational structure and physical characteristics of the area. The purpose is to create a new approach that connects affordable housing with sustainable development by defining a new identity for the residential projects of the CLDC. The five main design pillars for creating model eco-neighborhood development plans have been defined as follows:

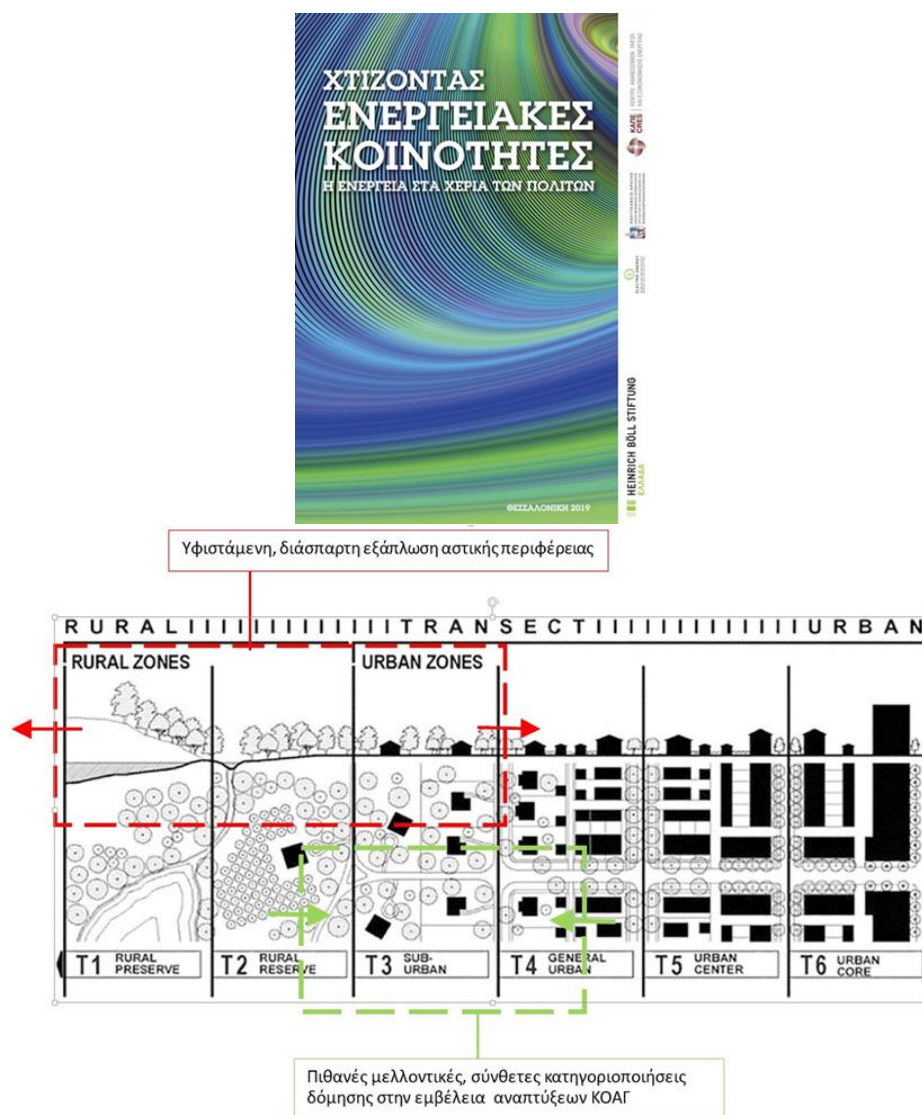

- Urban morphology that includes differentiated building scales and volumes that encourage appropriate density to support relevant infrastructure and services.
- The transition spaces and spaces of multiple activities, multiple surfaces with an emphasis on green infrastructure design.
- Movement within the neighborhood is based on the use of sidewalks, bike paths and shared streets that develop a network of sustainable transport and limit the use of private means of transport.
- The production and use of energy and the management of water are done locally. Also, the design of the buildings is based on the principles of environmental design.
- Social planning aims at the connectivity between open/public and private spaces and the development of social participation.

1.2 Energy Communities

On the basis of the aforementioned planning and development pillars, the opportunity is created for the creation within the development areas of "Energy Communities" (ECOIN Figure 1). These communities are an important tool for the energy transition but also for the more active participation of the local society and the strengthening of the role of consumers through the local production of energy from RES. The opportunity to create Energy Communities is inextricably linked to the principles of sustainable development, it contributes to the implementation of the European energy policy for 2050 and is combined with saving energy costs which significantly helps vulnerable social groups, as "tackling energy poverty within the region, in which the headquarters of an ECON is located, it is, under the legislation, the purpose of establishing an ECON." [8].

1.3 Development in the urban periphery

Following Duany and Talen's (2002) classification of the urban-rural intersection, the range of typologies and spaces in relation to urban planning is categorized into 6 zones that differ according to the level and intensity of the urban character from the urban center to the countryside as shown in Figure 2.

Figures 1 & 2. Strategic manual for the development of energy communities & transect planning classification of the urban-rural intersection

In Cyprus, the current situation, while fluctuating between T1 and T6, presents particularly multiple and frequent changes between the rural landscape (T1) and the suburbs (T3) in an arbitrary and scattered manner. In addition to the well-known negative environmental impacts of this type of scattered building within the natural and rural landscape, communities located far from urban centers usually rely on the private vehicle for their daily needs. For this reason, the new eco-neighborhoods proposed through this study can contribute positively to the more compact development of regional urban areas, reducing the use of private transport within the community, through appropriate building density and at the same time, urban planning and complementary public transport to cover basic uses / needs in the scope of the area under study.

Within urban centers over the past two decades, there has been a significant increase in high-rise buildings, such as student residences and luxury apartments. However, a large proportion of the building stock is in an unfavorable condition within the historic cores. At the same time, outside the urban centers, there is a low density of buildings, due to urban sprawl and the construction of single-family houses in the countryside and peripheral areas. These two observations, scattered development in the urban periphery and the growth of apartment buildings in the urban centers, contributed to the

Proceedings

ISBN: 978-618-5765-02-6

lack of complex housing types and possibly to the lack of housing opportunities for low- and moderate-income groups.

As residential areas continue to expand onto agricultural land, the suburbs of urban centers in Cyprus today and their surrounding communities are today sites of modern commercial activities and other complex land uses in a landscape that combines urban and rural lifestyles. At the same time, many young families are today looking for an alternative solution to the high cost of owning a home close to the urban center or the existing suburbs, with opportunities for services and the comforts of a modern lifestyle close to their place of residence. Thus, the new developments of the CLDC, by creating new composite types of housing, mixed uses and combinations of building densities, can contribute positively to the regional development of these areas. For this reason, the future building developments of the CLDC should manage the relationship of the urban to the suburban, by weighing opportunities versus challenges (Figures 3, 4 & 5).

Figure 3. Diagram indicating suburban typologies on the left versus urban typologies on the right, in Cyprus today

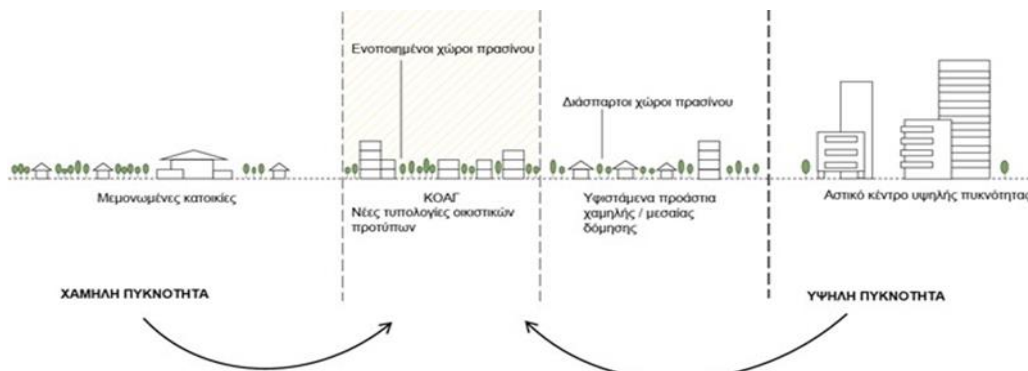

Figure 4. This second diagram indicates the same dichotomy in terms of density considerations

Figure 5. Visualization of proposed neighbourhood unit oriented development

2. METHODOLOGY

The methodology of the present study is based on the opportunity to develop new tools for the production and evaluation of urban planning of settlements with the aim of developing innovative types and alternative organizational configurations of residential development. Through the systematic analysis and codification of design specifications based on known urban design standards, possibilities are combined to encourage sustainable mobility and empower outdoor public spaces, with the aim of reducing the use of private transport as much as possible. Also, the need to approach the topography of each plot, and the need to design infrastructure and land uses with a low environmental footprint and for the environmental management of rainwater and other architectural environment characteristics, are also considered.

Then, the urban morphology is processed using three familiar housing models: maisonette, semi-detached house and the two-three-story apartment building, the evolution of various arrangements developed through the adaptation of the relationship between built and unstructured space. The "typical" building block that often arises in Cyprus is examined, due to the association of access roads to private plots. In transforming the scale of the typical Cypriot building block, examples are presented in a large new building block (or super-block) with an area of one hectare, using all the previous tools. Combinations with a distinct identity at this scale are presented and a first insight into the opportunity to evaluate the wider neighborhood unit is given. The specific identities give rise to a discussion about the evolution of details in relation to the multiple factors that make up the proposed eco-neighborhoods.

Having worked out local characteristics with the organizational and supra-local relations within the wider areas for each case, design intentions at the neighborhood level for the whole block are created, which will be examined in more detail as to the following:

1. The morphology of built-up space and the percentage of coverage
2. Transition areas / common areas
3. Green infrastructure
4. Circulation
5. Energy and environmental planning
6. Building densities (units / hectare)

In the final study, Schematic Local Plans (masterplans) are proposed, encompassing the necessary infrastructures and the complex evaluation criteria that determine them. In this way, the opportunity

is offered to the private sector to find different ways of addressing the building needs through the process of announcing an architectural competition at the level of the scale of the new building blocks. The three main categories of scales that interact in the design of Schematic Local Plans are:

1. Scale (1) the new building blocks that will create a connected network of outdoor transition spaces and emphasize the strengthening of the collective responsibility of residents towards their neighborhood, especially in matters of park maintenance and the operation of other community events such as the organization of small markets, etc.
2. Scale (2) has as its basic framework the unit of the neighborhood, i.e. the entire building block. A sustainable system will be created with various renewable energy solutions and a layout along the main traffic axes.
3. Scale (3), the on-site organizational directions of each area, the indicators from the study of the social profile of the potential beneficiaries and the local urban planning issues in relation to the boundaries of the parcels will be considered.

3. DESIGN – PRODUCTION AND EVALUATION TOOLS

An important part of this study is the creation of a system of coding and categorization of various elements in order to create a clear urban planning tool with specific specifications for good local practices and global design standards translated into the Cypriot context of institutions and practice. As a result, a new organizational structure of roads, streetscape creation scenarios and standard strategies are proposed that aim to optimize the planning of future residential developments of the KOG.

3.1 Planning typologies of roads, connections and transition areas.

High-quality public spaces and various ways of street design are shaped by urban design practices that encourage sustainable mobility. Safety in relation to travel speed, multiple means of transport and the enhancement of sustainable mobility, public and private space relations, shared streets, urban infrastructure and planting spaces act as design parameters. Specifically, the following typologies of roads are "Primary Collectors", "Secondary Collectors" and "Local Public Use Roads" of the Traffic Policy of Local Plans of the Department of Town Planning and Housing, based on the "Guidelines for Functional Hierarchy / Categorization and Basic Desired Urban Functional Characteristics" Road Network - 3rd Amendment". New design guidelines are proposed in this guidance panel and specifically in the 'Local Public Roads' category.

3.2 Building square connections (BSC)

Connecting across building blocks using intermediate shared paths is a flexible tool that provides travel route options, increases ground-level ventilation and permeability, and ensures pedestrian priority. At the same time, it can operate with or without parking spaces, depending on the need for access by motor vehicles or the limitation of presence of connections to building blocks and common use routes.

3.3 Transition areas

In addition to the allocation of open public spaces resulting from the provisions of Local Plans, green infrastructure is used at the boundary of the plot for their utilization by the co-owners, as spaces of transition from private to public space. A sense of ownership by the same users will encourage their maintenance. At the rear boundaries of residential plots, which may border agricultural plots, it is proposed to address the nature of the boundary and the relationship between the two land uses, by considering public connections and private space in the urban environment where there is an agreement between the residents and Local Authorities for the organization and maintenance of these areas.

3.4 Basic typologies

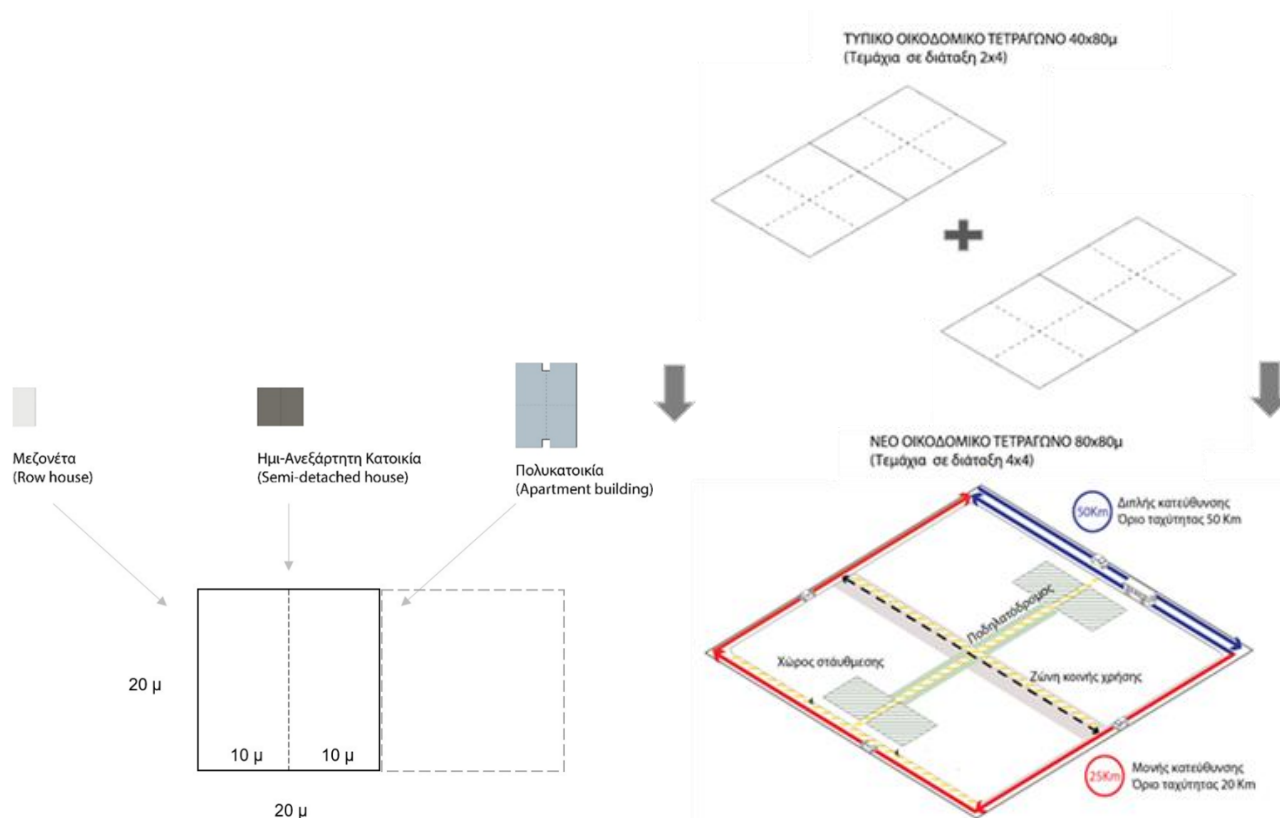

The most common typologies of residential construction are the single-family house, the maisonette, the semi-detached house and the multi-family house (Figure 6). The single-family house is avoided as a design type due to building density and cost reduction. There are many examples worldwide where uniformity is avoided regardless of typology and which are harmonized with local residential and user needs. These three types of residential developments encourage the use of simplified forms and materials, saving construction costs, without compromising the quality of the architectural composition.

Figure 6. Common typologies of residential construction : the single-family house, the maisonette or semi-detached house and the multi-family house

The drawing below leads into the next section of discussion and conclusions, with regards to the character of the residential blocks in the study areas: it shows that the block is in line with the sizes of the existing blocks of the CLDC and smaller than the typical suburban blocks. Therefore, the 400 square meter (20 x 20 meter) block acts as the basic unit and defines the dimensions for a building system based on this size (Figure 7).

Proceedings

Figures 7. 400 square meters (20 x 20 meters) block as the basic residential development unit.
Figure 8. Development diagram of a large building block

Essentially, this is a small block that begins to function as a pattern for the creation of a new type of building block of unified residential development, based on the aforementioned typologies, when two of these “halves” come together. Thus multiplying the pieces and connecting them together, may create initial opportunities for new layouts.

3.5 Superblock design

The typical building block in Cyprus is determined by the dimensions of approximately 40 x 80m. This can be used as an initial guide for the layout of the 3 typologies with initial simple combinations and new organizational structures of the typical building block. The composition of similar types is organized with different relationships and the resulting building densities for each building block in the total number of units (Figure 8).

The diagram shows the transition from the scale of the typical Cypriot building block to the scale of a new, larger building block. The large building blocks discourage the use of cars and allow for more complementary combinations of the three building types and of related open spaces for collective use. These open spaces can be granted both inside and outside the large building block. At the scale of one hectare (100x100m) the different morphologies of the built space and the transition spaces create specific conditions in relation to the building density that varies between 35-40 units/hectare.

For traffic between and around the neighborhood unit, the tools for planning streets, block connections and transition areas are used. Car use is limited and speed within the unit is reduced. Their application is expected to be adapted to the unit scale of the entire neighborhood as the end result of the composition of multiple large blocks.

3.6 Comparison of layout to neighboring built-up areas

For purposes of comparison, the typical system of the neighboring built-up areas within the block of the CLDC has been included indicatively. It would correspond to 7 units per hectare if the plots consisted of detached houses in Kokkinotrimithia and 14 units per hectare in Polemidia (Figure 9).

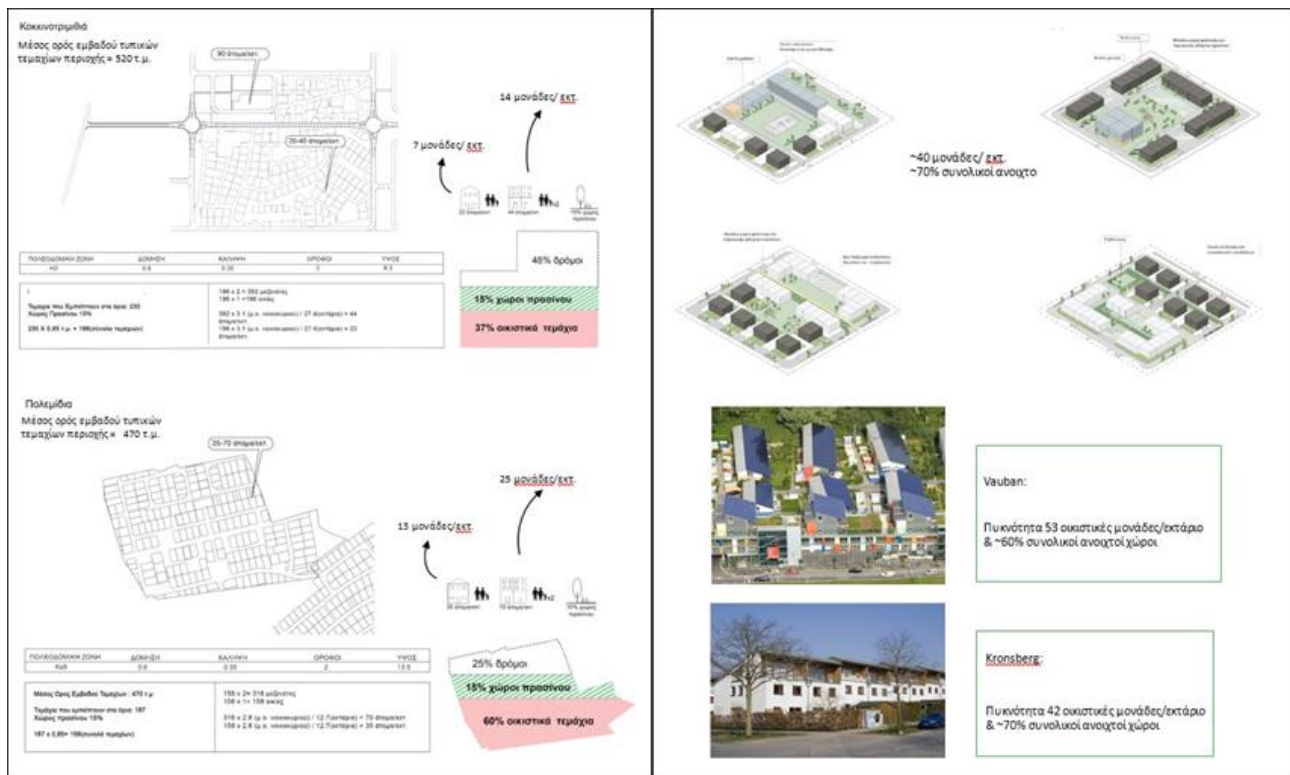

Figure 9. Comparison of layout to neighbouring built-up areas

In contrast, if the existing divisions of typical plots of each area were used, with the new type of a large building block and the use of various and smaller units in various hectare arrangements, these would be consistent with those observed in European neighborhood unit standards. Similarly, total open spaces (green spaces whether public, private or shared) also show higher percentages when compared to known patterns in European neighborhood unit standards.

4. AN EXAMPLE AND AN EPILOGUE IN LIEU OF CONCLUSIONS

In this particular neighborhood unit example, the built space creates a central perimeter typology, consisting of 41 residential units of mixed habitation typology, corresponding to 100-125 people per hectare.

The housing units enclose a central green, collective area with sports facilities and two common transition areas that penetrate the neighborhood unit at its ends, as shown in Figure 10.

Figure 11. Perceiving the proposed superblocks as pieces of a puzzle, where a network of different uses and semi-public spaces is created in resonance with eco-neighbourhood practices.

Extended abstract

The object of this paper focuses on the exploration of cities as carbon sinks, that function more like forests, as self-sufficient hybrid green bio-lungs that produce the resources to thrive and enhance quality of life in densely populated urban centers. Humanity is experiencing a paradigm shift in which the notions of matter, sustainability and quality of life in densely populated urban centers are being redefined. Almost a century since the establishment of Bauhaus in Weimar by prominent architect Walter Gropius, on 8 June 2022 Bauhaus Earth launched, and established at the MAXXI Museum in Rome the New European Bauhaus initiative, named “Toward re-entanglement: a charter for the city and the earth”, while creating a manifesto expressing that our cities can act as carbon sinks and create equitable development opportunities by becoming climate positive, creating new value systems and promoting equitable societies.

After the Charter of Rome launching, the “Reconstructing the Future for People and Planet” conference, hosted by Bauhaus Earth and the Pontifical Academy of Sciences, took place between 9-10 June 2022. The New European Bauhaus vision is looking at a different way to deal with our built environment. Prof. Hans Joachim Schellnhuber, founder of Bauhaus Earth, stated that there are three conditions for achieving climate restoration. The first is the reduction of greenhouse gas emissions by 2050, the second is the better protection of natural ecosystems and the third one is the creation of additional carbon sinks. Following this line of thought, Ursula von der Leyen, initiator of the “European Green Deal”, states that all 27 members agreed on two goals: to be climate neutral by 2050 and to reduce greenhouse gas emissions by at least 55 percent by 2030. The “Reconstructing the Future: Cities as Carbon Sinks” conference papers were published in 2023, while many initiatives have been launched ever since.

To this end, this paper is to highlight the “European Action Plan for the City and the Earth” presented at the Mies van der Rohe Pavilion, in Barcelona, on 4 October 2022, as an initiative of Bauhaus Earth, IAAC - Institute for Advanced Architecture of Catalonia, European Forest Institute (EFI) and Barcelona City Council. Since Barcelona was selected as the European Forest City 2022, the Barcelona Protocol called on European cities to take a lead, while underlining that the future of the earth, its ecosystems and our own civilization will be decided in and by our cities.

1. INTRODUCTION

Proceedings

of the International Conference on **Changing Cities VI:**
Spatial, Design, Landscape, Heritage & Socio-economic Dimensions
Rhodes Island, Greece • June 24-28, 2024
ISSN: 2654-0460
ISBN: 978-618-5765-02-6

The construction sector is responsible for over 35% of the EU's total waste generation and accounts for about 50% of all extracted resources and an estimated 5-12% of total GHG emissions. Forests cover 31 percent of the planet. Approximately half of this forest area is reasonably intact, and more than one third is primary forest. The net loss of forest area has decreased significantly since 1990, but deforestation and forest degradation continue at alarming rates resulting in significant loss of biodiversity. The world is not on track to meet the target of the United Nations Strategic Plan for Forests to increase forest area by 3 percent worldwide by 2030. Urban and built-up areas are equal to 1% of the total land area of the world [1]. The carbon sequestered in a tree has already been absorbed from the atmosphere. The benefit of sustainability and responsible construction is to protect wood so as not to release carbon back into the atmosphere. Storing carbon in buildings may create cities that could act as oxygen capacitors. The more we build with wood, the more carbon is stored to protect our environment and our existence on the planet. The use of mass timber construction has the potential to counterbalance short-term declines in the carbon stock of forests [2]. As they regrow, they will renew their place in the carbon cycle, absorbing carbon dioxide. In general terms, as global temperatures rise, increasing the effects of climate change on forests, the relocation of carbon from the forest to the urban environment may counterbalance these effects, along with those caused by dwindling land-based carbon sinks. The Charter for the City and the Earth, initiated by Bauhaus Earth is committed to a call to action towards the systemic transformation of buildings and cities to rebalance nature's health [3]. To this end, this paper is to highlight the "European Action Plan for the City and the Earth" presented at the Mies van der Rohe Pavilion, in Barcelona, on 4 October 2022 [4].

Since Barcelona was selected as the European Forest City 2022, the Barcelona Protocol called on European cities to take a lead, while underlining that the future of the earth, its ecosystems and our own civilization will be decided in and by our cities.

“The future of the earth, its ecosystems, and our own civilization will be decided in and by our cities. Only if we ensure that the material, means, and methods with which we build and manage our cities are primarily drawn from regionally available and sustainably managed biological resources can we transform our urban settlements from culprits of climate change to catalysts of eco-systemic healing. The vision for a regenerative built environment has been described in the 2022 Charter for the City and the Earth, presented in Rome. Now is the time to put this vision into reality. The Barcelona Protocol calls on European cities to take a lead.”

ACTION FRAMEWORK

3. MASS IS MORE

The “European Action Plan for the City and the Earth” presented at the Mies van der Rohe Pavilion, in Barcelona, on 4 October 2022, as an initiative of Bauhaus Earth, IAAC - Institute for Advanced Architecture of Catalonia, European Forest Institute (EFI) and Barcelona City Council. Mass Is More was a project by the Institute for Advanced Architecture of Catalonia (IAAC) and Bauhaus Earth at the Barcelona Pavilion. The two-week exhibition explored the use of regenerative and carbon-negative architectural materials, exposing the multi-layered processes behind the construction of the built environment. Mass is More radically transformed the Pavilion with large laminated timber structures that represent a material departure from the Modern Movement – mostly concrete and steel – in favour of renewable, carbon storing biomaterials that are sourced regionally and sustainably. The installation is related to the thin planes of Mies van der Rohe's pavilion in Barcelona, using cross-laminated timber.

Figure 2. Architectural Drawings. Image Credits: IAAC & Bauhaus Earth. (<https://www.archdaily.com/990470/mass-is-more-installation-arquitectura-avanzada-de-cataluna-iaac-plus-bauhaus-earth>), Accessed May 2024.

If the 19th century was characterized as the century of steel and the 20th century as the century of concrete, then the 21st century is positioned to become the century of wood. This assertion is not solely based on wood's constructive qualities, but also on its potential positive externalities. Industrialized solid wood possesses the capacity to establish an exemplary model of a circular economic flow. Being of renewable origin, its utilization promotes sustainable forest management. Moreover, it demonstrates the ability to securely sequester CO₂, and its lightweight nature, ease of transport, and insulating properties make it an advantageous structural material. Furthermore, it facilitates rapid construction, offering enhanced control over construction sites, reduced risks, and minimized pollution. The new installation at Barcelona Pavilion, develops a conversation between the cutting-edge materials of the 20th century and those of the 21st century. Featuring a series of components produced from cross-laminated timber panels sourced from local forests, the installation showcases the structural potential of wood and its appropriateness for building more sustainable structures with significantly reduced environmental impact. Alongside the physical installation, the exhibition highlights the narrative of the new materiality through different sections.

3.1 Forest to City Diorama

The exhibit includes a 4.8-meter-long diorama that illustrates the path of wood from the forest to the city, highlighting its properties as a carbon-storing material. This includes the harvesting of trees used to produce the pavilion, followed by extraction, processing, and assembly, and extends to the replanting process that symbolizes the regeneration and sustainable use of the material, presenting the topic with radical transparency.

3.2 Mass Timber Curved out Topography

The pavilion's onyx central wall is reimagined with new textures created from a CLT panel composed of multiple wood species. Replicating the original marble geometry, the panel is digitally milled to create a three-dimensional mass timber topography that reveals its various layers.

3.3 Comparative Analysis of Architectural Elements

The visual installation showing the carbon footprint of different elements found in both pavilions. An interactive digital application provides a comparison of the environmental impacts between the 1929 Barcelona Pavilion and the mass timber installation. To ensure an accurate comparison, only architectural elements such as the roof, walls, columns, and floor were taken into account. The comparative analysis includes the embodied carbon emissions in each element, as well as the energy consumed, kilometers travelled, and steps taken during the extraction, manufacturing, transportation, and assembly processes. This digital feature is accompanied by analogue tags on various vertical elements of both pavilions, listing all materials used in their construction. Moreover, visitors can watch a video installation by filmmaker Jaume Cebolla within the pavilion, which depicts the transformations of the wood harvested for the mass timber structure from a first-person perspective.

3.4 Mass Timber Pavilion

The design of the installation reflects the original pavilion's formal grid, creating an alternative narrative and offering a new way to experience the site with new pathways and view corridors.

Proceedings

of the International Conference on **Changing Cities VI:**
Spatial, Design, Landscape, Heritage & Socio-economic Dimensions
Rhodes Island, Greece • June 24-28, 2024
ISSN: 2654-0460
ISBN: 978-618-5765-02-6

Throughout the tour, visitors will see different uses and representations of wood and modern building technology. The entrance to the space reverses the traditional circulation, allowing visitors to first pass through the trees in the garden behind the pavilion. An elevated walkway leads to a cantilevered platform that provides unprecedented views of the Barcelona Pavilion. This platform also grants access to an auditorium. This transition is related to link the processes from forest to mass timber bridge, showing the gradient from raw to processed material transformation.

Figure 4. Fabrication Grid & Tectonic Language. Image Credits: IAAC & Bauhaus Earth. (<https://www.archdaily.com/990470/mass-is-more-installation-arquitectura-avanzada-de-cataluna-iaac-plus-bauhaus-earth>), Accessed May 2024.

3.5 Floating CLT Blank

A 12 x 2.5 meter industrialized wood panel has been installed in the pavilion's pond, illustrating the 19th-century process of transporting materials directly from the forest to the factory via the river. This line of thought, exhibiting the new "brick" of construction.

4. CONCLUSION

Cities play a pivotal role as hubs for absorbing CO₂ emissions. The majority of emissions stemming from buildings occur during the construction phase, encompassing material sourcing, rather than from their operational emissions. [5] In this context, the sustainable management of productive forests emerges as an optimal natural solution for mitigating carbon dioxide (CO₂) emissions. Furthermore, numerous productive forests are not optimally managed for carbon sequestration due to factors such as intensive logging practices and abbreviated harvesting rotations. However, the advocacy for wood as a primary building material could catalyze heightened demand for certified wood products, thereby incentivizing the adoption of more sustainable forest management strategies. The transition towards integrating wood into urban environments necessitates the implementation of incentives to overcome prevailing barriers. These barriers encompass sectoral uncertainties, a scarcity of companies and experts specializing in industrialized solid wood, inadequate incentives and regulatory frameworks supporting wood-based construction, and a general lack of awareness regarding the environmental benefits of wood. New initiatives should be born with the intention of overcoming these challenges and barriers, with the aim of communicating, coordinating and connecting agents in the use of these construction systems, accelerating their growth.

Extended abstract

Construction is arguably the most important pillar of our financial system and architecture is undoubtedly a very important part of this. The building industry, that architects operate, is one of the major contributors to climate change. 36% of CO₂ emissions is generated in the process of construction alone, but even though it negatively affects the quality of life for everyone, is not an expense that is paid accordingly by the responsible individuals. At a time of energy transition, how contemporary architectural design can contribute to climate goals and improve the quality of life for all citizens?

Recognizing the worldwide urge for a transition towards greener, sustainable, beautiful and inclusive cities and rural areas with prosperous citizens, as it was validated by United Nations Agenda 2030 for Sustainable Development and the New European Bauhaus (NEB), this paper attempts to investigate the value of contemporary architecture mapping its externalities to the environment, and consequently to wellbeing. Architecture plays a crucial role in the NEB initiative, driving the transformation of the built environment and promoting sustainable living, aesthetics and inclusion for the benefit of everyone. Knowing that the value of contemporary architecture is often underestimated, this paper aims to illustrate the cultural value in conjunction with economic value of architecture, contributing in understanding the overall impact of contemporary architecture to the environment and to shed light on good practices. The cultural value derives from the fact that architecture as public good produces externalities and “in the economics of heritage, has been represented as a multifaceted and shifting concept that has no single unit account” (Mazzanti 2003, Choi 2010). The economic value is defined using methods of economic analysis and can be expressed in monetary terms. Given that the resources are finite and their management is always an issue, it is important to assess both market and nonmarket values of architecture and to shift the focus from a strictly economic-centered towards a more people-centered, long-term evaluation in architecture management and policy making. After all, nonmarket effects or externalities of contemporary architecture have significant impact on the natural and built environment and its residents, extending to present and future generations, that can even exceed the hard economic effect and therefore should be explored and taken into account during decision making.

Extended abstract

The intertwining relationship between space, sports, and urban culture along the Eastern Adriatic coast, particularly in Split post–World War II, exemplifies how geopolitical, social, and physical landscapes can shape and are shaped by athletic and urban cultural practices. In the aftermath of WWII, Yugoslavia embarked on a project of socialist modernization that significantly impacted urban development and sports across the country, including its coastal regions.

As the host city of the Mediterranean Games in 1979, Split became a central hub for this transformation. The period preceding the Games witnessed a surge in the construction of sports facilities, public parks, and recreational areas, seamlessly integrating sports into the fabric of everyday life and urban culture.

The complexity of the planning, organization, and managing of the Games extended beyond mere physical infrastructure; it underscored the significance of mobile and the intangible infrastructures crucial to orchestrating a multinational athletic contest and its associated spaces. Apart from the organizational bodies, other labor mobilities were involved; volunteers of socialist youth organizations, high-skilled sports workers, and enthusiasts played a pivotal role in the event's 'construction' process and execution, reflecting a broader ambition to promote a collective identity and a lifestyle that values physical fitness, leisure, and sports as essential components of citizenship. Moreover, the Games also highlighted the role of sports in diplomacy and international relations during the Cold War era, reaffirming Yugoslavia's position amidst the iron curtain, an unaligned, progressive identity open to visitors from all sides.

Within the Yugoslav socialist system and less than three years, the infrastructural renaissance of Split was successfully realized, as a long-term result of rational and efficient planning of all the elements of the Games, therefore outliving its dominant political dimension and specific historical circumstances.

Today, the enduring legacy of this period remains palpable, as the relationship between space, sports, and urban culture amalgamated heritage, socialist modernization, and the Adriatic landscape. Revisiting such case-studies serves as a broader lesson on the role of health and hygiene in articulating the modernist goals of the 20th century, but also prompts a revisiting of the contemporary goals of the New European Bauhaus and the hidden infrastructures making their realization possible. Drawing parallels between state-led initiatives enabling systemic interventions in recreation, green spaces, citizen inclusion and high-quality architecture is more than timely.

The urban condition and the challenges of the 21st century: understanding threats and principles of intervention through water

T. Calix

Center for Studies in Architecture and Urbanism, Faculty of Architecture, University of Porto, Portugal,

*Corresponding author: E-mail: teresa.calix@arq.up.pt, Tel +351 963 391 321

Extended abstract

This paper intends to present the syllabus of the course Urbanística 2 of the Integrated Master in Architecture of the Faculty of Architecture of the University of Porto. Urbanística 2 is a theoretical subject that reflects on the urban condition and the challenges of the 21st century.

The recent development of the contents of this course has made it possible to adjust it to the principles defended within the framework of the initiative 'NEB goes South': a platform founded by six architecture schools at universities in six different countries, which recognise the shared geographical and cultural legacy of the countries of southern Europe. 'NEB goes South' considers education as its primary goal, taking into account the decisive role of higher education and research institutions in promoting inclusive participation to present solutions, organising and disseminating the results.

The perspectives addressed in Urbanística 2, and the content covered in the course are based on the principle that defends that implementing shared values of sustainability and inclusion as established by the New European Bauhaus cannot only be understood as an environmental or economic project, it must also be understood as a new cultural 'project' in which the whole of society is involved and where educational institutions play a decisive role. Creative solutions are crucial to improving urban areas, changing mentalities and raising awareness of the essential issues of our time.

Water is the topic that mobilises discussion and makes students aware of the complexity of perspectives and the diversity of issues that converge in cities. Water is emphasised as a central element in the past history of urban agglomerations and, above all, as a determining factor for the qualified future of their existence: the risks of its absence or excess are presented and discussed using concrete examples that describe the effects of the current climate changes framework.

The natural water network and the artificial supply system, water-related artefacts, and permeable and impermeable areas, among others, give visibility to traditionally imperceptible topics. To future architects, it must be clear that architectural or urban projects that respond to the population's discerning questions must acquire new levels of depth and integrate new demands that address the effects of climate change.

By crossing disciplinary boundaries, water reveals the importance of a multidisciplinary approach. It demonstrates new possibilities of intervention and the correlated role of different disciplines that emerge within the threatening reality of contemporary urban realities.

This paper presents the sequence of issues addressed, the exercise proposed for the students' assessment and the results obtained in the scope of the course in the last three years.

Designing communities with the “New European Bauhaus”- The architecture of coming together

C. Tremetousiotis

Student of Architecture, National University of Athens, Greece

Corresponding author: E-mail: charistrem@me.com Tel +30 6934271292

Extended abstract

The work entitled “Eating Together as Architectural Program” began during the pandemic, when people were staying at home and social life was abruptly disrupted. A return to natural landscapes re-establishes the communities in their primal form by creating spaces of coexistence and exchange around a table. This archaic form of sharing was situated in selected natural settings with the aim to bring forth cultural context and natural beauty. Not long after the New European Bauhaus was launched, small groups of people started to gather together and explore the power of ritual and place. “Eating Together” is a project based on the New European values “Beautiful, Together, Sustainable”. The presentation features a number of such case studies, which lead to a normative expression of design principles and cultural underpinnings gathered in a toolbox. By investigating the hidden potential of landscape, eating tables become the module to structure the open space and design ritual and co-existence.

“Beautiful, Together, Sustainable” lead to a set of anthropological design tools which are next applied within the urban tissue of downtown Athens, opening new and unexpected possibilities of city life.

This project explores how an architectural program can be obtained originating from the study of activated landscapes, both natural and urban. The gatherings that served as case studies for the project were specifically linked to their locations under a singular thematic. Both natural and man-made landscapes were chosen for this study to look into the ways they interact with it. This study concludes by presenting a generalized theory around architectural design and its principles.

“Beautiful, Together, Sustainable” points to the reinvention of cityscapes in the ways already explored through the first leg of the project: the values governing gatherings around the table now provide complex analogies and activate the potential of cities. New spaces, uses and programs emerge from the experience beyond the built and is transliterated in sustainable, simple urban enclosures for newly established communities. Building concepts are conceived from unconventional frameworks and architectural programs are informed by the rich experiences cultivated through coming together. This approach creates new architecture that not only redefines the urban landscape, but also enhances the quality of life for European citizens and communities.

Delving deeper into the design ethos we challenge conventional paradigms with which new possibilities allow to sculpture the Athens of tomorrow. The project adopts a holistic view to not only redefine the physical aesthetics of urban space but to also cultivate vibrant communities and sustainable eco systems opening the way for a more resilient future.

Abstract

Tourism sector gradually recovers from the severe environmental and socio-economic impacts of the Covid-19 pandemic while there is currently attempts to handle the consequences of the war in Ukraine and the Gaza Strip, the Middle East. The World Tourism Organization (UNWTO) by means of the Glasgow declaration 'Climate Action in the Tourism Sector' signed by its members in 2021, encourages faster actions to protect tourism destinations and businesses threatened by the climate crisis. The signatories committed to apply the terms of the Agreement on 5 main axes: Measure, Decarbonize, Regenerate, Collaborate and Finance. Tourism development is extremely fragile while the global community facing the risk of the climate crisis, enhances the aim of resilience so as to reinforce socio-economic development and cohesion. This paper aims to point the necessity to understand and clarify the importance of socio-cultural values in the tourism sector. In cases these values are not apparent, a strategic plan of actions and objectives will provide a sustainability in each regional unit of study in order to reinforce local identity and tourism development. Such actions relate to the environmental transformations which do not exclusively involve to common green spaces but also the materials and intangible values of the area. In addition to this, all actions have to deal with the economic impact of tourist activities; sustainable tourism has also limits, as for example, from the growing differentiation within communities, from social conflicts, from problems deriving from the decision-making process adopted, from the lack of technical knowledge and training, from changes in the social structure. Community-based tourism is part of the practical dynamics of the supply and demand of the market; and its development is grounded on synergies among the local stakeholders with touristic interest, and tourism experts having the knowledge to strengthen and highlight the environmental and socio-economic background of the areas. Keywords: sustainable tourism, tourism resilience, landscape transformations, cultural management, The Glasgow Declaration.

Keywords: sustainable tourism, tourism resilience, tourism, landscape transformations, cultural management.

1.Introduction

As the Tourism sector gradually recovers from the severe environmental and socio-economic impacts of the Covid-19 pandemic, it is called upon to face the corresponding consequences of a war situation between Russia and Ukraine as well as that in the Middle East in the Gaza Strip.

The World Tourism Organization (UNWTO) with the Glasgow declaration 'Climate Action in the Tourism Sector' signed by its members in the year 2021, encourages faster actions to protect tourism destinations and businesses threatened by new facts of the climate crisis. The signatories committed to base this agreement on 5 main axes: Measure, Decarbonize, Regenerate, Collaborate and Finance. Tourism development is an extremely fragile case for the global community which, faced with the risk of the climate crisis, must acquire a character of resilience in order to obtain a stable Socio-economic development.

2.The strong upheavals in World Tourism from 1990 to 2024.

The concept of tourism includes a multidimensional interpretation and synthesis which has a supralocal and multinational character. With globalization policies affecting the societies and

Proceedings

economies of the planet, their influence on tourism was inevitable and experienced a great flourishing which reshaped the daily human life. The world tourism organization(UNWTO) had already predicted this development in its researches from the year 2013(Figure 1.1). International tourist arrivals have risen from 278 million in 1980 to 1035 million in 2012 and was expected to grow by 3.3% a year on average from 2013 to 2020. The multifaceted conditions created during the pandemic period in the first half of the year 2020 were unexpected and unfavorable for international transport and for entrepreneurship based on tourism. Both the health crises and the economic crisis since 1990, had affected the tourist arrivals map whose data is reflected in the Figure 1.2. of statistical forecasts as issued by the UNWTO on 2023 report. In the light of these dynamic developments, the expansion of the tourism business worldwide has taken on different aspects. For example, the creation of professional relationships between hotel units, tourist agents and other investment fuds, in recent years has become more powerful, trying to give tourism entrepreneurship a global character. Among the reasons that have pushed towards the internationalization of tourism businesses are some that are common to all tourism sectors, including, in particular, the internationalization of demand. This new trend arises as a result of increasing disposable wealth and a redefinition of the value placed on leisure time for vacations.

At the same time, additional factors of influence have been the increasing mobility of international labor and an aspect that is no longer secondary, the greater mobility of social and migratory flows.

3. The Glasgow Declaration: an importance of Environmental Sustainability in Tourism

The Conference of the United Nations on Climate Change was held in Glasgow in November 2021, where the world's leaders gathered to discuss the interventions to be made to face the phenomenon of climate crisis. It is on the occasion of this event that an important document is drawn up, destined to become another milestone in the fight against climate change and in the definition of tourism sector strategies: the declaration of Glasgow. This statement contains in itself the need and urgency to accelerate climate action on the part of the tourism sector, in order to cut the amount of greenhouse gas emissions in the next decade and to reach the so-called Net Zero Emissions by 2050. A first point to reflect on is precisely the way in which the travel experience proposed to the visitor is created: if priority were given to the well-being of the community and ecosystems rather than preferring activities with a high environmental impact, tourism could be considered an excellent example to hope for a more eco-sustainable future. The Glasgow Declaration on climate action aims to bring together and create a common path between various governments and all institutional bodies, financial institutions, international organizations, civil society, private sector and education.

The signatories of the Declaration, in order to ensure a concrete commitment, operate following five different directions:

- **measure:** make the data, methodologies adopted and tools relating to travel and tourism available and accessible to the entire tourism sector, ensuring that they are in line with the United Nations Framework Convention on Climate Change.
- **decarbonise:** set and meet targets aligned with global carbon reduction objectives in the tourism sector, this would include transport, infrastructure, related activities, accommodation, food and drink and waste management.
- **regenerate:** restore and protect ecosystems, promoting nature's ability to naturally absorb carbon dioxide, safeguard biodiversity, food security and water supply; ensure that tourism helps and supports the areas most in difficulty; promote a better relationship between visitors/local community and nature.
- **collaborate:** share information on risks and solutions to various problems with all stakeholders. Strengthen governance and capacity for action at all levels.

- **finance:** ensure that resources are sufficient to achieve the objectives set out in climate plans, including funding for training, research and implementation of appropriate fiscal and policy tools.

4.The Environmental role of Sustainability in Tourism

The concept of sustainable tourism therefore, as it has been structured, envisages on the one hand the reduction of tensions and frictions that are created by the complex of interrelationships between the tourism industry, tourists, the environment and the host communities. In addition to this, the construction of a process in which human resources, together with natural ones, are able to persist over time without sacrificing quality and are able to respond to an ever-increasing demand, due to the spread of tourism even in those Countries experiencing strong expansion and once considered not touristically relevant. The concept of "sustainable development" associated with tourism has now become a globally accepted term, very widespread in common language, in the political panorama and among professionals in the hospitality sector, especially for promotional purposes; however, several authors identify limits to this concept.

The debate on the negative externalities produced by mass tourism historically focused on problems related to social and economic aspects. In the end of the 1980s' and beginning of the 1990s', the discussion was focused on problems relating to environmental aspects and also begin to be taken into consideration, like protection of natural resources and sites of historical and cultural interest. The distorted development model focused on objectives based exclusively on concepts such as progress, growth and modernization that appeared successful in those years, where well-being and quality of life were associated exclusively with economic rules, considered the natural environment exclusively as a source of production and improvement without taking into account the limitations of resources and the deterioration of the natural environment.

Already in 2012, the European Union issued a guide with the cooperation of the European Commission's Directorate-General for Development and Cooperation - EuropeAid in order to promote the values and perspectives of Sustainable tourism with the project entitled: " Enhancing capacities for sustainable tourism for development in developing countries". The World Tourism Organization (UNWTO) emphasizes the need to maximize tourism's contribution to development and international perception, while minimizing its negative impacts, paying particular attention to the development potential of developing countries. The Figure 2.1 depicts the methodology which is useful as a tool in order to constitute a system for assessing the state of the areas of interest but also a system for identifying weaknesses and gaps and examining possible actions.

5. Cultural and Social elements as tool for Tourism Sustainability

The cultural and social impacts of tourism are visible through the various modifications that underline the representations, material and immaterial, of the local culture. Researchers focus on three main cultural forms that attract visitors when they visit a destination: the forms of inanimate elements, therefore places with unique architectural or artistic characteristics, historic buildings, monuments, secondly another socio-cultural forms as attractions, it is considered the reflections in the normal daily life of a community. The visit mostly has the aim of observing local social, economic and leisure activities, in an attempt to understand their lifestyles, ideologies and customs. The third form are considered all animated elements like music festivals, carnivals, battle re-enactments, displays of old contraptions. Anthropologists have studied the acculturation process for decades and have understood that the intercultural meeting of two social groups of different origins is never one-way, but turns out to be a two-track exchange.

From another point of view, the relationship between tourism and social and cultural impacts proposed by Richards, supports that the distinction between cultural tourism and other forms of tourism is essentially that of being centered on the educational function. Cultural tourists can learn about a destination's culture and gain new experiences related to that culture in a variety of ways, depending on the forms of culture they consume. On the other hand, Littrell writes that culture can be defined as a set of attitudes, beliefs, ideas and values, models of normative behavior, or lifestyle and by people's artifacts such as works of art and cultural products. From this point of view, therefore, cultural tourism does not only concern the visit of places and monuments, but more than anything else it could be understood as the experience that the visitor has by coming into contact with the culture of the place, or with the attitudes, beliefs, ideas and values, patterns of normative behavior, or lifestyle, and from people's artifacts such as works of art and cultural products. These activities involve gathering new knowledge and experiences. Cultural tourism therefore includes not only the consumption of cultural products of the past, but also of contemporary culture or the 'lifestyle' of a group of people or region.

Various dimensions of culture are used in the context of tourism, although each has its own position independent of its mobilization for economic purposes. Therefore the key concepts that emerge in the context of cultural tourism are: cultural heritage, cultural diversity and cultural creativity. However, as regards a greater interest in consumption, it should be noted that the growing presence at cultural attractions does not in itself constitute proof that people are increasingly interested in culture. In fact this could be due to the fact that there are more people traveling or hiking and this phenomenon could lead to a greater number of people visiting cultural attractions simply because there are more visitors present in a particular location. Furthermore, various studies have underlined how there are various levels of consumer motivation towards culture which can be schematized as a concentric circle where at the center there is a category of people whose cultural motivation is very strong, at the opposite extreme a category which has no cultural reasons for visiting, while in the center we can highlight a very high percentage of people motivated in part by culture or for whom the cultural aspect is an addition to the motivation for the trip. However, a phenomenon of recent decades is the exponential growth of cultural offerings and tourist attractions.

6. Conclusion

This article aims to emphasize the necessity to obtain a perception at the level of national of a regional entity but also at the level of visitors and hosts in order to clarify the importance of socio-cultural values in the tourism sector. In cases where these values are not clearly discernible, it is time to take a plan of actions with decisions that will grant a durable character to each regional unit of study in order to be integrated with its tourism identity. Such actions are the environmental transformations which do not focus exclusively on the formations of green but also on the formations of materials and intangible values of the area. In addition to this for all the actions that have to deal

Proceedings

with the economic impact of tourist activities, it must be clear that the form of sustainable tourism also has dictated limits, for example, from the growing differentiation within communities, from social conflicts, from problems deriving from the decision-making process adopted, from the lack of technical knowledge and training or from changes that have occurred to the social structure. Although it is difficult to recognize it, especially in light of its characteristics, community-based tourism is part of the practical dynamics of the supply and demand of the market. The importance of perception necessarily develops with synergies both of the local users of a destination with potential touristic interest and with scientific groups of different scientific fields who are capable, through scientific knowledge, to strengthen and highlight the environmental and socio-economic background of the areas.

Tourism Sustainability and Cultural Resilience on Mykonos Island: Rethinking the dynamics and the adaptation of a creative conceptual model for the resilience-sustainability network in tourism

Dr E. Linaki

Urban and Regional Planner, Postdoc Researcher, School of Architecture,
National Technical University of Athens, Greece

Corresponding author: E-mail: eleni.linaki@gmail.com, Tel +30 6946013268

Extended abstract

The initial idea of this paper starts from the concept of connecting cultural resilience with sustainable tourism on Mykonos Island. The notion of resilience is attracting increasing awareness in many academic disciplines and sectors. Resilience, in sustainability terms, has recently become a notable aspect in tourism literature as a term that encompasses sustainability, while acknowledging multiple contexts such as touristic capacity, vulnerability, decolonization, post-development and detouristification. The global effects of climate change such as rising temperatures, rising sea levels and extreme weather events, combined with the ever-increasing tourist numbers, especially in Greek islands such as Mykonos, have a major impact on cities and urban life, but also in historic places and monuments, due to their basic construction materials and their different urban planning. Based on the above, the proposal concerns the connection of resilience, as a new parameter of the evaluation of the tourism sustainability of cities, through the creation of a conceptual model for assessing the impact of resilience in places. The main goal is to introduce, through bibliographic research, related projects and papers which reflect or discuss the role of tourism sustainability in resilience worldwide and propose a new model or potential activities as part of the change, thus an efficient complementary tool that supports tourism through the concepts of sustainability and resilience on Mykonos Island.

Towards a Design Framework for Slow Travel: Investigating Human Environmental Perception during Cycling

D. Riga

PhD Candidate in Urban Planning, Design and Policy, Department of Architecture and Urban Studies,
Politecnico di Milano, Italy

Corresponding author: E-mail: dafnitheodosia.riga@polimi.it

Abstract

Slow tourism as an alternative form of tourism has gathering momentum in academic research in recent years, especially since discussions on environmental sustainability and human well-being intensified due to the COVID-19 pandemic. As part of a slow tourism experience, slow travel mobilities are commonly carried out through active modes of movement, such as walking and cycling. Slow and active mobility for commuting purposes in urban settings has been extensively analysed by scholars, yet little research exists on its experiential and affective dimensions for leisure and tourism purposes in non-urban contexts. With the aim to lay the foundations for a comprehensive framework that explores human environmental perception and related affective experiences during slow travel, this paper presents an ongoing study that investigates the case of cycling in non-urban contexts. Using the method of intercept survey, the study adopts a person-centred approach that values the diversity and subjectivity of human environmental perception, thus yielding findings of qualitative and empirical nature. A preliminary analysis of the findings illustrates the differences in environmental perception and affective experience according to the various speeds and purposes of cycling. By unveiling the salient environmental features that influence a cycling experience for tourism and leisure purposes, the ultimate goal of this research is to contribute to design guidelines for cycling routes and slow travel infrastructures.

Keywords: *slow travel; environmental perception; cycling; landscape; person-environment relationship*

1. INTRODUCTION

Over the past two decades, a shift in forms of tourism has been pointed out in academic research and beyond, as a result of diverse factors affecting tourist decisions: the widespread economic crisis in Europe and elsewhere as a trigger for more modest choices [1]; the inherent unsustainability of mass tourism and its negative impact on landscape, communities and tourists themselves [2]; which leads to a search for authenticity and sense of place [3]. Alternative tourism practices are advancing, as discussions on climate change, environmental sustainability and human well-being have particularly intensified due to the COVID-19 pandemic [4]. Within this context, *slow tourism* is regarded as a sustainable form of tourism that encapsulates a range of spatio-temporal practices, immersive modes of travel and ethical relations that stem from the tourist's will to connect with and experience territories and places [5]. While slow tourism broadly encompasses practices of both movement and immobility, tourist mobilities between destinations are described by the term *slow travel* and are carried out through active modes of movement. Despite the emphasis that scholars ascribe on the *experiential* dimension of slow travel, as well as its potential in fostering an interaction between tourist and landscape, little research exists on how such an experience is articulated and on its practical implications for the design of slow travel infrastructures. This paper is based on the hypothesis that slower speeds and active modes of movement enrich human environmental perception and generate affective responses, which impel individuals to experience and engage with the surrounding landscape. By exploring the person-environment interaction within the context of slow

travel mobility, the purpose of this paper is to invite planners, designers and policy makers into the discussion for establishing a design framework for slow travel infrastructure that is measured around human spatial experience while on the move.

2. THEORETICAL FRAMEWORK

2.1 Slow travel

In order to define what is *slow*, it is crucial to refer to what is *fast* and to the effects of speed in everyday life, from mobility to tourism and from the human body to whole territories. As Tomlinson argues, “first of all, speed is fast” [6: 2]. Scholars have long argued that the high speeds of human mobility have eradicated the sense of distance and annihilated space and time: modern travellers battle against timetables, transit time, traffic and delays, but not against the obstacle of space [7, 8]. The operating speed of modern tourism alienates humans from landscape, transforming them into mere consumers of destinations [9] who experience “fewer and shallower interactions with the social and spatial environment” [10: 10]. The process of the journey is eclipsed by a redundancy of departures and an anticipation of arrivals [6], as if “to get there fast is better than to travel slow” [11].

Within the concept of slow philosophy [12], slow tourism emerges as an opposition to mass tourism and as a by-product of a life outlook valuing *slowness*. Although no clear definition of slow tourism exists, Pileri and Moscarelli [9] have attempted to describe its key characteristics along three main dimensions (additional references provided by the author):

1. Environmental dimension: As concerns for the environmental impact of air and car travel increase, slow tourism advocates for decarbonising practices through sustainable mobility and active travel modes [13-15].
2. Ethical dimension: Slow tourism aims to tackle the consequences of mass tourism and territorial marginality, by establishing socio-economic regeneration strategies and seeking to raise awareness on the impact of tourists within a place [13-17].
3. Experiential dimension: Experiential stimuli perceived through slow experience shape the relationship between an individual and their surroundings. In this context, slow tourism practices encourage active engagement with place and landscape [13, 15, 18].

The three dimensions under which slow tourism can be defined refer to both practices of travel (movement) and stay in a destination (immobility). As scholars highlight, travel mode and overall travel experience within a slow tourism framework are pivotal to the discussion [13, 19], and are more narrowly defined under the term *slow travel*. Leed [20] considers travel as a *process of passage*, that is a continuous change of place that differs qualitatively from departures and arrivals, since it entails movement. In other words, (slow) travel does not constitute a merely interstitial experience of seamless movement from A to B, but rather an experience with its own structure, logic and consequences [20, 21]. Adopting a critical stance towards the fact that slow tourism and slow travel are often used as synonyms [5, 9], we henceforth purposefully situate the research presented in this paper within the slow travel framework, by studying experiences of movement during the stage of passage.

2.2 Cycling, environmental perception and affective experience

Travel mobilities are an integral part of the tourist experience: what humans travel for is not necessarily the destination, but the experience of being on the road and in the world in a particular way. Slow travel mobilities are practiced through active modes of movement where the body itself generates motion, as in walking and cycling [22] and entail multiple benefits [23]: with regard to the environment, they contribute to reducing carbon emissions; on a human scale, the physical activity enhances individuals' health and well-being, and allows for a rich sensory experience and immersion within a landscape.

Active movement at speeds below 20 km/h is a form of multisensory perception of the environment, that involves an overlapping of visual, auditory, olfactory, tactile and kinaesthetic stimuli [9, 24-26]. The movement generated by a body in motion is a continuous encounter with the environment and a negotiation of the body's relationship with space [27]. This person-environment interaction is mediated simultaneously by environmental properties and by the person's perception, affective responses, purposes, preferences and culture [23]. Affective responses [23, 28] take place when an individual "evaluates an environment and attributes to it an emotional – and therefore subjective - quality, such as being pleasant, interesting, exciting, stressful, and so on" [23: 4]. Under the lens of slow and active mobility, cycling practices form an experience of affective nature, which strongly depends on the individual's sensory perception on one hand, and on the elements that constitute the physical environment on the other [23, 24, 29-32]. During cycling, an individual perceives different physical features and urban design qualities, which in turn trigger different affective responses towards the surroundings [23, 27].

To date, while research on slow travel has explored travel mobilities under an ethical lens with studies on individuals' motivations, goals and mode choice [33, 34], the experiential features of slow travel remain quite under-researched [35]. Slow and active mobility for commuting purposes in urban settings has been extensively analysed by scholars, yet little research exists, to the author's best knowledge, on its experiential and affective dimensions for leisure and tourism purposes in non-urban contexts. As Larsen argues, "unlike coercive everyday mobility, [travel mobility] is not only a trivial question of overcoming distance and reaching, it is also a way of being in, and experiencing various landscapes" [35: 81]. To better comprehend travel experiences, there is a need to assess individuals' subjective affective reactions in motion, with relation to the objective physical characteristics of the environment [27]. So far, there has been a lack of empirical evidence on individuals' environmental perception and affective experience during slow travel (for a few exceptions see: 27, 36, 37).

This paper aims to provide qualitative evidence on the environmental perception and affective experience of individuals during cycling for leisure in the North Italian non-urban landscape. Drawing from the hypothesis that different forms, purposes and speeds of movement give rise to different affective responses [27], we will examine the particularities of environmental and sensory perception (visual, auditory, olfactory and kinaesthetic) of cyclists and explore affective responses generated by physical features of the environment. Such an attempt calls for an interdisciplinary approach [38]: combining inputs from environmental psychology and urban design, we will address the multitude of factors at play in the person-environment relationship during slow travel.

3. METHODOLOGY

The study presented in this paper is part of an ongoing PhD research project that discusses the influence of different speeds and modes of movement on individuals' environmental perception and experience while being on the move. By collecting empirical information and comparing findings for three modes of movement (walking, cycling, driving) when used for leisure or tourism purposes in non-urban contexts, the research project aims to identify the physical features of the environment perceived by individuals at different speeds, as well as the respective affective responses they generate. For the purposes of the project, the author has conducted several studies that examine the spatial and affective experience of walkers, cyclists and car-drivers in peri-urban and rural areas in Northern Italy. Although the project is of comparative nature, a separate preliminary examination of the findings may provide insightful evidence to inform existing literature for each mode of movement. Aiming to contribute to a deeper understanding of human environmental perception during cycling for leisure and tourism, the focus is on the spatial experience of cyclists.

The person-environment relationship evidently involves two main variables: humans and space. Given that both participants and the environmental setting under investigation matter equally, specific locations were chosen, where the method of *intercept survey* was implemented to investigate

participants' perception of the surrounding landscape during a cycling activity. Cyclists passing from the chosen locations were randomly stopped by the author, who briefly introduced the subject and method of the survey and requested their participation. Participants were invited to complete a questionnaire composed of closed and open-ended questions, addressing their purpose and duration of cycling activity, familiarity with the surroundings, perception of speed during movement, environmental features perceived along the route, and demographic data. The questionnaire was administered *verbally* so as to enhance flexibility in participants' responses while maintaining a pre-defined structure. In several cases, participants were eager to provide additional personal observations in-between questions, thus rendering the data collection process similar to a semi-structured interview. The immediacy of this method reduces the risk of bias in participants' responses (as opposed to methods of prior recruiting, focus groups, or post-activity questionnaires), since participants are given the chance to voice their own experiences *in situ* [39]. The fact that participants were interviewed *while being on the move* allowed for documenting their experience in the most direct and unmediated way possible, considering that "all perceptions and interactions are influenced by motion and should be monitored while on the move" [27: 2].

The locations in which data collection was performed were chosen to accommodate the possibility of intercepting both long-distance and short-distance cyclists, thus assessing cycling activities that differ in duration (from hours to days) and purpose (leisure/ tourism, physical activity). As argued by Hannam et al., there is a need for more in-depth research concerning the embodied experiences of the particular *modalities* of cycling, which can be distinguished between "long distance autonomous self-propelled touring, long-distance package cycling tours, short distance exploration of urban sites and rurality" [18: 60]. The study took place on the embankments of Castelnuovo Bocca d'Adda and Piacenza along the Po river, and of Governolo along the Mincio river. On all three sites the embankments are accessible to bicycles and are part of or in proximity to national (Bicitalia, VENTO) and international (EuroVelo) cycling routes¹. While in close proximity to urban centres (and hence frequented by local cyclists as well), the three locations present a distinctive semi-rural landscape that is characteristic of the Po valley: running parallel to the river, the routes are marked by various types of vegetation, plains and crop fields.

4. FINDINGS

The intercept survey took place on the three locations in September-October 2023, always on a Saturday to ensure a higher number of participants. Out of 54 cyclists intercepted, 31 agreed to participate at the intercept survey (response rate = 57%). Seven participants are 65-74 years old, six are 35-44, six are 45-54, five are 55-64, four are 25-34, and three are less than 17 years old. Among them, 24 were men, while only seven were women. 16 participants were cycling alone, and 14 with a partner or in a small group. Most participants (n=23) reside in the provinces where the survey took place (LO, MN, PC); six reside in Northern Lombardy; and two participants are long-distance cyclists from abroad performing a touring holiday. When asked about the mode(s) of movement they use in their daily commuting routine, most of them stated that they drive (n=18) and/or cycle (n=16) and/or walk (n=8); only one participant uses public transport.

Closed questions

¹ It is important to note that the embankments are accessible to vehicular traffic; typically constructed in asphalt, they constitute secondary roads that are mostly used by local inhabitants. Although some of the locations investigated are part of a national cycling route, to date there exists no cycling infrastructure (except for signage) that separates vehicular and cycling traffic. Cyclists often choose the embankments because of lower vehicular traffic; yet their safety is often at risk, due to violation of speed limits (or even absence of road signs) and irresponsible driver behaviour [40].

Question	Multiple choice	Responses (N=31)	Branching question
<i>Which is the purpose of your cycling activity today?</i>	<i>leisure/tourism</i>	28	
	<i>physical activity</i>	3	
<i>For how long will you be cycling?</i>	<i><30 minutes</i>	3	
	<i>30 minutes – 1 hour</i>	3	
	<i>1 hour – 2 hours</i>	13	
	<i>half day</i>	6	
	<i>the whole day</i>	4	
<i>Have you cycled along this route in the past?</i>	<i>yes</i>	19	
	<i>no</i>	12	
<i>Did you pause during the cycling activity?</i>	<i>yes</i>	19	<i>4a. If yes, why?</i>
	<i>no</i>	12	
<i>Did you ever feel the need to accelerate or slow down?</i>	<i>yes, accelerate</i>	10	<i>5a. If yes, why?</i>
	<i>yes, slow down</i>	3	
	<i>yes, both</i>	12	
	<i>no</i>	6	
<i>Is there something you did not enjoy during the cycling activity?</i>	<i>yes</i>	23	<i>6a. If yes, what did you not enjoy? Why?</i>
	<i>no</i>	8	
Open-ended questions			
Name three elements (natural and/or artificial) that you perceived along the route and that remained in your mind.			
Which part of the route did you prefer? Why?			
Describe the context of the route in three words.			

Table 1. The questionnaire used for the intercept survey.

Closed questions and corresponding responses are illustrated in Table 1; branching questions prompt explanatory responses that will be discussed further below. The former are analysed in a quantitative manner, whereas the latter, together with open-ended questions are analysed qualitatively. A large number of participants cycling for leisure or tourism verifies the adequacy of the locations chosen for the intercept survey and suggests the accuracy of findings regarding the aim of this study.

Question 4 intends to explore a dimension of the cycling activity that is indirectly linked to the concept of immobility within the context of slow tourism: it stems from the hypothesis that slower speeds, as well as immobility, allow for engaging and interacting with the surrounding landscape and other individuals. Some participants who responded positively to question 4 further added that they paused cycling to “explore” or “observe the landscape”, “take photographs” or “visit friends” (question 4a). Nevertheless, most participants appear to have paused for reasons that do not regard the environmental setting along the route, but for satisfying instrumental needs [39] such as taking a break for coffee, lunch, or to rest.

Through question 5, the study attempts to contribute to the literature suggesting that perception and experience [23, 26], as well as perception of speed [9, 27, 29, 41] are highly subjective and experiential. Among participants who expressed a need to accelerate, we identified two participants that were cycling for physical exercise (question 1); responding to branching question 5a, they stated that they “like speed and adrenaline”. Others justified their response by a need to “see more of the landscape and cover a larger distance” or to “catch up with the rest of the group”. This last observation highlights the importance in distinguishing single cyclists from groups, as the latter implies a kaleidoscopic perception of speed that compels individuals to synchronise with the group’s rhythm. Participants that felt the need to both accelerate and slow down referred to a constant effort of adapting to their own needs, while others acknowledged that a difference in speed implies a different perception of the landscape. In this regard, one response conveys this message quite aptly: “by

Proceedings

accelerating, it's possible to go further and keep up with the group; by slowing down, cycling is more of a stroll, an inner meditation with an outward gaze". Only a few participants expressed the need to slow down while cycling: one of them had previously reported a pause (question 4) in order to admire the landscape.

Unlike closed questions that mostly address instrumental factors of the cycling activity, open-ended questions were conceived so as to probe participants' affective experience with regard to the environmental setting. In this case, participants were free to choose their own wording and provide elaborate responses from a subjective point of view. Consequently, the analysis of responses was performed in a more flexible manner, either by grouping responses into categories of emerging environmental features or highlighting specific words or phrases mentioned by participants, which are of particular interest in relation to the research aim and hypothesis.

In question A, participants had to recall three *natural* or *artificial* elements that they perceived along the route (the question was thus structured to exclude possible references to other humans, that are beyond the subject of this study). As expected, most participants (n=25) mentioned the presence of water: the most recurring words were *river*, *water*, or the names of the rivers *Po* and *Mincio*. Secondly, participants referred to vegetation (n=16) (*grass*, *flowers*, *poplars*, *plants*, *nature*) and the built environment (n=14) (*churches*, *farmsteads*, *houses*, *factories*, or the *rowing club*, *bridge*, and *flyover* in Piacenza). At the intersection of natural and artificial elements we find references to the agricultural dimension of the landscape (n=10), such as *croplands*, *fields*, *plains* and *manure*. A few participants referred to animals (n=9) by naming the species they perceived (*pheasant*, *hare*, *goat*, *pigeon*, *mosquito*) or simply by stating "birds".

Question B aims to take findings on environmental perception to a further level, by encouraging affective responses that refer to an overall perception of the landscape rather than to separate elements. As has been shown, the concept of preference or likeability [41] is key for the interpretation of the perceptual process for it is closely related to an individual's purposes [42] (in our case we might claim that, for instance, a long-distance cyclist has different purposes with regard to the environmental setting than a local participant cycling for less than an hour). Once more, the importance of the river stands out among participants' responses: most (n=15) preferred that part of the route was "along the river", "on the embankment" or "on the floodplain", while three participants referred to the meanders of the river as a "panorama" of "invaluable landscape quality" where "the field of view widens". By cross-referencing responses with demographic data, we note that local participants refer to specific localities, as for instance the Bocca dell'Adda "where people go for fishing and to be in contact with the river".

Similarly, question C seeks to unveil affective interpretations regarding the whole environmental context of the routes traversed by participants. The question was intentionally conceived so as to direct participants' responses and choice of wording the least possible: according to Russell [28], when asked to describe an environment, individuals choose wording that might refer to the physical (objective) components of the environment perceived and/or their own affective (subjective) judgements towards it – yet most responses combine both [22]. It was therefore expected that in responding to question C participants would use the first words that crossed their minds, without consciously distinguishing between objective and subjective meanings. A variety of adjectives and nouns in participants' responses equally refer to the physical and affective components of landscape: *relaxing* (n=10), *freedom* (n=5), *quiet* (n=5), *green* (n=4), *beautiful* (n=4), *horizon* (n=4), *flat*¹ (n=3), *serenity* (n=3), *happiness* (n=3), *stimulating* (n=1), *gratitude* (n=1), *peace* (n=1) but also *adrenaline* (n=1). Considering the fact that most responses contain both types of words, we might assume that,

¹ *Flat* here is intended literally: we noted that participants from Northern Lombardy, who are more familiar to mountainous landscapes, all referred to the fact that the landscape of the Po valley is flat.

even the ones referring to an objective interpretation of the environment might also imply subsequent affective judgements. For example, *green* might literally refer to vegetation, but in combination with *relaxing* and *serenity* the response acquires a subjective meaning that could refer to the restorative effects of nature [42]. Although participants were instructed to use only three words, many seized the opportunity to express opinions and affective judgements by elaborating on their thoughts. For instance, one participant characterised the environment as “beautiful, it makes you forget all the rest”; one described it as a “natural landscape with the effects of human life in it”; while one said, “beautiful but not as in older times: the river [Po] has lost its importance”.

In general, responses to open-ended questions reveal the influence of verbal expression and choice of wording on the findings. Firstly, we note that some participants simplify their responses by using generalising wording (e.g. *nature*, *landscape*, *panorama*), while others choose more refined words to express their perception of the environment. This is particularly noted in question A, where we discover the following differences in conveying a similar meaning: *plants* vs. *poplar*, *water* vs. *meanders of the river*, and so on. Firstly, this observation may relate to the fact that environmental perception is subjective and depends on memory and past experience¹ [27, 38], which mediate an individual’s capacity to recognise an environmental feature, (know how to) name it and recall it if needed [41]. Secondly, and more importantly, this process is also mediated by speed, through the hypothesis that slower speeds favour the intake of multisensory stimuli and allow an individual to notice, name and recall. Among participants with less elaborate wording, we find the ones cycling for physical activity and referring to adrenaline and speed: this may be justified by the fact that higher speeds narrow down individuals’ attention “to the essential activity of riding in order to avoid risks” [27]. On the other hand, participants who intended to slow down during cycling (question 4) used a more refined wording in describing the landscape, suggesting that they had the opportunity to closely observe their surroundings, recall their observations and express them by replying to the open-ended questions. Participants who identified specific animal species in question B claim to have performed stops during their cycling activity, hence verifying the assumption that slowing down or pausing favours environmental perception, immersion and contact with the landscape. Finally, the fact that in question B some participants used detailed wording to describe elements related to water, such as *locks*, *dockings*, *bridge*, *riverboat*, *embankment*, and *floodplain*, might imply either familiarity with such elements of the landscape or higher attention in environmental perception.

Vision predominates over the rest of the senses [27, 43] and the “fundamental visual nature of tourism experiences in general” has been acknowledged [35: 81]. While open-ended questions explicitly addressed visual stimuli, we nevertheless purposefully sought to leave room for references to diverse sensory stimuli. Participants named environmental features that do not only correspond to the visual system: one mentioned the *sound of the birds* (auditory), while another referred to *manure* (olfactory). A few participants provided insights on their kinaesthetic experience by referring to factors that may contribute to physical fatigue and consequently slow down the cycling activity: such factors were the *wind* (n=3), *low stamina* (n=1) and, in the case of a long-distance cyclist, the excessive *weight* of the bicycle charged with bags and luggage. Additional observations that relate to kinaesthetic experience can be derived from question A, in which three participants provide implicit affective responses of negative nuance, by arguing that “drivers do not respect cyclists” or that “there are too many lorries along the route”. More than half participants (n=12) reporting on what they did not enjoy along the route (question 6a) mentioned vehicular traffic. From another angle, some participants (n=3) express

¹ Overall, by cross-referencing responses to questions A and 3 with demographics for each participant, it is possible to determine whether the participant has prior experience within the particular environmental setting. However, inasmuch as such an analysis might yield interesting insights to individual behaviours, performing a case study on each participant’s responses was beyond the scope of the preliminary analysis presented in this paper.

Proceedings

their preference for parts of the route with less traffic (question B), thus reiterating the intrusive nature of vehicles on the embankments. Specifically, one participant who alluded to *freedom* as an affective dimension of the cycling activity subsequently disapproved of the presence of vehicles, suggesting a hindrance to safety and sense of freedom. This observation is consistent with previous research in urban contexts, which has shown that the freedom experienced by urban cyclists “is stolen spatially and psychologically from the hegemonic regime of automobility” [25: 10]. We may infer that this kind of conflict is further intensified when it comes to leisure cycling in non-urban contexts, which appertains to purposes of leisure within a *relaxing* and restorative context and is associated with a variety of positive and even transformative experiences [42].

5. CONCLUSION

This study set out to explore the particularities of environmental perception and affective experience of cyclists during a leisure activity along the embankments of the Po valley. In addressing the person-environment relationship from an interdisciplinary standpoint, the research called for a qualitative method that is person-centred and respects social diversity and subjectivity. This was achieved through the intercept survey and the analysis of the findings in both quantitative and qualitative terms. Although at a preliminary phase, the analysis demonstrates that environmental perception and affective experience vary according to individuals’ background, purposes, and subsequent speeds of cycling.

The ultimate goal of the study is to advocate for the importance of studying human environmental perception and affective experience, and to emphasise that an interdisciplinary approach is crucial [38] for informing policies on slow travel infrastructures. By identifying physical features of the environment and individuals’ experience of landscape, as well as their continuous interplay, we pursue raising awareness and strengthening the role of this debate in the field of planning and design for slow tourism and travel. In this light, the method and findings presented in this study contribute to setting a framework for the study of perceptual and affective dimension of travel experiences, and provide evidence that can be applied in the design of slow travel infrastructures. Primarily, the study reveals that a dominant environmental feature in the landscape increases likeability and stimulates perception: in our case, the presence of water was mentioned by most of participants as a memorable and likeable environmental feature, while many of them noticed and referred to elements related to water. In terms of planning, the perceived continuity and cohesion of the landscape as a result of large-scale features of natural or cultural significance suggests an additional value of environmental and affective importance, that should be considered in the planning and design of slow travel routes in non-urban contexts. The findings confirm the hypothesis that slower speeds, as well as pauses during a cycling activity, contribute to an enhanced perception of environmental features and observation of the landscape. This relates to the definition of slow travel as part of an overall slow tourism agenda that comprises practices of both mobility and immobility: as suggested by the findings, environmental perception, observation and engagement with the landscape occur more than often during pauses from the cycling activity. This implies that, in planning for slow travel infrastructures, designers should provide for rest areas that do not merely satisfy instrumental needs, but also stimulate perception [21]. By extension, references to auditory, olfactory and kinaesthetic stimuli align with the premise that cycling and other forms of slow travel are part of a multi-sensory experience; planning for slow travel should hence account for all the senses and not solely vision.

Abstract

The new challenges related to climate change invite us to reflect on the choices to be made in urban areas. Technology and new scientific advances can not only be used to make the city function better, but also to achieve sustainability goals. To do this, new technologies must be added to 'ancient' knowledge, confirming that the objectives set must be able to exploit all available knowledge. Urban sustainability cannot ignore the recognition of the city as a public and social good, activating urban, infrastructural, and resource distribution policies aimed at consolidating density and intensity between physical space and the space of flows. The city is not just 'nature', which is why the urban ecosystem is assumed to be similar to 'an ecosystem in transition', the dynamics of which are determined by human action, the reaction of natural elements and mutual conditioning. The green and digital transition is based on sustainable development principles and should become an activator in enhancing the attractiveness of territories, also affecting the tourism sector worldwide. Tourism resilience implies providing unique cultural and natural experiences and digitally facilitated booking and travel planning, avoiding an imbalance in the tourism ecosystem. In 2022, the European Commission presented the 'Transition Pathway for Tourism', a plan jointly created with the tourism ecosystem players that details key actions, objectives, and conditions to be realised with the involvement of the tourism community. In this way, tourism and business development opportunities can be revealed in territories that contain, in their very marginality, new resources to bring about lasting change. Matera is known as the city built into the stone, an example of historical resilience, a UNESCO heritage site, and European Capital of Culture in 2019. In this area, humans have been able to adapt the territory according to their needs, exploiting the workability of tuff (Gravina calcarenite), a calcarenitic sedimentary rock that characterises the entire Murgia plateau and the Murgia Materana. However, the transformations of the territory combined with new climatic emergencies and large tourist flows entail risks to which it is necessary to respond with innovative targeted techniques. The surveying, mapping, and monitoring of the built environment are indispensable for understanding phenomena that develop on an urban scale such as water management in the light of climate change. A smart vision of the city is proposed inspired by the Sustainable Development Goals (SDGs), in particular the protection and eco-sustainable promotion of the territory (SDG 15), the availability and smart management of water resources (SDG 6), and the promotion of actions to combat climate change.

Keywords: resilient city; risk mitigation; sustainable and digital transition; smart tourism; Matera

1. INTRODUCTION

The theme of the city is gaining more and more importance in the political debate because of the renewed planning attention imposed by urban policies, for their capacity to open up to the processes of European integration, and as far as the cities of the South are concerned, for their capacity to propose themselves as an anti-crisis factor investing themselves with an essential role in the success of territorial and social cohesion policies. Culture penetrates the life of the city and the social sphere, and discussions are held on the knowledge of space as a project of social anticipation, moulding sensitivities and thoughts on the city and the territory, as has happened in the past in the laboratory of the city of Matera.

Today, the relationship between city and territory is once again being discussed in Italy. Every time the structure of the economy and society changes, the urban issue returns to the foreground. Matera is an interesting observatory for studying several phenomena: it is a creative city, a destination for fast-growing national and international tourism and, therefore, continually subject to human action, but at the same time a city with a serious infrastructure deficit and a geomorphological conformation that is particularly exposed to hydrogeological risk. Matera can once again become a laboratory of policies to help understand what the role of a medium-sized European city can be at a time when the values of urbanity are being tested by the overwhelming force of global metropolises and post-metropolises: whether the heritage of a city's histories still has the capacity to structure larger territories, whether urban space can once again become a form of citizenship, an incubator of the city's civic value, and whether this value can be made visible in urban design and its forms [1].

The orientation of the ecological, digital and tourism transition in European programmes considers the fragility of our territories and the effects of climate change, adopting climate mitigation measures and investing in improved energy infrastructure.

Digital modelling can contribute to the creation of more resilient and adaptive cities, while recognising the challenges and limitations of implementing it in complex scenarios such as the one analysed. Urban resilience represents a crucial topic for the achievement of the Sustainable Development Goals (SDGs) proposed under the United Nations (UN) 2030 Agenda [2].

For the proposed case study, we examine available cartographic products and digital models from diverse sources and spatial scales, exploring their significance and discussing their role in achieving resilient sustainability.

