**Objectives:** The present study investigate the sleep status of patients on the first night in the postoperative ICU using modern wearable wristbands and RCSQ questionnaires to quantitatively assess the impact of TOS and MIS modes on postoperative sleep status.
**Methods:** A single-center observational study was performed (Ethic Approval:KY2022-145-A). Sixty-one post-anesthesia patients who were successfully resuscitated were enrolled. Surgical characteristics were obtained. The sleep status on the night of surgery was assessed by the patient- and nurse-completed RCSQ and Huawei (HW) wearable sleep monitoring wristband.
**Results:** Compared to the TOS group, patients in the MIS group had higher nurse-RCSQ score ($60.9 \pm 16.9$ V.S. $51.2 \pm 17.3$, $p = 0.030$), self-RCSQ sleep score ($58.6 \pm 16.2$ V.S. $49.5 \pm 14.8$, $p = 0.027$), and HW sleep score ($77.9 \pm 4.5$ vs. $68.6 \pm 11.1$, $p < 0.001$) (Figure 1). The Bland–Altman plot showed that the HW sleep score was in good consistency with the patient-RCSQ score (95.1%) and nurse-RCSQ score (96.7%) (Figure 2). HW quantitative sleep analysis showed the minutes of total sleep ($503.0 \pm 91.4$ V.S. $437.9 \pm 144.0$, $p = 0.037$), rapid eye movement (REM) sleep ($81.0 \pm 52.1$ V.S. $55.8 \pm 44.5$, $p = 0.047$) were longer and the deep sleep continuity score (56.4, IQR: 7.0 versus 47.5, IQR: 12.1, $p = 0.001$) was higher in the MIS group compared with the TOS group (Table 1).

**Table 1 (abstract 000605)** Huawei quantitative sleep analysis

| Variables | Minimally invasive surgery ($n = 28$) | Traditional open surgery ($n = 33$) | *p* value |
|---|---|---|---|
| Total Sleep time (min, SD) | 503.0 (91.4) | 437.9 (144.0) | 0.037 |
| Deep sleep time (min, SD) | 145.7 (55.6) | 125.6 (79.7) | 0.254 |
| Light sleep time (min, SD) | 282.0 (92.3) | 255.1 (94.5) | 0.268 |
| REM sleep time (min, SD) | 81.0 (52.1) | 55.8 (44.5) | 0.047 |
| Deep sleep ratio (%, IQR) | 29.7 (7.8) | 27.2 (12.4) | 0.332 |
| Light sleep ratio (%, IQR) | 55.8 (11.2) | 61.1 (17.0) | 0.149 |
| REM sleep ratio (%, IQR) | 14.5 (6.9) | 11.7 (7.3) | 0.128 |
| Deep sleep continuity score (IQR) | 56.4 (7.0) | 47.5 (12.1) | 0.001 |
| Awakening frequency (IQR) | 2.4 (2.0) | 2.5 (2.3) | 0.868 |

SD: standard deviation. IQR: interquartile range

**Conclusions:** MIS, compared with TOS, contributed to higher sleep quality for ICU patients after surgery, manifested as longer sleep time, longer REM sleep time, and better continuity of deep sleep. Wearable sleep monitoring wristbands hold the potential for quantified sleep assessment and tailoring perioperative sleep management strategies in the surgery ICU.

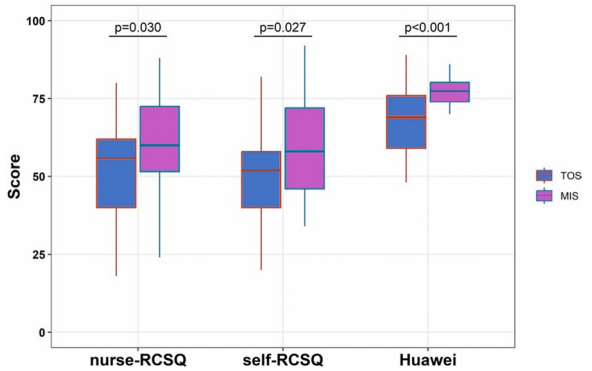

**Fig. 1 (abstract 000605)** The self-RCSQ, nurse-RCSQ and Huawei sleep scores. Boxplots display the median (center line), interquartile range (IQR) (upper and lower hinges) of self-RCSQ (a), nurse-RCSQ (b), and Huawei (c) sleep scores

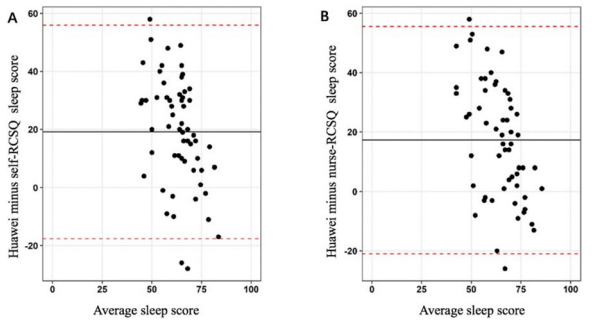

**Fig. 2 (abstract 000605)** The Bland–Altman analysis between Huawei and RCSQ sleep scores. A horizontal line was drawn at the mean difference and at the mean difference plus and minus 1.96 times the standard deviation of the differences, with the x-axis reporting average levels of sleep scores. (a) Huawei sleep monitoring wristband versus self-RCSQ assessment of total sleep score. (b) Huawei sleep monitoring wristband versus self-RCSQ assessment of total sleep score

## 000607 The clinical usefulness of GLS, MAPSE and S´ in critically ill patients

O. Cavefors[1], O. Bech-Hanssen[2], R. Björn[3], J. Oras[1]
[1]Anesthesiology and Intensive Care Medicine, Sahlgrenska University Hospital, Gothenburg, Sweden; [2]Deptartment of Clinical Physiology, Sahlgrenska University Hospital, Gothenburg, Sweden; [3]Department of Cardiology, Sahlgrenska Universitetssjukhuset, Gothenburg, Sweden
**Correspondence:** J. Oras
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000607

**Introduction:** Left ventricular ejection fraction (LV EF) is the most common echocardiographic parameter for assessing LV systolic function but is limited by dependence on loading conditions. Other parameters related to LV longitudinal function as global longitudinal strain (GLS), mitral valve annular plane excursion (MAPSE), and tissue Doppler annular velocities (S´). These are less dependent on loading conditions, still the PRICES statement [1] report that there are insufficient data on their clinical usefulness.
**Objectives:** The aim of this study was to assess the clinical usefulness of GLS, MAPSE, and S' by assessing their feasibility and possible associations with mortality at 90 days in a mixed population of critically ill patients.
**Methods:** This is a secondary analysis of a study assessing LV dysfunction defined by LV EF and regional wall motion abnormalities in a mixed population of critically ill patients [2]. All included patients had echocardiography performed in accordance with current guidelines within 24 h from admission. Clinical data was recorded on admission and at the time of echo. Three apical LV views (A4C, A2C, PLAX) were used to measure GLS. MAPSE and S´ were measured in the A4C view, using the mean value of the measurements in the septal and lateral side. LV EF was estimated using the Simpsons method. Patients were sub-grouped for specific conditions, i.e., those with (1) a history of or acute ongoing cardiac disease, (2) admission with sepsis, or (3) none of the above.
**Results:** A total of 411 patients were included in the parent study of whom 377 patients had any measurement of GLS, MAPSE or S'. MAPSE was measured in most patients ($n=364$, 88%) followed by S´($n=339$, 82%) and GLS ($n=269$, 65%). Ejection fraction was successfully measured with the Simpson method in 320 (78%). Using Pearson's test, there was a positive correlation between LV EF and GLS (0.718), LV EF and MAPSE (0.520), and LV EF and S´(0.444). Patients with cardiac disease ($n=61$) had lower values in all parameters (LV EF, GLS, MAPSE, S´) compared to patients without these conditions ($n=221$), while patients with sepsis ($n=118$) had lower values in GLS, MAPSE and S´ (Table 1) compared with other. The lowest values in all parameters were in patients with cardiac disease.
At 90 days, 101 patients (27%) had died. Mortality over 90 days was higher in patients with GLS > -15%, MAPSE < 10 mm, and S´< 7.5 (Figure 1). In a logistic regression analysis with adjustments for the SAPS 3 score, age, and the specific conditions of cardiac disease and sepsis, GLS was associated with an increased risk of death (OR 0.89, $p=0.006$), as was MAPSE (OR 0.11, $p<0.001$) and S´ (OR 0.85, $p=0.005$). In contrast, LV EF was not associated with an increased risk of death (OR 0.99, $p=0.369$).

**Table 1 (abstract 000607).**

| | Sepsis, $n=118$ | Cardiac disease, $n=58$ | Other, $n=221$ |
|---|---|---|---|
| Ejection fraction, % | 57 ± 13 | 48 ± 16* | 59 ± 12 |
| GLS, % | −15.0 ± -4.5* | −12.3 ± -5.1* | −17.6 ± −5.0 |
| MAPSE, mm | 11 (9–12)* | 9 (8–12)* | 13 (11–15) |
| S´, cm/s | 8 (7–10.5)* | 7 (4.5–9)* | 9 (7–11) |

*$p < 0.05$ after Bonferroni correction vs group Other

**Conclusions:** In conclusion, the echocardiographic parameters GLS, MAPSE and S´are clinically useful for assessing LV function in critically ill patients. Prognostication seems to be superior to LV EF. MAPSE appears to be the most useful of these three, being easily measured and were strongly associated with mortality after risk-adjustments.

**Introduction:** While several studies have found that excessive fluid administration can contribute to the development of cerebral edema and worsen neurological outcomes in brain-injured patients, there are limited reports of an association between fluid accumulation and neurological outcomes in patients with out-of-hospital cardiac arrest (OHCA) receiving extracorporeal cardiopulmonary resuscitation (ECPR).
**Methods:** We conducted a sub-analysis of the multicenter observational cohort SAVE-J II study, including adult OHCA patients who received ECPR between 2013 and 2018 and survived for at least 3 days. Patients who received renal replacement therapy were excluded. The cumulative fluid balance (CFB) was defined as the difference between total infusion volume excluding blood transfusions and urine volume during the first 3 days of hospitalization divided by body weight on admission, and patients were classified into large CFB and small CFB groups based on the median CFB value. The primary endpoint was the neurological status at 30 days (Cerebral Performance Category [CPC], scores range from 1 to 5, with higher scores indicating greater disability). The relationship between CFB and neurological outcomes was investigated using propensity score matching and ordinal logistic regression analysis, adjusting for factors that may be related to neurological outcomes.
**Results:** The study included 488 patients with a mean age of 57 years, of whom 82.6% had a witnessed arrest, 58.2% received bystander CPR, 79.1% had a first documented rhythm of VF/VT, and the median times from emergency call to EMS arrival, EMS arrival to hospital arrival, and hospital arrival to ECMO initiation were 7, 25, and 27 min, respectively. Acute coronary syndrome was identified as the cause of cardiac arrest in 51.6%, and 91% underwent targeted temperature management after ECPR initiation. At 30 days, the neurological outcomes were as follows: CPC 1, 22.7%; CPC 2, 8.4%; CPC 3, 9.0%; CPC 4, 19.3%; and CPC 5, 40.6%. The median CFB was 107 mL/kg, with 244 patients classified into the large CFB group and 244 patients into the small CFB group. After propensity score matching, 179 patients were selected in each group, and a shift in the distribution of scores on CPC toward worse outcomes was observed in favor of the large CFB group over the small CFB group (generalized odds ratio 0.55, 95% CI 0.37–0.82).
**Conclusions:** Fluid accumulation after ECPR initiation may worsen neurological outcomes. Prospective studies should investigate whether a restrictive fluid strategy improves neurological outcomes in ECPR patients.

### Predictors of the ICU admission in trauma patients referred to trauma level I center in southern of Iran

M. Yadollahi[1], R. Fanaei[1], P. Fazeli[1], G. Sabetian[2]
[1]Trauma research center, Shiraz University of Medical Sciences, Shiraz, Islamic Republic of Iran; [2]Dept. of Critical Care Medicine, Trauma Research Center, Shiraz University of Medical Sciences, Shiraz, Islamic Republic of Iran

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000612

**Introduction:** Trauma is one of the underlying causes of hospitalization, disability, and mortality across the world, accounting for one-tenth of causes of mortality around the world, in particular, in Low and Middle-Income Countries (LIMCs) (1). Not only does trauma diminish the disability-adjusted life years (DALY) in different societies, but it also can directly and indirectly impose huge burden of socio-economic challenges on the healthcare system and people, which includes treatment costs, reduced productivity, disabilities, and depriving family of income during hospital length of stay (2).
According to the World Health Organization (WHO) classification, Iran is regarded as a middle-income less-developed country, encountering a high mortality and morbidity rate, which results from trauma. It is estimated that trauma-related mechanism of injuries is the second cause of death following cardiovascular diseases (3). Thereby, patients with traumatic injuries are required to be admitted in the ICU. Previous investigations have reported several factors including anatomical, physiological and clinical variables may be considered as the predictors for the ICU admission in trauma patients (4).
Hence, the purpose of the current study is to recognize and determine the required predictors for the intensive care unit (ICU) admission among trauma patients referred to Rajaee (Emtiaz) hospital, trauma level I center, in southern of Iran.
**Objectives:** Trauma is accounted for the fourth and fifth leading causes of morbidity and mortality around the world. The purpose of the current study is to recognize and determine the required predictors for the intensive care unit (ICU) admission among trauma patients referred to Rajaee (Emtiaz) hospital, a trauma level I center, in southern of Iran.
**Methods:** This is a single-center cross-sectional study that evaluates the predictor factors for ICU admission in patients with trauma. The study population included 6801 trauma patients who had referred to the largest trauma center in southern Iran, (Shiraz, Iran) between January 2023 to February 2024. The injured patients under the age of 15 years were excluded from the study.
Data were extracted from patients' records using a case report form, which includes the age, gender, length of hospitalization, ICU length of stay Injury severity score (ISS) was calculated according to the researchers' previous article (5). The first values of the Glasgow coma scale (GCS), systolic blood pressure (SBP), respiratory rate (RR), percent of saturated $O_2$, and the outcome of traumatic patients were collected by the trained specialist when the patient was admitted to the hospital. Chi-square and quantitative independent *t*-test data were used to analyze the qualitative data. Odds Ratios (ORs) and 95% Confidence Intervals (CIs) were calculated to evaluate the strength of any association. Logistic regression was used to determine the predictor factors for ICU admission among traumatic patients. Analyzes were also performed using SPSS software version 25.
**Results:** The mean age of 6801 traumatic patients included in this study was $41.3 \pm 20.57$. There was a significant difference between patients admitted and non-admitted to the ICU ($44.59 \pm 22.89$ vs. $40.53 \pm 19.92$, $P = 0.0001$). Male patients mostly constituted the study traumatic (78.6%) and ICU-admitted patients (77.3). Moreover, ICU-admitted patients substantially had a lower R.R, SO2, SBP and GCS in comparison with non-admitted patients, respectively ($16.81 \pm 5.03$ vs. $16.64 \pm 3.36$, $P = 0.0001$), ($92.85 \pm 6.1$ vs. $95.4 \pm 21.09$, $P = 0.031$) and ($12.73 \pm 3.71$ vs. $14.91 \pm 0.85$, $P = 0.0001$). While the mean of ISS, hospital length of stay and the mortality rate in ICU admitted patients were drastically higher than non-admitted patients, respectively ($15.27 \pm 10.62$ vs. $6.46 \pm 5.06$, $P = 0.0001$), ($11.27 \pm 11.71$ vs. $3.99 \pm 5.27$, $P = 0.0001$), ($6.84 \pm 8.46$ vs. $0.1 \pm 0.01$, $P = 0.0001$) and (12.3% vs. 0.4%, $P = 0.0001$).
**Conclusions:** Our study suggests that systolic blood pressure, Glasgow coma scale and Injury severirty score can be considered as chief predictors for trauma patients to admit in ICU.

### Hospital and 1-year mortality rates and risk factors in ICU survivors with solid malignancies: a single-center retrospective cohort study.

S. Y. Lee, J. W. Huh, S. B. Hong, C. M. Lim, J. H. Ahn
Department of pulmonary and critical care medicine, Asan Medical Center, Seoul, Republic of Korea
**Correspondence:** L. Su Yeon
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000613

**Introduction:** Patients with solid malignancies represent a significant proportion of intensive care unit (ICU) admissions. Their ICU mortality rates have decreased due to advances in critical care. However, there is a lack of studies on the in-hospital and 1-year mortality among ICU-survived patients with solid malignancies. This study aimed to identify in-hospital and 1-year mortality rates and risk factors at the time of ICU discharge.
**Methods:** In this retrospective cohort study, adult patients with solid malignancies admitted to the medical ICU in a tertiary hospital between 2016 and 2022 were analyzed. Patients who survived and were discharged from the ICU were included. Patients were excluded if they died in the ICU, were transferred from the ICU to another hospital, or stayed in the ICU for only 1 day for monitoring or postoperative care.
**Results:** Of the 708 patients who survived in the ICU, 24.4% ($n = 178$) died in the hospital and 61% ($n = 432$) died within 1 year. At the time of ICU discharge, 20.9% of patients had delirium, 3.8% had coma, and 80.6% had impaired mobility. Oxygen device was used in 88.7%, including bilevel positive airway pressure (BiPAP) in 4.9% and high-flow nasal cannula (HFNC) in 15.5%. Delirium (OR 1.8, $p = 0.018$), coma (OR 6.87, $p < 0.001$), limited mobility (OR 2.36, $p = 0.016$), and use of any oxygen device (OR, from 3.8 to 26.6; all $p < 0.01$) at ICU discharge were significant risk factors for in-hospital mortality. The 1-year survival rate was significantly lower in patients with delirium (35%), coma (26%, $p < 0.001$), or limited mobility (37%, $p = 0.003$). Patients who received oxygen therapy with BiPAP had the lowest survival rate at 23% ($p < 0.0001$).
**Conclusions:** In our study, a considerable portion of ICU-survived patients with solid malignancies died in the hospital and within 1 year after ICU discharge. Mental impairment, mobility impairment, and remaining pulmonary dysfunction at ICU discharge were strong risk factors for in-hospital and long-term mortality. These conditions may act as barriers to further oncologic treatment after ICU discharge.

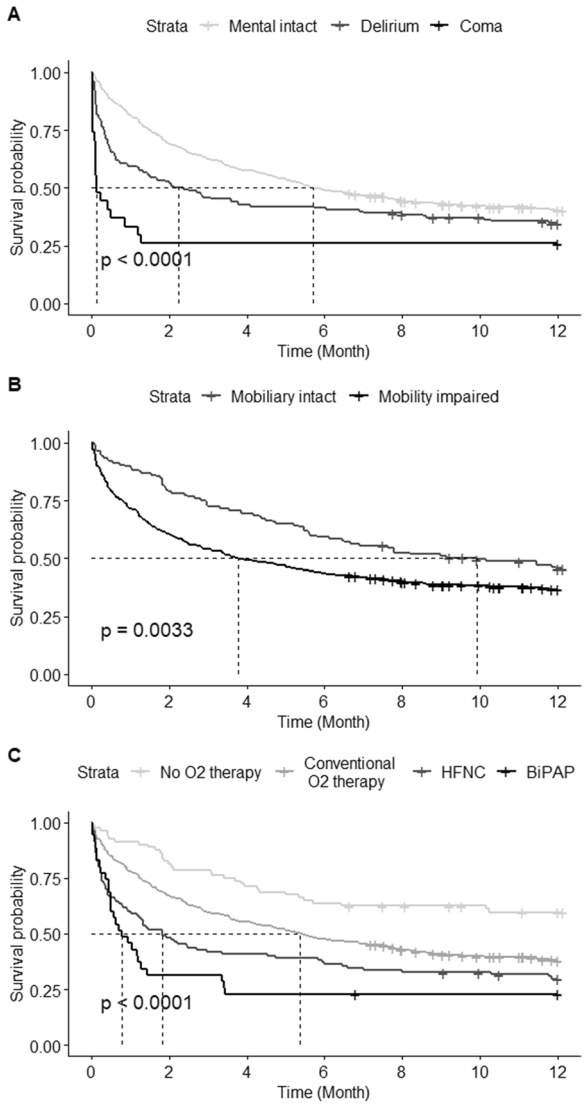

**Fig. 1 (abstract 000613)** One-year survival curve (A) according to delirium and coma status (B) according to mobility status (C) according to oxygen device at the time of ICU discharge

**Topic:** Haematologic-oncologic issues in the ICU

**Trends in inflammatory markers according to antibiotics susceptibility in gram-negative *sepsis***

D. Kim, J. H. Lee, I. Park, S. H. Kang, N. Kim, Y. W. Um, J. Kim, J. H. Lee, Y. H. Jo
Department of emergency medicine, Seoul National University Bundang Hospital, Seongnam-si, Republic of Korea
**Correspondence:** I. Park
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000614

**Introduction:** The application of susceptible antibiotics in patients with sepsis is pivotal. While susceptible antibiotics may rapidly reduce the inflammatory response by eradicating the bacteria, understanding of longitudinal changes of inflammatory markers according to antibiotics susceptibility is limited.

**Objectives:** The aim of the study is to compare early trends in inflammatory markers, including white blood cell (WBC), platelets, albumin, and C-reactive protein (CRP), in patients with gram-negative sepsis treated with susceptible and non-susceptible antibiotics.
**Methods:** A retrospective cohort study of sepsis patients in a single emergency department was conducted. Microbiologic culture data (blood, genitourinary, respiratory, others) and antibiotics treatment in sepsis patients were acquired. WBC, platelet, albumin, and CRP variables from study enrollment to 72 h were acquired. Subgroup analysis with focus on source control and type of antibiotics was performed.
**Results:** Of the 683 patients, 440 patients (64.4%) were treated with susceptible antibiotics. In trend analysis, a decrease in WBC at 24 h preceded both an increase in platelets at 48 h and a decrease in CRP at 72 h in both groups. Trends in WBC, platelets, albumin, and CRP were not significantly different between the two groups. Subgroup analysis revealed a difference in albumin trends between susceptible and non-susceptible in the source control group, while no differences were identified in the group without source control.
**Conclusions:** The observed trends in WBC, platelet, albumin, and CRP within the first 72 h may not serve as reliable markers for distinguishing between gram-negative sepsis patients treated with susceptible and non-susceptible antibiotics. Additionally, the subgroup analysis suggests a potential association between albumin trends and source control, warranting further exploration of its clinical significance.

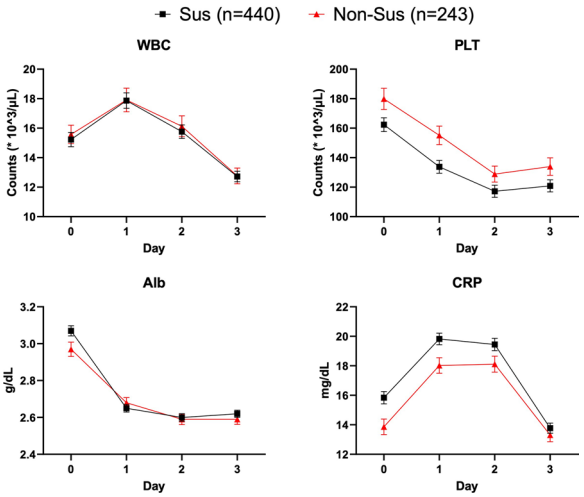

**Fig. 1 (abstract 000614)** Comparison of trends in inflammatory markers between sepsis patients according to antibiotics susceptibility

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000617

**Introduction:** Patients with severe chronic liver disease (CLD) are susceptible to recurrent complications (1,2). The Liver Frailty Index score (LFI), comprising three performance-based tests (hand grip, sit-to-stand, and balance), categorizes patients with liver disease into frail, pre-frail, and robust classes (3). Those meeting the frailty criteria defined by the LFI exhibit higher rates of adverse outcomes (4). In this study, we examine the correlation of the LFI with early outcomes after liver transplantation (LTx). We introduced the LFI in a home telemonitoring system for liver cirrhosis to predict rehospitalization and worsening of the disease.
**Objectives:** To assess whether higher LFI scores correlate with increased risk of mortality, complications, and length of stay (ICU and overall) following LTx in a transplant center located in southern Italy.
**Methods:** We reviewed retrospective data (April 2021–March 2024), comparing pre-transplant LFI assessments with hospital records, documenting age, death, n. of OR sessions, ICU readmission, days on ventilation, neuro consult, and tracheostomy during the LTx hospitalization. A descriptive analysis of postoperative (PO) outcomes was done, with a focus on ICU settings.
**Results:** 210 LTx patients were evaluated, with a mean age of 55 (ST ± 10.6). Metabolic and alcoholic etiologies were more prevalent in frail patients compared to hepatocellular carcinoma (HCC) etiology in the robust class (Table 1). Frail patients showed reduced access to LTx among those evaluated at the time of work-up (33.3%). Pre-frail individuals constituted approximately 48% of the total cohort (Table 2). Following LTx, frail patients had higher mortality (16.7%), readmission to the ICU (29.2%), and reoperation (16.7%) rates compared to other classes (Figure 1). They also exhibited longer PO mechanical ventilation time (4 days), higher rates of re-intubation (33.3%) and tracheostomy (25%). Additionally, there was a significantly higher frequency of neurological consultations (29.2%). Their overall length of stay (LOS) was longer (42.2 days), with prolonged ICU stay (17.6 days) (Figure 2). A higher proportion of frail LTx recipients required post-discharge assistance (16.7%) compared to robust patients (1.2%) (Figure 3).
**Conclusions:** Screening for frailty is an effective tool in the hands of a multidisciplinary team for identifying patients at higher risk of transplant complications. Our findings underscore a positive association between LFI scores and PO outcomes, emphasizing the importance of addressing frailty through pre-habilitation interventions. Healthcare systems should consider the potential impact on costs, including increased LOS and ongoing care needs post-discharge, while also exploring strategies to improve functional status and transition frail patients to a better LFI class.

**Table 1 (abstract 000617)** Etiology of Liver Transplanted Population

| | Frail (%) | Pre-frail (%) | Robust (%) |

### Comparison of time for endotracheal intubation with flexible tip bougie versus standard bougie during videolaryngoscopy in simulated cervical spine immobilization in adult patients: a prospective, randomized control study

R. Sinha[1], B. R. R. Ray[2], K. Ranjith[3], M. Kaur[4], D. Vanalal[5], J. Punj[6]
[1]Anaesthesia, Pain Medicine & Intensive care, All India Institute of Medical sciences, New Delhi, India, Delhi, India; [2]Anaesthesiology, Pain Medicine and Critical Care, All India Institute Of Medical Sciences, New Delhi, India; [3]Anesthesiology, Pain Medicine and critical care, All India Institute Of Medical Sciences, New Delhi, India; [4]Anesthesiology, All India Institute Of Medical Sciences New Delhi, New Delhi, India; [5]Department of anaesthesiology, pain medicine and critical care, All India Institute Of Medical Sciences New Delhi, New Delhi, India; [6]anaesthesia, All India Institute Of Medical Sciences, New Delhi, India
**Correspondence:** R. Sinha
*Intensive Care Medicine Experimental* 2024, **12(suppl 1):** 000618

**Introduction:** The incidence of cervical spine injury ranges from 1.8 to 9% which leads to difficult intubation due to poor glottic visualization due to neck immobilization. Endotracheal tube introducer helps to facilitate oral intubation in fixed cervical spine situations. Flexible tip bougie may help during in insertion of endotracheal tube in these situations.

**Objectives:** Primary objective was a comparison of endotracheal intubation time with flexible tip bougie and standard bougie in a simulated difficult airway. The secondary objectives were a comparison of a number of attempts, the need for maneuvers, and complications between the groups.
**Methods:** A day before surgery, pre-anaesthetic check-up was done and informed consent was obtained. Airway assessment including mouth opening and modified Mallampati grade was done without or with AMBU Perfit Ace adult adjustable cervical collar.
Seventy-six adult patients were allocated and randomized into two groups for oral endotracheal intubation in simulated cervical spine stabilization with a cervical collar. In the operation theatre, standard monitored and train of four monitors were applied. After administration of general anaesthesia (2mcg/kg fentanyl and 2mg/kg propofol) and non-depolarising muscle relaxant; the trachea was intubated with the help of flexible tip bougie (group F) or standard bougie (group B) using CMAC video laryngoscope size 3 or 4 Macintosh blade. We evaluated the time for intubation, best glottic view, railroading ETT, removal of the bougie, number of attempts, ease of bougie insertion, the need for maneuvers (BURP, cricoid pressure), and complications during intubation. The second attempt was tried if SpO2 decreased to 93% or total time exceeded more than 120 s. If 2nd attempt failed then the anterior part of the cervical collar was removed and intubation was done after proper positioning the patient.
**Results:** Demographic data, BMI, and neck circumference were comparable in both groups. The mean time required for endotracheal intubation was comparable but the mean time for bougie insertion was significantly shorter in Group F as compared to Group B. (Table 1).

**Table 1 (abstract 000618)** Comparison of time parameters between Group F and Group B

| Time parameters Mean ± SD, Seconds | Group F ($n=37$) | Group B ($n=37$) | *p* value |
|---|---|---|---|
| Time for best glottic view | 10.95 ± 7.12 | 10.26 ± 5.86 | 0.65 |
| Time for insertion of bougie | 5.76 ± 2.7 | 9 ± 9.29 | **0.048** |
| Time for railroading endotracheal tube | 15.55 ± 17.45 | 16.4 ± 14.39 | 0.82 |
| Time for removal of bougie | 3.17 ± 1.58 | 3.18 ± 1.01 | 0.96 |
| Total time for intubation | 34.88 ± 20.41 | 39.27 ± 22.05 | 0.37 |
| Time for procedure | 45.07 ± 20.69 | 51.85 ± 20.64 | 0.16 |

**Conclusions:** In conclusion, flexible tip bougie insertion time is shorter as compared to standard bougie insertion in simulated cervical spine stabilization. Flexible tip bougie resulted in decreased number of intubation attempts in comparison to standard bougie. However total time for intubation, railroading ETT, bougie removal, ease of bougie insertion, need for manoeuvres and complications during intubation were comparable in both the groups.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000619

**Introduction:** The timing of tracheostomy in coronavirus disease 2019 (COVID-19) patients does not affect survival. In addition, few studies have shown an association between the timing of tracheostomy and long-term prognosis, particularly with PICS.
**Objectives:** We aimed to determine the relationship between tracheostomy timing and long-term outcomes in tracheostomy-requiring patients with COVID-19.
**Methods:** This prospective observational study was a secondary analysis of the "Post-intensive care outcomes in patients with Coronavirus Disease 2019 study" and was conducted in 32 intensive care units (ICUs) in Japan. Adults with COVID-19 who received ventilatory management and were discharged from the ICU between March 2020 and March 2021 were included. Follow-up questionnaires were mailed 1 and 2 years after ICU discharge. Those who received tracheostomy within and later than 14 days were classified into early and late groups, respectively. Mortality and post-intensive care syndrome (PICS) incidence, defined by the Barthel Index and Hospital Anxiety Depression Scale and Short Memory Questionnaire scores, were compared 1 and 2 years after ICU discharge.
**Results:** Overall, 508 ventilated patients with COVID-19 were included, of whom 101 underwent tracheostomy (45 and 56 patients in the early and late groups, respectively). Ventilation duration was significantly shorter in the early group than in the late group (19 [interquartile range: 14–28] vs. 39 [28–59] days, $P<0.01$). The corresponding in-hospital mortality rates were 31.1% (14) and 28.6% (16, $P=0.83$). The 1-year mortality rates in the early and late groups were 35.9% (14/39) and 36.2% (17/47), respectively ($P=1.0$). The corresponding PICS incidence rates were 52.4% (11/21) and 65.4% (17/26, $P=0.39$). The 2-year mortality rates in the early and late groups were 36.8% (14/38) and 37.0% (17/22), respectively ($P=1.0$). The corresponding PICS incidence rates were 64.7% (11/17) and 77.2% (17/22, $P=0.48$). After adjusting for age and sequential organ failure assessment score at ICU admission, intergroup differences in the 1- and 2-year mortality rates were found to be insignificant ($P=0.82$ and 0.83, respectively).
**Conclusions:** Ventilation duration was significantly shorter in the early group; however, intergroup differences in the in-hospital death, 1-year death and PICS incidence rates, and 2-year death and PICS incidence rates were insignificant. Post-tracheostomy PICS symptoms persisted for much longer than 2 years in > 50% of the patients.

### Stroke code in a county hospital: management by an intensivist

A. Alonso, M. Cózar, P. Sánchez, A. Ubeda
Intensive care unit, Hospital Punta de Europa, Algeciras, Spain
**Correspondence:** A. Ubeda
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000621

**Introduction:** Stroke is one of the leading causes of disability and mortality worldwide, making early reperfusion treatment essential. In recent years, the creation of remote teams responsible for assessing this condition and its treatment has been promoted with the aim of improving care in areas without 24-h neurologist coverage.
**Objectives:** To analyze the management of stroke code by an intensivist, including factors related to the prognosis of these patients. Evaluate the usefulness of telestroke in our environment.
**Methods:** Prospective cohort analysis in which acute strokes with activation of "stroke code" were included between January 2017 and November 2023. Demographic outcomes, comorbidities, contact with telestroke, reperfusion therapy, assistance time, complications, ICU and hospital length of stay (LOS), mortality, and neurological sequelae. Statistical analysis: categorical variables (frequencies and percentages) and quantitative variables (mean and standard deviation or median and interquartile range). Comparisons: X2 test (percentages), Student's t test (means), and Mann–Whitney U test (medians). Multivariate logistic regression. Statistical significance at $p<0.05$.
**Results:** 273 patients were included. Age 67.9 ($\pm$13.6). Sex: man 59.7%. Time (min): door-to-CT 25 [17; 42], emergency department-ICU call 22 [5; 49.3], CT-to-needle 44 [26; 65], door-to-needle 70 [53.5; 94.7]. Telestroke 28.5%. Fibrinolytic therapy 41.4%. Thrombectomy 19.4%. Mortality 18.3%.
Telestroke ($n=78$) vs. Non-telestroke ($n=195$) were compared. Thrombectomy 37.2% vs. 12.3%, $p<0.001$. Hemorrhagic Transformation 23.1% vs. 9.2%, $p=0.006$. Time CT-to-needle 70 [49; 91] vs. 37 [23.7; 52.7], $p<0.001$. Time door-to-needle 90 [68; 129] vs. 62 [51; 87], $p=0.001$. Rankin at discharge $\leq 2$: (37.3% vs. 53.6%, $p=0.024$). Rankin at discharge (3 [1; 5] vs. 2 [0; 4], $p=0.013$).
Previous years ($n=157$) vs. 2023 ($n=111$) were compared. Fibrinolytic therapy 50.9% vs. 29.7%, $p<0.001$. ICU activation 77.1% VS. 91.9%, $p=0.002$. Time CT-to-needle 51 [29; 70.5] vs. 34.5 [25; 45], $p=0.037$. Complic: MV 21% vs. 9.9%, $p=0.024$. ICU-LOS 1 [0; 3] vs. 1 [0; 2], $p=0.034$. Hospital-LOS 9.5 [5; 15] vs. 6 [4; 10], $p<0.001$. Rankin at discharge 3 [1; 5] vs. 1 [0; 4], $p=0.004$. Rankin at discharge record (p0.012): $\leq 2$ (42.3% vs. 58.5%), > 2 (57.7% vs. 41.4%).
Dead ($n=50$) vs. Survivors ($n=218$) were compared. Sex: man 76.0% vs. 55.6%, $p=0.015$. Age 72.2 ($\pm$10.7) vs. 67.1 ($\pm$14.1), $p=0.006$. Comorbidity: CKD (16.0% vs. 5.5%, $p=0.018$), neoplasia (24% vs. 7.3%, $p=0.002$). Fibrinolytic therapy (26% vs. 45.8%, $p=0.02$). Complications ($p<0.001$): MV 62% vs. 5.9%, hemorrhagic transformation 34% vs. 8.7%. ICU-LOS (2.5 [1; 7] vs. 1 [0; 2], $p<0.001$). The number needed to treat (fibrinolysis): 8.
Multivariate logistic regression: Neoplasia (OR 6.6, IC 95% [2.22–19.86], $p<0.001$), Fibrinolysis (OR 0.33, IC 95% [0.13–0.79], $p=0.016$), previous

CKD (OR 6.0, IC 95% [1.79–19.6], $p = 0.003$), complication: MV (OR 37.6, IC 95% [15.6–99.7], $p < 0.001$).
**Conclusions:** The leadership of the "stroke code" assumed by the intensivist has made it possible to reduce the time until fibrinolysis, complications, ICU and hospital LOS, and neurological sequelae.
Telestroke consultation were associated with delays in reperfusion therapy, greater complications, and neurologic sequelae.
The need for MV, previous CKD, and neoplasia were observed as independent risk factors for mortality, while fibrinolysis was a protective factor.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000624

**Introduction:** Persons with long-term critical illness often suffer from decreased physical, mental, and cognitive capacity, which can lead to impaired well-being. Although current well-being is often assessed in research studies, the expected future well-being and factors that could contribute to the expected well-being are scarcely described.
**Objectives:** To determine factors associated with expectations of future well-being in persons with long-term illness.
**Methods:** Baseline data of a randomised controlled study, (The teleyoga study, clinicaltrials.gov: NCT03703609) are used in which participants were recruited from four hospitals in Sweden between 2018 and 2022. Inclusion criteria: > 18 years, cared for at intensive care or cardiology unit during the last 36 months and clinically stable at the time of inclusion. Exclusion criteria: inability to perform data collection or intervention due to severe physical or mental limitation, expected survival of less than 6 months.
Expected well-being was measured with Cantril's ladder of life, where patients could rate their expected (in one year) well-being on a ladder from bottom (0: worst possible life) to top (10: best possible life). Based on the literature, factors considered associated with expected well-being were age, sex, Body Mass Index, living condition, economic situation, comorbidities (Charlson comorbidity index (CCI)), cognition (Montreal Cognitive Assessment, MoCA), depressive symptoms (Hospital Anxiety and Depression scale, HADs), sleep (Minimal Insomnia Symptom Scale, MISS) and exercise capacity (6-min walk test).
Linear regression was performed with variables associated with expected well-being in univariate analysis ($p < 0.05$, see table).
**Results:** In total 303 persons with long-term illness were included. The mean score on the expected well-being was 7.5 (SD 1.75). The mean age was 65 years (SD 12) and 70% was male, 78% were married or in a relationship, and 90% rated their financial situation as good. In total 18% of patients were considered depressed (> 7 on HADs), 32% experienced sleeping difficulties (> 6 on MISS), and 54% had mild to moderate cognitive impairment (< 26 on MoCA). Patients walked a mean of 456 m on the 6-min walk test (SD 124). The mean score on CCI was 4 (SD 3).
The multivariate analysis showed that persons with long-term illness that were younger ($p$-value 0.005), male ($p$-value 0.006), married or being in a relationship (p-value 0.043), had fewer comorbidities ($p$-value 0.018) and had fewer depressive symptoms ($p$-value < 0.001) expected a higher future wellbeing the coming year (see table).
**Conclusions:** Expectations for future well-being were associated with age, sex, marital status, comorbidities, and mental health but unexpectedly not with functional measures such as sleep, cognition, or exercise capacity.

**Table (abstract 000624)** Univariate and multivariate statistics to assess factors associated with expected well-being

Table Univariate and multivariate statistics to assess factors associated with expected well-being

**Introduction:** Expert perspectives on ECCO2R – what could be its future role respiratory failure?
Introduction. Facilitating ultraprotective ventilation by ECCO2R has been considered for patients with acute respiratory failure. Thus far, study results are contradictory and terms like "ultraprotective ventilation" may require clarification. In addition, different technologies potentially impact outcome of clinical studies.
**Objectives:** Objectives: Outline a framework for ECCO2R based on clinical experience and provide guidance for a new trial.
**Methods:** We convened a meeting of 15 European intensivists and nephrologists and used a modified Delphi process to provide updated insights into the role of ECCO2R in acute lung failure, including ARDS and to identify recommendations for a future randomized controlled trial. Over four rounds of iterative questioning, including a pre-meeting survey, a live survey during the meeting, and two post-meeting surveys (voting and survey all anonymous) was performed. Round 3 survey included newly published literature, the secondary analysis of the REST trial, the ESICM guidelines, and the VT4COVID, a second post-meeting survey (Round 4) was shared with the authors to understand their definition of ultra-protective ventilation and the role of ECCO2R.
**Results:** Participants ranked VT, ΔP, PPlat, and RR as the four most important respiratory parameters to monitor and agreed that a protective ventilation strategy for patients with mild-to-moderate ARDS should have a target VT of < 6 mL/kg PBW, maximum ΔP of 15 cmH2O, and maximum PPlat of 29–30 cmH2O Figure 1A–C). Based on the ECCO2R data published after the meeting, most participants indicated that ultra-protective lung ventilation should have a maximum VT ≤ 6 mL/kg PBW, (Figure 2A). Fourteen (93%) participants agreed that ECCO2R would be needed in most patients to implement ultra-protective lung ventilation (*consensus*) (Figure 2B). All participants indicated that ultra-protective lung ventilation facilitated by ECCO2R would require a maximum ΔP (100%, *consensus*), with the *majority* selecting 14–15 cmH2O as their preference (Figure 2C). A range of 251–350 mL/min or 351–450 mL/min as the minimum blood flow rate was required for effective use of ECCO2R (Figure 3). A *majority* of participants (73%) indicated a minimum $CO_2$ removal rate of 80 mL/min delivered by continuous renal support machines was required for ECCO2R to be effective (Figure 4). During the post-meeting survey, 14/15 (93%, *consensus*) participants stated that a new randomized trial of ECCO2R is needed in patients with ARDS. A ΔP of ≥ 14–15 cmH2O was suggested by 12/14 participants (86%) as the primary inclusion criterion.
**Conclusions:** ECCO2R might have potential as a treatment for patients with respiratory failure in whom ventilation of less intensity like UPLV is indicated. A future randomized trial is necessary, and values like driving pressure and ventilatory ratio could help to identify the adequate patient subgroups that have a potential benefit from ECCO2R combined with less intensive ventilation. Also to be considered are that differences in technology, e.g. use of centrifugal pumps (initially optimized to generate high blood flow > 2 l/min) for low blood flow in ECCO2R, may contribute to unfavorable clinical outcomes; there could be a potential for devices in a flow range up to 400 ml/min based on the peristaltic drive like in CRRT if they provide a sufficient removal capacity for $CO_2$.

*Intensive Care Medicine Experimental* 2024, **12(suppl 1):** 000626

**Introduction:** Myocardial injury and cardiac dysfunction have been reported among critically ill COVID-19 patients. Although the focus has generally been on the right ventricle (RV), left ventricular (LV) dysfunction also occurs and is associated with myocardial injury (1). A recent study showed that RV injury was associated with LV dysfunction in 18% of cases (2), suggesting both ventricles should be assessed in relation to each other.

**Objectives:** The aim of this study was to evaluate the incidence of LV systolic dysfunction and its association with outcomes such as acute myocardial injury (AMInj), length of stay in the intensive care unit (ICU), days free of organ support and mortality, adjusted for RV dysfunction, preexisting cardiac disease, Simplified Acute Physiology Score III (SAPS-III) and Sequential Organ Failure Assessment (SOFA).

**Methods:** Retrospective, observational study of 189 adult patients with laboratory-confirmed COVID-19, treated in the ICU at Linköping University Hospital during 2020–2022. All had at least one echocardiogram performed in the first 10 days of care.

Left ventricular dysfunction was defined as left ventricular ejection fraction < 50% (Simpsons biplane method).

Right ventricular dysfunction was defined as at least two of the following; Tricuspid Annular Plane Systolic Excursion < 17 mm, RV s' < 9.5 cm/s, Fractional Area Change < 35%, Free Wall Strain > −20%.

Acute myocardial injury was defined as high-sensitivity troponin T (hs-TnT) > 14 ng/l with an absolute change of > 20%.

**Results:** LV systolic dysfunction was present in 16.5%, RV dysfunction in 22.0% and biventricular dysfunction in 9.2%. AMInj occurred in 70.5%. There was a significant association between LV and RV dysfunctions. Patients with LV systolic dysfunction had higher hsTnT and a greater proportion suffered AMInj at admission. LV systolic dysfunction was independently associated with AMInj even after adjustment for important confounders. There was no association between LV systolic dysfunction and ICU length of stay, days free of organ support, ICU- or 30-day mortality (Table 1).

**Table 1 (abstract 000626)** Outcomes

| | Normal LV systolic function | LV systolic dysfunction | *p* |
|---|---|---|---|
| RV dysfunction | 19 (17,1%) | 12 (60,0%) | < 0,001*** |
| AMInj at admission | 25 (20,3%) | 13 (52,0%) | < 0,001*** |
| AMInj during ICU stay | 84 (65,1%) | 21 (84,0%) | 0,064 |
| Peak hsTnT | 65,2 (14,5–63,0) | 305,5 (36,0–226,0) | < 0,001*** |
| Peak NTproBNP | 2763,0 (440,0–2275,0) | 14300,4 (1950,0–35000,0) | < 0,001*** |
| Days free of organ support, first 30 days | 15,7 (3,5–25,0) | 15,2 (4,0–22,0) | 0,683 |
| ICU length of stay | 14,8 (5,5–21,5) | 15,5 (5,0–32,0) | 0,565 |
| 30d mortality | 21 (15,9%) | 2 (7,7%) | 0,372 |
| ICU mortality | 23 (17,4%) | 2 (7,7%) | 0,376 |

**Conclusions:** LV dysfunction occurred commonly in critically ill COVID-19 patients. These patients also often had RV dysfunction and increased cardiac biomarkers. More than half of patients who developed LV dysfunction had acute myocardial injury at admission and there was an independent relationship between LV dysfunction and AMInj. LV dysfunction was not associated with organ failure, ICU LOS or mortality.

### Prolonged and difficult ventilatory weaning and reintubations—how to anticipate?

C. Torrão, H. Castro, I. Aragão
Unidade de Cuidados Intensivos 4 (UCIP), Centro Hospitalar Universitário de Santo António, Porto, Portugal

**Introduction:** It is estimated that 40% of the duration of mechanical ventilation is spent with the process of weaning. Approximately 20% of ventilated patients have difficult or prolonged weaning, which is associated with worse outcomes. Weaning success is dependent on a structured approach, which includes a correct assessment and identification of risk factors, and timely and specific interventions.
**Objectives:** To study the risk factors to anticipate difficult and prolonged weaning in our patients.
**Methods:** Retrospective observational study of adult patients with difficult and prolonged weaning according to WIND classification, admitted in a mixed intensive care unit (ICU) at a university hospital in a period of three years—2021 to 2023. We analyzed patients' electronic records to collect data concerning demographics, comorbidities, cause for ICU admission, SAPS II, reintubations, tracheostomies, mortality, ICU, and hospital length of stay. Statistical analysis was performed with IBM SPSS Statistics. Comparative analysis was conducted and a p value less than 0.05 was deemed statistically significant.
**Results:** During the study period, 1307 patients were admitted; 844 were submitted to mechanical ventilation and 427 patients (50,1%) were excluded: 254 (30.1%) for missing data, 162 (19,2%) for ventilatory support < 2 days, and 11(1,3%) transferred before weaning.
We analyzed the weaning, extubation and reintubation events of 417 patients and compared the groups: simple ($n=264$, 63,3%), prolonged ($n=92$, 22,1%), and difficult ($n=61$, 14,6%) weaning.
Patients with prolonged and difficult weaning had more frequent body mass index > 30kg/m2 ($n=38$, 41,3% and $n=11$, 18,0% versus $n=39$, 14,8%, $p<0,001$) and reduced ejection fraction heart failure (HFrEF) ($n=5$, 5,4% and $n=11$, 18,0%, versus $n=17$ 6,4%, $p=0.003$).
Patients were similar with respect to the other analyzed variables at admission. As expected, they had longer ICU and hospital length of stay ($27\pm16$ and $17\pm8$ versus $9\pm6$ days, $p<0,001$ and $58\pm44$ and $50\pm36$ versus $31\pm30$ days, $p<0,001$, respectively), longer ventilation duration ($20\pm12$ and $12\pm7$ versus $6\pm5$ days, $p<0,001$), and higher ICU mortality ($n=14$, 15,2% and $n=5$,8,2% versus $n=8$, 3,0%, $p<0,001$).
Among patients with difficult and prolonged weaning, 47 (49,5%) were reintubated and had a larger proportion of tracheostomies ($n=41$, 44,6% and $n=12$, 19,7% versus $n=3$, 1,1%, $p<0,001$). Early reintubation (first 48 h) was more frequent than later reintubation ($n=39$, 83,0% versus $n=8$, 17,0%). Reintubated patients had longer ICU length of stay ($23\pm12$ and $30\pm19$ days) than non-reintubated patients ($19\pm12$ days, $p=0.033$).
**Conclusions:** Based on our data, we propose to add to our standard practice: in obese patients the transpulmonary pressure monitoring (compliance and asynchronies), the systematic evaluation of airway occlusion pressure 100 ms and early diaphragmatic rehabilitation (diaphragmatic dysfunction); and in HFrEF patients the routine use of non-invasive ventilation in weaning, guided by bedside echocardiography.

**Introduction:** Extracorporeal Membrane Oxygenation (ECMO) is a life support technique for patients with reversible refractory respiratory and/or circulatory failure. ECMO patients are at higher risk of infections, but the characterization of infections during ECMO and risk factors are not clearly defined.
**Objectives:** To describe the incidence, type, microbial etiology, risk factors, and impact on outcomes of nosocomial infections during ECMO.
**Methods:** In an ongoing multicenter worldwide-open prospective observational study, we enrolled patients treated with ECMO, excluding patients < 18 years old, with expected survival < 24 h, pregnant women, and ECMOs as Cardio-pulmonary resuscitation or as a bridge to lung transplant. Only microbiologically confirmed infections diagnosed from the day of cannulation until 48 h after decannulation or death were considered.
**Results:** From January 2023 to March 2024, 105 patients were enrolled in 9 centers, and 43 from 7 European medical-surgical ICUs ended follow-up and were included in this analysis (75% males, 58 [45–65] years old, Sequential Organ Failure Assessment Score 7 [4–10]) who underwent peripheral ECMO primarily for respiratory support (68% veno-venous, 32% veno-arterial). Twelve patients (28%) suffered from 16 infections (46.9 infections/1,000 ECMO-days) after 5 [3–11] days of life support. We identified 6 ventilator-associated pneumonia (VAP), 4 bloodstream infections, 2 catheter-related bloodstream infections (CRBSI), one pulmonary aspergillosis, one colitis, one Herpes Simplex Virus reactivation, and one ECMO cannula infection. 2 VAP and one CRBSI infection were polymicrobial. Multidrug-resistant (MDR) organisms cause 25% of bacterial infections. Patients who needed at least one ECMO circuit change were more infected (33% vs. 10%; OR 4.67 (0.86 – 25.31), $p = 0.059$). Ten patients (23%) died (31.1 deaths/1,000 ECMO-days). Infected patients had longer intensive care unit stay (30.5 [17.5–39] vs. 16 [9–23] days; $p = 0.013$), mechanical ventilation (21.5 [14–35.5] vs. 9 [7–23] days; $p = 0.007$), and ECMO support (9 [7–14] vs. 5 [4–7] days; $p = 0.006$). Infected patients had a similar death rate to non-infected (28.4 vs. 33.3 deaths/1,000 ECMO-days; $p = 0.674$), while infections caused by MDR bacteria were associated with a higher percentage of death (75% vs 15%, $p = 0.044$).

**Table (abstract 000628)** Pathogens of the bacterial nosocomial infections during Extracorporeal Membrane Oxygenation

| Gram stain and pathogen | Overall n. (n. mdr) | VAP n. (n. mdr) | BSI n. (n. mdr) | CRBSI n. (n. mdr) |
|---|---|---|---|---|
| Gram + | 9 (1) | 2 (0) | 4 (1) | 3 (0) |
| E. faecium | 4 (0) | - | 1 (0) | 3 (0) |
| Staphylococcus aureus | 2 (1) | 1 (0) | 1 (1) | - |
| Enterococcus spp | 1 (0) | - | 1 (0) | - |
| Others Gram + | 2 (0) | 1 (0) | 1 (0) | - |
| Gram - | 3 (2) | 3 (2) | - | - |
| P. aeruginosa | 3 (2) | 3 (2) | | |
| Klebsiella spp | 2 (1) | 2 (1) | - | - |
| Enterobacterales (other) | 1 (0) | 1 (0) | - | - |

*VAP*: Ventilator Associated Pneumonia; *BSI*: Blood Stream Infection; *CRBSI*: Catheter Related Blood Stream Infection; *mdr*: multidrug resistant.

**Conclusions:** Infections during ECMO support are common; up to 25% involve multidrug-resistant organisms. In addition, infection is associated with prolonged need for mechanical ventilation, extracorporeal support, and intensive care unit stay.

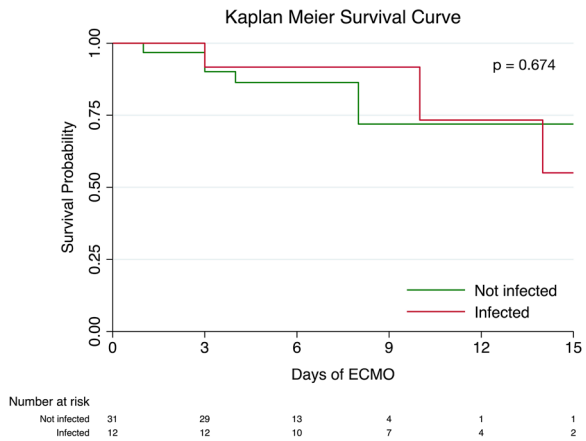

**Fig. (abstract 000628)** Kaplan–Meier survival curve comparing infected vs. not infected patients

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000629

**Introduction:** Intensive care unit (ICU) acquired diaphragm weakness is a common consequence of mechanical ventilation (MV) (1). Diaphragm weakness contributes to difficult weaning, which is associated with increased morbidity, mortality, and healthcare costs (1). Furthermore, it can lead to physical disability and impairment of intensive care survivors (2). Diaphragm weakness is caused by a combination of atrophy and contractile weakness of muscle cells, also called myofibers. In the previous years, several mechanisms underlying ICU-acquired diaphragm weakness have been identified. Increased autophagy and apoptosis were identified to underlie diaphragm atrophy in rodents and brain-dead organ donors receiving controlled MV (5). Brain-dead organ donors and controlled-ventilated rodents have distinct clinical characteristics compared to mechanically ventilated ICU patients and thus, do not adequately reflect diaphragm pathophysiology in critically ill patients. Whether apoptotic mechanisms contribute to diaphragm atrophy and weakness in mechanically ventilated patients is currently unknown.
**Objectives:** We aimed to investigate whether apoptotic mechanisms underlie diaphragm atrophy and weakness in mechanically ventilated ICU patients.
**Methods:** Diaphragm biopsies of mechanically ventilated ICU patients undergoing abdominal or thoracic surgery for clinical reasons with and without established myofiber atrophy (myofiber cross-sectional area (CSA) < 2000 um2, CSA > 2500 um2, respectively) were compared to biopsies of patients undergoing thoracic surgery for a, pulmonary nodule (controls). RNA sequencing was performed ($n = 26$) on whole tissue samples. Cross-sections were stained using a TUNEL ($n = 27$) assay and activated caspase-3 ($n = 21$) staining to identify apoptotic cells. Furthermore, myonuclei were stained with a specific antibody (PCM-1) to distinguish myonuclei from other cell types present in the cross-sections.
**Results:** In the transcriptomic analysis, both ICU groups were analyzed as one group due to poor clustering results with principal component analysis. We identified 2977 differentially expressed genes (1741 upregulated in the ICU group and 1236 downregulated). Panther pathway enrichment analysis of significant (FDR < 0.05) differentially expressed genes revealed marked upregulation of the P53 and apoptosis pathways (20/81), P53-pathway associated genes differentially expressed and (16/108) apoptosis-pathway associated genes differentially expressed. TUNEL staining revealed an increased apoptotic index (TUNEL + myonuclei/total myonuclei) in the ICU group with atrophy and cleaved caspase-3 staining revealed an increased apoptotic index (cleaved caspase-3 + myonuclei/total myonuclei) in both ICU groups.
**Conclusions:** P53 and intrinsic apoptotic pathway activation are associated with diaphragm atrophy in mechanically ventilated ICU patients. Myonuclear apoptosis may compromise transcriptional capacity and therefore recovery of the diaphragm after atrophy, possibly contributing to weaning failure and physical disability of intensive care survivors.

**Introduction:** Ventilator associated pneumonia is a high prevalence and mortality infection in the ICU, specially during the COVID-19 pandemic. In 2011, the "Pneumonia Zero project" was drafted in Spain to reduce the incidence of VAP with a series of basic recommendations, among which selective digestive decontamination was included.
**Objectives:** To analyze the impact of selective digestive decontamination (SDD) on the incidence of ventilator-associated pneumonia (VAP) in the ICU of a county hospital with poor compliance with zero pneumonia measures, as also analyze the factors related to the development of pneumonia.
**Methods:** Retrospective descriptive analysis was performed using a prospective cohort obtained from a 15-bed ICU collected between June of 2019 to October of 2023. Demographic variables, comorbidities, prognosis scores (APACHE II and SAPS II), risk factors, ICU-acquired infections microorganism isolation, ICU and hospital length of stay (LOS), antimicrobial therapy used, and mortality were collected. Statistical analysis: continuous variables (mean and standard deviation or median and interquartile range),categorical variables (percentages and frequencies). Comparison: Chi-square test (percentages) and T-student test (mean) or Wilcoxon test (median). Multiple logistic regression. Statistical significance was set at $p < 0.05$.
**Results:** 745 patients were included. SDD patients ($n = 30$) vs. non-SDD patients ($n = 715$). APACHE II on admission (16 [11; 21] vs. 11 [8; 18.5], $p = 0.025$). Origin ($p < 0.001$): community 66.7% vs. 42.9%, other ICU 20% vs. 3.2%, ward 13.3% vs. 53.7%. Type of admission ($p = 0.014$): scheduled surgery 3.3% vs. 7.5%, urgent surgery 10% vs. 17.1%, coronary 3.3% vs. 7.5%, non-coronary medical 73.3% vs. 66.9%, trauma 10% vs. 0.8%. Prior antimicrobial therapy (48 h) 16.7% vs. 42.1%, $p = 0.009$. First ICU-acquired infection ($p < 0.155$): secondary bacteriemia (6.7% vs 6.6%), VAP (3.3% vs. 5.6%). Second ICU-acquired infection ($p = 0.127$): secondary bacteriemia (0% vs. 1.1%), VAP (6.7% vs. 5.7%). Days of mechanical ventilation (VM) (6.5 [3; 13.5] vs. 3 [1; 8], $p < 0.001$). Days of the central venous catheter (CVC) (10 [6; 18.5] vs. 5 [2; 12], $p = 0.001$). Days of the urinary catheter (UC) (10 [6; 20.5] vs. 6[2; 12], $p = 0.001$). Days of the arterial catheter (5 [3; 10.7] vs. 2 [0; 7], $p < 0.001$). ICU LOS (days) (10 [6; 18.5] vs. 6 [2; 13], $p = 0.002$). VAP incidence (14.2 cases/1000 days VM vs. 21.05 cases/1000 days VM). Multivariate logistic regression (VAP): Sex (man) (OR 2.08, IC 95% [1.14–4.17], $p = 0.023$), origin other ICU (OR 4.17, IC 95% [1.51–10.73], $p = 0.004$), days of MV (OR 1.16, IC 95% [1.13–1.19], $p < 0.001$).
**Conclusions:** The beginning of the SDD protocol meant a decrease in the incidence of VAP to 14.2 cases/1000 days of VM. Sex, origin from another ICU, and the days of MV were observed as independent risk factors of VAP.

**Introduction:** Burn patients with septic shock present circulatory failure which increases morbidity and mortality. Initial treatment to manage hypotension includes fluid therapy and vasoactive medications. In case these treatments are not effective hydrocortisone is administered as a rescue treatment.
**Objectives:** To investigate differences between ICU burn patients with septic shock who received hydrocortisone therapy and those who did not.
**Methods:** This retrospective cohort study included burn ICU patients with septic shock. Data between patients who received hydrocortisone as rescue therapy for refractory septic shock and those who did not receive hydrocortisone were compared. The following data were included in statistical analysis: demographic characteristics, total body surface area (TBSA%) burnt, APACHE II score, SOFA score, ICU length of stay, hydrocortisone administration, noradrenaline dosage, C-Reactive Protein (CRP), procalcitonin (PCT), and acute kidney injury (AKI) incidence.
**Results:** We included 31 patients, 19 (61%) of whom were male. Mortality was 19.4%. Six(19.4%) patients received hydrocortisone. The mean duration of hydrocortisone treatment was 5.33 ± 2.34 days. Descriptive characteristics are shown in Table 1. Patients who received hydrocortisone were at higher dosages of noradrenaline at the beginning of sepsis ($p = 0.016$) and 48 h after the onset of septic episode ($p = 0.049$). CRP was lower by −5.64 mg/dl after 48 h in patients who received hydrocortisone ($p = 0.03$). Maximum PCT values were also lower in patients who received hydrocortisone ($p = 0.033$).No association was found between administration of hydrocortisone and sex ($p = 0.65$, OR = 1.78, 95% CI 0.30, 10.72), acute kidney injury ($p = 0.49$, OR = 6, 95% CI 0.22, 162.53) and mortality ($p = 1$,OR = 0.89, 95% CI 0.14, 5.85).

**Table 1 (abstract 000632)** Characteristics of septic shock patients

| | Hydrocortisone | | No hydrocortisone | | *p* |
|---|---|---|---|---|---|

## Revolutionizing ICU mortality prediction: XGBoost-based model outperforms other scoring systems

R. Karasneh[1], S. Al-Azzam[2], K. Al-Zoubi[2], M. Araydah[3], D. Rahhal[2], Y. Al-Azzam[4], Z. Kharaba[5], S. Kabbaha[6], M. Aldeyab[7]

**Introduction:** Accurate prediction of mortality in intensive care units (ICUs) is essential for enhancing patient outcomes and optimizing healthcare resource allocation 1.
**Objectives:** This study aims to establish an effective predictive model for mortality and to explicate factors strongly associated with mortality.
**Methods:** This study was conducted using electronic records of ICU admissions for adult patients, excluding those under 18, to a single-tertiary healthcare center from July 2012 to July 2022. A novel ICU mortality prediction machine learning model was developed with a focus on the 30-day mortality rate as the primary predictor. Clinical data including demographics, comorbidities, laboratory results, and medication groups were used for model development to achieve superior prediction accuracy. Descriptive analysis was conducted, class imbalance was addressed using Synthetic Minority Over-sampling Technique (SMOTE), and missing data was treated using imputation methods. Model performance was evaluated against alternative machine learning algorithms, including logistic regression, conventionally employed in traditional scoring systems.
**Results:** The dataset comprised 26,248 ICU admissions for 13,567 patients. The final dataset of 13,304 adult patients yielded 72 features reduced to 65 after feature selection of extracted data using LASSO. Comparative analysis revealed that the XGBoost model performed better than other scoring systems, manifesting heightened accuracy (87.91%), sensitivity (92.88%), and Area Under the Receiver-Operating

Characteristic Curve (AUC-ROC) Score/Curve (94.29%). Notably, the patient's length of hospital stays, albumin levels, and urea levels emerged as the most substantial predictors for ICU mortality each exhibiting respective SHAP values of 0.5, 0.41, and 0.37.
**Conclusions:** An ICU mortality prediction model was developed, underscoring the pivotal role of predictors such as hospital stay duration, albumin, and urea levels in predicting patient outcomes. The heightened accuracy and sensitivity of the XGBoost model signifies its potential as an invaluable tool in the critical task of mortality prediction within the ICU context.

**Introduction:** Sepsis-related complex immune and oxidative response continues to pose a perilous challenge for clinicians. Imbalance between oxidative stress and anti-oxidative protective mechanisms, favoring the oxidant levels, significantly contributes to the sepsis process and may lead to organ damage and failure. Amongst various anti-oxidative micronutrients, zinc has recently been acknowledged for its potent anti-oxidative and immunomodulatory functions.
**Objectives:** The aim of this prospective study is to investigate the homeostasis of certain biomarkers of oxidative stress and of zinc, as a central antioxidative micronutrient, in critically ill patients.
**Methods:** The study was performed in a sample of critically ill patients with sepsis (S) ($n=120$), compared to patients with non-infectious inflammation (T) ($n=120$) and to healthy controls (H) ($n=77$). Patient serum samples were collected during the first day of Intensive Care Unit (ICU) admission. Photometric analyses of total products of lipid peroxidation, and of the enzymatic reaction with a predefined oxidative substance were used for total oxidative stress (TOS) and total antioxidant capacity (TAC) quantification, respectively. Atomic absorption spectrometry was used for zinc quantification in serum.
**Results:** The ratio of total oxidative stress over total antioxidant capacity (TOS/TAC) was significantly elevated in septic patients (S), compared to non-infectious critically ill patients (T) and to healthy controls (H) ($p=0.005$). Zinc serum levels were significantly reduced in both groups of critical illness (mean value Zn; S group 50.9 µg/dl vs. T group 46.6 ± 12 µg/dl vs. H group 81.9 ± 12 µg/dl, $p<0.001$) (Fig. 1a). TAC was significantly depressed ($p<0.001$) and TOS and TOS/TAC ratio significantly elevated ($p<0.001$) in sepsis (S) compared to control groups (T and H) (Fig. 1b). Zinc was negatively correlated with TOS (Spearman's rho = −0.37, $p=0.001$) and TOS/TAC (rs = −0.39, $p=0.001$) and positively with TAC (rs = 0.22, $p=0.033$). Concerning mortality, TOS/TAC ratio was significantly elevated in non-survivors (median = 7.1; IQR 2.7–21) compared to survivors (1.5; IQR 0.67–2.8) ($p=0.001$), but the difference in serum zinc levels between the outcome groups did not reach statistical significance (survivors 60 ± 22 µg/dl vs. non-survivors 54.7 ± 16 µg/dl).
**Conclusions:** The upregulation of oxidative stress and repressed anti-oxidant capacity, accompanied by the downregulation of zinc, seem to characterize the developing processes of sepsis. Furthermore, low zinc levels are related to the oxidative patients' status, which is associated with mortality.

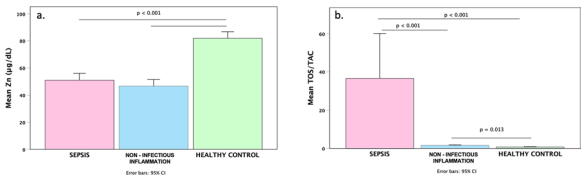

**Fig. 1 (abstract 000634)** Zinc (a) and TOS/TAC (b) mean serum levels differed significantly in septic critically ill patients compared to healthy controls and/or non-infectious critically ill patients. *TOS/TAC: total oxidative stress over total antioxidant capacity.*

### Modular Educational Programme for Organ Donation (MEPOD): the implementation of a novel national simulation course for multidisciplinary healthcare professionals

J. Khera[1], J. Overend[2], A. Gilbert[3], R. Cuthbertson[3], N. MacCallum[3]
[1]Department of Intensive Care, St George's Hospital, London, United Kingdom; [2]Critical Care Complex, Middlemore Hospital, Auckland, New Zealand; [3]Department of Intensive Care, University College Hospital, London, United Kingdom
**Correspondence:** J. Khera
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000635

**Introduction:** The Organ Donation Taskforce recommends "all clinical staff likely to be involved in the treatment of potential organ donors should receive mandatory training in the principle of donation."1 Additionally, organ donation facilitation is within intensive care and anaesthetic training doctors' curricula.2 The National Deceased Organ Donation Course (NDODC) run by NHS Blood and Transplantation (NHSBT) is aimed at only senior intensivists and is consistently oversubscribed.3 Providing excellent end-of-life care is challenging and opportunities to gain clinical training in organ donation can be infrequent, making simulation training desirable and necessary.
**Objectives:** Deliver an accessible modular educational programme based on NDODC for healthcare professionals in a psychologically safe environment.
Enable intensive care and anaesthetic doctors to meet their training requirements.
**Methods:** In collaboration with NHSBT, we produced 3 simulation modules to deliver in-situ at London ICUs. Modules included

Diagnosing Death using Neurological Criteria (DNC), Donor Management and Optimisation (DMO), and Donation after Circulatory Death (DCD).
Delegates completed a pre-and post-course survey which included module-specific questions rated on a Likert scale of confidence. We also tested technical knowledge and invited course delivery feedback. To assess for statistically significant differences between pre-and post-course confidence scores, median confidence scores followed by a one-sided paired Wilcoxon signed rank test was performed. P-values were adjusted for multiple comparisons using the False Discovery Rate adjustment of Benjamini and Hochbery (1995) with a significant result taken as adjusted $p < 0.05$.
**Results:** A total of 30 delegates attended 5 MEPOD modules across 3 London hospitals. 100% of delegates would recommend MEPOD to their colleagues. The median post-course confidence scores were higher than pre-course scores for every question, for all courses. After FDR adjustment, there were significant differences for all questions bar one in the one-sided Wilcoxon test, illustrating greater post-course confidence. Figures 1 and 2 illustrate confidence gained in working with a SNOD 77% vs 100%, and diagnosing and recording circulatory death 62% vs 100% respectively.
**Conclusions:** We effectively implemented a modular educational programme in organ donation for multidisciplinary delegates at London hospitals. An improvement in confidence ratings across all modules and unanimous recommendation was demonstrated. This novel project has increased collaboration and accessibility to simulation training for the multidisciplinary ICU team. Limitations include small delegate numbers meaning we were unable to account for seniority of delegate, location of module, and differences between participants completing all 3 modules in one day as opposed to single module attendance. Our future plans include delivering MEPOD nationally with the support of NHSBT educational leads in organ donation.

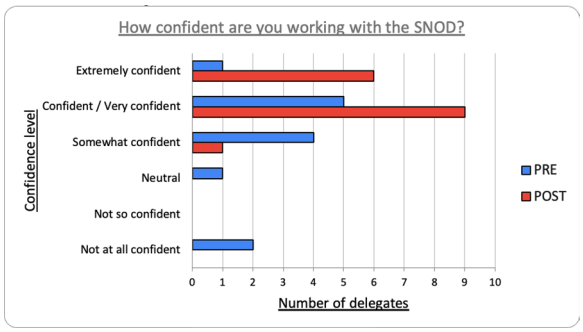

**Fig. 1 (abstract 000635)** Graph demonstrating delegates' confidence in working with a SNOD. Pre-MEPOD survey (blue) and post-MEPOD survey results (red)

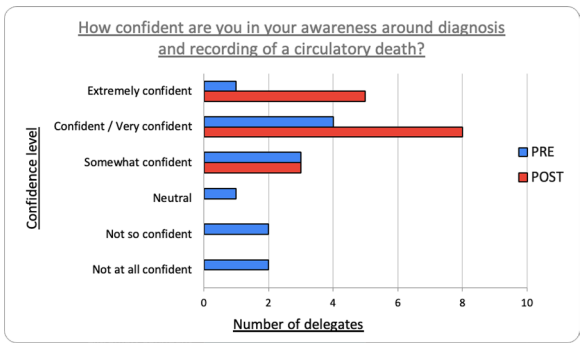

**Fig. 2 (abstract 000635)** Graph demonstrating delegates' confidence in their diagnosis and recording of circulatory death. Results show pre-MEPOD survey (blue) and post-MEPOD survey (red)

## Congenital hypoproconvertinemia in pregnant women: four clinical cases of effective correction of changes in the hemocoagulation system

E. Kotova[1], A. Zhavaranak[1], A. Gritsan[2]
[1]Anaesthesiology and Intensive Care, Republican Scientific and Practical Center "Mother and Child", Minsk, Belarus; [2]Anaesthesiology and Intensive Care, V.F. Voino-Yasenetsky Krasnoyarsk State Medical University, Krasnoyarsk, Russia.
**Correspondence:** A. Gritsan
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000636

**Introduction:** Hemorrhage is a cause of preventable maternal death. Congenital coagulopathies increase this risk. The low frequency of their occurrence (0.5–1%) makes it difficult to develop a unified algorithm for the management of patients. Targeted hemostatic replacement therapy under the control of thromboelastometry can reduce the risk of hemorrhagic and thrombotic complications in pregnant women with hereditary coagulopathies.
**Objectives:** present clinical observations of hemostasiological therapy in the management of four patients (three of whom are pregnant) with congenital hypoproconvertinemia (factor VII deficiency).
**Methods:** From 2018 to 2023, four patients aged 21–45 years with FVII deficiency were treated. Three patients had no or minimal history of hemorrhagic syndrome. In one case there was abnormal uterine bleeding.To monitor hemostasis, in addition to routine coagulation tests, thromboelastometry was used.
**Results:** Two women underwent cesarean section for obstetric indications. For the purpose of preoperative preparation and in the postoperative period, an antifibrinolytic (tranexamic acid) 1 g and interval programmed administration of prothrombin complex concentrate were used: 2000 IU every 12 h for 5 days. In the third case, replacement therapy was carried out with a prothrombin complex concentrate in a maximum single dose of 3000 IU for the purpose of preoperative preparation for hysteroresectoscopy and 500 IU 8 h after the intervention under the control of the international normalized ratio, prothrombin time for 5 days of the postoperative period. In the fourth case (factor VII activity < 1%, CT in Extem = 281), childbirth was carried out through the vaginal birth canal. The decision to target therapy with prothorambin complex concentrate was made based on the results of ROTEM, rather than by calculation based on the international normalized ratio (initial value 6.72); with the introduction of 1000 units of prothrombin complex concentrate, INR = 1.7 and ROTEM norm were achieved (ST in Extem = 80). It was decided to refuse further administration of the prothrombin complex concentrate. Blood loss during natural childbirth was 250 ml and 500 ml during surgical delivery, not exceeding the physiological one. No hemorrhagic complications were noted in all patients in the postpartum period.
**Conclusions:** The tactics of a single use of prothrombin complex concentrate under thromboelastometry control made it possible to reduce the effective dose of prothrombin complex concentrate in the absence of hemorrhagic manifestations and reduce the risk of thrombotic complications. Multicenter studies are required to create an evidence base for the use of this technique.

**Topic:** Transfusion and haemostasis disorders

**Correspondence:** S. Al-Azzam
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000639

**Introduction:** In the realm of patient care, maintaining optimal glycemic control is a cornerstone of treatment1. Therefore, leveraging the latest healthcare advancements, the power of comprehensive health records and cutting-edge machine learning algorithms to pioneer a novel approach to predicting hypoglycemia within hospital settings is crucial2.
**Objectives:** To develop and validate a robust machine-learning model utilizing electronic health records (EHR) to forecast the risk of hypoglycemia among Intensive Care Unit (ICU) patients in Jordan.
**Methods:** The present study drew upon a substantial cohort of ICU admissions over ten years from July 2012 to July 2022 with patients younger than 18 years old or those without at least one glucose reading during their ICU stay were excluded. A random forest algorithm was used for candidate predictor variables selection including patients' demographics, length of stay (LOS), comorbidities, received medications, and laboratory results. The primary outcome of interest was the occurrence of any hypoglycemic episode during the patient's ICU stay. Developing and testing predictor models were conducted using Python machine learning libraries.
**Results:** A total of 26,248 ICU admissions for 13,567 were extracted. Out of 1,896 included patients, 206 experienced at least one hypoglycemic episode. A total of 43 candidate predictor variables were taken into consideration. Eight ML models were trained to predict hypoglycemia. Models showed predicting power with a range of (74.53–99.69) for AUROC. Except for Naive Bayes, the six remaining models performed distinctly better than the basic logistic regression usually used for prediction in epidemiological studies. CatBoost model was consistently the best performer with the highest AUROC (0.99), accuracy and precision, sensitivity and specificity, and recall. An increased predicted risk of ICU hypoglycemia was observed for glucose, white blood cell count, magnesium, urea, and LOS.
**Conclusions:** Machine learning models were developed to anticipate the likelihood of hypoglycemia in ICU patients. This is crucial for early detection, personalized glycemic management, and identification of patients at higher risk of hypoglycemia. Ultimately, it will enable timely interventions, optimized treatment strategies contributing to more efficient and proactive critical care management.

### Heparin-induced thrombocytopenia in the cardiac intensive care unit. A unique, 8-year, single-centre experience

L. Szyda, J. D. Kasprzak
Department of Cardiology, Medical University of Lodz, Łódź, Poland
**Correspondence:** L. Szyda
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000641

**Introduction:** Heparin-induced thrombocytopenia (HIT) is a rare immune-mediated disorder related to the use of unfractionated heparin or low-molecular-weight heparin associated with significant thrombotic risk and death. Despite the widespread use of heparin in the cardiac intensive care unit (CICU) there is no data concerning epidemiology, risk factors and treatment efficacy of HIT in acute cardiac settings. Of note, there are also many other than HIT causes of thrombocytopenia occurring in acute patients, but no comparison of these two distinct clinical scenarios has been made so far. Non-heparin anticoagulants are recommended for the treatment of HIT. However, no specific therapeutic recommendations for the acute cardiac population exist. We want to share our unique 8-year experience concerning heparin-induced thrombocytopenia in the intensive cardiac care unit setting.
**Methods:** We retrospectively collected data of all patients with HIT and of all patients with thrombocytopenia from other causes in whom HIT had been firmly excluded and who were hospitalized in our cardiac intensive care unit in 2016–2024. We performed statistical analysis to determine epidemiological, prognostic, therapeutic characteristics and clinical outcomes in our patients with HIT.
**Results:** Among 30 960 patients hospitalized in our cardiology department 12 were diagnosed with HIT (incidence of 1:2 580). All patients with HIT were hospitalized in the ICCU. Clinical characteristics of patients with HIT are summarized in Table 1. Dabigatran was the most commonly used non-heparin anticoagulant for HIT in our CICU. 4 patients with HIT died during index hospitalization and 8 survived. Higher C-reactive protein level at admission was associated with increased mortality in acute cardiac patients with HIT. Non-survivors had higher CRP levels at admission as compared to survivors, 190 [125–247] mg/l vs. 22 [9–71] mg/l respectively ($p = 0{,}03$). However, there was no difference in in-hospital mortality between the patients with HIT and the patients with thrombocytopenia from other causes ($p = 0{,}7426$).
**Conclusions:** Heparin-induced thrombocytopenia constitutes a relevant clinical issue in the CICU and is associated with similar mortality as compared to other causes of thrombocytopenia. The use of direct oral anticoagulants and especially dabigatran seems safe and efficace in acute cardiac patients with HIT. C-reactive protein level may be an important prognostic factor for HIT.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000642

**Introduction:** Patient care is affected by patient factors and health system factors (1,2). Understanding how strain on the latter affects the quality of patient care and outcomes is important, but conducting experiments in this area is complex and ethically difficult. As such, naturally occurring strain events such as the COVID-19 crisis provide a unique insight into a period of exceptional health service pressures on intensive care units (ICU) across countries and settings (3).
**Objectives:** TTo report ICU shortages as a strain surrogate during both COVID-19 surges and evaluate their correlation with patient outcomes.
**Methods:** Secondary analysis of the ESICM UNITE-COVID study (4,5) which collected patient and site-specific data during the 2020 and 2021 surges of COVID-19. The patient-level outcomes were collated for each site to include mortality, length of stay, and a complications score encompassing the number of complications during the patients' stay. On a site level, data on shortages and their impact on clinical practice (shortage without change or shortage with change) were collected for sedation medications, analgesic medications, invasive lines, microbiological treatments, ventilators, renal replacement therapy, tracheostomy care and others. A cumulative shortage score with equal weighting for each category was calculated for both types of shortage (labelled as "simple shortage score" and "practice change score").
**Results:** There was a significantly higher level of simple shortages (mean score 2.9 in 2020 and 2.3 in 2021) than shortages that changed practice (mean score 1.2 in 2020 and 0.8 in 2021) with $p = 0.03$.
Overall the main shortages that resulted in a change in practice were related to sedatives and analgesics and access to ventilators and renal replacement therapy. This was particularly striking during the 2020 surge where nearly a third of sites reported shortages in sedation and ventilator access resulting in a change in practice. In 2021 there were still shortages resulting in a change in practice, however, to a lesser extent. Microbiological treatments and invasive lines were the only shortages that were essentially the same between the two surges.
Linear regression of the complications score with shortage score (corrected for patient comorbidities and severity of infection) showed significantly higher level ($p = 0.0004$) of complications with higher levels of shortages resulting in a change of practice.

**Table 1 (abstract 000642)**

| **Surge period of:** | **2020 surge** | | **2021 surge** | |
|---|---|---|---|---|
| Type of shortage | Change in practice | Without change | Change in practice | Without change |
| Sedation | 33% | 61% | 17% | 44% |
| Analgesia | 25% | 48% | 16% | 34% |
| Invasive lines | 5% | 22% | 3% | 20% |
| Microbiological treatment | 7% | 25% | 10% | 24% |
| Ventilator | 27% | 50% | 16% | 34% |
| Renal replacement therapy | 16% | 38% | 9% | 40% |
| Tracheostomy | 9% | 23% | 6% | 18% |
| Other | 0% | 27% | 0% | 14% |
| Mean shortage score | 1.2 | 2.9 | 0.78 | 2.3 |

**Conclusions:** There were significant shortages throughout both surges of COVID-19 resulting in changes in practice and therefore representing significant strain with potential impact on quality of patient care and safety. The correlation of shortages that changed practice

with complications indicates that patient care was of lower quality in ICUs that experienced higher levels of system pressures (reflected in necessity to change practice). The causes and potential mitigations for this will require further investigation.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000644

**Introduction:** A recent randomized controlled trial showed that polymyxin B hemoperfusion (PMX-HP) improved hemodynamic status in patients with septic shock [1]. Early administration of PMX-HP may decrease the duration of vasopressor therapy [2], but its short-term hemodynamic effect remains unknown.

**Objectives:** Whether early administration of PMX-HP for septic shock would improve the short-term hemodynamic status as well as the clinical course, including mortality?

**Methods:** BEAT-SHOCK (BEst Available Treatment for septic SHOCK) registry was a prospective observational study consisting of 309 adult patients with septic shock requiring high-dose norepinephrine ($\geq$0.2 microg/kg/min). As the exploratory analysis, we enrolled 82 patients treated with PMX-HP and divided them into two groups by the median time (265 min) from ICU admission to administer PMX-HP (early administration group [$n=40$] and late administration group [$n=42$]). The primary outcome is short-term hemodynamic status, including mean arterial pressure and vasopressor-inotrope score (VIS; calculated from doses of dopamine, dobutamine, norepinephrine, epinephrine, vasopressin, milrinone, and levosimendan) within 48 h after ICU admission.

**Results:** In the 82 patients, the median time from ICU admission to administer PMX-HP was 265 min (interquartile range [IQR] 113–480), and the median duration of PMX-HP was 1016 min (IQR 533–1359). The median age was 69.5 (IQR 58.5–80.8) and 72 (IQR 63.8–80) years old ($P=0.77$), and 21 (53%) and 25 (60%) patients were male ($P=0.52$) in the early and late administration groups. The dose of norepinephrine at ICU admission was 0.33 (IQR 0.24–0.47) and 0.30 (0.22–0.34) microg/kg/min in the early and late administration groups ($P=0.17$). Within 48 h after ICU admission, mean arterial pressure was significantly higher at some time points, and VIS was significantly lower at most time points in the early administration group (Figures 1 and 2). In the 28- days, vasopressor-free days were 23 (21–25) and 21 (0–24) days ($P=0.027$), and ICU-free days were 18 (1–23) and 14 (0–19) days ($P=0.025$) in the early and late administration groups, respectively. The cumulative mortality rates at 90 days were 15.3% and 31.3% in the early and late administration groups (adjusted hazard ratio 0.38; 95% confidence interval 0.13–1.09).

**Conclusions:** In patients with septic shock, early administration of PMX-HP was associated with higher mean arterial pressure and lower VIS within 48 h after ICU admission. Additionally, it might be associated with an improved clinical course.

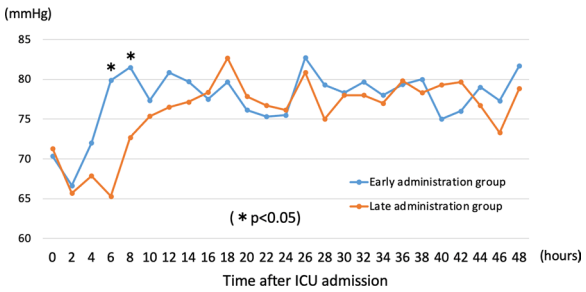

**Fig. 1 (abstract 000644)** Mean arterial pressure within 48 hours after ICU admission
We expressed each data by median value. We used Wilcoxon rank sum test for each comparison.

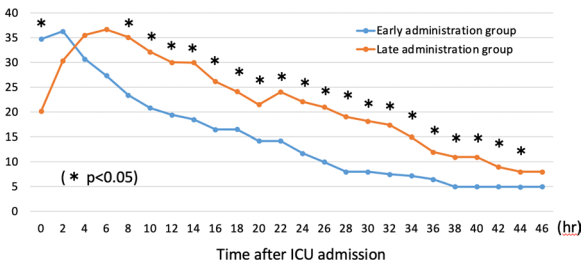

**Fig. 2 (abstract 000644)** Vasopressor-inotrope score within 48 hours after ICU admission
We expressed each data by median value. We used Wilcoxon rank sum test for each comparison.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000645

**Introduction:** The ratio between brain oxygen pressure (PbtO2) and partial pressure of arterial oxygen (PaO2), i.e. the BOx ratio, has been recently described as a clinically useful tool to understand abnormal oxygen delivery mechanisms in head trauma patients. However, its prognostic role in subarachnoid hemorrhage (SAH) has not been well explored.
**Objectives:** To investigate the prognostic role of the BOx ratio in SAH patients.
**Methods:** We reviewed our cohort of patients admitted to the Intensive Care Unit (ICU) with non-traumatic SAH treated from March 2015 to October 2023, in whom PbtO2 monitoring was considered according to a local protocol. For each patient, the mean PbtO2 and the mean BOx ratio were computed over all ICU stays. Hospital mortality was considered as the primary outcome. We performed a multivariate analysis to study the association between the mean BOx ratio and hospital mortality.
**Results:** Of the 263 SAH patients admitted over the study period, 64 were monitored with PbtO2 and included in the analysis. Of those, 30 patients (47%) died during their hospital stay. No differences in age, gender, and clinical score on admission were found between survivors and non-survivors. The occurrence of delayed cerebral ischemia (DCI) and intracranial hypertension (ICHT) was respectively 54% vs. 41% and 63% vs. 87% ($p=0.401$, $p<0.001$) in both groups, respectively. The mean values of PbtO2 were $25\pm6$ mmHg in survivors and $23\pm9$ mmHg in non-survivors ($p=0.40$), while the mean BOx ratio was $0.23\pm0.07$ in survivors and $0.20\pm0.08$ in non-survivors ($p=0.183$). In the multivariate analysis, adjusted for the occurrence of DCI and ICHT, neither mean PbtO2 (OR 0.967; CI 95% 0.897, 1.041; $p=0.37$) nor mean BOx ratio (OR 0.58; CI 95% 0.0, 1.8; $p=0.07$) was independently associated with hospital mortality.
**Conclusions:** In this cohort of non-traumatic SAH patients, a lower BOX ratio was not associated with an increased risk of hospital mortality.