2. SPATIAL POLICIES AND RESILIENT TOURISM

As cities rapidly expand, more infrastructure is increasingly needed. Considering it as an opportunity, the scale of global infrastructural development will be an unprecedented opportunity to reorient and rethink the urbanisation process from one that is inherently destructive to one that is sustainable and resilient [3]. This is the promise and challenge of smart cities as a key idea for building resilient urban structures. The vision and mission of smart cities are inspired by SDG 11 to "improve inclusive and sustainable urbanisation and the ability to plan and manage human settlements in a participatory, integrated and sustainable manner", such as the protection and eco-sustainable promotion of the territory (SDG 15), and the availability and smart management of water resources (SDG 6).

To overcome these challenges, the EU has adopted the European Green Deal, the new growth strategy that will transform Europe into a modern, resource-efficient, and competitive economy. The European Green Deal aims to make Europe climate-neutral by 2050, boost the economy through green technology, create sustainable industries and transport, and reduce pollution. In this way, opportunities for tourism and business development can be unveiled in territories that contain, in their very marginality, unprecedented resources to bring about lasting change. The approach known by the expression 'place-based' or 'place-oriented development' corresponds to the articulation of real phenomena and it is up to the local level to make concrete proposals to enhance the supply of services and identify development paths, overcoming the limits of both the top-down approach – the unreality

of a project established without involving local communities – and the bottom-up approach – the illusion that places have all the economic and cognitive resources required to implement effective development strategies [4]. The development potential that many areas of the country possess is largely under-exploited, consisting of significant natural, cultural, and human resources, whose activation could make an important contribution to growth. In fact, the abandonment of these areas or 'predatory' exploitation, i.e. exploitation that consumes local natural resources without creating significant benefits in terms of employment, income, and innovation, not infrequently produces negative outputs and, therefore, social costs for the entire nation, related to hydrogeological instability and the degradation of the cultural and landscape heritage [5].

The concept of resilience appears more and more in risk management strategies, specifically with the new European policy aimed at developing local-scale resilience plans by 2030. Risk-based approaches provide a rational method for weighing mitigation costs and adaptation measures. By contrast, starting from the uncertainties associated with natural hazards, resilience focuses on the ability of an affected system to absorb extreme shocks, restore good levels of functionality in the short term and plan improved services for the next phase [6].

The practices of sustainable urban tourism along the lines of the 2030 Agenda following Matera European Capital of Culture in 2019 look at temporary residences, management of public space and the old town, mobility for the fair distribution of tourist flows, and mitigation of natural hazards. Therefore, tourism is directly related to environmental and social safety and security, as well as to the importance of technological innovations for risk monitoring.

3. METHODS AND TECHNIQUES FOR RISK MITIGATION

Urban areas, particularly those with historical significance, face a range of risks, including natural disasters, environmental degradation, urbanisation pressures, and cultural heritage preservation challenges. According to Varnes' risk concept, the spatial and temporal probability of occurrence of potential damaging events, as well as the distribution of the elements at risk in space and time, considering also changing vulnerabilities, collectively, contribute to an elevation in overall risk levels. As climate patterns become more unpredictable and extreme, the susceptibility of urban areas to natural hazards amplifies [7, 8]. Moreover, the ageing infrastructure, which may not have been initially designed to withstand contemporary environmental stresses, becomes increasingly vulnerable. The rapid expansion of urban settlements further exacerbates the situation by exposing more people and assets to potential risks.

Therefore, it is imperative for urban planners, policymakers, and stakeholders to integrate comprehensive risk management strategies into urban development plans to mitigate these escalating risks effectively. This integration involves various aspects, such as incorporating resilient infrastructure designs, establishing early warning systems, promoting sustainable land use practices, and enhancing community preparedness and response capabilities. In this context, the surveying, mapping, and monitoring of the built environment are essential for the understanding of phenomena that develop at urban scale such as the management of historical sites in view of climate change. The current era provides us with important digital tools and the opportunity to test innovative workflows for sustainable city development and building resilient cities. The surveying of urban spaces is constantly increasing due to new technologies that have emerged for participatory planning such as drone mapping, photogrammetry, 3D modelling and digital twin construction. Aerial vehicles such as drones or Unmanned Aircraft Systems (UaSS), equipped with sensors such as cameras, LiDAR (Light Detection and Ranging), represent a fast-developing approach for urban context monitoring [9].

Recent developments in cartographic applications are leading not only to the implementation of accurate, up-to-date map bases with shared specifications, but also to new ways in which the traditional cartographic medium is now used. These include interactive maps and mobile applications

that can provide real-time information to visitors, such as recommended routes, trail conditions or sensitive areas to avoid, as well as to educate visitors about the importance of conservation. Cartography plays a major role in setting strategies for sustainable tourism, helping to balance the needs of visitors, environment, and local communities [10]. The key points are listed below:

1. **planning and management:** cartographic media provide detailed information about the area, helping organisers to better understand the natural and built environment, guiding tourism planning, helping to minimise environmental impact and maximise benefits for local communities;
2. **accessibility:** maps can show access routes to tourist sites, helping to manage visitor flows and reduce wear and tear on sensitive areas;
3. **education:** cartographic bases can be used to educate visitors about the importance of historical and cultural preservation, increasing awareness and appreciation for the environment and local communities, and promoting more respectful and sustainable tourism;
4. **monitoring and evaluation:** mapping techniques, through Geographic Information Systems (GIS), can be used to monitor changes over time, such as soil erosion or vegetation growth, helping to assess the effectiveness of sustainable tourism strategies and plan necessary changes.

4. MATERA, AN INTERESTING CASE STUDY

4.1 The urban context between present and past

Matera, the oldest urban settlement where life has been going on uninterruptedly since prehistoric times to the present day, a great little jewel in the deep South of Italy that has decided to defy time, winning its challenge by becoming a UNESCO World Heritage Site and European Capital of Culture in 2019. On 17 October 2014, Matera was designated to be European Capital of Culture in 2019, a historic achievement that represents the consecration of the city to culture and tourism.

The urbanised area of Matera comprises cores that arose at different times, such as the original Sasso Barisano and Sasso Caveoso, the plain, the consolidated city, the villages La Martella and Venusio, and the urban expansion areas. Each core retains structural and urbanistic characteristics specific to its historical development context. However, each has undergone transformations.

The first core of the built-up area of Matera, called the Civita, was built on a rocky spur jutting out with steep walls into the ravine and located at an altitude of about 400 m asl. The earliest settlements of the city were dug-out dwellings in which the limestone blocks removed by digging were used for the front parts of the housing units. As the years went by, a network of narrow streets and dwellings made up of housing units, neighbourhoods and hanging gardens began to stratify.

The layered terracing system ensured good surface water regulation, allowed the collection of outflows, the interception of drainage water and the accumulation of condensation water.

The ancient quarters, Sasso Caveoso and Sasso Barisano, are located within two small catchment areas in which a low-ranking hydrographic network is developed, with the two main river courses resting on V-shaped valleys, once used as real open-air sewers until their reclamation in the 1950s, and now drained (Figure. 1).

Figure 1. The main features of the Sassi Districts from OpenStreetMap (OSM).

The urbanisation of the modern city has obliterated the natural hydrographic network of the two creeks, whose main courses are morphologically recognisable only in their lower reaches, in correspondence with the roads Via Fiorentini and Via Buozzi. Nowadays, these roads serve as the primary destinations for tourists, hosting numerous activities catering to tourism and street furnishings. Other hydraulic works, mainly built to collect and store rainwater for self-consumption, are the cisterns carved out of calcarenite. The larger ones are located upstream of the Sassi at the boundary with the overlying clays. One of these is the Palombaro Lungo cistern, with a capacity of 5 million litres of water, built starting at the end of the 18th century in today's Piazza Vittorio Veneto. The complex system of cisterns and canalisation works ensured the storage of water resources and the fulfilment of the sanitary needs of the population of the time. In addition, these systems ensured good surface water regulation and protection from sudden runoff phenomena [11, 12].

Currently, the cisterns and the old drainage channels known as “grabiglioni” have lost their role in regulating the hydraulic flow. The cisterns have been diverted to other tourism-related tasks, whereas the “grabiglioni” coincide – as mentioned – with two roads, which nonetheless still serve as valley floor for the two creeks, with a consequent hydro-geomorphological hazard factor for the numerous tourist activities. More in general, for a large part of the urban area the issue of channelling rainwater during intense events is particularly relevant to mitigate hydraulic risk, also due to the insufficient outflow offered by the sewer network [13, 14].

4.2 Available cartographic products and potentiality

The available dataset of Matera city includes information provided by Basilicata Region on a geotopographic regional database (RSDI). Topographic data from a regional survey consist of a Digital Surface Model (DSM) and a Digital Terrain Model (DTM) with a resolution of 5 metres × 5 metres and dated 2013 for the whole region [15]. This regional aerial survey has been combined with building boundary polygons and street segments from OpenStreetMap to create a 3D model, augmented with varied semantic annotations [16].

Recently, with a view to equipping itself with adequate cartographic tools, to improve the functioning of the 'municipal machine' and at the same time provide the territory with a cognitive base that meets the changing needs of society, the Municipality of Matera has recently implemented a project to produce an evolved cartographic base of its territory, through services for optical photogrammetric and LiDAR acquisition.

The project involved the production of the Numerical Technical Map of the urban centre (scale 1:1000) and of the entire municipal territory of Matera (scale 1:2000), including 5 cm and 10 cm

Proceedings

orthophotos, point clouds and numerical terrain models, with the intermediate products required for the purpose. The aerial imaging was carried out with a Leica DMC III camera by flying with 8-10 cm ground pixels over the entire territory and 4-5 cm over the urban centre.

The LIDAR was carried out with a RIEGL VQ-580 II sensor with a density of approximately 40 pts/sqm over the entire municipal area, while for the urban area the density was approximately 130-140 pts/sqm (Figure 2). The rendering involved the punctual application of the Shared Specifications in accordance with Italian Ministerial Decree 10/11/2011, which establishes the reference standards for cartographic productions at various scales.

Below are provided:

1. an example of a Digital Surface Model (DSM) extracted from the LiDAR point cloud in the Sassi area, where the density of buildings and the depth of drainage can be seen;
2. the optical image imprint acquired with the positioning of Ground Control Points (GCPs) used in the Aerial Triangulation phase.

Figure 2. Elevation view of the LiDAR cloud of the spatial portion of the “Sassi” Districts.

Figure 3. Detail of the aerial photogrammetry mosaic with indication of the Photographic Points of Support, denser in the central area

The knowledge base created by the municipal administration is undoubtedly an extremely positive achievement, necessary for the understanding of territories and the proper management of urban and suburban spaces. However, the understanding of territories gained from aerial platforms produces a representation of the territory that is no longer considered sufficient today.

In fragile and complex territories such as the one in question, it is now necessary to implement a "Digital Twin" that models not only the terrain and the built blocks (external changes and roofs) as in traditional cartography, but the modelling extends, if necessary, to include the parts not reached by photogrammetric surveys with exhaustive "exterior/interior" models [17].

The implementation of a digital twin, extended to at least the Sassi area, would achieve the following objectives:

improvement of hydraulic modelling, including not only the terrain and the rooftops but also all water collection and regulation works both belonging to each unit and for collective use, even reaching the modelling of underground conduits;

visibility analysis starting from significant points in the context, up to creating virtual reconstructions of monuments, offering immersive experiences for research, education, and tourism while preserving the original structures;

analysis for predicting phenomena related to sunlight exposure, such as the presence of light/shadow on various days of the year and the prediction of heat islands, a phenomenon emphasised by the rocky nature of the territory and the intensification of issues related to global warming;

establishing the basis for continuous monitoring of monuments, providing real-time data on structural integrity, environmental impact, and potential threats such as erosion or vandalism, allowing for timely interventions and conservation efforts;

the production of "virtual tours" that allow immersive paths accessible remotely;

For the production of such databases, optical and LiDAR sensors are required, which can essentially be listed as follows:

Oblique cameras, which are photographic sensors integrating up to 5 appropriately angled cones, now available to be mounted on aerial drones.

Optical cameras with 360° lenses, for the creation of virtual tours.

LiDAR devices that utilise SLAM (Simultaneous Localization and Mapping) technology for accurate georeferencing of the shots: essentially, each position is estimated based on previous positions, thus obtaining the possibility of modelling even in environments where the GNSS signal is not available (inside buildings, caves, underground channels, etc.).

These aforementioned sensors can be mounted on unconventional supports (backpacks, robots, underwater and amphibious drones), ensuring the possibility of acquisition even in special contexts like the one under examination.

5. CONCLUSION

The city lives thanks to its inhabitants and over time space is shaped by human activity and natural processes. But along with this comes the invisible dimension of new technologies that pervasively influence the perception and accessibility of places.

The success of a European Capital of Culture is not only measured by what happens in the fateful year, but rather by whether it contributes to a significant and sustainable change in the development trajectory of the city and its territory.

The alteration of hydrological forcing due to climate change raises important questions about the availability of future water resources and the frequency of extreme events. In this highly uncertain context, it appears useful to reconsider the model of Matera as a resilient city in the past, through the recovery of the city's ancient catchment, storage, and transport infrastructures to rebuild the important land protection functions of ground and surface water regulation.

Therefore, the utilisation of innovative technologies in risk management represents a paradigm shift towards more proactive, efficient, and resilient approaches to safeguard cultural heritage.

The critical analysis of the different experiments highlights the heterogeneity of the topics dealt with and the countless points of view to be developed on the issue of city and landscape through the lens of complexity and digitalisation, with tools and methodologies that can be replicated in different

contexts to involve local communities in structuring and enhancing the territory according to the needs of residents and temporary inhabitants.

Kos, a well-being destination based on the Hippocratic philosophy

A. Karayanni

Praxis Plus, 101 Amerikis str, Rhodes, Greece

Corresponding author: E-mail: info@praxisplus.gr; T. +30-697-4353-017

Extended abstract

Kos belongs to the complex of the 12 Dodecanese islands, the motherland of Hippocrates II (460-370 BC), named “Father of the Medicine”. A Philosopher, Scientist, Author, doctor, one of the great minds in the ancient Greek World.

Hippocrates was a contemporary of Plato (429-347 BC) and Aristotle (384-322 BC) and of some of the great playwrights of Athens. His therapeutic methods started with careful observation of the environment, nutrition, living habits. He had a holistic approach to diagnosis and treatment. “Healthy mind in a healthy body” was the milestone of the Hippocratic philosophy. Thus, he introduced principles of Science in the therapy of Man’s Body and Mind in Asklepieion.

HIPPOCRATES QUOTES

“Your foods shall be your “remedies” and your “remedies” shall be your foods.”

“Everything in excess is opposed by nature.”

“Natural forces within us are the true healers of disease.”

“Walking is man’s best medicine. If you’re in a bad mood go for a walk. If you are still in a bad mood, go for another walk”.

“Health is the greatest human blessing”.

“If we could give to every individual the right amount of nourishment and exercise, not too little and not too much, we could have found the safest way to health”.

THE HIPPOCRATIC GARDEN

The pharmacological knowledge reflected in the Hippocratic Collection is remarkable. They used herbs, minerals, leaves, flowers, juices, roots and plants which they regarded as having curative properties. Out of them, they prepared powders, tablets, drops, suppositories, vaginal uvula, crèmes, syrups, ointments, spirits, and many others.

At least 250 different plants are mentioned in the Hippocratic Collection. More than 220 different sorts have been planted in the “Garden of Hippocrates” of the International Hippocratic Foundation in Kos.

His Pharmacology is still the source to identify and isolate several modern medicaments like Aspirin against fever, Coumarines for anticoagulation, Ephedrin against cough, Vincristin against cancer, Tamoxiphen against breast cancer, and many others.

Kos is a famous tourism destination, with a coastline of 112 km approx. 2 million arrivals and 35.000 population. It is a mediterranean oasis for history enthusiasts, natural beauty, cultural landscapes offering genuine Greek hospitality. Bicycle is widely used by locals and visitors due to the infrastructure and the flat land.

The advantage of the Hippocrates heritage in Kos, is the unique KPI that transforms positively the inhabitants’ way of living. Also, transforms the concept of a holiday into a unique holistic well-being to experience offering: stress reduction up to revitalization, good sleep, mind stimulation, harmony between body and mind, fullness, calmness, happiness. Good habits, the sea, the gastronomy based on local products of high quality, the knowledge of Hippocratic philosophy starting from schools, can change Kos, improving lives in a sustainable way with ESG practices inspired by his philosophy for health and well-being for over 2.500 years.

**Corresponding author: E-mail: stefloukis@slbl.gr, Tel +30 6939616885*

Extended abstract

In the realm of sustainable tourism, the development of green tourism infrastructure stands as a cornerstone for promoting environmentally responsible travel practices. This abstract explores innovative examples of green tourism infrastructure, encompassing eco-friendly accommodations, renewable energy solutions, sustainable transportation systems and AI Technologies.

Eco-friendly accommodations are at the forefront of sustainable tourism initiatives, offering guests an immersive experience in harmony with nature while minimizing environmental impact. These accommodations showcase innovative design features such as passive heating and cooling, rainwater harvesting systems, and utilization of recycled and locally sourced materials. Case studies from around the globe demonstrate how eco-lodges, treehouses, and green hotels are redefining hospitality through sustainable practices.

Renewable energy solutions play a pivotal role in powering green tourism infrastructure, reducing carbon footprints and dependence on fossil fuels. From solar panels and wind turbines to geothermal heating and biomass energy, renewable energy technologies are transforming tourism destinations into models of sustainability. Success stories highlight the integration of renewable energy systems into resorts, campsites, and remote eco-tourism destinations, demonstrating their feasibility and efficacy in achieving energy independence.

Sustainable transportation systems are essential for reducing emissions and mitigating the environmental impacts of tourism-related travel. Green tourism initiatives are embracing eco-friendly transportation options such as electric vehicles, bicycles, and public transit networks powered by renewable energy. Case studies showcase innovative transportation solutions in tourist destinations, including bike-sharing programs, electric shuttle buses, and zero-emission ferries, enhancing mobility while minimizing environmental harm.

Through the presentation of innovative examples and case studies, this abstract aims to inspire stakeholders in the tourism industry to adopt green tourism infrastructure as a means of fostering sustainable travel experiences. By investing in eco-friendly accommodations, renewable energy solutions, and sustainable transportation systems, destinations can attract environmentally conscious travellers while preserving natural resources and protecting fragile ecosystems.

This abstract provides a comprehensive overview of green tourism infrastructure, highlighting its importance in promoting sustainable tourism practices and offering practical examples of its implementation. It serves as a foundation for further exploration and discussion on sustainable tourism initiatives focused on infrastructure development. Also presents how AI tools and ai technology can help in this transformation.

The revitalization of the thermal baths in Lesbos as a value for the development of sustainable tourism

K. Gougoula

Architect Engineer, Msc “Protection of monuments”, School of Architecture,
National Technical University of Athens, Greece

Corresponding author: E-mail: kgougoula@mail.ntua.gr, Tel +30 6958497679

Extended abstract

This abstract delves into the nuanced narrative surrounding the revitalization of thermal baths in Lesbos, elucidating their potential as a cornerstone for sustainable tourism development. With a geological predisposition conducive to thermal springs, Lesbos has harbored a rich history of bathing practices dating back to ancient times. The island's unique topography and the existence of natural thermal sources have set the stage for the evolution of a distinct thermal bathing culture.

The early 20th century witnessed a concerted effort to leverage these natural assets for tourism development. Notably, the establishment of the Kourtzi Thermal Baths and the opulent Sarlitzza Palace Hotel exemplified an ambitious drive to attract spa tourism. These endeavors, however, faced challenges over the years, and the thermal baths gradually faded from the tourism spotlight.

In recent times, a resurgence of interest in the island's thermal heritage has emerged. A series of initiatives aimed at the restoration and enhancement of existing Ottoman hammams and baths showcase a commitment to preserving this cultural legacy. The integration of modern amenities with traditional architectural elements seeks to strike a balance between heritage conservation and contemporary visitor expectations.

The development of thermal tourism enhances the traveler's experience, fostering a closer connection with the natural environment and contributing to the dissemination of the broader cultural heritage of the region, such as production, trade, and the economy. The integration of thermal baths into the tourism narrative not only provides a rejuvenating escape for visitors but also becomes a conduit for a more profound engagement with the island's cultural and economic fabric. By immersing travelers in the therapeutic embrace of thermal springs, Lesbos not only offers a unique wellness experience but also creates a platform for them to explore and appreciate the local agricultural practices, trade traditions, and economic dynamics that sustain the island's vibrant community.

In conclusion, the revitalization of thermal baths in Lesbos emerges as a multifaceted initiative with profound implications for sustainable tourism. The integration of historical thermal assets with contemporary conservation efforts forms a unique tapestry that captures the essence of the island's cultural and environmental heritage. The intersection of thermal tourism, agricultural values, and traditional practices provides Lesbos with a distinctive competitive edge in the realm of sustainable tourism.

As we navigate the complexities of modern tourism, the revitalization of thermal baths stands as a testament to Lesbos' commitment to preserving its cultural identity, fostering sustainable development, and offering visitors an authentic and rejuvenating experience. In essence, the thermal baths become not just a historical relic but a dynamic force propelling Lesbos into a future where sustainable tourism takes center stage.

Extended abstract

This paper analyses and classifies the environmental conflicts and disputes in the peri-urban area of Athens as part of a macroscopic analysis of land-use conflicts related on the environment for a period before and during the Greek Crisis” (2005-2014) in order to understand the evolutions of environmental and territorial policies in local, metropolitan and national level. In the postmodern context of the rise of “civil societies” and “environmental awareness”, as well as the postindustrial rapid transformation of urban and suburban space, territorial conflicts and disputes become a key factor that influences the development of territorial policies. Hence the study of the social, economic, political and geographical factors that make the conflicts occur and evolve is essential to understand the process of policy making.

Our research extends to the role of environmental protection in the formation of environmental policy, through the study of conflicts from many perspectives such as the macroscopic study of many diffuse and different cases at the regional level. More specifically, we investigate the spatial recording of conflicts related to the environment and land uses, in combination with the categorization and analysis of the actors of the defence of the environment, i.e. ecological organizations, associations and movements. The recording period covers the years from 2005 to 2014, a period in which, on the one hand, there is a simultaneous development of social demands that give particular importance to the defence of the environment and the quality of life, and on the other hand, new environmental defence actors are emerging as well as new environmental challenges. Through the recording, categorization and analysis of conflicts and environmental defense actors (citizen initiatives, organizations, etc.) an attempt is made to analyze environmental governance as a product of a process shaped, not only by general historical or structural rules, but by specific local conditions, as well as by specific more complex mechanisms of emergence and development of environmental conflicts. The research is part of the general international research approach of recording, classifying, categorizing and analyzing conflicts at the regional level, taking into account the method developed by the group of researchers of the French-speaking geographical community, under the coordination of the INRA’s research laboratory AgroParisTech, emphasizing the relationship of land use conflicts, with the ecological and environmental movement and public environmental policies.

The paper presents part of the outcome of the Ph.D thesis on “Environmental Conflicts and Governance in Athens’ suburban area: Macroscopic study of the environmental defence’s actors and environmental policies (2005-2014)” supported in Panteion University in December 2023.

Extended abstract

Tourism as sector of economy, faces nowadays an increasing pressure to align with environmental, social, and economic objectives, while at the same time, sustainable development forms the cornerstone of global initiatives. Sustainable tourism, as defined by the World Tourism Organization (UNWTO), aims to balance the immediate and long-term impacts of tourism activities, striving to meet the needs of tourists, the industry, the environment, and local communities. Although this equilibrium is essential for fostering the three pillars of sustainable development, assessing and maintaining this balance poses significant challenges, particularly in monitoring the environmental footprint of tourism and its effects on local and global ecosystems.

The adoption of environmental sustainability indicators has become a pivotal strategy for tracking progress towards achieving sustainable development goals. These indicators provide valuable insights into the environmental repercussions of economic activities within the tourism sector, offering a clearer understanding of how these operations affect a nation's environmental health. Our research leverages earth observation data to scrutinize the environmental condition in key tourism destinations and recognises the importance of informal decision-making in preserving critical tourism locales. Our research tracks Key Performance Indicators (KPIs) such as Air Quality, Green Spaces vitality, Urbanization trends, and Water resource pressures, aiming at offering insights into sustainable tourism practices.

It proposes a novel approach to the development of Sustainable Tourism Development Indicator (STDI). Our initiative seeks to address the lack of efficient and reliable tools for quantifying the environmental sustainability of tourism activities. In order to achieve this goal, we have used satellite Earth Observation (EO) data from the Copernicus program, added to detailed in-situ statistical data. The STDI provides a comprehensive, and economically feasible framework for evaluating tourism's sustainability. Our methodology encompasses data collection, preparation, analysis, and visualization, ensuring a holistic view of tourism's environmental impact. We aim at measuring the current sustainability of tourism practices and also advocating an environmentally friendly governance and facilitation methods. This paper presents the concepts underpinning the STDI, outlines the methodological rigor, and it highlights the advantages of the approach over traditional assessment methods.

As a valuable resource for governments, industry stakeholders, and conservation entities, the STDI facilitates a nuanced understanding of tourism's environmental consequences, identifies stress points, and aids in crafting sustainable development strategies. In addition, our research underscores the STDI's potential in enhancing decision-making processes and promoting environmental conservation, thereby playing a pivotal role in advancing sustainable tourism management. The integration of a well-constructed STDI ensures a balanced approach to human and environmental development, further contributing to the global agenda for sustainable tourism. This work offers a forward-thinking

Proceedings

solution to one of the most pressing challenges in tourism today: achieving a sustainable harmony between tourism development and environmental preservation through the innovative deployment of the Sustainable Tourism Development Indicator (STDI), facilitating a deeper understanding of tourism's environmental impacts but also lays the groundwork for more sustainable tourism policies and practices globally.

Urban scale digital twins, sustainable tourism and resilience: Sustainability, Ecology and Ekistics in Constantinos A. Doxiadis and Adriano Olivetti's approaches to urban planning

M. Charitonidou

Principal Investigator and Postdoctoral Researcher, Athens School of Fine Arts, Greece

Corresponding author: E-mail: m.charitonidou@icloud.com, Tel +30 6947460886

Extended abstract

Recently, within the field of smart cities, the notion of urban scale digital twin has acquired a central place. The term 'digital twin' refers to the digital representation enabling comprehensive data exchange and can contain models, simulations and algorithms describing their counterpart and its features and behavior in the real world. A 'digital twin' is a digital representation of a physical process, person, place, system or device. The term 'digital twin' firstly emerged in the field of manufacturing sector to refer to digital simulation models that run alongside real-time processes. Digital twins are digital replicas of physical entities. Their creation is based on the use of advanced technological applications, such as sensing, processing, and data transmission. Within the current debates, urban scale digital twins play a key role in the so-called smart and sustainable tourism. The paper aims to shed light on the concept of sustainable tourism, which is related to the intention of considering the environmental and social dimensions of a destination. Moreover, the paper analyses how smart tourism aims to integrate intelligence in various aspects, such as mobility, living, people, governance, economy, and environment. At the core of the paper is the objective to relate the role of sustainability in the ongoing debates concerning smart tourism to the concepts of 'ekistic grid' and 'entopia' in the approach of Greek urban planner Constantinos A. Doxiadis, on the one hand, and to the concept of 'concrete utopia' in the approach of Italian industrialist Adriano Olivetti. Particular emphasis is placed on exploring why Doxiadis was particularly interested in the environmental issues concerning architecture and urban planning. An important book for understanding the role of sustainability in Doxiadis's thought is his book entitled *Ecology and Ekistics*. Doxiadis completed the first draft of *Ecology and Ekistics* in the summer of 1975, shortly before his death. Gerald Dix became its editor and the final version was published in 1977. At the core of the book entitled *Ecology and Ekistics* is the argument that a condition of global ecologic balance is of pivotal importance for providing environments that can offer to man or *anthropos* satisfactory conditions. The paper examines the role of care and recreation in re-thinking heritage and city branding and the ways in which urban scale digital twins and other artificial intelligence applications can contribute to such endeavors. It pays special attention to how "city branding" can serve in establishing urban regeneration strategies, relating the ideas of Constantinos A. Doxiadis and Adriano Olivetti regarding urban planning strategies to the current debates around smart cities, smart tourism, resilient planning, and regenerative urban design. One of the main objectives of the paper is to shed light on how urban scale digital twins can contribute to the combination of "city branding" and sustainable development.

Keywords: *Constantinos A. Doxiadis; Adriano Olivetti; big data; urban scale digital twins; concrete utopias; artificial intelligence; digital universalism; Ekistics; smart tourism; ecology; sustainability; regenerative design; resilient cities; city branding*

Extended abstract

The application of Artificial Intelligence (AI) technologies in urban planning spans a broad spectrum of areas such as spatial planning, land use and zoning strategies, enhancing physical and digital accessibility, and the incorporation of citizens' perspectives and inputs into the urban planning process. The results can be used as a basis for optimizing the structural and functional aspects of urban environments, leading to the design and implementation of more inclusive, efficient, and sustainable urban plans.

More particularly, the emerging fields of AI application in urban planning include:

1. **Land use and infrastructure planning and forecasting:** AI plays a crucial role in allocating appropriate type and surface of land use, defining also the geometry of urban spaces, and predicting future population needs in infrastructure, housing and other urban functions.
2. **Citizen Participation and Consultation:** AI facilitates the presentation of proposed solutions in formats that are easily understandable by the general public, enhancing the public consultation process. Moreover, it analyzes extensive feedback and inputs from citizens, transforming them into actionable insights that inform and enrich urban plans.
3. **Optimizing Physical Accessibility:** In the context of innovative urban models such as the 15-minute city and superblocks, AI is instrumental in optimizing physical accessibility, ensuring urban spaces are more navigable and conducive to sustainable living practices.
4. **Adaptive Urban Planning:** AI supports the dynamic use of land and buildings, accommodating different activities and functional requirements throughout the day and across seasons.
5. **Sustainability and CO₂ Reduction:** Through the optimization of spatial layouts and building morphology, AI contributes significantly to the reduction of CO₂ emissions. This is achieved within the broader context of sustainable local development, aligning urban planning efforts with environmental conservation goals.

The above potential are ever more important considering the scarcity of urban public space in many cities, the emergence of in-between spaces introduced and partially remaining after the COVID-19 pandemic, some of which are significantly underutilized (e.g. pop-up bike lanes), as well as the need to accommodate newer smart charging and energy demand response requirements.

Extended abstract

With the increasing prevalence of remote work in today's workforce, it's crucial to examine how this trend is impacting our physical homes, workspaces, and urban infrastructures. This paper explores the need to adjust urban planning policies to accommodate the new reality of remote work, whether within or outside city boundaries.

Concerning residential land use, urban planning policy will be influenced by various factors. Areas planned in a way that favours mixed-use communities and offer a range of amenities and services within walking distance, will be more and more attractive to residents. The rise of remote work also prompts a rethinking of transportation in cities, possibly leading to neighborhood designs prioritizing walking, biking, and public transport over car-centric layouts. Home locations may shift due to decreased dependence on proximity to workplaces, resulting in increased demand for homes in suburban or rural areas, that provide more space and affordable living options. The need for larger living spaces will grow as people will increasingly create home offices, requiring a reevaluation of the established planning standard of around 40 m²/person (in Europe). Architectural and urban planning standards should also adapt to support outdoor workspaces in balconies, porches, and yards. Energy consumption in homes will likely increase, necessitating infrastructure upgrades for high-speed internet connectivity and increased use of renewable energy.

In terms of workplaces within urban planning policy, the shift to remote work means a change in how workspaces are designed and used. Many companies may move away from large, centralized offices to embrace smaller satellite locations, coworking spaces, and home offices. This transition enables companies to reduce their energy, real estate and operation costs, diversifying demand for locations, sizes and other characteristics of working spaces. Additionally, remote work is driving demand for more flexible workspaces that are designed to accommodate remote workers. This means that there will be a rise in the popularity of coworking spaces that offer flexible leases, shared amenities, and the ability to work in a community environment.

Funded by the European Union Horizon Europe project R-Map (GA101132497), this research is in its early stages, starting in February 2024. At this point, the paper primarily relies on a literature review, with the expectation of enhanced insights from the first findings to be presented at the CCVI conference in June 2024.

Extended abstract

Urbanization, while driving economic growth and social progress, poses significant challenges to environmental sustainability. As cities expand, so do their ecological footprints, leading to pollution, habitat disruption, and resource depletion. In response, environmental protection has emerged as a critical strategy to mitigate these impacts and promote sustainable urban development. This abstract advocates the integration of environmental protection planning into urban development discussions, emphasizing its importance in the context of the special session on emerging trends in cities.

At the heart of this discussion is the presentation and demonstration of an innovative Environmental Protection Planning tool developed for cities and regions. The tool was developed in the context of the EU funded project “ROBIN - Deploying circular BIOecoNomies at Regional level with a territorial approach” (European Commission, Horizon Europe G.A. 101060504) and will be also utilized for “RIBES - Regional Inclusive Biobased Entrepreneurship Solutions” (European Commission, Horizon Europe G.A 101134911). This tool, designed to prevent and control pollution while enhancing habitat preservation, offers a systematic approach to assessing environmental conditions, identifying barriers, and improving performance across various urban development sectors. The tool encompasses 32 indicators spanning key environmental management sectors, including solid waste, liquid waste, air emissions, water sources, energy sources, green entrepreneurship, natural ecosystems, and sustainable processing. Each sector addresses specific challenges and opportunities, such as integrating circular and bio-based practices to combat climate change and promote sustainable practices across urban and regional administration.

Through the demonstration of this tool, participants will gain insights into practical strategies for enhancing environmental protection within urban contexts. They will learn how to leverage data-driven approaches to identify priority areas for intervention, implement targeted policies and initiatives, and monitor progress towards sustainability goals. Moreover, the tool's emphasis on regional circular bioeconomy integration underscores the importance of aligning environmental protection efforts with broader economic development objectives. By promoting such principles cities can foster innovation, create green jobs and enhance the resilience of their economies while safeguarding the environment.

All, in all, advancing environmental protection planning in cities is essential for achieving sustainable urban development in the post-COVID era and beyond. This paper provides a platform for dialogue, knowledge sharing, and capacity building, empowering stakeholders to drive positive environmental change and build more resilient, inclusive, and livable cities for future generations.

The dynamics of remote work in changing cities across Europe

K. Fellnhofer

CEO of Research and Innovation Management GmbH, Austria

Senior Researcher, ETH Zürich

Corresponding author: E-mail: katharina@rim.eu.com, Tel +436644212920

Extended abstract

This paper will originate out of the R-MAP project which seeks to analyze the impact of remote working arrangements on urban and rural disparities in Europe. It aims to develop an Integrated Impact Assessment Framework and visualization platform to monitor and assess the individual, social, economic, environmental, and spatial impacts of remote working arrangements. The project examines current remote working trends in six regions, forecasts future impacts over the next 5-10 years through scenario building and provides tailored policy recommendations for local governments in urban and rural settings.

Our paper focuses on the collected data and its analysis from a minimum of 20,000 individuals across Europe through Prolific. Our endeavor is to ensure representation across gender, age, and nationality as comprehensively as possible. The survey aims to gather insights into workers' perceptions, intentions, and needs regarding remote working arrangements. The survey covers various aspects related to remote work, including geolocated data on past, current, and future working and living conditions. We will randomly assign individuals to three groups: one group will answer questions about remote conditions in the past, another about the present, and a third about the future. The survey also addresses concerns such as extra costs, job security, productivity, career advancement, health and safety risks, family and care arrangements, and overall well-being. Participants' input will help identify individual and societal needs, including the right to disconnect, financial support, and support for specific groups like women.

The analysis of the data will provide insights for policy advice on analyzing the impact of remote working arrangements on urban and rural disparities in Europe. This information will be instrumental in understanding the dynamics of remote work and its effects on different regions.

*Corresponding author: E-mail: chrysipapadimitriou@gmail.com, Tel +30 6932741552

Extended abstract

The onset of 2020, designated by the United Nations as the commencement of the 'Decade of Action' for achieving the Sustainable Development Goals (SDGs) by 2030, was significantly disrupted by the economic and societal impacts of the COVID-19 pandemic. This has notably hindered the capacity of developed nations to advance these objectives, with immediate repercussions on environmental indicators. The pandemic underscored the vulnerability of the SDGs to various global challenges. Constraints on human movement and supply chain interruptions have precipitated labor shortages in local agriculture and food sectors, leading to considerable losses and an increase in perishable food waste, particularly due to the diminished demand from closures of food service industries (impacting SDGs 6, 12, 14, 15). On a positive overview a shift towards locally-sourced production and digital services has promoted sustainable consumption practices, however demanded increase in the local agroindustries effecting climate changes, use of agrochemicals, use and/or pollution of local water resources (SDGs 11, 12, 13, 15). However, the surge in online deliveries has escalated plastic packaging waste, exacerbating municipal waste management issues. The pandemic also generated significant biomedical waste and intensified the generation of electronic waste due to a higher reliance on telecommunication devices, as remote work became more prevalent (SDGs 7, 11, 12, 13, 15). Although lockdowns led to a temporary decrease in water pollution due to reduced industrial activities, this is not a sustainable solution. The pandemic-related disruptions in waste management systems, including staff shortages and operational constraints in treatment and recycling facilities, have impeded waste processing efforts (relating to SDGs 12, 13, 14, 15). Additionally, the breakdown of plastic waste into microplastics poses a severe threat to marine life and, by extension, human health through the food chain (impacting SDGs 14, 15).

Keywords: COVID 19; environment; single use plastics; sustainability goals; wastes

1. INTRODUCTION

The purpose of the Sustainable Development Goals (SDGs) was to focus worldwide attention and unify societal efforts to monitor and enhance progress toward achieving the 169 specific targets underpinning the 17 goals. These goals exemplify various aspects of development, with the success of the SDGs based on two critical elements: sustainable economic growth and globalization. However, COVID-19 inhibited the ability of industrialized nations to support the development of others, revealing the SDGs' vulnerability to global crises. According to Naidoo and Fisher, 2020 [1], nearly two-thirds of the SDG targets were either threatened or poorly equipped to combat the pandemic's effects, and about 10% could potentially worsen in future pandemics.

The long-term economic impacts of COVID-19, which relate to factors like labor, capital stock, and productivity, as well as distributional effects, introduce uncertainties [2]. These challenges disrupt the progress of the SDGs, which can be directly or indirectly impacted. Directly affected goals include 1, 2, 3, 4, 8, 10, and 12 (Fig.1), while goals 5, 6, 7, 9, 11, 13, 14, 15 (Fig.1), and 16 are indirectly impacted due to shifts in priorities [3]. Goal 17 (Fig.1), remains crucial for reinvigorating global efforts and regaining lost momentum in advancing the SDGs post-COVID.

ISSN: 2654-0460
ISBN: 978-618-5765-02-6

Figure 1. Sustainable Development Goals - (The logos of the SDGs are sourced from www.un.org/en/sustainable-development-goals)

The COVID-19 pandemic has significantly increased the generation of biomedical waste (BMW). Items such as facial tissues, gauze, masks, oxygen masks, test tubes from nasopharyngeal swabs, cotton swabs, saline bags, disposable syringes, and needles used in treating COVID-19 patients, all were increased up to 25% on a daily basis. The existing facilities, like incinerators, are often inadequate to handle this increased volume of waste, raising the risk of hazardous waste being disposed of improperly [4,5] (SDG 14). Additionally, the health risks from mishandling infectious COVID-19 waste are particularly acute for sanitation workers in developing countries who lack access to proper safety equipment (SDG 3, 8).

The pandemic's associated restrictions have led to a global shift towards working from home, dramatically increasing the demand for electronics, such as laptops, mobile phones, and digital thermometers. A survey by Blancco and Joensuu found that 97% of companies purchased new laptops, and 77% of Americans acquired new devices to facilitate remote work [6]. This shift is expected to persist post-pandemic, as companies continue to upgrade digital technologies and home office setups, contributing to a significant rise in electronic waste (SDG 3, 11, 12).

Despite the United Nations' SDG report for 2020 predicting a 6% decrease in greenhouse gas emissions due to COVID-19, the "United in Science 2020" report noted atmospheric CO₂ levels remained above 410 ppm in the first half of 2020, with no signs of decline attributable to the pandemic. However, global fossil CO₂ emissions were estimated to have decreased by 4-7% in 2020 due to confinement policies, with a drop of 17% in April 2020 compared to 2019, though by June they had nearly returned to 2019 levels, within a 1-8% lower range [7,8]. While the reduced industrial and commercial activity during lockdowns led to a significant decrease in water pollution, this was just a temporary side effect. During the lockdown, the cutting down of certain major industrial operations significantly reduced the input of industrial effluents on surface waters. However, disruptions in waste collection services may have led to poor solid waste management, resulting in increased dumping into water bodies [8,9] (SDG 6). Although there was a temporary reduction in direct marine pollution due to decreased activity at sea [10], the pandemic increased the use of single-use plastics which has a direct effect in marine pollution. It is estimated that nearly 75% of these masks will end up in landfills or as marine litter, Oceans Asia reported finding at least 70 face masks along just a 100-meter stretch of Lantau Island's beach, with an additional 30 washed up onshore at the end of February. Moreover, the breakdown of bio/oxodegradable plastic waste will be turned into microplastics entering agricultural soils and marine ecosystems and potentially enter the human food chain [5].

2. MAIN POST COVID FACTORS AFFECTING ENVIRONMENTAL SUSTAINABILITY

2.1 Food Waste

In the post – COVID era, the goal of "Zero Hunger" (SDG 2) needs to be reconsidered in the context of interplay between the economic and environmental dimensions of food systems. This can be achieved by developing sustainable solutions that integrate the circular economy model and food waste management. Efficient policies should promote circular economy-based applications such as material and energy recovery, development of secondary products, green solutions, infrastructure development, industry interactions, and job creation, all contributing to the achievement of the SDGs. Applying circular economy principles across supply chains and production processes could also create additional economic opportunities (SDG 8). The 'Farm to Fork' strategy could be considered to speed up the transition towards sustainable food systems that aim for a neutral or positive environmental impact, help mitigate climate change, reverse biodiversity loss, and ensure food security, nutrition, public health, while preserving affordability and promoting fair trade. This transition will help governments achieve multiple SDG indicators, including SDG 2 (end hunger, malnutrition, food security, agriculture, fair trade), SDG 6 (water use efficiency, wastewater treatment), SDG 8 (economic growth; productivity, employability), SDG 12 (food loss and wastage), SDG 13 (climate change adaptation measures), and SDG 15 (forest and land degradation, loss of biodiversity, natural habitats). Additionally, food waste contributes to 8% of annual anthropogenic GHG emissions; hence, developing circular economy strategies could lead to annual savings of 1.7 billion tonnes of CO₂ [11]. Enhanced collection, redistribution, and valorization systems will further develop economic opportunities from organic materials. Valorization mechanisms such as composting, anaerobic digestion, and hydrothermal carbonization for inedible food and unavoidable food waste may facilitate resource recovery but also create job opportunities [12,13]. Repurposing waste into new products also presents substantial economic opportunities.

Establishing food banks and distribution centers plays a critical role in alleviating hunger and enhancing food security.

2.2 Biomedical Waste

The use of single use disposable items has been crucial in reducing viral transmission and controlling the spread of the virus. However, the increased demand for healthcare during the pandemic and the acceleration of vaccination drives globally have led to a significant increase in biomedical waste (BMW) generation. Addressing health issues (SDG 3) requires safe and reliable methods for the segregation and disposal of BMW due to its high infection and injury risk. Typical BMW generation is estimated about 0.5 kg per patient per day, while in developing countries is 0.2 kg per patient per day [14]. According to the World Health Organization, 85% of BMW is non-hazardous, but the remaining 15% includes potentially infectious waste [15]. These values were increased at least 25% on a daily basis during the pandemic. Improper handling and disposal of BMW can lead to soil and groundwater contamination, destruction of beneficial microbes in septic systems, and physical injuries from sharps, with these issues more prevalent in developing countries due to inadequate infrastructure [12]. During the pandemic, accessing appropriate treatment facilities and ensuring safe waste disposal are critical to managing health and environmental hazards [16]. Effective healthcare waste management can accelerate progress towards multiple UN Sustainable Development Goals, particularly SDG 3 (Good Health and Wellbeing), SDG 6 (Clean Water and Sanitation), SDG 8 (Decent Work and Economic Growth), SDG 12 (Responsible Consumption and Production), and SDG 13 (Climate Action). Minimizing waste, segregating at the source, avoiding incineration, and recycling conserve resources and energy. Organic wastes can produce methane, a potent greenhouse gas, but controlled biodigestion allows for methane capture and use as biofuel, reducing CO₂ emissions and aiding climate change mitigation. Sustainable waste management technologies like biodigestion and autoclaving can enhance healthcare system resilience (SDG 12). Developing a

Proceedings

regional network to share experiences and lessons learned can improve BMW management systems during and beyond the current pandemic.

2.3 Plastic Waste

Plastic pollution has been a considerable global environmental problem due to its pervasive presence in the environment. The COVID-19 pandemic has increased this problem, leading to an estimated generation of 1.6 million tonnes of plastic waste per day since the outbreak began [17]. Addressing plastic pollution not only reduces environmental harm but also curtails fossil fuel consumption—20% of total oil production goes into plastic manufacturing [18]. Initiatives like bioplastics derived from organic waste streams exemplify the shift toward renewable resources, reducing reliance on fossil-based plastics [19].

Recycling creates local jobs and builds regional economies. However, recycling faces technical challenges and higher costs compared to conventional waste disposal methods. Moreover, transitioning to sustainable technologies like pyrolysis, which can produce commercially valuable by-products, enhances material and energy recovery following circular economy principles [5].

Developing waste handling capacities and infrastructure, along with policies focused on material and energy recovery, and integrating the informal sector, can enhance economic activity and create jobs. Extended producer responsibility, boosting investor confidence, and encouraging responsible consumer behavior support the long-term economic sustainability of plastic recycling. The 2018 amendment to the EU directive on packaging waste promotes the recycling and reuse of packaging, facilitating a transition to a circular economy. The EU directive on single-use plastics is also advancing separate collection systems for specific waste streams like beverage bottles to improve recycling rates. While mismanagement of plastics was about 41% in 2016 and is projected to rise by 2040, integrating plastic recycling with circular economy strategies can reduce GHG emissions by 25% [20].

2.4 Electronic waste

The increasing consumption in electronic devices sector, reduced product lifespans, and limited repair options, global e-waste production was estimated to double by 2045 from a baseline of 53.6 million tonnes in 2019, equals to an average of 7.3 kg per capita [6, 21]. Additionally, the shift towards remote working increased the need for robust technical infrastructure and digital transformation, further boosting e-waste volumes due to the pandemic [6]. Given the high demand for raw materials in the production of electrical and electronic equipment, e-waste is also closely linked to SDG indicators on material footprint and domestic material consumption (SDGs 8.4.1, 12.1.1, 8.4.2, and 12.2.2). The pandemic's associated restrictions have led to a global shift towards working from home, dramatically increased the demand for electronics, which will be disposed by the end at their life cycle.

Improper disposal of e-waste poses significant health and environmental risks due to toxic substances such as hazardous additives, which are usually toxic metals. Annually, around 50 tonnes of mercury and 71,000 tonnes of plastics are released into the environment from undocumented e-waste flows, posing serious health risks to exposed workers [21] (SDG 3). E-waste management is crucial for achieving several SDGs, including decent work and economic growth (SDG 8), good health and well-being (SDG 3), clean water and sanitation (SDG 6), and protecting aquatic life (SDG 14).

3. DISCUSSION

Yuan et al. [22], calculated the combined shock loss and growth delay loss across all countries, weighted by their populations, under COVID-19's impact on global progress towards the Sustainable Development Goals (SDGs), as depicted in Fig. 2. The goal most severely impacted is SDG 1 (No Poverty), second only to SDG 9. This severe impact is primarily due to the pandemic-driven

economic lockdowns that threaten to increase extreme poverty (i.e., SDG 1.1 and 1.2) in many countries, and the interconnectedness with other goals amplifies these effects and hampers progress towards achieving SDG 1 that was previously on track. Following SDG 1, the goals of industry, innovation, and infrastructure (SDG 9); sustainable cities and communities (SDG 11); quality education (SDG 4); strong institutions (SDG 16); good health and well-being (SDG 3); and affordable and clean energy (SDG 7) are next in line in terms of impact. Notably, the impacts on SDGs 4, 7, 9, and 11 are significant.

The SDGs that were most effected have indirect effects on all the environmental SDGS due to their high degree of interconnectivity. The possitive effects that are shown in Fig.2 are just short term and profound during the lockdowns. The increase of wastes and their disposal, the exsessive amounts of single use plastics along with inadequate management practices pose a ongoing environmental threat. Moreover, the increase of industrial activiaties in order to compensate with the losses occurred during the pandemic increased the amounts of industrial effluents.

In conclusion, the overall findings indicate significant, albeit less visible, impacts on SDG development beyond the immediate effects. These results suggest that the impact of COVID-19 on global progress towards the SDGs could be substantially underestimated if both the growth delay loss and the indirect shock loss from cascading effects are not fully considered.

Figure 2. Effect of COVID-19 impacts expressed as shock loss and growth dealay on SDGs (adapted from Yuan et al., 2023).

4. CONCLUSION

The COVID-19 pandemic has significantly disrupted progress towards achieving the UN Sustainable Development Goals (SDGs). In particular, deficiencies in waste management systems, which are closely linked to various SDGs, have raised health and environmental concerns, thus drawing urgent attention from policymakers. The need for incorporating circular economy principles such as

Proceedings

recovery, recycling, repurposing, remanufacturing, refurbishing, repairing, reusing, reducing, is essential in order to accelerate SDG achievement in a post-COVID world. Furthermore, the importance of different waste components—food, plastic, biomedical, and electronic waste on the environmental SDG, is highlighted as there was a dynamic change in their quantities and management practices. These efforts could support both the public and private sectors in achieving short- and long-term SDG objectives. Although adopting circular economy-based waste management presents challenges, the study suggests that post-COVID economic recovery measures could catalyze a global shift toward its full implementation, thereby ensuring the timely achievement of the environmental SDGs.

Extended abstract

The outbreak of the pandemic in 2020 resulted in a significant increase in remote work, a trend that has continued even as conditions have improved. This shift has had far-reaching implications for living and working conditions and has further accentuated the urban-rural divide. Although remote work has become more widespread, its social implications and impact on the urban-rural divide are still not fully understood.

The R-Map project aims to investigate, predict, and propose solutions for the impact of remote work on the urban-rural divide in Europe. Through advanced research methods and collaboration with stakeholders, R-Map seeks to improve our understanding of the consequences of remote work. The project aims to accurately predict future trends using multiple data sources and advanced modelling techniques. By focusing on the spatial, economic, and social dimensions, this aims to address the ongoing challenge of bridging the urban-rural divide. It recognizes the complexity of the issue and the impact of remote work on these different aspects.

The key objectives of this project are to comprehend current trends in remote work, evaluate their social, economic, and spatial impacts, present trends clearly and concisely for decision-makers, forecast future impacts, involve stakeholders in policy discussions, and communicate research findings effectively. The methodology involves an exploratory phase that includes a literature review, the creation of a statistical model to analyse the impact of remote work on the urban-rural divide, the development of a platform for policymakers, and the examination of six case studies in Europe. The case studies are from Greece (Thessaloniki), Italy (Milan), Turkey (Istanbul), the UK (Surrey), the Netherlands-Germany (cross-border case), and Austria-Switzerland (cross-border case).

The project's expected impacts include scientific advancements in evaluating the impact of remote working arrangements, economic benefits such as improved digital infrastructure, increased digital literacy, and job opportunities, as well as social benefits such as increased flexibility for businesses and workers, improved health and well-being, and the creation of a platform for policymakers.

Abstract

The COVID-19 pandemic has triggered a significant change in urban development, legislation, and planning, bringing out unique difficulties and opportunities. Simultaneously, the transition from conventional office environments to remote work cultures has occurred in recent years, fundamentally altering the nature of collaborative work. Engineering teams, once limited by geographical closeness, now work in different locations, requiring sophisticated digital tools to collaborate effectively. However, current toolsets frequently neglect the incorporation of virtual environments and human interaction, impeding genuine creative collaboration in distant work contexts.

The paper examines the most recent studies and advancements in workplace design, specifically examining adaptive architecture and extended reality (XR) environments through virtual and augmented reality (VR and AR) technologies as transforming factors. Adaptable architecture utilizes adaptable design concepts to fit changing work settings, while XR spaces AR show potential in improving worker satisfaction and creativity as well as productivity. To ensure optimal interaction between humans and digital environments and promote effective collaboration, it is crucial to optimize office interior design and human-machine interfacing (HMI) for remote work, regardless of physical location.

Furthermore, the paper outlines the future course of office design, highlighting the significance of establishing workplaces that not only foster innovation and collaboration but also emphasize the well-being of employees. The forthcoming office will utilize advanced technologies and innovative architectural methods to create stimulating and efficient workspaces that cater to individual requirements. This will foster creativity and productivity within evolving remote work cultures.

Keywords: *remote work; Adaptive architecture; Augmented reality (AR); Collaboration*

1. INTRODUCTION

Working remotely has become an established standard all over the world. It offers many advantages, such as reducing travel and promoting a prosperous globalized society that is mindful of preserving the planet's resources and climate. It is crucial to develop a sustainable, human-centered and inclusive remote work culture that fosters creative solutions for future challenges, benefiting all industrial ecosystems and contributing to a prosperous European and worldwide society. However, the commonly used tools for collaboration among distributed teams are still heavily reliant on 2D computer screens for interaction and information presentation. While this method is suitable for decision-making, it presents a significant obstacle for co-creative collaboration, idea generation and design, as there are radically different when experienced in 2D and require proper spatial and social cues conveyance and rich channels of perception [35][36]. Therefore, teams still often have physical meetings for creative work, even though not all members can always attend, which leads to a loss of creative potential. extended reality (XR) technologies have the potential to solve this problem, enabling interaction and immersion in future online and distributed workplaces. Multimodal and flexible design of these workplaces will allow for inclusiveness and openness to all members of society, including those with handicaps limiting their physical access to the workplace.

Additionally, recent times have also seen the rise of hybrid working scenarios, where participants join remotely and physically have the same experience [37][38]. For physical participants, XR technologies can enhance the physical space and create interactive experiences by using augmented reality (AR), such as for a product demonstration. For remote participants, XR technologies can take advantage of VR to create fully immersive experiences that can be accessed from anywhere in the world, such as a virtual conference or a VR game. Hybrid working environments combined with XR technologies have the potential to transform the way we work and interact with each other, by providing more flexibility and enhancing our digital experiences in terms of creative work.

2. IMPACT OF COVID-19 ON URBAN DEVELOPMENT FOCUSING ON WORK ENVIRONMENTS

2.1 Changes in Urban Development

The COVID-19 pandemic has had a major impact on work dynamics, both at individual and urban levels. This impact is primarily due to the fast and widespread shift to remote work, exemplified by the widespread use of Zoom meetings. These implications are expected to have both short-term and long-term consequences [2]. The pandemic compelled numerous industries to swiftly adjust to remote employment, prompting inquiries on the future of urban existence after the outbreak. Traditionally, urban planning and architecture have frequently prioritized the segregation of residential and commercial areas, especially to promote better well-being in industrial settings. Nevertheless, the discipline of Urban Design should allocate greater consideration to the intricacies of professional life and urban economies. In the past, the connections between office design, work organization, and the changing characteristics of workplaces have been explored in an architectural study [3]. In addition, more recent research on creative clusters has investigated the impact of the physical surroundings on economic activities [4], highlighting the importance of semi-public and public areas in contemporary work practices [5].

Considering these alterations, it is imperative to incorporate a wide range of productive and commercial endeavors inside metropolitan environments. This encompasses providing assistance to dynamic and rising sectors, such as technology, creative industries, and traditional manufacturing. To do this, it is crucial to have urban designs and architectural styles that can easily adjust to different activities, efficiently controlling the movement of commodities and individuals as well as seamlessly incorporating them with residential and other purposes. Further exploration is required in urban design research to examine the spatial functions of various productive activities [2]. Furthermore, there is a notable potential to create the physical surroundings in a manner that encourages industries which support both health and sustainability, such as green economy and circular economies, while simultaneously tackling disparities in work-related health. Urban construction in the future ought to focus on the quality of work the surroundings, guaranteeing access to green spaces and social facilities while also accommodating various commute patterns as work expands outside traditional office locations to include homes and public areas [2].

2.2 Opportunities and Challenges Presented by the Pandemic

The Covid-19 pandemic has accelerated emergent working practices and changes in work organization, presenting several challenges. Work is no longer confined to traditional office spaces but is extending into homes, semi-public spaces, public spaces, mobile environments like public transportation and ultimately in the autonomous driving car creating a need for new workspace typologies that integrate work with other purposes [1]. This shift necessitates the careful design of housing to accommodate homeworking, along with the articulation between workspaces and open spaces to support diverse commuting patterns. The demise and delocalization of offices are leading to more diffuse patterns of work locations, pushing work into residential areas [2]. This requires a rethinking of the role of offices and the mix of activities and services in residential areas to support

home and flexible working, as well as social needs like co-working spaces. The decreasing demand for traditional office space has significant implications for the future of business clusters, offering opportunities for creative reuse of freed-up built spaces [2]. The design of quality working environments must consider the wider neighborhood, ensuring access to open and green spaces, social amenities, and physical activities.

Data from the European Trade Union Institute (ETUI) in the 2023 issue of *Benchmarking Working Europe* [6] shows a significant increase in homeworking, with 24% of EU workers working from home at least sometimes in 2021, up from 12% in 2012. This trend is even more pronounced in some countries, such as the Netherlands, where 54% of workers teleworked at least partially in 2021. The growing preference for remote and hybrid work is influencing job vacancies and openings, with many employers offering flexible work arrangements to attract applicants [8]. However, these new working patterns also present challenges, such as job intensification and the blurring of work and personal time during homeworking days. Additionally, the increased managerial oversight and remote surveillance to monitor productivity can spill over into greater managerial control during office days. The blurring of home and office work lines has important implications for employers, who are now more regularly confronted with personal wellbeing concerns of their employees. Employers who fail to address these novel requests may face issues like "quiet quitting" or even the "great resignation," as employees seek better work-life balance and job satisfaction in the post-pandemic era [7].

2.3 Remote Work – Flexibility (Locally and with Respect to Time) – Positive Impact on Climate

The Flexible Office concept, which combines technical and organizational components, has significant potential not only to positively impact climate change by also promoting remote work flexibility [9]. Organizationally, it involves selecting suitable employees, designing adaptable office spaces, and defining roles and rules. This process includes ensuring employee willingness to participate through meetings that communicate the benefits and address any prejudices or fears. Technically, it requires equipping employees with mobile phones, laptops with mobile network access, remote access solutions, and virtual private networks. This setup allows employees to work effectively from home or customer offices, reducing the need for daily commuting and thus lowering carbon emissions from transportation [9].

While remote work's decoupling from traditional office spaces is transformative, it also brings about several positive environmental impacts. The reduction in commuting time directly decreases road traffic and pollution, aligning with early proponents' visions of telework as an eco-friendly solution. However, the overall environmental footprint of remote work remains complex, as it involves additional energy consumption for home heating, electricity, and IT equipment [10]. Despite these factors, the shift towards remote work can significantly reduce the urban carbon footprint by transforming consumption patterns and lifestyles, potentially leading to greener suburban and city center environments. By carefully managing the technological and organizational aspects of remote work, companies can enhance their sustainability efforts while maintaining productivity and employee satisfaction [9].

3. TRANSITION TO REMOTE WORK CULTURES

3.1 Evolution from Conventional Office Environments

Emerging trends within society have been shifting how we as humans work and adapt to new environmental scenarios through the quick integration of effective solutions to new human needs within a socio-economic context. Within the scope of work environments, globalization, digitalization, and evolving socio-economic needs have shifted how we achieve our tasks towards a remote work culture. In 2020 COVID-19 acted as a catalyst by forcing many organizations to adapt to remote work rapidly and reevaluate their processes to ensure safety for their workers [11]. Organizations have shifted how they operate as decision makers in the pursuit of new viable ways to

overcome bottlenecks produced due to the lack of physical available presence. Moreover, the pandemic brought to light the importance of considering vulnerabilities due to an outbreak and it now proposes a new layer for engineers and architects to consider when developing new spaces and products [12]. Infrastructures now need to ensure a proper environment to prevent the endangerment of their workers against the impact of possibly arising diseases without damaging creative or precise processes.

Enabling a remote work culture has become an established standard all over the world. It offers many advantages, such as reducing travel and promoting a prosperous globalized society that is mindful of preserving the planet's resources and climate. As organizations continuously adapt to current and new paradigms it is crucial to persevere in the exploration of creative environments, which break with conventional paths of reasoning – thereby facilitating the benefits of remote work while mitigating its drawbacks and ensuring a sustainable and productive environment for employees within an organization [13].

3.2 Impact on Collaborative Work Dynamics

In the workplace of the future, innovations shall be collaboratively created with increased dynamism and sustainability. People shall be able to work creatively, exchange ideas, and socialize in a subject-specific manner. To this end, compatibility with a global remote work culture is paramount. Yet the focus on exploring technology is not sufficient to ensure the practical relevance and diffusion of an innovation. Incorporating IT applications, such as collaboration systems, into core business strategies is becoming essential not only for transforming businesses but also for generating new business models. The key to sustained competitive advantage lies in leveraging high-level knowledge and dynamic capabilities to continuously innovate and maximize the use of tools, which aid collaborative work dynamics [14].

It is essential for engineers, designers, and architects to keep a holistic approach to find viable solutions, which cover the interaction needs presented during joint activities. Moreover, organizations require awareness of their limitations since they can redirect ideas towards noble solutions while following a human centered approach – thereby, leading to innovative solutions [15]. Therefore, allowing new layers of problem understanding to guide the improvement of collaboration dynamics within a work context is required. By incorporating collaborative dynamics, specific collaboration elements such as principled engagement and shared motivation can enhance systems change, equity, and sustainability. These dynamics interact to create causal chains that lead to improved collaborative outcomes, which consequently impacts the qualitative and creative outcomes of an organization [16].

3.3 Digital Tools for Remote Collaboration

One way to define a work collaboration is as the mutual work and communication between two or more people with the common goal to solve task-based problems. In the past, we have had the opportunity to collaborate through auditory communication and solve limited task-based problems, such as information communication and planification. However, with emerging technologies as enablers, we have opened the doors to transcend work through innovative solutions to inefficient problem-solving strategies[17]. This creative mentality has broken the barrier, not only to emulate office related environments, such as a collaborative whiteboard system [18] or the mutual creation of presentations [19], but it has also allowed designers to manipulate space through virtual realism. Thereby expanding the range of exploration towards an effective implementation of digital tools, which allow to explore, create, inform, and evaluate as well as to collaboratively envision new ways to transcend and increase the efficiency of the existing digital solutions.

Virtual work environments that enable new forms of communication and multimodal design can be examined through an active spatial exploration that looks at the future of work and situates it within a technologically enabled ecology of interfacing. Spaces such as an interface need to be defined

through the situated vs. virtual interaction context workers will face. Therefore, in the pursuit of hybrid space development, designers need to explore planes of work dynamics that can be understood through degrees of presence. This leads to a perspective shift on the concept of work itself: it will shift towards situated and virtual environments, which enable an exploration on the context of space through interaction scenarios that are experience-rich, time-based, and environmentally modelled.

However, we need to understand current limitations which can result in a lack of virtual environment integration. Current limitations to take into consideration are:

1. **Limited collaboration capabilities:** Remote or hybrid teams often face challenges in collaborating effectively due to limited social cues, emotion conveyance, and interaction tools. Videoconferencing puts participants on a screen, which leads to a narrower cognitive focus and hence cognitive cost for idea generation. On a personal level, there are limitations due to missing channels of perception. This can restrict creativity and problem-solving abilities. [20,21]
2. **Lack of physical presence:** Teams working on physical products may face challenges in visualizing and understanding the physical characteristics of the product, especially when working remotely. [13]
3. **Reduced engagement and motivation:** Remote or hybrid teams may face challenges in maintaining engagement and motivation levels, which can impact creativity and productivity. [13, 21]
4. **More pronounced inequalities among user groups:** studies show that remote and hybrid teams face inequalities based on factors such as education, age, gender, occupation, and income. [15, 20]
5. To overcome these limitations and innovate how we achieve work within society, designers require to leverage state-of-the-art technologies, including VR, AR, and MR environments – thereby enabling immersive and interactive environments for remote teams. These technologies allow teams to collaborate in a shared virtual space, where they can visualize and interact with physical products or cybernetic systems, thereby improving their understanding and problem-solving capabilities.

3.4 Human Interaction Deficits in Digital Workspaces

Human interaction deficits pose a significant challenge in digital workspaces. Despite the facilitation of functional communication through digital tools, these often fail to replicate the depth of human connection formed through in-person interactions. This deficit can lead to negative mental states among remote workers, fostering feelings of isolation and disconnection, which in turn affect job satisfaction and productivity [22]. Additionally, the frequent use of remote work environments reduces spontaneous, informal interactions, such as hallway conversations and lunch breaks, which aid creativity and innovation.

To address these challenges, the development of digital workspace environments must prioritize fostering social interaction and community-building [22]. This involves creating digital platforms that encourage informal communication and the development of relationships among remote workers. To develop new solutions to current limitations, designers require considering holistic procedures to achieve sustainable, human-centered, and inclusive remote work cultures, which foster creative solutions for future challenges, benefiting all industrial ecosystems, including large industries as well as small and medium-sized enterprises [13]. However, the commonly used tools for collaboration among distributed teams are still heavily reliant on 2D computer screens for interaction and information presentation. While this method is suitable for decision-making, it presents a significant obstacle for co-creative collaboration, idea generation, and design. These activities are inherently different when experienced in 2D and require the conveyance of proper spatial and social cues, as well as rich channels of perception.

While digital workspaces offer numerous advantages, addressing human interaction deficits is critical for maintaining employee well-being and fostering creativity and innovation. There are six individual factors, which serve as moderators for negative effects of interaction deficit: personality, age, gender, work and technology presences, computer self-efficiency, mindfulness [22]. It is the responsibility of the organization to integrate these factors within the design of new solutions to guarantee noble results. By developing more immersive digital tools and adopting organizational practices that emphasize regular, meaningful communication, remote work environments can become more effective and supportive of their workforce.

3.5 Overview of Emerging Digital Toolsets for 3D Representation and Engineering

The range of digital tools has expanded towards all megatrends within a society. To review how VR and AR as well as any combination of it (MR) are used in a physical environment, e.g. the future office, it is important to explicitly fulfill remote collaboration on physical tasks [20]. The use of a head worn AR display and camera can allow a remote expert to give feedback, while the integration of AR technology enables them in real-time to almost seamlessly merge and interact with virtual and physical objects. This collective operation between real and computer-generated virtual environments is one example of many emerging solutions, which digitally increase the range of dynamics for their application [20].

However, these tools often have technical limitations, such as bandwidth constraints or technological immaturity, that can impede teams' effectiveness [13]. One significant challenge is the absence of natural 3D representations of real humans and the difficulty in naturally manipulating virtual 3D objects. In hybrid environments, achieving a seamless integration of physical and virtual elements can be problematic. For instance, in virtual meetings, accurately displaying participants as 3D representations that mirror their physical appearance remains a complex task. Additionally, challenges such as balancing task-specific productivity with creativity and learning, navigating uncertainty, and the lack of support in decision-making processes are still present in multiple areas of the industry [13].

To address the previously mentioned challenges, various exemplary solutions and toolsets have been developed across the industry:

1. **Apple Vision pro:** An advanced AR headset that enhances remote collaboration through immersive experiences with lifelike 3D visualizations and interactive environments. [23]
2. **Meta AI and Meta Quest 2:** Meta's AI-powered tools and VR headsets enable natural and intuitive interactions in virtual spaces, boosting collaboration and engagement in remote work scenarios. [24]
3. **Nvidia Omniverse Platform:** A collaborative platform that facilitates real-time teamwork among designers and engineers on intricate 3D simulations and digital twins, seamlessly integrating physical and virtual processes. [25]
4. **Eve - Cloud Simulation Platform:** Cloud-based platform built on open-source components, which allows for easy development of different simulation scenarios to enable iterative development and testing of products. [26]
5. **Tronis[®] & GenVis[®] - Immersive Adaptive Virtual Workspace:** A toolset as basis for creating an immersive adaptive virtual workspace which allows for multi-user interfacing. A product can be placed directly in its virtual operational environment. The tool shall be enhanced by distinct virtualized 2D interaction surfaces leveraging the co-creative potential of teams. [27]
6. **Collaborative Telepresence Tool:** Collaborative telepresence tool to enable real-time communication and information exchange between remote teleworkers and physical workers. The tool will provide near-real spatial awareness by incorporating a highly advanced stereographic camera and surround microphones that provide an accurate and detailed representation of the

physical environment. The robot will be controlled remotely through the 5G network using a Meta Quest 2 headset. [28]

7. **CoVR Platform:** CoVR, a flexible, secure, multi-layer, client-agnostic protocol and software platform for local and remote collaborative MR. To meet data security requirements of most industrial use cases, the server layer is strictly separated from the data provider layer which handles the actual contents of the MR environment (e.g., CAD models) in which users are collaborating. [29]
8. The current body of tools available either targets a specific use case or serves as an aid tool to facilitate targeted tool development. However, it is necessary to intentionally direct the future innovation of workspace environment through distinct lenses of design. Although innovation can be methodologically viewed under three scopes (feasibility, viability, and desirability) [30], it is necessary to keep a holistic consideration of different scopes, which commonly affect connected megatrends within a society.

4. INNOVATIONS IN WORKPLACE AND FUTURE DIRECTIONS IN OFFICE DESIGN

4.1 Technology: Emerging Trends and Technologies - Simulation, Virtual Reality (VR), Augmented Reality (AR) Environments, Mixed Reality (XR), Visual and Interactive Haptic Surfaces, AI.

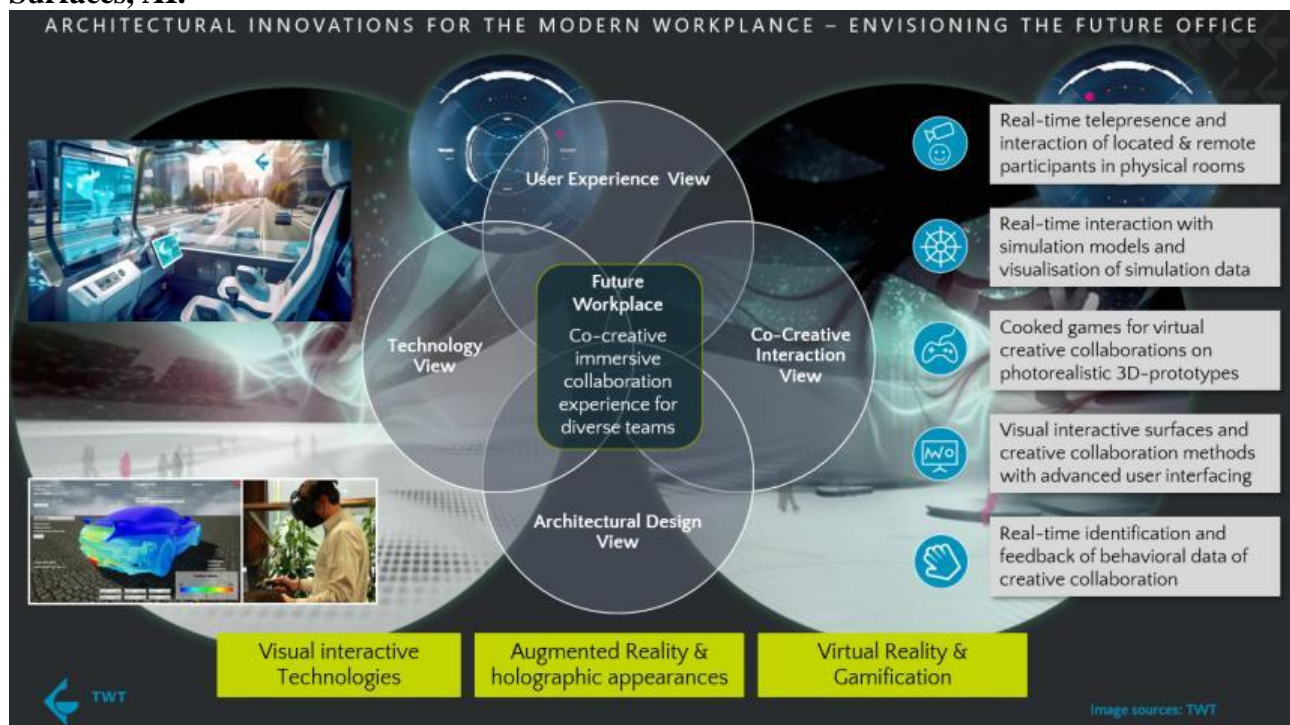

Figure 1. Overview of the four interrelated views, which are to be examined in the paper, i.e. Technology, User Experience, Social Interaction Experience and architecture design. In green color the extending reality technologies to be explored.

The first perspective revolves around technology, specifically AR and VR devices that utilize interactive surfaces and create holographic representations in real-world environments. Virtual places can be created to closely resemble real environments using advanced technologies and game design techniques, allowing for interactive and immersive experiences. Virtual worlds can be accessed remotely and may incorporate three-dimensional items and avatars that can manifest as holograms in actual areas. Actual individuals or critical communication attributes such as facial expressions may

Proceedings

ISBN: 978-618-5765-02-6

be depicted as avatars within virtuality. These technologies aim to create a smooth and immersive experience of AR and VR technologies by developing, improving, and implementing them. The current technologies must be examined to see how they might be improved in terms of presenting information, enhancing user and social engagement, and increasing the complexity of architectural design to foster creativity. Innovative algorithms are also required to develop adjustable virtual 3D photorealistic items for AR, holographic appearances, VR avatars, and VR spaces. These algorithms compute the creative state of the user and the team based on inputs from implanted sensors [29]. To achieve this objective, it is crucial to investigate the capabilities of artificial intelligence algorithms. Additionally, recent times have also seen the rise of hybrid working scenarios, where participants join remotely as well physically and while needing to have the same experience to successfully and equally work together. For physical participants, XR technologies can enhance the physical space and create interactive experiences, e.g. by using AR technologies for product demonstrations. For remote participants, XR technologies can take advantage of VR to create fully immersive experiences that can be accessed from anywhere in the world, such as virtual conferences or VR games. Hybrid working environments combined with XR technologies have the potential to transform the way we work and interact with each other by providing more flexibility and enhancing our digital experiences in terms of creative work.

Collaborative technologies will enhance the use of XR technology for creative collaboration in engineering design, professional training, and innovative product strategy with a focus on an immersive user experience. When designing creative collaborative workspaces, it might at first be helpful focus on two of the critical high-tech sectors in Europe - automotive and robotics - which require innovative and sustainable product developments that enable distributed teams to creatively work together at a distance. These sectors tend to be especially open to innovative technologies. Afterwards, the concepts can be adapted to other industries. It is essential that the multimodal and flexible design of the designed workplaces allows for inclusiveness and openness to more members of society, intersectional with gender, age, ethnicity or education.

4.2 User Experience: Role in Enhancing Workspaces, Potential Benefits for Worker Satisfaction and Productivity

From a user experience perspective, enhancing workspaces focuses on the user's interaction with technology in a creative approach, determining the most effective method of conveying information to foster creative output. It is crucial to recognize that not all technical solutions are universally applicable across different requirements and industries. To boost creativity and user acceptance, it is crucial to systematically integrate human considerations into technological innovation. This approach involves a comprehensive analysis of both individual and collaborative experiences, accounting for diverse team characteristics such as technological affinity, gender, age, origin, and cultural background. By doing so, the aim is to understand the effects arising from these variables and their combinations, offering a unique opportunity for personal growth and learning.

To achieve these objectives, an agile participatory co-creation method should be implemented by involving adaptable user groups and both homogeneous and heterogeneous teams from the outset of the development process. This user engagement follows a funnel methodology, starting with a broad investigation into existing knowledge of innovation processes in various sectors. It is supplemented by qualitative interviews with research and development (R&D) personnel about their experiences with online innovation processes and enhancement needs. Diversity in gender, age, origin, and disciplinary background is emphasized during the interview partner selection process. In generating technological concepts and prototypes, the mobility, energy, and architectural sectors should be prioritized, involving users at every stage. After establishing procedures and prerequisites for R&D collaborations in these sectors, case studies are to be conducted for deeper user involvement, testing early prototypes, and observing the real-world usage. Users from other industries will be regularly

involved at crucial development stages to provide feedback on mockups, early prototypes, persona workshops, and final prototype evaluations, ensuring the technology concepts and prototypes are refined for broader application.

Creating genuine breakthroughs requires collaboration among individuals from diverse knowledge domains and backgrounds, utilizing well-curated information sets and digital tools. The optimal level of creativity is achieved when individuals or teams face a balanced challenge that is not too easy to be unengaging, nor too difficult to be overwhelming. Additionally, immediate well-being and the ability to transition between states of creativity, relaxation, or leisure are significant for maintaining high productivity and satisfaction. This holistic approach ensures that it not only enhances productivity and innovation but also contributes positively to overall worker satisfaction and well-being, providing a secure and confident environment for innovation.

4.3 Social Interaction Experience

The third view is a more detailed look into the social interaction experience view which is about bringing together more than one user to work creatively. One of the most important questions is how to represent remote users in the physical representation of the workspace to collaborate effectively and efficiently while creating a realistic and immersive feeling for all involved users during interactions. Apart from real time communication, the interaction shall appeal to all senses with respect to cognition possibly in terms of audio-visual, haptic, and olfactory aspects and allow all users to feel like equals independent on whether they joined the meeting physically or remotely.

4.4 Architecture Design: Adaptive Architecture, Definition and Principles

The fourth view is the architecture design view. Creativity is profoundly influenced by the environment in which it happens. Therefore, behavioral design in terms of architecture will consequently be applied and creative ergonomic working in an environment that promotes creativity will be researched. As in architecture, we are trying to transit from one digital space or tool to another. Using the Voronoi method, we connect rooms with each other not just through a single point but through a surface (Figure 2). This method gives us the opportunity to identify and create smaller spaces through the system and to design transitions that are important to provide the right information, timing, and experience for the users. This system adapts for everyone individually and can always be transformed and reconfigured. The bubbles represent different actions, spaces, and tools that can be used in the digital creative workspace. At the same time, a specific topic can occur in different profiles, but the size of the bubbles defines the use, the importance, but also the involvement of users. As the bubbles burst, they create space for new ones, leading to a completely new system and organization. To be able to design a system like this, it is important to use the right tools and explore different technologies like artificial intelligence.

The four interrelated views are applied to case studies of creative work from different fields of industry branches and societal contexts. For the industry branches, the focus is on the automotive industry as well as the energy, the architecture, and construction sector. The aim is to get both a large variety in peoples' backgrounds as well as different types of creative work and being ultimately able to transfer these results to a large variety of different industries or societal contexts.

Figure 2. Representation of different spaces / rooms using the Voronoi method. From left to right different user profiles may be associated with the different spatial formations. This idea of spatial design serves as one of the basic concepts exploring the architecture design view

5. CASE STUDIES

To further explore as well as show promising implementations of innovations for the future office to enhance creativity, productivity, and well-being, we are describing specific case studies of work experience. To this end, we are bringing together the crucial inter-related aspects in designing the future workplace, i.e. architectural design of physical and virtual spaces, virtual and digital technologies in terms of immersive XR experiences, and interactive surfaces, user-experience, and social interaction as well as collaboration. We are staging these aspects in three case studies in which the company *TWT GmbH Science & Innovation* together with its international scientific partners is successfully pushing digital transformation and virtual product development for the research and development departments of global automotive players such as Mercedes-Benz, Porsche, BMW, Audi, and Daimler Truck for more than 35 years. This puts TWT in an excellent position in exploring relevant specific work scenarios for developers of high-tech products, systems, and components in terms of the needs and conditions for being creative, productive, and collaborative on a global scale. The following three case studies will be presented:

- a. Product engineering conducted by a world-wide distributed engineering team
- b. Expert training on virtual prototypes
- c. Mobile work in an autonomously driving vehicle

In our exploration of the different case studies, we are aiming for giving a framework for elaborated research and development programs on future offices especially in terms of consequently bringing together the potentials of immersive VR and AR technologies and the need for well-designed physical spaces.

5.1 Product Engineering Conducted by a World-wide Distributed Engineering Team

We assume a globally developing and operating commercial vehicle manufacturer. The vehicle platforms to be developed are designated for European, North American, and Asian markets fulfilling the specific needs of customers locally as well as on a global scale. The commercial vehicle manufacturer runs research and development sites in metropolitan areas in Europe, North America, and Asia. The engineers shall be enabled to co-creatively optimize the vehicle characteristics, e.g. aerodynamics, weight, installation space, thermal aspects, fuel efficiency, and sustainability using computer aided design technologies and simulation. While optimizing the products, systems, and components for every market the engineering teams shall seek for commonality on a global scale. For this scenario the future office space shall be envisioned for an engineering team with two experts on each site in Europe, North America, and Asia. To get the best co-creative engineering results, it is very important that every team member is enabled to engage optimally for providing ideas. Therefore, the best situation would be if this team of engineers meets in one room directly interacting with each other as well as with the component they want to optimize. They shall be enabled to place the component of interest literally in the center to visualize as well as directly adapt certain aspects in terms of optimizing the characteristics of it. Furthermore, it is very important that the engineering team is enabled to generate, enhance, reengineer, or redesign the component of interest iteratively while visualizing the respective results in real-time. Therefore, what is needed is an elaborate virtual representation of the component in 3D which can be interacted with equally by every engineer at every site through VR techniques. The engineers shall be able to immerse into this 3D-environment interacting with the component and with each other at the same time. To this end, gaming engines as well as interaction concepts from multiuser computer games are very promising solution candidates.

In terms of architectural aspects for this scenario, a standardized physical space at every research and development site, one in the European, one in the North American, and one in the Asian metropolitan area is needed. The standardization needs to be given both with respect to physical dimensions and with respect to technical installation. We envision such VR hubs as a must in modern workplaces.

5.2 Expert Training on Virtual Prototypes

Good training experience, both on individual and on team level, depends on engagement between the participants as well as with the topic to be learned. To this end, the immersive co-creative experience which comes along with different modes of XR is unprecedented.

When taking training and XR into consideration, three use cases come to mind: 1. training users to handle XR technology; 2. using XR technology to train experts, 3. using XR to train safety and health topics, and 4. using XR to familiarize potential users with new topics and tools.

1. Training to use XR: With any new technology and tool, there needs to be an introduction for the users. Thus, the first use case to explore and work on is the training and onboarding of all users who will be working with immersive XR technology. The training program can be conducted remotely, using an interactive XR simulation to teach trainees the technical skills and best practices for using XR tools. Trainees can be given hands-on assignments and challenges to develop their skills and apply their knowledge to real-world problems. Moreover, artificial intelligence or adaptive learning can be used to create optimal user experience and learning.

2. Using XR to train experts: Imagine an engineer who is new to a specific topic of optimizing certain physical properties of a component or a whole vehicle and therefore will need training on complex industrial systems. In this scenario, XR technology will enable engineers to remotely access and interact with a virtual representation of the component or vehicle, allowing them to learn how to diagnose and optimize issues without having to physically be on-site. This is particularly useful for companies with facilities spread across multiple locations, as it would eliminate the need to send trainees on long, expensive trips for training. In group settings, remote training utilizing XR technology can include elements of social interaction and collaboration, enabling workers to communicate and work together as a team despite being in different locations. This can help to foster a sense of connectedness and promote the wellbeing of trainees, which is important for employees who may feel isolated or disconnected due to remote work arrangements.

3. Using XR to train safety and health: To ensure safety and worker wellbeing, the virtual training environment should be designed to simulate real-world conditions and potential hazards, allowing trainees to practice their skills in a controlled, risk-free environment. XR technology can also provide real-time feedback and guidance to trainees during the training sessions, helping them to develop their skills and identify areas for improvement. For example, if trainees were learning how to operate a large robotic arm, the XR environment would simulate the arm's movements and behavior, as well as any safety protocols that need to be followed when working around it. Further, risky scenarios can be experienced without risking the health and well-being of the trainees. Additionally, the XR training would be structured to promote trainees wellbeing by minimizing the physical and emotional strain of traditional training methods: Trainees would be able to access the XR environment from their own homes or a designated training facility, rather than having to travel to a remote location. The immersive and interactive nature of the XR training would also help to keep trainees engaged and motivated, reducing the risk of burnout or disengagement.

4. Using XR to familiarizing: Another use case for remote training scenarios in the robotics/automotive field utilizing XR for immersive co-creative experiences could be in the training and showcasing of new manufacturing processes and technologies to stakeholders who are not specialists in the field. For example, a robotics company may want to train their sales team on the new features of their latest robot model, but they may also want to showcase these features to potential customers who are not familiar with robotics. To accomplish this, they could create a remote training

scenario using XR technology that allows different stakeholders to participate in an immersive co-creative experience. In this scenario, the sales team and customers could join a virtual environment where they would be able to interact with the robot in real-time. The XR technology would allow them to explore the robot's features and capabilities in a way that feels as if they were physically present with the robot. They could also receive guided training from the company's robotics experts on how to operate and maintain the robot. During this immersive experience, the sales team and customers could work together to decide on the type of robot and its features needed to meet the customer's specific needs. This would allow the customer to see firsthand how the robot could be used to improve their manufacturing processes and ultimately increase their bottom line.

5.3 Mobile Work in Autonomously Driving Vehicles

As the automation of vehicles progresses, they are becoming increasingly interesting as workspaces. Viewing automated vehicles as work environments opens new possibilities on designing the interior and using innovative technology. In the following section, a description of the methodological approach along the defined views of technology, user experience, co-creative interaction, and behavioral design in future car offices will be presented.

MoHAFe is a research project which focusses on Mobile Hybrid Working in Automated Vehicles [33]. The project started in 2023, is funded by the Ministry of Economics, Labor, and Tourism Baden-Württemberg/Germany and is realized by TWT GmbH Science & Innovation, who has strategic partnerships in terms R&D with automotive premium OEMs (Mercedes-Benz, Porsche, Audi, BMW) since more than 35 years, in cooperation with Fraunhofer Institute for Industrial Engineering, which is contributing both scientific and R&D expertise in the aforementioned areas. The aim of MoHAFe is to research and demonstrate hybrid working in cars with SAE automation levels 3 to 4 [34], which will become even more attractive and more frequently applicable as a result of the planned new EU regulation that allows automated driving at speeds of up to 130 km/h [32]. The technical and organizational goal is to use the car as a workplace and to adapt to the developments towards sustainable mobile work promoted by the Covid pandemic. Use cases have been developed which address work scenarios for one or more people in the vehicle, including training tasks and collaboration with remote users who are each involved in one or more tasks. Further, personas have been created based on research and surveys conducted to define the possible range of future users. Different innovative technologies were analyzed, and VR and AR technologies are used as required, with a special focus on user needs in terms of a positive overall experience. Within the scope of the project, both a virtual as well as a physical prototype will be developed. By developing the virtual prototype of a future car office using the simulation tool Tronis®, TWT GmbH is expanding its expertise as an innovation provider in the mobility sector in order to make innovative progress in the further development of the vehicle within the automotive and supplier industry in Baden-Württemberg/Germany. Through Tronis®'s VR interface the future car office can later be experienced in XR scenarios and further be discussed and adapted in creative XR meeting environments.

In 2023, at the world's biggest tech fair, the Consumer Electronics Show (CES) in Las Vegas, the BMW Group presented its new vision vehicle for the first time. This vision vehicle enables a completely new kind of interaction and communication between humans and vehicles. [31] This example illustrates the potential for innovative and interactive designs in automated vehicles, aligning with the objectives of the MoHAFe project to transform cars into dynamic work environments.

6. CONCLUSION

Creativity is about generating new ideas, concepts, or products based on a given body of knowledge. The body of knowledge of society, economy, and manufacturing industry may be different, but it is getting more and more complex and versatile for all spheres where creative work happens. To this end, creative work producing true innovations is about bringing together people from different knowledge disciplines and backgrounds to work collaboratively to be supported by adequately composed sets of information as well as digital tools. The most effective and efficient amount of creativity of the individual or a team evolves at the threshold of being underchallenged to being overwhelmed with the problems to be solved. Moreover, immediate well-being and the possibility to change and adopt new perspectives or even switch from a state of being creative into a state of recreation or leisure is of paramount importance. Therefore, office spaces as well as workspaces in general need to be designed in a way that allows for these effects to happen. As hybrid and virtual teams become a standard in many industries, workspaces need to adapt to these new conditions. XR environments enable a variety of work scenarios, including training opportunities. In addition, innovations are expanding the spaces in which work is possible and must therefore also be considered, such as autonomous vehicles.

Extended abstract

Throughout the past decades, large metropolitan areas have been extensively equipped with advanced digital infrastructures, while rural towns have often been left behind. In the Italian contexts, for example, the lack of infrastructural investments combined with an aging population and migration trends of economically active people are some of the most tangible effects of a long-lasting depopulation problem.

As a result of the recent COVID-19-induced digital transformations, such as online learning and remote working, an interdisciplinary academic investigation at the intersection of city planning, digital technologies, and cultural heritage preservation is particularly relevant to examine the development trajectories of small towns in Italy. On the one hand, this research aims to understand how digital technologies can help us monitor at a granular level the shrinking towns of Italy. On the other hand, it aims to understand how digitization can offer new development opportunities while leveraging small towns' heritage and local productions.

Firstly, our research team employed a series of large spatial datasets to visualize the rich complexity of the Italian countryside in geographic information systems from two angles of inquiry: digital access and cultural heritage. Secondly, proposals for digital platforms supporting better conservation and use of local cultural heritage and products were developed. Thirdly, a series of data-informed and spatially relevant policy recommendations were elaborated, accompanied by design guidelines on how to foster collaborative workspaces in inner areas.

We believe that digitization can be a powerful force for change – as long as it is adapted to the rural context and implemented with the involvement of local communities themselves. Various stakeholders have been involved in the research development, such as regional and municipal authorities and small business owners, in order to better understand the problems to face and address them.

The research project is the result of a collaboration between Massachusetts Institute of Technology (MIT) and Politecnico di Milano (PoliMi) faculty members and students who integrated computational and visualization skills with regional planning frameworks in the Italian Alps and Sicily.

**CITIES' CULTURAL HERITAGE MANAGEMENT IN TIMES OF
CLIMATE CHANGE**

Changing Cities VI, Rhodes, 24 - 28 June 2024

Organized and chaired by Prof. Nikolaos Samaras

Prof. Nikolaos Samaras, Department of Planning and Regional Development, University of Thessaly,
Greece

Cities' cultural heritage management in times of climate change. The contribution of the conservation of the built heritage of Historic Center of cities in the direction of using the climate factor in planning. Case study: Larissa, Greece.

N. Samaras

Department of Planning and Regional Development, University of Thessaly

Corresponding author: E-mail: nxsamaras@uth.gr Tel +30 6987151068

Extended abstract

Although cultural and urban environments are seen separated from the natural environment in planning and development by local authorities and governments, a transdisciplinary approach to cultural heritage seems to be necessary, at least could be an alternative, nowadays, when we are facing serious global risks, with climate change being the main one with climate change being the main one. This view must include important dimensions of intangible heritage, such as practices, knowledge, skills that communities, groups, and individuals recognize as part of their cultural heritage, transmitted from generation to generation, in response to their environment, their interaction with nature and their history. In this framework, knowledge, skills, and practices concerning climate, been applied traditionally, could become an object of safeguarding, aided by the existence of old buildings, as records of the historical continuation of the city and the successful management of the climatic factor, as well.

As climate change is expected to increase the frequency and duration of severe heat stress events, there are studies examining the relationship between urban geometry and microclimate within a city center, particularly through the 'heat island' and 'urban canyon' effects. Built heritage conservation, in a historic center, contributes to local sustainable development both by preserving the historical character and by keeping the urban geometry. Trying to turn the threat to opportunity, the climatic factor can be seen as the privileged field of interrelationship between the natural, urban and cultural environment of a city. This cannot be ignored in the pursuit of sustainable development by cities like Larissa, where the most negative aspect of its climate -high temperatures occurring during summer- makes it unattractive for residents, visitors or investors.

Abstract

Lake Karla, a natural lake that dried up by human factor and as is turned out for the wrong purposes, restored in the decade of 2000 bringing a message of hope to the area where it is located. With a not entirely clear coastline in the past, the future lake restoration was a broad term used for different techniques aiming to bring a lake back to or closer to anthropogenically undisturbed conditions. In various ways it can be offered as a tourist destination with great development potential through the alternative form of tourism, ecotourism.

In addition to the potential and capabilities of the area, is examined walking tourism as a form of activity next to the lake with variety of stops and points with cultural interest, animal and bird watching and connection with wild flora.

After the European windstorm and later medicane hit Thessaly (Daniel and Elias), witch after turned into category one hurricane, caused catastrophic damage all over the region. The environmental footprint was huge and brought uncertainty about the future.

Keywords: ecotourism, coastal tourism, cultural tourism, impacts of extreme weather conditions.

1. INTRODUCTION

In Greece, Lake Karla, examined as a case study in this paper, until the year 1962, was a natural lake known by the ancient times by the name of Boibeis (Ancient Greek: Βοιβηϊς, modern transliteration Voivis) and considered an important ecosystem of the Mediterranean region, acting as a natural reservoir that provides water storage and recharges groundwater [1].

The need for flood protection and more agricultural land led to the drying up of the lake. As a result, the area of the lake has decreased and the wetland has been degraded creating a series of environmental problems such as groundwater depletion, groundwater pollution, floods, extreme weather events, etc. In the year 1981 a final decision to restore part of the former lake was taken by the Greek government and today the reservoir and its complementary works have been built [2].

The new lake is an artificial reservoir located in the same 50 point where the oldest natural lake was located and received the designation of vital water ecosystem. It is a Natura and Ramsar site that diverts water from Pinios, protects the surrounding plains from flooding, helps to irrigate the crops grown in the surrounding areas, while part of the city of Volos is watered from it or at least it was watering before storms hit the area on September 2023 [3,4].

The local population was forced to change their profession twice since they were always engaged in fishing while after the drying of the lake they were forced to engage in agriculture. In the year 1962, when the lake was drained, 60,000 acres of land became available for cultivation, which fueled the residents with hope that their lives would improve, but they received neither title deeds nor any related compensation or financial support [5], a fact that that when in the middle of 2000 it was decided by the state to reconstitute it, the relevant legislation now compels the former fishermen who were forced to become farmers, to leave their fields and not to sow their properties without any compensation at

Proceedings

all after a legal dispute and an appeal to the European Court of Human Rights (ECHR), finally, at the end of the summer of 2016, the beneficiaries disbursed their awarded compensation [6].

In conclusion, the area had no tourism, but its potential could support different types of tourism development such as that of ecotourism.

2. ECOTURISM DEVELOPMENT OPPORTUNITIES, WALKING TOURISM WITH POINTS OF CULTURAL INTEREST

The goal of ecotourism is to ensure that tourism and conservation are interdependent—not just that they can coexist, but that they should. The assumption that ecotourism can help wildlife and biodiversity, create incentives for landscape conservation and help local communities is explicitly stated in all definitions of the term [7]. Ecotourism is now defined as “responsible travel to natural areas that conserves the environment, sustains the well-being of the local people, and involves interpretation and education”. Education is meant to be inclusive of both staff and guests and some of its basic principles are:

1. Minimize physical, social, behavioral, and psychological impacts.
2. Build environmental and cultural awareness and respect.
3. Provide positive experiences for both visitors and hosts.
4. Provide direct financial benefits for conservation.
5. Generate financial benefits for both local people and private industry.
6. Deliver memorable interpretative experiences to visitors that help raise sensitivity to host countries' political, environmental, and social climates.
7. Design, construct and operate low-impact facilities.
8. Recognize the rights and spiritual beliefs of the Indigenous People in your community and work in partnership with them to create empowerment. [8].

Lake Karla has a privileged geographical position, since the lake is located approximately in the middle of the country and in the middle the main road of the country: the Athens-Thessaloniki Road, but also between two large cities of Volos and Larissa, which gives it an easy access. The agriculture around the lake is mostly about cotton crops, a fact that provides harmony and beauty to a future visitor. The climate of the wider area of Karla is characterized as Mediterranean with dry and hot summers and cold and wet winters. It is a Natura2000 site with a variety of flora and fauna ready to get discovered [9,10].

The area includes the restored Lake Karla, thirteen reservoirs, a small artificial wetland, low hills and a small part of the foothills of the adjacent mountains, the supply of canals and thirty settlements. Most of the plain (80%) is used for extensive agriculture with a variety of annual crops, fallow, pastures and a network of irrigation and drainage channels. Fauna such as 20 reptiles species, 4 amphibians [11], 13 fish species and 2 cyprinid species [12] and more than 30 bird species such as the rare Spur-winged lapwing bird species [13], flamingos [14,15], and the legendary heron specie witch one species of heron that lived in Karla Lake was the Starling heron, which had a strange croak, was 69 to 81 centimeters long, had short legs, a thick neck, and a brownish tint to its wings, and black stripes on its back. Locals called that bird ‘swamp beast’ and had a hole myth beyond it that still is heard [16,17].

Figure 1: Flamingos in lake Karla

Figure 2: a flying heron
Alexandros Oikonomidis

In 2014, at Lake Karla, following a request - proposal of the Management Agency of the Ecodevelopment Area of Karla Mavrovouni Kefalovrisos Velestinos, in 2014, signs prohibiting hunting were placed in the reserve, according to Official Gazette 459/D/6.9.2010. The twenty signs

that were installed provide continuous information, positively activate the public, raise their awareness and all together attempt to achieve environmental protection in order for the reserve to be managed as well as possible [18].

According to the definition of ecotourism, Karla Lake as an ecotourism destination should provide the visitor with enjoyment and help them appreciate nature while promoting any accompanying cultural features of the past and present, and to provide beneficially active socio-economic participation of local populations. Ecotourism can include either cultural or environmental tourism and, in addition, benefits to the local population should be an integral part of the activity. ecotourists typically seek experiences that provide a sense of closeness to the natural attractions and local communities that first brought them to a destination [19,20]. The area where Lake Karla is located meets the characteristics of the destinations necessary to develop ecotourism such as:

1. Natural features preserved in a protected landscape
2. Evidence that tourism does not harm natural systems such as waterways, coastal areas, wetlands and wildlife areas;
3. Low-density development, where natural areas are abundant and the built landscape does not dominate,
4. Designated outdoor recreation areas that protect fragile resources (cycleways, footpaths etc.) for both locals and visitors
5. Thriving small community businesses owned by local residents such as food stalls and other craft businesses;
6. Locally owned hotels, restaurants and hospitality businesses with friendly staff,
7. Friendly interaction between locals and visitors,
8. Basic public facilities for shared use by tourists and locals (e.g. public showers, toilets, etc.),
9. Local festivals and events that show an ongoing sense of pride in the natural environment and cultural heritage of the local community [20].

In the area of Lake Karla there are certainly ten recommended routes of ecological and cultural importance. For each specific route results have been provided regarding their cultural value, ecological value, others for education, and protection for different uses such as walking, cycling and horse riding. About the total value of each route, the route concerning the regions Armenio-Achilion-Kalamaki-Elafos-Sklithro-Polidendri forest (royal estate in the past), shows a greater preference than the route Kanalia and walks next to the lake.

The following image and table provide a thematic map of the proposed eco-cultural routes. It seems that the most routes are located in the east and southeast of the area, with reference to Lake Karla and the surrounding wetlands. Nevertheless, a significant part of the routes crosses natural, semi-natural and rural areas, documenting the ecological and cultural character and the cultural importance and ecological value of the proposed routes, represented and highlighted by the scores of the respective categories.

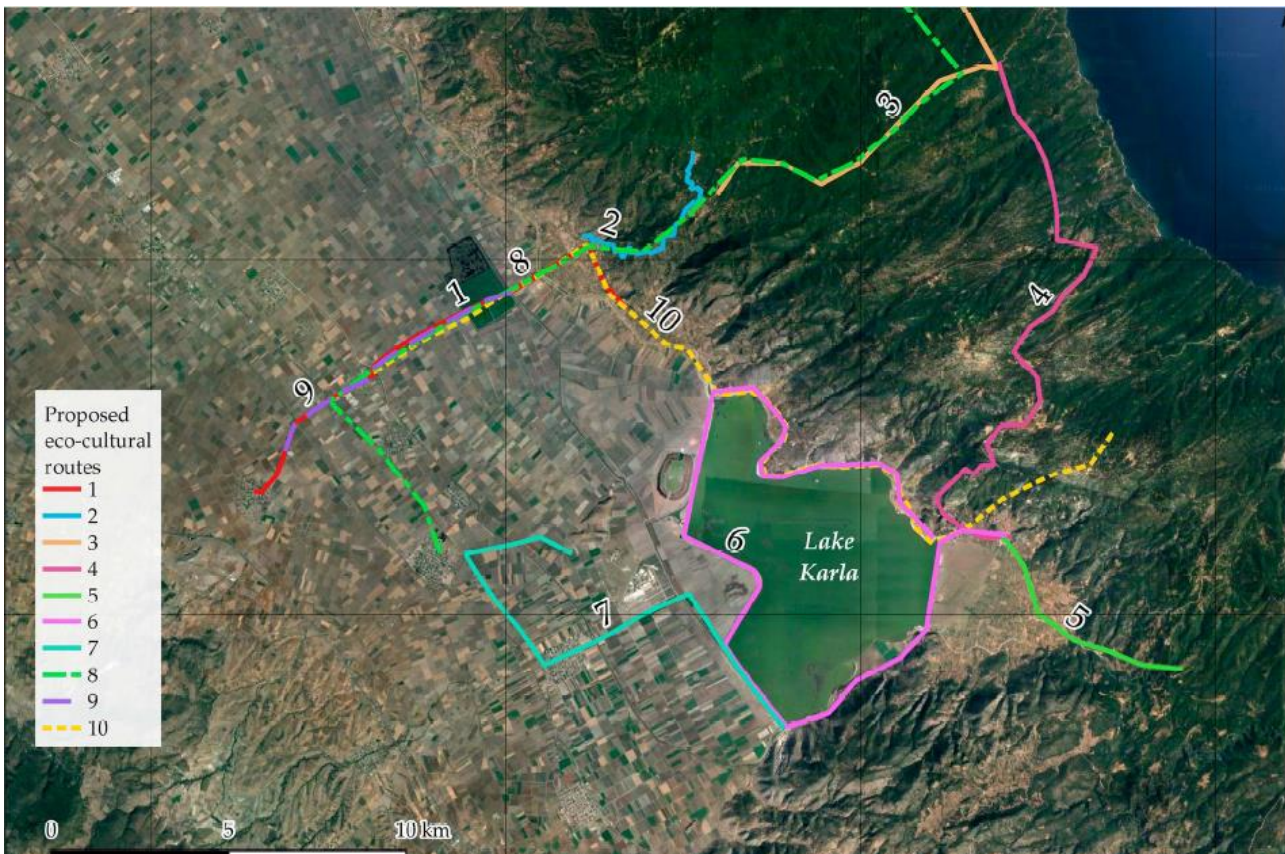

Figure 3: Thematic map of the proposed eco-cultural routes is presented. Route numbers follow table 1. Baseline map source: Google Earth [21].

Route Number	Route Description	Cultural Importance (a)	Ecological Value (b)	Opportunities for Education (c)	Accessibility for Different Uses, i.e., Hiking, Cycling and Horse Riding (d)	Total Rating
1	Farmer Monument Kileler-Achillio-Kalamaki-Paleoskala	5	3	4	4	16
2	Kalamaki-Elafos-Panagia Kampana	5	4	5	5	19
3	Elafos-Skiithro-Rakopotamos	3	5	5	5	18
4	Skiithro-Keramidi-Kanalia	3	4	4	5	16
5	Kanalia-Kerasia	3	5	5	4	17
6	Kanalia-Trail around lake Karla	5	5	5	4	19
7	Lake Karla-Stefanovikio-Panagia Armeniou-Panagia PetrasSotiriou	4	3	3	3	13
8	Armenio-Achillio-Kalamaki-Elafos-Skiithro-DasosPolidendriou (former Royal estate)	5	5	5	5	20
9	Kileler greenhouses-Farmer Monument-VIOLAR-Achillio-Kalamaki reservoirs	4	3	4	3	14
10	Achillio-Kalamaki-Paleoskala-Lake Karla observatory-Ancient Oak forest park	3	5	5	5	18

Table 1: Rating scale: 0: Not important, 1: Very low, 2: Low, 3: Medium, 4: High, 5: Very high Proposed eco-cultural routes followed by expert judgment rating, under the criteria of: (a) cultural importance, (b) ecological value, (c) opportunities for education, and (d) accessibility for different uses, i.e., hiking, cycling and horse riding [21].

In the wider area of Lake Karla there are not only these ten trails for walking, cycling or riding, but these ten suggested ones take the visitor up to the mountains, along the top of the ridges or to the shores of the lake. Suggested routes vary in terms of the degree of difficulty and depending on the area chosen by the visitor, the length and points of interest also vary. It should be noted that some

Proceedings

of the International Conference on **Changing Cities VI:**
 Spatial, Design, Landscape, Heritage & Socio-economic Dimensions
 Rhodes Island, Greece • June 24-28, 2024
 ISSN: 2654-0460
 ISBN: 978-618-5765-02-6

trails are easy while others are more demanding, while many trails start or end from/in places that are not accessible by public transportation. The selection of these trails was based on a variety of criteria, such as: (a) promotion of hiking, (b) outdoor recreation, (c) natural and cultural interest, (d) popularity, and (e) use [22].

In terms of degree of difficulty, altitude, availability of drinking water, signposts, parking and other useful information are presented in Table 2 below:

Route	Degree of difficulty of the route	Maximum altitude	Lower altitude	Signs	Safe drinking water	Bus routes	Parking	Tips
Ano Kerasia-Kerasia	Easy	657 meters (Ano Kerasia)	133 meters (Kerasia)	Red signs-signs	Kerasia	Volos – Kerasia	Kerasia-Ano Kerasia	Distance of Kerasia from Volos 36 km. Distance Ano Kerasia from Volos 43 km
Flamouri Monastery	Medium	776 meters	569 meters	Red signs-signs	Flamouri monastery	No	Ano Kerasia	Possibility of transportation to Flamouriou Monastery, with available vehicle or motorbike
Kerasia – Sourvia Monastery	Difficult	705 meters (Sourvia monastery)	133 meters (Kerasia)	Red signs-signs	Kerasia-Panagia Leschani	Volos – Kerasia	Kerasia	More hiking required, narrow paths, ups and downs
Keramidi – Paleoskala	Medium (single way) Difficult (with return)	683 meters	50 meters (Paleoskala)	National Trail marking-Red signs	Keramidi	Volos-Kanalia, Volos-Keramidi	Keramidi	Keramidi is 52 km from Volos
Ano Kanalia - Pargos (39°30.489 S - 22°48.252 E)	Difficult	568 meters	49 meters	Red signs - signs	Kanalia	Volos – Kanalia	Kanalia	Distance of Kanalia from Volos 34 km.
Glafyra – Agios Nikolaos	Easy (single way)	423 meters	52 meters	Red signs-signs	Glafyra Kanalia	Volos-Kanalia	Kanalia Glafyra	Distance of Kanalia from Volos 34 km.
Kanalion	Medium (with return)					Volos-Glafyra		Distance Glafyra from Volos 14 km.
Kanalia-Drakopigado	Difficult	434 meters	63 meters	No	Kanalia	Volos-Kanalia	Kanalia	Pay attention to the separation of paths and paths for sheep and goats
Stefanovikeio (39°27.510 S - 22°44.309 E)	Medium	102 meters	47 meters	No	No	Volos-Stefanovikeio	Parking at Stefanovikeio	Distance of Stefanovikeio from Volos 25 km
-Agios Athanasios hill								
Stefanovikeio-(Petra) Skala (39°30.316 S - 22°45.310 E)	Medium	87 meters (Petra)	47 meters (Skala)	No	Stefanovikeio	Volos-Stefanovikeio	Parking at Stefanovikeio	Distance of Stefanovikeio from Volos 25 km
Kato Kalamaki-Karlas wetland	Easy	55 meters (Kato Kalamaki)	44 meters (pumping station)	No	No	No	Kato Kalamaki-Paleoskala-Shallow artificial wetland	Distance Kato Kalamaki from Volos 50 km, and from Larissa 43 km

Proceedings

To avoid more people - visitors on the paths and eco-routes than the carrying capacity allows, the time required for each activity should be taken into account. For example, for walking, which is the most common activity, the time required to walk one kilometer is set at twenty minutes and the maximum number of visitors is forty walkers per kilometer, which means that if more than forty visitors, within a period of twenty minutes, the carrying capacity will be exceeded, despite the fact that this number is less than the carrying capacity of the routes. one proposal is to allow twenty hikers, every twenty minutes to enter each route, in order to maintain the number of people per kilometer, a number significantly lower than the carrying capacity, supporting not only the use of ecological and cultural resources, but also the satisfaction of visitors, as the hike will take place on a route without people [21].

Beyond the enjoyment of a hike on the lake, the options for starting, stopping and more broadly in the area of the above routes, contain elements of tangible and intangible cultural heritage. examples of these are:

- Agios Nikolaos Kanalion on the eastern shore of the lake with construction dates back to the end of the 12th to the beginning of the 13th century, while the use of ancient stone plinths on its walls is characteristic
- The prehistoric settlement at Paleoskala at the foot of Mount Mavrovouni on the eastern shore of the Lake is also considered a cultural heritage monument. The settlement presents many periods of habitation such as the latest, late Neolithic and early Bronze Age. The settlement was excavated in the years 2001-2002, while some buildings that were uncovered date back to the first half of the second millennium BC
- Karlas Lake Culture Museum (KE.ME.BO), The Museum is part of the museums of the Ministry of Culture, has a trademark registered with the Ministry of Development, develops collaborative ties with other museums, and participates in the museums of the Prefecture of Magnesia. The purpose of its establishment was to create a multi-cultural space in which visitors of all ages can learn about the history of Lake Karla, through their participation in speeches and workshops as well as musical theater events. In order to achieve this goal, the association of Friends of the Museum was created at the same time, and with their voluntary participation, they offer their services
- The first Lake Karla festival, modeled on the Prespa Festival, was organized in the summer of 2023 and established at the old Kanalia High School, with the participation of local clubs, well-known Greek artists and Karlas Lake cultural Museum that offers free guided tour for the public
- Folklore Museum of Stefanovikeio in the name of the great benefactor of the place, Pavlos Stefanovik Stylitsis
- Management body of lake Karla conducts environmental information programs for the public in order to sensitize visitors and turn them into aware citizens, who will understand what are the problems that facing the region in terms of the environment and will want to participate in the activities to solve them (Π.Ο.Κα.Μα.Κε.Βε)
- Wild Orchid Research and Protection Center (ΚΙ.ΠΙΟ.ΚΕ)
- Helias Lefousis Museum

3. HOW STORMS DANIEL AND ELIAS EFFECTED LAKE KARLA AND WHAT ARE THE PROSPECTS

Thessaly in just 3 years' time was hit by extreme rainfall phenomenon. Storm Daniel was an extreme weather phenomenon with heavy rains and storms that first hit Greece, Bulgaria and Turkey and then moved towards Libya, also causing heavy rainfall, resulting in massive property damage and the death of at least 11,500 people, after two dams burst, while tens of thousands of people in Libya are still missing. The bad weather Daniel started on September 4, 2023 from the Ionian sea, with a focus on

the wider area of Thessaly, causing enormous destruction and human losses. Other areas affected by the bad weather in Greece were Domokos in Fthiotida, and Evia [23]. The damages caused by Daniel from 5th of September until 12 of September 2023 were:

- Agricultural land: 292,652 acres (91.0% rate)
- Built-up areas (with urban/residential use and technical infrastructure): 4,834 hectares (1.5% rate)
- Forest and grassland: 1,311 hectares (0.4% rate)
- Water surfaces, wetlands and others: 22,861 acres (7.1% rate) [24].

Storm Elias was the second major storm to strike Greece within a short span, causing heavy rainfall that led to the overflowing of rivers and widespread floods in the Thessaly region. Satellite imagery captured the significant amount of sediment carried away by the floods as the Pinios River discharged into the Aegean Sea. On September 27, 2023, Volos experienced an extraordinary 298 mm (11.7 inches) of rainfall within a 14-hour period due to Storm Elias, surpassing the city's September average by more than eightfold.

These events underscored the pressing need for a centralized Water Basin Authority capable of making effective decisions for water management. Additionally, it exposed the detrimental impact of unauthorized construction by farmers, who built dams and roads to shield their crops without properly maintaining waterways. This lack of maintenance exacerbated the devastation caused by the floods, highlighting the urgent requirement for comprehensive and coordinated water management strategies. [25,26,27].

Lake Karla that after its restoration was 35.000km²-38.000km² after the storms of September 2023 returned to its original size of 180.000 km [28].

Figure 4: before & after the storm [29]

All the cultural and historical sights didn't affect and remained untouched and ready for future visiting. Recovery in the disaster area is expected to take two years, requiring a strategic plan to prevent and manage similar events in the future. Building 100 to 250 smaller check dams in valleys and gullies, along with nature-based solutions, can reduce peak surface discharges and soil erosion. Despite these efforts in the mountains, additional flood prevention measures are needed in valleys. Lake Karla's capacity is insufficient for future extreme weather events, necessitating smaller artificial infrastructures to manage water flow and mitigate flood risks [27].

The municipality of Thessaly proposes the following measures as a solution to the problem that occurred in the area:

- Repair and upgrade of flood protection embankments.
- Redesign of bridges aimed at configuring the necessary space for the Pinios River.
- Deepening of the riverbed of the Pinios and its tributaries, including the complete clearing of flood-prone areas from crops, especially perennial crops, and the removal of any obstacles hindering the free flow of water.

Creation of overflow retention areas with controlled flooding and drainage of the area between flood protection embankments [30].

We have recently conducted a visit to the archaeological site of Paleoskala and are pleased to provide our observations. Following the recent storm event named "Daniel," concerns had arisen regarding potential inundation of the site. However, our examination revealed that Paleoskala remains unaffected by rising water levels, indicating its resilience in the face of natural adversities.

Paleoskala's strategic location and meticulous planning have evidently shielded it from the impacts of environmental challenges, particularly in a region prone to flooding. This observation underscores the importance of foresight and careful consideration in the preservation and accessibility of archaeological sites.

Our visit reaffirmed the significance of strategic planning in ensuring the continued preservation and enjoyment of cultural heritage sites such as Paleoskala. Despite external factors such as adverse weather events, the site's design and positioning facilitate its accessibility to visitors, allowing for the appreciation of its historical significance.

In conclusion, our experience at Paleoskala serves as a poignant reminder of the importance of archaeological preservation and the benefits of thoughtful planning in safeguarding cultural heritage for present and future generations. We encourage interested parties to visit this remarkable site and witness its rich history firsthand.

4. CONCLUSION

This study explores the potential of Lake Karla as an ecotourism destination, aiming to harmonize tourism with conservation efforts and local community well-being. Lake Karla's geographical significance and rich biodiversity offer opportunities for immersive nature experiences. Efforts to protect the region, including hunting prohibition and environmental education initiatives, underscore the commitment to conservation. Proposed eco-cultural routes showcase natural and cultural heritage, supporting local businesses and cultural institutions. Key attractions, including historical sites and festivals, enrich the visitor experience. Collaborative efforts enhance sustainability. Lake Karla exemplifies ecotourism's potential to promote conservation, support communities, and foster cultural appreciation in Greece.

After the “Daniel” & “Elias” storms, the whole picture changes. A new challenge was in front of this plan that needed a strategy to address flood risks in Thessaly, emphasizing the principle of "built back better."

Key elements include identifying flood-prone areas for strategic relocation, implementing flood protection infrastructures like controlled zones and check dams, and expanding water retention capacity. To ensure effectiveness, the proposal calls for the establishment of a dedicated working group and coordination committee. Additionally, it highlights the need for a 24/7 alert system and the involvement of the National Observatory of Athens for essential data and expertise. This approach aims to bolster Thessaly's resilience against future floods while fostering sustainable development.

Urban Governance Tools integrated with cultural heritage planning: The case study of Ceramics Allatini, in Thessaloniki, Greece

S. Prigkou

PhD Candidate, Department of Urban & Regional Planning
University of Thessaly, Greece

Corresponding author: E-mail: sprigkou@uth.gr, Tel +30 6979335119

Extended abstract

As cities face challenges of climate change and urban decay, understanding how to effectively manage cultural heritage in the midst of these crises becomes crucial. A broader range of motivations related to the public interest is now evident in influencing the design of new developments. These motivations vary in scope and priority based on local circumstances and identity. Carmona (2016: 707) outlines nine primary motivations that to varying degrees will inform the operation of urban design governance. Specifically, he refers to environmental imperatives in the light of climate and ecological crises: these have impacts across the scales and associated regulatory regimes, from the strategic design of cities and decisions over where new development is located, to the detail of building and landscape design and construction. In the meantime, the work of the EU Member States' expert group summarized in a report entitled "Strengthening cultural heritage resilience for climate change", among its recommendations, proposes that national-/regional-level and local-level administrations must include cultural heritage and the cultural domain in all actions and plans addressing mitigation of and adaptation to climate change. Actions must be undertaken to fully integrate culture and cultural heritage issues into environmental sustainability and climate policymaking both at national/regional/local levels and international level. It is quite interesting to investigate which urban governance tools and in what way are taking into consideration the factor of cultural heritage through the lens of climate crisis. By attempting a quick literature review it seems that public participation tools could be integrated in the field of cultural heritage planning and management, concluding to an inclusive planning system, prioritizing the factor of resilience to climate change/crisis. The case study of the building complex of Ceramics Allatini at the east part of the city of Thessaloniki is examined in order to investigate which urban governance tools are used, in what way, how participatory planning and public participation has taken place overall and which have been the conflicts and consensus regarding the project.

Keywords: *urban design governance, urban governance tools, climate crisis, climate change, cultural heritage, public participation*

Extended abstract

This paper aims at discussing new schemes potential for industrial heritage re-use. The Agricultural Research Station, in the city of Serres, will be the main focus, and it will be further argued as part of the former National Agricultural Research Institute.

Looking onto the Agricultural Research Station a significant aspect of the city's industrial past will be revealed, resting upon the industrial architecture history of the first half of 20th century in Greece. The case study belongs to a wider network of model farms that had been developed since mid-19th century, on a national level. This network promoted education and research on agricultural production and has gradually been expanding up until mid-20th century, in almost every prefecture across Greece. Each model farm unit was designed to take advantage of distinct local agricultural production characteristics. The Station presented in this paper, has functioned as a model farm unit training young professionals, while combining agricultural education and livestock production methods. It was inaugurated in 1908-09 and had gradually adjusted to new technological demands and rapid economic changes, while preserving its distinct identity. The infrastructure lies derelict today. Its location on the city's southern edge, and its nodal position amidst road networks, has been and still is of importance. The size, the architectural features and the spatial relation to the city fabric provides the station with a great re-use potential. It is of significant importance for contemporary primary sector and future economic context. This derelict Station has received limited attention, so far, compared to other units within the same network.

The paper discusses different architectural scenarios for the reuse of Serres Agricultural Research Station. It attempts to investigate new schemes of re-integration and new views for integrating this industrial building into the city's life. All design schemes focus on re-use, and re-alignment of key and secondary elements (access, direction, axial accumulation, clustering, pathways, connectivity, adjacency, land use). All design-schemes focus on re-articulation of volumes (uniting, expanding, delegating, growing, restricting) and the re-configuration of interior, exterior and semi-open spaces and territories. This presentation aims at highlighting the importance in re-engaging with historical buildings, sites, complexes and territories. This paper argues for re-imagining architecture on the city's edge, as well as re-defining interface between old and new, future and existing, private and public, real and virtual, formal and informal, certain and ambiguous. All scenarios promote regeneration urgencies on pressing urban matters in medium sized cities of northern Greece.

Extended abstract

The bridge of Sarakina is located 8,5 km southwest of Kalambaka. It was built to connect Sarakina village to Diava village by bridging Pinios river (Salambria). Heading from Sarakina village to Diava, we come across a meteoric rock just before the construction of the first (left) abutment. This rock was the reason that the local villagers named the bridge as the "bridge of stone". The bridge is a monument of the post-Byzantine times; it dates back to 1520 AD and was built by Bishop of Larissa, Bishop Vissarion II. It is a remarkable monument of architectural heritage in the prefecture of Trikala with impressive form and stability preserved for many centuries. The original construction of the bridge consisted of six arches with the largest of them having a height of 9.70m and a length of 19.70m. At the beginning of the 19th century, probably due to the excavation in the middle, two arches of the bridge on the Diava side collapsed, resulting in the interruption of the communication between the villages for several years. According to evidence, it was roughly repaired and supported by wooden elements and later by reinforced concrete beams, as two new half-piers were constructed asymmetrically to bridge replacing the new structure with the original one. Following the decade of 70s, additional interventions were made in the bridge; it was widened, and new pavements were constructed. Because the modern bridge was part of a local road connecting Kalambaka with mountain villages until 2005. It was in the late 2010s, that a restoration study was contacted by the Ministry of Culture and the restoration of the bridge was financed by the Region of Thessaly. By the end of summer 2023, the restoration works were almost completed. But then, on 4th September "Daniel" - a Mediterranean cyclone, hit hard all the region of Thessaly with extreme rainfall. As a result, part of the original monument, the largest middle arch, collapsed.

Cultural heritage management in times of climate change requires research on climate change adaptation strategies and methodologies for safeguarding tangible cultural heritage from the constant pressures on it and the associated consequences that cause deterioration.

Keywords: built cultural heritage; restoration; climate change; monumental bridge of Sarakina; Thessaly;

Literature as a tool for creating cultural routes: The Example of the Historical Novel "Thrassa"

A. Tsolaki

Researcher

Corresponding author: E-mail: tsolaki.artemis@gmail.com, Tel +30 6972264965

Extended abstract

In recent decades, specialized alternative tourism has emerged to address the evolving preferences of travelers, filling gaps in tourism demand. Specifically, there has been a discernible shift from 'mass' to 'personalized' tourism experiences. This transition has spurred the development of innovative tourism products tailored to meet the specific needs of modern travelers (Kokkosis, C. et al., 2020). Cultural tourism, in particular, has witnessed a notable increase in market share within the global tourism industry. This growth can be attributed largely to socio-economic changes that have elevated the living standards and educational levels of tourists (Richards, G., 1996).

Cultural routes represent a specialized and branded form of cultural tourism product, integrating monuments, local businesses, institutions, and communities into a cohesive and functional network (Berti, E. et al., 2015). The value of cultural itineraries in promoting tourist destinations and enhancing their competitiveness is recognized both within Europe and internationally (OECD, 2009). The European Commission's establishment of the Cultural Routes of Europe in 1987 marked a pivotal moment, highlighting cultural routes as an innovative tourism product that contributes significantly to local development and fosters a shared European identity (Council of Europe, 2019).

Acknowledging the significance of the "tourist experience" as a driving force in tourism development (Y. Stamboulis, P. Skayannis, 2003), this paper utilizes literature as a foundation for crafting a memorable cultural route (Chen, Rahman, 2018). Specifically, the historical novel "Thrassa" will serve as the narrative thread linking tangible and intangible elements of cultural heritage mentioned within its pages. Visitors will have the opportunity to explore locations depicted in the novel, immerse themselves in the atmosphere of Byzantine Thrace, and engage in participatory activities to learn about the region's history and traditions.

This proposal seeks to develop a high-quality cultural product aimed at attracting new visitors while extending the tourist season and increasing daily tourist expenditures.

Extended abstract

In this paper, tangible cultural heritage in times of transition refers to monuments that have undergone transformations or have been completely destroyed, in history, as the political and cultural context has changed during their long-term construction.

From the Egyptian monumental architecture of the Pharaohs and the Forum Romanum of the Emperors to the Renaissance temple architecture of the Popes and the unwanted communist heritage of former Eastern Europe, there are typical examples of monuments that have fallen victims of political or religious expediency.

Examples of temples modified during construction to meet new ambitious plans or temples of past gods demolished and their building materials used to build new ones, statues of the vanquished whose facial features were forged to resemble the victors, symbols of an unwanted heritage removed in order to be replaced by others that would serve a new political narrative, are the subject of study in this paper.

By analysing monuments of different historical periods that have undergone significant alterations with greater or lesser damage during their long-term construction, the aim of this paper is to demonstrate the different modes of management followed, in relation to the political or religious considerations that dictated these choices, considered in their historical context.

The search for information about these aborted phases, or censored versions of the life of the monuments, in written sources or in excavation research is a challenging field of study, which is not only limited to its historical and archaeological interest, but aspires to discover the key to understanding and interpretation, also, of similar phenomena in the present and future.

Keywords: *cultural heritage, tangible heritage, in transition, under political or/and religious expediency*

Place Promotion and Artificial Intelligence: A Framework of Basic Principles for Image Generation Practices

D. Kalergis

Assistant Professor, Dept. of Planning and Regional Development, University of Thessaly
Corresponding author: E-mail: dkalergis@uth.gr, Tel +30 24210 74438

Extended abstract

Place promotion is an important element of urban strategy, of multiple scopes, that aims to form a marketing profile of a specific location, city or region, and enhance in many ways its attractability usually at a global scale. This effort usually emphasizes a certain destination and its distinct characteristics to attract visitors, tourists, investors, and residents to a particular place and destination. This promotion of uniqueness involves a variety of attractions and living experiences to stimulate economic growth, enhance reputation, and foster local development. Traditional promotion practices incorporate a wide range of marketing initiatives, including advertising campaigns, digital media strategies, event organizing, tourism partnerships, and a vast number of promotional materials such as brochures, websites, and social media. The key objective is to create a compelling narrative and symbolic imagery that will highlight the places' distinctive features, local heritage, cultural attractions, and other aspects of an attractive profile. Central to most of promotional strategies is the "image" of the place, the visual understanding and conception of this unique location.

Today, place promotion faces several challenges mainly from rapidly evolving consumer preferences, technological advancements, and a growing evolution of global socio-economic dynamics. These challenges that affect the urban sphere and, in this sense, apply to place promotion include: a) digital transformations (machine learning, social media algorithms, etc.), b) intensified competition (differentiation stress), c) sustainability and responsible tourism (socio-cultural impacts), d) crisis management and resilience, e) authenticity issues, f) accessibility and inclusivity, and g) regulatory and legal restraints.

This paper attempts to theoretically integrate artificial intelligence (AI) in place promotion strategies as a game-changing opportunity in this field of marketing. More precisely, it explores the principles of image generation using AI tools and techniques that present the ability to produce captivating representations of places, focusing on promotion, as well as cognitive distinction. It also initiates a critical framework of visual content, brand identity and destination interest. Additionally, it examines ethical considerations and challenges associated with AI-generated content in place promotion, emphasizing the importance of the authenticity of a place.

Finally, the paper examines the opportunity of AI functions that may boost place promotion tactics like: i. Content creation efficiency, ii. Personalization and targeting, iii. Enhance creativity and innovation, iv. Accessibility and inclusivity, v. Data-driven insights and vi. Ethical and regulatory considerations.

Keywords: *place promotion; Artificial Intelligence; sense of a place; image generation, authenticity*

Participatory Planning and AI: A tool for negotiating common interests.

Extended abstract

Participatory urban planning and artificial intelligence (AI) represent a dynamic intersection of technology and community engagement in shaping the future of cities. In recent years, the complexities and challenges associated with urban planning have grown exponentially, necessitating innovative approaches to accommodate diverse interests and foster sustainable development. The concept of participatory urban planning involves actively involving residents, stakeholders, and community members in the decision-making processes that impact their surroundings. This approach emphasizes inclusivity, transparency, and collaboration to ensure that urban development projects reflect the needs and aspirations of the people they serve.

Artificial intelligence, on the other hand, offers unique capabilities to analyse vast amounts of data, extract insights, and optimize decision-making processes. By leveraging AI technologies, urban planners can gain valuable insights into population dynamics, traffic patterns, environmental impact, and infrastructure requirements. AI can help identify trends, predict future scenarios, and inform evidence-based planning strategies that are responsive to the evolving needs of urban populations.

When combined, participatory urban planning and AI create a powerful synergy that can transform the way cities are planned, designed, and managed. AI tools can facilitate community engagement by providing accessible platforms for citizens to share their feedback, preferences, and suggestions for urban projects. These insights can then be analysed using AI algorithms to identify patterns, preferences, and priorities among diverse stakeholders.

Moreover, AI can assist in scenario planning, risk assessment, and decision support, enabling urban planners to evaluate the potential impacts of different development scenarios and make informed decisions. By integrating AI into participatory urban planning processes, cities can enhance efficiency, transparency, and equity in decision-making, ultimately leading to more sustainable and inclusive urban development outcomes.

In conclusion, overcoming our "techno-phobia" and not being seduced by "techno-latria", the integration of participatory urban planning and artificial intelligence holds significant promise for creating smart, responsive, and mainly people-centred cities. By harnessing the collective intelligence of communities and the analytical power of AI, urban planners can navigate the complexities of urban development with greater foresight, precision, and inclusivity.

Keywords: *Participatory urban planning; community engagement; Artificial Intelligence; scenario planning; risk assessment*

Urban Governance through the lens of Artificial Intelligence: Literature review of the tool of digital twin city

S. Prigkou

PhD Candidate, Department of Urban & Regional Planning, University of Thessaly, Greece
Corresponding author: E-mail: sprigkou@uth.gr, Tel +30 6979335119

Extended abstract

Smart cities are considered, by many countries and governments, to provide solutions to crucial contemporary urban issues and challenges such as climate change and population growth. Later logical and innovative progressions changed the information wildernesses, giving rise to another wave of troublesome advances with profound impacts on urban society. Tools like the Internet of Things, blockchain, artificial intelligence technology etc. offer extraordinary potential within the change of the current urban administration worldview toward smart cities. This paper focuses on the tool of the digital twin city concept marking a paradigm shift in urban governance of contemporary cities, while helping cities deploy real-time remote monitoring and enable more effective decision-making. DT can be defined as “a virtual representation of a physical system (and its associated environment and processes) that is updated through the exchange of information between the physical and virtual systems” (VanDerHorn and Mahadevan, 2021). A digital twin consists of three parts: physical products, digital products and the connections between them, while integrating data, models and digital entities. Reviewing the literature, it appears that the use of the tool helps cities deploy real-time remote monitoring and enable more effective decision-making, while it serves both citizens and decision-makers, by enabling participation in urban governance processes and monitoring government decisions, from the one side, while urban governance can be achieved in a more orderly manner, on the other side. Findings/conclusions will serve to better understand the concept and how it relates to urban governance and future issues arising from the use of the tool in urban planning and planning as well.

Facial Recognition in Cities: A Catalyst for Political Polarization and Local Media Dynamics

P. Tsimpoukis

PhD Candidate, Department of Information-Communication, University of Toulouse, France

Corresponding author: E-mail: panagiotis.tsimpoukis@univ-tlse3.fr, Tel +30 6986235061

Extended abstract

In 2019, during carnival season, the city of Nice in France transformed into an unprecedented technological laboratory: the municipal authority of the city decided to pilot a facial recognition system, which was installed at one of the entrances of the carnival. The images collected were processed in real-time by the Israeli software AnyVision, with the aim of testing whether they could recognize specific faces. While other cities like Marseille and the small town of Moirans implement as well biometric surveillance applications to enhance security in the city, many reactions were manifested in the public sphere concerning the potential perils of this technology. This involved activists, citizens, stakeholders related to the regulation of artificial intelligence (AI), as well as political parties. In reality, the implementation of facial recognition technologies in cities was the first application of artificial intelligence to cause political polarization in the French public sphere.

In our study, we analyzed 27.530 articles from national and local press, as well as 3.599.000 tweets discussing AI. In the national press, we observed a political polarization, with the entry of new actors criticizing facial recognition. This criticism was mainly linked to the Global Security Law, voted in 2021, which allowed police live-feed access to body cameras and drone footage. The concern focused on the possibility of the collected images being processed using facial recognition software. On Twitter, this criticism involved left-wing and far-right actors and political parties, who heavily criticized biometric surveillance applications, as well as conspiracy theorists. In contrast, in the local press we did not observe political polarization regarding this issue. Our analysis indicates that in the local press, the discourse around artificial intelligence -even after the installation of facial recognition software in some cities- focused on the practical applications of this technology, on innovation, on events related to artificial intelligence, and on funds allocated to local businesses and research centers for further AI technology development. The local press avoided to set on the agenda the political implications of the application of facial recognition in cities, as well as the stakes posed by such applications for the protection of citizens' data, the preservation of their rights, and the maintenance of city public space as a foundation for democracy.

The local media provide the informational backbone of what people know about social life in their city, ensuring social cohesion and contributing to "imagining the city". At the same time, discourses around Smart Cities, including applications of artificial intelligence, become more prevalent in the public sphere. However, the implementation of such applications may foster political polarization and raise ethical questions. The role of local press could be pivotal in intermediating city infrastructure planners and citizens, aiming not only to reduce polarization but also to spotlight concerns such as the protection of citizens' personal data and rights, which should be considered by city planners and local authorities.

Keywords: *facial recognition; artificial intelligence; cities; local press; France*

Artificial Intelligence in Redesigning Urban Space: Case study the region of Thessaly, Greece

D. Kalergis^{1*} & M. Triantafyllidi²

¹ Assistant Professor, Dept. of Planning and Regional Development, School of Engineering,
University of Thessaly (e-mail: dkalergis@uth.gr)

² Adjunct Lecturer, Dept. of Planning and Regional Development, School of Engineering, University
of Thessaly (e-mail: mtriantaf@uth.gr)

Extended abstract

The present paper aims to investigate the way Artificial Intelligence (AI) interferes with urban space matters as long as urbanization proceeds along with digitalization, leading humanity to a different way of living space. Nowadays, the typical model of cities is thought to be old-fashioned, while smart cities evolve rapidly in terms of their built environment, infrastructure and population. Moreover, climate crisis affects urban, rural and suburban space, so it is critical to clarify the way AI could help prevent natural disasters through the case study of Thessaly, which is the main purpose of this paper.

Specifically, AI could initially lead to green urban space creation by applying sustainability, taking into consideration legal, ethical and public health issues. In this way urban planning could be differentiated from recent planning methods, emphasizing on forming microclimate and integrating plants and greenery in living space. Would that be sufficient enough for preventing physical catastrophes in a building environment? That could be examined through the case study of Thessaly, a region in central Greece, with reference to the recent wildfires and flooding incidents in 2023.

It is important to mention that the methodology followed in the present paper, consists of the analysis of field research results besides a literature review of Artificial Intelligence in urban space. Specifically, we intend to examine the way AI could have prevented the devastation Thessaly has suffered, due to the recent wildfires and floods, through a hypothetical planning scenario after using AI analyzing and planning methods.

Last but not least, the results will be discussed in terms of a paper, taking into consideration human living in contemporary urban space. Upgrading human life status is expected to go along with creating more interesting urban space, through changes in urban design i.e. more spacious public places, easy transportation means or use of sustainable energy sources, which AI would suggest.

In conclusion, this paper intends to analyse results emerging from Artificial Intelligence use in urban space in a contemporary digital era. It would be interesting to indicate various ways for urban evolution, always thinking about human existence in living space. The case study of Thessaly could assist in this way, so that mistakes and omissions are not replicated and a better built environment for conscious citizens is built.

Keywords: *Artificial Intelligence, urban space, built environment, infrastructure, climate crisis*

Urban (r)evolution and tech optimism: The dialectic of city and utopia

A. Koutoulaki^{1*}, S. Kotsopoulos²

¹ School of Architecture, National Technical University of Athens, Greece, ankoutoulaki@gmail.com

² School of Architecture, National Technical University of Athens, Greece,
skotsopoulos@arch.ntua.gr

*Corresponding author: E-mail: ankoutoulaki@gmail.com, Tel: +306948822230

Abstract

This paper examines the factors shaping contemporary ideas of urban utopia and the characteristics of the ideal city, how these concepts are approached in the context of the environmental crisis, and our current urban planning capabilities. The research explores current trends, practices, and tools in urban planning, illustrated through examples and a case study in a particular neighborhood of Athens, Greece. After a brief overview of urban evolution, highlighting utopian proposals and movements influencing urban planning, we examine the digital revolution and the environmental crisis as key forces shaping contemporary urban design. The research demonstrates how these forces define the modern city through innovations such as digital twins, MIT CityScope, dynamic, incentive-based, and algorithmic zoning, and the MIT Radar Plot is calculated as a case study in Exarchia, Athens. The findings suggest that addressing the climate and energy crisis requires developing technology-integrated, sustainable urban solutions.

Keywords: *sustainable resilient equitable cities, smart technologies, climate change.*

1. INTRODUCTION

The modern city faces significant challenges that influence urban architectural vision and planning. This study addresses two questions: What determines the contemporary ideas around urban utopia, and what does the ideal city appear to be? How is it approached through the lens of current capabilities in urban planning that have emerged through the digital revolution and the environmental crisis? The study discusses current trends, practices, and planning tools through examples and a case study at the center of Athens, Greece.

At the beginning of the 21st century, cities have developed unprecedentedly, leading to intense social inequalities and severe environmental problems. However, they also offer opportunities for a future of greater prosperity, environmental sustainability, and social justice. According to a United Nations report, 70% of global greenhouse gas emissions are produced in cities, and two out of every three people will live in urban environments by 2050. [1] Managing city life requires attention and demands a paradigm shift in our urban planning and development approach.

This study begins with a concise review of significant ideas on contemporary urban trends, followed by a brief historical overview addressing urban evolution in association with select utopian proposals and movements that influenced urban planning. It then focuses on the digital revolution and the environmental crisis as the driving forces shaping current conditions, contemporary practices, and visions in urban design. Specific examples of emerging technologies and their applications are discussed to illustrate these points. Singapore, a model of a sustainable, smart city, is examined as the world's first example of a Digital Twin. Innovations developed at the MIT Media Lab are highlighted, including CityScope and the Dynamic, Incentive-based, Algorithmic Zoning in Kendall Square. Some of these principles

are applied in a case study at the center of Athens by calculating a Radar Plot in the Exarchia district. Utilizing this methodology from the City Science research group at MIT Media Lab, the results are compared with the “model city” of Barcelona to better evaluate the urban conditions in Exarchia.

Modern cities emerge from the digital revolution and the environmental crisis. The challenges, goals, and regulations associated with the climate and energy crisis, technology evolution, globalization, and the shifting economic and political landscapes necessitate developing technology-integrated, sustainable cities. Cities must progress towards enhanced living conditions while minimizing their environmental footprint. They must rely on dynamic tracking and response to various real-life conditions. Responsiveness, adaptability, resilience, density, proximity, diversity, sustainability, livability, collectivity and equity are central themes of the new ideal urban paradigm narrative. The modern city is envisioned as a sustainable, compact, walkable, and user-friendly urban environment infused with nature. It is well-connected, embraces sociocultural diversity, and features mixed-use neighborhoods. It needs to be resilient, capable of promptly embracing economic, social, and environmental changes, responding to them, and adapting quickly and efficiently. The development of this type of city is the only direction toward achieving the United Nations' sustainable development goals and attaining the objective of "net zero" by 2050. [2] To accomplish this, involving communities in the design and decision-making processes is essential while promoting substantial behavioral changes.

2. BACKGROUND

Michael Batty's "The New Science of Cities" (2013) and "Inventing Future Cities" (2018) books provide a framework for understanding cities as complex, dynamic systems. Batty emphasizes networks, flows, and interactions, advocating for new scientific approaches to address the complexity of urban development in the digital age.[3][4] William J. Mitchell's "City of Bits" (1995) and "Me++: The Cyborg Self and the Networked City" (2004) books explore the impact of digital technologies on urban environments. Mitchell's insights into networked communities and "Electronic Agoras" challenge traditional notions of urban space, highlighting the transformative potential of digital connectivity.[5][6] Antoine Picon's "Smart Cities: A Spatialized Intelligence" (2015) book focuses on integrating digital technologies into urban environments. Picon's analysis of geolocation, augmented reality, and digital urban awareness underscores how technology can enhance urban intelligence and responsiveness, while advocating for a balanced approach to technological integration, recognizing both its benefits and ethical challenges. [7]

By the early 20th century, electricity and internal combustion engines further altered cities, enhancing city safety and efficiency, with centralized resources, infrastructure, and suburban expansion marking this period. In 1898, Ebenezer Howard's Garden Cities aimed to blend urban and rural benefits but faced criticism for impracticality and environmental impact. [8] The City Beautiful Movement (1890-1930) sought to beautify cities but was criticized for prioritizing aesthetics over public health. [8] The first mobility revolution in 1908 introduced diverse transportation modes, and a pivotal shift occurred in 1927 with the adoption of zoning regulations and the mass production of automobiles. [9] Le Corbusier's Radiant City (1920-1940) proposed strict zoning and tall buildings but was criticized for lacking livability. [8] Post-World War II, the New Towns Movement aimed to decentralize population centers but was seen as lacking character. [8] Meanwhile, cities faced reconstruction, deindustrialization, and suburban migration, becoming globalization hubs by the 1960s. [9] Furthermore, the third industrial revolution marked the rise of digital technology. Since the late 20th century, New Urbanism has influenced U.S. urban planning, advocating for pedestrian-friendly spaces and

Proceedings

of the International Conference on **Changing Cities VI:**

Spatial, Design, Landscape, Heritage & Socio-economic Dimensions

Rhodes Island, Greece • June 24-28, 2024

ISSN: 2654-0460

ISBN: 978-618-5765-02-6

community cohesion, but it has been criticized for creating artificial environments. [8] Simultaneously, the Fourth Industrial Revolution transformed communications, work, and daily life through advancements in technology and information systems. [9] The digital revolution's ability to provide computing power and internet access to every individual generated vast amounts of data, leading to the development of "smart cities" in the early 21st century.

This study argues that the environmental crisis and the digital revolution are key global forces shaping urban development and the vision of a modern urban utopia. Cities produce 70% of global greenhouse gas emissions, and by 2050, two-thirds of the population will live in urban areas. [1] In 2023, NASA reported the highest average surface temperature on record. [8] Managing urban life requires immediate attention and a paradigm shift in urban planning and development. The 2022 IPCC Synthesis Report states that how cities are designed, managed, and powered will determine future urban GHG emissions.[9] Sustainability is crucial for balancing the environment, economy, and social interaction, enhancing residents' well-being. The challenges of climate and energy crises, technological advancements, globalization, and evolving economic and political landscapes necessitate developing sustainable, technology-integrated cities. These cities aim to enhance living conditions while minimizing environmental impact, characterized by dynamic monitoring and response capabilities. Key concepts of the new urban paradigm include resilience, responsiveness, adaptability, density, proximity, diversity, sustainability, livability, collectivity, and equity. The modern ideal city is envisioned as a sustainable, compact, walkable, and user-friendly environment integrated with nature. It will be well-connected, culturally diverse, and feature mixed-use neighborhoods. [11] Additionally, it will be resilient and capable of swiftly adapting to economic, social, and environmental changes. Developing such cities is essential for achieving the United Nations' sustainable development goals and reaching "net zero" emissions by 2050. [2]

Leveraging city data alongside emerging technologies such as Artificial Intelligence (AI), Machine Learning (ML), the Internet of Things (IoT), and Blockchain can provide valuable insights and promote sustainable development. [12] These advancements enable the creation of data-driven and agent-based simulation platforms and methodologies like CityScope and Digital Twins to effectively address the complex challenges of contemporary urban environments. Additionally, technologies like Building Management Systems (BMS), Management Automation Systems (MAS), and agent-based modeling (ABM) facilitate real-time monitoring and optimization of energy consumption, resource and waste management, traffic flow, and mobility. Technological innovations such as MIT's Ori Living architectural robotics, [13] LO3 Energy's decentralized smart microgrids, [14] and Waymo's autonomous electric vehicles may contribute to sustainable urban development and environmental and energy crisis mitigation. However, technology alone cannot solve the challenges faced by today's cities.[16] Achieving the ideal urban environment requires changes in behavior, lifestyles, and the design and decision-making processes.

A digital twin is a digital representation of the physical urban landscape, encompassing its infrastructure and dynamic interactions. This pioneering urban planning approach incorporates real-time data and informed predictive simulations. Singapore is the world's first example of a digital twin city. The "Virtual Singapore" (Figure 1) is a dynamic, interactive, and user-friendly 3D digital model of the city, integrating data from various sources. Technologies such as GIS, satellite imagery, LiDAR, photogrammetry, AI, ML, and IoT, offer a comprehensive view of infrastructure, environment, and social interactions. Its goal is to enhance living conditions, public infrastructure, disaster resilience (Figure 2), and energy efficiency. [17]

Figure 1: Virtual Singapore, Marina Bay Sands Hotel,

Figure 2: Virtual Singapore, Emergency Services,
<https://www.youtube.com/watch?v=y8cXB SI6o44>

Positioned at the intersection of urban planning, human-computer interaction, and social sciences, the CityScope of the MIT Media Lab City Science Group facilitates evidence-based discussions about built environments. It aims to enhance community engagement among diverse stakeholders—government, industry, academia, and civilians—promoting collaborative decision-making. Given cities' social and political challenges, such as inequality, police brutality, and safety concerns, the City Science Group reconsiders well-being in this context. CityScope combines models, simulations, and platforms to tackle spatial design and urban planning challenges. This data-driven platform simulates the impacts of interventions on urban ecosystems before detailed design and execution. Comprising computational and physical layers, CityScope features a screen and a tangible input table with projection mapping using LEGO modules. Real-time data updates are displayed in the Radar Plot, showcasing key performance indicators like proximity, diversity, density, innovation potential, public health, building energy consumption, mobility, and safety. (Figure 3) The CityScope methodology involves five stages: Insight: Analyzing urban data to understand current conditions and trends, resulting in a Radar Plot that assesses aspects such as density, diversity, proximity, and energy. Transformation: Implementing interventions to enhance city performance based on these insights. Prediction: Forecasting the impacts of these changes, modeling effects on behavior and resource use to develop effective strategies. Consensus: Ensuring citizen participation by making data and proposals accessible through the CityScope platform. Governance: Regularly updating these processes with community input. This advanced methodology offers a pioneering, data-driven approach to urban planning. [18]

ISBN: 978-618-5765-02-6

environmental performance, identifies deficiencies, and maps incentives to address these needs. Developers then select from this list, with a predefined pro forma determining the allowable floor area and benefits without negotiation. The incentives are algorithmically adjusted as each project is built, ensuring they remain optimal for the community's goals. For example, as of 2023, Kendall Square in Cambridge, Massachusetts, faces a significant imbalance between housing, amenities, and jobs. By dynamically mapping and adjusting incentives using this algorithm, shortages in senior, early career, and essential workforce housing can effectively be addressed. (Figures 4,5,6) [9]

Figures 4,5,6: Algorithmic zoning dynamic diagram progress, <https://www.youtube.com/watch?v=4RJJaQfPM0Y4&list=PLdxKi6kbAWz45Q6Ly4fduIIC3uIT9FqU5&index=2>

To secure community acceptance of significant density increases, such as the proposed housing for 42,000 people in Kendall Square along with necessary schools and amenities, it is essential to address the widespread global NIMBY ("Not In My Backyard") opposition to change. The primary challenge is to transform this resistance into a supportive "Yes, In My Backyard" attitude. One approach to incentivize community acceptance of increased density involves offering developers bonuses in exchange for contributions to a community endowment. This strategy can streamline approvals, reduce risks, and save time, making it attractive to developers. As density increases, a portion of the added value is allocated to the community endowment and distributed to community members based on proximity to the project, length of residence, financial need, and other relevant factors. Additionally, a voting process can foster a sense of ownership and equity. Developers can set minimum and maximum density thresholds for their projects, allowing the local community to adjust the density within these limits. If baseline density is maintained, no funds are added to the endowment, while higher densities result in greater contributions. This system gives the community a direct stake in the project, providing necessary assets and a share of the project's wealth, thus transforming NIMBY (Not In My Backyard) into YIMBY (Yes In My Backyard). Achieving this transformation necessitates significant technological innovations, such as mathematical models, advanced data analytics, smart contracts, simulation tools, and agent-based modeling. While innovations such as battery chemistry and autonomous vehicles are important, community-scale solutions can address a substantial portion of emissions. [9]

3. IMPLEMENTING RADAR PLOT IN THE CENTER OF ATHENS: EVALUATING THE DENSITY, DIVERSITY, AND PROXIMITY OF EXARCHIA

One of the key technologies within the CityScope project is the radar plot. This tool measures diversity, density, and proximity within a community or city, allowing for comparisons with a benchmark city to evaluate the effectiveness of proposed interventions. Essentially, it visualizes the degree to which an urban intervention creates an integrated community with respect to housing, commercial buildings, cultural facilities, and third places (cafés, restaurants, etc.). In Figure 1, the orange line represents the benchmark, Barcelona, Spain, renowned for its dense, walkable neighborhoods. The inner grey line compares the current site's metrics, while the outer black line illustrates changes following a simulated intervention on the CityScope table. [19] (Figure 7)

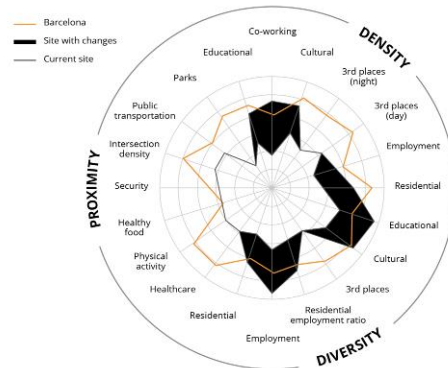

Figure 7: Radar plot, MIT Media Lab “Beyond smart cities: Emerging Design and Technology” course, Module 4 Unit 1 Notes, 2021

The radar plot integrates with land-use models and agent-based models (ABMs) like CityScope, requiring two key data types: static geolocated physical urban data (e.g., buildings, roads, infrastructure) and static geolocated urban-use data (e.g., amenities, land use, events, census data). In the Athens experiment, data was collected and manually inserted, as this technology is not yet available in Greece. Collecting quantitative and qualitative data at the community scale is crucial for gaining precise insights into local habits and movements, which larger-scale data cannot offer. Collaboration among academia, industry, government, and society is necessary to enable effective interventions that enhance community engagement, governance, and decision-making. This project aims to help districts achieve metrics comparable to Barcelona by improving residents' proximity to workplaces, reducing traffic congestion, and increasing area density and diversity. Cities are defined by the relationship between the population living and working in an area and the availability of nearby amenities. Balancing housing, commercial space, retail venues, cultural institutions, and other amenities is crucial. As urban density increases, this balance must ensure that benefits like enhanced idea exchange and more employment opportunities outweigh drawbacks such as traffic congestion, stress, reduced contact with nature, and pollution. While often seen negatively, if density is managed with effective urban design, it can enrich urban communities, creating a more vibrant and dynamic environment. [19] Well-balanced urban ecosystems require diversity, achieved through a mix of economic, spatial, and social characteristics, to ensure resilience and high performance. The Shannon index is used to evaluate this diversity. This index assesses ecosystems with numerous individuals by applying a formula to a representative sample.[20][21] Urban proximity assesses the availability and closeness of social, economic, and physical activities within urban environments. Future high-performing cities may feature compact urban districts with daily amenities within walkable communities. Metrics include

Proceedings

walkable access to parks, housing, jobs, mass transit, schools, and amenities.[20] Cities are complex systems but using Agent-Based Models (ABMs) in simulations and representing data in radar plots allows diverse data to be presented on the same scale. The radar plot adapts to each city's unique challenges, considering key indicators based on Jane Jacobs's principles [22]: mixed primary-use areas to enhance diversity and support various activities, short blocks to increase pedestrian routes and economic activity, a mix of old and new buildings to accommodate various socioeconomic backgrounds, and high population density to foster cultural interaction. These factors collectively promote a thriving, diverse, and resilient urban environment. [19] To understand the impact of local data collection and modern tools on urban planning and decision-making, we used the MIT Media Lab's Radar Plot tool [23] in the center of Athens, focusing on the broader area of Exarchia, defined by Leof. Alexandra, 3rd of September, Panepistimiou, and Asklipiou streets. This area was selected for its significant historical and cultural importance and recent discussions surrounding creating a new metro station at the central square. The survey assessed the density, diversity, and proximity of a 1.2 km² area to analyze its urban characteristics and compare them to Barcelona, aiming to evaluate the district's quality of life through data, analysis, and visualization.

Step 1: Selection of a study area of approximately 1 km².

Initially, we used Google Earth to identify a central reference point in Exarchia and measured a 1 km radius around it. (Figure 8) We then delineated the final study area of 1.2 km² based on the MOHAP (Urban Spatial Analysis Units) defined by Panorama Census Data. (Figure 9)

Figure 8: The study area on Google Earth,
<https://earth.google.com/>

Figure 9: Study area's MOHAP,
<https://panoramaps2.statistics.gr/>

Step 2: Data collection.

We collected data for the region using the following sources:

GIS, Geographical Information System of the City of Athens [24]: This platform provides detailed spatial data, including land use and infrastructure. (Figure 10) Google Maps [25] was combined with the GIS database to identify and count land uses such as hotels, restaurants, banks, and supermarkets. (Figure 11) Greek Census Data Panorama (ELSTAT) [26]: This source provides statistical data on demographic, economic, and household characteristics of the area, such as population, gender, occupation, type of housing, and tenancy status, through CSV files, based on the most recently available 2011 census. (Figures 12, 13, 14)

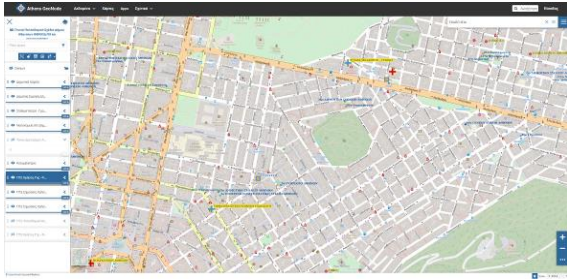

Figure 10: Study area on GIS Platform, http://gis.cityofathens.gr/maps/new?layer=geonode:parking_amea&view=True#/

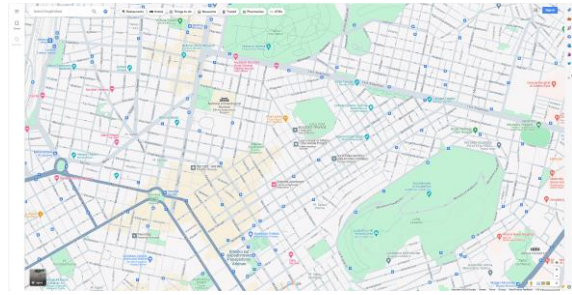

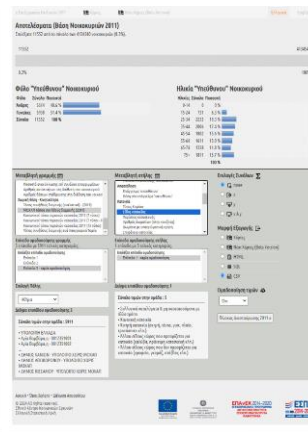

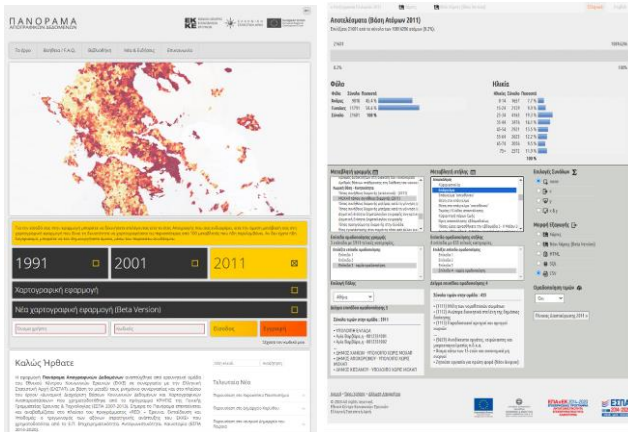

Figure 11: Study area on Google Maps, <https://www.google.com/maps>

Figures 12, 13, 14: Panorama Statistics Platform, <https://panorama.statistics.gr/>

Step 3: Data Entry.

We counted the number of different amenities and services in the study area. Using Google Maps, we identified and counted hotels, restaurants, banks, supermarkets, nightlife venues, leisure and wellness centers, cultural sites, fashion stores, luxury stores, shopping malls, technology stores, post offices, workplaces, safety and policing elements, health food outlets, sports facilities, and healthcare access. Panorama Statistics helped us count the male and female populations, public rented housing, owner-occupied housing subsidy, private permanent housing, non-domestic housing, temporary housing and other housing types. We also counted managers, administrators, professionals, associate professionals, administrative support staff, service and sales workers, craftsmen, and related workers, machine and plant operators and assemblers, unskilled workers, skilled agricultural and fishery workers, other arts-related occupations, and other occupations. GIS aided in identifying parks, schools, hospitals, social housing, public transport stops, and intersection density. Where data was unavailable, we made reasonable estimates or used a value of 0.0001, following MIT Media Lab guidelines. Subsequently, we entered the data into Excel in the relevant cells (Figure 15).

Name of your city	Athens			
Name of the district you've chosen	Exarchia			
	Data	Units	Output	Description
Area size	1,2	Km²	1,20	
People working in the area	10904	Number	10904,00	All people employed in area, including commuters.
Residents	7455,6	Number	7455,60	All people living in area, including those who work elsewhere.
Total people = District users			18359,60	
DENSITY				
Amenities	Number of amenities	Units	Output	Description
Hotels	314	Number	628,00	Hotels: Large and small.
Restaurants	22	Number	119,83	Restaurants: All public venues for breakfast, lunch, or dinner.
Nightlife	28	Number	244,01	Nightclubs, bars, live music, and other entertainment venues.
Leisure and wellness	59	Number	211,45	Pharmacies, dental care, eyecare, gyms, spas, clinics, doctors' practices, and hospitals.
Culture	61	Number	646,04	Libraries, museums, cinemas, bookstores, and art galleries.
Fashion shops	16	Number	16,00	Clothing only
Luxury shops	13	Number	13,00	Jewelry, perfume, tobacco, etc.
Shopping centers	7	Number	7,00	Any branded cluster of multiple shops and restaurants, shopping centers, malls, etc.
Technology shops	26	Number	26,00	Car sales, electronics, hardware stores, etc.
Supermarkets	19	Number	299,68	Supermarkets, markets, convenience stores, etc.
Banks	8	Number	8,00	Banks and ATMs.
Schools	25	Number	262,88	All grades K-12, schools, universities, kindergarten, and professional training.
Post offices	19	Number	19,00	Post offices, including FedEx, UPS stores, but not mailboxes.
Working places	35	Number	368,03	Offices and co-working spaces.
Infrastructure	Number of amenities	Units	Output	Description
Parks	5	Number	64,58	Parks: Green spaces that are publicly accessible and distinct from building and sidewalk landscaping.
Public transport stops	64	Number	103,06	Count all distinct lines at each stop, bus stops, bus lines, train stops, train lines, tram stops, etc.
Intersection density	152	Number	152,00	All street crossings, car, bike, and pedestrian. This can be difficult to calculate, so choose a number depending on how visually similar your district is to the following districts shown on the right.
Police and security elements	1	Number	20,00	Police stations and emergency alarm boxes.
Healthy food shops	18	Number	98,00	Distinguish from the more general restaurants: vegetarian restaurants, health-food stores, juice bars, etc.
Sports places	16	Number	595,66	Specifically gyms, sports facilities, and sports shops.
Access to healthcare	19	Number	319,38	Specifically hospitals, clinics, and pharmacies.
DIVERSITY				
Residential diversity				
Type of housing	Number	Simpson index	Shannon index	Description
Public rental housing	5480	-0,15	-0,1536	Apartment blocks or houses that are rented.
Subsidized home ownership housing	0,0001	0,00	0,0000	Housing subsidized by the government.
Private permanent housing	5507	-0,15	-0,1534	Houses owned by the inhabitants.
Non-domestic housing	4	0,00	-0,0012	Houses used for commercial purposes.
Temporary housing	0,0001	0,00	0,0000	Refugee camps or informal settlements.
Other	561	-0,06	-0,0638	Other types of housing that do not fall into the above categories.

Figure 15: Data on Radar Plot Excel Sheet

Step 4: Analysis of the Radar Plot and Evaluation of the Results.

After entering the data, the radar plot visually depicts the comparison between the study area (blue line) and the Barcelona model area (green line) concerning three key parameters: density, diversity, and proximity. (Figure 16)

Figure 16: Radar Plot for Exarchia, Athens, Greece

4. RESULTS

- Residential Density: The study area has a lower housing density than Barcelona, suggesting fewer dwellings.
- Employment Density: Employment density in the greater Exarchia area is significantly lower, indicating fewer jobs and employment opportunities than in Barcelona.
- Density of Third Places: Exarchia shows mixed results for eating and leisure places. Daytime venues (such as cafes and libraries) have a similar density to Barcelona, while nighttime venues (such as bars and clubs) have a lower density.
- Density of Cultural Venues: Cultural density is higher in the greater Exarchia area, indicating more cultural venues such as museums, theatres, and galleries.
- Density of Co-Working Spaces: Exarchia has a significantly lower density of co-working spaces compared to Barcelona.
- Density of Educational Institutions: The density of educational institutions, such as schools and universities, is significantly lower in Exarchia.
- Gender Diversity: Gender diversity is relatively higher in the study area compared to Barcelona.
- Education Diversity: Exarchia has considerably lower educational diversity, indicating less diversity in educational backgrounds among the population.
- Cultural Diversity: Cultural diversity is lower in Exarchia, indicating fewer diverse cultural venues and activities.
- Dining and Recreational Spaces Diversity: There is less diversity in food and leisure venues in Exarchia than in Barcelona.
- Housing Diversity: Housing diversity is lower, indicating fewer housing types.
- Employment Diversity: Employment diversity is relatively higher, indicating a greater variety of job types and industries in the greater Exarchia area.
- Residential/Employment Ratio: Diversity in terms of the housing-to-employment ratio is higher in Exarchia, indicating a greater balance between available living and working spaces.
- Proximity Access to Health Care: Proximity to healthcare is lower in Exarchia, indicating more limited access to medical and care facilities for residents on foot.
- Proximity Access to Sports Venues: Proximity to sports and wellness facilities is significantly greater in Exarchia than in Barcelona, indicating direct access on foot.
- Proximity Access to Healthy Food: Proximity to healthy food is significantly lower in Exarchia, suggesting less direct access to nutritious food by walking.
- Proximity Access to Look-out (Police): Proximity to police stations is extremely lower in Exarchia, suggesting no direct access to security departments on foot.
- Proximity Access to Parks: Proximity to parks is significantly lower in the study area compared to Barcelona, suggesting limited access to green spaces for residents on foot.
- Proximity Access to Public Transport: Proximity to public transport is significantly lower in Exarchia, indicating difficulty in direct access to public transport.
- Road Intersections: Proximity to road intersections is lower in the study area.

5. DISCUSSION

The basic urban performance metrics we outlined earlier determine high-level key indicators, including innovation potential, building energy, mobility, public health and wellness, and safety and security. (Figure 17)

Figure 17: Urban Indicators of Exarchia

The presented analysis indicates that the broader area of Exarchia has a high density of cultural, dining, and leisure facilities that primarily operate in the morning and midday hours. The area balances available living and working spaces and hosts a diverse range of residents in terms of gender and employment types. Additionally, Exarchia exhibits greater proximity to sports facilities compared to the Barcelona model area. However, several areas require improvement, including the density of housing, workplaces (both cooperative and non-cooperative), and educational institutions. Enhancements in accessibility to public transport, healthcare, healthy food, security services, and green spaces are also necessary. The area falls short in promoting human interaction and flexible mobility, with lower proximity to road intersections than Barcelona. Furthermore, the diversity of educational types and sectors, as well as residential, cultural, dining, and leisure facilities, needs to be increased. Regarding urban indicators, building energy consumption is notably high at 77%, with vehicle energy consumption at 53%. These figures underscore the urgent need for energy reduction strategies. Social well-being is around 55%, while safety and diversity are near 58%. The innovation potential stands at 70%, which is promising for regional development. Unfortunately, no data on the district's urban income was available. This data can inform urban planning decisions to enhance the quality of life in the greater Exarchia area.