**Correspondence:** B. Tilburgs
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000647

**Introduction:** Patients who survive their intensive care unit (ICU) stay, often encounter new or worsening physical, cognitive, and metal health problems known as the Post-Intensive Care Syndrome (PICS). While the primary goal of an ICU admission is to secure patients' survival, it is equally imperative to reduce long-term health problems after ICU treatment. ICU length of stay (LOS) and pre and post ICU LOS are objective variables which can easily be observed by all healthcare professionals and may contribute to identifying patients who are at risk for developing PICS.
**Objectives:** To determine the association between ICU-LOS, pre and post ICU-LOS and PICS one year after ICU admission.
**Methods:** A longitudinal prospective multicenter cohort study was conducted in seven hospitals from the MONITOR-IC study. Patient characteristics, including ICU LOS, pre and post-ICU LOS, were collected from the patients' medical records and the Dutch National Intensive Care Evaluation registry (NICE). In addition, at ICU admission and 12 months post ICU, patients completed validated questionnaires regarding physical, cognitive, and mental problems of which composite scores for each domain (physical, cognitive, mental) were calculated. When patients experienced only physical problems they were categorized as patients with PICS in one domain. When patients experienced physical and cognitive problems, they were categorized as patients with PICS in two domains etc. To determine the associations between patients' ICU LOS, pre and post-ICU LOS and PICS domains one year after an ICU admission, adjusted multinominal logistic analyses were used. These analyses included patients characteristics such as age, gender, disease severity, and baseline physical, cognitive and mental problems.
**Results:** In this study, 3118 patients admitted between 2016 and 2020 were analyzed. Of these 31% were admitted for a medical, 12% for an acute surgical, and 57% for a planned surgical reason. They had an average ICU LOS of 3 days, a pre ICU LOS of 2 days and a post ICU LOS of 8 days. One year after an ICU admission 63% experienced physical, 11% cognitive, and 31% mental PICS. In addition, 34% experienced no PICS, 34% experienced PICS in one domain, 23% in two domains, and 9% in three domains.
Compared to patients who do not experience PICS, the Odds ratios of ICU LOS and post-ICU LOS significantly increase for patients who experience PICS in one, two or three domains one year after an ICU admission. See Table 1.

**Table 1 (abstract 000647)** Multinominal regression analyses of ICU LOS, pre ICU LOS, post ICU LOS, and PICS in 1, 2 or three domains

| Frequency of PICS domains | Independent variable | B | Exp(B) | 95% confidence interval | | Sig |
|---|---|---|---|---|---|---|
| | | | | Lower | upper | |
| 1 | ICU LOS | 0.056 | 1.057 | 1.023 | 1.092 | < 0.001 |
| | pre ICU LOS | −0.010 | 0.990 | 0.966 | 1.016 | 0.451 |
| | Post ICU LOS | 0.024 | 1.024 | 1.007 | 1.042 | 0.006 |
| 2 | ICU LOS | 0.053 | 1.055 | 1.019 | 1.092 | 0.003 |
| | pre ICU LOS | −0.013 | 0.987 | 0.957 | 1.018 | 0.411 |
| | Post ICU LOS | 0.032 | 1.033 | 1.014 | 1.052 | < 0.001 |
| 3 | ICU LOS | 0.061 | 1.063 | 1.022 | 1.106 | 0.002 |
| | pre ICU LOS | −0.027 | 0.973 | 0.924 | 1.025 | 0.305 |

| Frequency of PICS domains | Independent variable | B | Exp(B) | 95% confidence interval | | Sig |
|---|---|---|---|---|---|---|
| | | | | Lower | upper | |
| | Post ICU LOS | 0.048 | 1.049 | 1.026 | 1.074 | < 0.001 |

PICS = Post intensive care syndrome; ICU = intensive care unit, LOS = length of stay

**Conclusions:** Even though ICU LOS and post ICU-LOS are significantly associated with the development of PICS in one or more domains one year after an ICU admission, the Odds ratios are small and might not be appropriate to identify patients who are at risk for developing PICS.

### Differences in the impact of hypothermia on mortality between pediatric and adult trauma patients

N. Kurata, M. Nishikimi, S. Ohshimo, N. Shime
Department of Emergency and Critical Care Medicine, Graduate School of Biomedical and Health Sciences, Hiroshima University, Hiroshima, Japan
**Correspondence:** N. Kurata
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 000651

**Introduction:** Pediatric patients, characterized by a larger body surface area-to-mass ratio compared with adults, are inherently predisposed to rapid heat loss and subsequent hypothermia. Previous studies reported a consistent association between hypothermia and worse outcomes in trauma patients across age groups, but there have been few comparative studies focusing on the differential mortality attributable to hypothermia between pediatric and adult trauma cohorts.
**Objectives:** The aim of this study was to evaluate the difference in mortality associated with hypothermia on hospital admission between pediatric and adult patients.
**Methods:** We retrospectively analyzed patient data from the Japan Trauma Data Bank date collected from January 2019 to December 2022. We compared the differences in mortality based on the body temperature on hospital admission between pediatric (< 18 years) and adult (≥ 18 years) trauma patients. Mortality differences were quantitatively evaluated through adjusted spline curve analyses, incorporating various covariates (e.g. injury sites, measuring techniques of body temperature, Focused Assessment with Sonography in Trauma (FAST) findings, transfusion at the emergency department, mechanical ventilation requirements, and Injury Severity Score (ISS)). An interaction effect between age categories and body temperature was introduced to evaluate its effect on mortality. The primary outcome was defined as mortality at hospital discharge.
**Results:** A total of 60,617 patients were analyzed, with 3002 classified as pediatric and 57,615 as adult. The median age in adults was 66.8 years with a median ISS of 14; pediatrics had a median age of 9.7 years with a median ISS of 11. The mortality was higher in hypothermic patients (< 36 ℃) compared with that in normothermic patients in both pediatric (14.9% [72/483] vs 1.2% [31/2,518], $p < 0.001$) and adult (15.1% [2,271/15,050] vs 4.6% [1,975/42,565], $p < 0.001$) groups. The effect of decreased body temperature on mortality was profoundly modified by the age category (pinteraction < 0.001) (Figure).
**Conclusions:** The impact of hypothermia on hospital admission on mortality was more pronounced in pediatric trauma patients compared with adults. Preventing hypothermia may be more important in pediatric trauma patients.

**Introduction:** In the randomized open trial DexiNIVE (NCT02958150) it was shown that the intensive care unit (ICU) patients undergoing noninvasive mechanical ventilation (NIV) with acute respiratory failure (ARF) sedated with dexmedetomidine (DEX) were more comfortable. In addition, DEX did not increase the risk of orotracheal intubation (OTI), did not lead to further adverse effects, and did not have an impact on mortality. Considering resource utilization data from this trial, it was performed a secondary, cost-minimization analysis assessing the economics of DEX versus standard clinical practice (SCP).
**Objectives:** To assess the costs of the use of DEX vs SCP during the NIV in patients with ARF.
**Methods:** A cost-minimization analysis was performed in this study.
The cost estimates were based on the calculation of the resources used in the treatment and their costs.
The perspective of the study was the hospital perspective.
To describe ICU stay costs, hospital stay costs, total hospitalization costs, pharmacological costs, OTI costs, and total costs, the median and interquartile range (IQR) of each of them in each group were used since they did not follow a normal distribution.
The Mann–Whitney U test was used to compare each type of cost between the two groups.
This analysis was performed using IBM SPSS Statistics version 25.0.
Moreover, the bootstrapping method was applied to calculate the probability of savings using DEX, in ICU stay costs, total hospitalization costs, pharmacological costs, OTI costs, and total costs.
1000 simulations were performed using Microsoft Excel, where new patient samples were created by patient selection (with replacement).

**Results:** The median (IQR) of ICU stay costs was 11.690 (6.680–22.545) euros in the DEX group vs 11.690 (5.010–23.380) euros in the SCP group, $p = 0{,}602$.
The median of total hospitalization costs was 24.178 (11.690–33.914) euros in the DEX group vs 23.566 (13.573–34.358,50) euros, $p = 0{,}899$.
The median of pharmacological costs was 65,18 (64,75–129,50) euros in the DEX group vs 0,25 (0–1,12) euros, $p = 0{,}000$.
The median of OTI costs was 0 (0–0) euros in the DEX group vs 0 (0–0) euros, $p = 0{,}469$.
The median of total costs was 24.242 (11.974,81–33.978,97) euros in the DEX group vs 23.566 (13.708–34.358,61) euros, $p = 0{,}943$.
The probability of a cost saving using DEX in patients of ICU stay was 44.8%; of total hospitalization was 67%; of pharmacological costs was 0%; of cost saving of OTI costs was 23,7%; and of cost saving of total costs was 70,5%.
**Conclusions:** The use of DEX during NIV in ICU patients with ARF does not lead to a significant increase in costs.
Moreover, when a simulation is performed by increasing the sample size, the probability of total cost savings using DEX is high.

**Introduction:** Acute respiratory distress syndrome (ARDS) is a life-threatening condition characterized by hypoxemia and diffuse chest infiltrates. With moderate to severe ARDS, prone positioning during mechanical ventilation has been proven to reduce mortality. However, despite discontinuing prone position ventilation due to fulfilling the criteria, some patients still experience worsening. The aim of our study is to find an appropriate discontinuing point for prone position ventilation. Acute respiratory distress syndrome (ARDS) is a life-threatening condition characterized by hypoxemia and diffuse chest infiltrates. With moderate to severe ARDS, prone positioning during mechanical ventilation has been proven to reduce mortality. However, despite discontinuing prone position ventilation due to fulfilling the criteria, some patients still experience worsening. The aim of our study is to find an appropriate discontinuing point for prone position ventilation.
**Methods:** We retrospectively reviewed 70 patients who received prone position ventilation for ARDS at Chonnam National University Hospital from Jan. 2021 to Dec. 2022. The criteria for successful discontinuing prone position ventilation were defined as a ratio of arterial oxygen partial pressure to fractional inspired oxygen (P/F ratio) of $\geq 150$ mm Hg, with a positive end-expiratory pressure (PEEP) of $\leq 10$ cmH2O and an FiO2 of $\leq 0.6$ in the supine position at least 4 h after the end of the last prone session. The failure of prone position ventilation is defined as P/F ratio $< 150$ mmHg within 24 h after the end of prone position ventilation.
**Results:** Among 70 patients who underwent prone position ventilation, 32 were excluded from the study. Of these, 24 patients expired during prone position ventilation, 6 required extracorporeal membrane oxygenation (ECMO), and 2 developed hypoxia following prone position ventilation. Thirty-eight patients successfully discontinued prone position ventilation. The mean age of these patients was 70.9 years, and 20 (52.6%) were male. The most common cause of ARDS in this group was Corona Virus Disease 2019 (COVID-19). The median P/F ratio was 185.3 mmHg, measured 4 h after switching to the supine position following the last prone session. Among 38 patients, 21 patients (55.3%) had a P/F ratio $< 150$ mmHg within 24 h after the last prone session, which was significantly associated with higher mortality rates (81.0% versus 35.3%; $p = 0.05$). Patients with a P/F ratio $< 180$ mmHg in the supine position at 4 h after the last prone session were significantly more likely to experience failure of prone position ventilation (Odds Ratio 63.75; 95% Confidence Interval 6.40–635.01; $p < 0.001$). Kaplan–Meier analysis showed that the median survival time was shorter for patients with prone position ventilation failure (24 days versus not reached; Hazard Ratio 3.4; 95% CI 1.332–8.721; $p = 0.011$).
**Conclusions:** In ARDS, P/F ratio of $< 150$ mmHg within 24 h after discontinuing prone position was associated with a high mortality. And P/F ratio of $< 180$ mmHg measured 4 h after switching to the supine position following the last prone session was significantly associated with P/F ratio of $< 150$ mmHg within 24 h.

**Introduction:** The use of Extracorporeal Membrane Oxygenation (ECMO) remains associated with high rates of complications, weaning failure, and mortality in part due to a knowledge gap on how to properly manage patients on ECMO support. To address relevant patient management issues, we designed a "Randomized Embedded Multifactorial Adaptive Platform (REMAP)" in the setting of ECMO (REMAP ECMO) and a first embedded trial domain investigating the effects of routine early left ventricular (LV) unloading through intra-aortic balloon pumping (IABP) (Figure 1).
**Methods:** REMAP ECMO describes a registry-based platform allowing for the embedding of multiple response adaptive randomized controlled trials (RCTs) (trial domains) which can perpetually address the effect of relevant patient management issues on ECMO weaning success. A first trial domain studies the effects of LV unloading by means of an IABP as an adjunct to veno-arterial (V-A) ECMO versus V-A ECMO alone on ECMO weaning success at 30 days in adult cardiogenic shock patients admitted to the Intensive Care Unit (ICU) (Figure 2).
**Results:** The primary outcome of this trial is "successful weaning from ECMO" being defined as a composite of survival without the need for mechanical circulatory support, heart transplantation, or left ventricular assist device (LVAD) at 30 days after initiation of ECMO. Secondary outcomes include the need for interventional escalation of LV unloading strategy, mechanistic endpoints, and quality of life. Trial data will be analyzed using a Bayesian statistical framework. The adaptive design allows for a high degree of flexibility, such as response adaptive randomization and early stopping of the trial for efficacy or futility (Figure 3).
**Conclusions:** The REMAP ECMO trial platform enables the efficient roll-out of multiple RCTs on relevant patient management issues. A first embedded trial domain will compare routine LV unloading by means of an IABP as an adjunct to V-A ECMO versus V-A ECMO alone.

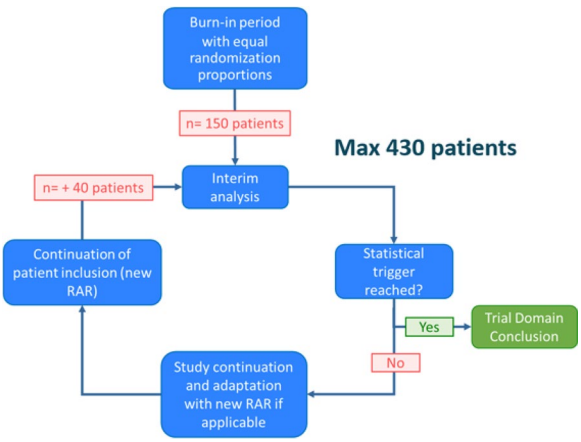

**Fig. 5 (abstract 000654)** Response adaptive randomization (RAR) and statistical triggers. The trial will start with a burn-in period during which all patients will be included with equal randomization proportions for the duration of 150 patients. After this burn-in period, a first interim analysis will test whether statistical triggers are reached, leading either to a trial domain conclusion or study continuation and adaptation with new RAR if applicable. These interim analyses will be performed after every following 40th patient is randomized and has reached their 30-day follow-up, until a maximum of 430 patients are included

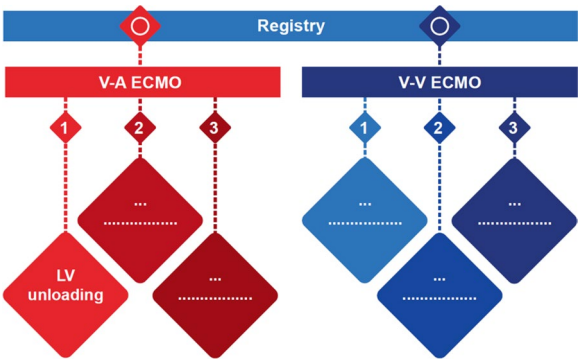

**Fig. 1 (abstract 000654)** Architecture of the REMAP ECMO platform. (*VA = venoarterial ECMO, VV = Venovenous ECMO, LV unloading = left ventricular unloading)*

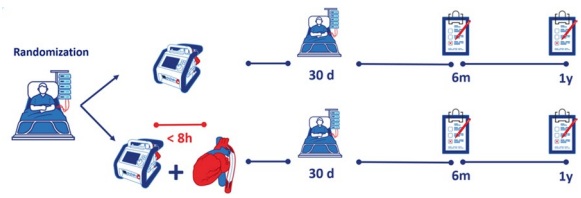

**Fig. 3 (abstract 000654)** ALeft Ventricular Unloading trial design. Patients are randomized to a strategy with V-A ECMO in combination with IABP versus V-A ECMO alone. IABP placement must occur within 8 h (< 8h) after ECMO initiation. The primary endpoint will be measured at 30 days (30d) after ECMO initiation Other follow-up moments will follow at 6 months (6m) and 1 year (1y) using questionnaires

### Analysis of nitrogen balance test in patients with traumatic brain injury

J. Yu
Neurosurgery, Severance Hospital, Seoul, Republic of Korea
**Correspondence:** J. Yu
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000656

**Introduction:** During the acute stage of traumatic brain injury, individuals require increased nutritional assistance due to elevated metabolic and catabolic activity. Protein emerges as a critical component in such circumstances, with nitrogen balance serving as a reliable indicator of protein levels within the body. This study investigate nitrogen balance within patients admitted to the Neurocritical Care Unit (NCU),

exploring its correlation with disease severity and discerning variances between traumatic and non-traumatic cases.
**Objectives:** The purpose of this study was to analyze the catabolic phases of TBI patients through the Nitrogen Balance Test (NB Test).
**Methods:** Patients admitted to NCU from June 2019 to March 2022, both traumatic and non-traumatic (e.g., Tumor, stroke, etc), were retrospectively studied. Each patient stayed in NCU for at least 7 days, and had a nitrogen balance test with 1-week interval. We evaluated trends in nitrogen balance values and compared disease severity indicators (initial GCS, SOFA, APACHE, ICU stay days, presence of operation, etc.).
**Results:** A total of 280 patients were admitted to the NCU and underwent the initial nitrogen balance assessment. Among them, 160 underwent a second test, and 90 underwent a third test. The initial nitrogen balance averaged at $-6.77 \pm 4.9$, while it measured $7.24 \pm 5.1$ in the first week and $-4.3 \pm 5.3$ in the second week. However, parameters related to disease severity did not exhibit a statistically significant relationship with nitrogen balance values. Trauma patients, in comparison to non-trauma patients, displayed notably lower nitrogen balance values in the first week ($-11.2$ for traumatic patients versus $-7.2$ for non-traumatic patients; $p = 0.005$). No significant differences were observed between initial and second-week nitrogen balance values.
**Conclusions:** In actual clinical situations, physicians should be aware of the catabolic phases of acute TBI events indicating notable protein loss in the patients. Therefore, we should consider the additional supply of protein during the management of TBI patients.

**Introduction:** Surviving sepsis campaign do not recommend the use of intravenous immunoglobulins (IVIG) in sepsis or septic shock because of the lack of scientific evidence. Nevertheless some authors[1,2,3], reported particularly in patients presenting streptococcus pyogenes severe infections with shock, an improvement of outcome with IVIG.
**Objectives:** To evaluate the administration of IVIG versus placebo in patients with septic shock due to severe group A streptococcus infections.
**Methods:** We performed a randomised controlled study and enrolled 40 patients admitted to university hospital ICU between 2002 and 2005. The patients were 35 + -10 years old without previous comorbidity and all were mechanically ventilated for severe septic shock and received the same antibiotics in the first hour of admission for suspicion of invasive streptococcus infection.
The patients were randomised into 2 groups:
**An IVIG group** of 20 patients received IVIG 36 h after admission in ICU.
**A control group** of 20 patients receiving saline as a placebo 36 h after ICU admission
IVIG was administered for 3 days at a dose of 1g/kg the first day and 0.5g/kg over 2 days.
We recorded in the 2 groups: SOFA score day 1 and day 4, P/F ratio /12h, blood lactate every hour, blood cultures, blood gases, creatinine, C. reactive protein every day(CRP), transaminases, blood cell count, coagulation parameters, blood concentration of immunoglobulins(IgG), limb ischemic lesions, ICU stay, hospital length of stay, ICU mortality and 28-day mortality.
Statical analysis used the Mann–Whitney test and results were expressed as Mean ±standard deviation

**Results:**

**Table (abstract 000657).**

| | IVIG GROUP | CONTROL GROUP | P |
|---|---|---|---|
| SOFA score day 4 | 4.2 + -0.2 | 7.2 + -0.4 | 0.001 |
| P/F ratio day3 | 250 + -7 | 190 + -10 | 0.03 |
| Lactate mmo/l day 3 | 2.6 + -0.2 | 4 + -0.5 | 0.001 |
| CRP mg/l day3 | 152 + -6 | 359 + -3 | 0.001 |
| limb ischemic lesions % | 5% | 25% | 0.001 |
| ICU stay/days | 12 + -2 | 18 + -1 | 0.003 |
| 28 day mortality | 12% | 30% | 0.001 |

*Variables in relation with outcome in IVIG and control group

**Conclusions:** We observed that early intravenous administration of polyvalent immunoglobulins associated with adequate antibiotics improve outcome of patients with group A streptoccocal septic shock.

### Traumatic brain injury-induced cardiac autonomic dysfunction (from bench to clinical experiments

S. Kim[1], J. Oh[2]
[1]Physiology, Yonsei University, Sinchon Campus, Seoul, Republic of Korea; [2]Neurosurgery, Yonsei University, Sinchon Campus, Seoul, Republic of Korea
**Correspondence:** J. Oh
*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000658

**Introduction:** Traumatic brain injury (TBI) frequently causes cardiac autonomic dysfunction (CAD), which is associated with increased morbidity and mortality. However, the exact mechanism of CAD has not been elucidated yet. Hereby we tried to elucidate the cellular mechanism of CAD and try to assess the CAD in real patients.
**Methods:** TBI model was induced by a controlled cortical impact in rats. We assessed the heart rate variability and baroreflex sensitivity, which was indicated that CAD, based on the severity. And then we measured the excitability the intracardiac ganglion (ICG) neuron and stellate ganglion (SG) neurons in TBI rats. And we also check the baroreflex sensitivity (BRS) in TBI patients, according to the severity.
**Results:** In the TBI rat model, the BRS according to the degree of severe trauma was $0.98 \pm 0.08$ ms/mmHg in the control group,

whereas it was 0.45 ± 0.09 and 0.47 ± 0.08 ms/mmHg in the Mild TBI(mTBI) and Severe TBI (sTBI) groups. ($p < 0.01$) Then we measured excitability and K currents in SG and ICG. The SG neurons of the control group and sTBI group discharged at 4.2 ± 0.4, 6.5 ± 0.4, 8.6 ± 0.5 spikes/s, and 7.4 ± 0.3, 10.5 ± 0.4, 13.0 ± 0.4 spikes/s, in response to 1X, 2X, and 3X threshold current stimulations. respectively. The ICG neurons of the control group and sTBI group discharged at 5.7 ± 0.4, 8.0 ± 0.5, 11.0 ± 0.6 spikes/s and 2.0 ± 0.3, 4.0 ± 0.7, and 5.8 ± 0.6 spikes/s in response to 1X, 2X, and 3X threshold current stimulations, respectively.

The transient A-type K + (KA) currents, but not the delayed rectifying K + currents were significantly decreased in SG neurons in TBI rats, compared with sham-operated rats. Consistent with these electrophysiological data, the transcripts encoding the Kv4 α subunits were significantly downregulated in SG neurons in TBI rats, compared with sham-operated rats. TBI causes downregulation and upregulation of M-type K + (KM) currents and the KCNQ2 mRNA transcripts, which may contribute to the hyperexcitability of the SG neurons and the hypoexcitability of the ICG neurons, respectively. Finally, we evaluated the baroreflex in TBI patients. BRS was 5.7 ± 3.2ms/mmHg in mTBI groups and 3.57 ± 3.1ms/mmHg in severe sTBI groups.

**Conclusions:** From bench to clinical situation, we research the CAD in TBI rat models and TBI patients. In our results suggest the CAD in TBI situation was based on the sympathetic and parasympathetic incoordination. And additionally, perspectives and interpretations of the Cushing triad must change.

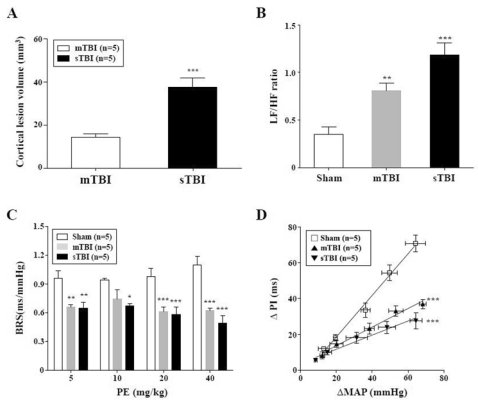

**Fig. 1 (abstract 000658)** Assessment of the HRV and arterial baroreflex in the sham-operated (control), mTBI, and sTBI rats. **Introduction:** As generative Artificial Intelligence (GenAI) tools continue advancing, rigorous evaluations are needed to understand their capabilities relative to experienced clinicians and nurses.

**Objectives:** This study aims to objectively and qualitatively compare the diagnostic accuracy and response formats of ICU nurses versus various GenAI models.
**Methods:** 74 ICU nurses participated in a simulation-based assessment involving 4 written clinical scenarios representative of real practice. Simultaneously, we asked ChatGPT-4 and Claude-2.0 to provide initial assessments and treatment recommendations for the same scenarios. The responses from ChatGPT-4 and Claude-2.0 were then scored by certified ICU nurses for accuracy, completeness, and response time.
**Results:** Nurses consistently achieved higher diagnostic accuracy than AI across open-ended scenarios, though certain models matched or exceeded human performance on standardized cases. Reaction times also diverged substantially. Qualitative response format differences emerged such as concision versus verbosity. Variations in GenAI model system performance across cases highlighted generalizability challenges.
**Conclusions:** While GenAI demonstrated valuable skills, experienced nurses outperformed in open-ended domains requiring holistic judgment. Continued development to strengthen generalized decision-making abilities is warranted before autonomous clinical integration. Response format interfaces should consider leveraging distinct strengths. Rigorous mixed-methods research involving diverse stakeholders can help iteratively inform safe, beneficial human-GenAI partnerships centered on experience-guided care augmentation.

**Clinical decision-making performance scores (mean and standard deviation) for nurses and large language models across four intensive care units case scenarios**

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000662

**Introduction:** Mechanical power of ventilation (MP), a summary parameter reflecting the energy transferred from the ventilator to the respiratory system, has associations with outcomes. INTELLiVENT–Adaptive Support Ventilation (ASV) is an automated ventilation mode that changes ventilator settings according to algorithms that target a low work – and force of breathing.
**Objectives:** To compare MP between automated ventilation by means of INTELLiVENT–ASV and conventional ventilation in critically ill patients. We hypothesize that automated ventilation results in less MP when compared to conventional ventilation.
**Methods:** International, multicenter, randomized crossover clinical trial in patients that were expected to need invasive ventilation > 24 h. Patients were randomly assigned to start with a 3-h period of automated ventilation or conventional ventilation after which the alternate ventilation mode was selected. The primary outcome was MP in passive and active patients; secondary outcomes included key ventilator settings and ventilatory parameters that affect MP.
**Results:** A total of 96 patients were randomized. Median MP was not different between automated and conventional ventilation (15.8 [11.5–21.0] vs 16.1 [10.9–22.6] J/min; mean difference −0.46 (95%–CI −1.61 to 0.69) J/min; $P = 0.43$). Subgroup analyses showed that MP was lower with automated ventilation in passive patients (17.2 [12.8–23.2] vs 19.2 [14.4–24.6] J/min; mean difference −1.13 (95%–CI −1.89 to −0.37) J/min; $P < 0.01$), and not in active patients (14.6 [11.0–20.3] vs 14.1 [10.1–21.3] J/min; mean difference 0.82 (95%–CI −2.13 to 0.49) J/min; $P = 0.22$).
**Conclusions:** In this cohort of unselected critically ill invasively ventilated patients, automated ventilation by means of INTELLiVENT–ASV did not reduce MP. A reduction in MP was only seen in passive patients.

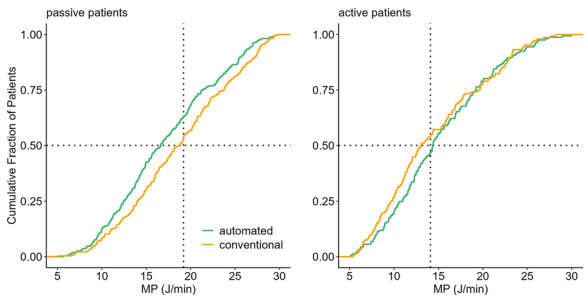

**Fig. (abstract 000662)** Distribution plots of MP with automated ventilation and conventional ventilation in passive and active patients, showing all measurements of every patient. Vertical dotted lines represent the median value with conventional ventilation. Horizontal dotted lines show the respective proportion of patients reaching each cutoff. Abbreviation: MP, mechanical power

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000663

**Introduction:** In Japan, a hyper-aged society that is prominent in the world, adrenaline is routinely administered to elderly patients with out-of-hospital cardiac arrest (OHCA) due to asphyxia as advanced life support. However, given the pathophysiology of asphyxia, adrenaline is not effective and may increase the number of patients with poor neurological status.
**Methods:** We retrospectively studied patients aged 65 years or older with asphyxial OHCA registered in the All-Japan Utstein Registry of Fire and Disaster Management Agency between 2013 and 2021. Patients who were not in cardiac arrest at the time of EMS arrival were excluded. Patients were divided into adrenaline-treated and non-treated groups, and propensity-score matching was used to balance possible confounders that might affect prognosis. The primary endpoint was neurological status at 1 month (Cerebral Performance Category [CPC] 1–2 defined as good, CPC 3–4 as poor, CPC 5 as death).

**Results:** Of the 53,994 eligible patients, 31.2% received prehospital adrenaline, 18.6% resumed the return of spontaneous circulation (ROSC), 7.5% were alive, 1.4% had good neurological status, and 6.1% had poor neurological status at 1 month. The propensity-score matching process selected 14,991 patients from the adrenaline-treated and non-treated groups. Compared with non-treated groups, adrenaline-treated groups incurred a higher rate of ROSC (35.3% vs. 12.2%, $p < 0.001$), survival (8.9% vs. 7.5%, $p < 0.001$), poor neurological status (8.1% vs. 6.0%, $p < 0.001$), and a lower rate of good neurological status at 1 month (0.8% vs. 1.5%, $p < 0.001$). In multivariable logistic regression after matching, adrenaline administration was associated with increased odds of poor neurological status (odds ratio [OR] 1.44, 95%CI 1.32–1.58), and decreased odds of good functional status (OR 0.55, 95%CI 0.44–0.69).
**Conclusions:** The results of this study suggest that adrenaline administration to elderly asphyxial OHCA patients is associated with poor neurological prognosis. From the standpoint of healthcare economics, adrenaline administration to such patients may be discouraged.

**Topic:** Cardiac arrest

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000667

**Introduction:** To optimise rehabilitation after intensive care, surviving patients are invited to follow-up appointments, but many do not attend these appointments. Therefore, the aim of the study was to prospectively collect information on reasons for not attending follow-up appointments and to investigate whether the quality of life and posttraumatic symptoms differed between those who attended ICU follow-up and those who did not.
**Methods:** Adult patients treated at the intensive care unit for > 72 h between August 2017 and December 2018 and invited to follow-up appointments three months after discharge from the intensive care unit were included in the study. Patients who declined a follow-up appointment were asked for reason(s). Further, the patients responded to questionnaires assessing health-related quality of life and symptoms of posttraumatic stress. Quantitative content analysis was used to identify reasons for not attending follow-up appointments. Mann Whitney U test and Chi2 test were used to compare differences in health-related quality of life and posttraumatic stress symptoms between the groups.
**Results:** Of the 150 invited patients, 126 (84%) did not attend their ICU follow-up appointment. Some had recovered on their own, but the majority did not attend due to reduced physical health or logistical reasons that prevented them from attending. Others stated that they felt psychological reluctance towards visiting the ICU. Health-related quality of life scores and symptoms of posttraumatic stress were similar between the groups.
**Conclusions:** The study provides information about patients who did not attend ICU follow-up appointments and contributes to the evidence supporting the use of digital healthcare interventions and a more thorough selection for ICU follow-up.

**Table 2 (abstract 000667)** Health-related quality of life (RAND-36) and symptoms of posttraumatic stress (PTSS-14) between ICU survivors who attended and did not attend ICU follow-up appointments

| | Attended follow-up | Did not attend follow-up | p-value |

**Correspondence:** A. Herraiz
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000670

**Introduction:** Delayed cerebral ischemia (DCI) is a major determinant for poor neurological outcomes after aneurysmal subarachnoid hemorrhage (aSAH). Blood inflammation biomarkers have been studied to predict DCI. Monocyte distribution width (MDW), a sepsis biomarker that reflects the enlargement of monocytes after infection, may represent a novel inflammation biomarker associated with DCI.
**Objectives:** The objectives were: to analyse the relationship between traditional inflammation biomarkers and the development of DCI; to analyse the relationship of MDW and the development of DCI.
**Methods:** Retrospective observational cohort study of patients with aSAH from a single center since 2018. Statistical analysis. Descriptive: qualitative variables expressed in proportions; quantitative variables expressed in mean (SD) or median (IQR). Normality distribution was

analyzed using the Shapiro–Wilk test. Bivariate analysis: two categorical variables were analyzed using the Fisher's exact test or Chi-Square test; abnormal quantitative variables were analyzed using the Mann–Whitney test; normal quantitative variables were analyzed using the Student's t-test.

**Results:** $N = 168$. Females: 60.1%. Age: 57.1 (SD 12.9) years. GCS: 14 (IQR 4). Fisher Grading Scale IV: 75.6%. Hunt-Hess II: 33.9%. Hunt-Hess III: 23.2%. DCI: 69.4%.

GCS of patients without DCI *vs.* GCS of patients with DCI: 15 (IQR 3) *vs.* 13 (IQR 6); ($p = 0.02$). No differences in DCI were observed according with age ($p = 0.7$) and sex ($p = 0.4$). DCI was related with Hunt-Hess ($p = 0.003$), whereas Fisher Grading Scale was not associated with DCI ($p = 0.23$). The correlation between Hunt-Hess and Fisher Grading Scale reached statistical significance ($p = 0.047$).

The day of the onset of aSAH, leukocytes were higher in patients with DCI *vs.* without DCI: $14.8 \times 109$/L (IQR 4.5) *vs.* $12.3 \times 109$/L (IQR 5.8); ($p = 0.002$). Leukocytes 3 days after aSAH were also higher in patients with DCI *vs.* without DCI: $13.2 \times 109$/L (IQR 5.6) *vs.* $10.8 \times 109$/L (IQR 4.8); ($p = 0.03$). No differences in the leukocyte count were observed after the fourth day of the onset of aSAH (pns). Fibrinogen values were constantly higher in patients with DCI *vs.* without DCI during all the Intensive Care Unit (ICU) stay, with statistical significance observed in all comparisons ($p < 0.05$). IL-6 was higher during the first week of the neurological disease in patients with DCI *vs.* without DCI, reaching its peak on day 3 after the onset of illness: 24.5 pg/mL (IQR 42.6) *vs.* 11 pg/mL (IQR 33.4); ($p = 0.04$). CRP had a similar kinetics than IL-6, being higher in patients with DCI *vs.* without DCI, expressing its maximum values on day 3 after the beginning of the aSAH: 49.1 mg/L (IQR 86.6) vs. 19.1 mg/L (IQR 72); ($p < 0.00$). PCT values were also persistently higher in patients with DCI *vs.* without DCI during the evolution of the disease in the ICU, reaching statistical significance in all comparisons ($p < 0.05$). MDW was also higher 3 days after the onset of aSAH in patients with DCI *vs.* without DCI: 21.3 (IQR 4) *vs.* 19.1 (IQR 4.3); ($p = 0.005$).

**Conclusions:** Patients with aSAH that developed DCI expressed higher values of inflammation biomarkers than those without DCI, especially during the first 3 days of the onset of bleeding. MDW could be considered a new early biomarker of DCI after aSAH.

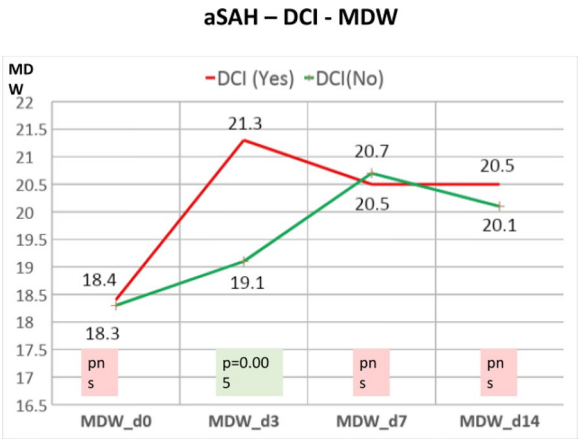

**Fig. (abstract 000670)** MDW tendency in patients with DCI and without DCI

**Introduction:** Community hospitals account for the majority of hospitals and hospital beds in Canada [1]. However, most health research is conducted in academic hospitals. Consequently, a large proportion of the patient population is excluded from clinical trials, denying individuals who seek care in these centers equitable access to novel treatments. Excluding community hospitals from the research also limits its generalizability of study results and slows trial recruitment, which can increase expenditures and delay mobilization of study findings into practice [2,3]. The COVID-19 pandemic highlighted opportunities to improve Canada's clinical research infrastructure, which must include increasing the research capacity of community ICUs [4]. Therefore, it is critical to refine our understanding of the factors that influence research participation in these settings, to help those interested in building research programs and increasing community hospital participation.
**Objectives:** This study aimed to identify and describe the factors that influence (a) community hospital research participation and (b) the development, implementation, and sustainability of a community ICU research program.
**Methods:** Principles of qualitative descriptive methodology informed the sampling strategies, data collection, and analysis [5]. In-depth semi-structured interviews were conducted virtually with a purposeful sample of individuals who were interested in or actively participating in Canadian community ICU research. Interview data were triangulated with field notes and survey data, which included multiple-choice and open-ended questions about demographics and existing research program characteristics. Qualitative data were analyzed using both conventional content analysis and rapid qualitative analysis [6,7]. Quantitative survey data were analyzed using descriptive statistics.
**Results:** The final sample included 38 (23 healthcare professionals, 10 research staff, and 5 hospital administrators) participants from 20 different community hospitals across 6 provinces in Canada. Participants described factors across individual, unit, institutional and external levels that influence community ICU research participation in Canada. Participants reported on: (1) the infrastructure necessary to initiate and sustain a research program, (2) personnel characteristics important for program growth, (3) key relationships and connections, and (4) the influence of the COVID-19 pandemic.
**Conclusions:** Despite significant barriers that impact community hospital research participation, community ICU professionals are motivated to engage in research. To increase community ICU research participation, these findings suggest that all levels of the Canadian healthcare system need to invest in research infrastructure, establish policies that embed research within health service delivery and facilitate relationships through mentorship, collaboration, and professional networks.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000672

**Introduction:** Damage control surgery (DCS) with temporary abdominal closure (TAC) using the Bogota bag method is a widely used technique in the management of severely injured trauma patients. During DCS, pads are often packed into the abdominal cavity and adjacent to the wounds to control bleeding and contamination. While this approach has been shown to improve survival in critically injured patients, it has also been associated with a high incidence of ventral hernia development, which can lead to significant morbidity and require additional surgical interventions.
**Objectives:** This study aims to investigate the outcomes of DCS with Bogota bag, focusing on mortality, wound infection rates, and hernia development, and their association with microbiological findings from the packing pads.
**Methods:** A retrospective study was conducted on 126 severely injured trauma patients who underwent DCS with Bogota bag TAC. During the surgery, pads were packed into the abdominal cavity and adjacent to the wounds. These pads were then cultured for microbiological analysis (culture_wound for pads adjacent to wounds and culture_abd for intra-abdominal pads). The association between positive pad cultures and mortality, wound infection, or hernia development was evaluated.
**Results:** Among the 126 patients, 20 (15.9%) died during hospitalization. The mortality rate was not significantly associated with positive pad cultures (50% in non-survivors vs. 35.8% in survivors, $p = 0.3119$). The most frequently identified pathogens in non-survivors were *Acinetobacter baumannii* (40%, 8/20), Pseudomonas aeruginosa (25%, 5/20), and *Enterococcus faecium* (20%, 4/20).
Wound infection was observed in 46 patients (36.5%) and was significantly associated with positive pad cultures (78.3% in patients with wound infection vs. 15% in those without, $p < 0.001$), suggesting that contamination of the pads during DCS may be a major contributor to the development of wound infections. The most common causative agents of wound infection were Staphylococcus aureus (43.5%, 20/46), *Enterococcus faecalis* (37%, 17/46), Escherichia coli (28.3%, 13/46), and Klebsiella pneumoniae (19.6%, 9/46).
The predominant pathogens identified from different sample types were as follows: blood cultures—Acinetobacter baumannii (35%, 7/20), *Enterococcus faecium* (25%, 5/20), and Candida albicans (15%, 3/20); respiratory samples—Acinetobacter baumannii (30%, 6/20), Pseudomonas aeruginosa (25%, 5/20), and Klebsiella pneumoniae (20%, 4/20); wound cultures—Staphylococcus aureus (43.5%, 20/46), *Enterococcus faecalis* (37%, 17/46), Escherichia coli (28.3%, 13/46), and Pseudomonas aeruginosa (21.7%, 10/46); intra-abdominal cultures—*Enterococcus faecalis* (32.6%, 15/46), Escherichia coli (28.3%, 13/46), and Candida albicans (17.4%, 8/46).

Hernia development was noted in 9 patients (7.1%), but it was not significantly associated with positive pad cultures (66.7% in patients with hernia vs. 35.9% in those without, $p = 0.1429$).
**Conclusions:** This study highlights the complex challenges faced by severely injured trauma patients undergoing DCS with Bogota bag TAC. The high incidence of wound infection and its strong association with contaminated packing pads underscore the importance of implementing strategies to minimize contamination during DCS. The predominance of nosocomial pathogens such as Acinetobacter baumannii, Pseudomonas aeruginosa, and *Enterococcus faecium* in non-survivors suggests that infections caused by these organisms may have a significant impact on patient outcomes. Similarly, the high prevalence of Staphylococcus aureus and *Enterococcus faecalis* in wound infections indicates their potential role in the development of this complication. Further research is needed to confirm these hypotheses and to develop targeted prevention and treatment strategies for infections caused by these pathogens in patients undergoing DCS.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000674

**Introduction:** The limitations on personal interactions due to the pandemic have restricted the provision of palliative care to patients in Intensive Care Units (ICUs) and have made it more challenging to provide support to their families. Even today, the impact of ICU hospitalization on the development of mental health disorders like Major Depressive Disorder (MDD) and Post-Traumatic Stress Disorder (PTSD) remains unclear.
**Objectives:** This study aims to explore the prevalence of MDD and PTSD symptoms among patients admitted to an academic ICU during the pandemic. It also seeks to analyse the correlation between these mental health disorders and various demographic and clinical factors, comparing their incidence among patients hospitalized with COVID-19 and those with other illnesses.
**Methods:** A cross-sectional study design was employed, involving patients admitted to the ICU from January 1, 2020, to January 1, 2022. Demographic and clinical data were gathered from the Electronic Health Record (EHR) system. A questionnaire, adapted from the "Mini International Neuropsychiatric Interview" (MINI)1 and aligned with DSM-IV criteria, comprising 10 closed and open-ended questions, was utilized as a screening tool for PTSD and MDD.
**Results:** The study encompassed 100 ICU patients, with COVID-19 accounting for 28% and non-COVID-19 cases comprising 72%. The prevalence rates of MDD (27.8%) and PTSD (33%) did not significantly differ between COVID-19 and non-COVID-19 patients (Fig.). However, patients with COVID-19 experienced longer durations of mechanical ventilation ($p < 0.001$) and ICU stay ($p = 0.003$). Notably, feelings of fear, trepidation, or despair were significantly more common among COVID-19 ICU patients compared to non-COVID-19 patients (5.7% vs. 3.3%, $p = 0.043$). Symptoms like melancholy, its duration, and daily lack of interest exhibited strong predictive abilities for MDD (AUC 0.885, $p < 0.001$; AUC 0.904, $p < 0.001$; AUC 0.736, $p = 0.001$, respectively), irrespective of the cause of admission. Similarly, issues affecting work and social life and causing distress significantly predicted PTSD across all patients (AUC 0.885, $p < 0.001$).
**Conclusions:** Approximately one-fourth of ICU patients, whether with or without COVID-19, exhibit MDD symptoms, while around one-third display PTSD symptoms within approximately two years post-ICU discharge. Among various emotions, patients hospitalized with COVID-19 are characterized by feelings of fear or despair. Furthermore, melancholy and lack of interest are associated with MDD, whereas disruptions in work and social life predict PTSD in ICU patients, regardless of COVID-19 status.

### Impact of comorbidity on long-term mortality in older ICU patients

A. Aronsson Dannewitz, M. Lipcsey, R. Gedeborg
Surgical sciences, Uppsala University, Uppsala, Sweden
**Correspondence:** A. Aronsson Dannewitz
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000676

**Introduction:** An understanding of how a critical condition interacts with preexisting comorbidities to determine the long-term survival probability is important.
**Objectives:** To describe the impact of comorbidity on long-term mortality in older ICU patients.
**Methods:** The mortality after a first ICU admission in patients ≥ 55 years old from 2006 to 2012 registered in the Swedish Intensive Care Registry was compared to age- and sex-matched controls from the general population. Kaplan–Meier curves describe survival with a landmark at 1 year. Cox regression adjusted the comparison for age, sex, and comorbidity. Quantitative measures of comorbidity were based on linkage to hospital discharge diagnoses from in-patient care five years preceding the index date for the ICU admission [1]. Associations between specific comorbidities and survival were adjusted for age, sex, and quantitative measures of other comorbidities.
**Results:** During the 7-year study period there were 140 008 patients ≥ 55 years old with a first admission to an ICU and 23% were 80 years or older. The prevalence of comorbidities and the median SAPS3 increased with increasing age, along with the mortality rate during the first year (Fig. 1).
ICU patients surviving the first year remained at increased risk compared to the general population, but this difference was completely attenuated after adjustment for baseline comorbidity (HR, 1.03; 95% CI 1.02 to 1.04) (Fig. 1). When stratified for age, a slightly elevated risk remained after 1 year in the age group 55–64 years (HR, 1.17; 95% CI,

1.05 to 1.32). This increased risk was attenuated with increasing age and was not seen in the age group 75 and older (HR, 0.98; 95% CI, 0.96 to 0.99).

The associations between specific comorbidities and mortality rate were variable depending on the type of comorbidity, recency of hospitalization for that specific condition, and follow-up period (before/after the landmark). E.g. a prior hospital admission for infection was associated with an increased mortality rate after an ICU admission, with a gradient indicating that more recent hospitalizations conferred a higher risk (Fig. 2). The strongest association was seen in patients surviving the first year after ICU admission (adjusted HR, 1.50; 95% CI 1.42 to 1.59).

**Conclusions:** Older patients admitted to the ICU have a higher baseline burden of comorbidity, higher severity of illness, and consequently a higher mortality during the first year. Those that survive the first year after an ICU admission return to the mortality rate of the general population having similar baseline comorbidity. The results do not support any major concern for the selection of patients for ICU admission in relation to age and comorbidity. For some types of comorbidities, the recency of a prior hospital admission may predict both short- and long-term mortality rates.

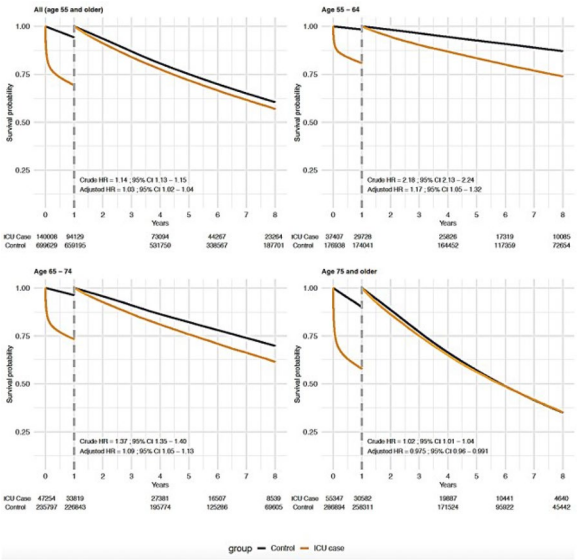

**Fig. 1 (abstract 000676)** Landmark analysis of survival probability after admission to intensive care. Survival described by Kaplan–Meier curves is compared to age- and sex-matched control groups from the general population, and separately for different age groups. Hazard ratios (HR) with 95% confidence intervals (CI) have been estimated in Cox proportional hazard models adjusted for age, sex, and comorbidity

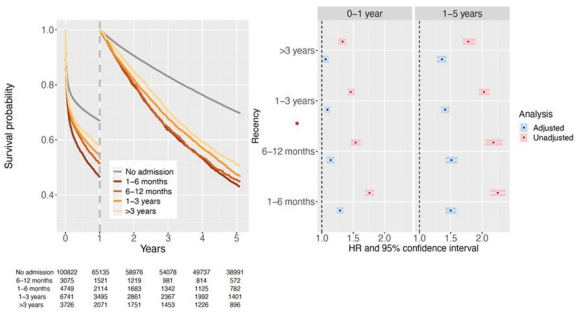

**Fig. 2 (abstract 000676)** Landmark survival analysis described by Kaplan–Meier curves (left panel), stratified for recency of previous hospital admission with infection as the main discharge diagnosis. Hazard ratios (HR) with 95% confidence intervals (CI) (right two panels) have been estimated from Cox proportional hazards models separately for each time period, comparing an unadjusted analysis with an analysis adjusted for sex, age, and other comorbidities

**Introduction:** Most Canadians receive their care in community hospitals, yet most clinical research is conducted in academic hospitals. Compared to academic hospitals, community hospitals are more likely

to be located in rural and suburban communities and are more likely to serve populations with higher proportions of recent immigrants [1], lower socioeconomic status [2], and reduced access to subspecialized care [3]. Thus, research conducted exclusively in academic hospitals may not accurately reflect the patient population in community hospitals.
**Objectives:** Community-acquired pneumonia (CAP) is a significant cause of morbidity, disproportionately affecting older individuals and those with comorbidities [4]. Given previous literature identifying sociodemographic differences between academic and community hospital populations, this study aimed to compare CAP patients treated in academic and community hospitals with respect to their baseline and clinical characteristics, treatments, and outcomes.
**Methods:** This nested observational cohort sub-study of the Community-Acquired Pneumonia: Toward InnoVAtive Treatment (CAPTIVATE) trial, included hospitalized adults with CAP recruited between March 1st, 2018, and September 31st, 2023 from 15 Canadian hospitals; 10 academic and 5 community. Inclusion criteria were hospitalized patients > 18 years of age with an admitting diagnosis of acute CAP defined by having one of fever, chills, leukocytosis, leukopenia; one of cough, sputum, dyspnea; and new infiltrates on chest x-ray consistent with CAP [5–8]. Exclusion criteria were Emergency Department visits without hospital admission, readmissions, and admissions for other reasons. The primary outcome was 28-day mortality. Secondary outcomes were hospital mortality, ICU admission rates, organ dysfunction, and ICU and hospital length of stay. Unadjusted and adjusted analyses for age, sex, and co-morbidities using logistic, Cox, and censored quantile regressions were conducted.
**Results:** Patients in community hospitals were older (mean [SD] 75.0 [15.7] years vs 68.3 [16.2] years; $p < 0.001$), more likely to be female (49.7% vs 41.0%, $p = 0.002$), and had more comorbidities (75.9% vs 64.8%, $p < 0.001$). More patients in community hospitals received corticosteroids (49.2% vs 37.4%, $p < 0.001$). Community hospital patients had a higher likelihood of developing acute respiratory distress syndrome (OR 3.13, 95% CI: 1.87, 5.24, $p \leq 0.001$), and acute cardiac injury (OR 2.53, 95% CI: 1.33, 4.83, $p = 0.005$). In unadjusted and adjusted analyses, the 28-day mortality difference did not meet statistical significance (OR 1.43, 95% CI: 0.98, 20.7, $p = 0.062$ and OR 1.23, 95% CI: 0.81, 1.87, $p = 0.332$, respective).
**Conclusions:** Patients with CAP in Canadian community and academic hospitals differed with respect to their age, clinical characteristics, treatments and outcomes, emphasizing the importance of including community hospitals in clinical research studies to ensure the generalizability of results.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000678

**Introduction:** Pulmonary aspergillosis in the Intensive Care Unit (ICU) has increased over recent years due to Influenza and COVID-19 pandemics. Its treatment is continuously under review due to the emergence of new antifungals and the high mortality associated with this condition.
**Objectives:** Development of a care protocol after reviewing the cases diagnosed with pulmonary aspergillosis in our ICU.
**Methods:** Observational and retrospective study conducted in a second-level hospital ICU from January 2022 to October 2023. All patients diagnosed with Pulmonary Aspergillosis during this period were included. Demographic and clinical variables, treatment administered and changes, complications, and mortality were collected. Values with $p \leq 0.05$ were considered statistically significant. Statistical analysis was performed using SPSS 15.
**Results:** Eleven patients were included (64% male). The median age was 62 years (range: 45–77), APACHE-II score median was 17 (range: 12–25), and body mass index median was 29.17 (range: 22.7–45). 81.8% had COVID-19 Associated Pulmonary Aspergillosis (CAPA).
72.7% had hypertension, 27.3% dyslipidemia and diabetes mellitus. 36.4% of patients had some form of immunosuppression. Only one patient had chronic liver disease, two patients had chronic kidney disease on admission and one was on peritoneal dialysis.
*Aspergillus fumigatus* was the most frequently identified microorganism (54.54%), followed by *Aspergillus terreus* (27.27%). Multiple Aspergillus species were present in 5 patients at diagnosis.
The most frequent initial treatment was voriconazole (54.5%) followed by liposomal amphotericin B (36.4%) and isavuconazole (9.1%).
Treatment was changed in 54.5% of patients, with 50% of cases due to toxicity (hepatic or renal), and in 33.3% because the empirical treatment used was not appropriate for the microbiological isolation. No relationship was found between patient history and the development of toxicity. In the two patients with hepatic toxicity, voriconazole was attributed as the cause, leading to a treatment change. The cause of renal failure was attributed to amphotericin, leading to a change in treatment.
Among patients receiving voriconazole, serum levels were only requested in half of cases, with 75% of these cases being subtherapeutic. The median waiting time for voriconazole level results was 8 (range: 7–10) days. Overall mortality was 37%.
**Conclusions:** In our centre, due to difficulties in obtaining voriconazole levels, this drug was not considered the first-choice treatment of Pulmonary Aspergillosis (difficulties in extracting levels and long waiting times for results). Isavuconazole and Liposomal Amphotericin are the first-choice antifungals after the implementation of the new protocol.

### The significance of creep fluids and the modified Renal Angina Index (mRAI) during the initial week in the ICU: correlations with fluid overload, the composition of administered fluids, and outcomes

T. Antonopoulou[1], S. Ilia[2], S. Varda[1], E. Kondili[3], G. Briassoulis[1]
[1]PostGraduate Program Emergency and Intensive Care in Children Adolsescents and Young Adults, School of Medicine, University of Crete, Heraklion, Greece; [2]Pediatric Intensive Care Unit, University Hospital, School of Medicine, University of Crete, Heraklion, Greece; [3]Intensive Care Unit, School of Medicine, University of Crete, Heraklio, Greece

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000679

**Introduction:** Fluid overload (FO) can lead to severe complications, extended mechanical ventilation support, and even mortality. The Renal Angina Index (RAI) has emerged as a validated tool for predicting Acute Kidney Injury (AKI), a condition associated with significant morbidity and mortality.
**Objectives:** This study aims to investigate the sources, composition, and volume of administered fluids in ICU patients and their correlations with RAI and clinical outcomes.
**Methods:** This retrospective monocentric observational study analyzed adult patients admitted to an academic ICU between 2017 and 2023. One hundred patients meeting inclusion criteria were assessed for various parameters including fluid input sources, daily and cumulative fluid balance, FO (%), AKI according to KDIGO criteria, and RAI and modified RAI (mRAI) within the first 24 h.
**Results:** Among 100 patients (with 84% having comorbidities, 52% presenting AKI at admission, and 32% mortality), no significant difference in overall outcome was observed between balanced crystalloids and N/S 0.9%. Balanced crystalloid solutions such as Ringer's Lactate and Plasma-Lyte, along with combinations with D/W solutions, were predominantly used for resuscitation and maintenance fluids. Notably, hyperchloremia associated with N/S 0.9% was not observed. Acidosis and elevated lactate values within the first 3 days were linked to high FO ($p<0.05$, $p=0.021$). Creep fluids, comprising various fluid types, contributed significantly to positive fluid balance and FO ($p<0.001$). Cumulative balance and FO were notably higher on the 3rd ($p=0.005$, $p=0.003$) and 7th ($p=0.018$) days of hospitalization in patients who died. Pathological mRAI scores (6–40) were associated with a higher percentage of AKI (KDIGO 2, day 3) (36.7% vs. 19.6%, $p=0.046$). Abnormal mRAI (present in 49% of patients) correlated with increased ICU (42.9% vs. 21.6%, $p=0.019$) and hospital mortality ($p=0.002$). mRAI showed a stronger predictive ability for ICU mortality compared to other renal function markers within the first 24 h (AUC 0.76 (0.62–0.89), $p=0.002$).
**Conclusions:** Creep fluids contribute significantly to FO during the initial ICU days. Cumulative balance and FO are associated with mortality. The mRAI index emerges as a crucial predictive tool for AKI occurrence and better predicts ICU mortality compared to other early renal function markers.

### AFTER admission bundle – implementing documentation for invasively ventilated patients presenting to intensive care

A. Hu[1], R. Hart[1], A. Muir[1], A. Macdonald[2]
[1]Department of Critical Care, Queen Elizabeth University Hospital, Glasgow, United Kingdom; [2]School of Medicine, University of Glasgow, Glasgow, United Kingdom
**Correspondence:** A. Hu
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000680

**Introduction:** Critically ill patients requiring invasive ventilation on admission must have concise documentation on presentation to the intensive care unit (ICU) to avoid patient safety issues, ensure appropriate initial investigations are performed and to communicate information with the wider multi-disciplinary team.
The AFTER bundle was developed by the critical care team at the Queen Elizabeth University Hospital (QEUH) in Glasgow to provide a brief yet comprehensive way of documenting the integral information of patients admitted ICU who required intubation and ventilation on admission. The components of the bundle included: airway grade using the Cormack-Lehane scale, functional status prior to admission, endotracheal tube (ETT) review on chest X-ray, review of ECG, and if relatives or next of kin had been informed of their admission.
**Objectives:** To establish the AFTER bundle as part of the ICU admission proforma, and to assess compliance with completion of the bundle.
**Methods:** Data was retrospectively reviewed in 436 patients admitted to ICU at QEUH who required invasive ventilation between May 2023 and March 2024.
**Results:** Over the course of the 11 months, there was a general improvement in completed documentation of airway grade (57.4% vs 90.2%) and functional status (63.0% vs 86.3%). There was again a general rise in completed documentation of ETT reviews on chest X-ray from May 2023 (33.3%) to March 2024 (52.9%). An overall decline in ECGs performed (92.6% vs 64.7%) and reviewed (90.7% vs 64.7%) on admission was noted. Relatives or next of kin being updated upon admission have been relatively static (77.8% vs 76.5%). Overall, the completion of the AFTER bundle has remained relatively static – 22.2% vs 23.5%.
**Conclusions:** The overall compliance of completion of the AFTER bundle was low and static. This was due to differing compliance rates of different components of the bundle; the reasons for this included misunderstanding of what should be documented, investigations already requested but pending, and no immediate available next of kin information. In certain cases, resuscitation took priority over

documentation and so workload may have prevented full completion of the bundle. Better awareness of what constitutes each part of the bundle should be implemented; this has already started by being included during the induction of new doctors rotating through to ICU (including emailing 'pre-induction packs') and the implementation of a general admission bundle for both medical and nursing staff.

**Association of PaO2/FiO2 ratio with mortality: optimal cutoffs and impact of the level of respiratory support**

A. Pölkki[1], M. Reinikainen[1], T. Selander[2], P. Pekkarinen[3]
[1]Department of Anaesthesiology and Intensive Care, Kuopio University Hospital and University of Eastern Finland, Kuopio, Finland; [2]Science Service Center, Kuopio University Hospital, Kuopio, Finland; [3]Division of Intensive Care Medicine, Department of Anaesthesiology and Intensive Care, University of Helsinki and Helsinki University Hospital, Helsinki, Finland
**Correspondence:** A. Pölkki
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000681

**Introduction:** The ratio of arterial oxygen partial pressure to the fraction of inspired oxygen (P/F ratio) is commonly used to evaluate the severity of respiratory failure (RF) in organ dysfunction scores, such as the Sequential Organ Failure Assessment (SOFA) score [1]. However, the optimal cutoffs for the P/F ratio are unknown, as is the impact of the level of respiratory support provided.
**Objectives:** We determined four cutoffs rounded to the nearest 25 mmHg value for the P/F ratio to split the cohort into five categories of worsening RF. We also studied the impact of the level of respiratory support on the association between the P/F ratio and hospital mortality.
**Methods:** We conducted a registry study on patients admitted to the intensive care unit (ICU) at Kuopio University Hospital, Finland, between January 2013 and July 2018. Postoperative non-emergency surgical patients were excluded.
The lowest P/F ratio during the first 24 h in the ICU was recorded. The level of respiratory support was determined: no respiratory support, conventional oxygen therapy (COT), non-invasive ventilation (NIV), and invasive mechanical ventilation (IMV). Optimal cutoffs for the P/F ratio were determined using the Contal and O'Quigley method [2] to define mild, moderate, severe, and very severe RF in relation to hospital mortality.
The suitability of the cutoffs was assessed by measuring the accuracy of predicting hospital mortality using the Area Under the Receiver Operating Characteristic (AUROC). The accuracy of the cutoffs proposed was then compared to the respiratory SOFA score. The comparison was done using the DeLong method.
**Results:** The number of study patients was 5848 and the overall mortality was 12.9%. The best four cutoffs proposed for predicting hospital mortality were < 300 mmHg for mild, < 225 mmHg for moderate, < 150 mmHg for severe, and < 75 mmHg for very severe RF. The number of patients decreased, and mortality increased towards more severe RF categories (Table 1).

**Table 1 (abstract 000681)**

| | No RF | Mild RF | Moderate RF | Severe RF | Very Severe RF |
|---|---|---|---|---|---|
| Proportion of patients | 30.5% | 27.8% | 25.8% | 13.3% | 2.7% |
| Mortality | 7.0% | 8.8% | 14.1% | 25.9% | 45.5% |

The cutoffs proposed were more accurate (AUROC 0.667, 95% Confidence Interval [CI] 0.646–0.688) compared to the respiratory SOFA score (AUROC 0.653, 95% CI 0.632–0.674), $p = 0.02$. Mechanical respiratory support (NIV/IMV) was associated with increased hospital mortality in a univariable logistic regression analysis (Odds Ratio [OR] 1.47, 95% CI 1.28–1.66), but not in a multivariable model adjusting for P/F ratio (OR 1.11, 95% CI 0.90–1.32).
Visual inspection of hospital mortality plotted against P/F ratio corroborated the higher mortality in patients on NIV or IMV, but also suggested that almost all patients with P/F ratio < 150 mmHg were on NIV or IMV. Furthermore, the association of P/F ratio with mortality was less clear at values > 225 mmHg.
**Conclusions:** The P/F ratio cutoffs of 75 mmHg, 150 mmHg, 225 mmHg, and 300 mmHg appear suitable to determine the level of RF. The cutoffs proposed outperformed the respiratory SOFA score in hospital mortality prediction accuracy. Mechanical respiratory support was associated with higher hospital mortality but did not have independent predictive value when adjusted for P/F ratio, possibly because almost all patients with P/F ratio < 150 mmHg were on mechanical respiratory support in this cohort.

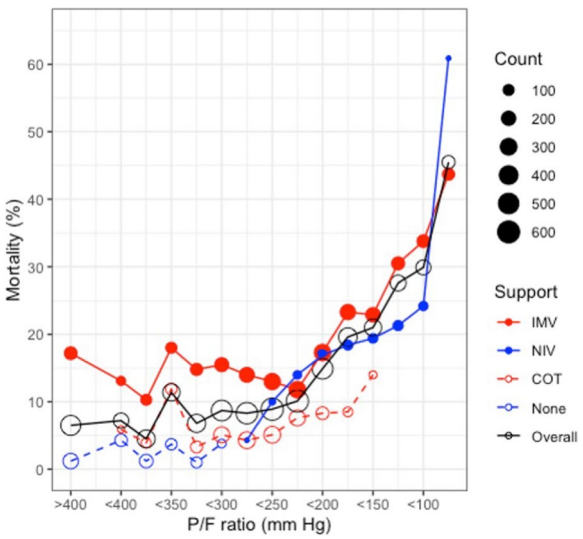

**Fig. 1 (abstract 000681)** The association of the P/F ratio with mortality in patients with different levels of respiratory support, distributed in 25 mmHg increments. The size of the circle represents the number of patients in each stratum with different P/F ratios. Data points with < 20 patients are omitted for clarity

**Introduction:** Establishing adequate fluid management is assential in critically ill patients, both insufficient and excessive volumes worsen the prognosis. Especially fluid accumulation is associated with severe complications such as metabolic acidosis, coagulopathy, bleeding, organ dysfunction, and death. Many authors recently claim in their publications that restrictive fluid therapy (RFT) may be better for the outcome of severe trauma patients. Hence the purpose of this study is to evaluate their survival and mortality.
**Methods:** Prospective observational cohort study, during 2022–2023, at Hospital General de Cd. Victoria "Dr. Norberto Treviño Zapata", Tamaulipas, Mexico. Patients with Severe Trauma over 18 years old, were admitted to the ICU. They were classified into 2 groups; having fluid accumulation greater than 1.5 L prior to admission to the ICU, and a group without exposure. We excluded patients previously resuscitated at another institution. We evaluated mortality, fluid accumulation, acute renal failure, lactate, coagulopathy, hours of ventilation, prolonged stay in the ICU. We evaluate continuous variables with ± SD means in independent and related groups with T student, categorical variables with proportions, using Chi(X2) and relative risk.
**Results:** Follow-up of 50 patients admitted with Severe Trauma. Age 37 ± 13 (18–63), male 82%, etiologist: craniocerebral trauma 56%, lung 10%, cardiovascular 4%, solid abdominal organs 22%, hollow viscus 8%, previous to ICU admission: Surgery 48%, no surgical 52%, shock origin: hypovolemic 46%, vasodilated 22%, corrected shock 32%, TAM < 60 mmHg: 73 ± 48 (12–288) minutes, Mechanical ventilation 88%, norepinephrine 72%, vasopressin 8%.
water total accumulation at ICU admission: 3166 ± 2248 (600–10840) ml, ICU stay. 12 ± 5.5(3–15) days, VMi 7.0 ± 5 (2–12) days, APACHE 19.1 ± 6.9 (6–39), SAPS II 41.1 ± 13.9 (10–76), SOFA 8.16 ± 4.9 (4–16)).
Albumin entry-exit (3.2 ± 0.08; 3.72 $p < 0.03$). PaO2/FiO2 in–out (321–362 mmHg $p > 0.880$). MORTALITY. 58%.

| variable accumulation > 1500ml | Survivings (n = 21) | No survivings (n = 29) | p-value < 0.05 |
|---|---|---|---|
| APACHE II | 17.4 ± 6.6 | 21.5 ± 6.7 | 0.035 |
| SOFA | 8.0 ± 3,3 | 9.57 ± 3.6 | 0.129 |
| MAP < 60mmHg. (t/minut) | 58.7 ± 48.2 | 87.7 ± 61.3 | 0.004 |
| Vasodilated Shock | 80% (10) | 20% (2) | 0.009 |
| Vasoconstrict shock | 60% (n = 14) | 39%(n = 09) | 0.015 |
| Risk Factor Model Incluiding mortality | RR | IC-95% | p-value < 0.05 |
| > 1500 ml | 2.89 | 1.10–7.25 | 0.005 |

**Conclusions:** Most had low urine output, associated by fluid accumulation greater than 1500 ml, resulting increasing risk of mortality.

**Introduction:** Sepsis can lead to cognitive impairment, but there is no specific test or treatment directly targeting cognitive impairment in sepsis. Previous studies by the project team have found that the onset of sepsis causes an increase in brain tissue Aβ. Many laboratories have proposed the hypothesis that peripheral blood mononuclear cells are part of the pathogenesis of neurodegenerative diseases. However, little is known about the altered distribution of immune cells in the peripheral blood of septic patients progressing to AD, and the state of immune cell-specific function remains unclear.
**Objectives:** In order to investigate the major cellular and generative mechanisms of peripheral Aβ secretion at the time of sepsis progression to AD peripheral blood mononuclear cell subpopulation changes and onset. We plan to analyze scRNA transcriptome from public databases of Sepsis, AD patients, and normal older adults to assess changes in cellular subpopulation abundance, cellular localization of gene expression, and activation of signaling pathways during the presubjective phase of the study.
**Methods:** Public databases were searched and included: scRNA sequencing data of PBMC from Sepsis, AD and normal elderly (Fig. 1, 2A). Combining the gene count matrix and cell classification information, we used the "Seurat" R package to generate the objects. To characterize the tissue distribution of meta-clusters, odds ratios (OR) were calculated for indications of preference (or propensity distribution) as well as the ratio of the actual number of cells observed to the expected number of cells for each cell cluster in each tissue (Ro/e) was used to quantify the degree of preference of each subpopulation for the tissue. We explored the preference of different cell subpopulation sources according to the STARTRAC method of Zhang Zemin's team.

**Results:** 27 cell clusters and highly disease-specific clusters were revealed after individual visualization of cells from sepsis, AD cases, or healthy individuals (Figure 2B-C). Cells were categorized into nine immune cell subtypes, which were further annotated according to the expression of marker genes (Figure 2D-E). Compared with sepsis, patients with AD had decreased numbers of monocyte/macrophage subsets and increased numbers of T cells and NK cells (Figure 3A-B). The tissue distribution of meta-clusters showed that each subpopulation and defined cell type had different preferences (Figure 4A-B). Cellular subpopulation analysis revealed that the progression of sepsis to AD was characterized by a decrease in the number of monocytes/macrophages, hematopoietic stem cells (HSCs), and platelet subpopulations, and an increase in the number of T/NKT and B-cell subpopulations (Figure 5A). Cellular localization of gene expression showed that the APP was highly expressed in the C11, C18, C20, C21, C22, C26, and C05 cell subpopulations, i.e., Monocytes/macrophages, platelets, HSC, and undefined cell subpopulations (Figure 5B-D). Combining the above results, we concluded that Monocyte/macrophage-associated cell clusters C20 and C22, platelet subpopulation C11 and HSC subpopulation C18 may be highly correlated with the progression of Sepsis to AD (Figure 5E-F). We will follow up with cell trajectory analysis and signaling pathway analysis of the above cell subpopulations to elucidate the cell subpopulation alterations and related signaling pathways involved in the progression of Sepsis to AD in peripheral blood.

**Conclusions:** On the basis of the above analysis of PBMC sequencing data from sepsis and AD patients, we directly analyzed gene expression at the single-cell level to gain a deeper understanding of the composition, cellular state, and cellular dynamic transitions of PBMCs in sepsis and AD patients. By analyzing the distribution of immune cell subpopulations and cellular subpopulations of different abundance encoding the Aβ amyloid gene in the peripheral blood of sepsis patients at the onset of sepsis, AD patients, and normal elderly patients, and by identifying the different cellular subpopulations and specifically expressed genes based on scRNA-seq analyses, we aimed to point out the key molecular biomarkers in the blood of certain sepsis patients progressing to AD, to provide a subsequent mechanistic study and to observe whether protein and pathway associations and immune-related functional alterations exist prior to sepsis and AD.

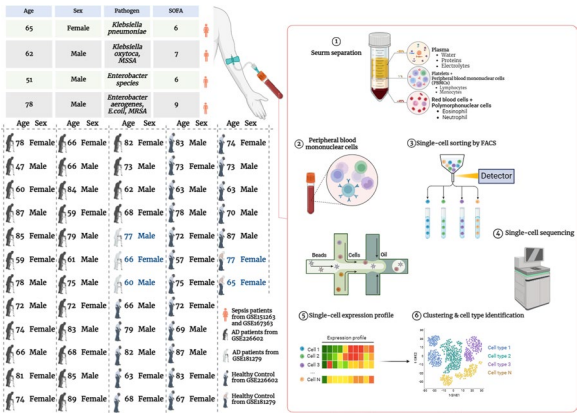

**Fig. 1 (abstract 000685)** Data included in this study and single-cell sequencing process

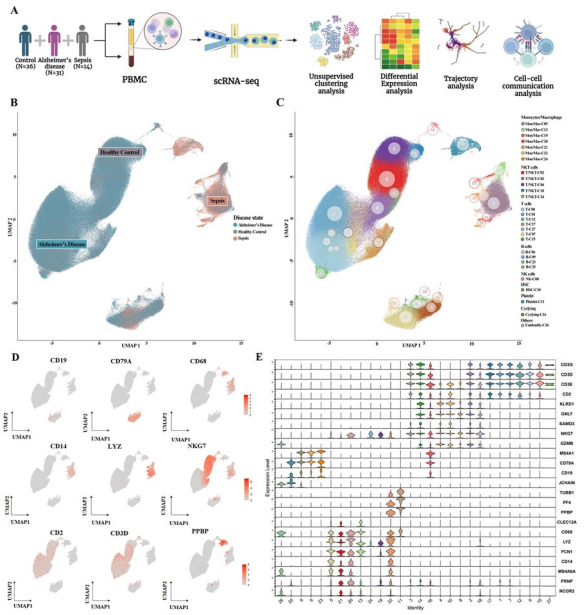

**Fig. 2 (abstract 000685)** Single-cell mapping of PBMC from normal tissues, septic patients, and Alzheimer's Disease. (A) UMAP profiles of scRNA-seq from 71 samples (26 normal controls, 31 AD patients, and 14 sepsis patients) visualized to show 3 disease states; (B) UMAP analysis showing sample distribution; and (C) UMAP atlas visualization of scRNA-seq transcriptome displayed the annotation and color codes for 27 immune cell subclusters; (D) Typical cell-surface markers defining B cells, Monocytes/macrophages, NKT cells, NK cells, T cells, platelets and HSCs; (E) Violin plots indicated expression level of canonical annotation marker gene. PBMCs, Peripheral blood mononuclear cell; UMAP, Uniform Manifold Approximation and Projection; scRNA-seq, single-cell RNA sequencing; Mac/Mon, macrophage/monocyte; HSC, hematopoietic stem cell; NK, natural killer

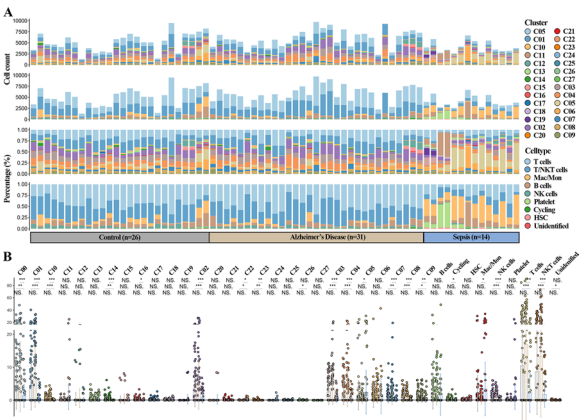

**Fig. 3 (abstract 000685)** Cell Counts from Normal Tissue, Alzheimer's Disease, and Sepsis Patients. (A) Proportions and cell counts for each cell cluster and cell subtype across disease types; (B) Quantitative bar graphs showing comparisons of percentages of each cell cluster and immune cell type between HC, AD, and sepsis patients. Statistical analysis was performed using an unpaired two-sided Student's t-test. Data are expressed as mean ± SD. NS, $P > 0.05$; *, $P < 0.05$, **, $P < 0.01$, ***, $P < 0.001$, ****, $P < 0.0001$. The variability in absolute cell counts of different cell subpopulations in AD and Sepsis can be seen in the figure,

suggesting that the immune cell expression profile of their PBMCs is altered after Sepsis develops into AD

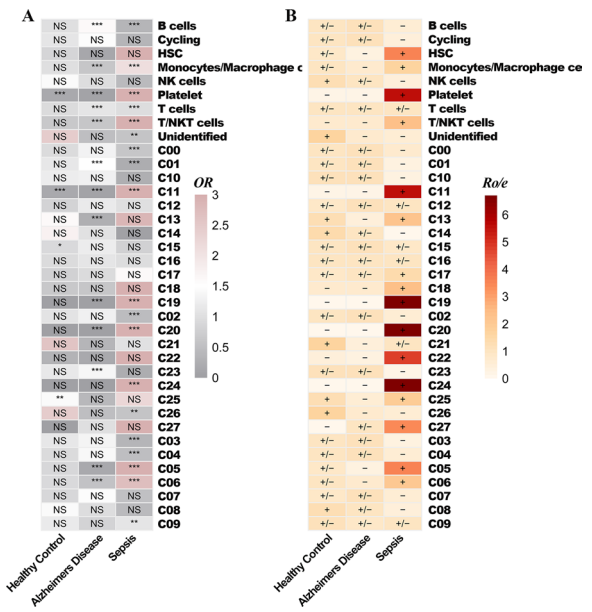

**Fig. 4 (abstract 000685)** Correlation of cell subpopulations with PBMC tissue origin. (A) Heatmap showing ORs of cell clusters present in each tissue, OR > 1.5 indicates that the cell group is more preferred to be distributed in the corresponding tissue; (B) Heatmap showing the ratio (Ro/e) of the actual observed to expected number of cells in each cell cluster in each tissue, + indicates that a particular cell cluster proportionally has a higher number in the group equivalent to the other two groups with preference for that tissue, ± indicates no preference, — indicates less number in the reorganized group compared to the other groups. odds ratios (OR, odds ratio) indicate a preference, and we explored the preference of different cell subpopulations origins according to the STARTRAC method of Zemin Zhang's team. To characterize the tissue distribution of meta-clusters, odds ratios (OR) were calculated and used to indicate preferences. Specifically, for each combination of meta-cluster i and tissue j, a 2 by 2 contingency table was constructed, which contained the number of cells of meta-cluster i in tissue j, the number of cells of meta-cluster i in other tissues, the number of cells of non-i meta-clusters in tissue j, the number of cells of non-i meta-clusters in other tissues. Then Fisher's exact test was applied to this contingency table, thus OR and corresponding p-value could be obtained. P-values were adjusted using the BH method implemented in the R function p.adjust. We found that all ORs > 1.5 or ORs < 0.5 had adjusted p-values < 1e-10. Hence, a higher OR with a value > 1.5 indicated that meta-cluster i was more preferred to distribute in tissue j, a lower OR with a value < 0.5 indicated that meta-cluster i was preferred not to distribute in tissue j

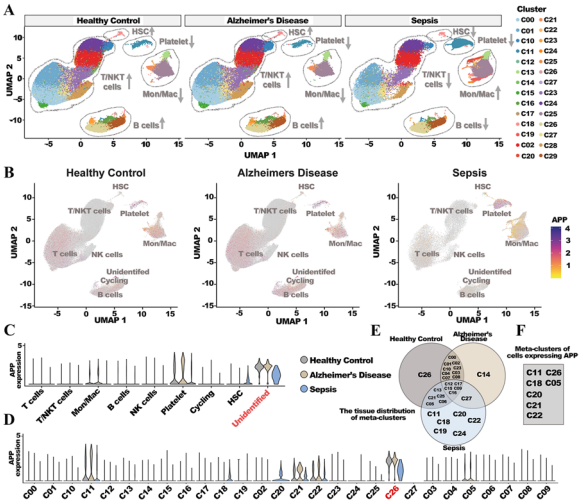

**Fig. 5 (abstract 000685)** Sepsis progression to AD peripheral blood subpopulation changes and APP-expressing cellular localization. (A) UMAP plot showing cellular subpopulation changes in healthy control, AD and sepsis patients; (B) UMAP plot showing cellular localization of APP expression; (C) Violin plot demonstrating APP gene expression high and low in different cellular subpopulations; (D) Violin plot demonstrating APP expression is highly expressed in different cellular subpopulations; (E) Venn diagram showing the preference of healthy control, AD and Sepsis for different cell clusters characterizing the changes in the subpopulation of BMCs in which Sepsis develops into AD, with C11 being platelets, C18 being HSCs, C19/C20/C22/C24 being monocytes/macrophages, and C14 being NKT cells; (F) APP high-expressing cell subpopulations, of which C20/C21/C22/C05 are all monocytes/macrophages. From the tissue preference and APP expression subpopulation preference, it was concluded that the progression of Sepsis to AD was associated with a decrease in the types of monocyte/macrophage subpopulations, an increase in the types of B cell subpopulations, an increase in the types of T/NKT cell subpopulations, a decrease in the number of platelet cells, and an increase in the number of hematopoietic stem cells. Among them, the monocyte/macrophage-associated cell clusters C05/C19/C20/C21/C22/C24, platelet C11, and hematopoietic stem cell C18 may be highly associated with the progression of Sepsis to AD

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000687

**Introduction:** In patients with acute illness, compensatory tachycardia initially serves to maintain adequate cardiac output, oxygen delivery, and tissue oxygenation but may persist despite appropriate fluid and vasopressor resuscitation or may be secondary to inotropic therapy. Sustained tachycardia is a predictor of adverse outcomes in critical illness. Ivabradine, a highly selective inhibitor of the sinoatrial node's pacemaker current (I*f* or "funny" current), mitigates heart rate by modulating diastolic depolarization slope without affecting contractility.
**Objectives:** To report the existing evidence on the use of ivabradine in critically ill patients.
**Methods:** A systematic literature search was performed up to September 2023 in the MEDLINE/PubMed® database. The search included only original human studies published in English in peer-reviewed journals. The search was performed using the following terms: ("ivabradine"[MeSH Terms] OR "ivabradine"[All Fields]) AND (("critical care"[MeSH Terms] OR ("critical"[All Fields] AND "care"[All Fields]) OR "critical care"[All Fields] OR ("intensive"[All Fields] AND "care"[All Fields]) OR "intensive care"[All Fields])). The trial protocol is registered in PROSPERO (CRD42023449267), in adherence with to the *Preferred Reporting Items for Systematic Reviews and Meta-Analysis—Protocols* (PRISMA-P) guidelines.
**Results:** After the first screening procedure, 39 studies were assessed for eligibility on a total of 93 records identified after the initial research (Table 1). Among these, 29 were excluded; 9 studies (4 randomized controlled trial, 5 case report/series), including a total of 234 patients, were included in the qualitative analysis. Ivabradine showed a potential role for improving hemodynamics in patients with multiple organ failure [1 study] and cardiogenic shock (e.g. due to myocardial infarction or myocarditis) [4 studies], in those with mechanical circulatory support, low cardiac output syndrome [2 studies] following tachycardiomyopathy after heart transplant or heart surgery, and septic shock [2 studies]. In addition, the combination of dobutamine with ivabradine has been explored to capitalize on dobutamine's positive inotropic action while mitigating its positive chronotropic effects, resulting in a more efficient cardiac cycle and improved hemodynamics.
**Conclusions:** At present, the use of ivabradine in critically ill patients has been poorly described. Future studies dealing with potential advantages or adverse events related to this drug use in these heterogeneous patients' populations are required.

**Table 1 (abstract 000687)** Study screening flowchart

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000690

**Introduction:** The optimal strategy for fluid resuscitation and hemodynamic management in sepsis treatment remains uncertain. We developed and validated an artificial intelligence (AI) decision-making model using a machine learning approach in continuous spaces to provide real-time guidance for sepsis treatment.
**Methods: Data source and population:** Patients diagnosed with sepsis from the electronic ICU collaborative research database (eICU-CRD) (training cohort) and the medical information mart for intensive care-IV (MIMIC-IV) (validation cohort) were included.
**Variables, medical actions, and outcome:** A total of 36 variables and 5 medical actions (fluid, three categories of vasopressors, and hydrocortisone) were incorporated into the model training process. We identified the time at which patients fulfilled all of the inclusion criteria as the onset time and divided the 24 h after the onset time into twelve 2-h intervals.
**Imputation:** The Self-Attention Imputation for Time Series was employed **(**Fig. 1).
**Development of the AI model:** We developed an AI model based on offline and deep reinforcement learning. Our model architecture comprised four main components: a history capture model, a generative model, a perturbation model, and Q-networks. The offline reinforcement problem of optimal decision-making in a continuous state-action space was effectively solved based on the time-series data of 41 clinical metrics for 12 intervals for each patient (Figs. 2 and. 3).
**Results: Patients:** Overall, 13,564 and 6,660 patients with sepsis from the eICU and MIMICIV databases, respectively, were included.
**Calibration of the AI model:** Good model calibration was verified through the visualization of the correlation between the return of the clinician's policy and patients' 90-day mortality, as depicted in Fig. 4A, B, C, D illustrate the average returns observed for both survivors and non-survivors.
**Impact of AI model on mortality:** After propensity score matching, the subgroup of patients (25%) with treatments most closely resembling the AI decision exhibited a significantly lower mortality rate, compared with the subgroup (25%) least similar in the eICU cohort (OR 0·45 [0·37–0·54], $p < 0·001$) and MIMIC-IV cohort (OR 0·73 [0·59–0·90], $p < 0·001$). We also found that patient mortality increases as the disparity between the clinician's strategy and that of the AI model, which demonstrated the validity of our model (Fig. 5).
**Comparison between the AI model and clinicians' strategy:** The differences between the AI model and the clinician's fluid intake, the rate of the three types of vasopressor, and whether hydrocortisone was applied within 24 h of the onset time are illustrated in Fig. 6. The AI model tended to prescribe less fluids, particularly after the first 6 h of sepsis. For the first class of vasopressors, the strategy of the AI model was approximately the same as that of the clinicians. For the second and third classes of vasopressors, the model tended to administrate larger dosages than the clinicians. The proportion of glucocorticoid usage in the AI model was similar to that of clinicians.
**Conclusions:** Our model, developed using AI algorithms guided by sequential data, offers personalized and clinically interpretable treatment decisions for sepsis with the aim of reducing mortality rates. Our findings aid in enhancing the accuracy of treatment decisions, paving the way for future real-time medical behavioral optimization driven by AI.

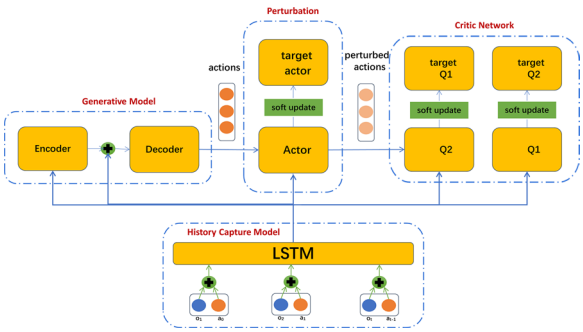

**Fig. 3 (abstract 000690)** Model Construction

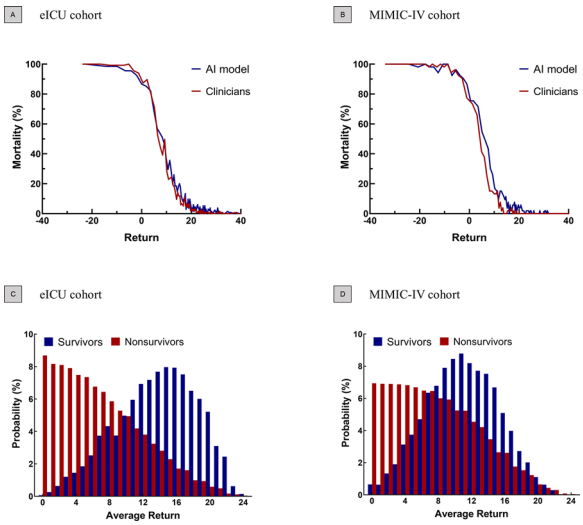

**Fig. 4 (abstract 000690)** Correlation between Q value and return and mortality
In Fig. 4, both "return" and "average return" represent the reward values associated with specific actions taken in medical decisions. Return presents the actual data of reward values corresponding to each patient's treatment actions, while average return divides the reward values into 25 parts, assigning a scalar value from 0 to 24 to each part. This process transforms the continuous distribution of reward values into a discrete scenario. Fig0.4A and B illustrate the relationship between the return and 90-day mortality in the bootstrapped 10,000 data from the eICU and MIMIC-IV cohort. Returns of actions were sorted into 100 bins, and the mean observed mortality (blue line for AI model, red line for Clinicians) was computed in each bin. Treatments with a low return were associated with a high mortality risk, whereas treatments with a high return led to better survival rates. Fig0.4C and D depict the average return in survivors and non-survivors in the bootstrapped 10,000 data from the eICU and MIMIC-IV cohorts. Among survivors, a higher proportion of patients had higher returns, while among non-survivors, a higher proportion of patients had lower return.

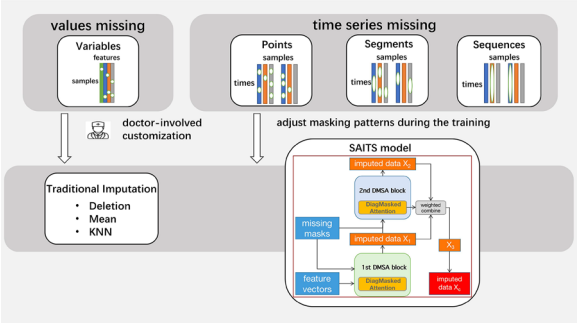

**Fig. 1 (abstract 000690)** Process of imputation
Continuous time series of patient data, including treatment at each time step, were used for modeling the AI treatment policy. A self-attention-based imputation method was adopted to complete the time series data with a long sequence missing pattern for some features. Patient survival at hospital discharge defined reward. Offline deep reinforcement learning was used to generate and estimate optimal treatment strategies—the AI policy. To encourage the model more Given the completed states of a patient, the trained model could predict the the optimal continuous and discrete treatment. The results were evaluated on two independent datasets from the eRI database.

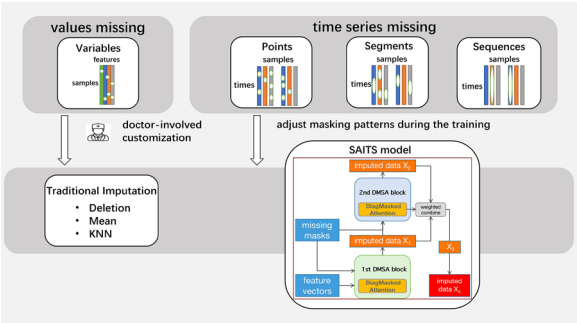

**Fig. 2 (abstract 000690)** Development and evaluation of the AI model
Utilizing a time-series data of 36 clinical variables and 5 medical actions (fluid, three categories of vasopressors, and hydrocortisone) within 24 h of sepsis onset, we developed a real-time AI decision model in the eICU and MIMIC-IV datasets. Patient survival at 90 days after ICU admission is defined as a reward. Reinforcement learning was used to estimate and evaluate optimal treatment strategies.

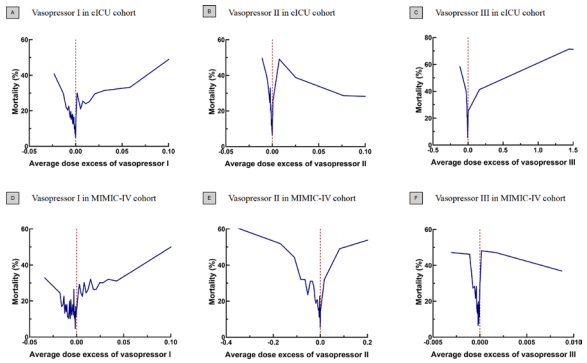

**Fig. 5 (abstract 000690)** Comparison of average dose excess received per patient of vasopressors with corresponding mortality
Comparison of how mortality varies with the difference between the dose recommended by the AI policy and the dose used by the clinicians. When the difference is smaller, we see lower observed mortality rates, suggesting that patient survival can be improved when clinicians act on the learned policy in AI. Vasopressor I (A), Vasopressor II (B), Vasopressor III (C) in the eICU cohort and Vasopressor I (D), Vasopressor II (E), Vasopressor III (F) in the MIMIC-IV cohort.

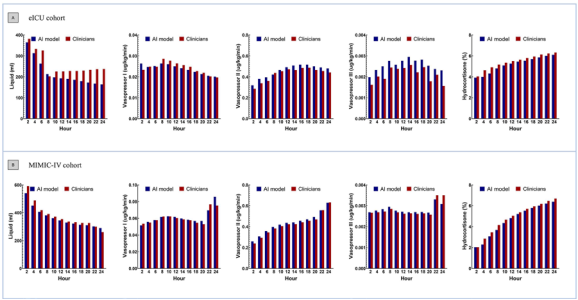

**Fig. 6 (abstract 000690)** Comparison between the AI model and clinicians' strategy in the eICU and MIMIC-IV cohort
Fluid input, vasopressor I, vasopressor II, vasopressor III, and hydrocortisone in the eICU cohort; (B) Fluid input, vasopressor I, vasopressor II, vasopressor III, and hydrocortisone in the MIMIC-IV cohort.

### Opening *Pandora*`s box by generating intensive care diary entries through artificial intelligence

E. Peschel[1], S. Krotsetis[2], A. H. Seidlein[3], P. Nydahl[4]
[1]University Hospital of Schleswig–Holstein Kiel, Kiel, Germany; [2]Nursing Research and Development, University Hospital of Schleswig–Holstein, Lübeck, Germany; [3]Institut of Ethics and History of Medicine, Interdisciplinary Surgical ICU, University Medicine Greifswald, Greifswald, Germany; [4]Nursing Research and Development, University Hospital of Schleswig–Holstein, Kiel, Germany.

**Introduction:** Intensive care diaries have a positive effect on the mental state of patients and relatives by closing memory gaps and improving the understanding of their experiences (3). Nevertheless, this intervention is not implemented in practice all overdue several challenges like staff shortages and a lack of time (1). The increasing integration of AI in our everyday lives and in the nursing care sector means that there is great potential to support or assist nurses in their activities. Assistance within the intervention by AI could also be a way of dealing with the problems associated with the implementation of the intervention (4). Specifically, AI could be an opportunity to write personalized diary entries based on medical and nursing records (5).
**Objectives:** The purpose is to develop a hypothetical study protocol for a multicenter, mixed-methods study to understand the impact and usability of AI-generated diary entries for ICU patients (2).
**Methods:** Patients with a stay of more than 72 h receive both a handwritten diary written by trained nursing staff and an AI generated diary. After discharge, the AI-generated diary entries will be created from the medical and nursing records using AI-supported software and printed out as a diary. Before the diaries are handed over, the entries are checked by trained nurses. It is transparently communicated whether it is the AI-generated diary or the handwritten diary (Fig. 1). Within three months after discharge, an appointment is arranged to hand over and read together with the family and trained staff. An interview raised the experiences, concerns and thoughts of the patients and relatives. In addition, the usability of the intervention is assessed by a questionnaire (2).
**Results:** The expected results could be that patients and relatives point out the differences or similarities of language and content. In addition, concerns regarding data processing and the use of AI can be mentioned, as well as ideas and suggestions as to how they would like to see it used. Possible effects on the results of using AI must be considered. Nursing is person-centred, personal, and individual. Therefore, diary entries are also a highly personalized and intimate intervention that has an impact on the nurse-patient relationship. In addition, different perspectives, such as ethical, nursing, legal and technical aspects, must be taken into consideration (2).
**Conclusions:** It is possible to generate personal diary entries by using AI-technology. However, this raises different questions and concerns from multiple perspectives, especially from the ethical and professional nursing side. As researchers, this and many more aspects should be thoroughly discussed before a real study is initiated. After all, what impact would it have if AI were to demonstrate a better aspect than the human intervention? (2).

### Causes of death and hemodynamic profiles in ARDS patients fatalities due to SARS-CoV-2

C. Laidet[1], M. Goudelin[1], B. François[2], F. Sanchez[1], AL. Fedou[1], T. Daix[2], J. Vaidie[1], P. Vignon[2], B. Evrard[2]

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000692

**Introduction:** Previous studies have shown that patients with the Acute Respiratory Distress Syndrome (ARDS) primarily die from sepsis and rarely from refractory acute respiratory failure (1,2). However, the mechanism of circulatory failure due to sepsis has never been explored.
**Objectives:** This study aimed to (i) determine the primary mechanism leading to death, (ii) explore the mechanism of circulatory failure before death and (iii) assess how respiratory failure acts as a mediator between sepsis and circulatory failure in patients with ARDS secondary to SARS-CoV-2.
**Methods:** We included patients admitted to the intensive care unit of Limoges Teaching Hospital (France) between March 2020 and June 2021 with ARDS secondary to SARS-CoV-2 and who died. We

determined the presence of severe or irreversible organ dysfunction in 8 systems according to previously used definitions (1,2) in the 48 h preceding death. The primary cause of death was defined and adjudicated by two independent physicians based on the failure that contributed most to death or to the decision to withdraw life support. A search for sepsis according to Sepsis-3 criteria was conducted within 7 days prior to death. Hemodynamic conditions of patients with circulatory failure who had echocardiography in the 72 h prior to death were reviewed. Mediation analysis was performed to study the potential mediation effect of a respiratory failure—defined by either a respiratory acidosis (pH < 7.1 and or PaCO2 > 100 mmHg) or severe sustained hypoxemia (PaO2 < 40 mmHg)—on the relationship between sepsis and severe circulatory shock (Figure A).

**Results:** Forty-nine patients (35%) of the 172 admitted died. Eighteen (37%) were identified with sepsis with a median time to death of 3 days. Seventeen patients (35%) died with irreversible circulatory and respiratory failure, 13 (27%) with isolated irreversible circulatory failure, and only 3 (6%) with isolated irreversible respiratory failure (Figure B). The causes of death differed according to whether or not sepsis had been identified prior to death. Circulatory failure was the main cause of death in 94% of patients with sepsis, compared to 52% of non-sepsis patients ($p = 0.007$). Deaths attributed to respiratory failure were more frequent in patients without sepsis (29% vs. 6%, $p = 0.007$). Neurological failure accounted for 6 deaths (12%). The introduction of vasopressors occurred a median of 3 days before death. Hemodynamic profiles prior to death were similar between patients with and without sepsis, with right heart dysfunction being the predominant finding (Figure C). A hyperkinetic LV profile was seen in 47% of cases, while only 11% had LV systolic dysfunction. Mediation analysis revealed a significant direct relationship between sepsis and circulatory failure, with a modest mediation effect of respiratory failure (Figure D).

**Conclusions:** Our study reveals that in patients with ARDS secondary to SARS-CoV-2, the primary cause of death is circulatory failure, predominantly precipitated by sepsis. Mediation analysis reveals a modest, albeit non-significant, mediation effect of respiratory failure on this relationship.

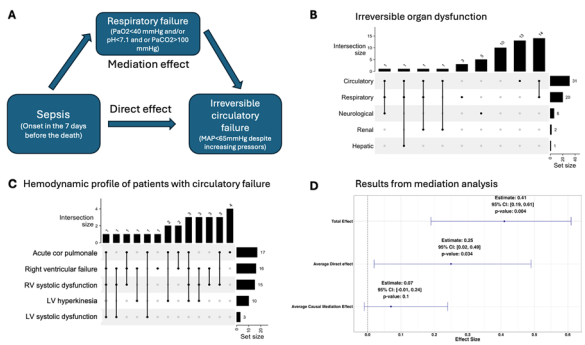

**Fig. (abstract 000692)** Directed acyclic graph illustrating the relationship between sepsis and circulatory failure, with a focus on the mediating role of respiratory failure. **B.** UpSet plot showing the irreversible organ dysfunction depicted in each patient. **C.** UpSet plot illustrating the hemodynamic profiles of patients who developed circulatory failure prior to death. **D.** Forest plot presenting the outcomes of a mediation analysis, examining the influence of respiratory failure on the link between sepsis and circulatory failure

## Long-term outcomes after extracorporeal membrane oxygenation in the Netherlands

F. Jolink, M. Onrust, W. Van Den Bergh, P. Van Der Voort, A. Oude Lansink-Hartgring
Department of critical care, University Medical Center Groningen, Groningen, Netherlands

**Introduction:** Extracorporeal membrane oxygenation (ECMO) is increasingly utilized in intensive care units (ICU), providing essential support for patients with respiratory or cardiac failure. However, there is limited knowledge about long-term outcomes and quality of life after ECMO.

**Objectives:** To report on five-year survival, health-related quality of life (HRQoL), and work-status of patients who received venoarterial ECMO, venovenous ECMO or extracorporeal cardiopulmonary resuscitation (ECPR).

**Methods:** This is a follow-up study of a previously conducted and published prospective multicenter observational cohort study on the survival and cost-effectiveness of ECMO (ref 1). Patients received ECMO support or ECPR between August 2017 and July 2019. The study was performed in ten university hospitals and major non-university hospitals in The Netherlands. Mortality rates were obtained by consulting the Dutch municipal records database. All patients from the original study cohort, who were still alive after five years, received a questionnaire. HRQoL was assessed using the EuroQol-5D-5L questionnaire and work status was assessed using the productivity cost questionnaire.

**Results:** A Kaplan–Meier analysis (Figure 1) shows high mortality in the initial year after ECMO, but thereafter plateauing survival curves. Of the initial 428 included participants, 194 (45%) were alive after one year and 155 (36%) were alive after five years. Five-year survival was 45% in patients who received ECMO for respiratory support, 42% for cardiac support and 26% for ECPR. The mean age at the initial ICU admission of the five-year survivors was 52 years (SD 14). ECMO duration was 186 h (SD 208), Length of ICU stay was 24 days (SD 19), and in-hospital stay was 36 days (SD 25). 77 patients (50%) received ECMO on a cardiac indication, 58 patients (37%) for respiratory failure and 20 (13%) were ECPR patients.

All five-year survivors received a questionnaire by mail, which was returned by 105 (67%) participants. Five-year HRQoL was rated higher than one-year HRQoL, with a median EQ-index value of 0.82 (IQR 0.73 – 1.0) compared to 0.81 (IQR 0.68–0.91). HRQoL on a visual analogue scale (0—100) was rated 75 ((median) IQR 65–85), which was the same as the score after one year. After five years, the majority of patients are either employed (30%) or retired (31%), with 22 individuals (25%) declared unfit for work.

**Conclusions:** The patient category undergoing ECMO or ECPR has a high mortality despite ECMO utilization. However, in the survivors, the risk of mortality diminishes and stabilizes after the first year of ECMO support. Long-term HRQoL is generally acceptable, although with some impairment in day-to-day functioning. Additionally, some patients can to return to work.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000694

**Introduction:** Prone positioning (PP) in patients ventilated for moderate-to-severe acute respiratory distress syndrome (ARDS) has shown hemodynamic benefit by unloading the right ventricle (RV) after 18 h (1). However, the immediate central hemodynamic impact of changing cardiac loading conditions induced by the initiation of PP, especially in the presence of acute cor pulmonale (ACP), has been little studied (2,3).
**Objectives:** The aim of the study was to assess the early impact of PP on ventricular function using three-dimensional transesophageal echocardiography (TEE-3D) in patients ventilated for severe ARDS.
**Methods:** We retrospectively studied patients under invasive mechanical ventilation for severe ARDS secondary to COVID-19 who required a PP session. A TEE-3D was performed just before and within the hour following the initiation of PP. Hemodynamic and respiratory parameters were collected simultaneously at the time of each assessment. ACP was defined as the combination of RV dilation (end-diastolic RV/left ventricular [LV]area $\geq 0.6$) and a paradoxical septal motion. Measurements were made independently by two experts from different centers and their reproducibility was assessed by measuring the intraclass coefficient (ICC).
**Results:** Between March 2020 and December 2021, 24 patients were studied. Eleven patients (45%) had isolated RV dilation and 13 (55%) had ACP. After PP, systolic arterial pressure slightly decreased from 139 mmHg (IQR [119,150]) to 132 mmHg (IQR [117–144], $p=0.037$), and systemic vascular resistance from 1841 mmHg/L/min (IQR [1492,2380]) to 1517 mmHg/L/min (IQR [1428,1803], $p=0.050$). Pulmonary compliance and driving pressure improvements were more pronounced in patients without ACP versus those with ACP. Specifically, the mean difference in static compliance improvement was +25% (CI95%: [−10,60]), and the improvement in driving pressure was -20% (CI95% [-41,1]). PP significantly unloaded both ventricles (Figure A and B). The ejection fraction of both ventricles remained stable, as well as the RV free-wall longitudinal strain (Figure C). Median RV/LV end-diastolic volume ratio was unchanged (Figure D), confirming homogeneous unloading of both ventricles by PP. PP induced a significant decrease in the right atrioventricular pressure gradient (Figure E) and a significant increase in RV-pulmonary artery coupling (Figure F). Results were similar in patients with and without ACP. Inter-observer reproducibility for ventricular volume measurement in TEE-3D was excellent (ICC for RV end-diastolic volume measurement: 0.92, $p<0.001$).
**Conclusions:** In patients ventilated for severe COVID-19 related ARDS, PP early unloads the two ventricles, and significantly reduces RV afterload while increasing RV-PA coupling.

**Introduction:** Latent class analysis (LCA) has identified two inflammatory phenotypes in acute respiratory distress syndrome (ARDS) and sepsis with divergent biological, clinical, and therapeutic features (1). However, the generalizability of these inflammatory phenotypes to patients with severe pneumonia is unknown, and differences in microbiologic profile between these phenotypes remain incompletely understood.
**Objectives:** To use LCA to identify underlying latent molecular subphenotypes in severe pneumonia and characterize their clinical and microbiological features.
**Methods:** We studied two observational cohorts (EARLI or mBAL) of patients ($n=415$) with clinically and radiologically confirmed pneumonia and admitted to the intensive care units of two hospitals in San Francisco (2). We performed LCA using clinical data and plasma biomarkers from a day of enrollment as class-defining variables. We compared the concordance of the new latent classes with previously identified ARDS phenotypes using a validated parsimonious classifier model (3). We evaluated differences in clinical outcomes and respiratory pathogen microbiology between classes.
**Results:** We found that a 2-class model best fit the data ($p=0.074$). The 71 (17%) patients with a hyperinflammatory phenotype had higher in-hospital mortality (61% vs 18%, $p<0.0001$), elevated plasma inflammatory biomarkers, creatinine, and bilirubin levels, and lower blood pressure (Figure A). The parsimonious classifier model performed with an area under the ROC curve of 0.80, indicating overlap with previously identified phenotypes. Respiratory and blood cultures were more often positive in hyperinflammatory pneumonia (Figure B and C). *Enterobacterales* species, *Staphylococcus aureus* and *Streptococcus pneumoniae* were the most commonly identified pathogens from respiratory culture in this group. *S. pneumoniae* was also more common in blood cultures from the hyperinflammatory group compared to the hypoinflammatory group (13% versus 2%, $p=0.001$). Viral PCR testing was performed in 21% of patients in both phenotypes, and there were no significant differences in the identification of respiratory viral pathogens by phenotype ($p>0.9$).
**Conclusions:** Using LCA, we identified two inflammatory phenotypes in severe pneumonia, characterized by differences in mortality, inflammatory biomarkers, and clinical microbiology. These phenotypes demonstrate similarities to previously identified inflammatory phenotypes of ARDS and sepsis, supporting the idea that these phenotypes are present across syndromic diagnoses in critically ill patients.

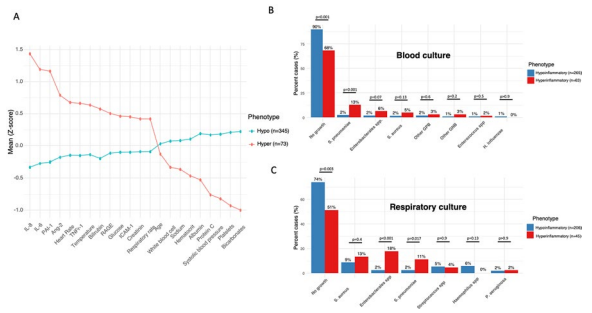

**Fig. (abstract 000696)** Average values per variable determined by latent class analysis, highlighting differences between inflammatory phenotypes in severe pneumonia. **B.** Comparison of positive blood culture pathogens rates between phenotypes among patients who underwent blood culture drawn. P-values (Fisher's Test) are used to compare the proportions of each pathogen between phenotypes among those sampled. **C.** Comparison of positive respiratory culture pathogens rates between phenotypes among patients who underwent respiratory sampling (bronchoalveolar lavage or tracheal aspirate).P-values (Fisher's Test) are used to compare the proportions of each pathogen between phenotypes among those sampled

**Introduction:** Acute respiratory distress syndrome (ARDS) is the most common pulmonary complication in critically ill patients that often results in unfavorable outcomes. A unilateral development of acute lung injury (ALI) is observed in approximately 23% of ARDS patients.
**Objectives:** So far, no research guiding PEEP through esophageal pressure in unilateral ALI was performed.
**Methods:** Separation of lungs in mechanically ventilated pigs was established by a modified double lumen tube. ALI was induced in the left lungs by 0.3% Triton X-100 lavage. After induction of ALI, pigs were randomized to PEEP 5 cmH2O (A) or a PEEP that corresponds to a transpulmonary positive end-expiratory pressure (TPPEsExp) between 1–3 cmH2O (B) and were ventilated for 6 h. We characterized ALI by microscopic lung injury score (LIS) as defined by the ATS by two blinded pathologists. Results are presented as mean ± standard deviation.
**Results:** Twelve pigs were randomized to the study groups. At baseline, no relevant differences in lung mechanics were observed. After 6 h mechanical ventilation of both lungs with a tidal volume of 6 ml/kg bodyweight in group A PEEP was 5 ± 0 vs 10.8 ± 2.1cmH2O in group B; TPPEsExp was -2.6 ± 2 in group A and 1.2 ± 1.7cmH2O in group B; mechanical power in group A was 18.6 ± 2.7 vs group B 18.1 ± 1.7 J/min; driving pressure was in A: 12.3 ± 1.7 vs B: 9 ± 1.4cmH2O; respiratory system compliance was in A: 23.2 ± 5.7 vs in B: 31.8 ± 3.4 ml/cmH2O.In lower lung lobes LIS were: group A right: 0.22 ± 0.07; B right: 0.17 ± 0.09; group A left: 0.49 ± 0.10; B left: 0.52 ± 0.14; Upper lobes LIS were: A right: 0.18 ± 0.1 B right: 0.2 ± 0.07; A left: 0.38 ± 0.16 B left: 0.3 ± 0.1.
**Conclusions:** In our strict unilateral ALI model a PEEP management corresponds to a transpulmonary positive end-expiratory pressure (TPPEsExp) between 1–3 cmH2O increased respiratory compliance

and decreased driving pressure at the same level of mechanical power. Nonetheless, after 6 h no differences in LIS could be observed.

### Exploring the effects of hyperoxic intermittent stimuli on reticulocyte levels: a randomized pilot study

M. Salvagno[1], C. Balestra[2], M. Khalife[3]
[1]Soins intensif, Hospital Erasme, Bruxelles, Belgium; [2]Environmental, Occupational & Ageing "Integrative Physiology" Laboratory,, HE2B—Haute École Bruxelles-Brabant, Ixelles, Belgium; [3]Anesthesia, Institut Jules Bordet, Bruxelles, Belgium

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000698

**Introduction:** Anemia is a prevalent issue among hospitalized patients, particularly in critically ill patients and in those undergoing surgery, including oncological procedures [1]. This condition often necessitates red blood cell transfusions, which carry inherent risks. With the rising incidence of cancer and aggressive treatments, the demand for transfusions has increased, posing challenges exacerbated by a dwindling blood donor pool. The normobaric oxygen paradox (NOP) has emerged as a potential avenue to increase EPO levels, offering therapeutic promise [2]. While some studies support its efficacy, research in this area remains limited, especially in clinical settings.
**Objectives:** This study aims to assess the effectiveness of a normobaric oxygen paradox (NOP) protocol in stimulating erythropoiesis, as measured by changes in reticulocyte counts, in cancer patients undergoing abdominal surgeries.
**Methods:** This is a prospective, single-center, controlled, randomized pilot study. A total of 49 patients undergoing abdominal surgery were retrospectively evaluated from a precedent trial performed at the Bordet Institute from February to November 2011. Adult patients undergoing abdominal oncological surgeries and who were admitted to the intensive care unit (ICU) for at least 24 h were enrolled, excluding those with severe renal insufficiency or who received transfusions during the study period. Participants were randomized into two groups at the admission to the ICU: a normobaric oxygen paradox (NOP) group and a control (CTR) group. The NOP group received 60% oxygen for two hours on days 1, 3, and 5 post-surgery, during the recovery in the ICU and the ward when discharged, while the CTR group received standard care.
**Results:** The final analysis included 33 patients (median age 62 [IQR 58–66], 28 (84.8%) males), with no withdrawals or deaths during the study period. No significant differences were observed in baseline surgical characteristics or perioperative outcomes between the two groups. In the NOP group ($n = 16$), there was a significant rise ($p = 0.03$), along the study period, in the percentage of reticulocyte

levels in comparison to the CTR group ($n=17$), with median values of 36.1% (IQR 20.3–57.8) versus -5.3% (IQR −19.2 to 57.8), respectively, suggesting enhanced erythropoiesis. Despite this, the increases in hemoglobin and hematocrit levels did not significantly differ between the groups. Finally, the duration of surgery exhibited a statistical tendency (p 0.08) to be negatively correlated with the difference in hematocrit levels at the end of the study period.
**Conclusions:** This pilot study provides preliminary evidence supporting the potential of normobaric oxygen therapy in stimulating erythropoiesis in cancer patients undergoing abdominal surgeries. While the NOP protocol resulted in increased reticulocyte counts, further research with larger sample sizes and multi-center trials is warranted to confirm these findings and explore the optimal oxygen therapy regimen and long-term effects. If validated, normobaric oxygen therapy could offer a non-invasive and cost-effective approach to managing postoperative anemia, reducing reliance on blood transfusions and recombinant erythropoietin therapy, which could be of interest, especially in critically ill patients.

### *Beta*-lactam antibiotic concentrations and the acquisition of multi-drug resistant bacteria in critically ill patients

M. Salvagno[1], A. Farinella[2], A. Minini[1], L. Attanasio[1], A. Cunha[1], M. Menozzi[1], A. Saravia[1], F. S. Amado[1], J. Gorham[1], M. Hites[3], D. Fage[4], F. S. Taccone[1], E. Gouvea Bogossian[1]

**Introduction:** Antimicrobial resistance (AMR) is a worldwide healthcare emergency [1]. Adequate drug regimens result in drug concentrations able to kill bacteria and reduce bacterial growth [2]. However, whether insufficient beta-lactam antibiotic concentrations can be associated with AMR emergence remains controversial [3].
**Objectives:** The aim of this study was to assess the impact of insufficient beta-lactam levels on the acquisition of AMR in critically ill patients.
**Methods:** Retrospective single-center cohort study including patients admitted to the intensive care unit of a tertiary University hospital from 2009 to 2014, who required a broad-spectrum beta-lactam antibiotic and had at least one therapeutic drug monitoring (TDM). Patients were categorized as having inadequate drug levels if the trough concentration (Cmin) fell below the clinical breakpoint for Pseudomonas aeruginosa (i.e., 8 mg/L for cefepime/ceftazidime, 16 mg/L for piperacillin/tazobactam and 2 mg/L for meropenem). AMR was defined according to breakpoints recommended by the European Committee on Antimicrobial Susceptibility Testing (EUCAST) using the disk diffusion method.
**Results:** A total of 444 patients (male gender, $n=313$, 71%; mean age $58\pm15$ years) were enrolled in the study. Patients received piperacillin/tazobactam ($n=168$), ceftazidime/cefepime ($n=58$) or meropenem ($n=218$); among them, 65 (15%) had insufficient drug levels. Nine of these 65 (13.8%) patients with insufficient antibiotic levels acquired at least one pathogen with AMR within 15 days of TDM, when compared to 84/379 (22%) in the other group (OR 0.56 [95% CI 0.27–1.19]; p = 0.13). In a multivariable competing-risk analysis including male gender, APACHE score on admission, previous colonization by other MDR bacteria, urinary catheter, central venous catheter, mechanical ventilation, previous hospitalization, previous surgery, insufficient antibiotic levels were not associated with AMR acquisition (sHR 0.84 [95% CI 0.42–1.68]). Similar results were found when a higher threshold, to define insufficient drug levels, was used (Cmin < 4 times the clinical breakpoint).
**Conclusions:** In this study, insufficient beta-lactam levels were not independently associated with AMR acquisition. Future prospective studies are needed to evaluate better the relationship between low drug levels and antibiotic resistance acquisition.

*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000701

**Introduction:** The liver plays a crucial role in filtering toxins from the blood, but when it's impaired, toxins can accumulate and affect brain function. Disturbances in the urea cycle play a significant role in the pathophysiology of the condition. This can lead to a range of symptoms, from mild confusion and forgetfulness to severe disorientation, personality changes, and in extreme cases, coma.
Hepatic encephalopathy (HE) is a condition that affects brain function due to liver disease. HE is a complication in 70% of patients with liver cirrhosis. HE can be a serious and life-threatening condition, close to 30% is the one-year mortality of patients with HE in the Republic of Moldova.
**Objectives:** Our goal of this study is to determine the correlation between the grade of HE and the stage of liver failure.
**Methods:** The retrospective study was carried in ICU, MCH "Sf. Treime" during 2022–2023. All patients with hepatic failure were managed by clinical protocols and guidelines.
The severity of hepatic encephalopathy (HE) was assessed using the scoring system: West Haven Criteria.
**Results:** During the years 22–23, 1,515 patients with hepatic insufficiency were admitted to the MCH "Sf. Treime", in ICU total $n=188$ (12.5%) of patients with liver cirrhosis and hepatic encephalopathy age $56{,}21\pm10{,}17$.
Immediately admitted from Emergency Care Unit 63 patients (33.5%) with HE grade IV West Haven criteria (WHC). $N=125$(66.4%) patients were transferred from the Department of Hepatology with EH grade I-IV WHC.
$N=123$ patients with cirrhosis of the liver with positive liver enzyme test, low prothrombin and albumin levels, moderate or severe ascites, and thrombocytopenia. $N=75$ (60, 97% + 3.17)of them with HE gr IV WHC, $n=42$ (22,34% + 2.37.1) with grade HE II-III WHC, $n=6$ ($3.19\%\pm1.01$) with HE gr I WHC.

N = 65 patients with a normal rate of prothrombin level, thrombocytes and protein, liver enzymes with a normal rate or slightly elevated, without ascites. $N = 43(22.87\% \pm 2.1)$ of them with HE gr I-II WHC, $n = 15$ (7.97% ± 2.01) with HE gr III WHC and $n = 7$ (3.27% ± 2.16) patients with HE grade III-IV WHC.
No strong correlation was found between laboratory parameters and severity of HE ($p = 0.025$).
**Conclusions:** The degree of severity of HE doesn't depend on the stage of liver failure. The presence of desorders of standard laboratory parameters in liver failure can't be an indicator of severe HE.
It is important to define ammonium level and aminoacids profiles in urea cycle disorders.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000702

**Introduction:** Quantification of muscle mass is relevant in clinical practice, especially in elderly patients. Although computed tomography (CT) is considered the "gold standard" for muscle mass quantification, it is not a practical method. In these cases, bioelectrical impedance (BIA) would be a more applicable and practical tool.
**Objectives:** To study the correlation between BIA and muscle area measured on CT and the accuracy of BIA in discriminating elderly patients with adequate muscle area on CT.
**Methods:** Diagnostic study carried out in patients older than 65 years admitted to a general ICU of a private hospital who underwent tomography of the thoracic region and BIA from Dec/2021 to Jun/2022. The quantification of the muscle area was performed at the T12 level with specific software (CoreSlicer©). BIA was performed up to 7 days after CT and the estimate of muscle mass was calculated using the Talluri equation (MMTalluri). The data measured with BIA and the muscle area in the CT were correlated with Spearman's correlation. Area under the ROC curve (AROC) analysis was applied to assess the accuracy of BIA in identifying patients with adequate muscle area on CT.
**Results:** We included 48 patients (median age 81 years [IQR 74–88], 65% male, 73% admission of medical cause, 27% died during hospitalization). CT at T12 showed a muscle area of 74.5 cm2 [IQR 61.3–90.8 cm2], and 54.2% had a low muscle area. Correlations of skeletal muscle area by CT and BIA variables were significant for skeletal muscle mass ($r = 0.74$; $p < 0.001$), lean body mass ($r = 0.72$; $p < 0.001$), MMTalluri ($r = 0.72$; $p < 0.001$) and phase angle ($r = 0.36$; $p < 0.012$). However, only phase angle (AROC 0.68, 95% confidence interval 0.51–0.84) and MMTalluri (AROC 0.67, 95% confidence interval 0.51–0.83) were discriminative for detecting adequate muscle area.
**Conclusions:** The results of this study suggest that BIA has, at best, a modest accuracy for assessing the skeletal muscle area in critically ill elderly patients. In these cases, other methods of assessing the quantity of muscle mass are suggested.

### Audit of blood glucose control amongst adult intensive therapy unit patients in a district general hospital

G. Moore[1], A. Lee[2]
[1]Intensive Care Medicine, Stoke Mandeville Hospital, Aylesbury, United Kingdom; [2]Intensive Care, Stoke Mandeville Hospital, Aylesbury, United Kingdom
**Correspondence:** G. Moore
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000706

**Introduction:** Hyperglycaemia after critical care admission is associated with increased in-hospital mortality [1]. In the United Kingdom, the Royal College of Anaesthetists defines hyperglycaemia as a blood glucose level greater than 10 mmol/L, and states that, in best practice, insulin should be given to adult patients in critical care in cases where blood glucose levels are greater than 10 mmol/L for more than 6 h [2]. Within Buckinghamshire Healthcare NHS Trust, setting blood glucose targets forms part of the daily review checklist for patients on the Intensive Therapy Unit (ITU).
**Objectives:** To measure and improve compliance with the local policy of setting blood glucose targets daily and the national standard of commencing insulin therapy in ITU patients who have been hyperglycaemic for more than 6 h.
**Methods:** Data that had been collected as part of routine clinical care were harvested from the digital record-keeping software. Each patient day was taken as an individual data point. Each patient day was audited for the documentation of blood glucose targets, and whether appropriate insulin therapy had been commenced within 6 h of hyperglycaemia being recorded. A baseline data set was collected from 11th March to 17th March 2024. An intervention was subsequently implemented whereby members of the medical team were reminded daily at the morning handover meeting to document all daily targets when reviewing patients. A re-audit was performed looking at data from 18th March to 24th March 2024.
**Results:**

**Table 1 (abstract 000706)** Patient days pre and post-intervention with documented blood sugar targets, hyperglycaemic events, and insulin therapy

| | Total patient days | Patient days with a documented blood sugar target | Patient days with a documented blood sugar > 10 mmol/L for > 6 h | Patient days where insulin therapy was started within 6 h of hyperglycaemia |
|---|---|---|---|---|
| Pre-intervention | 61 | 16 | 28 | 18 |
| Post-intervention | 60 | 43 | 19 | 16 |

Table 1 shows that pre-intervention a blood sugar target was documented in only 26% of the daily reviews audited, compared to 72% post-intervention. This translated into a significant improvement in the proportion of hyperglycaemic episodes being treated with insulin. In the first week of data collection insulin therapy was commenced promptly in 18 of the patient days audited, out of the 28 patient days which showed hyperglycaemia lasting more than 6 h (64%). Post-intervention this rose to insulin treatment being commenced promptly in 16 out of 19 patient days in which hyperglycaemia was documented (84%).

**Conclusions:** The intervention implemented as part of this audit cycle was effective in improving compliance with both the local and national standards around the monitoring and treatment of hyperglycaemia in critical illness. Whilst causality cannot be proven, it is possible that the improved documentation of blood sugar targets led to the increased recognition and treatment of hyperglycaemia that was evident in the second week of data collection.

**Correspondence:** G.L. Schwarz

*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000707

**Introduction:** Gender disparities in intensive care provision are well-known and they have so far been attributed mainly to biological and social factors (1). Gender differences in the patients' own treatment intensity preferences are not well described (2,3). In a scenario-based questionnaire of 202 Norwegian outpatients aged ≥ 80 years, we found that the ICU admission preferences of very old patients varied widely and that the male gender increased the likelihood more than two-fold that respondents would opt for ICU admission in the hypothetical event of acute critical illness (4). These gender differences were supported by analyses adjusted for age, marital status, religion, healthcare professional background, comorbidity, frailty, and health-related quality of life.

**Objectives:** We aimed to describe gender differences by analyzing free-text comments that elaborated on the underlying rationale of the respondents' ICU admission choices.

**Methods: We conducted a postal survey of a purposive sample of potential ICU candidates aged ≥ 80, exploring their ICU admission preferences in several hypothetical scenarios of acute critical illness. For each scenario, there were three mutually exclusive response options: (i) wishing to be admitted to ICU, (ii) wishing not to be admitted to ICU, and (iii) wishing to not engage in the decision. Additionally, space was provided for free-text comments. For this substudy, we analyzed free-text comments using Systematic Text Condensation (5), a method for thematic cross-case analysis of qualitative data inspired by phenomenology and further developed for the medical context as a pragmatic procedure within the social constructivist tradition. Using an explanatory sequential approach, we present preliminary findings from the qualitative analysis and descriptive respondent gender statistics.**

**Results:** Very elderly outpatients ($n = 202$; 55% females) made choices pertaining to 590 hypothetical clinical scenarios and provided 331 free-text comments [188 (57%) of female respondents] elaborating the rationale for and considerations underpinning their ICU admission choices. By analyzing these free-text comments, we identified four preliminary main categories:

1. Wishing for the impossible (e.g. being in control despite being comatose).
2. Trust, mainly in the health care providers and the health care system, but also in family members and in higher powers.
3. The course of life comprises three sub-categories: age itself, accepting the end of life, and being considerate towards future generations.
4. Hope, comprising four sub-categories: hope for comfort, hope for cure/survival, hope for dignified closure and priority for quality of life over length of life.

Figure 1 shows gender distribution within categories and sub-categories. We collapsed sub-categories with comparable gender distribution and small numbers.

**Conclusions:** In this purposive sample, we identified gender differences regarding the values and notions underlying very old survey respondents' ICU admission choices in the hypothetical event of acute critical illness. These findings add to existing evidence (2,3). Further research is needed to explore and better understand gender differences regarding very old patients' treatment intensity preferences. Our findings indicate that variations in the patients' personal goals of treatment might provide an additional explanation for gender differences in ICU provision.

### Does organ transplantation center establishment have an impact on consent rates for cadaveric organ donation at an university hospital In Eskisehir, Turkiye

M. S. Yalcin[1], R. Ozdemir[1], B. B. Yelken[2], E. Karakoç[3]
[1]ANESTHESIOLOGY AND REANIMATION, Eskişehir Osmangazi Üniversitesi Tıp Fakültesi Hastanesi, Eskişehir, Turkey; [2]Anesthesiology and reanimation department, intensive care unit, ESKISEHIR OSMANGAZI UNIVERSİTY, MEDİCAL SCHOOL, ESKISEHIR, Turkey; [3]Anesthesiology and reanimation department, intensive care unit,, ESKISEHIR OSMANGAZI UNIVERSİTY, MEDİCAL SCHOOL, Eskişehir, Turkey
**Correspondence:** M.S. YALCIN
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000708

**Introduction:** Organ transplantation represents a crucial therapeutic option for patients with end-stage organ failure. This procedure can be performed either from living or deceased donors. However, obtaining consent for deceased donor organ transplantation, particularly from first-degree legal relatives, remains a challenge in Turkey. Several reasons contribute to organ rejection, including limited cases of death from lung and heart failure, misconceptions regarding brain death versus coma, lack of trust in healthcare services, fear of organ trafficking, expectation of miracles, low socio-educational levels, and socio-cultural attitudes influenced by religious pressures.
**Objectives:** This study aims to investigate the influence of a center's establishment as an organ transplantation facility on the consent rates for organ donation among relatives of patients. Specifically, we focused on analyzing the changes in consent rates following the establishment of the transplantation center at Eskisehir Osmangazi University Hospital in 2018. To achieve this objective, we compared the demographic data of patients diagnosed with brain death between 2018 and 2023 with those between 2014 and 2017. Additionally, we examined the consent rates for organ donation among family members during these periods.
**Methods:** Data from patients diagnosed with brain death between 2018 and 2023 at Eskisehir Osmangazi University were collected and analyzed. The demographic information and consent rates for organ donation among family members were compared with those from a previous study conducted between 2013 and 2017 in Eskisehir. Moreover, a comparative analysis was conducted between Eskisehir and Bursa, two provinces with similar socio-cultural backgrounds, regarding consent rates for organ donation.
**Results:** Between 2018 and 2023, a total of 57 patients were diagnosed with brain death at Eskisehir Osmangazi University Hospital. Among them, 19 relatives consented to organ donation, while 38 relatives refused consent for organ donation. The consent rate for organ donation in Eskisehir increased from 25.7% (2013–2017) to 33.3% (2018–2023). However, due to insufficient data on patients diagnosed with brain death, the observed increase cannot be deemed statistically significant. Therefore, further studies involving larger patient cohorts are necessary to validate these findings.
**Conclusions:** The establishment of an organ transplantation center appears to positively impact the consent rates for organ donation among relatives of patients diagnosed with brain death. However, comprehensive studies involving larger patient populations are warranted to confirm these findings and address the existing limitations in data collection.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000709

**Introduction:** Acute intoxication with hypoglycemic sulfonamides (HGS) is life-threatening poisoning due to the potential of hypoglycemia with its neurological complications and sequelae.
**Objectives:** Describe the epidemiological, clinical, therapeutic, and prognostic characteristics of acute intoxications with hypoglycemic sulfonamides (HGS) admitted to the intensive care unit.
**Methods:** This was a retrospective descriptive study conducted in a toxicology Intensive Care Unit over a period of 5 years (2019–2023). We included patients admitted to the ICU for intoxication with HGS. Patients with polydrug poisoning involving HGS and another drug interfering with carbohydrate metabolism, particularly metformin, were excluded.
**Results:** Thirty-six patients were included. The mean age was $26 \pm 10$ years. Eight patients (22%) were children. The gender ratio was 0.5. Six patients (17%) were diabetic, of whom 5 were treated with HGS. Twelve patients (33%) had a psychiatric history and 15 patients had a history of at least one suicide attempt. It was a suicidal act in all cases. Glimepiride intoxication accounted for 66% of cases ($n = 24$) and glibenclamide intoxication for 33% of cases ($n = 12$), with average presumed ingested doses of $50 \pm 32$ and $41 \pm 28$ mg, respectively. Hypoglycemia was the main reason for admission, present in 35 patients with an average onset time of 4 h. The mean initial capillary blood glucose was 0.5 mg/dl [0.23–1.4]. The main symptoms of hypoglycemia noted were asthenia (38%), profuse sweating (36%), and headaches (19%). No patient experienced seizures or coma. Eighteen patients (50%) presented with hypokalemia at admission. Our management focused on continuous glucose serum infusion, with an average administered glucose quantity of $113 \pm 75$ g/24 h. No patient received octreotide. The average length of hospital stay was 3 days. All patients survived.
**Conclusions:** Anti-diabetic medication intoxications are becoming more common in the intensive care unit. For hypoglycemic sulfonamide-induced acute poisoning, serious complications can be avoided with prompt and appropriate care.

**Topic:** Poisoning/Toxicology/Pharmacology

### Adult generalized tetanus: successful experiences from a resource limited centre in a developing country

V. Surapaneni, S. Chougale, P. K. Singh, A. Ahuja, D. Chaudhry
Pulmonary and Critical Care Medicine, Pandit Bhagwat Dayal Sharma Post Graduate Institute of Medical Sciences, Rohtak, India
**Correspondence:** V. Surapaneni

*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000710

**Introduction:** Tetanus is a preventable, yet life-threatening neurologic disorder characterized by trismus and muscle spasms(1). Although it is a rare disease in modern times, due to vaccination practices, it remains prevalent in developing countries (1).
**Objectives:** In this study we aimed to share our experience of managing five patients of adult generalized tetanus, over the past one year.
**Methods:** It was a single-center, retrospective study, evaluating the medical records of patients who presented to the emergency room with the diagnosis of Tetanus between April 2023 to March 2024. For diagnosis, we used the WHO definition which employs clinical assessment, consideration of factors like history of the wound and presence of symptoms such as lockjaw, muscle spasms, and rigidity of the neck or abdomen(2). For data analysis, we used hospital records, covering demographics, injury type, incubation period, antibiotic use, need for mechanical ventilation, tetanus antitoxin/immunoglobulin dosage, sedative/analgesic administration, muscle relaxants used, ICU and hospital stay duration, presence of autonomic instability, pneumonia, and other complications. Tetanus severity was graded using the Ablett system: Grade 1(mild), mild to moderate trismus with no respiratory compromise; Grade 2 (moderate), moderate trismus and moderate respiratory compromise with an increased respiratory rate (>30 breaths per min); Grade 3(severe), severe trismus with increased respiratory rate (>40 breaths per min) and tachycardia (>120 beats per min); Grade 4 (very severe), severe manifestations with autonomic dysfunction(3).
**Results:** Of the five patients, 4 were male and all 5 were from rural areas. 4 patients recovered and one patient died. The mean age was 43 years. None of them had any history of prior vaccination. Out of the five patients, 1 patient had moderate disease, 2 patients had severe disease and 2 patients had very severe disease. All the patients required mechanical ventilation. The mean duration of onset of disease from the day of injury was 13.2 days. Autonomic instability was seen in 3 patients and pneumonia developed in 4 patients during their course of hospital stay. Median duration of hospital stay was 38 [IQR:29.5–51.1] days. Patients in the Severe group needed prolonged mechanical ventilation and heavy sedation combined with muscle relaxants. All five patients developed critical illness myopathy due to prolonged hospital stay and the use of muscle relaxants. Improvement in muscle weakness was observed during the follow-up visits. All the patients received human tetanus immunoglobulin on admission and were vaccinated with tetanus toxoid during follow-up. Wound debridement was done in two cases.
**Conclusions:** Although the incidence of tetanus is decreasing globally, it remains prevalent in developing countries. Patients presenting with severe generalized tetanus require prolonged ICU stay.

*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000711

**Introduction:** Caring for critically ill patients in the Intensive Care Unit (ICU) presents special challenges to the staff because of the complexities of the technology utilized and the critical illness of the patient. [1–3] This study explores nursing praxis at an ICU in Greece and critically discusses the power relations in which the nurses acted as carers and clinical decision-makers, as well as the kind of meanings and identities that emerged in the cultural ethos of critical care.[4] Clinical Decision-making is an important aspect of ICU nursing, and whether nurses participate in it has been a long-standing subject of inquiry. [5–9].
**Objectives:** To understand how power relations, rituals, and practices determine the care delivered at a hospital in Greece, with a particular focus on the participation – formal and informal—of nurses in the clinical decisions of the ICU team.
**Methods:** This study falls within the realm of critical medical anthropology and phenomenology. Data were collected via two-year participant observation at a teaching ICU in Greece and via 20 in-depth interviews. Interviews were analyzed according to the thematic approach of Braun and Clarke.[10] The study was completed in 2021.
**Results:** "Routine", that is scheduling of care and work on a day-to-day basis, emerged as a technology of discipline. For example, "bed-baths" and “bedmaking” were part of a strict “monochronic” routine every morning, and were consistent with a culture of hierarchy and exclusion, in which the nurses on this particular unit were subjectified as agents of basic somatic (bodily) care rather than specialist care. This deterred nurses from formally participating in the clinical decisions of the ICU team. However, ethnographic fieldnotes and narratives of the nurses also led to the following findings: a) during the rituals of bed-baths and bed-making, nurses were in total synch with their patient’s care needs as they entered their polychronic time dimension; b) morning bed-baths facilitated the creation of a "zone" of privacy; c) nurses acted as agents of critical care, as the "ears" and "eyes" of doctors and patients through “nursing gaze”; d) nurses were subjectified as visible negotiators of care and treatment in the case of emergency and rapid patient deterioration; and e) the cultural habitus of intensive care activated a discourse of compassionate care.
**Conclusions:** In this study, ICU nurses were found to settle power relations and strengthen their negotiating power towards the doctors by applying their specialist knowledge in practice. On the other hand, most of the time they acted as informal clinical decision-makers and rendered themselves more "visible" via their compassionate patient care. This particular finding in Greece constitutes a significant differentiation from similar studies in other countries.

## Advancing antibiotic stewardship in severe community-acquired pneumonia: machine learning insights from the MIMIC-IV database

J. Ferreira-Coimbra[1], M. Paulo[2], N. Feixa-Rodrigues[2]
[1]Intensive Care Medicine, São João University Hospital, Porto, Portugal; [2]School of Technology, Polytechnic Institute of Cávado and Ave, Barcelos, Portugal
**Correspondence:** J. Ferreira-Coimbra
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000713

**Introduction:** Severe community-acquired pneumonia continues to be a major health challenge globally, contributing significantly to morbidity and mortality rates. The administration of empirical antibiotic therapy is a common approach, yet it is increasingly complicated by the emergence of multidrug-resistant pathogens, notably Methicillin-resistant Staphylococcus aureus (MRSA) and Pseudomonas aeruginosa. This rise in resistance complicates effective antibiotic management. Hence, we advocate for the application of machine learning techniques to analyze extensive clinical datasets, such as MIMIC-IV. This approach has the potential to create predictive models that could assist healthcare professionals in early identifying patients at elevated risk of developing infections caused by these resistant pathogens using data from the first 72 h of admission.
**Methods:** We conducted a retrospective analysis of severe pneumonia cases using the MIMIC-IV database, focusing on a cohort of 940 unique hospital admissions involving critically ill patients. The study extracted an array of patient data for analysis, including demographics (race, insurance status, marital status, age), clinical variables (length of hospital stay, temperature, heart rate, respiration rate, oxygen saturation, systolic and diastolic blood pressure), and microbiological data (specimen types, tests conducted, results, and timing of test requests post-admission to the Emergency Department (ED)). These data points were used for the development of predictive models employing various supervised machine learning algorithms: Multi-Layer Perceptron (simple neural network), Random Forest Classifier, Extra Trees Classifier, and Gradient Boosting Classifier. These models aimed to predict the presence of Gram-Positive Bacteria, Gram-Negative Bacteria, and more specifically, MRSA and Pseudomonas in microbiology test results within the first 72 h of admission. To address data imbalance, model performance was assessed using the macro F1-score across a fivefold cross-validation process.
**Results:** Our analysis encompassed 940 hospital admissions where patients were diagnosed with severe pneumonia, totaling 6,949 microbiological tests. Within this dataset, 124 tests confirmed MRSA, while 797 identified Pseudomonas infections. The performance of our predictive models was encouraging, with the Random Forest Classifier achieving the highest macro F1-score of 84.11%. In contrast, the Gradient Boosting Classifier had the lowest performance, with a macro F1-score of 76.01%.
**Conclusions:** Our research underscores the significant potential of supervised machine learning algorithms in identifying the likelihood of MRSA or Pseudomonas aeruginosa as the causative agent in severe pneumonia. These predictive models can serve as essential tools for healthcare providers, enabling more precise antibiotic selection, which in turn supports antibiotic stewardship initiatives and helps combat the rise of antimicrobial resistance. Integrating these models into clinical workflows could markedly enhance patient management, minimizing the unwarranted use of broad-spectrum antibiotics. To ensure these models can be effectively adopted in everyday clinical practice, further prospective studies for their validation and refinement are crucial.

## Comparison of risk factors and outcome for candidemia versus bacteremia in critically ill patients: a retrospective multicenter study

S. Ilia[1], M. Loukaki[2], E. Mihailidis[2], G. Schinoplokakis[2], E. Vitsaxaki[3], G. Hamilos[4], E. Kondili[5], G. Briassoulis[2]
[1]Pediatric intensive care unit, university hospital, medical school, University of Crete, Heraklion, Greece; [2]PostGraduate Program Emergency and Intensive Care in Children Adolsescents and Young Adults, School of Medicine, University of Crete, Heraklion, Greece; [3]Infection Control Committee, University General Hospital of Heraklion, Iraklio, Greece; [4]Microbiology Laboratory, School of Medicine, University of Crete, Heraklion, Greece; [5]Intensive Care Unit, School of Medicine, University of Crete, Heraklio, Greece
**Correspondence:** S. Ilia
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000715

**Introduction:** Candidemia is an alarming problem with increasing prevalence in critically ill patients admitted to an intensive care unit (ICU) associated with morbidity and mortality. However, the risk factors and outcomes associated with candidemia may vary compared to those associated with bacteremia.
**Objectives:** This study aimed to identify critically ill patients at high risk of candida versus bacterial bloodstream infections (BSI) and assess their characteristics and outcomes.
**Methods:** This was a multicenter retrospective observational case–control study on critically ill patients admitted to the ICU of three large Greek hospitals in Crete. Each eligible patient with candidemia (case) was matched to a control with bacteremia and to a second control with no BSI.
**Results:** Overall, 403 patients were enrolled, 91 with candidemia (C-BSI), 157 with bacteremia (B-BSI), and 155 with no-BSI. Candida species included C. albicans ($N=24$, 26.4%) mainly with 15% resistance to azoles, and C. non-albicans ($N=67$, 73.6%), mainly with 25.6% resistance to echinocandins. Risk factors associated with C-BSI included immunosuppression ($p=0.006$), total parenteral nutrition ($p=0.03$), previous fungal colonization ($p<0.001$), and Candida score ($p<0.001$), while demographic factors were not found to significantly contribute to the development of BSI. Clinical severity was significantly higher on the day of infection for B-BSI group (SAPS-II score C-BSI 47 vs. B-BSI 55 vs. no-BSI 34, $p=0.005$). The timeframe between ICU admission and BSI (C-BSI 24 days vs. B-BSI 14 days, $p=0.001$), mechanical ventilation duration (C-BSI 35 days vs. B-BSI 23 days vs. no-BSI 14 days, $p<0.001$), ICU stay (C-BSI 35 days vs. B-BSI 24 days vs. no-BSI 14 days, $p<0.001$)

and hospital stay (C-BSI 42 days vs. B-BSI 31 days vs. no-BSI 20 days, $p<0.001$) were longer in candidemia group (Fig 0.1). Patients with increased Candida score (OR 2.0, p = 0.006), with longer duration of mechanical ventilation (OR 1.14, $p=0.03$), and lower clinical severity (SAPS-II) on the day of BSI (OR 0.9, $p=0.006$), were more likely to develop candidemia than bacteremia. Mortality was 74.7% in C-BSI, 72.6% in B-BSI, and 57.4% in non-BSI ($p=0.004$). Increased Candida score (AUROC 0.634, 95% CI 0.520–0.747, $p=0.021$) and clinical severity on the day of BSI (SAPS-II AUROC 0.770, 95% CI 0.675–0.866, $p<0.001$) were identified as mortality predictors.
**Conclusions:** Immunosuppression, elevated candida score, prolonged mechanical ventilation, and extended ICU stay emerge as discernible risk factors for the development of candidemia as opposed to bacteremia. These results can aid in identifying patients who are most likely to benefit from empiric antifungal therapy.

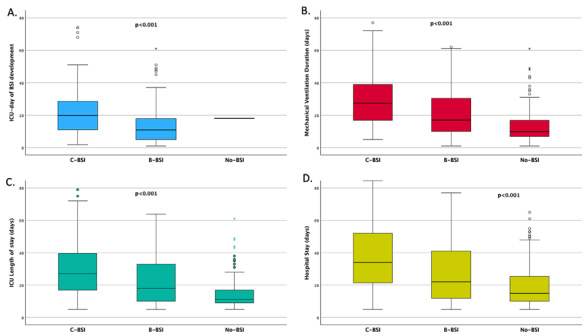

**Fig. 1 (abstract 000715)** Timeframe between admission and bloodstream infection (A), mechanical ventilation duration (B), ICU length of stay (C), and hospital length of stay (D) in patients with candidemia (C-BSI), with bacteremia (B-BSI), and with no bloodstream infection (No-BSI)

**Introduction:** Frailty, persistent symptoms, physical and cognitive problems are frequent after critical COVID-19. However, their co-occurrence and post-discharge trajectories are unknown.
**Objectives:** To study the concordance between physical and cognitive problems after hospital discharge due to critical COVID-19 during a 1-year follow-up.
**Methods:** Prospective cohort study in COVID-19 patients admitted to ICU and discharged alive from the hospital. Participants were assessed for frailty (assessed using the Clinical Frailty Scale), persistent COVID-19 symptoms (duration ≥ 2 months), and cognitive impairment (harmonized 10-point Cognitive Screener) at 1, 3, 6, 9, and 12 months post-discharge. Concordance between physical and cognitive problems was evaluated with proportions and Cramer's V bias-corrected. Clusters of physical and cognitive impairment were defined using sequential analysis, and Cohen's kappa coefficient evaluated the agreement.
**Results:** We followed 428 participants for one year (mean age of 64 years, 57% males, and 61% required invasive mechanical ventilation). Physical and/or cognitive problems were experienced in 80% of responders at least once during follow-up (263/331 participants), and half reported any problem even after one year. Most participants experienced health problems in a single health domain, with co-occurrence less than 8% in every assessment (Cramer's V bias-corrected less than 0.08 in any assessment) [Figure]. The sequential analysis identified three clusters each of cognitive and physical trajectories with no agreement (kappa = 0).
**Conclusions:** Critical COVID-19 survivors frequently experience physical and/or cognitive problems, yet these conditions and their trajectories are discordant. Multidimensional evaluations post-ICU discharge can aid in delivering tailored rehabilitation programs.

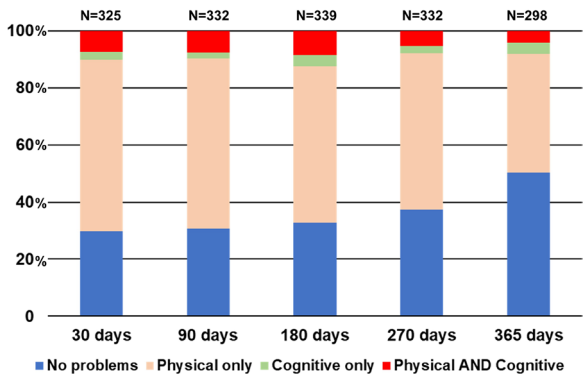

**Fig. (abstract 000716)** Prevalence and cooccurrence of physical and/or cognitive problems in critical COVID-19 survivors during one-year follow-up

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000718

**Introduction:** Acute kidney injury (AKI) after lung transplantation (LTx) is common and associated with increased mortality, particularly in those requiring renal replacement therapy (RRT).
**Objectives:** This retrospective analysis aimed to identify perioperative risk factors for AKI and RRT immediately after LTx, with a secondary focus on evaluating outcomes in the AKI and RRT population in the intensive care unit (ICU).
**Methods:** A cohort of 465 adult patients who underwent LTx at Vall d'Hebron University Hospital from January 1, 2018, to December 31, 2022, was analyzed. Patient characteristics and postoperative outcomes in the ICU were compared using chi-square, Fisher's exact test, Mann–Whitney U test, and logistic regression, as appropriate. Multivariate analysis was conducted including all statistically significant variables in the univariate analysis. Survival analysis using Kaplan–Meier

curves and comparison using log Rank tests were also performed. All statistical analyses were conducted using SPSS versión 23.0 (IBM, New York, US).

**Results:** A total of 109 patients (23.4%) had AKI postoperatively, with 28 needing RRT (6.4%). Factors associated with higher AKI and RRT rates included cardiopulmonary bypass (CPB), prolonged CPB, elevated lung allocation score (LAS), lung retransplantation, postoperative bleeding, polytransfusion, delayed chest closure, extracorporeal membrane oxygenation (ECMO) use, and PGD grade 3 on days 1, 2, and 3 (Table 1). Multivariate analysis identified retransplantation, delayed chest closure, PGD grade 3 at 24 h, and CPB as independent risk factors (Table 2). Outcomes showed prolonged mechanical ventilation and ICU stay (Figure 1), accompanied by significantly higher ICU mortality rates (3.7% vs 16.5% vs 53.6% -no AKI vs AKI vs RRT-), compared using survival curves (Figure 2).

**Table 1 (abstract 000718)** Univariate analysis of risk factors for presenting AKI or requiring RRT

| | Acute Kidney Injury | | Requiring RRT | |
|---|---|---|---|---|
| **Variable** | **OR (95% CI)** | ***P* value** | **OR (95% CI)** | ***P* value** |
| Age | 0.988 (0.970–1.007) | 0.216 | 0.977 (0.948–1.006) | 0.122 |
| LAS | 1.025 (1.011–1.040) | 0.001 | 1.036 (1.015–1.056) | 0.001 |
| CPB | 2.896 (1.827–4.589) | < 0.001 | 17.791 (6.607–47.911) | < 0.001 |
| CPB duration (mins) | 1.002 (1.002–1.013) | 0.004 | 1.006 (1.001–1.011) | 0.030 |
| Delayed chest closure | 2.156 (1.081–4.301) | 0.029 | 1.612 (1.092–2.380) | 0.016 |
| Reintervention for bleeding | 3.815 (2.151–6.766) | < 0.001 | 7.202 (3.251–15.955) | < 0.001 |

| Retransplantation | 4.243 (1.780–10.118) | 0.001 | 7.125 (2.540–19.989) | < 0.001 |
| ECMO | 4.667 (2.546–8.556) | < 0.001 | 10.319 (4.617–23.062) | < 0.001 |
| PGD 3 at day 1 | 10.540 (5.006–22.194) | < 0.001 | 31.033 (4.101–234.841) | < 0.001 |
| PGD 3 at day 2 | 8.163 (4.333–15.380) | < 0.001 | 26.889 (6.162–117.329) | < 0.001 |
| PGD 3 at day 3 | 8.068 (4.253–15.304) | < 0.001 | 28.284 (6.347–126.038) | < 0.001 |

**Table 2 (abstract 000718)** Multivariate analysis of risk factors for presenting AKI or requiring RRT

| | Acute Kidney Injury | | Requiring RRT | |
|---|---|---|---|---|
| **Variable** | **OR (95% CI)** | ***P* value** | **OR (95% CI)** | ***P* value** |
| Retransplantation | 4.162 (1.385–12.512) | 0.011 | 6.188 (1.462–26.199) | 0.013 |
| PGD 3 at day 1 | 2.324 (1.358–3.977) | 0.002 | 3.398 (1.195–9.659) | 0.022 |
| CPB | - | - | 7.143 (2.18–23.406) | 0.001 |
| Delayed chest closure | 2.387 (0.977–5.833) | 0.056 | 3.394 (1.180–9.765) | 0.023 |

**Conclusions:** AKI and RRT are significant postoperative complications, associated with higher mortality rates. Identifying independent risk factors emphasizes the need for targeted interventions to improve outcomes and reduce morbidity and mortality in ICU.

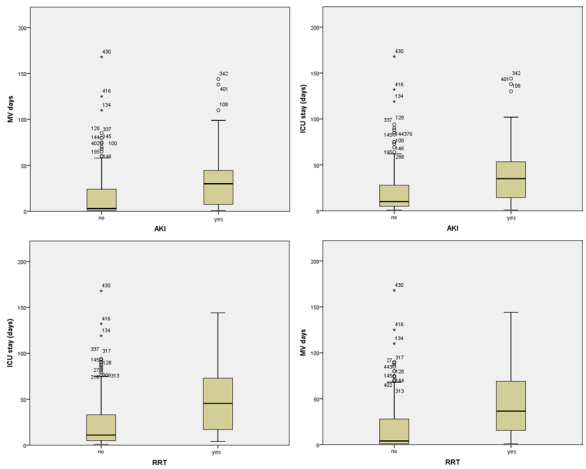

**Fig. 1 (abstract 000718)** The box plots display longer mechanical ventilation times and longer stays in the ICU in the population with AKI and in those requiring RRT

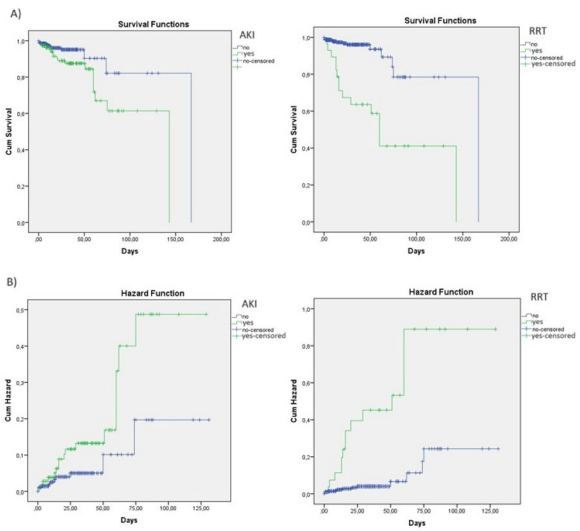

**Fig. 2 (abstract 000718)** A) Kaplan Meier curves showed lower survival in patients with acute renal failure (left) and need for RRT (right). As analyzed in the survival curves with a p-value of 0.016 in the log-rank of AKI and $p < 0.001$ in the log rank of RRT B) Hazard ratio curves show a higher cumulative risk in patients with AKI (left) and RRT (right)

**Introduction:** The effect of positive end-expiratory pressure (PEEP) of 5 mmHg and/or pressure support (PS) of 5 mmHg, referred to as 'minimal or no ventilator support' in daily practice during SBT on ventilation distribution is unknown. At ESICM 2023, we presented an interim report on the effect of PEEP and/or PS on ventilation distribution in various subgroups during SBT. We now present the final report of this study for 102 patients.
**Objectives:** This study aimed to investigate the effect of PEEP and 5 cmH2O PS on regional ventilation during SBT in various patient groups using Electrical impedance tomography (EIT).
**Methods:** Patients on mechanical ventilation who were planned to be extubated were included in this study and classified into 5 groups (group 1: COPD, group 2: reduced left ventricular function, group 3: obesity, group 4: low BMI, group 5: others). A 30-min SBT was divided into three 10-min phases to assess changes in ventilation distribution in the supine position. Phase 1 with a PEEP and PS of 5 mmH2O; Phase 2 with a PEEP of 0 mmH2O and PS of 5 mmH2O; and Phase 3 with T-piece. During SBT, respiratory impedance changes in the ventral and dorsal regions were recorded on EIT. All participants were extubated after passing the SBT.
**Results:** Between April 1, 2022, and March 31, 2024, 102 patients were enrolled. The mean age was 71.0 years, 67.3% were male. On admission, diagnoses were as follows: sepsis (25.5%), heart failure (18.6%), intracranial hemorrhage (15.7%), and respiratory failure (10.8%). Notably, 12% of the patients reintubated within 72 h post-extubation. In Groups 3 and 5, total lung ventilation significantly decreased when PEEP and PS were removed. In Group 4, dorsal ventilation increased significantly when PS was removed. Interestingly, this group also showed a trend towards increased ventral ventilation when PEEP was removed, although this was not statistically significant. In Groups 1 and 2, no significant differences in the effects of PEEP and PS could be detected. The change in ventilation distribution after extubation is now being analyzed and will be reported at ESICM 2024.
**Conclusions:** These results indicate that the effect of PEEP on ventilation distribution significantly depends on the patient's BMI and that even low PEEP and PS, considered physiologically minimal, can affect ventilation distribution in patients during SBT.

**Topic:** Acute respiratory failure and mechanical ventilation

**Introduction:** Fasting in enteral feeding induces repair pathways such as ketogenesis, mitochondrial biogenesis, anti-inflammatory and antioxidant defenses promoting physical reconstitution in critically ill patients.(1, 2) Fasting-mimicking cyclic, enteral feeding with 12 h of nighttime fasting is sufficient to generate a metabolic fasting response without risking a caloric deficit especially if enhanced by additional supplementation of exogenous ketones.(2, 3) However, little is known about the impact of cyclic, ketogenic enteral feeding on the physical postoperative reconstitution of the critically ill.
**Objectives:** Equicaloric, cyclic enteral daytime feeding with ketogenic nighttime fasting (supported by exogenous ketone salt supplementation (ß-hydroxybutyrate)) compared to continuous standard enteral nutrition as per patients' nutritional requirements does improve muscular reconstitution of critically ill patients.
**Methods:** A prospective, monocentric, randomized, interventional study including all ICU patients > 18 years requiring enteral nutrition post elective surgery (Ethical approval 22-1398_1). Exclusion criteria are organ failure, state post pancreatectomy, metabolic disorders, autoimmune diseases, pregnancy/breastfeeding, and contraindications against enteral nutrition. All patients are randomized to either 1) 24 h conventional enteral nutrition (control group) or to 2) cyclic enteral feeding with ketogenic nighttime fasting (interventional group). The interventional group receives 12 h daytime feeding followed by 12 h of nighttime fasting supported by exogenous ketone salt supplementation. The primary endpoint of this study is the physical reconstitution of the patient measured by the daily urea-creatinine ratio and the delta of the ICU mobility Scale (0–10 points) before ICU-admission and at ICU discharge. Secondary endpoints are length of mechanical ventilation (LOMV) and length of ICU stay (ICULOS).
**Results:** So far inclusion of 13 patients (7 control group vs 6 interventional group) with a mean age of 74.00 ± 11.82 vs 65.17 ± 8.33 yrs, a sex distribution of 42,9% vs 33.3% female, a mean BMI of 22.29 ± 3.19 vs 26.79 ± 5.96 and a mean SOFA-score of 7.86 ± 2.67 vs 9.50 ± 1.64. All patients received enteral feeding in concordance with their indirect calorimetric requirements without any adverse events. Ketone levels in the interventional group ranged between 0.1–1.0 mmol/l. The urea-creatinine ratio (marker for muscle wasting) was similar in both groups at the beginning of the study, but higher in the standard versus the interventional nutrition group after the fourth postoperative day (see Figure). Regarding the secondary endpoints: LOMV (53.71 ± 101.27 h vs 135.33 + 184.46 h) and ICULOS (3.71 ± 4.92 vs 10.00 ± 8.99 days) were shorter in the control vs interventional group. There was no difference of the delta ICU mobility Scale (8.29 ± 0.76 vs 8.33 ± 0.82 points).
**Conclusions:** Cyclic enteral feeding with nighttime fasting and ketosis did not show any adverse side effects and was able to meet the nutritional requirements. ICULOS and LOMV seemed to be longer in the interventional vs control group, whereas the urea-creatinine ratio presented to be higher from the fourth postoperative day onward in the control group. Given the small sample size so far these results should only be evaluated as trends and more data is required to confirm these trends.

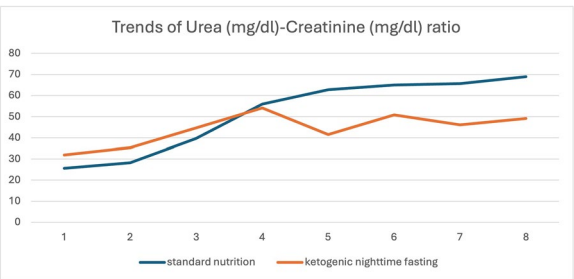

**Fig. (abstract 000721)** ATrends of the urea-creatinine ratio in the control (standard, continuous, enteral nutrition) vs interventional group (ketogenic nighttime fasting)

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000722

**Introduction:** Sepsis-associated liver injury (SALI) often occurs in patients with sepsis due to microcirculatory changes and inflammation-induced cell dysfunction of the liver [1]. However, the prognostic significance of remains unclear in sepsis.

**Objectives:** To explore the association between SALI and clinical outcomes in critically ill adult patients with sepsis.

**Methods:** This nationwide, prospective study analyzed critically ill adult patients with sepsis admitted to 15 general or tertiary hospitals in South Korea between September 2019 and December 2022. Patients with liver cirrhosis or lacking data on total bilirubin or prothrombin time were excluded. SALI was defined as total bilirubin $\geq$ 2 mg/dL and prothrombin time $\geq$ INR 1.5 [2]. The primary outcome was mortality at 28 days according to SALI status.

**Results:** Of the 4830 patients eligible for analysis, 399 (8.3%) developed SALI. There was no difference in the likelihood of 28-day death (adjusted Hazard ratio [HR] 1.11; 95% Confidence interval [CI] 0.89–1.38) between patients with SALI and patients without SALI, after adjusting for covariates (Figure 1). The use of cubic spline models to examine the association between total bilirubin level and the risk of death within 28 days did not alter the hazard ratios in both patients with SALI and without SALI ($p$-value for nonlinear = 0.950) (Figure 2). However, patients with a total bilirubin $\geq$ 2 mg/dL at ICU Day 2 (adjusted HR 1.47; 95% CI 1.23–1.74) and 3 (adjusted HR 1.84; 95% CI 1.52–2.23) were associated with higher 28-day mortality compared to patients with a total bilirubin < 2 mg/dL (Figure 3).

**Conclusions:** In patients with sepsis, SALI was not associated with 28-day mortality. However, hyperbilirubinemia (total bilirubin $\geq$ 2 mg/dL) at ICU Days 2 and 3 was associated with higher mortality at 28 days of ICU.

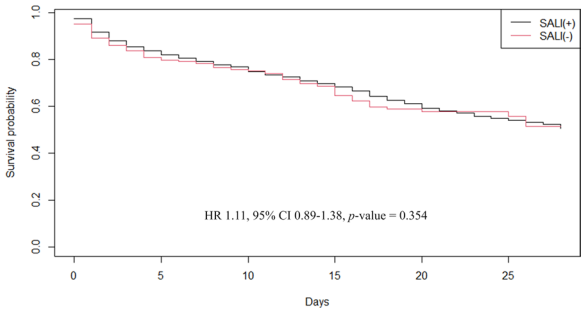

**Fig. 1 (abstract 000722)** Survival probability within 28 days according to Sepsis associated with liver injury. SALI; Sepsis associated liver injury, HR, hazard ratio; CI, confidence interval. 28-day survival probability was calculated by multivariate Cox Proportional hazard regression model with adjustment for age, comorbidities (Neurologic disease, liver disease, kidney disease, hematologic malignancy, and solid tumor), initial sequential organ failure assessment score, type of infection (urinary and other infection), laboratory findings (hemoglobin, platelet count, aspartate aminotransferase, alanine aminotransferase, total bilirubin, albumin, prothrombin time, c-reactive protein, and lactate), adjunct steroid, and source control

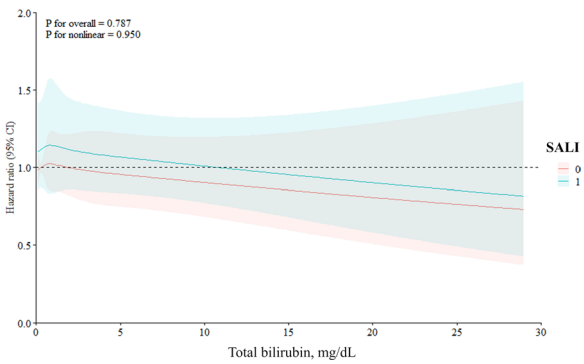

**Fig. 2 (abstract 000722)** Restricted cubic spline curve of total bilirubin for 28-day mortality in patients according to Sepsis associated with liver injury. Graphs show hazard ratios for 28-day death according to the level of total bilirubin adjusted for age, comorbidities (Neurologic disease, liver disease, kidney disease, hematologic malignancy, and solid tumor), initial sequential organ failure assessment score, type of infection (urinary and other infection), laboratory findings (hemoglobin, platelet count, aspartate aminotransferase, alanine aminotransferase, albumin, prothrombin time, c-reactive protein, and lactate), adjunct steroid, and source control. A restricted cubic spline Cox proportional hazards regression model was conducted with 4 knots at the 5th, 35th, 65th, 95th percentiles of total bilirubin (reference is the 5th percentile). Red and Green Solid lines with shadow shape indicate Hazard ratios with 95% Confidence intervals in patients with SALI and without SALI, respectively. SALI; Sepsis associated with liver injury; CI, confidence interval

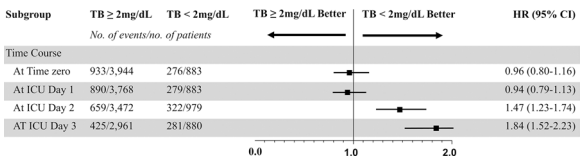

**Fig. 3 (abstract 000722)** Subgroup analyses for 28-day mortality across the level of total bilirubin from time zero to ICU Day 3. TB; Total bilirubin, HR, hazard ratio; CI, confidence interval, ICU; Intensive care unit. The 28-day mortalities were adjusted for age, comorbidities (Neurologic disease, liver disease, kidney disease, hematologic malignancy, and solid tumor), initial sequential organ failure assessment score, type of infection (urinary and other infection), laboratory findings (hemoglobin, platelet count, aspartate aminotransferase, alanine aminotransferase, albumin, prothrombin time, c-reactive protein, and lactate), adjunct steroid, and source control using multivariate Cox proportional regression models

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000723

**Introduction:** A reporting system to recognise positive professional behaviour is an essential component of clinical governance. The QEUH GREAT-ix project launched in January 2020 and attempted to:
· Boost staff morale.
· Celebrate staff that perform well.
· Apply Safety-II concepts to maximise corporate learning.
**Objectives:** To identify, promote, and learn from excellence in the daily practice of staff in Critical Care at the Queen Elizabeth University Hospital.
**Methods:** Following a successful pilot, the GREAT-ix project was introduced across all Critical Care Units. Educational events were delivered and executive buy-in was gained from senior management. Submissions were initially paper-based via 'post-box', then upgraded to an electronic QR code-based submission portal in August 2022. 188 GREAT-ix have been submitted since the transition to electronic submissions was made.
A GREAT-ix team was formed, tasked with promoting submissions, creating and disseminating certificates and publicizing newsletters.
GREAT-IX submission data are maintained and analyzed to allow the identification and reinforcement of themes consistent with excellent practice.
**Results:** This project has been well-received with considerable engagement by the MDT. A total of 188 GREAT-ix submissions have been received since the project went electronic in August 2022. The following qualitative categories were the most highly represented in an analysis of all submissions, with excellence in;

1. Excellence in Patient Care (68).
2. Excellence in Teamwork (50).
3. Excellence in the Support of Colleagues (28).
4. Excellence in Leadership (31).
5. Excellence in the Provision of End-of-Life Care (11).

**Conclusions:** Since its launch 4 years ago, 298 GREAT-ix certificates have been issued. This learning-from-excellence mechanism has become a routine and core part of our clinical governance process. Engagement remains high, allowing outstanding staff and team performance to be captured and celebrated. Promoting the positive professional behaviours represented in submissions is vital and should be reinforced, particularly in recent times of crisis.

**Topic:** Information systems and data science

### Evaluation of the use of alfentanil infusions in a general adult critical care unit

B. Roberts, L. Cooper, A. Parker, A. Wilson
Adult Critical Care, Manchester Royal Infirmary, Manchester, United Kingdom
**Correspondence:** B. Roberts
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000726

**Introduction:** Sedative and analgesic medications via bolus or infusion are frequently required in critical care units to facilitate invasive ventilation and patient comfort. Careful titration of opioid medication is required to balance the potential benefits and risks from significant and potentially prolonged doses. We reviewed the use of Alfentanil infusions within our unit in order to assess whether routine practice may be improved.
**Methods:** Retrospective data was extracted for all patients in our general adult Critical Care Unit between 01/08/21 and 01/08/22 who received alfentanil infusions. Patients without height and weight data were excluded. Alfentanil infusion rates and doses were assessed on initiation and at intervals over the first 72 h. We calculated actual doses as well as dose/kg/hr for both actual and ideal body weight (IBW).
We undertook contemporaneous anonymized survey of the Critical Care medical, nursing, and pharmacy multi-disciplinary team (MDT) to review current attitudes in the use of alfentanil. Responses were collected in April 2024.
**Results:** We reviewed data for 306 patients and excluded 25 patients with incomplete height or weight data leaving 281 patients in the final analysis.
197 patients (70%) were initiated on a dose of $\geq$ 2.5mg/hour with the median starting dose being 2.5mg/hr [IQR 2.0–3.5mg/hr]. There was no decrease in median dosing over at least the first 72 h of infusion. The initial median dose per Kg IBW was 38mcg/kg/hr [31-53mcg/kg/hr] with a wide variation (min 7mcg/kg/hr, max 134mcg/kg/hr).
We observed only a weak positive correlation between the starting dose and IBW (r 0.0.19, $p < 0.05$). Figure 1 shows the initial dose of Alfentanil /Kg IBW versus Actual body weight. Figure 2 shows the median Alfentanil dose/hour for the first 72 h after initiation of infusion.
Survey responses were collated from 84 members of the MDT. 46 respondents (55%) identified 2.5mg/hr (5mls/hr) as the rate of alfentanil most ventilated patients were initiated on. 7 respondents (8%) identified weight as a dosing parameter utilised to select this rate. Commonly offered reasons for not subsequently decreasing the alfentanil dose included patient discomfort (31%), ventilator dyssynchrony (14%) and fear of the risk of loss of airway (13%).
**Conclusions:** Bedside practice of setting infusion rates for alfentanil rather than a weight or ideal body weight-based dosing may contribute to the observed alfentanil doses. The range of IBW dosing observed indicates neither actual or ideal body weight has a strong influence on initial dosing strategy. Infusion rates remained similar over the first 72 h and survey responses suggest a reluctance to reduce dose for fear of causing patient discomfort, ventilator dyssynchrony, or accidental extubation, but may also represent a failure to respond to routinely measured sedation and pain scores.

Further quality improvement work may be useful in developing more patient-specific dosing strategies and may assist in the avoidance of over-sedation.

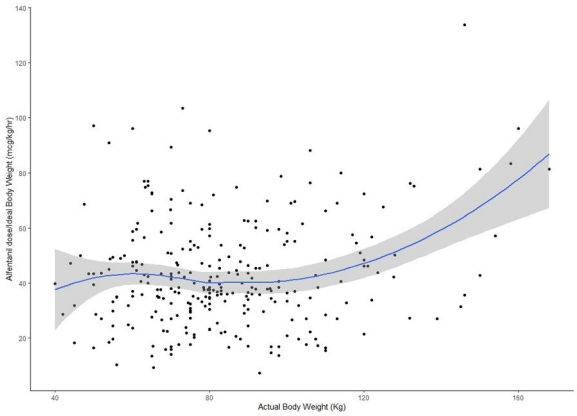

**Fig. 1 (abstract 000726)** Initial Dose of Alfentanil (mcg/Kg/hour Ideal Body Weight) versus Actual Body Weight (Kg) in Critical Care Patient

## 000727

### The influence of mobilisation components on disability following critical illness: a secondary analysis of a prospective cohort study

M. Paton[1], L. Natalie[2], E. Paul[2], C. Hodgson[2]
[1]Physiotherapy, Monash Medical Centre, Clayton, Australia; [2]School of Public Health and Preventive Medicine, Monash University, Faculty of Medicine, Nursing and Health Sciences, Clayton, Australia

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000727

**Introduction:** Mobilising patients in intensive care (ICU) is considered part of standard care(1,2), yet guidance on its implementation (frequency, intensity, timing) remains sparse despite the large evidence base(2,3,4).
**Objectives:** To determine the impact of mobilisation components (frequency, intensity, and timing) during an ICU stay on disability levels at 3- and 6-month post-admission.
**Methods:** Post-hoc analysis of patients from three ICUs in Victoria, Australia from a prospective cohort study determining predictors of death or disability following critical illness, conducted between August 2017 and January 2019. As part of this study, patients mechanically ventilated for > 24 h completed blinded telephone interviews reporting health and disability using the 12-level World Health Organization Disability Assessment Schedule 2.0 questionnaire at baseline, 3- and 6 months. Mobilisation components (frequency, intensity via the Intensive Care Mobility Scale [IMS], and time till the first active session [defined as an IMS ≥ 1]) were obtained retrospectively from medical records. Multivariable linear regression analyses determined the influence of mobilisation components on disability progression following critical illness.
**Results:** Analysis of 397 participants (64% male, mean age 54 ± 16yrs) with a mean ICU stay of 9 ± 8 days showed active mobilisation (i.e. IMS ≥ 1) occurring every 2 ± 2 days, with the first active session nearly 4 ± 3 days post-ICU admission. Univariable analysis showed that all mobilisation components were significantly associated with 3mth disability, but only intensity and timing influenced 6mth disability (Table 1). Multivariable regression identified intensity as an independent factor in decreasing disability at both 3- and 6 months after adjusting for age, sex, illness severity, and admission diagnosis, while delaying active mobilisation significantly increased disability (Table 1). The number of mobilisation sessions completed did not independently affect disability.