The proposed process presented in this paper highlights the importance of local data collection and analysis to understand urban areas comprehensively. By comparing Exarchia with a model city like Barcelona, strengths and areas for improvement can be identified, enabling data-driven and objective urban design. Visualizing community data and comparing it with model cities aids in understanding abstract quantitative data more concretely and improving the targeting of sustainability by making informed decisions. It also promotes community involvement, making urban planning a truly participatory process. Data reliability is crucial. In this example, we could approximate the actual situation of the study area to some extent but not entirely due to difficulties such as limited access and incomplete data recording. Updating recorded data is also a significant challenge, as current methods are time-consuming. Unfortunately, in Greece, the digital era focuses more on digitizing bureaucracy than fostering a true technological revolution. Addressing these issues requires the development of more efficient and reliable data collection and updating methods. Innovations such as CityScope, digital twins, and dynamic, incentive-based, algorithmic zoning can exponentially enhance sustainable development and the resilience of cities while also addressing the environmental crisis.

Repeating the experiment with the 2021 census data would offer valuable insights into the area's development over a decade, particularly during critical events such as the economic crisis and the COVID-19 pandemic. Utilizing agent-based simulation models could also facilitate real-time updates on current conditions, suggest data-driven solutions, forecast intervention impacts, and assess these

Proceedings

interventions using data. Given the controversy surrounding the new metro station intervention, a collective, real-time, data-driven urban planning approach with integrated simulations could present an effective solution. Harnessing new modeling capabilities is crucial to advancing toward more sustainable cities, moving swiftly beyond bureaucracy, speculation, and delays.

The "Smart Islands" as Step for the Sustainable Tourism Development

A. Xanthis

Architect & Teaching Assistant of School of Humanities-Department of Mediterranean Studies in University of the Aegean

Corresponding author: E-mail: agaxanthis@gmail.com, Tel +30 6946119705

Abstract

Sustainability may be a practical response of human to the overconsumption that he himself has implemented in his effort for more growth according to the dictates of the global market.

Perhaps it is the cure to the depletion of resources and goods, perhaps it is the solution to the resulting threats such as climate, energy, migration crises.

Planet Earth is at its limits and needs a radical change of emphasis and attitude from the "builder" man.

This execution also extends to tourism, one of the most dynamic international services in the global economy with social and environmental implications.

Sustainable tourism development is the basis of the new quality tourism of the islands of Greece that seek a new direction exploiting the answers through the "smart islands".

The beautiful islands of the Dodecanese are case studies collecting all the possibilities for a sustainable path, as a response to contemporary challenges for the future.

We must design now in sustainable terms to have a tomorrow that is no worse ecologically than today.

Keywords: *sustainable development; smart islands; sustainable tourism; Dodecanese; Rhodes*

1. INTRODUCTION

The international system is in a major difficulty having lost the constants that existed since 1990. The "new order" set new terms in the public discourse revolving around the economy, security, technology and development. Globalization based on these forces gave a form of immeasurable growth on the depletion of the earth's natural resources. This resulted in economic as well as social imbalance, a major issue of the modern era.

The energy crisis in relation to the economic, health, climate and immigration make up a framework full of uncertainty, instability and fluidity

The world runs to the rhythms of artificial intelligence, to the discovery of the universe, to robots, but without avoiding inherent violence, assertion, self-interest. The world can be read from beginning to end, but it can also be read fragmentarily due to temporal discontinuity and the dominance of the "I am" [1].

Whether at the level of the country, or at the personal level, individual interest comes to confirm the emergence of a new type of human who pursues profit and the vanity of pleasures [2].

The pressure of the markets and the immeasurable entrepreneurship pushed the economy to precede the social balance creating a multitude of inconsistencies, discontinuities and social upheavals. The new century has dawned with a host of hybrid security, labor and environmental threats.

The targeted use of natural resources and the impressive rise of technological capabilities have provided a framework for interventions in nature, where 75% of the terrestrial environment and 40% of the marine environment have been seriously altered. Demand for natural resources and material goods is expected to explode by 2060, while three times what our planet can "sustain" is already being consumed.

Total Risk!

Proceedings

of the International Conference on **Changing Cities VI:**

Spatial, Design, Landscape, Heritage & Socio-economic Dimensions

Rhodes Island, Greece • June 24-28, 2024

ISSN: 2654-0460

ISBN: 978-618-5765-02-6

The U.N. tried [3] in 2000 to set six (6) central values and principles for the twentieth century under the title “Millennium Declaration” based on freedom, equality, solidarity, tolerance, respect for nature and shared responsibility.

We strongly distinguish the reference to the principle of sustainable development in production and consumption patterns with the call for a global change to achieve the well-being of both us and our descendants.

This will was confirmed in 2015 with the 17 goals for sustainable development, which are also the axis of activities and actions for a sustainable, resilient future of our planet.

In this more general view, the city, which is the modern depiction of the production process, the area of social services and decisions, was included in the planning of sustainable urban development. The need to protect the natural and built environment as well as the maturation of policy change on the basis of a more gentle development led the international community to present sustainable development as the maximum goal for the future of humanity. The art of planning sustainable urban development involves the art of give away cooperation, common benefit, perspectives. After all, “medium-sized” cities are the bases of universal design and also are the most promising urban laboratories of the future [4].

In this development spirit, the activity of tourism is opening the issue of sustainable tourism development. Both the World Tourism Organization and the E.U. (article 195 of the Treaty of Lisbon, where tourism can: 1.promote competitiveness, 2.encourage cooperation between states and 3.develop tourism as an integrated approach in the context of other policies [5]) place also tourism in the framework of sustainability, looking forward to a tourism that promotes a healthy economy in terms of resilience, social cohesion and environmental protection.

In this dialogue the islands are a separate unit, where the Greek Constitution and a number of European directives (e.g.1012/C 181/03) consider the islands as a special unit due to their geographical character with the positive but also negative effects and influences.

In fact, the monoculture of tourism on the many islands of the Aegean in terms of economic growth brings about a series of issues of over-tourism, change in social composition but also damage to the natural environment. For this, a brave policy of sustainable planning and proper prevention is necessary to mitigate the negative consequences by using measures but also technical projects that will improve the carrying capacity of the city-island system to be able to cope the incremental numbers and long-term restructuring [6] .

Tourism is a key factor in social, ecological and economic life on our islands.

And so, within the new spirit of sustainable development, tourism must be shaped as an element of prosperity and progress with the aim of the "smart islands" responding to the quality of the “islanders” as well as the tourists.

We can say that the tourist becomes a citizen and the citizen becomes a tourist and both of them enjoy “well being” in the same place.

2. INTERNATIONAL SCENE - EUROPE

The world today is in a difficult situation. The prevailing liquidity creates flashpoints and regional concerns. It is a fact that after the fall of the “Berlin Wall” (1989) and the composition of the “new order of things” a constant insecurity thrives which is aggravated by constant multi-crisis. The first is presented at the beginning of the new century with the terrorist attack on the twin towers of the International Monetary Fund in the heart of New York by terrorist forces opening the file terrorism and Islam in the public debate. Then the financial crisis of 2008 appears in the world economy with an impact on the entire international system. And the puzzle of crises in the new century continues with the covid-19 pandemic, where global health has been shaken with thousands of deaths across the planet. Even today the post-pandemic period continues with negative results in the health sector with the World Health Organization being concerned. The two wars that have broken near the borders

of Europe this decade, the one of them in Ukraine and the other one in the Middle East, rearrange international relations once again in a geopolitical picture with intractable predictions and with subsequent new forms of crises. One of them is alimentary crisis other is energy, also is the immigration crisis which comes to add up with the previous crises. She comes from the countries of Africa and South Asia at the beginning of the previous decade and also from the war in the Syrian region. The world is at a “global rotation” and the West looking for appeasement and peace solutions but with other world powers taking a wait-and-see attitude, such as China and India.

Essentially, we are talking about a complexity of crises that do not derive purely from geopolitical disputes, but also from a economic-geography dimension. If we accept that the two recent wars are being fought for the restoration of “national interests”, first with the invasion of Russia in Ukraine, and second with the “national presence” in the “Gaza Strip” in Middle East we agree that a character of two wars is “(in)regularity of global stability”, is wars of sovereignty.

So we conclude that the international scene has really been surrounded by a vast instability.

The entire environment is charging even more by the general “climate crisis” that has plagued our planet in recent decades. This particular crisis is directly linked to the economic crisis but also to the energy crisis, taking into consideration that energy is the pillar of modern development. They are interconnected and together with the high technology of 6G. They make a geometrical square for powerful stakeholders.

“Climate change” is one of the major issues of international conferences and meetings. The recent -COP 28- Climate Change Conference in United Arab Emirates once again submit one form of hope for a reduction in greenhouse gas emissions and the gradual phasing out of fossil fuels by 2050 despite the declared lack of funding from the international fund [7]. But it is gratifying that the major energy consuming countries have begun to realize the danger and damage caused by “climate change” and are now planning a change in energy policy by strengthening Renewable Energy Sources (RES), hydrogen (H²), energy derived from nuclear use and other alternatives forms.

The “climate change” makes pressing to elaborate all together plans and decides for a political transformation within narrow and comparative time limits. We must do more to prevent devastating climate change. It is our duty to create free and sustainable cities.

Let us choose to join forces and make a jump into tomorrow, we can doing a shock to the “heart of the world” [8].

Europe, having its sensitivities, has put into the wider planning the transition to a green agreement following the terms of sustainable development resulting from Agenda 2030 with the 17 specific goals and 169 sub-goals from U.N. for prosperity, peace, good management resources, proper democratic governance and strengthening the role of the citizen. It refers to a plan that touches all human activities for a just and sustainable society [9].

Europe takes the lead on the green road. Europe pursues the transition in “smart cities”.

In a recent statement, the French President spoke passionately about collective priorities to reduce CO² emissions, achieve carbon neutrality by 2050, preserve biodiversity and fight poverty and inequality. This can be done in the spirit of “One Planet” resulting from the corresponding Paris Agreement (2016) on climate change [10].

The E.U. is care for the islands and gives very interesting and constitutes a specific policy in the spirit of territorial cohesion.

Europe's Islands Strategy 2020	Europe's Islands Strategy 2030+
Smart growth: growth based on the knowledge economy and innovation	Quality islands: exploiting local resources in special markets through the use of quality products and services (+tourism)
Sustainable Development: economy more efficient in the use of resources - green and competitive	Green islands: rational use of water, land, energy and anything that offend the natural environment
Enlargement without exclusions: employment with social and territorial cohesion	Equal opportunity islands: equal opportunities (businesses-individuals) with those of the European Mainland

Figure1. Schematically the outline of policy for the European’s islands [11]

3. GREECE, A COUNTRY ON THE SUSTAINABLE ROAD WITH USE THE "SMART ISLANDS"

The attempt of the international community to launch policies in favor of the environment, seeing the danger that was developing with the over-use of fossil fuels and especially oil with negative effects on the quality of life in urban centres. The trend of urbanization and the “rapid circulation” of public transport pushed at the end of the 70s, an urban planning for the "Smart City". This model sought a city with less consumption and parallel savings in a partnership between the private and public sectors. This initiative aimed at a sustainable development based in the three pillars which they produce equally and justice: the economy, society and the environment. This would be done through actions to deal with climate change, the radical restructuring of the productive business model, the conservation of natural resources and specially saving water, the restructuring of the administration and the use of "smart" measures - applications and methodologies for less energy than oil.

We can minimize the adverse effects of over-development by properly managing urban regions with humane dimensions on the basis of the sustainable development process.

The efficient use of urban land and energy resources through an optimum distribution of population within a balanced system of settlements would go a long way towards preserving natural capitals [12].

Essentially, we are talking about a shift in the way of job and consumption for the benefit of the ecosystem and, at the same time, the quality of human living conditions.

In 2007, the manifesto for Sustainable European Cities was adopted in Leipzig, Germany, based on specific initiatives and effective actions based on: 1.The quality of public space, 2.The modernization of infrastructure and building stock, 3. Education and training, 4.In the protection of the natural environment, 5.In the strengthening of the local economy and market, 6.In the improvement of public transport, 7.In the care of degraded neighborhoods [13].

This approach opened a door for the international community to plan the manufacture of products in a different way, to use the circular economy, to distinguish the environment as a dimension that offers value to humans. This success "awakened" developed countries to see development with other eyes, with the eyes of a planet in danger.

The continuous immeasurable growth and increase of the population brought about a series of problems that certainly have an impact on the human race. This form of threat has many dimensions and expands without recognizing borders and religions. Essentially, the environmental crisis is a threat that also has a moral dimension within it [14].

Many of the scientists have been written about sustainable cities to gradually move to “smart cities” with the valuable help of technology. Certainly, however, the socio-political background was offered by sustainable cities to the general arrangement of modern urban planning.

An example is the ten (10), “The Melbourne Principles for Sustainable Cities” [15]:

- Vision
- Economy and Society
- Biodiversity
- Ecological Footprints
- Model Cities on Ecosystems
- Sense of place
- Empower people to participation
- Partnerships
- Sustainable Production and Consumption
- Governance and Hope

The “Smart Cities” in the European area combine the urban small industry and the infrastructures of the future looking at three vertical priority areas: 1.Sustainable mobility, 2.Sustainable contraction and 3.Network and process integration in the fields of energy, ICTs (*Information and Communications Technology*) and transport [16].

Each one of these priority areas is divided into several key implementation themes or “Key enables”:

- Policy: citizen focus, regulation, planning
- Information management: Knowledge, indicators, standards, databases
- Economy: new business models, public and private markets, funding

In continuation of the Smart Cities initiative, in March 2017 in Brussels, the Declaration on "Smart Islands" was signed, which is coordinated at a pan-European level by the Sustainable Islands Network-“DAFNI” [17].

The “Smart Islands” Initiative is a bottom-up effort of European island authorities and communities. It builds on years of collaboration between European islands and seeks to communicate the significant potential of islands to function as laboratories for technological way, social, environmental, economic and political innovation. The “Smart Islands Initiative” is inspired by the Smart Cities and Communities – it seeks to improve life on islands through sustainable, integrated solutions that make the most out of islands’ competitive advantages. More so, the “Smart Islands” initiative underscores the role of islands in accelerating Europe’s transition into a low carbon, sustainable and economy.

A Smart island is...

the insular territory that embarks on a climate resilient pathway, combining “climate Change” mitigation and adaptation efforts, in order to create sustainable local economic development and a high quality of life for the local population by implementing smart and integrated solutions to the management of infrastructures, natural resources and the environment as a whole, supported by the use of ICT, all while promoting the use of innovative and socially inclusive governance and financing schemes.

Key Areas of Interventions:

Energy, Transport, Water, Waste, Governance, ICT and Economy [18].

► Ten (10) basics steps according the Declaration to be transforming the islands with a “smart character” are the following elements.

The way of smart islands is directs prosperous and creation societies [19]:

1. Take action to mitigate and adapt to climate change and build resilience at local level
2. Trigger the uptake of smart technologies to ensure the optimal management and use of our resources and infrastructures
3. Move away from fossil fuels by tapping our significant renewables and energy efficiency potential
4. Introduce sustainable island mobility including electric mobility
5. Reduce water scarcity by applying non-conventional and smart water resources management
6. Become zero-waste territories by moving to a circular economy
7. Preserve our distinctive natural and cultural capital

Proceedings

of the International Conference on **Changing Cities VI:**

Spatial, Design, Landscape, Heritage & Socio-economic Dimensions

Rhodes Island, Greece • June 24-28, 2024

ISSN: 2654-0460

ISBN: 978-618-5765-02-6

8. Diversify our economies by exploiting the intrinsic characteristics of our islands to create new and innovative jobs locally
9. Strengthen social inclusion, education and citizens' empowerment
10. Encourage the shift towards alternative, yearlong, sustainable and responsible tourism

Thus, the Greek islands are gradually trying to join the European spirit in the direction of "intelligent behavior and operation". The undertaking is difficult because the previous urban planning is absent and illegally construction has increased due to pressure from mass tourism. This has the effect of building obstacles for the contemporary transition to a green environment in the hope of reducing the energy footprint and protecting nature. This beautiful Greek nature is also the competitive advantage of the islands, which must be preserved by taking measures for the benefit of their islanders and tourists.

The planning of a national spatial tourism in combination with the peculiarities of each region is imperative and morally given for the sustainability of Greece's development path. With the thought that the tourism is the main source of income for the entire geographical area of the Aegean arc and also that it contributes decisively to the national economy, the government must immediately plan measures and carry capacity limits for tourism growth, assessing the cost/ benefit (value of money). The preservation of the natural and architectural beauty of the islands is the only way for a quality and alternative tourism, which together with mass tourism can shape a new business context landscape.

Greece needs to "take a rest" our islands from mass tourism and direct their development to a sustainable tourism path through interventions to change the building and construction model. This proposal can go from the concept of "smart islands" to cooperation between the state, business and islanders. By applying the ten (10) steps that have been mentioned previously in Declaration of "Smart Island" we can see the future of our islands, with another eye.

The necessity becomes imperative because time works against the islands if we do not change the development line. We must act quickly and methodically.

And this line also concerns the islands of the Dodecanese prefecture in the South of Aegean, which are a "key part" of the national economy as well as the tourist image of Greece, must act immediately. The change of course from the mass tourism of the 1970s and onwards, is imperative in the way of alternative forms of tourism offering quality to both tourists and citizens-islanders. The islands of the Dodecanese are offered for this object as a case study with environmental, social, cultural and economic criteria. The balance of all four of these sectors will draw a sustainable future for the region. We can all together achieve the goal of sustainability because without the cooperation and partnership of people the deterioration and pollution of the environment will worsen, the climate threat will be nourished and thus the islands will lose their "emerald" status.

Tourism is a socio-economic phenomenon based on the 6Ps (in transition) [20]:

Education-Culture-Environment-Quality-Politics and Protection.

The combination of these parameters gives away a plan and implementation axis for the successful outcome of sustainable steps for our islands. The aim is to preserve the natural character of our islands against the onslaught of profit and territorial overturning.

Insularity is a maximum political target. The Greek Constitution provides for it, the European Commission provides for it also.

It is up to us to make our islands open laboratories of ecological and sustainable development for the benefit of the current situation and future generations also.

Tourism must follow the limit, nature must be revitalized and human must work with the aesthetics that leads to the "depth of the beautiful" [21].

We owe it to our next generation and we owe it to the place that hosts us.

We did not inherit the environment from our ancestors but we borrowed it from our descendants.

4. ALTERNATIVE FORMS OF TOURISM AS A ANSWER TO QUALITY

TOURISM- THE CASE OF THE DODECANESE

The region of Dodecanese holds the lead in tourism traffic in Greece. This of course brings a great economic benefit to our islands with the parallel strengthening of the relevant infrastructures as well as the relative increase in the population and employees. But the increase in the numbers of current tourism does not mean the sustainable course of the place. The island place is an ecological, rare system. For that hat we must be preserved and taken care of [22].

The tourist mass pressure in certain months of the year (summer), create a multitude of problems in terms of the balance: nature-human-environment. This function is also the question in the modern era in the context of climate change and economic migration. The combination between environment, society and economy at the geographical limit of our islands is still today the goal of the government's plans.

The government and the local government also must cooperate in the final planning of our islands within a national spatial plan without delay and suspensions [23].

This call to do something for sustainable solutions in the general frame of smart and sustainable cities is necessary.

This approach also comes to the "complex of the islands of the Dodecanese" so that they can disengage from the shackles of the "monoculture" of tourism in an alternative, durable, sustainable way for the rational development of a local place [24].

Alternative different forms of tourism provide the autonomy of the tourist, contact with nature, respect for the cultural environment, healthy life and last they succeed to preservation of the architectural structure of the area.

This road can design a new development model based on tourism without removing activities from the other two productivity sectors, that is agriculture and industry

We propose a list of interventions from alternative forms of tourism for all our islands of the Dodecanese combining tourism, the environment and the island society

We read this list below [25]:

This idea can bring our islands back to the new path of revitalization in the spirit of preserving the unique landscape, sustainable development, attractiveness, maintaining and increasing the population, accessibility and also the "intelligent use" of the infrastructure to benefit of the citizen. The "Smart Island" can find a support in alternative forms of tourism following the tenth point of the Declaration for "Smart Islands", (which we have mentioned previously).

Rhodes is already at the stage of following the "smart islands" [26], also attempts to in a holistic sustainable development plan called "The Rhodes Co_Lab".

Also the islands of Halki, Tilos and Astypalaia from the prefecture of Dodecanese have projected a complete transition program to the "Green and Smart Islands" [27].

island	existing situation	Proposed state-complementary to the existing one
Rhodes	Mass tourism, cruise, marine tourism, third age (>60) citizens, student/international airport, tourist port and marina (relations with opposite "beach"-Turkey), seasonal tourism.	Agri-tourism, gastronomy, sports, Yachting (+ new marina), conference, therapeutic, spa, wellness, educational (ASTER and University of the Aegean), urban, ecotourism, rural, cultural, Golf Afandou, "watercourse", ecological.

Kos	Mass tourism, Yachting (existing marina), wine tourism - international airport, first steps in cruising, cycling, seasonal tourism.	Medical tourism – therapeutic, spa (Kos, «home» of Hippocrates), gastronomy, ecotourism, rural, conference, cultural, cycling, wine tourism and walking tourism
Kalimnos	Mass tourism, climbing-international airport- daily trips in Turkey, seasonal tourism.	gastronomy, ecotourism and rural, marine and "fishing" (multiple fish farms), climbing and diving tourism
Karpathos	Mass tourism, Windsurfing, Subaqua -international airport, seasonal tourism.	ecotourism and rural tourism, diving and surfing
Chalki	Mass tourism, partly walking (operates satellite of Rhodes)-today fully «eco-island», seasonal tourism.	walking, "fishing" (lots of fish farms) tourism, diving tourism
Simi	Mass Tourism, religious and marine, international Yachting-(good relations with the opposite “beach”- Turkey) - *operates satellite of Rhodes	Fishing tourism, gastronomy, ecotourism and rural, watercourse of airplane.
Tilos	Low flow-tension of tourism, island with “zero waste”, archaeological museum of small elephants	Ecological, Walking tourism, "Green Island", Cultural tourism
Nisiros	Low flow-tension of tourism, Volcano (Geothermal) Tourism, seasonal tourism.	Religious, Ecological, Tourist marine refuge of "Palos"
Leros	Low flow-tension of tourism, religious tourism seasonal tourism.	Therapeutic, maritime, (it has one of the largest natural harbour in the Aegean) - Yachting
Patmos	Tourism based on religious form (monastery of “Agios Ioannis”), cruise seasonal tourism.	Island with special religious importance, gastronomy, cruise
Astypalaia	Medium flow-tension of tourism, marine tourism, seasonal tourism	Ecotourism and rural tourism
Kasos	"Satellite" island of Karpathos, measured tourist flow, seasonal tourism.	Ecotourism and rural tourism
Lipsi	Low flow-tension of tourism, refuge marine life, seasonal tourism	ecotourism, marine-Yachting tourism
Kastellorizo-Megisti	Medium flow-tension of tourism, daily trips in Turkey, seasonal tourism	Marine tourism, monastic, climbing and diving tourism, watercourse of airplane

Proceedings

Agathonisi	Low flow-tension of tourism, seasonal tourism	Marine, nature lover tourism, water park, watercourse of airplane
------------	---	---

Figure 2, Alternative forms of tourism in the Dodecanese of Greece

5. CONCLUSION

The world today is going through a constant restlessness under the pressure of threats and fear. Geopolitical, environmental, immigration, climate, energy, food, hybrid construct a framework difficult to solve. Nevertheless, human resists the challenges with his strength, trying to create suitable living conditions. The growing population of the earth together with the over-consumption of products put the natural balance of the planet at risk. The international priority for a sustainable development in all over world has set an outline of changes for a holistic "green deal". This planning starts from the city, extends to the region, the country, the continent and the whole world.

It is a sustainable test of human's abilities to see the future with another consuming side, the side of the limits and the measure for the endurance of the natural sources of supply in the intended sustainable development.

The "smart city" comes in our days to answer the challenges of the modern resident through a design of the circular economy, the rational use of natural resources, the reduction of pollution and the proper management of waste and water. Europe concerned about climate change is following the imperatives of the 2022 "Green Deal" to transition to a green region by adapting energy conditions for the climate [27].

In sequence of all the previous ones, the islands of the Dodecanese, which constitute a separate ecological geographical entity, are directed towards an "intelligent development" responding to the imperatives of the time.

The tourism as a key factor in the islands' economy must adapt to the new political lines for "smart islands". This adaptation can be done through the change of mass tourism model to a sustainable tourism development using alternative forms of tourism as a response to the balance between economy, society and environment of our beautiful islands.

This is the answer for the future of our islands!

Planning and Design Strategies for public open spaces and "smart" applications in period of pandemic

M. Akrivopoulou

Urban Planner, Department of Urban Planning and Regional Development,
University of Thessaly, Greece

Corresponding author: E-mail: makrivopoulou@uth.gr, Tel +30 6943049897

Extended abstract

This paper explores the dynamic interaction between urban public spaces, urban planning and the unprecedented challenges posed by the pandemic COVID-19, with a particular focus on the city of Volos, Greece. The study begins by defining the fundamental concepts of public open spaces and their integral role in the urban fabric, providing a contextual basis for the subsequent analysis.

The research delves into the profound impact of the pandemic on public spaces globally, requiring rapid adjustments in their design, use and management. A comprehensive examination of the unique effects of COVID-19 on public spaces in Volos reveals both the vulnerabilities and opportunities presented by the crisis.

Based on these observations, the paper offers a number of applied guidelines for effective management of public spaces by local authorities during a pandemic such as strategies for temporary land-use changes in public open spaces, use-density of public open spaces and crowd control, measures for sanitation of public open spaces, and community involvement in both decision making and applied measures.

It highlights the importance of resilience and adaptability in urban planning.

In addition, the study explores the integration of 'smart' applications and technologies to enhance public space management during a pandemic, using AI-based tools, contactless services and data-driven decision making. Such innovations are investigated as valuable assets to ensure the safety and functionality of public open spaces in the face of unforeseen challenges.

Extended abstract

This study uses mobile positioning data provided by a telecommunications operator to examine both population and tourist mobility. The primary aim is to offer a nuanced understanding of these dynamics, correlating them with official statistics and tourism-related variables. It assesses tourist mobility using mobile phone data to understand the temporal and spatial factors influencing tourist flows. The study provides insights into tourist movement patterns and population dynamics in the region, highlighting the importance of hotel infrastructure in supporting local tourism and the need for more comprehensive and accurate analysis.

The methodology encompasses a hybrid approach of data extraction, transformation, and loading (ETL) from various sources, followed by the application of the Knowledge Discovery in Databases (KDD) methodology. It involves ETL processes to structure mobile data, integration with geographic information, and the use of machine learning models (both supervised and unsupervised) to investigate the influence of temporal and spatial variables on the number of visitors. Spatial autocorrelation analysis is also used to identify patterns in visitor density.

The analysis revealed a strong positive correlation between mobile positioning data (MPD) estimates and the 2021 Census data, validating MPD's reliability as a complementary tool for demographic and tourist analyses. Patterns in foreign tourist movements were identified, with peaks at weekends and preferences for daytime and night-time activities. A positive relationship was found between visitor numbers and factors such as public holidays, train routes, weekends and areas with historical points and tourist attractions. The impact of holidays on visitor numbers was particularly significant and varied with the length of the visit.

In conclusion, this integrated study provides valuable insights into tourist movement patterns and population dynamics in Viseu Dão Lafões. It represents a step forward in providing long-term trend analysis and assessing the impact of government policies on tourism, highlighting the importance of exploratory analysis in various social, environmental and economic aspects in Portugal.

RETHINKING THE FUTURE OF CITIES; Impacts & challenges of teleworking

Prof. A. Gospodini

Professor, Department of Planning & Regional Development, University of Thessaly, Greece

Corresponding author: Email: gospod@uth.gr

Extended abstract

The recent COVID'19 pandemic and community lockdowns introduced a large-scaled shift towards working from home (WFH), resulting in immediate but temporal impacts on city- centres, urban transportation networks, functional features of residential neighbourhoods and buildings. However, in the post-Covid era, teleworking is both expanding and growing. There are two new categories of teleworkers; (a) 'nomadic teleworkers' and (b) 'over-time teleworkers': The former includes those teleworking from places other than home and office - on trains, at motorway service stations, in airports, in the clients' premises, in holidays resorts, etc., - based on the development of mobile ICT, especially portable computers and mobile phones. The latter includes those teleworking from home outside the normal working hours (early in the morning, late at night, during weekend, etc.).

The percentages of teleworkers are rapidly growing worldwide. More specifically, in the European Union (i.e. the mean percentage of 28 member-states), home-based teleworkers were 5% in 2000, and only 7% in 2007. By 2022, the percentage increased to 10.2% with Ireland having the highest score (25.3%) and Romania the lowest (1.4%) [Data: <https://www.statista.com/statistics/879251/employees-teleworking-in-the-eu>]. Cultural variations appear to play a significant role in the differences among countries; in north-European countries telework is a better-established practice than in south-European counterparts. In 2022, 27.5% of US employees teleworked at least part-time – which was the average of all private establishments (U.S. Bureau of Statistics <https://www.bls.gov/>). Therefore, an increasing number of companies worldwide are adopting WFH policies, indicating that teleworking is likely to be a long-term trend in the labour market.

Urban economists, geographers and sociologists, urban planners and designers, and urban transportation engineers, have always had the tasks to analyse, predict, plan, and design urban space taking into account multiple variables, and focusing on the “lieu” where economic activities occur in cities, and where people reside. The goal of this roundtable discussion is to bring together academics from different disciplines to set up future scenarios for the possible boom of teleworking, and its major impacts (spatial, morphological, economic, and social) on cities. The discussion will focus on the following issues:

- How will the rise of telework impact the economic and social identities of city-centres?
 - Will increase in telework lead to a decrease in needs for large office space by private enterprises in city-centres, and thus, creating a surplus of vacant spaces and buildings in city-centres? How will this affect the office real estate? Additionally, what kind of businesses will move into the abandoned spaces of the city-centres?
 - What will be the impacts of such relocations on travel patterns in the city? Will urban transportation infrastructure (motorways, metro, suburban train lines) be underused and devalued?
 - What are appropriate gentrification processes for repurposing abandoned office buildings in city centres? Could the rise of telework make housing more affordable in the city centre? Could vacant offices in city cores be transformed into residential units? Could this promising strategy contribute to reducing housing prices?

- Will the vacant office buildings in city centres be transformed into tourist accommodation (e.g. small flats available for short-term rental through electronic platforms), and spaces for culture and leisure-oriented businesses?
- Will the economic identity of city-centres shift towards culture and tourism as symbolic economies?
- What are the anticipated changes for hosted activities and reuse of heritage buildings in the city centres?
- How will the rise of telework reshape inner-city neighbourhoods and suburbs?
 - Will private enterprises relocate to neighborhoods and suburbs, looking for better environmental conditions? What will be the impacts on real estate prices?
 - Will the increase in telework lead to new demands for cultural amenities, shopping, recreation, amusement, etc. in inner city residential areas, as well as in suburbs? How could these needs be addressed in the residential areas of compact Mediterranean cities, and the low-density north European and American cities?
 - Could residential neighbourhoods be transformed into self-sufficient urban units? Are new approaches such as the ‘X-Minute-city’ and chrono-urbanism a sustainable solution? Will an ‘holistic’ kind of neighbourhood be the new task for urban planners, urban designers, and architects? Is this a new opportunity to generate inclusive neighbourhoods in a just-city?
 - Will the existing house-typology undergo alterations? What’s the new role/function, typology and configuration of public spaces in ‘holistic’ neighbourhoods? What are the design and planning guidelines for ‘green and blue infrastructure’ as well as for sustainable mobility networks?

Abstract

Cities' resilience is an essential requirement for modern urban development. Urban trends that are related to natural (climate change) as well as economic and social phenomena (pressures on public health, geopolitical tensions, migration) are manifesting themselves at all planning levels, from the global to the local. These challenges, which vary in scale and degree of interaction, necessitate the adoption of strategic urban resilience planning in respect to a place's vulnerability. This study focuses on the spatial resilience of small towns, using the Municipality of Saronikos, a small to medium-sized growing city with insufficient strategic planning in the Regional Unit of Attica, Greece, as a case study. It seeks to add to the debate on the conceptual relationship between resilience, adaptive capacity, crises and governance of urban systems, as well as to emphasize the critical role of strategic planning and 'good' governance on the path to urban resilience. The research was based on the conduct of interviews with municipal officials and representatives of civic groups, following a SWOT analysis. One important finding is that dysfunctional governance produces an unpredictable picture, making it difficult to implement strategic goals effectively.

Keywords: *urban resilience; urban governance; strategic planning; adaptation; Municipality of Saronikos*

1. INTRODUCTION

Spatial systems are places of concentration of economic, social, environmental and political activities. The complexity of these activities, along with increased urbanization, results to the formation of pressures, disruptions and crises, with the result that each city typically grows at its own random yet structured rate [1]. Each city, depending on its characteristics and evolutionary capacity, is called upon to address disruptions through appropriate strategic planning. Cities are seen as complex, adaptive and emerging systems, consisting of multidimensional and interconnected subsystems such as governance networks, urban metabolism, urban infrastructure and socio-economic dynamics [2]. The urban environment is never in balance and is characterized by multi-functionality and increased spatial entropy [1]. The size of a city, its population, the structure of its networks and the activities it develops all contribute to its complexity [3]. In exploring its dynamic behavior, nonlinear systems cause confusion and division, and it is difficult to determine their relevance to urban planning [4]. Therefore, the evolutionary process is at the same time the source of problems but also the framework through which adaptation and sustainability are ensured [5].

Resilience management is an approach that emphasizes proactive action to make a system flexible in the face of future crises, despite its heterogeneity [6]. The goal of urban resilience is to make the city capable of adapting to disturbances and improving daily operations and services to its residents at any time. Simultaneously with the development of socio-economic and political dimensions, characteristics such as preservation, transition and transformation are taken into account [7]. Its defining aspect is "panarchy", which explains the hierarchical framework in which natural and human systems are interconnected via adaptive cycles. The concept of hierarchy is not related to the established vertical power control from top to bottom, but to the semi-autonomous levels generated by the interactions of variables with similar speed and spatial characteristics [8]. Strategies to enhance

Proceedings

adaptability and resilience are implemented in accordance with national institutional characteristics in urban planning systems [9].

Resilience is studied by analyzing adaptive resource management and adaptive governance [10]. The literature describes governance in various ways, depending on the stakeholders involved, the processes, mechanisms, institutions and administrative structures, the socio-political situation and the objectives pursued. It includes government, the private sector, civil society, methods and processes of planning, management and decision-making, with the perspective of flexible systems [11]. It depicts the ongoing interactions between members of a network, as a result of interdependence, resource sharing and negotiating common goals. Although networks are guided by central authority, they are not accountable to it due to frequent changes (such as state reforms), hence they develop autonomy through self-organization. Governance is of greater importance than government itself [12] and contributes with preventive strategies to local development [13]. According to the European Commission and the White Paper, four key challenges defined the framework for "good governance": greater citizen participation, more effective policies, debate participation, and redefining political-institutional institutions with clear goals [14]. Urban governance emphasizes the need for "management" (an intra-organizational approach) of cities [11]. An integrated model of urban governance includes the structural framework (state restructuring), the institutional environment (distinction of bodies and modes of governance), the political culture and the role of leadership [15].

2. RESEARCH QUESTIONS AND METHODOLOGY

The paper aims to contribute to the debate about the conceptual relationship between resilience, adaptive capacity, crises, and urban system governance, as well as to highlight the crucial role of strategic planning and 'good' governance in achieving urban resilience. The municipality of Saronikos, a small to medium-sized growing city, with insufficient strategic planning in the Regional Unit of Attica, Greece, was used as a case study. Considering the theoretical background and the 5 fundamental questions (Who, What, When, Where, Why) related to urban resilience [2], some research questions that arise are: Who decides what is prioritized to increase the Municipality's resilience? What are the most pressing concerns that the Municipality must address? What role does governance and the participatory process play?

Initially a SWOT Analysis was performed in order to understand the case study's characteristics, with the goal of documenting the strengths-weaknesses and opportunities-threats observed in specific development pillars. It is believed that such a systematization will aid in the recommendation of specific measures - at the operational planning level - at a later stage. Following the SWOT analysis, the core methodology was based on the conduct of interviews with stakeholders, i.e. municipal officials and representatives of opposition groups, through which the Municipality's most critical issues are identified.

The question of timing is also a significant research question; however, it is not addressed in this work. It is important to note that after a crisis, not all parts of the system respond equally quickly. Different levels of resilience exist within the city, as evidenced by some functions recovering more quickly than others. In order to create a benchmark state that would permit the usage of resilience, a time limit (before and after) to indicate the disaster should be defined [16].

3. CASE STUDY AREA: THE MUNICIPALITY OF SARONIKOS

The Municipality of Saronikos is one of the 66 Municipalities of Attica Region. It shares a border with the municipality of Markopoulo in the north, with the locality of Lavreotiki in the east and with Kropia in the west. It was established with the Kalikratis program in 2010 and the merging of the municipalities of Kalivia (the capital of the city) and Anavissos, as well as the communities of Kouvara, Palaia Fokaia and Saronida. Its area is 139.42 km², its population is 29.703 inhabitants (census 2021) and it is classified as a medium-sized city within the European Union's urban network. It features a 27km coastline, temperate environment with mild winters. It is considered the "home of the Kuros" of the archaic period, as well as the ancient "Asteos" roof that led pilgrims to the temple of Neptune in Sunio. It is the home of Byzantine monuments and temples as well refugees that arrived in Greece from Asia Minor 1923.

There is population growth and a trend of settlement in holiday and first residential areas in the surrounding area (20,000 additional inhabitants in the summer and roughly 10,000 in the winter). In addition, the municipality receives roughly 15,000 visitors every weekend during the summer and 6,000 visitors during the winter. Its privileged geographical position is reinforced by its proximity to the international airport "El.Venizelos" as well as the close distance from the port of Lavrio and Rafina. It is located 30min from the capital. The residential organization of the Municipality of Saronikos is unique in that it includes 30 minor communities, the bulk of which are located in the seaside zone, in addition to the urban centers of the cities-villages.

The Municipality of Saronikos is developing on the basis of the Athens Master Plan (RSA, L. 4277/2014). The RSA is a set of objectives, directions, priorities, measures and programmes for Attica's spatial, urban and residential organization, while simultaneously protecting the environment and adhering to the principles of sustainable development. It has as its vision for the period 2014-2021 the social, economic and environmental upgrading of Attica, with increased national and international role and with cultural identity, innovation, new entrepreneurship and local productive and social capital as key development pillars. The city of Athens lends its urban identity to the wider Attica region, boosting its competitiveness. The result is a system of expansions and infrastructures that connects all activities into a single spatial-functional system, the system of the metropolitan area, synthesizing the complexity of governance [17].

The municipality of Saronikos has launched a strategic / operational plan for 2012-2014, and since then, no new plans or modifications have been made. The vision of the Municipality is defined as follows: "A place that offers a distinctive quality of life, beautiful and creative, modern and human, open to the world, to new challenges and opportunities". The strategy outlines strategic objectives, whose accomplishment will set the local community on a course for growth in the interest of its residents. Accordingly, the mission of the Municipality of Saronikos was defined as "The governance of local affairs and the provision of excellent public goods and services to meet the needs of its inhabitants and local actors, with a view to the sustainable social and economic development of the area through the implementation of a policy that will contribute the most to achieving sustainable development and social peace".

4. RESULTS

Step 1: SWOT Analysis

The SWOT analysis as a tool is designed to i) strengthen the internal potential elements of the spatial unit as well as the opportunities offered by the external environment and ii) mitigate the internal weaknesses and threats arising from the outside environment. Through this process, it aims to i) reduce uncertainty, ii) identify the dominant and critical determining factors (internal-external) and iii) establish a documented strategic link of development action with the endogenous potential of the region and with the external environment [18].

Proceedings

The SWOT analysis conducted for the Municipality of Saronikos is presented in Table 1. The pillars that were chosen to build the analysis were: a. Health and well-being, 2. Economy and society, 3. Infrastructure and Environment, 4. Leadership and strategy. The selection of the pillars was based on the approach of ARUP and Rockefeller which identify 12 indicators that describe the fundamental characteristics of a resilient urban system through the City Resilience Framework.

Table 1. Swot analysis of the Municipality of Saronikos

		Positive factors	Negative factors
Internal factors	Pillars	Strengths	Weaknesses
	1st: Health & Well-being	Favorable geographical location Availability of clean land suitable for crops and irrigation from wells Participation of citizens in volunteering Places to accommodate citizens in case of cold and heat emergency	Non-existent sewage system Absence of state health services, municipal clinics unmanned by staff-equipment Environmental pollution in summer due to insufficient cleaning sector Abolition of the Open Municipal University and KEDIVIM
	2nd: Economy & Society	Stable population course Highlighting local identity and art with cultural events Sufficient hotel facilities	Informal settlements (not included in financing, disadvantage and hinder development) Reduction in production of the agricultural sector due to weak cooperatives Weak commercial urban centers Unexploited archaeological sites Lack of financial autonomy (most revenue comes from the state) Increased objective real estate values
	3rd: Infrastructure & Environment	Voluntary tree plantings - "Reforestation Award" Greek Green Awards 2022 Electric lighting network with upgrade to LED (characteristic of smart cities)	Lack of public transport, sidewalks and cycle paths Problematic intra-municipal road axes Non-existent disabled infrastructure Arbitrary construction in the peri-urban area and illegal placement of canteens on the seafront Fragmented coastal zone
	4th: Leadership & Strategy	Effectiveness of Civil Protection, based on incident recording (2021 award from the Ministry of Climate Crisis-Civil Protection) Saronic Municipality WEB GIS-Geospatial data platform regarding urban development	Non-existent strategic planning to promote the image of the Municipality Complexity of services due to overlapping responsibilities Inability to serve citizens due to organizational problems and knowledge level (non-evaluation of staff)
External factors	Pillars	Opportunities	Threats
	1st: Health & Well-being	Member of the National Intermunicipal Network of Healthy Cities Implementation of the "Housing and Work" program (Ministry of Labor and Social Affairs)	Risk of fire in the summer
	2nd: Economy & Society	Cooperation with the Municipality of Lavreotiki (Development Association) Job opportunities since the creation of the airport Employment program for the unemployed aged 55-67 (OAED)	The global financial crisis of 2008 has not brought back technical professions (especially in construction)

ISBN: 978-618-5765-02-6

	Operation of Anavissos School of Tourism Professions	
3rd: Infrastructure & Environment	Sorting of bio-waste in brown bins 15/02-31/12/2023 (E.P. "Transport Infrastructures, Environment and Sustainable Development 2014-2020") Clothing recycling program to reduce landfill waste Approved "Green Corners" (A. Tritsis Program) Approved extension of the suburban railway to the port of Lavrio, crossing part of the Municipality	Missing spatial planning framework that ignores the local community in the proposal to install wind turbines on Mount Paneio
4th: Leadership & Strategy	RSA guidelines Twinning with foreign cities	State directive not to hire permanent employees, resulting in temporary employment contracts

Step 2: Identifying critical issues through interviews

In the interview procedure, qualitative assessment was employed to determine resilience. The questionnaire was developed using the literature background, the swot analysis, and important research issues about crises and governance. The respondents were chosen based on criteria that sought to reflect as many categories of persons as possible who had adequate awareness of the topics at hand. The total number of questions is ten, and the number of responders is five, with the results presented as generalized findings.

1. What is the vision of the Municipality of Saronikos?

During the debates, it was discovered that there is no distinct vision, but that it is dependent on the priorities set by the coalition elected to power, thus it either concentrates on providing public services or on tourism marketing.

2. Is there a resilience plan for the city?

The responses were 'no' or 'I am not aware of'. In 2012, the analysis of the municipality's strategic and operational plan was released, however it was not based on the notion of resilience.

3. Is the Municipality of Saronikos included in any other regional, national or international strategy?

The answers were mostly unfavorable, except for referring to the replacement of electrification in led, which can be regarded an attempt to integrate into the notion of smart cities. One success factor for the municipality, as mentioned by one of the respondents, is its capacity to draw financing from a variety of sources and programs.

4. What, in your opinion, are the most essential challenges (risks) that the municipality is tasked with managing?

The risk of fire, which is a common occurrence in the area, comes first, followed by floods due to the presence of several streams. Then there's the issue of waste local unemployment and a lack of infrastructure.

5. Does the municipality have skilled personnel to carry out disaster risk management?

All of the respondents discussed civil protection, but from diverse perspectives, as follows: i) their training is insufficient, and they perform as a result of their honorarium; ii) they are fully trained because they constantly participate in certified programs (Red Cross, NAPRIMED, INCA), but lack equipment; and iii) the number of existing skilled personnel is insufficient, owing to short contracts. According to the latter viewpoint, the state's directive not to hire for some time during the financial crises of the '00s is a suppressive factor of development. When there are no permanent employees to fill important positions, training contractors can be a temporary solution.

Proceedings

of the International Conference on **Changing Cities VI:**
Spatial, Design, Landscape, Heritage & Socio-economic Dimensions

ISSN: 2654-0460
ISBN: 978-618-5765-02-6

6.To what extent does the municipality engage in participatory planning processes that solicit citizens' comments and suggestions regarding their needs?

The Municipality's technical program is overseen by the consulting committee. Furthermore, the Cleisthenes law (recent administrative reform) requires municipal councils to grant the right to participate to all citizens. Associations and cooperatives are seen as more active than the preceding ones, which submit their requirements once a year. It is worth noting the respondents' suggestion to establish KEP-type offices (KEPs serve as citizens' points of contact with government services) in extended spatial neighborhoods where citizens' confidentiality regarding their requests will be maintained. As a result, there will be no priority owing to prejudice and arbitrariness at the level of the public servant.

7.Is there a municipal strategy in place to create job possibilities (particularly for vulnerable populations) and market-building activities?

The municipality's plan involves getting involved with programs. The social services provided by the SSI's third pillar connect the unemployed with the OAED. The Social Solidarity Income (SSI) began to be implemented in 2017, with the aim of facilitating citizens experiencing conditions of poverty and social exclusion. The Municipality's legal bodies provide priority to the unemployed for a number of temporary employment opportunities as well as for housing.

8.Are adaptation and mitigation strategies for climate change proposed in planning processes?

Among the initiatives identified are the replacement of public lighting with LEDs, the “branch pruner”, and the Kalivia bioclimatic school. The building of wind turbines on Mount Paneio has divided public opinion, as suitable studies must also be submitted.

9.Do you believe the municipality adequately informs residents about the risks to which they are exposed?

The municipality's website is deemed insufficient, however there is a social media update and warning signs (with fire hazard indicators).

10.Are there measures in place to monitor legislative implementation?

The municipality is overseen by the central administration for the legitimacy of its decisions.

5. DISCUSSION

Factors affecting a city's resilience include risks to human, social and environmental systems as well as the degree of their readiness [19]. They originate either from long-term pressures (demographic changes, urbanization, political instability, climate change, prolonged poverty, persistent conflicts) or from sudden events (sicknesses, market fluctuations, outbreaks of violence, economic volatility, geophysical phenomena) [20,21]. In recent decades, the area under study has been under pressure from residential development (either formal or informal) as well as critical occurrences such as frequent fires. This development has made it difficult to distinguish between the unique qualities of each of these types of space and has resulted in an informal merger of urban and rural space. Since there is no shared objective, the different communities of the Municipality of Saronikos produce heterogeneity of activity, making it impossible to coordinate for collective output. The identified problem in local self-government is that personal relationships surpass objective planning, resulting in critical issues such as a lack of basic infrastructure and transportation system interconnection, unregulated construction in the peri-urban space, and signs of natural environment degradation.

The city of Saronikos faces changing threats, resulting in a disorganized and uncreative city. It might be claimed that it distinguishes partially passive and stable behavior (mechanical perception features), making the place unreliable in undesirable situations. On the other hand, it has the features of an adaptive system in that it continues to evolve, albeit slowly. Because there are often shortages of equipment and trained personnel in emergency situations, decisions must be made using the following: classification criteria, priority level, alternative strategies, objective target, assessment of possible results, assistance from specialists, discussion with stakeholder groups, adequate training of

Proceedings

people managing emergencies, the ability to calculate actual expenses and immediate reaction [22]. At this point, panarchy theory suggests that dealing with urban complexity must be approached on several scales, because each level conveys a set of information to the next and the relationships within them are modified without compromising the system's integrity [23].

While strategic planning establishes the framework for the development of cities through the dynamic involvement of all stakeholders, the inadequacy of urban planning methods to adapt to such a challenge highlights the necessity for good governance [24]. Regardless of the availability of financing sources, dysfunctional governance produces an unpredictable landscape, making it difficult to effectively implement strategic plans, with the realization of complexity, possible crises, and sometimes insufficient governance to handle a problem [11,13,25]. Cooperation in the realm of governance frequently occurs by chance or in the event of an emergency. Risk governance is also an important mechanism for coordinating risk management at the local, regional, and national levels among public authorities, administrations, the business sector, and civil society [26]. Strategic planning (identifying of needs-opportunities, search for actions) can be combined with prospective processes (foresight) in risk management procedures [27].

A multi-level governance environment can be viewed as a fluid mosaic of multiple and overlapping areas of jurisdiction and competence over specialized domains of sectoral policies that can more effectively respond to changes in demand. Flexibility is another feature of such a model [25]. A significant drawback of urban systems, such as the case study area of this research, is their organization when done from top to bottom using central control mechanisms in uncoordinated ways. In this instance, if policy-making and planning are viewed as system features, with control mechanisms incorporated as fundamental functional factors, it will be easier to achieve the objective of sustainable cities [1].

6. CONCLUSION

The work is based on the notion that governance is both the result and the means of a management procedure that aims to develop a common understanding of problem-solving through participation. Approaches around governance challenge conventional notions of the sovereignty of a hegemonic state [11]. The urban governance crisis is defined as i) problems arising from the diffusion of key functional relationships (transportation, education), necessitating a unified approach and/or coordination, ii) non-unified urban planning, and iii) deficiencies in the political legitimacy of decision-making bodies and citizen acceptance (democratic deficit) [14]. The concept indicates forms of public action where the hierarchically structured system is catalyzed, allowing for the participation and service of many actors' interests, as well as the attainment of common goals [28]. Its implementation presents difficulties due to insufficient institutional framework, weaknesses of administrative and audit bodies, indifference to institutional actors' participation, syndical and micro-political logic and lack of democratic procedures [29].

In a nutshell the critical issues that have arisen from the preceding analysis are a lack of basic infrastructure and transportation system interconnection, unplanned development on the outskirts of the city plan, natural environment degradation primarily due to fire events, business survival issues, and underutilized historical and cultural heritage. Another critical factor is the inadequacy of municipal services' staffing, which is linked to organizational issues and decreased productivity. Without a coherent strategy, efforts to increase the Municipality's resilience have been scattered. As a result, there is a lack of financial strategy and focus on revenue-generating development initiatives. 'Kallikratis' (an administrative reform program at the end of the 2010s) was implemented with flaws, in a limited time for diagnosing weaknesses, adapting and homogenizing the new structure, with a small number of implementation phases, and without giving weight to the unique local characteristics and needs.

Risk and crisis lurk in every system (social, institutional, urban etc.) and governance is a critical aspect in increasing urban resilience since it incorporates the perspective of adaptation. The risks of an urban system are found in both its internal and external environments. The Municipality of Saronikos is a place that faces changing threats, therefore identifying the weak and strong areas that need to be addressed will help to establish a sound strategy. It is distinguished in part by passive and stable conduct (characteristics of the mechanical perception of resilience), which renders it unreliable in adverse events. On the other hand, it exhibits the features of an adaptive system in that, despite moving slowly, it does not stop evolving. However, dysfunctional governance produces an unpredictable picture, making it difficult to implement strategic goals effectively.

The Municipality of Saronikos is a complex system, and protecting it is not an easy task. Because of its qualities, it requires careful handling to increase its durability. After all, resilience is synonymous with the survival instinct, which evolved as a result of the creation of a city in order to protect itself. Cooperation among all stakeholders (residents, actors) is essential for the sharing of ideas while ensuring financing availability. Continuous monitoring of changeable factors using indicators is critical for reinforcing this area, which, when combined with expertise, can aid in its robust design. The Municipality of Saronikos' society can be strengthened by applying the theoretical approach of adaptive cycles by protecting and preserving the experience on which change will be based, and by encouraging participation at all levels of administration and governance [13,30]. This circular process is based on the principles of participation, transparency, and accountability and effectiveness [31]. A critical situation does not always result in disaster, but it is caused by the exposure of the element at risk and its vulnerability. When resilience is an initial goal rather than a post-solving need, disaster response is activated, allowing the system to recover [32]. In this respect, cities that invest in and implement resilience-building strategies are better prepared to deal with shocks and chronic stresses.

Religious Archaeology

Transition from religious to cultural

The socio-cultural and economic changes that inevitably occur in contemporary cities contribute to the phenomenon of abandonment in specific urban areas, both residential and industrial, with a consequent perspective of decay. Consider, for example, the areas of former factories, with their spaces and buildings left neglected, which no longer shock us, but are instead catalogued within the realm of industrial archaeology. It has been acknowledged that these repulsive places can, in reality, become attractive and serve as an opportunity for urban development through their regeneration, involving communities in becoming participants in the project of change. This scenario is quite different when it comes to places of worship, the so-called "sacred places," where a sense of belonging, more cultural than religious, can generate social conflicts, especially in the era of free digital communication. Outcry arises if they are abandoned or repurposed, but it must also be emphasized that there is a persistent inclination to build new ones—mostly empty boxes inducing static rituals, examples of pure formalism, relegated to the fringes of urban development plans and scarcely utilized.

We are facing a new phenomenon: Religious Archaeology. Unused churches, convents, and chapels, which no longer spark interest, especially among the youth, are managed by clergy less inclined to contemporaneity. Today, sacred places take different forms, causing confusion in socio-cultural language. Consider, for instance, a stadium perceived as the "temple of football," with the ensuing "hand of God" à la Maradona or the "faith" in a sports team or pop star like Madonna. It is, therefore, imperative to rethink sacred space in new dimensions and urban settings, suitable for interaction with communities, in novel aggregative contexts such as shopping centers, sports facilities, transportation infrastructures, and urban parks.

The question arises: what to do with religious archaeology? Demolish it or repurpose it? And what about the "new" parish centers, underutilized and lacking in quality? Our cities are no longer uniform seats of Catholic communities; they no longer require oversized religious structures. A more realistic approach involves sustainable projects distributed in the most attractive locations of the metropolis, offering spaces suitable for various beliefs, and fostering the hope of peaceful coexistence and socio-cultural enrichment.

For too long, religious architecture has been directed merely towards construction; a pause for reflection is advisable, and a kind of "biological standstill" would undoubtedly help regenerate both the clientele and the designers.

Keywords: *Religious archaeology, Urban Regeneration, abandoned church, abandoned religious structure, reuse of religious place.*

Abstract

The study explores categorising future's ruins, focusing on global literature. Urban ruins and architectural waste prompt inquiry, shaping new architectural awareness. It aims to categorise and interpret future's ruins [1]. Ruins represent urban voids, non-productive areas integral to modern cities. Cities evolve, generating urban architectural ruins as spatial traces of human activity. These ruins, devoid of distinct character, actively shape urban fabric. The research classifies future's ruins, potentially subdividing them based on industrial sites, transit hubs, and critical infrastructure. It outlines three ruin categories, documenting historical mitigation techniques. Urban areas will transform structurally, converting utilised spaces into residual zones. Urban infrastructure changes, centres becoming polluted, and pristine areas diminishing. Given the construction sector's role in pollution, documenting these areas is vital to address ruins and reshape urban fabric, fostering healthier environments. Infrastructure includes transport and utilities, construction involves industrial and commercial buildings, and environmental efforts encompass renewable energy and conservation. This categorisation informs future ruin analysis, addressing urban development and sustainability challenges.

Keywords: urban decay; brownfield; urban resilience; drosscape; future's ruins; infrastructure; sustainability.

1. INTRODUCTION

Throughout the past century, numerous urban centres have undergone phases of expansion and contraction, precipitating fluctuations in industrial development. The ongoing evolution and evolving demands of industrial production, coupled with the pervasive crises affecting various industrial sectors, have engendered the proliferation of abandoned and deteriorated engineering sites and landscapes.

Within an evolving terrain characterised by constant transformation [2], the presence of future's ruins serves as evidence of continuous human evolution and the changing face of cities worldwide. Ruins, often overlooked or dismissed as mere remnants of the past, play a significant role in shaping contemporary urban environments. As urban areas expand and evolve, the emergence of such ruins highlights the complexities and challenges inherent in urban planning and development [3]. Despite their significance, future's ruins pose several challenges to urban planners and policymakers. The presence of these ruins raises questions about urban sustainability, environmental impact, and social cohesion. Additionally, the lack of comprehensive categorisation and understanding of future ruins hinders efforts to address their implications effectively.

This research aims to address these challenges by exploring the categorisation, interpretation, and implications of future architectural ruins. Based on international literature and case studies, the study seeks to develop a comprehensive framework for categorising and interpreting future's ruins. It aims to identify the factors contributing to the emergence and persistence of these ruins within urban

environments and evaluate existing strategies and techniques used globally to mitigate their impact on urban development. Furthermore, the research aims to propose innovative approaches and solutions for urban planners and policymakers to effectively manage and repurpose architectural ruins in the context of sustainable urban development.

Resilience and sustainability offer a compelling response to the research inquiry. By deploying preemptive strategies aimed at averting the genesis of future ruins, we effectively constrain our forthcoming options, proactively seizing nascent opportunities before their imperative emergence. [4] Through these objectives, this research seeks to contribute to a deeper understanding of future's ruins role in urban landscapes and provide practical insights for shaping future urban environments.

2. URBAN SUSTAINABILITY AND URBAN RESILIENCE

The categorisation of future's ruins in this study is based on the final transformation and scale of revitalization of the areas involved, as well as the surrounding areas. Examining the effects of urban ruins at focal points of upgrading cities or entire regions, the concept of sustainable urban development emerges. Sustainable urban development incorporates the collaboration of urban sustainability and urban resilience.

As the vulnerability of an area can easily be questioned by urban planners, policy-makers, and entire governments adapting to a new urban world, exploration into the shaping of damaged areas, buildings or infrastructures increasingly reflects an interest in sustainable urban resilience.

While urban resilience is characterised as a passive process of facilitating, maintaining and recovering the ecosystem of a city or region, urban sustainability is an active process of integration and progress in the compositions of a city. [5] These two components of sustainable urban resilience serve as the primary outcome and footprint for avoiding future disasters.[6] Based on the Paris Agreement on climate change, which was awarded by the European Union in October 2016 and constitutes the first legally binding global agreement on climate, as well as committing to the Green Deal, the European Union pledged to become the first climate-neutral economy and society by 2050 [7,8]. Among other things, the Green Deal includes measures such as:

- Investments in environmentally friendly technologies.
- Support for innovation.
- Development of cleaner, healthier, and more beautiful transportation.
- Elimination of carbon emissions from the energy sector.
- Ensuring that buildings become more energy-efficient.
- Improvement of standards worldwide.

There is thus an immediate need to transform existing infrastructure and building complexes into upgraded, economically, socially, and environmentally sustainable projects [10, 11, 12]. In the three categories of future ruins being investigated, namely infrastructure projects, industrial areas, and sustainable-environmental infrastructures, sustainability and resilience are encountered as imprints. Therefore, the categorisation of these is generally based on the concept of sustainable urban resilience.

3. CATEGORISING FUTURE'S RUINS

The paper presents three categories of future ruins and records techniques used in the past to avoid them based on global literature. Characteristic examples are provided per category, along with ways to avoid them. In the coming years, urban centres and settlements will need to completely change their structure, and many of these spaces we use will be transformed into residual areas. Existing infrastructure is changing, urban centres are being modified into polluted spaces, and healthy areas

Proceedings

are disappearing. As the building sector now accounts for the largest share of responsibility for atmospheric pollution, recording these areas is essential for creating a model for tackling ruins and establishing strategies for shaping the existing urban fabric on an urban architectural scale, leading to the development of the standard of living in a healthy environment.

Specifically, infrastructure includes transportation and service systems such as roads and mass transit, electricity production and distribution, water supply, and telecommunications networks. A second category encompasses construction projects such as industrial and commercial buildings, as well as specialised structures like military camps and hospitals. Finally, a third category comprises environmental and sustainability projects, including renewable energy infrastructure and environmental protection. This categorisation provides a framework for recording and analysing future ruins to address the challenges of urban development and sustainability.

3.1 Three Categories of future's ruins

Provides an analysis of future ruin categories, towards sustainability and urban resilience, for infrastructure types, presented in a clear format with supporting references and bibliography to demonstrate their conceptual basis.

I. INFRASTRUCTURES

- Transportation Infrastructure
 - a. Roads and highways
 - b. Bridges
 - c. Public transit systems
 - d. Airport, railway and seaports
- Utilities Infrastructure
 - a. Power Generation and Distribution (Solar farms, power plants, grid improvements)
 - b. Water Treatment and Distribution Systems
 - c. Waste Management Facilities (Landfills, processing plants, recycling centres)
- Telecommunications Infrastructure
 - a. Cell Towers and Broadband Network Expansion
 - b. Fiber Optic Cable Laying and Infrastructure Improvements

II. INDUSTRIAL DOMAINS

- Manufacturing facilities
 - a. Manufacturing infrastructures (car, trains, shipyards etc)
 - b. Warehouses (logistics, storage infrastructures)
 - c. Power Plants
- Commercial domains
 - a. Office buildings
 - b. Retail spaces
 - c. Public buildings
- Special infrastructures
 - a. Hospitals
 - b. Military camps
 - c. Prisons

III. ENVIRONMENTAL AND SUSTAINABILITY DOMAINS

- Renewable Energy
 - a. Solar Farms
 - b. Wind Farms

Proceedings

c. Hydroelectric Power (barrier, aqueduct, tank etc)

3.2 The NDSM case

The case of NDSM serves as a characteristic example of an architectural relic in the category of industrial domains, which has been transformed into something entirely new. Residential areas and cultural centers have replaced the abandoned shipyard, providing impetus for new investments in the area and the expansion of the initial design to all sectors of the region.

Amsterdamsche Droogdok Maatschappij (ADM), founded in 1877 on the north bank of the IJ in Nieuwerdammerham, developed into a central shipbuilding hub. With privately owned facilities including a foundry and pipeline and engine manufacturing plants, ADM grew significantly until its closure in 1985. In 1907, Verschure & Co Scheeps werf en Machinefabriek joined ADM, strengthening the area's industrial dynamism. At the same time, the establishment of NDSM and other shipyards turned the north bank of the IJ into an important industrial zone. In 1921, the official annexation of the adjacent villages by the municipality of Amsterdam established the Amsterdam-Noord district. Large passenger ships such as *Op ten Noort* and *Christiaan Huygens* (1927) were built in the new NSM yard, underscoring the development of the industrial infrastructure. The merger with NDM in 1946 and the construction of the *Osofond* in 1949 propelled NDSM to a leading position in the shipbuilding industry. In the 1960s, NDSM found it difficult to compete with Asian shipyards, leading to mergers and government subsidies. Lastly the NDM closed its doors in 1985.

The rebirth of NDSM is like the phoenix rising from the ashes. Europe's leading shipyard was transformed into a cultural center with international recognition. In 2018, it is a destination location for tourists and festival-goers from all over the world, with the marina hosting sailing ships. Its presence has been transformed into a combination of many roles: industrial monument, festival site, marina and artistic enclave. During the 70s and 80s, the Amsterdam-Noord area suffered from pollution and unemployment. Today, NDSM is a unique combination of past and present, a golden triangle between shipbuilding heritage, artistic culture and market power.

NDSM was once a shipyard that built and repaired ships up to 1984. After the abandonment of the 90-acre site, a development initiative emerged and regeneration, avoiding the dilapidated state. The adjustment started on 1990s when many buildings were occupied and later developed as sites work and cultural use. Completion of the project by 2034 includes the converting NDSM-West into a mixed-use residential area and NDSM-Oost into city park with art galleries and monumental buildings. This project has been marked as prime example of avoiding ruins of the future as represented by the dynamic reuse of existing infrastructure to cover modern ones intervals. This development was based on a comprehensive strategy, including of the techniques used for its safe restoration and renovation existing buildings.

The process began with extensive excavations and studies to assess the situation of buildings and infrastructure. The combination of these factors led to the developing a sustainable space, enhancing community and cultural life area. Overall, this procedure highlights the importance of its rational use of existing infrastructure and sustainable development to create resilient and urban observation environments. The readjustment of the NDSM in Amsterdam followed a comprehensive strategy sustainable development and avoiding future disasters. Some of the basic urban sustainability and urban resilience principles and techniques used include:

1. Recycling and Reconstruction: Reuse of existing buildings and infrastructure to reduce the environmental footprint and avoid it disposal of materials.

2. Community Participation: Active inclusion of the local community in the process development, securing support and understanding.
3. Sustainable Development: Ensuring that development is sustainable from ecological, social and economic point of view.
4. Multifunctional use: Exploitation of existing structures for various uses, such as events, offices, residences and art spaces.
5. Interface with the Environment: Integration of the environmental dimension in planning, in order to preserve natural beauty and biodiversity.

The future of NDSM looks promising as the plans for its development are ambitious. Major projects such as empty plots and Pontkade highlight the area as a vibrant cultural and residential space. Over the next decade, more buildings are expected to be constructed and activity to focus on sectors such as the creative industry. By bringing together the attractions of life, work and leisure, NDSM is expected to become an important hub of culture and innovation at an international level.

With the Haven-Stad development plan foreseeing the construction of thousands of new residences, and the prospect of high-rise buildings in NDSM West and its connection to Houthaven, the protection of the historic and cultural heritage becomes imperative. The establishment of an active NDSM fund for the preservation and repurchase of old buildings is crucial for maintaining the traditional value of the NDSM. [13,14].

4. CONCLUSION

The present study examines the categorisation of future ruins, focusing on international and global literature. The presence of ruins in the urban fabric and the parasitic growth of architectural waste raise questions and contribute to the formation of a new architectural consciousness. The aim of the research is to explore the possibility of categorisation and interpretation of future ruins. The concept of ruins constitutes a multi-faceted notion closely associated with the term urban void. The presence of these voids, characterised as non-productive and indefinite areas without clear boundaries, is one of the most significant characteristics of modern cities. These spaces appear both at the periphery and within the interior of a city, coexisting with its continuous development. As humanity evolves, the continuous transformation of cities leads to the development of urban architectural ruins. The ruins represent a kind of spatial trace of human activity. Rather than being mere remnants and reminders, they function as an intermediate landscape without their own distinct character. Nevertheless, they actively engage with and play a significant role in the urban fabric. This research aims to categorise future ruins to contribute to their classification and mapping. Industrial sites, hydraulic works, mass transit facilities, and critical infrastructure are examined, with future ruins possibly subdivided into various subcategories.

Extended abstract

In order to achieve resilient and sustainable urban environment, it is important to consider the fact that some times what residents like and wish differ from the views of both the authorities and the architects / urban planners.

The coincidence of the catastrophic phenomena of climate change, the energy crisis, the two wars, the economic crisis, plus the consequences of the Covid-19 pandemic, constitute a very particular and intriguing reference level to explore the views of the residents in relation to the present and future aiming at a resilient and sustainable urban environment.

This survey investigates the views of residents regarding the city of Thessaloniki. The research focuses mainly on the following two levels:

2. What the residents consider as important points / places / regions / locations of their city.
3. What the residents consider as the most important / serious / urgent problems and issues that have to be considered for the proper functioning of the city and its resilient and sustainable future.

The research has been conducted under the scope of environmental social psychology, which examines people's relationships and interactions with the built environment that surrounds them. Data collected through interviews and questionnaires are presented and analyzed, regarding the subjective considerations and semantic charges as expressed by the inhabitants of Thessaloniki.

The results of a social survey conducted in the greater area of Thessaloniki are presented in order to investigate the views of the residents on issues related to the urban environment, climate change, the energy and economic crisis and also the extreme phenomena.

The conclusions are expected to be useful to both the authorities and also the architects / urban planners.

Keywords: Social survey, Environmental social psychology, people's opinions, urban sustainability

1. INTRODUCTION

At the UN General Assembly (Paris 2015), all member states agreed on seventeen Sustainable Development Goals, of which the eleventh refers to the goals for Sustainable and Resilient Cities.

Since cities are considered responsible for 70% of energy consumption and 75% of greenhouse gas emissions, but at the same time there are problems in adequate, safe and affordable housing as well as in services and necessary amenities, it becomes necessary and imperative to make cities sustainable and resilient, both in the face of present circumstances and the challenges of the future.

Although the recent COP27 and COP28 highlighted the problems of disagreement on common goals by all states, the messages that were heard very loudly and clearly, made it known that there is no longer much room – from governments to us, ordinary citizens, to make cities viable.

2. THE SURVEY

This social survey in the greater area of Thessaloniki, took place after the recent elections in all of the municipalities of the region, and aims at the views of the people regarding their city. 1394 questionnaires were collected, which covered the wider area of Metropolitan Thessaloniki.

The results of the social survey are presented below:

Figure 1. Sex

Figure 2. Age

Figure 3. Area of residence-Working area

1.1. Section A

Figure 4. What do you consider to be the most important points / places / locations / buildings of the city?

Aristotelous Square seems to be ahead in all points, (Historical significance 86.97%, Architecture 83.49%, Related activities 86.35%, Frequency of use 87.01%, How much they like it 93.18%).

Next is **Tsimiski Street** (Frequency of use 79.81%, How much do you like it 73.41%), the **new seafront** (Frequency of use 57.42%, How much do you like it 69.32%) and the **old seafront**

Proceedings

 Spatial, Design, Landscape, Heritage & Socio-economic Dimensions
 Rhodes Island, Greece • June 24-28, 2024

ISSN: 2654-0460

ISBN: 978-618-5765-02-6

(Frequency of use 62.41%, How much do you like it 73.28%) all with a large percentage at the frequency of use but also at the other factors.

Then people mentioned the "landmarks" of the city, **White Tower** (Historical/Cultural significance 83.01%, Architecture/location 84.01%, How much do you like it 83.01%). **Church of Agios Dimitrios**, (Historical/cultural significance 68.38%, Architecture/location 62.45%, How much do you like it 54.21%). **Arch of Galerius, Rotunda** (Historical/cultural significance 61.45%, Architecture/location 62.33%, How much do you like it 59.42%), etc. but all with a small frequency of use (below 30%).

International Trade Fair (and the **Telecom Tower**) are also mentioned as landmarks, but also with a high frequency of use, 49.32% (for the Fair).

Moreover, an impressive percentage emerged regarding the frequency of use of **shopping centers on the perimeter of the city** (82.36%), in combination with related activities (81.42%), but also the availability of parking spaces (71,59%)

A.S.S.A Method Chart (Kosmopoulos, 1991)

Figure 5

References follow for all the "landmarks" of the city, such as **Agia Sofia street** and pedestrian street, **upper city with the castles, Ladadika, Kapani and Modiano markets, the YMCA, the City Concert Hall, the Ministry of Macedonia - Thrace**, with relatively various characterizations but also a relatively lower frequency of visit (less than 30%).

A.S.S.A Method Chart (Kosmopoulos, 1991)

Figure 6

1.2. Section B

Please make a sketch of the city as you think about it, marking up your familiar routes, as well as the points of interest to you:

Here are some of the Sketch map of the residents:

Sketch 1

Sketch 2

As we saw in the first part of the survey, (the answers), but also in the second part, (the sketches), the views of the residents about the important places of the city and which of them they like best, are well described.

1.3. Section C

■ a - Constant and general care is required ■ b - Needs resolution in the near future ■ c - Serious and Urgent

Figure 7. What do you consider to be the most serious / important issues problems / deficiencies for the city of Thessaloniki? Please list up to 10 and evaluate them according to the severity/importance you believe they have:

As for the responses to the third part of the survey, citizens indicate which ones they consider to be the most serious / important issues / problems / deficiencies of the city, and express their opinion on them. Here are the most important ones:

Traffic (98.03%): More bus routes are needed. More Municipal car parks and parking places. Clear and safe separation of lanes and areas for bicycles and skates. Continuous care of the roads’ surfaces (potholes). Unabstracted access to first aid and fire brigade vehicles). Of course, there is also the constant hope that the Metro will relieve traffic. Finally, there are many traffic problems, both on the ring road and in the city, regarding the construction of the Flyover new road (92.31%).

Sidewalks (92.37%): To limit their occupation by tables and motorcycles, take care of their paving, lighting, and access for people with disabilities (65.97%), and care to be taken of the tree lines.

Open spaces (91.27%): The majority want more green spaces with sitting areas and playgrounds that are regularly cared for.

Cleanliness (94.31%): More frequent cleaning of streets, sidewalks, and open spaces, care and cleaning of drainage wells so that roads do not flood, and more waste bins and recycling bins, with frequent collection, are requested.

Crumbling/Preserved buildings (59.38%): For the listed buildings scattered in the city, their maintenance is requested, or if necessary, the demolition of those deemed dangerous for collapse.

Streams (58.46%): It has been reported that many streams in the wider area need cleaning to avoid flooding.

Social care (50.18%): Residents are calling for more crèches, social welfare and care for the elderly, especially those living alone, and for housing and care for the homeless people sleeping on the sidewalks (51.39%). Stray animals should also be taken care of (43.21%).

Safety: The need to prevent illegal acts is highlighted with the desire for security cameras and increased police patrols (84.52%), and night street lighting (83.41%).

2. CONCLUSIONS

Both the tourist guides of the city and the leaflets that can be bought or are offered for free, as well as the Greek National Tourism Organization and the local Municipalities, mention lists of monuments and places to visit. But what this survey highlighted is which places/locations the residents themselves consider as important, and they have assessed their importance.

Moreover, the residents have mentioned what they consider to be the main problems in the city of Thessaloniki, and have assessed the necessity of solving them.

Consequently, we believe that the social research can help to achieve a convergence of views, but also another focus of view for any planned interventions in the city, and we hope that the local and regional authorities can exploit its results.

Regarding the traffic issue, more bus routes are requested, the need for more car parking spaces and municipal parking places (the availability of parking spaces is the reason why shopping centers on the perimeter of the city have become the preference of residents), and definitely to have a clear and safe separation of lanes and areas for bicycles and skates, so that there is no risk of accidents and the road surface (potholes) is taken care of. There should also be free access to essential vehicles). Of course, it is also hoped that the Metro will relieve traffic. And, of course, there are strong concerns about the disruption that the Flyover new road construction causes.

As far as sidewalks are concerned, it is requested to limit their occupation by tables and motorcycles, to take care of their paving, lighting, and access for disabled people, and to take care of tree lines.

When it comes to open spaces, the majority want more green spaces with sitting areas and playgrounds that are regularly looked after.

Regarding cleanliness, more frequent cleaning of streets, sidewalks, and open spaces is requested, care and cleaning of drainage wells so that roads do not flood, flammable objects and pruning products are removed to avoid fires, and more waste bins and recycling bins, with frequent collection. In terms of social care, residents are calling for more crèches, social welfare and care for the elderly, especially those living alone, and for housing and care for homeless people sleeping on the sidewalks. Also take care of stray animals.

Regarding the listed buildings scattered throughout the city, their maintenance is requested, or if necessary, the demolition of those deemed dangerous for collapse.

It is reported that many streams in the wider area need cleaning to avoid flooding.

A large percentage want more public and municipal libraries and cultural centers, while they say they do not need more nightclubs, "eateries" and cafes.

Proceedings

There are requests for two-way communication (smart city) with Municipalities, so that citizens might inform about possible problems (garbage, lighting, traffic lights, potholes, etc.) and that themselves are immediately be informed about possible problems (floods, earthquakes, fires, etc.).

The need to prevent illegal acts is highlighted with the desire for security cameras, night lighting and increased police patrols.

In conclusion, we notice that even without the residents having studied UN Goal 11, the residents themselves wish and hope for the realization of a Sustainable and Resilient City for the Thessaloniki of Tomorrow!

3. ACKNOWLEDGEMENTS

The processing and analysis of the results was done by the members of k-ecoprojects, and I am thankful. Most of all I am thankful to the residents of Thessaloniki who participated in the survey by completing the questionnaire.

Abstract

Urban river floods pose significant challenges to modern societies, impacting health, property, infrastructure, cultural heritage, and the environment. Over centuries, the perception of flood risk has evolved from an external threat to a societally constructed risk, influenced by vulnerability and exposure. Geographic Information Systems (GIS) have emerged as an effective, interdisciplinary tool for flood risk assessment, integrating natural and socio-economic data to create comprehensive flood risk maps. This paper reviews 60 academic studies to identify the strengths and limitations of GIS in flood risk mapping and underscores the importance of incorporating social dimensions and vulnerability indices. The inclusion of local community participation and social dynamics is crucial for developing effective, context-specific flood risk management strategies.

Keywords: urban river floods, social evolution, flood, risk management, river culture, GIS

River Floods: A Continuous Threat to Urban Societies

Urban environments are complex yet fragile ecosystems that are exposed to climate risks and their consequences for societies. Natural hazards, such as floods, pose a continuous threat to the development and sustainability of contemporary societies, as they can cause significant damage to health, property, infrastructure, cultural heritage and environment.

According to the Directive 2007/60/EC of the European Parliament and the Council, a flood is defined as “the temporary covering by water of a land not normally covered by water”. Last decades have been characterized by a significant increase in the frequency of floods, leading to substantial socioeconomic and environmental consequences. Between 2000 and 2021, floods represented 40% of all natural disasters and affected, directly or indirectly, more than 140 million people per year worldwide. [1], [2] Arrighi’s analysis in 2021 revealed, that more than one thousand cultural heritage sites all over the world, that underlined that 35% of natural and 21% of cultural and mixed UNESCO national world heritage sites, are currently in risk because of river floods, in terms of hazard and exposure.[3]

The inundation risk posed by urban rivers is influenced by several determinants, such as the natural characteristics of the river itself, including its morphology, dimensions, vegetation, water depth, and downstream hydrological conditions. Simultaneously, contemporary factors underscore the amplification of flood occurrences, due to rapid urbanization, demographic expansion, artificialization of natural areas upon riparian ecosystems, and the climatic alterations due to global warming. [4], [5]

Historical Floods: Myths and Early Risk Management

Throughout history, urban rivers have played a pivotal role in shaping human settlements, offering plenty of advantages. They have served as a natural defence system for ancient cities, navigation routes for commerce and trade, and harnessed hydraulic potential for diverse industrial purposes, including tanning, milling, and more recently, electricity generation.

First communities were trying to explain the mysteries of natural disasters, by giving these phenomena a spiritual character, with mythological and folklore stories all over the world highlighting how the rivers were inspiring respect, awe and fear in human societies.

These narratives, from Scandinavian mythology, when Odin and his brothers killed the giant Ymir, whose blood inundated the earth, to the Biblical tale of the Great Flood in Genesis, when Noah's ark served as the vessel of salvation, illustrate how ancient civilizations searched ways to interpret and contextualize devastating inundations.[6], [7]

According to ancient Greek mythology, rivers were "born" by the Titans Oceanus and Tethys and considered to be gods. Kifissos River (Athens and Boeotia), Ilissos (Athens), Maiandros (Asia Minor), Alfeios and its tributary Kladeos (Peloponnese, Olympia), are some of these Greek mythological river Gods. People were praying to the water element for protection, blessing and assistance, while they would offer prayers and sacrifices to them, seeking protection on their journeys over their waters, blessing for good flow and behavior of the rivers, and other favorable actions. [8]

From Allies to Obstacles: Rivers in the Age of Industrialization

As societies were evolving, industrialization and rapid growth of the population, alongside with the technological evolution changed radically the behavior of the societies against the rivers. That resulted in extensive land consumption and artificialization, affecting riverbanks, floodways, and water basins. The previous respect for the water element, was switched, when the now called "modern city" started perceiving rivers as obstacle rather than asset. Measures such as canalization, dam construction, and the implementation of artificial barriers, or even entirely covering of them, have been taken in previous decades to address climate hazards like floods or droughts, or in order to prevent water pollution in the cities. [9]

The process of artificialization has been identified as a significant disruptor of the natural hydrological cycle. This disruption leads in decreased vegetal interception, evapotranspiration, and infiltration, coupled with an increase in both the volume and velocity of surface runoff. These changes are primarily attributed to vegetation removal, soil imperviousness, modifications to natural drainage patterns, and the implementation of artificial drainage systems. [1]

An illustrative example of the consequences artificialization can be observed in Trikala (Thessaly, northern Greece) where Letheus river had been artificialized multiple times including the covering of sections of the river and the construction of dams. These interventions, despite several warnings issued in the late 19th century, led to the largest and most destructive flood of the Letheus River. This flood event occurred in June 1907, resulting in numerous fatalities and extensive property damage. Diakakis (2012), in his comparative evaluation of 545 flood events in Greece of the period 1880–2010, identified the Trikala flood as the most destructive in terms of human casualties, that caused at least 300 fatalities. [10], [11]

Another severe event was that of November 2017 in Mandra, (Attica, central Greece) owed to the covered torrents of St. Catherine and Soures. It was the result of a 150–160 mm rainfall event of 7 h duration that provoked a flash flood, with a death toll of 23 people and 6000 people being affected. Crucial was the role of the settlement's location, on the two streams, with no planning standards. [11], [12], [13] These types of events underscored that the urban integration of the river primarily requires the removal of potential obstacles to smooth flow and the urgent construction of necessary flood control infrastructures.

Proceedings

More recent example is that of Dubai flood on April 2024, were a huge and non-expected rainfall caused a great socio-economic-infrastructure impact on the city. The cruelty of the event itself, probably related to the climate changing conditions, alongside with the urban planning of the city that didn't take into consideration flood risk, led to a great catastrophe for the area. [14]

Modern Perspectives: Social Dimensions of Flood Risk

After the 1980s the perception of floods as an external risk for the society has been reconsidered. [15] Decision makers agreed on the fact that natural disasters, such as floods, are mostly socially constructed events related -as an internal risk- to the vulnerability of a system, and its characteristics. Anderson underlines since 1995 that “*Whereas previous assessments focussed on the "acts of nature" that come from outside human agency, later assessments have acknowledged that it is largely human actions, decisions and choices that result in people's vulnerability to natural events.*” [16]

Natural disasters are not necessarily 'disastrous' as they are inherently occurring phenomena on the planet. The actual risk arises from the adverse impacts of these phenomena on human-made environments. [17] Weichselgartner underlines that “*a natural disaster, in a pure sense does not exist; rather there is the interaction of changes in physical systems with existent social conditions. The disaster itself occurs within society and not within nature.*” [18]

Social vulnerability is a term that explain this susceptibility of a population or a social system towards these climate extremes, because in a theoretical non vulnerable system, there is no need of adaptation to natural risks. ¹ [19], [20] Various researchers and sociologists have pointed out that disasters have more to do with the social, political, and economic aspects of a group, since they reveal most of the times inequalities, injustices and weaknesses they affect mostly the socially vulnerable population.[21], [22], [23], [24] Poor population can be more vulnerable, since they can present a lack of access to coping resources and represent weak links in mitigation capacities. Elder people, women, people with disabilities or immigrants can be more vulnerable in a crisis situation, because of unequal access to information and education, physical and societal difficulties or due to communicational barriers.