**Table 1 (abstract 000727)** Influence of mobilisation components on progression of disability following critical illness

| | Univariable analysis | | | | | | Multivariable analysis | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Outcome | 3mth | | | 6mth | | | 3mth | | | 6mth | | |
| | *β* | 95% CI | *p* | *β* | 95% CI | *p* | *β* | 95% CI | *p* | *β* | 95% CI | *p* |
| **IMS level achieved** | -4.04 | -5.34, -2.74 | < 0.0001 | -2.98 | -4.4, -1.56 | < 0.0001 | -2.21 | -2.57, -0.85 | 0.001 | -2.15 | -3.69, -0.61 | 0.005 |
| **Time till active mobilisation** | 1.76 | 0.82, 2.7 | 0.0002 | 1.14 | 0.18, 2.1 | 0.019 | 1.31 | 0.37, 2.25 | 0.006 | 1.13 | 0.11, 2.15 | 0.029 |
| **Frequency of mobilisation sessions** | -0.19 | -0.29, -0.09 | < 0.0001 | -0.10 | -0.20, 0.00 | 0.056 | -0.03 | -0.13, 0.13 | 0.505 | 0.06 | -0.06, 0.18 | 0.35 |

*β* Unstandardised regression coefficient (beta), *CI* Confidence Interval, *IMS* Intensive Care Mobility Scale, *p* probability level

**Conclusions:** Increasing intensity and prompt mobilisation implementation during an acute ICU admission was associated with decreased disability in survivors at 3- and 6 months post-ICU admission, although there may be unknown confounders.

### Feasibility of respiratory oscillometry in patients with acute hypoxemic respiratory failure

D. Ponomarev[1], J. Wu[2], Z. Hantos[3], C. W. Chow[2], G. Roman-Sarita[4], E. C. Goligher[1]
[1]Interdepartmental Division of Critical Care Medicine, University of Toronto, Toronto, Canada; [2]Division of Respirology, Department of Medicine, University of Toronto, Toronto, Canada; [3]Department of Anesthesiology and Intensive Therapy, Semmelweis University, Budapest, Hungary; [4]Department of Respiratory Therapy, Toronto General Hospital, Toronto, Canada
**Correspondence:** D. Ponomarev
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000728

**Introduction:** Oscillometry is a respiratory function test used to measure total respiratory impedance during tidal breathing revealing resistive and elastic properties of the lung that may provide useful information about illness trajectory. Elevated lung reactance area (AX) reflects increased lung elastance and heterogeneous distribution of lung compliances across the airway calibers, likely due to inflammatory injury and small airway obstruction (1).
**Objectives:** To assess the feasibility of oscillometry and describe lung mechanics in non-intubated patients with acute hypoxemic respiratory failure (AHRF).
**Methods:** Adult patients with AHRF receiving non-invasive respiratory support with fractional inspired oxygen concentration ($FiO_2$) $\geq$ 0.4 and flow $\geq$ 6 L/min underwent oscillometry at baseline and after resolution of AHRF. The primary endpoint was the number of enrolled patients who completed the baseline measurement. Continuous data are medians (25th, 75th percentile) unless stated otherwise.
**Results:** Between July 2022 and August 2023, ten patients were enrolled. The main barriers to inclusion were inability to cooperate and extreme hypoxemia with FiO2 > 0.8. All recruited patients tolerated oscillometry. At baseline, FiO2 was 0.8 (min 0.4, max 0.8), and oxygen saturation (SpO2) of 94% dropped to a nadir of 82% at the end of oscillometry and recovered within 2 min. Lung elastance was increased, with AX of 25 (15, 32) cm H2O/L (462 [327, 610]% predicted). Resistance was largely not altered, except for two patients with COVID-19, where it was increased. We found no association between baseline AX and SpO2/FiO2. Hypoxemia resolved in nine patients and follow-up oscillometry was obtained in eight participants. In four patients, higher baseline AX of 33 (31, 37) cm H2O/L (547 [362, 727]% predicted) was linked to faster resolution of AHRF (7 [min 5, max 13] days) and marked improvement in lung elastance (follow-up AX 15 [13, 16] cm H2O/L or 246 [145, 340]% predicted). By contrast, the other four patients with lower baseline AX of 14 [12, 17] cm H2O/L (462 [354, 498]% predicted) showed longer time to resolution of AHRF (18 [min 2, max 27] days) and unchanged lung stiffness despite clinical improvement (follow-up AX 17 [14, 20] cm H2O/L or 536 [402, 607]% predicted).
**Conclusions:** Respiratory mechanics can be assessed in non-intubated patients with AHRF by oscillometry in carefully selected patients. The extent of the increase in lung elastance was not related to the degree of hypoxemia. The impairment of lung mechanics persisted after the resolution of hypoxemia in some, though not all, patients. This may suggest varying disease trajectories elucidated by oscillometry.

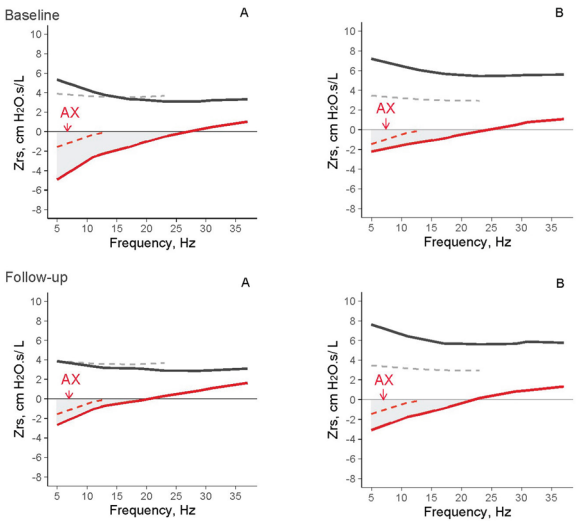

**Fig. (abstract 000728)** Example of oscillometry in a patient with acute hypoxemic respiratory failure secondary to community-acquired pneumonia (panels A) and COVID-19 (panels B) at baseline and follow-up. Respiratory resistance and reactance are depicted in black and red, respectively. Dashed lines indicate predicted values. AX is the reactance area

### causal effect of genetically predicted eosinophil levels on sepsis and mortality risk: a two-sample mendelian randomization analysis

J. Ren, X. Gao, R. Li, G. Wang
Critical Care Medicine, The Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China
**Correspondence:** G. Wang
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000731

**Introduction:** Although several observational studies have investigated the relationship between eosinophil levels and the risks of sepsis and mortality, the findings have been inconclusive, and the causal associations remain uncertain.
**Objectives:** The aim of this study was to use the Mendelian randomization (MR) approach to thoroughly examine the potential causal links between eosinophil levels and the risks of sepsis and its associated mortality.
**Methods:** We conducted a bidirectional two-sample MR investigation using genome-wide association study summary statistics of the eosinophil levels (eosinophil count, eosinophil percentage of white cells, and eosinophil percentage of granulocytes), sepsis, and sepsis mortality at 28 days. The inverse-variance weighted (IVW) method was used as the primary analytical approach to establish reliable causality. In addition, we performed sensitivity and multivariable MR analyses to examine the stability of the IVW results.
**Results:** Our results showed that the genetically predicted decreased eosinophil count (sepsis: odds ratio [OR] = 0.930, 95% confidence interval [CI] 0.872–0.992, $P$ = 0.028; sepsis mortality: OR = 0.832, 95% CI 0.719–0.963, $P$ = 0.014), eosinophil percentage of white cells (sepsis:

OR = 0.911, 95% CI 0.854–0.972, $P = 0.005$; sepsis mortality: OR = 0.814, 95% CI 0.705–0.939, $P = 0.005$), and eosinophil percentage of granulocytes (sepsis: OR = 0.918, 95% CI 0.861–0.979, $P = 0.009$; sepsis mortality: OR = 0.821, 95% CI 0.712–0.947, $P = 0.007$) were causally related to increased risks of sepsis and sepsis-related mortality at 28 days. These findings remained stable even after conducting various sensitivity and multivariable MR analyses. In addition, our reverse MR results showed that the risks of sepsis and its associated mortality were not associated with eosinophil levels.

**Conclusions:** Our research highlights the importance of considering eosinophil levels when assessing the risks of sepsis and its related mortality. Additional studies are necessary to confirm these findings and investigate the underlying mechanisms.

### Unveiling the interplay of elastase and neutrophil recruitment in acute lung injury

J. Ren, R. Li, G. Deng, C. Zhang, G. Wang
Critical Care Medicine, The Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China
**Correspondence:** G. Wang
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000732

**Introduction:** Acute lung injury (ALI) is a critical inflammatory condition with global implications, characterized by dysregulated accumulation and persistent activation of neutrophils. Neutrophil releases inflammatory mediators such as neutrophil elastase (NE), which exacerbates ALI. Our previous research has demonstrated that inhibiting NE decreased neutrophil infiltration and ameliorated lung injury in vivo. However, the underlying mechanism linking NE to neutrophil recruitment remains unclear.

**Objectives:** The aim of this study was to investigate the impact of NE on neutrophil migration both in vivo and in vitro.

**Methods:** In a lipopolysaccharide (LPS)-induced ALI mice model, immunohistochemical staining was employed to identify the distribution of NE. Subsequently, the effect of NE on neutrophil recruitment was evaluated using an NE inhibitor (NEi). Furthermore, human lung microvascular endothelial cells (HULECs) were directly exposed to human recombination NE. Gene expression levels of CXCL1, CXCL2, and CXCL3, crucial for neutrophil recruitment to the inflammatory site, were quantified by quantitative real-time polymerase chain reaction. The expression of I-kappa-B-alpha (IKB-α), a regulator of nuclear factor kappa B (NF-κB) activation, was assessed via western blotting. The pharmacological inhibitor BAY 11–7082 was utilized to inhibit NF-κB activation in vitro.

**Results:** Our in vivo experiments revealed that NEi treatment significantly suppressed the upregulation of NE induced by LPS. Additionally, NEi intervention effectively attenuated the elevated expression of CXCL1, CXCL2, and CXCL3 in the lungs of ALI mice. In vitro findings indicated that NE increased the expression of CXCL1, CXCL2, and CXCL3, as well as phosphorylated IKB-α levels. Treatment with BAY 11–7082 successfully inhibited the production of CXCL1, CXCL2, and CXCL3 in HULECs.

**Conclusions:** These results highlight the significant role of NE in activating the NF-κB signaling pathway, thereby promoting the upregulation of CXCL1, CXCL2, and CXCL3 expression which facilitates neutrophil recruitment and perpetuates ALI pathogenesis. Our study provides insights into potential therapeutic strategies in critical care settings by shedding light on the intricate interplay between neutrophil migration and NE in ALI progression.

### Efficacy of recombinant human soluble thrombomodulin on for reducing the occurrence of circuit coagulation in continuous kidney replacement therapy for septic AKI

M. Akatsuka[1], Y. Nakamura[2], H. Tatsumi[1]
[1]Department of Intensive Care Medicine, Sapporo Medical University School of Medicine, Sapporo, Japan; [2]Division of Clinical Engineering, Sapporo Medical University Hospital, Sapporo, Japan
**Correspondence:** M. Akatsuka
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000733

**Introduction:** Continuous kidney replacement therapy (CKRT) is an essential therapeutic modality that is used to remove accumulated fluid and waste products in patients with acute kidney injury (AKI) and to remove chemical mediators in patients with sepsis. However, CKRT circuit coagulation often occurs, especially in cases with low platelet counts, which reduces the filtration function of the hemofilter, and frequent coagulation necessitates circuit replacement, resulting in problems such as downtime and insufficient blood purification volume due to the interruption of CKRT. Administration of recombinant human soluble thrombomodulin (rhTM) has been reported to have certain effects on renal damage and coagulation abnormalities in septic AK1), 2). However, the effect of rhTM on circuit coagulation during CKRT remains to be determined.
**Objectives:** The aim of this study was to clarify the efficacy of rhTM for reducing the occurrence of circuit coagulation in CKRT for septic AKI patients.
**Methods:** We carried out a retrospective observational study. The study subjects were patients with septic AKI who were admitted to the ICU between January 2012 and December 2020 and underwent CKRT. The definition of sepsis was according to Sepsis-33) and AKI was defined by the KDIGO guidelines4). The patients with a platelet count of 52,500/μL or less were included in this study. We obtained information on the characteristics of patients including age and sex, SOFA score, APACHE II score, focus of infection, length of ICU stay, shock, number of ventilation days, number of days of CKRT, circuit coagulation, life-time of hemofilter, KDIGO classification, and disseminated intravascular coagulopathy (DIC) as well as laboratory data. The primary outcome was circuit coagulation during the CKRT. Logistic regression analysis using propensity score as the adjusted variable was also performed to determine the risk estimates for the association between rhTM administration and circuit coagulation. The hemofilter's lifetime curves obtained through Kaplan–Meier analysis were compared by using the log-rank test.
**Results:** A total of 126 patients were included and 77 patients were excluded due to the exclusion criteria. Forty-nine patients were eligible for the study. Circuit coagulation occurred in 51.0% of the patients. The rhTM and non-rhTM groups consisted of 13 patients (26.5%) and 36 patients (73.5%), respectively. The circuit coagulation rate was significantly lower in the rhTM group than in the non-rhTM group (odds

ratio [OR], 0.18; 95% CI 0.04–0.86; $P=0.032$). The lifetime of the hemofilter was significantly longer in the rhTM group than in the non-rhTM group (OR, 1.06; 95% CI 1.01–1.11; $P=0.032$), which was further supported by findings of Kaplan–Meier analysis ($P=0.020$). Moreover, the number of CKRT-free days was significantly greater in the rhTM group than in the non-rhTM group (odds ratio [OR], 1.12; 95% CI 1.03–1.22; $P=0.011$).

**Conclusions:** This study showed that rhTM therapy during CKRT for septic AKI reduced the occurrence of circuit coagulation and extended the lifetime of the hemofilter. Furthermore, rhTM administration was associated with increased CKRT-free days.

Further study should be initiated to expand the study on the efficacy of rhTM administration in septic AKI patients for circuit coagulation inhibition during CKRT.

### The correlation between period of anemia and duration of mechanical ventilation in patients admitted to the surgical intensive care unit

A. Piriyapatsom, T. Siriyothiphan
Anesthesiology, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand
**Correspondence:** A. Piriyapatsom

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000734

**Introduction:** Anemia is common in critically ill patients, particularly those requiring mechanical ventilation (MV). While previous studies showed the association between anemia and poor outcomes during prolonged MV, the impact of anemic duration on MV duration remains unclear. This study aimed to evaluate the correlation between period of anemia and MV duration in patients admitted to the surgical intensive care unit (SICU).

**Methods:** This was a retrospective study conducted in the SICU at a tertiary university hospital in Bangkok, Thailand, between December 2020 and January 2023. Patients aged ≥ 18 requiring MV support for > 96 h were included. Patients whose data missing or those readmitted to the SICU were excluded. Period of anemia was defined as the ratio of days with hemoglobin < 8 g/dL to days with MV support. Patients were categorized into no anemia (period of anemia = 0) and anemia group (period of anemia > 0) for comparison. The correlation between the period of anemia, as well as the amount of red blood cell (RBC) transfusion and MV duration, were evaluated using linear regression analysis controlling for potential confounding factors such as age, illness severity, and organ dysfunction. Hospital mortality and its associated risk factors were analyzed using multivariate logistic regression analysis.

**Results:** Of 235 patients, 72 (51.4%) patients experienced anemia during MV support. The anemia group significantly had lower average hemoglobin level during MV support (9.3 ± 5.1 g/dL vs. 11.3 ± 2.1 g/dL, $P<0.001$) but no difference in MV duration (median 8 [IQR 6–11] days vs. median 7 [IQR 6–8] days, $P=0.05$). They also received significantly more RBC transfusion ($P<0.001$). The period of anemia and the amount of RBC transfusion showed no correlation with MV duration ($r=0.01$ and $r=0.261$, respectively). Period of anemia was associated with increased hospital mortality (odds ratio 1.03, 95% confidence interval 1.01–1.05).

**Conclusions:** There was no correlation between the period of anemia as well as the amount of RBC transfusion and MV duration in patients receiving MV support > 96 h in the SICU. Therefore, the strategy of administering transfusion to anemic patients receiving MV to facilitate weaning should not be supported. However, period of anemia was associated with increased hospital mortality. Appropriate perioperative management of anemia should be emphasized to improve outcomes in these patients.

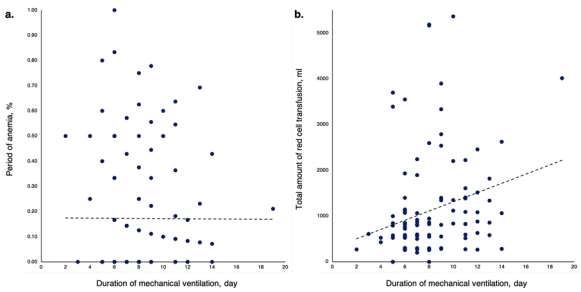

**Fig. (abstract 000734)** Correlation between (a.) period of anemia and (b.) total amount of red cell transfusion and duration of mechanical ventilation. The period of anemia and the amount of red cell transfusion showed no correlation with duration of mechanical ventilation ($r=0.01$ and $r=0.261$, respectively)

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000735

**Introduction:** Sevoflurane has taken over the world of ambulatory surgery as the inhalational agent of choice due to its rapid recovery profile [1,2]. Sevoflurane, however, has a much higher cost compared to isoflurane. In short-duration procedures, the difference in emergence time between isoflurane and sevoflurane is not expected to be clinically very different considering the uptake and distribution profiles of these agents with respect to time [3].
**Objectives:** The primary objective was to demonstrate the non-inferiority of isoflurane in terms of emergence time with a non-inferiority margin of 3.2 min at an α of 0.025 and 95% power. The secondary objectives were to compare the consumption of inhalational agents and costs.
**Methods:** After institute ethical committee approval and written informed consent 100 patients with pelvic malignancies presenting for brachytherapy, were randomized to receive either isoflurane or sevoflurane for BIS-targeted (40–60) maintenance anaesthesia through a Laryngeal mask airway post-induction with propofol and fentanyl.
**Results:** The upper limit of the 97.5% CI of the mean difference in emergence time between isoflurane and sevoflurane groups was + 0.63 (below the NIM of + 3.2 min) (Fig. 1). The average cost per case of inhalational anaesthetic consumption was 2.6 (95% CI 2.5 to 2.8) times higher with sevoflurane compared to isoflurane. There was no difference in terms of hemodynamics, time to discharge, and postoperative cognitive dysfunction.
**Conclusions:** Isoflurane is non-inferior to sevoflurane in terms of emergence time in ambulatory brachytherapy procedures (< 30 min) and is potentially cost-effective.

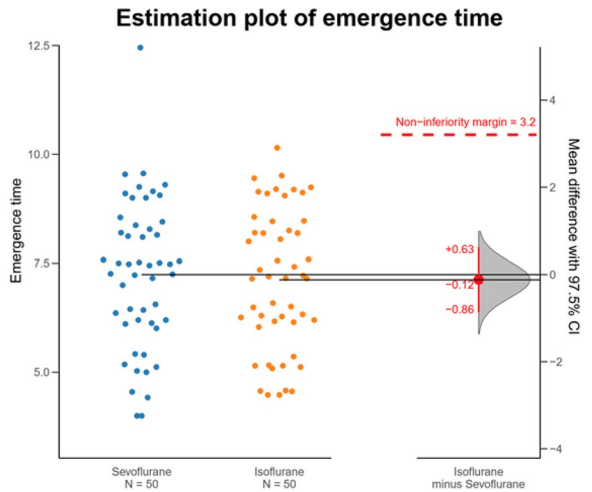

**Fig. 1 (abstract 000735)** Estimation plot demonstrating non-inferiority of Isoflurane compared to Sevoflurane in terms of emergence time

### Association between left ventricular ejection fraction and insufficient contrast-enhancement of thoracoabdominal CT angiography in patients requiring veno-arterial extracorporeal membrane oxygenation

R. Akiyama[1], M. Nishikimi[2], K. Yokomachi[1], C. Fujioka[1], M. Kiguchi[1], K. Awai[1]
[1]Department of Diagnostic Radiology, Hiroshima University Hospital, Hiroshima, Japan; [2]Department of Emergency and Critical Care Medicine, Hiroshima University, Hiroshima, Japan
**Correspondence:** R. Akiyama
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000736

**Introduction:** In the patients on the veno-arterial extracorporeal membrane oxygenation (V-A ECMO), arterial blood flow comes from two sources; the retrograde blood flow from V-A ECMO and the anterograde blood flow from the patient's native heart. The disruption of balance of these two blood flows can lead to insufficient contrast enhancement on thoracoabdominal computed tomography angiography (CTA), but there were few studies to investigate the association between these two blood flows and the occurrence of insufficient contrast enhancement.
**Objectives:** The aim of this study is to evaluate the association of left ventricular ejection fraction (EF) and ECMO flow with the occurrence of insufficient contrast-enhancement of thoracoabdominal CTA in patients requiring V-A ECMO.
**Methods:** Twenty-nine patients treated with V-A ECMO who underwent thoracoabdominal CTA at Hiroshima University Hospital were retrospectively analyzed. The correlation ratios between the values of EF and ECMO flow, and the degree of contrast enhancement at the internal mammary artery (IMA) level were evaluated. The association between preserved EF (≥ 30%) and the occurrence of insufficient contrast enhancement, defined as less than 200 Hounsfield unit (HU) of the aorta at the IMA level, was also evaluated by Fisher's exact test.
**Results:** The higher values of EF were statistically significantly correlated with lower HU values of aorta (correlation ratio; −0.406 [−0.700 to −0.003], $p = 0.044$). On the other hand, the values of ECMO flow were not correlated with HU values of the aorta. While all 14 patients with reduced EF did not have the occurrence of insufficient contrast-enhancement of CT (0% [0/14]), 46.7% (7/15) of the patients with preserved EF did ($p = 0.006$).
**Conclusions:** Insufficient contrast-enhancement of thoracoabdominal CT angiography did not occur in the patients on V-A ECMO with reduced EF but occurred in those with preserved EF, although ECMO flow was not associated with it. We must be careful with the injection technique in the patients with V-A ECMO with preserved EF.

### Remimazolam ameliorates LPS-induced apoptosis in acute lung injury based on network pharmacology and experimental validation

R. Li, C. Zhang, J. Ren, G. Deng, G. Wang
Critical Care Medicine, The Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China
**Correspondence:** G. Wang
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000737

**Introduction:** Acute lung injury (ALI) presents a substantial challenge to global health, necessitating urgent attention and innovative solutions. Remimazolam (REM), an emerging sedative, has exhibited promising anti-inflammatory properties that have the potential to improve ALI. Nevertheless, the current dearth of evidence impedes our capacity to definitively determine whether REM can alleviate ALI.
**Objectives:** This study aimed to investigate the effects of REM on ALI and reveal this underlying mechanism.
**Methods:** The LPS-induced ALI mice model was used to assess the impact of REM on lung injury by hematoxylin and eosin (HE) staining. Subsequently, to explore its protective mechanism on ALI, a network pharmacology strategy was performed. Potential targets for REM and ALI were obtained from online databases. The target genes for REM on ALI were determined by taking the intersection of the REM and ALI targeting gene sets. Then, RNA-sequencing (RNA-seq) were used to identify the differentially expressed genes (DEGs) among control, ALI mice treated with and without REM. GO and KEGG pathway analyses were performed for the gene set from network pharmacology and RNA-seq. Finally, TdT-Mediated dUTP Nick End Labelling (TUNEL) staining was conducted on lung tissue sections to assess the impact of REM on apoptosis in mice. Western blotting was performed to evaluate the anti-apoptotic effects of REM on human umbilical vein endothelial cells (HUVECs) and mouse lung alveolar epithelial cells (MLE-12) (Figure 1).
**Results:** HE staining revealed that REM effectively mitigated lung injury in ALI mice (Figure 2A). Network pharmacology showed that a total of 217 REM target genes and 3081 ALI/ARDS target genes were acquired and 80 candidate target genes were identified. RNA-seq analyses revealed 4365 DEGs between control and ALI mice, and 140 DEGs between ALI mice treated with and without REM. GO and KEGG pathway analyses indicated that the therapeutic effects of REM on ALI were significantly enriched in terms related to apoptosis, including intrinsic and extrinsic apoptosis, and endothelial and epithelial apoptosis, et al. Verification experiments in ALI mice showed that REM treatment significantly reduced the elevated number of TUNEL-positive vascular endothelial cells and alveolar epithelial cells induced by LPS (Figure 2B). The results of western blotting revealed that REM markedly decreased the expression of cleaved caspase-3 and increased the expression of Bcl2/Bax ratio in HUVECs and MLE-12, respectively (Figure 2C-D).
**Conclusions:** This study indicated the anti-apoptotic effects of REM on ALI by inhibiting endothelial and alveolar epithelial cell apoptosis, suggesting its promising role in the management of ALI and emphasizing the necessity for further clinical investigations.

**Physiological effects of bi-level high-flow nasal cannula in healthy individuals: a proof of concept trial**

J. W. Huh[1], W. J. Seo[2], J. H. Ahn[3], S. Y. Lee[1], C. M. Lim[1]
[1]Department of Pulmonary and Critical Care Medicine, Asan Medical Center, Seoul, Republic of Korea; [2]Division of Pulmonary and Critical Care Medicine, Inje University Ilsan Paik Hospital, Goyang-si, Republic of Korea; [3]Department of Pulmonary and Critical Care Medicine, University of Ulsan College of Medicine, ASAN Medical Center, Seoul, Republic of Korea
**Correspondence:** J.W. Huh
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000739

**Introduction:** High-flow nasal cannula (HFNC) delivers a continuous, unidirectional high flow of oxygen (Uniflow) throughout the respiratory cycle. Despite its positive pressure effects in the nasopharynx, the persistent high flow during expiration imposes additional work of breathing and disrupts the patient's neural respiratory cycle. We devised a bi-level high-flow system (Biflow) allowing separate flow rate adjustments for inspiration and expiration.
**Methods:** Twelve adults (7 male, 5 female, average age 46.3 years) participated in the study. For Uniflow, flow settings of 30 (U30), 40 (U40), and 50 (U50) L/min were tested. In the Biflow, inspiratory flow rates were matched to the Uniflow settings, while expiratory flow rates varied from 10 L/min to 30 L/min. Physiologic parameters, nasopharyngeal pressure, pressure–time product (N-PTP) as an energy cost proxy, end-expiratory lung impedance (EELI), and subject comfort were assessed.
**Results:** Uniflow decreased respiratory rate and elongated expiratory time compared to natural breathing. However, these effects were less pronounced during Biflow (Table 1). Compared with the Uniflow, both expiratory and inspiratory N-PTP were lower during the Biflow (Figure 1). Transcutaneous $CO_2$ was lower during the Biflow compared with natural breathing or Uniflow. EELI did not differ between modes. All participants completed the study protocol without side effects.

**Table 1 (abstract 000739)** Change of synchronized respiratory parameters according to the flow setting

| | Setting | RR (/min) | Inspiratory time (sec) | Expiratory time (sec) | I:E ratio |
|---|---|---|---|---|---|
| Baseline | Natural breathing | 15.6 (13.5–17.4) | 1.3 (1.1–1.4) | 2.3 (1.8–2.7) | 0.5 (0.5–0.6) |
| Flow 30 | U30 | 13.5 (10.0–15.8)* | 1.7 (1.5–2.2)* | 2.9 (2.1–4.0)* | 0.7 (0.5–0.8)* |
| | B30/10 | 13.3 (12.0–18.0) | 1.9 (1.6–2.2)* | 2.4 (1.9–2.6) | 0.8 (0.7–1.0)*,** |
| | B30/20 | 13.9 (13.1–17.9)** | 1.6 (1.3–1.8)* | 2.3 (1.9–2.8)** | 0.7 (0.6–0.9)* |

**Introduction:** Critical care nurses deliver complex and specialized nursing to patients with a wide range of diagnoses and critical conditions. Their daily workload in the intensive care units (ICU) should

be investigated and described. The workload can be assessed by the objective Nursing Activities Score (NAS) (1) for each patient, and subjective scores from nurses by the NASA-Task Load index (NASA-TLX) (2). The items in NASA-TLX represent mental demand, physical demand, temporal demand, overall performance, frustration level, and effort.

**Objectives:** The study aimed to investigate ICU patients and nurses' workload, and to explore correlation between NAS and NASA-TLX.

**Methods:** This prospective observational study was conducted in mixed ICUs, from local to university hospitals in Norway. Data was collected in each unit for 14 days in November 2023 to May 2024. Data from all patients was collected from medical charts (age, reasons for admission and length of stay, NAS per shift), and by a paper-based survey of all nurses on duty (nurse shifts and NASA-TLX –scores) for the same period. Descriptive statistics and correlation analysis were conducted.

**Results:** Results from 6 ICUs (Table 1), show number of ICU beds varies from 3 to 10, units have postoperative, day surgery or recovery beds. The total number of patients was 589 with a length of stay from a median 2:48 h to 4 days 09:23 h and mean age of 55 years. The survey had a response rate per unit from 62 to 99% (Table 2). A total of 2,060 NASA-TLX scores from all shifts were represented. The main findings were a correlation from 0.30 to 0.45 between patients NAS and nurses NASA-TLX. The highest subjective workload was found in ICU-1 and ICU-5, however ICU-4 had the strongest correlation between objective and subjective workload.

**Conclusions:** Workload was assessed in two dimensions, representing a weak to moderate strength of correlation between objective and subjective workload. Factors associated with workload have to be further explored.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000742

**Introduction:** As the aging population increases, there has been an increase in the number of elderly trauma patients. Rib fractures occur relatively frequently in these elderly trauma patients and can lead to pulmonary complications. The frailty index is a tool used to assess the vulnerability of the elderly.

**Objectives:** The purpose of this study was to evaluate clinical outcomes in elderly trauma patients with rib fractures by utilizing the frailty index.

**Methods:** Between 2019 and 2023, a retrospective review of the medical records was performed on 128 patients aged 65 and over who visited a Level I trauma center with multiple rib fractures. These patients were divided into two groups according to their frailty index, with those having a frailty index of 0.27 or above being classified into the frail group. We analyzed the risk factors for pulmonary complications in elderly patients with multiple rib fractures using logistic regression analysis.

**Results:** In our study, we compared retrospectively non-frail ($n = 94$) and frail ($n = 34$) groups based on the modified frailty index. Despite

similar demographic compositions and injury severity score in both groups, the frail group showed higher in-hospital mortality rates (2.1% vs. 11.8%; $p=0.023$) and longer lengths of ICU stay (2.0 ± 3.8 vs. 10.6 ± 12.6 days; $p<0.001$) and longer length of hospital stay (14.7 ± 11.1 vs. 28.3 ± 25.3 days; $p=0.004$). The frail group was more susceptible to developing pulmonary complications and required ventilator support more longer durations. Frailty was identified as a risk factor for in-hospital mortality (OR, 6.07; 95% CI 1.1–34.8; $P=0.043$) and pulmonary complications (OR, 10.8; 95% CI, 3.8–30.8; $p<0.001$).

**Table 1 (abstract 000742)** Outcomes of non-frail and frail groups in elderly patients with multiple rib fractures

| | Non-frail(n = 94) | Frail(n = 34) | P-value |
|---|---|---|---|
| In-hospital mortality, n (%) | 2 (2.1) | 4 (11.8) | 0.023* |
| Hospital LOS, days mean ± SD | 14.7 ± 11.1 | 28.3 ± 25.3 | 0.004* |
| ICU LOS, days mean ± SD | 2.0 ± 3.8 | 10.6 ± 12.6 | < 0.001* |
| MV duration, days mean ± SD | 0.5 ± 1.9 | 5.6 ± 7.9 | < 0.001* |
| Unplanned intubation, n (%) | 3 (3.2) | 6 (17.6) | 0.005* |
| Unplanned ICU re-admission, n (%) | 4 (4.3) | 7 (20.6) | 0.004* |
| Pneumonia | 9 (9.6) | 18 (52.9) | < 0.001* |
| Pulmonary thromboembolism | 1 (1.1) | 1 (2.9) | 0.449 |
| ARDS | 0 (0.0) | 6 (17.6) | < 0.001* |
| Discharge to home, n (%) | 43 (45.7) | 10 (29.4) | 0.01* |

**Table 2 (abstract 000742)** Univariate and Multivariate analyses for risk factors of pulmonary complications

| | Univariate | | | Multivariate | | |
|---|---|---|---|---|---|---|
| | OR | 95% CI | P-Value | OR | 95% CI | P-Value |
| SBP | 0.98 | 0.97–1.00 | 0.050* | 0.99 | 0.98–1.01 | 0.677 |
| GCS | 0.20 | 0.05–0.90 | 0.036* | 0.54 | 0.08–3.59 | 0.523 |
| Chest AIS | 3.70 | 1.19–9.17 | 0.005* | 1.42 | 0.42–4.76 | 0.570 |
| Injury severity score | 1.12 | 1.05–1.19 | < 0.001* | 1.12 | 1.04–1.19 | 0.002* |
| Frailty | 9.45 | 3.69–24.18 | < 0.001* | 9.07 | 3.29–24.9 | < 0.001* |

**Conclusions:** This study indicates that frailty may play a crucial role in determining the clinical outcomes of elderly patients with multiple rib fractures, underscoring the need for management strategies suitable for this vulnerable group. There is a significant need for further research into such predictive tools to establish customized management approaches for vulnerable groups like the elderly patients.

*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000744

**Introduction:** While polytrauma patients require blood products, the use of these blood products may increase mortality due to complications that may arise.
**Objectives:** Our aim in this study is to determine the relationship between the use of different blood products and mortality and to determine whether they can be used as mortality predictors.
**Methods:** Patients diagnosed with polytrauma hospitalized in the ICU between June 2020 and June 2023 were retrospectively evaluated. Patients' files, archive records, and hospital automation recording systems were examined in detail. All patients' age, gender, accompanying chronic diseases, trauma etiology, use of blood products, number of ventilator days, intensive care unit stay, hospital stay, blood lactate level, hemoglobin measurements, platelet measurements were evaluated, and their relationships with mortality were examined. Frequency and percentage were provided for categorical data, while median, minimum, and maximum were provided as descriptive values for continuous data. The normality of variables was assessed using the Kolmogorov–Smirnov test. "Mann Whitney U-Test" was used for intergroup comparisons, and "Chi-Square or Fisher's Exact Test" was used for comparing categorical variables. "Spearman's Correlation Analysis" was used to examine the relationship between continuous variables.
**Results:** A total of 4053 patients were treated in the ICU between the specified dates, and a total of 75 patients with a diagnosis of trauma were included in the study. While 62 of the 75 patients were discharged with full recovery, 13 of them died in the ICU. Considering their mortality, the use of FFP in patients who died was significantly lower than in those who were discharged, while platelet replacement was statistically significantly higher. The PaO2/FiO2 ratio of the mortal group was significantly lower. The vasopressor requirement in the nonsurvivors group was significantly higher. The 2nd to 5th-day lactate levels of nonsurvivors were significantly higher, and meanwhile, 1st to 5th-day platelet counts were significantly lower. HCO3 levels on the first and second days of hospitalization of nonsurvivors were significantly lower than survivors.
**Conclusions:** Nonsurvivor polytrauma patients were mostly thrombocytopenic and had received platelet solutions. Although there was no significant difference in erythrocyte replacement between survivors and nonsurvivors, reevaluation should be considered to examine the relationship between higher lactate levels, lower bicarbonate levels, and lower platelet counts in nonsurvivors.

## Pilot study: a preliminary machine learning model to predict successful extubation in ICU patients with pneumonia

A. Lee[1], Q. Y. Goh[2], S. Chew[1], J. Cheng[2]
[1]Anaesthesiology, Singapore General Hospital, Singapore, Singapore; [2]Surgical intensive care, Singapore General Hospital, Singapore, Singapore
**Correspondence:** A. Lee
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000745

**Introduction:** Pneumonia, one of the most common infectious diseases worldwide, currently stands as Singapore's fifth most common cause of hospitalisation and second most common cause of death (1). Of those hospitalised, 10–20% would require admission to the Intensive Care Unit (ICU) and invasive mechanical ventilation (2).
Studies show that 10–20% of extubated patients will require re-intubation within 48 h of liberation from invasive mechanical ventilation (3–4). However, this is associated with increased mortality and length of hospitalisation (5). Currently, no single tool is able to accurately predict extubation success in mechanically ventilated patients (6). This suggests a possible limitation in clinicians' abilities to predict successful extubation and a more powerful clinical decision-making tool is needed to fill this gap.
**Objectives:** This pilot study aims to develop a preliminary machine learning (ML) model that would act as a proof of concept to subsequently develop a ML model that can be implemented as a clinician aid towards extubating patients with pneumonia.
**Methods:** A retrospective cohort study was conducted involving patients admitted to our institution's surgical ICU from 2019 to 2021. This study included patients above 21 years old, admitted for any cause of pneumonia requiring invasive mechanical ventilation. Patients who were unintentionally or terminally extubated were excluded. Three ventilator variables were extracted: end-tidal carbon dioxide levels, patient respiratory rate and patient achieved tidal volume.
These ICU admissions were then randomised and split into 2 non-overlapping cohorts: 70% for training and 30% for a validation cohort. In collaboration with a team of engineers from the National University of Singapore, two baseline models for prediction were created and four deep-learning models were examined.
**Results:** 26 patients were included in this pilot study and all relevant data were extracted. 20 patients formed the training cohort and the remaining 6 patients formed the validation cohort.
A sliding window (see Fig 0.1) was developed to capture the temporal dependencies of the data. Of the four ML models, the convolutional neural network (CNN) model showed the best performance, with improved performance the larger the sliding window size. As seen in Table 1, at a window size of 60 h, the mean absolute error (MAE) of the CNN model is 41% less than the Mean baseline model.

**Table 1 (abstract 000745)** Mean MAE for each model and window size

| Window Size | Mean | DTR | LSTM | GRU | CNN | TCN |
|---|---|---|---|---|---|---|
| 15 | 64.62 | 77.17 | **49.41** | 54.57 | 50.75 | 54.57 |
| 20 | 64.46 | 77.06 | 48.84 | 53.70 | **48.13** | 52.39 |
| 25 | 64.43 | 73.95 | 53.71 | 53.87 | **49.05** | 51.15 |
| 30 | 64.26 | 70.55 | 51.17 | 53.23 | **46.05** | 48.27 |
| 35 | 63.88 | 71.01 | **45.09** | 53.60 | 46.87 | 48.80 |
| 40 | 63.49 | 74.37 | **44.45** | 54.38 | 45.40 | 51.20 |
| 45 | 63.08 | 72.09 | 48.53 | 54.88 | **44.33** | 51.55 |
| 50 | 62.85 | 66.14 | **41.28** | 56.13 | 44.80 | 47.33 |
| 55 | 62.81 | 66.83 | 43.99 | 61.77 | **42.98** | 48.86 |
| 60 | 62.59 | 67.81 | 45.42 | 62.90 | **37.06** | 49.03 |

Additionally, despite the limited amount of data and variables used, the CNN model was able to predict the general pattern of the length of mechanical ventilation when compared to actual data (see Fig. 2).
**Conclusions:** The results of the pilot study showed the potential of applying ML models in mechanically ventilated patients with pneumonia. With further data, we aim to build on this study and create a more robust model to determine the optimal time of extubation to minimise extubation failure.

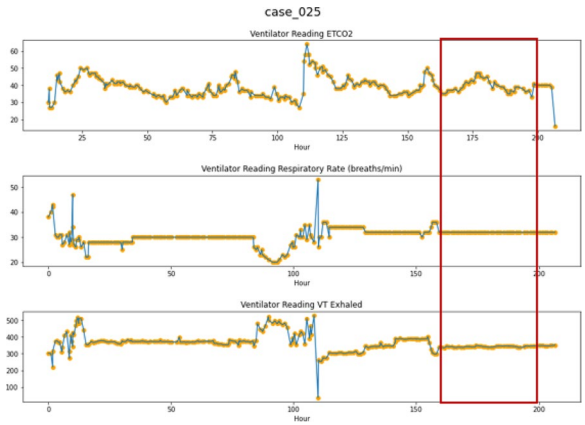

**Fig. 1 (abstract 000745)** A visual representation of a sliding window (red box). The ML model interprets all the data within the window and moves forward 1 h at a time to extract time series from all data at each step

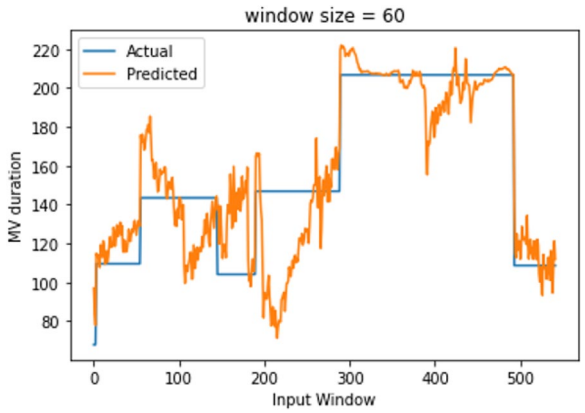

**Fig. 2 (abstract 000745)** The blue line shows the actual duration of mechanical ventilation versus the ML predicted value on the orange line of each patient in the validation cohort

## Exploring antibacterial consumption and pathogen surveillance over 5 years (including the COVID-19 pandemic) in a large adult general intensive care unit

D. Young[1], C. McKenzie[2], S. Gupta[3], D. Sparkes[3], R. Beecham[3], D. Browning[4], A. Dushianthan[2], K. Saeed[2]
[1]Pharmacy department, University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom; [2]Faculty of Medicine, University of Southampton, Southampton, United Kingdom; [3]Critical care department, University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom; [4]Microbiology department, University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom
**Correspondence:** D. Young
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000747

**Introduction:** Antimicrobial resistance is a globally recognized health emergency. Intensive care is an area with significant antimicrobial consumption, particularly with regard to broad-spectrum antibacterials, meaning that stewardship programs are essential.
**Objectives:** The aim of our project was to explore antibacterial consumption, partnered with pathogen surveillance, over a five-year period in a tertiary referral adult general intensive care unit (ICU).
**Methods:** Patient characteristics and ICU activity data were extracted from the Intensive Care National Audit and Research Centre (ICNARC) reports and ICU daily summaries spanning April 2018 to March 2023. Cumulative antibacterial usage (excluding erythromycin for its prokinetic properties) was derived by aggregating the total doses administered from the clinical information system (MetaVision). The World Health Organisation AWaRe classification and defined daily doses were applied to standardize and interpret the data which was indexed for ICU bed occupancy. For pathogen surveillance, we obtained positive ICU blood culture details and accompanying antibacterial sensitivities from the microbiology information system (PathManager). A 14-day patient-level deduplication rule was applied.
**Results:** Total mean [SD] number of ICU admissions was 1645 [22] per annum. Of these, 60% were male and 6.3% met the Sepsis-3 definition of septic shock upon admission to the ICU (Table 1). A comparison between ICU populations admitted before and after the COVID-19 pandemic peak (2020/21) identified a number of notable differences: increased average daily unit bed occupancy (21.6 vs. 25.2 respectively) and a higher proportion of admissions with sepsis (28.4% vs. 32.5% respectively). Additionally, the post-pandemic period saw an increase in the number of patients admitted with complex diagnoses.
Over the entire five years, the overall proportion of antibacterial use by AWaRe classification[1] was access 42.6%, watch 54.7% and reserve 2.6% (Figure 1). 147 positive blood culture isolates were reported (Figure 2), with the most concerning antibacterial resistance identified in 7.5% (9 *Escherichia coli* isolates with resistance to third-generation cephalosporin; 2 *Klebsiella pneumoniae* isolates with resistance to third-generation cephalosporin, aminoglycoside and fluoroquinolone). The COVID-19 pandemic peak year was associated with increased ICU bed occupancy, a greater number of positive blood cultures but lower antibacterial consumption.
The ratio of observed risk-adjusted mortality rate for all patients (based on the ICNARC model) was consistently below the expected values: 2018/19 – 0.78; 2019/20 – 0.85; 2020/21 – 0.89; 2021/22 – 0.88; 2022/23 – 0.79.
**Conclusions:** Despite an increasingly complex workload, a large proportion of overall antibacterial consumption remained within the access category (according to the AWaRe classification). The prevalence of most concerning antimicrobial resistance, with respect to pathogens, and mortality rate remained satisfyingly consistent. These findings underscore the ongoing value of daily collaboration between senior pharmacists, consultant microbiologists, and ICU ward staff at the ward round, allowing for early escalation/ de-escalation strategies.

This has resulted in a robust antimicrobial stewardship program that promotes the careful use of antibiotics to combat the threat of antimicrobial resistance.

**Table 1 (abstract 000747)** Patient characteristics and unit activity

| Characteristic | | 2018/19* | 2019/20* | 2020/21* | 2021/22* | 2022/23* |
|---|---|---|---|---|---|---|
| Total admissions | | 1676 | 1651 | 1645 | 1614 | 1647 |

**Introduction:** Sepsis is the third leading cause of death worldwide and the main cause of in-hospital mortality. Despite decades of research, sepsis remains a major challenge faced by patients, clinicians, and medical systems globally [1]. Early identification and prediction of patients at risk of sepsis is critical [2–4]. Annually, 15 million individuals undergo abdominal surgery, with 30% of them facing a significant risk of developing sepsis postoperatively [5,6]. In light of this, our study aims to develop an artificial intelligence (AI) algorithm designed for the early prediction of postoperative sepsis, potentially transforming patient care by enabling timely interventions.
**Objectives:** Our research aims to improve postoperative care in surgical wards by leveraging photoplethysmography (PPG) wearable devices and explainable AI (XAI) for the early prediction of sepsis. Given the high morbidity and mortality rates associated with delayed sepsis diagnosis, our objective is to establish a real-time, non-invasive monitoring system that accurately and promptly predicts the onset of sepsis.
**Methods:** An observational clinical pilot study is being conducted at the General University Hospital of Larissa [7], involving patients who have undergone abdominal surgery and were subsequently admitted to the surgical wards. Vital signs are continuously monitored using PPG wearable devices, with data integrated alongside Electronic Health Record (EHR) information, including laboratory results, for sepsis prediction. Identification of sepsis cases adhered to the Sepsis-3 criteria [8]. We employed the Extreme Gradient Boosting (XGBoost) algorithm for early sepsis prediction, prior to the manifestation of clinical symptoms (Figure 1). To address the AI "black-box" issue, we created a digital patient twin for personalized predictive insights, facilitating clinician understanding of sepsis risk etiology, especially in less monitored settings. The AI model was trained using the MIMIC IV database [9] and is currently being validated using prospectively collected data (Figure 2).
**Results:** The AI model, trained on data from approximately 20,000 patients, demonstrated a 97% accuracy, 87% sensitivity, and 98% specificity in predicting sepsis six hours before onset. This represents a significant improvement over traditional methods like qSOFA, which predicts sepsis with 89% specificity, reducing false positive rates by over fivefold. Our findings suggest that continuous vital sign monitoring through medical-grade wearable devices may enhance sepsis prediction compared to periodically collected data methods.
**Conclusions:** The integration of wearable technology and explainable AI in patient monitoring at the general surgery wards signifies a revolutionary advance in postoperative care, notably enhancing patient outcomes and reducing hospital stays. This approach not only elevates patient safety standards in surgical wards but also promotes proactive healthcare interventions for sepsis management.

## Transdermal nicotine replacement therapy in critically ill patients: a systematic review and meta-analysis

P. Khanna, A. Maheshwari, D. Lal, B. Yalla
Anaesthesia,pain medicine & critical care, All India Institute Of Medical Sciences, New Delhi, New Delhi, India
**Correspondence:** P. Khanna
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000750

**Introduction:** The prevalence of smoking among hospitalized patients, particularly those admitted to intensive care units (ICUs), underscores the critical need for the effective management of nicotine dependence in this vulnerable population. As smokers constitute a substantial portion of ICU admissions, estimated between 22 and 45%, addressing nicotine withdrawal becomes paramount, especially considering the hemodynamic instability and multiorgan dysfunction that commonly occur in critically ill patients1. Nicotine Replacement Therapy (NRT) serves as a cornerstone in managing withdrawal symptoms; however, its efficacy and safety in the ICU setting remain under scrutiny. While NRT has demonstrated effectiveness in preventing and treating withdrawal symptoms in hospitalized patients and in improving cessation rates post-discharge, its impact on critically ill patients is not well understood2. This systematic review and meta-analysis aimed to determine the effect of a transdermal nicotine patch in critically ill patients compared with a placebo.
**Objectives:** To determine the effect of transdermal nicotine patch administration on critically ill patients in comparison to a placebo.
**Methods:** A literature search was performed using electronic databases, such as PubMed, Google Scholar, Embase, Cochrane Reviews, MEDLINE, and the US Clinical Registry. Randomized controlled trials and controlled cohort studies assessing the impact of transdermal nicotine compared to placebo on in-hospital mortality in critically ill ICU patients were included. The primary outcome was the incidence of in-hospital mortality. The secondary outcomes included the incidence of delirium, incidence of ICU mortality, length of hospital stay, length of ICU stay, and length of mechanical ventilation. Inverse variance and Mantel- Haenszel statistical analysis methods were used for continuous and dichotomous data. All results were quantitatively analyzed using a random-effects model.
**Results:** Nine studies with 2272 patients were included in both groups and showed no significant difference in in-hospital mortality between the two groups, with an RR of 0.79 (95% CI 0.61–1.54], p = 0.89; (I2 = 52%, $p = 0.04$), but showed a higher incidence of delirium in the NRT group (RR 3.25, 95% CI 2.30–1.65; $p = 0.59$), with considerable heterogeneity between the studies (I2 = 70%, $p = 0.0009$). There were no significant differences in the incidence of ICU mortality, length of hospital stay, length of ICU stay, or length of mechanical ventilation between the two groups.
**Conclusions:** Transdermal nicotine therapy in critically ill patients did not demonstrate a reduction in in-hospital mortality. Instead, it resulted in an increased incidence of delirium, without any discernible difference in the incidence of ICU mortality, length of hospital stay, length of ICU stay, or length of mechanical ventilation consequently; there is currently no compelling reason to employ nicotine in this particular context (and warrants further large- scale randomized controlled trials to assess the safety and efficacy of nicotine replacement therapy due to the predominantly observational nature of the included studies).

## Temporal harmonisation of individual patient trajectories in the MIMIC-IV dataset using pair programming with a custom GPT

M. Garg, A. Agrawal, G. Menon
Dean (Biosciences and Health Research), Trivedi School of Biosciences, Ashoka University, Sonipat, India
**Correspondence:** M. GARG
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000751

**Introduction:** Intensive care units (ICUs) present with tremendous physiological and pathological challenges. Most ICU disorders present with an inherent heterogeneity which often remains undetected due to a lack of objective and specific biomarkers [1], [2], [3]. Efficiently leveraging medical data could be effective in understanding this heterogeneity, consequently advancing precision medicine. In line, ICUs, being widely tech-enabled, allow for the digitisation of medically relevant data. This could optimise clinical research, provide relevant context for translational biology and enhance evidence-based medicine in the electronic medical records (EMR) era [4].
In our study, we utilised a customised LLM to process the MIMIC-IV dataset. While multiple pre-processing pipelines have been reported [5], [6], we wanted to develop individualised patient trajectories without data loss which can retain the hierarchical structure of the dataset. This would allow for temporal harmonisation and application of multimodal clustering algorithms which provide maximum information extraction. These can be then used for further downstream analysis to identify disease heterogeneity.
**Objectives:** 1. Creation of anonymised individual patient files maintaining hierarchical data structure and minimising data loss.
2. Creating temporally harmonised data trajectories with uncertainty awareness to allow for clustering and comparative analysis
**Methods:** The dataset was processed using a custom GPT—CodeR built on the GPT-4 platform. The GPT was optimised using instructions to validate the code before output, minimise errors, and give detailed explanation. The primary language for the GPT was Python.
Strict precautions were maintained and no data was uploaded to the ChatGPT online platform complying with the Credentialed Data Use Agreement signed during data access. No attempt at reidentification was made during the creation of the patient trajectories.
**Results:** Using pair programming with CodeR, the MIMIC-IV dataset could be pre-processed to create individual JSON files for each patient. All relevant fields linked to common fields were arranged in a hierarchical fashion to allow for easier comparison (Fig. 1A). No fields were omitted, and original datatypes and missing values were retained. Validation was done by random manual screening. Temporal harmonisation was done by converting all time stamps to an ISO format. For each JSON, the first time stamp recorded was converted to '0' and all others were adjusted accordingly (Figure 1B). This allowed for creation of a bound time space which could be used for comparison of different patients.
**Conclusions:** The work creates a framework for handling EMR data, retaining its relational structure for easy harmonisation, comparisons, and processing without data loss or imputation. Using LLM-based python programming allows the retention of scalability which may be lost with relational databases [7]. In addition, it enables physicians to perform exploratory analysis, which reduces data hesitancy and fosters interdisciplinary collaboration with data scientists through development of a common vocabulary [8]. Currently our ongoing work plans on:

1. Creating uncertainty-aware multivariate trajectories for irregularly sampled data combining neural networks and statistical models
2. Using graph networks and longitudinal clustering to identify patient clusters while considering heterogeneity of treatment effects.
3. Validating with external datasets and prospective experimental biomarkers for biological validation

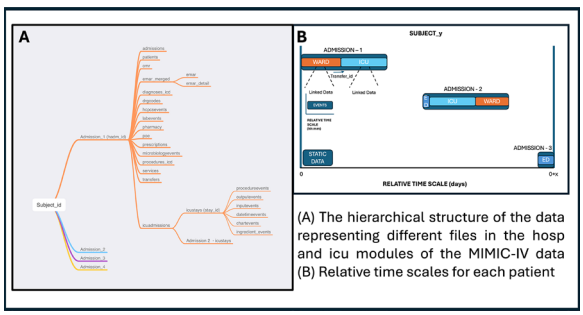

**Fig. 1 (abstract 000751)** (A) LLM-based pair programming was used to create a separate JSON files for each patient which retained the missingness and data types for each field while arranging the data into a hierarchical structure using common anchor fields. Each end field is a collapsed representation. (B) The bound time space is created for each patient by plotting date and time stamps on a relative time scale. This allows for temporal harmonisation and comparison between different patient trajectories**Reference(s)**

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000752

**Introduction:** Each day spent in the ICU contributes to decreased physical function and reduced quality of life. This is secondary to the physical, psychological, and cognitive impairments that survivors face following an extended stay in the ICU. In other diverse populations, nutritional and physical interventions are combined to promote muscle gain and improve physical function. However, this concept has only been explored in the context of critical illness in the last 10 years. Thus, a systematic review was performed to explore this concept and provide recommendations for future research and practice.
**Objectives:** This review aims to explore the effect of combined physical and nutritional interventions, on physical function and health-related quality of life, across the critical illness continuum. A narrative synthesis of the eligible studies will provide the basis for future recommendations.
**Methods:** A systematic review was conducted across 5 databases. Inclusion criteria were RCTs published between 2000 and 2023, with participants aged ≥ 18 years, with an ICU stay ≥ 4 days. Interventions included any combination of physical and nutritional rehabilitation. In addition, only studies with outcomes that encompassed physical function or health-related quality of life were included. The Risk of Bias 2 (ROB2) tool was implemented to determine the risk of bias in each eligible study. Due to the wide heterogeneity in included studies, a 4-stage narrative synthesis process was conducted to formulate the recommendations from this review.
**Results:** A total of 9153 articles were screened although only 6 studies met the inclusion criteria. The included studies spanned the critical illness continuum, from ICU through to the community setting.
A theoretical model was developed in the initial stage of the narrative synthesis, outlining the hypothesised pathways in which a combination of physical therapy and nutrition may impact physical function and health-related quality of life. This was developed using only the included studies and informed the reasoning behind combined interventions in the context of critical illness.
The relationships within and between each study were examined using a variety of narrative techniques to form 5 recommendations for clinical practice and future trials. Specifically, the use of Electrical Muscle Stimulation in acute critical illness, the need to define 'high protein' in the context of critical illness, nutritional supplementation further along the recovery continuum, the importance of qualified healthcare professionals in the delivery of specialised interventions to complex populations, and finally considerations for a core outcome set for future research in this area.
**Conclusions:** There may be some physical benefits to combining physical and nutritional interventions in survivors of critical illness. However, further research is needed to identify which combinations may be the most beneficial at each stage in the continuum. Recommendations from this study aim to inform this process.

### Association between serum acylcarnitine profile after ICU discharge and mid-term muscle outcomes: an observational study

S. Delrez[1], F. Boemer[2], C. Colson[1], P. Minguet[1], S. Neis-Gilson[1], B. Lambermont[1], A. F. Rousseau[1]
[1]Department of Intensive Care, University Hospital of Liège, Liège, Belgium; [2]Biochemical Genetics Laboratory, University Hospital of Liège, Liège, Belgium
**Correspondence:** S. Delrez
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000753

**Introduction:** In our previous studies, we observed an altered serum acylcarnitine (AC) profile in survivors of an intensive care unit (ICU) during the 3 months after discharge. This profile was associated with markers of protein catabolism.
**Objectives:** The aim of this observational study was to investigate the association between serum AC profile measured at ICU discharge and muscle outcomes assessed 3 months later in survivors of a prolonged ICU stay.

**Methods:** Adults enrolled in our post-ICU follow-up program and who attended the consultation 3 months (M3) after discharge were included. Serum AC concentrations were assessed using liquid chromatography with tandem mass spectrometry within 7 days following ICU discharge (T0). Exclusion criteria were known primary carnitine deficiency and ongoing treatment with zidovudine, valproate, cyclosporine or cisplatin at T0. Muscle outcomes included urea/creatinine ratio, sarcopenia index, quadriceps, and handgrip strengths measured using dynamometry and frailty (i.e.: difference in Clinical Frailty Score (CFS) between M3 and the pre-ICU status).
**Results:** A total of 127 patients (86 men (67,7%), 63(55–70) years, SAPS II 36 (26–56)) who survived an ICU stay of 13 (8–33) days were analyzed. Free carnitine (C0) concentration was 44.4 (33–52.2) µmol/L. C0 deficiency was observed in 2/127 (1.6%). The total AC/C0 ratio (normal $\leq 0.4$) was 0.37 (0.28–0.47) at T0. An AC/C0 ratio > 0.4 was observed in 55/127 (43.3%). The short-chain and long-chain ACs reached respectively 1.2 (0.9–1.7) µmol/L and 0.9 (0.6–1.2) µmol/L. At M3, the urea/creatinine ratio and the sarcopenia index were respectively 38.3 (28.3–50.3) and 0.7 (0.6–0.9). Quadriceps strength was 2.9 (2.1–3.7) N/kg and the handgrip strength was 25 (19–34) kg. CFS increased by 1 (0–1) point at M3 compared to pre-ICU level. In univariate analysis, none of the AC profile markers were associated with any of the muscle outcomes. Multivariate analyses are ongoing.
**Conclusions:** In patients surviving a prolonged ICU stay, there was no association between serum AC profile markers at ICU discharge and muscle outcomes at M3. The interest of AC profile as a predictive marker of post-ICU muscle outcomes, as assessed in daily practice and considered individually, is questionable. Further analysis should investigate if the AC profile could predict a composite muscle outcome, reflecting the interconnection between muscle mass, strength, and function.

## Association between VTE and 28-day mortality in patients of critical care medicine: secondary data mining from the large-scale clinical database MIMIC-IV

B. Liu
Department of Critical Care Medicine, West China Hospital of Sichuan University, Chengdu, Sichuan Province, China
**Correspondence:** B. Liu
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000754

**Introduction:** Venous thromboembolism (VTE) is a common complication in intensive care unit (ICU) patients and can lead to poor prognosis in critically ill patients. However, the factors affecting the prognosis of ICU patients with combined VTE remain unclear, and there is a lack of models to predict prognosis based on risk factor combinations.
**Objectives:** This study aimed to screen for independent risk factors for 28-day mortality in critically ill VTE patients and to develop a predictive model for clinical assessment of survival.
**Methods:** We identified patients with VTE using the MIMIC-IV database, data were split into two groups based on death or survival within 28 days. Variables were selected for display and comparison between groups based on the significance and availability of stepwise analysis. Multivariate Cox proportional regression model predictions were constructed by R software. The performances of the models was tested and compared by AUCs of the receiver operating characteristic curves and decision curve analysis. A nomogram model was used to assess the survival prognosis of critically ill VTE patients.
**Results:** We included a total of 1162 critically ill VTE patients, including 1002 in the 28-day survival group and 160 in the 28-day death group. In multivariate Cox regression analysis, age (OR: 1.03, 95% CI 1.02–1.05, $P < 0.001$), partial thromboplastin time(PTT)_max (OR: 1.01, 95% CI 1.00–1.01, $P < 0.001$), sepsis (OR: 2.15, 95% CI: 1.22–3.80, $P = 0.008$), malignancy (OR: 2.10, 95% CI 1.48–2.98, $P < 0.001$), severe liver disease (OR: 2.19, 95% CI 1.26–3.81, $P = 0.005$), and respiratory failure (OR: 1.48, 95% CI 1.02–2.15, $P = 0.039$) were independent risk factors for 28-day death in critically ill VTE patients. The area under the curve (AUC) was 0.76, which was used to build the nomogram model with a C-index of 0.795, indicating that the nomogram had good differentiation. Furthermore, Decision Curve Analysis (DCA) showed that the nomogram was clinically useful and had better discriminative ability to identify critically ill VTE patients at high risk.
**Conclusions:** Age, sepsis, malignancy, severe liver disease, and respiratory failure were independent risk factors for 28-day death in patients with critical VTE. Among them, severe liver disease, sepsis, and malignancy ranked in the top three, respectively. We developed and validated a prognostic nomogram model to assist clinicians in assessing the survival prognosis of critically ill VTE patients.

## Net albumin leakage in patients in the icu with suspected sepsis. a prospective analysis using mass balance calculations

D. Seldén, Å. Norberg, O. Rooyackers
Department of clinical science, intervention and technology, Karolinska Institute, Stockholm, Sweden
**Correspondence:** D. Seldén
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000755

**Introduction:** Albumin kinetics in septic shock have been extensively studied, yet recommendations for its clinical use remain weak (1). Fleck et al. demonstrated an increased transcapillary escape rate (TER) of albumin from the vascular system; however, TER does not provide insight into lymphatic return from the interstitium to the circulation (2). Mass balance calculations takes the lymphatic return in account and have been used to assess net albumin leakage (NAL) from the circulation in surgical patients (3).
**Objectives:** The primary objective of this study was to evaluate NAL in ten patients with suspected sepsis admitted to the ICU, with the hypothesis that it would manifest as a net positive leakage. The secondary aim was to investigate associations between NAL and fluid overload, glycocalyx shedding products, and potential causes of increased NAL.
**Methods:** This prospective, observational analysis included ten patients within the first twelve hours of ICU admission due to suspected sepsis at Karolinska University Hospital Huddinge in 2017. Albumin, hematocrit, and hemoglobin levels were sampled at hours 0, 1, 2, 4, 8, and 24. NAL was estimated using mass balance calculations, which in short compare proportional changes in albumin and hemoglobin concentrations over time, adjusting for infusions and losses. If albumin concentration is decreased proportionally more or raised proportionally less than hemoglobin, this is interpreted as a net albumin leakage, NAL. That is, the amount of grams leaving the circulation to the interstitium minus the return to the circulation via the lymphatic system. The t-test was used to assess changes from baseline. ANOVA was used to measure the change of NAL and syndecan-1 from zero at hour 0, 4, and 24. Simple linear regression was used to quantify the relationship between NAL and albumin infusions. Data are presented as mean ± SD or median and range.
**Results:** Baseline characteristics are summarized in Table 1. At 24 h, NAL was 8 ± 10 g ($p = 0.029$). There was no correlation between the NAL and the fluid balance ($r2 = 0.003$, $p = 0.87$), and similarly, no correlation was observed with syndecan-1 levels ($r^2 = 0.003$, $p = 0.64$). The temporal pattern of NAL, syndecan-1, and the association of NAL with albumin administration is illustrated in Fig. 1. NAL was significantly raised over time (Fig 1a), syndecan-1 levels were high but did not change over time (Fig. 1b) and albumin administration was positively correlated to NAL (Fig 1c).
**Conclusions:**

1. During a time period of 24 h, there was a net positive albumin leakage from the circulation supposedly to the interstitium in 10 patients with suspected sepsis of 8 ± 10 g.
2. There was no correlation between the net albumin leakage and the fluid balance nor syndecan-1 levels.
3. Administration of albumin infusion seemed to increase the net albumin leakage.

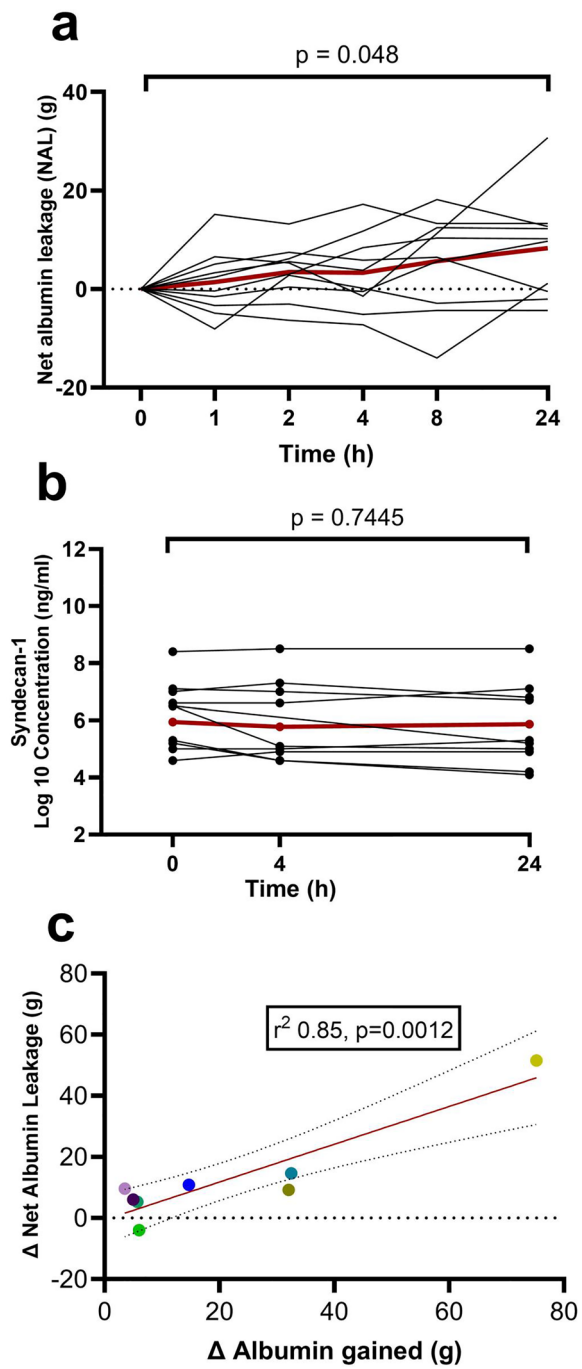

**Fig. 1 (abstract 000755)** Temporal pattern of (**a**), net albumin leakage (NAL) (**b**), syndecan-1. Red line represents the mean of ten patients. Changes over time are assessed by ANOVA. (**c**), the mean change in albumin gained (ΔAlb) versus mean change in NAL (ΔNAL) in 8 patients at 33 different timepoints in the ICU. Each dot represents the mean amount of albumin gained by a patient (x-axis) and the subsequent corresponding change in NAL (ΔNAL) between 1–16 h later (Y = 0.6180*X—0.5863, r2 = 0.85, p = 0.0012)

**Table 1 (abstract 000755)** Values are presented as median (range), fraction (%), or mean (95% confidence interval). BMI = body mass index, CRP = C-reactive protein. Septic shock was defined as a suspected infection in a patient receiving antibiotic therapy, resuscitated with IV crystalloid 30ml/kg, and on vasopressors with a lactate level > 2

| | Patients n = 10 |
|---|---|
| Length (m) (mean ± SD) | 1.79 ± 0.1 |
| BMI (kg/m$^2$) (median, range) | 23 (17, 33) |
| Sex (male) (%) | 100 |

*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000756

**Introduction:** Immunoadsorption is increasingly recognized as an alternative to therapeutic plasma exchange (PEX) and used for the supportive treatment of neurological disorders such as Guillain–Barré syndrome, chronic inflammatory demyelinating polyneuropathy, myasthenia gravis, neuromyelitis optica spectrum disorders, multiple sclerosis, and autoimmune encephalitis. Immunoadsorption can solve some drawbacks of PEX such as anaphylactic reaction from fresh frozen plasma (FFP), transmission of blood-borne organisms, and the time-consuming preparation of FFP.
**Objectives:** To evaluate the short-term clinical efficacy and safety of treatment of HA280 immunoadsorption (IA) column in Guillain Barré syndrome.
**Methods:** A prospective, interventional study on Guillain Barré patients who were under immunoadsorption therapy by HA 280 column at the Center for Critical Care Medicine, Bach Mai Hospital from

August 2022 to March 2023. Data including age, gender, mechanical ventilation, the change of muscle strength according to Medical Research Council (MRC) score after IA cycles, Disability of patients according to Hughes score after IA cycles, catheter site infection, anaphylaxis, clinical bleeding, coagulation disorders: PLT < 150 T/l, PT < 70% or APTTb/c > 1,2, fibrinogen < 2 g/l were collected. T- Tests were used for statistical analysis.

**Results:** 23 patients were included in the study with an average age of 55.4 ± 13.90 years (min 30, max 76). In the cohort, males accounted for 60.9%. IA was performed 101 times in 23 patients. 17 out of 23 patients did not require invasive mechanical ventilation, the six remaining patients were supported with invasive mechanical ventilation. The median frequency of IA in the two groups was 4 and 5 respectively. In the non-invasive mechanical ventilation group, the median MRC scale for muscle strength in the upper limb muscle groups before and after IA procedures were 2 and 5 respectively. In the mechanical ventilation group, the upper limb muscle strength also recovered, but slower (2 and 3 respectively). The results of lower limb muscle groups showed a similar pattern.

After the IA procedures, significant improvement in GBS Hughes disability scores was seen compared to prior treatment (6 vs 5, respectively). The number of patients having Hughes score 4 before IA procedures were 17 and after IA were 2.

Adverse events only occurred in 6 of 101 procedures (5.9%) in which four episodes of catheter site bleeding, once of femoral vein thrombosis and once of column clotting. Thrombocytopenia was not noted.

**Conclusions:** HA 280 column helped improve muscle strength according to the MRC score and Disability with Hughes score in Guillain Barré syndrome patients. It may be considered as a potential alternative treatment for PEX.

### Circulating nucleosomes as a novel biomarker for sepsis

F. Su[1], A. Moreau[2], M. Savi[3], F. Annoni[4], K. Xie[5], J. L. Vincent[6], F. S. Taccone[4]
[1]Intensive Care, Hospital Erasme, Bruxelles, Belgium; [2]Intensive care, Civil Hospital Marie Curie, Charleroi, Belgium; [3]Department of anesthesia and intensive care, Humanitas University, Pieve Emanuele, Italy; [4]Soins intensif, ULB Erasme, Anderlecht, Belgium; [5]Critical Care Medicine, Tianjin Medical University General Hospital, Tianjin, China; [6]Soins intensif, ULB Erasme, Brussels, Belgium.
**Correspondence:** F. Su
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000757

**Introduction:** Circulating nucleosome levels are commonly elevated across both physiological and pathological conditions. Within sepsis, activated neutrophils release granule proteins and chromatin, resulting in the formation of neutrophil extracellular traps (NETs) which entrap and kill bacteria through a process known as NETosis. Elevated levels of NETosis and nucleosomes appear to correlate with the severity and mortality of sepsis. Furthermore, the utility of circulating nucleosome levels as biomarkers for NETosis, organ dysfunction, and sepsis diagnosis or prognosis or guide sepsis therapy remains uncertain. Technical limitations in nucleosome detection preclude definitive answers through systematic review/meta-analysis.

**Objectives:** To explore the origins, immunostimulatory functions, and potential toxicity of nucleosomes in sepsis.

**Methods:** We conducted a comprehensive search on Cochrane and Medline libraries from 1996 to February 1, 2024, to identify articles examining the involvement of circulating nucleosomes in NETosis and their potential to distinguish between septic patients from those with uncomplicated sepsis to septic shock- and individuals with Systemic Inflammatory Response Syndrome (SIRS), unrelated to infection. Studies involving animals, patients lacking probable infection, and neonates were excluded from consideration. Patient and study characteristics were independently extracted by two investigators, with any discrepancies resolved through consensus.

**Results:** Our search yielded 110 potential studies, of which 18 met the inclusion criteria, encompassing a total of 39 SIRS, 873 sepsis patients, 280 septic shock, 117 other ICU control patients, and 340 healthy volunteers. The predominant methods utilized for analyzing plasma/serum samples for nucleosome measurements were enzyme-linked immunosorbent assay (ELISA), employing both homemade and commercially available kits. Among the 7 studies exploring the relationship between nucleosome levels and other NETs biomarkers, all reported a significant correlation. Notably, in 6 out of 9 studies, admission nucleosome levels were significantly elevated in septic patients compared to healthy volunteers. Furthermore, nucleosome levels were also associated with sepsis severity scores, such as Sequential Organ Failure Assessment (SOFA) and/or Acute Physiology, Age and Chronic Health Evaluation (APACHE II) scores. Of the 13 studies reporting on mortality,

8 indicated significantly higher nucleosome levels in non-survivors compared to survivors.
**Conclusions:** Circulating nucleosome levels emerge as a promising marker of NETosis in the early stages of sepsis, exhibiting moderate diagnostic performance for sepsis and strong correlations with both severity and prognosis. However, these observations primarily stem from single-center, observational studies, often employing home-made ELISA kits and small sample sizes.

### Theranostics approach to NETosis in sepsis and experimental human endotoxemia: impact of NETosis and potential Anti-NETs-therapeutics

F. Börner[1], C. Neumann[2], D. Beyer[2], J. Halbauer[2], A. Jansen[3], N. Bruse[3], J. Gerretsen[3], O. Sommerfeld[2], P. Pickkers[3], M. Bauer[2], M. Kox[3], M. Kiehntopf[1], A. Press[2]

**Correspondence:** F. Börner
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000758

**Introduction:** Neutrophils are innate immune cells recruited early to sites of inflammation, releasing pro-inflammatory cytokines and mesh-like structures comprised of DNA, histones, and various granular proteins known as neutrophil extracellular traps (NETs) [1]. NETs are potentially toxic and may play a key role in mediating tissue injury, inducing a prothrombotic state associated with vascular impairment, thereby contributing to organ damage. Evidence from multiple studies suggests that the imbalance between production and clearance of NETs is detrimental to organ health in various diseases [2]. NETosis could, therefore, be considered a biomarker of organ dysfunction. Hence, strategies aimed at modulating NET-associated processes could have a therapeutic impact on various inflammatory diseases. Recently, endogenous C-terminal peptides of alpha-1-antitrypsin (CAAPs), generated by inhibition of proteolysis and found to be upregulated in severe pro-inflammatory conditions [3], are postulated as novel antagonists of NETosis that may improve organ function and survival [4, 5].
**Objectives:** We aimed to determine whether circulating nucleosomes and cell-free DNA, both markers for NETosis, are associated with inflammation and organ dysfunction in a cohort of healthy volunteers subjected to experimental endotoxemia (intravenous administration of lipopolysaccharide [LPS]) and in patients with sepsis. Furthermore, we explored whether CAAPs could serve as a theranostic inhibitor to reduce NET release and disease burden.
**Methods:** Thirty-two healthy volunteers who were challenged with 1 ng/kg LPS at Radboud University Medical Center and 77 critically ill sepsis patients from the MS ICU trial at the Jena University Hospital were included in this study. EDTA plasma was obtained before and frequently after the LPS challenge in volunteers and within the first 24 h after sepsis onset in patients. Cell-free DNA and nucleosomes were quantified using Sytox Green and ELISA, respectively. Additionally, cytokine profiles and clinical severity markers were determined. CAAPs were quantified by UPLC-MS/MS in a subset of the experimental endotoxemia cohort displaying high plasma cytokine concentrations (LPS high responders). Finally, the therapeutic potential of CAAPs was assayed by performing in vitro experiments in primary human leukocytes stimulated with phorbol ester or LPS, and NET release was assayed using the same methods as outlined above.
**Results:** Quantification of cell-free DNA and nucleosomes in the plasma of LPS-challenged volunteers indicated increased NETosis during the acute phase of systemic inflammation (maximum NET release at 4–6-h post-LPS). In septic patients, significant correlations between NET-related nucleosomes and cardiovascular SOFA ($r = 0.39$, $p = 0.002$) and CRP concentrations ($r = 0.41$, $p = 0.0009$) were found. Furthermore, nucleosomes also tended to correlate with respiratory and renal SOFA, further strengthening the possible contribution of NETosis to organ dysfunction by inducing an inflammatory prothrombotic state and/or vascular impairment. In LPS high responders the generation of sepsis-related CAAPs C36 and C42 paralleled with the increase of NETosis markers, and in vitro investigations confirmed inhibition of NETosis by incubation with CAAPs.
**Conclusions:** Systemic inflammation induces NETosis, which is related to organ dysfunction in sepsis. As such, inhibition of an excessive NETosis may hold promise for attenuating organ damage in pro-inflammatory conditions and potentially improving the survival of critically ill patients. However, a deeper understanding of individual NET burden is crucial for tailoring therapeutics to mitigate NETosis, such as applying NET-inhibiting CAAPs. Therefore, further research is warranted to develop a theragnostic approach aimed at preventing or reducing NETosis, which could be achieved through quantifying NET markers and controlling endogenous NETosis inhibitors, potentially establishing CAAPs concentration as a novel therapeutic target.

**Introduction:** Prognostication in patients with severe acute brain injury (SABI) admitted to the ICU can be challenging. Biomarkers released into the blood have shown promising results in predicting neurological outcomes in patients with traumatic brain injury (TBI). (1, 2) However, for patients with SABI of various other etiologies, literature remains scarce.
**Objectives:** In this pilot study we aimed to explore the optimal sampling point for Glial Fibrillary Acidic Protein (GFAP), Neurofilament Light (NFL), and Neuron Specific Enolase (NSE) in patients with SABI admitted to the ICU. Furthermore, we studied trends between survivors and non-survivors.
**Methods:** This prospective cohort study conducted between January 3, 2023, and July 27, 2023, included all patients with SABI defined as subarachnoid or intracerebral hemorrhage, intracranial infection, traumatic brain injury, or acute ischemic stroke and a GCS score $\leq 8$ prior to inclusion. Inclusion was within 24 h after brain injury. Data on demographic and baselines characteristics were collected from the electronic patient records. Blood samples were collected using gel-separator tubes (STG-5) for serum at 24 h, 72 h, 7 days and 14 days. Single Molecule Array (SIMOA HD-X) was used to determine biomarker concentrations of GFAP and NFL. NSE concentrations were assessed with electrohemiluminescence immunoassay (ECLIA).
**Results:** A total of 39 patients with SABI were included. TBI was diagnosed in 17 patients (43%) and subarachnoid hemorrhage in 8 patients (20.3%). Patients had severely impaired consciousness at hospital admission, the median GCS score was 4 (IQR 3–6). In 13 patients (33.3%) pupillary reactivity was absent in either one or both pupils. The median ICU length of stay was 5 days (IQR 3–8). At hospital discharge 16 patients (41%) were alive, of which 4 (10.3%) were discharged to their homes, the remaining to rehabilitation facilities. Serum biomarker concentrations over time are illustrated in Figure 1. No significant differences in serum biomarker concentrations on days 1 and 7 were found between survivors and non-survivors at hospital discharge. However, a threefold increase was found for GFAP on day 3 median 14,656 pg/ml (IQR 2932–23,788.5) in survivors versus a median 47,674.5 pg/ml (IQR 13700.5–110,561) in non-survivors ($p = 0.014$). In Figure 2, the biomarker trends between survivors and non-survivors are visualized.
**Conclusions:** This pilot study suggests sampling should be performed in the first few days for NSE and GFAP. For NFL a time point later should be considered, as it increases over time. Further research in larger cohorts of patients with SABI is needed to validate these findings and explore the potential utility of biomarkers in neuroprognostication in the ICU.

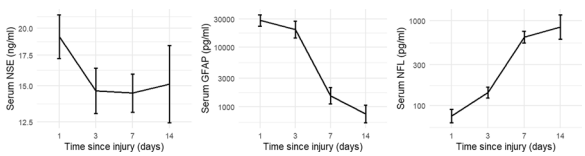

**Fig. 1 (abstract 000759)** Timecourse of mean serum concentrations of neuron-specific enolase (NSE), glial fibrillary acidic protein (GFAP), and neurofilament light (NFL). The y-axis is log-transformed (log10). The x-axis depicts the sampling time since brain injury. Error bars indicate SEM. GFAP = Glial Fibrillary Acidic Protein, NFL = Neurofilament Light, NSE = Neuron Specific Enolase

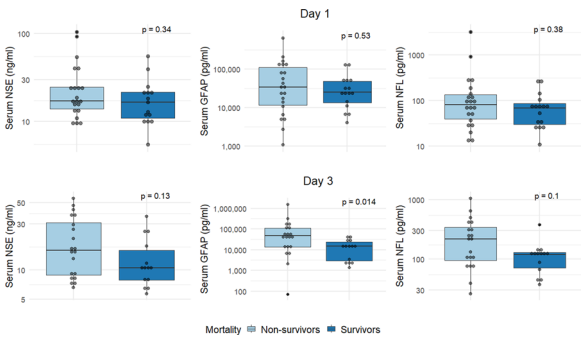

**Fig. 2 (abstract 000759)** Serum concentrations measured at days 1 and 3 after brain injury of neuron-specific enolase (NSE), glial fibrillary acidic protein (GFAP), and neurofilament light (NFL) between survivors and non-survivors at hospital discharge. Boxplots show the median and interquartile range. GFAP = Glial Fibrillary Acidic Protein, NFL = Neurofilament Light, NSE = Neuron Specific Enolase

**Introduction:** In sepsis, circulating nucleosome levels are commonly increased in proportion to the disease severity and mortality.
**Objectives:** The objective of the present study was to measure circulating nucleosome levels and histone post-translational modification (including acetylation, citrullination, and methylation) in a clinically relevant ewe model of septic shock, particularly in the context of anti-histone therapy.
**Methods:** in 24 mechanically ventilated, hemodynamically monitored female sheep, sepsis was induced through fecal peritonitis. Following surgical preparation and stabilization, the animals were randomly assigned to one of three groups: control, concurrent treatment (CuT, immediate intervention), and post-treatment (PT, 4 h later) groups ($n = 8$ each). Anti-histone therapy involving sodium-B-O-methyl cellobioside sulfate (Grand Pharma, Wuhan, China)was administered as a bolus (1 mg/kg) followed by continuous infusion (1 mg/kg/h). The experimental period spanned 24 h, during which the experimenters remained blinded to group allocation. Plasma nucleosome levels and their post-translational modifications (acetylation, citrullination, and

methylation) were measured at baseline and every 4 h thereafter, by ELISA (Belgian Volition SRL, Isnes, Belgium).
**Results:** The control group showed increased circulating nucleosomes, while decreased in the treatment groups ($p = 0.24$). Citrullination levels were peaking at 8 h after sepsis, while methylation levels reached peak levels 12 h after sepsis. Acetylation was rarely detected in samples. Additionally, histone neutralization appeared to reduce methylation ($p = 0.08$) and citrullination ($p = 0.12$) in this model.
**Conclusions:** These findings underscore the complex dynamics of nucleosome modifications in response to sepsis and suggest a potential therapeutic measure through histone neutralization. Further investigation is warranted to fully elucidate the underlying mechanisms and evaluate the potential clinical implications.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000762

**Introduction:** Nucleosomes are released during cellular damage and cell death, and histone post-translational modifications (PTM) (such as methylation often with on/off gene expression) significantly impact disease progression.
**Objectives:** We explored the temporal dynamics of nucleosomes and their post-translational modifications (PTM) (including acetylation, citrullination, and methylation) in septic vs cardiogenic shock.
**Methods:** In one model, septic shock was induced in eight female sheep via fecal peritonitis. The animals received fluid resuscitation, antibiotics, vasopressors, and peritoneal lavage. The experimental period spanned 24 h, during which plasma samples were collected at baseline and every 4 h for nucleosome measurements. In another model, cardiogenic shock was induced in 8 mixed-sex pigs by subocculding the anterior interventricular and circumflex arteries using an angioplasty balloon to reduce coronary blood flow for 120 min, followed by resuscitation. The experiment lasted for 8 h, with serum samples collected at baseline, post-ischemia, and every 4 h thereafter. All animals were mechanically ventilated and hemodynamically monitored throughout the experiment. Nucleosomes and their post-translational modifications (acetylation, citrullination, and methylation) were measured using ELISA (Belgian Volition SRL, Isnes, Belgium).
**Results:** circulation nucleosome levels e increased more in the septic shock than in the cardiogenic shock model. Acetylation and citrullination reached peak levels rapidly following the onset of sepsis, whereas methylation increased more gradually during the later phases of septic shock. Conversely, the changes in acetylation, citrullination, and methylation were less evident in cardiogenic than in septic shock.
**Conclusions:** These two studies indicate different patterns of circulating nucleosomes and their post-translational modifications (PTMs) in septic and cardiogenic shock, suggesting distinct underlying mechanisms being at play. Further studies are warranted to elucidate these mechanisms and explore the potential implications in the pathophysiology and clinical management of these conditions.

### 3 Duration of mechanical ventilation is not associated with an increase in estimated mean pulmonary artery pressures

**Introduction:** The right ventricle (RV) in health serves to conduct venous return from the right atrium to the pulmonary circulation while avoiding increases in right atrial pressure (RAP) to minimise venous excess. Elevated pulmonary artery systolic pressure (PASP) represents the pressure generated by the RV to push blood through the pulmonary circulation, which can be determined by factors including pulmonary vascular resistance, left ventricular systolic/diastolic function and ventilator driving pressures [1].
PASP can be raised acutely (e.g. pulmonary embolism) or chronically (pulmonary arterial hypertension) and can result in RV dysfunction. Impaired RV stroke volume can translate to increased RAP which impairs preload and therefore cardiac output, and by ventricular interdependence can also limit LV end-diastolic volume [2]. These factors could contribute to slow weaning from mechanical ventilation in the critically ill.
The right ventricle (RV) in health serves to conduct venous return from the right atrium to the pulmonary circulation while avoiding increases in right atrial pressure (RAP) to minimise venous excess. Elevated

pulmonary artery systolic pressure (PASP) represents the pressure generated by the RV to push blood through the pulmonary circulation, which can be determined by factors including pulmonary vascular resistance, left ventricular systolic/diastolic function and ventilator driving pressures [1].
PASP can be raised acutely (e.g. pulmonary embolism) or chronically (pulmonary arterial hypertension) and can result in RV dysfunction. Impaired RV stroke volume can translate to increased RAP which impairs preload and therefore cardiac output, and ventricular interdependence can also limit LV end-diastolic volume [2]. These factors could contribute to slow weaning from mechanical ventilation in the critically ill.
**Objectives:** To determine whether increased estimated pulmonary artery systolic pressures correlate with increased duration of mechanical ventilation.
**Methods:** We examined 97 patients that had been mechanically ventilated over a 3 month period (12/23–02/24). The clinical record for each patient was examined for echocardiography reports performed during admission. The pressure gradient (PG) data were calculated directly from the echocardiography reports based on the simplified Bernoulli equation applied to the peak velocity (Vmax) of the tricuspid regurgitant jet, PASP estimated from PG + median estimated RAP. Correlation between 'advanced respiratory days' and estimated PASP was performed using Pearson's product-moment coefficient. All analyses were performed using R (version 4.3.2).
**Results:** 8 patients had a transthoracic echocardiogram performed during their admission which was sufficient to estimate pulmonary arterial systolic pressure (PASP). There appears to be no correlation between mean estimated PASP and number of days of mechanical ventilation ($r^2 = 0.076$; see Figure 1).
**Conclusions:** In this small study of 8 patients, there was no detected correlation between estimated PASP and number of days of mechanical ventilation. However, this is based on a small sample size of 8 patients so the influence of other factors in individual cases could obscure a true relationship. 11 mechanically ventilated patients could not be included because they did not have a sufficient TR jet to estimate PASP, however, other echo parameters could have been used to assess for pulmonary hypertension. Pressure gradient from TRVmax can also fail to represent PASP in situations of pressure equalisation from severe tricuspid regurgitation e.g. due to annular dilatation. Future work will involve examining a prospective larger data set to further investigate whether a correlation exists.

**Introduction:** Titration of positive end-expiratory pressure (PEEP) in patients with acute respiratory distress syndrome (ARDS) with and without coronavirus 2019 (COVID-19), remains a challenge, with guidelines being unable to make a strong recommendation for one strategy in particular [1, 2]. Several COVID-19 studies have suggested harm from ventilation using high PEEP [3–5]. These studies, however, originated from the initial waves of the pandemic, where high PEEP ventilation was frequently administered, and with some patients potentially receiving it without a justified need.
**Objectives:** Since we know practice and patient characteristics changed during the course of the first year of the pandemic [6], we aimed to assess the impact of high PEEP/low fraction of inspired oxygen (FiO2) ventilation on outcomes during the second wave of the national outbreak in the Netherlands.
**Methods:** Retrospective observational study of invasively ventilated COVID-19 patients during the second wave. Patients were categorized based on whether they received high PEEP/low FiO2 or low PEEP/high FiO2 ventilation according to the ARDS Network tables, based on the strategy most frequently employed in the initial 3 calendar days of ventilation. The primary outcome, intensive care unit (ICU) mortality, and secondary outcomes hospital, 28-day, and 90-day mortality, were compared between groups using a (shared-frailty) Cox proportional hazard model. Additional secondary outcomes included duration of ventilation and length of stay, both analyzed through a competing risk model, ventilator-free days (VFD–28) and occurrence of kidney injury. Propensity matching was performed to correct for factors with a known relationship to ICU mortality.
**Results:** This analysis included 790 COVID–ARDS patients. Of the included patients, 142 were classified as high PEEP/low FiO2 patients and 648 as low PEEP/high FiO2 patients. At ICU discharge, 32 (22.5%) of high PEEP patients and 254 (39.2%) of low PEEP patients had died (HR 0.66 [0.46–0.96]; P = 0.03; see Figure). High PEEP patients had overall lower mortality rates, a shorter duration of ventilation and length of stay, more VFD–28, and a lower incidence of kidney injury. In matched analysis, 23 (22.3%) out of 103 high PEEP patients and 152 (41.3%) out of 368 low PEEP patients met the primary endpoint (HR 0.59 [0.38–0.92]; P = 0.02).
**Conclusions:** High PEEP/low FiO2 ventilation was associated with improved ICU survival and improved secondary outcomes in patients with COVID–ARDS.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000766

**Introduction:** Acute respiratory distress syndrome (ARDS) results in severe hypoxemia refractory to oxygen therapy and can cause a high mortality rate. A lung ultraprotective ventilation strategy with low tidal volume (Vt < 6 ml/kg predicted body weight) and high positive end-expiratory pressure (PEEP) may prevent ventilator-induced lung injury (VILI) by reducing the driving pressure (Plateau–PEEP) that was demonstrated reducing mortality. Extracorporeal carbon dioxide removal (ECCO2R) is a form of extracorporeal gas exchange that allows substantial CO2 removal from blood across a gas exchange membrane at low blood flow rates. ECCO2R has been shown to be an effective way to reduce airway pressures and lung volumes in ARDS patients.
**Objectives:** To assess the feasibility and technical aspects of ECCO2R to facilitate lung ultraprotective ventilation strategy in patients with ARDS.
**Methods:** A prospective, intervention study was conducted in severe and moderate ARDS patients supported with ECCO2R in the Center for Critical Care Medicine, Bach Mai Hospital from August 2023 to March 2024. We used the Prismax machine and PrismaLung + with an area of 0.8 $m^2$. Data including age, gender, mechanical ventilation parameters, arterial blood gas, blood flow, catheter size, and circuit thrombosis during ECCO2R were collected. T- Test was used during statistical analysis.
**Results:** 10 patients were included in our study with an average age 54.4 ± 12.22 years (min 34, max 70), males accounted for 80. P/F ratio was 122.7 ± 47.14 and compliance was 16.6 ± 4.85 (ml/cmH20). Catheter 13.5 F size was applied on 7/10 (70%) of patients reaching a blood flow of 350–380 ml/min and 3/10 patients used catheter 14.5 F with a maximum blood flow of 450 ml/min. Before ECCO2R, in patients having severe respiratory acidosis, pH was 7.20 ± 0.09 and PaCO2 was 63.1 ± 14.25 (mmHg) ($p < 0.05$). Respiratory acidosis improved significantly during ECCO2R: after 72 h, pH was 7.38 ± 0.08 and PaCO2 was 47.0 ± 8.21 (mmHg) ($p < 0.05$). Mechanical ventilation parameters after 2 h of ECCO2R were improved. After 72 h, tidal volume (Vt) decreased from 6.5 (IQR: 5.5–7.0) to 5.0 (IQR: 4.0–5.7) (ml/kg) ($p < 0.05$), driving pressure dropped from 20.5 (IQR: 18.0–24.5) to 19 (IQR: 17–23) (cmH2O) ($p > 0.05$) and the respiratory rate declined from 30 (IQR: 27.2–31.2) to 22 (IQR: 20–27.5) (bpm) ($p < 0.05$).
**Conclusions:** Use of ECCO2R to facilitate lung prospective ventilation strategy was feasible. Catheter 14.5F size should be used for patients supported with ECCO2R with Prismax machine and PrismaLung + to achieve maximum blood flow to promote enhanced elimination of carbon dioxide.

### PEEP calculation: comparison of the best compliance method vs the pulmonary elastic recoil formula in patients with ARDS secondary to SARS-CoV-2 infection. A retrospective study

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000767

**Introduction:** In patients with moderate-severe ARDS secondary to SARS-COV-2 infection who were under mechanical ventilation, it is necessary to carry out adequate titration of PEEP within the management. Currently, various methods are available, we focus the study on two useful methods that can be carried out in any center. The use of the best compliance method has been described previously and it is an effective approach to obtain adequate PEEP that will maintain lung protective goals. It is proposed that the simplified formula below for pulmonary elastic recoil pressure will serve as a new proposal within therapeutic measures.
PEEPel = P. Plateau -13.5 ± 2.
**Objectives:** Demonstrate that the calculation of PEEP through the pulmonary elastic recoil formula presents similar results compared to the best compliance method.
**Methods:** A Retrospective analysis was carried out with patients who presented moderate-severe ARDS secondary to SARS-CoV-2 infection who were under mechanical ventilation. As a process study where PEEP was obtained by better compliance, the calculation was compared with the initial plateau pressure with statistical test, frequencies, percentages, and interquartile range. For the comparison between both methods, Rho of Spearman was used.
**Results:** One hundred eighty-four ARDS patients under mechanical ventilation were included; to whom PEEP titration was performed by both methods described, the correlation performed by Rho Spearman's method of 0.426 with statistical significance < 0.001, with lower confidence intervals of 0.296 and upper confidence interval of 0.541. Demographic values: mean age 60 ± 12.7, male predominance 143 (77.7%), a mean SOFA score 6 (2, 8), APACHE II 12 (8,19), SAPS II 27.5 (22, 43).
**Conclusions:** With the previous results, there is a correlation between both methods for the titration of the appropriate PEEP, however, the use of the formula in this study was carried out with the plateau pressure established for a better compliance method. It would be recommended to carry out a prospective study in the same patient population, with a basal plateau pressure to evaluate as a new easily accessible PEEP titration method option for the future.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000768

**Introduction:** ICU survivors often suffer long-lasting physical, psychological, and cognitive impairments termed PICS as a consequence of their critical illness (Inoue et al., 2019; Needham et al., 2012). Rehabilitation to prevent and/or reduce the negative effects of critical illness starts in the hospital and continues post-discharge from the hospital (Hodgson et al., 2021). While active mobilization in the ICU is well investigated (Hodgson et al., 2022; Schweickert et al., 2009), less is known about the rehabilitating effects of cognitive, sensory and socially stimulating activities (Collet et al., 2023).
**Objectives:** To explore and describe current early rehabilitation practices among Scandinavian ICU healthcare professionals.
**Methods:** From September 2022 to June 2023, we conducted a multicenter, electronic survey among healthcare professionals working full- or part-time in Danish, Swedish or Norwegian ICUs. Participants were asked to describe what they perceived as rehabilitation during and after the patient's ICU stay, and asked to quantify the importance and time used within six a priori defined domains: Cognitive, physical, sensory and social stimulation, participation in personal care and other rehabilitation interventions. Quantitative data were summarized in absolute numbers and percentages using STATA (StataCorp, 2021), and qualitative data were analyzed using the framework method (Gale et al., 2013). Assessment by an ethical committee followed national legislation. The study was registered at VIA University College, Aarhus, Denmark.
**Results:** A total of 518 participants responded to the questionnaire, 78% were nurses, and the remaining were physiotherapists, physicians, occupational therapists, and others. Rehabilitation began at ICU admission (70%) when the patient was ABC stable (19%) or at least circulatory stable (7%). Participants reported spending approximately 40% of their working time on rehabilitating activities and estimated that about 90% of all patients would benefit from rehabilitation.
Cognitive stimulation was considered highly important and involved communication activities, activities of daily living, television and radio, and delirium prophylaxis. Physical stimulation consisted of physiotherapy, mobilization (sitting on the bed, standing), training and activities of daily living, and visiting outdoors in a wheelchair or hospital bed. Rehabilitation activities progressed from passive to active, balancing rest and activities and aimed at strengthening the patient's autonomy, self-management, and will to recover. Family members were seen as important to the patient's rehabilitation.
**Conclusions:** In Scandinavia, ICU rehabilitation starts at ICU admission and progresses as the patient regains strength, with attention to balancing rest and activity. Involvement in cognitive and socially stimulating activities and activities of daily living are seen as important for helping the patient towards rehabilitation and independence.

**Introduction:** Rocking motion therapy has been shown to calm people with dementia but has never been investigated in delirious patients in the intensive care unit (ICU).
**Objectives:** The aim of the RockingICU trial was to investigate the efficacy and safety of a rocking motion versus non-rocking motion chair on the duration of delirium and intensity of agitation in ICU patients with delirium. We hypothesised that rocking motion therapy would increase the number of days alive without coma or delirium at 14 days of follow-up.
**Methods:** In this multicentre, investigator-initiated, parallel-group trial we randomly assigned delirium-positive adult ICU patients to a minimum of 20 min rocking motion therapy or a minimum of 20 min in the same chair without rocking motion daily. The primary outcome was days alive without coma or delirium two weeks after randomisation. Secondary outcomes were the number of days alive and without life support, ICU length of stay, and the number of participants that received antipsychotics, sedatives, or benzodiazepines during the intervention, and the number of times the intervention was discontinued.
**Results:** We enrolled 149 patients; 73 were randomly assigned to rocking motion therapy and 76 to non-rocking motion therapy. Primary outcome data were available in 141 patients. The median number of days alive without coma or delirium after 14 days was 8.8 days (interquartile range, 1.0–13.0) in the rocking motion group and 9.4 days (1.0–13.0) in the non-rocking motion group, with a mean difference of −0.73 days (95% confidence interval: −2.05 to 0.58; $p=0.28$). At day 14, 8 of the 70 participants (11.4%) in the rocking motion group had died and 10 of the 70 participants (14.2%) in the non-rocking motion group (risk difference −2.28%-points, 95% CI −13.63 to 8.85, $p=0.69$).

The mean difference in the number of days with coma and delirium between the rocking motion group and the non-rocking motion group was 0.40 days (95% CI −0.67 to 1.68, $p = 0.42$). There were no statistically significant differences between groups in the number of days alive and without life support, ICU length of stay, and the number of participants that received antipsychotics, sedatives, or benzodiazepines during the intervention. In total, 11/70 (15.7%, 99% CI 6.4–29.9) in the rocking therapy group and 7/71 (9.9%, 99% CI 3.0–22.5) in the non-rocking group had the intervention stopped earlier than the protocolised 20 min at least once (risk difference 5.82%-points, 99% CI −7.73 to 19.42, $p = 0.27$).

**Conclusions:** Among patients with delirium in the ICU, the use of rocking motion therapy did not lead to a statistically significantly greater number of days alive without coma or delirium at 14 days than non-rocking motion therapy. More patients aborted the intervention in the rocking motion therapy group than in the non-rocking motion therapy group. The reasons for discontinuation appeared to be unrelated to the intervention.

## Relevant predictors of HFNO failure and the effect of flow rate—a machine learning-based approach

P. Hilders, P. Elbers, M. Otten, T. A. Dam, L. A. Biesheuvel, A. Jagesar[1]
Intensive care adults, Amsterdam UMC, locatie VUmc, Amsterdam, Netherlands

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000774

**Introduction:** Due to the risk of complications involved in the process of endotracheal intubation (ETI) and the subsequent positive pressure ventilation [1, 2], clinicians typically strive to mitigate the need for invasive ventilation by considering non-invasive respiratory support modalities, such as non-invasive ventilation (NIV) or high-flow nasal oxygen (HFNO) [3]. Given the unclear effects of intubation timing on clinical outcomes, gaining a deeper understanding of the risk factors that drive the need for escalation to intubation could help the clinician ascertain whether prolonged non-invasive treatment will lead to a desirable outcome.

Therefore, the present study aims to identify and validate the most important predictors for intubation risk in critically ill patients who receive HFNO, and to evaluate the effect of flow rate on relevant clinical outcomes and HFNO failure.

**Methods:** In this study, we employed several machine learning-based approaches to predict the risk of HFNO failure, which we defined as the need for escalation of respiratory support treatment or patient mortality, within 4 h after discontinuation of HFNO treatment. The primary dataset in this study was extracted from the MIMIC-IV database, which contains high-resolution, deidentified medical data from approximately 300,000 patients. Additionally, we extracted a secondary validation dataset from the Dutch Data Warehouse (DDW), a large multicenter data warehouse containing data from 3464 critically ill COVID-19 patients in the Netherlands.

For our machine learning models, we used logistic regression, random forest, decision trees, and XGBoost. After training the models, we performed evaluation using sensitivity, specificity, accuracy, and AUROC scores and visualised the most relevant predictors using SHapley Additive exPlanations (SHAP).

To evaluate the effect of flow rate on the risk of HFNO failure, we used propensity score matching and a Cox Proportional Hazards analysis.

**Results:** In our experiments, 779 patients from the MIMIC-IV database and 239 patients from the DDW dataset were included for subsequent analysis. Using the primary MIMIC-IV dataset, the XGBoost model yielded the highest performance with an AUROC score of 0.72 (0.67–0.77), outperforming logistic regression (AUROC 0.69 (0.63–0.74)), random forest (AUROC 0.69 (0.62–0.76)), and the decision tree (AUROC 0.61 (0.51–0.71)). The SHAP visualisation revealed that the most important predictors of HFNO failure were APS-III score, sepsis, urine output, weight, and mean SpO2 (Fig. 1).

When using the DDW validation dataset to both train and evaluate an XGBoost prediction model, the model achieved an AUROC of 0.64 (0.52–0.75). In contrast, when the best-performing model from the primary MIMIC-IV dataset is evaluated on the DDW validation dataset, the model yielded an AUROC score of 0.61.

Furthermore, our analysis shown in Figure 2 revealed a significantly higher risk of HFNO failure (Hazard ratio 4.99 (2.30–10.84), $p < 0.005$) among patients who received a relatively high flow rate ($\geq$ 40L/min). This effect persisted even after compensating for potential confounding effects through propensity score matching.

**Conclusions:** This study underscores the predictive value of sepsis diagnosis, APS-III score, urine output, admission weight, and average $SpO_2$ in anticipating the risk of HFNO failure, even before treatment initiation. In addition, our findings suggest that, in propensity score-matched cohorts, patients requiring higher flow rates are at a significantly elevated risk of HFNO failure. These results may aid critical care professionals in making better-informed decisions regarding the potential gain of providing HFNO therapy for critically ill patients and regarding the appropriate timing of respiratory support escalation to invasive ventilation.

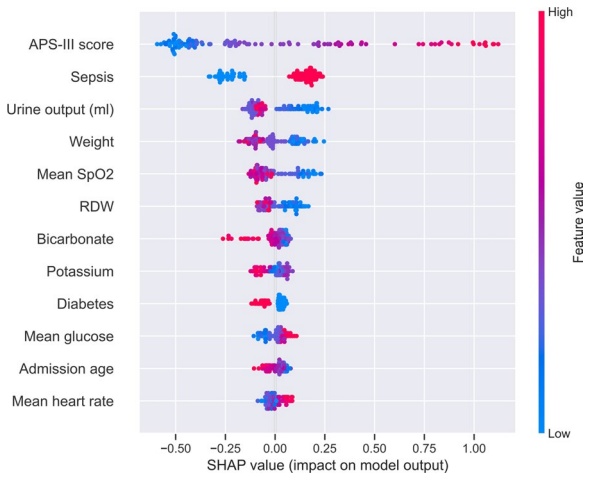

**Fig. 1 (abstract 000774)** A visualisation of SHAP values for the most relevant predictors of HFNO failure, using a trained XGBoost prediction model. A higher SHAP value corresponds to a higher likelihood of the model predicting that HFNO failure will occur. APS-III: Acute Physiology Score III, RDW: red blood cell distribution width, $SpO_2$: oxygen saturation

**Introduction:** More children are surviving to adulthood with life-limiting conditions or complex health needs. They may require admission to adult critical care units either during the transition phase or soon afterwards. A recent UK national report (1) highlighted how the process of transition is often fragmented and challenging for patients, relatives, and healthcare teams. Despite national guidelines defining a process to help patients transition between paediatric and adult critical care services (2), established pathways do not currently exist in our area. Critical Care input into the transition process is vital to ensure patient-centered care plans can be agreed, and to prepare the patient and their family for the different environments of the adult unit.
**Objectives:** To identify patients aged 16–19 years old admitted to our Critical Care service who transitioned from paediatric care with complex medical needs or a life-limiting condition. To help define the patient cohort that may benefit from a bespoke Critical Care transition pathway.
**Methods:** We retrospectively identified patients aged 16 to 19 years old who were admitted to the 3 Critical Care units within our Trust from March 2018 to October 2023. We sourced our data from the national ICNARC audit database. We interrogated electronic and paper notes to identify patients with complex, multispecialty or life-limiting conditions, and assessed the level of organ support required and outcomes.
**Results:** 560 patients meeting our age and timeframe criteria were admitted. Of these, 492 were excluded as their admissions were due to trauma or elective admissions unrelated to an underlying complex health condition.
Of the 68 patients that we identified as having complex multisystem disease, the mean age of the cohort was 17.87 years, with an equal split of males and females. 48 patients were emergency admissions, and 20 elective surgical admissions were related to their complex health condition. For example, one patient was admitted for elective cardiac surgery and had underlying Loeys-Dietz syndrome causing cardiac pathology.
The median ITU length of stay (LOS) was 3.5 days (range 0.1 to 404.3 days) and median hospital LOS was 9.5 days (range 1 to 409 days). 33 patients required advanced respiratory support, 18 required advanced cardiovascular support and 8 patients required renal support.
84.0% of the patients survived to discharge from ITU, with 83% surviving to hospital discharge. 85% of the emergency patients survived to ITU discharge, with 83% surviving to hospital discharge, and 81% alive 1 year after ITU discharge.
**Conclusions:** Young patients with complex medical conditions may require ITU support as they survive into adulthood. Most of this cohort has good outcomes in terms of survival and relatively short-term ITU requirements. We can now look at how we can adapt our services to better predict and prepare for paediatric patients with complex medical conditions requiring adult critical care services.

### Skill Mix in the Intensive Care Unit

A. van Esch, M. Van Mol
Departement of Intensive Care, Erasmus University Medical Center, Rotterdam, Netherlands
**Correspondence:** A. van Esch
*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000776

**Introduction:** The shortage of nursing staff in intensive care units (ICUs) is a well-documented worldwide challenge [1]. Contributing factors include excessive workload, moral distress, and perceived failings in providing quality patient care. Innovative approaches are needed to sustain nursing care, especially in high-stress environments such as ICUs [2]. New care models, involving skill mix among specialized nurses and carers, could reduce workload and offer opportunities to grow in clinical leadership for ICU nurses and potentially improve quality of care.
**Objectives:** This study aims to explore the experiences of ICU nurses in a pilot project with the start of carers in an integrated team, with a focus on skill mix, quality of care, and job satisfaction.
**Methods:** The design of the study was a quantitative cross-sectional survey at two-time points in a tertiary hospital. The self-developed questionnaires were sent digitally at a three-month interval to all ICU nurses and nurse trainees of two pilot ICUs. Questionnaire 1 primarily focused on assessing opinions and attitudes regarding skill mix in the ICUs, as well as the involvement of carers. Questionnaire 2 evaluated the implementation of a skill mix and the integration of carers into

the nursing team. The study population comprised a total of 119 ICU nurses. Data were analyzed using descriptive statistics.
**Results:** A total of 95 (80%) participants completed questionnaire 1 prior to the pilot project. The majority (72%) was positive about the involvement of carers within the team and 81% reported that various care tasks in the ICU were suitable to differentiate in a skill mix. However, 54% expressed concerns about maintaining the quality of care, and 52% expected that patient safety might be compromised. Almost all (96%) were satisfied with their work as ICU nurses.
After the start of carers in the ICU team, 58 participants completed questionnaire 2 (49%). Collaboration with carers was perceived positively (83%), and 52% reported that carers were clear about their skills and tasks related to ICU care. However, 83% did not experience a reduction of workload, nor additional time to grow in clinical leadership due to the integration of carers. The majority (59%) expressed concerns about maintaining quality of care. Job satisfaction remained high (97%).
**Conclusions:** ICU nurses initially report a positive attitude towards interprofessional collaboration and a skill mix within the ICU teams. However, this enthusiasm is tempered by practical challenges, including concerns about the maintenance of care quality and potential mismatches between the competencies of carers and the demands of an ICU environment. These challenges may hinder ICU nurses' professional advancement and, thus, threaten the sustainability of the nursing workforce.

### Effects of high-protein, arginine and glutamine supplementation of enteral nutrition on pressure ulcers in critically ill patients: A primary report of a randomised trial

L. Ferlicolak, E. M. Erener, N. D. Altintas
Internal Medicine Division of Intensive Care Medicine, Ankara University Faculty of Medicine, Ankara, Turkey
**Correspondence:** L. Ferlicolak
*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000777

**Introduction:** Pressure ulcers (PUs), especially in critically ill elderly patients, are recognised as a significant problem. Due to the increased metabolic demands of repairing tissue damage, the presence of PUs in the critically ill has implications for nutritional management.
**Objectives:** This study aimed to evaluate the effect of nutrition supplemented with high protein, arginine, and glutamine on PUs in critically ill patients.
**Methods:** We prospectively collected data from patients with PUs in the ICU who were fed enterally with high protein, arginine, and glutamine (Impact Glutamin®) or standard formula. Patients were included in the study if they were haemodynamically stable, not in shock, and had received a target dose of standard formula feeding. Patients were randomly assigned to the study or control group. Unfortunately, we did not have indirect calorimetry. Therefore, the caloric requirements of all patients were calculated and given according to the formula (30 kcal/kg/day). After admission to the study we checked and noted PUs' sizes weekly (1st,2nd,3rd).
**Results:** Ten patients were included in the study. The mean age was 81.7 and 6 (60%) were female. The mean Charlson Comorbidity Index was 6.9, APACHE II score was 31.6 and the admission SOFA score was 7.9. The most common admission diagnosis was sepsis in 6(60%) patients. Except for one patient, all had a high risk for malnutrition (mean mNUTRIC score was 7.3). The mean body mass index was 23.62. According to randomization, 4 patients were in the study group. In the study group, all PUs had a reduction of at least 2 cm (min 2 cm-max 8 cm) in each diameter after 3 weeks. In contrast, only 2 PU in the control group showed a decrease in diameter over the study period. In addition, two others increased in diameter and the remaining two were stable. ICU mortality was 40% and hospital mortality was 60%.
**Conclusions:** We have observed that the healing of PUs in critically ill patients is improved by a diet supplemented with protein, arginine, and glutamine. While standard care of PUs with the use of appropriate wound care products and regular repositioning is the mainstay of treatment, special nutritional formulas may be effective in the management of PUs.

### Comparing cipepofol and propofol for sedation in ICU patients with hypotension: a single center prospective cohort study

Z. Zeng, Z. He
Department of Critical Care Medicine, Nanfang Hospital, Guang Zhou Shi, China
**Correspondence:** Z. he
*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000778

**Introduction:** ICU physicians often use sedative medications to manage agitation and minimize its negative consequences. Multiple clinical studies have demonstrated that the novel sedative drug cipepofol has sedative effects that are not inferior to propofol and can reduce the incidence of cardiovascular adverse events. Currently, there is limited research on the use of cipepofol for sedation in ICU patients, and its application in ICU patients with hypotension has not been reported.
**Objectives:** This study aims to investigate the effectiveness of cipepofol in sedating ICU hypotensive patients, and further explore its impact on the dosage of vasopressor drugs.
**Methods:** Clinical data were prospectively collected from patients requiring sedation and concomitant use of vasoactive drugs to maintain MAP $\geq$ 65 mmHg in the ICU ward of the Department of Intensive Care Medicine at Southern Hospital. The primary endpoint was the success rate of sedation in both groups, and the corresponding between-group rate differences and 95% confidence intervals were estimated according to the Newcombe-Wilson method. Propensity score matching (PSM) analysis was used to match patients receiving cipepofol to propofol. The Cox proportional hazards, logistic regression, and linear regression models were used to assess the association between cipepofol and outcomes.
**Results:** In both the cipepofol group and the Propofol group, 295 patients (97.0%) and 148 patients (97.4%) successfully achieved the required level of sedation during over 70% of the study period without any rescue therapy. The difference between the two groups was -0.33%, and the 95% CI for the rate difference was (-3.51%, 2.85%), falling within the equivalence margin of (-10%, 10%), indicating that the sedative effect of Cipepofol is equivalent to that of Propofol. Additionally, the dose of norepinephrine used in the Cipepofol group was significantly lower than that in the Propofol group (5.75 vs 9.62 μg/kg/h, $P < 0.001$). A total of 214 patients in the Cipepofol group and 128 patients in the Propofol group completed the propensity score matching. Despite a statistically significant difference in norepinephrine dosage reduction associated with the use of cipepofol (6.67 vs 10.01 μg/kg/h; $P = 0.02$), but it did not improve patients' duration of mechanical

ventilation (5.25 days vs 6.7 days,HR 0.94, $P=0.3$) or ICU mortality rate (11.2% vs 13.2%,HR 0.67, $P=0.24$).

**Table 1 (abstract 000778)** Association between sedation administration and clinical outcomes in critically ill patients with hypotension

| | Unmatched Patients | | | | Propersity-scores-matched Patients | | | |
|---|---|---|---|---|---|---|---|---|
| | Cipepofol (n = 304) | Propofol (n = 152) | HR (95 %CI) | *P* value | Cipepofol (n = 214) | Propofol (n = 128) | HR (95% CI) | *P* value |
| Dosage of sedation drugs, mg/kg/h | 2.24[1.81, 2.73] | 1.98 [1.64, 2.48] | 1.26 [1.10, 1.44] | 0.001 | 2.26 [1.84, 2.77] | 2.00 [1.67, 2.50] | 1.25 [1.08, 1.45] | 0.004 |
| Dosage of analgesic drugs, μg/kg/h | 1.82 [1.35, 2.51] | 1.72 [1.39, 2.68] | 1.39[0.81, 1.51] | 0.58 | 1.84 [1.32, 2.55] | 1.72 [1.43, 2.48] | 1.35 [0.871, 1.46] | 0.52 |
| Dosage of norepinephrine, μg/kg/hc | 5.75[1.81, 17.52] | 10.01[4.96, 24.38] | 0.59 [0.43, 0.79] | 0.03 | 6.67[2.33, 20.35] | 10.01[4.44, 23.74] | 0.68 [0.44, 0.87] | 0.02 |
| Duration of MV, day | 4.50[1.60, 10.72] | 5.80 [3.42, 10.75] | 0.90[0.66, 1.51] | 0.37 | 5.25[1.83, 12.38] | 6.70 [3.58, 10.93] | 0.94 [0.76, 1.26] | 0.30 |
| ICU mortality, n(%) | 29 (9.7) | 22 (14.7) | 0.63[0.35, 1.14] | 0.13 | 24 (11.2) | 17 (13.2) | 0.67[0.34 −1.29] | 0.24 |

The dosage of analgesic drugs were presented and compared using MED10(10mg Morphine equivalent dosing), including remifentanil, morphine, esketamine, hydromorphone.

Cox regression was used for estimating the impact of Ciprofol use on mortality outcomes adjusting for confounding variables, including age, gender, BMI, APACHE II scores, SOFA scores, baseline creatinine and ALT.

Linear regression was used to evaluate the association between Ciprofol use and sedation drugs, analgesic drugs, norepinephrine or duration of MV. HR was calculated using the formula HR = eβ.

**Conclusions:** In hypotensive patients in the ICU who received sedation within 24 h, the sedative effect of Cipepofol is equivalent to propofol, and it can reduce the dosage of norepinephrine used.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000779

**Introduction:** In recent years, extracorporeal blood purification (EBP) therapies have emerged as a promising treatment modality aimed at modulating the inflammatory response in sepsis (1–3).

**Objectives:** We aimed to retrospectively compare the clinical, laboratory values and mortality of patients with COVID-19 and non-COVID-19 who received EBP therapies for sepsis.

**Methods:** Patients admitted to the intensive care unit (ICU) with a diagnosis of sepsis and undergoing EBP therapy between March 2020 and May 2022 were retrospectively evaluated through hospital data with the approval of the local Ethics Committee. Septic patients were categorized into two groups based on etiology: those admitted

with COVID-19 etiology (EBP COV) and those admitted with etiologies other than COVID-19 (EBP Non-COV). The groups were compared in terms of clinical and laboratory results before and after EBP therapy.
**Results:** In the EBP COV group, 193 patients were included, whereas the EBP Non-COV group comprised 108 patients. Demographic and clinical characteristics of the cases in the groups are shown in Table 1. Before EBP therapy, neutrophil–lymphocyte ratio (N/L), lactate dehydrogenase (LDH) and D-dimer levels were higher, C-reactive protein (CRP), lymphocyte, and procalcitonin (PCT) levels were lower in the EBP COV group compared to the other group ( $p < 0.05$). Evaluation of post-EBP therapy laboratory changes revealed a significant decrease in ferritin and interleukin-6 levels in the EBP COV group, and a significant decrease in procalcitonin and white blood cell levels in the EBP Non-COV group ($p < 0.05$). Changes in LDH, D-dimer, lymphocyte, N/L, and lactate levels were not significant in both groups ($p > 0.05$), whereas CRP and platelet changes were significant in both groups ($p < 0.05$).

**Table 1 (abstract 000779)** Comparisons of Characteristics of the Patients

| | | EBP COV (n = 193) | EBP Non-COV (n = 108) | P |
|---|---|---|---|---|
| Gender | Female | 41 (%21.2) | 30 (%27.8) | 0.200 a |
| | Male | 152 (%78.8) | 78 (%72.2) | |
| Age (years) | | 61.1 ± 11.8 | 54.6 ± 16.4 | **< 0.001** b |
| LOS in ICU (days) | | 15.8 ± 8.8 | 22.1 ± 16.8 | **< 0.001** b |
| Prognosis | Death | 124 (%64.2) | 69 (%63.9) | 0.950 a |
| | Discharge | 69 (%35.8) | 39 (%36.1) | |
| Days in Ventilator | | 7.7 ± 8.7 | 14.6 ± 15.0 | **< 0.001** b |
| Respiratory Therapy | Mask | 1 (%0.5) | 11 (%10.2) | **< 0.001** a |
| | HFNO | 67 (%34.7) | 8 (%7.4) | |
| | IMV | 125 (%64.8) | 89 (%82.4) | |
| Time between admission- EBP (days) | | 5.3 ± 3.2 | 10.2 ± 10.4 | **< 0.001** b |
| APACHE II | | 27.4 ± 10.5 | 27.1 ± 8.5 | 0.831 b |
| SOFA | | 5.8 ± 2.0 | 6.9 ± 2.1 | **< 0.001** b |

EBP COV: Extracorporeal Blood Purification COVID, EBP Non-COV: Non COVID, LOS: Length of Stay, ICU: Intensive Care Unit, HFNO: High Flow Nasal Oxygen, IMV: Invasive Mechanical Ventilation, APACHE: Acute Physiology and Chronic Health Evaluation, SOFA: Sequential Organ Failure Assessment, a: Chi-square Test (n/%), b: Independent Samples t Test (Mean ± SD).
**Conclusions:** In non-COVID patients, despite the later EBP therapy, higher pre-treatment CRP, PCT levels and SOFA scores, and longer duration of stay in the ventilator and ICU, the mortality rates of septic Covid and non-Covid patients who received EBP therapy were similar.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000780

**Introduction:** Delirium is a neurobehavioral syndrome characterized by alterations in cognitive functions, attention, and consciousness, along with increased or decreased psychomotor activity and irregularities in the sleep–wake cycle. It has a high incidence in the intensive care units. The use of the Confusion Assessment Method for the Intensive Care Unit (CAM-ICU) is recommended for delirium Screening in intensive care units.
**Objectives:** The primary aim of this study is to determine the incidence and risk factors of delirium in patients admitted to the intensive care unit using the CAM-ICU scale. The secondary aim is to record the clinical and epidemiological characteristics of patients, assess the outcome of delirious patients in the intensive care unit and establish the impact of delirium on morbidity and mortality.
**Methods:** A total of 128 patients aged 18 and older, with a Richmond Agitation- Sedation Scale (RAAS) score ≥ -3 and Glasgow Coma Scale (GCS) score > 7 who responded to verbal stimuli, were included in the study. The CAM-ICU scale was applied daily to patients until a positive result was obtained or until they were discharged from the intensive care unit. Clinical follow-up continued until the patients were discharged from the intensive care unit.
**Results:** The study involved the application of the CAM-ICU scale to patients an average of 3 times (IQR 2–5) with delirium detected in 27 (%21,1) out of 128 patients on the 2nd day (IQR 1–4) of their hospitalization. The median age of patients was 66 years (IQR 53–75) and 58.6% (n = 75) were male. Advanced age, the implementation of restraints, low GCS at admission, high APACHE II and SOFA scores at admission, lack of visits, sleep deprivation, elevated levels of troponin and pro-BNP, and a history of malignancy or lung disease were identified as risk factors. Delirious patients were observed to have longer stays in the intensive care unit and a higher mortality rate.
**Conclusions:** The findings of this study identified risk factors involved in the incidence and development of delirium in the intensive care unit. Delirium prolongs the length of stay in the intensive care unit and increases mortality. To reduce the incidence of delirium, these identified risk factors, shown to be effective by routine screening with CAM-ICU, should be recognized and preventive measures should be taken in intensive care units**.**

**Topic:** Sedation, analgesia and delirium

## 000781 Acute kidney injury in patients with out-of-hospital cardiac arrest receiving extracorporeal cardiopulmonary resuscitation: a retrospective multicenter study in Japan

A. Inoue, T. Taira, K. Yamashita, T. Nishimura, S. Ijuin, S. Matsuyama, S. Ishihara

**Introduction:** Acute kidney injury (AKI) is frequently found in intensive care unit (ICU) and is associated with unfavorable outcomes. However, little is known about AKI in patients with out-of-hospital cardiac arrest (OHCA) receiving extracorporeal cardiopulmonary resuscitation (ECPR).
**Objectives:** This study aimed to examine the incidence of AKI and the association between AKI and mortality in patients with OHCA receiving ECPR.
**Methods:** We performed a secondary analysis of the SAVE-J II study, a retrospective multicenter study of OHCA patients ≥ 18 years treated with ECPR between 2013 and 2018. Adult patients with OHCA of presumed cardiac etiology who were admitted to ICU were included. AKI was defined as the patients' serum creatinine level within 4 days after ICU admission according to Kidney Disease Improving Global Outcomes (KDIGO) stages. The primary outcome was in-hospital mortality.
**Results:** Of 2,157 patients registered in the SAVE-J II study, 943 patients were ultimately included for analyses. The median age was 60 years (interquartile range: 48–68), 83.5% of patients were men, and in-hospital mortality was 56.1%. AKI was observed in 631 patients (66.9%) within 4 days after ICU admission. Multivariable analysis showed that AKI was significantly associated with in-hospital mortality (odds ratio [OR], 4.15; 95% confidence interval [CI], 3.05–5.66; $p < 0.001$). Furthermore, compared with KDIGO 1 stage, KDIGO 2 and 3 stage was associated with a higher in-hospital mortality rate (KDIGO 2 OR, 2.64; 95% CI, 1.67–4.17; $p < 0.001$, KDIGO 3 OR, 3.72; 95% CI 2.42–5.71; $p < 0.001$).
**Conclusions:** AKI was commonly recognized in the acute phase and associated with in-hospital mortality in patients with OHCA receiving ECPR.

**Topic:** Acute Kidney Injury and haemofiltration.

## 000782 History of cancer diagnosis in critically ill sepsis patients: a nationwide register-based cohort study in Sweden

A. But[1], G. Strandberg[2], M. Lipcsey[3], J. Hästbacka[4]
[1]Faculty of Medicine, University of Eastern Finland, Kuopio, Finland, Helsinki, Finland; [2]Intensive care unit, department of surgical sciences, Uppsala University Hospital, Uppsala, Sweden; [3]Surgical sciences, Uppsala University, Uppsala, Sweden; [4]Anaesthesiology and Intensive Care, Tampere university, Tampere, Finland
**Correspondence:** J. Hästbacka
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000782

**Introduction:** Frequently co-occurring sepsis and cancer share common risk factors and pathophysiological features (1). Moreover, the immunosuppression effect of cancer therapy increases the risk of infection and sepsis (2). Cancer patients are at an increased risk of sepsis especially within the first year after cancer diagnosis (3). On the other hand, a recent study reported an increased incidence of cancer among sepsis survivors (4). However, little is known on the prevalence of cancer among sepsis patients compared to the general population.
**Objectives:** To assess the overall and site-specific prevalence of cancer in sepsis patients relative to the general population.
**Methods:** Sepsis patients treated in the intensive care units between 2005 and 2017 (N = 36 824) were identified from the Swedish Intensive care registry using ICD-10 code for sepsis. The study cohort included those aged ≥ 20 years and was linked with cancer data (2001–2017). We compared the 1- and 5-year observed prevalence of cancer in the sepsis cohort to that expected according to the NORDCAN statistics (5) for the general Swedish population using standardized (age and calendar year) prevalence ratios (SPR).
**Results:** Median age at sepsis was 69 years (IQR 60–78), 57.5% were men, 7890 (21.4%) had at least one cancer diagnosis within the preceding five years and 3210 (8.7%) had ongoing cancer treatment. The proportion of those with a history of cancer remained the same over time (Fig. 1). Overall, 9696 cancer diagnoses were set within five years before sepsis, of which 5234 were within one year before sepsis. Colorectal (21%), hematological (19%), nonmelanoma skin (15%), prostate (8%), and breast (5%) cancers were the most common. The overall 1- and 5-year SPRs were 5.73 (95% CI 5.53–5.94) and 2.78 (2.70–2.85) in men; 5.38 (5.14–6.63) and 2.55 (2.46–2.64) in women. A higher prevalence was seen for a wide range of cancer sites; the 1-year SPRs tended to be higher than 5-year SPRs (Figs. 2, 3). The former varied in men from 1.16 (1.03–1.31) for prostate cancer to 20.14 (15.22–26.65) for gallbladder cancer; in women from 1.27 (1.07–1.50) for breast cancer to 18.23 (12.50–26.59) for cancer of esophagus. A lower 5-year prevalence was seen for prostate (0.81, 0.76–0.87) and breast (0.77, 0.69–0.85) cancers.
**Conclusions:** Those with a history of cancer are highly overrepresented among critically ill sepsis patients compared to the general population. Almost all cancer forms contribute to the increased prevalence. Slightly over half of cancer diagnoses are set within one year before sepsis.

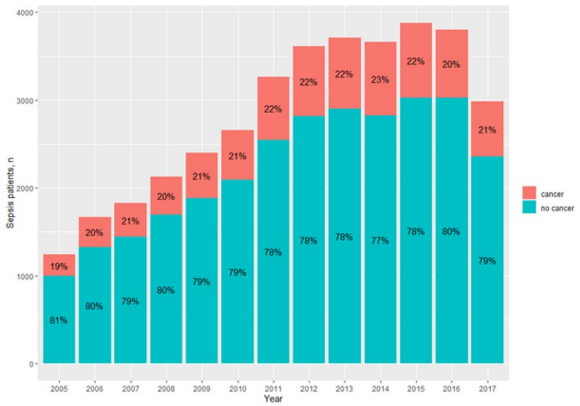

**Fig. 1 (abstract 000782)** Number of sepsis patients by calendar time and proportion with/without history of cancer before sepsis

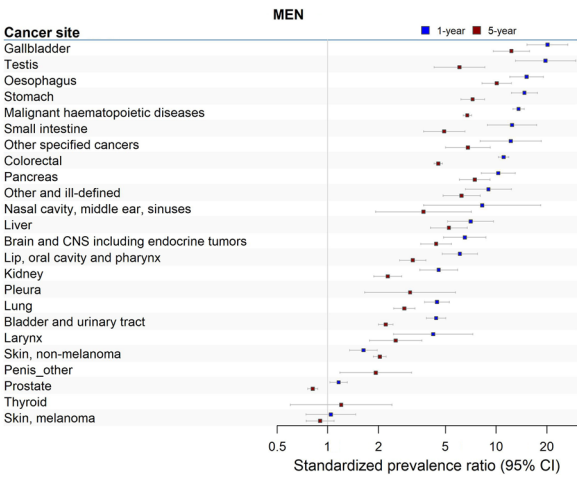

**Fig. 2 (abstract 000782)** SPRs by cancer site in men for cancers diagnosed within one and five years before sepsis

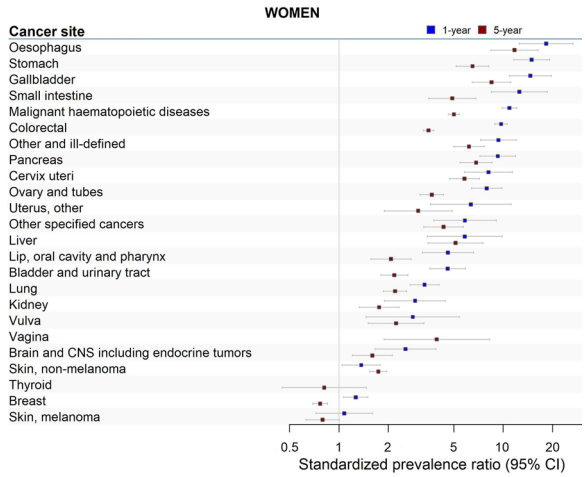

**Fig. 3 (abstract 000782)** SPRs by cancer site in women for cancers diagnosed within one and five years before sepsis

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000786

**Introduction:** Respiratory effort should be closely monitored in mechanically ventilated ICU patients to avoid both overassistance and underassistance. Surface electromyography of the diaphragm (sEMGdi) offers a continuous and non-invasive modality to assess respiratory effort based on neuromuscular coupling (NMCdi) [1, 2]. The sEMGdi-derived electrical activity of the diaphragm (sEAdi) has potential as a non-invasive alternative for respiratory effort monitoring, as compared to invasive modalities based on oesophageal pressure and invasive diaphragm EMG. Widespread use in clinical practice is currently limited, as the sEMGdi signal is prone to distortion by crosstalk, from the heart and other muscles [3].
**Objectives:** We developed an advanced analysis as well as quality criteria for sEAdi waveforms and investigated the effects of clinically relevant levels of PEEP on non-invasive NMCdi.
**Methods:** NMCdi was derived by dividing end-expiratory occlusion pressure (Pocc) by sEAdi, based on three consecutive Pocc manoeuvres at four incremental (+2 cmH2O/step) PEEP levels in stable ICU patients on pressure support ventilation. Measurements were repeated every other day until successful extubation. Pocc and sEAdi quality was assessed by applying a novel, automated advanced signal analysis, based on tolerant and strict cut-off criteria, and excluding inadequate waveforms. The coefficient of variations (CoV) of NMCdi was evaluated after basic manual and automated advanced quality assessment. The effect of an incremental PEEP trial on NMCdi was examined using Generalised Estimating Equations (GEE).
**Results:** 593 manoeuvres were obtained from 42 PEEP trials in 17 ICU patients. Waveform exclusion was primarily based on low sEAdi signal-to-noise ratio (Ntolerant = 155, 37%, Nstrict = 241, 51% waveforms excluded), irregular or abrupt cessation of Pocc (Ntolerant = 145, 35%, Nstrict = 145, 31%), and high sEAdi area under the baseline (Ntolerant = 94, 23%, Nstrict = 79, 17%). Strict automated assessment allowed to reduce CoV of NMCdi to 15% from 37% for basic quality assessment (Fig 1). As PEEP was increased, NMCdi decreased significantly by 4.9 percentage point per $cmH_2O$ (Fig 1).
**Conclusions:** Advanced signal analysis of both Pocc and sEAdi greatly facilitates automated and well-defined identification of high-quality waveforms. In the critically ill, this approach allowed to demonstrate a dynamic NMCdi (Pocc/sEAdi) decrease upon PEEP increments, emphasising that sEAdi-based assessment of respiratory effort should be related to PEEP-dependent diaphragm function. This novel, non-invasive methodology forms an important methodological foundation for a more robust, continuous, and comprehensive assessment of respiratory effort at the bedside.

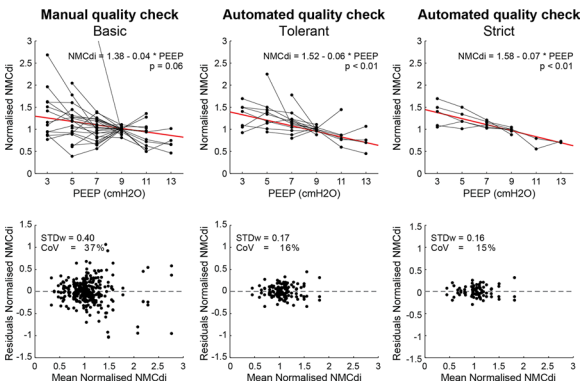

**Fig. 1 (abstract 000786)** Effect of PEEP and quality criteria on NMCdi – Top: PEEP effect on NMCdi. Black lines show the median NMCdi per PEEP level within a measurement session (one patient, one day). In red the GEE model is shown. Bottom: Residuals in NMCdi after subtraction of the mean NMCdi at that PEEP level for that patient at that day. NMCdi components PTPocc and ETPdi are unitless after normalisation to their median value at PEEP = 9 cmH2O

**Introduction:** Long-term cognitive and pulmonary impairments are frequent in intensive care unit (ICU) survivors admitted with severe hypoxaemic respiratory failure. However, there is still considerable uncertainty regarding the long-term effects of oxygen therapy in these patients[1]. A low partial pressure of arterial oxygen (PaO2) has been associated with reduced cognitive performance[2], while concerns exist about the potential harm to pulmonary function when pursuing higher oxygenation targets[3].
**Objectives:** To assess the effects of a PaO2 target of 8 kPa (lower target) versus a PaO2 target of 12 kPa (higher target) in ICU patients with acute hypoxaemic respiratory failure on one-year cognitive and pulmonary functions. We hypothesised that targeting a PaO2 of 8 kPa would aggravate cognitive impairment and reduce pulmonary impairment compared to targeting a PaO2 of 12 kPa.
**Methods:** In the present study we analysed two pre-specified one-year outcomes of the *Handling Oxygenation Targets in the ICU* (HOT-ICU) [4] trial and its amendment trial, *Handling Oxygenation Targets in COVID-19* (HOT-COVID)[5]. In the HOT-ICU trial 2928 adult ICU patients with acute severe hypoxaemia were randomised 1:1 to a lower versus a higher PaO2 target during the ICU stay up to 90 days, including re-admissions. The HOT-COVID trial tested the same interventions in 726 patients with confirmed COVID-19. One-year survivors, randomised at selected Danish sites, were eligible to participate in the present follow-up study. The Repeatable Battery for the Assessment of Neuropsychological Status (RBANS) and full-body plethysmography, including diffusion capacity for carbon monoxide (DLCO), were performed by blinded and trained research personnel. Primary outcome measures were the age-adjusted global cognitive score from the RBANS and the DLCO, presented as the percentage of the predicted value according to age, height, and sex. Analyses were conducted using a linear mixed model, accounting for the clustering of patients within the trials and sites.
**Results:** A total of 417 patients participated in one-year follow-up. The RBANS was performed in 189 patients in the lower-target group and 190 in the higher-target group; DLCO was obtained in 196 patients in the lower-target group and 198 in the higher-target group. The median RBANS global cognitive score was 79 (interquartile range (IQR), 66 to 99) in the lower-target group and 79 (IQR, 58 to 90) in the higher-target group (adjusted mean difference (MD): 2, 95% confidence interval (CI): -2 to 6, p = 0.41). Fig. 1 presents the RBANS performance in each intervention group stratified by the background age-adjusted mean. The median DLCO was 68% (IQR, 55 to 83%) in the lower-target group and 74% (IQR, 55 to 87%) in the higher-target group (adjusted MD: -5%, 95% CI: -9 to -1%, p = 0.007). Figure 2 presents DLCO by intervention group, categorised by severity.
**Conclusions:** In ICU patients with acute hypoxaemic respiratory failure, a lower oxygenation target of 8 kPa did not aggravate cognitive impairment but did worsen pulmonary impairment after one year compared to a higher oxygenation target of 12 kPa PaO2. Results should be considered exploratory only.

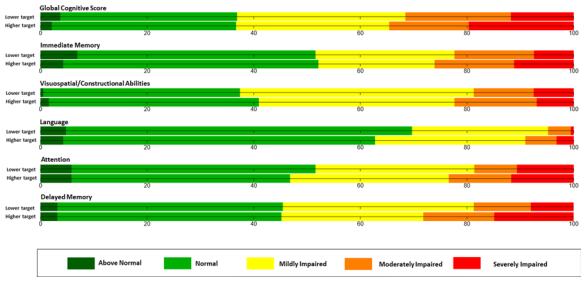

**Fig. 1 (abstract 000787)** Cognitive function
Distribution of the Repeatable Battery for the Assessment of Neuropsychological Status (RBANS) global cognitive scores and the index scores from the five domains (i.e. immediate memory; visuospatial/constructional abilities; language; attention; delayed memory). Scores are stratified into 5 categories according to the background age-adjusted cognitive performance: Above normal (> 115 points); Normal (85–115 points); Mildly impaired (70–84 points); Moderately impaired (55–69 points); Severely impaired (below ≤ 54 points). Presented by the oxygenation target group. Data from survivors participating in the RBANS test: n = 189 in the lower-target group; n = 190 in the higher-target group.

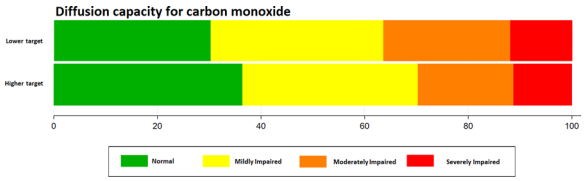

**Fig. 2 (abstract 000787)** DLCO
Distribution of diffusion capacity for carbon monoxide (DLCO) measurements according to the percentage of predicted value based on the Global Lung Function Initiative network equations: Normal (> 80%); Mildly impaired (60%–80%); Moderately impaired (40%–59%); Severely impaired (< 40%). Presented by the oxygenation target group. Data from survivors participating in lung function testing: n = 196 in the lower-target group; n = 198 in the higher-target group.

**Introduction:** Direct laryngoscopy (DL) is the classical reference method used in urgent orotracheal intubation (OTI). Nowadays, the use of the Video-laryngoscopy (VL) is increasing over time. It's used to approve the visibility of the upper airways especially in difficult expected intubation.
**Objectives:** To compare the VL to VD in terms of the first-time success in the intensive care unit (ICU) and according to the operator's experience.
**Methods:** It was a prospective comparative study conducted in the ICU of Zaghouan's regional hospital between January and December 2023. We included all patients who needed an urgent OTI with an age superior to 18 years old. We excluded pregnant women, obese patients with a BMI superior to 30 kg/m$^2$, those who were intubated for a cardiac arrest, and those with an indication for a better visualization of the upper airway. Two groups were individualized by randomization by applying a ratio 1:1 as following: Group 1 (27 patients): Intubated by Video laryngoscopy—Group 2 (27 patients): Intubated by Direct laryngoscopy.
First and second-year interns were classified as novice operators, while third and fourth-year interns were considered trained operators.
**Results:** During the study period, 54 patients were included. Median age was 61 [42–70] years and gender ratio was 1.2. Median IGSII and APACHII scores were respectively 42 [28–53] and 16 [13–22]. The main reasons for OTI were neurological and respiratory distress in 20 patients (37%). Median ICU Length of stay was 6 [2–20] days. Mortality rate was 61%.
According to the Cormack and Lehane scale, 47 patients (87%) were classified as grade 1–2, while seven patients (13%) were classified as grade 3–4. Twenty-six patients (48%) were intubated by novice operators, whereas 28 (52%) patients were intubated by trained operators.
First-attempt success was achieved in 26 patients (96%) of Group 1 compared to 18 patients (67%) in Group 2 ($p = 0.005$).
Median time to successful intubation was 60 [30–120] seconds for Group 1 versus 120 [60–120] seconds for Group 2.
The proportion of patients with successful first-pass intubation did not differ significantly between both groups performed by novice operators (92% vs 77%, $p = 0.59$).
However, the proportion of successful first-pass intubation performed by trained operators was 57% with DL versus 100% with VL ($p = 0.02$).
**Conclusions:** Video-laryngoscopy improved first-attempt success during urgent orotracheal intubation compared to direct laryngoscopy for trained operators, but it did not differ significantly in novice operators.

**Topic:** Acute respiratory failure and mechanical ventilation

## 000789 Early diagnosis of sepsis in emergency room

**Introduction:** It is challenging to detect sepsis early in patients who are admitted to the Emergency Room (ER). Organ dysfunction usually does not become evident until the damage has already been done. Sepsis can cause immunoparalysis, Septiloop is a challenge test that has been developed to diagnose sepsis and monitor immune response during stages of immunosuppression.
**Objectives:** To evaluate the characteristics of patients who came to the ER with suspicion of infection and high risk of developing sepsis (NEWS scale > = 3) and to assess the performance of Septiloop in diagnosing sepsis.
**Methods:** We conducted a preliminary prospective observational cohort study of patients with suspected infections with a high risk of developing sepsis (measured by a NEWS scale > = 3). We drew blood and performed severity scores at baseline, 4 h, and 24 h. Sepsis was defined according to the Sepsis 3(2) definition by two blinded researchers.
**Results:** We included 104 patients, out of which 72 (69%) developed sepsis within the first 24 h. The baseline characteristics are summarized in Table 1, no differences in age or comorbidities were found. The Septiloop test has shown significant differences between patients with or without sepsis at baseline.
**Conclusions:** SeptiLoop is a new tool that can aid in the early detection of sepsis and the identification of immunosuppression in high-risk patients. However, larger multicenter studies are necessary to confirm and even extend these findings.

**Table (abstract 000789)** Baseline characteristics

| Variable | Sepsis-3 (N=72) | No Sepsis-3 (N=32) | P-value |
|---|---|---|---|
| Age Median [IQR] | 75.5 [63-82] | 73.5 [64.5-81.5] | 0.732 |
| Gender Male, N (%) | 43 (60%) | 23 (72%) | 0.333 |
| Body Mass Index, Median [IQR] | 26.75 [23.5-30.05] | 24.7 [22.55-28.65] | 0.314 |
| Heart Failure, N (%) | 14 (19%) | 3 (9%) | 0.32 |
| Chronic Pulmonary Disease, N (%) | 20 (28%) | 11 (34%) | 0.655 |
| Diabetes mellitus, N (%) | 28 (39%) | 8 (25%) | 0.25 |
| Chronic kidney disease, N (%) | 19 (26%) | 11 (34%) | 0.552 |
| Infectious Focus, N (%) | | | 0.193 |

**Introduction:** Subarachnoid hemorrhage (SAH) is a life-threatening emergency with significant mortality and long-term disability. Chloride is the most abundant strong anion in the body, playing a major role in cell volume regulation by impacting the transmembrane osmotic gradient (1), as well as the arterial vasomotor tone and neuromuscular excitability (2).
**Objectives:** To investigate the relationship between chloremia and neurological outcomes after an SAH.
**Methods:** We conducted a single-center observational study including adult patients admitted to the Intensive Care Unit for non-traumatic SAH from November 2015 to December 2022. Chloremia was measured daily during the first 3 days after admission as standard care. Hyperchloremia was defined as a chloride level above 105 mmol/L. The clinical course of hospitalized patients was followed, and neurological outcome was determined according to the Glasgow Outcome Scale (GOS) 3 months after admission.
**Results:** Among the 262 patients included, 110 (42%) had a World Federation of Neurological Society (WFNS) score on admission 4 or 5. A total of 131 (50%) patients had favorable neurological outcome (GOS 4–5). Median chloride levels were 110 (IQR 106–113) mmol/L on day 1, 110 (IQR 107–113) mmol/L on day 2, and 107 (IQR 104–111) mmol/L on day 3. Hyperchloremia was present in 213 (82%), 199 (84%) and 154 (71%) patients on days 1, 2 and 3 respectively. Chloride levels were significantly lower on the first 3 days of ICU stay in patients with favorable outcomes (GOS 4–5) when compared to those with unfavorable outcomes (GOS 1–3, $N=131$ (50%), $p<0.001$ – Figure 1, panel A). Hospital survivors ($N=184$, 70%) also had lower chloride levels in the first 3 days compared to non-survivors ($N=78$ (30%), $p=0.01$ – fig*ure 1, panel B). In a multivariate analysis including age, WFNS score on admission, occurrence of rebleeding or delayed cerebral ischemia, chloremia on day 3 was independently associated with unfavorable neurological outcome (OR 1.141; 95% confidence intervals [1.051; 1.250]) and mortality (OR 1.100; 95% confidence intervals [1.017; 1.195]).
**Conclusions:** High chloride level was significantly associated with an increased risk of unfavorable neurological outcome and mortality after SAH.

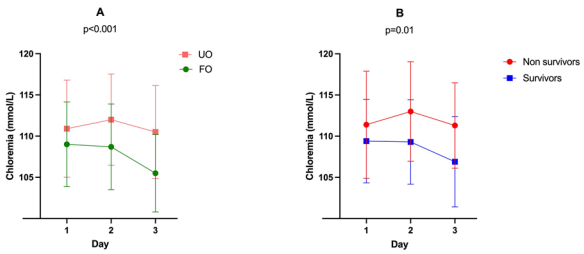

**Fig. 1 (abstract 000790)** Chloremia in the first 3 days of ICU stay according to neurological outcome 3 months after admission (panel A) and hospital mortality (panel B). FO: favorable outcome; UO: unfavorable outcome

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000791

**Introduction:** The recruitment-to-inflation (R/I) ratio is a promising technique to individualize positive end-expiratory pressure (PEEP) level in patients with acute respiratory distress syndrome (ARDS) [1]. However, this technique has only been validated using the pressure–volume curve technique, and the optimal threshold differentiating low and high recruiters remains unknown.
**Objectives:** The aim of this study was to evaluate the diagnostic performance of the R/I ratio to identify patients with high recruitability by PEEP, using computed tomography (CT) as a gold standard.
**Methods:** We conducted a prospective single-center study on adult ARDS patients under invasive mechanical ventilation. The R/I ratio was measured on the ICU ventilator between PEEP 5 and 15 cmH2O as previously described [1] before the transfer of the patient to the imaging facility, where 4 low-dose CT scans were performed: at-end-expiration and at-end-inspiration at the PEEP level chosen by the clinician, and at end-expiration at both PEEP 15 and 5 cmH2O. Alveolar recruitment between PEEP 5 and 15 cmH2O was computed as the weight of the non-aerated compartment at PEEP 5 cmH2O minus its weight at PEEP 15 cmH2O, standardized to total lung weight. Patients were classified as high-recruiters if the recruited lung weight induced by a PEEP decrease from 15 to 5 cmH2O corresponded to at least 5% of total lung weight [2]. The primary endpoint was the area under ROC curve (AUROC) to predict low or high recruitability on CT. We estimated that with a sample size of at least 17 patients with high lung recruitability

on CT, the study would provide at worst a ± 0.15 precision for the 95% confidence interval (CI95%) of the AUROC, assuming an AUROC of at least 0.8 and with a two-tailed hypothesis.
**Results:** 44 patients were included, and 6 [14%] were subsequently excluded for suspected air leaks on the respiratory circuit, as the difference between set VT on the ventilator and measured VT on CT scan exceeded 60 ml. Most patients presented with severe ARDS (27/38 [71%]), and 8/38 [21%] were classified as high-recruiters on CT. Median non-aerated lung weight at PEEP 5 cmH2O amounted to 51% [IQR:39%-58%] of total lung weight. Median R/I ratio amounted to 0.48 [IQR:0.28–0.73], and was non-significantly lower in the low-recruiters as compared to high-recruiters on CT (0.43 [IQR:0.25–0.66] vs. 0.70 [IQR:0.51–1.00], $p = 0.07$). The correlation between the R/I ratio and lung recruitability on CT was not statistically significant ($R^2 = 0.07$; $p = 0.11$). The AUROC of the R/I ratio to predict high recruitability on CT amounted to 0.74 (CI95%: [0.49–0.93]). The optimal R/I ratio differentiating low- and high-recruiters amounted to 0.57. Median sensitivity and specificity at this threshold were 25% [CI95%:0%-63%] and 93% [CI95%:83%-100%], respectively.
**Conclusions:** With the limit that the study is ongoing and underpowered, the R/I ratio may have an acceptable diagnostic performance to identify high-recruiters by PEEP on CT, with excellent specificity.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000794

**Introduction:** The cardiovascular disease is the principal cause of mortality in Europe and in Spain in 2022, 29,068 patients died because of ischemic heart disease. The machine learning (ML) improves the early detection and treatment of these pathologies.
**Objectives:** The objective of this study was to develop prediction algorithms in Python, that can predict coronary disease in patients who consults at the emergency department with thoracic pain.
**Methods:** This is a retrospective and analytic study, that includes patients over 15 years of age who consulted in the emergency room due to chest pain and who underwent cardiac catheterization. The variables were analyzed and those that had the greatest correlation with positive cardiac catheterization were selected. Three supervised learning models were carried out.
**Results:**

**Table 1 (abstract 000794)** Characteristics of the sample

| | Sample (281) | Coronary disease (171) | No coronary diesease (110) |
|---|---|---|---|
| Man | 69 | 70 | 66 |
| Age mean (SD) | 65.8(12) | 67(10) | 63(14) |
| Arterial Hypertension | 64 | 69 | 56 |
| Diabetes | 24 | 31 | 12 |
| Ischemic heart disease | 26 | 28 | 22 |
| Smoker | 19 | 19 | 18 |
| Others | 49 | 52 | 43 |
| ECG ST elevation | 16 | 22 | 5 |
| ECG non-ST elevation/ negative T | 34 | 43 | 20 |
| ECG normal/ no changes | 44 | 29 | 67 |
| TNT admission | 61 | 74 | 40 |
| TNT 3 h | 39 | 60 | 6 |

281 patients who were admitted to the emergency room from 2022 to 2024 were included. There were no null values. The characteristics of the sample are described in Table 1. A correlation matrix was made (Graph 1). The variables with p value ($p < 0.05$) were age, ST segment elevation, ST depression/ T negative in electrocardiogram (ECG), positive troponin (TNT) at admission and positive curve at 3 h. The selection of the variables was carried out with the featurewiz library.
For the internal validation of the models, the sample was divided into training (80%) and test (20%) and a cross-validation with K folders with 50 splits was made.
The first model was logistic regression, Table 2 resumes the performance of the algorithms. Then a decision tree model was created, obtaining a tree with 5 nodes, 14 terminal nodes, entropy criterion (Graph 2). Finally, a k-nearest neighbors model was developed and Graph 3 combines the confidence map with the scatter plot of the test and training groups.

**Table 2 (abstract 000794)** Performance comparison of different ML models in the test group

| Models | Sensitivity (%) | Specificity (%) | Accuracy | AUC | MSE |
|---|---|---|---|---|---|
| Logistic Regression | 74 | 79 | 75 | 0.76 | 0.24 |
| Tree Decision | 74 | 63 | 75 | 0.67 | 0.6 |
| k-NN | 82 | 89 | 84 | 0.71 | 0.56 |

**Conclusions:** The use of ML can help to predict different pathologies. The algorithms develop in this study can predict de coronary disease however have less accuracy compared with other studies.

**Introduction:** Patients receiving venoarterial extracorporeal membrane oxygenation (VA-ECMO) frequently develop arterial hyperoxaemia, which may be harmful. However, lower oxygen saturation targets may also lead to harmful episodes of hypoxaemia.
**Methods:** In this registry-embedded, multicentre trial, we randomly assigned adult patients receiving VA-ECMO in an Intensive Care Unit (ICU) to either a conservative (target $SaO_2$ 92–96%) or to a liberal oxygen strategy (target SaO2 97–100%) through controlled oxygen administration via the ventilator and ECMO gas blender. The primary outcome was the number of ICU-free days to day 28. Secondary outcomes included ICU-free days to day 60, mortality, ECMO and ventilation duration, ICU and hospital lengths of stay, and functional outcomes at six months.
**Results:** From September 2019 through June 2023, 934 patients who received VA-ECMO were reported to the EXCEL registry, of whom 300 (192 cardiogenic shock, 108 refractory cardiac arrest) were recruited. We randomised 149 to a conservative and 151 to a liberal oxygen strategy. The median number of ICU-free days to day 28 was similar in both groups (conservative: 0 days [IQR 0 to 13.7] versus liberal: 0 days [IQR 0 to 13.7], median treatment effect: 0 days [95% CI -3.1 to 3.1]). All secondary outcomes and adverse events were similar in both groups. The conservative group experienced 44 (29.5%) major protocol deviations compared to 2 (1.3%) in the liberal oxygen group ($P < 0.001$).
**Conclusions:** In adults receiving VA-ECMO in ICU, a conservative compared to a liberal oxygen strategy, did not affect the number of ICU-free days to day 28.

**Introduction:** Use of Human Albumin Solution (HAS) in Critical Care units is a controversial topic, with limited or uncertain evidence supporting usage in certain conditions. As a human blood product, there is a significant risk of side effects, such as disease transmission, transfusion reactions, and circulatory overload. It is an expensive medication, with recent UK shortages.

Our NHS trust has two general intensive care units on 2 sites. The critical care team noted high usage rates and expenditure on HAS in recent years (~ £50k/yr 2020–21 or ~ €58,000).

Over the last few years, the team adopted a multimodal quality improvement project featuring a safety update, new guidelines highlighting the evidence base, and an updated e-prescribing system—adding an albumin protocol that requires an indication to be selected. Looking at prescribing over the last 4 years, usage has decreased. However, the rationale for and appropriateness of albumin prescription has not been formally audited in this time.

**Objectives:** To audit the prescription of albumin against our guidelines setting the following standard:

- 100% of patients will have documented indication for prescription of HAS in keeping with Critical Care guidelines

To obtain descriptive data for comparison of HAS prescription in critical care according to guidelines and any subsequent improvement after intervention.

**Methods:** Details of all patients prescribed 20% HAS in both critical care units from July-Nov 2023 were obtained via a report of electronic prescriptions. Prescriptions were reviewed and data gathered for age, site, volume prescribed, and indication. Electronic notes, prescriptions and fluid-balance charts were reviewed to determine if it was in keeping with guidelines (Fig 0.1).

If the indication was sepsis, this was deemed 'appropriate' if the patient received > 2L IV fluid resuscitation prior and was on vasopressors—as a surrogate for haemodynamic instability/shock. Albumin expenditure was compared using pharmacy cost reports (Fig 0.2).

**Results:** Spending and usage of albumin at both sites has decreased significantly over the last 4 years (Fig 0.2) as per expenditure analysis, decreasing by around ~ £35,000 (~ €40,000).

There were 30 prescriptions of 20% HAS in 22 patients. 100% had an indication on the prescription (mandatory on e-prescribing), with majority receiving 20g or 40g of 20% HAS.

The majority of prescriptions stated 'sepsis' as the indication, with the second largest indication being 'other' (Fig 0.3). Of the 8 'other' prescriptions there were 5 different patients: 2 given for specialist indications (dialysis, poisons advice to aid venlafaxine binding), 2 for shock (tumour lysis syndrome, multi-organ failure/shock on anaesthetic induction)—both deemed 'appropriate'. The other 4 prescriptions were for the same patient, essentially for hypoalbuminaemia and open abdominal wound (indication of 'sepsis/shock', inappropriately).

When looking at indications, 63% (19 prescriptions) were 'appropriate'. Of 11 prescriptions deemed 'inappropriate', all were 'other' or 'sepsis' categories. However, 7 of these were the same patient, which given the small sample size, skewed results. One of the 'other' indications was 'shock, alcoholic', the rest were sepsis/shock and hypoalbuminaemia. There were 17 HAS prescriptions for 'sepsis': 11 '(65%) 'appropriate', 6 'inappropriate' (4 patients). None of the 4 had > 2L crystalloid resuscitation prior, although 3 were on vasopressors.

**Conclusions:** In a UK general intensive care unit a multi-modal approach using education, guidelines and alterations to e-prescribing showed a reduction HAS prescribing costs over a 4 year period.

HAS is prescribed in keeping with guidelines the majority of the time in our critical care units. However, 1/3 of prescriptions are probably inappropriate and unlikely to provide benefit to the patient, with increased cost and risk of side effects. Analysis was limited by small numbers and lack of definite data from prior to the guidelines for direct comparison.

Having presented the data and analysis at our cross-site governance meeting, we have re-circulated the guidelines and provided further evidence-based education on albumin usage to our critical care teams. As 'sepsis' was the majority of 'inappropriate' indications, we have focused our learning on the need for adequate crystalloid resuscitation prior, and are looking at adding additional guidance on the e-prescribing system. We are re-auditing in the near future, aiming to cement the improvement in appropriate HAS prescriptions in our units.

| **EVIDENCE SUPPORTS USE** | |
|---|---|
| INDICATION | ALBUMIN PRODUCT/DOSE |
| Large volume paracentesis (drainage of ascites) in patient with chronic liver disease | HAS 20% 100ml 1 bottle per every 3L ascites drained (increased to 1 bottle every per every 2L if renal function impaired) |
| Spontaneous bacterial peritonitis (SBP) | HAS 20% 100ml 1.5g/kg on day 1 (usually 4-8 bottles), then 1g/kg on day 3 (usually 2-5 bottles) |
| Hepatorenal syndrome | HAS 20% 100ml 1g/kg on day 1 (usually 2-5 bottles)<br>**Then**<br>HAS 20% 100ml 1-2 bottles daily for 2-16 days. |
| **AREA OF UNCERTAIN BENEFIT** | |
| INDICATION | NOTES |
| Large volume paracentesis (drainage of ascites) in patient with ascites not due to chronic liver disease | May be indicated dependent on individual patient circumstances |
| Sepsis - resuscitation as per surviving sepsis guidelines, with continued cardiovascular instability after 40mL/kg crystalloid | Ensure resuscitation with crystalloid prior to considering albumin. Consider involving a Critical Care Consultant as determined by patient clinical condition. |
| **NO EVIDENCE OF BENEFIT – NOT TO BE PRESCRIBED** | |
| INDICATION | EVIDENCE BASE |
| Volume resuscitation for hypovolaemia | No difference in length of stay / ventilated days and RRT. In trauma reveals an increase in mortality. |
| Mild acute lung injury and ARDS | May improve oxygenation but no effect on mortality |
| Hypoalbuminemia – in the absence of ascites, SBP or hepatorenal syndrome | No difference in survival or sustained improvement in organ dysfunction. Using albumin offers no additional benefit, with additional adverse effects. |
| Low serum albumin in haemodynamically unstable patient in critical care | Lack of evidence to support use |
| **EVIDENCE OF HARM – NOT TO BE PRESCRIBED** | |
| INDICATION | EVIDENCE BASE |
| Volume resuscitation in brain injury | Significantly higher mortality & fewer favourable neurological outcomes. |

**Introduction:** Venous Thromboembolism (VTE) is common in critical illness, affecting as many as 1 in 3 patients admitted to critical care (1). VTE prevention strategies typically include intermittent pneumatic compression devices, graduated compression stockings or a combination of these. Both methods have several limitations: including contraindications, poor compliance, mechanical upkeep, and risk of falls (2). Although well-established, international guidelines on VTE prophylaxis in critical care are variable and based on low-quality evidence (3,4,5). This study tested the feasibility of an alternative, novel, neuromuscular stimulation device to prevent VTE in critically ill adults.
**Objectives:** The primary objective of this trial was to show the feasibility of comparing application of the gekoTM device to intermittent pneumatic compression stockings in new patients admitted to critical care. Secondary objectives included the collection of pilot data for relevant outcomes, which may inform the design of a future efficacy trial.
**Methods:** This single-centred, open-label, parallel-group, randomised feasibility trial recruited patients admitted to critical care at risk of VTE. Patients were randomised to the intervention group (Geko) or control group (intermittent pneumatic compression devices) for up to ten days. Pre-specified measures of feasibility and associated thresholds included: adherence to assigned intervention, recruitment rate, and data completeness.
**Results:** 40 patients were randomised, 20 to each group. Data were available from 38 patients for analysis. The recruitment rate was 3.3 patients per month (93.3% of the target rate). Adherence to the Geko was 84.2% in the intervention group, versus 86.1% in the control arm. Common reasons for non-adherence included: inability to sleep with devices on, discomfort when devices programmed at higher levels, refusal due to delirium/confusion. There were 4 mild adverse events of skin irritation seen in the intervention group.
**Conclusions:** The application of the Geko device was feasible, safe, and well-tolerated by patients admitted to critical care who were at high risk of VTE. Larger, well-designed randomised controlled trials would be required to investigate Geko's efficacy and cost-effectiveness compared to existing alternatives.

### Goal-directed vasopressor vs. fluid administration and spinal cord microcirculatory blood flow following aortic-cross-clamping induced ischemia–reperfusion: a pilot study in pigs

M. Gräßler[1], C. Behem[1], S. Wipper[2], H. O. Pinnschmidt[3], A. Rapp[1], T. Suntrop[1], C. J. C. Trepte[1]

**Correspondence:** M. Gräßler
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000800

**Introduction:** Spinal cord injury induced by ischemia/reperfusion is a major complication of aortic repair. Despite efforts to prevent spinal cord injury, it still commonly occurs and impacts patient outcomes. The microcirculation is of paramount importance for tissue perfusion and oxygen supply and may be dissociated from macrohemodynamic variables clinically used to guide resuscitation. Fluids and vasopressors are commonly used for hemodynamic resuscitation, however their specific effects on spinal cord microperfusion are unknown.
**Objectives:** We aimed to compare the effects of vasopressor- and fluid-based hemodynamic resuscitation on spinal cord microperfusion in a translational acute pig model of aortic cross-clamping.
**Methods:** This was a randomized trial of 16 anaesthetized mechanically ventilated pigs. Ischemia/reperfusion was induced by supraceliac aortic-cross-clamping with prior ischemic preconditioning with an ascending order of 1-, 2-, 5-, 10-, and 30-min intervals to improve the survival of the animals during the study protocol. Pigs were

randomized to receive either goal-directed vasopressor therapy with norepinephrine to a target mean arterial pressure (MAP) of 80 mmHg or goal-directed fluid therapy with balanced isotonic crystalloids until no improvement of cardiac output could be achieved. Spinal cord microcirculation was measured using Laser-Speckle-Contrast- Imaging as well as fluorescent microspheres. Further cerebrospinal fluid drainage was used to maintain normalized cerebrospinal fluid pressure.
**Results:** The microcirculation of the lower spinal cord decreased significantly following the ischemia/reperfusion injury caused by aortic cross-clamping (0.103 (0.088–0.120) vs. 0.030 (0.026–0.035) ml*min-1*g-1 in fluorescence microsphere analysis, $p<0.001$; 77.16 (58.72–101.38) vs. 12.54 (9.63–16.32) p.u. in Laser-Doppler measurements, $p<0.001$). After ischemia/reperfusion injury the microcirculatory blood flow was significantly higher in pigs assigned to vasopressor therapy than in pigs assigned to fluid therapy (0.138 (0.111–0.172) ml min-1 g-1 vs. 0.099 (0.080–0.122,$p<0.001$). Microcirculatory resuscitation was not uncoupled from macrohaemodynamic variables.
**Conclusions:** The results of this trial suggest that there are beneficial effects of vasopressor-based resuscitation on lower spinal cord microcirculation compared to fluid-based resuscitation in an experimental model of aortic cross clamping.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000801

**Introduction:** A meta-analysis of randomized controlled trials showed that paracetamol increases significantly systolic arterial pressure (SAP). However, the effects of paracetamol infusion in intensive care unit (ICU) patients may be opposite and hypotension after paracetamol administration is not uncommon.
**Methods:** We conducted a meta-analysis of observational studies reporting hemodynamic changes in ICU patients receiving parenteral paracetamol for fever/sepsis and/or pain/analgesia. The primary outcome was a change in mean arterial pressure (MAP) using the nadir value recorded within the first 30 min. Secondary outcomes were: cumulative incidence of hypotensive events, changes in SAP, diastolic arterial pressure (DAP) and heart rate (HR). Outcomes were analyzed using a random-effect model (inverse variance approach) and reported as mean difference (MD) with 95% confidence interval.
**Results:** We included 13 studies reporting the cumulative incidence of hypotension (as defined by each study) following paracetamol administration was 54.2% ($n=186/343$). Eight studies provided values of MAP, which significantly decreased after administration of parenteral paracetamol (MD:-7.53 mmHg [-9.58;-5.49]; $p<0.0001$; $I2=10\%$; Figure 1). When evaluating the effects on MAP at longer timeframe, the analysis of nine studies yielded almost identical results (MD:-7.66 mmHg [-9.66;-5.67]; $p<0.0001$; $I2=7\%$). We found also a significant reduction after paracetamol administration in SAP (seven studies, MD:-14.23 mmHg [-19.21;-9.24]; $p<0.0001$; $I2=28\%$; Figure 2) and DAP (six studies, MD:-3.77 mmHg [-6.21;-1.32]; $p=0.003$; $I2=23\%$; Figure 3), with no significant changes in HR (four studies, MD:-1.97 mmHg [-6.52;2.58]; $p=0.40$; $I2=0\%$).
**Conclusions:** This is the first metanalysis quantifying the hemodynamic impact of paracetamol administration to ICU patients. Paracetamol produces hypotensive events in over half of the population, with a mean reduction in MAP over 7 mmHg within the first 30 min after administration, with no effects on HR.

### Ghrelin: inhibiting ferroptosis to protect against sepsis-induced intestinal injury

H. Qiliang[1], B. Li[2]
[1]Department of Critical Care Medicine, The First Clinical Medical College of Lanzhou University, Lanzhou, China; [2]Department of Critical Care Medicine, The First Hospital of Lanzhou University, Lanzhou, China
**Correspondence:** H. Qiliang

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000803

**Introduction:** Ghrelin offers benefits in sepsis therapy, but its impact on sepsis-induced intestinal injury is not well-defined. This study investigates the therapeutic efficacy of ghrelin in alleviating sepsis-induced intestinal damage, focusing on its potential to inhibit ferroptosis and protect intestinal barrier integrity.
**Objectives:** To examine the roles of ghrelin in alleviating sepsis-induced intestinal injury, especially in ferroptosis, and protect intestinal barrier integrity.
**Methods:** We evaluated ghrelin and Ferrostatin-1 (Fer-1) in C57BL/6 mice with CLP-induced sepsis, assessing bacterial load, intestinal integrity, inflammation, oxidative stress, and ferroptosis through histopathology and biochemical assays.

**Results:** Ghrelin and Fer-1 effectively reduce bacteremia, sepsis severity, and oxidative stress in intestinal cells. They decrease apoptosis, as shown by TUNEL assays, and lower DAO and FABP2 levels, markers of intestinal barrier damage, indicating barrier restoration. Furthermore, these agents normalize cytokine levels (IL-6, IL-1β, TNF-α, IL-22), disrupted in sepsis, showcasing their anti-inflammatory effects. Western blot analysis shows they reverse sepsis-induced changes in ferroptosis-related proteins (4-HNE, FTH1, GPX4, ACSL4, PTGS2, SLC7A11), underscoring their role in ferroptosis inhibition (Fig 1).
**Conclusions:** Ghrelin protects against sepsis-induced intestinal injury by inhibiting ferroptosis, highlighting its therapeutic potential for sepsis.

## Activation of hippocampal cGAS-STING pathway exacerbates sepsis-associated encephalopathy

X. Wang, Z. Zifan, Y. Wu
Department of Critical Care Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wu Han Shi, China
**Correspondence:** Z. Zifan
*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000806

**Introduction:** Sepsis is a severe infectious condition that triggers systemic inflammatory response syndrome, often leading to multiple organ dysfunctions, notably sepsis-associated encephalopathy (SAE). SAE, a severe complication of sepsis, affects central nervous system function and results in cognitive and memory impairments. Oxidative stress is an integral component of the pathogenesis of SAE, with mitochondria serving as the primary site of oxidative stress, potentially playing a significant role in the pathogenesis of SAE by activating the cGAS-STING pathway 1 2.
**Objectives:** Our study aims to investigate the activation of the cGAS-STING pathway induced by sepsis-associated mitochondrial damage and its role in cognitive dysfunction in SAE. Additionally, the study seeks to evaluate whether intervention in this pathway using the STING inhibitor H151 can ameliorate cognitive impairments in SAE, providing new insights and strategies for the treatment of SAE.
**Methods:** The SAE mice models were induced in C57BL/6 mice using cecum ligation and puncture (CLP) surgery. Subsequently, the mice were randomly divided into six groups: sham operation (Sham) group, sepsis (CLP) group, sepsis with intraperitoneal (i.p.) PBS injection (PBS + CLP) group, sepsis with H151 i.p. (CLP + H151) group, cGAS AAV overexpression (cGAS + -AAV) group, and control virus (Control-AAV) group. Hippocampal stereotactic injection of cGAS AAV virus was used to overexpress and activate the hippocampal cGAS-STING pathway. Intraperitoneal injection of H151 was used to block STING. The activation level of the hippocampal cGAS-STING pathway was evaluated by Western Blot, and the cognitive ability of mice was assessed using the Novel Object Recognition Test (NORT).
**Results:** The expression of the hippocampal cGAS-STING pathway was markedly elevated in mice from the CLP group compared to those in the Sham group. Administration of the STING inhibitor H151 via intraperitoneal injection (750 nM) significantly reduced hippocampal STING expression. Concurrently, these treated mice exhibited a notable increase in the duration of novel object exploration during NORT. Conversely, mice receiving AAV injection for hippocampal cGAS overexpression displayed a significantly decreased exploration time for novel objects in the NORT.
**Conclusions:** Our study confirmed the pivotal role of the hippocampal cGAS-STING pathway in the cognitive impairment of SAE. Suppression of this pathway activity by intraperitoneal injection of H151 effectively improved cognitive impairment in SAE mice, offering a novel strategy for the treatment of SAE. This discovery serves as a significant reference for further research on the pathomechanism of SAE and the development of therapeutic strategies.