Resilience describes the capacity of a system facing a risk to organize, predict, prepare, respond, resist disturbances, absorb impacts, recover, and reorganize, in order to maintain the same function and structure and continue to fulfill its purpose [28], [29], [30] Godschalk provides a well-framed definition of resilient cities, stating that resilience entails a city's capacity to recover from severe events without experiencing immediate chaos or lasting harm. He underscores the value of networked social communities and robust lifeline systems in building stronger cities through learning from past events. A resilient city, according to him, is a city that equally takes into consideration the natural systems (topography, soil, waterways...) and anthropogenic parameters (buildings, roads, energy facilities...) [24]

In order to deal with the floods, the European Commission enacted a Directive (ED) 2007/60/EC for the assessment and management of flood risks, requiring from each member the production of Flood Hazard (FHM) and Flood Risk Maps (FRM). These maps should focus on prevention, protection, and preparedness. In order to give rivers more space, these plans should, where possible, consider the conservation and/or restoration of floodplains, as well as measures to prevent and reduce damage caused by floods to human health and life, the environment, cultural heritage, economic activity, and

¹ *Although, history has witnessed as well and pure natural disasters and other events that occurred on the planet on a scale much larger than what the scale that humanity could affect (e.g., planetary temperature changes such as those that occurred towards the end of the 'Precambrian' geological era, which saw the coldest period in the planet's history leading to the extinction of many animal organisms, prolonged periods of drought, volcanic eruptions, etc.), which are beyond the scope of the present research.*

infrastructure. [31] In order to achieve this goal from this ED, and plan sufficient FHM/FRM, an urgent need for a comprehensive and sustainable approach has been revealed, involving the participation of all stakeholders. Contemporary urbanization strategies have started to reconsider their perception towards urban floods and adaptation strategies, aiming to define new solutions that embrace resilient and flexible projects that are promoting the idea of socially coexisting with urban fluvial floods rather than combating them. [9], [32], [33]

Mileti, in his book “Disasters by Design: A Reassessment of Natural Hazards in the United States”, emphasized as early as 1975, the importance of adopting an interdisciplinary approach against natural disasters with a long-term perspective that includes engagement with local communities. According to him, “*Local resiliency with regard to disasters means that a locale is able to withstand an extreme natural event without suffering devastating losses, damage, diminished productivity, or quality of life and without a large amount of assistance from outside the community*” [34]

The main challenge towards this reconsideration of the urban approaches though, lies in the difficulty of collecting, assessing and evaluating technical and social data from diverse perspectives and fields, and effectively communicate them to local authorities and stakeholders in a way that is easily understandable and coherent.

In this regard this paper proposes the use of Geographic Information System (GIS) software as an interesting tool that could serve as a connecting element for this reconsideration process towards an effective flood risk management culture for the contemporary societies.

GIS as an efficient Tool for Flood Risk Assessment

Geographic Information Systems (GIS) is a computer system designed to create digital representations of the Earth's surface by visualizing specific characteristics. Since its inception 60 years ago, GIS has rapidly evolved to a vital tool in various fields of application, research, and global business. Initially developed in Canada in 1963 by Roger Tomlinson for national land-use management, GIS has since grown into an integrated computer system for data visualization, storage, and manipulation. [5], [35], [36] ESRI's ArcGIS, the commercial form of the program was initially launched in 1981, while Quantum GIS (QGIS), founded in 2002 as a free and open-source alternative. [37], [38] Today, GIS serves as an essential information database, analytical tool, and decision support system, facilitating complex spatial analysis and visualization.

Urban river floods are multi-dimensional events that combine both spatial and non-spatial data. [5], [39] Identifying risk zones within cities and understanding their interactions with the urban fabric are crucial steps in developing effective urban flood management plans. GIS can perform hydrologic and social analyses and thus it has been a valuable resource for researchers, urbanists and public authorities all over the world in order to produce natural risk maps for the cities. [2], [40], [41]

GIS is commonly used alone or alongside with other systems and programs. For example, RS or Remote Sensing, is a well knowing technique using satellite or aerial imagery to gather data about land cover, topography, and other relevant factors. Hydrological Modelling (such as HEC-RAS, wetspa, hydrotel, swat or ArcHydro - an extension of ArcGIS) involves using computational models to simulate the flow of water during flood events, using as data terrain, land use, soil type, precipitation, and drainage networks to predict flood extents and depths. MCDM, or Multi-Criteria Descision-Making techniques (AHP, FUZZY AHP, ANP, DEMATEL, PROMETHEE, WLC, MAUT, TOPSIS, VIKOR, ELECTRE etc) are used to evaluate and prioritize multiple criteria or objectives. Last years, Machine Learning, or ML, algorithms (DT, RF, SVM, ANN, LR) have been used in order to analyse large datasets to identify complex patterns and relationships between various factors and flood risk. The use of these methods separately or the collaboration is standing as an efficient way of data analysis Flood maps production.

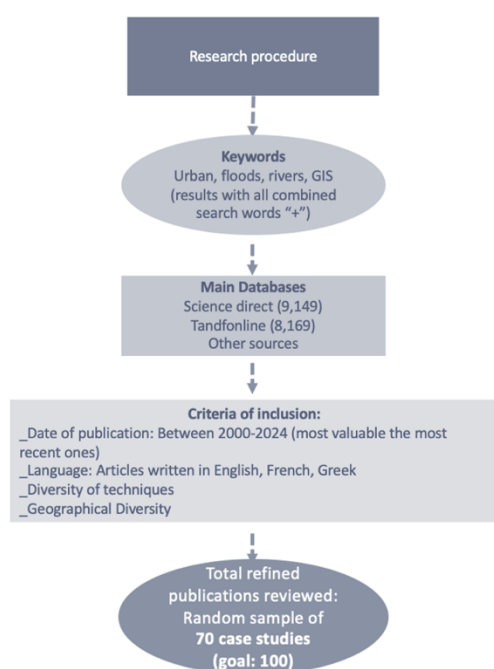

Criteria of evaluation

Throughout academic literature, there is a continuously increasing number of applications of GIS technology as a methodological tool in order to examine flood hazard and risk in different case studies, evolving alongside with the technological development and our knowledge on the matter.

This paper is effecting a state of the art in an amount of 60 papers, using a mixture of different criteria of evaluation in order to study and analyse the benefits and limitations of this tool in the FRM production.

The methodology for search, inclusion, and evaluation adheres to the parameters outlined in Table 1. Specifically, the chosen papers center on the examination of riverine or urban flash floods with the aim of producing flood analysis or flood risk maps. Selection criteria prioritize relevance to the research topic, publication year to trace methodological evolution, and geographic diversity of case studies to encompass varied socio-economic and geographical contexts across continents and countries.

Flood management and a GIS modeling method to assess flood-hazard areas—a case study	Greece	Europe	2011	FHM	B		x					Flow accumulation, slope, land use, rainfall intensity, geology and elevation	Tandfonline	
Flood risk assessment and mapping in peri-urban Mediterranean environments using hydrogeomorphology. Application to ephemeral streams in the Valencia region (eastern Spain)	Spain	Europe	2012	FRM	A	X						Hydrogeomorphological factors (topographic features, paleochannels and alluvial fans), and streambed characteristics) human exposure factors (LULC), economic value of properties, population density, critical infrastructures	ScienceDirect	
Regional scale flood modeling using NEXRAD rainfall, GIS, and HEC-HMS/RAS: a case study for the San Antonio River Basin Summer 2002 storm event	USA	American/Australia	2005	FHM	A	X						Elevation, soil, LULC, streamflow, rainfall-precipitation, river geometry	ScienceDirect	
Modeling of the flooding in the Okavango Delta, Botswana, using a hybrid reservoir-GIS model	Botswana	Africa	2006	FHM	A							Hydrological data	ScienceDirect	
GIS-based multi-criteria analysis for flood prone areas mapping in the trans-boundary Shatt Al-Arab basin, Iraq-Iran	Iran	Asia	2021	FRM or FSM	B and D					x		Rainfall data, elevation slope, soiltype, rockformations, soiltype, LULC	Tandfonline	
Flood susceptibility mapping using an improved analytic network process with statistical models	Iran	Asia	2020	FRM or FSM	B and D							Slope, Altitude, Aspect, Distance from River, Rainfall, Topographic Wetness Index (TWI), Slope Length (LS), Plan Curvature, Land Use/Land Cover (LULC), Geology/Lithology	Tandfonline	
GIS-based MCDM - AHP modeling for flood susceptibility mapping of alluvial areas, southeastern Tunisia	Tunisia	Africa	2016	FSM	B		x			x		Elevation, land use/land cover, lithology, rainfall intensity, drainage density, distance from the drainage network, slope, and groundwater depth	Tandfonline	

Findings: Bridging Technical and Social Aspects in Flood Risk Mapping

By examining Table 3, it is evident that the largest percentage, 32%, of the papers used qualitative-based empirical modeling techniques (such as MCDM/AHP) to produce Flood Hazard Mapping (FHM) and Flood Risk Mapping (FRM). Smaller percentages of papers used GIS in collaboration with statistical methods, hydraulic models, machine learning techniques, or a mix of techniques to achieve even more accurate results. Out of the 60 papers reviewed, 36 papers, have verified the results of their maps either using technical programs like ROC (Receiver Operating Characteristic) or by utilizing historical data from previous floods.

Almost 30% of the papers focus on FHM production, while the rest are focused on flood susceptibility and flood risk mapping. By examining the input criteria for the FSM/FRM production is interesting to notice that elements such as elevation, slope and river network are consistently examined across these studies, while variables like curvature and lithology are addressed in only a subset of them. (Table 2)

However, in terms of urban and social criteria, while land use and land cover (LULC) emerge as the predominant factor observed in the majority of papers, it can provide only a preliminary understanding of social parameters. While technical criteria represented the 74% of used factors in the totality of the papers, only 20% of factors are related with human infrastructures and, even less, 6% of factors have socio-economic character.

It's interesting to mention that analyses that include socio-economic criteria are found in high majority in articles of the last five years (only 3 articles included these types of criteria before, on 2008, 2012 and 2017), proving this increasing reconsideration on the matter of including social parameters. Although, they were still representing a minority of the FSM / FRM (34% of the articles included these types of criteria from 2019 to 2024).

Even though the majority of articles was focused on mostly technical analysis to produce the flood risk maps, there are some articles that searched deeper the socio-economic side of the vulnerability. Ajtai et al. (2023) made a social vulnerability analysis for their FRM, searching the index and the value of each social characteristic. They agreed that social vulnerability is influenced not only by the inherent characteristics of a certain community, but also by location, spatial distribution, hazard type, and hazard characteristics. The interaction between all these factors leads to complex relationships that must be considered and carefully analyzed. [42]

Bulen and Miles (2024) defended that Participatory GIS (PGIS) can help bridge the gap between modelled and perceived flood risk by involving the local community in research and questioning them on their past flood experiences. They conducted a survey in Reading, a large town in Central Southern England, incorporating local communities into the Flood Risk Management (FRM) production using PGIS. The study found a high level of agreement between participatory mapping and flood model outputs, demonstrating that local communities, with prior flood exposure or flood risk education, possess valuable knowledge that can inform effective flood risk strategies. [43]

Discussion/Conclusion

Urban river floods pose significant challenges to communities worldwide. The perception of flood risk has evolved from viewing natural disasters as external threats to recognizing them as internal societal risks requiring an efficient socio-technical interdisciplinary approach. Sustainable and resilient urban futures demand tools that facilitate research for urban designers, policymakers, and stakeholders. The contemporary cities need to think beyond the technical solutions to prevent catastrophic events, and to truly understand the social dynamics of each place and the way that society interacts in the case of crisis in order to propose urban and political solutions that reflect the special needs of each place.

Aknowledging the diverse social factors influencing vulnerability—such as population experience with disasters, socioeconomic inequalities, gender norms, and political-cultural contexts—enables

better identification of critical zones for urban reconsideration and development of targeted urban strategies. The society stands in the core of an urban environment, that defines its dynamics and evolution so it is critical to be an essential factor to be taken into consideration into the risk management strategies. The participation of the population in the decision making and the understanding of the social dynamics of each place is crucial in order to propose sustainable solutions. Geographic Information System has emerged recent years as an important tool, offering powerful capabilities in data visualization, analysis, decision-making support and fast and comprehensible maps production. GIS is software that can easily import, analyze and visualize various data, assess flood hazards, understand spatial dynamics, and communicate simply the results in a form of understandable basic maps. Stakeholders, such as urban designers and policymakers can exploit the multilayered nature of GIS technology in order to identify the urban priority areas for flood management strategies according to the socioeconomic priorities of the places.

The results of this literature review underline that despite the fact that the contribution of socio-economic factors in flood risk analysis can result in more precise flood maps, technical criteria remain predominant in flood risk assessments using GIS technology. Recent years indicate a progressive increase towards the integration of socio-economic data, proving an evolving recognition of the importance of social dimensions in flood risk management. However, this integration is still in its preliminary stages and requires further research.

The pursuit of urban resilience vis-à-vis climate hazards necessitates a comprehensive framework that combines natural and social dimensions. The incorporation of socio-economic data in map production is crucial for identifying vulnerable populations and urban areas, reassuring that flood risk management strategies are not only technically accurate but also socially equitable. Prioritizing the requirements and experiences of population and employing qualitative approaches, interdisciplinary collaboration, and participatory methods in the flood risk assessment is essential in order to create resilient and sustainable urban environments and mitigate the impact of natural disasters.

By analyzing the socio-economic fabric of urban areas, stakeholders can identify marginalized communities that are mostly affected by flooding events. Moreover, recognizing the socio-economic drivers of vulnerability enables the formulation of targeted interventions that address root causes rather than mere symptoms.

Interdisciplinary collaboration lies at the heart of effective flood risk management strategies. Reinforcing a collaboration and an efficient dialogue between experts from diverse fields (such as hydrology, urban planning, sociology, and economics) can result to the development of innovative solutions that integrate technical expertise and socio-economic insights for a better risk management. Furthermore, necessary are participatory methodologies that involve local communities in the decision-making processes related to flood risk management. By incorporating local knowledge, values, and experiences into planning, into a bottom-up approach, interventions are more likely to resonate with the needs and aspirations of affected communities and reinforce the resilience of the population.

In conclusion, the pursuit of urban resilience in the face of climate risks demands a holistic approach that integrates both natural and social dimensions. By centering on the needs and experiences of diverse urban populations, cities can become more adaptive, inclusive, and sustainable, thereby mitigating the impact of natural disasters and enhancing the well-being and resilience of their inhabitants.

Extended abstract

Cities do not lack of Nature. This presentation attempts to identify Nature not in cases of a tropical jungle forest, or a distant idyllic mountain, but also in cities, i.e., in densely populated, concrete, highly polluted and fastest-growing environment, where wildlife co-exists with humans and the built environment. That is, acknowledging City and Nature as one indivisible ecosystem. Contemporary metropolises and most cities face heavy impacts of urbanization that affect their very basic services: street infrastructure, sanitation, housing, human livelihoods and health. At the same time, anthropogenic pressures such as constant noise, chemical pollution, poor air quality, traffic, buildings' density, space disruption, dominance of cement and water impermeability, seem to also threaten the overall stability and resilience of urban biodiversity.

Additionally, it is estimated that climate change effects on cities such as heat waves, water scarcity, increased frequency of floods, can be an aggravating factor that intensifies urban growth impacts and further augments the existing pressures on urban biodiversity. Eventually these pressures may alter city's biological limits, disrupt ecological processes and dissolve arrangements and compositions. Responding to the above challenges, it is expected that ecosystems in urban areas should be able to change their behaviour and evolution patterns (adapt) and avoid threats so as to thrive living in the city.

Being a co-tenant of a shared living habitat and nature's ultimate ecosystem engineer, man is expected to convey the urban ecosystems' particular functions and interdependences with climate change. Current urban planning and design approaches integrate both mitigation measures that promote self-sufficient walkable neighborhoods, green infrastructures, sustainable urban mobility and transportation, energy savings and reduction in burning fossil fuels, and the implementation of adaptation strategies for buildings, materials, transportation systems, water and energy infrastructure resilience. However, there is more to understand on how urban species are changing over time in order to shape cities as a heaven for all living organisms.

This attempts to point out the complex interconnection of climate change with other challenging environmental urban conditions, to highlight existing tools for integrated assessments of urban biodiversity conservation, and to present best practices of city planning worldwide that may be adjusted for Greek cities. Ultimately, urban nature should emerge as an equally important "stakeholder" in the climate change responds and discussion; and it should be considered in future design of cities towards a more biodiverse and sustainable –urban well-being for all.

Keywords: *urban nature; biodiversity; urban planning; integrated sustainable solutions; adaptation*

Extended abstract

In this paper, the heating and cooling degree days of four different cities of Greece are evaluated using long-term climatic data. The ASHRAE method has been chosen in order to calculate the degree-days, with the required daily dry bulb temperature data obtained by the meteorological stations of the National Observatory. The study period involves the decade 2011-2020 and the selected cities are Kastoria, Trikala, Maroussi and Heraklion, representative of the 4 climatic zones in Greece. For the calculations of the cities' Heating degree-days (HDD), a base temperature of 16°C has been chosen while for Cooling degree-days (CDD) the base temperature was set to 24°C. Degree-days for all the cities are estimated on a monthly and an annual basis.

In terms of the mean annual air temperature, marginal deviations have been reported for each city throughout the years. Yet, the average annual air temperature values have been found significantly lower for the colder climatic zones (i.e. Kastoria and Trikala) compared to the warmer ones (i.e. Maroussi and Hraklion). Interestingly, the position of the weather stations and its respective microclimatic conditions, will affect the estimated values of the HDDs and CDDs. Regarding the annual values of the HDDs, the highest values are noticed in Kastoria following Trikala, Maroussi and Heraklion. The highest differences, reaching 73,8% - 83,8% have been noticed between Kastoria and Heraklion. On the other hand, Maroussi presents the highest annual values of the CDDs, followed by the corresponding CDDs of Trikala, of Heraklion and finally of Kastoria. As far as the CDDs are concerned the most important percentage deviation over the decade studied is that of 79,1% - 99,2% between Maroussi and Kastoria.

Abstract

Climate change poses an urgent global challenge, particularly impacting Africa, a continent with reduced greenhouse gas emissions. This study highlights the critical need for enhanced climate action in line with the Paris Agreement, focusing on Africa where rising global temperatures exacerbate coastal vulnerabilities. Climate change is a multifaceted crisis, leading to shifts in global climate patterns, including temperature increases, rising sea levels, and more frequent extreme weather events. Addressing this requires a multi-level approach, encompassing greenhouse gas emissions reduction, renewable energy transition, and climate adaptation, and mitigation at local, national, and international levels. Mangroves serve as a natural defence for Africa's coastal cities against climate impacts. Found in coastal intertidal zones, they provide ecological benefits, including shoreline protection and marine life habitat. However, their preservation demands complementary measures, such as effective land use planning and development regulations. Africa's coastlines, also often hit by extreme climatic events like cyclones, tsunamis and others face increased risks due to the diminishing natural defences provided by mangroves. These ecosystems are essential for mitigating climate change effects on coastlines, acting as buffers against wave energy and protecting offshore ecosystems from sediment runoff. Additionally, mangroves are vital for the social sustenance and economy of coastal communities, offering resources such as food, medicine, and timber.

This research conducts a comprehensive analysis of mangrove depletion in Africa, evaluating policies, initiatives, and community efforts directed towards their conservation and regeneration. It proposes strategies to enhance coastal resilience against climate threats like erosion and cyclonic events, aligning with Sustainable Development Goals 11 (Sustainable Cities and Communities) and 13 (Climate Action). These strategies emphasize the importance of combating climate change and its adverse effects.

Unfortunately, mangroves are in decline. To reverse this trend, strategies including policy reform, support for NGO and community-led mangrove conservation projects, and promotion of sustainable practices are vital. Notable efforts, such as those in Mozambique, demonstrate the potential of these approaches in reducing erosion and safeguarding ecosystems during climatic events. The study not only examines mangrove loss in Africa but also underscores the significance of NGO and community involvement in their restoration. Unfortunately substantial portion of mangrove depletion is attributed to human activities, with natural factors like cyclones also playing a role.

In conclusion, the study stresses that mangrove conservation is crucial for mitigating climate change and enhancing coastal resilience in Africa. Effective global collaboration, policy development, and training of the community increasing knowledge in mangrove conservation are essential, transcending environmental importance to become key elements of sustainable development and climate adaptation in Africa.

1. INTRODUCTION

One of the key concerns is that ongoing global climate change is expected to alter global biodiversity patterns significantly [1,2]. Climate conditions are a well-known driver of community and species distribution patterns from the global to the regional scale [3,4]. The predicted climate changes, such as higher temperatures, shifts in precipitation, and intensified storm activities, are likely to trigger substantial changes in these biogeography patterns [5]. Coastal areas have been identified as regions where vulnerability intersects with biodiversity hotspots. These coasts are particularly exposed to multiple changing pressures, including extreme weather events, sea level rise, intense anthropogenic activities, and regional habitat loss[6].

The vulnerability of coastal ecosystems has raised significant concerns within the conservation community. Coastal ecosystems often harbour a variety of rare and specialized species and provide crucial ecosystem services, such as serving as nurseries for marine life in the case of mangroves (Figure 1). Africa, in particular, hosts exceptional biodiversity, including endemic species and extensive coastlines. The inter-tidal habitats provided by African mangroves support significant fish and benthic faunal species diversity and perform numerous locally and globally important functions. However, these vital ecosystems are threatened by local anthropogenic pressures such as overfishing and mangrove deforestation, as well as global phenomena like climate change and sea level rise. African coasts already experience major environmental shifts, including a decline in rainfall in western regions and warming in the western Indian Ocean that exceeds global averages [7,8].

Figure 1. Photograph of a mangrove forest in Mozambique.

Human-induced global warming is a key driver of shifts in the distributions and ecological functioning of the world's ecosystems and the species they support. In Africa, land-use change has already resulted in severe biodiversity loss, and its conservation must remain a global priority. Climate change is altering rainfall regimes and temperatures across the continent, which in turn is expected to affect biodiversity and ecosystem services. Africa's coasts are particularly vulnerable to these climatic shifts, as they support rich biodiversity and are expected to experience continued population growth and climate impacts. Mangroves, one of the most important ecosystem types on African coasts, rely on stable environmental gradients, which are unlikely to naturally keep pace with the rapid sea level rise driven by global warming [11].

The resilience and adaptability of urban landscapes are critical as cities drive global economic growth and development [12]. African urban centers have grown exponentially in population over the last 60 years, with more than half of the world's population growth in the first half of this century expected to occur in sub-Saharan Africa [13]. Rapid expansion and increased urbanization may lead many cities to overlook critical social-ecological resources that provide vital ecosystem services central to the well-being of citizens. African coastal cities, in particular, are extremely vulnerable to the impacts of climate change due to an increased likelihood of flooding and severe storms. These impacts have potentially devastating effects on informal settlements, central business districts, transportation systems, and coastal infrastructure, including ports, energy, and water infrastructure.

Protecting coastal areas from erosion and other climate change impacts requires immediate attention and effective strategies. Mangroves and other nature-based solutions (NBS) play a crucial role in this protection, offering natural defences against extreme weather events and supporting biodiversity [14–16]. Their conservation and restoration are essential not only for maintaining biodiversity but also for ensuring the safety and resilience of coastal communities [13,17,18]. As such, a comprehensive approach integrating habitat protection, sustainable resource use, and innovative policy measures is paramount to safeguarding these invaluable ecosystems.

2. METHOD AND RESULTS

A comprehensive review of the literature was conducted on May 2, 2024, utilizing the Scopus database. The search was focused on the keywords 'mangrove', 'Africa' and 'NBS'. The inclusion criteria were defined to encompass articles published from the year 2020 to the present. This period was chosen to ensure the relevance and contemporaneity of the data.

From this search, a total of 30 articles were selected. These articles were meticulously examined, and the respective databases cited within them were also considered. The selected articles and their referenced databases are thoroughly documented and are integral to the scope of our study.

In addition to the academic literature, websites of several non-governmental organizations (NGOs) actively involved in mangrove protection were reviewed. These organizations were chosen based on their recognized contributions and ongoing projects related to mangrove conservation. The information gathered from these sources provided a broader context and practical insights, complementing the academic data and enriching the overall analysis.

The preservation of mangroves is of paramount importance due to their role as natural buffers against coastal erosion, storm surges, and flooding. Mangrove ecosystems provide critical services such as stabilizing shorelines, reducing the impact of natural disasters, and protecting coastal communities. Additionally, they are vital carbon sinks [19], sequestering significant amounts of carbon dioxide and thus contributing to the mitigation of climate change. By preserving mangroves, we not only safeguard biodiversity but also enhance the resilience of coastal areas to environmental changes and disasters. As natural solutions, mangroves are cost-effective and social and economic sustainable, offering long-term protection and multiple ecological benefits.

Furthermore, data presented in Figures 3 and 3 were obtained from the Global Mangrove Watch (GMW) database [10]. These figures include "*Estimates of mangrove areas in West African countries in 1996 and 2020*" and "*Estimates of mangrove cover in East African countries in 1996 and 2020*". The GMW aims to provide geospatial information on the extent of mangroves and changes over time. This data is vital for the national wetland professionals, decision-makers, and NGOs. The primary objective of the GMW is to offer countries without a national mangrove monitoring system an initial baseline of mangrove extent and change maps. This support helps prevent further loss and degradation of mangrove forests.

Country	Mangrove area (km ²) 1996	Mangrove area (km ²) 2020	Change (%)
Angola	293,25	283,57	-3,30
Benin	29,12	28,77	-1,20
Cameroon	1963,56	1970,01	0,33
Cote d'Ivoire	57,85	54,48	-5,83
DRC	238,00	236,84	-0,49
Equatorial Guinea	256,34	255,95	-0,15
Gabon	1759,46	1747,01	-0,71
Gambia	607,72	609,72	0,33
Ghana	180,67	179,52	-0,64
Guinea	2278,75	2211,45	-2,95
Guinea-Bissau	2742,92	2688,32	-1,99
Liberia	186,82	183,37	-1,85
Mauritania	3,25	3,44	5,85
Nigeria	8604,33	8442,43	-1,88
Republic of Congo	20,18	20,11	-0,35
Sao Tome & Principe	0,48	0,48	0,00%
Senegal	1266,03	1269,74	0,29
Sierra Leone	1600,47	1529,03	-4,46
Togo	0,53	0,50	-5,66

Figure 2. Estimates of mangrove areas in West African countries in 1996 and 2020 (adapted [9,10]).

Country	Mangrove area (km ²) 1996	Mangrove area (km ²) 2020	Change (%)
Comoros	0,97	0,97	0,00%
Djibouti	8,89	7,50	-15,64%
Egypt	2,94	2,24	-23,81%
Eritrea	93,37	77,91	-16,56%
French Southern Territories	6,72	6,72	0,00%
Kenya	549,90	544,30	-1,02%
Madagascar	2826,44	2775,67	-1,80%
Mauritius	5,53	4,32	-21,88%
Mayotte	6,77	6,76	-0,15%
Mozambique	3186,45	3027,35	-4,99%
Seychelles	3,83	3,83	0,00%
Somalia	36,79	35,15	-4,46%
South Africa	25,66	26,43	3,00%
Sudan	17,70	9,39	-46,95%
Tanzania	1136,96	1107,87	-2,56%

Figure 3. Estimates of mangrove cover in East African countries in 1996 and 2020 (adapted [9,10]).

The data on mangrove areas in West and East African countries between 1996 and 2020 reveal concerning trends of reduction, with some isolated improvements. In West Africa, the most significant reductions occurred in Côte d'Ivoire (-5.83%), Togo (-5.66%), and Sierra Leone (-4.46%). In contrast, Mauritania (+5.85%), Cameroon (+0.33%), Gambia (+0.33%), and Senegal (+0.29%) registered small increases in mangrove area, indicating possible effective conservation and reforestation efforts. São Tomé and Príncipe maintained its mangrove area constant, suggesting stable management of these ecosystems.

In East Africa, the most pronounced losses were observed in Sudan (-46.95%), Egypt (-23.81%), and Mauritius (-21.88%), highlighting even more severe degradation. Conversely, Comoros, the French Southern Territories, and Seychelles maintained their mangrove areas unchanged, while South Africa

Proceedings

saw a slight increase of 3.00%. These data suggest significant variation in the effectiveness of conservation policies and the pressure on mangrove ecosystems in different countries.

Comparing the major variations between West and East Africa, it is notable that East Africa exhibits more extreme percentage losses, as seen in Sudan and Egypt. In both cases, factors such as deforestation, coastal development, and climate change are common determinants. The conservation of mangroves is essential for biodiversity protection, climate change mitigation, and supporting local communities. Therefore, it is crucial to implement more robust conservation policies, increase awareness of the importance of these ecosystems, and foster international cooperation to share best practices and resources.

This dual approach, integrating both scholarly articles and NGO resources, along with geospatial data from the GMW, ensures a comprehensive understanding of the current state of mangrove ecosystems in Africa and the efforts being made towards their conservation. The selected articles, additional data sources, and geospatial estimates are detailed in the references section of this paper, providing a robust foundation for our research.

3. DISCUSSION

Mangrove forests, as pantropical coastal wetland ecosystems, provide numerous ecological services, such as functioning as fish nurseries, protecting shorelines, storing carbon, and controlling erosion. However, these ecosystems face multiple stressors. Over the past three decades, more than half of the world's mangrove areas have been lost, primarily due to deforestation driven by urban, agricultural, and aquaculture expansion. Climate change, particularly sea-level rise and increased frequency and intensity of extreme weather events like tropical storms, further threatens mangroves [20].

Traditionally, coastal protection relied on civil engineering solutions, including groins, seawalls, breakwaters, and storm barriers. However, these hard structures often cause ecological damage and reduce biodiversity by disrupting natural dynamics [21]. This realization has led to a shift towards nature-based solutions (NBS), which are inspired and supported by natural processes to address societal challenges cost-effectively while providing benefits for human well-being and biodiversity [22].

NBS offer multiple co-benefits, such as natural capital, green jobs, clean air, water regulation, recreational opportunities, and urban regeneration. Despite their potential, the adoption of NBS is slow due to the lack of standardized methods for assessing their multifunctional performance, which hampers the establishment of a solid evidence base demonstrating their advantages over traditional grey infrastructure [22].

Healthy coastal ecosystems, such as mangrove forests, play a crucial role in reducing flood risks. Their root systems and dense vegetation attenuate wave energy, trap sediments, and reduce erosion, providing critical protection and stability to coastal areas [21]. Understanding and promoting these natural processes is essential for effective coastal management (Figure 4). Figure 4 illustrates the dynamic interactions between hydrodynamic processes (e.g., sea level rise), morphological processes (e.g., subsidence), and ecological processes (e.g., tree growth). These interactions affect wave attenuation capacity and surface elevation changes, which in turn influence the functionality and persistence of mangrove ecosystems [23].

Figure 4. Hydrodynamic, morphological, and ecological processes interact in mangroves, determining their functionality and persistence [23].

However, much remains unknown about the effectiveness of NBS in extreme weather conditions. Future research and collaboration between engineers and ecologists are necessary to improve our understanding and application of NBS. Projects like LIFE Coast-Adapt in southern Sweden [24] and Seagrass Protect in the Western Indian Ocean are pioneering efforts to explore the interaction between submerged vegetation and coastal dynamics, advancing our knowledge and application of NBS for coastal protection [23].

Recently, NBS have been gaining popularity and are becoming integral to coastal management strategies in many countries. Despite their effectiveness, NBS is still a relatively new practice, raising concerns regarding their environmental and anthropogenic impacts. Additionally, there are several disadvantages and pitfalls that need to be addressed to enhance the implementation of NBS. Overcoming these challenges and concerns will be crucial for the broader adoption and success of NBS in providing sustainable and resilient coastal protection [25]. As the impacts of climate change intensify, there is a growing need for better guidelines on coastal adaptation management and NBS, as well as more evidence of their effectiveness. It is hoped that this will encourage governments and landowners to shift their perspective and, whenever possible, move away from relying solely on hard constructions toward adopting softer solutions [26].

The biogeomorphic dynamics in mangroves are characterized by continuous interactions between hydrodynamic, morphological, and ecological processes. The current state of a mangrove forest determines its capacity to attenuate hydrodynamic energy (i.e., reducing wave height and water levels) and its resultant functionality. Improving our understanding of these dynamics and providing robust evidence of NBS effectiveness will be critical in promoting their wider adoption as viable alternatives for coastal protection in the face of climate change [23].

An important but challenging approach is establishing "*Mangrove Benefit Plans or Funds*" from ecotourism revenue and taxes to support conservation efforts. Financing for mangrove conservation is crucial for African coastal communities and achieving climate goals. Discussions emphasize the need for investment in green infrastructure, with budgeting and policy alignment being essential steps [27].

Challenges for national strategies include a lack of interest in mangroves, constrained budgets, and limited political visibility. The concept of NBS requires more discussion to clarify its scope and principles and designing NBS inclusively can address local challenges and social justice concerns. Incorporating NBS into urban planning in Africa can address issues like green space depletion and water pollution while building resilience against climate risks. A citizen co-created approach can increase knowledge and integrate local insights. Promoting urban and peri-urban agriculture through NBS can support food production. Knowledge exchange between African Countries and other regions can enhance NBS implementation and management [27].

Studies, such as the one by O'Donnell et al., [28] have shown that mangroves perform well during storms and provide significant co-benefits, including carbon storage and habitats for juvenile fish. However, urban areas often replace vegetated shorelines with hardened structures. Future research should focus on overcoming barriers to conserving and implementing NBS along residential coastlines to enhance their adoption and effectiveness.

In conclusion, promoting NBS as viable alternatives for coastal protection requires improved understanding, robust evidence of their effectiveness, and better guidelines for coastal adaptation management [25]. Integrating NBS into broader coastal management strategies can provide sustainable and resilient solutions to climate change impacts. This discussion is further elaborated in the case study of Mozambique, highlighting the specific challenges and successes in mangrove conservation.

3.1. The Case Of Mozambique

Efforts to preserve mangroves in African countries often lack cohesion, resulting in inadequate protection due to insufficient policies, laws, and institutional frameworks. This issue is particularly prominent in Mozambique, where mangroves extend along the coastline, covering approximately 3,027.35 km², making them the largest mangrove forests in East Africa [29]. These vital ecosystems host eight mangrove species, primarily along major rivers such as the Zambezi, with the Zambezi River Delta alone housing half of the country's mangroves [30]. Despite their ecological and economic importance, mangroves face significant threats from deforestation driven by agricultural expansion, aquaculture, and industrial activities, leading to sedimentation and the degradation of surrounding ecosystems [29].

In addition to environmental challenges, inadequate urban sewage treatment poses health risks, while certain areas like Mossuril have witnessed mangrove conversion for salt production. Large-scale infrastructure projects like the Cahora-Bassa dam exacerbate mangrove degradation by altering water flow. Moreover, industrial pollution from activities such as oil and gas extraction, alongside crude oil transportation, further jeopardizes these ecosystems. Over time, Mozambique has experienced a decline in mangrove coverage, necessitating updated legislation and strategies to mitigate these threats [29].

In the study by Macamo, C.C.F. et al. [18], a case study highlights successful mangrove co-management in Nhangau, Mozambique, showcasing a promising model for sustainable restoration and conservation. Collaborative efforts involving the community, local government, and NGOs have led to initiatives such as mangrove planting, law enforcement, and the promotion of alternative income-generating activities. These efforts have resulted in tangible benefits, including mangrove rehabilitation, heightened community awareness, and improved ecosystem services. Nonetheless, challenges persist, necessitating strengthened legislation, improved management mechanisms, and enhanced financial sustainability.

This study offers valuable insights into the dynamics of community-based mangrove management and emphasizes the importance of stakeholder involvement in achieving positive outcomes. Future research should focus on the ecological aspects of mangrove restoration and compare replanted sites

with natural stands to inform decision-making and support the long-term sustainability of mangrove ecosystems in Mozambique.

4. CONCLUSION

Mangroves thrive in salty, oxygen-poor environments, expanding land where they flourish, acting as sediment traps, and buffering sea level changes biochemically. These behaviours are crucial to coastal communities, making mangroves exceptional in such habitats. The combination of biological and physical processes in mangroves produces a range of ecosystem goods and services. However, mangroves face significant threats, including conversion to aquaculture ponds, road construction, timber and fuel collection, and erosion. The urgency of conserving mangroves has intensified due to human-induced climate change and natural disasters like tsunamis and hurricanes.

Nature-based solutions (NBS) are emerging as vital strategies for protecting coastlines against extreme weather events. Mangroves, as part of NBS, play a pivotal role in coastal resilience by attenuating wave energy, trapping sediments, and reducing erosion. These natural defences are increasingly recognized for their effectiveness in mitigating the impacts of climate change and extreme weather events on coastal communities.

The first step in mangrove conservation is identifying the remaining resources, which is part of the purpose of Section 5's analysis. However, more knowledge of mangrove locations is insufficient without proper management within a broader context. Biodiversity, particularly well-documented in mangroves, is fundamental. Identifying diverse remnants can aid in establishing and conserving mainland reserves.

A variety of conservation tools, applicable worldwide, should be employed to conserve mangrove forests. These include habitat protection, technical research assistance, stewardship promotion, education, emissions reduction, sustainable resource use, and the development of high-value goods and services.

Future policy recommendations and research could benefit from a comprehensive assessment of tropical forests and ecosystems through remote sensing. This can inform investment allocation, emission reduction strategies, and global carbon impact assessments. Enhanced monitoring of forest carbon storage can further clarify local and global carbon impacts, aiding conservation efforts. Harvest design modifications, guided by inclusive practices and global conventions, can mitigate logging impacts and encourage forest restoration. Governmental incentives and restrictions should be realigned to promote sustainable practices and forest protection. Additionally, public awareness and education on forest conservation are crucial to support these efforts.

In conclusion, mangrove conservation is essential for protecting coastal areas against the increasing threats of climate change and extreme weather events. By integrating NBS into coastal management strategies, we can enhance the resilience and sustainability of these vital ecosystems. Collaborative efforts involving habitat protection, community engagement, and innovative policy measures are crucial for the long-term preservation of mangroves and the myriad benefits they provide to coastal communities.

Extended abstract

Over the last two decades most European cities have focused on developing coherent and innovative urban policies for climate change mitigation and adaptation, while creating a livable, sustainable, and resilient urban environment for their residents. To achieve these goals, key concepts and common strategies have been emerged, concerning both urban and transport planning and design, such as: green-blue infrastructure, nature-based solutions, public space and building greenification, ecological corridors, sustainable or green mobility patterns, transit-oriented development, “ville de proximité”, 15-minute city etc.

The paper focuses on the case of Paris, as a representative example of a European metropolis, which has a significant legacy both in green public spaces and mass transport systems (metro, bus). The city disposes an important green-blue infrastructure, progressively and top-down planned especially since the mid-19th century. Since the beginning of the 21st century, this infrastructure has been enriched through bottom-up design and reappropriation processes, while incorporating the ecological approach and the enhancement of biodiversity. At the same time, policies to enhance sustainable mobility, such as the introduction of modern tram lines, the strengthening of utilitarian cycling with the bike-sharing system (Velib’) and the extended network of cycle paths, the extensive low-traffic zones and streets pedestrianisation (rues aux écoles, rues végétales), which were accelerated since the pandemic and in view of the 2024 Olympic Games, provided multiple opportunities for public space redesign at street level.

The paper delves into the urban strategies employed by the municipality to prioritise green public spaces and efficient sustainable mobility systems, drawing insights from plans, initiatives and actions, such as Plan Climat, Plan biodiversité de Paris, Etude des Espaces publics à végétaliser à Paris, Plan Vélo, Plan Piéton, Réinventer Paris, Réinventons nos places, Embellir Votre Quartier, and Permis de végétaliser, which have shaped Paris’s approach to sustainable and resilient urban development during the last two decades. Based on literature review and field research, the paper attempts to explore these multifaceted plans, strategies, and actions, as well as their implementation processes to assess their potentials and limitations.

The Paris experience demonstrates the positive impact of integrating green public spaces with sustainable mobility. These initiatives have not only improved the quality and livability of the urban environment but also enhanced the well-being of its residents. Lessons learned from Paris innovative strategies, planning and design tools and participatory processes could provide valuable insights for cities seeking to address climate change impacts and achieve urban sustainability and resilience.

The Socio-Economic and Green Aspects of Adaptive Reuse - Adaptive Reuse as a Vehicle towards Viable Redevelopment in Cyprus

D. Parpas¹, A. Savvides²

Extended abstract

This paper grips on the practice of adaptive reuse and its great potential to contribute to smart redevelopment schemes focusing on the built fabric's resilience and its viable regeneration/redevelopment.

By adaptively reusing an asset, the underlying abandonment is minimized along with its adverse effects on both the social and built fabric. Adaptive Reuse is beneficial as it connects the new version of the building to its original character and the embedded narrative. Therefore, the sense of place can be retained, and certain values are conserved (such as social, cultural, historical). Relevant links to the past and significant memories are kept, and historical or cultural landmarks are safekept. Going off from this realization, core social values such as pride and memory can be enhanced by careful consideration of adaptive reuse strategies which highlights that adaptive reuse contributes to maintaining the character and the vitality of the built fabric, while at the same time contributing to the continuation of the livability of certain areas going through social or economic changes, thus making them resilient and durable.

Furthermore, adaptive reuse as a practice can be characterized as "smart" as it preserves regional flavor while minimizing impacts on the environment; recycling participates in this process as a more viable path is followed concerning materiality and sources, and the grey energy associated with these. However, through long periods of recession, any kind of development or redevelopment within the built fabric can be postponed or discouraged. Taking for example the negative economic effects of the COVID-19 Pandemic and the war outburst surrounding Cyprus, the building industry has been greatly struck. Henceforth, this paper overviews data and showcases examples from the current situation in Cyprus relating to new developments/ constructions as opposed to regenerated/ reused assets and their socio-economic reflections. The data derives from both governmental sources and private architects' archives. The findings indicate that, when comparing similar cases, adaptively reused units or complexes are not necessarily more affordable. Nevertheless, it is noted that sometimes more informal strategies are implemented, and simpler actions are taken, with minimal transformations, that truly affect positively both the units and their context (small and extended scale). Finally, the paper discusses how the narrative around adaptive reuse, described at the beginning, can provide food for future redevelopment schemes for them to fall under the scope of resilience and sustainability.

Extended abstract

Cities have always been vulnerable to various environmental risks. These threats have been growing in recent years: accelerated urbanization and rapid development are encountering ever-increasing negative ramifications of climate change. Floods represent one of the most dangerous natural disasters, which, if woven into the urban fabric, represent a global problem threatening the densely populated environment. European cities are increasingly suffering from severe floods, and the case studies of cities with built-in examples of urban flood resilience could provide a database for lessons learned.

The Dutch city of Rotterdam represents the European front-runner in dealing with climate risks smartly and proactively from the strategic to the implementational level. The comprehensive case study of the City of Rotterdam aims to understand interdependencies between spatial problems related to floods, strategic and urban planning measures to deal with them and the effectiveness of concrete built-in solutions to achieve urban flood resilience. The analysis, evaluation, and discussion start from a broader aspect and continue with a more specific perspective. A case study analysis is structured in two steps.

In the first step, the literature was reviewed in a broader context. The analysis was structured in two thematic groups related to (i) a review of the identified scientific articles using keywords “flood resilience” and “Rotterdam” in WOS Core Collection and Scopus and (ii) the identification of strategies and plans shaping the city with proposed measures and examples of possible solutions to achieve flood resilience. The actual built solutions were examined in the second step to determine applied criteria and measurable indicators.

The first analysis identified an existing legislative strategic and planning framework and means implemented in it to achieve urban flood resilience. The second analysis resulted in a comprehensive collection of design solutions to enable flood resilience and their classification according to the type of flood problems they respond to. Systematic analysis of selected constructs in literature resulted in defining context – it provided insight into approaches (frameworks, models, methods, tools, etc.) in achieving resilience and an overview of all relevant strategic and planning documents, which implement solutions for identified flood problems on this specific example and further provide lessons learned about planning and urban design criteria in post-disaster flood situations. The paper presents the initial phase of the pilot case study for Rotterdam City, part of the proposed and ongoing doctoral research focused on urban flood resilience criteria on a neighbourhood scale. Further research of the selected case studies aims to identify urban design criteria and measurable indicators which enable urban flood resilience for specific urban flooding problems.

Extended abstract

This session will present the results of preliminary efforts to enhance multi-hazard resilience in Dili Municipality, Timor-Leste, in the aftermath of Tropical Cyclone Seroja (2021). Heavy precipitation in combination with the topography and local development patterns, triggered flash floods and landslides that led to the devastation of roads, bridges, public facilities and other infrastructure. This climate event is part of a larger pattern influenced by the effects of global climate change. Severe droughts plague the region for extended periods, punctuated by violent tropical storms that will reportedly only increase in intensity and frequency.

Supported by the Global Fund for Disaster Risk Reduction (GFDRR), the Consortium is tasked with developing design-driven, risk-informed spatial strategies to improve the municipality's capacity to adapt to wet, dry and in-between conditions, while improving baseline resilience to events like, floods, earthquakes and tsunamis that are also prevalent in the area. The team is using a combination of grey and green infrastructure, including nature-based solutions, to facilitate landscape restoration and smart urban growth while also mitigating multi-hazard risk. Proposed recommendations are validated and prioritized to reflect the local context, values, and perspectives through a rigorous multi-stakeholder engagement process.

The Consortium will open the session with a presentation on Dili Municipality's risk profile, identify opportunities for designed intervention at the urban and regional scale, and address the very process of the challenge itself. Next, our team will discuss how international resilience efforts might be structured to optimize the resilience value to the city, leveraging innovative approaches to engagement and capacity building to inform urban governance and financing strategies. The team will close the session by opening the discussion to our audience.

Extended abstract

Urban agriculture (UA) is the collective name for a wide variety of farming activities that occur within the boundaries of a city or the direct sphere of influence of a city. A shared feature of UA types is a limitation in space: horizontally, vertically, or both. Farming is generally not the primary function in the urban ecosystem; however, its spatial role should not be underestimated. Urban green spaces connected with urban agriculture are widely accepted as a nature-based solution for effectively addressing societal challenges related to urbanization. In Polish cities, urban agricultural areas comprise large percentage of the cultivated area (about 43.5% of urban areas in general are located within the city limits. According to public data, 7.8% of individual farms in Poland are urban farms. Resilience is understood as a certain perspective or way of thinking, as a set of solutions that increase opportunities in various dimensions (social, physical or financial), as anticipatory planning for building potential and increasing the capacity of resilience (absorption of shocks and regeneration). Having said that, urban agriculture has a potential for climate resilience.

In general, the future of agricultural land use in Europe is uncertain. Competition for land between agriculture and urban land use is very intensive. The problem requires a wide policy agenda and needs to be addressed by various policy instruments combined with legal instruments. The second group comprise mostly of the regulatory ‘command and control’ planning approaches. However, there is a growing interest in the other type of instruments, for example the market-based instruments (MBI).

The presentation and the following paper aims to present a potential for innovative instruments for urban agriculture protection and identify barriers to implement such solutions. The paper analyzes both theoretical frameworks and practices for protecting agricultural land use through various instruments in Polish cities. The analysis is three-fold. Firstly, we identify strengths and weaknesses of the Polish system of UA, both in a historical and contemporary context. Secondly, future challenges resulting from the current global and local conditions will be indicated as well. Thirdly, we departure from the traditional focus on economic tools (mainly subsidies) for supporting agriculture in search for more efficient, inclusive, equitable and integrated UA. Protecting urban agriculture requires flexible, stimulating and context-sensitive tools. In this regard, we formulate *de lege ferenda* conclusions and recommendations. Our framework is national-context-sensitive, so it may be used for various national case studies, too. Moreover, such results may contribute to further comparative studies.

Evaluation of the polycentric operational model for a Greek city

K. Christoforaki

Dr. Architect Engineer – Urban Planner, School of Architecture, National Technical University of Athens, Greece

Corresponding author: E-mail: ka.christof@gmail.com, Tel +30 6937961619

Abstract

The COVID-19 pandemic has become a pivotal point for reevaluating how users engage with urban environments. The swift transformations observed not only in the economic and social sectors but also in daily life have prompted a global reconsideration of the functioning of developed cities under these new circumstances. Furthermore, the imperative to address climate change has spurred research into the optimal operational model for modern cities, encompassing mundane functions and needs, car usage, networking, and communication.

The polycentric city formation model emerges as a response to these challenges. This contemporary theory integrates technological advancements and is user-oriented, aiming to cultivate a greener, environmentally friendly urban space that contributes to the fight against climate change. Given the shift toward a more sustainable environment and a user-friendly city structure which aligns with the principles of sustainable mobility, and also the potential of the available technology, the implementation of a structure with multiple centers, a mix of functions, and extended networking can generate a new urban topography rooted in 21st-century environmental principles.

This paper extends previous research, where the polycentric city model was evaluated using economic theory, specifically through applying a cost-efficiency analysis. The objective was to establish foreseeable outcomes of such a formation, and quantify potential benefits on environmental, economic, and social levels. The analysis employed ex-ante evaluation, simulation techniques, and indicators to define the cost-effectiveness ratio. The findings revealed that the cost of implementing a polycentric operational model in Greece, while dynamic and varied case by case, is relatively low compared to the resultant benefits. Most of these benefits align with the European Sustainable Development Goals, a strategy to which all European countries and cities are already committed and working towards fulfilling. The seemingly lower cost for Greek cities to transition to a polycentric model is attributed to their small-scale urban fabric and the mix of uses, both essential factors when implementing this operational model. Neighborhood formation is already favored and present at a foundational level, providing Greek cities with an advantageous starting point in terms of the potential costs of restructuring from scratch.

This paper is part of an ongoing research and builds on the previously established evaluation model and employs a case study to validate the evaluation method, producing a series of observations and estimations regarding the costs and benefits of polycentric city operations.

Keywords: *post-pandemic city, urban environment sustainability, polycentric city.*

1. INTRODUCTION

The polycentric city constitutes a development model that has been examined in various variations in urban planning theory since the last century. In contemporary discussions within urban planning, the concept evolved to the 15-minute city that emerged as a compelling vision aimed at fostering more livable, sustainable, and resilient urban environments. Essentially, the 15-minute city model advocates for reconfiguring cities to ensure that residents can conveniently access essential services, amenities, and job opportunities within a 15-minute walk or bike ride from their residences. This vision signifies a reappraisal of conventional urban development patterns, which typically prioritize

Proceedings

Spatial, Design, Landscape, Heritage & Socio-economic Dimensions
Rhodes Island, Greece • June 24-28, 2024
ISSN: 2654-0460
ISBN: 978-618-5765-02-6

automobile-centric infrastructure, towards a structure with multiple small scale centralities within the urban fabric.

Among the European cities, the city of Paris has been leading in the implementation of the 15-minute city concept, leveraging its distinctive urban layout and cultural heritage to redefine how urban life is organized spatially. Through strategic interventions and policy measures, Paris seeks to cultivate compact, polycentric neighborhoods where everyday needs can be met within close proximity. This approach aims to decrease reliance on cars, encourage active transportation, and improve overall quality of life.

Nevertheless, the 15-minute city model poses several threats along with its benefits. As pointed out in previous work [1] implementing the 15-minute city model in Paris, or any urban setting, presents both achievements and obstacles. While Paris has demonstrated notable adaptability in capitalizing on opportunities arising from the COVID-19 pandemic to advance its urban agenda, uncertainties persist regarding the applicability and efficacy of certain strategies, particularly in diverse urban contexts characterized by varying scales and socio-economic dynamics.

After drawing insights from Paris' experience, this paper aims to delve into the complexities of implementing the 15-minute city model and assess its implications for urban planning practice in the Greek city. By critically examining both the successes and limitations of Parisian initiatives, valuable lessons can be gleaned for other cities embarking on similar urban transformation endeavors. The chosen case study is the city of Ilioupolis, a municipality in southeast metropolitan Athens, with a characterizing urban plan similar to the 19th century garden city. The city is organized around several roundabouts that have become very closely related to the identity of Ilioupolis. In this paper, these roundabouts become the core of the proposed scenario of the 15minute city model.

The uniqueness of the urban design of the area predisposes and promotes centralities at the points where we encounter the roundabouts. When exploring the case study, the already existing trend of centralization development at these points is taken into account, a trend that seems to have accelerated after the COVID-19 pandemic. In this way, the proposed centralities of the 15-minute city examined in this research are the product of bottom-up processes and not predetermined top-down locations, as in the case of Paris, for example. Moreover, this paper emphasizes the importance and necessity of flexible, context-sensitive approaches to urban planning that prioritize both equity and sustainability, both of which are significantly boosted via community engagement.

Ultimately, through a comprehensive analysis of the case study of Ilioupolis, this paper aims to contribute to the ongoing discourse surrounding innovative urban planning strategies and their potential to shape more inclusive, resilient, and vibrant Greek cities for the future.

2. MUNICIPALITY OF ILIOUPOLIS

2.1 Urban fabric characteristics

Ilioupoli is a municipality that was developed to meet the increased housing demands created by the large refugee influxes to Greece following the Asia Minor Disaster of 1922. It is a suburb of Metropolitan Athens, located in the southeastern part of the basin. It is situated at the foothills of Mount Hymettus and is only a few kilometers away from the center of Athens. It was declared a municipality in 1963 (Government Gazette 45/A/19-4-63). It has always been crossed by several streams, the most significant being 2-3 branches of the Pikrodafnis stream, most of which are now covered. In the area where the municipality of Ilioupoli is now developed, there was a small estate during Ottoman rule, called the "Kara estate." The buyer in the following years was A. Nastos, who later sold the land initially required for the construction of the Municipality of Ilioupoli.

In 1925, the "Greek Company for Urban and Rural Settlements Drandakis - Pagkalos, and CO" was established with the aim of constructing the settlement according to the plan of Aristomenis Valvis, as modified in 1928 after its first approval in 1925. Ilioupoli initially targeted a wide range of residents. It had a rural section, a semi-rural section, and a general population section, which were

Proceedings

of the International Conference on **Changing Cities VI:**
Spatial, Design, Landscape, Heritage & Socio-economic Dimensions
Rhodes Island, Greece • June 24-28, 2024
ISSN: 2654-0460
ISBN: 978-618-5765-02-6

distinguished from each other based on the size of the available plots of the settlement. In the general population section, the size of the plots reached that of the center of Athens. The smallest acceptable plot size was set at 112.5 sq.m. and remained so until 1940. Along the way, the rural section was abolished as buyers could not afford it financially. According to the "General Guide to Ilioupoli" (1960), anyone "...found a place for a home, the rich and the poor, the scientist and the professionals, the employees and the workers..."

Figure 1. Plan of Ilioupolis (1925) [2]

The original plan by Valvis for the settlement of Ilioupoli was characterized by a clear effort to mimic the principles of a garden city. Strong curves, numerous concentric circles and roundabouts lead to the creation of small building blocks. This initial plan underwent modification with evident signs of improvement in 1928 (Government Gazette 227/1928).

In 1930, the "Anonymous Construction and Industrial Company of Ilioupolis Athens" was founded, a company that, along with the "Greek Company for Urban and Rural Settlements Drandakis, Pagkalos, and CO" and with the "Anonymous Transportation Company of Ilioupolis," undertook the execution of the plan.

However, the image of the city of Ilioupoli in its early years was not very encouraging regarding the completion of the plan and its settlements. Nevertheless, it was widely advertised in newspapers, urging buyers to invest in land purchases, which (according to said advertisements) would not lose their value, and thus the investors would profit from a potential devaluation of the currency (a practice not uncommon in 20th century Greece). The main service networks of the city were ultimately completed after World War II, a period during which the Municipality began to grow systematically.

3. EXISTING, EMERGING AND PROPOSED CENTRALITIES

3.1 Existing centralities

In Ilioupoli, the General Urban Plan (GUP) was approved in 1988 (Government Gazette 407/D/1988, reissued Government Gazette 1225/D/1994) and is still in effect, defining the allowed land uses of the city (Fig.2). The GUP includes the entire current area of the Municipality, along with the successive expansions after the initial approval of the city plan. The same GUP separates 14

Proceedings

neighborhoods - Urban Units as they appear on the map below (Fig. 3). The division of neighborhoods seems to have been made based on geometric characteristics of the town plan and with the intention of an equal distribution of the covered area per unit. There does not appear to be an intention to create independent centers per neighborhood, and the circular nodes are, in most cases, not placed at the center of each unit, but seem to serve as meeting points for two or more neighborhoods. Given that the already defined neighborhoods have a maximum distance range of 1.5 kilometers from each boundary, this distance can work perfectly with the scenario of the 15-minute city and promote accessibility using bicycles, walking, or other non-motorized vehicles.

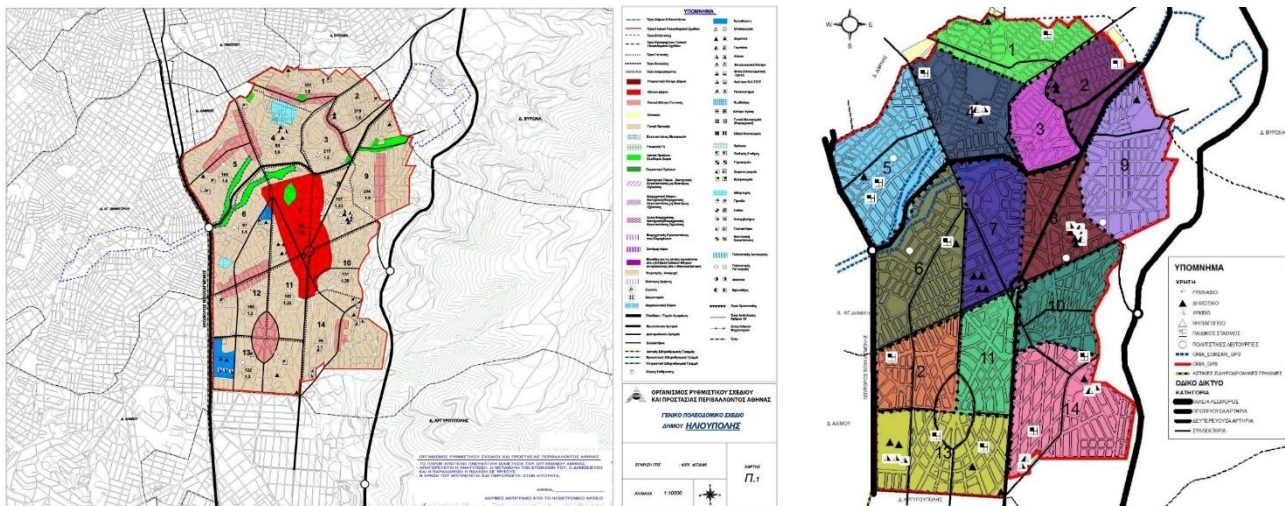

Figure 2. General Urban Plan of Ilioupoli [3]

Figure 3. Neighbourhood division [4]

For many years, and up until the end of the 2010s, when the economic crisis changed the density of commercial uses, Ilioupoli developed commercial and recreational activities mainly around Ethnikis Antistaseos Square, which is the central square of the Municipality and located at the intersection of neighborhoods 7-8-10-11. This development aligns with the General Urban Plan of the city, which designates the square and part of the axes leading to it as the "city center," differentiating it from other adjacent squares in other neighborhoods designated as "neighborhood centers."

Another secondary center of smaller scale was developing at Independence Square in neighborhood 1, just before the intersection of neighborhoods 1-3-4, while with lower intensity and uses related only to commerce, two more centralities were found, located, one at Karaiskaki Square (Kanaria) at the intersection of neighborhoods 4-5-6-7 and one at 28th October Square in the heart of neighborhood 8.

We can observe that, unlike the central square of Ilioupoli, the secondary centers created initially did not follow the current General Urban Plan regarding the determination of the neighborhood centers. The General Urban Plan placed these units mainly along axes and not on circular nodes, not exploiting the centrality they provide due to their layout.

3.2 Emerging centralities

After the economic crisis, new centralities began to emerge, mainly around the development of commercial and leisure activity zones in areas that showed less interest until 2010. This trend strengthened towards the end of the economic crisis around 2019, and despite the slowdown experienced during the period 2019-2021 due to the pandemic, it accelerated at a faster pace in the last two years (Table 1).

Proceedings

The newly created centralities also tend to indeed move along axes, as initially predicted by the General Urban Plan (GUP), but still concentrate on those connecting the most developed squares of the Municipality. Thus, we observe a new center at 25th March Square at the intersection of neighborhoods 6-7-11-12, another one at Agia Paraskevi Square at the intersection of neighborhoods 11-12-13, and one more at Agia Mavra Square at the intersection of neighborhoods 8-9-10. The commercial and leisure uses also tend to expand on the axes between squares as shown in the consolidated map below (Fig.4).

CENTRALITIES \\NUMBER PER USES	RETAIL			LEISURE			MARKET		
	2014	2019	2024	2014	2019	2024	2014	2019	2024
25th March Square	12	14	15	3	4	7	2	2	2
Agia Paraskevi Square	2	2	2	2	6	6	4	4	4
Agia Mavra Square	4	2	2	3	4	6	0	1	2

Table 1. Uses per centrality.

The above-mentioned businesses are found either on the square or within a radius of less than 100 meters from it. The nearly doubling of leisure establishments along with the increase in retail and food market shops are trends encountered in all three cases. This trend was not -yet- present in other squares of the Municipality.

3.3 Proposed centralities

Examining the distribution of existing and emerging centralities in the Municipality, along with a 500meter radius of service for each centrality, we observe that there is a significant overlap across its entire extent of the city, with only two neighborhoods having room for improvement.

The first one is Neighborhood 14. The prominent topography of the neighborhood, located precisely at the foot of Mount Hymettus, as well as the strong boundary formed by Kyprou Avenue, which serves as the main and high-speed axis for vehicular traffic coming from Alimou-Karea Av. towards south Athens, dividing the neighborhood from the rest of the Municipality, result in the relative isolation of the neighborhood. Therefore, it is suggested to explore the creation of a local center in around the Ilioupolis municipal swimming pool, as the pre-existing use already establishes a degree of centrality to the area. The proposal aims to further strengthen this centrality and accommodate the part of the city that is relatively separated from the rest of the municipality.

The second point of low coverage from the existing and emerging centralities is the boundary between Neighborhoods 2 and 3, along which the General Urban Plan (GUP) initially established the use of the neighborhood center. While there is a market operating in the area with some shops, the intense adjacency with Alimou-Karea Av., the increased traffic, and the wide width of the road at this part of the city, have not favored cohesion in operations and the creation of a cohesive centrality up until today.

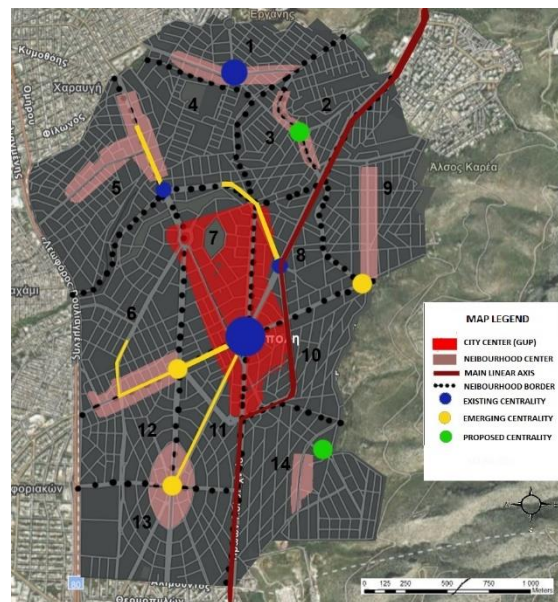

Figure 4. Centralities per type

4. QUANTITATIVE ESTIMATION OF MODEL IMPELEMENTATION COSTS

The centralities identified in the study area create a dense network capable of covering the entire Municipality with a service radius ranging from 500 to 700 meters. A total of 7 centralities were identified, and two more were proposed. In proportion to the city's population, which, according to the 2021 census, stands at 76,730 residents, this means that approximately 8500 residents are served per centrality. During the implementation of the 15-minute city model, it is important to protect specific established features defined by urban planning legislation. This means that the new proposed centralities are not intended to compete with the current commercial center of the Municipality. The Ethnikis Antistaseos Square, representing the municipal center, retains its primary central character in any case, as reflected in the intense overlap of service radius of the neighboring centralities under examination. The goal is to strengthen smaller local units that can maintain a degree of differentiation among them in terms of character, functions, and size.

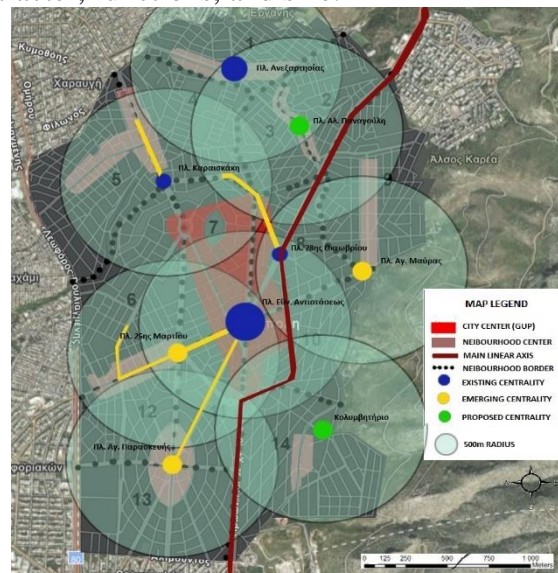

Figure 5. 500m radius per centrality

In this section, we proceed to the parameterization of the centralities according to the desired outcome. This means determining the expected character of each centrality, the desired functions per

Proceedings

point, while assessing the degree of satisfaction of the desired condition from the current situation. This comparison will highlight the necessary interventions needed to achieve the predetermined goal for each centrality. These requirements can then be evaluated in terms of cost and effectiveness.

Building upon the functions introduced by the model of K. Moreno for Paris, where the key operating axes were proximity, mixed-use, density, repetition, we observe a high degree of satisfaction of these conditions in the case of the Municipality of Ilioupoli. The city is indeed characterized by a dense fabric with mix of uses and its small scale favors proximity to each center.

In terms of proposed uses, K. Moreno positioned schools at the center of neighborhoods and set the six basic uses that need to be satisfied: residence, work, market, education, health, and recreation.

In the present context, we choose to set open spaces/squares as the center of the unit, which already demonstrate a dynamic concentration of mixed functions. Additionally, while in the case of Paris, where the stronger separation of uses and the size of the city are evident, residence needs to be defined as a default requirement, in the context of the Municipality of Ilioupoli (and the broader Greek cityscape), the function of residence is considered to be satisfied throughout the examined area. Specifically, in the Municipality of Ilioupoli, according to the Operational Program of the Municipality of Ilioupoli [5], which drew data from the 2011 Census, out of a total of 11,885 buildings, only 677 are not used for residential purposes (exclusive or mixed use).

On the contrary, given the inadequate public transportation network in the greater Athens area, which results in increased use of private vehicles mainly for commuting to and from work, it appears that additional public service points and remote working opportunities are much more necessary in the present context.

During the pandemic, three points were highlighted regarding remote work and public service in Greece: a) remote operation without the requirement for physical presence is largely feasible and effective, b) remote work burdens employees with the need to secure a workspace at home, which is not always feasible in terms of living conditions, space, and equipment, and c) there is an inevitable shift of operational costs from businesses to employees.

In this case study, the proposal for municipal remote work operational centers (hubs) ensures a safe environment close to home, allowing employees to have a fully equipped workspace in a common working space open to the public and businesses. The available space can be a public or private building, and private capital can be leveraged with incentives provided to private enterprises. The successful development of such a structure within the Municipality will achieve a reduction in private vehicle usage, decrease commuting time to and from work, create job opportunities for single-parent households and/or young parents, and improve the user's quality of life. All of these are Sustainable Development Goals as adopted by the EU.

However, in the case of examining central Athens or any other city with significant tourist interest, the aspect of residency should revert to the parameters, while the demand for remote work structures would decrease. It should be noted that the exclusion of residency from this specific parameterization does not imply that protective measures for residency should not be considered to the extent that it is estimated that the proposed interventions will affect it (e.g., to avoid the phenomenon of gentrification). These measures should be examined during the stage of establishing the institutional framework for the implementation and execution of the 15minute city model in Greece.

Table2 presents the coverage of functions (YES/NO) per identified centrality in the Municipality of Ilioupoli. The indication "+" is used in case of desired enhancement of the specific use:

Table 2. Coverage of functions (YES/NO) per identified centrality

To save resources, specifically concerning public service/healthcare facilities and remote working spaces, a larger radius per central point can be utilized. It is thus proposed a service clustering every three centralities. In this case study, remote working spaces may be established at 25th March square, at Anexartisias square, and at Agias Mavras square, while healthcare/public service facilities may be located at 28th October square and Ag. Paraskevis square, in addition to Karaïskaki square, which is in close proximity to the existing municipality's healthcare infrastructure. Even with this proposed clustering for these specific functions, the user's commute will not exceed the one-kilometer limit. Data on employment in the municipality of Ilioupolis, sourced from the Operational Program of the Municipality of Ilioupolis, report that out of a total of 30,527 employees in the municipality, 84.79% are employed in the tertiary sector of services [5]. This implies that even if there is a possibility of remote work for 1 out of 3 employees in the service sector, over 8,500 commutes to and from work are prevented per user.

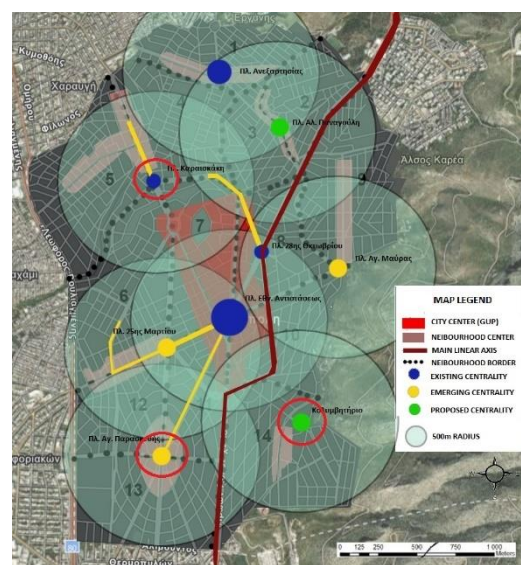

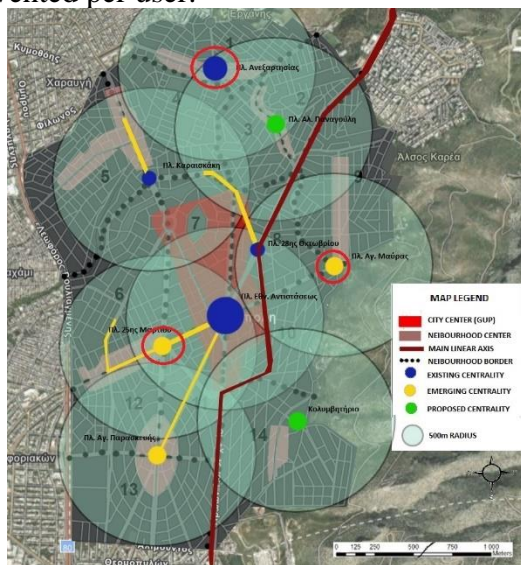

Figure 6. Proposed locations for remote working hubs

Figure 7. Proposed locations for healthcare facilities

In the previous section, the goals and needs for the operation of centralities in the Municipality of Ilioupolis were outlined. From the table that presented the coverage of functions (YES/NO) per identified centrality in the Municipality of Ilioupolis, we observe that the actual requirements of the local centers mainly involve enhancing existing functions and uses rather than adding new ones. This ensures that the proposal follows a dynamic already present in the area and guarantees a reduction in

Proceedings

potential disruption of balance, as well as an increased likelihood of acceptance by the public. Specifically, as concluded from the above, the following are required:

Enhancement of existing use:

Retail in 4 centralities

Leisure in 3 centralities

Market in 1 centrality

Installation of new use:

Remote working facilities in 3 centralities

Healthcare/public service in 2 centralities

It should be noted, however, that an exact estimation of the level of enhancement needed is not yet possible, given that both remote work and public service/healthcare facilities are expected to attract daily users to the proposed locations, thus boosting retail and leisure uses to some extent either way. Furthermore, requirements for enhancing uses overlap with the installation of the new uses in all cases except for Panagouli Square, meaning that the city interventions can and will have multiple impact on several sectors.

According to the above analysis, the actions that the Municipality of Ilioupolis should take to support the above scenario are as follows:

Δ1. Enhancement of commercial, leisure and market uses in the designated areas.

Δ2. Establishment of 2 healthcare/public service facilities and 3 remote work facilities.

Δ3. Development of a network between centralities with safe routes that comply with the sustainable mobility principles.

Δ4. Modernization of regulatory framework to facilitate proposed interventions.

Actions Costs/Requirements	Δ1	Δ2	Δ3	Δ4
Leasing of building infrastructure				
Adapting building infrastructure				
Technical equipment				
Operating costs/Consumables				
Operating costs/Energy				
Incentives for private individuals				
Urban equipment				
Creation/upgrading of pedestrian traffic network				
Upgrade/Enhancement of green network				
Enhancement of public transportation				
Consultation organization				
Person-hours for consultation				
Diffusion of results				

Table 3. Requirements/costs per Action

In the above table, we have defined the minimum requirements for promoting the scenario of multiple centralities in the case study of Ilioupolis Municipality. We observe that, apart from the need for equipping, leasing, and/or adapting municipal buildings to accommodate the new uses of healthcare/public service and remote working facilities, there is a strong overlap of requirements per set Action. This implies increased efficiency of the resources allocated to meet each predetermined requirement.

Furthermore, we observe that overall, the requirements consist of mild-scale interventions that are either explicitly included in existing strategic priorities of the Municipality (e.g., the Operational

Proceedings

of the International Conference on **Changing Cities VI:**

Spatial, Design, Landscape, Heritage & Socio-economic Dimensions

Program of the Municipality of Ilioupolis 2015-2019) or are part of the requirements arising from compliance with European Sustainable Development goals. This fact, on the one hand, makes such interventions a constant target of the municipal authority and, on the other hand, entails the possibility of securing funding from European sources that will not burden the municipal budget.

It is therefore estimated that the substantial burden that the exploration of the 15-minute city model will impose on the Municipality of Ilioupolis will be small and mainly focused on issues of strategic development and management, consultation organization, resource leverage, and incentive development. In terms of efficiency however, this cost, besides being a constant need of Greek local government at all levels, is estimated to be much smaller in comparison to the benefits that the city and the user will derive in terms of daily living, resilience, risk management, as well as in relation to today's requirements for environmental protection.

5. CONCLUSION

In conclusion, the study on the implementation of the polycentric operation in the Municipality of Ilioupoli that promotes the 15minutes city model sheds light on the potential benefits and challenges associated with this urban development approach. Through an analysis of the identified functions and needs of the centralities, it becomes evident that the proposed strategy aligns with existing community dynamics and strategic priorities, thereby minimizing potential disruptions while maximizing public acceptance. The outlined actions required for supporting this scenario highlight the municipality's commitment to sustainable urban development, leveraging both existing strategic frameworks and European funding opportunities. Despite the anticipated modest increase in administrative and organizational efforts, the potential benefits for residents in terms of everyday living, resilience, and environmental protection far outweigh the associated costs. Ultimately, the pursuit of the polycentric 15minute city model represents a forward-thinking approach to urban planning that prioritizes the well-being and sustainability of the community in Ilioupoli, and potentially for more Greek cities.

Abstract

The issue of urban quality of public space has become a significant concern in city management strategies, as evidenced by international and European policies. A research project conducted by Citera-Sapienza University, funded by the Municipality of Rome, aimed to develop guidelines and tools to enhance the quality of urban pavements. The study posited that the quality of cities is inextricably linked to the quality of their streets, pavements, and squares. The complex urban structure and historical layers of Rome provide a unique opportunity for experimentation with various approaches to urban planning and management, with the ultimate goal of achieving urban quality. The study identified innovative solutions for different types of paving, including for vehicles, pedestrians, cyclists, and trams, as well as parking areas. In light of the city's diverse spatial contexts, the study sought to contribute to the urban quality and character of Rome's streets by elucidating its distinctive typological and morphological attributes.

Keywords: *urban quality; technological innovation; digitalization; sustainability; management of the built environment.*

1. INTRODUCTION

The maintenance and reconfiguration of public space is influenced by a number of socio-economic and cultural factors. Changes in the lives of European citizens, such as pandemics, wars, economic instability, green policies and the rising cost of raw materials, are determining new configurations in urban space. For example, the rising cost of petrol and the advent of e-mobility are influencing urban mobility, with more and more people using electric bicycles and scooters. However, this transformation has not been planned in a unified and conscious manner, leading to interference in urban mobility. The COVID-19 pandemic has also had an impact on the urban street, with the closure of parks and an increase in outdoor businesses. Restrictions on vehicular traffic to reduce carbon dioxide emissions, together with the need to develop rail transport, are leading to further changes in public space. These changes, which are part of the metamorphosis of contemporary life, are bound to persist. These changes, which are largely unplanned, are only one aspect of the broader challenges associated with the metamorphosis that contemporary life is undergoing. They are likely to persist. In light of this, it is crucial to explore ways to streamline and mitigate the impact of these changes. This entails understanding how to structure and streamline the process of change, as well as proposing alternative scenarios for the city of Rome. These scenarios should aim to enhance the city's resilience and sustainability, while reducing the negative effects of mobility, sociality, and trade.

The definition of the '*Linee guida e strumenti operativi per il miglioramento della qualità urbana delle pavimentazioni stradali carrabili, ciclabili e pedonali degli spazi pubblici Roma Capitale*' was informed by the study of the principal element of the research, namely the roads. The term "street" is derived from the late Latin locution "via strata," which refers to a ballasted road. This term is derived from the Latin past participle "stratus," which is derived from the verb "sternere," meaning to lay down or pave. This definition is well expressed in its encyclopaedic definition: "long strip of ground made flat and firm, which the ancients used to pave to go from place to place." The term "way" is used as a synonym for the word "road," which in turn is derived from the Latin term "via." This term, in turn, is derived from the verb "vehere," which means to carry or to lead. In contrast to the word "road," the word "way" is used to describe a series of actions that occur in different contexts. This etymological reading suggests that the concept of concentrating research on the aggregative function of the street in the strict sense should be extended to encompass its role as a public space that is not solely intended for transport and movement from place to place. The street, which was originally a paved surface characterised by its materiality, has developed into a social and commercial hub, while still fulfilling its primary function of allowing pedestrian and vehicular movement.

The study of the road fabric at the urban scale, which determines the urban network, provides the foundation for understanding the settlement fabrics, which can be considered the negative of the road. These settlement fabrics comprise the morphological composition of urban planning studies in the broadest sense. The research was conducted at a smaller scale, focusing on proximity, to investigate in detail the spatial and perceptual configurations. The most appropriate tools for this study were identified as the cross-section, the plan and axonometry. In order to achieve this objective, a selection of urban planning treatises developed in the European context at the turn of the 19th and early 20th century has been chosen, with a particular focus on aspects related to the study of the street. This is because the authors selected were in part concerned with the observation of urban transformations, generated by the advent of modernity and the invention of the automobile, which have been significant factors in the organisation of the road system and the public space of social aggregation. Alternatively, they were directly concerned with the transformation of urban agglomerations.

2. MATERIALS AND METHODS

The research hereinafter presented commences with an analysis of the current state of good practices employed in the qualification of public spaces within compact, stratified, modern and contemporary cities. The study developed a typology of the compositional, functional, technological and material elements that constitute the city's street layout. In fact, the street plays a role in structuring and characterising the urban morphology in its historical complexity and in relation to the urban fabrics, which in turn influence the settlement typologies. These typologies can be categorised into three main areas:

- the street;
- the square;
- the green system.

The study of these complex systems has been articulated by breaking down the final elements through which they are concretely configured. As an example, the road, in addition to being classifiable in terms of urban planning and traffic, is made up of a set of concrete elements that can be gradually broken down: urban wings, trees, carriageway, lane, pavement, pavement, verge, drainage, manhole cover, etc. The considerable overlap between the various urban elements with different functions suggests that the architectural design of the street should be based on criteria that are always up-to-date and sensitive to the definition of quality elements of public spaces. These elements play a crucial role in the lives of citizens [1] and concern a multiplicity of aspects, including the theme of urban pavements. This is part of a broader theme of the quality of public space [2], since the street is the

soul of the city [3]. There is no doubt that through a partial reading of the city by stratigraphic levels, the layer constituted by urban paving – streets, pavements, squares – has an essential function in contributing to the quality of urban life. This element is the foundation of urban decorum and furnishings and interweaves the physical component with the functional and usage component of the city in a continuous state of transformation. The research aims to return to tradition, to the ‘genius loci’, to the sense of community and to the real inclusion of the citizen in civic life, inspired by the principle that the human being as an entity has not changed in its intrinsic nature throughout history. While customs, technologies, and production processes may evolve over time, the essence of humanity remains constant. The innermost tensions and needs of humanity, in all their complexity and universality, have remained unchanged throughout history.