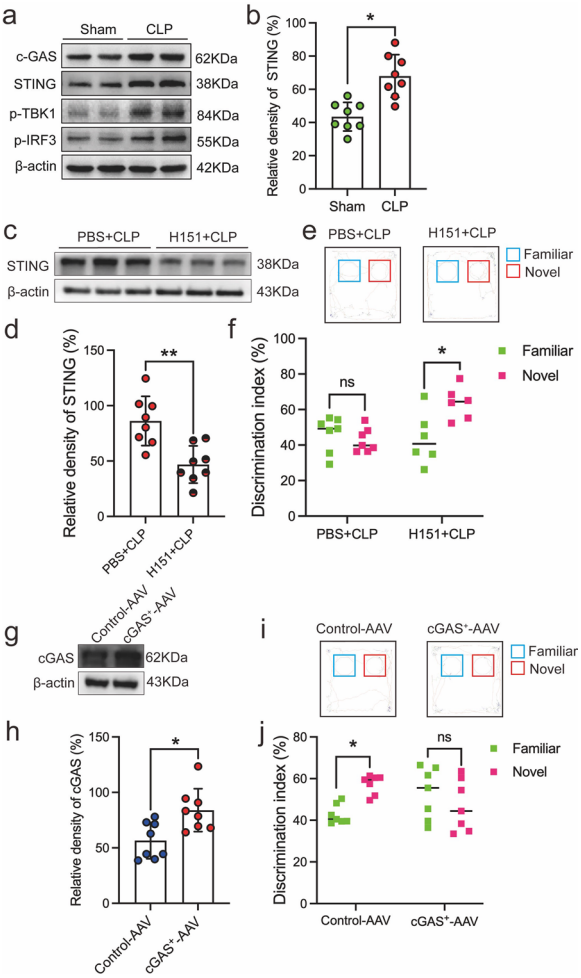

**Fig. (abstract 000806)** (a, b), hippocampal cGAS-STING pathway expression is significantly increased in mice after cecum ligation and puncture (CLP). (c, d) intraperitoneal injection of STING inhibitor H151 (750 nM/only) significantly reduced hippocampal STING expression. (e, f), H151 i.p. significantly increased time to novelty exploration in NORT in septic mice. (g, h), hippocampal injection of cGAS overexpresses AAV. (i, j), hippocampal injection of cGAS overexpressing AAV significantly reduced the time mice spent exploring novel objects in NORT. Data are expressed as mean ± variance and t-test was used for comparison between groups. $^{*}p < 0.05$, ns: not significant

### High level of patient-ventilator asynchrony thoughout mechanical ventilation is associated with poor prognosis

X. Chen, Y. Chi, Y. Long, L. Su
Icu, Peking Union Medical College Hospital, Beijing, China
**Correspondence:** X. Chen
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000808.

**Introduction:** During mechanical ventilation (MV), the mismatch between patients' needs and machine's delivery, known as patient-ventilator asynchrony (PVA), can cause patient discomfort and dyspnea, and may contribute to poor prognosis. Monitoring PVA in critically ill patients is valuable for lung protection. Ventilator waveforms are commonly used in clinical practice as noninvasive and user-friendly parameters, and our group has devised a real-time monitoring platform (the RemoteVentilateView platform) for the identification and monitoring of PVA.
**Objectives:** To observe the level and types of PVA, and examine their associations with patients' prognosis, PVA throughout MV of patients from ICU admission up to 28 days were analyzed.
**Methods:** This retrospective, observational, multicenter study was conducted in four ICUs, including 50 patients that were on ventilators connected to the RemoteVentilateView platform and ventilated for more than 24 h. Within 2 h of initiating MV, physicians enrolled the patient, and the platform would automatically begin recording and monitoring, which were stopped manually when the patient was discharged from ICU or was removed from MV. The platform recognizes 8 types of PVA, including ineffective trigger, double trigger, reverse trigger, auto-trigger, flow insufficiency, overshoot, premature cycle, and delayed cycle. Our analysis included a total of 15,144 h of ventilation.
**Results:** The Asynchrony index (AI, the proportion of asynchronous breaths to total breaths) was applied to evaluate the frequency of PVA. Gross AI among 50 patients was 12.5% (10.1, 18.0). Non-survivors had a higher level of AI than survivors [22.1 (13.2, 25.6) % vs 11.5 (8.5, 16.3) %, p = 0.002]. We also found that using AI as a predictor, a cutoff value of 14% could be used for survival outcomes. Patients with an AI ≥ 14% had a higher 28-day mortality than those with AI < 14% (42.86% vs. 13.79%, $p = 0.021$). In the investigated patients, those who received MV due to infection demonstrated a significantly higher ineffective trigger index compared to patients without infection [4.6 (3.3, 6.9) % vs 2.0 (0.1, 4.2) %, $p = 0.010$]. Specifically, patients diagnosed with lung infection had a much higher ineffective trigger index than those undergoing cardiac surgery [4.8 (3.7, 7.1) % vs 0.1 (0, 4.1) %, $p = 0.016$].
**Conclusions:** PVA is common in patients receiving MV in the ICU. High PVA was associated with poor prognosis, such as higher 28-day mortality. Poor outcomes could be predicted by AI ≥ 14%. Among multiple asynchronies, only ineffective triggers demonstrated significantly different levels between patients with or without infection. Future studies could pay more attention to the relationship between different types of asynchrony and prognosis with the underlying mechanisms involved.

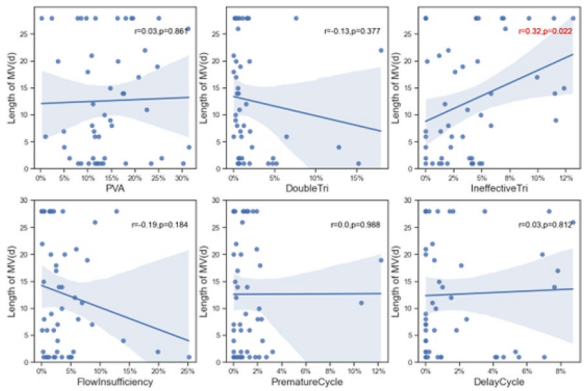

**Fig. (abstract 000808)** Association between Length of MV and asynchrony index. Among all kinds of asynchronies, only an ineffective trigger index has been associated with the duration of MV

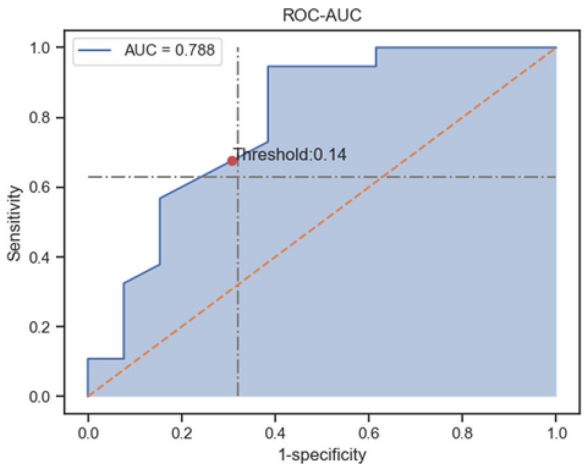

**Fig. (abstract 000808)** Receiver operating characteristic (ROC) curve of AI throughout MV for 28d mortality

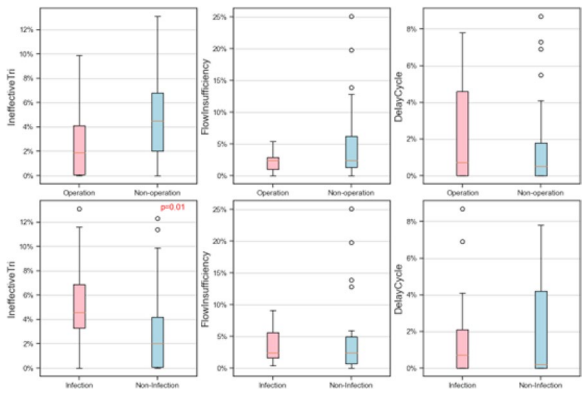

**Fig. (abstract 000808)** Levels of different types of asynchrony in patients. Those diagnosed with infection demonstrated a higher level of ineffective trigger

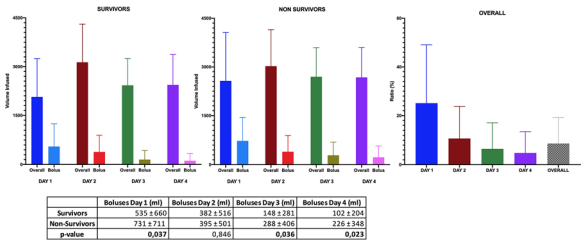
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000809

**Introduction:** Fluid administration is the first line treatment of for critically ill patients admitted to the ICU with septic shock, aiming to increase venous return and, hence, cardiac output and tissue oxygen delivery. However, despite fluids administration being one of the most common and early interventions, the modality and the overall volume are still debated. Specifically, the amount of fluids given by boluses (FB) or by continuous infusions (including drugs and medications) in the early phases of shock treatment is often unknown. [1,2,3].
**Objectives:** We conducted a retrospective analysis on the use of fluids in septic patients, with the primary aim of analyzing the proportion of FBs over infusions in days 1–4. We secondarily described the different types of fluids given and four main pharmacological categories (i.e. vasoactive, sedative/analgesic, anti-infective, and other drugs). Finally, we assessed if fluid administration modality and fluid types may impact ICU mortality.
**Methods:** We enrolled patients admitted with a diagnosis of septic shock from 1st July 2021 to 31st December 2023, during the first 4 days of ICU stay. Data related to fluid administration were exported from the electronic health records system (ICCA®, Philips Healthcare): fluid balance, boluses, infusions by pumps, and enteral infusions. Age, severity score, overall fluid balance, and the percentage of volume of each fluid type over the 4 considered days were included in a multivariable logistic regression model, evaluating the association with ICU survival.
**Results:** We analysed 220 patients, with 66 patients (30.0%) who died. Overall, on Day 1 FB was 25.1% and was reduced to 4.8% (8.7) on Day 4 (overall, only 8.6% (10.5) of fluids given). Non-survivors received a higher amount of IV fluids as compared to survivors only on Day 1 [2,493 (1,489–2,963) vs. 1,855 (1,167–2,638); p 0.022]. Fluid infusion represented 49.3% (22.8) of the overall fluid intake, being the balanced solution the most represented [27.4% (22.0)]. All IV drugs represented 34.0% (12.9) of the total, while PO/NGT intake was 18.0 (15.7%). A positive fluid balance [OR 2.14 (1.33 – 3.43)], was the most important factor associated to ICU mortality.
**Conclusions:** This retrospective analysis based on a precise evaluation of fluids given over the early phases of septic shock, showed that the overall amount of fluid given by boluses is small (from about 25% on Day 1 to about 5% on Day 4). Our data confirm that a positive fluid balance over the first 4 days of ICU is associated to mortality.



| | Boluses Day 1 (ml) | Boluses Day 2 (ml) | Boluses Day 3 (ml) | Boluses Day 4 (ml) |
|---|---|---|---|---|

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000810

**Introduction:** In our ICU, we do not have voriconazole levels, so isavuconazole (ISV) has become the standard treatment for pulmonary aspergillosis (PA).
**Objectives:** To analyze PA in critically ill patients admitted to our ICU who have been treated with ISV.
**Methods:** A retrospective descriptive observational study of patients with PA treated with ISV during their admission to our ICU, from February 2019 to July 2023. It is a multipurpose ICU with 12 beds, expanded to 24 during the pandemic. The characteristics of the patients, reason for admission to the ICU, diagnosis of PA, aspergillus species identified, treatment and clinical cure are analyzed. The diagnosis of PA was made according to the 2020 ECMM/ISHAM consensus criteria (1).
**Results:** During the study period, 48 patients were diagnosed with PA and treated with ISV. The average age was 62.1 years (95% CI 58,6–65,5) and 34 (70.83%) were men. The most common personal history was high blood pressure (23, 47.9%), followed by diabetes (15, 31.2%) and obesity (11, 22.9%). They had a mean APACHE II score of 19.22 (95% CI 17,12–21,32). The reason for admission to the ICU was COVID pneumonia in 30 patients (62.5%), community pneumonia of another etiology in 6 (12.5%), abdominal sepsis origin in 4 (8.3%), polytrauma in 4 (8.3%) and other reasons in 4 (8.3%). All patients were on mechanical ventilation, 8 (16.7%) with continuous renal replacement therapy and 2 (4.2%) with ECMO therapy. The mean SOFA score at the time of ISV initiation was 7.4 (95% CI 6,6–8,2). In 27 patients (56.3%) the laboratory diagnosis of PA was made by bronchoalveolar lavage (BAL) -culture and/or PCR and/or positive galactomannan (GM)-, in 2 (4.2%) by serum GM and in the remaining cases by bronchial aspirate culture (BAS). Aspergillus species was identified in 33 (68.8%) patients: 18 (54.5%) *A. fumigatus*, 12 (36.4%) *A. terreus*, 3 (9%) *A. flavus*, 3 (9%) *A. niger* and 2 (6%) *Aspergillus sp*. In 4 (8.3%) more than one species was identified. ISV was started empirically due to suspicion of PA in 34 (70.8%) patients. During a variable amount of time, according to responsible physician criteria, 32 (66.7%) patients received another antifungal treatment associated with ISV: 16 (50%) IV and/or nebulized liposomal amphotericin B (LAB), 13 (40.6%) LAB plus echinocandin and 3 (9.4%) echinocandin. The length of treatment with ISV was 17.3 (95% CI 15,2–21) days. No side effects that would require discontinuation of the ISV were recorded. Presented clinical cure 28 (58.3%) patients.
**Conclusions:** Of the 48 critically ill patients with PA treated with ISV, this was started empirically in 70.8%. The most frequently aspergillus species isolated was *A. fumigatus* (68.8%) followed by *A. terreus* (36.4%). 32 patients (66.7%) received combined antifungal treatment at some point in course; the combination of ISV with IV and/or nebulized LAB being the most common. No side effects that would require discontinuation of ISV treatment were recorded. 28 (58.3%) patients presented clinical cure.

**Introduction:** Different biomarkers are used for rapid bedside assessment of the severity of sepsis. Neutrophil to Lymphocyte ratio (NLR), serum lactate is frequently used for this purpose1. To evaluate the individual as well as combined efficacy of NLR and serum lactate clearance, measured in the emergency department (ED), in predicting 28-day mortality.
**Objectives:** To evaluate the individual as well as combined efficacy of NLR and serum lactate clearance, measured in the emergency department (ED), in predicting 28-day mortality.
**Methods:** This was a prospective observational single-center study. Conducted in the emergency department of a tertiary care centre in north India (CTRI/2018/08/015371). Adult patients between 18 to 80 years, are admitted to the emergency department with sepsis. Along with baseline demographic and hemodynamic variables, NLR, serum lactate, and lactate clearance (LC) at 6 h were collected. The primary outcome was 28-day mortality.
**Results:** Out of 50 patients, 33 survived (66%). Non-survivors had lower systolic, diastolic, mean blood pressure, lower LC, tachycardia, high SOFA score, vasopressors requirement, mechanical ventilation requirement, and high NLR. NLR ($\geq$ 11.13) was best correlated with 28-day mortality (AUROC 0.87), followed by initial lactate ($\geq$ 3.3, AUROC 0.77) and lactate clearance ($\leq$ 17.07%, AUROC 0.73). Multivariate logistic regression revealed NLR and LC were independent predictors of mortality, with weak correlation between them. However, their combination did not perform better(AUROC 0.82)than individual markers.
**Conclusions:** NLR and LC can be used with moderate certainty in predicting 28 day mortality.

**Topic:** Sepsis

### Serum lactate at the ICU admission predicts mortality in unexpected in-hospital cardiac arrest

H. Kamohara, S. Suda, T. Ikeda
Critical Care Medicine, Tokyo Medical University Hachioji Medical Care Center, Hachioji, Japan
**Correspondence:** H. Kamohara
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000813

**Introduction:** In-hospital cardiac arrest (IHCA) is major differences from OHCA regarding not only background but also initial response. To control prompt ICU beds during ICU surges under disseminating lethal infection, it is relevant to evaluate the prognosis after IHCA immediately.
**Objectives:** To identify various biomarkers as a prognostic factor on the day of ICU admission after unexpected IHCA in the general ward.
**Methods:** This study was a retrospective single-center observation for 5 years from April 2014 to March 2019. We collected 95 adult patients who entered the ICU under sustained return of spontaneous circulation (ROSC) after IHCA in the general ward and compared various candidates as a prognostic biomarker between survivors and non-survivors at 28 days after IHCA.
**Results:** Fifty-one patients were included. Cardiovascular disease is higher in survivors (31.8% vs 9.7%, $p = 0.026$). Vasopressors use was lower in survivors (50.0% vs 83.9%, $p = 0.01$). Lactate, T-Bil, BUN, LDH, and SOFA scores were significantly lower in survivors. Platelets were significantly higher in survivors. AUC-ROC analysis for prediction of mortality demonstrated significantly by Lactate, T-Bil, BUN, Platelet, LDH, and SOFA. Cut-off values were obtained with Lactate (4.7 mmol/L), T-Bil (0.7 mg/dL), BUN (44 mg/dL), Platelet ($17.9 \times 104$ / µl), LDH (383 U/L), and SOFA score (11 points). Multivariate logistic regression analysis indicated Lactate had high correlation with mortality (OR:6.6, $p < 0.001$). Kaplan–Meier survival curve analysis demonstrated that the lower Lactate group (less than 4.7 mmol/L) had better survival ($P < 0.001$).
**Conclusions:** Lactate levels at ICU admission reflected the prognosis of unexpected IHCA patients. We established the optimal cut-off value

for a mortal prediction that contributed to make decision of the next management.

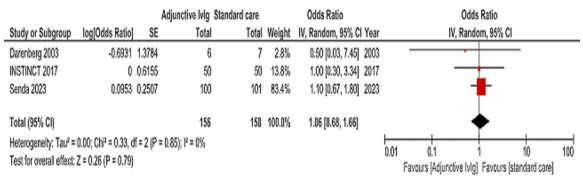
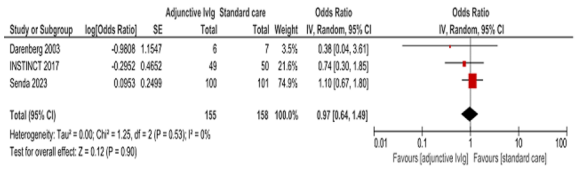
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000814

**Introduction:** The standard care in the management of necrotising soft tissue infections (NSTI) includes broad-spectrum antibiotics, urgent surgical intervention, and supportive care. The efficacy of adjunctive intravenous immunoglobulin (IvIg) in relative to standard care in the management of these patients is not well established.
**Objectives:** We aimed to perform a systematic review and meta-analysis to evaluate the effects of adjunctive IvIg in compared with standard care in the outcomes of patients with NSTI.
**Methods:** We searched Pubmed, Cochrane and Embase databases for the randomised and non-randomised controlled trials published in the English language up to 17 January 2024 comparing adjunctive IvIg with standard care in patients with NSTI. Statistical analysis was performed using Review Manager 5.4.1. Odds ratio with a 95% confidence interval were pooled with random effects model. Heterogeneity was assessed with $I^2$ statistics. Quality assessment and risk of bias were performed according to Cochrane recommendations.
**Results:** We included a total of 655 patients from 5 studies of whom adjunctive intravenous immunoglobulin (IvIg) was used in 330 patients (50.38%). In the pooled data, there was no difference in the overall mortality (combined 28 and 30 days mortality) between the two groups. (OR:1.06; 95% CI:0.69–1.66; $p = 0.79$; $I^2 = 0$). There was also no difference in the overall mortality (combined 30 and 180 days) between the two groups (OR:0.97; 95% CI:0.64–1.49; $p = 0.90$; $I^2 = 0$). We found that the in-hospital mortality was not different when adjunctive intravenous immunoglobulin was compared with standard care in these patients.(OR:0.98; 95% CI:0.67–1.46; $I^2 = 0$).
**Conclusions:** In this meta-analysis, with 655 patients receiving atleast single dose (0.5–2.0 g/kg) of adjunctive intravenous immunoglobulin (IvIg) in patients with NSTI followed for a period up to 180 days, the overall mortality and in-hospital mortality were not different when compared with standard care.



A: There is no difference in the overall mortality (combined 28 and 30 days mortality) in patients with NSTI receiving adjunctive IvIg compared with standard care.



B: There is no difference in the overall mortality (combined 30 and 180 days mortality) in patients with NSTI receiving adjunctive IvIg compared with standard care.

**Introduction:** Sepsis-induced coagulopathy (SIC) is an important complication in critically ill patients with sepsis, contributing to increased morbidity and mortality. A hallmark of SIC is profound fibrinolysis inhibition triggered by elevated levels of plasminogen activator inhibitor-1, leading to prothrombotic effects and heightened susceptibility to thrombosis and organ dysfunction.
**Objectives:** The incidence of SIC and its implications have been mainly studied in the East Asian population. We planned this prospective observational study to find out the incidence of SIC and its effect on clinical outcomes in critically ill patients admitted to the medical ICU of a tertiary care academic hospital in North India.
**Methods:** Consecutive consenting patients admitted to the ICU were screened over a period of nine months (June, 2023 to March, 2024). Patients with pre-existing coagulopathy, acute liver failure, patients on anti-haemostatic drugs, thrombotic thrombocytopenic purpura, hemolytic uremic syndrome, and idiopathic thrombocytopenic purpura were excluded. The baseline parameters were recorded along with APACHE II and daily SOFA scores. Patients were screened daily for sepsis using Sepsis-3 criteria, and a SOFA score of $\geq 2$ indicated the presence of sepsis. Screening for SIC was performed using the SIC score, with a score of 4 or higher defining SIC. All SIC patients were assessed for disseminated intravascular coagulation (DIC) using the International Society on Thrombosis and Haemostasis (ISTH) DIC score, with a score $\geq 5$ indicating DIC. The clinical outcomes were assessed in terms of days of mechanical ventilation, vasopressor use, length of stay, and ICU mortality.
**Results:** A total of 50 adult patients who developed sepsis were enrolled and their baseline characteristics were analyzed. (Fig. 1, Table 1) Amongst these, 36% (18/50) of patients were diagnosed with SIC. Patients with SIC had significantly higher requirements of vasopressor support, renal replacement therapy and mortality compared to those without SIC (Table 2).
**Conclusions:** This prospective study showed a 36% incidence of SIC with a higher requirement for vasopressor support, renal replacement therapy, and mortality in these patients.

**Table (abstract 000815)** Tables of results

| Characteristic | Overall, N=50 | SIC<4, N=32 (64%) | SIC≥4, N=18 (36%) | Difference | p-value |
|---|---|---|---|---|---|
| ICU Mortality | 13(26%) | 1 (3.13%) | 12 (66.67%) | 64% | <0.001 |
| Vasopressor support (Yes/No) | 26(52.00%) | 10 (31.25%) | 16 (88.89%) | 58% [32% - 84%] | <0.001 |

### Exploring the role and mechanisms of acute thymic atrophy in the immune dysfunction of sepsis

X. Chen[1], M. Zheng[1], H. B. Qiu[2]

**Introduction:** Immune dysfunction is a critical factor in the onset and progression of sepsis, significantly influencing patient outcomes. The thymus, responsible for T cell maturation, plays a crucial role in the immune response. Recently, a clinical study shed light on the significant role of the thymus in adult disease.Acute atrophy of thymus was was evident following cecum ligation and puncture (CLP) in animal experiments. Furthermore, thymic atrophy was also observed in the peripheral blood of septic patients, suggesting that this phenomenon may occur in individuals with sepsis as well. These findings underscore the importance of understanding the impact of thymic atrophy in adult disease and its potential implications for patient care. However, the link between acute thymic atrophy and immune dysfunction in sepsis, as well as the underlying mechanisms, remains poorly understood. This area of research warrants further investigation to enhance our understanding of sepsis pathophysiology and potential therapeutic interventions.

**Objectives:** This study aimed to investigate the impact and underlying mechanisms of acute thymic atrophy on immune dysfunction in sepsis.
**Methods:** In this study, C57/B6 mice were subjected to cecal ligation and puncture (CLP) to induce sepsis. The thymus was then examined for changes in appearance and weight at various time points post-CLP. Additionally, the ratios of thymic and peripheral T cell subpopulations, as well as the absolute numbers of T cells, were analyzed to understand the impact of acute thymic atrophy on the immune system in sepsis.Rag-GFP mice were subjected to cecal ligation and puncture (CLP) to induce thymic output, with the GFP fluorescence signal serving as a visual indicator at various time intervals. Thymectomy was conducted in C57/B6 mice to mimic the decrease in thymic output. Subsequently, two weeks later, cecal ligation and puncture (CLP) was performed to investigate the impact of thymectomy on the ratio and quantity of peripheral T cell subpopulations as well as their function post-CLP. We conducted sequencing of the transcriptome and proteome of crucial cell subpopulations believed to be involved in acute thymic atrophy. This approach aimed to identify specific molecular targets that may play a significant role in the development of thymic atrophy.
**Results:** CLP resulted in acute thymic atrophy with reduced thymic output, reduced peripheral T cell numbers, reduced naive T cell ratio, reduced TCR-stimulated proliferative function, and led to increased mortality after secondary infections($p < 0.05$). Thymectomy similarly resulted in reduced peripheral T-cell numbers, reduced Naive T-cell ratios, and reduced TCR-stimulated proliferative function, but thymectomy followed by CLP resulted in an observed attenuation of acute phase mortality compared with sham followed by CLP ($p < 0.05$). Transcriptome sequencing was conducted by isolating and sorting the subpopulation of CD4 + CD8 + double positive (DP) cells that exhibited the most notable changes during acute thymic atrophy. This analysis revealed differential gene pathways that were enriched for cellular pyroptosis. The identification of active-caspase1 has uncovered a significant occurrence of pyroptosis in TCRb- T lymphocytes during the initial phases of sepsis, involving in the development of multiple organ dysfunction syndrome in the acute stage of sepsis.
**Conclusions:** Acute thymic atrophy in the acute phase of sepsis is mainly caused by the pyroptosis of a large number of thymic immature T cells, which aggravates the multiple organ dysfunction syndrome of sepsis. Even worse, thymic atrophy leads to a decrease in the production of T cells by the thymus, further contributing to the long-term immune suppression in sepsis.

**Introduction:** Fluid balance is a fundamental parameter in the management of critically ill patients that has been broadly investigated amongst patients with different characteristics. Nevertheless, there is sparse scientific evidence regarding its prognostic value in critically ill patients with nutritional support. The objective of this study is to analyze the influence that fluid balance in the first week of ICU admission has in terms of mortality, length of ICU stay and length of total hospital stay in critically ill patients with nutritional support.
**Methods:** This was an observational longitudinal retrospective unicentric study that took place in the ICU of a tertiary care hospital between September 2022 and February 2023. Patients aged ≥ 18 years with a hospitalization period ≥ 7 days, who received nutritional support for ≥ 2 days were included. The main outcome was survival, followed by length of ICU stay and total hospital stay.
**Results:** Data from 97 patients was analyzed, with 59.80% of them being males and an average age of 60.60 years. Mortality amongst the sample was 43.30% A significant difference in fluid balance on days 4–7 was found between survivors and non-survivors ($p < 0.05$). On the other hand, the fluid balance of days 1–3 showed no significant differences. After performing a multivariate analysis using the Cox regression model, fluid balance on days 4–7 was not confirmed to have a positive or negative effect on survival in relation to length of ICU stay or total hospital stay (OR = 1).
**Conclusions:** The results suggest an association between fluid balance in days 4–7 and mortality in the critically ill patient with nutritional support. However, this cannot be verified, as this association was not confirmed in the multivariate analysis. Further prospective studies with larger sample sizes are needed to obtain more representative and reliable results.

### 000821 Diagnostic Accuracy of the Geneva Clinical Scale for Diagnostic Prediction of Pulmonary Embolism in Adults Aged 18 and Older Admitted Between 2009 and 2020 with Suspected Pulmonary Embolism at a Third-Level Institution in Colombia: a retrospective cohort

M. Pérez-Garzón[1], C. López-Vega[2], A. Bastidas-Goyes[3], L. Ortiz-García-Herreros[1], E. Ramos-Isaza[4], M. Aramendiz-Narvaez[3], H. Robayo-Amortegui[5]

**Introduction:** Venous embolism stands as the third most frequent cause of cardiovascular-related deaths, a phenomenon gaining increasing significance in aging populations (1). Standardized clinical decision rules (CDRs) have been formulated to establish this pre-test probability. These instruments incorporate variables extracted from medical history, physical examinations, and diagnostic tests to quantify the probability of a clinical diagnosis, prognosis, or response to treatment in each individual patient (2). For diagnosing pulmonary embolism, noteworthy CDRs include the Wells and Geneva scales, both of which have been simplified from their original versions and validated in diverse populations (3,4,5). The original Geneva scale, developed in 2006 through logistic regression analysis (2), is a CDR based on objective clinical elements, encompassing 8 independent variables with different weights contributing to the final result (4,6). To address potential calculation errors, a simplified version was derived, assigning equal weight to different variables. The exception is a double weighting for a heart rate exceeding 95 beats per minute. This simplified scale has been validated, demonstrating the possibility of simplifying the original scale without compromising diagnostic acuity (2,5). Both scales classify clinical probability based on the score into mild, moderate, and severe categories, or probable and improbable cases of thromboembolism.
**Objectives:** Evaluate the general applicability of the Geneva scale for diagnosing PE in adults aged 18 and older admitted with suspected PE to a Third-Level Institution in Colombia. Secondary objectives included characterizing the population with suspected PE based on clinical probability, risk factors, and established diagnostic criteria, as well as determining diagnostic performance applied to a Third-Level Institution.
**Methods:** A retrospective cohort study with diagnostic test analysis was conducted on patients in the emergency department or hospitalized between 2009 and 2020 with suspected pulmonary embolism at a Third-Level Institution in Colombia. The original and simplified Geneva

scores were applied to 1237 subjects aged 18 and older with suspected pulmonary embolism and compared with confirmatory results from pulmonary angiography. All necessary variables for constructing the original and simplified Geneva rules were recorded, and calculations for sensitivity, specificity, likelihood ratios 50 (LR), and Receiver Operating Characteristic Curves (ROC) curves were performed.

**Results:** From the sample collected between 2009 and 2020, information from 2098 patients was gathered. Among these, 1237 met the inclusion criteria, constituting 58% of the collected sample (Figure 1). The mean age was 60.49 with an SD of 19.38, and a majority of patients were female (52.8%). Exclusions comprised 860 patients, representing 42% of the initial sample. Among them, 18 were pregnant, 9 were under 18 years old, and 830 lacked suspicion or clinical signs of PE upon admission or during hospitalization. Out of the excluded, 488 patients (39%) were confirmed with a PE diagnosis by CTPA.

The Geneva original score exhibited a sensitivity, specificity, Positive Likelihood Ratio (LR+), Negative Likelihood Ratio (LR-), and Area Under the Curve (AUC) of 60%, 54%, 1.3, 0.728, and 0.506, respectively. The simplified Geneva score showed 59%, 57%, 1.4, 0.7, and 0.546 for sensitivity, specificity, LR+, LR-, and AUC, respectively.

**Conclusions:** The use of the original or simplified Geneva score in our population may not be useful for a diagnostic approach to pulmonary embolism. Both scales demonstrate almost negligible discriminatory capacity, necessitating the evaluation of other standardized clinical decision rules to assess the diagnosis and pretest probability of pulmonary thromboembolism.

### Relatives' perceptions of their involvement in decision-making for patients in ICU: a pilot study

T. Callus[1], C. Danbury[2]

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000822

**Introduction:** This pilot study examines the current practice of the involvement of patients' relatives in the context of ICU decision-making. Against the legal and professional backdrop of placing the patient and their subjective values, beliefs, and wishes at the heart of all treatment decisions, we explore the extent to which relatives believed they were involved in the decision-making and how they perceived their actual and desired role. We are increasingly aware that relatives are also susceptible to suffering from post-intensive care syndrome so understanding their involvement in the decision-making process for their loved one is an important aspect of care. We set out briefly the current legal framework that applies to decision-making and the role of relatives, before presenting our findings and analysis. The work is ongoing with the next stage starting in 2024/2025 looking at the role of relatives across the UK in a number of sites, funded by a grant from the MPS Foundation. It is anticipated that the project will be replicated across the member states of the ESICM in due course.
**Methods:** This was a pilot study to identify areas of decision-making practice which would benefit from greater scrutiny to improve both patient and relative experience and to ensure that HCPs have a consistent approach to the implementation of shared decision-making which respects the fundamental need to place the parent at the heart of their treatment: 'no decision about me, without me'. The study adopted a phenomenological approach to increase insight into individual experiences of the patients' relatives in the decision-making process including their own perception of their role. Coupled with a grounded theory approach, the study enabled us to examine how the existing framework is both applied and perceived in practice.
The study used anonymous questionnaires administered to relatives of patients admitted to one of the intensive care units within the hospital.
**Results:** What is apparent from our small-scale pilot study is that the necessary engagement with relatives about the patient's wishes (i) does not always happen; and (ii) when it does, the perception of many relatives is that the purpose is simply to be told of the decision that the HCP has taken. Nearly 87% of respondents (52/60) thought that part of their role was to listen and be told of the clinical treatment decision and out of this group nearly 50% (24/52) thought this was their only role. Only 4/52 (8%) thought they should also convey what they knew the patient wanted. Across all of the respondents, 25/57 (44%) said they knew the Patient's opinion, but only 9/57 (16%) said they had conveyed this to the clinical team.
Interestingly, overall respondents indicated that they thought their role *should* be to say what *they* think is best for the patient (25/57; 44%). However, out of these 25 respondents, only 9 thought that should be their sole role.
**Conclusions:** Notwithstanding the limits of this small study, some interesting observations can be made which support further research through a larger representative study. Most notably, whilst decision-making requires greater engagement with the patient's own values, beliefs and opinions, it appears that in practice, HCPs are not routinely able to identify these, at least where the patient cannot communicate. This suggests that further training may be helpful for HCPs to clarify their role and to assist them in explaining to relatives what part they can legally play in the decision-making process.
It seems that the belief that 'doctor knows best' is deeply entrenched, as illustrated by the proportion of our respondents who thought their role was to listen and be told what treatment decisions had been taken. This has not really changed as Epstein found in 2011 that 'family members' contributions to decision-making are frequently ignored in clinical consultations and in research on decision-making'. The feeling of disempowerment is one factor that may lead to family members developing Post Intensive Care Syndrome – Family (PICS-F).

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000823

**Introduction:** In-hospital cardiac arrest (IHCA) is a potentially fatal emergency that demands immediate and coordinated action to maximize patient survival. Successful outcomes for IHCA rely on a proficient resuscitation team, immediate initiation of effective cardiopulmonary resuscitation and defibrillation, and organizational frameworks to facilitate IHCA response (1).
**Objectives:** The main objective of the study is to describe the clinical and evolutionary characteristics of patients attended by the IHCA team at our center. As a secondary objective, we aim to retrospectively identify abnormalities in vital signs or the appearance of potentially alarming symptoms in the hours preceding cardiac arrest (CA).
**Methods:** This is a descriptive retrospective study that includes all patients assessed by the in-hospital cardiac arrest team over a period of 3 years. For each patient, demographic and clinical variables (admission department, cause of CA), information related to CA management (initial electrocardiographic (EKG) rhythm, therapeutic interventions), evolutionary data (return of spontaneous circulation, hospital discharge), and abnormalities in vital signs or mention of potentially alarming symptoms in the nursing records preceding CA were collected. Statistical analysis was conducted using R 4.1.2 for Windows.
**Results:** 93 patients were included. The median age was 73 years (IQR 59–81). 73% of the patients were male. The causes of cardiac arrest, initial rhythm, evolution, and reasons for non-initiation/interruption of maneuvers are detailed in Table 1. In 31 patients (33%), abnormalities in vital signs or the appearance of potentially alarming symptoms were identified and, of those, the most frequent were: low oxygen saturation (16%), arterial hypotension (10%), increased work of breathing (7%), and oliguria (5%).

**Table 1 (abstract 000823)** Causes of CA, initial rhythm, evolution, and reasons for non-initiation/interruption of maneuvers

| Service where IHCA occurs: | Percentage |
|---|---|
| Medical Service | 74 |
| Surgical/Medical-Surgical Service | 26 |
| Cause of CA: | |
| Unknown | 35 |
| Respiratory Insufficiency | 23 |
| Procedure-related | 10 |
| Hemorrhage | 5 |
| Others | 27 |
| Initial EKG rhythm (only in confirmed CA): | |
| Asystole | 80 |
| Pulseless Electrical Activity | 13 |
| Ventricular Fibrillation | 5 |
| Ventricular Tachycardia | 2 |
| Outcome: | |
| False CA | 24 |
| Does not regain spontaneous circulation | 51 |
| Dies in ICU | 5 |
| Survives hospital discharge | 20 |
| Reasons for not initiating/terminating CPR: | |
| False CA | 62 |
| Poor prognosis/Futility | 35 |
| Do Not Resuscitate order | 3 |

**Conclusions:** In our registry, survival following an episode of IHCA is globally low. The most frequently identifiable causes of IHCA are respiratory failure and procedure-related. In a significant proportion of patients, abnormalities in vital signs or the appearance of potentially alarming symptoms are identified in the hours preceding IHCA.

"Policlinico-San Marco", Catania, Italy; [5]Department of anesthesiology and intensive care, University Hospital "G. Rodolico", Catania, Italy
**Correspondence:** F. Sanfilippo
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000824

**Introduction:** Assessment of fluid-responsiveness (FR) is crucial in cardiac surgery patients. Assessment of Inferior Vena Cava collapsibility (IVCc) and Aortic Valve Velocity Peak variability (AV-Vpeak) are commonly utilized for FR. However, several obstacles preclude their use in cardiac surgery patients (chest drains, poor acoustic windows). Appealing alternatives might be the variability of Ascending/

Descending Aortic Velocity Peak (Aorta-Vpeak) from the suprasternal window, or Internal Jugular Vein collapsibility (IJVc).
**Objectives:** To determine the feasibility of alternative methods for FR assessment.
**Methods:** Prospective observational single-centre study on 56 healthy volunteers (Ethical Approval obtained). We evaluated the feasibility of Aorta-Vpeak variability [(Velocitymax-Velocitymin)/Velocitymean] and of IJVc [(Diametermax-Diametermin)/Diametermax], and their ability in predicting FR. These were compared with other parameters: AV-Vpeak variability and the IVCc (both subcostal and transhepatic window, both M-mode and with automated border detection software). FR was determined according to changes in cardiac output (CO) between baseline and its highest value within two minutes after passive leg raising. A cut-off of 10% increase was used to define FR. CO was obtained with non-invasive continuous monitoring. We analysed the Area Under the Receiver Operating Characteristic Curve (AUC-ROC); the correlation between variables was analysed with Pearson r coefficient.
**Results:** Feasibility of suprasternal Aorta-Vpeak and IJVc were 96.4% and 94.6%, respectively. The highest value of AUC-ROC was observed for AV-Vpeak (0.83; cut-off 10%, sensibility 88%, specificity 64%), whilst the performance of other methods was suboptimal (Table 1). Suprasternal Aortic-Vpeak showed significant correlation with AV-Vpeak ($p = 0.003$; moderate degree $r = 0.40$). Conversely, IJVc had no correlation with all the IVCc measurements (subcostal or transhepatic, M-mode or automated border detection).
**Conclusions:** Despite limited FR predictivity, in healthy volunteers we found excellent feasibility for Suprasternal Aorta-Vpeak variability and IJVc, warranting further investigations in cardiac patients. The significant correlation of Aorta-Vpeak with the AV-Vpeak variability is physiologically sounded and seems worth of investigation in patients.

| Method | AUC value |
|---|---|
| AV-V peak (5-chamber view) | 0.83 |
| Suprasternal Aortic-V peak | 0.50 |
| IJVc M-Mode | 0.46 |
| IVCc subcostal in M-mode | 0.56 |
| IVCc subcostal in automated border detection | 0.62 |
| IVCc transhepatic in M-Mode | 0.54 |
| IVCc transhepatic in automated border detection | 0.67 |

**Fig. (abstract 000824)** Area Under the Curve (AUC) of different methods for prediction of fluid responsiveness in healthy volunteers. AV-V:Aortic valve velocity; IVC: inferior vena cava collapsibility; IJV: Internal jugular vein collapsibility

*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000825

**Introduction:** Nutrition and exercise may mediate preservation of muscle mass and function, but studies on the effectiveness of a combined intervention in critically ill patients are lacking. Hence, we studied the effect of a combined exercise and high protein nutrition intervention on muscle mass and function in critically ill patients.
**Methods:** We performed a randomized controlled trial (RCT) in adult critically ill patients. All patients received standardized exercise and 1.5 (intervention) or 1.0 (control) g/kg/day protein. The primary outcome was a change between day 1–3 (T1) and day 8–10 (T2) in contractility of single myofibers (maximum force, normalized force, and calcium sensitivity of both slow-twitch fibers and fast-twitch fibers). Secondary outcomes were myofiber cross-sectional area (CSA) and proportion of fast-twitch fibers from cryosections, bio-electrical impedance derived fat free mass (FFM), ultrasound-derived quadriceps muscle layer thickness (QMLT) and diaphragm thickness. Differences between groups were tested by using Mann–Whitney U tests. Correlations for both separate measurements and change over time between in vitro and bedside measurements were studied by Pearson's Rho correlation coefficient.
**Results:** In total, 10 patients had two muscle biopsies taken. Protein provision was not significantly different between groups (intervention 1.1[1.7] vs control 0.9[0.1] g/kg). Myofiber contractility did not significantly change in the total group, and changes were not significantly different between study groups (Fig 1). Myofiber CSA did not significantly change over time in the total group (-737 ± 1254 um2). FFM and QMLT did not significantly change over time, nor were there significant differences between groups. We found strong and significant correlations for separate measurements for myofiber CSA and FFMI ($r = 0.68$, $p = 0.010$, Fig 2-A) and maximum force of the fast-twitch fibers and QMLT ($r = 0.72$, $p = 0.029$, Fig 2-B). Regarding change over time, we found strong and significant correlations for slow-twitch fibers and FFM ($r = 0.97$, $p = 0.002$, Fig 2-C) and maximum force of fast-twitch fibers and QMLT ($r = 0.96$, $r = 0.039$, Fig 2-D).
**Conclusions:** To our best knowledge, this RCT is the first to study the effect of a combined exercise and high protein nutrition intervention on changes in myofiber CSA and contractility in critically ill patients. We found a mean decrease of approximately 17% of myofiber CSA. Albeit, we found no significant change in contractility parameters or bedside measurements over time for the total group nor differences between study groups. Changes in contractile parameters over time were widely spread, possibly reflecting the heterogeneous patient population. We did find strong correlations between contractility parameters and both FFMI and QMLT, and myofiber CSA and FFMI. Bedside measurements such as FFM and QMLT may provide valuable information on muscle function, but further research is needed.

**Correspondence:** S. Majumder
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000826

**Introduction:** Sepsis is still a common cause of morbidity and mortality worldwide. Delay in treatment of patients with sepsis and septic shock increases mortality. The blood biomarkers may provide faster information for the assessment of the microbial etiology of infection. In our study we compared 4 biomarkers, neutrophil–lymphocyte count ratio [NLCR], red cell distribution width [RDW], procalcitonin [PCT], c reactive protein [CRP]) for their diagnostic and prognostic ability in sepsis/septic shock.
**Objectives:** Comparison of biomarkers (neutrophil–lymphocyte count ratio, red cell distribution width, procalcitonin, c reactive protein) in diagnosis and prognosis of sepsis/septic shock.
**Primary Objective** Comparative efficiency of neutrophil–lymphocyte count ratio (NLCR), Red cell distribution width (RDW), which are a part of complete blood count with the traditional biomarkers, procalcitonin (PCT) and C reactive protein (CRP) for their diagnostic and prognostic ability in sepsis and septic shock.
**Secondary Objective** Association of RDW, NLCR, CRP, PCT with 28 days morbidity and mortality in patients with sepsis and septic shock.
**Methods:** After review of the Institutional Ethical Board, our study was conducted over a period of 1 year. It was a prospective observational study where data was collected from patient admitted to Intensive Care Unit with sepsis and septic shock and meeting the inclusion criteria. Patients were managed according to the Surviving Sepsis Campaign. On admission, along with patient's demographic characteristics, baseline vital parameters (heart rate, blood pressure, oxygen saturation, temperature, respiratory rate) and baseline laboratory investigations were noted. The RDW, NLCR, CRP, and PCT values were followed up over a period of 28 days or till discharge/death of the patient. Also, the duration of ICU stay, requirement of dialysis, mechanical ventilation, and vasopressors were noted, along with the 28 days ICU outcome.
**Results:** A total no of 200 patients were included in the study, of whom 150 patients had sepsis and septic shock and 50 patients had non septic conditions. Out of a total of 150 sepsis/septic shock patients 97 (65%) survived and 53(35%) patients died.PCT had the highest diagnostic AUROC when compared with other biomarkers (AUC of 0.956, sensitivity of 90% and specificity of 98%). Also, PCT had the highest prognostic AUROC amongst other biomarkers in our study (AUC of PCT for prognosis over 28 days period was 0.720).
The baseline mean RDW was 15.994 ± 2.34 in survivors and 17.423 ± 3.11 in non-survivors (p **0.04**). The baseline mean values of other biomarkers were not significant between survivors and non-survivors. The median survival time in patients with elevated RDW was 21.3 days compared to 26.5 days in patients with normal RDW (p **0.011**).
**Conclusions:** Rapid identification and early institution of therapy for sepsis and septic shock has a major impact on the clinical course, management, and outcome of critically ill intensive care patients.
We performed the present study to compare the diagnostic and prognostic efficiency of NLCR, RDW, PCT, and CRP in sepsis and septic shock.
Procalcitonin showed better diagnostic and prognostic performance when compared with other biomarkers of sepsis i.e. C reactive protein, Red cell distribution width, and Neutrophil Lymphocyte count ratio. Procalcitonin had an even better diagnostic efficiency in bloodstream infections when compared with other biomarkers.
However, Red cell distribution width at admission and increase in RDW level was associated with a reduced median survival time over 28-day period in the ICU and hence may be used as a prognostic tool in sepsis/septic shock patients.

### Impact of night-time room entries on sleep in ICU: a polysomnographic observational study

X. Drouot[1], Q. Heraud[2], J. P. Frat[3], R. Coudroy[3], C. Rault[4], F. Arrivé[3], F. Boissier[3], D. Chatelier[3], S. Le Pape[3], A. Veinstein[3], M. L. Debarre[3], A. Thille.[3]

**Introduction:** Sleep in intensive care unit (ICU) patients is very frequently disturbed. These sleep disruptions are associated with prolonged duration of weaning from a ventilator and with higher mortality. Noise and light levels are often reported by patients as sleep-disrupting factors. Room entries by healthcare providers during night-time might also disrupt sleep. The aim of this study was to quantify their impact on sleep.
**Methods:** This is an observational monocentric prospective study involving conscious adults admitted to ICU, not receiving sedatives. Patients with brain diseases or treated with neurological drugs were

not included. After participants' informed consent, sleep was recorded from 7 pm to 8 am using a mini-polysomnograph. Sleep was scored manually by an expert sleep specialist. An entry-exit counter (infrared beam) positioned at the doorstep of the patient's room recorded the number, the hour, and the direction of the passage (in or out).
**Results:** Among 45 included patients, 27 were analyzed. Median [25th – 75th] age was 65 years [59–69]. The main reason for ICU admission was acute respiratory failure (70%). Among the 27 patients, 19 were receiving non-invasive oxygenation support, 4 were intubated, and 4 were spontaneously breathing with ambient air.
The median duration of sleep recording was 675 min [641–699]. Median sleep time was 180 min [108–214] and 3 patients (11%) displayed atypical sleep. The median number of room entries during sleep recording was 29 [22 -36] and 21% [14–36] occurred while patients were sleeping.
Considering the 27 recordings and all entries, median sleep time in the 10 min *after* room entry was significantly lower than sleep time during the 10 min *before* (0.0 min [0.0–1.8]) vs. 2.3 [1.0- 4.0], respectively, $p = 0.001$).
**Conclusions:** Our study confirms that sleep duration is short in ICUs. Room entries by healthcare providers during nighttime may be an important sleep-disrupting factor. Real-time sleep monitoring of ICU patients could be of interest to reduce room entries while patients are sleeping. Such monitoring could be of help to combat sleep disruptions and their consequences and, more generally, to improve sleep in ICUs.

**Introduction:** In 2016, the local sedation protocol for post-cardiac arrest (CA) patients in Brest, France treated with targeted temperature management (TTM) was changed from iv midazolam to inhaled isoflurane. The pharmacokinetic profile of isoflurane may potentially facilitate a rapid wake-up and better short-term cognitive function, facilitating earlier extubation and ICU discharge.
**Objectives:** We aimed to explore the impact of introducing inhaled sedation in our ICU as first-line therapy for post-CA survivors with a focus on delirium incidence and neurological outcome at ICU discharge.
**Methods:** Among 510 post-CA patients admitted to our ICU during the study period, 87 midazolam-sedated patients and 87 patients receiving isoflurane via the Sedaconda ACD were analyzed after propensity matching based on age, time to return of spontaneous circulation, gender and first rhythm. Opioid analgesia was provided in both groups. TTM at 33 °C was maintained for 24 h, followed by slow rewarming at 0.25 °C/h. Neurologic assessment included daily CAM-ICU assessments for delirium and Cerebral Performance Category (CPC) scoring at ICU discharge, where a value $\geq 3$ was considered a good neurological outcome.
**Results:** Isoflurane patients had lower delirium incidence than midazolam patients (16.1% vs 32.2%; $P = 0.03$), while there was no significant difference in CPC scores at ICU discharge. Mortality did not differ between groups. Isoflurane patients had lower cumulative sufentanil dose ($956 \pm 1418$ vs $1433 \pm 1148$ ug, $P < 0.001$), shorter ventilation duration ($78 \pm 99$ vs $167 \pm 155$ h, $P = 0.01$), shorter ICU length of stay ($7.9 \pm 6.4$ vs $8.5 \pm 9.4$ days, $P = 0.01$) and needed renal replacement therapy less frequently (17.8% vs 37.9%, $P = 0.03$).
**Conclusions:** Isoflurane sedation during TTM after CA was associated with a reduction in delirium incidence, ventilator duration and ICU length of stay. Neurological outcomes at ICU discharge and mortality did not differ between groups.

*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000830

**Introduction:** Cardiac arrest (CA) in patients with COVID-19 is associated with poor survival. Early reports of outcomes of COVID-19 patients who suffered in-hospital cardiac arrest (IHCA) or out-of-hospital cardiac arrest (OHCA) suggested mortality rates of 97–100%. However, large-scale studies examining the impact of COVID-19 on outcomes after CA are limited.
**Objectives:** To compare mortality rates and risk factors for mortality after CA in patients with and without COVID-19 in the first year of the pandemic (2020) and in the year preceding the pandemic (2019).
**Methods:** We performed a retrospective cohort analysis of hospitalized adult patients with CA (both IHCA and OHCA) using the 2019–2020 Nationwide Inpatient Sample (NIS), a large national database in the United States. We stratified patients based on the presence or absence of COVID-19 infection at the time of CA. We performed multivariable logistic regression analyses using patient demographics (age, sex, race, home income quartile, insurance coverage, do-not-resuscitate order), the 31 Elixhauser comorbidities, and hospital demographics (size, teaching status, rural hospital) as covariables.
**Results:** We identified 129,737 patients who had a CA during the study period. In 2020, 70,806 patients had a CA, of which 11,134 (15.7%) had COVID-19 infection. The unadjusted post-CA mortality in patients with COVID-19 was higher (88.2%) compared to patients without COVID-19 in 2020 (59.1%) and 2019 (56.4%). In 2020, mortality after CA in COVID-19 patients was highest in December (91.3%) (Supplementary Table 2). Patients who survived CA with COVID-19 had a longer mean length of stay in the hospital, compared to those without COVID-19 (9 vs 4 days) and were less likely to receive the percutaneous coronary intervention (1.6% vs 14.6% without COVID-19 in 2020 and 16.1% in 2019). Of CA patients with COVID-19, 2.0% were discharged home, compared to 14.6% of CA patients without COVID-19 in 2020 and 15.5% without COVID-19 in 2019.
In the multivariable logistic regression model, factors associated with increased odds of mortality after CA in patients with COVID-19 were obesity (OR 1.33; 95% confidence interval (CI) 1.14–1.54), uncomplicated diabetes (OR 1.60; 95%CI 1.32–1.93) and renal failure (OR 1.24; 95%CI 1.04–1.48). Patients with COVID-19 had four times higher odds of mortality from CA compared to patients without COVID-19 in 2020 (OR 4.02; 95%CI 3.75–4.32). Patients without COVID-19 who suffered a CA in 2020 had an increased odds of mortality compared to patients without COVID-19 in 2019 (OR 1.22; 95%CI 1.13–1.33).
**Conclusions:** Mortality after CA was increased in patients with COVID-19 compared to those without COVID-19 in 2020. In addition, mortality after CA in patients without COVID-19 increased in the first year of the pandemic (2020) relative to the year prior (2019).

### Phenotypic characterization of intensive care patients with infection: a cluster analysis

A. Oliveira[1], A. R. Fernandes[2], G. Mendes[1], M. Fernandes[1], M. Vera-Cruz[1], J. Gonçalves-Pereira[1]
[1]Intensive Care Unit, Hospital de Vila Franca de Xira, Estrada Carlos Lima Costa, Vila Franca de Xira, Portugal, Vila Franca de Xira, Portugal; [2]Lisbon University, Lisbon School of Medicine, Lisboa, Portugal
**Correspondence:** A. Oliveira
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000831

**Introduction:** Infection and sepsis present significant challenges in intensive care units (ICUs), often leading to adverse outcomes such as increased mortality and prolonged hospitalization. Its severity and clinical course are influenced by a multitude of factors, including host characteristics and pathogen virulence. While numerous studies have examined the predictors and outcomes of infection and sepsis in ICUs, according to risk factors or clinical evolution, the heterogeneity of the patient population and the infectious agents poses challenges to developing universally applicable treatment approaches.
**Objectives:** To develop a phenotyping method through cluster analysis using host and pathogen characteristics, to better understand the heterogeneity of patients with infection and sepsis.
**Methods:** Retrospective study, conducted at the ICU of Hospital Vila Franca de Xira. Data from patients admitted between January 2015 and December 2019 were collected. Cluster analysis was performed using three variables: patients' age (categorized into four groups), infection focus, and isolated microorganisms (categorized into 15 subgroups). Primary outcomes assessed included ICU and hospital, both mortality rate and length of stay (LOS).
**Results:** Among 1923 patients, 721 (37.5%) had at least one microbiological isolate during their ICU stay. Infected patients were characterized by older age and higher severity, and experienced increased mortality and longer ICU LOS. Cluster analysis identified five distinct patient clusters with different trajectories and outcomes (fig. 1), including differences in mortality rate, ICU LOS, vasopressor, renal replacement therapy, and invasive mechanical ventilation requirements (Table 1).

**Table 1 (abstract 000831)** Host characteristics and outcomes by cluster

| | Cluster 1 (N 253) | Cluster 2 (N 146) | Cluster 3 (N 43) | Cluster 4 (N 127) | Cluster 5 (N 152) | *p* |

SAPS II – Simplified Acute Physiology Score II; ICU—Intensive Care Unit; H—Hospital; RRT—Renal Replacement Therapy. Data presented as N (%) except *- mean ± standard deviation or ** Median [interquartile range].

**Conclusions:** There is considerable heterogeneity of the ICU population admitted with infection and sepsis. Using pathogen (isolated microorganism) along with host (focus of infection, age) characteristics allows phenotypic characterization.
Identifying distinct patient clusters with differing outcomes, contributes to the development of personalized approaches to clinical trials, management, and resource allocation in the critical care setting, ultimately aiming to improve patient outcomes.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000833

**Introduction:** *C. parapsilosis* (CP) is an increasing cause of invasive infection in critically ill patients. We studied risk factors for ICU-acquired CP-BSI, the incidence of fluconazole and echinocandin resistance and outcomes.
**Methods:** Patients admitted between January 2013 and October 2022 with at least one positive sample for CP during their ICU stay (infection and/or tracheal colonization) were included. Risk factors for CP-BSI and for fluconazole and echinocandin susceptibility were studied.
**Results:** 144 patients with *CP* were identified, 45 (31.3%) of whom had CP-BSI. 17 of the 45 CP-BSI (37.8%) were catheter-related and 28 (62.2%) cases were classified as primary BSI. Patients with CP-BSI were comparable to the 99 non-BSI in demographics (sex, age, diagnostic category, urgent and elective admission, incidence of diabetes, hypertension, cardiovascular disease, chronic renal dysfunction, immunosuppression, severe acute pancreatitis, prior abdominal surgery, COVID-19, APACHE-II, and specific risk factors (invasive mechanical ventilation, vasopressors, acute kidney failure, renal replacement therapy, parenteral nutrition > 6 days, steroids > 2, propofol infusion, central venous catheter > 6 days, antibiotics > 6 days, and prior antifungals). ICU-Length of stay was significantly longer in CP-BSI than in non-BSI patients (63.5 ± 37.7 *vs*. 46.6 ± 51.4, $p = 0.037$). The mean (SD) timepoint of CP-BSI was 29.3 ± 26.0 days into ICU admission. Attributable mortality rates were comparable. Susceptibility for fluconazole was 55% (54 of 100) and 59% for echinocandins (59 of 100). There were statistically significant differences in susceptibility of blood and all other site isolates for fluconazole (13 of 45, 28.9% vs. 42 of 55, 76.4%, $p = 0.000$) and echinocandins (19 of 45, 42.2% vs. 40 of 55, 72.7%, $p = 0.002$), respectively. Appropriate empirical antifungal therapy was significantly lower in CP-BSI (23 of 40, 57.5% vs. 29 of 35, 82.9%, $p = 0.018$).
**Conclusions:** We did not identify specific risk factors for ICU-acquired CP-BSI in critically ill patients with CP isolates. We observed a higher fluconazole and echinocandin resistance in CP-BSI, a finding with important implications for empirical treatment.

## "Glad to be saved but still longing for death"- The complexity of needs in patients admitted to the ICU after suicide attempt

A. Helme[1], J. Hagen[2], M. Bjørnaas Asphjell[3], T. Grimholt[4], K. Hofsø[5], T. Rustøen[6]

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000834

**Introduction:** Patients admitted to an Intensive Care Unit (ICU) after a suicide attempt are in a vulnerable situation. ICU stays are characterized by significant distress and discomfort, but we lack knowledge about the experiences of patients in ICU after suicide attempts. Therefore, exploring the suicide attempt patients' experiences with care at the ICU can provide valuable insights for optimizing their treatment and recovery process. There is an urgent need for deeper insights into patients' experiences of care during ICU treatment, as the treatment of attempted suicide begins at the ICU.
**Objectives:** This study aims to explore the patient experiences of care while admitted to an ICU after a suicide attempt, and to understand which aspects are important for patients to experience themselves being well taken care of emotionally.
**Methods:** A qualitative study was conducted, and data were collected through semi-structured interviews of patients treated in the ICU after a suicide attempt. The studies were performed at four ICUs in Oslo, Norway from 2022 to 2023. Patients were asked for inclusion while in the ICU. Inclusion criteria: ≥ 18 years, stayed ≥ 12 h in the ICU, and have attempted suicide. Exclusion criteria: Psychologically unable to be interviewed, not able to read or understand Norwegian. Ten individual interviews were conducted by the first author, an ICU nurse/PhD candidate, shortly after the suicide attempt. The sample includes patients aged 19–96 (median 40), 4 females and 6 men. The interviews were analyzed by using Thematic Analysis.
**Results:** We developed three main themes: *Professionals displaying authenticity*, *Addressing suicidality*, and *Importance of small talk and simple gestures*. Patients expressed the importance of healthcare professionals shedding their professional facades and being more personal. Patients emphasized the importance of direct conversation regarding suicidality, accompanied by a willingness to engage in conversation. They highlighted the value of casual conversation, such as greeting with a smile and engaging in small talk, as it requires minimal effort but can have a profound impact. An example could be to engage in small talk while the blood pressure was being measured. Additionally, the patients appeared highly sensitive to feelings of rejection, indicating that seemingly gestures such as not taking time to sit down or not seeking eye-contact might be perceived as off-putting. The patients felt well taken care of regarding the somatic aspects.
**Conclusions:** The patients wanted the healthcare professionals to be authentic in their interactions to promote trust and openness, engage in conversations about suicidality and create a friendly and safe atmosphere through simple gestures and small talk. In forthcoming patient encounters in the ICU, this insight can be utilized to improve treatment and care for this subgroup of ICU patients and to inspire further research.

### Transition from ICU to hospital ward – the experience of patients and their relatives

I. Greve[1], T. P. Sonne[2], K. Armbruster[2], L. Russell[1]
[1]Dept. of Intensive Care, Copenhagen University Hospital Gentofte, Hellerup, Denmark; [2]Dept of Pulmonology, Copenhagen University Hospital, Herlev Gentofte, Gentofte, Hellerup, Denmark
**Correspondence:** I. Greve
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000835

**Introduction:** The transition from ICU to hospital wards is a vulnerable time for patients and their relatives [1,2,3]. Unplanned transitions may expose patients to the risk of medical errors and adverse events and lead to poor patient and family satisfaction with care [4].
Previous studies have indicated that relatives have a significant role in providing support during the transition phase [5].
Transition from ICU to ward has been studied previously, although mostly from the administrative perspective [2,6,7]. In this study, we are looking at the transition phase from both the patient and their relative's perspectives.
**Objectives:** To gain insight into patients and theirs relatives experiences of the transition phase from ICU to hospital ward.
**Methods:** A qualitative study using semi-structured interviews of patients and their relatives two days after ICU discharge. Interviews were transcribed and key themes identified using thematic content analysis. All participants gave their informed consent.
**Results:** We interviewed six patients and seven relatives. The median age of the patients was 76 (IQR 69–79) years and 33% were female. The median age of the relatives was 68 (IQR 68–78) years and 72% were female. The median time in the ICU was 3 (IQR 3–8) days. All patients had received organ support, including invasive or non-invasive respiratory support.
Five main themes related to transfer from ICU to a standard hospital ward were identified: 1. Relief (of being past the most critical phase); 2. Feeling unsafe; 3. Lack of communication; 4. Not being acknowledged; 5. Another level of care.
Interestingly, the relatives' perspectives differed noticeably from the patients in some areas. Whereas several patients emphasized a feeling of being abandoned: *"Well – care and attention? [I wish] that someone would come by and ask- are you okay? Because there was nothing", t*he relatives were more concerned about the lack of information from the staff: *"So, when I came as a relative, I would have liked to be greeted and for someone tp explain what had happened and how things work here—that is basically the most important thing".*
The themes that were most dominant in both groups were lack of communication and feeling unsafe (Tables 1 and 2).
**Conclusions:** The first days after arriving at the ward after ICU discharge seem to be when patients and their relatives are most vulnerable. The way the staff meet them is of the uttermost importance. Therefore, as ICU nurses, we should aim to facilitate this process together with nurses at the receiving ward, structuring the transition around the needs of patients and their relatives.

**Table 1 (abstract 000835)** Feeling unsafe

| Not sure the treatment is correct |
|---|
| *"She didn´t know so much, the nurse. She didn´t know if I had pneumonia, and nothing about the pain relievers – or about anything at all"* |
| *"I had to talk to two doctors and they said the opposite of each other. So, one person said one thing, and then she went home and the other doctor did the opposite"* |
| *"Things didn't really seem to be in control, and it made me feel unsafe when I left [my relative] at the place because I wasn´t sure they knew what they were doing"* |

**Quotes from patients and relatives**

**Table 2 (abstract 000835)** Lack of communication

| Not being greeted at arrival at the ward |
|---|
| *"Well, I think it´s great that the nurse from ICU accompanies the patient [to the ward] but it would be good if there also was someone here to receive you. So it was like a transition that the patient was a part of"* |
| *"It would have helped if a nurse, or at least somebody from the ward, had said "Hello, we are here and we will take care of him". It would have helped a lot because I was so sad when I left...[Getting emotional]"* |
| *"It was busier down here [at the ward]. There is not exactly a caretaker available immediately and I would say that is actually a shame, because you feel a bit abandoned"* |

### Difficult airways, easy solutions: a two-cycle standards-based prospective audit

A. Truelove, G. Kumaran, K. Coppack, T. Mumtaz
Critical Care and Anaesthetics, Barnet Hospital, London, United Kingdom
**Correspondence:** A. Truelove
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000836

**Introduction:** The results of the fourth national audit project (NAP4) showed that at least one in four major airway events in a hospital are likely to occur in the intensive care unit (ICU) or the emergency department; some of the key reasons for this include poor identification of at-risk patients, inadequate provision of skilled staff and equipment to manage these events successfully, and a failure to anticipate and plan for problems. Airway strategies are defined as "a predetermined set of sequential plans designed to manage the failure of previous attempts at airway management and ultimately achieve oxygenation, ventilation and protection against aspiration", with NAP4 recommending that every ICU should identify patients at risk of airway events and an airway strategy including primary and back-up plans should be made and documented for each patient. The plan should also identify any additional equipment and skills needed to carry out the plan and be clearly communicated in case of an airway emergency. After a case series of critically unwell patients at high risk of airway events in the ICU of a district general hospital, an ICU emergency plan was designed (Figure 1) but uptake and documentation remained poor.
**Objectives:** Every ICU patient should have an algorithm to manage intubation; the default should be the generic difficult airway society (DAS) algorithm but pre-identified patients, e.g. with known previous difficult intubation, known tracheostomy or laryngectomy, should have alternative plans in the DAS format.
**Methods:** The ICU emergency airway plan was designed to include key information relevant to the NAP4 guidelines. This included patient details, airway classification (native, tracheostomy, or previous laryngectomy), intubation details (Cormack-Lehane grade or VCI score, endotracheal tube size and length, date of tracheostomy, type of tracheostomy), whether the patient required the generic or a modified DAS airway plan, and a turning plan.
A two-cycle closed loop audit was performed involving serial snap audits of all ICU patients assessing four key points: level of acuity; whether a poster was present; whether the patient had been previously intubated, and if so, whether the grade and blade were detailed

or an alternative airway plan was needed or given; whether a tracheostomy was present, and if so, whether details were recorded or an alternative airway plan was needed or given.
An action plan to improve uptake and documentation between the two snap audits was designed that included multidisciplinary staff education, the printing and laminating of additional posters, ensuring the posters and board markers were easily accessible, and the design of a reminder poster (Figure 2) in the doctor's office and nursing stations.
**Results:** There were similar numbers of patients across both audits (16 vs 17), with slightly lower patient acuity in the second audit likely due to seasonal differences (69% level 2 and 31% level 3 vs 82% level 2 and 18% level 3) and fewer patients with tracheostomies (31% vs 18%). There was a large increase in the number of posters at bedside (50% vs 94%); a similar number of patients previously intubated (69% vs 59%); but a significant increase in the documentation of previous grade (36% vs 90%) and type of blade used (80% vs 18%) for intubation. There was also a large increase in the documentation of complete tracheostomy information given by type, size, and date inserted (20% vs 100%). One patient in each cycle required an alternative DAS plan, with this not being documented in the first cycle, but documented appropriately in the second cycle.
**Conclusions:** The use of laminated, reusable, easy-to-fill-out ICU airway emergency plans, together with simple interventions such as reminder posters and multidisciplinary education, can significantly improve patient safety with regard to airway management in ICUs. Further work will be needed to be done to continue to ensure high stakeholder involvement in documentation, especially given the high turnover of patients in our unit, and the regular rotation of trainee doctors. Our airway posters and interventions can also be easily adapted to suit other units with similar and different patient populations.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000837

**Introduction:** The Faculty of Intensive Care Medicine (FICM) initiated a "Reverse Mentoring Programme" in 2023, aimed at addressing challenges faced by doctors in training (DiT) from ethnic minority or

international medical graduate (IMG) backgrounds. This initiative stemmed from a successful pilot in the Yorkshire and Humber deanery for Training Programme Directors (TPDs) and aimed to tackle "differential attainment" persistently observed among its workforce. By recruiting minority ethnic and IMG DiT to mentor senior Faculty members, the FICM sought to enhance awareness of race-related issues in medical training among educational leaders, thereby fostering more equitable training opportunities.
**Objectives:** The objectives of the Reverse Mentoring Programme were twofold: to enhance the understanding of senior FICM educational leadership regarding challenges faced by ICM DiT related to race, ethnicity, or background, and to explore the feasibility of expanding reverse mentoring to reach a broader audience. Mentors aimed to increase awareness of challenges faced by ethnic minorities and IMG DiT, raise consciousness about unconscious bias and discrimination, gain insights into root causes of microaggressions, and develop strategies to disseminate data on training inequity.
**Methods:** The programme utilized a structured approach for participant selection and engagement. Fourteen mentor–mentee pairs were identified, engaging in meetings spanning approximately six months, focusing on semi-structured discussions about individual training experiences. Facilitated inductions, midpoint, and end-point meetings to ensure collective reflection and strategy discussion. Virtual meetings were conducted via Microsoft Teams, with recordings for absentees.
**Results:** Feedback from both mentor and mentee groups indicated positive experiences with the programme. Key recommendations emerged, including publishing, and disseminating findings widely, incorporating education on ethnic diversity and inclusivity (EDI) throughout the ICM curriculum, recognizing the importance of cultural education alongside clinical training, improving allyship through support networks, ensuring transparency and active utilization of data, and appointing specific EDI leads.
**Conclusions:** The Reverse Mentoring Programme proved effective in improving understanding of challenges faced by ethnic minorities and IMG DiT. It led to positive changes in personal practice and approach to diversity and inclusion. Expansion of the programme, along with implementing recommendations, is crucial to fostering equitable conditions for all doctors to thrive in their careers. Mentors also reported gaining management and leadership skills, as well as a deeper insight into the mindset of trainers, resulting in increased optimism for the future of diversity and inclusion in ICM training.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000838

**Introduction:** High prevalence of inappropriate proton pump inhibitor (PPI) prescriptions in Intensive Care Units (ICU) mainly relates to administration route. Despite evidence about the potential risks of PPIs' overuse, transition from intravenous to enteral PPI administration upon initiation of enteral nutrition remains inconsistently implemented, imposing financial burdens and affecting patient care. Focusing on enhancing PPI prescriptions in an ICU from a tertiary hospital, we designed a quasi-experimental, single-center, audit-type study followed by feedback. The study was authorized by the hospital's Ethics Committee (nº 125/2023).
**Objectives:** Primary objective: To determine the time, in days, during which ICU patients have an appropriate PPI prescription (indication and posology).
Secondary objectives: To assess the perception of medical staff regarding the adequacy of PPI prescriptions and, to characterize inadequate PPI prescriptions and the direct costs associated.
**Methods:** The study was divided into three phases:
1) A retrospective analysis of the first 50 patients discharged from the ICU since January 2023. Patients with a length-of-stay under 24 h were excluded. Indications for treatment with PPI were considered correct if they aligned with current guidelines. Route of administration was considered inadequate if the patient was on enteral nutrition and PPI was administered intravenously. Costs per unit were considered for IV pantoprazole, pantoprazole capsules, and for lansoprazole orodispersible tablet. Data collection and analysis used Microsoft SQL Server Management Studio and Microsoft Excel.
2) Implementation of an anonymous online questionnaire to assess the perception of medical staff ($n = 49$) regarding PPI prescriptions in the ICU (June 2023), followed by presentation of the results.
3) Implementation of measures aligned with the results of both phases.
**Results:** 1) We included 98 patients (62 years median age, 33% female). A total of 137 PPI prescriptions were found, corresponding to 889 days of treatment; 25.98% of the prescriptions were adequate both in indication and dose. The route of administration was inadequate in 60.07% of the prescriptions days, representing an extra cost between 222,87€ and 273,62€ + VAT (see Table 1).
2) Online questionnaire was answered by 93.9% of the medical team. When questioned "I consider that, in my clinical practice, I prescribe PPI appropriately (indication and route of administration)", 69.6% of the medical team answered 'mostly yes'.
3) A proposal for hospital introduction of lansoprazole orodispersible tablets was submitted and a protocol will be implemented after approval.
**Conclusions:** Frequency of inadequate PPI prescriptions in our ICU was similar to current literature. Nevertheless, the medical team was unaware of the inadequacy of PPI prescription, giving us the possibility to improve medical care. Evaluating prescription practices might improve efficiency of resource allocation in ICU.

**Table 1 (abstract 000838)** Characterization of inadequate PPI prescription

| Inadequacy | Days (n) | Days (%) | Cost (€) | Cost with correct prescription (€) | Potential savings (€) |
|---|---|---|---|---|---|
| No indication | 59 | 6,64 | 37,44 | – | 37,44 |
| Inadequate route | 534 | 60,07 | 390,35 | 116,73–167,48 | 222,87–273,62 |
| IV-PPI + oral feeding | 111 | 12,49 | 81,14 | 2,22 | 78,92 |
| IV-PPI + feeding tube | 423 | 47,58 | 309,21 | 114,51–165,26 | 143,95–194,70 |

**Introduction:** There is a lack of data on the optimal hemoglobin threshold for blood transfusions in patients with acute spontaneous intracranial hemorrhage (ICH).
**Methods:** In this secondary analysis of a multicenter, parallel-group, pragmatic trial (NCT02968654), patients admitted to the intensive care unit with an acute brain injury were randomized to receive 1 unit of red blood cells when their hemoglobin levels dropped to 7 g per deciliter or less (restrictive group) or 9 g per deciliter or less (e.g. liberal group) over 28 days. For this study, only patients with ICH were analyzed. The primary outcome was the occurrence of an unfavorable neurological outcome, defined as a Glasgow Outcome Scale Extended score of 1–5, at 180 days post-randomization.
**Results:** On a total of 850 patients eventually randomized to the trial, 144 (16.9%) patients presented with ICH and were analyzed for the primary outcome; 73 in the restrictive group and 71 in the liberal group. As the results of the main trial are under revision, findings on baseline characteristics, transfusion protocols compliance, hemoglobin values over time as well as on primary outcome comparing the two groups will be presented at the ESICM congress in Barcelona.
**Conclusions:** In this subgroup analysis of a large randomized trial, we will provide the first evidence on the impact of two different transfusion strategies on the occurrence of unfavorable neurological outcome in ICH patients.

**Introduction:** The heterogeneity in the host response in sepsis, which can entail both hyperinflammation and profound immune suppression, has hampered the development of effective immunomodulatory treatments. Therefore, a shift towards a more individualized treatment approach tailored to individual patient factors is warranted. We aimed to identify genomic markers associating with the magnitude of the inflammatory response and the extent of immune suppression during experimental human endotoxemia, a standardized controlled model of systemic inflammation induced by bacterial lipopolysaccharide (LPS), resembling hallmarks of both the hyperinflammatory and immunosuppressive phenotypes observed in sepsis patients.
**Methods:** LPS (1 ng/kg) was administered intravenously twice one week apart to 101 healthy volunteers (50 female, 51 male, age 23 [21–25] years). During both LPS challenge days, blood was serially sampled

to determine plasma cytokine concentrations. Area under the in vivo (IV) plasma cytokine concentration–time curves (AUCs) served as an integral measure of the cytokine response (Fig. 1). The first LPS challenge served to quantify the primary IV (hyperinflammatory) cytokine response, while the difference in cytokine response between the first and second LPS challenge was used to determine the degree of IV endotoxin tolerance, which bears many similarities to sepsis-induced immunosuppression. Furthermore, on the first challenge day, circulating CD14 + /CD16- monocytes were isolated at two time points: one hour before ($T = -1$) and 4 h after ($T = 4$) LPS administration, and RNA sequencing was performed. Ex vivo (EV) cytokine production capacity EV tolerance was assessed by stimulating isolated monocytes at both timepoints with LPS for 24 h and measuring cytokine concentrations in supernatants. To identify genomic regions associating with interindividual differences in the host response, the cohort was genotyped, and quantitative trait locus (QTL)-analysis was performed using matrix eQTL. Significance was determined at FDR < 0.05.

**Results:** We associated 3,333,357 genetic variants with IV cytokine production and IV tolerance, thereby identifying one cytokine (c) QTL and one tolerance (t)QTL. SNP rs10261383 was identified as a cQTL, although not reaching genome-wide significance, it was associated with the magnitude of the primary IV TNF response (FDR < 0.05, *p*-value 1e−07, Fig. 2A). Subjects carrying two alternate alleles for this SNP exhibited a more pronounced response for most pro-inflammatory cytokines (Fig. 2B). No associations with EV cytokine production capacity were found (Fig. 2C). SNP rs7576783 emerged as a genome-wide tQTL associated with TNF and G-CSF tolerance (FDR < 0.05, *p*-value 1e−08, Fig. 3A). Subjects homozygous for the alternate allele developed little IV tolerance for any of the cytokines, except for IL-10 (Fig. 3B). No associations with EV tolerance were identified (Fig. 3C). The SNPs of the identified c- and tQTLs are located within *LINC00525* and in the promotor-region of *AC104623.2*, respectively. According to the Genotype-Tissue Expression (GTEx) Project, both SNPs are cis-expression (e)QTLs for their respective genes in various tissues. However, eQTL analysis using our monocyte RNA-seq data did not identify these SNPs as eQTLs, as both genes were not expressed in this cell type.

**Conclusions:** There is considerable variability in the in vivo host response and development of endotoxin tolerance following LPS administration, even within a highly homogeneous cohort of healthy volunteers. We identified two genetic variants associated with this in vivo immunological variation, but not with ex vivo cytokine responses or tolerance in isolated monocytes. This, in combination with the lack of expression of the associated eQTL genes, suggests that these SNPs influence the host response by affecting cells other than monocytes. Further elucidation of this influence and exploration of these genetic variants in patient cohorts could ultimately prove to be of value in identifying sepsis patients eligible for immunomodulatory treatments.

### Life after critical care: post-COVID-19 pandemic adult ICU rehabilitation goal setting and documentation in a UK district general hospital

J. Zanin[1], K. Gollub[1], T. Ali[2], M. Desai[1]

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000842

**Introduction:** Post-intensive care syndrome (PICS) is the cognitive, psychiatric and/or physical disability occurring after admission to the intensive care unit (ICU). 1, 2 It can lead to impaired role functioning and quality of life for the survivor, as well as psychological impairment for family members. 2 Rehabilitation goal setting during the ICU admission reduces the risk of PICS-related morbidity. 3 In order to improve daily functioning and prevent future morbidity and mortality, in the UK, quality standards from the National Institute for Health and Care Excellence state that 100% of adults in critical care should have their rehabilitation goals agreed within 4 days of admission to critical care or before discharge. 4 With services exiting the emergency response phase of the COVID-19 pandemic, it is essential to re-prioritise rehabilitation goal setting.
**Objectives:** To evaluate the documentation of rehabilitation goals to determine the extent to which Stoke Mandeville Hospital ICU is performing in relation to the NICE Quality Statement 158 (QS158).
**Methods:** Retrospective observational cohort review of admissions to Stoke Mandeville Hospital ICU between 1 January 2022 and 31 March 2022. Admissions were excluded if medical records were not available or if the patient transitioned to end-of-life care within 4 days of admission. A data collection proforma was used to systematically appraise scanned medical records by 2 auditors, with 10% of records dual screened to ensure inter-rater reliability. Discrepancies were discussed with intensive care consultants. Admissions were analysed according to length of stay [short stay ($\leq$4 days), and long-stay (>4 days)]. Rehabilitation goals were defined as non-treatment goals aiming to optimise functioning or reduce disability.
**Results:** Of 127 ICU admissions during the study period, 24 were excluded (6 no records available; 18 end-of-life care). Notes from 103 admissions were analysed [62(60%) short stay ($\leq$4 days); 41 (40%) long stay (>4 days)]. At least 1 rehabilitation goal was set in accordance with QS158 timeframe in 52 (84%) and 34 (83%) of short versus long stay admissions, respectively. Goals were most commonly set by doctors for both groups. Rehabilitation goals set by other multidisciplinary team members varied between groups in a manner that was generally consistent with duration of critical illness, ICU-related interventions, and phases of rehabilitation.
**Conclusions:** There is a need for a standardised approach to documenting holistic rehabilitation goals in a manner that has low administration burden. Such an approach should clearly delineate the difference between treatment versus rehabilitation goals and be integrated into bedside electronic patient records. A more systematic approach to documentation may lead to improved rehabilitation for patients during their ICU admission, which may in turn reduce the burden of PICS.

**Introduction:** Ultrasonography has extensively been used to evaluate diaphragmatic motion characteristics, such as excursion and thickening, both in healthy subjects and ICU patients. More recently, the ultrasonographic technique of diaphragmatic Tissue Doppler Imaging (TDI) has also allowed real-time recording of the diaphragmatic motion velocity waveform.
**Objectives:** To examine the changes in the special features of diaphragmatic motion when shifting between different modes of assisted ventilation using ultrasonography.
**Methods:** Consecutive ICU patients in weaning progress while on pressure support ventilation (PSV) were studied; the level of support was the minimum to obtain a tidal volume (Vt) between 6 and 8 ml/kg of predicted body weight (PBW). Ultrasonographic measurement of thickening fraction (TF), peak contraction (PCV) and peak relaxation (PRV) velocities and relaxation rate (slope of TDI diaphragmatic relaxation waveform) was performed, before ventilation mode was switched to NAVA. In NAVA, the NAVA gain was set to obtain the same peak pressure as that during PSV, and Vt between 6 and 8 ml/kg of PBW. The same ultrasonographic parameters (TF, PCV, PRV, relaxation rate) were assessed when a stable respiratory pattern on NAVA was achieved.
**Results:** Two-hundred and nineteen respiratory cycles [109 in PS mode (PS level $10.0 \pm 7.0$ cmH20) and 110 in NAVA mode (NAVA level $1.4 \pm 1.0$ cmH20/μV)] were analysed in 19 patients (8 female), aged $58.1 \pm 12.7$. Due to study design, there were no significant differences between PSV and NAVA modes in ΔPressure (11.2 cmH20 vs 12.1 cmH20, $p=0.41$), Ppeak (18.5 cmH20 vs 19.4 cmH20, $p=0.48$), Vt (504.2 ml vs 493.4 ml, $p=0.70$) and Cdyn (57.0 ml/cmH20 vs 61.4 ml/cmH20, $p=0.48$). There were also no differences between PS and NAVA modes in Edimax (9.5 μV vs 10.1 μV, $p=0.57$) and Edimin (1.5 μV vs 1.7 μV, $p=0.64$). Similarly to the ventilatory parameters, assessment of the sonographic indices of diaphragmatic motion also revealed no differences between PS and NAVA modes [PCV (2.55 cm/s vs 2.65 cm/s, $p=0.64$), PRV (2.34 cm/s vs 2.52 cm/s, $p=0.42$), relaxation rate (14.1 cm/s2 vs 17.2 cm/s2, $p=0.21$) and TF (0.25 vs 0.27, $p=0.64$)].
**Conclusions:** Diaphragmatic ultrasonography, including TDI, allows real-time assessment of special features of diaphragmatic motion. Our study demonstrated that despite the unique characteristics of the two different assisted ventilation modes used, no significant differences in the ultrasonographic indices of diaphragmatic motion were recorded when similar inspiratory pressures were used.

**Introduction:** Critical care beds are a limited resource, yet research indicates that recommendations for postoperative critical care admission based on patient-level risk stratification are not reliably followed (1–3). It is unclear how prioritisation decisions are made in real-world settings, and the effect of this prioritisation on postoperative outcomes. Observational studies attempting to answer this question have produced mixed results due to confounding-by-indication, whereby patients chosen for critical care admission often have more risk factors for poor postoperative outcomes, which may be unobserved (4–9).
**Objectives:** This study had two aims. Firstly, to determine if the probability of postoperative critical care admission is affected by critical care bed availability. Secondly, to determine the effect of postoperative critical care admission on morbidity using instrumental variable techniques to reduce the effect of unobserved confounding.
**Methods:** This was a pre-specified analysis of an observational cohort study of adult patients undergoing inpatient surgery, conducted in 274 hospitals across the United Kingdom and Australasia (10). The primary outcome was postoperative morbidity at day seven. Patients with absolute indications for critical care admission or having very low-risk procedures were excluded. Critical care occupancy prior to surgery was recorded. Logistic regression models were used to evaluate the relationship between critical care admission and patient and health system factors. The causal effect of critical care admission on outcome was estimated using variation in critical care occupancy as a natural experiment in an instrumental variable analysis.
**Results:** 19,491 patients from 248 hospitals were eligible for analysis, of whom 2107 had direct postoperative critical care admission. Increasing surgical risk predicted critical care admission as did increased availability of critical care beds (Odds Ratio 1.04 [1.02 to 1.06] per available bed), however the probability of admission varied significantly between hospitals (median OR 3.05). Morbidity occurred in 15% of patients and was associated with surgical risk. There was no evidence of a difference in morbidity with critical care admission [Odds Ratio 0.91 (0.57 to 1.45)], although there was a trend towards increasing benefit with increasing preoperative surgical risk (Fig. 1). The estimate of harm in the instrumental variable analysis was significantly reduced compared to methods that adjust for observed characteristics only (Fig. 2).
**Conclusions:** Postoperative critical care admission is variable and related to bed availability. Statistical methods that adjust for unobserved confounding significantly reduced estimates of harm previously associated with postoperative critical care admission. Our findings provide rationale for a clinical trial to evaluate the potential for benefit of postoperative critical care for patients in whom there is no absolute indication for admission.

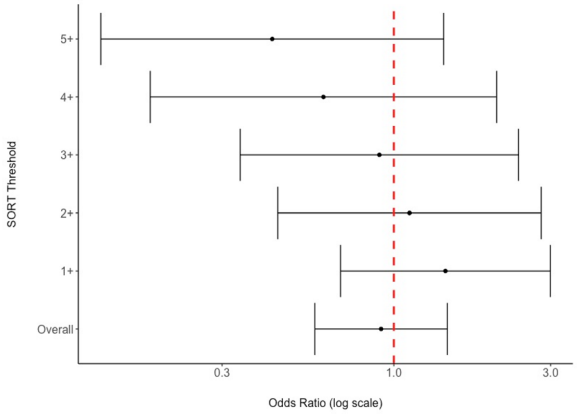

**Fig. 1 (abstract 000844)** Odds ratio estimates for postoperative morbidity incidence associated with Critical Care admission, stratified by SORT mortality estimate, in the instrumental variable analysis. SORT, Surgical Outcomes Risk tool.

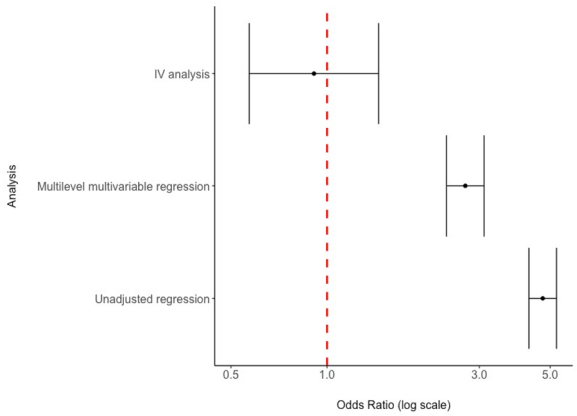

**Fig. 2 (abstract 000844)** Odds ratio estimates for postoperative morbidity incidence associated with Critical Care admission for logistic regression models, which perform risk adjustment on observed confounding only, and the instrumental variable analysis. Multilevel multivariable regression was adjusted for patient and surgical risk factors, with hospital site as a random effect

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000846

**Introduction:** Antibiotics represent one of the classes of drugs most commonly associated with elevations in liver enzymes. In some instances, they may precipitate drug-induced liver injury (DILI) [1], a severe adverse event that can progress to acute liver failure (ALF) [2].
**Objectives:** The aim of this study was to assess whether, in critically ill adult patients, there is an association between beta-lactam antibiotic concentrations and the elevation of liver enzymes.
**Methods:** A single-center retrospective cohort study including critically ill adult patients admitted to the intensive care unit of Erasme University Hospital (Brussels, Belgium) was conducted from January 2009 to December 2014. Therapeutic Drug Monitoring of broad-spectrum beta-lactam antibiotics was performed according to the decision of the treating physician. To compare the concentrations of the different types of antibiotics, the ratio between the trough drug concentration (C0) and the minimal inhibitory concentration (MIC) corresponding to the latest EUCAST clinical breakpoints for *Pseudomonas aeruginosa* (C0/MIC), following local protocols, was used. Liver enzymes were measured on the day of the TDM measurements. Liver enzyme elevation were categorized into hepatocellular (HI), cholestatic (CI), and mixed (MI) injury, based on the R-Ratio; this ratio was calculated by dividing the alanine transferases (ALT) by the alkaline phosphatases (ALP), utilizing multiples of the upper limit of normal for both values: an R-Ratio greater than 5 indicated HI, while a ratio less than 2 signified CI and between 2 and 5 a MI. A multivariate logistic regression analysis was performed, considering severity on admission, age, gender, use of anti-inflammatory drugs and concomitant antibiotics to assess the association of beta-lactam antibiotic concentrations with liver injury.
**Results:** Out of the 425 patients included in this study, 154 (36.2%) developed liver enzyme elevation; which were classified as HI in 40 (10.1%), CI in 22 (7.8%) and MI in 11 (2.6%) patients, respectively. The median time from admission to TDM was 5 (3–8) days and from antibiotic initiation to TDM measurement 2 (1–4) days. The C0/MIC was significantly higher in patients with elevated liver enzymes when compared to others (2.79 [1.35–5.00] vs. 2.34 [1.00–4.49] mg/dL, $p < 0.05$). However, from the logistic regression analysis, C0/MIC was not significantly associated with the occurrence of liver injury. In a subgroup analysis considering patients treated with piperacillin/tazobactam ($n = 164$), a threshold concentration of 20.95 mg/L was identified as an independent risk factor for liver enzyme elevation [odds ratio 2.58 (1.20–5.55)].
**Conclusions:** In this retrospective analysis, we did not observe a significant association between plasma concentrations of all beta-lactams and liver enzyme elevation. Nevertheless, exposure to high piperacillin/tazobactam levels may increase the risk of this complication.

### Experience of using the bidirectional femoral arterial cannula (Biflow) for adult patients' cannulation in VA ECMO as a strategy for prevention of limb ischemia: case series

K. Carvajal-Canizales[1], M. Pérez-Garzón[1], A. Quintero Altare[2], L. Gomez-Barrera[3], C. Poveda-Henao[1], M. Mercado-Diaz[1], H. Robayo-Amortegui[2]

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000847

**Introduction:** In 2019, the Society for Cardiovascular Angiography and Interventions (SCAI) proposed a new classification of cardiogenic shock emphasizing the use of extracorporeal mechanical support from stage C onwards. (1) Following this update, the use of veno-arterial ECMO (VA) has been increasingly consolidated as part of the tools to provide hemodynamic support, thereby increasing the need to implement strategies for possible risks associated with cannulation. Within the types of cannulations in the setting of non-cardiotomy associated cardiogenic shock, percutaneous femoro-femoral peripheral cannulation has been implemented, thus increasing the inherent complications such as bleeding, ischemia, and limb amputation. Therefore, there has been a need to implement strategies aimed at reducing these risks with a femoral artery cannula with bidirectional perfusion hole (Biflow) (2)
**Objectives:** Describe the implementation of using the BiFlow cannula in the VA-ECMO scenario within the context of cardiogenic shock as a strategy to reduce the risk of limb ischemia associated with cannulation.
**Methods:** A case series study was conducted to evaluate patients admitted to the extracorporeal life support unit of a high-complexity

hospital and ECMO reference enter, affiliated with the Extracorporeal Life Support Organization (ELSO), in Bogotá D.C, Colombia, between January 21, 2020, and December 31, 2021 (Fig. 1). Subjects over 18 years of age were enrolled with an indication for VA-ECMO according to ELSO guidelines, with BiFlow cannulation at the femoral artery level. Patients who died within the first 6 h of cannulation, those cannulated in another configuration, or those requiring a change in cannulation type were excluded. The study examined sociodemographic characteristics, comorbidities using the Charlson Comorbidity Index, clinical variables upon admission including vital signs, laboratory findings, and radiological results. Additionally, calculations were performed for APACHE II score, SOFA score, SAVE score, and oxygen debt (DEOx) within the first 24 h of admission to the intensive care unit (ICU). The DEOx was calculated using the formula proposed by Dunham et al. (4), which relates lactate and base excess through the equation: DEOx = 6.322 (Lactate) − 2.311 (BE) − 9.013 (3). Additionally, the limb intervened with the BiFlow cannula underwent arterial Doppler and NIRS (% oxygen saturation) monitoring, as well as clinical evaluation of signs of limb ischemia. Qualitative variables were reported in frequencies and percentages, while quantitative variables were summarized using medians, interquartile ranges, means, and standard deviations. Bivariate analysis was conducted between patients who experienced complications and those who did not with the use of the BiFlow cannula. Finally, a multivariate logistic regression analysis of mechanical complications was performed.

**Results:** Fifteen patients were included, of whom 93.3% were male, with an average age of 45.5 (SD 14.6) years. The most prevalent comorbidities were hypertension in 46.7% and smoking in 33.3% of cases (Table 1). The mechanical complication rate was 66.6% ($n = 10$), with hypoperfusion being the most frequent mechanical complication at 66.7%, followed by hematoma at 26.7% (Table 2). Despite three patients experiencing critical ischemia, none required limb amputation. Multivariate analysis revealed independent associations related to mechanical complications, such as pre-cannulation hemoglobin (OR 1.71, 95% CI 0.94–3.11; $p$ 0.077), pre-cannulation vasopressin dose (OR 2.72, 95% CI 0.90–8.17; $p$ 0.073), and post-cannulation inotropic use (OR 13.5, 95% CI 0.87–207.6; $p$ 0.062) (Table 3).

**Conclusions:** The use of the BiFlow cannula for critically ill patients under VA ECMO support is an option to avoid critical and irreversible ischemia of the limb, however, complications, especially hypoperfusion, are not uncommon. Anemia and the need for pre-ECMO vasopressin is associated with complications. The correlation of data needs to be further studied with a larger population and other studies to define early interventions in critically ill patients.

**Introduction:** Hemodynamic instability is a common occurrence in critically ill patients, primarily caused by a decreased preload, contractility, and/or afterload (Glassford et al., 2014; Sevransky, n.d.). Effectively managing hemodynamic instability necessitates a comprehensive understanding of its causes and associated pathophysiological mechanisms.
**Objectives:** This research aims to assess whether there is a significant variance in the morphology of peripheral arterial blood pressure (ABP) waveforms in critically ill patients before and after the administration of norepinephrine, fluids, and inotropes. We posit that each intervention will manifest clinically relevant alterations in peripheral ABP waveform morphologies, facilitating the discrimination between causes such as preload, afterload, and contractility.
**Methods:** In this observational study, 55 patients receiving a fluid bolus of 500 ml or more were enrolled to represent preload changes, and 73 patients with a norepinephrine infusion of 2 mg/ml or higher were included to signify afterload changes. Both infusions were administered in isolation, with no concurrent administration of other drugs 15 min prior to and 10 min post-intervention. The difference in 18 ABP morphology features pre- and post-hemodynamic intervention was computed. *The analysis will be expanded to also include patients with inotrope infusions.*
**Results:** The preliminary results focusing on norepinephrine and fluid administration indicate that, for the norepinephrine intervention analysis, 4 out of 18 features exhibit statistically significant differences solely pre- and post-noradrenaline intervention (Fig. 1A), while for the fluid intervention, this is to 5 out of 18 features (Fig. 1B). Notably, three features change in both interventions.
**Conclusions:** This study identifies distinct peripheral ABP waveform morphologies that enable the differentiation between deficits in preload and afterload, contributing to the understanding of the etiology of hemodynamic instability.

### Transcranial Doppler on the general ICU: though the looking (stained) glass of brain perfusion

N. Roslan[1], N. Ahmed[1], M. Ibrahim[1], R. Cashmore[2], M. Tanaka[1], A. Wong[1]

**Introduction:** Recent consensus and expert recommendations of the ESICM highlighted that qualitative analysis using transcranial Doppler (TCD) of the middle cerebral artery's (MCA) waveform is one of the basic skills for an Intensivist. Competencies in ultrasound can only be achieved through formal theoretical and hands-on training. Unlike cardiac and lung ultrasound, there is a paucity of evidence and guidelines as to how best to become competent in this skill. There is a perception that neuro ultrasound is 'too difficult' for the general intensivist. Drawing comparisons with cardiac ultrasound, some patients may have difficult windows to obtain adequate images. Studies, mostly in paediatric patients, suggest that between 15 and 30% of the general population do not have adequate temporal windows to perform transcranial Doppler of the MCA.
**Objectives:** To assess the feasibility of obtaining a standard TCD of the MCA in the general ICU population. This would help inform development of training recommendations on appropriate number of scans to achieve competencies.
To assess the interobserver variability of MCA TCD measurements.
**Methods:** Four clinicians autonomous in TCD (formal course and completed more than 100 scans each), performed TCDs of the MCA through the transtemporal window for all general critical care patients. All patients were positioned supine at a 30 degree elevation and the MCA was insonated bilaterally. Identification of MCA required appropriate direction of flow, depth of 40 to 65 mm, and Doppler spectra. All operators were trained using the same approach (identifying the mesencephalon, sphenoid wing, and MCA). A protocol was designed which identified the following metrics: the visualisation of the mesencephalon, sphenoid bone, and MCA, as well as the ability to acquire the peak systolic (PSV) and end diastolic (EDV) MCA velocities. Each scan was repeated by another operator who was blinded to first operator. Exclusion criteria included patients with soft tissue/skull injury in

the temporal region, agitated patients and other patients where the acoustic window was impossible to get to. The relationship between the results of the two operators was assessed using scatterplots and interclass correlation (ICC).

**Results:** 15 patients were scanned by a pair of operators.

In almost all the patients (86.7%), it was possible to visualise the MCA on colour Doppler or obtain a pulse-wave Doppler trace of the vessel. It was not possible to visualise the sphenoid bone with confidence in the majority of patients.

There was excellent level of agreement for PSV and EDV obtained by the operators (ICC for the PSV was 0.8 (95% CI 0.47–0.94) and ICC for EDV was 0.8 (95% CI 0.45–0.93)), unlike for the PI (ICC for the PI was 0.58 (95% CI 0.09–0.85).

**Conclusions:** In our study, it was possible to obtain a TCD of the MCA in the vast majority of patients on our general ICU. We had adequate windows in a higher proportion of patients compared to published literature.

It was also noted that the level of agreement between the operators was excellent. Whilst attempts were made to have the paired scans performed as closely as possible to each other, velocities within the MCA are affected by minor changes to patients' physiology such as coughing or straining. Hence it might be more useful to classify the images, e.g. Suzuki criteria, rather than report the velocities and ratio per se.

The limitations of our studies include the fact that the scans were performed by reasonably experienced operators. It would be expected that less experienced operators would be less successful.

In conclusion, our studies has shown that TCD of the MCA is very feasible in the general ICU population and has an excellent level of agreement between operators. This has implications for the learner when it comes to building up logbook numbers to achieve competency. However, we have also shown that there is significant variation in the obtain velocities despite similar level of expertise in the operators. This highlights the need for a more standardised approach in performing the examination.

**Table 1 (abstract 000850)** Percentage of patients where views/measurements were obtainable

| | Mesencephalon | Bony landmark (Sphenoid) | Bony landmark (Sphenoid) | MCA on Color Doppler | MCA on Color Doppler | MCA PW-Doppler | MCA PW-Doppler |

### Invasive line documentation: scope for Improvement

J. Hunter[1], R. Stevenson[1], N. Odell[1], R. Hart[1]
[1]Critical Care, Queen Elizabeth University Hospital, Glasgow, United Kingdom

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000851

**Introduction:** Patients in critical care are subject to many interventions, such as, placement of invasive lines. Documentation of best practice technique is a vital component of clinical governance. A snapshot audit revealed that a "missed documentation episode" occurred every 5 days during the audit period which equates to 35% compliance rate. A quality improvement (QI) team was tasked with improving our procedural documentation. Therefore, this new project focuses not only on ensuring that every invasive line inserted in critical care has associated documentation, but will also assess the quality of completion of the documentation.

**Objectives:** By November 2024, we will demonstrate that > 90% of indwelling central and arterial lines inserted in the critical care unit will have corresponding, fully completed documented evidence of insertion in line with local policy

**Methods:** Data collected weekly from five randomly selected CVC & A-line documentation. Data concerning four aspects of this documentation were collected.

Q1. Does this invasive line have associated documentation?
Q2. Has the procedure documentation been completed fully?
Q3. Is the name of the person who inserted the CVC/Aline documented?
Q4 –All—all elements completed successfully.

Several PDSA cycles were carried out with a change idea associated to each. These were infographics, educational resource at induction, addition to daily handover checklist and regular MDT presentation.

**Results:** On track to achieve the Aim Statement of > 90% of CVC and Arterial Line documentation fully completed by November 2024, our latest median line indicates CVC documentation compliance at 80% and arterial line documentation at 100%.

**Conclusions:** The success of this project is having a mechanism of knowing what we previously did not know. This self-awareness will allow continued unit discussions allowing us to react in real time to current performance. There has been a significant improvement in compliance with fully completing the invasive line documentation. Multiple line documentation episodes fail due to missed procedure documentation and lack of documentation of the operator name. A heavy workload has been highlighted as a common reason

why invasive line documentation is not completed correctly. It is well established that sustainability in QI can be challenging. Continuous data collection and having QI embedded in our unit culture are key to achieving sustainability.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000852

**Introduction:** Acute respiratory distress syndrome (ARDS) is a clinical syndrome characterized by an acute hypoxemic respiratory failure related to lung inflammation. Pneumonia and sepsis are the most common causes of this syndrome, turning ARDS into a critical public health problem. Despite recent advances in pharmacological strategies, clinical trials have not demonstrated a reduction in ARDS-associated mortality. This is in part connected to the singularity of the pulmonary physiological barrier which hampers drug delivery, more specifically, at distal areas.
**Objectives:** Here, we aim to demonstrate the suitability of polymeric nanocapsules (NCs) as a platform for the delivery of therapeutics to the lungs by nebulization, evaluating their structural properties and lung biodistribution in a model of acute lung injury (ALI).
**Methods:** Fluorescent (cyanine 5) poly(lactic-co-glycolic acid) (PLGA) NCs were prepared by a double emulsion-solvent evaporation method. Nebulization was conducted with a commercial vibrating mesh nebulizer (Aerogen Solo, Galway). To study the hydrodynamic diameter and morphology of the NCs, a nanoparticle tracking analysis (NTA) and a scanning electron microscopy (SEM) evaluation were performed. Besides, the in vivo biodistribution and uptake of NCs was evaluated in healthy and ALI rats. The lungs were analyzed by flow cytometry, confocal microscopy and IVIS Spectrum In Vivo Imaging System.
**Results:** After nebulization the NCs remained spherical and monodispersed, without significant morphological changes. The in vivo studies proved that nebulized NCs were homogeneously distributed in all lung lobes, even in the ALI animals 16 h after the administration. The cellular uptake of the NCs by epithelial alveolar type II (ATII) cells was significantly higher in healthy animals compared to injured rats (showing a 64% and 43% of retention, respectively). Also, nebulization reduced the macrophage-mediated lung clearance of our PLGA NCs promoting NCs tissue retention and absorption.
**Conclusions:** In conclusion, the nebulization of PLGA NCs does not affect their structure nor their main function, allowing their homogeneous biodistribution in the lungs and efficient cellular uptake in vivo, making them a suitable vehicle for non-invasive pulmonary drug delivery.

### Improving the End of Life care process in ICU

L. Quffa[1], J. Gwyn[2]
[1]Anaesthesia, University Hospitals Birmingham- Informatics, Birmingham, United Kingdom; [2]Intensive care, University Hospitals Birmingham-Informatics, Birmingham, United Kingdom
**Correspondence:** L. Quffa
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000843

**Introduction:** Up to 60% of deaths in ICU occur following an End of Life (EoL) care process, previously known as the withdrawal of life-sustaining treatment. There are many reasons why EoL care is commenced in ICU, for example, if a patient deteriorates despite treatment or if poor functional outcome is likely. The decision for EoL care is difficult and many challenges exist, particularly when communication and guidance are lacking, or there is a relationship breakdown between clinicians and families. This is not to mention the significant emotional impact on staff caring for a patient at the EoL.
Upon decision to commence EoL care for a patient, our local ICU practice recommends documentation of the discussion, completion of a simple, clinical checklist and prescribing of anticipatory medications (not standardised).
**Objectives:** To explore the impact of EoL care on staff and identify areas for improvement of the EoL care process in ICU.

**Methods:** Two surveys were sent, to nurses and clinicians (doctors and critical care practitioners), at 2 district general hospitals in Birmingham, UK. There were 33 responses over a period of 3 weeks between October and November 2023.
**Results:** Half of clinicians felt involved in EoL care decisions and 42% felt comfortable to advise how to perform EoL care processes (such as adjusting ventilator settings or discontinuing inotropic infusions). Just over 57% of clinicians had been asked by nurses to perform these tasks. Qualitative feedback from clinicians demonstrated the need to highlight the EoL checklist, the desire for education on EoL care and to be involved in family discussions more frequently.
Only 47% of nurses found EoL care plans clear, easy to follow and well documented. Most nurses (84%) felt comfortable in adjusting the ventilator and discontinuing vasopressors or inotropes. Feedback from nurses demonstrated the need for improved communication and clearer documentation from clinicians to families, the emotional burden of EoL put on nurses and the desire for a shared approach with clinicians during the process.
The EoL care checklist was improved with clearer instructions, holistic considerations and allocating staff involvement. Prescribing guidelines and a staff wellbeing checklist were created. Feedback and teaching were given to the department.
**Conclusions:** The amendment of the EoL care checklist has made it easier to follow, more holistic and individualised to the patient, and addresses which staff will be involved in the EoL care process. Prescribing guidelines will standardise practice and ensure safe doses will be administered to aid the comfort of patients. The staff wellbeing checklist recognises the emotional impact of EoL care and encourages nursing colleagues to take breaks before and after the process, debrief and signposts who to contact for support. Along with the teaching session and feedback presented, we hope that the EoL care process within our ICU will be improved for our patients.

*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000854

**Introduction:** Unplanned readmissions to ICU represent a significant issue within healthcare systems, contributing to increased patient mortality rates, healthcare costs, and reduced efficiency in the utilization of medical resources. The development of an effective predictive model for early identification of high-risk patients is essential for enhancing clinical decision-making and optimizing resource allocation.
**Objectives:** This study aimed to construct and validate a risk prediction model for unplanned readmission to the ICU based on machine learning algorithms, providing clinicians with a tool to timely identify patients who may require additional attention and management.
**Methods:** We conducted a retrospective analysis of 445 patients discharged from the general ICU of a tertiary hospital in Lanzhou, Gansu Province, China, from 2017 to 2022, using a case–control study design. Data preprocessing and univariate analysis were performed, followed by feature selection using Lasso regularization and model-variable scoring based on eXtreme Gradient Boosting (XGBoost). We then developed five predictive models, including logistic regression, support vector machine, decision tree, random forest, and XGBoost. Model parameters were optimized using internal cross-validation and grid search. The models were evaluated using the receiver operating characteristic curve (ROC Curve), calibration curve (Calibration Curve), decision curve analysis (DCA Curve), F1 score, and Kappa coefficient. The random forest model, which demonstrated the best performance, was selected for external validation using 120 patient data records from June 2023 to March 2024.
**Results:** The selection process yielded nine pivotal predictive variables, including physical restraints, reintubation, cough capacity grading, self-funded healthcare payment modality, oxygen concentration, neutrophil count, sepsis presence, daytime transfer timing, and early warning scores. Among the five models developed, the random forest model exhibited the highest discrimination (AUC = 0.889), good calibration (Brier Score = 0.136), and clinical utility in internal validation. External validation indicated that the model had high accuracy (0.786), sensitivity (0.818), specificity (0.881), and negative predictive value (0.831), with an F1 score of 0.72 and a Kappa value of 0.447, demonstrating the model's robust predictive performance. DCA analysis showed that the model outperformed the two extreme curves within a 5% to 60% risk threshold range.
**Conclusions:** This study successfully developed and validated a machine learning-based random forest prediction model that effectively distinguishes patients at risk for unplanned ICU readmissions. The model exhibits good discrimination, calibration, and clinical application value, offering substantial support for clinical decision-making. Future research should encompass validation with larger, multicenter datasets to further improve the model's generalizability and accuracy.

### Assessment of residual sedation in patients with traumatic brain injury after cessation of midazolam infusion: is there a threshold concentration?

T. Smeets[1], H. Endeman[2], B. Koch[1], D. Gommers[2], N. Hunfeld[2], M. van der Jagt[2]

*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000856

**Introduction:** In critically ill patients with traumatic brain injury (TBI) treated with continuous infusion of midazolam for sedation, Therapeutic Drug Monitoring (TDM) of midazolam and its metabolites can help to differentiate between residual sedation and neurological status. A sum concentration of midazolam and metabolites is used, since the metabolites 1-OH-midazolam and 1-OH-midazolam-glucuronide have a sedative potency compared to midazolam of 60–80% and 10%, respectively. Based on previous literature in non-brain injured patients, it is assumed that sum concentrations of < 100 ug/L of midazolam and metabolites no longer have a significant sedative effect (1, 2). We hypothesized that TBI patients are more sensitive to midazolam exposure resulting in a lower threshold value for residual sedation.
**Objectives:** To assess the threshold sum concentration of midazolam and metabolites for residual sedation after cessation of midazolam infusion in critically ill TBI patients.
**Methods:** We performed a retrospective study at the adult intensive care unit of Erasmus MC University Medical Center between 07-2017 and 03-2024. TBI patients were included for analysis if at least one

midazolam plasma concentration < 100 ug/L was available after cessation and sequential Glasgow Coma Scale (GCS) scores were available. The sum of the Eye and Motor scores from the GCS were used to assess the residual sedation threshold, which was defined as the last available serum level that resulted in a decreased GCS of ≥ 2 EM points difference compared to the maximum GCS within the following 7 days.
**Results:** Of the 80 screened TBI patients, 52 were eligible for analysis ($n = 20 > 100$ ug/L and $n = 8$ lack of sequential GCS scores). Of the 52 patients, 65% ($n = 34$) were scored as residual sedation and 35% ($n = 18$) as no residual sedation. The sum midazolam concentration in the residual sedation group and no residual sedation group were 14 ug/L [5–34] and 6 ug/L [3–23], respectively (Fig. 1). In the patients with residual sedation an improved EM score of 3 [IQR 2–5] was observed within 3 days [IQR 1–4].
**Conclusions:** In TBI patients with residual midazolam sedation the threshold concentration is much lower than described in non-brain injured critically ill patients and residual sedation might be present at very low to undetectable plasma concentrations. Therefore, clinicians should be reluctant to make prognostic decisions based on low GCS in the presence of low plasma concentrations of midazolam and active metabolites.

**Introduction:***Streptococcus pneumoniae* is the most frequent cause of community-acquired pneumonia, while *Pseudomonas aeruginosa* leads in nosocomial respiratory infections.
Respiratory diseases are often accompanied by hypercapnia, which can impair macrophage function, hindering infection containment. In lung infections, macrophages shine not only as phagocytes, but also as major immunomodulators and local recruiters of immune cells.
Studying the role of macrophages in bacterial infection under hypercapnia will provide insights into the development of new therapies.
**Objectives:** To evaluate the inflammatory response of macrophage-like THP-1 as a result of infection with *P. aeruginosa* or *S. pneumoniae* under different CO2 concentrations, and determine the impact of macrophage response in bacterial survival.
**Methods:** Cultures of macrophage-like THP-1 cells were separately infected with *P. aeruginosa* (multiplicity of infection (MOI) 1:50) or *S. pneumoniae* (MOI 1:20) for 1 h at 37 °C under normocapnic (5% CO2) or hypercapnic (15% CO2) conditions. Then, extracellular and intracellular bacterial survival post-infection was evaluated through seeding in blood agar plates.
24h after infection, at 37 ºC and 5% or 15% $CO_2$, cell culture supernatant was analysed through ELISA technique for inflammatory (IL-1β), chemoattractant (CCL-2, IL-8) and anti-inflammatory (IL-10) mediators.
**Results:** Macrophages exhibit a higher pro-inflammatory and anti-inflammatory response to *P. aeruginosa* infection compared to *S. pneumoniae* infection. Nevertheless, under hypercapnic conditions, IL-1β secretion is enhanced in both infections 1 h and 24 h post-infection (Fig. 1A-B), while IL-10 decreases only in *P. aeruginosa* infection (Fig. 1C). Regarding phagocyte chemokines, hypercapnia decreases the secretion of CCL-2 and IL-8 chemokines in the both infection models compared to the levels secreted under normocapnia, although they are not significantly different. Although in *P. aeruginosa*-infected macrophages the secretion of chemokines is inhibited, in *S. pneumoniae* infection macrophages could play a pivotal role as recruiters (Fig. 1D-E).
Finally, no differences in post-infection bacterial extracellular survival were determined (Fig. 1F). However, *P. aeruginosa* could be establishing intracellular niches within macrophages since intracellular growth is detected 24h post-infection (Fig. 1G). No intracellular growth was detected 24h post-infection for *S. pneumoniae*.
**Conclusions:** Macrophages perform different defensive responses against *P. aeruginosa* and *S. pneumoniae* infection. Hypercapnic condition on bacterial-infection response could play a detrimental role.

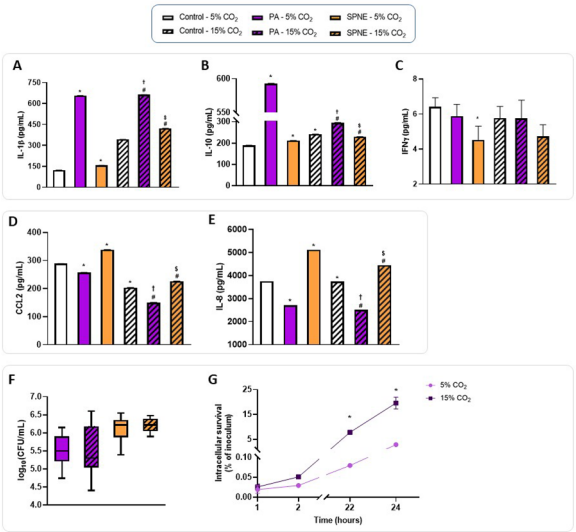

**Fig. 1 (abstract 000857)** Biological response of macrophage-like THP-1 cells after infection and consequent bacterial survival. (A-E) Protein concentration in the cell culture supernatant of inflammatory (A, C), anti-inflammatory (B) and chemoattractant (D, E) mediators 24 h post-infection with P. aeruginosa or S. pneumoniae of the THP-1 cells culture. (F) Extracellular bacterial survival of P. aeruginosa and S. pneumoniae immediately at the end of infection. (G) Intracellular bacterial survival of P. aeruginosa THP-1 cell compared to the initial inoculum administered. $n = 9–12$ in protein analysis; $n = 8–15$ in extracellular and $n = 3–5$ in intracellular bacterial survival assays. **Introduction:** Survival and functional dependence in patients with ischemic stroke and ASPECTS ≤ 7 treated with mechanical thrombectomy and admitted to ICU
**Objectives:** To study the differences in survival and outcome of acute ischemic stroke (AIS) patients treated with MT according to the observed value on the Alberta Stroke Program Early Computed Tomographic Score (ASPECTS)
**Methods:** Retrospective study (January 2015- May 2023). All patients admitted to ICU with an AIS treated with MT were included. Patients were classified according to the ASPECTS values in Group A (ASPECTS ≤ 7) and B (ASPECTS > 7). The following variables were recorded: age, gender, NIHSS score on admission, time between symptoms onset and hospital admission and between symptoms onset and recanalization, systemic thrombolysis before MT, TICI score, ICU and hospital length of stay, destination after hospital discharge and ICU, hospital and 6-month survivals. Functional dependence was measured at hospital admission and 6 months after the discharge using the RANKIN scale.
**Results:** 316 patients were included. Group A $n = 98$ and B $n = 218$.
Group A: mean age 70 ± 13 years; 43.6% male ($n = 41$), NIHSS on admission 18 ± 5. Time between symptoms onset-hospital admission: 3 ± 2h and between symptoms onset and recanalization: 4 ± 2h (30% wake-up stroke). Systemic thrombolysis before MT: 27.7% ($n = 26$). TICI score of 3: 82% ($n = 78$). ICU and hospital length of stay: 5 ± 8 days and 19 ± 20 days. Survivals: ICU 84% (n = 79); hospital: 70% ($n = 66$) and 6-month: 60% ($n = 57$). 40.4% ($n = 38$) were admitted to a rehabilitation facility. RANKIN on admission 0 ± 1 vs. 4 ± 2 at 6 months.
Group B: mean age 71 ± 12; 49.5% male ($n = 109$). NIHSS on admission 15 ± 6. Time between symptoms onset-hospital admission: 3 ± 3h and between symptoms onset and recanalization: 5 ± 2h (20% wake-up stroke). Systemic thrombolysis before MT: 34% ($n = 75$). TICI score of 3: 89% ($n = 114$). ICU and hospital length of stay: 2.8 ± 5.6 and 15 ± 13 days. Survivals: ICU 92.7% ($n = 204$); hospital: 82.2% ($n = 181$) and 6-month 78.6% ($n = 173$). 22.2% ($n = 49$) were admitted to a rehabilitation facility. RANKIN on admission 0 ± 1 vs. 2 ± 2 at 6 months.
**Conclusions:** Patients with ASPECTS ≤ 7 and MT had lower ICU and 6-month survivals and worst functional outcome at 6 months.

**Introduction:** Respiratory muscle function plays a critical role in maintaining adequate ventilation and gas exchange 1), particularly in critically ill patients 2). While much attention has been devoted to investigating inspiratory muscles, such as the diaphragm 3–4), less attention has been focused on expiratory muscles 5). High-flow nasal cannula (HFNC) oxygen therapy offers heated and humidified oxygen at high flow rates 6), potentially affecting the inspiratory and expiratory muscles. Understanding the effects of HFNC on respiratory muscle activity could provide valuable insights into optimising respiratory support strategies in critically ill patients.
**Objectives:** This study investigated the effects of HFNC on respiratory muscle activity using ultrasound assessment, specifically to assess changes in expiratory muscle thickness during HFNC at different flow rates.
**Methods:** This prospective observational crossover study included 30 adult patients admitted to our mixed intensive care unit. Patients indicated for HFNC after their first extubation (acute respiratory failure, at high risk of reintubation and post-cardiac surgery) were included. End-inspiratory and end-expiratory thicknesses of the diaphragm, rectus abdominis muscle and abdominal muscles (external oblique [EO], internal oblique [IO] and transversus abdominis [TrA] muscles) were measured using ultrasound initially in low-flow oxygen therapy and then during HFNC at flow rates of 30, 40 and 50 L/min. After the HFNC protocols, low-flow oxygen therapy was resumed. The primary endpoint was the thickening fraction (TF) changes in the respiratory muscles with different HFNC flow rates. The thickening fraction of abdominal muscles (TFABD) was used to categorise patients into two groups reflecting expiratory muscle recruitment. Data from each point were analysed by repeated measures analysis of variance with multiple comparisons for effect over time. $P < 0.05$ was considered statistically significant.

**Results:** For the TF of all muscles, only the difference in diaphragm TF at 50 L/min was significant compared to the baseline ($p=0.0022$). Patients with TFABD of < 0% demonstrated a significant decrease in TFABD at 40 and 50 L/min ($p=0.0048$ and 0.0052, respectively). Additionally, in patients with TFABD of < 0%, HFNC at a given flow rate significantly reduced TFIO ($p=0.029$, 0.0009 and 0.0298 at 30, 40 and 50 L/min, respectively) and TFTrA ($p=0.0047$ at 50L/min) compared to patients with TFABD of > 0%. TFIO and TFTrA were strongly correlated with TFABD ($r=0.7764$ and 0.7122, respectively).
**Conclusions:** During HFNC, respiratory muscle activity assessed by ultrasound was widely changed. Furthermore, decreased TFABD was associated with reduced TFIO and TFTrA. These findings underscore the importance of further research exploring the effects of HFNC oxygen therapy on respiratory muscle activity.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000862

**Introduction:** Vasopressors and albumin are frequently used for the treatment of shock in burn patient to support hemodynamic status, but their use is not well-described in the burn literature.
**Objectives:** This study aimed to investigate the coadministration of noradrenaline and albumin during the resuscitation of postburn shock.
**Methods:** This study was conducted in a specialized burns ICU in 2023. Adult burn patients with postburn shock receiving noradrenaline and albumin during the resuscitation phase were included. Data regarding patient characteristics, burns characteristics, prognostic scores, noradrenaline and albumin use resuscitation fluid volume were recorded.
**Results:** Data of 30 intubated patients admitted to a Burn ICU during 2023 were analyzed retrospectively (for the first 8 months and prospectively thereafter). Mean age of patients was $54.33 \pm 16.51$ years and TBSA (total body surface area) burnt was $34.57 \pm 16.61\%$, ICU mortality rate was 23%. Twenty-four patients (80%) received albumin during the first 24-h period, 27 (90%) during the second and 26 (87%) during the third postburn days. All patients were under continuous noradrenaline administration as a part of shock treatment. Median noradrenaline dosage was 0.19 mcg/kg/min (0.08-0.37) at 24 h, 0.21mcg/kg/min (0.1-0.38) at 48 h and 0.28 mcg/kg/min (0.11-0.38) at 72 h. Using Friedman's test, no statistical significance was found among noradrenaline dosage at admission, 24 h, 48 h, and 72 h ($p=0.13$). No correlation was found between maximum noradrenaline dosage and fluid administration during the first 24 h (Spearman's rho, $p=0.46$). Noradrenaline dosage was higher by 0.09 mcg/kg/min in patients who received albumin in the first 24 h ($p=0.03$) and higher by 0.23 mcg/kg/min in patients who received albumin in the third day ($p=0.038$).
**Conclusions:** Our results show that albumin was frequently used during acute burn resuscitation; albumin supplementation was associated with higher doses of noradrenaline as an adjunct in managing burn shock.

**Introduction:***Klebsiella* spp infections emerge as a particularly critical problem in Greece due to increasing antimicrobial resistance and lack of therapeutic alternatives. It is noteworthy that mortality resulting from Klebsiella infections in the ICU can reach up to 51%. The need for novel therapies has thus become urgent.
**Objectives:** The aim of this preliminary, ongoing study is the investigation of therapeutic efficacy of three antimicrobial combinations of ceftazidime–avibactam in patients with Pandrug Resistant Klebsiella pneumoniae New Delhi Metallo-β-lactamase (NDM). The primary objective was the sterilization of blood cultures in 14 days.
**Methods:** 24 patients were included (17 male, 7 female) with median age of 57, from June 2023 to February 2024.
10 patients had suffered severe traumatic brain injury, 4 patients were major trauma patients, 5 patients presented with intracerebral haemorrhage and 5 patients underwent abdominal surgery. Median length of stay in the ICU was 22 days.
All 24 patients presented with PDR NDM *Klebsiella pneumoniae* blood steam infections. Antimicrobial synergy with ceftazidime–avibactam was tested in the microbiology lab. The combinations that proved to be in vitro effective were: Ceftazidime/avibactam + aztreonam, Ceftazidime/avibactam + colistimethate and Ceftazidime/avibactam + meropenem.
8 patients received ceftazidime/avibactam + aztreonam (Group 1)
10 patients received ceftazidime/avibactam + colistimethate (Group 2)
6 patients received ceftazidime/avibactam + meropenem (Group 3)

**Results:** Group 1: 7 out of 8 patients presented with sterile blood cultures by the 14th day The synergistic effect of ceftazidime/avibactam + aztreonam was effective in 87.5% of the patients. 6 patients were transferred out of the ICU by the 16th day.
Group 2: 6 out of 10 patients presented with sterile blood cultures by the 14th day. The synergistic effect of ceftazidime/avibactam + colistimethate was effective in 60% of the patients. 5 patients were transferred outside the ICU by the 18th day.
Group 3: 2 out of 6 patients presented with sterile blood cultures by the 14th day. The synergistic effect of ceftazidime/avibactam + meropenem was effective in 33.3% of the patients. 3 patients were transferred outside the ICU by the 21th day.
**Conclusions:** The combination of ceftazidime/avibactam + aztreonam seems to be more effective in the treatment of PDR *Klebsiellapneumoniae* NDM. The search for effective antimicrobial treatment of PDR *Klebsiella pneumoniae* NDM is crucial, especially in Greece.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000866

**Introduction:** The high-intermediate risk pulmonary embolism (PE) represents a serious medical condition with a calculated mortality rate around 15%. The primary therapeutic strategy recommended for its management is systemic fibrinolysis. However, catheter-guided mechanical thrombectomy has been yielding satisfactory results in recent published trials.
**Objectives:**

- Identify demographic characteristics in patients with intermediate-high risk PE according to the treatment employed in a multidisciplinary ICU in a tertiary hospital.
- Establish the severity of the clinical situation by analyzing admission scales and risk factors.
- Describe therapies in the study population and their mortality outcomes.

**Methods:** Analytical cross-sectional study including 48 patients diagnosed with intermediate-high risk PE in the unit. Patients treated with invasive techniques and systemic pharmacological therapy were selected. Demographic data as well as severity and mortality predictive scales at admission were collected. Complications associated with admission and mortality rates were evaluated.
**Results:** Out of 48 patients with moderate-to-severe risk PE, 22.9% ($n = 11$) were treated with thrombectomy and/or fibrinolysis. Two cases underwent systemic thrombolysis and nine underwent mechanical thrombectomy.
Most patients were male (82%) with a mean age of 65 years.
The prognostic score at admission, according to the PESI scale, in patients undergoing mechanical thrombectomy was above 141 (high risk) with an estimated mortality according to the APACHE II scale between 24-55%.
Patients undergoing mechanical thrombectomy (81.8%) presented right heart chamber overload in 88.8% of cases, requiring post-procedure amines in two of the described cases.
One patient treated with fibrinolysis died. In mechanical thrombectomy, mortality was 55%, with one case being a consequence of the therapy.
**Conclusions:** Intermediate-high risk PE is more prevalent in males > 65 years old, with high mortality at admission. This was more frequent in the group treated with mechanical thrombectomy.
The sample size does not allow for conclusive results; it will be expanded to improve as a pilot project in which we continue recruiting patients.
In the future, it is possible that guidelines may recommend mechanical thrombectomy as the first-line therapy over fibrinolysis, given the good outcomes and low morbidity and mortality.

**Topic:** Acute respiratory failure and mechanical ventilation

**Introduction:** Air pollution is becoming a major public health issue as it has been proved to be one of the most important risk factors in cardiovascular diseases. Particulate matter (PM) which constitutes part of the air pollution, are the ones most likely to cause health problems. Several studies have focused on the effects of exposure to PM as a contributor factor triggering cardiac failure or myocardial ischemia; however, there are still no studies on the outcomes of patients undergoing major cardiac surgery.
**Objectives:** To study the impact of air particulate matter on outcomes after major cardiac surgery.
**Methods:** A retrospective observational study has been made with data from patients who have undergone major cardiac surgery in Hospital Central Universitario de Asturias (Oviedo, Spain) between 2019 and 2022. Data on PM2.5 and PM10 was obtained from the closest station to each patient address, and values from the last 14 days before surgery averaged. Main outcome measurements were ICU discharge and death, and were modelled using Cox regression to calculate hazard ratios and their 95% confidence interval. Results are expressed as median and interquartile range.
**Results:** PM data were available for 2042 patients out of 3859 operated in the study period. Median age was 70 (62–77) years. 676 (33%) patients were female. Median SAPS3 was 45 (38–53). ICU length of stay was 3 (2–4) days. There were 124 (6%) and 316 (15%) cases of urgent and emergent surgery, respectively. Mortality was 7% (148 patients, 2%, 6% and 24% in scheduled, urgent and emergent surgery, respectively). Median exposure to PM2.5 in the 14 days before surgery was 10.45 (8.40–12.36) mg/m$^3$, whereas median of exposure to PM10 in the same period was 21.30 (17.93–26.37) mg/m$^3$. After adjustment by age, sex and type of surgery, mean PM2.5 before surgery was associated with an increased risk of death (HR 1.10 [1.01–1.18], $p = 0.028$).
**Conclusions:** PM levels before major cardiac surgery are associated with an increased mortality.

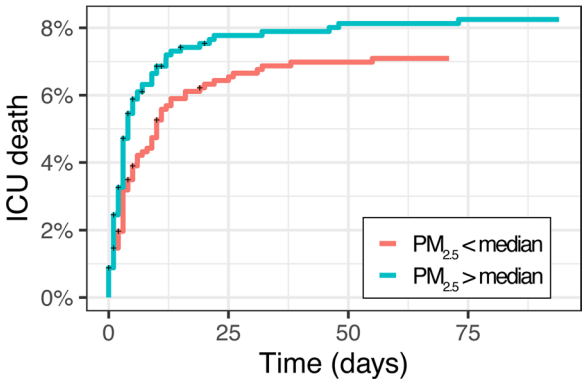

**Fig. 1 (abstract 000869)** Cumulative incidence of death according to the median PM2.5 14 days before surgery (HR 1.10 [1.01–1.18], $p = 0.028$, per unit increase)

**Topic:** Perioperative care

### 000870 Profiling the physical recovery of patients admitted to a general intensive care unit (ICU)

J. Dowds[1], S. Mc Entagart[1], G. Sheill[1], I. Martin-Loeches[2]

**Introduction:** Functional impairment and disability impacting on quality of life is common in ICU survivors (Rousseau, et al., 2021). Functional scores performed at ICU discharge can predict discharge location at 3 months (Eggman, et al., 2022).
**Objectives:** The aim of this study is to profile the recovery pathway, rehabilitation interventions and outcomes of a general ICU population.
**Methods:** Ethical approval was granted by the TUH SJH ethics committee. All patients admitted from 1st Sept 2023 until 22nd Dec 2023 were screened for inclusion (received care in ICU > 72 h). Exclusion criteria were death, transition to end of life care, new orthopaedic or neurological injury, multiple admissions to critical care areas, discharge against medical advice and discharged home directly from ICU. Data were obtained from the inpatient hospital databases and included demographic and baseline information, time to achieve functional mobility goals in ICU (Manchester Mobility Score [MMS]; Chelsea physical functioning assessment tool—[CPax]) at ICU discharge and at 3 months' post ICU discharge (hospital discharge information, total length of stay, discharge destination mobility status and onward referrals).
**Results:** 339 patients were screened for participation. 145 patients met the inclusion criteria (64.1% [$n = 93$] were men; average age 61.4yrs (SD 14.88); 52.8% [$n = 76$] were surgical admissions; 41.3% [$n = 60$] were mechanically ventilated; 12.4% [$n = 18$] had a tracheostomy; average length of ICU stay 7.5 days [SD 7.84]; 86.2% were independently mobile pre ICU admission). The median day to achieve MMS 2 = sit over edge of bed was D1 (range 1-20); MMS 4 = standing practice was D1 (range 1–26); MMS 5 = transfers was D1 (range 1–27); MMS 6 = mobilising was D3 (range1–43). 46.9% ($n = 68$) of this cohort achieved MM5 transfer to chair on D1. The average CPax at ICU discharge was 37.4 (SD 8.59). Average length of total hospital stay was 32.8 days (SD 30.08), 79.7% ($n = 117$) patients were discharged home at 3 months' post ICU discharge, at this time point 72.7% ($n = 104$) were independently mobile.
**Conclusions:** Over half of this cohort of patients were surgical admissions to ICU. The study centre is a complex cancer surgery centre with enhanced recovery after surgery protocols which stipulate early mobility targets. This cohort had a high CPax score on ICU discharge reflective of the high volume of surgical patients. Further investigation of the impact of functional measures in ICU on long term recovery is warranted.

**Introduction:** Patients with cancer or hematological malignancy are fragile and may experience complications requiring unplanned intensive care hospitalization, which can be associated with significant morbidity and mortality. Defining adequate therapy goals and intensive care unit (ICU) admission criteria for these patients presents a constant challenge. This study aimed to assess the mortality rate among haematologic-oncologic patients admitted to the ICU and the predictive factors associated with high ICU mortality.
**Methods:** This retrospective cohort study was conducted in the intensive care unit (ICU) of Intercommunal Hospital Group Le Raincy Montfermeil from January 2017 to March 2024. Factors related to mortality were assessed through univariate and multivariate analysis.
**Results:** In total, 80 patients were admitted to the ICU during the study period. The mean age was 66 ± 10 years. The mean SAPS II was 53 ± 21. Fifty-eight patients (72%) had cancer, and 22 (28%) had hematological malignancy. Pulmonary cancer was the most prevalent solid tumor (43%), and lymphoma was the most prevalent hematological malignancy (40%). Most of the patients (68%) were transferred from the haematologic-oncologic unit. Of the 80 admitted patients, 32 (40%) were admitted for sepsis and 24 (30%) for acute respiratory failure. Other less prevalent diagnoses were pancytopenia, coma, hydroelectrolytic disorders, and cardiac arrest. Thirty patients (38%) underwent mechanical ventilation, and 43 (54%) patients required vasopressor support. The mean length of stay in the ICU was 6 days, similar between deceased and surviving patients. In this cohort, 46 patients died, and 34 were discharged. A limitation of therapeutic efforts was decided for 35 patients (44%). Univariate analysis found that sepsis was more prevalent in the group of deceased patients. Multivariate analysis demonstrated that serum lactate at admission was significantly associated with increased mortality in the ICU, with an odds ratio of 1.35 [1.12–1.72]. The use of mechanical ventilation also significantly increased ICU mortality, with an odds ratio of 5 [1.48–20]. However, sepsis was not independently associated with ICU mortality in haematology and oncology patients.
**Conclusions:** The main finding of this study is the high mortality rate of patients with cancer or hematological malignancy admitted to the ICU. Hyperlactatemia and the need for mechanical ventilation were significantly associated with higher ICU mortality. The establishment of clear goals and approaches for the admission and treatment of haematology and oncology patients in the ICU is urgently needed.

**Introduction:** Circulating DNA and nucleosomes are a new class of biomarkers for severe respiratory infection and sepsis. The most serious of these cases undergo extracorporeal membrane oxygenation (ECMO), but the effects on circulating DNA and chromatin biomarkers are unknown. To understand the changes and origins of circulating DNA in patients with severe infection-related respiratory failure, we performed next-generation sequencing to profile plasma cell-free DNA (cfDNA) in patients before, during, and after ECMO treatment. We used Oxford Nanopore Technologies (ONT) because it does not require amplification, enables both long and short DNA sequencing and is most suitable for near-patient rapid analysis in the hospital setting. Our previous work showed that shallow whole-genome ONT sequencing with 0.5 × genomic coverage could determine changes in cell of origin and cfDNA fragmentation patterns using this approach [1].
**Methods:** We analyzed plasma cfDNA from more than 60 timepoints from 8 patients, with one timepoint collected before ECMO, multiple timepoints during ECMO, and one or more timepoints up to 2 days after decannulation. All patients were referred to the Guy's and St. Thomas' Severe Respiratory Failure Service and were placed on ECMO in accordance with national guidelines [2]. We measured global chromatin levels for each sample using an antibody-based assay for H3.1 nucleosomes (Nu.Q®) and sequenced cfDNA using ONT long-read, amplification-free sequencing. We determined Cell of Origin of circulating DNA using computational deconvolution of genome-wide DNA methylation levels from ONT sequencing reads.
**Results:** We obtained a median of 16.9 million reads per timepoint (lowest = 9.3 M, highest = 26.4 M), corresponding to 1.3 × genomic coverage. Using unsupervised clustering, we identified significant differences between fragmentation patterns before and during ECMO. We used DNA methylation Cell of Origin analysis to understand the relative contribution of cells from the infected tissue vs. cells from the immune system overall and with respect to the fragmentomic changes observed. We also investigated the sensitivity of shallow ONT sequencing to detect pathogenic DNA in 6 of 8 patients with confirmed bacterial infection.
**Conclusions:** ONT sequencing can reveal key molecular markers from circulating cell-free DNA patients with severe infections. The ability of ONT to profile both fragmentomic properties as well as DNA methylation allowed us to identify changes associated with severe respiratory failure and ECMO. The suitability of ONT sequencing for near-patient, rapid sequencing makes it a promising technology in the critical care setting.

**Introduction:** Vitamin D is involved in both innate and adaptative immune responses, with virtually all immune cells expressing vitamin D receptors and some having the ability to hydroxylate vitamin D to its active form [1]. Vitamin D supplementation in respiratory infections has been a research topic for many decades, but its role is still controversial. With the start of the COVID-19 pandemic, new research emerged on the topic. Lower levels of 25-hydroxyvitamin D have been associated with worst severity of SARS-CoV2 infection [2]. Moreover, multiple observational studies and randomized-controlled trials (RCT) have been published regarding the effects of vitamin D supplementation. A recent systematic review and meta-analysis [3] showed no benefit on mortality, intensive care unit (ICU) admissions and rate of mechanical ventilation in COVID-19 patients. When pooling only observational studies, there was a statistically significant decrease in mortality (with a higher GRADE of recommendation than the pooled RCTs). Only 2 of 16 included studies focused on patients admitted to the ICU.
**Objectives:** We performed a retrospective cohort study in patients hospitalized in a single-center ICU to further study the prognostic impact of vitamin D supplementation in critical patients with SARS-CoV2 infection.
**Methods:** We included 126 COVID-19 patients hospitalized in the ICU between April and October 2020. 72 patients received 250,000 UI of cholecalciferol *per os*, at 24 h and 48 h after admission. 54 patients admitted in the same period that did not receive supplementation were included in the control group. For initial statistical analysis we used the two-samples unpaired Wilcoxon test, and Chi-squared or Fisher's exact test.
**Results:** Baseline characteristics were similar between groups, including APACHE-II and SAPS scores. Median vitamin D levels at admission were 76 ng/mL, and similar between groups ($p = 0.683$), with higher levels in the supplemented group at day 3 ($p = 0.009$). 87% required ventilatory support for a median duration of 10.5 days, with no significant difference between groups ($p = 0.847$). The need for vasopressors ($p = 0.650$) and renal replacement therapy ($p = 0.499$) was also similar. Patients that received vitamin D had a lower ICU mortality (OR 0.103 with 95%CI [0.02–0.42]), intra-hospital mortality (OR 0.26 with 95%CI [0.08–0.8]) and 60 days after discharge mortality (OR 0.196 with 95%CI [0.05–0.62]), according to a multivariate logistic regression adjusting for age, chronic kidney disease, creatinine at admission, APACHE-II and SAPS scores. In a survival analysis, all-cause mortality was reduced in the supplemented group (HR 0.34 with 95%CI [0.15-0.76])—view Fig. 1.
**Conclusions:** High-dose vitamin D supplementation was associated with lower all-cause mortality in critically ill COVID-19 patients admitted to the ICU.

**Introduction:** Hypoxic–ischemic brain injury (HIBI) is a major determinant of both long-term neurologic injury and death in patients who survive cardiac arrest [1, 2]. While small studies have examined early neurophysiologic changes in HIBI, none have characterized patients from acute injury to long-term neurologic outcomes. Additionally, invasive monitoring excluded patients requiring anticoagulation; new Transcranial Doppler (TCD) neuromonitoring will allow us to characterize all patients with HIBI.
**Objectives:** This study aims to demonstrate feasibility of (1) patient recruitment, (2) acquiring multi-domain variables (neurophysiology, biomarkers of neurologic injury, and imaging), and (3) determining six-month post-discharge neurocognitive outcomes in a cohort of patients with HIBI after cardiac arrest.
**Methods:** This was a prospective cohort study conducted in the critical care unit of a tertiary academic hospital in Vancouver, Canada. We obtained approval from the University of British Columbia Clinical Research Ethics Board (H22-00208) and the study was registered in Open Science Forum (https://doi.org/10.17605/OSF.IO/QBW5K). We included patients 16 years of age or older admitted to critical care who remained comatosed (GCS $\leq$ 8) following a cardiac arrest. Informed consent was obtained from the Legal Authorized Representative. We measured flow-velocity in the middle cerebral artery using transcranial Doppler (TCD). We also collected biomarkers of neurologic injury daily for the first 3 days, and on day 7, as well as any imaging (CT or MRI) or electroencephalography performed while in hospital. Post-discharge outcomes assessment were assessed at 6 months for survivors (either in-person or remotely), and included patient outcome assessments, blood biomarkers, and an MRI brain.
**Results:** Thirty patients were enrolled between June 2022 and May 2023, with a mean age of 59 years (SD 17) and 7 (23%) females. Eighteen (60%) presented with a shockable rhythm. The median time to ROSC was 18 min [IQI 10 to 34], and 12 (40%) survived to hospital discharge. We obtained a TCD in 23 (77%) patients, 3 had no insonation window, and there were technical failures in 4. All patients had a CT scan, 21 (70%) had EEG, and 10 (33%) had an MRI. Biomarkers were collected in 29 of 30 (97%) on day-1, 28 of 30 (93%) on day-2, 21 of 26 (81%) on day-3, and 12 of 17 (71%) on day-7. Outcome assessments were completed in 9 of 12 (75%) survivors: 2 declined to participate and 1 was lost to follow-up. Four had in-person assessments, and 5 were completed remotely. Only 1/4 in-person participants had an MRI. Approximately 20% of survivors had reported higher levels of disability.
**Conclusions:** We demonstrated feasibility in recruitment, obtaining neurologic biomarkers, TCD, and 6-month neurologic outcomes for a remote battery. In-person assessments, including MRI and biomarkers, were not feasible. We expect approximately 20% of participants to have higher disability at time of follow-up.

### Inhibiting CXCR2-mediated cytokine sensing to target neutrophil dysfunction in sepsis

N. Liu[1], M. Bauer[2], A. Press[3]
[1]Department of Anesthesiology and Intensive Care Medicine, Friedrich-Schiller-Universität, Jena, Germany; [2]Department of anesthesiology and intensive care medicine, Jena University Hospital, Jena, Germany; [3]Nanophysiology group department of anesthesiology and intensive care medicine, Jena University Hospital, Jena, Germany
**Correspondence:** N. Liu
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000877

**Introduction:** Neutrophils are pivotal in defending the host against pathogens during sepsis, but their functions, including migration, antimicrobial activity, and immunosuppression, are compromised. Restoring neutrophil function improves sepsis outcomes, suggesting targeting neutrophils as a promising therapeutic strategy. Specifically, dysregulation of CXCR2, a chemokine receptor critical for neutrophil maturation and recruitment, correlates with sepsis severity. Inhibiting CXCR2 has shown efficacy in clinical trials and animal models, but the interaction between CXCR2 treatment and its ligand during sepsis remains incompletely understood.
**Objectives:** Our study evaluated the therapeutic potential of CXCR2 inhibition with Danirixin in sepsis, investigated the relationship between CXCR2 inhibition and blood IL-6 levels, examined the expression profiles of Cxcr2 and its ligands in immune cells, and characterized the immune response to Danirixin treatment in septic mice.
**Methods:** Low and high severity sepsis was induced in C57BL/6J mice using a fluid, analgesic and antibiotic resuscitated Peritoneal Contamination and Infection (PCI) model with pathogen loads resulting in 50% and 10% 7-day mortality. Cohorts received three doses of the Cxcr2 antagonist Danirixin or a vehicle solution at 6, 30 and 54 h post-infection. Inflammation was accessed repeatedly from venous blood samples at 6, 24, 48 h and 7 days after infection. Blood IL-6 level was used in a logistic regression model to stratify septic mice at risk of death. CIBERSORTx deconvolution was applied to microarray analysis of septic mice to decipher Cxcr2 expression profiles in immune cells 6 h and 24 h after infection. In addition, we investigated pathogen load and histopathological changes and tissue immune infiltration using microbiology and histology.
**Results:** Notably, only the high-severity sepsis model showed a significant reduction in mortality rate (87% vs. 52% in the control group). However, blood IL-6 levels did not correlate with CXCR2 inhibition. Survivors in the low-severity group, after 48 h of Danirixin treatment, had lower IL-6 levels compared to the control group. Genes that are major ligands for Cxcr2 (Cxcl1, Cxcl2, Ifit2, and Ifit3) were predominantly expressed in macrophages and Th cells. Conversely, survivors in the high-severity group treated with Danirixin exhibited elevated IL-6 levels 24 h post-PCI. The IL-6 level at 24 h emerged as a significant predictor of septic survival, with a cut-off of 2327 pg/mL. The group predicted to survive treated with Danirixin had no deaths, while most deaths occurred in the group predicted to die. Bulk sequencing data revealed systemic inflammation and immunosuppression. Blood and lungs exhibited a high neutrophil to lymphocyte ratio at 6 and 24 h post-sepsis, while the liver and spleen showed increased macrophages and lymphocytes.
**Conclusions:** Our study highlights the potential of CXCR2 inhibition as a therapeutic strategy in sepsis, particularly in high-severity cases. While Danirixin treatment led to a significant decrease in mortality rates in high-severity sepsis, its impact on blood IL-6 levels varied across severity groups. Gene expression analysis revealed distinct expression patterns of Cxcr2 and its ligands in immune cells, indicating the complexity of their interactions during sepsis. Overall, these findings contribute to our understanding of modulation of neutrophil function and immunomodulation in sepsis, suggesting CXCR2 as a promising target for future therapeutic intervention.

**Correspondence:** L. Doliwa
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000880

**Introduction:** Adequate nutrition of critically ill patients remains challenging, because factors such as pathophysiology of the life-threatening disease, chronic diseases, and status of nutrition at admission impede the estimation of the individual energy expenditure (EE) (Kamel et al., 2022, Israfilov and Kir, 2021, Preiser et al., 2014). In patients with aneurysmal subarachnoid hemorrhage (SAH), activation of the sympathetic nervous system could increase EE and few data exist for traumatic brain injury (TBI), and intracerebral hemorrhage (ICH) (Dilrai et al., 1992, Touhu et al., 1990, Tatucu-Babet OA et al. 2020).
**Objectives:** We aimed to compare EE in patients with SAH with endovascular securing of the (SAHi), SAH with microsurgical securing of the aneurysm (SAHs), TBI, and ICH. Critically ill patients suffering from sepsis served as controls.
**Methods:** This single-center prospective study included patients suffering from SAH, TBI, ICH and sepsis. We performed indirect calorimetry (IC; QNRG +, COSMED, Rome, Italy) at 3 timepoints (TP; TP1: day 1-3; TP2: day 5-7 and TP3: day 12–15). IC was performed twice per timepoint and the mean values used for further analysis. Exclusion criteria were spontaneously breathing patients requiring oxygen supplementation, ventilated patients with an inspiratory oxygen fraction > 70%, a positive end-expiratory pressure > 12 mbar, leakage from the airway system, and patients requiring non-invasive ventilation. The results of IC were used for the adjustment of nutritional therapy according to hospitals standards. The individual EE at all three timepoints was compared using a generalized mixed model analysis with sequential Bonferroni correction.
**Results:** From June 1, 2021 to February 28, 2023, 110 Patients were included (SAHi: 30, SAHs: 13, TBI: 22, ICH: 23 sepsis: 22). At TP1, EE for SAHi was (mean ± standard deviation) 1633 ± 404 kcal, 1504 ± 459 for SAH, 1470 ± 473 for TBI, 1403 ± 409 for ICH, and 1557 ± 461 for sepsis (ICH vs. SAHi: $p < 0.01$, ICH vs. sepsis: $p < 0,01$, all other: n.s.). At TP2, EE

for SAHi patients was 1723 ± 386, SAHs 1755 ± 374, TBI 1579 ± 362, ICH 1534 ± 326, and sepsis 1416 ± 256 (ICH vs. SAHi: $p < 0{,}01$, ICH vs. SAHs: $p < 0{,}05$, all other: n.s.). At TP3, EE was 1458 ± 246 for SAHi, 1653 ± 167 for SAHs, 1856 ± 200 for TBI, 1644 ± 564 for ICH, and 1514 ± 282 for sepsis (all n.s.).
**Conclusions:** During the first week after ictus, EE in ICH patients was lower than in SAH and sepsis patients. Further data are required to confirm our results and to elucidate the mechanisms for a decreased EE in ICH patients. Until further data are available and due to a high interindividual variability, we suggest using IC for the estimation of caloric needs in neurocritically ill patients.

### Plasma renin kinetics in comparison with lactates in assessing shock reversal in septic shock: a prospective study

A. Srinivasan[1], S. Samavedam[2]
[1]critical care medicine, Virinchi Hospitals, Hyderabad, India; [2]Critical care medicine, Ramdev Rao Hospital, Hyderabad, India
**Correspondence:** A. Srinivasan
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000881

**Introduction:** Septic shock is defined as a subset of sepsis in which particularly profound circulatory, cellular and metabolic abnormalities are associated with a greater risk of mortality than with sepsis alone. (1) The conventional biomarker for hypoperfusion in septic shock is elevated lactate levels and though it predicts mortality, its specificity is low. (2) As a part of pathophysiological mechanism of septic shock, there is deregulation of renin angiotensin aldosterone pathway3 and as a surrogate we studied plasma renin activity (PRA) and its performance weighing lactate kinetics in shock reversal in patients with septic shock.
**Objectives:** Primary outcome:
1. Predictor of icu survival
Secondary outcome:
1. Number of vasopressor days
2. Incidence of acute kidney injury
3. ICU length of stay
**Methods:** Our study design is single centered, prospective and observational. Ethical committee approval and CTRI enrolment were done prior to recruitment. As an interim analysis, we enrolled 30 adult patients with septic shock as per sepsis-3 definition (1) within 48 h of diagnosis. Blood samples of PRA and lactates were sent for analysis at admission and at 6 h. Rest management were uninterrupted by the investigator and lies within the discretion of the treating intensivist. Statistical analysis was done using SPSS software version 27.
**Results:** The demographic profile is comparable between both groups. Mean PRA levels among non-survivors were 15.05 ± 9.3 pg/ml and 39.01 ± 8.5 pg/ml at admission and at 6 h, respectively, whereas there is no change in the absolute values of lactate at both time frames (3.8 ± 2.7 mmol/L and 3.4 ± 1.92 mmol/L at admission and at 6 h, respectively). Among survivors mean PRA were 1.61 ± 2.35 pg/ml and 8.15 ± 11.4 pg/ml at admission and at 6 h, respectively, and lactate levels were 1.74 ± 0.56 mmol/L and 1.95 ± 1.29 mmol/L at admission and at 6 h, respectively. Both PRA and blood lactates at two different time points, at admission and 6 h predicted survival, but the statistical significance of renin outperformed lactates at both time points ($p$ value < 0.01 for PRA at 0 and 6 h versus p value of 0.002 and 0.016 at admission and at 6 h for lactate). Receiver operating curve analysis could not be performed for the limitations in sample size being an interim analysis. Secondary analysis showed, though both predicted mortality, length of ICU stay is uninfluenced by these biomarkers. Moreover, acute kidney injury at day 2 as per KDIGO definition (4) predicts mortality in our study population ($p$ value 0.035). Days spent on vasopressors did not correlate to outcomes.
**Conclusions:** Although both PRA and lactates predicts mortality, PRA independently is a better outcome predictor than lactates when assessing in-hospital mortality in patients with septic shock.

### Evaluation of limitation of the therapeutic effort in form of non-admission in the intensive care unit in a third-level hospital

C. Quirós Aguirre[1], J. Martínez Matencio[1], E. Fernandez Garcia[1], T. Aldabó Pallás[1]
[1]Intensive Care Unit, Virgen del Rocío University Hospital, Sevilla, Spain
**Correspondence:** C. Quirós Aguirre
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000882

**Introduction:** Discussion of Limitation of the Therapeutic Effort (LTE) is an important part of the ethical aspect in the Intensive Care Unit (ICU). Admission to ICU and whether or not to initiate invasive treatments with a patient is sometimes a difficult choice that must be guided by the consideration of potential benefits versus risk of unreasonable obstinacy. A form of LTE would be the non-admission of a patient to the ICU by this principle. Regarding the recent national study ADENI-UCI, our unit made an observational prospective study in order to evaluate the cases classified by our unit as Limitation of the Therapeutic Effort in form of Non-admission in the Intensive Care Unit (LTE-NO-ICU) in order to better understand the decision-making process and improve quality of care.
**Objectives:** To describe the most relevant variables of the cases which were classified as LTE-NO-ICU by our unit in order to evaluate our decisions about this type of LTE.
**Methods:** An observational prospective study was elaborated by our unit with the information transmitted in the morning rounds about the cases classified as LTE-NO-ICU. The data were collected during 10 months (from June 2023 to March 2024, both included) and a

follow-up until hospital discharge was made. Patients variables (age, sex, comorbidities, functional capacity, reason of admission to hospital and previous admissions to ICU), consult to Critical Care variables (time of consult, unit that consults, reason of consult, severity according to APACHE II and SOFA scales), decision of LTE-NO-ICU variables (reason of LTE, changes in the decision, recording of the decision in the patient's medical history) and evolutional variables (death/discharge, hospital stay, sedation, analgesia) were considered. A descriptive analysis of the sample was elaborated. The results are presented in the form of percentage for categorical variables and in terms of mean and standard deviation for continuous quantitative variables.

**Results:** Our unit was consulted in 896 cases, of which 803 were admitted to ICU (89,6%) and 93 (10,4%) of the patients were classified as LTE-NO-ICU. A total of 63 patients were included in this study, with 30 cases being excluded due to insufficient follow-up. The mean age was 70 years, with a standard deviation (SD) of 14 years. Of all of them, 39 (61,9%) were male. In APACHE II scale the mean score was 23 with a SD of 8. In the SOFA scale the mean score was 8 with a SD of 4. Image 1 shows the patients' clinical variables and Image 2 shows the variables concerning the consult to ICU.

The most common reason for LTE-NO-ICU was futility of the treatment (50,8%). This decision was registered in patients' clinical history in 76,2% of the cases. There were 2 cases in which this decision was revoked. There was 1 case of refusal of admission by the patient.

During that hospital stay, 40 patients (63,5%) died. Sedation was needed in 34 patients (54%) and analgesia in 24 patients (38,1). Mean hospital stay was 13 days.

**Conclusions:** Our results were similar to those published in the ADENI-UCI study, although an improvement in data collecting and follow-up of the patients classified as LTE-NO-ICU is needed in order to guarantee quality of care.

### Assessment of lung overdistension using computed tomography (CT) in invasively mechanically ventilated patients: a systematic review

A. Mousa[1], J. Tessers[1], L. Heunks[2], M. Schultz[1], F. Paulus[1], PR. Tuinman[1]
[1]Intensive Care, Amsterdam UMC, Amsterdam, Netherlands; [2]Intensive Care, Radboud University Medical Center, Nijmegen, Netherlands

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000883

**Introduction:** Inflation of alveoli beyond their physiological limits during mechanical ventilation, known as lung overdistension, causes injury [1]. Precise tools for assessment and quantification of this overdistension are crucial for personalized ventilation strategies and improving patient outcomes. Computed tomography (CT) is often described as the gold standard to evaluate lung volumes [2]. However, there is no clear definition in terms of cut-off values and assessment of the CT images which best reflects overdistension. This systematic review aims to describe the different cut-off values and description to assess lung overdistension in mechanically ventilated patients using CT.
**Methods:** This systematic review was designed in accordance with PRISMA guidelines. We searched PubMed, Embase, Web of Science and Cochrane databases. Studies were eligible for inclusion if adult patients, either in the intensive care unit or the operating room, were invasively mechanically ventilated and underwent CT-measurements to assess overdistension of the lung. Cut-off values to define overdistension during mechanical ventilation as well as amount of overdistension measured are reported. If applicable, the modality used to evaluate the accuracy of the index test (i.e. the reference test) was also reported.
**Results:** Out of 4426 studies, a total of 11 studies were included, including a total of 211 patients, Table 1. All studies were conducted in acute hypoxemic patients. Three studies used a reference test: two used pressure–volume curve (P–V curve) and one used electrical impedance tomography (EIT). Cut-off values used in the studies to define overdistended lung tissue were similar with Hounsfield unit (HU) below − 900. Studies described overdistension either as volume, percentage of fraction of the lung. One study did not use HU to define overdistension but rather the change in air content between end-inspiration and end-expiration, expressed as strain. Limitation of the included studies are that sample sizes were small (n between 6 and 32) and often no reference test was used.
**Conclusions:** This systematic review shows that studies using CT as a tool to assess lung overdistension use nearly the same definition based on the air content of the lung. However, there is a variety between studies regarding defining overdistended regions as volume or percentage of the total lung. In addition, one study showed that the thickness of slices of the CT greatly influence the amount of overdistension, thereby emphasizing the need for protocolized assessment of lung overdistension in patients. Further research is needed to assess the relation between overdistension assessed by CT and patient outcomes.

### Assessment of lung overdistension using electrical impedance tomography (EIT) in invasively mechanically ventilated patients: a systematic review

A. Mousa[1], J. Tessers[1], A. Jonkmann[2], M. Schultz[1], F. Paulus[1], PR. Tuinman[1]
[1]Intensive Care, Amsterdam UMC, Amsterdam, Netherlands; [2]Intensive Care, Erasmus University Medical Center, Rotterdam, Netherlands
**Correspondence:** A. Mousa
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000884

**Introduction:** Lung overdistension (i.e. excessive inflation of alveoli) is known to cause injury during mechanical ventilation [1]. Electrical impedance tomography (EIT) is a promising non-invasive imaging tool allowing for bedside assessment of the distribution of ventilation and thus overdistension [2]. However, there is no clear method for how to define overdistension with EIT. This systematic review aims to describe the different methods to assess overdistension in mechanically ventilated patients using EIT.

**Methods:** We followed PRISMA guidelines and searched PubMed, Embase, Web of Science and Cochrane databases. Studies were eligible for inclusion if adult patients, either in the intensive care unit or the operating room, were invasively ventilated and underwent EIT-measurements. Studies were excluded if there were no cut-offs values described for assessment of lung overdistension. Primary outcomes were cut-off values to define overdistension and the amount of measured overdistension. If applicable, the modality used to evaluate the accuracy of the index test (i.e. reference test) was also reported.
**Results:** Of the 4426 studies screened, nine with a total of 253 patients were included, Table 1. All patients had acute hypoxemic failure patients. Three studies used a reference test: two used pressure–volume curve (P–V curve) and one used computed tomography (CT). Three studies used cut-off values to classify pixels in region-of-interest as overdistended. All other studied defined pixels as overdistended if compliance decreased with increasing pressure. Four studies used the same method to define overdistension.
**Conclusions:** Studies using EIT to assess lung overdistension report different methods to define overdistension. While popularity of EIT is increasing, our study emphasizes the need for standardized methods to describe overdistension in order to compare study results and translate the results to clinical practice. Further research is needed to assess the relation between overdistension assessed by EIT and patient outcomes.

**Table 1 (abstract 000884)** Studies included in the systematic review. If applicable, the reference test to compare EIT measurements is reported

**Introduction:** Sepsis refers to a life-threatening organ dysfunction caused by the host's dysregulation of the immune response to infection [1]. According to the latest data from the Global Burden of Disease study, nearly 50 million people worldwide develop sepsis annually, with approximately 11 million deaths [2]. Immunosuppression is a crucial factor affecting the prognosis of sepsis patients, and T cell exhaustion is a significant marker of sepsis-induced immunosuppression. Our team has previously discovered that abnormal activation of the T cell surface receptor 2B4 is one of the key indicators of immunosuppression [3]. It was previously believed that sepsis-induced immunosuppression occurred in the middle to late stages of the disease, but our preliminary research and recent reports have shown that immune suppression caused by sepsis is already evident in the early stages of the disease [4]. Abnormal activation of PD-1/PD-L1 is a significant cause of immunosuppression in sepsis patients. Blocking PD-1/PD-L1 can effectively reverse T cell dysfunction and improve bacterial clearance [5]. However, due to factors such as patient heterogeneity, the prognosis of patients has not been significantly improved. Currently, there is still a lack of precise therapeutic options targeting immunosuppression.
**Objectives:** Immunosuppression is a crucial factor influencing the prognosis of sepsis patients, yet the underlying mechanisms of sepsis-related immunosuppression remain elusive. PD-L1, a common immune checkpoint, has been recently implicated in the development of sepsis-induced immunosuppression through its expression on endothelial cells. SAPs, a novel form of intercellular communication, may regulate PD-L1 expression. This study aimed to investigate whether macrophage-derived SAPs mediate sepsis-induced immunosuppression by modulating PD-L1 expression in endothelial cells.
**Methods:** Spatial transcriptomic analysis and model construction were used to confirm the overexpression of PD-L1 in endothelial cells in sepsis models and its role in mediating T cell exhaustion. Cellular experiments were conducted to demonstrate that macrophage-derived SAPs stimulate the overexpression of PD-L1 on the surface of mouse lung microvascular endothelial cells, and proteomic analysis was performed to investigate the potential regulatory mechanisms.
**Results:** Spatial transcriptomic analysis of lung tissue revealed that PD-L1 (CD274) was most highly co-expressed with endothelial cell markers (PECAM-1) in sepsis model mice compared to controls, and this phenomenon was confirmed in mice with CLP-induced sepsis. A significant positive correlation was observed between PD-L1 expression and lung T cell exhaustion. The levels of SAPs were significantly elevated in sepsis patients and animal models with immunosuppression, and drive analysis traced their origin primarily to macrophages. In vitro experiments showed that SAPs collected from LPS-stimulated macrophages could induce overexpression of PD-L1 on the surface of mouse lung microvascular endothelial cells when co-cultured together, and this effect was significantly inhibited by the addition of

a SAPs blocker. In vivo experiments confirmed that LPS-SAPs also promote the overexpression of PD-L1 in mouse lung endothelial cells. Proteomic analysis of in vitro collected LPS-SAPs and Con-SAPs revealed significant differences in proteins related to ubiquitination modification pathways. Co-IP experiments targeting the overexpressed proteins indicated a strong protein interaction between TRIM25 and endothelial cell PD-L1 in LPS-SAPs, suggesting that SAPs may mediate sepsis-induced T cell exhaustion and immunosuppression through the ubiquitination modification of endothelial cell PD-L1 by TRIM25.
**Conclusions:** Macrophage-derived SAPs in sepsis may promote the overexpression of PD-L1 in endothelial cells through ubiquitination modification, leading to T cell exhaustion and subsequent immunosuppression.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000888

**Introduction:** The poor sensitivity of X-rays compared to CT scans for the diagnosis of lung pathologies is well established in patients with febrile neutropenia. The utility of bedside lung ultrasound in neutropenic children has not been extensively studied. The present study was designed to investigate the correlation of lung ultrasound (LUSS) score with P/F ratio (ratio of arterial oxygen partial pressure (PaO2 in mmHg) to fractional inspired oxygen (FiO2)) in paediatrics neutropenic patients admitted to the ICU
**Objectives:** The primary objective of the study was to investigate the correlation between lung ultrasound score (LUSS) and P/F ratio [ratio of arterial oxygen partial pressure (PaO2 in mmHg) to fractional inspired oxygen (FiO2)].
**Methods:** Neutropenic patients aged less than 16 years admitted to the ICU and on fixed FIO2 devices like invasive mechanical ventilation (IMV), non-invasive ventilation (NIV), high-flow nasal cannula (HFNC), or room air were included after written informed consent from the patient and/or parent. The LUS score was calculated at the time of admission by scanning all six zones of the lung bilaterally by the person trained in lung ultrasound. LUS was calculated based on the previously described method (Mojoli et al.). The correlation between LUS and PF ratio was tested using Spearman's rank correlation coefficient. The study was approved by the institutional ethics committee.
**Results:** A total of 25 patients were enrolled. The median age was 6 years. The median sofa score was 6 and the APACHE II score was 19. The median total leukocyte count (TLC) was $0.73 \times 109$/L and the absolute neutrophil count (ANC) was $0.11 \times 109$/L. Six patients were receiving vasopressors at the time of enrolment. 10 patients were on mechanical ventilation, and eight patients received HFNC. Midian LUS score was 28. We noted a moderate negative correlation between the LUS score and PF ratio ($r = -0.5724$ $p = 0.003$).
**Conclusions:** LUS score has a moderate negative correlation with PF ratio in febrile neutropenic children. The role of LUS in the prediction of survival and ventilator outcomes needs further evaluation in a prospective study.

### Self-reported fatigue 6th months after ICU discharge: a preliminary results of the FICUF study

N. Elhadjene[1], J. Morel[1], M. Reynaud[1], A. Pregny[1], A. Crouzet[1]
[1]Department of Anaesthesiology and Critical Care, Chu Nord Saint-Étienne, Saint-Priest-en-Jarez, France

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000889

**Introduction:** Mortality rates in intensive care units (ICUs) have recently decreased, leading to a rise in survivors who face physical, psychological, and cognitive sequelae after ICU discharge [1]. In 2012, the Society of Critical Care Medicine (SCCM) gathered these symptoms into a new syndrome called Post-Intensive Care Syndrome (PICS) [2]. The definition of PICS has been updated in 2021 to broaden the spectrum of post-ICU sequelae, with a particular focus on fatigue [3]. Fatigue can be defined as "an overwhelming and persistent subjective sense of physical, emotional, and/or cognitive exhaustion unrelated to recent physical activity". Morel et al. highlighted a high prevalence of fatigue, affecting more than half of survivors (57%), 6 months to 5 years after hospital discharge [4].
**Objectives:** The aim of this study was to assess the prevalence and risk factors of fatigue in ICU survivors at 6 months after ICU discharge.
**Methods:** This prospective cohort was conducted between 2 July 2022 and 2 April 2024 in a single one university hospital centre. Consecutive patients over 18 years old, admitted to the intensive care unit (ICU) who required a mechanical ventilation for more than 5 days or an ICU length of stay more than 10 days, were invited to be evaluated in the post-intensive care unit 6th month after ICU discharge. Scheduled postoperative ICU admission patients were excluded. We defined fatigue using a 13-item scale: the Functional Assessment of Chronic Illness Therapy Fatigue (FACIT-F). We used a cut-off score of

34 to define fatigue [4]. The study was approved by the local ethics committee (IRBN962022/CHUSTE) and registered at clinicaltrials.gov (NCT05984069).

**Results:** In this preliminary study, a total of 199 patients were eligible between 2 July 2022 and 2 April 2024. Of these, 108 patients died and 17 patients had a post-ICU telephone evaluation, so only 74 patients were included in the analysis. The prevalence of fatigue was 51.4% (38/74). There was no statistical difference in baseline characteristics between the two groups (Table 1). The Medical Research Council (MRC) score was lower in the fatigue group (40.5 ± 10.8 vs 51 ± 11.8, $p = 0.08$). Patients with self-reported fatigue had more ICU-acquired weakness at ICU discharge (87.5% vs 42.9%, $p = 0.07$) (Table 2). In the fatigue group, quality of life was worse (62.9% vs 22.2%, $p < 0.001$), depressive disorder using HAD-D was higher (48.6% vs 11.1%, $p < 0.001$), autonomy impairment using IADL was more important (83.3% vs 58.6%, $p = 0.04$) and physical activity time using Godin-Leisure time score was lower (8 ± 21 vs 21 ± 37, $p = 0.01$) (Table 3).

**Conclusions:** In this preliminary study, self-reported fatigue at 6 months after ICU discharge is a major symptom present in more than half of ICU survivors. Early prevention of fatigue after ICU discharge and physical activity prescription should be systematic to reduce psychologic disorder and improve quality of life.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000890

**Introduction:** The incidence of multi-organ failure presents a significant diagnostic and therapeutic challenge in sepsis [1]. Still lacking research about the incidence, coexistence, first-episode situation, and prognosis of various organ failures [2].

**Objectives:** To explore the incidence, coexistence, and first-episode situation of organ failure in patients concerning prognosis.

**Methods:** We performed a single-centre retrospective cohort study conducted in the ICU of a large hospital in China from January 2020 to June 2022. Organ dysfunction was assessed and quantified based on organ-specific SOFA scores ≥ 3 points.

**Results:** Among 2,255 included patients, the incidence of cardiovascular failure was the highest ($N = 1683$, 74.63%), while liver failure was the lowest (N = 167, 7.41%). The most common multi-organ failure combination was cardiovascular and respiratory failure ($N = 279$, 14.33%). The average onset times of organ failure in order, were cardiovascular, neurological, respiratory, coagulation, renal, and liver (10.5 h, 14.5 h, 14.8 h, 19.4 h, 28.2 h, and 53.8 h, $P < 0.001$). Respiratory (HR: 1.31, $P = 0.006$ vs HR: 1.19, $P = 0.009$), cardiovascular (HR: 3.48, $P < 0.01$ vs HR: 2.02, $P < 0.01$), neurological (HR: 3.4, $P < 0.01$ vs HR: 2.7, $P < 0.01$), and renal (HR: 1.86, $P < 0.01$ vs HR: 2.07, $P < 0.01$) failures were related to increased in-hospital and one-year mortality rates. The 30-day and one-year survival rates for liver failure were the lowest compared to others (66.7%, $P < 0.0001$ vs 20%, $P < 0.0001$).

**Conclusions:** In septic patients, cardiovascular failure was predominant, often paired with respiratory failure. The sequence of initial organ failure was cardiovascular, neurological, respiratory, coagulative, renal, and hepatic in order. Liver failure indicates the poorest short and long-term prognosis compared to other organs.

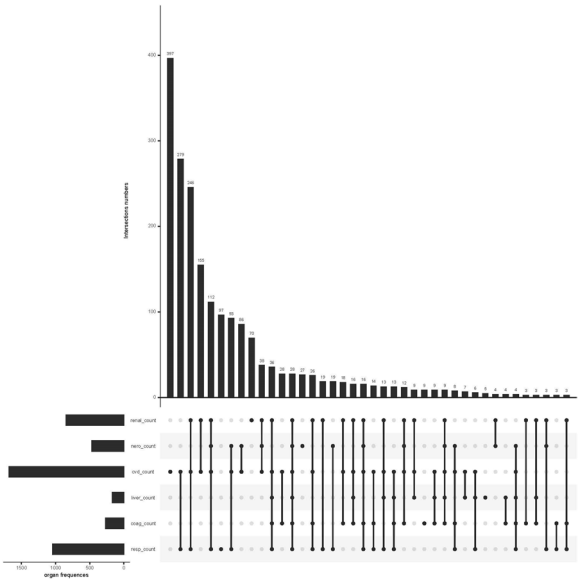

**Fig. 1 (abstract 00890)** Distribution of unique combinations of organ dysfunction sorted by occurrence frequency

The single most common organ dysfunction was cardiac (displayed in the horizontal bar graph in the lower left panel), whereas the least frequent was liver. The main panel shows each unique combination of organ dysfunctions (as indicated by the corresponding pattern of dots) along with their occurrence frequency in the cohort (vertical bar graph above each unique combination).

| | 0 | 1 | 2 | 3 | 4 | 5 |
|---|---|---|---|---|---|---|
| Respiratory | 18.6% / 97 | 41.3% / 320 | 73.2% / 365 | 82.8% / 174 | 87.9% / 58 | 96.4% / 28 |
| Coagulation | 33.3% / 9 | 30.8% / 39 | 56% / 50 | 78.9% / 76 | 87.7% / 65 | 96.4% / 28 |
| Liver | 60% / 5 | 58.3% / 12 | 55.6% / 27 | 84.1% / 44 | 88.2% / 51 | 96.4% / 28 |
| Cardiac | 30% / 397 | 49.2% / 555 | 74.5% / 435 | 84.1% / 201 | 88.1% / 67 | 96.4% / 28 |
| Nervous | 22.2% / 27 | 70% / 110 | 83.2% / 137 | 88.1% / 135 | 87.1% / 31 | 96.4% / 28 |
| Renal | 34.3% / 70 | 53.3% / 182 | 76.3% / 321 | 85.2% / 182 | 88.9% / 63 | 96.4% / 28 |

**Fig. 2 (abstract 00890)** Mortality associated with different types and numbers of organ failures
Each organ failure is represented by a line. In each box, the number below the diagonal line presents the number of patients with the column title-presented number of additional failing organ systems in addition to the organ failure of that line. The percentage above the diagonal line presents the annual mortality of these patients. For example, the one-year mortality rate is 34.3% when there is solely renal failure. However, when renal failure is combined with failures in four other organs, this rate escalates to 88.9%.

### The antimicrobial peptide LL-37 disturbs mitochondrial membrane integrity in cytotoxic T-lymphocytes during sterile inflammation and induces immunometabolic paralysis

S. Hirschberger[1], S. Nibler[1], R. Tomasi[2], S. Peterß[3], S. Kreth[4], M. Hübner[5]
[1]Anesthesiology, LMU University Hospital Munich, München, Germany; [2]Department of Anesthesiology, LMU, Munich, Germany; [3]Department of Cardiac Surgery, LMU, Munich, Germany; [4]Department of anesthesiology, University Hospital, LMU Munich, Munich, Germany; [5]Anesthesiology, LMU, Munich, Germany
**Correspondence:** S. Hirschberger

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000891

**Introduction:** Sterile inflammation in response to major surgery leads to immunosuppression of human cytotoxic T-lymphocytes (CTL) [1]. The precise mechanism underlying this phenomenon is only incompletely understood. Antimicrobial peptides (AMP) represent a highly conserved and powerful defense mechanism against bacteria. Cathelicidins are one major form of AMP; by charge-dependent incorporation into the highly negatively charged membranes of bacteria, cathelicidins puncture the bacterial cell wall, compromise bacterial membrane integrity and eventually lead to bacterial lysis. The CAMP gene (mature peptide: LL-37) represents the only cathelicidin expressed in humans. [2]
**Objectives:** During bacterial septic shock, low LL-37 blood concentrations have been reported [3]. We detected strongly elevated levels of serum LL-37 during sterile inflammation post major surgery. We thus hypothesized that—during sterile inflammation and absence from bacterial burden—an erroneous reaction occurs: LL-37 incorporates into mitochondrial membranes due to their charged organelle membrane, resulting in perforation of the mitochondrial membrane instead of bacteria. This might compromise CTL metabolism, thereby inducing immunosuppression.
**Methods:** Patients undergoing elective major surgery (e.g. cardiopulmonary bypass surgery or off-pump cardiac surgery, orthopedic surgery) and healthy volunteers were included after written informed consent (Ethics approval 17-241, LMU Munich). Magnetic cell separation was used to isolate CTL. Isolation of mitochondria was performed via Microbead-separation. Protein expression was determined by Western Blot and ELISA. Confocal microscopy was performed using MitoTracker green. Mitochondrial membrane potential and oxidative phosphorylation were quantified via JC1 and Seahorse, respectively. Fluorescence of calcein-labeled K562 co-incubated with CTL was used to evaluate cytotoxicity. Cell proliferation was measured via EdU assay on a flow cytometer.
**Results:** After major surgery, we detected high intracellular levels of LL-37 in human CTL, whereas preoperative CTL showed no expression of LL-37 (Figure A). Isolated CTL mitochondria of patients post major surgery exhibited a significantly reduced mitochondrial membrane potential ΔΨm ($-32.5\% \pm 19\%$, $p = 0.0299$, $n = 5$). To determine whether LL-37 co-localizes with the charged mitochondrial membrane of CTL, we co-incubated human CTL of healthy donors with LL-37. Indeed, Fam-labeled LL-37 co-localized with CTL mitochondria as indicated by co-staining with Mitotracker, which was further corroborated by Western Blot of isolated CTL mitochondria, detecting LL-37 within the organelle fraction (Figure B/C). LL-37 led to a severe deterioration of mitochondrial integrity as depicted by a collapse of ΔΨm (Figure D). Mitochondrial function was also impaired due to LL-37: CTL depicted a continuous decline of oxidative respiration after injection of LL-37 (Figure E). Considering the pivotal role of mitochondrial metabolism for CTL immunology, we assessed the immune effector function of CTL after LL-37 treatment and detected a significant reduction of cell lysis capacity and cell proliferation (Figure F/G).
**Conclusions:** Sterile inflammation after major surgery results in elevated LL-37 serum concentrations. Due to the absence of bacteria, LL-37 erroneously incorporates into CTL mitochondria, thus disturbing their organelle function and compromising immune cell effector function. We here report a dichotomous role of LL-37: whereas increased LL-37 provides beneficial antibacterial support during sepsis, it may have detrimental impact on CTL immunometabolism during sterile inflammation induced by major surgery. Targeting these adverse off-target effects may offer a base for future treatment approaches.