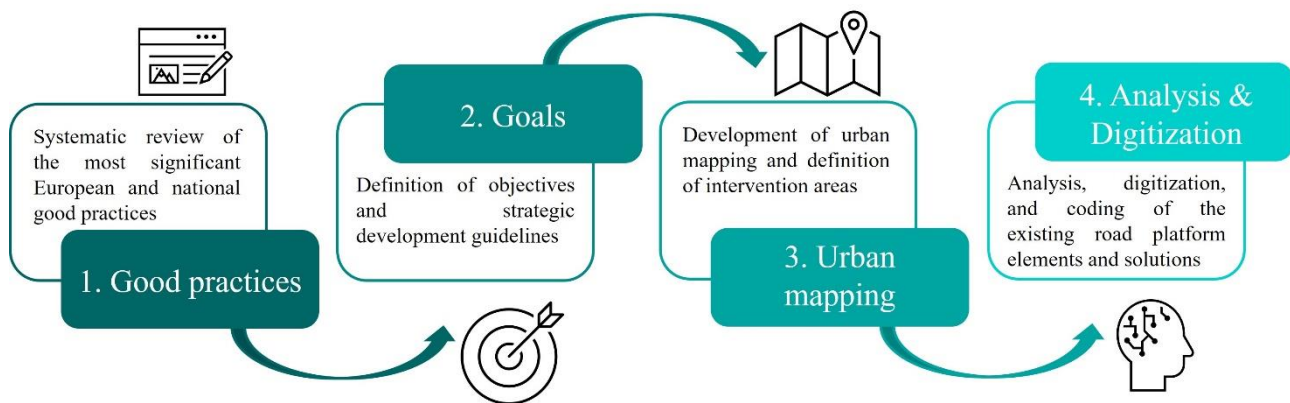

Figure 1. Methodology flowchart for the development of guidelines and tools aimed at enhancing the quality of urban pavements.

The methodology to develop guidelines and tools to enhance the quality of urban pavements is based on 4 main steps (Figure 1):

- 1st step: systematic review of the most significant European and national good practices;
- 2nd step: definition of objectives and strategic development guidelines based on the state of the art at the international and national levels;
- 3rd step: urban mapping;
- 4th step: analysis, digitization, and coding of the existing road platform elements and solutions.

2.1 State of the art and good practices

The authors selected for this study were chosen based on their contributions to the field of urban planning. Joseph Stubben's treatise, "Urban Development" [4] is a comprehensive study of urban planning in Europe, including numerous planimetries and road sections of cities across the continent. Many of these cities are located in our study area, specifically in the Iberian Peninsula. Of particular interest in this author's work are the graphic aspects, namely the use of the section as the most effective tool in the representation of the road platform in relation to the settlement tissues, and the quality of the representation in general, which lends itself excellently to the description of the road. Furthermore, the author implements a comparative vision in the vast sampling of roads analysed. The second treatise we studied was Camillo Sitte's "The Art of Constructing the City" [5], in which the author deals mainly with the square, the public space par excellence. He focuses a great deal on the perception of spaces and the relationship between the urban backdrop and the open space, between the road network and these nodes, as well as the material composition of the compositional elements. This approach is significant and interchangeable for the study, albeit of linear rather than punctual elements. These elements present some common characteristics in the uses of the street, some similar

Proceedings

elements in the urban scene. These include urban wings, paving, monuments, fountains, kiosks, commercial activities, verges, interstitial greenery and albedo. The third author we have discussed is Eugene Henard [6], whose work is entitled 'Study on the Transformations of Paris'. In this text, Henard presents a series of futuristic scenarios regarding the urban and road layout for Paris. These scenarios are presented in a dystopian key, but they are not so distant from transformations that have actually taken shape in the composition of roads within consolidated cities in the European sphere. The fourth author analysed in the context of the development of the research is Ildelfonso Cerdà, who developed the plan for the urban transformations of Barcelona [7]. Cerdà paid particular attention to the conformation of the street from multiple points of view, in an exhaustive and even ironic way, in relation to the current and future transformations of the street in a broad sense. He dedicated a large chapter to the street within his treatise.

A systematic review of the most significant European and national good practices was also conducted to align knowledge with the state of the art on the specific topic. The good practices selected as most relevant at European level were the cases of Amsterdam and Barcelona, while at national level the cases of Milan and Bologna were deemed to be of particular interest. The selection was based on two criteria. The first concerns the period between 2011 and 2021, during which the most advanced measures in the field of urban sustainability were adopted by European cities. The second criterion considered the extent to which the policies adopted paid attention to the degree of stratification of the urban fabrics analysed and in particular to the relationship between the historic centre and the expanding city. In considering the cases in which the policies adopted paid attention to the degree of stratification of the urban fabrics analysed, and in particular to the relationship between the historic centre and the expanding city, it is evident that these variable conditions contribute to determining the objectives of standardising solutions. In the case of Barcelona's Superilles programme [8], which has become the model for the transformation of the streets of the entire city, the city council has identified the new 'panot for the 21st century' as a potential solution [9]. The first century of the programme preserves its value as an intangible heritage, while incorporating innovative solutions and technologies that make it more sustainable for the future. This sustainability is based on the composition of materials and manufacturing processes, reuse and recyclability.

In the context of Europe, it is notable that cities that have long favoured the development of soft mobility systems include Amsterdam. This city has adopted a method known as the 'Puccini method', which has been in use since 2021. This method is a manual that standardises solutions for the design of public spaces, including streets, squares and gardens. The method has adopted a set of sustainability standards, which must be met by every project and subsequent contract. In addition, this set of urban policies contains a mapping of pavements, a mapping of the lighting system and a mapping of the main structure of urban vegetation systems. Amsterdam's design guidelines can be found in two manuals that contain the technical details of the urban policies, including drawings and a list of the materials used. The *Handboek Groen* [10] provides guidance on the planning and management of greenery, while the *Handboek Rood* [11] offers advice on the design of urban elements.

It is also worth noting the city of Paris, which has developed a digital mapping model, created by the APUR Agency, for use from 2022 onwards by the Administration for the management of interventions on the road network. Additionally, the city has produced an *Atlas du Mobilier Urbain Parisien*, which is intended to assist in the planning of its maintenance. The relevance of the Paris case can be attributed to the mapping and systematisation activity carried out over a vast area on which highly articulated structures are triggered, as well as to the generation of an online platform, free and fully accessible, which demonstrates the replicability and transferability of this type of operation to different contexts. In the national context, the "Manuale dello spazio pubblico - Linee guida per la progettazione" [12] represents a flexible tool for the design of public spaces. In a recent resolution, the Municipality of Milan joined with *Milano Città 30* to set the speed limit in urban areas

Proceedings

of the International Conference on **Changing Cities VI**:
Spatial, Design, Landscape, Heritage & Socio-economic Dimensions

ISBN: 978-618-5765-02-6

at 30 km/h as of 1 January 2024. This resolution anticipates the possibility of setting 50 km/h limits on some main roads after that date, a course of action that has been taken by Paris and Brussels. The Municipality of Bologna [13] also initiated the process of becoming City 30. This was achieved through the formulation of a document outlining the principles of urban quality. This document provided guidance on the design and implementation of open spaces for public use, including new urbanisation and redevelopment projects. The aim was to clarify and better interpret the concepts of quality and public use, in accordance with the prevailing regulations.

2.2 Definition of objectives and strategic development guidelines

In the context of urban public spaces, road pavements constitute the surface layer and are subject to continuous maintenance due to wear and tear and to technological and material upgrades to counter disruptive issues regarding environmental sustainability. In the compact city, the maintenance of pavements and their replacement is not a simple and interference-free process since the image and material consistency of these determine the image of the city's public spaces in their historical and material connotation rooted in the collective imagination. The surfaces of these spaces must respond to multiple needs, including those of a perceptive-landscape and historical-iconographic nature, in order to guarantee high levels of safety, well-being, usability and liveability. Therefore, the urban context and the functional requirements to which the pavements must respond according to the type of use that characterises them, necessarily influence the choice of morphology, material and installation. In the case of resurfacing an urban pavement, it is desirable, where possible, to preserve the site's construction traditions, respecting its material and chromatic characteristics, taking into account climatic and lighting conditions and the needs for comfort, efficiency and sustainability.

Careful road design can make a significant contribution to mobility, the environment, and human health. This can be achieved through the planting of trees, the adoption of specific materials to improve the microclimate, reduce air and noise pollution and increase the resilience of the urban system [14]. The road pavement construction sector is constantly evolving to optimise performance levels and durability. The following are some of the goals that can be achieved through careful road design [15]:

- Reduction of air pollution;
- Reduction of noise pollution;
- Reduction of heat island;
- Increased water drainage;
- Increased energy efficiency;
- Increased perceptive quality.

The protection of the city's historical features through the replacement of pavements with more efficient and sustainable materials from an economic and environmental impact point of view is a complex process. On a national and international (European) level, these activities have been organised and implemented through maintenance plans developed mainly in the technical sphere by the local administrations of the different cities. Noteworthy are the experiences of Barcelona, Amsterdam and Paris in the European context; of Milan and Bologna in the national context. The Experimental Study for the Definition of Guidelines and Operational Tools for the Improvement of the Urban Quality of Roadway, Bicycle and Pedestrian Pavements in the Public Spaces of Roma Capitale, prepared by the Interdepartmental Research Centre Territory Building Restoration Environment (CITERA), is a pertinent example of good practice within this context.

2.3 Urban mapping

The increased attention given to the user, the qualitative dimension of accessibility and usability of movement spaces, the heterogeneity and extent of urban contexts, and the plurality of morphological

characteristics of urban settlement fabrics require a new methodological approach for identifying standardized typological and constructive solutions aimed at meeting the needs of the diverse and resilient ecosystem. The innovative aspect of the research lies in the systemic approach that we have adopted in studying pavements. This approach differs from the purely viability-based approach that is more commonly used in modern interventions, which do not relate to the formal city in its morphological peculiarities. In an era strongly influenced by a prevailing globalisation, we believe that experimentation through the conjugation of crucial issues such as sustainability, environmental impact, reduction of heat islands and soil permeability must be integrated with the study of identity characteristics that cannot be divorced from the use of traditional materials in relation to the historicity of the fabrics. This is necessary to create new solutions that improve living conditions for citizens and preserve those characteristics proper to each settlement fabric. The conservative approach is innovative, through the original use of classic elements such as stone, which can be integrated into spatial configurations of permeable pavement fields. This approach has the potential to significantly reduce the environmental impact of total cementification, while preserving the aesthetic and formal features that constitute the collective recognition of the city by its inhabitants. The research in question therefore proposes a meticulous, cross-disciplinary approach, in continuity with the urban planning vision linked to the formal aspects of the city and in contrast with a mere viability approach typical of the post-war period and the advent of the automobile, which is highly reductive, and impoverishing compared to the richness of a formalistic approach.

The challenge in achieving this objective lies in identifying a cultural value that enhances it, as the utilisation of new technologies is employed to enhance the living conditions of users and to guarantee levels of eco-sustainability without compromising the identity imparted by the composition and materiality of the elements. To define a series of standardized solutions, it is essential to conduct a series of large-scale studies, oriented towards a critical overlap of different planning tools that can influence programming and management choices related to urban pavement characteristics. To the tissues of the regulatory plan, which identify homogeneous parts of the city, specific tools such as the general traffic plan, the urban sustainable mobility plan (PUMS), and the urban heat island map can be overlaid. Urban-scale studies must be based on a specifically elaborated basis, capable of expressing the connotation of the morphology of the city's environmental system.

2.4 Analysis, digitization and coding of the existing road platform elements and solutions

Another innovative aspect of the research is the instrumental one, namely the use of digital programmes. Given the extent of pavements and the heterogeneity of the constituent elements of the road platform in modern cities, it is deemed useful to establish a classification and a unique coding system to identify the main typologies and corresponding materials of urban pavements, as well as the interferences/nodes among the constituent elements of the road platform. The encoding of the constituent elements of the road platform serves as a starting point for the subsequent modeling of objects in the BIM environment - Building Information Modeling, to which specific technical specifications (such as materials, stratigraphy, dimensions, weight, color) and related laying and maintenance interventions can be associated to optimize the management system. The development of the case studies was carried out entirely within the BIM environment, which proved to be highly useful for the extrapolation of the graphic designs and the abacuses related to the quantities for computation [16-17]. Furthermore, software was employed for the visualisation and processing of images and renderings to simulate mood boards with the material characteristics of the pavement surfaces and road elements (driveway and pedestrian ramps, verges, tree beds, drains, manholes). 3D modeling software has been used to assess the microclimate and ensure sustainable and resilient urban design through innovative solutions aimed at enhancing thermal comfort while mitigating the heat island effect [18].

3. THE CASE STUDY OF THE CITY OF ROME

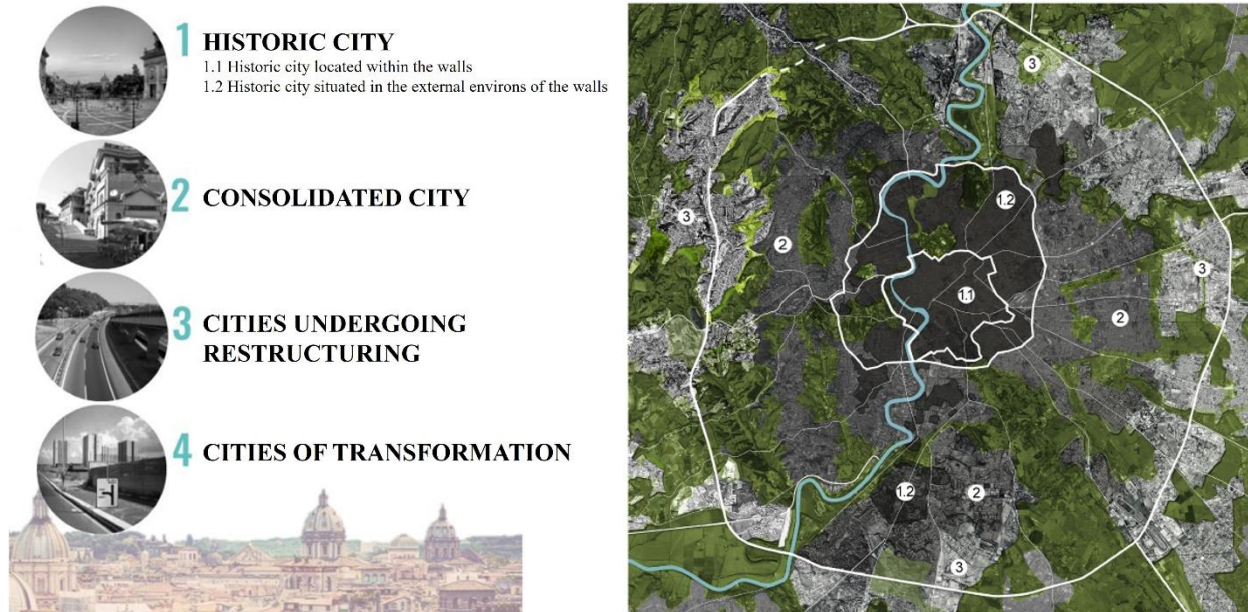

Figure 2. Division of the city into four main intervention contexts.

The investigation of the most efficacious methodologies delineated above revealed the pivotal elements employed to formulate the directives. In accordance with the overarching sustainability objectives, pioneering solutions were identified for vehicular, pedestrian, bicycle, and tram pavements, and those for car parks. Furthermore, in accordance with the strategic framework of existing urban plans, a subdivision of the city into four principal intervention settings was proposed: the historic city located within the walls; the historic city situated in the external environs of the walls; the consolidated city; and the city that is currently undergoing restructuring (Figure 2).

The articulation of the city of Rome by fabrics represents a genuine revolution because it acknowledges the diversity and typological/morphological complexity of the different parts that it is composed of. Over the course of its millennia-long history, this has resulted in the emergence of settings that differ from one another. It is therefore essential to discern these settings if the city's many identities and specific features are to be valued and preserved. It was, consequently, unavoidable that a study aimed at enhancing and improving the quality of the road space should make reference to the plurality of the typological/morphological articulation of the body of the city.

This was particularly the case in the specific instance of the mapping of Rome's road network, which required the provision of a framework that would enable the different spatial situations to be given shape and urban quality. Due to the extensive nature of pavements and the heterogeneous composition of the road platform, a classification and univocal coding were developed to identify the primary typologies, the corresponding materials for urban pavements, and the nodes in the BIM environment (Figure 3).

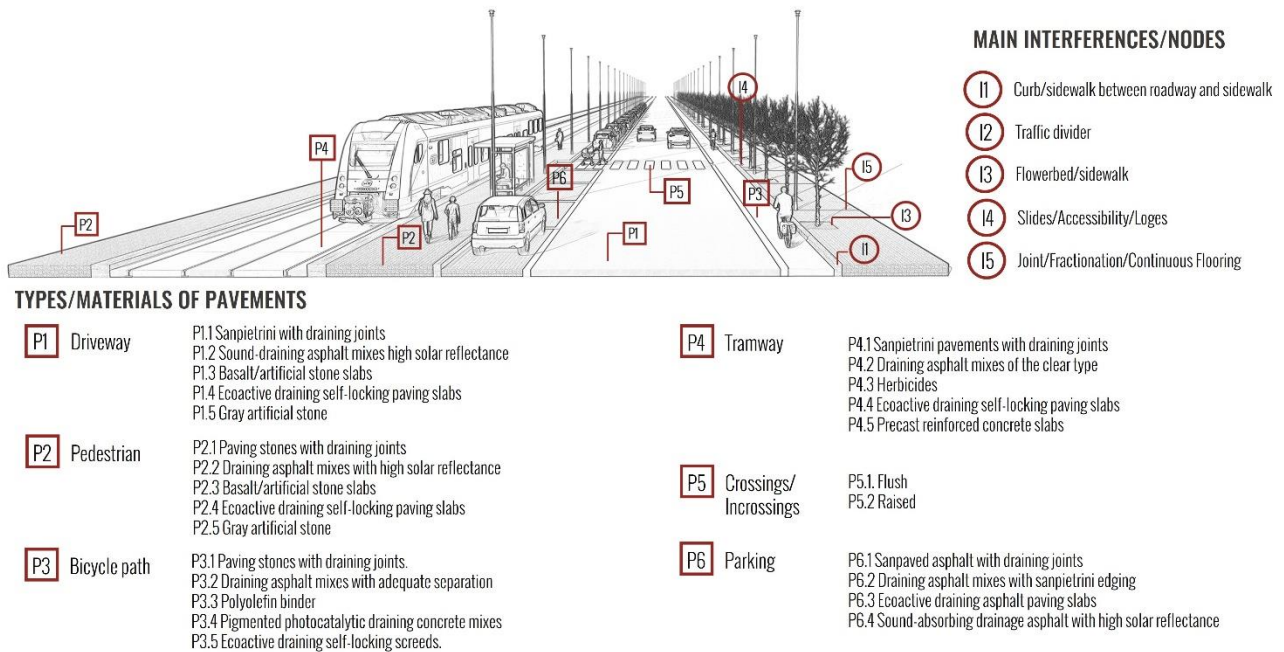

Figure 3. Coding of the existing road platform elements and solutions.

The effects on microclimate of the planned solutions for improving the urban quality of roadway, bicycle and pedestrian pavements in public spaces in Rome were tested using three-dimensional simulation software. Such software made it possible to measure the physical interactions that are generated within an urban context, consisting of open spaces (man-made or natural) and buildings, and to describe through specific parameters (temperature, humidity, wind speed, etc.) and outdoor well-being indices (Physiological Equivalent Temperature – PET, Urban Thermal Climate Index – UTCI, etc.) the microclimate (Figure 4-5). All of the activities involved in the research work have converged in the development of integrated digital models in the BIM sphere for the applied systematisation of new technologies and the prudent use of traditional materials in a sustainable manner, with particular attention to soil permeability.

This is achieved through the design of contextualised road sections in relation to the settlement fabrics. The methodology employed in the study involved considering the various options for pavement replacement in relation to urban fabrics and the building types that characterise them, with particular attention paid to urban historical-identity features. Starting from concrete cases and therefore from the detail, a typological classification was carried out in a standardised abacus (verges, drains, tree cups, manholes, paving surfaces).

Figure 4. Example of the input data for the actual state and post operam simulations

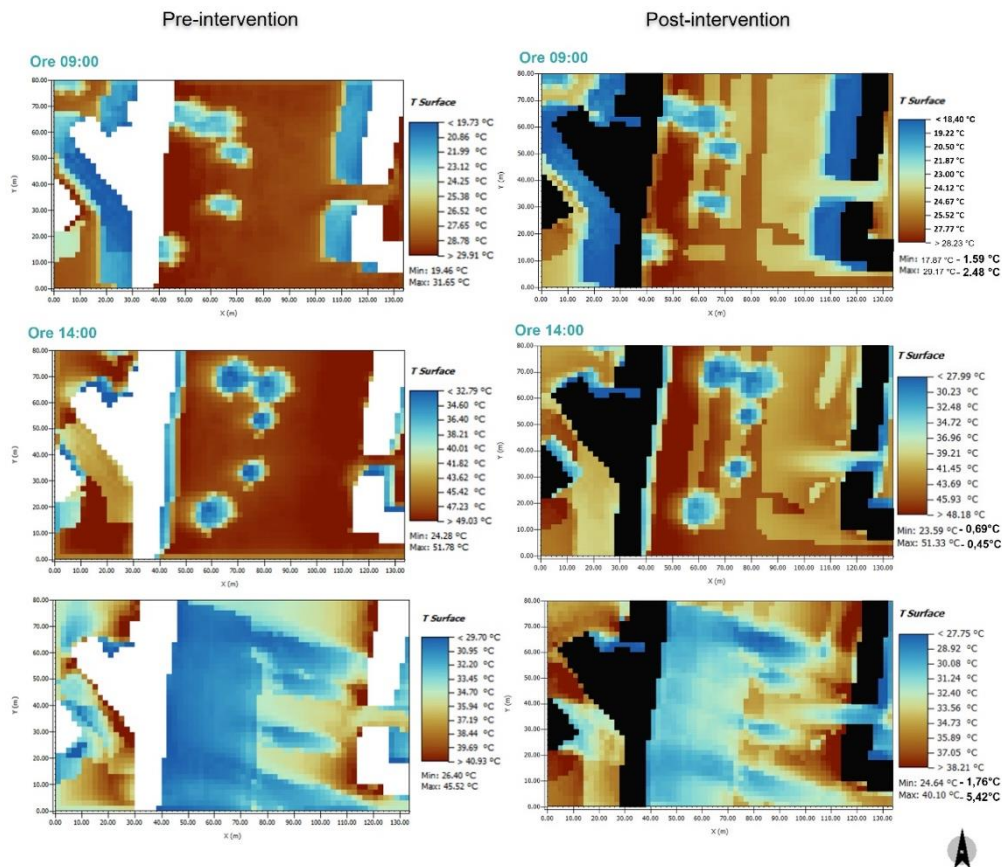

Figure 5. Results of simulations for verifying pavement surface temperatures conducted on 14/07/2023

The following section presents a summary description of the activities developed within the framework of the research project:

- The initial phase of the project, which was conceptual in nature, involved the systematic documentation of exemplary practices from both domestic and international sources. This was achieved through the use of textual cards and drawings.
- The second phase of the project involved the study and classification of urban fabrics through the identification and mapping of urban fabrics at an urban scale. This was followed by the development of projects for exemplary street sections of the city of Rome for the various settlement fabrics.
- The third synthesis phase resulted in the standardisation of the solutions in an abacus of the paving surfaces and road elements (pedestrian and vehicular ramps, kerbs, drains, tree beds) (Figure 6-7-8). Additionally, mood boards were created to simulate the material combination through the development of renders, thereby making explicit the textures and thus the aesthetic-formal result of the solutions.

4. CONCLUSION

The proposed research is characterised by its novel and original approach to the systematic integration of diverse digital tools to support regional management and facilitate the attainment of objectives pertaining to ecological transition and sustainable development, in accordance with both the fundamental tenets of the PNRR – namely, environmental sustainability and digitisation.

The system allows the creation of a dynamic and constantly updated road classification system, beginning with digital cartography processing and updating in open format and progressing to the scale of technological details through a single click transition to BIM [19] vision and logic. Further,

it permits the retrieval of detailed information on architectural, interior, and infrastructural components at the requisite scales. Potential avenues of inquiry for activities aimed at enhancing the quality of urban areas may encompass the integration of sophisticated technological advances, such as AI and the IoT [20], which offer a novel avenue for promoting the implementation of ecological and digital transitions, a novel form of "sustainable innovation."

The development of digital technologies offers useful tools to facilitate planning, execution and maintenance procedures, which are essential for improving the safety and sustainability of road infrastructures [21]. One such example is the creation of a digital representation of a physical asset, which may include data such as historical conditions and relevant data. This digital duplicate can be employed in the implementation of predictive maintenance, which is of significant importance for the improvement of environmental, economic and social sustainability in accordance with the strategic objectives of the European policy framework.

Abstract

The architectural visionaries of the 1960s and 1970s, including Lebbeus Woods, Paolo Soleri, Cedric Price, and the collective brilliance of the Archigram group, have left an indelible mark on the discipline, earning them the moniker "paper architects." Their avant-garde projects not only pushed the boundaries of conventional architecture but also served as blueprints for future urban landscapes. Even today, their ideas continue to echo in contemporary discussions surrounding urbanism and the rise of digital cities, underscoring the timelessness of their visionary concepts.

This paper provides an overview of the innovative and abstract concepts, represented by these paper architects, comparing them with digital urbanism. Through an examination of their groundbreaking projects, it seeks to unravel the core paradigms that underpinned their architectural visions. These architects dared to imagine audacious urban futures that transcended conventional spatial, technological, and societal norms, challenging the status quo with their radical designs.

A retrospective analysis of their master plan projects serves as a lens through which to elucidate their key principles and methodologies, offering valuable insights for contemporary urban development in the digital age. Of particular interest is how these architects leveraged artistic drawings as not just means of representation, but as tools for experimentation and communication, breaking free from the constraints of traditional architectural practice to envision bold new possibilities.

Moreover, this research endeavors to investigate the integration of digital influences into the urban design process. By synthesizing lessons gleaned from past visionary endeavors with the capabilities afforded by digital tools and techniques, it aims to chart novel pathways for urban development in the digital era. The convergence of analog visionary thinking with digital technologies presents unprecedented opportunities for reimagining urban spaces, fostering greater sustainability, inclusivity, and resilience.

Through a nuanced exploration of the intersections between analog innovation and digital evolution in architecture and urbanism, this paper seeks to inspire a renewed dialogue on the future of our cities. By honoring the legacy of these paper architects while embracing the transformative potential of digital technologies, it aspires to propel urban design towards new frontiers of creativity and ingenuity. In doing so, it aims to cultivate a deeper understanding of the dynamic relationship between past, present, and future in the ever-evolving urban life.

Keywords: *Paper architects; Digital cities; Urbanism; Architectural evolution; Architectural drawing*

1. INTRODUCTION

In today's rapidly evolving urban landscape, the intersection of architecture, technology, and urbanism has given rise to a new paradigm: digital cities [1]. It is becoming commonplace for communities, cities, and regions to create their own counterparts in the virtual world. These initiatives are often termed 'virtual' or 'digital' cities because they represent virtual renditions of physical spaces. [2] Since the emergence of the World Wide Web in 1991, there has been ongoing speculation about the concept of the 'digital city'. This digital dimension can be seen as a transformed version of architecture, considering changes in medium, context, and design processes. [3]

However, the concept of a virtual or digital city remains uncertain. Many attempts to define this phenomenon are speculative and metaphorical, addressing only parts of its complex impacts and often overlooking significant aspects. Most research on virtual cities focuses either on the design elements

of city websites or on the possibilities of VR (virtual reality) and 3D modelling for urban simulation. [4] The terms 'virtual city' and 'digital city' have an almost infinite number of interpretations, creating a degree of interpretative flexibility that affects their definition. This occurs not only among practitioners but also within urban studies. In this context, this research offers its own interpretation of virtual cities, supported by literature and inspired by the principles of paper architecture. [5]

The interpretation of the meaning of digital cities in this paper is represented by learning from paper architects (Paolo Soleri, Archigram, Cedric Price and Lebbeus Woods) from 20th century and using the transformative potential of digital advancements in 21th century, in order to create the new meaning of the phenomenon. Visionary architects are known for their experimentalist approach (a concept borrowed from science and introduced into architecture by Peter Cook in his 1970 book *Experimental Architecture*), which they portrayed through analog media; artistic drawings and abstract diagrams. By integrating their analog with digital approach, this research emphasizes that the essence of architectural production lies not in the medium itself but in the experimentation. Revisiting the past, in which paper architects predicted and proposed innovative analog solutions for future cities that would utilize digital technologies, can provide valuable insights into how our digital future might look.

The desire was to go beyond architecture, to define new languages and energies for projects destined to an 'invisible city', a city without architecture as it had been traditionally understood, but conceived for the future, based on the sensitivity and intuition of the present. [6]

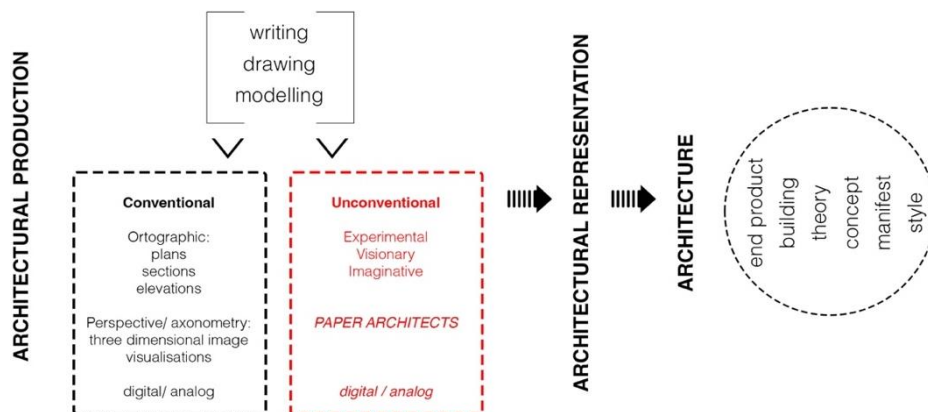

Figure 1. Conceptual diagram of architectural methodology, Drawn by the author.

The Paper architects produced a number of design projects on the subject of digitality, either imagining how computers might affect the life of city dwellers, or investigating what changes such machines would bring to architecture. Working with analog tools and thinking about an abstract digital future, paper architects deployed concepts that would have come to be crucial in recent discussions in architecture based on digital reality. Their research into digitality, conducted without the aid of computers, led them to explore fundamental questions about the intersection of technology, society, and the built environment. By envisioning how computers might impact urban life and reimagining the relationship between time, space, and architecture, these visionary architects laid the groundwork for contemporary discussions on digital reality.

From selected projects such as Babel II by Paolo Soleri, Plug in City by Archigram, Potteries Thinkbelt and Fun Palace by Cedric Price, and Centricity by Lebbeus Woods will input for the creation of digital cities will be drawn.

Figure 2. Paper architects and their notable projects: It features Paolo Soleri's *Babel IIB*, Archigram's *Plug in City*, Cedric Price's *Potteries Thinkbelt* and *Fun Palace*, and Lebbeus Woods' *Centricity*.

At every instant there is more than the eye can see, more than the ear can hear, a setting or view waiting to be explored. Nothing is experienced by itself, but always in relation to its surroundings." [7]

2. PAPER ARCHITECTURE

2.1 Paolo Soleri and *the Babel II*, Cyber city

"Architecture is the physical form of the ecology of the human, that configuration of matter which allows for the best energetic and willful flux." [8]

"The city is a human problem that has to find its answer within ecological awareness." [9]

Urban density, protection of undeveloped land, zero-impact cities—these are just some of Paolo Soleri's concepts, hastily labeled as utopian by zealous reactionaries, that have entered the consciousness of an entire generation of aspiring architects and have become the main expressions of contemporary sustainable design. By the end of the 1950s, the Italian American architect he explored

ISBN: 978-618-5765-02-6

the concept of creating megastructures, self-contained urban environments that function as self-sufficient cities. He developed the Arcosanti project which was based on the principles of arcology — the fusion of "architecture" and "ecology" — where Soleri proposed megastructures that minimize land use and support a living, organic system, encouraging human ecology. Soleri's projects marked an important era for future city visions. His approach sought to radically reshape fragmented cities and foster collectivity in an expanding urban population, framed within a global and environmental understanding.

Figure 3. Paolo Soleri's *Babel IIB*, floor plan and drawing of an elevation, source: *The city in the image of a man*, Paolo Soleri

The future city, in Soleri's view, is Babel II, conceptualized for a population of 520,000 people. The design featured vertical shafts for transportation, with platform-grounds anchored to these shafts. The periphery housed residential spaces, the medial belt contained gardens and waste processing plants, and the center included civil facilities and workplaces. The top platform-ground was designated for cultural institutions such as schools, labs, studios, theaters, and libraries. At ground level, parks, gardens, and playgrounds comprised the hyper-structure.

Soleri's work on Babel II was innovative for several reasons. Firstly, it proposed a high-density urban environment that integrated ecological principles. By minimizing land use and emphasizing vertical growth, Babel II aimed to reduce the environmental footprint of urban development. Soleri's approach was to view the city as a living organism, where each part is interconnected and interdependent, much like the elements of a natural ecosystem. Secondly, Babel II incorporated cybernetic principles, viewing the city as a system with feedback loops that enhance its functionality and sustainability. Soleri believed that the built environment should operate similarly to a biological organism, where the flow of matter and energy is abundant and uninterrupted. "Life is where the flow of matter and energy is abundant and uninterrupted," Soleri wrote, emphasizing the importance of efficient energy transformation in urban design. Soleri employed traditional architectural techniques on a massive scale, using drawing and conceptual models as tools for exploring and communicating his ideas. His methodology was deeply influenced by his understanding of natural systems and his commitment to creating sustainable urban environments.

Soleri's visionary ideas, particularly those embodied in Babel II, provide valuable insights for the development of digital cities. The decentralized and networked nature of Babel II, with its emphasis on feedback loops and systemic integration, parallels the structure of digital cities. In digital environments, where virtual and physical spaces intertwine, Soleri's principles of arcology and cybernetic urbanism can guide the creation of sustainable, efficient, and resilient urban systems.

"The city," he says, "is a bio- mental organism of a thousand minds." [10]

2.2 Archigram and the Plug in City, Cluster city

Archigram's "Plug-in City," conceived by Peter Cook in the 1960s, presents a radical urban design vision challenging conventional static infrastructure. It proposes a dynamic megastructure where modular, mobile units adapt to evolving needs and technologies. This approach shifts from top-down planning to an organic, bottom-up process, fostering a continuously evolving cityscape. Modular units, movable within the megastructure, accommodate changing population sizes and societal needs, reflecting an organic growth model. The project's emphasis on decentralization and modularity aligns with contemporary digital cities, emphasizing flexibility and real-time responsiveness. User participation and customization, central to Archigram's vision, resonate with digital city principles, fostering inclusive urban ecosystems. Moreover, "Plug-in City" has influenced architectural theory, inspiring futuristic urban concepts. Its plug-in design offers insights for urban regeneration, advocating for incremental, context-sensitive interventions. In essence, "Plug-in City" anticipates many aspects of digital cities, providing a visionary framework for adaptable, resilient urban environments. [11]

2.3 Cedric Price and the Potteries Thinkbelt & Fun Palace, Moving city

Cedric Price, an architect and urban planner, envisioned transformative projects aimed at revitalizing stagnant communities and fostering dynamic interactions between education, industry, and culture. Two of his most revolutionary proposals, the Potteries Thinkbelt and the Fun Palace, offer profound insights into the development of modern digital cities. These projects exemplify the integration of technology, flexible infrastructure, and collaborative spaces—key elements that underpin the concept of digital urbanism. [12]

The Potteries Thinkbelt, proposed between 1964 and 1967, was conceived as a bold response to the economic decline in northern Staffordshire, an area historically dependent on pottery manufacturing [13]. Price's revolutionary proposal aimed to transform this industrial wasteland into a vibrant hub of advanced technical education and research. This networked, mobile learning facility for 20,000 students was designed to transcend conventional educational buildings, catalyzing institutional and economic revitalization. [14] Price imagined the Thinkbelt as a lifelong learning facility, offering flexible, adaptable educational environments throughout users' lives. The project's dynamic nature was reflected in its infrastructure, which included student accommodations, transport systems, and various configurations of teaching units such as inflatable lecture theatres, capsule facilities, and fold-out decks. These components allowed the Thinkbelt to adapt to changing needs and demands, embodying the principles of flexibility and mobility [15].

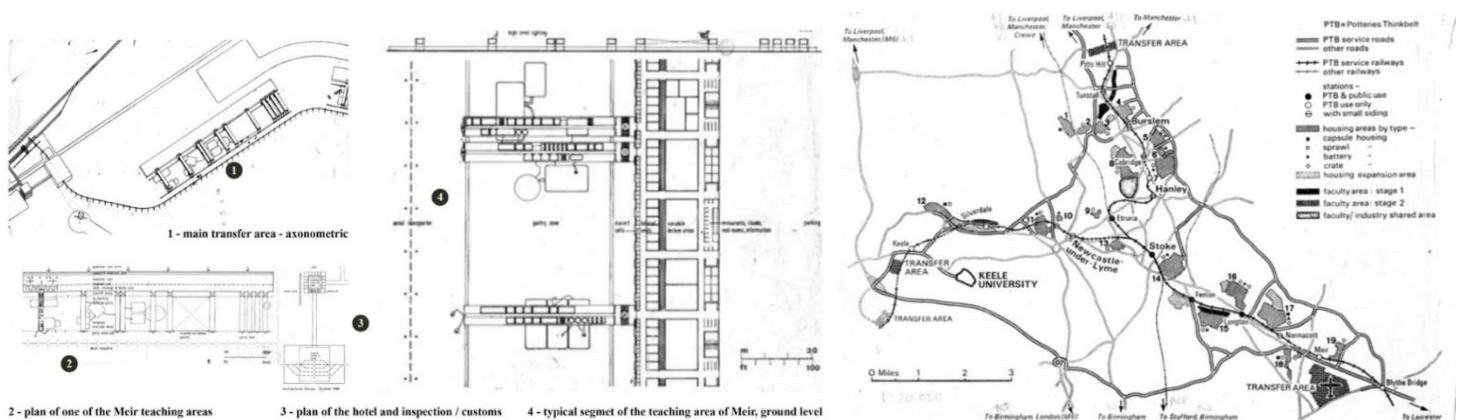

Figure 4. Cedric Price, the Potteries Thinkbelt, source: *Architectural design* 1966

Proceedings

of the International Conference on **Changing Cities VI:**
Spatial, Design, Landscape, Heritage & Socio-economic Dimensions

ISBN: 978-618-5765-02-6

Key elements of the Potteries Thinkbelt included utilizing railway carriages and mobile structures to create adaptable learning environments that could be easily relocated based on need and demand. Encouraging local industries to develop in close conjunction with university training and research programs, eliminating the divide between education and practical application, and aiming to restore a sense of community by aligning educational pursuits with local economic needs and cultural heritage were also crucial aspects. Housing for professors, researchers, and students was categorized into ‘crates,’ ‘sprawls,’ ‘capsules,’ and ‘batteries,’ ensuring varied and flexible living arrangements. [16] The Thinkbelt was envisioned to connect to broader infrastructural networks, reflecting Price’s belief that buildings and technologies must be catalysts for social and spatial interaction. [17] The Fun Palace, co-designed with theatre director Joan Littlewood, was another ground-breaking project that envisioned a flexible, adaptive structure dedicated to cultural and educational activities. Described as "a laboratory of fun," the Fun Palace was intended to be an ever-changing space that could accommodate a wide range of activities—from theatre performances and art exhibitions to scientific experiments and community gatherings. [18]

Fun palace: an axonometric showing the basic range of physical components

Fun palace: a type base that displays virtual elements - screens

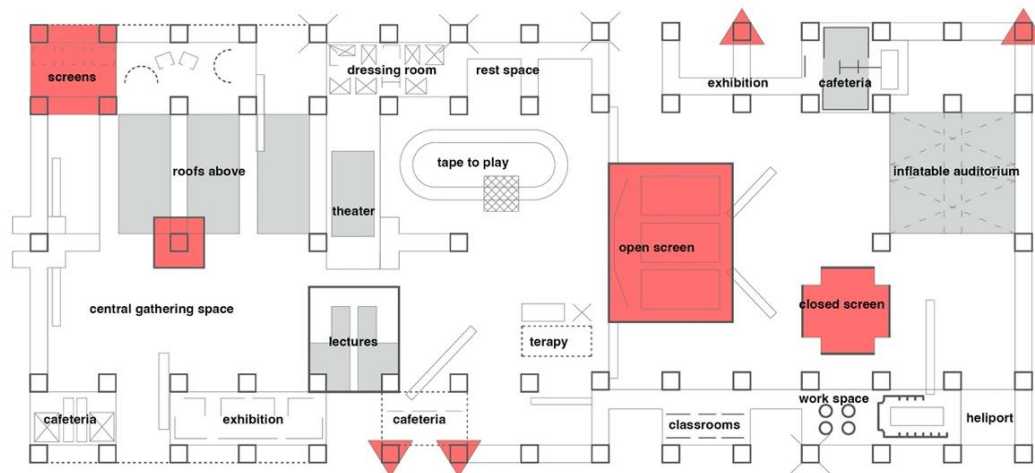

Figure 5. Comparative analysis of virtual and physical elements in the Fun Palace project, source: Drawn by author

Its adaptive architecture utilized modular and movable components to allow the space to be reconfigured based on user needs and activities. Emphasizing the role of users in shaping the space, the Fun Palace reflected Price's belief in architecture as a participatory and democratic process. Incorporating emerging technologies to enhance interactive experiences and facilitate learning and creativity was also a core element.

Both the Potteries Thinkbelt and the Fun Palace embody ideas that are highly relevant to the development of digital cities today. These projects show how important it is to have flexible, adaptable infrastructure that can keep up with technological changes and evolving user needs. The way the Potteries Thinkbelt integrates education, industry, and culture highlights the need for collaboration across different sectors to drive innovation and economic growth. Similarly, the participatory design of the Fun Palace underscores the importance of involving citizens in shaping urban spaces, a principle that digital cities can enhance through ICT for better user engagement and co-creation. Moreover, the Potteries Thinkbelt's potential for national and international connectivity fits well with the global interconnectedness of digital cities. Price's vision of buildings and technologies as catalysts for social and spatial interaction highlights the importance of creating urban environments that are not only functional and efficient but also vibrant and engaging. [19]

2.4 Lebbeus Woods and the Centricity, Radical city

"Maybe I can show what could happen if we lived by a different set of rules." [20]

"Centricity is a city in which architecture is not merely a background for living, a paradigmatic convenience, and even less a luxury afforded by the few; rather, it is an active part of the knowing and doing of each inhabitant, nothing less than a medium for living founded in physical knowledge and knowledge of the physical." [21]

Lebbeus Woods, a visionary architect renowned for his radical approach to urban design, viewed architecture not as a static construct but as a dynamic instrument for exploration and experimentation. Inspired by his fascination with science, particularly physics, Woods saw architecture as a medium to probe the underlying principles of the universe. His iconic project, "Centricity," embodies this philosophy, proposing a city characterized by overlapping centers and complex interactions reminiscent of emergent patterns observed in natural systems.

Contrary to its name, "Centricity" presents a decentralized notion of the center, depicting a city where numerous centers unpredictably overlap and interpenetrate each other. These centers constantly interfere with each other, creating disturbances and conflicts while simultaneously amplifying a collective energy akin to atoms. Woods envisioned "Centricity" as a hypothetical city governed by universal laws, embodying unpredictable forms and infinite variations. This concept mirrors individual human beings, forming the basis for community and emphasizing communication as the foundation of its architecture. For Woods, "Centricity" transcends purely material need, with structures serving both as instruments of play and as means of acquiring physical knowledge. He referred to these structures as "laboratories of living," highlighting their role in facilitating experiential learning. In developing "Centricity," Woods employed a distinctive methodology, using drawing as a tool for inquiry and communication. His sketches and illustrations went beyond visual representations, serving as a means of conceptualizing and articulating complex ideas about urban dynamics.

Figure 6. Lebbeus Woods: Centricity, source:

https://archive.org/details/centricitydrawings/1988.02_LWoods_Centricity_55.jpg

Beyond Woods' individual contributions, scholars like Crang (2000) recognize his work as instrumental in formulating new ideas of cities, including the concept of "centri-cities." These parallel cities, according to Crang, are characterized by complex interactions and differences, standing in opposition to classical notions of urban hierarchy. Woods' vision of "centri-cities" reflects a heterarchical city of dialogue, emphasizing incompleteness and incoherence as essential qualities. The decentralized nature of "Centricity," with its emphasis on overlapping centres and complex interactions, aligns with the dynamic and interconnected nature of digital urban environments. In digital cities, where virtual representations of physical spaces intertwine with real-world interactions, the principles of emergence and complexity espoused by Woods become increasingly relevant.

3. TOWARDS DIGITAL CITIES

The transition from paper architects' speculative visions to the realization of digital cities illustrates a profound evolution in urban design, driven by technological advancements and changing societal needs. The conceptual projects of Cedric Price, Paolo Soleri, Archigram, and Lebbeus Woods laid the groundwork for reimagining urban spaces in ways that transcend traditional architectural constraints. Cedric Price's Potteries Thinkbelt and Fun Palace introduced the idea of flexible, mobile infrastructure capable of responding dynamically to shifting educational and cultural demands. These projects anticipated the modular and adaptable nature of contemporary digital cities, where smart technologies enable real-time adjustments to urban environments based on data-driven insights.

Paolo Soleri's Babel II proposed an ecological mega-structure that minimized land use while promoting vertical growth and sustainability. This concept aligns closely with today's green architecture and smart city initiatives that integrate environmental consciousness with technological innovation. Soleri's vision of a cybernetic city, operating as a living organism with efficient energy and resource flows, prefigures the interconnected systems and feedback loops fundamental to modern digital urbanism.

Archigram's Plug-In City conceptualized a modular urban framework, where interchangeable parts could be easily reconfigured to meet changing needs. This idea resonates with the principles of digital cities, where infrastructure is designed to be flexible and scalable, incorporating IoT (Internet of Things) devices and smart grids to optimize urban functionality. Similarly, Lebbeus Woods' Centricity explored radical, decentralized urban forms, emphasizing the transformative power of architecture to create equitable and resilient communities. This vision is mirrored in the

decentralized, networked nature of digital cities, which leverage technology to enhance connectivity and democratize access to urban resources.

Collectively, these projects from paper architects highlight the importance of adaptability, sustainability, and integration in urban design. They offer valuable insights for the development of digital cities, emphasizing that the essence of future urban environments lies not just in technological adoption but in the holistic integration of social, ecological, and spatial dynamics. By drawing on these visionary ideas, contemporary urban planners and architects can craft digital cities that are not only technologically advanced but also human-centric and ecologically responsible. This synthesis of past visionary thinking and present digital capabilities provides a robust framework for addressing the complex challenges of modern urbanization.

4. CONCLUSION

Creating visionary projects has often been marginalized as insignificant to the progress of urban development in the real world. However, as Neuman and Hull suggest, "if we cannot imagine, then we cannot manage," [22] highlighting that the practices of conceptualization, envisioning, and performing future cities are essential for addressing their increasing complexity. This research methodologically approached the topic by first selecting significant 20th-century works that vividly express potential future collective life. These projects were then categorized and analysed to identify principles applicable to the development of digital cities. By examining the agency within these visionary concepts, this research aims to provide a valuable visual resource and guide for catalysing new perspectives and rethinking the application of future digital city visions. By connecting the past visionary work of architects like Paolo Soleri, Archigram, Cedric Price, and Lebbeus Woods with the emerging paradigm of digital cities, this paper underscores the continuity and relevance of their innovative ideas. These historical projects offer essential insights into adaptability, sustainability, and integration, which are critical for the evolution of digital urban environments. Consequently, revisiting and integrating these experimental approaches with contemporary digital tools can enrich our understanding and implementation of future urban designs, ultimately creating more dynamic and human-centric.

EU Biodiversity Strategy for 2030 on the example of Belgrade Linear Park Project

L. Vujović

First year PhD student of the Faculty of Architecture, University of Belgrade

Corresponding author: E-mail: lukavujovic81299@gmail.com, Tel +381 646477582

Abstract:

The European Union recently introduced the Biodiversity Strategy for 2030, encompassing guidelines for cities to define plans for greening urban spaces to protect ecosystems. These guidelines encourage cities to create natural spaces within the urban landscape, providing numerous benefits such as improved well-being and pollution reduction. As part of this strategic plan, a draft guide was published in 2021 to assist cities in preparing greening plans.

The research focuses on the Linear Park project in Belgrade as a case study, aiming to examine the challenges and opportunities associated with implementing the EU Biodiversity Strategy by 2030. Belgrade, as the capital of Serbia, serves as a good example for studying the application of these strategies. Its rich historical and cultural heritage, coupled with rapid urbanization pressure, underscores the urgency of sustainable urban planning. The location of Belgrade, between the Sava and Danube rivers, provides conditions for realizing biodiversity strategies. Recent initiatives for urban development create a favorable environment for investigating the effectiveness of integrating natural solutions into urban planning processes.

The linear park is a project of public space spanning 4.5 km along a former railway track. The goal of this project is to create new public spaces with a predominant park function, fostering innovative and sustainable solutions. Through a case study of this project, initiated in 2021, an analysis of the quality of such a solution in relation to the EU Strategy for 2030 can be conducted. The research's methodological approach is based on the analysis and application of general strategies from the draft document "Urban Greening Plan" which is a part of the EU Biodiversity Strategy for 2030.

The research aims to identify the problems and potentials of the Linear Park Project in comparison to the main goals and research methods in the "EU Biodiversity Strategy for 2030". This work will contribute to the research on Belgrade's urban greening strategies, following the principles of integrating natural solutions into urban development processes, using the example of the Belgrade Linear Park.

Keywords: *EU biodiversity strategy; Urban greening plan; Belgrade Linear Park; Urbanism; Nature*

1. INTRODUCTION

In the last few years, there has been a growing global focus on urban sustainability, emphasizing the role of green urban solutions in addressing the challenges of climate change. This shift in paradigm highlights the importance of collaborative approaches in designing and implementing strategies that integrate nature into the urban fabric. The most significant strategy that deals with biodiversity and nature conservation in urban environments is the EU Biodiversity Strategy for 2030. This strategy, which is part of the broader agenda of the European Green Deal launched by the EU Commission in 2019 [1], focuses on species conservation, nature protection, and the introduction of changes that will help address these issues. The main goal of this article- bringing nature back to cities is the starting point for the case study selection. The urban renewal project of industrial heritage currently under implementation, the Belgrade Linear Park, was chosen as a case study. This case study was selected due to its close connection with the principles and goals of biodiversity strategies. The project transforms 47 hectares of various neglected and contaminated areas into a unique ecosystem that

Proceedings

Spatial, Design, Landscape, Heritage & Socio-economic Dimensions

Rhodes Island, Greece • June 24-28, 2024

ISSN: 2654-0460

ISBN: 978-618-5765-02-6

spans along the banks of the Danube River. The study aims to present, evaluate, and identify the qualities and potentials in the projects of the Linear Park from the perspective of the thematic framework set by the EU Biodiversity Strategy for 2030 [2]. One of the particular features of this park is that it was designed and planned by different architects and planners, so a wide range of applied solutions are presented.

This study contributes to the broader discourse on urban sustainability by examining how localized projects can embody the fundamental goals of the EU Biodiversity Strategy, providing a blueprint for other cities aspiring to integrate the main goal of this Strategy into their urban development processes. Additionally, this study will provide guidelines regarding the potential for further implementation of solutions based on green infrastructure, nature-based solutions, and healthy ecosystems in the existing architectural and urban projects in the Linear Park.

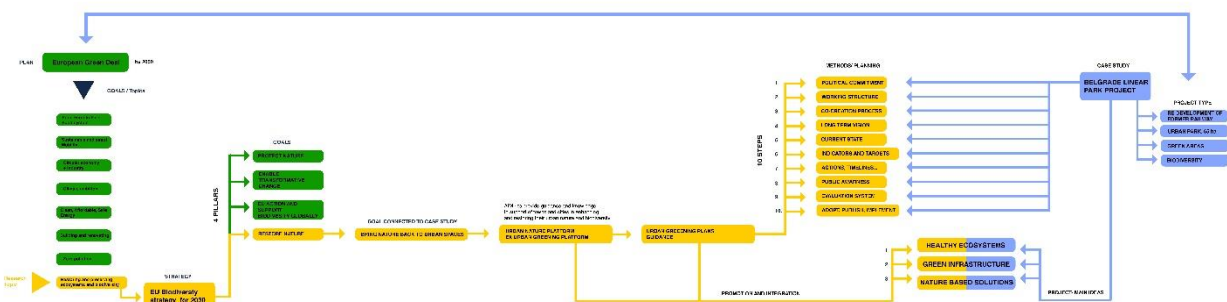

Figure 53 Research diagram, Goals and Plans, source: drawn by author

2. MATERIALS AND METHODS

In the initial step of the research, the primary goals and topics of the European Green Deal agenda and the EU Biodiversity Strategy were defined. The strategy represents a document that outlines objectives regarding environmental conservation and ecosystem protection. This step is significant as it demonstrates the relevance of the chosen research and the importance of the topic in the contemporary context. A continuous selection of goals was carried out, with an emphasis on those related to the reintroduction of nature into urban spaces. By identifying three main objectives derived from the strategy and associated documents (Urban Nature (Greening) plan), the foundations are set for the evaluation and recognition of implemented features within the case study. Through these three objectives and the case study, guidelines are established for the further development of the specific Linear Park project as well as potential future projects aimed at reintroducing nature into urban environments. The material used in the research can be divided into three types. The first type comprises planning documents (EGD, EU Biodiversity Strategy for 2030, Urban Greening plan), the second relates to the research process and planning of the Linear Park, and the third includes architectural and urban projects developed within the park. The materials from which aspects of urban planning solutions were analyzed consist of diagrams, graphical supplements, drawings, and textual descriptions of the projects.

2.1 The European Green Deal

The EU Green Deal, launched in December 2019 by the European Commission [3], represents a comprehensive agenda aimed at making Europe the first climate-neutral continent by 2050 [4]. The need to achieve the goals of the EU Green Deal arose as a necessity in the context of significant environmental degradation. The Commission points out that environmental and climate-related challenges are this generation's defining task [5]. As one of the goals of this agenda, the preservation and restoration of ecosystems and biodiversity were set. In addition to this goal, elements of the green

agreement include goals and strategies connected with the food system, mobility, circular economy and industry, climate, energy, pollution problems, and renovation.

2.2 EU Biodiversity strategy for 2030

The goal of preservation and restoration of ecosystems and biodiversity was introduced with the large strategy named the EU Biodiversity Strategy for 2030 - "Bringing Nature Back into Our Lives," published in 2020 by the European Commission [6]. The EU Biodiversity Plan 2030 is the most significant strategy launched by the EU Commission in 2020. The framework of this plan covers the member states of the European Union as well as states that want to be involved in the mentioned project. The need to nurture nature and ecosystems arose after the global pandemic of COVID-19, which drew attention to the problems of destruction and poor maintenance of nature. The great importance of this biodiversity conservation strategy would be reflected in both industry and capital, the business sector. According to the document there are 4 main pillars on which this plan rests: i. Nature protection, ii. Restoring nature, iii. Enabling transformative change, iv. A global biodiversity agenda [7]. The key aspect of this strategy that is connected with urban project is mentioned in the second pillar with the aim of restoring nature. *The Biodiversity Strategy aims to stop and reverse this trend by promoting the systematic integration of healthy ecosystems, green infrastructure and nature-based solutions into all forms of urban planning* [8].

2.3 Urban Nature (Greening) Plan

EU Biodiversity Strategy for 2030, pillar 2, identifies the greening of urban and peri-urban areas as one of the key commitments by 2030. This document and commitment are recommended by the EU Commission for all cities with a population larger than 20,000 inhabitants. Establishing green spaces can provide a wide range of benefits for cities. "Air and water pollution can be reduced by greening, provide protection from flooding, droughts and heat waves, and maintain a connection between humans and nature" [9]. The document defines crucial phases and steps for cities to reverse the process of urban nature ecosystems destruction. The strategy promotes nature-based solutions, green infrastructure, and healthy environments. These should include measures to create biodiverse and accessible urban forests, parks and gardens; urban farms; green roofs and walls; tree-lined streets; urban meadows; and urban hedges. They should also help improve connections between green spaces, eliminate the use of pesticides, limit excessive mowing of urban green spaces, and other biodiversity harmful practices. Such plans could mobilize policy, regulatory, and financial tools.

Currently, the Urban Nature Plan is in the preparation phase. So far, guidance has been published to help local authorities achieve the plan's goals "develop ambitious Urban Greening Plans" (now called Urban Nature Plans). This guidance was developed in collaboration between Eurocities and ICLEI [10]. They emphasize that developing an urban plan needs to include citizens and stakeholders. They invited cities with experience in implementing urban greening plans, and through this collaboration, the document was created. *The Urban Nature Plan is defined in 10 steps (mentioned in figure 1).*

3. CASE STUDY BELGRADE LINEAR PARK PROJECT

Belgrade Linear Park is a project aimed at redeveloping the old railway corridor that connects Beton Hala Waterfront and Pancevo Bridge. This project, currently awaiting realization, is located in the capital of Serbia, Belgrade. The redevelopment aims to transform the old railway into a green space within the Plan of General Regulation of Belgrade. The project area spans 46.7 hectares. In September 2018, the Assembly of the City of Belgrade adopted a Decision on the Development of the Plan of Detailed Regulation (PDR) for Linear Park, Belgrade. In December 2019, the CLEVER Cities Co-Creation methodology was applied in planning the Linear Park. This methodology provides "a complete co-creation pathway that encourages decision-makers to embed citizen engagement methodologies as an approach to co-design and co-implement nature-based solutions"[11]. During

Proceedings

of the International Conference on **Changing Cities VI:**
Spatial, Design, Landscape, Heritage & Socio-economic Dimensions
Rhodes Island, Greece • June 24-28, 2024
ISSN: 2654-0460
ISBN: 978-618-5765-02-6

the process of co-creation and implementation of the park planning methodology, surveys and questionnaires were organized through which users and residents of the area expressed their ideas and nature-based solutions. This applied methodology in planning included a long-term vision for the project. Between December 2018 and December 2019, various analyses and evaluations were conducted, leading to clear priorities. Although this project was initiated before the publication of the EU Biodiversity Strategy for 2030, its planning includes steps highlighted in the draft document Urban Nature (Greening) Plan, with a special emphasis on co-creation. After setting goals and implementing ideas, the process resulted in a call issued by CEUS, the Office of the Chief Urban Planner, the Association of Belgrade Architects, and the EuPOLIS consortium, inviting young architects and planners to propose their solutions for the Linear Park spaces. The call was announced in December 2019 [12]. The reasons for issuing the call were defined with four goals: i. to contribute to the resilience of the central city zone to climate change by increasing the extent and quality of greening and surface water regulation of this area, recognizing several risks to public health and well-being, ii. to simultaneously improve the quality of the environment and promote the strategic development of Belgrade as a healthy and green city through the application of nature-based solutions, iii. by creatively and innovatively selecting programs of activities and contents specific to such a space, the Linear Park can contribute to the urban transformation of the surrounding area and enhance the attractiveness of the central city zone and the city as a whole, creating conditions for sustainable economic development. iv. With the help of sustainable urban mobility measures, through the promotion of pedestrian, bicycle, and environmentally friendly public city transport in the broader zone around the Linear Park, accessibility and connectivity of central urban areas and the waterfront will be improved [13]. A total of 145 young people in 28 teams responded to this call. At the end of February 2020, the ten teams were chosen by a Professional Committee comprised of 10 members to develop conceptual designs for 10 sections of the Linear Park. The park was separated in 10 zones that were divided to selected teams for future project development. The idea was to create 10 specific zones that will remain connected with parks linear form and movement patterns.

Figure 54 Belgrade Linear Park, map, source, PGR Linear Park

According to the Plan of General Regulation for Linear Park, that was published later, in August 2021, the general goal of the development of the plan is the urban transformation of the railway corridor. This transformation is based on few key principles, i. *formation of the public urban space which connects other public spaces in the city*; ii. *the offer of various public contents within the plan of green areas*, iii. *v. realization of environmental, social and economic function of the linear park, as an ecosystem in the urban space, by improving the microclimate characteristics, biodiversity, functional characteristics of space, public health and well-being of citizens, etc., for by calming the*

ecological corridor by continuously planting ra-similar forms of vegetation (tree rows, groupings of trees, etc bushes, massifs of trees, flower beds, different nature-in- spirited solutions, etc.) [14].

The case study analysis was conducted through its relationship to the three established research goals and the biodiversity strategy: **1. Creation of healthy ecosystems, 2. Promotion of green infrastructure, 3. Integration of nature-based solutions.**

3.1 Healthy ecosystems

Healthy ecosystems can be described as systems that are resilient, capable of sustaining a diverse array of species. These ecosystems in urban areas contain various plants that improve air quality and regulate temperature differences in cities during the summer months with their natural surfaces. Healthy ecosystems neutralize pollution and enhance human well-being. To create such ecosystems in cities, it is necessary to design spaces that are in line with sustainability and nature-based concepts. They are most commonly achieved through the design and construction of parks, forests, and various green public areas [15]. Implementing nature-based solutions is one way to create healthy ecosystems. As part of the planning of the Linear Park in Belgrade, a significant step in creating a healthy ecosystem is the division of the park into 10 units, each separately designed to promote different ideas regarding biodiversity, environments, pollution prevention systems, etc. These units create a public network of green spaces, which is the basic idea of revitalizing this former industrial waterfront zone of the city.

3.2 Green infrastructure

Green infrastructure, according to the European Commission, refers to a strategically planned network of natural and semi-natural areas designed to deliver a wide range of ecosystem services, such as water purification, air quality improvement, climate regulation, and biodiversity conservation. It encompasses various types of green spaces, including parks, forests, wetlands, green roofs, and urban gardens, as well as blue spaces like rivers, lakes, and coastal areas [16]. The European Commission emphasizes the multifunctionality of green infrastructure, highlighting its role in enhancing urban resilience, promoting health and well-being, supporting biodiversity, and fostering social cohesion. Green infrastructure is seen as a critical component of sustainable urban development, providing a cost-effective approach to addressing environmental challenges and improving the quality of life in cities and regions across Europe.

3.3 Nature based solutions

The Commission defines nature-based solutions as "Solutions that are inspired and supported by nature, which are cost-effective, simultaneously provide environmental, social and economic benefits and help build resilience. Such solutions bring more, and more diverse, nature and natural features and processes into cities, landscapes and seascapes, through locally adapted, resource-efficient and systemic interventions." [17] Architectural and urban interventions falling under nature-based solutions aim to integrate nature into their interventions. The integration of nature-inspired solutions implies that they are efficient, sustainable, cost-effective, and provide various types of positive impacts on people. Such solutions can be designed and planned at different scales, from the scale of park furniture to interventions on buildings, to interventions in public, urban space, and infrastructure projects. Some of these solutions include green roof projects, urban gardens, vertical farming, at the level of urban interventions: green spaces, eco-urban furniture, the concept of a living garden, and many others. As part of the call for young architects to propose their solutions for the Linear Park, the competition brief required architects to integrate various types of nature-based solutions into their designs of individual park segments. The main goal of the call for conceptual solutions was to achieve urban renewal of the former railway space through innovative and sustainable solutions involving bioclimatic design principles, integrated planning, and the application of nature-based solutions. One

Proceedings

of the documents referenced in the competition brief is the UNALAB Technical Handbook Of Nature-Based Solutions, prepared by the University of Stuttgart [18], which contains individual nature-based solutions in space of various scales, providing detailed information on technical and design parameters, implementation methods, and technical explanations. For this research 14 of these solutions are presented as a types that can be inserted into a Linear Park projects.

3.4 Linear Park segments

From the 28 young teams and their proposals within the competition, 10 solutions were selected for the 10 zones of the Linear Park. The solutions largely relied on the required aspects of efficiency, biodiversity, sustainability. A special emphasis in this article is given to the relationship between the selected 3 projects, 3 units, and the jointly set goals of the Linear Park project and the EU biodiversity strategy, namely green infrastructure, nature-based solutions, and healthy ecosystems.

3.4.1 Segment 3: LINKPARK

This solution heavily leans on the principles of connecting green spaces. Corridors are designated with various purposes: the main line, active line, tram line, eco-auto line, and biodiversity line. [19]

Nature-Based Solutions: To promote biodiversity, the landscape design includes the planting of 20 different species of low and high vegetation, aiming to enhance the well-being of space users. Aromatic gardens along paved paths serve as a nature-inspired intervention. The potential for utilizing solar energy is recognized, offering the opportunity to create systems that function independently in terms of energy.

Green Infrastructure: This approach seeks to integrate spaces with different types of paths and corridors, which, combined with other sections, can represent significant green infrastructure. The Eco-auto line aims to reduce carbon dioxide emissions by allowing only zero-emission cars. Opportunities for establishing green infrastructure and a healthy system are presented. Biodiversity line has been applied as the fundamental principle of connectivity between spaces, with the main idea of creating a new element of green infrastructure

Healthy Ecosystems: While nature-inspired solutions aren't the main focus, their easy implementation remains possible. Leveraging the potential for waterfront access is achieved by placing a cantilevered public space above the river. Measures outlined in the EU Biodiversity Strategy, such as creating accessible amenities for residents and improving the connectivity of green public spaces, are evident. This project also mitigates pollution and negative impacts like car traffic on biodiversity.

3.4.2 Segment 4

The project for segment 4 is located in a park zone surrounded by residential neighborhoods and adjacent streets. The characteristic feature of the solution is the sloping, hilly terrain resulting from accentuating the existing leveling. [20]

Nature-based solutions: In line with the objectives of implementing nature-based solutions, the project for segment 4 incorporates a variety of solutions: i. Solar-powered street furniture, ii. Rainwater harvesting for park irrigation, iii. Thermal canopies, iv. Green roofs. The urban furniture used represents an innovative solution due to the use of recycled materials. This segment prominently incorporates existing infrastructure, such as a steel bridge, transforming it into a walkway that brings users closer to water bodies. Green roof systems are utilized on two pavilions designed to promote biodiversity.

Healthy ecosystem: Through a wide range of designed solutions, this segment can meet the conditions outlined in the EU Biodiversity Strategy for 2030 through an urban greening plan and its goal of promoting healthy ecosystems. Creating a healthy ecosystem requires the implementation of various plant species and ensuring the entire system is self-sustaining and resilient. This project for

Proceedings

of the International Conference on **Changing Cities VI:**
Spatial, Design, Landscape, Heritage & Socio-economic Dimensions
Rhodes Island, Greece • June 24-28, 2024
ISSN: 2654-0460
ISBN: 978-618-5765-02-6

segment 4 implements a series of modern solutions for regulating temperature in summer and winter, utilizing the natural ground temperature to achieve thermal balance. Nature-inspired bench solutions using solar energy significantly contribute to the formation of a healthy ecosystem. Noise protection is achieved by creating continuous embankments on the park's edges. Research has been conducted regarding existing strong winds at the location, and tall vegetation has been planted accordingly.

Green Infrastructure: In line with the goal of promoting and implementing the concept of green infrastructure, similar to other segments, there is a strong emphasis on connecting and complementing natural spaces. Unlike segment 3, which did not create new water surfaces, segment 4 features the creation of two lakes that complement the park's green oases.

3.4.3 Segment 7

Segment 7 of the Linear Park has a distinctive linear shape and is situated between significant urban zones. The project in this section emphasizes the introduction of new amenities at the location. The proposal includes the construction of a museum and outdoor pavilions, as well as the design of continuous pathways through low and high greenery.

Nature-Based Solutions: Unlike other sections, the primary focus of nature-based solutions in Segment 7 is the implementation of green roofs on the new buildings. This nature-inspired solution contributes to reducing the urban heat island effect and improving air quality. Although the project is still in its conceptual phase, this implementation opens up possibilities for additional solutions in terms of energy efficiency and system sustainability. Green bus shelters are planned.

Healthy Ecosystem: The museum and pavilion projects, as well as the designed public spaces, use natural materials such as stone and wood. These materials can help regulate temperature differences during summer days and nights. A key aspect of the project, aligned with healthy ecosystem principles, is its focus on human well-being, featuring amenities for recreation, education, and relaxation. The structures have an alluvial form to create micro-natural environments with greenery interwoven between the buildings.

Green Infrastructure: Segment 7 continues the park's continuity by creating pathways that connect to surrounding sections. Emphasis is placed on permeable pavements that mimic natural processes. Water features are designed as corridors that traverse the park, ensuring that this section integrates with the park's green corridor without disrupting it.

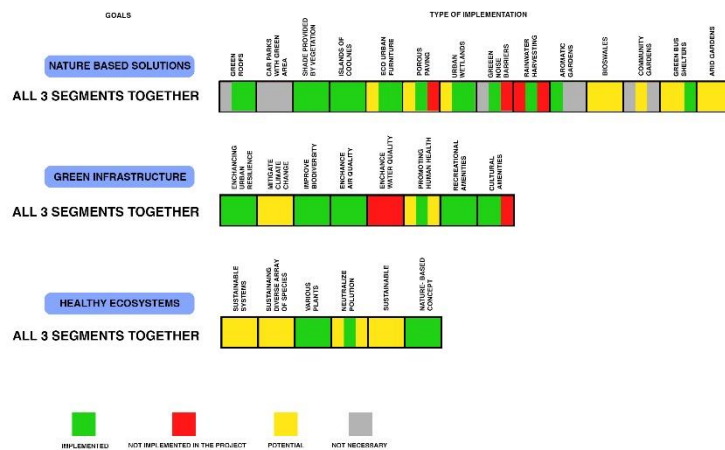

Figure 56 Simultaneous presentation of implemented solutions, source: drawn by author

4. CONCLUSION

The project of the Belgrade Linear Park implements various concepts related to the core goals of the EU Biodiversity Strategy in a specific manner. By segmenting it into 10 units that implement principles of nature-based solutions, green infrastructure, and healthy ecosystems in different ways, a wide range of solutions is achieved. In terms of nature-inspired solutions, these segments implement anywhere from 3 to 8 different types of solutions. This spectrum of implementing various solutions represents significant potential for development. To meet the needs of healthy ecosystems, the entire park must become sustainable in terms of energy, maintenance, species diversity, pollution neutralization, and the implementation of self-sustaining systems. To ensure the park aligns with these

Proceedings

goals, priority can be given to high-quality solutions that can be implemented throughout the park. Through analysis, it is noticeable that at least one solution has been implemented for each of the selected systems possible to install in this context, affirming the idea of achieving a large number of different solutions. The quality of segment separation is reflected in the diversity of plant and animal species, as well as the presence of various microenvironments contributing to community well-being. By displaying a comprehensive final table, it can be clearly seen that one of the units has included a greater number of quality systems than others, leading to an imbalance at the unit level. In terms of green infrastructure, such an approach, with a division into 10 units, affirms the basic principle of connecting green and water spaces within the park. All units equally contribute to enhancing urban resilience, improving biodiversity, enhancing air quality, and providing numerous recreational amenities. What is not present in the solutions but could be significant due to the park's location and proximity to the river is the possibility of implementing water quality improvement systems. In terms of realizing global strategies at the local project level, based on research, there is a clear link in the initiative to apply various principles of biodiversity conservation. To realize these solutions, it is necessary to integrate all necessary stakeholders and enhance the received projects in terms of mutual synergy and joint implementation of systems to bring nature back into urban environments. By using data collected within this case study, future projects can balance the relationship between project units and segments through system synergy and the integration of quality solutions. Additionally, the process in planning the Linear Park, which is applied and relies on processes and goals defined by the EU Biodiversity Strategy, can represent a significant pilot project for future local projects in Serbia and worldwide.

Abstract

Rapid urbanization presents challenges for designing future cities that enhance residents' quality of life and well-being. Literature has shown that dense environments can potentially contribute to heightened stress levels. Urban stress reduction is a critical concern in contemporary urban studies, involving multiple disciplines to understand how density environments positively impact well-being. Research shows that people tend to seek out natural environments, and aesthetic responses to natural settings positively impact psychological stress and emotional states. Moreover, literature has explored the beneficial impact of fractal dimensions, typically found in natural environments, on cognitive processes and stress reduction. Previous research often used images of natural scenes to calculate fractal dimensions and explore nature's restorative effects. However, there is a lack of deeper exploration of fractal dimensions within dense urban settings. This study sets its foundation in Shenzhen, one of the world's youngest cities, and more specifically in its urban villages, selected here for their unique character and high-density characteristics. This research aims at providing an exploratory analysis of the fractal character of those villages. High-resolution images and eye-level viewpoints are here systematically analysed to provide a different perspective on urban high-density environments through the lenses of spatial geometrical properties and visual complexity. A Python-based box-counting method for determining the fractal dimensions of photographic images is used. The results illustrate that the fractal dimension of urban village street patterns ranges from 1.73 to 1.89, indicating mid-to-high complexity. Secondary commercial streets show the highest complexity, while newly built secondary cluster streets exhibit the lowest complexity. By applying fractal analysis to high-density environments, we explored possible connections between natural patterns and built environments, as well as highlighted important methodological considerations. A deeper understanding of fractal properties within urban settings can shed light on how people perceive complex environments. This study highlights significant potential for future research to explore the fractal characteristics of dense urban areas and their impact on individuals' perceptions.

Keywords: *Fractal Dimensions; Urban Villages; Stress Reduction; High-Density Cities; Visual Complexity*

1. INTRODUCTION

Increasingly fast worldwide urbanization leads to more and more dense environments within cities. High-density environments are characterised by high population density, high-rise building complexes, and crowded streets. Besides, citizens in high-density cities are facing challenging psychological stress [1], making urban stress reduction an urgent issue in contemporary urban and architectural studies [2, 3].

Urban villages are one of the high-density environments that have developed in response to rapid urbanization processes. They are characterized by central location within the city, affordable rent, an abundance of employment opportunities, and diverse land-use types [4]. They feature extremely high-density mid-rise building blocks, often referred to as hand-shake buildings with narrow alleys and high population densities.

Proceedings

Urban villages in Shenzhen represent a unique urban phenomenon, reflecting the city's fast-paced urbanization from a small town into a modern metropolis. These villages effectively accommodate a substantial influx of migrant populations and foster vibrant commercial areas. The high-density construction prevalent in these villages often lacks of sufficient public open space, thereby making the streets between buildings critical as public domains. Urban villages exhibit a vibrant street system for non-motorized vehicle and pedestrian activities, diversified living services, and face-to-face interactions among people promoted by its small scale. High-density construction, combined with a lack of vegetation, significantly impacts the quality of the urban environment and the living experience of residents.

To better understand urban villages and their streets' fractal character, this study aims to provide a systematic fractal analysis within one village and its streets, a setting that has not previously been analysed for fractal dimensions. Specifically, images were collected and analysed from one of the urban villages in Shenzhen, named Tangshuiwei Village, to determine the fractal character of its streets. In the context of rapid urbanization and urban stress reduction, this study aims to detect potential natural patterns within high-density urban environments using fractal dimension analysis.

2. FRACTAL DIMENSIONS IN BUILT ENVIRONMENTS

Fractal patterns are prevalent in natural scenes [5, 6, 7, 8, 9], and they display self-similarity and scale-free characteristics. The fractal dimension (D) is a statistical parameter used to measure the complexity of geometric fractal patterns [10, 11]. The intrinsic link between fractals and natural environments enhances individuals' aesthetic appreciation for fractal patterns. The pervasive presence of fractals in nature, particularly those of mid-complexity, has led to the adaptation of the human visual system to process them efficiently. Humans display an aesthetic preference across fractal images, regardless of whether these images are generated by nature's processes, by mathematics, or by the human hand [6]. Studies have revealed that fractals elicit psychological reactions in people, with mid-complexity fractals linked to alleviating stress [7, 14, 32].

The fractal character of an image can also be quantified by its fractal dimension (D). For fractals described by a D value close to 1, the patterns observed repeat in a way that builds a very smooth, sparse shape. However, a D value closer to 2 manifests repeating patterns building the shape of an intricate and detailed structure [15]. Therefore, fractals are widely used as a graphics tool for simulating and generating natural-like geometrics.

Within studies of the built environment, urban form, urban residential patterns, and transportation networks exhibit fractal characteristics [16, 17]. Fractal dimension analysis can be applied to these complex systems. All these examples of the measurement of urban form are focused on plan views or aerial photographs to analyse their geometrical properties. Besides, fractal dimensions have also been applied at smaller scales, such as streetscapes or street vistas.

In studies of fractal dimensions of street views, most researchers employ integrated software like ImageJ, and correlate the analysis results to physical features such as greenery, boundaries, and street furniture [18, 19, 20]. Cooper (2008, 2013) focused on everyday streets to explore the relationship between visual quality and fractal dimension and identified a positive correlation between fractal dimension and visual quality ratings, noting that a city street with a mean fractal dimension of 1.718 scored highest in visual quality. Research has also related the results to self-rating visual quality surveys, such as visual variety, visual interest, and visual complexity [21]. Furthermore, most research on fractal dimensions and visual perception mainly utilizes generated images instead of real-world scenes [22]. However, there are few studies measuring the overall visual perception of street scenes using real-world photographic images and a Python-based calculating program.

According to the prevalence of fractal patterns in nature and their restorative effect, the ability to quantify fractal characteristics of an image within built environments is an insightful perspective through which to investigate visual complexity in high-density settings.

3. METHOD

3.1 A case study in an urban village

Minzhi Urban Village is one of the many urban villages in Shenzhen. It is located in Longhua District, between Minzhi Avenue and Longhua Avenue. Tangshuiwei Village is one of the urban villages within the Minzhi Village complex, located in the northeastern part of Minzhi Urban Village; it is neighbored by Shaxia Village.

Figure 1. Tangshuiwei Village in Minzhi Urban Village (Longhua District, Shenzhen)

Image resource: <https://images.app.goo.gl/bBkY9j9ut5ad5KQD8>

3.2 Data collection

The images were taken using a Sony α 6400, and the collecting parameters were set at image size as 6000 \times 3376 pixels (max), 300dpi, field of view = 50°, camera pitch = 0°, and the height of the camera was set as 1.55m. Sampling points were set at 10-meter intervals along various street types, totalling a sampling distance of 3 kilometres, to represent a sequence of views for each street typology.

Based on the Urban Residential Area Planning and Design Standards [23], and the Shenzhen City Urban Planning Standards and Guidelines [24], Table 1 summarizes urban road systems categories and typologies.

Table 1. Classification of Shenzhen's Urban Road Systems

	Typology	Function
Urban Road System	Freeways	Handle through traffic, port traffic, and external city transport functions.
	Arterial Roads	Accommodate long-distance rapid transit and freight movement within city districts.
	Secondary Roads	Manage medium and short-distance passenger and freight traffic, distributing traffic from main arteries.
	Distribution Roads	Promote a network system of small blocks and dense road networks.
Residential Area Roads	Main Streets	Urban Secondary Roads accommodate both motorized and non-motorized traffic.
	Cluster Streets	Main access routes for entering and exiting residential neighbourhoods, usually including one bicycle lane and one

ISBN: 978-618-5765-02-6

Alleys	pedestrian path. The road surface width should not be less than 4.0 meters. Final level of access to residences, primarily used by residents for entry and exit. These roads mainly accommodate bicycle and pedestrian traffic. The road surface width should be no less than 2.5 meters.
--------	--

Main Streets are the main access routes for entering and exiting residential neighbourhoods, serving as a main thoroughfare, connecting various parts of the development. In residential areas, they typically reach a minimum carriageway width of 7.3 meters to ensure adequate space for vehicles. Secondary Streets are secondary roads within a residential area intended for moderate traffic, providing access to properties or facilities. They reach a minimum width of 5.0 meters. Considering the unique characteristics of urban villages, where secondary streets also serve as important commercial streets and feature streets between building clusters, we categorized street types within urban villages into four typologies (Table 2).

Table 2. Street Typologies in Urban Villages

	Typology		Function	Circulation
1	Main Streets		Urban roads within the residential area	motor vehicle lanes, non-motor vehicle lanes
2	Secondary Streets	commercial streets	Auxiliary roads within the residential neighbourhood	non-motor vehicles, pedestrians
		cluster streets		
3	Back Alleys			non-motor vehicles, pedestrians

3.3 Fractal dimensions calculation

There are various methods for calculating fractal dimension, including standard box-counting, partitioning, and differential box-counting [25, 26, 27]. Box-counting method is frequently adopted for the estimation of fractal dimensions [11], and has been used to quantify the characteristic complexity of a city, including its growth patterns, road and rail networks, open spaces, and skylines [28].

Box-counting method involves covering computed pattern O with a grid of boxes and counting the number of non-empty boxes that contain any part of the pattern. This process is repeated while gradually reducing the box size. The number of grids $N(\epsilon)$ and the size of the box ϵ are recorded and plotted to a log-log diagram in each repeated step [29].

$$D(O) = \lim_{\epsilon \rightarrow 0} \frac{\log(N(\epsilon n))}{\log(1/\epsilon n)}$$

Previous studies analysing the fractal dimensions of built environment's images have often used integrated software such as ImageJ. With advancements in computer image processing technology and programming, it is now possible to further explore fractal analysis of built environment images. In this study, we programmed and coded the box-counting method in Python. To be processed, each image was first converted to grayscale. Gaussian blur was applied to reduce noise and smoothen the image. Otsu's thresholding method was then used to create a binary image, which segmented the image into foreground and background. Additionally, canny edge detection was applied to the blurred image to highlight edges. These edges were combined with the binary image and the resultant combined image was further cleaned for subsequent fractal analysis. Following pre-processing, the fractal dimension analysis using the box-counting method involved Box Size Determination, Box Counting, and Log-Log Plotting. The box sizes were determined through a geometric progression

Proceedings

from half the minimum dimension of the image down to 2 pixels. The counts were plotted against the box sizes on a log-log scale. A linear regression was then performed on this plot to determine the slope. In conclusion, this method effectively combines a pre-processing step, box-counting calculation, and presentation of the fractal dimension value using a log-log diagram, providing valuable quantitative measures of the complexity of the street typology images.

4. RESULTS

Each street typology was analysed to determine its mean fractal dimension (D) for all images in the sample ($n = 60$), which quantifies the complexity of patterns within spatial streets' layout (Table 3).

Table 3. Average fractal dimension ranking of 4 street typologies

Ranking	Street Typologies in the Urban Village	Mean D
1	Secondary Commercial Streets	$D=1.829$
2	Main Streets	$D=1.827$
3	Back Alleys	$D=1.823$
4	Secondary Cluster Streets	$D=1.796$

In terms of mean D , secondary commercial streets present the highest mean D of 1.829. The lowest mean D is demonstrated by back alleys at 1.796. Secondary commercial streets present a fractal dimension of 1.829, which was the highest among the categories analysed, manifesting repeating patterns and detailed structure, likely due to their multifunctional nature. The highest index of fractal dimension was interpreted as the presence of numerous service functions within the specific zone [30]. This type of street holds multiple functions, supporting a variety of commercial activities and high pedestrian and vehicular traffic, leading to a dense and intricate road structure. These streets form vibrant commercial zones of the urban village, offering a wide range of dining and essential services. The shops are predominantly ground-floor establishments adjacent to residential areas, making them the most important and active public spaces within the urban village.

Main streets within urban villages possess a fractal dimension of 1.827, the second highest among the street typologies. This suggests the street pattern of this typology is complex, serving a broader array of urban traffic demands including higher volumes and more diverse types of vehicles and pedestrians.

Back alleys, with a mean D value of 1.823, show slightly greater complexity compared to secondary cluster streets, reflecting the function of connecting individual residences within more compact and possibly irregular layouts, catering to very local needs.

Secondary cluster streets have a fractal dimension of 1.796, indicating a relatively high level of self-similarity typical for residential areas. These streets are likely characterized by a more regular, integrated network. This type of street is in the new district of Tangshuiwei Village, which is a newly built and designed pedestrian area. Finally, best approximation value was calculated to show the street photographic images that can best represent the four street typologies, as well as the maximum individual D and minimum individual D value in each street typology (Table 4).

Table 4. Best approximation D value

Main Streets	Secondary Commercial streets	Secondary Cluster Streets	Back Alleys
--------------	------------------------------	---------------------------	-------------

$D=1.829$

$D=1.844$

$D=1.795$

$D=1.828$

Step	Grid Size	Marked Boxes(N)
1	1688	8
2	798	40
3	377	141
4	178	547
5	84	2125
6	39	2125
7	18	34660
8	8	160586
9	4	612313
10	2	2372836

(b)

diagram (b) grid size

A log-log diagram of secondary commercial streets illustrates the appearance of a fractal dimension within an urban village’s street patterns. From this diagram, the straight line indicates that from half the minimum dimension of the image down to a size of 2 pixels, the images of urban villages have self-similar textural characteristics like fractals. Spaces with a fractal structure usually appear a hierarchical order, rhythm and diversity, and such spaces offer visual quality by influencing individuals’ perception positively [31, 32].

Table 5. Maximum and minimum D value and representative images

Street typologies in Urban Villages	max_value_image	min_value_image
1 Main Streets	$D=1.900$ 	$D=1.757$ 

2 Secondary Commercial Streets

 $D=1.866$  $D=1.769$ 

3 Secondary Cluster Streets

 $D=1.836$  $D=1.760$ 

3 Back Alleys

 $D=1.882$  $D=1.736$ 

The maximum individual D was recorded for main street and it's approximately 1.9. The minimum individual D was recorded for the back alley at 1.736.

D values of four street typologies in the data set fell within 1.73-1.89, indicating a mid-to-high visual complexity range ($D=1.5-2.0$) of detailed textures that have more visual excitation and visual diversity [29, 33]. The resulting fractal dimensions of different scenarios often fall into the interval of 1.0–2.0. The intervals between 1.0–1.3 and 1.3–1.5 are defined as the low-to-mid level, where the scenarios can be seen as 'well-recognized' and 'better for goal-directed navigation'. The interval between 1.5-2.0 is defined as mid-to-high level, where the scenarios can be seen as 'arousing' and 'exciting' [29]. Meanwhile, visual diversity increases as the D value increases from 1.3-1.7 [33].

5. DISSCUSSION

Tangshuiwei Village in Shenzhen was selected as a case study for the exploration of its fractal characteristics. A Python-based box-counting method was used to calculate the fractal dimension of photographic images at eye-level on the streets. Data sets were pre-processed using Canny edge detection and binary images, preserving detailed architectural features and small alleyways, and clear delineation of building edges and pathways was ensured. The results obtained here manifest that

Proceedings

urban villages show a certain fractal pattern along their streets; their fractal dimensions fall into 1.73-1.89, manifesting mid-high complexity. Secondary commercial streets show the highest complexity, while newly built secondary cluster streets exhibit the lowest complexity. The maximum individual D was recorded for main streets and it's approximately 1.9. The minimum individual D was recorded for back alleys at 1.736.

By applying fractal dimensions analysis to high-density environments, this study attempts at searching for natural patterns within built high-density. Fractal dimensions are a natural property [10, 33], showing fundamental fractal character can help describe how complex systems are organised. Like natural environments, high-density environments display self-similar textural details, leading to higher fractal dimensions due to clustered lines [35]. They have complex scenes where the human visual system tends to perceive the overall profile (e.g., building, forest) rather than finer details (e.g., building facades, leaves) [36]. Fractal characteristics at eye-level within high-density environments can support the perception of detailed textures and patterns.

Through this presented Python-based box-counting method, some considerations when using box-counting method in high-density environments can be concluded. Preserving detailed architectural features and small alleyways during preprocessing is crucial for accurate analysis. Hence, reserving clear delineation of building edges and pathways is vital for understanding the spatial organization and density of these areas. Furthermore, varied lighting conditions caused by narrow streets and high buildings can affect the thresholding methods used in preprocessing, making it important to account for shadow and light variations.

These measurements could provide pivotal insights for urban planning and development, providing new perspectives on the visual complexity of street patterns within high-density environments such as urban villages.

6. CONCLUSION

This study sheds light on an alternative method for the exploration and quantification of spatial visual complexity in high-density urban environments, and more specifically in a unique condition typical of Shenzhen: urban villages. The purpose of this study was to find natural patterns within built high-density, and further compare different street typologies of urban villages according to their fractal character. In the process, methodological considerations were provided, establishing a reference for future research.

Further investigation can consider exploring the relationship between fractal dimensions in high-density and how people interact with and perceive complex environments, including how the visual complexity of street scenes in high-density affects visual perceptions, or how different street typologies influence psychological states (e.g. relaxation or stress). These results may inform the perception of urban high-density environments, driving design strategies to address positive visual impacts, and potentially contributing to inform design guidelines for the future of urban density.

Extended abstract

Frequently, initiatives aimed at establishing sustainable urban environments overlook the input of city dwellers. Inclusivity is paramount, and the decision-making process should actively involve citizens, including those with disabilities, allowing them to play a meaningful role in shaping decisions about the places they reside in. This paper delves into the realm of storytelling, examining its potential as not only a valuable data source but also as a conduit for fostering community engagement and a way of amplifying the voices of the residents.

Building from participatory narrative inquiry methods, this research pursues the value of telling and sharing stories, in the processes of regeneration and development of green spaces in the city of Sofia, Bulgaria. In doing so, the investigation endeavours to reconcile the prevalent top-down sustainability strategies frequently adopted by city councils with the more organic vision of green city development articulated by its citizens. Recognising the escalating demand for a harmonised understanding among all stakeholders involved, the research methodology incorporates the three pivotal phases of participatory narrative inquiry: collection, sense-making, and return. By embracing this approach, the investigation aims to foster a collaborative and inclusive framework that integrates the perspectives of both city authorities and residents, promoting a more holistic and effective approach to sustainable urban development.

Stories have the power to enhance the intrinsic value of a locale, infusing it with personality and a distinctive identity. This prompts a crucial question: how does the individual narrative serve as a tool for comprehending and re-imagining the urban landscape? Furthermore, in what ways can these singular stories contribute to shaping a broader vision of a sustainable and eco-friendly environment? The significance of this research lies in its potential to foster citizen engagement through the art of storytelling, a fundamental human activity. This approach serves not only as a means of learning but also as a conduit for introducing innovative ideas. Consequently, it promotes a more inclusive and grassroots approach to addressing the sustainability goals of the city of Sofia. The exploration of narratives becomes a cornerstone for cultivating a collective consciousness that aligns with the values of citizen involvement, propelling towards more sustainable urban futures.

Extended abstract

The impact of climate change on the health and well-being of older adults is multifaceted and demands a nuanced understanding. As global temperatures continue to rise, older individuals' vulnerability to heat-related illnesses intensify, creating a pressing health concern. Moreover, the increasing frequency and intensity of extreme weather events pose additional risks, from flooding to extreme temperatures, affecting the health and quality of life of the older population.

In the urban context, transformations driven by climate change adaptation efforts contribute to the complexity of these challenges. Rising air pollution levels, the emergence of heat islands in densely populated areas, and inadequate infrastructure increase the health risks for older populations.

The consequences of climate change on the urban environment also have social implications. Evolving community structures may lead to social isolation among older individuals as traditional support systems shift, underscoring the need for solutions that address not only environmental factors but also the social aspect of urban life. Understanding this intersection of climate change, ageing, and urbanization is essential to protect the health and overall well-being of older adults.

To deepen the knowledge of how climate change affects the health and quality of life of older adults, a systematic review was conducted. Employing the PICO strategy and adhering to Cochrane guidelines, the review searched three databases (PubMed, Scopus, and Greenfile) for relevant articles published between 2015 and 2022. Nineteen studies were included in this comprehensive analysis.

The findings of these studies reveal a compelling association between various climate change phenomena and heightened risks of mortality and morbidity among older adults. Cardiovascular, respiratory, renal, and mental health issues, alongside physical injuries, emerged as significant outcomes. Importantly, vulnerability factors such as gender, socioeconomic status, education level, and age were identified as key influencers shaping the impact of climate change on older adults' health.

Direct health impacts were linked to ambient temperature variability, extreme temperature events, strong winds, sea temperature fluctuations, extreme El Niño-southern Oscillation (ENSO) conditions, and droughts. Indirect effects manifested through air pollution resulting from wildfires, further exacerbating health challenges among older populations.

This systematic review emphasizes the urgent need for prompt and efficient strategies to address and alleviate the repercussions of climate change on the older population. As climate change events become more severe and frequent, it is imperative to facilitate population adaptation for survival.

However, there are inherent limitations to human adaptation and temperature tolerance, particularly within more vulnerable groups. Therefore, prioritizing the implementation of public health initiatives aimed at the dissemination of bioclimatic design guidelines aimed at reducing exposure to the impacts of climate change is crucial, namely high temperatures, which includes the development of resilient urban environments that specifically cater to the needs of vulnerable populations.

Abstract

The modern way of life, combined with the rapid technological, economic and social changes, led to the movement of a large part of the population of many western countries, from rural areas and their settlement in large urban centers. The innate need for contact with nature led to the creation of urban green spaces, which are however quite often degraded and encroached upon, amid bad urban building practices and economic over-exploitation, by activities stemming from the modern capitalist system. In the theoretical framework of the present paper, the concepts of green economy and sustainability are studied, as well as the historical evolution of urban green spaces and their role, while it is attempted to evaluate sustainable regeneration methods, with the aim of protecting the natural environment and improving the living standards of local communities. As far as the practical context is concerned, this includes the regeneration procedures design of the area near the University of Thessaly facilities, in the city of Karditsa and the enactment of a proposal regarding the creation of a model botanical garden, describing its structure and individual functions.

Keywords: *green economy, sustainable development, urban regeneration, urban green spaces, botanical garden*

1. INTRODUCTION

1.1 General introductory and bibliographical information

Urban green areas were already developed from the first years of population movement from rural areas and the formation of the first cities. The removal of populations from the nature, contributed to establishing the need to include a part of the natural environment in their daily life (Spencer & Cross, 2017). As a consequence, the creation of the first urban tissues, was accompanied by the development of the first green spaces, in the form of parks or botanical gardens, while applying the established urban planning standards.

The rapid growth of the industry, resulted in the degradation or complete destruction of green spaces, by creating factories, roads, housing or work structures. During the later years, the aforementioned environmental degradation and the significant benefits of urban green spaces were perceived, while several initiatives were implemented to create green spaces and integrate them into the urban fabric (Marini, 2016).

During the modern era, the intense phenomenon of urbanization has as a consequence the concentration of large sections of the population in the large urban centers, at the same time that the rate of development of the mentioned phenomenon is rapidly increasing. The said increase further reinforces the need to create new urban green spaces, easily accessible by the inhabitants for free and daily use. At this point, it is worth noting, that in several regions of the Greek territory the

phenomenon of anarchic construction is extremely intense, damaging the free urban spaces and particularly the public green spaces, causing intense negative consequences in the wider urban environment, directly degrading the quality of life of the residents.

Picture 1 The rapid growth of cities during the industrial revolution (Sarigiannis, 1987)

Parks, due to the extent of the area in which they belong, occupy the largest percentage of the total urban green spaces. However, in several modern cities, the number of parks is not sufficient in terms of ensuring the needs of all residents, with a significant part of the existing parks showing an image of destruction and abandonment. The regeneration of the existing urban green areas, accompanied by the creation of new ones, through the utilization of unused urban lands, could be a drastic solution to the aforementioned problem. Already, in many foreign countries, many similar actions are under development, at the same time that in the Greek reality, only a few proposals are put into the implementation stage (Marini, 2016).

1.2 Types of urban recreations

In order to improve the quality of life of residents in a city or an urban area, it is necessary to create and ensure certain conditions. These conditions are not only about improving economic parameters, but residential development through social, environmental and cultural improvement and development. That is why, although historically, an urban regeneration originally referred to the reconstruction and reuse of old buildings and other facilities, today, urban renewals generally refer to targeted interventions in the existing urban environment, to improve the conditions and quality of life of the residents. (Αραβαντινός, 2011).

The forms and types of regeneration vary and depend on the characteristics of the cities that are applied each time. They are of course also determined by the nature of the changes and the targeting. When urban regeneration first appeared, it involved definitions related to urban renewal, reconstruction, restoration and therefore were exclusively concerned with the regeneration of the urban shells. Along the way, the renovations concerned the restoration of the uses and functions of

Proceedings

the cities, so the definitions were related to remediation, re-use and re-installation. In the modern era, the definitions of urban regeneration concern modernization, revival and reconstruction, with the aim of improving the conditions and the standard of living of the inhabitants of urban centers (Stefanou & Mitoula, 2002).

The two main categories of urban regeneration are distinguished according to the degree of intervention, into partial and radical. The category that is selected each time depends on the needs of each region. According to article 8 of the Law, 2508/1997, urban regeneration is the set of interventions that have an urban planning, social, economic and special architectural character, which arise from related studies with the aim of improving the living conditions of the residents, the built environment, highlighting the cultural, aesthetic and other characteristics of an area (Aravantinos, 1997).

A partial regeneration has a sanitary character with the aim of improving the existing network of an area. The partial renovations concern the creation of free spaces, green spaces, changing the facades of buildings, changes in their interior layout, completion of necessary infrastructure, etc.. This method avoids the strong negative economic, social and political effects of radical renovations (Aravantinos, 1997).

Despite all the effects of their implementation, radical renovations were deemed necessary and took place at least from the end of World War II until the 1970s in urban centers in the US and Europe. It is about leveling and total demolition of the existing building volume and the rebuilding of an area for its reconstruction. Post-war modernism (1945-1970), characterized by a contrast between modernism and tradition and essentially promoted dealing with everyday practices as a priority (functional design) with the parallel pursuit of an ecological balance and integration of the built space into the natural environment (monumental and naturalistic design). After WWII, high-rise apartment buildings begin to spread significantly in Greece, especially in the capital, but its construction begins to become rough and unattractive and its materials mediocre. Due to high urbanization many old houses were demolished to make way for huge building complexes. Among these old houses there were also remarkable examples of neoclassical architecture (Skoulatoy, Dimakopoulou, & Kondi, 2001).

This phenomenon was and still is quite intense in the city of Karditsa itself in which the building capital with architectural and urban planning interest, to the extent of its utilization requirement, it is even today, despite its obvious deterioration, large, which nevertheless continues to decline. In many cases and after a radical renovation, organized building with an urban layout plan was not followed and thus many problems arose, such as expropriations that financially burdened the municipality, concentration of land ownership in a few companies, development of construction companies that undertook renovations based on profit-making criteria only, abandonment of areas by low-income residents due to an increase in the cost of living in the redevelopment areas, etc (urenio.org, 2023).

During the early 1970s the theoretical approach of modernist planning is abandoned and is replaced by small-scale and limited-cost regeneration actions, preservation, conservation and utilization of cultural heritage in the context of a current of eclecticism, historicism and romantic reminiscence of the past. Therefore, a shift in traditional morphology, formality and the past of each country is observed, which coexists with advanced prefabrication techniques.

The free arrangement of the buildings is removed, as is the spatial continuum of the urban fabric and the synchronic virtual multiplicity of cubist layouts. Instead of free composition historicism brings back elements such as the street, the square and the block, which are constitutive features of the city fabric (urenio.org, 2023).

2. THE FOREST BOTANICAL GARDEN OF THE UNIVERSITY OF THESSALY

2.1 Introduction

The aim of a botanical garden can be one of the following, or under certain circumstances all of them:

- 2 The preservation and protection of biodiversity through the conservation of rare species
- 3 Further scientific study of the plant species
- 4 Environmental education and awareness
- 5 Recreation

An additional goal should be the harmonious coexistence of all the above functions, especially when such a space exists in a purely educational space such as a University, where an additional educational character can be served, such as the area of this paper.

The location of the Garden is proposed to be on the premises of the University of Thessaly (former Technological Educational Institute (T.E.I.) of Thessaly) and specifically in its facilities, which are utilized for the needs of the Department of Forestry, Wood Sciences and Design and Department Public and One Health.

For the needs of this work and especially for the needs of the writer's thesis under the supervision of the other members of the co-authoring group, from which the present publication arose, a complete Topographic survey of the area was made as well as a survey of the existing Town Planning elements that apply to the area which are summarized below. Specifically, with the use of complete Topographical equipment, i.e. Total station SOKKIA Set630RK, with angular accuracy 15cc as well as dual-frequency GPS with measurement accuracy H: $\pm 8\text{mm} + 0.5\text{ppm}$ και V: $\pm 15\text{mm} + 0.5\text{ppm}$ (RTK), the exact location of which is shown in the relevant picture. With the use of GPS, the mapping became dependent on the Greek Geodetic Reference System (G.G.R.S. '87) and by solving the routing any errors were corrected. All horizontal and, secondarily, elevational elements of the survey area were then mapped, as shown to the picture below:

Picture 2 Excerpt of Topographic Survey of the study area. Own survey

2.2 Structure of the proposal

In the Forest Botanical Garden of the University of Thessaly the subdivision of the area described above is proposed of the surroundings of Building A which houses the needs of the aforementioned Higher Education departments of the University of Thessaly, in individual areas and their distribution in the areas below:

1. Walking & recreation areas
2. Historical forest plants area
3. Medicinal and aromatic plants area
4. Ornamental plants of the region area
5. Foreign forest plants area
6. Area of native forest plants of the Greek area
7. Forest plants of the region area
8. Herbarium and systematic section area
9. Greenhouse area
10. Recreation area- refreshment room
11. Wooden structures and more specifically:
12. Wooden hut at the proposed entrance to the Garden
13. Wooden fencing, for the discreet separation of the individual parts of the garden
14. Wooden table seats, especially in the recreation area
15. Wooden urban equipment
16. Outdoor amphitheater with mixed construction

3. PROPOSALS AND CONCLUSION

3.1 Urbanization and green spaces

It is a fact that the phenomenon of urbanization has not only affected the size and number of modern cities, but it has determined to a huge extent the way the urban environment is structured. One of the parameters of these alteration is the change in the natural environment, both inside the cities and outside them. During the great systemic changes of the last century and the transformation of many Western economies, including Greece's, urban green spaces began to disappear or shrink on a massive scale and were replaced by new building structures, bringing about the fragmentation of residential construction. It is estimated that to date, around 30% of the open spaces and green spaces of major European cities has been disappeared, providing the required space for the construction of new building facilities (Hrehorowicz - Gaber, 2015). The loss of urban green spaces is recorded in both developed and developing countries of the world, while it becomes directly dependent on the prevailing socio-economic factors (Gairola & Noresah, 2010).

The ever-increasing population density and continued urban spatial expansion has brought about a number of negative impacts on green spaces, having literally wiped out a large part of them. The last few years, numerous studies have recorded the rate of urban growth and mainly the subsequent loss of free open spaces and urban green spaces or the consequent negative environmental effects (Odindi & Mhangara, 2012), while all of them recognize the human factor as the cause και τη μεταβολή της οικιστικής του εγκατάστασης στα νέο-διαμορφωμένα αστικά κέντρα (Yuan, 2005). Additionally, remaining urban green spaces have been recognized as the most valuable resource of modern urban ecosystems (Gairola & Noresah, 2010).

More generally, it is concluded that urban green spaces, can stop the negative effects of intense urbanization, significantly improving the quality of life of societies (Li & Pussella, 2017), since, as it has been formulated, this depends on the balancing of the distribution of the building facilities, of transport infrastructure and natural environment areas (Gulgun, 2015). The types of urban green

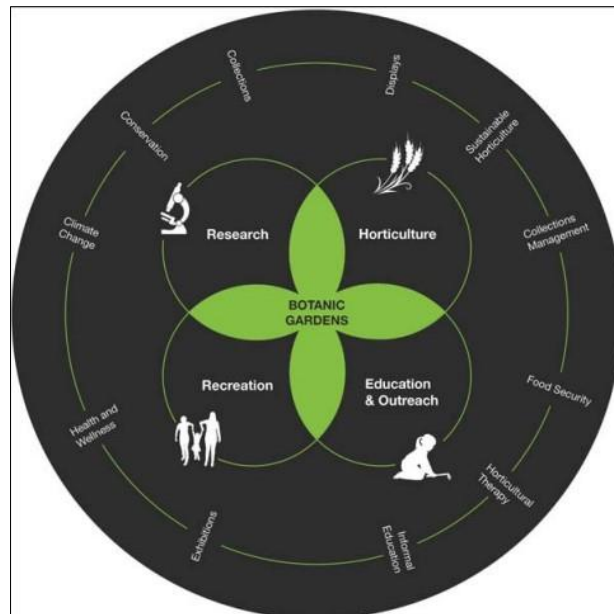

Proceedings

of the International Conference on **Changing Cities VI:**
Spatial, Design, Landscape, Heritage & Socio-economic Dimensions
Rhodes Island, Greece • June 24-28, 2024
ISSN: 2654-0460
ISBN: 978-618-5765-02-6

spaces, as well as their individual functions, have a direct impact on the quality of life of the residents and for that reason underestimating their importance endangers the sustainable development of urban areas.

3.2 The multidimensional role of botanical gardens

Urban green spaces take a number of forms, one of the most important being botanical gardens. Botanic gardens are considered to be "sources of growing plants for public entertainment and preserving them for scientific or educational purposes, while having a local, national or international role" (Aldous, 2007), while some bibliographic references are talking about their important role "in the tourism development of specific areas and the support of regional or international networks regarding the conservation, sustainable utilization and recording of native or alien flora" (Willis, 2005).

Picture 3 The multidimensional role of botanical gardens

[source: <https://www.publicgardens.org/resources/role-botanic-gardens-twenty-first-century>]

More generally, botanical gardens are considered as structures for the protection and preservation of flora and biodiversity, while providing opportunities for environmental and scientific education, as well as economic or tourism development resources, while their functions and services have a direct impact on the cultural and social development of local societies (Aldous, 2007).

Botanic gardens undoubtedly play a crucial role in the conservation of many plant species, while their wider natural or artificial landscapes raise public awareness of biodiversity issues, acting both as collectors of living and preserved plant species, as well as supporting structures for the protection of rare and endangered species of flora, which are no longer found in their natural environments (Jorgenson, 1986). Equally important is the contribution of botanical gardens to the environmental education of society, spreading the importance of protecting the natural environment, through the multi-faceted approach and awareness of different audiences (Aldous, 2007). Regarding the environmental benefits offered by the operation of botanical gardens, these are found in the regulation of the urban microclimate, the improvement of internal hydrological processes, the absorption of atmospheric pollutants and the restoration of the biodiversity conditions of the areas in which they are located (Nowak, Stevens, Sisinni, & Luley, 2002). Recent studies have shown that large urban green spaces, such as botanical gardens, contribute to the reduction of global warming, significantly

Proceedings

of the International Conference on **Changing Cities VI:**
Spatial, Design, Landscape, Heritage & Socio-economic Dimensions
Rhodes Island, Greece • June 24-28, 2024
ISSN: 2654-0460
ISBN: 978-618-5765-02-6

slowing the accumulation of carbon dioxide in the atmosphere (Primack, Ellwood, Galliant, & Miller-Rushing, 2021).

The benefits of the operation of the botanical gardens, in addition to the environmental, also have a financial sign, since by acting as visitor attraction poles which they contribute to the tourism development of many areas, offering work and activity opportunities to local communities and of course scientific and educational. Additionally, many economic benefits arise from the reduction of energy costs associated with the existence of natural green spaces. Reducing local air temperatures, through water transpiration and the provision of natural shading, the need of energy use to cool buildings is significantly reduced, especially during the summer months (Aldous, 2007). Finally, from a social point of view, researches have shown that the mental upliftment offered by the operation of botanical gardens for the inhabitants of cities, is inextricably linked with their socialization, the adoption of a healthier lifestyle, their productivity increase (Kaplan, 1992) and crime reduction (Kuo & Sullivan, 2001). Also, through the opportunities for cultural activities and events, not a few examples around the world have shown that the operation of botanical gardens can also contribute to the cultural development of previously degraded urban areas.

3.3 The Greek reality

Comparing the urban green spaces of most European cities with those of large Greek urban centers, it can be easily established that Greece lags significantly in the number of green spaces, occupying the penultimate position among 27 countries of the European Union.

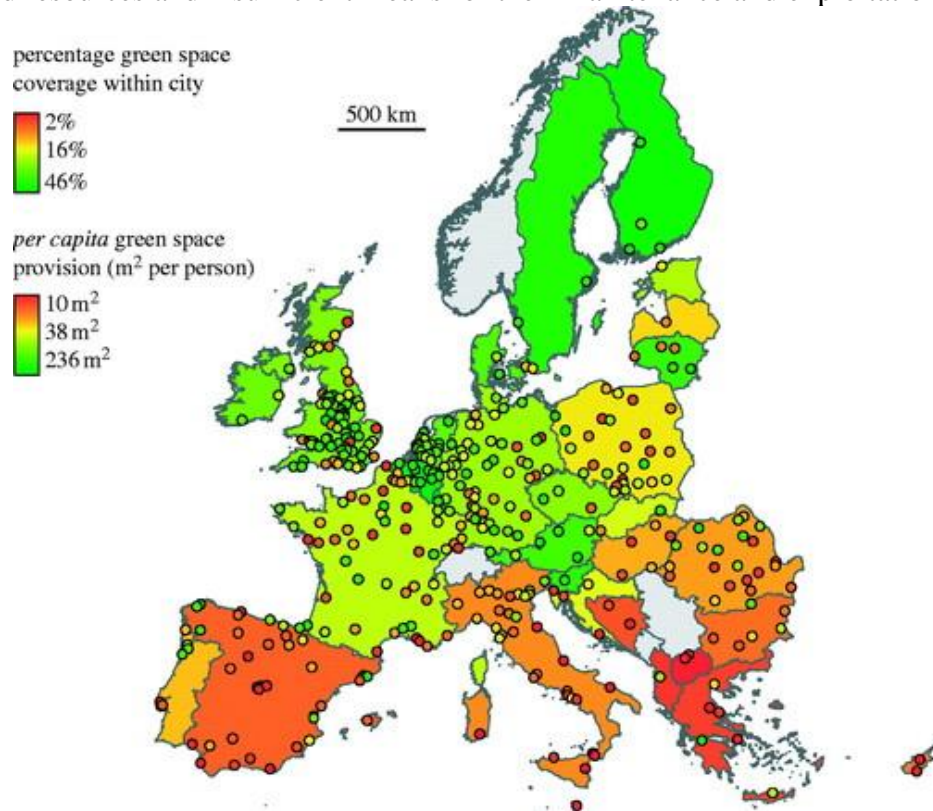

Picture 4 The urban green in the EU countries (European Environment Agency, 2013)

Proceedings

of the International Conference on **Changing Cities VI:**
 Spatial, Design, Landscape, Heritage & Socio-economic Dimensions
 Rhodes Island, Greece • June 24-28, 2024
 ISSN: 2654-0460
 ISBN: 978-618-5765-02-6

According to the report of the European Environment Agency, in 60% of Greek cities the percentage of green spaces is less than 20%, while in the remaining 40% the coverage rate does not exceed 29% (European Environment Agency, 2013). From these data, it can be concluded that Greek cities do not incorporate elements of the natural environment, while the encroachment of green spaces and natural forest areas has been a common practice during the urban planning of the last decades. Furthermore, in many urban centers, degraded and abandoned spaces are found, which are factors of further economic and environmental degradation, limiting the possibility of substantial development of the specific areas. The regeneration of such spaces is considered a necessary condition for the transition to sustainable urban development and the optimal use and exploitation of every free space in modern urban centers. In any case, all invasive actions for the regeneration of degraded areas should be implemented with a view to protecting the natural environment, the non-alteration of any historical or cultural value of the premises and upgrading the standard of living of the local communities.

Regarding the Greek botanical gardens, their number and size is noticeably smaller compared to the counterparts of the European urban centers, despite the fact that Greece is a country with enormous territorial and climatic diversity and many rare species of vegetation can thrive in many of its areas. From the study of the most important Greek botanical gardens, it was found that in most of them, the building infrastructure is not sufficient to host a wide variety of plant species, while in the Athens's historic botanical gardens, an image of abandonment is presented, with the relevant state agencies having limited resources and insufficient means for their maintenance and exploitation.

Picture 5 The existence of green spaces in European countries and cities (Fuller & Gaston, 2009)

3.4 The Forest Botanical Garden of the University of Thessaly

The Forest Botanical Garden of the University of Thessaly, as designed and proposed in the context of this paper as well as in the corresponding thesis as described above, is proposed to operate on an area of 29,829.8 square meters, with the parameters described above, constituting a modern and model botanical garden of Central Greece. The operation of the Garden is mostly focused on facilitating and enhancing the education of students in the Department of Forestry, Wood Science and

Proceedings

of the International Conference on **Changing Cities VI:**
Spatial, Design, Landscape, Heritage & Socio-economic Dimensions
Rhodes Island, Greece • June 24-28, 2024
ISSN: 2654-0460
ISBN: 978-618-5765-02-6

Design, covering a large part of the research needs of the specific department, with the collection, cultivation and utilization of native plant species. Furthermore, through educational programs, in collaboration with the bodies of Primary and Secondary Education of the Prefecture of Karditsa, the opportunity is given to promote the awareness of students and the general public on critical environmental issues as is the huge contribution of flora to the balance of local ecosystems. The operation of the Garden is believed to strengthen the ex-situ efforts to preserve the biodiversity of the wider area, while it will be a pole of attraction for the residents of neighboring areas, acting as a special place of recreation and entertainment.

The building structure of the Garden will include, among others, a multi-purpose building, recreation area, herbarium, greenhouse, parking areas, etc., while the wooden structures that include gazebos, flower beds, benches, waste bins, fences and walkways, are expected to further enrich the aesthetics of the Garden, since the use of natural materials, mainly wood, will not burden the overall environmental landscape. To improve the architectural structure of the Garden, the proposed interventions concern the opening of new paths and their appropriate coating with the recommended materials, while the creation of a small lake will allow the hosting of aquatic vegetation, while at the same time it will aesthetically enrich the overall structure. Furthermore, the creation of sloping ground, through earthworks processes, aims to facilitate the general cultivation and irrigation process. Regarding the hosted species of the Garden, is recommended to include plants that show an increased ability to adapt to the particular climatic and hydrological conditions of the area such as trees and shrubs of the sub-mediterranean vegetation zone, as well as hydrophytic azonic species.

In conclusion, it should be mentioned that both the planned urban green space and urban parks in general, should be integrated into the wider urban fabric through efficient traffic connections. Generating income from many sides, however, utilizing the existing south-east corner of the campus as the main one, is considered that will facilitate access by visitors, who can move on foot, by bicycle or by car, while the target is, through the corresponding interventions proposed above, the accessibility of the area with alternative means of transportation such as the bicycle, the use of which is anyway particularly increased overall in the city of Karditsa, and other means of micromobility, such as the electric scooter, providing visitors with the possibility of safely parking and/or charging them. At the same time, due to the imminent increase in the traffic load, as a natural continuation of the operation of an attraction pole, such as the proposed Forest Botanical Garden, may lead to the need of taking a series of Traffic-related measures, such as cutting off through-flows within the University area, difficulty of entry-exit conditions as well as transit within it, boosting accessibility from the West entrance of the campus to prevent visitors from using the local road network, etc. Furthermore, the use of the garden should extend to its entire area and include activities aimed at a wide range of age groups and be free for all visitors. All of the above, in combination with the performance of a supra-local public benefit, in the zone that extends around the perimeter of the garden, is assumed that they will contribute to the maximum extent to the increase of the visitation of the area, utilization and long-term sustainability of the project and they will definitely not burden the area in which the specific infrastructure is located in terms of traffic or in any other way. After all, the disengagement from motorized means of transport and the shift to other, more environmentally friendly means, including Public Transport not so much due to fuel used but mainly due to capacity (a single bus can transport dozens of visitors to the Garden as well as any other destination) presents a very high degree of overlap with the corresponding environmental footprint which is attempted to be given to the area through the construction and operation of the proposed Forest Botanical Garden.

Finally, it is pointed out that the basic character of the wider academic area within which the specific land use is proposed to be located, it is assumed in advance that it remains unchanged and non-negotiable, with all the conquests of the previous years which govern the way a campus of this type operates, such as maintaining asylum, the utilization of all the spaces by the official bodies of the

Decarbonizing Communities Through Planning for Change and Adaptability

A. Friedman

Full professor, urban planner and architect, director of the Affordable Homes Research Group at McGill University Peter Guo-hua Fu School of Architecture and principal of Avi Friedman Consultant Inc.

Corresponding author: E-mail: avi.friedman@mcgill.ca, Tel +01 514 484-0236

Extended abstract

Planning for change is a way to rise to the challenges presented by the constantly changing technological, social, and economic realities in today's urban environments. An adaptable design approach can also help decarbonize cities by reducing demolition and material waste.

Depending on location, cultural and economic realities in which they are embedded, large-scale developments can take years to build. Municipal planning approval can also be lengthy and given the time that lapses between a project's inception and its execution, the fate of a plan is subject to the whim of changing market demands. Sometimes, a development project's relevancy does not survive the time it takes to be built. Therefore, housing design that follows current practice may rendered inappropriate for an unpredictable future.

This paper argues that neighborhoods can be planned to flexibly respond to the alterations they may face over the course of their development process and the years that follows. It challenges the traditional large scale residential planning paradigm to introduce a flexible approach. The modified approval process offers a piecemeal method to planning one that can easily be altered according to market demand and newly emerging economic and social realities. The process was implemented by the author in the planning of a community in the town of La Prairie, near Montreal, in Quebec, Canada in collaboration with a private developer and a municipality.

The paper also regards design for adaptability in the unit level. Subdivisions built in North America are undergoing extensive change to make them suitable for contemporary lifestyle and technology changes which results in waste that ends up in landfills. The author introduces a dwelling design that facilitates interior modification while reducing the need for extensive demolition. The energy efficient design includes demountable partitions and special conduits for the introduction and upgrading of utility lines.

By looking at the macro and micro levels the author will outline the rationale for the need for planning adaptable communities and homes, introduce relevant concept and design and will illustrate them using the planning of a community and a home that were designed for change.

Investigation of the compatibility of national waste management policies in the European Union and proposal of a common decision-making process

A. Kiakou

Department of Planning and Regional Development, University of Thessaly, Greece

Corresponding author: E-mail: nkiakou1@gmail.com, Tel +30 6976060403

Extended abstract

Economic growth, urbanization, and industrialization have increased the volume of various non-hazardous and hazardous wastes, worldwide. Waste management deficiencies on the part of some countries are one of the causes of environmental degradation. This paper aims to identify the compatibilities between the European Union's member countries concerning the national factors considered for defining the suitable location of waste management units and to create a common multi-attribute documentation model as a tool for deciding the suitable location of such units.

The first issue is resolved through the comparative evaluation of countries with the relative importance (rating) of each of the attributes (location criteria) assigned by the stakeholders per country, structured in levels to create a tree of weighted attributes, known as *the value tree of the multi-attribute utility theory (MUAT)*. The categories of attributes were selected from the literature research.

Solving a location problem for this industry affects a wide range of participants: units, governmental authorities, and civil society. Considering that the paper aims to create a common decision-making model, the agreement among different parties is pursued. MUAT is the case of the multicriteria analysis method where participation of interested parties is possible and aims to reach a *consensus*. The model should also be flexible and subject to improvement as conditions change. This can be reached with the MUAT since as the structured factors are changed, the model allows the factors to be re-evaluated by the participants.

Initially, the attributes are evaluated regarding their competence by a group of experts, the planners. Weights were attributed by stakeholders for each factor in terms of suitability for facility location. Attributes are also evaluated by the civil society actors in terms of the impact of such installations on society. To formulate a common model, the *consensus of the parties* is the objective pursued. It is therefore appropriate, for the factors to be re-evaluated by the stakeholders to obtain common weights.

The new element this paper introduces in addition to the literature, concerns the pursuit of consensus in a large group of participants of different interests who are active in the EU. Therefore, it can be applicable at the EU geographical scale. It also pursues the inclusion of the civil society in the decision-making process. Although the model is simple, consensus from all different parties and consistency and validity of the factors are difficult to achieve. In the next stage of the research, the final common weights will be used in formulating the common decision-making model. The final purpose of the proposed model is that it can ensure applicability in any case of location decision process of the waste industry in the EU.

“Terrains Cultivés”-Experiential textiles-clothing recycling Center in Ioannina city

P. Vardaka^{1*}, K. Kotzia²

¹ Msc Architect Engineer, Department of Architectural Engineering, Polytechnic School, University of Ioannina, Greece

² Diploma Thesis Supervisor, Assistant Professor on Architectural Design, Department of Architectural Engineering, Polytechnic School, University of Ioannina, Greece

Extended abstract

The abstract is based on the Diploma Thesis entitled “Terrains Cultivés-Experiential textiles-clothing recycling Center in Ioannina”, presented in February 2023, which regards the design of a recycling complex for clothes and fabrics integrated in the urban tissue of the city of Ioannina.

Based on a thorough examination of the clothing industry worldwide the Thesis explores the possibilities of shifting from a linear process of treating textiles to a circular one by extending a garment’s life cycle. As a result, a new way of thinking about clothes is proposed to be cultivated with the establishment of an Experiential Clothing Recycling Center in Ioannina city center. The first step in creating a grounded recycling system is to familiarize the public with the sustainable mentality by bringing it into their daily life, making it a habit. The starting point for the concept was the mandatory measures that are to be applied by the EU to all countries-members in 2025 as far as garment recycling is concerned and their strategy for 2030.

The Diploma Thesis investigates how architecture and urban design can contribute as experiential and programmatic tools in familiarizing people with a new sustainable and ethical model of textile products management, which is based on the circular economy model and aims to minimize the waste of clothes. For that cause, the Textiles Recycling Center is proposed to be designed in Ioannina, a city of northern Greece. Through its holistic design and connection to the city-life it can constitute a collective environment that creates a community by bringing together people and experts from different artistic and scientific fields to cooperate and be part of this educational process.

The site is chosen because it is characterized by three key points that are used strategically for the integration of the complex in the urban life. Primarily, it is located next to the Center of Traditional Crafts near the historical center and the old neighborhood "Siarava", where the tanneries of the city were located until the 20th century, preserving the character of the city as “a vast workshop”. Secondly, it serves as an interface between the city center and the lake, because of its location and scale, thus creating an urban passage that can be transformed into a designed experiential place. Additionally, its close proximity to the city center facilitates the establishment of links between the functions of the complex and the local professionals, not just the visitors. Finally, constituting another episode of the lakefront the complex can function as an urban apparatus that enhances the municipality’s urban planning vision for the expansion of the lakeside route and the connection of more urban areas with a promenade by the lake.

In conclusion, the proposal addresses an issue of a supralocal nature by scaling it down to the local, attempting to cultivate the conditions for a more sustainable management of the fashion derivatives by engaging and integrating the local community both socially and commercially.

Extended abstract

Nature-based solutions (NBS) are perceived as key for many sustainability challenges in cities such as climate change adaptation and mitigation strategies. However, the preconditions and advancements on implementation for green NBS in cities vary among European countries. One factor influencing the uptake of green infrastructure in urban settings is acceptance by citizens. Previous research has explored the acceptance of NBS in particular cities or countries, yet so far, the literature comparing differences between countries and influences of urban environments on preference for NBS remains scarce.

Therefore, this paper investigates the different patterns of acceptance for urban NBS in two European countries. The study was conducted within the Horizon 2020 project UPSURGE funded by the European Union, which aims to enable the uptake of NBS for the mitigation of air pollution and climate change. UPSURGE focuses on generating guidance for the implementation of NBS in European cities. In this context the present study surveyed the socio-economic background and built environment in cities in Greece and the Netherlands. Additionally, preferences for NBS were tested via the application of a discrete choice experiment (DCE). In particular acceptance of different types of NBS and forms of benefits such as temperature reduction, participation and additional costs were explored in the DCE. Next to an analysis of the utilities derived by the features of NBS, we studied whether there are latent classes in each of the countries from which varying preference for NBS can be identified.

The results indicate that citizens show similar preferences for the type of NBS and the aspects of NBS such as temperature reduction and accessibility in Greece and the Netherlands. However, the comparison of the latent classes of the two countries reveals that there are diverging drivers for the acceptance of NBS in the two countries. While in Greece preference for NBS between the different latent classes is distinguished by spatial characteristics, the latent class segmentation in the Netherlands is rather linked to values and attitudes. Furthermore, in the Netherlands the utilities derived from green infrastructure are less prominent when compared to Greece due to differences in exposure to climate change and the felt and experienced effects. As a result, it must be recognized that the relevance and functions of NBS will vary among European countries, due to aspects such as climate change affectedness and characteristics of the built environment. The results also offer practical implications for securing the success of NBS within different neighborhoods and population segments.

Sustainable Urban Development Policies in Greece. The perceptions of Citizens

A. Liaskopoulou^{1*}, I. Papadopoulos¹

¹ Department of Forestry, Wood Sciences & Design – University of Thessaly, Greece

*Corresponding author: E-mail: aliaskop@uth.gr, Tel +30 697 6579470

Abstract

The purpose of this research is to investigate the perception of Greek citizens regarding Green Growth and in particular to the research questions: a) whether Green Growth can lead to a more environmentally and friendly entrepreneurship, b) whether the financing for the transition towards Green Growth either from the European Union or from national resources is sufficient, c) if personal responsibility plays a role in the creation of sustainable consumption and production models, d) if there is an intention of Greek citizens' active participation to protect the environment and e) what are the most important policies that will lead Greece to a Green Growth.

The profile of the participants in this survey was 378 citizens from different regions of Greece and it was conducted in 2023. The statistical processing of the data was carried out using IBM SPSS ver. 26. We analysed them using the tools of descriptive statistic, crosstabulation, calculation of demographic means and frequencies, and non-parametric Kruskal-Wallis tests for independent samples.

The results of the survey showed that Greek citizens believe in a large percentage that "Green Growth" in Greece and the turn to a more environmentally and friendly entrepreneurship seems to be a realisable aim. From them the women are more optimistic about the issue, in relation to men. The financing of the green growth from EU is considered as moderate. About this thematic the younger people are more hesitant than older people. Majority of Greek citizens consider as very important the role of personal responsibility in society's transition to sustainable models of consumption and production, with women having a statistically more positive opinion than men. A significant portion of Greek citizens declare their intention to active participation for the protection of the environment, which may also be a challenge for the Greek state to take measures in order to promote the importance of the environment and to provide incentives for the active participation of Greek citizens. Using the non-parametric Kruskal-Wallis statistical test, the statistical analysis showed that there is no statistically significant difference for the participation of citizens in environmental actions in relation to their age. Finally, energy saving actions and taxation of polluting business activities are considered very important for the promotion of the Green Growth.

This research contributes to the national and international debate on the green and just transition of European economies based on citizens' needs and challenges emerging at national level.

Keywords: *Green Growth, Green Innovation, Green Entrepreneurship, Financing, Personal Responsibility of Citizens.*

1. INTRODUCTION

In scientific research, the concepts of sustainable development have become highly relevant to policies related to environmental management and there is an evolving discussion about the concept of sustainability that introduces a new way of understanding the society-nature relationship [1].

According to [2] *“climate change and environmental degradation are a threat for the existence of the European Union and for all the World. To address these threats, the European Green Deal is Europe's new growth strategy, which will transform the E.U into a modern, resource-efficient, and competitive economy. The European Green Deal aims to make Europe climate neutral by 2050, boosts the economy through green technology, creates sustainable industry and sustainable transport and reduces pollution”*. It is worth noting that the European Green Agreement is financed with 1.8 trillion. euros both from the Next Generation EU recovery plan and from the EU budget.

According to the Global Green Growth Institute, green growth is defined as *“the approach that seeks to deliver an environmental and economical sustainable and inclusive society. It thus seeks opportunities for economic growth with low carbon emissions and low climate impact, prevents or remediates pollution, keeps ecosystems healthy and productive, and leads to the creation of green jobs as well as poverty reduction and enhanced social inclusion”* [3].

In the context of the Green Growth Index [4], which the Global Green Growth Institute [5] published first time in 2019, the protection of natural capital is one of the four important dimensions of green growth [6]. It links with the efficient and sustainable use of resources, green economic opportunities and social inclusion [7].

In addition, natural capital [8], is a core to green growth because of its role in creating new sources of growth and expanding economic opportunities in the form of green investment and jobs, among the others [9]. But green growth also emphasizes the role of people, so social inclusion becomes a key mechanism for people not only to contribute, maintain and distribute economic benefits, but also to protect the sources of that growth, i.e. natural capital.

Cities and regions have emerged as catalysts for green growth around the world: organizations such as C40 Cities are bringing together mayors from around the world to commit to a Global Green New Deal [10]. Of all the international actors, Europe was most firmly on the path to a green and digital transition before COVID-19, and now looks poised to lead the way with the "greenest recovery in the world", through continued support for Green Deal across the continent. It mobilizes around the goal of being carbon neutral by 2050, incorporating a just transition mechanism to support the phasing out of fossil fuel industries and a green industrial strategy, which is seen as a 'compass' and an 'engine' for recovery [11].

2 LITERATURE REVIEW

Research on the achievement of the United Nations Sustainable Development Goals (SDGs) [12] has shown that developed countries benefit more by focusing on social and environmental factors.

According to research [13] the adoption of a holistic planning process and sustainable urban development creates a possibility to further support the progress towards achieving the sustainability agenda of cities.

Researchers report that Sustainable Urban Development can be implemented through an integrated analysis of different modes of governance [14].

Governments have a wide variety of tools in their arsenal to redirect economic activity towards a green transition and must adopt an approach involving the range of financial and non-financial levers as a fiscal stimulus [15].

There is the recommendation for a shift to a new form of economic theory that is more environmentally friendly: a) the creation of ambitious green public investment packages to revitalize the global economy in the required direction and b) the formation of innovation systems by financing

economically and socially weaker teams, and c) cross-sector partnerships for green innovation and ambitious missions to accelerate climate solutions [16].

The concept of green entrepreneurship [17] is in its infancy at the moment, but is moving towards the maturity phase, while environmental sustainability and entrepreneurship focus on the production of green goods. However, this research concludes that the impact of the green market on Sustainable Development and Green Entrepreneurship has not yet been explored in depth.

According to the Neumann [18], the effect of green entrepreneurship on sustainable development, showed that higher levels of green entrepreneurship are positively related to economic and social development but not to environmental development. And it concludes that the recognized economic and social importance of green entrepreneurship warrants intensified with the policy efforts to support the discovery, creation and exploitation of green business opportunities.

The governments in recent years, increasingly, seek to become more active in pursuing environmental initiatives for the success of sustainable development. In this effort, models are being developed that focus on cooperation between local governments, residents and organizations [19]. After all, a sustainable development strategy can serve as a tool of management and political control. To develop and implement such a strategy at the local level, municipalities may use citizen participation approaches. In their article Meschede and Mainka [20], developing a model of citizen participation's approaches during different phases of adopting a sustainable development strategy in German. The results show that most municipalities count on citizens' participation mainly in the implementation phase of the strategy and less during its development.

Regarding the personal responsibility of citizens to achieve sustainable development, Tkáčová et al [21], emphasize the necessity of a balance between human needs and the carrying capacity of these needs in the context of sustainable development through interdisciplinary higher education curricula in Slovakia. In this the individual tasks of sustainable human behavior and individual responsibility analyzed from the perspective of university students regarding the roles and individual responsibilities that exist for sustainable development.

In Greece, research [22] showed that urbanization quality indicators have a positive effect on sustainable development goals. It has also been shown that there is a significant relationship between integrated land use strategies and sustainable development goals, while some general recommendations are formulated regarding sustainable urban development and the importance of creating the necessary conditions for its implementation, through significant changes in all social levels.

3. THE RESEARCH OBJECTIVE

The main purpose of this research is to investigate the perception of Greek citizens regarding to the Green Growth. Other objectives of the research are to investigate: a) whether green growth can lead to a more environmental friendly entrepreneurship, b) whether the funding for the transition to green growth, either from the European Union or from national resources, is sufficient, c) whether personal responsibility plays a role in the creation of sustainable consumption and production models, d) whether there is an intention of active participation of Greek citizens in protection the environment and e) what are the most important policies that will lead Greece to a green growth.

Based on the literature review and the objectives of the research, the following research hypothesis are investigated:

1. $H_{1.1}$: Green Growth leads to a more environmentally friendly entrepreneurship.
2. $H_{1.0}$: Green Growth doesn't lead to a more environmentally friendly entrepreneurship.
3. $H_{2.1}$: The personal responsibility of women in the transition of society to sustainable models of consumption and production is considered more important than that of men.
4. $H_{2.0}$: There is no significant difference between the man's and woman's responsibility regarding the transition of society to sustainable models of consumption and production.

5. H_{3.1}: Younger citizens do not plan to take part in actions for the environment.
6. H_{3.0}: Younger citizens plan to take part in actions for the environment.

4. METHODOLOGY

Considering the objectives, the questionnaire was chosen as an appropriate methodological tool, which is mainly used in "field or overview research", which includes the present research. Regarding the approach to citizens, the basic principles of ethics, anonymity and voluntary participation were fully respected [23].

The size of the research sample amounted to 378 Greek citizens from all over the country. The distribution of the questionnaires took place in the period of November 2023- February 2024. The questions were formulated through the Google Form template and the link sent either via email or via social media (Facebook, Messenger, Viber). Before conducting the main survey, a pilot survey was conducted on 10 citizen respondents to ascertain the clarity and understanding of the questions.

The main statistical analyzes to calculate the results were done using SPSS ver. 26. Also we use the Cronbach Alpha reliability coefficient (estimated at 0.92), which shows the reliability of the responses according to Siomkos and Vasilikopoulou [24], the descriptive statistical analysis, the crosstabulation analysis, the calculation of the means and frequencies of the demographic data as well as the non-parametric Kruskal-Wallis tests for independent samples, as the sample did not follow a normal distribution, after applying the Kolmogorov-Smirnov test ($p < 0.05$).

Finally, regarding the demographic characteristics of the participants in this research, were found: In terms of gender, a total of 143 men (37.8% of the participants) and 235 women (62.2% of the total sample of participants) participated. Regarding age, the majority of participants i.e. 43.4% belonged to the age group of 18-25 years. The 26-35 age group comprised 9.8% of the total sample, while the 36-45 age group comprised 12.7% of the participants. A large number of participants (30.7%) also belonged to the 46-60 age group. Finally, 3.4% of the participants belonged to the over 60 group. Regarding the educational level, the majority of the participants, a total of 42.6% were university graduates, while 28% of the total sample held a Master's degree. High school graduates also took part in the survey, with a percentage of 17.5%, while 9.3% of the participants were PhD holders. Regarding occupation, 44.4% of the sample were students and 37.8% worked as civil servants. Private employees (7.1%), freelancers (6.1%), unemployed (2.6%) and retired (1.9%) also participated in the survey, of which the majority (60.3%) said residents of a city with 50,000 inhabitants. 18.8% live in a city of over 50,000, while only 8.7% live in a village, 6.6% in a town and 5.6% on an island.

5. RESULTS

Green Growth in Greece and the turn to a more environmentally friendly entrepreneurship seems to be an achievable goal, as 59.7% of the citizens answered surveyed estimate that this can be achieved to a large to very large extent. So, research H_{1.1} is confirmed that "Green Growth", according the citizens can lead to a more environmentally friendly entrepreneurship.

The correlation analysis (crosstabulation) showed that there is a statistically significant correlation between green growth as a realizable goal and the gender of the respondents ($X^2=19.996$ for $\alpha < 0.001$), i.e. women are more optimistic about this issue than men (Fig. 1).

Figure 1. Will the Green Development contribute to the promote of more environmentally friendly entrepreneurship in relation to the gender of the survey respondents?

One of the main issues for the implementation of green development in Greece is the adequate funding from the EU. The survey showed that 44.4% of respondents believe that it will be moderate, 25.4% that it will be insufficient and 30.2% that will be sufficient. In other words, hesitancy appears, but also moderate optimism on the issue of financing.

The correlation analysis (crosstabulation) showed that there is a statistically significant correlation between the adequate financing of green development by the EU. and the age classes of the respondents ($X^2=27.087$ for $\alpha<0.05$), i.e. the younger people are more hesitant than the older ones on the issue of adequate financing of green development by the EU.

In parallel with the financing of green growth by the E.U., 68.6% of Greek citizens believe that national funds will be mostly required for this purpose. The older Greek citizens (84.6% for over 60 years) who have more experience in their lives believe that national funds will also be required to finance green growth.

Quite interesting is the opinion of Greek citizens about the important role of their personal responsibility in society's transition to sustainable models of consumption and production, as 86.5% of them consider it as very important. Only 5.3% of them consider it little or not at all important. In fact, women consider it very important at a rate of 64.7% and in fact there is a statistically significant correlation between the role played by the personal responsibility of citizens in the transition of society to sustainable models of consumption and production and the gender of the respondents ($X^2=27.200$ for $\alpha<0.001$), with women having a more positive opinion than men (Table 1). Therefore, the hypothesis $H_{2.0}$ is confirmed, that the personal responsibility of women in the transition of society to sustainable models of consumption and production is considered more important than that of men. It is also worth mentioning that 47.9% of the participants in the survey of Greek citizens consider that the actions for the protection of the environment have a great influence on the decisions of international organizations such as the UN, OECD, etc., with men being more cautious.

Particularly interesting seems to be the intention of Greek citizens to active participation for protection the environment, this is expressed to a relatively moderate degree (25.9%), but it is worth noting that 38.4% of them wants to do that and (Figure 2) , and this is encouraged factor. Perhaps this result can also be a challenge for the Greek state to take measures to promote the importance of the environment and provide incentives for the active participation of Greek citizens.

The data were then analyzed using the non-parametric Kruskal-Wallis statistical test for more than two independent samples, because the sample did not follow a normal distribution, after applying the Kolmogorov-Smirnov test ($p<0.05$). The statistical analysis showed that there was no statistically significant difference in means of planning citizens' participation in environmental protection actions between ages, $H(4)=5.291$, $p= 0.259>0.05$.

Proceedings

Based on the above, it is verified the Research H_{3.0}, according the third question that there is no statistically significant difference for the participation of citizens in actions for the environment in relation to their age. Thus, younger citizens do not plan more than older ones to take part in actions for the environment.

Table 1. Crosstabulation of the sex to the role of personal responsibility in society's transition to sustainable consumption and production models

			Sex		Total	
			Male	Female		
How much important is the personal responsibility in society's transition to sustainable consumption and production models?	Not at all	Count	4	0	4	
		Expected Count	1.5	2.5	4,0	
	A little	Count	12	4	16	
		Expected Count	6.1	9.9	16,0

Figure 2. Intention of Greek citizens to actively participate in actions for the protection of the environment

Proceedings

Finally, during the investigation of citizens' views on Green Growth, it was examined how important they consider certain factors as policies to promote. According to the statistical analysis, very important policies for the promotion of Green Growth (Table 2) considered energy saving actions (M=4.38) and the taxation of polluting business activities (M=4.15).

Table 2. Suggested Policies for Green Development (*Likert scale: 1-5; 5= extremely important*)

Policies for Green Development	Means	(1) Unimportant	(2) Somewhat important	(3) Quite important	(4) Very important	(5) Extremely important	(5)+(4)
Energy saving actions	4,38	0,8	2,9	8,2	54,5	33,6	88,1
Taxation of polluting business activities	4,15	3,2	6,1	13,5	50,3	27,0	77,3

6. CONCLUSION

From the results of the research, we can conclude that Greek citizens believe in a large percentage in achieving sustainable development and that "Green Growth" in a developed country like Greece can lead to a more environmentally friendly entrepreneurship, focusing on social and environmental factors, as also investigated [12]. Therefore, this can be a valuable tool in a holistic State planning to support progress towards achieving the urban sustainability agenda [13],[14]. After all, the concept of green entrepreneurship in Greece is currently in its infancy and has not been investigated in depth [17], so this research gives even more value, as environmental sustainability and entrepreneurship focus on the production of green goods. Additionally, through this research it appears that the economic and social importance of green entrepreneurship justifies intensified policy efforts to support the discovery, creation and exploitation of green business opportunities, as Neumann [18] also argues.

In the effort to implement green growth, it is deemed necessary to finance it from the European Union, as well as the national resources of Greece. After all, according to the European Commission [2] it is a priority for the European Green Agreement which is financed with 1.8 trillion. euros both from the Next Generation EU recovery plan and from the EU budget. Although it appears that the younger Greek citizens are more hesitant than the older ones regarding the adequate financing of green development with EU funds.

The fact that the vast majority of Greek citizens consider very important the role of their personal responsibility in society's transition to sustainable models of consumption and production, with women having a statistically more positive opinion than men, should to develop the study programs in both higher and secondary education, regarding the sustainable development of cities and the wider regions of Greece, in order to strengthen the knowledge about green sustainable development through experiences and at the same time to analyze the individual tasks of sustainable human behavior and individual responsibility [21].

As a significant portion of Greek citizens declare through this survey their intention to actively participate in actions for the protection of the environment, it is proposed that the Greek State develop an appropriate strategy with a modern model that focuses on cooperation between Ministries, Regions, Municipalities, their residents, but a support network organization, for the active participation of citizens in environmental actions, similar to what has emerged from research [19] in Germany. After all, as the same research notes, "most municipalities count on citizens' participation mainly in the implementation phase of the strategy and less during its development".

Finally, it is proposed that the Greek State develop special indicators of quality of life resulting from green sustainable development through the creation of the necessary conditions and structural changes at all social levels, as Kalfas et al [22] mention in their research.

Limitations of the research could be mentioned both in terms of the larger sample size and the conceptual content of the research, since the concept of green development, while it is well known, nevertheless does not seem to have been easily understood in the present research, the social and its economic dimension. After all, until now there are no clear support programs and financial tools for both businesses and citizens. Therefore, any answers were given according to the ideological and general life attitude of the respondents.

In a further research, entrepreneurship and green professions could be linked with citizens' knowledge and their connection with green development in all three of its main pillars.

Abstract

In contemporary society, the term ecological degradation refers to the alteration of territories by anthropogenic activities and at the same time to the awareness of the exhaustion of the natural resources that sustain the survival of humanity. The practices of modernity, addressing the environmental issue, are inspired by the narrative of harmonious nature and explore the changes in the planetary landscape with a focus on their impact on humans, ignoring the transformations of more-than-human landscapes. Architectural proposals, as material registrations of the contemporary way of living, are oriented towards the creation of bounded inert landscapes, whose development depends solely on the adequate control of their conditions by the human factor and socio-economic considerations

The current study examines contemporary ecological theories interwoven with new-materialism approaches to the social question and the human-non-human interaction, in an attempt to highlight the multiplicity of the ecological degradation phenomenon. At the same time, the field of architecture will be explored by examining qualities inherent in the narrative of the Anthropocene Era.

The first section analyses key points of contemporary ecology, which raise questions about the multiplicity of entities and their interrelationships in the geological present. Focusing on the work of the French philosopher Bruno Latour, we will examine narratives of the mythological existence of nature, highlight correlations between artificial and natural environments, and analyse the term society-social, questioning both the primacy of the term man and the term nature.

The second section focuses on the role of architecture in our geological present. International design practices and strategies that include both biotic and abiotic systems will be explored, revealing the multiplicity of each landscape. In contrast to organized boundary design, the proposals that will be presented are oriented towards composing conditions and highlighting the interrelationships between the entities that make up dynamic shifting landscapes of coexistence.

Keywords: *ecological degradation; new-materialism; Anthropocene; Bruno Latour; dynamic shifting landscapes*

1. INTRODUCTION

The first section explores contemporary philosophical considerations intertwined with social and territorial approaches, aiming at highlighting the complexity of the ecological issue and exploring the interrelationships between entities in the geological present. By studying the history of human habitation of the earth, practices of modern societies are analysed as expressions of modernity's perceptions of the nature-culture scheme and human-non-human relations. This path seeks to identify and redefine the agents that intensify ecological degradation, inspiring a narrative of the earth beyond human exceptionalism, oriented towards the development of ecological practice and the emergence of new ways of inhabiting Earth and alterity.

1.1 ECOSOPHY THEORY, THE THREE ECOLOGIES | F. GUATTARI

The French philosopher and psychoanalyst Felix Guattari in his book *The Three Ecologies* describes the modern age as a field where fundamental categories of society are being degraded. He observes that the practices of capitalist society are evolving into an ideology of unlimited competition and introduces the term Integrated World Capitalism or IWC to describe the factor that influences the domains of production which contribute to the framing of subjectivity. The perceptions and necessities resulting from subjectivities are shaped by the forces of a global market, which makes Integrated World Capitalism a catalytic factor in ecological degradation and capable of widening the gap between human and environment.

The urgent need to rehabilitate and save the degraded natural landscape often focuses human praxis on a one-dimensional study of environmental instability. Guattari attempts to highlight the complexity of the ecological question by developing the concept of Ecosophy. In contrast to the considerations of Deep Ecology, Guattari's Ecosophy constitutes the set of interactions between three fundamental categories: human subjectivity, society and environment. These categories are related to the Three Ecologies: mental, social and environmental.

Mental ecology is oriented to the correlation between subject and individual, rethinking the agents that influence their interaction, calling for the creation of autonomous subjectivities that evolve affectively by eliminating the extensive influence of the agents of Integrated World Capitalism.

Social ecology refers to the primordial subjectivity which must be reorganized through the affective interrelation of social coordinates.

Environmental ecology describes the ecosystem as the domain where social interactions take place, and refers to the productive interrelationships between them. Environmental ecology encompasses the set of entities and actors that shape the landscape, articulating an aesthetico-political narrative of the environment, contrasting with the advocacy of the ideal figure of nature as observed in Deep Ecology.

Ecosophy is an ethico-political partnership of the three ecologies, concerning the understanding of existence as part of the environment. By presenting the redefinition of fundamental units, it reveals the interrelationships that we, as conscious environmental beings, need to understand in order to decelerate the rates of ecological degradation. In other words, Ecosophy refers to the interrelationships of constantly shifting entities, such as subjectivity and society, that contribute to the development of "an environment in the process of reinvention."

1.2 THE ECOLOGICAL CONDITION FOLLOWING INDUSTRIALISATION, INTRODUCTION TO THE ANTHROPOCENE

The Modernism era, which is a crucial point of reference for post-war considerations, expressed the 'purity' of the image of nature free from man-made interventions, creating a narrative of human exceptionalism. Contemporary ecological theories interpret geological developments as inextricably linked to the individual and collective practices of society. The study of geological history is oriented towards the inclusion of the acting entities of the planetary landscape and examines the multiplicity of interrelationships between them.

In the post-industrial period (after the 19th century) geological changes are characterised by a Great Acceleration, as the needs of human habitation expand. Mass production and the redefinition of the energy economy, as a discharge for the needs of overpopulation and economic competition, contributed to the transformation in sectors of production. Anthropogenic ecosystems spread rapidly and invaded the territories of wildlife, leading the scientific community to describe the last two centuries as the period of the Sixth Mass Extinction of Species.

The phenomenon of global climate change has stimulated the development of a public debate, initially structured by the natural sciences, but at the same time provoking a more interdisciplinary

examination of ecological issues. The work of the Danish chemist Paul J. Crutzen became a focal point for subsequent ecological approaches. Crutzen studied anthropogenic activities and became aware of their ability to alter the chemical equilibrium of the environment and, by extension, the geological processes. His research interest is oriented towards reading human history as a chronology of chemical correlations and changes. In 2000 he introduces the term Anthropocene Epoch to describe a turning point in the identification of geological and human history. In Anthropocene studies, the term environment is understood as a synergy of subjectivities, natural and artificial structures as the ability of human agency to influence geological change is identified.

The main issue in Anthropocene theory lies in the generalised rendering of the human term, as the term presents a homogeneous human impact, unable to include the social inequalities of contemporary reality. The American philosopher Donna Haraway suggests that the term Anthropocene needs to be transformed, introducing the alternative narratives Capitalocene, Phytocene and Chthulucene.

In the Capitalocene, the role of the geological factor is attributed to the antagonism nurtured by capitalism and the anthropogenic practices encouraged thereby. The term Phytogeocene describes the process of forced labour, slavery, colonialism, and racism, through the placement and movement of plants, human animals and microbes, which formed modernity and capitalism by constituting the industrial revolution.

Anthropocene-related considerations are a springboard for the redefinition of the natural and social sciences, while at the same time intertwining with compositional practice and architectural approaches. The Finnish thinker Jussi Parikka refers to the term global systems, which are ethico-political partnerships of human history that develop through intersecting transformations and incorporate the discharges of anthropogenic practices.

In Parikka's descriptions, the evolution of architecture is a material narrative of man's interaction with the land in the consecutive shifts of history. In the attempt to redefine the limits set by global systems, a demand is made for a reconfiguration of architectural thinking, which is called upon to invent new practices that will reverse the depletion of land resources and create conditions for coexistence by enhancing biodiversity in the planetary landscape.

1.3 EARTH AS A LIVING ORGANISM | B. LATOUR, J. LOVELOCK

Modernity narrative, interwoven with the reflections of Deep Ecology, conveys the image of a self-sufficient nature, an inexhaustible landscape capable of covering the needs of human habitation in eternity. The earth is presented as a vast inorganic machine whose underfunctioning is due solely to man's insufficient control of it. As the French philosopher Bruno Latour argues, the antagonism fostered by globalised capitalism opposes the earth to the economy, with the result of considering the discharges of the climate crisis exclusively in terms of their impact on humans, without regard to the energies of the earth and non-humans.

Latour opposes Galileo's view of homogeneity in the solar system as he observes the differences between the Earth and the other celestial bodies in terms of their equilibrium conditions. Latour's observations coincide with the work of British thinker James Lovelock, whose focus is on understanding the Earth as a living organism, embodying all the entities associated with the terrestrial world and the interactions between them in the critical zone between the earth crust and the atmosphere. Lovelock introduces in 1960, in collaboration with the American biologist Lynn Margulis, the Gaia hypothesis, which describes the earth "as a self-regulating and living body composed of microorganisms, bacteria and chemicals". In contrast to Galileo's inert earth "in motion", Gaia is active, reacting and transmuted by the biotic and abiotic forces developing in its soils.

Lovelock's Gaia refutes anthropocentric readings of harmony in nature. In his study, each entity can be transformed into an agent of geological transformations, as the organisms that are part of Gaia do not adapt to an environment, as in the Darwinian view, but instead shape the surrounding territories

in search of the most favourable conditions for their development. The constant modifications of neighbouring entities make it impossible to separate the action of the organism from the environment before the influence of that action.

The typical understanding of the study of "nature" through the one-dimensional reading of its layers does not apply to Gaia. Nothing is considered inert or external. Space in Gaia is a derivative of time, shaped by the interaction of life and climate, "the space in which we live, that of the critical zone, is the same space towards which we congregate; it extends as far as we do; it lasts as long as the entities that make us breathe". Gaia theory therefore invites us to recognize the influences of acting entities on the planetary landscape, regardless of the scale they occupy. Latour describes the phenomena of reciprocal boundary transgressions between neighbouring entities as "waves of action" and argues that these overlaps between them constitute the real actors as they constitute the conditions regulated by the necessity of habitation of living entities. The waves of action reflect the energies of Gaia in the continuity of the geological epochs, turning her narrative into a grounded study of life that calls for new modes of habitation directed towards the Earth.

1.4 NEW WAYS OF INHABITING EARTH, THE CONCEPT OF "EARTHING" | B. LATOUR

Latour also introduces the term New Climatic Regime to describe the modern era, in which the survival of the human species is based on its relationship with the Earth. The waves of action generated by social actors bring about changes in the geological continuum and create contradictions in the relationship between humans and the Earth. The changes caused by globalisation in the sectors of production and subjectivities have led to the broadening of inequalities and the distancing of people from the Earth. Latour examines socio-political developments by considering the study of poles of attraction, a term he inserted to describe "the vectors along which the various political actors are positioned". He refers to the Local and the Global as the dominant poles of attraction that influence social developments and, by extension, the trajectory of geological history.

The Global constitutes the basic instrument of globalisation as it embodies the narrative of an ever-expanding progress that presupposes the abolition of local qualities, in order for a new global culture to emerge.

Latour understands globalization as a mixture of two contradictory elements, globalization-plus and globalization-minus. The first term describes progress as a form of expansion of mental and territorial boundaries, the transition from a local to a global perspective that contributes to the emergence of complexity, characterizing the coexistence of entities with the earth. On the contrary, the realisation of globalisation created the narrative of a shared vision, but expressed by a small part of the total population of the earth, with the result that the global became "a robust local vision"

Globalisation has contributed to widening the gap between the local and the global and at the same time eliminated the common ground created by the claims of modernisation. The finite quantity of natural resources and detachment from the land, combined with the inconsistency of attractions, led to the disorientation and inertia of society. These conditions contributed to the emergence of a new pole of attraction, which Latour calls the Out-of-this-world. The third attractor does not recognize the material limitations and territorial barriers of nature and sees the planet as an endless landscape of natural resource deposits. People who embrace the prescriptions of the Outworld claim that they do not inhabit the Earth of climate crisis, and in this light fail to recognize the impact of their actions in disrupting the ecological balance, while developing a narrative of escaping the Earth and seeking alternative forms of habitation on other planets. For Latour, the third attractor is the main factor that contributes to the reinforcement of phenomena of localism, as the concept of coexistence on a common planet is abandoned and, at the same time, to the increase in migratory flows due to the limitation of habitable lands and the extensive widening of inequalities.

The ecological movements, in their attempt to react to the forces of globalisation, intensified the dichotomy of modernisation - ecologize, or in other words modernity - anachronism. According to Latour, the resolution of the ecological question presupposes the creation of a common world, a place that is not defined by the contradictory relationship between the Local and the Global and the actions of geopolitics. In examining the necessity of redefining the social spectrum, he refers to finding a fourth pole of attraction, which he places opposite the Out-of-this-World. The new attractor, in contrast to the narrative of escape from the Earth, is directed towards it, calling for new ways of re-inhabiting territories, expressing the need for society to "land on Earth" , what Latour calls the Terrestrial.

Latour embodies in Terrestrial a philosophical context for inhabiting the critical landscape of the Anthropocene. The political expression of returning to the land fails to be situated within the existing political system, raising questions about the necessity of redefining political actors and abolishing the Left-Right and Local-World dichotomies. The boundaries set by the notion of society are extended to include more-than-human entities whose interactions are characterised as social actors. The Terrestrial Attractor, in contrast to modernity, approaches the definition of progress as the ability to recognize the multiplicity that characterizes the planetary landscape and the effort to preserve diversity.

The redefinition of the nature image in the Gaia narrative, combined with the dissolution of the boundaries imposed by the Earth, are proposals for inhabiting the landscape of the climate crisis, while at the same time attempting to reshape the fields of earth sciences and architectural thought. Fundamental architectural considerations are subject to redefinition in the New Climate Regime, in the attempt to free the compositional process from the influences of the Local and the Global. Architectural form is released from the norms of the past, and creates a ground for the development of alternative narratives that aim to problematize society by highlighting the complexity of critical issues.

2. COMPOSING LANDSCAPES OF CO-EXISTENCE

The second section is concerned with the explanation of applied architectural examples in the light of the above-mentioned philosophical baggage. Through the work of Gilles Clement, James Corner, Anhuradha Mathur & Dillip Da Cunha, correlations between ecological and compositional practice are attempted, aiming to create new territories for understanding, thinking and analysing spatial experience.

2.1 THE LANDS OF BIODIVERSITY | GILLES CLEMENT

Gilles Clement's work is oriented towards highlighting and enhancing the diversity of a landscape, recognising the immaterial and material forces exerted on it. He rejects planning that favours the development of singular species in the landscape as this discourages the development of new forms of life. Diversity refers not only to the coexistence of different species, but also to the difference in interactions between similar entities.

Third Landscape theory refers to territories located in the intermediate space between natural and urban landscapes, in which the dominant actors are non-human entities, providing narratives of autonomous entities from which human agency is absent. These landscapes develop intense biodiversity as their evolution is not constrained by the homogenizing practices of modernity and the antagonism fostered by capitalism.

In defining the autopoietic ability of the Third Landscape, Clement does not attempt to remove anthropogenic practices from his study. The lands of the Third Landscape are material records of the Anthropocene epoch, and refer to the intermediate of the human-non-human relationship. The complexity and biodiversity found in these lands are based on the overlapping interrelationships of

the entities that inhabit them, through which the conditions for the development of a shifting landscape in constant reshaping are created.

The Garden of the Third Landscape is located in the Saint Nazaire region of France, an area with a history of maritime transport. In 1940, German troops occupied the town and built the submarine base in the port of Saint-Nazaire, an oversized building made of concrete that lost part of its roof as a consequence of the bombing of the area.

The Third Landscape Garden is a system of three smaller gardens, the Garden of Labels, the Garden of Aspen Trees and the Garden of Stone and Grasses. These gardens survive on the dry concrete roof without extensive technical maintenance.

The gardens Clement designs are places of unpredictability, where visitors encounter the rhythm and mobility of nature: the seasonal changes of flowering and the process by which leading species are gradually replaced, ensuring that the profile of the garden is constantly transformed.

These territories embody the heterogeneities that inhabit urban landscapes and constitute fields for redefining the complexity that characterizes the coexistence of entities with the land. Clement envisions a network of acting entities, a form of society in which human influence is limited, creating the conditions for the development of an autopoietic shifting landscape. The diversity presented by the Garden contrasts with the homogeneity of its metropolitan landscape of installation, raising questions about the redefinition of the entrenched practices of modernity and their influence in limiting the evolution of species.

2.2 DESIGNING "SPONGES" IN COASTAL LANDSCAPES | JAMES CORNER- FIELD OPERATIONS

The architect James Corner conceives of nature as a whole composed of the practices of evolution and habitation of heterogeneous entities. His work is part of landscape urbanism through which he critiques the distinction between natural and artificial environments, as he identifies the homogeneity that characterizes cultural and natural landscapes in an era of accelerating geological change.

His studies are characterized by the integration of multiple disciplines and media of representation that contribute to the development of a multifaceted design approach. The mobility presented by a landscape is expressed by Corner's mappings, which transform the compositional practice into a process of discovering the complexity that characterizes the architectural intervention.

In Corner's design practice, the principles of contemporary ecology can be found, which are transformed into urban qualities. The term urbanity now includes the intangible and material relations that constitute an ecosystem, reinforcing the view of the non-separability of artificial and natural environments.

Proceedings

Corner's architectural work refers to interventions related to the Terra Fluxus model, a term that characterizes interventions and landscapes that are assimilated by the environments they are applied to rather than imposed on them. In contrast to the Terra Firma narrative, which refers to fixed and immutable constructions, Terra Fluxus is a condition in which the architectural proposal seeks to create a landscape in constant redefinition, a sympoietic process in progress rather than a final form. The South Bay Sponge project is located in San Francisco Bay, California. The South Bay is composed of several cities sited on the shoreline with near-zero altitude, vulnerable to upcoming sea level rise. East Palo Alto, one of the South Bay cities, is the lowest altitude community and is selected as the planning springboard for Field Operations because of its vulnerable nature. Flooding is the primary problem of East Palo Alto and neighboring cities, resulting from rising sea levels and the alteration of the natural drainage system provided by the area's creeks. In addition, the area has a shortage of usable land and at the same time, a misdistribution of embankments along the shorelines. Field Operations decided that their work should be a form of collaborative planning, aiming to achieve new forms of cooperation at the social and political level. By organising meetings and discussions with the residents of the Bay on the design and qualities of the proposal, they attempted to establish a shared ecological thinking and practice, a way of inhabiting this peculiar landscape. Identifying the wetlands and salt marshes element, the team starts by proposing a soil swap. Through this 'swapping', the protection of the coast is achieved while at the same time creating areas of suitable altitude for the installation of new infrastructure related to transport, commerce, housing and recreation.

Complementing this background is the strategy of land use exchange. The character of this strategy is twofold. The first objective is to decongest low-lying areas in order to create the space needed for proper flood management in the area. At the same time, a practice of densifying building in appropriate areas is applied to encourage dense and mixed-use development.

The sponge landscapes that complement the coastline are large-scale green infrastructures that present a range of ecological conditions, lakes, marshes and even large green spaces that concentrate residential and recreational uses in combination with existing housing estates. The 'sponges' help to maintain sea levels, while at the same time forming areas for controlling water pollution and hosting rainwater harvesting 'reservoirs'.

Observing the prevailing conditions of the streams in the area, it is proposed to widen them at points to enhance their drainage capacity and slow down the velocity of the flood waters. At the same time, the micro-delta created by their outlets in the bay will be redesigned to create areas of high biodiversity.

South Bay Sponge, by combining the factors that constitute the immaterial and material forces of the landscape, creates conditions, soils that favour the interaction between the elements that make up the landscape. The buffering design that Field Operations employs enables the landscape to change over time and maintain its ecological balance. Sponge's methods of design and dissemination of the Sponge idea, through talks, ongoing public outreach and collective planning, reflect the way of coexistence envisioned by James Corner in the societies where the ecological condition is established.

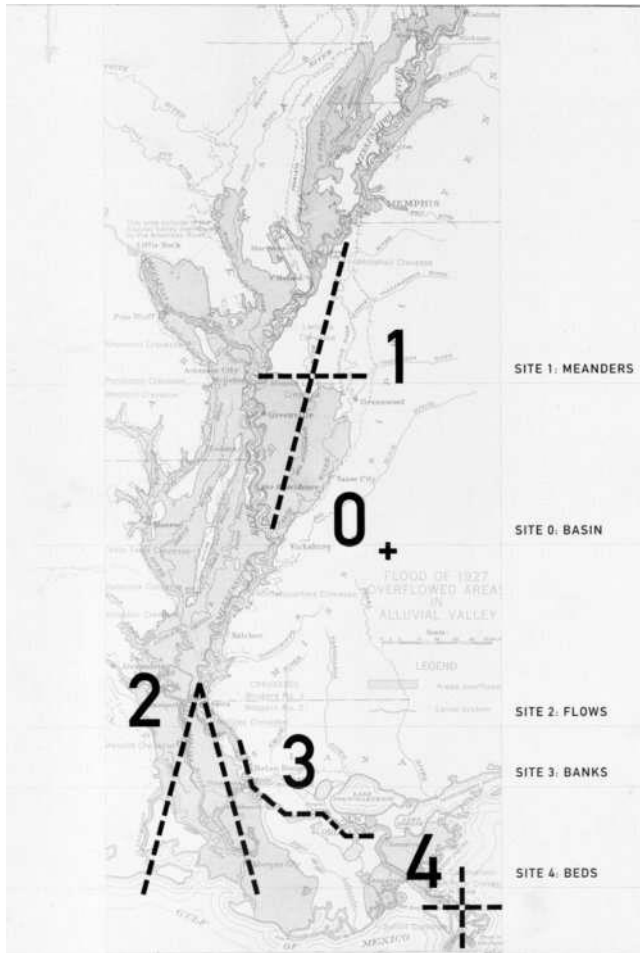

2.3 DYNAMIC INHABITATION OF A CHANGING LANDSCAPE | ANURADHA MATHUR & DILIP DA CUNHA, MISSISSIPPI FLOODS

The ambiguity of Mathur Da Cunha's work is based on the interdisciplinary nature of their research. The architects' mappings are territorial records of the acting entities of the landscape in question and contrast with the anthropocentric representation of geological conditions.

Mathur & Da Cunha's first published work is an analysis of the Mississippi River, which runs through North America from the United States border with Canada to the state of Louisiana. In their study, the river is presented as a living phenomenon, in contrast to material and ideological constructs that viewed the river as an object that is confined and categorized based on its behavior.

Historically, the Mississippi landscape has experienced a high number of floods in a short period of time. Mathur & Da Cunha approach the river landscape by traversing a path of analysis and mapping through five different landscapes with each individually holding a catalytic role in the mobility of Mississippi lands.

Their design process starts from Landscape 0, where the Mississippi River Basin Model is located, a multi-square-kilometre structure that serves as an outdoor laboratory, a simulation of the active landscape of the Mississippi River, designed to control and limit its dynamics.

Landscape 1 is defined by the meanders of the river, where the factors that shaped its meandering form are located. The architects in this section focus on the Mississippi's autopoietic capacity, which is traced to the ground displacements resulting from the erosive force of water flow at its bends.

Landscape 2 incorporates all of the river flows that have been the subject of study for interventions attempted on Mississippi River lands. For Mathur Da Cunha, the control of flows based on socio-economic considerations is a reference point for the occurrence of cultural and territorial changes in the landscape.

As Landscape 3, the banks of the river are described where the construction of embankments is identified to protect residential areas from overflow, and at the same time to create waterways to serve commercial development.

Finally, Landscape 4, refers to the riverbeds, where sedimentation is now prevented due to the velocity of the water.

In *Mississippi Floods*, Mathur Da Cunha describes the changes that occurred, after the colonial period, in the ways of inhabiting the dynamic landscape of Mississippi. At the same time, the architects recognize practices of coexistence in the lifestyles of the region's indigenous inhabitants, cosmologies that are intertwined with the qualities of Latour's Terrestrial Attractor.

The study seeks to develop an universal debate, calling for the necessity of finding earthly habitation practices that are in danger of being erased by the narrative of deconsecration fostered by modernity.

3. CONCLUSION

Summarizing through the examples analyzed, it became evident that the design process can be released from its usual form and become more open to new meanings. The emergence of the biodiversity and interrelationships between the acting entities of a landscape, its ability to self-organize, to move and the multiplicity of biotic and abiotic forces, constituted the common denominator of the approaches studied. In contrast to the strict and robust demarcation, the architects' alternative mappings expressed fluid and caring design manipulations.

Deep ecology as an expression of conservative critique, refers to inert geological landscapes, a striking paradox for the unfavourable conditions of the time. Climate change, the finite limits of natural resources and the mass extinction of species require new considerations that test the limits of the notion of nature. The human-technological mediation of nature negates its romantic essence, putting the focus on rethinking the relationship between man and nature.

Felix Guattari's Ecosophical Praxis concerns an environment in a constant process of reinvention, as it crosses the spheres of the mental, the social and the environmental, laying the foundations of contemporary ecological thought. Capitalist economic logic entangles ecologies and technologies that are evolving at an ever-accelerating pace, confronting us with the inevitable scenario of the Anthropocene. The Earth as a site of economic exploitation, whose functionality is judged by the adequacy of human control, contradicts the theory of Gaia as developed by James Lovelock and Bruno Latour. In the theory of the two thinkers, the evolutionary processes of entities are characterized by overlapping violations of their boundaries, violations that alter space as a function of time. The confusion of the poles of the Local and the Global distorted the perspective of a common place of evolution, creating assumptions of escape from Earth. Observing the distancing of humans from the Earth, Latour proposes ways of re-imagining and re-appropriating its territories; systems of creation whose development is based on passive entity-environment relations.

Summing up, an attempt was made to redefine the relationship between ecology and architecture as it has been established so far. The relationships with material traces and the human histories of these transformations call for a deep engagement with different forms of life. Architecture, in contributing to the creation of environments, is embedded in landscapes-intermediate nature-civilization, in

Proceedings

critical industrial landscapes. The architectural proposals analysed in the second section undertook buffering interventions, allowing the development of events, creating the conditions for autonomous and self-organizing landscapes.

«It is about an architecture in mid-stream, which undergoes constant changes and emerges from the accidental occurrence of events in complicated social, political, economic, ecological, technological, material and conceptual fields.» (Frichot, 2019).

Extended abstract

In the conference paper, "Coastal Cities Examined through Cinematic Lens: Athens-Copenhagen," we delve into the multifaceted intersection of architecture in an urban environment, climate change, and sustainability through the lens of an artistic documentary film called 'Shores Apart'. The project explores the lives of old fishing communities in Greece and Denmark, offering a profound examination of the intricate relationship between the changing climate, cultural practices, and sustainable living. The urban structures that are shaped around the proximity to the shores and harbor scapes, are one of the core elements in the physical representation around the life that unfold. Our primary objective is to illuminate the divergent narratives on the shores and urban dwellings of these two coastal regions, drawing attention to the profound impact of climate and landscape variations. As climate change increasingly becomes a defining factor in the lives of coastal communities, our presentation underscores the significance of utilizing documentary filmmaking as a powerful tool for architectural investigation. Key themes to be addressed in our conference paper include the influence of climate as a differentiating factor between Greece and Denmark, each marked by contrasting maritime environments. The paper will delve into the cultural significance embedded in the oral storytelling of the old fishing communities, emphasizing the preservation of intangible cultural heritage through cinematic documentation. Additionally, we will explore the sustainability challenges posed by climate change to these communities, highlighting the urgent need for conservation efforts and sustainable practices to protect the urban structures.

Our project approach involves a cinematic exploration of the urban structures around the shores that have developed from activities on the water, starting with fishing and transportation. The cities have grown from this, but today we see that the cities are taking over and the fishing and other original trades are disappearing, making the proximity to the water mostly a mere spectator's delight. A general lack of knowledge and awareness of the natural environment has made many people in the cities feel disconnected from it.

Keywords: *shores, climate change, resilience, sea, sustainability, geonome, filming*

1. INTRODUCTION

This research examines the evolving relationship between Athens and Copenhagen and their coastal environments, historically rooted to a large extent in fishing and now dominated by tourism, recreation, and real estate. Both cities, originally developed due to their accessible ports and sustainable fishing communities, face new challenges as urban growth and climate change reshape their interactions with the sea.

Proceedings

This study also introduces the concept of the "geome¹"—the geographical and geological foundations essential for sustainable urban development. By comparing the adaptive strategies of these two cities, such as flood defenses and green infrastructure, we explore how respecting the geome can enhance urban resilience. Additionally, we highlight the role of cinematic tools in capturing and conveying the human scale of interactions with the geome, providing a powerful means to advocate for sustainable urban practices. Through this lens, we aim to illustrate the importance of integrating natural landscapes into urban planning to ensure the ecological and social sustainability of coastal cities. Through comparative analysis and juxtaposing the urban experiences of our coastal nations, we can discern patterns, trends, and differences that may not be readily apparent when studying each country in isolation.

Figure 1. logo of the geome

2. THE URGENCY OF COASTAL URBAN RESILIENCE

It was more than 15 years ago, that McGranahan et al. (2007) pointed out that two-thirds of the world's cities with over five million people were located in coastal areas less than 10 meters above sea level, and 13 percent of the world's urban population lived within these low-lying coastal areas (McGranahan, Balk, & Anderson, 2007). The claim by McGranahan et al. is crucial for our presentation as it underscores the scale and urgency of the challenges faced by coastal cities worldwide. The challenges facing coastal cities are multifaceted. According to the Intergovernmental Panel on Climate Change (IPCC), global sea levels could rise by up to 1 meter by 2100, inundating low-lying areas, exacerbating coastal erosion, and leading to more frequent and severe flooding events (IPCC, 2019). This projection is particularly alarming for cities like Copenhagen, where many districts are at or near sea level.

By highlighting that a significant proportion of the world's urban population resides in low-lying coastal areas, it emphasizes the widespread vulnerability to climate change. This data point sets a foundational context for our exploration of Athens and Copenhagen, illustrating that the issues they face are part of a global pattern. The scientific basis for this claim lies in the inherent geographical and environmental dynamics of coastal regions, where natural processes and human activities converge, making them key areas for studying the impacts of climate change and developing resilient, sustainable urban practices.

¹ The term "geome," is coined by the authors of this research paper, Rasmus Iversen and Natalia Bazaïou. This concept emphasizes the intrinsic connection between natural landscapes and urban environments, highlighting the importance of integrating ecological and geological elements into city planning to enhance resilience and sustainability.

3. A COMPARATIVE STUDY OF ATHENS AND COPENHAGEN

Our research central argument posits that the historical relationship of Athens and Copenhagen with the sea has undergone a profound transformation. Through comparative analysis and juxtaposing the urban experiences of our coastal nations, we can discern patterns, trends, and differences that may not be readily apparent when studying each country in isolation. Climate plays a pivotal role in differentiating coastal regions, significantly impacting urban architecture and infrastructure. In Greece, the Mediterranean climate dominates, characterized by hot, dry summers with average temperatures ranging from 30°C to 35°C, and mild, wet winters with temperatures around 10°C to 15°C. This climate influences the urban architecture with features designed to mitigate heat and maximize comfort. In contrast, Denmark's coastal landscape is shaped by a temperate marine climate, with mild winters averaging around 0°C to 2°C and cool summers with temperatures around 17°C to 22°C. The annual rainfall in Denmark is approximately 700mm (27.5 inches), with consistent precipitation throughout the year (Climate Change Knowledge Portal, 2024). Urban infrastructure in Copenhagen reflects this climate, emphasizing insulation and moisture resistance. Historically, both cities relied heavily on the sea for fishing, which was a cornerstone of their local economies and cultural practices. Fishing communities in both cities were traditionally organized around small, family-owned boats and local fish markets, creating tight-knit communities that were integral to the local culture and economy. In Copenhagen, the GL. Strand area served as a bustling hub for fishermen, where boats would dock to unload their daily catch, which was then sold at the dock market. Similarly, in Athens, areas like Mikrolimano in Piraeus and the central fish market of Varvakeios were focal points for the city's fishing activities, with generations of families engaged in fishing, fish trading, and related maritime occupations. The original foundation of the coastal environment in both Athens and Copenhagen was based on the natural landscape and topography, which provided easily accessible ports and supported sustainable fishing activities. These areas, historically characterized by small, local nuclei of fishing communities, were integral to the socio-economic fabric of both cities.

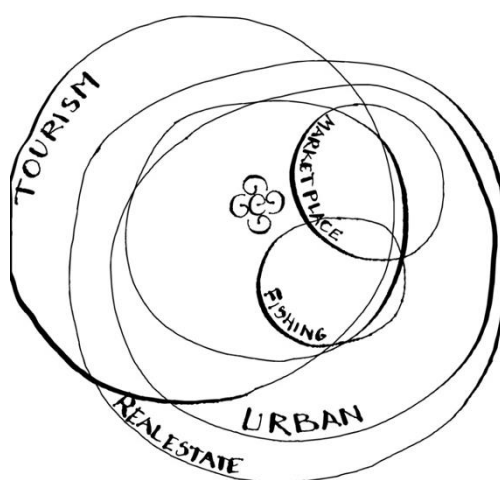

Figure 2. Changes in Urban Fabric 01

However, in contemporary times, these fishing nuclei are increasingly overwhelmed by the pressures of real estate markets and tourism. As urban growth accelerates, there is a tendency to overlook the natural environment and forget the fundamental reasons for the initial development of these coastal areas. This oversight leads to a critical tipping point where the natural environment collapses—a phenomenon highlighted by various environmental scientists and urban theorists who argue that sustainable development must account for the intrinsic value of natural landscapes (Rockström et al., 2009; Beatley, 2014).

To further investigate our scope, we introduce the concept of the "geome"—paraphrasing the term "genome"—to refer to the geographical and geological elements that form the fundamental basis of any dwelling. The geome represents the natural, foundational aspect of urban environments, akin to a city's ecological DNA. It is crucial to recognize and preserve the geome to ensure the sustainability and resilience of urban areas. When cities are built in opposition to their geome, they become less resilient to environmental changes and less capable of supporting long-term human habitation.

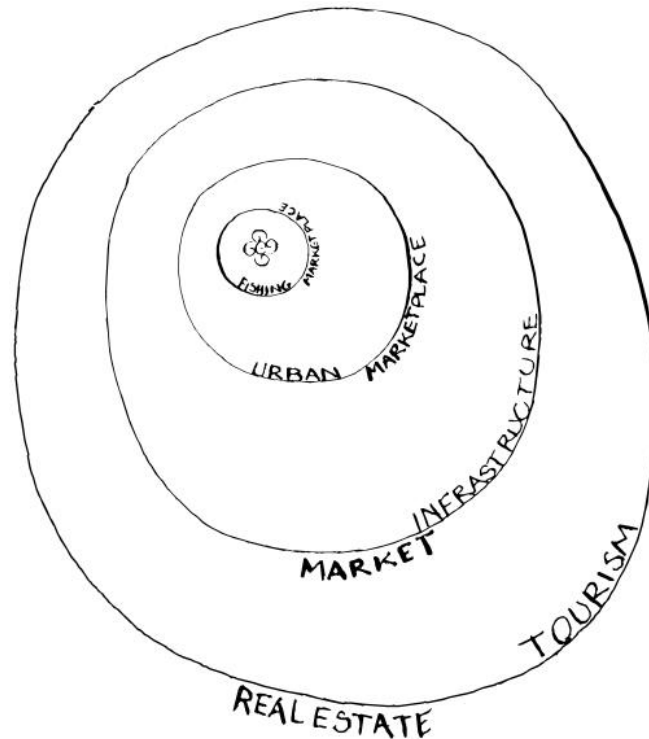

Figure 3. Changes in Urban Fabric 02

French anthropologist Marc Augé famously remarked that "the sea on the seashores is an analogy to oblivion that gives shape to memory." This observation points out the sea's dual role as both a force of erasure and a custodian of history. Similarly, the geome serves as the natural memory of a place, providing the environmental context and stability upon which urban development should be based. Ignoring the geome leads to a loss of this natural memory, resulting in urban environments that are disconnected from their ecological foundations and thus more vulnerable to environmental crises.

By acknowledging the geome and integrating it into urban planning and development, cities can restore and enhance their natural resilience. This approach ensures that growth respects the ecological and geological underpinnings of urban areas, fostering societies that are more adaptable and sustainable in the face of environmental challenges.

In contemporary times, however, the economic and social functions of coastal areas in both cities have shifted significantly towards tourism, recreation, and real estate development. This shift is evident in the proliferation of marinas, beachfront hotels, and luxury residential developments that now dominate these seascapes. This contemporary engagement with coastal areas has brought new challenges, particularly in the context of climate change.

In Copenhagen, rising sea levels and increasing flooding risks have necessitated the development of sophisticated infrastructure designed to protect urban environments from these threats. The Danish approach includes comprehensive strategies like the Cloudburst Management Plan, which integrates green infrastructure such as permeable pavements and rain gardens, alongside robust flood defenses

like the construction of the Lynetten sea wall and storm surge barriers around vulnerable districts like the harbor area (Copenhagen Municipality, 2012). These measures manage excess water, protect vulnerable areas, and enhance urban resilience. The implementation of these infrastructures has reshaped the relationship between Copenhagen's residents and the sea, transforming it from a source of economic sustenance to a focal point of climate resilience. The presence of flood defenses and green spaces has turned coastal areas into multifunctional zones where people can enjoy recreational activities while being aware of the protective measures in place.

Similarly, Athens faces the dual pressures of coastal development and climate change-induced risks. The city has responded with a combination of structural and non-structural measures aimed at mitigating flood risks and adapting to rising sea levels. Specific initiatives include the restoration of coastal vegetation and the installation of natural breakwaters along the Athenian Riviera to stabilize shorelines and enhance natural defenses against erosion and flooding (Hellenic Ministry of Environment and Energy, 2019). Additionally, Athens has upgraded its drainage systems and implemented the Faliro Bay Regeneration Project, which includes the construction of new flood defenses and the creation of public parks and pedestrian pathways (Spanogianni, E., & Theodora, Y. 2020). These projects intend to protect the city from flooding and also create new public spaces that host a closer and more sustainable relationship between people and the coastal environment. If these measurements are enough and successful cannot be part of this research.

Despite the shift towards tourism and recreation, both cities retain pockets of their historical fishing functionalities. In Copenhagen, the Nyhavn harbor area still houses a few fishing boats and seafood markets, maintaining a tangible connection to the city's maritime heritage. Similarly, in Athens, the Mikrolimano harbor in Piraeus remains a vibrant fishing port where traditional fishing activities continue alongside seafood restaurants and leisure facilities. These remaining fishing facilities preserve a small part of the cultural heritage of both cities, reminding us slightly of their historical relationship with the sea. However, they don't ensure that the evolution of urban coastal areas will continue including space for traditional practices alongside new economic and recreational uses. This evolving relationship emphasizes the importance of coastal areas as spaces where environmental protection, urban development, and public engagement must converge.

4. CINEMATIC TOOLS

Cinematic tools offer a direct and intuitive way of perceiving and sharing the human scale and interactions with the *geonome*. By employing visual storytelling techniques, we vividly capture the relationship between people and their natural environment, illustrating how the geonome shapes daily life and urban experiences. Through the narrative film, the dynamic interplay between urban development and natural landscapes can be explored in depth. For instance, aerial shots can reveal the topographical features that define a city's geonom, while ground-level footage can showcase the human activities and interactions that occur within these spaces.

Figure 4. Urban Landscapes Through the Lens: Cinematic Perspectives on Coastal Cities

The immersive nature of film allows viewers to experience the geome on a visceral level, making the abstract concept of geographical and geological foundations more tangible. By highlighting how urban growth impacts natural environments and vice versa, cinematic tools can effectively communicate the importance of preserving and integrating the geome into urban planning. Moreover, films can document the adaptive strategies and infrastructural changes that cities like Athens and Copenhagen implement to cope with challenges such as sea level rise and flooding, thereby providing concrete examples of how respecting the geome can enhance urban resilience. Cinematic tools enrich architectural research and offer insights into the study of public space dynamics. Through cinematic techniques, it's easier to capture the multifaceted nature of public spaces. The concept of "urban cinematography," as pioneered by urban scholars like Richard Koeck, emphasizes the use of filmic techniques to document and analyze urban environments, including public spaces (Koeck, 2016). The concept of "cinematic urbanism" highlights how cinematic representations shape our perceptions of urban spaces and vice versa (Bruno, 2002). By employing methods such as time-lapse photography and aerial cinematography, it is easier to reveal the temporal and spatial dynamics of public spaces, showing patterns of use, movement, and interaction. The cinematic representation of public space has been explored in various films and documentaries. Through an interdisciplinary approach informed by Richard Koeck's concept of "urban cinematography," by urban theorists like Giuliana Bruno, the project endeavors to capture the temporal and spatial dimensions of urban phenomena. By adopting a cinematic lens, this research project aspires to stimulate scholarly discourse, engage diverse audiences, and foster a deeper understanding of the complexities inherent in contemporary urban life.

Conclusion

In conclusion, the historical and contemporary relationships of Athens and Copenhagen with the sea underscore the critical importance of integrating the geome—the geographical and geological foundations—into urban planning and development. As both cities transition from fishing-based economies to tourism and real estate-driven growth, the pressures on their natural environments intensify. The adaptive strategies employed to mitigate the effects of climate change, such as flood defenses and green infrastructure, demonstrate the need to respect and preserve the geome to ensure urban resilience. Cinematic tools play a crucial role in illustrating these dynamics, providing an intuitive and impactful means of perceiving and sharing how human interactions with the geome shape urban experiences. By acknowledging the geome and using it as a basis for sustainable

Proceedings

development, cities can foster environments that are both resilient and reflective of their natural heritage, ensuring that growth does not come at the expense of ecological stability. Drawing inspiration from philosopher Gaston Bachelard's notion of the "poetics of space," (Bachelard, 1994)our cinematic exploration delves into the evolving relationship between coastal communities and their urban environment, wanting to invite viewers to reimagine their connection to the natural world, embracing the poetic essence of coastal living.

Blossoming solutions: A discrete choice experiment on nature-based solutions in European cities

A. Wanner*, M. Jungnickel, U. Pröbstl-Haider

Department of Landscape, Spatial and Infrastructure Sciences, University of Natural Resources and Life Sciences, Vienna, Peter-Jordan-Str. 82, 1190 Vienna, Austria

*Corresponding author: E-mail: alice.wanner@boku.ac.at, Tel +43 47654-85325

Extended abstract

As European cities face a multitude of climate change related issues, nature-based solutions are emerging as an answer to growing concerns about biodiversity loss, rising temperatures and poor air quality. Calls to action are being heard from all governance levels and leaders are recognizing the importance of integrating citizens and stakeholders in solution finding. Therefore, investigating the opinion of citizens, vital to participatory processes, and the trade-offs they are willing to make in order to green their cities have yet to be given the attention in research it deserves. The aim of the presented study, stemming from research within the UPSURGE project (Horizon 2020), was to understand urban citizens across Europe and to answer the question, why citizens value specific attributes of nature-based solutions, what differences are the most prominent and how urban planners can use this information in their development strategies.

To answer this complex question, a survey with an integrated discrete choice experiment was conducted in six countries (Greece, Hungary, Netherlands, Poland, Slovenia & United Kingdom). The survey was distributed via a panel and the obtained sample consisted of roughly 1,000 respondents per country. The hypothetical choices for respondents included attributes such different types of NBS and possible environmental improvements, but also possible communal fees which may arise from implementation and disruption to accessibility through removing sealed traffic areas to make space for NBS. This design is a reflection of the real world, in which space is sparse and trade-offs must be made when developments are planned in urban areas.

The results illustrate an initial comparison of the discrete choice experiment across all six countries and reflect the variety of exposure to climate change across the continent and different attitudes towards participation in the design process of nature-based solutions. For example, Greece and the United Kingdom show diverse preferences in the environmental function the nature-based solutions should fulfill. Participation was especially important in Poland and Slovenia. The Netherlands was the most sensitive to changes in accessibility. By delving into and understanding these results, participatory processes can be supported to help planners and politics define priorities, design participation opportunities for their citizens and decide on governance measures with long-term dedication to development plans. The study has made clear, that cultural differences and exposure to climate change mean that there is no transferable “one solution fits all” when it comes to nature-based solutions. The results of the discrete choice experiment can be integrated into a decision support tool for practitioners. With such a tool, planners and practitioners are supported in long-term sustainability strategies to make European cities places in which we have faced our issues jointly and overcome them together.

Keywords: *nature-based solutions; discrete choice experiment; European cities*

Cities and Climate Crisis; How Design Principles and Policy can Impact on Carbon Emissions

A. Nikologianni

Climate Crisis Expert & Research Fellow, College of Architecture, Arts, Design & Media
Birmingham City University, UK

Corresponding author: E-mail: natasa.nikologianni@gmail.com, anastasia.nikologianni@bcu.ac.uk, Tel

Abstract

Climate crisis, environmental and biodiversity challenges and socio-economic difficulties are amongst the bigger issues of today's cities and regions. Landscape design plays a significant role on matters related to environmental sustainability, identity, health and wellbeing, economics, governance and politics. The current pressure for the development of urban and regional strategic approaches can only be appropriately addressed through systemic and behavioural change as well as a strong landscape focus in order to have holistic responses to urban transitions. Looking how policy impacts on design principles and environmental design, it unpacks the key characteristics required for systemic and behavioural change and discusses the key elements of a smooth transition to resilient and environmentally friendly cities.

This research touches upon the importance of carbon in landscape design and how cities can improve their environmental profile using a combination of a landscape holistic approach supported by policy and connected to current and potential carbon emissions. Findings indicate that a combination of both top down and bottom-up approaches is required, including strategic spatial visions for the cities influenced by policy/legislation and scientific characteristics such as carbon calculation. The lack of the necessary policy is often an obstacle on cities' sustainable development, not allowing for new approaches and innovative concepts to be integrated. Intangible concepts such as spatial quality and wellbeing and scientific calculations (e.g. carbon emissions and sequestration) are both significant for the cities and their wider areas impacting on the ways in which urban conurbations can become environmentally friendly.

Keywords: *landscape design; cities; policy; carbon; emissions; city transition; systemic change.*

1. INTRODUCTION

The climate crisis is becoming one of the most important challenges of our times, impacting on cities, regions, human settlements and biodiversity. The danger to human lives and the environment is acknowledged by the United Nations Intergovernmental Panel on Climate Change [1] that identifies several issues such as global sea level rise, melting of ice and snow, an overall warming of the climate system as well as an increase in air and ocean temperatures. Cities, urban conurbations, and landscapes need to be designed taking climate and environmental phenomena into account. As explained by Yu and Sun [2], environmental awareness is a crucial part of social development in urban areas. Cities have the ability to effectively deal with carbon metabolism, generated by the development of sustainable cities, as a result of the interest and active participation of their communities [3]. What is needed is for the carbon emissions of a city to be fully acknowledged and for policy and design strategies to be in place.

Policy and governance focusing on the climate crisis need to be reviewed and updated [4] as a measure to deal with carbon emissions in urban areas. This paper explores selected governance and policy models related to the landscape, as well as landscape design principles, aiming to identify necessary steps and key strategies. The fragmented way policy and science deal with the landscape

[5], affects the way communities operate and therefore our broader sense of quality of life and wellbeing. Especially in a city context, the landscape is often considered as the green or open space that surrounds the conurbations when it, in fact, is the ‘‘vast infrastructure upon which we depend for everything’’ [6, 7]. Through an examination of a major project in Birmingham (UK), the City of Nature, as well as several policy and carbon guidelines from professional bodies such as the Landscape Institute (LI), this research hopes to support cities to improve their environmental profiles, by integrating holistic strategies on landscape design and carbon. Results demonstrate that developing technologies are important, but both systemic and behavioural change are required for cities to address their carbon footprint and emissions.

2. LITERATURE

The discussion on cities and policy is not recent. More than a decade ago, Stone et al. [8] were suggesting that Greenhouse Gas (GHG) emissions, heat management strategies etc needed to be included in city and regional climate action plans, however the importance on how spatial strategies affect the growth of carbon emissions has not been widely discussed. Several sources highlight different aspects of sustainable cities. Tang et al. [9] state that economic growth and carbon emission reduction are key for effective development of low carbon conurbations. Lamb et al. [10] conclude that cities are the major player in the 1.5°C target (Paris Agreement 2015) but acknowledge that there is a gap on policy around sustainable and climate needs. It is important to mention that land and land use have also been recognised very relevant in the context of climate crisis, and as Stone et al. explain both local and regional scales need to be addressed in relation to land and its uses, for example high/low carbon emissions, fluxes and more [8]. The importance of policy and legislation for the landscape has been highlighted by the Council of Europe, suggesting that the better understanding of policy in relation to the landscape the greater impact on its implementation [11]. In addition, focusing on spatial planning, Giannakourou [12] has stated that the ‘‘European Union (EU) in spatial planning has no binding force and cannot prescribe concrete legal or institutional requirements’’, however a swift in governance and policy is already being observed on urban and regional scale. Stremke et al. [13] discussing about the wider term of the landscape, suggest that the landscape impacts on both quality of life and human interactions. Although, when it comes to policy and the climate crisis, the goals usually point at GHG emissions and sinks [8], missing the key aspects of the wider spatial area, communities and the city activities and needs.

Policy action plans with regards to climate change are constantly being developed and there are calls for a wider spectrum of such policy measures, especially as current management frameworks do not cover the whole complexity on climate and temperature changes [8]. As a result, governments and local authorities need to develop strategies dealing with carbon emissions on the urban as well as the regional scale. Tang et al. [9] taking it a step further, suggest that cities’ planning systems need to incorporate environmental and carbon strategies. Highlighting similar gaps from a landscape perspective, Zhou et al., [14], mention that often social and cultural factors are not associated with landscape sustainability, but it is important to develop both the more scientific approach (ecology, ecosystem etc) and the broader community understanding. Discussing about the social character of the landscape, it has been suggested that a potential action plan should embed local administration processes and policies on its landscape proposal [15].

3. BIRMINGHAM CITY OF NATURE POLICY & PLAN

Several cities are looking into alternative governance methods and updated policies in relation to the climate crisis and the environment. However, the climate policies to date sometimes have a limited approach with regards to the climate crisis and especially when it comes to the landscape. Birmingham City Council declared Climate Emergency in 2019 and has been a Biophilic city for several years. With the climate and environmental emergency increasing, there is certainly a lot of interest in the city to improve its natural environment and address climate change. Birmingham city

Proceedings

council is the largest local authority in Europe and therefore its aim is to lead by example, adopting innovative policy and organisational practices.

This paper uses Birmingham City Council's City of Nature programme as a case study to explore the governance and policy models when dealing with environmentally friendly cities, carbon emissions and city plans. The broader programme of the City of Nature was built on Birmingham's Future City Plan 2040 with a focus on sustainability, enhancement of green and blue spaces as well as maintenance. It connects into local, regional and national policies and strategies [16]. The first steps have been for the city of Birmingham to identify its future as a green and bold city able to address the challenges of a changing environment [17]. The city pledges to increase its green spaces becoming a city of a 1000 green spaces and trades [18] and connecting its communities with environmental principles and ways of living. Introducing the United Nations Sustainable Development Goals (SDGs), the plan connects the broader spatial vision with key indicators such as climate crisis, biodiversity, health and community engagement [16].

The significance of the city of Nature project has been the goal for systemic change within the city processes as well as a continuous evaluation of the decision-making procedures of the wider community. Embracing the concepts of sustainability, climate and environmental crisis, circular economy and citizen engagement, this innovative project has put the landscape of the city in the core of its spatial development while it also establishes new methodologies to achieve a truly green city. Following this approach, Birmingham was the first city in the UK to adopt an Urban Forest Master Plan in 2021, and with more than 1 million trees, has been awarded with the Tree Cities of the World status [19]. As mentioned in the formal 'Future City Plan' document, the delivery plan of the project has actively involved the whole council as well as third sector partners, through a City of Nature Alliance, in order to improve the way in which the city deals with the natural environment [19]. Part of the success of the project has been its wide partnership with educational institutions and third parties. Taking inspiration from the Naturally Birmingham and the Future Parks Accelerator (FPA) projects and following the city's Route to Zero Climate Emergency Plan, the City of Nature has been infused with several ideas that connect landscape with people. Working together with local and European landscape-led projects such as the EIT SATURN programme and being educated about new visioning approaches (West Midlands National Park Lab – WMNP Lab), has opened the pathway of a systemic change. In addition, the challenge of long-term visioning for the city has helped to understand the landscape and identify the needs of the city and its wider community. Through a series of workshops and methodologies run by the WMNP Lab, SATURN and other partners, the City of Nature partnership had the opportunity to work on its stakeholder engagement and capacity building methodologies, allowing for bolder and stronger policy alterations.

It is stated that to materialize the programme's ambition a 'collective change by the council and the city as a whole' is required [17] and therefore, the ethos and core aims of the City of Nature need to be acknowledged at all stages of decision making and across all parties of the council [16].

3.1 Policy and governance

One of the key parts when dealing with policy and spatial plans is to be aware of the strategies and regulations in place and also be fully prepared to embrace new methodologies and techniques. The City of Nature plan has been aligned with the 2021 Environmental Act, while it has followed several ideas from the Landscape Review 2019 – (Glover Review) such as connecting people with nature [19]. It has gained expertise from across the globe, looking at how cities respond to access to green space. As a way to respond to the open space inequality, the local authorities of Birmingham are the first in the UK to develop an Environmental Justice measurement tool, working on for fairness and citizen engagement with regards to environmental laws, policies and regulations.

The successful environmental strategy of a city is often secured by the commitment of its governance to the aim of the strategy as well as the wide spectrum of the decision-making process followed. Prior

to the City of Nature project, Birmingham was part of the Liveable Cities programme run in the UK from 2012-2017 examining the key elements of a sustainable city, where it was found that the effectiveness of a city strategy has to do with the level of interaction between its governance, planning and finance departments [19]. Learning from past experiences and being keen to leave a legacy of a green and low emission city with access to the landscape, the Alliance formed for the City of Nature project, has put specific emphasis on the project's governance itself. Continuous discussions, the creation of new bodies and the effort to have common agendas have been instrumental in Birmingham's success on a systemic and behavioural change. The creation of a strong vision for the future of the city, together with the close collaboration of local departments has been instrumental in this urban focused scale. A number of changes in the way in which the council was operating as well as the interaction with communities and third parties have been noticed as a result of the policy and decision-making processes re-evaluation. The plan created for the scope of the project, has been embedded in policy documents of the city of Birmingham. This has worked both ways; on the one hand, the goals set for the project are secured, on the other hand the innovative scheme of the City of Nature has contributed to the city's Carbon Net Zero climate ambitions [20]. Among the key findings is that a city scale vision needs to be shared between its decision makers, experts and communities and it requires behavioural change and a strong commitment to climate and environmental goals. A well-thought and strong net zero, place-based urban strategy has many growth and regeneration opportunities resulting to healthier, more sustainable and greener cities. Vision is key but cannot bring systemic change if it is not embedded in policy and legislation of a city. Especially when it comes to the impact of carbon emissions, policy needs to be in place to guarantee the commitment of governance and third-party processes.

3.2. Guidance on landscape-focused carbon policy

Especially in the UK several institutions have started providing guidance in relation to the climate crisis. With regards to the landscape, the Landscape Institute (LI) professional body of the landscape architecture profession together with the British Association of Landscape Industries (BALI) have recently published a report on carbon reduction in the sector. The report aimed to enhance knowledge on carbon emissions and support professionals to calculate and find solutions for the emissions in relation to spatial planning and the wider projects of the sector. It was mentioned that even though in the built environment standards on carbon action emerge, most of them have a limited relevance to landscape [21]. As a result, existing standards, such as BS EN 1597812, BS EN 17472:202213 and 'CEN TC/350 Sustainability of construction works' do not provide the necessary specifications for the landscape [21]. However, new regulations are being developed with the 'PAS 2080 2023 Carbon management in buildings and infrastructure', to have more relevance with the planning sector, but still quite limited from the landscape approach. Suggestions from the LI/BALI carbon report [21] encourage the creation of a 'dedicated sector-wide strategy for the landscape and carbon', so the calculation, understanding and spatial planning in relation to carbon emissions can be much more accurate and effective.

4. DESIGN PRINCIPLES

The principles of design are very significant among the design professions and usually the drivers behind the final masterplan of a city or an area. However, design principles are not a concern of the wider audience and when it comes to a city, they are often believed to be relevant to the aesthetic part of a plan. In addition, Dramstad and Fjellstad have examined how science and policy affect the landscape, questioning the way in which policies impact on landscape strategies and sustainable development [21]. Drawings can communicate ideas, and the principles of design have the ability to embed a certain character or ethos to the built project. Using the powerful mediums of design and drawing on a city scale development, the narratives and landscape ideas have much greater potential

to be effectively communicated to a wider audience, including decision makers, civil servants, third parties and the community of the area. Even though a swift on certain processes has started to be noticed, the management process of large infrastructure developments leaves landscape design at the fringe of this process. As much as design principles can be the pillars of a masterplan for the designer, they can also become a tool to improve the imagination of the wider audience and support the narrative. As a result, such principles are key to understand the somehow difficult concepts of carbon emissions, carbon sequestration, environmental approaches and sustainability on city scale. The Design Council has argued that design thinking is a necessary process when creating the vision of a scheme[22], and the outcome of this process, the design, provides a better understanding of the ideas proposed. The concept takes shape and is being expressed in a visual form through design [23] and this enhances the notion of this research, that the principles of design can impact on the way in which carbon emissions are addressed in cities. The principles created for a specific spatial proposal can communicate the ideas of sustainability and environmental ethos to professionals and local authorities, helping towards the issues of communication observed between governments, administrations and citizens [24].

Birmingham's 'Our Future City' proposal has highlighted that the design of an area must be bold, inspire and connect with the community who uses it most [17]. Acknowledging the significance of design and strong proposals, the 'Our Future City' proposal has stated the commitment of the council to work with and support stakeholders to deliver the visions proposed for central Birmingham. In addition, it is mentioned that the delivery of the vision can be secured through certain policies and planning applications [17] emphasizing the significance of policy within design and planning. Overall, the principles applied for a city scheme, have the power to impact on the extent to which the concepts of sustainable development and carbon will appear on the masterplan.

5. CONCLUSION

Following innovative schemes, the structure and processes in place, as well as recent guidance on landscape and carbon, this paper concludes that policy and legislation play a significant role in carbon emissions on a city scale. With a growing need to infuse climate resilience and sustainability into every design and provide solutions for the contemporary challenges of our cities (heat demands, sustainable transport, carbon emissions, embodied carbon on design and planning), councils need to step up and lead by example. New policies and legal requirements need to be put in place when dealing with carbon emissions on the urban scale, not only for the buildings, transport and energy sectors, but also for the landscape and open spaces. Using the principles of design can effectively explain and visualize how the proposed environmental concepts can be implemented in a city and therefore speed up the process and improve the overall outcome. The carbon emissions of a city come from a variety of different sources. This research suggests that if certain policy is in place and the decision makers are fully aware of the possibilities and the benefits of a holistic spatial approach, then it would be much more effective to deal with carbon emissions. The council's commitment has been proven key to any major development and together with the support of policy, the vision for sustainable cities can become reality.

Mapping multispecies inhabitation of the Axios Delta complex: conflicts and conviviality in the climate change era

E. Kasselouri

PhD student in Urbanism, Department of Architecture and Arts, Università Iuav di Venezia, Italy

Corresponding author: E-mail: ekasselouri@iuav.it, Tel +30 6977254956

Extended abstract

This study aims to investigate the conflicting or convivial relations between human and non-human systems in the discharge area of Axios River by using interpretative mapping. The Delta, which is formed by four different waterways (Axios, Aliakmon, Gallikos & Loudias), is examined under the lens of multispecies inhabitation. The delta complex has a critical role as a biodiversity reservoir which is challenged by the overall human pressures in the area. A variety of fauna and flora co-habits the territory, and is adjacent to the human settlements, the urban infrastructure, the production fields and facilities. The deltaic territory constitutes an important wetland on the national and European level, being in parallel a highly productive land for agriculture and aquaculture. Along with the increasing human pressure from all the relevant activities in the area, climate change forms an active threat to all the species and the local ecosystems. Even though river deltas provide favorable conditions for the inhabitation of various species, they appear to be more vulnerable to the effects of the gradual sea level rise. Erosion, inundation and saline intrusion are intensifying coastal fragility and further modifying the spatial characteristics of the deltaic coastal territories. Especially in the Mediterranean basin, this fact contributes to the loss of coastal biodiversity and to the modification of the coastal line, altering ecosystems and livelihoods.

Could this transitional phase be imprinted in maps? Through interpretative mapping, the aim here is to investigate how conflicts or balanced coexistence find their spatial expression. Which are the challenges that the delta is facing and how does climate change influence coastal inhabitation and protection? How is the tool of mapping helping on reading the appropriated territory and analyzing the existing or projected relations? Mapping the various spatial conditions of the deltaic territory illustrates that a different approach on coastal inhabitation is necessary under the changing climatic conditions. By transitioning towards a new balance, the hybrid character of this territory is challenged and adapted. Climate change adaptation and mitigation refers to the protection of both human and non-human inhabitants, placing the relation between man and nature in the center of the discussion. Mapping is therefore used as a tool to redefine a multispecies approach in coastal inhabitation. By drawing plans and cross-sections, the intention of this study is to test this methodology in analyzing but also in reinventing the identity of the Axios Delta complex in the climate change era.

Extended abstract

The experience of natural phenomena related to climate change involves changing modes and elements closely related to landscape and urban-architectural transmutations. Changes related to the climate sphere, are by definition, associated to anthropogenic practices of planetary exploitation effecting and altering the natural balance of the global ecosystem. The paper emphasizes the main role that landscape undertakes in the process of analysis, interpretation, and configuration of the new habitats of change, establishing a mutual and constant link. Consequently, the landscape that is a terrain of dynamic relationships, both visible and invisible, generates scenarios of climatic and environmental modifications involving multiple aspects: perceptual, economic, social and identity. The survey proposes an interpretive and reconstructive analysis of a unified vision of the Abruzzi landscape of lake Fucino, a protagonist over the centuries of massive physical, landscape and climatic metamorphoses. The landscape of the floodplain was influenced by the course of the seasons in which it irregularly underwent outgrowths and decreases, as it lacked a natural outflow. The regulation of water runoff relied on the presence of natural sinkholes that were unable to counteract the magnitude of the effects due to weather events responsible for the damage of flooding of rural land and urban centers around the perimeter of the lake. It should be emphasized that works for draining the lacustrine waters that occurred through the construction of an outfall, lasted for many centuries - initiated in 41 A.D. by the Roman emperor Claudius and completed, only, in 1875 by Prince Alexander Torlonia. The outfall allowed the resolution of the problem of management and regulation of the lake water regime and flow by allowing the outflow of the basin waters into the Liri River. This has however, caused a transformation of the habitat and climate and the loss of Mediterranean biodiversity. The analysis is based, on a two-pronged approach: iconographic reading of past representations and surveys of the landscape through a comparison before and after implementation of the engineered water works, and a prognosis of the current landscape in relation to climate crisis.

The Role of Dilemma Games as a Mediation Tool between Citizens & Policy Makers for Urban Rooftop Utilization: A Cypriot Case Study

A. Merry^{1*}, M. Kyriakou²

¹ Case Study Coordinator, Leader Spatial Design and Artefact Research Unit, Assistant Professor, Frederick University, Cyprus

² Architect/Urban Planner/Researcher, Urban Gorillas NGO, Cyprus

*Corresponding author: E-mail: art.ma@frederick.ac.cy, Tel +35725730975

Extended Abstract

This paper presents the role of a games-based activity as mediation tool between citizens and policy stakeholders in the field of sustainable urban planning and more specifically the reutilization of rooftops in the fight against climate change. The paper presents a case study methodology demonstrating the initial results of a pilot case based in Nicosia, Cyprus. The case study is part of a larger research project entitled 'GREAT' (Games Realizing effective and Affective Transformations). Great is a 3-year co-funded project under EU Horizon and UKRI. Research and Innovation in the 'GREAT' project aims to demonstrate that games have positive impact on social engagement and can create new forms of dialogue between citizens and policy stakeholders. By exploring the potential of games, it provides a platform for citizens to express their preferences and attitudes on policy issues.

The context of the 'GREAT' research is climate change and this paper displays a case study which focuses on the exploration of the reutilization of urban rooftops in the city of Nicosia, Cyprus. The case study is designed in collaboration with Urban Gorillas, NGO, Nicosia who are members of the European Creative Rooftop Network (ECRN), a network of organizations, across 9 European cities promoting the creative and optimal use of urban rooftops to tackle contemporary urban challenges, which is co-funded by the Creative Europe Programme. This partially undiscovered layer of urban space offers a diversity of opportunities. From the generation of new places to meet and the creation of cultural breeding grounds to innovative living labs exploring sustainability. As a result of the initiatives of the 'rooftop' project, the GREAT team of Frederick University and Urban Gorillas, NGO have combined expertise to utilize the GREAT methodology to engage with multiple stakeholders promoting a new form of dialogue using the positive impact of games, allowing each group to express their attitudes and facilitate dialogue to policy issues. The initiative aims to drive change in the way our buildings are designed and how the utilization of currently 'lost' spaces of the city can be reclaimed in the context of the climate emergency.

The game displayed in this paper is entitled 'Rooftop Revolution' and encompasses a role play perspective. The game presents participants with positives, challenges, incentives and fairness factors in relation to rooftop utilization. The game places the 'players,' citizens and stakeholders within situations that have real world implications, allowing them to explore how we can find balanced and fair policy solutions for all.

The paper ultimately displays an innovative methodology which can replicated in the same game format to suit multiple dilemmas to explore policy recommendations amongst target groups, thus yielding different results from traditional focus groups, workshops and consultations. Furthermore the 'GREAT' case study methodology has the potential to be applied to urban planners and stakeholders alike to address critical Urban challenges related to the climate emergency and beyond, as well as improving the connection between citizens opinions and the policy making process.

From UN Agenda 2030 to the organization of a mega sustainable event: the case study of Paris 2024 Olympics

C. D'Ercoli

PhD student in Science and Technology for Sustainable Development, University "G. D'Annunzio" Chieti-Pescara, Italy

Corresponding author: E-mail: celeste.dercoli@unich.it, Tel +39 3397324924

Extended abstract

In 2015, with the publication of the UN Agenda 2030, sport was recognized as instrumental for sustainable development. The Agenda consists of guidelines for the future and is in line with the recommendations of the 2020 Olympic Agenda. The International Olympic Committee (IOC) believes that sports and the Olympics can help develop the majority of the Agenda goals, such as ensuring a healthy life and promoting well-being for all, contributing to making cities inclusive, safe, and resilient, guaranteeing sustainable consumption and production patterns, promoting inclusive economic growth, or taking actions to combat climate change.

The next Olympics will be held in Paris in 2024 and will be the first organized according to the sustainability principles set up by the Agenda. This case is supposed to mark a turning point in the history of the Olympics. However, these objectives remain fairly vague in that they are not defined by concrete criteria.

This paper reports on the development of a method that starting from the analysis of the Agenda goals provides a series of requirements to discretise and evaluate quantitatively the long-term sustainability of the event. This study investigates, with particular focus on the urban and architectural aspects, the relations between the event and the host city, between people and context and between event and environment. Much importance is given to public infrastructures, the well-being of visitors and athletes and the needs of the host city. We study the Olympic venues, assessing how many of them already exist, are temporary, or have been built for the event, as well as which materials were used in the realization. We pay attention to the legacy of the event, which implies planning from the beginning the future of the city after the Games. In fact, the Olympics in Paris are part of a wider process of expansion of the city: the construction of a large infrastructure network, the Grand Paris Express, and the redevelopment of the suburban district of Seine Saint-Denis. Moreover, the majority of the venues are existing and it is very strong the relation with the heritage of the city.

With this method, we can easily analyse the results of studies and field research, like visits to the building site, and evaluate the impact of the event. This study is the beginning of a process that allows us to analyse and compare different Olympic editions within a single coherent framework.

Designing a smart tourism destination in Greece: the case of Piraeus

A. Oikonomou

Department of Planning and Regional Development, School of Engineering, University of Thessaly

Corresponding author: E-mail: thanasis_oikonomou@hotmail.com, Tel +30 6978255209

Extended abstract

This paper reports on the development of a smart tourism destination in Greece. Smart tourism represents the convergence of ICT and tourism and denotes the transformation of tourism through technology. It indicates a new tourism braced by integrated efforts at a destination to collect and analyze data extracted from diverse sources in combination with the use of advanced information technologies to transform travel experiences to make them more enriched, efficient and sustainable. In this regards smart tourism is a social phenomenon arising from the incorporation of ICT with the tourism experience. Moreover, smart technology has been significantly changing the way visitors make diverse travels decisions, such as those pertaining to transportation, accommodation and activities available at a desired tourism destination.

Greece has established itself as one of the top international tourism destinations. However, the Greek tourism industry needs to invest in digital transformation in order on the one hand to respond to the international trends and on the other hand to upgrade the overall experience of the visitor. Every potential smart tourism destination needs to have a comprehensive strategy for digital development, with the provision of incentives and their immediate implementation, so that the destination can follow the pace of digital development of other destinations.

The paper presents the phases of designing Piraeus as a smart tourism destination. Piraeus is one of the largest cities in population in Greece with a great history and the largest port of the country. The development model is divided into two main levels: at the design level and at the level of implementation. During the planning phase, it must be determined who will participate in this project (stakeholders). Subsequently, the Municipality is called upon to outline the strategy and objectives of the project, with the creation of an integrated strategic plan and at the same time, it is important to seek collaborations with private bodies or research centers/universities and similar alliances in Greece or abroad. An additional critical factor in the planning phase is the search for financial resources to support the entire project. For this reason, it is necessary to utilize the available financial resources at national and international level, while resources can be leveraged by local society bodies or private initiative.

Once the vision and objectives of the project are finalized through the strategic plan, the stage of implementation follows. This stage includes the execution of all the steps planned in the previous stages. At the same time, a project monitoring mechanism is defined, which is responsible for the smooth supervision and completion of the project. A dominant role during the implementation stage is the development of the necessary infrastructure and applications that will support the project, while at the same time the monitoring mechanism will monitor the progress of the implementation of the proposed actions, evaluate their results and if deemed necessary, the plan's strategy will be redefined. Both during the planning stage and during the implementation stage, stakeholder participation will play a key role in achieving the goal of transforming Piraeus into an integrated "smart tourism destination".

Abstract

Climate change is the occurrence of long-term and significant changes in the Earth's overall climatic conditions, usually associated with an increase in greenhouse gases in the atmosphere and as a result of human activities. It is therefore also referred to as global warming. IPCC reports indicate that cities will be affected the most in climate change scenarios. Especially densely populated cities are more vulnerable to risks associated with climate change, such as extreme heat, excessive rainfall, flooding, and sea level rise. Sustainable urban planning and management make the role of cities important in combating climate change. For these reasons, various policies at the global level to combat climate change and the search for technological solutions are on the agenda of countries. National governments have a major role to play in pursuing various strategies such as encouraging societies to adapt to climate change, becoming a stakeholder in international agreements to build resilience to climate change, investing in projects, subsidizing projects. Turkey and the Mediterranean Basin countries are regions that have the potential to be severely affected by the impacts of climate change. To cope with these impacts, Turkey and other Mediterranean Basin countries should prioritize sustainability policies and strengthen their infrastructure to adapt to climate change. This study aims to examine the extent to which Turkey, a Mediterranean basin country in a changing world with changing climatic conditions, has implemented its national-level climate change mitigation and adaptation policies and strategic plans in regional resources and projects through development agencies at NUTS 2. With this aim, the policies of the Ministry of Environment, Urbanisation, and Climate Change on climate change will be examined, and the alignment with the projects that 29 development agencies support or programs with a focus on climate change at NUTS 2 will be examined. This study will reveal which regions of Turkey, a Mediterranean basin country, are strong and which regions are vulnerable in terms of climate change resilience studies at the national level on a NUTS 2 scale. The study is expected to offer a similar approach for other nations in the Mediterranean basin.

Keywords: *Urban Management, Climate Change Policies, Strategic Plans, Nuts 2, Turkey*

1. INTRODUCTION

Climate change, also referred to as global warming, is defined as the increasing trend of global temperatures, often manifested as shifts in temperature, precipitation and weather phenomena. These changes are primarily triggered by human activities, especially the release of greenhouse gasses. The burning of fossil fuels (coal, oil and natural gas), deforestation, industrial processes and some agricultural practices contribute significantly to these emissions. The importance of climate change lies in its widespread and profound impacts on natural and human systems. It poses risks to biodiversity, water resources, agriculture, human health and infrastructure. The Intergovernmental

Proceedings

of the International Conference on **Changing Cities VI:**
Spatial, Design, Landscape, Heritage & Socio-economic Dimensions
Rhodes Island, Greece ● June 24-28, 2024
ISSN: 2654-0460
ISBN: 978-618-5765-02-6

Panel on Climate Change (IPCC) has comprehensively documented these impacts, emphasizing the urgency of global action to mitigate and adapt to these changes. The impacts of climate change at the global level are highly diverse and spread over a wide spectrum. Some of the most notable impacts include temperature rise, sea level rise, increase in extreme weather events, biodiversity loss and water scarcity. Average global temperatures have increased in recent decades, leading to more frequent and intense heat waves. The melting of polar ice caps and the thermal expansion of seawater have caused sea levels to rise, threatening coastal communities by flooding and erosion. The frequency and severity of extreme weather events such as hurricanes, typhoons, floods and droughts have increased. The disruption of ecosystems and habitats caused by changes in climatic conditions results in species migration, population declines and extinctions. Furthermore, changes in rainfall patterns affect freshwater availability, exacerbating water scarcity in many regions. In the case of the Mediterranean Basin, these effects are more pronounced and region-specific. Temperature increases are particularly pronounced in the summer months, while the frequency of extreme heat waves has increased in the region. Sea level rise has led to serious erosion and flooding in the coastlines of the Mediterranean Sea. Furthermore, the region is experiencing more frequent and intense rainfall events and longer periods of drought due to climate change. This is resulting in biodiversity loss, which threatens sensitive ecosystems and endemic species in the Mediterranean Basin, destabilising ecosystems. There is also a pressing need to address the pressure on water resources in this region, with increasing water demand and decreasing water availability requiring serious changes in agricultural and water management policies. This puts severe pressure on water resources, negatively affecting agriculture, drinking water resources and hydropower generation. Furthermore, the rise in sea levels and coastal erosion present significant challenges to infrastructure, livelihoods and ecosystems in coastal areas. The agricultural sector is also experiencing difficulties due to changes in temperature and rainfall patterns, which are jeopardizing crop productivity and food security. In addition, the region is facing an increased frequency of natural disasters, with the rise in extreme weather events such as extreme rainfall, floods, severe storms and forest fires threatening living conditions and the sustainability of the region.

It is evident that governments and urban administrations play a pivotal role in the fight against climate change. Governments are at the vanguard of this fight through the formulation and implementation of policies and strategies. These strategies include participation in international agreements such as the Paris Agreement, the development and implementation of national policies and regulations promoting renewable energy, energy efficiency and sustainable land use. In addition, infrastructure investments such as improving water management systems and developing sustainable transport networks also have an important place. It is of the utmost importance that the general public be made aware of the causes and consequences of climate change, as well as the necessity for sustainable practices. Urban governments are also of critical importance in the mitigation of climate change, as cities are major contributors to greenhouse gas emissions and are particularly vulnerable to climate impacts. Sustainable urban planning encompasses a number of strategies, including the design of cities to reduce energy consumption and emissions, the incorporation of green spaces, and the promotion of public transport and non-motorised transport. Furthermore, resilience must be enhanced by implementing measures to safeguard urban areas against extreme weather events, improving drainage systems and constructing resilient infrastructure. It is evident that governments and urban administrations play a pivotal role in the fight against climate change. consequences of climate change, as well as the necessity for sustainable practices. Urban governments are also of critical importance in the mitigation of climate change, as cities are major contributors to greenhouse gas emissions and are particularly vulnerable to climate impacts. Sustainable urban planning encompasses a number of strategies, including the design of cities to reduce energy consumption and emissions, the incorporation of green spaces, and the promotion of public transport and non-motorised transport. Furthermore, resilience must be enhanced by implementing measures to safeguard urban areas against extreme weather events, improving drainage systems and constructing resilient infrastructure.

The objective of this scientific study is to examine Turkey's climate change policies at the national level and to analyze the alignment of these policies with regional practices at the NUTS 2 level. In this context, the initiatives carried out by the Ministry of Environment, Urbanisation and Climate Change will be given particular attention. Additionally, the study aims to assess the effectiveness of development agencies in supporting climate change resilience projects. This analysis will thus enable an in-depth examination of the extent to which national policies overlap with local-level practices and the role of development agencies in this process.

2. LITERATURE REVIEW

The Paris Agreement, which was adopted in December 2015, represents a significant international agreement that is aimed at combating climate change and its negative impacts. This framework is based on the United Nations Framework Convention on Climate Change (UNFCCC) and represents a significant advancement in global climate policy. The Paris Agreement establishes a new international legal regime with the objective of limiting the global temperature increase to below 2 degrees Celsius above pre-industrial levels during this century and of continuing efforts to limit the temperature increase to 1.5 degrees Celsius [1]. The agreement includes provisions for regular reviews, transparency and reporting, which will require countries to submit their nationally determined contributions and increase their commitments over time [2]. Furthermore, the agreement emphasises the role of climate finance, capacity building and technology transfer in supporting adaptation and mitigation efforts [3]. The Paris Agreement differs from previous climate agreements such as the Kyoto Protocol in that it adopts a more inclusive and enforceable approach, whereby countries set their own targets [4]. The Agreement aims to gradually intensify the fight against climate change by introducing a 'ratchet mechanism' that aims to periodically review and increase national commitments [5]. Furthermore, it is the first international climate agreement to mention human rights, indigenous rights and gender equality, reflecting a holistic approach to climate policy [6]. Article 15 of the Agreement establishes an adaptation mechanism with the objective of facilitating the implementation of its provisions and promoting compliance. However, the details of this mechanism are still being developed [7]. The Paris Agreement represents a pivotal shift in the governance of international climate change, with a focus on inclusive, flexible and increasingly ambitious climate action. The success of the Paris Agreement will depend on the effective implementation of its provisions, the maintenance of strong international cooperation, and the continued scaling up of national commitments.

The Mediterranean Basin is one of the regions most vulnerable to climate change. Countries in this region have developed a range of policies with the objective of mitigating and adapting to the impacts of climate change. A substantial body of scientific research has been conducted to compare the climate change policies of the countries in the Mediterranean Basin. The national adaptation policies of France, Greece, Italy and Spain were analyzed, and it was observed that these countries address coastal threats and adaptation measures from different perspectives. It can be observed that coastal protection projects are characterised by limited private sector involvement and difficulties in determining the financial resources allocated to research initiatives [8]. The Mediterranean region is experiencing a significant and increasing risk from climate change, with implications for water,

ecosystems, food, health and safety. In order to reduce these risks, it is necessary to assess the potential adaptation options available [9] [10]. The countries of the Mediterranean Basin are susceptible to the adverse effects of climate change, including rising temperatures, droughts and wildfires, which present a significant risk, particularly in terms of public health. Those countries with lower incomes and older populations are more susceptible to the adverse effects of climate change [11]. The tourism sector in the Mediterranean has demonstrated considerable resilience and adaptive capacity in the face of climate change. Although climate change has not resulted in a significant decline in tourism demand, improved welfare and economic developments have offset this decline [12]. Vector-borne diseases (VBDs) in the Mediterranean region are directly related to climate change, and adaptation and preparedness policies are of significant importance in order to prevent the spread of these diseases. The level of preparedness varies among countries in the region [13]. Mediterranean Basin countries have developed a range of adaptation and mitigation strategies to address the impacts of climate change. The strategies employed by countries in the region vary according to their specific needs and circumstances. The efficacy of implemented policies is contingent upon international collaboration and the capacity of local governments.

Although Turkey has taken important steps on climate change, it has historically been a relatively late country in global climate policies. When the historical development and current status of Turkey's climate change policies are analysed; Turkey was late in climate policies by signing the United Nations Framework Convention on Climate Change (UNFCCC) in 1992 and the Kyoto Protocol in 2009. It has shown an increase of 110.4% in greenhouse gas emissions between 1990-2013 and, unlike developed countries, has not taken binding mitigation commitments [14]. In 2016, Turkey fell short in combating climate change at national and local scale despite the early implementation of the Paris Agreement and it was emphasized that political will is a key requirement for transition to a low carbon economy [15]. Turkey's climate change policies have not been sufficiently integrated with social policies and the social impacts of climate change as well as political and economic barriers have been ignored [16]. The transition to low-carbon urban development in Turkey has accelerated with the EU accession process, but current climate policies have been insufficient to reduce greenhouse gas emissions and climate change vulnerabilities in cities [17]. Turkey's climate change policies have been analyzed with a governance approach and the mismatch between the country's economic development priorities and climate change management reduces policy effectiveness. Climate change has serious impacts on Turkey's agricultural sector and current policies may be insufficient to cope with future climate change impacts. Turkey endeavours to adopt sustainable development principles in its energy consumption and climate change policies and the use of renewable energy resources and energy efficiency should be increased [18]. Turkey's climate change policies have historically developed with a lag and still face various challenges today. Political will and international co-operation are critical for transition to a low carbon economy and effective combat against climate change.

The establishment of development agencies at the NUTS 2 level in Turkey was driven by the objective of accelerating regional development, enhancing local capacities and reducing regional development disparities. This literature review addresses the functions, importance and impacts of these agencies. The establishment of a regional governance structure in Turkey's harmonisation process with the European Union (EU) necessitated the establishment of development agencies at NUTS 2 level. A study of the case of Istanbul indicates that these agencies have a tenuous foundation from both political and economic perspectives. However, they have the potential to address significant regional economic development gaps [19]. It is important to consider the differing levels of development within NUTS 2 regions when measuring regional development performance and the balanced distribution of financial support mechanisms. Studies employing the Pythagorean Fuzzy Analytical Hierarchy Process and a TODIM-based ranking model permit the evaluation of welfare indicators in these regions [20]. A study of the Izmir Development Agency's development board indicates that

Proceedings

these boards have become dysfunctional platforms with low participation. It has been proposed that in order for development agencies to become more functional, their legal status and the structure of their organs should be re-evaluated [21]. The impact of development agencies on regional development has been evaluated in terms of geographical distribution and functionality. The establishment of development agencies in NUTS 2 regions is intended to reduce regional development disparities by mobilising local resources [22]. The effects of public investments and investment incentives on regional development have been examined. According to the fixed effects model, it has been determined that public investments have positive effects on regional development, with investments in transport and education exhibiting greater effects than other public investments [23]. The evaluations conducted on the activity reports of development agencies operating in 26 NUTS 2 regions in Turkey aim to ascertain whether these agencies are fulfilling their duties and responsibilities. The call for proposals mechanism of the agencies is considered an important component of their activities [24]. At the NUTS 2 level in Turkey, development agencies undertake a number of important functions, including the reduction of regional development disparities, the enhancement of local capacities and the acceleration of regional development. Nevertheless, the efficacy of these agencies is contingent upon a number of factors, including their legal status, the composition of their governing bodies, and the degree of local involvement.

The implementation of successful projects and initiatives in various fields in Turkey has played an important role in achieving local and national development goals. This paper analyses examples of these projects and initiatives and their success factors. A study of the success rate of projects in Turkey analysed 320 projects and found that 48% of projects were successfully completed, while 45% faced problems such as exceeding the budget, not being completed on time or not being fully completed. Among the success factors, the definition of requirements, planning of requirements and support from top management stand out [25]. The Sustainable Energy Action Plan (SEAP), implemented by a municipality in the Aegean Region of Turkey, encompasses initiatives designed to reduce carbon emissions. These projects include the implementation of zero-emission public transport, the conversion of energy-efficient buildings, and the development of smart traffic systems. It is evident that the role of top management and central government support is pivotal among the success factors [26]. A corporate foresight project conducted at Siemens Turkey included the redefinition of success factors for the better implementation of process-oriented elements and organisational changes, which was considered a success [27]. The success of urban regeneration projects in the Sulukule and Tepeüstü-Ayazma regions of Istanbul was evaluated using the analytical hierarchy process. The level of realisation of the objectives set by the actors at the beginning was used to measure the success level of the projects [28]. The green building certification process for existing buildings in Turkey was examined, and the success factors of the process were analysed by considering six LEED-certified projects. It can be argued that the commitment of owners and the support of top management are crucial factors in the success of such projects [29]. Urban regeneration projects in the Golden Horn region have been analysed in terms of the power dynamics of actors and the initiatives taken by top management, and have been successful even in cases where the participation of local communities and the private sector was limited [30]. The Information Society Strategy, Turkey's digital transformation project, has been subjected to critical analysis for its technical and methodological shortcomings, as well as for the ethical issues it has raised. Its high costs and ambitious socio-economic development goals have also attracted attention. A number of successful projects and initiatives in Turkey have achieved notable success in a variety of fields. Among the factors that have contributed to the success of these projects, it can be observed that accurate identification of needs, top management support, process-oriented approaches and the participation of local actors have played a significant role. These examples of success can also be instructive for future projects.

3. METHODOLOGY

Proceedings

The methodology of this study employs a variety of data collection sources to investigate the impact of the renaming of the Ministry of Environment and Urbanisation as the Ministry of Environment, Urbanisation and Climate Change on the policies of development agencies at the NUTS 2 level in Turkey. The principal data sources to be employed in this context are as follows: Government reports will be utilized as a significant data source within the context of the research. The reports in question provide a comprehensive account of the government's policies, strategies and practices in relation to the environment, urbanisation and climate change. Furthermore, the reports of the Ministry of Development and other relevant ministries will be analysed in this context. At the NUTS 2 level, development agencies produce a plethora of reports and publications pertaining to local and regional development. The annual activity reports, strategy documents, project reports and evaluation documents of these agencies are of critical importance in the data collection process of the research. These publications provide detailed information on the measures taken by the agencies regarding climate change at the local level, the projects they implement and the impacts of these projects. Articles and theses published in academic journals are important data sources that will strengthen the scientific basis of the research. The findings of studies conducted by universities and research institutions in Turkey will be employed to analyse the alterations in the climate change policies of development agencies and the consequences of these alterations. In this context, the relevant literature will be analysed by searching national and international academic databases. The objective of this study is to compare and evaluate the climate change policies in Turkey with international standards. The integration of these disparate data sources will permit the Ministry of Environment, Urbanisation and Climate Change to conduct a comprehensive and in-depth analysis of the impact of the name change on the policies of development agencies at the NUTS 2 level.

The study employs a range of data collection techniques to examine the impact of the renaming of the Ministry of Environment and Urbanisation as the Ministry of Environment, Urbanisation and Climate Change on the policies of development agencies at NUTS 2 level. The selection of these methods enables the research to conduct a comprehensive and in-depth analysis. Document analysis represents one of the principal data collection methods employed in the research. This involves a systematic review and analysis of a range of written documents. The documents will be subjected to a detailed analysis in order to ascertain the extent to which the change in the name of the ministry has resulted in alterations to the policies and practices of development agencies.

Following the renaming of the Ministry of Environment and Urbanisation as the Ministry of Environment, Urbanisation and Climate Change, an assessment has been conducted of the changes in the policies of development agencies at NUTS 2 level. A framework for evaluation will be developed in order to ascertain the impact of these changes on the alignment between national policies and regional projects. This framework will facilitate a comprehensive and reliable analysis of the data, thereby ensuring the accuracy and reliability of the findings.

The document provides an overview of the main policy areas, major projects, budgets and details of development agencies in Turkey. The work of development agencies in various fields, including energy efficiency, renewable energy, sustainable urbanism, and the budgets allocated to these projects, demonstrates their contribution to local and national development goals.

Development Agency	Main Policy Areas	Important Projects	Project Budget and Details
---------------------------	--------------------------	---------------------------	-----------------------------------

Istanbul Development Agency (ISTKA)	Green Economy, Smart Technologies, Education	Green Transformation Training Programmes	Cooperation with MoNE, curriculum development on ecology, waste separation, climate change in schools, no budget details given yet.
Izmir Development Agency (IZKA)	Spatial Planning, Disaster Management, Green Transformation	Wind Energy Meteorology and Environmental Conditioning Test Analysis Centre (RÜZMER), Industrial Symbiosis Project	RÜZMER: 384 million TL, Izmir Industrial Symbiosis Project: industrial waste reduction and improving supply chain relationships, Geothermal Resource Utilisation Project: no budget given.
South Marmara Development Agency	Renewable Energy, Green Hydrogen	Youth Energy Wind Energy Project, Renewable Youth Energy Project, HYSouthMarmara Project	Youth Energy: 350 thousand Euro, Renewable Youth Energy: 8 million Euro, HYSouthMarmara: 368 million Euro, South Marmara Hydrogen Coast Project: 20 million TL.
South Aegean Development Agency (GEKA)	Digitalisation, Efficiency, Disaster Resilience	Digitalisation in production, green transformation, disaster resilience projects	2023 Technical Assistance Programme: total budget 15 million TL, 100 thousand TL per activity.
Ankara Development Agency	Energy Efficiency, Water Management, Sustainable Agriculture	Climate Change Action Plan, Reduction of Electricity Distribution Losses	Climate Change Action Plan: no details given, Reducing Electricity Distribution Losses: increasing energy efficiency, reducing industrial emissions.

Mevlana Development Agency	Sustainable Agriculture, Renewable Energy, Smart Agriculture	Smart Agriculture Programme, Rooftop SPP Dissemination Programme	Smart Agriculture Programme: 30 million TL, Rooftop SPP Dissemination Programme: 15 million TL, Environmental Symbiosis Project in Marble Sector: 55 million TL.
Cukurova Development Agency	Green Growth, Agricultural Water Management, Energy Efficiency	Climate Change Adaptation Projects, Analysis of Agricultural Irrigation Infrastructure	Seyhan Basin Climate Change Adaptation Projects: no details provided, Adana Agricultural Irrigation Infrastructure Analysis: no details provided.
Western Mediterranean Development Agency	Medicinal and Aromatic Plants, Alternative Tourism, Entrepreneurship	There are no direct projects related to Climate Change	Projects focused on Medicinal and Aromatic Plants, Alternative Tourism, Entrepreneurship, Climate change is not emphasised in the 2018-2024 Regional Plan.
Euphrates Development Agency	Circular Economy, Sustainable Agriculture, Energy Efficiency	Treatment Plant of Malatya 1st OIZ, Smart Energy Monitoring System	Treatment Plant of Malatya 1st OIZ: no details given, Smart Energy Monitoring System: no details given.
Silk Road Development Agency	Agricultural Resilience, Water and Soil Conservation	TRC1 Region Agriculture Climate Change Resilience Programme	TRC1 Region Agriculture Climate Change Resilience Programme: water resources and soil protection, soil quality improvement projects, no details given.

Figure 1. Projects and policies of development agencies in Turkey

These criteria allow for a comprehensive assessment of the effectiveness of development agencies' initiatives. In this way, the extent to which changes in the policies of development agencies at NUTS 2 level following the name change of the Ministry of Environment, Urbanisation and Climate Change and their impact on regional development can be better understood.

Proceedings

4. RESULTS AND DISCUSSION

Turkey's approach to combating climate change has undergone a significant transformation with the renaming of the Ministry of Environment, Urbanization and Climate Change. This section will analyse Turkey's national climate change policies, key policies and strategic plans of the Ministry, and assess the implementation of these policies at the regional level. The Ministry has prepared a number of strategic plans and action plans, including the Climate Change Action Plan, the National Climate Strategy and Action Plan (2010-2023), and the Sustainable Development Goals. The aforementioned plans include targets to reduce carbon emissions, enhance energy efficiency, and adapt to climate change. It is evident that regional development agencies play a pivotal role in the implementation of national policies at the regional level, which has resulted in a notable shift in the policy priorities and strategies of the agencies. Agencies contribute to combating climate change at the local level by developing projects such as energy efficiency, the use of renewable energy resources, urban transformation and green building practices. Nevertheless, obstacles such as a lack of financial resources, a lack of capacity within local administrations and a low level of public awareness may hinder the effective implementation of policies. While successful projects and exemplary practices contribute to the effective implementation of national policies at the regional level, the shortcomings encountered in policy implementation necessitate the development of more effective strategies. In this regard, it is imperative to implement improvements in key areas such as the more efficient utilisation of resources, the enhancement of local capacity and the elevation of public awareness. The projects supported by development agencies are largely in alignment with national climate change policies and make a significant contribution to sustainable development and the mitigation of climate change at the local level. Nevertheless, further enhancements are required in the areas of inadequate resources, lack of capacity, and deficiencies in monitoring and evaluation processes. These recommendations will facilitate the enhancement of the efficacy and sustainability of the policies and projects of development agencies. The aforementioned analyses and assessments will assist in elucidating the nature of the alterations that have been implemented in the policies and strategies of development agencies at the NUTS 2 level in Turkey subsequent to the renaming of the Ministry of Environment, Urbanisation and Climate Change and the repercussions of these modifications on regional development.

5. CONCLUSION AND RECOMMENDATIONS

This analysis demonstrates the alterations in the policies and initiatives of development agencies at the NUTS 2 level subsequent to the renaming of the Ministry of Environment, Urbanisation and Climate Change. The projects of development agencies are generally aligned with national climate change policies and make a notable contribution to sustainable development and the mitigation of climate change at the local level. Nevertheless, there is a need for improvement in several areas, including the availability of resources, the capacity to implement projects, and the effectiveness of monitoring and evaluation processes.

In light of these observations, the following recommendations can be put forth: It is recommended that strategic planning and management processes be developed in order to ensure the effective use of financial and human resources. Training programmes and capacity-building activities should be implemented to enhance the capacity of local governments and development agencies. It is recommended that monitoring and evaluation processes of projects be strengthened in order to enhance the success and sustainability of projects. The implementation of these recommendations will facilitate the enhancement of the efficacy and sustainability of the policies and projects of development agencies.

This section will present a comparative analysis of climate change resilience in different NUTS 2 regions of Turkey. It will identify the regions that are most and least vulnerable to climate change adaptation. The impact of the renaming of the Ministry of Environment, Urbanisation and Climate

Change on the implementation of regional development policies will be evaluated. The Marmara Region is the most densely populated and industrialised region of Turkey, and climate change mitigation and adaptation projects are intensively implemented, particularly in Istanbul and its surrounding cities. The region's strengths include an abundance of economic resources, the prevalence of innovative technologies and sustainable urbanisation practices. However, it is also susceptible to pressures on infrastructure and natural resources due to high population density and rapid urbanisation. The Aegean Region is a region where the agricultural and tourism sectors are of significant importance, and development agencies focus on water management and energy efficiency projects. The region's strengths include the high potential for solar and wind energy and the prevalence of sustainable tourism projects. However, weaknesses include limited water resources and the increasing risk of water scarcity due to climate change. The Mediterranean region is particularly susceptible to the effects of climate change, with agriculture, tourism and water resources playing a pivotal role. The region's strengths include a high solar energy potential and tourism revenues. However, its weaknesses include high temperatures, drought risk and vulnerability to forest fires. Central Anatolia is a region where agriculture and animal husbandry are particularly intensive, and water management and sustainable agriculture projects are of great importance. The region's strengths include the adoption of innovative practices in agriculture and animal husbandry. However, limited water resources and the risk of soil erosion represent its weaknesses. The Black Sea region is characterised by high rainfall and extensive forested areas, and the implementation of water management and flood control projects is of significant importance. While the region is characterised by abundant water resources and forested areas, it is also susceptible to flood and landslide risk, as well as limited agricultural areas. The Eastern and Southeastern Anatolia Regions are among the least developed regions of Turkey and are highly vulnerable to the impacts of climate change. Development agencies have identified sustainable development and climate change adaptation projects as key priorities in these regions. While the potential of renewable energy resources is among their strengths, insufficient economic resources, infrastructure deficiencies and socio-economic difficulties are among their weaknesses.

Following the renaming of the Ministry of Environment, Urbanisation and Climate Change, the principal findings of the analysis of the alterations to the policies of development agencies at NUTS 2 level in Turkey will be presented, and the efficacy of development agencies in supporting climate change resilience will be evaluated. In light of the fundamental information obtained from national policies and regional practices, national climate change policies have established clear targets in areas such as energy efficiency, renewable energy use, sustainable urbanism and urban transformation. These targets are largely in alignment with the strategies and projects of development agencies at NUTS 2 level. The projects implemented by development agencies were designed and implemented in accordance with the strategies set by national policies, with the objective of contributing to national targets by taking into account local needs and conditions. The Marmara, Aegean and Mediterranean regions are notable for their resilience to climate change, due to factors such as their abundance of economic resources, use of innovative technologies and sustainable urbanisation practices. In contrast, the Eastern and Southeastern Anatolia regions are more vulnerable, due to a lack of economic resources, infrastructure deficiencies and socio-economic challenges. The implementation of development agencies' projects in areas such as energy efficiency, renewable energy projects and sustainable urbanisation practices has resulted in notable success in increasing environmental sustainability and combating climate change. The encouragement of local participation and the fostering of co-operation have enhanced the effectiveness and sustainability of the aforementioned projects. Nevertheless, the lack of adequate resources and the absence of capacity in certain regions have negatively affected the effectiveness of the projects. Furthermore, deficiencies in monitoring and evaluation processes have reduced the success and sustainability of the projects. While development agencies demonstrated efficacy in financing and managing projects, limitations in

financial and human resources in certain regions constrained the success of these initiatives. Agencies have encouraged the participation of local stakeholders in the projects and increased national and international cooperation in order to ensure that the projects are appropriate to local needs and sustainable. They have increased environmental and economic sustainability by using innovative technologies and sustainable practices. However, deficiencies in monitoring and evaluation processes have negatively affected the success of the projects. The findings of this study demonstrate that there have been significant alterations in the policies and projects of development agencies subsequent to the renaming of the Ministry of Environment, Urbanisation and Climate Change. It is evident that development agencies have achieved considerable success in combating and adapting to climate change at the regional level by developing projects in alignment with national climate change policies. Nevertheless, further enhancements are required in areas such as inadequate resources, lack of capacity, and deficiencies in monitoring and evaluation processes. In light of these findings, it is recommended that strategic planning and management processes be developed to ensure the effective use of financial and human resources. Training programmes and capacity-building activities should be organised to enhance the capacity of local governments and development agencies. Furthermore, monitoring and evaluation processes of projects should be strengthened to enhance the success and sustainability of projects. The implementation of these recommendations will facilitate the enhancement of the efficacy and sustainability of the policies and projects of development agencies. This section presents recommendations for enhancing the alignment between national policies and regional projects, as well as strengthening the role of development agencies, in line with the changes in the policies of development agencies at NUTS 2 level following the name change of the Ministry of Environment, Urbanisation and Climate Change. In order to facilitate the implementation of national climate change policies and strategies at the regional level, it is recommended that there should be closer coordination between development agencies and the Ministry. Furthermore, the establishment of joint working groups and advisory boards would be beneficial. This will ensure the more effective implementation of national policies at the local level and the alignment of regional projects with national strategies. It is recommended that regional development agencies conduct comprehensive analyses to identify local needs and priorities and develop projects in accordance with the findings. Consequently, the relevance of projects to local conditions will be enhanced, thereby ensuring more effective implementation of national policies at the regional level. It is recommended that monitoring and evaluation processes of projects be standardised and regularly applicable. This can be achieved by determining performance indicators and success criteria at both national and regional levels. This will enhance the efficacy and longevity of projects and guarantee the acquisition of the requisite data to gauge the efficacy of national policies. It is recommended that the financial and human resources capacities of development agencies be increased. In this context, additional budget allocations should be made, and agencies should be provided with training programmes. It is of the utmost importance that agencies address any deficiencies in their resources and capacities if they are to plan and implement projects in an effective manner. It is recommended that development agencies develop stronger cooperation with local administrations, civil society organisations, universities and the private sector. This will positively affect the success and sustainability of projects and accelerate regional development. It is recommended that support be provided to renewable energy projects, smart city applications and sustainable agricultural methods in order to promote the development of innovative technologies and sustainable practices. The encouragement of such projects will serve to enhance regional resilience. It is recommended that regular meetings, workshops and training programmes be organised to encourage knowledge and experience sharing among development agencies. Furthermore, successful projects and good practice examples should be shared with other regions. The recommendations set forth herein offer important steps to enhance the effectiveness and sustainability of development agencies' policies and projects in the wake of the renaming of the Ministry of Environment, Urbanization and Climate Change. It is of the utmost

Proceedings

of the International Conference on **Changing Cities VI:**
Spatial, Design, Landscape, Heritage & Socio-economic Dimensions

importance that there be greater coherence between national policies and regional projects, and that the role of development agencies be strengthened, if Turkey is to combat climate change and achieve its sustainable development goals.

This section will examine the implications of the changes in the policies of Turkey's development agencies at NUTS 2 level following the renaming of the Ministry of Environment, Urbanisation and Climate Change for other Mediterranean Basin countries. It will also consider how these findings can be applied in other countries in the region. The integration of Turkey's national policies and regional projects has been demonstrated to be an effective approach in combating climate change. The implementation of harmonised projects at the regional level, which are aligned with national objectives, enhances the strategic success of initiatives. This approach can be adopted by other Mediterranean countries, enabling them to develop effective solutions that are appropriate to local needs. The involvement of local stakeholders in development projects has been shown to enhance the success of such initiatives. This approach could be replicated in other Mediterranean countries, thereby facilitating the formation of a broader support base and enhancing the effectiveness of projects at the local level. The advancement of initiatives in the domains of energy efficiency, renewable energy, and smart urbanisation, through the utilisation of innovative technologies and sustainable practices, can serve as a valuable exemplar for other Mediterranean countries, offering potential avenues for replication. The strengthening of monitoring and evaluation processes has led to an increase in the effectiveness and sustainability of projects. The standardisation of these processes could similarly lead to an increase in the success of projects in other Mediterranean countries. The projects implemented by Turkey in different regions have been adapted to local needs and conditions, and it is recommended that other Mediterranean countries should also adapt their projects by taking into account local needs. Turkey's endeavours to integrate sustainable development goals and climate change policies can enhance environmental and economic sustainability by serving as a model for other Mediterranean countries. The endeavours to augment national and international collaboration have demonstrably enhanced the efficacy and longevity of the projects. These collaborations can be emulated by other Mediterranean countries. These lessons and recommendations can assist other Mediterranean Basin countries in developing more effective policies and projects to combat and adapt to climate change. Furthermore, the insights gained from

Turkey's experience present valuable opportunities to build more sustainable and resilient societies at the regional level.

Abstract

The objective of this paper is to evaluate the aesthetics of streetscapes characterized by buildings with different heights and front setbacks, and distinct levels of order and visual stimulus, by three groups of people with different levels and types of educational background. Although some studies have been made about the aesthetics of streetscapes, there is a need to deepen the existing knowledge, mainly, regarding aesthetic evaluations of these streetscapes by such groups of people.

Questionnaires available in the LimeSurvey software via the Internet, included nine streetscapes scenes in three sets and were answered by 250 people as follows: 62 architects, 169 non-architects college graduates and 19 non-college graduates. Non parametric statistical tests such as Kruskal-Wallis and Kendall W were used to analyze the data.

Results show, for example, that streetscape scene characterized by order and visual stimulus is clearly preferred, mainly due to similarity between buildings heights, colours and forms, and presence of clear visual stimulus. On the other hand, the scene characterized by disorder is visibly the least preferred by architects and by non-architects college graduates, mainly due to differences between buildings heights, colours and forms, and the absence of clear visual stimulus.

Keywords: *aesthetics of streetscapes; building height; building front setback; order and visual stimulus.*

1. INTRODUCTION

The importance of aesthetics of streetscapes has been mentioned by many authors and has been corroborated by many studies carried out in different cities and countries [1; 2; 3; 4; 5; 6]. The aesthetic evaluation is part of empirical aesthetics, which assumes that it is possible to evaluate, for example, a streetscape, to find generalizations and to understand the reasons for such evaluation based on a streetscape features [7], contrary to philosophical aesthetics which assumes that beauty is in the eyes of the beholder and, therefore, that aesthetic evaluations depend on each person's taste, are not subject to generalizations and cannot be objectively explained [7].

Although studies have shown that 'beauty is much more on the perceived object than in the eyes of the beholder' [e.g., 8], teaching of architecture and urbanism, regardless of the school and country, tends to favour the approach of philosophical aesthetics. This has generated architectural projects and urban interventions that disregard research results on urban aesthetics. This is the case of streetscapes characterized by tall buildings that tend to block or reduce pedestrians' views of the sky and to provoke less satisfactory aesthetic response by people in comparison to lower buildings that allow for a greater view of the celestial dome [9].

Moreover, disregarding the great importance of the ground floor in the relationship between the building and the street [10; 11], buildings set back, without a direct relationship with the street, as it is generally the case with buildings in modernist site layouts, tend to generate less pleasant urban experiences, due to lower visual stimulus, than buildings close to the front alignment of the lots [10; 12; 13]. Furthermore, studies involving empirical aesthetics have shown that buildings with order and

visual stimulus are preferred over those with disorder or with no visual stimulus like a blind wall or a wall with no openings [e.g., 8].

In addition, it is important to understand the aesthetic evaluations by people with different levels and types of educational background. In this respect, some apparently contradictory results still exist. Some of these results show that architects' aesthetic evaluations tend to be different from lay people's evaluations [14; 15]. For example, the best aesthetically evaluated houses by architects were the ones worst rated by other professionals and vice versa, in an evaluation of 40 houses [15]. Other results show that architects' aesthetic evaluations are clearly positive and tend to be similar to those of non-architects college graduates and non-college graduates when there is order and stimulus and that the differences tend to be visible in relation to a greater appreciation of the idea of order by architects and a greater appreciation of visual stimulation by non-architects [8]. Therefore, there is a need to produce new findings through studies in the area of empirical aesthetics to better substantiate existing results.