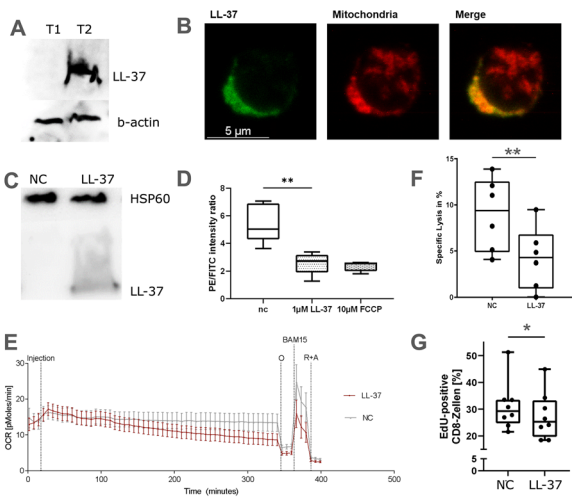

**Fig. 1 (abstract 000891)** **A** Protein expression of LL-37 and b-actin in human CTL prior to (T1) and at the end (T2) of major surgery.

**B** Confocal microscopy of human CTL from healthy donors incubated with1µM Fam-labeled LL-37 for 1 h, subsequently stained with MitoTrackerTM Deep Red and fixed with methanol. **C** Protein expression of LL-37 and HSP60 in isolated mitochondria of CTL from healthy donors incubated with LL-37. **D** Mitochondrial membrane potential ΔΨm was measured via JC1. CTL from healthy donors were stimulated overnight (anti-CD3/CD28). Mitochondria were isolated and incubated with vehicle control (nc), 1µM LL-37 or the protonophore FCCP(positive control). $n=4$. **E** Mitochondrial respiration as measured via Seahorse HS mini analyzer. CTL were incubated overnight using CD3/CD28 beads, "Injection": administration of eitherLL-37 or vehicle control (PBS), O: Injection of Oligomycin, BAM15: injection of BAM15, R + A: injection of Rotenone/Antimycin A, experiment was performed in triplicates. **F** Relative cell lysis capacity of human CTL as measured by calcein-fluorescence, $n=6$. **G** CTL proliferation was determined via EdU assay staining assessed on a FACS Canto II flow cytometer, $n=8$. *$p<0.0.5$, **$p<0.01$.Paired t-test or Wilcoxon matched-pairs signed rank test, as appropriate

**Introduction:** Studies have shown an underrepresentation of women in the authorship of research articles, and critical care was the only field in medicine experiencing a negative annual change rate in 2018 (1, 2). A recent article found that the percentage of women either as first or senior author has plateaued in the recent years (2). But no study has assessed the independent factors associated with the proportion of women in the authors.

**Objectives:** This study aimed to identify independent factors associated with the proportion of women in the authors of critical care randomized controlled trials (RCTs) published in high-impact journals. We also evaluated the women authors evolution over the last 25 years.

**Methods:** We conducted a meta-epidemiological study of critical care RCTs between 1999 and 2023, published in the NEJM, the Lancet, the JAMA, AJRCMM, ICM or CCM, retrieved through MEDLINE, CENTRAL, and Web of Science databases, and a previously published study (3). Gender was assessed based on names, online biographies, or publicly available photographs, as previously performed (2). Analyses were performed using univariate and multivariate generalized linear mixed models. Adjusted odds ratios (OR) were calculated with corresponding 95% confidence intervals.

**Results:** Over the 25-year period, 1203 critical care RCTs published in the studied journals were retrieved. Gender of all authors was assessed in 1199 RCTs (99.7%), which were included in the analysis. Overall, 4,335 out of 16,057 authors (27%) were women. Women were less frequently first authors (246/1,199 [21%], $p<0.001$), and less frequently senior authors (174/1,199 [15%], $p<0.001$). Women represented at least 50% of the authors in 137(11%) RCTs.

The proportion of women in critical care RCTs increased significantly over time (Fig. 1, $p<0.001$). In univariate analysis, the proportion of women increased significantly with year of publication ($p<0.001$) and higher sample size ($p<0.01$), and decreased significantly in European RCTs ($p<0.001$), sepsis and ventilation topics ($p=0.01$), RCTs with mortality as primary outcome ($p<0.01$), and RCTs endorsed by study groups ($p=0.01$). In multivariate analysis, the proportion of women increased significantly with the year of publication (OR = 1.05 [1.02–1.09], $p<0.01$) and the sample size (OR = 1.01 [1.00–1.01] per 100 patients, $p=0.01$), and decreased significantly in European RCTs (Fig. 2., OR = 0.53 [0.33–0.85], $p<0.01$), ventilation topic (OR = 0.50 [0.25–0.97], $p=0.04$), and RCTs with mortality as primary outcome (OR = 0.36 [0.14–0.92], $p=0.03$).

**Conclusions:** The proportion of women in the authors of critical care RCTs published in high-impact journals has increased over time, from 18% in 1998 to reach 32% in 2023. However, behind this finding lie disparities. Women are less frequently first and senior authors. Geographic discrepancies were found, as less women are included in European RCTs, when compared to North American countries or to the rest of the world.

**Introduction:** Since 2016, the World Health Organization has recommended universal antiretroviral therapy (ART) to all people living with Human immunodeficiency Virus (PLHIV). The impact of this recommendation in PLHIV admitted to ICU is unknown
**Objectives:** The aim of this study is to know the changes in the characteristics and outcomes of PLHIV admitted to the Intensive Care Unit (ICU) before and after this recommendation
**Methods:** Retrospective study of consecutive PLHIV admitted to the ICU of a University Hospital in Barcelona between 2006 and 2019, comparing the characteristics and outcomes between 2006 and 2015 (first period) and 2016–2019 (second period).
**Results:** A total of 505 admissions were included, mostly men (75%) with a median (P25–P75) age of 47.3 years (39.7–53.9). Ninety-one percent were diagnosed with HIV before admission and 83% of them were under ART. Most of the admissions came from the emergency department (59%) and the most frequent cause of admission was an infectious condition (54%). Mortality was lower in the second period compared to the first one, both in-ICU (7% vs. 14% (OR 0.44 [0.22–0.86]; $p=0.016$) and one year after ICU discharge (albeit this difference did not reach statistical significance, 13% vs. 17%, OR 0.61 [0.35–1.06], $p=0.081$). However, after adjusting for variables in the multivariable analysis, these differences disappeared due to differences between periods (in the second period, there were more patients receiving ART before admission (OR 2.11 [1.04–4.29]; $p=0.039$), less patients who were current or former IVDU (OR 0.41 [0.23–0.71]; $p=0.001$), less admissions for surgery (OR 0,54 [0.31–0.93]; $p=0.028$), lower need for IMV (OR 0.41 [0.25–0.66]; $p<0.001$), and less complications in the ICU such as surgical wound infection (OR 0.04 [0.00–0.27]; $p=0.001$) or non-catheter-related bacteremia (OR 0.13 [0.03–0.55]; $p=0.005$). Having higher SOFA score at admission (OR 1.11 [1.01–1.22]; $p=0.034$), need for IMV (OR 10.33 [3.61–29.59]; $p<0.001$) and presenting any complication in the ICU (OR 2.19 [1.1–4.36]; $p=0.026$) were predictors of in-ICU mortality, whereas having higher number of comorbidities (OR 1.60 [1.25–2.05]; $p<0.001$), higher SOFA score at ICU admission (OR 1.10 [1.02–1.19]; $p=0.019$), ICU admission from hospital ward vs. from emergency department (OR 2.95 [1.45–6.01]; $p=0.007$) and not continuing ART at ICU discharge (OR 13.86 [5.65–34.02]; $p<0.001$) were found as predictors of one-year mortality.
**Conclusions:** In-ICU mortality of critically ill PLHIV has decreased in the recent years. This reduction is attributable to changes in patients' characteristics, including the universal use of ART at ICU discharge.

**Introduction:** Nowadays, associated with improved vital prognosis of oncological diseases, there has been an increase in the number of patients with this pathology admitted to intensive care units (ICUs). Numerous factors influence the decision of whether an oncological critical patient benefits from ICU admission, with emphasis on quality of life and disease prognosis.
**Objectives:** To describe the characteristics and differences of patients with oncological diseases who are admitted or refused admission ICU and their prognosis at 6 months.
**Methods:** Descriptive study based on a prospective registry, including patients with oncological diseases evaluated by an ICU during the period of January-October 2023. Patients were classified into admitted and refused groups. Demographic data, comorbidities, oncological disease characteristics, functional class at admission (ECOG, performance status scale; and FRAIL, Clinical frailty index), reason for admission and refusal, ECOG and mortality at 6 months were collected. Median and interquartile range were calculated and compared using the Mann–Whitney U test.
**Results:** Ninety-nine patients were included, of whom 67 were admitted to the unit (67.7%) and 32 were refused admission. There were no statistically significant differences in gender (56.7% vs 71.9% males, $p$ 0.14), age (64 vs 66 years, $p$ 0.43) or body mass index (25.1 vs 23.7 kg/m$^2$, $p$ 0.65). A higher presence of pulmonary disease was observed in the refused group (40.6% vs 12%, $p$ 0.01). Regarding prognostic scales, differences were found in ECOG (score $\leq 2$ 92.5% vs 59.4%, $p<0.01$) and FRAIL (score $\leq 5$ 94% vs 65.6%, $p<0.01$). There were no differences in the location of the primary tumor, although more patients with localized oncological pathology were admitted (32.8% vs 3.1%, $p$ 0.01) or in remission (26.9% vs 3.1%, $p$ 0.05). However, the prevalence of needing other lines of treatment (28.1% vs 6%, $p$ 0.002), immunotherapy (37.5% vs 11.9%, $p$ 0.003) and metastatic extension (53.1% vs 35.8%, $p$ 0.1) was higher in the dismissed group. In admitted patients, the most frequent reasons for admission were shock (35.8%), respiratory failure (26.9%) and altered level of consciousness (19.4%). In dismissed patients, the main reasons for dismissal were tumoral disease (65.6%) and baseline condition (59.3%). At 6 months, higher mortality was observed in the refused group (68.8% vs 25.4%, $p<0.01$), as well as worse ECOG (score $\leq 2$ 44.4% refused group vs 92.3% admitted group, $p$ 0.001) in the survival group.
**Conclusions:** Sixty-seven point seven percent (67.7%) of patients with oncological pathology evaluated were admitted to our unit. Lower scores in FRAIL and ECOG were observed in admitted patients, as well as lesser extent and better response to oncological disease treatment. At 6 months, higher mortality and functional class were observed in the refused patient group.

### Influence of perioperative low-flow vs. high-flow extracorporeal membrane oxygenation for severe COPD patients undergoing lung volume reduction surgery on clinical outcome parameters

N. Daum[1], O. Hunsicker[1], N. Langer[1], J. Saccomanno[2], R. H. Hübner[2], M. Witzenrath[2], A. Elsner[3], J. C. Rückert[3], S. J. Schaller[1]

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000843

**Introduction:** Lung volume reduction surgery (LVRS) represents an effective treatment option for patients with chronic obstructive pulmonary disease (COPD) and severe emphysema [1]. Patients with compromised lung function are at elevated risk of perioperative mortality. Venovenous extracorporeal membrane oxygenation (vv-ECMO) can potentially ensure lung-protective ventilation strategies and support the prompt postoperative recovery of spontaneous breathing. Animal studies have demonstrated the superiority of high-flow ECMO over low-flow ECMO; however, clinical data in patients are currently lacking [2].
**Objectives:** Aim of the study was to investigate the influence of perioperative low-flow versus high-flow ECMO on clinical outcome parameters in severe COPD patients undergoing LVRS.
**Methods:** This retrospective analysis included patients undergoing LVRS with elective perioperative ECMO between July 2019 and February 2023 at Charité—Universitätsmedizin Berlin. The impact of low-flow versus high-flow ECMO on clinical outcome parameters was assessed. The Chi-square test or Fisher's exact test was applied for categorical data as appropriate. The Mann–Whitney U test was utilised for ordinal data. The significance level was set at $p < 0.05$.
**Results:** Data from 29 patients were used for analysis. Eleven patients received low-flow ECMO, while 18 received high-flow ECMO. Their ages were 70 [IQR 66–72] years and 64 [IQR 59–70] years, with 64% and 61% being male, respectively. The Charlson Comorbidity Index was 4 [IQR 4–6] and 4 [3–5], and the BMI was 22.7 [IQR 17.5–24.7] kg/cm$^2$ and 22.8 [IQR 20.1–25.8] kg/cm$^2$ in the low-flow and high-flow ECMO groups, respectively.
No significant differences were observed in terms of ECMO duration, intensive care unit length or hospital length of stay, hospital mortality and discharge to home between the low- and high-flow ECMO groups, respectively (see Table 1).
**Conclusions:** High-flow compared to low-flow ECMO for LVRS in severe COPD patients did not demonstrate significant advantages in clinical outcomes.

**Table 1 (abstract 000895)** Outcomes of perioperative low-flow versus high-flow ECMO

| Outcome | All patients | Low-flow ECMO | High-flow ECMO | p-value |
|---|---|---|---|---|
| ECMO duration (hours) | 25.9 [22.4-50.1] | 25.9 [14.2-42.0] | 26.1 [23.5-49.9] | 0.8 |
| ICU LOS (days) | 14 [7-26] | 14 [8-28] | 12 [7-26] | 0.9 |
| Hospital LOS (days) | 27 [17-44] | 31 [16-37] | 22 [17-50] | 0.7 |
| Hospital mortality (n) | 2 (7%) | 1 (9%) | 1 (6%) | 1.0 |
| Discharge to home (n) | 26 (90%) | 9 (82%) | 17 (94%) | 0.7 |

Data are presented as median [interquartile range] or n (%). *ECMO* Extracorporeal membrane oxygenation; *ICU* intensive care unit; *LOS* length of stay

### Use of isavuconazole in critically ill patients with continuous renal replacement therapy

V. Losada Martínez[1], N. Cruza Leganés[2], D. Fuentes Scott[3], MA. Taberna Izquierdo[2], B. Garcia Esteban[4]
[1]Intensive care, Hospital General Universitario Nuestra Señora del Prado, Talavera de la Reina, Spain; [2]Intensive Care Unit, General Hospital Nuestra Señora del Prado, Talavera de la Reina, Spain; [3]ICU, Hospital General Universitario Nuestra Señora del Prado, Talavera de la Reina, Spain; [4]Hospital Pharmacy, Universitary General Hospital Nuestra Señora del Prado, Talavera de la Reina, Spain
**Correspondence:** V. Losada Martínez
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000894

**Introduction:** Isavuconazole (ISV) as an antifungal treatment in critically ill patients has become a widely used option given its safety profile, the lack of monitoring of its levels and the action spectrum. In critically ill patients with bad clinical course, it is common to begin empirical antifungal treatment throughout their evolution as well as requiring continuous renal replacement therapy (CRRT).
**Objectives:** To describe the evolution of patients admitted to our ICU treated with isavuconazole during continuous renal replacement therapy.
**Methods:** A retrospective descriptive observational study of patients admitted to a 12-bed multipurpose ICU (extended to 24 during the COVID period). Patients admitted from 02/24/2019 to 08/12/2023 who received ISV treatment during continuous renal replacement therapy are included. Patient demographic variables, reason for admission, reason for ISV use, duration of treatment, and mortality of patients with confirmed aspergillosis treated with ISV during continuous renal replacement therapy are analyzed.
**Results:** A total of 25 patients received ISV treatment during continuous renal replacement therapy. The dose of the drug was not modified according to the technical information sheet. The mean age was 61.44 years (95% CI 56.83–66.04). 72% were men. The most frequent medical history was: high blood pressure followed by diabetes, dyslipidemia, chronic kidney failure and obesity. The mean APACHE II score was 19.32 (95% CI 16.40–22.23). The most frequent reasons for admission were: 9 (36%) community-acquired COVID19-pneumonia, 5 (20%) abdominal sepsis, 3 (12%) polytrauma and 2 (8%) community-acquired

bacterial pneumonia. 24 patients (96%) required invasive mechanical ventilation. The types of infection for which isavuconazole is started were: 19 (76%) ventilator-associated pneumonia, 3 (12%) sepsis without focus, 2 (8%) bacteremia. The mean SOFA score at the beginning of treatment with ISV was 9.32 (95% CI 8.03–10.60). Aspergillosis was confirmed by bronchoalveolar lavage culture or galactomannan in 8 (32%) patients. The mean duration of treatment was 11.76 (95% CI 8.33–15.19) days. 13 (52%) patients received combined treatment with liposomal amphotericin B, anidulafungin and caspofungin. The mortality of patients with pulmonary aspergillosis confirmed was 64% (16 patients).

**Conclusions:** Patients treated with isavuconazole and renal replacement therapy have high morbidity and mortality scores. The main reason for admission of these patients was infectious followed by polytrauma. The reason for starting isavuconazole was mostly VAP. Suspicion of aspergillosis was confirmed in 32% of patients treated with empirical isavuconazole. More than 50% of patients received combined treatment. Mortality in these patients was 62.5%.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000898

**Introduction:** The excessive inspiratory effort causes lung and diaphragm injury, and monitoring of inspiratory effort is important in respiratory management. The gold standard for the assessment has been the measurement of esophageal pressure swings (ΔPes), which is applicable to both intubated and non-intubated patients. For patients on mechanical ventilation, non-invasive measures such as P0.1 and ΔPocc have been investigated and used as indicators of inspiratory effort. However, there are few studies investigating whether these non-invasive parameters measured during non-invasive ventilation (NIV) can be reliable indicators of inspiratory effort.

**Objectives:** The aim of this study is to investigate the accuracy of P0.1 and ΔPocc during NIV.

**Methods:** Mechanically ventilated patients for more than 24 h were enrolled in this study, and the patients without tolerance of NIV or those with contraindication of esophageal catheterization (recent upper gastrointestinal surgery, bleeding varices) were excluded. Patients underwent measurements of P0.1, Pes0.1, ΔPocc and ΔPes during spontaneous breathing trial (SBT) on pressure support ventilation (PSV) mode with PS at 5 cmH2O and PEEP at 5 cmH2O followed by extubation. P0.1, Pes0.1, ΔPocc and ΔPes were again measured using the non-invasive ventilation (NIV) device at 5 min and at 1 h after extubation. An analysis was performed to evaluate the correlations between P0.1 and Pes0.1, as well as that between ΔPocc and ΔPes at each of these time points.

**Results:** A total of 23 patients were included for the analysis. The median age was 71.0 [IQR 54.5–77.5] and a median BMI of 23.4 [IQR 21.4–25.2] with 20 male patients (87%). During the SBT, P0.1 and Pes0.1 ($p<0.01$, $r=0.78$) as well as ΔPocc and ΔPes ($p<0.01$, $r=0.89$) showed strong correlations. P0.1 and ΔPocc measured using the NIV device after extubation also showed strong correlations with Pes0.1 and ΔPess both at 5 min and 1 h (P0.1 and Pes0.1 $p<0.01$, $r=0.77$; ΔPocc and ΔPes $p<0.01$, $r=0.75$ and P0.1 and Pes0.1 $p<0.01$, $r=0.69$; ΔPocc and ΔPes $p<0.01$, r = 0.74, respectively).

**Conclusions:** Our study indicates that non-invasive measurement of inspiratory effort during NIV accurately reflects inspiratory effort.

**Introduction:** Active surveillance for colonization by multidrug-resistant Gram-negative bacteria (MDR-GNB) in patients admitted to the Intensive Care Unit (ICU) is one of the most commonly employed measures for reducing infection/colonization. The Spanish Society of Intensive and Coronary Care Medicine (SEMIYUC) recommends, among other measures, the performance of rectal and oropharyngeal swabs. However, the effectiveness of nasopharyngeal swabs for detecting MDR-GNB may be limited depending on the local and epidemiological context.
**Objectives:** The main objective was to evaluate the effectiveness of pharyngeal swab in MDR-GNB (Enterobacterales, Pseudomonas aeruginosa and carbapenem-resistant Acinetobacter) in the context of rectal swab testing.
**Methods:** This is an observational and retrospective study conducted at a tertiary-level hospital within the context of the multicentre study MURAN-UCI. Over a period of 45 days, all patients admitted to the ICU underwent pharyngeal and rectal swab culturing for the detection of MDR-GNB (cephalosporin and/or carbapenem resistant Enterobacterales, *Pseudomonas aeruginosa* and Acinetobacter spp.) upon admission, at $7 \pm 2$ days, and at $14 \pm 2$ days. Demographic variables, comorbidities, severity of illness upon ICU admission (APACHE II), risk factors for multidrug resistance, MDR-GNB-associated infections, and the need for contact isolation measures were evaluated. Samples were cultured on commercial chromogenic media (CHROMID® CARBA SMART and ESBL; BioMérieux) and MacConkey agar with meropenem (2 mg/L) for detection of carbapenem resistant *Pseudomonas aeruginosa*, carbapenemase-producing Enterobacterales (CPE) and extended spectrum beta-lactamase producing Enterobacterales (ESBL). The identification was performed by MALDI-TOF MS (Bruker Daltonics, Bremen, Germany). Antibiotic sensitivity was determined using broth microdilution and interpreted according to EUCAST criteria. Carbapenemase production was detected using NG-Test® CARBA-5 immunochromatography and confirmed by the mCIM test (EUCAST). The prevalence and incidence of rectal and/or pharyngeal colonization by MDR-GNB during hospitalization were studied.
**Results:** A total of 186 patients were included, with males being more frequent at 117 (62%), and a median age and APACHE II severity score at admission of 60.5 years and 12.5 points, respectively. Two patients had a positive pharyngeal exudate culture for MDR-GNB (1%), while 16 (8%) were positive in rectal exudate cultures. The prevalence of colonization by MDR-GNB (rectal and/or pharyngeal) at admission was 6.9% (13 patients), with an incidence of colonization of 0.6 patients and 0.64 per 100 ICU days during the first and second weeks, respectively. Of the 21 positive isolations (19 rectal and 2 pharyngeal), the most frequent isolated species was *Escherichia coli* producing ESBL (8/21; 38%).
Pharyngeal exudate cultures for detecting MDR-GNB were only positive in patients with positive rectal exudate cultures, with no positive samples in those with negative rectal exudates (12 vs 0%; $p = 0.007$).
Patients colonized by MDR-GNB (rectal and/or pharyngeal), compared to non-colonized patients, had a higher risk of MDR-GNB infection (18 vs 2%; $p = 0.01$), in all cases the species involved in colonization and infection was the same (3/3; 100%), and more frequently required contact isolation measures (75% vs 0.6%; $p < 0.001$).
Lastly, risk factors associated with a higher risk of MDR-GNB colonization included COPD (25 vs 12%; $p = 0.04$), previous antibiotic treatment for more than 7 days (50 vs 9%; $p < 0.001$), longer ICU stay (median 5.5 vs 4 days; $p = 0.04$), and receipt of invasive ventilatory (87 vs 51%; $p = 0.01$) and vasopressor support (81 vs 54%; $p = 0.03$) during ICU stay
**Conclusions:** The frequency of detecting colonization by MDR-GNB through pharyngeal exudates was low, occurring only in patients with positive rectal exudates and not aiding in the detection of MDR-GNB colonization in patients with negative rectal exudates. Patients colonized rectally and/or pharyngeally by MDR-GNB are at a higher risk of developing infections caused by these organisms; their detection allows for the implementation of contact precautions.

**Introduction:** Detecting and estimating blood volume loss are important for the diagnosis and management of life-threatening hemorrhage. During hemorrhage, percent blood volume loss (BVL%) can be estimated as approximately one-half the percent fall in stroke volume (SV). Furthermore, using wireless, wearable Doppler ultrasound technology, we have shown that a 10% fall in SV correlates with a 7-to-10 ms (ms) reduction in the corrected flow time of the common carotid artery (ccFT). We therefore hypothesized that change in ccFT (ccFTΔ) would show a similar relationship with BVL% in a blood draw paradigm.
**Objectives:** Describe the relationship between falling percent blood volume loss and corrected flow time of the carotid artery in a blood draw paradigm.

**Methods:** The Research Ethics Board of the Mayo Clinic approved this study. A convenience sample of adult patients recruited by a physiology laboratory comprise this analysis. Exclusion criteria were: blood donation within 112 days, hemoglobin < 13.0 g/dL for men and < 12.0 g/dL for women, under the age of 18 or over 50, systolic blood pressure < 90 mmHg or > 180 mmHg, diastolic blood pressure > 100 mmHg, current smokers, BMI > 38 kg/m$^2$, known or planned pregnancy.
Subjects remained in the sitting position in a blood donation chair. A wearable Doppler ultrasound system (Flosonics Medical, Sudbury, Canada) was placed on the neck over the common carotid artery; as well, other non-invasive hemodynamic monitors were placed to measure vital signs throughout.
Subjects underwent phlebotomy over 8-to-12 min (approximately 50 mL/min) via a 16 or 18-gauge intravenous catheter. The blood volume withdrawn was not to exceed 13% of whole blood volume with a maximum withdrawal of 450 mL ± 10%. The subject's whole blood volume was estimated by the equation of Nadler. Vital signs and carotid Doppler were recorded continuously. The ccFT was determined by Wodey's equation.
Change in corrected flow time (ccFTΔ), and mean arterial pressure (MAPΔ) using Nexfin were compared to BVL% using two mixed linear regression models. The regression coefficient and slope were calculated to assess the strength of the relationship and the rate of change.
**Results:** We enrolled 21 subjects, 1 subject was excluded for low hemoglobin levels; data from 20 subjects and blood donations comprising 46,123 cardiac cycles are included. Table 1 shows the baseline subject characteristics and Fig. 1 presents regression results. On average 413.5 ± 39 mL of blood were drawn representing 8.6 ± 1.6% blood volume.
**Conclusions:** There was a significant and strong linear relationship between BVL% and ccFTΔ during blood draw, and the rate of change was similar to that of previous studies. Conversely, BVL% and MAPΔ showed a much lower rate of change and a weaker relationship. When blood loss is the sole mechanism for falling stroke volume, we estimate that for every 1 ms reduction in ccFT, there is an approximate 0.4 percent blood volume loss. Further validation in patients with hemorrhage is planned.

| Table 1: Subject characteristics (n = 20) | |
|---|---|
| Absolute value ± standard deviation | |
| Age (yr) | 31.9 ± 6.1 |
| Sex (female) | 9 |
| Weight (kg) | 80.8 ± 17.0 |
| Height (cm) | 173.9 ± 9.4 |
| BMI (kg/m²) | 26.6 ± 4.3 |
| Estimated blood volume (L) | 4.9 ± 0.9 |
| Systolic blood pressure (mmHg) | 122.4 ± 10.0 |
| Diastolic blood pressure | 78.1 ± 7.9 |
| Mean arterial pressure | 95.4± 5.3 |
| Oxygen saturation (%) | 97.4 ± 1.2 |
| Heart rate (bpm) | 80.8 ± 11.5 |
| Corrected flow time (ms) | 319.7 ± 8.4 |

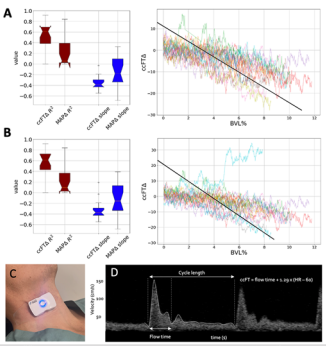

**Table 1 (left) and Fig. 1 (right) (abstract 000900)** A. Mixed linear regression modelling is summarized for the relationship between ccFT change vs BVL% (median $R^2 = 61\%$, slope = − 0.39, $p$-value < 0.05) and MAP vs BVL% (median $R^2 = 6\%$, slope = − 0.18, $p$-value < 0.05), left panel. Regression of ccFT change vs BVL% is plotted. Colors represent individual subjects, right panel. B. Results including outlier subject with large increases of ccFT change in response to BVL. C. The wireless, wearable Doppler D. the calculation of ccFT by Wodey's equation

**Introduction:** Congenital heart diseases are rare pathologies but highly complex in their management in the ICU. The majority enter our service in the postoperative period of cardiac surgery, so we must know their prognosis and evolution, as well as the need for mechanical assistance as support during the postoperative period.
**Objectives:** Describe the clinical course and characteristics of adult patients with congenital heart disease in need of mechanical circulatory support admitted to the intensive care unit (ICU).
**Methods:** Retrospective observational study in an ICU of a tertiary hospital from 2011 to 2023. Patients with congenital heart disease with ventricular assistance for any reason are included. Demographic variables, history, reason for assistance implantation, device configuration, length of stay in ICU and days on mechanical support, complications and evolution are collected. Statistical analysis of qualitative variables through frequencies and quantitative variables with median and interquartile range.
**Results:** We analyzed 16 (8.7%) patients with a history of congenital heart disease out of a total of 191 patients in need of ventricular assistance device (VAD). Among the 16 patients with congenital disease, the majority were women (62.5%) with a median age of 30 years (24.5–52.7). The majority were admitted to the ICU in the immediate postoperative of cardiac surgery. The postcardiotomy syndrome (31.2%) and primary graft failure in the immediate post-transplant (25%) were the most frequent mechanical circulatory support causes.
The most frequently implemented type of assistance is VA ECMO (venoarterial extracorporeal membrane oxygenation) (87.5%). In our cohort, 3 patients (18.7%) required heart transplantation during their stay at ICU. Variables for study are collected in Table 1.
In the statistical analysis we compared the subgroup of patients with congenital disease requiring VAD versus the total VAD population admitted to the ICU. In this study, we observed significant differences when we compared by sex (p0.01) and reason of assistance implant in both groups (p 0.003). Rest of the comparisons are in Table 2.

**Conclusions:** Patients with a history of congenital heart disease represent a rare group of patients in our units and are highly complex, requiring support with more than one mechanical assistance more frequently in the immediate postoperative period of cardiac surgery

### Edema score in ischemic cerebrovascular disease as an early predictor of intracranial hypertension in patient admitted to the Mexican National Institute of Neurology and Neurosurgery "Manuel Velasco Suárez"

J. Olvera[1], P. Virginia[1], J. A. Zepeda-Pérez[1], A. Lepe[2]
[1]Adult intensive care unit, National Institute of Neurology and Neurosurgery, Ciudad de México, Mexico; [2]Terapia intensiva, Naval Medical Center, Ciudad de México, Mexico
**Correspondence:** J. Olvera
*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000905

**Introduction:** The Enhanced Detection of Edema in Malignant Anterior Circulation Stroke (EDEMA) score was developed in the USA to predict potentially fatal malignant edema in patients with moderate to severe large hemispheric stroke. This simple score incorporated three clinical variables (glucose, stroke history, and reperfusion therapy) and two radiological variables (midline shift and cisternal effacement) that are readily available within 24 h of stroke onset. The EDEMA score for each patient was calculated by assigning points corresponding to the five predictors: basal cistern effacement (=3); midline shift > 0 to 3 (=1), 3 to 6 (=2) and 6 to 9 (=4), > 9 (=7); glucose ≥ 150 mg/dL (=2); no previous stroke (=1); and no acute intervention (no thrombolysis or thrombectomy) (=1). Therefore, the EDEMA score could range between 0 and 14.According to the American Society of Neuroimaging, a total of 169 CT investigations in 60 patients were analyzed: edema formation was classified as 0: no edema, 1: focal edema limited to 1 lobe, 2: unilateral edema > 1 lobe, 3: bilateral edema, 4: global edema with disappearance of sulcus relief, and 5: global edema with basal cisterns. Erasure. The mean ICP values were 12.0, 14.0, 14.9, 18.2, and 25.9 mm Hg in grades 1 to 5, respectively.
**Objectives:** General objective: To demonstrate the usefulness of the cerebral edema score as an early predictor of intracranial hypertension in patients with ischemic cerebrovascular disease
**Methods:** Study design: Observational, descriptive, prospective, cross-sectional study.
Study population: Patients admitted to the Neurological Intensive Care area from June to November with ischemic cerebrovascular disease. Sample size: A study was carried out with a total of 18 electronic records that have the necessary information. Sampling type: Sequential non-probabilistic.
**Results:** The value obtained from IP by transcranial Doppler performed at this institute was taken into consideration and from the following validated formula of $10.927 \times \text{IP} - 1.284$ the ICP was calculated, subsequently a relationship of the Edema score with the ICP was made, which could indicate that values from 1 to 6, 7.8 to 10 and more than 11 are related to a pic of 10, 20, 22, 24, respectively. On average, the patients spent between 3 and 14 days in the hospital and of the total sample, 5 patients died. With the data obtained, the statistical analysis was carried out in GraphPad Prism 9.5 software because they were unpaired qualitative variables, with a non-normal distribution according to the Shapiro–Wilk test and because the analysis was carried out between 2 groups, the statistical test was carried out. Mann–Whitney U to obtain $p$ value < 0.0001 considering the proposed score as statistically significant.
**Conclusions:** In the present investigation, the records of 18 patients who were admitted to the Intensive Care service, secondary to ischemic stroke, were analyzed, who already had a simple skull CT scan, which was analyzed individually in order to obtain the Edema score and determine an estimate of intracranial pressure through a proposed scale, the statistical analysis showed said scale is statistically significant. Therefore, this scale could be useful to predict intracranial hypertension and thus make medical decisions that will have a significant impact on the evolution and outcome of patients admitted to intensive care for low-income patients

**Introduction:** Sepsis is a potentially fatal organ dysfunction caused by a dysregulated host response to infection (1). Early diagnosis of sepsis and correct and timely antimicrobial treatment is associated with better clinical outcomes (2) (3); there are multiple scores that estimate the probability of presenting sepsis (4) (5) (6), Mortality remains high despite the fact that knowledge about the pathophysiology and treatment of sepsis has changed considerably in the last decade since it has been identified that early diagnosis and having care packages implemented in emergency departments improves short and long term outcomes (3), a possible solution is the construction of scales or identification of signs and symptoms that suggest early diagnosis of sepsis and that can be performed at primary care or even pre-hospital levels. It is important to have specific data to identify patients with sepsis at the local level. Objective: To identify the earliest signs and symptoms in a patient with sepsis that may be associated with the need for ICU admission or hospital mortality.

**Objectives:** To identify the earliest signs and symptoms that a patient with sepsis presents and that may be associated with the need for ICU admission or hospital mortality.

**Methods:** Prospective cohort study, using data from the clinical history of patients hospitalized in a tertiary level for suspected infection and a form filled out by the researchers when the patient was hospitalized and before 24 h of admission to the emergency department, included patients over 18 years of age, with suspected infection, during the period between 2021 and 2022. Patients with immunodeficiency, pregnancy, infections with prolonged treatment such as tuberculosis or deep mycosis, oral or parenteral antibiotic treatment for at least 3 days in the last 15 days, and terminal diseases such as metastatic cancer, neurodegenerative diseases in late stages or severe sequelae of cranioencephalic or spinal cord trauma were excluded.
The main outcome was mortality and the need for ICU, other variables were age, sex and race, Charlson index variables, SOFA and drugs affecting exposure variables. Vital signs, altered mental status, capillary refill and malaise, headache, nausea, chills, subjective fever, productive cough, dyspnea, dysuria, myalgia and arthralgias were recorded. Patients were recruited for 12 months, exposure variables were analyzed independently with respect to death or admission to ICU and then univariable logistic regression models were performed to estimate potential risk, then a multivariable logistic regression model was fitted to estimate the independent effect on mortality or admission to ICU.

**Results:** Of 1135 patients with suspected infection, 540 patients who did not meet the inclusion criteria were excluded, leaving 595 patients as shown in Fig. 1. 53.8% were men, the most prevalent comorbidities were diabetes (13.8%), chronic acquired pulmonary disease (16.5%) and congestive heart failure (11.4%). Antibiotics were administered on admission in 60.9% of patients. The most frequent foci were urinary (20.8%), respiratory (21.0%) and gastrointestinal (29.8%). Admission to the ICU was 11.4% and overall mortality was 8.2%. The most frequent symptoms were general malaise (87.7%), nausea (42.2%), subjective fever (29.7%), headache (28%) and dyspnea (25.8%). No differences were found between patients' signs. Among 85 (14.3%) patients who died in ICU due to sepsis, a crude association with mortality was found for: dyspnea OR: 2.29; (1.28–4.10), altered mental status OR: 3.50 (95% CI 1.64–7.48) and heart rate OR: 1.02 (1.00–1.03), but after adjustment for confounding variables age, SOFA score and Charlson index no statistically significant difference was found for any variable as shown in Table 1.

**Conclusions:** Sepsis is a complex syndrome with a high burden of morbidity and mortality in our population and worldwide. In-hospital mortality rates remain high. Male sex and age are variables associated with increased incidence of sepsis. No association with ICU admission or mortality was found for any of the signs and symptoms studied when adjusting for confounding variables, which seems to make early suspicion of sepsis in its initial stages difficult based on questioning and physical examination.

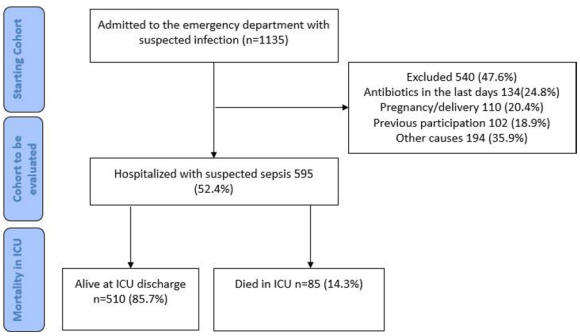

**Fig. 1 (abstract 000906)** Patient flowchart

**Table 1 (abstract 000906)** Multivariate logistic regression model for mortality or admission to the ICU

| Variable | No adjustment OR (IC95%) | With adjustment OR (IC95%) |
|---|---|---|
| Symptoms | | |
| General malaise | 0,99 (0,48 - 1,98) | 0,82 (0,36 - 1,85) |
| Headache | 0,61 (0,34 - 1,12) | 0,61 (0,30 - 1,21) |
| Nausea | 0,89 (0,52 - 1,53) | 0,89 (0,47 - 1,67) |
| Chills | 0,90 (0,43 - 1,89) | 0,50 (0,19 - 1,29) |
| Subjective fever | 0,66 (0,33 - 1,33) | 0,77 (0,33 - 1,78) |
| Productive cough | 1,23 (0,66 - 2,47) | 1,56 (0,72 - 3,33) |
| Myalgia/arthralgia | 0,56 (0,24 - 1,29) | 0,50 (0,18 - 1,35) |
| Dyspnea | 2,29 (1,28 - 4,10) | 1,24 (0,61 - 2,50) |
| Dysuria | 0,65 (0,28 - 1,49) | 0,37 (0,13 - 1,06) |
| Altered mental status | 3,50 (1,64 - 7,48) | 1,46 (0,57 - 3,71) |
| Signs | | |
| Temperature | 0,73 (0,47 - 1,13) | 0,75 (0,47 - 1,22) |
| Systolic blood pressure | 0,99 (0,98 - 1,01) | 0,99 (0,97 - 1,01) |
| Diastolic blood pressure | 0,98 (0,95 - 1,00) | 0,99 (0,96 - 1,02) |
| Heart rate | 1,02 (1,00 - 1,03) | 1,01 (0,99 - 1,03) |
| Respiratory rate | 1,02 (0,98 - 1,06) | 1,02 (0,97 - 1,06) |
| Glasgow Coma Scale | 0,48 (0,35 - 0,64) | 0,64 (0,47 - 0,86) |
| CAM – ICU | 0,82 (0,28 - 2,41) | 0,67 (0,21 - 2,15) |
| Capillary refill | 1,61 (0,96 - 2,69) | 1,57 (0,89 - 2,76) |

**Introduction:** Routine arterial blood gas sampling in ICU patients may result in iatrogenic anemia and consequent complications. There is no scientific consensus regarding the optimal sampling time after FiO2 interventions in mechanically ventilated patients. This knowledge gap results additionally to increased time wasting and costs.
**Objectives:** To address the lack of publications regarding the optimal sampling time of arterial blood gas after FiO2 interventions by estimating the time to stabilization of the PaO2/FiO2 ratio in mechanically ventilated ICU patients after receiving FiO2 interventions. Additionally, the potential heterogeneity in times for a few patient characteristics was examined.
**Methods:** The Kaplan–Meier method, was used initially to estimate an initial time, to event after sampling 50 ventilated ICU patients for six consecutive 5-min intervals. Time of stabilization was defined as the time after which the patient had two consecutive measurements within a 15% margin.
**Results:** Preliminary results suggested that 90% of the patient had a stable ratio at the 15 min measurement while 70% of the patients were stable at the first measurement (5 min). Time to stabilization was moderated by vasoconstrictor drug use but not respiratory failure status. Figure 1 presents the preliminary results for the full sample. All patients who were not using vasoconstrictor drugs were stable from the first measurement (5 min), as shown in Fig. 2. The two curves are significantly different ($p=0.01$) according to both the log-rank and Peto & Peto (1972) test.
**Conclusions:** Most patients were stable 15 min after intervention. A larger sample and more frequent measurements will help identify the true times and potential heterogeneity, as well as whether the amount and the type of vasoconstrictor drugs plays a significant role in the stabilization time.

**Introduction:** Critically ill patients needing extracorporeal membrane oxygenation (ECMO) support are at high risk of developing nosocomial infections, including those events associated with the extracorporeal system. There is no gold standard definition for infections related with the ECMO cannula. Furthermore, there is a lack or solid data about the factors related with cannula colonization/infection.
**Objectives:** The primary objective of the study was to identify the factors associated with a positive culture of the ECMO cannula.
**Methods:** Retrospective analysis of prospectively collected data including the information of all the adult patients who received veno-venous (V-V) or venoarterial (V-A) ECMO support for a minimum of 24 h, at the Vall d'Hebron University Hospital (Barcelona, Spain) during August 2021 to December 2022. By protocol patients received prophylaxis with daptomycin or vancomycin except specific contraindication. After decannulation the ECMO cannulae were aseptically retrieved, and the tip was sent to microbiological laboratory for culture using the Maki technique. We recorded clinical parameters of the patients and registered all the positive blood cultures 7 days prior and 7 days after decannulation. We compared the cohort of patients with positive cultures against the rest of the population. We finally retrieved the information of the microorganism identified in cultures. The analysis utilized Chi-square or Fisher's exact test for categorical variables and ANOVA for comparing means, while the Kruskal–Wallis test was employed for comparing medians in continuous variables.
**Results:** A total of 121 patients (mean age 51.8; 26.5% female; 65.3% V-V) were supported with ECMO. 198 cannulae were cultured [44 (18.2%) missing]. A positive result was identified in 33 (27.3%) patients (13.2% one positive cannula, 14.1% both), being *Staphylococcus epidermidis* the pathogen most frequently identified (34.4%), followed by *Candida parapsilosis* (20.3%). In comparison with the cohort with negative cultures, the duration of ECMO support was longer in patients with one cannula with a positive culture and even longer in those with two cannulae with positive cultures (11.5 vs 24.5 vs 49 median days, respectively, $P < 0.001$). Patients with positive cultures were more frequently cannulated at other center and transported to our ICU than patients with no positive cultures (38% vs 20.8%, P 0.08). Among the patients with positive cannula cultures, only in 4 (12.1%, 3% of the total) a positive blood culture for the same microorganism was identified; 2 for Staphylococcus epidermidis and 2 for Candida parapsilosis. In the 10 patients not receiving prophylaxis, the incidence of a positive cannula culture was the same than patients receiving daptomycin.
**Conclusions:** A long ECMO run and cannulation in other center are factors associated with increased risk of cannula colonization. Further studies are needed to study the clinical impact of these microbiological findings.

**Introduction:** Considerable effort has been put into improving care for patients with AMI in the ICU, with health equity as a key goal. Simultaneously, standards of care have changed to match the prevailing public health culture. This study examines how disparities in treatment of AMI in the ICU have morphed between 2001 and 2019 to showcase improvements and highlight gaps.
**Objectives:** Examine whether there are changes in prescribing patterns for analgesia and AMI-related drugs, patient outcomes; in-hospital mortality (IHM) and discharge location (DL), and disparities in treatment by sex and race.

**Methods:** This is a retrospective study of patients with AMI hospitalized in an urban academic tertiary care hospital in MA, USA, extracted from MIMIC-III [1] (2001–2012) and MIMIC-IV [2] (2008–2019) datasets. Based on the standard of care for MI, orders for ACE inhibitors, beta-blockers, statins and antiplatelets are extracted for each patient. Additionally, orders for analgesics are extracted and examined as five categories; any analgesia, any opioids, opioids-only, non-opioids-only, and multimodal. To limit the effect of confounders on the differences in treatment, only patients with a primary diagnosis of AMI with no recorded comorbidities are included. To eliminate overlap, only patients admitted in 2014–2019 are selected from MIMIC-IV. Barnard exact and Chi-square tests are used to obtain statistically significant differences ($p$-values $\leq 0.05$) in drug orders and outcomes. Outcomes are dichotomized; survival (favorable) vs mortality for IHM, and home (favorable) vs elsewhere for DL. Henceforth, MIMIC-III and MIMIC-IV are referenced as M3 and M4, respectively.

**Results:** There were 2521 and 2057 patients from M3 and M4, respectively, who met the inclusion criteria. Patients in M3 had longer LOS, higher incidence of shock and lower rate of favorable discharge, including higher IHM, but fewer of them had a STEMI diagnosis; Fig. 1. The prescribing patterns for analgesics changed with fewer opioid prescriptions and a substantial increase in non-opioid-only therapies, Fig. 2. Moreover, there was a significant decrease in ACE inhibitor orders, while orders for beta-blockers and statins significantly increased, Fig. 3. Regarding sex differences, more men received ACE-inhibitors, aspirin, beta-blockers and statins in M3, while in M4 more of them received analgesia, ACE-inhibitors, antiplatelets and statins. Racially, more Hispanic Americans received opioids in M4 while in M3 more White Americans received all treatments.

**Conclusions:** Temporally, this data suggests that following the opioid crisis, caregivers have restrained from ordering opioids; however, further work is required to determine whether opiates were overprescribed in the past or pain is currently undertreated, especially across racial groups where disparities in opioid orders still exist. Concerningly, disparities by sex are still extensive, more effort is required to eliminate them. Despite more patients in M4 having severe MI, they had better outcomes compared to M3, suggesting the treatment of MI has greatly improved.

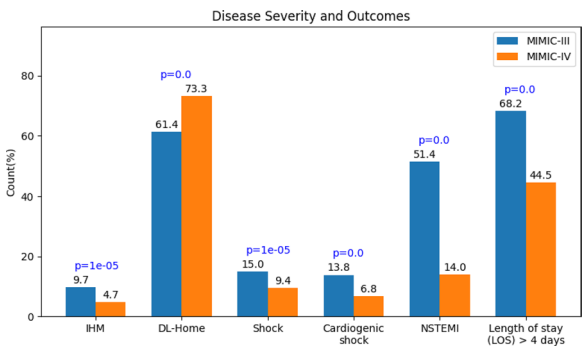

**Fig. 1 (abstract 000910)** Disease severity markers—the percentage (value above each bar in black) of patients in the study cohort who; died in hospital (IHM), were discharged to home (DL-Home), experienced shock (Shock), and separately, cardiogenic shock (Cardiogenic shock), had a NSTEMI diagnosis (NSTEMI), and were hospitalized longer than 4 days (LOS > 4 days). The p-values (rounded to 5 decimal places) are indicated above each M3/M4 pair of bars in blue)

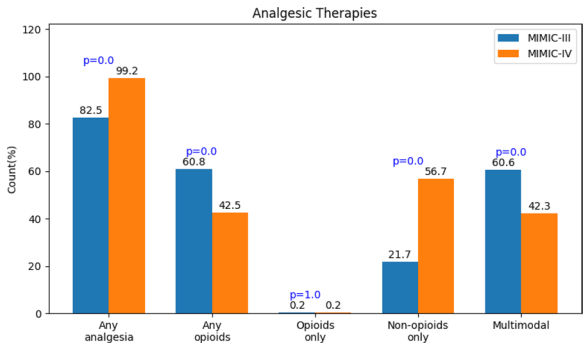

**Fig. 2 (abstract 000910)** Analgesic prescribing patterns—the percentage (value above each bar in black) of patients in the study cohort for whom an order was placed for each of the analgesic therapies. The $p$-values (rounded to 5 decimal places) are indicated above each M3/M4 pair of bars in blue)

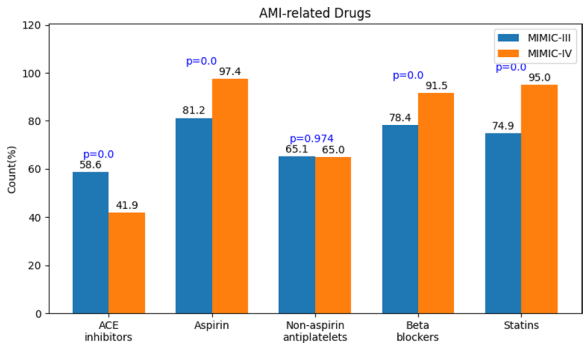

**Fig. 3 (abstract 000910)** AMI-related drugs prescribing patterns—the percentage (value above each bar in black) of patients in the study cohort for whom an order was placed for each of the AMI-related drugs. ### Veno-arterial extracorporeal membrane oxygenation in infarct-related cardiogenic shock: a Bayesian hierarchical model of randomized controlled trials

N. Schreiber[1], M. Eichlseder[2], E. Lukic[1], S. Orlob[1], C. Klivinyi[1], A. Pichler[2], M. Eichinger[2], S. Labenbacher[2], D. Freidorfer[2], L. Heuschneider[2], S. Fida[1]

*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000911

**Introduction:** Approximately 10% of hospitalized individuals with acute myocardial infarction (AMI) develop cardiogenic shock (CS), with mortality rates exceeding 40% (1). While the early use of mechanical circulatory support (MCS), including veno-arterial extracorporeal membrane oxygenation (VA-ECMO), may hold potential benefits (2), current guidelines only provide Class IIb recommendation based on a level C of evidence, indicating a high level of uncertainty concerning MCS in patients with AMI related CS (3).
In this context, accurately quantifying uncertainty regarding the use of VA-ECMO in infarct-related CS is crucial to facilitate well-informed treatment decisions.
**Objectives:** The objective of this study was to utilize a Bayesian framework to estimate the probability of benefit associated with VA-ECMO in patients with AMI-related CS by analyzing pooled data from existing randomized controlled trials (RCTs) that compare VA-ECMO to optimal medical therapy
**Methods:** All so far published RCTs comparing VA-ECMO to optimal medical therapy in patients with infarct-related CS were included for analysis (4–7). The primary outcome was 30-day all-cause death on a Risk-ratio scale.
To synthesize results from RCTs and account for between-study heterogeneity, we employed a Bayesian hierarchical model, using the 'bmrs' package in R version 4.3.3. Within a Bayesian framework, prior beliefs are integrated and updated based on emerging evidence (8).
Markov Chain Monte Carlo methods with 4 chains and 4000 iterations were employed for model parameter estimation.
We incorporated weakly informative neutral priors to reflect uncertainty about the effect of VA-ECMO on mortality in infarct-related CS patients. We used a normal distribution N(0,1) for the pooled effect size (μ) and a Half-Cauchy distribution HC(0,0.5) for between-study heterogeneity (τ2), ensuring that τ2 remained non-negative.
Results are depicted as posterior distributions, summarized by using the median of the posterior values for point estimates along with percentile-based 95% credibility intervals (CrI). Additionally, we calculated the posterior probabilities of benefit, presented as density plot.
**Results:** Four randomized controlled trials comprising a total of 565 patients were included in the pooled analysis (9). Utilizing the weakly informative neutral prior, our Bayesian hierarchical model determined that there was a 59.3% probability of VA-ECMO reducing 30-day mortality (RR 0.96, 95% CrI 0.65–1.38) (Fig. 1).
**Conclusions:** Prior frequentist meta-analyses concluded that VA-ECMO does not improve survival in patients with CS (9). In contrast, our analysis—by pooling data from all currently available RCTs and applying a neutral prior, wherein equal probability is assigned to harm and benefit—revealed a potential advantage of VA-ECMO regarding 30-day mortality among patients experiencing CS from AMI. The evidence concerning the efficacy of VA-ECMO should therefore be considered as indeterminate instead of negative (10).

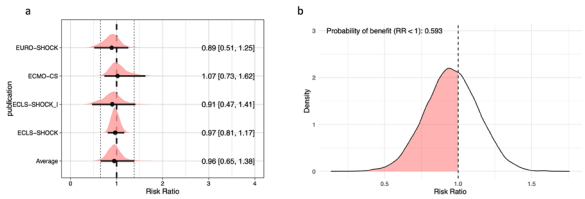

**Fig. 1 (abstract 000911)** a. Forest plot of the median estimated posterior Risk Ratios (black dots) with corresponding posterior distributions in red and 95% CrIs (black horizontal lines). The RR of 1 is depicted with a dashed vertical black line. The margins of the 95% CrI of the pooled average effect are depicted as fine dashed vertical lines. b. Posterior probability distribution of the median estimated pooled RR. The RR of 1 is depicted as dashed vertical black line. The probability of benefit (RR < 1) is depicted as red shaded area

*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000912

**Introduction:** In 1989 when considering whether to admit oncohematological patients to intensive care units (ICU) Dr Graziano Carlo Carlon wrote "Just say no" in an editorial published on Critical Care Medicine (1). Thirteen years later Groeger answered, on the same journal, "Consider saying yes" (2). It was 2003.
In 2013 Elie Azoulay suggested to "Think differently" (3) and that's what we have been trying to do in the last ten years.
The aim of this paper is to describe our population of critically ill patients with hematological diseases and their outcomes.

**Methods:** From 2012 to 2024, we prospectively collected clinical data upon admission and during ICU stay. Patients < 18 years were excluded. Clinical data included baseline characteristics, hematological disease, status, treatment (HSCT, CART), prognostic scores, reason for ICU admission. We also collected laboratory results, organ failures: need for mechanical ventilation (MV), vasoactive support, renal replacement therapy (RRT), documented infection. Outcomes included ICU, hospital, six and twelve months mortality.
**Results:** Results: Results are shown in Tables 1 and 2.
**Conclusions:** Oncohematological patients are still challenging for ICU physicians, patients often immunocompromised and thus exposed to different risks. Side effects of chemo or immunotherapies can be difficult to recognize and to treat. Cooperation with hematologist is essential. ICU physicians have to know outcomes and prognostic factors to provide these patients the best treatment, being aware that both withholding intensive care when justified, or to grant it when futile, is inappropriate (4).

**Table 1 (abstract 000912)** Admission and ICU course

### Ventriculitis in patients with external ventricular drainage in a neurointensive care unit

P. Carrera-Vazquez[1]; J. Cabrera-Arrocha[1]; P. Saavedra-Santana[2]; S. Ruiz-Santana[1]
[1]Intensive Care Medicine, University Hospital of Gran Canaria Dr. Negrín, Las Palmas de Gran Canaria, Spain; [2]Mathematics and informatics department, University of Las Palmas:, Las Palmas de Gran Canaria, Spain
**Correspondence:** J. Cabrera-Arrocha
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000900

**Introduction:** Healthcare associated ventriculitis and meningitis in patients with external ventricular drainage (EVD) is diagnosed in a variable percentage of up to 20%. Different risk factors and increased mortality and loss of neurological outcome have been identified.
**Objectives:** To identify the incidence of ventriculitis in patients with EVD in our Unit and the associated risk factors.
**Methods:** Longitudinal, retrospective study in a neurocritical ICU for adult patients performed from January 2020 to January 2023. Demographic data, Apache II score, diagnosis on admission [stroke, subarachnoid hemorrhage (SAH), traumatic brain injury (TBI), polytrauma]. Glasgow Coma Score (GCS) on admission and at discharge from ICU and hospital, Fisher scale grade, presence of intraparenchymal hematoma, intracranial surgery, site of EVD settings (ICU or operating room), days of external ventricular drainage until infection and total days of EVD, number of EVD, microorganism isolated in cerebrospinal fluid, systemic and intraventricular antibiotic used, length of stay in ICU and hospital, and hospital mortality were collected. Categorical variables are expressed as frequencies and percentages and continuous variables as mean and standard deviation (SD) when the data followed a normal distribution, or as median and interquartile range (IQR = 25th–75th percentile) when the distribution deviated from normality. Percentages were compared, as appropriate, by the Chi-square test or Fisher's exact test, means by the t-test and medians by the Wilcoxon test for independent data. Statistical significance was set at $p < 0.05$. Data were analyzed with the R package, version 4.2.1 (R Development Core Team, 2022).
**Results:** A total of 16 of the 110 patients with EVD suffered ventriculitis (14%) and 94 did not. The median (IQR) Apache II score scale was 18 (11.2; 24), the median (IQR) GCS was 8 (5; 11.8) at hospital admission and at hospital discharge 14 (13-15), and overall mortality was 35.5%, with no statistically significant differences between the two groups. In the univariate analysis we found statistically significant differences between the number of days with catheter in the group without ventriculitis 11.5 (5;19) and the number of days with catheter until the event 22 (11;30.5). Furthermore, in the 35 patients with TBI, we found statistically significant differences between the 34 who did not have ventriculitis compared with the only one who had ventriculitis.
The multivariate logistic analysis is shown in Table 1.

**Table 1 (abstract 000914)** Multivariate logistic regression for ventriculitis

| | ***P*-value** | **Odds-ratio (95% CI)** |
|---|---|---|
| TBI | 0.008 | 0.096 (0.010 to 0.945) |
| Catheter days *****, per day | 0.021 | 1.043 (1.007 to 1.079) |

(*) For patients who developed ventriculitis, the time until the event

**Conclusions:** EVD days, per day, to diagnosis of ventriculitis is a significant independent risk factor in our Unit. TBI and EVD was also a significantly lower independent risk of ventriculitis.

**Topic:** Neurointensive care

### Neuroprotective effect of argon inhalation on a model of photoinduced ischemic stroke

A. Kuzovlev[1], E. Boeva[1], O. Grebenchikov[1], R. Cherpakov[1], V. Antonova[1]
[1] V.A. Negovsky research institute of general reanimatology, Federal research and clinical center of intensive care medicine and rehabilitology, Moscow, Russia
**Correspondence:** A. Kuzovlev
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000915

**Introduction:** According to a number of experimental studies, both in vivo and ex vivo, argon is able to demonstrate certain neuroprotective effects in brain damage. In the case of an ischemic type of cerebral infarction, such an inert gas as xenon has performed well, but the effects of argon remain the subject of lively discussions.
**Objectives:** To determine the effect of three-time two-hour inhalation of an argon–oxygen mixture (Ar 70%/O2 30%) in comparison with an oxygen–nitrogen mixture (N2 70%/O2 30%) after a photochemically induced stroke on the severity of brain damage.
**Methods:** The experiments were carried out on male Wistar rats weighing 250-350 g ($n=35$). Vascular thrombosis was simulated in the prefrontal cortex of the rat brain using the following technique: after the introduction of a photosensitive dye, the head was fixed in a stereotactic frame, the skull was exposed and cleared of the periosteum. The hemispheres of the brain were irradiated with cold light at $\lambda=560$ nm for 15 min. After inducing a stroke, the animals were placed in a chamber with a constant supply of a gas mixture (N2 70%/O2 30%—group I, Ar 70%/O2 30%—group II) with a flow of 3 l/min. The exposure time in the camera was 2 h. The effectiveness was assessed by testing animals to determine neurological deficits (on the 3rd, 7th and 14th days after stroke) and performing an MRI scan of the brain on the 14th day.
**Results:** When performing an MRI scan of the brain on day 14 after modeling cerebral ischemia, there was a decrease in the average lesion volume in the argon application group, amounting to $0.8\pm0.2$ mm$^3$ versus $1.5\pm0.3$ mm3 in the control group ($p=0{,}01$). When evaluating the images, there was a decrease in the lesion when using argon, including in the motor neuronal region of the brain, compared with the control group. These changes corresponded to a decrease in the severity of neurological disorders and were a favorable predictor. Neurological deficits in the group of control animals on day 3 amounted to $7.1\pm1.5$ points versus $9.9\pm1.2$ in the group with argon ($p=0{,}049$). On day 7 in the control group, this indicator was $7.9\pm1.2$ points versus $9.8\pm1.1$ in the argon group ($p=0{,}029$). By the 14th day, the indicators of neurological deficit regressed in both groups, however, in the case of control, the values still corresponded to residual neurological disorders and amounted to $4.9\pm1.2$ points versus $7.3\pm1.2$ points in the argon group ($p=0{,}046$).
**Conclusions:** When modeling photochemically induced vascular thrombosis with the development of a focus of ischemic stroke of the brain, inhalation of oxygen–argon sweep daily once for 2 h for 3 days led to a significant decrease in both neurological deficit on days 4, 7 and 14, and the volume of ischemic stroke.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000916

**Introduction:** In the multicenter randomized trial CONFIDENT (1), administration of plasma collected from convalescent donors with neutralizing antibody titer of at least 1/320 to patients with COVID-19 ARDS requiring mechanical ventilation (MV) significantly reduced mortality. Secondary outcomes included functional status and quality of life (QOL) in survivors by day 90 (D90) and 365 (Y1).
**Objectives:** The aim of this post hoc analysis is to describe the functional evolution of these survivors during the year following intensive care unit (ICU) discharge and to search for predicting factors of functional outcomes.
**Methods:** Pre-admission (T0) functional status has been described by relatives, using the Clinical Frailty Scale (CFS), the Katz index of Independence in activities of daily living (score from 0 to 6, highest score reflecting independency) and the EuroQol 5-Dimension 5-Level (EQ5D) including an index value (ranging from − 0.6 to 1, where 1 is the best possible health state) and a visual analogic scale (VAS). Patients estimated their status using the same tools at D90 and Y1 after inclusion. The analyzed predictive factors included functional scores at T0, comorbidities, employment status and inflammation status during the first week after inclusion in the study. Results are expressed as median (IQR) or n (%).
**Results:** A total of 225 patients (151 (67.1%) men, aged 61(51–68) years) survived an ICU stay of 25 (14–43) days including 16 (10–27.5) days of mechanical ventilation. At T0, 69/225 (43.9%) patients had a professional activity. Evolution of the different parameters are described in the table below:

| Parameters | T0 | D90 | *p* value D90 vs T0 | Y1 | *p* value Y1 vs T0 |
|---|---|---|---|---|---|
| CFS | 3 (2–3) | – | – | – | – |
| Katz | 6 (6–6) | 6 (4–6) | < 0.001 | 6 (6–6) | 0.002 |

| Parameters | T0 | D90 | *p* value D90 vs T0 | Y1 | *p* value Y1 vs T0 |
|---|---|---|---|---|---|
| EQ5D | 0.9 (0.8–1) | 0.78 (0.5–0.9) | < 0.001 | 0.83 (0.68–0.93) | < 0.001 |
| VAS | 80 (70–90) | 70 (60–80) | 0.01 | 70 (60–85) | 0.012 |

At Y1, 19/119 (16%) did not recover in term of autonomy according to Katz index. Perceived quality of life at Y1 was inferior to that estimated by relatives at T0 in 45/80 (56.2%) patients according to EQ5D and in 45/72 (62.5%) patients according to VAS.
In multivariate analysis, CFS was associated with Katz index at D90 ($p < 0.001$) and EQ5D at Y1 ($p = 0.009$). ICU length of stay was associated with Katz index at D90 ($p < 0.001$), EQ5D at D90 ($p = 0.004$) and VAS at D90 ($p = 0.038$). C-reactive protein measured 7 days after inclusion was associated VAS at both D90 and Y1 ($p = 0.031$ and $p = 0.003$, respectively). Employment status, diabetes, or prior ongoing treatment with steroids were not associated with the studied functional outcomes.
**Conclusions:** In this homogenous cohort of COVID-19 ARDS survivors, autonomy and perceived QOL remained altered one year after inclusion. CFS, duration of ICU stay and inflammation parameters were associated with some autonomy and QOL related outcomes.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000917

**Introduction:** Use of HAS is contentious, with uncertain efficacy and cost-effectiveness. There are unclear mortality benefits, as shown by the SAFE and ALBIOS trials1, 2, albeit with a trend for improved hemodynamic stability2. HAS is recommended in surviving sepsis guidelines after use of large volumes of crystalloid3, but costs > 8 times more than 0.9% NaCl, posing a significant cost burden4. Evidence supports use of HAS in cirrhotic patients with ascites and in the management of hepatorenal syndrome5.
**Objectives:** Our study aims to provide an evaluation of HAS use patterns in four distinct intensive care units (ICUs) in southern England. By examining patient characteristics and the quantity of HAS administration, we seek to elucidate potential inter-unit variations in administration practice.
**Methods:** This retrospective study analysed HAS administration across four ICUs between March 2022 and April 2023. Data from electronic medical records, blood bank data, and the Intensive Care National Audit & Research Centre (ICNARC) were used to examine admission characteristics, primary diagnoses, APACHE II scores, and HAS administration and conduct comparative analysis.
**Results:** In this multi-centre retrospective observational study, 3037 pts were included. Notably, RSCH stands out as a tertiary surgical centre, with elective surgical patients constituting 45% of its admissions. Conversely, in Worthing Hospital, merely 14% of patients undergo elective procedures, while a majority were medical admissions.
The use of HAS in all hospitals closely corresponds to the distribution of medical and surgical admissions, save for one exception—St. Richards, which shows a markedly lower overall use. RSCH and ESH are frontrunners in giving HAS. RSCH particularly notable, as 16.5% of its admissions receive HAS, compared to the 2.7% observed at St. Richard's. Despite St. Richard's having higher APACHE II score, it administered the least HAS. Furthermore, there exists some variation in the type of HAS. RSCH favours a higher proportion of 5% HAS usage (43.4%), compared to < 5% in other units.
**Conclusions:** This contemporary snapshot of large cohort, multi-centre practice uncovers differences in HAS use, without any discernible specialty preference.
Even considering differences in case mix between units, there were significant differences in the use of HAS. The differences were in the type of HAS (5% vs 20%) and the proportion of patients receiving HAS and in the quantity of HAS administered. Variation often reflects clinical uncertainty. Further work should include further analysis of specific indications for HAS on a per patient basis.

### Post-traumatic amnesia on the critical care unit (CCU): what do we know and where do we go from here?

I. Adamson[1]
[1]Occupational Therapy, King's College Hospital, London, United Kingdom
**Correspondence:** I. Adamson
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000919

**Introduction:** 1.4 million per year attend hospital in England and Wales following a head injury (1). In July–September 2023 alone, King's College Hospital (KCH) admitted 588 patients via the Major Trauma Inpatient List, of these 85 with moderate–severe head injuries.
Post-traumatic amnesia (PTA) commonly occurs after traumatic brain injuries (TBI). Defined as 'the transient state of altered brain function' its duration is 'the period between the head injury and the resumption

of normal, continuous memory' (2). This duration can relate to the extent a patient returns to pre-TBI function, such as; returning to independence, study or employment (3, 4).
**Objectives:** To review the KCH CCU Multi-disciplinary Team (MDT) understanding of PTA; identify barriers impacting patient care; identify areas for development to enable enhanced care.
**Methods:** Between December 2023 and February 2024, a survey was conducted, including closed and open questions. It was disseminated by email to CCU staffing lists and promoted at MDT meetings. Quantitative data were collected and qualitative data analysed using Braun and Clarke's (5) thematic analysis.
**Results:** 45 responses were received from the MDT: 37% Nursing; 14% Physiotherapists; 12% Doctors; 11% Occupational Therapists; 11% Speech & Language Therapists; 9% Advanced Critical Care Practitioners; 2% Dieticians; 2% Pharmacists; 2% Social Workers.
The MDT reported common symptoms of PTA as 'challenging behaviour', 'confusion', and 'memory difficulties'.
Various challenging behaviour management approaches were noted, including non-pharmaceutical methods such as; verbal de-escalation (25%), identifying/avoiding triggers (38%), including the patient (20%) and environment considerations (43%). Alongside combined pharmaceutical management with non-pharmaceutical techniques (18%).
Liaison with next-of-kin was the primary role reported by 75% of the MDT. 92% of nursing staff reported using physical support to prevent movement/harm to self or others. This is of note when considering that the CCU nurses do not undertake Prevention and Management of Violence and Aggression training (PMVA) as standard on induction to the CCU.
Challenges faced included; safe de-escalation (64%), supporting family (66%), understanding behaviours (57%), and determining medications for PTA symptoms (57%).
84% of the MDT believed resources for managing challenging behaviour would aid patient care, along with a protocol for acutely agitated TBI patients (73%) and patient/family information sheets (82%).
**Conclusions:** Three key areas for development have been identified; consolidate resources for patient and family education, enhance training for staff in managing challenging behaviours (e.g. PMVA, environmental factors, de-escalation) and explore the application of a protocol for managing acutely agitated patients with an acute TBI.
Support from relevant stakeholders will be sought to incorporate these into development plans with MDT collaboration.

### Clinical characteristics and prognosis of patients with acute olanzapine intoxication

A. Ben Jazia[1], M. Jemii[1], H. Ben Ghezala[1], M. Kharrat[1], N. Brahmi[1]
[1]Intensive care, Centre d'assistance médicale urgente—CAMU, Tunis, Tunisia
**Correspondence:** M. Jemii

*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000922

**Introduction:** Olanzapine is an atypical antipsychotic drug that is increasingly used in intentional drug overdoses. Although acute olanzapine overdose is predominantly associated not only with anticholinergic symptoms and central nervous system depression, but also miosis and unpredictable fluctuations between somnolence/coma and agitation/aggression.
**Objectives:** To describe clinical characteristics and prognosis of patients admitted to the intensive care unit for acute olanzapine intoxication.
**Methods:** This is an observational, retrospective single-center study, over a period of 4 years (2020 to 2023). Inclusion of patients over the age of 14 years admitted to ICU for acute olanzapine monointoxication and also polyintoxication. We describe epidemiological, clinical and prognostic characteristics of these patients. The Poisoning Severity Score of the European Association of Poison Centres and Clinical Toxicologists (EAPCCT) assessed the intoxication severity.
**Results:** A total of 50 cases of olanzapine overdose were included. The mean age was $31 \pm 14$ years with a sex ratio = 0.6. The ingested olanzapine doses ranged from 30 to 1700 mg. All these patients were followed for psychiatric disorders: depression ($n = 13$), bipolar disorder ($n = 18$), schizophrenia ($n = 7$), personality disorder ($n = 3$) and unidentified in 9 patients. 44% of the patients in our study had a previous suicide attempt in their history. Patients presented with olanzapine monointoxication in 18% of cases in our study. For polydrug intoxication, an association with benzodiazepines was reported in 36% of cases. The most frequent findings were somnolence (50%), miosis (50%), agitation (30%), and extrapyramidal syndrome (8%). The Poisoning Severity Score was "minor" in 19 (38%), "moderate" in 2 (4%), and "severe" in 29 (58%) patients. 28 patients (56%) required invasive mechanical ventilation and only 2 patients died. 14 patients (28%) had an unspecified ingested dose of olanzapine. There was not a statistically significant association between increasing ingested olanzapine doses and poisoning severity.
**Conclusions:** Although olanzapine is tolerated relatively well in acute overdose, its evolution remains unpredictable specially if associated to other drug intoxication. It requires careful clinical monitoring, but rarely specific therapeutic interventions.

**Topic:** Poisoning/Toxicology/Pharmacology

**Introduction:** Metformin intoxication is associated with a hyperlactatemia varying to different degrees of severity. The increase in lactatemia in patients with metformin intoxication is frequent and constitutes a marker of severity and explains the higher incidence of recourse to urgent hemodialysis and leading to a high mortality rate.
However, the threshold value of lactate to predict poor incomes is a subject of controversy.
**Objectives:** The aim of this study is to determine the correlation between the level of lactate and poor incomes in patients with metformin intoxication.
**Methods:** This is an observational, retrospective single-center study, over a period of 4 years (2019 to 2022). Inclusion of patients over the age of 14 years admitted to ICU for metformin intoxication. We identify the predictive threshold for in-hospital mortality using the ROC curve and we study Pearson's correlation between blood lactate threshold and mortality.
**Results:** 223 patients were included. The mean age was $29 \pm 12$ years with a sex ratio = 0.5. Hyperlactatemia was reported in 182 patients (81,6%).

The cut-off value for blood lactate to predict intrahospital mortality was 15 mmol/L.
The area under the curve was 0.979; (95% CI 0.958–1; $p = 0.004$).
This new cutoff had a sensitivity of 100%, a specificity of 95,9%, a positive predictive value of 25% and a negative predictive value of 100%.
Youden's index = 0.96. The correlation coefficient between the threshold of 15mmol/L. And mortality $r = 1$ and $p = 0.004$.
**Conclusions:** The positive predictive value of the new threshold limits its adoption. Including a larger sample will allow for better analysis.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000926

**Introduction:** High-flow nasal cannula (HFNC) oxygen therapy has been increasingly utilized during endoscopy examination, however, the effects of HFNC during bronchoscopy examination in high-risk patients remain uncertain.
**Objectives:** To determine whether HFNC reduces the incidence of desaturation, defined as pulse oximetry (SpO2) ≤ 90% for over 10 s, compared to conventional oxygen therapy (COT) during nasal bronchoscopy examination in patients exhibiting any of the high-risk factors associated with hypoxemia during the procedure. These factors include hypoxemia, hypercapnia, or radiologically confirmed narrow trachea observed prior to bronchoscopy, in addition to patients classified as morbidly obese.
**Methods:** In this multicenter randomized controlled trial, patients scheduled for bronchoscopy examinations and presenting with high-risk factors were randomly assigned to receive either HFNC or COT. Baseline characteristics, vital signs, and continuous SpO2 measurements during the examination were meticulously documented, and a comparative analysis of desaturation incidence, frequency of examination interruption, and the necessity for treatment escalation between the two groups was conducted. This trial received approval from the Ethics Committees of the participating hospitals and was prospectively registered with ChiCTR.org.cn (ChiCTR2100055038).
**Results:** From September 30, 2022 to June 20, 2023, 148 patients were initially enrolled after consent, but six patients withdrew from the study, leaving 72 in the HFNC group and 70 in the COT group. HFNC demonstrated a significant reduction in the incidence of desaturation during bronchoscopy examinations (34.7% vs. 61.4%, $p = 0.016$). Patients receiving COT experienced more frequent instances of examination interruption (58.6% vs. 26.4%, $p < 0.001$) and required escalated treatment more often (57.1% vs. 30.6%, $p = 0.001$). No statistically significant differences were noted in the time to first desaturation, duration of desaturation, bronchoscopy withdrawal, total duration of bronchoscopy examination, or incidence of other adverse events.
**Conclusions:** In patients undergoing nasal bronchoscopy with identified high-risk factors, the implementation of HFNC demonstrates notable benefits, including a significant reduction in desaturation incidence, decreased need for examination interruption, and lower requirement for treatment escalation.

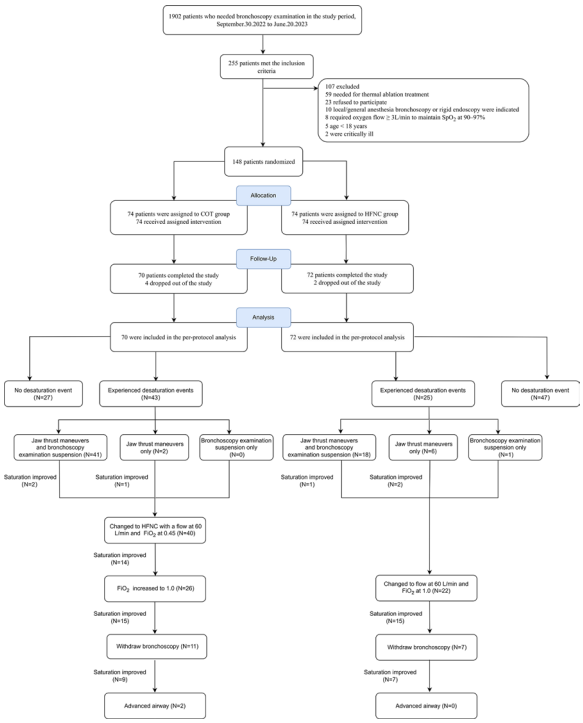

**Fig. 1 (abstract 000926)** Patient enrollment diagram and treatment algorithm
Among the 70 patients in the COT group, 43 (61.4%) experienced desaturation events, while only 24 (34.7%) out of 72 patients in the HFNC group had desaturation events ($p = 0.016$). For the 43 patients who desaturated in the COT group, jaw thrust maneuvers and/or bronchoscopy interruption only improved oxygenation for three patients. A switch to HFNC at 60 L/min and FIO2 of 0.45 enhanced oxygenation in 14 out of 40 patients, while increasing FIO2 to 1.0 was effective for 15 of the 26 remaining patients. Finally, bronchoscopy withdrawal improved oxygenation in 9 of 11 patients, with 2 still requiring advanced airway management. In comparison, for the 25 patients who desaturated in the HFNC group, jaw thrust maneuvers and/or bronchoscopy interruption improved oxygenation in 3 patients. Escalating FIO2 to 1.0 improved 15 out of 22 patients, and withdrawing bronchoscopy benefited all 7 who required it. HFNC, high-flow nasal cannula; COT, conventional oxygen therapy.

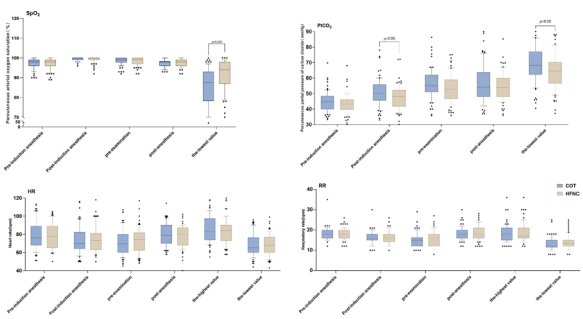

**Fig. 2 (abstract 000926)** Illustrates the alterations in SpO2, PtCO2, HR, and RR before and after anesthesia induction, before and after bronchoscopy examination, as well as the peak and nadir values recorded during the bronchoscopy procedure
The lowest SpO2 recorded during the examination was significantly lower in the COT group compared to the HFNC group ($p = 0.001$).

Additionally, the highest PtCO2 level recorded during the examination was higher in the COT group compared to the HFNC group ($p = 0.03$). SpO2, pulse oximetry saturation; PtCO2, transcutaneous pressure of carbon dioxide; HR, heart rate; RR, respiratory rate; HFNC, high-flow nasal cannula; COT, conventional oxygen therapy.

### Mitochondrial dysfunction in propofol infusion syndrome

A. Krajcova[1], J. Rulisek[2], M. Balik[2], V. Dzupa[3], P. Waldauf[1], F. Duska[1]
[1]Department of Anaesthesia and Intensive Care Medicine, 3rd Faculty of Medicine UK, Prague, Czech Republic; [2]Department of Anesthesiology and Intensive Care, General University Hospital, Prague, Czech Republic; [3]Department of Orthopaedics and Traumatology, 3rd Faculty of Medicine, Charles University, Prague, Czech Republic
**Correspondence:** A. Krajcova

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000927

**Introduction:** Propofol infusion syndrome (PRIS) is a very rare, but potentially lethal complication of propofol administration with a very high mortality rate (˃ 50%). Typical features of PRIS include unexplained metabolic acidosis, arrhythmias, hypertriglyceridemia, rhabdomyolysis, cardiac and/or renal failure. Previous studies have shown that propofol impairs mitochondrial metabolism [1]. However, its precise mechanism is not yet fully understood. In our work, we obtained muscle biopsies from two critically ill patients with suspected PRIS and we examined the bioenergetic profile in human skeletal muscle cells.
**Objectives:** Our goal was to measure global mitochondrial functions and fatty acid oxidation in human skeletal muscle cells obtained from biopsies from two critically ill patients with PRIS and compare them with two control groups (critically ill without diagnosis of PRIS and healthy volunteers).
**Methods:** Skeletal muscle cells were isolated from vastus lateralis muscle from critically ill patients diagnosed with PRIS ($n = 2$). The energy metabolism was assessed by Extracellular Flux Analysis. During the experiment, oxygen consumption rate (OCR) was measured at the baseline and after sequential addition of ATPase inhibitor, uncoupler and complex III inhibitor, which enabled to determine ATP production, proton leak and maximal capacity of the respiratory chain. The capacity of fatty acid oxidation (FAO) was measured as etomoxir-inhibitable OCR after adding of uncoupler and long-chain fatty acid palmitate. In cells, lipid droplets were also stained and imaged on electron and confocal laser scanning microscopy. All parameters were compared to values obtained in two control groups: (1) critically ill patients without a diagnosis of PRIS ($n = 10$), and (2) metabolically healthy controls (= patients undergoing elective hip replacement surgery; $n = 10$).
**Results:** In critically ill with PRIS, maximal respiratory capacity and fatty acid oxidation were significantly reduced in comparison with control groups (see Fig. 1, parts A and B). Interestingly, an increased accumulation of enlarged lipid droplets was found in the muscle cells of patients with PRIS (see Fig. 1, parts C and D). Gene expression (focused on lipid metabolism) and microscopic images of lipid droplets are currently analyzed.
**Conclusions:** In critically ill with PRIS, the most significant results were inhibition of fatty acid oxidation and lipid droplets accumulation in muscle cells.

### Long-term functional outcome and health-related quality of life in subarachnoid haemorrhage patients

E. Marques Mendes[1], D. Fernandes,[1] I. Maia[1], I. Coimbra,[1] JA. Paiva[2], E. Monteiro[2]
[1]Intensive Care Medicine, Centro Hospitalar Universitário de São João, Porto, Portugal; [2]Intensive Care Medicine, Centro Hospitalar Universitário de São João, Faculdade de Medicina da Universidade do Porto, Porto, Portugal

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000928

**Introduction:** Subarachnoid haemorrhage is a severe, life-threatening condition with high morbidity and mortality [1]. Improvements in critical care management reduced short-term mortality but increased the number of patients with functional and cognitive impairment and restrictions in quality of life. However, long time follow-up of functional outcome is scarce in literature [2].
**Objectives:** Assess mortality and functional outcomes at one and five years in the subgroup of patients admitted in Neurocritical Care Unit (NCCU) with aneurysmatic subarachnoid haemorrhage (aSAH).
**Methods:** Single-centre retrospective cohort study including all adult patients admitted to a NCCU from 2018 to 2019 due to aSAH. Patient´s outcomes were assessed by modified Rankin scale (mRankin) and Glasgow outcome scale (GOS) at one and five years follow-up. Health quality of life was collected by telephone interview using the EuroQol (EQ-5D-3L) questionnaire.
**Results:** A total of 65 patients admitted to NCCU were included, mostly women ($n=43$, 66%), mean age of 57 (±13) years (Table 1). At admission, 97% of patients had a previous favourable (0–1) mRankin ($n=63$) and median SAPSS II score was 29 (P25-P75: 22-45), with an expected mortality rate of 10%. Mortality rates at NCCU discharge and hospital discharge, at 1-year and at 5-year mortality were 11% ($n=7$), 11%, 3% and 2%, respectively. GOS was favourable (GOS 4–5) in 45% (n = 29) of patients at NCCU discharge, in 68% at one year ($n=44$), and in 65% at 5 years ($n=42$). Regarding health-related quality of life, the proportions of those reporting moderate to extreme problems were as follows: mobility 25%, self-care 25%, usual activities 31%, pain/discomfort 25% and anxiety/depression 47%. Approximately 35% ($n=19$) referred no problem at any dimension. In univariate analysis, no need for tracheostomy (OR 6.333, 95% CI 1.239–32.376, $p=0.016$), favourable GOS (4–5) at NCCU discharge (OR 5.882, 95% CI 1.110–31.170, $p=0.025$), age < 70 years (OR 6.333, 95%CI 1.239–32.376, $p=0.016$) and NCCU length of stay less than 20 days (OR 10.895, 95%CI 1.265–93.856, $p=0.011$) were associated with favourable GOS (4–5) at 5-year follow-up. Regarding quality of life, presence of moderate-to-extreme mobility problems were associated with tracheostomy (OR 11.625, 95%CI 1.962–68.870), mechanical ventilation (OR 1.583, 95%CI 1.242–2.019, $p=0.030$), NCCU length of stay above 20 days (OR 6.417, 95%CI 1.490-27.641, $p=0.08$) and unfavourable GOS (1-3) at NCCU discharge (OR 6.417, 95%CI 1.490–27.641, $p=0.08$). Presence of moderate-to-extreme self-care problems were associated with tracheostomy (OR 5.556, 95%CI 1.107–27.893, $p=0.026$) and moderate-to-extreme anxiety/depression was associated with vasospasm (OR 3.667, 95%CI 1.049–12.814, $p=0.038$).
**Conclusions:** The vast majority of survivors had no major limitations. Absence of tracheostomy, younger patients, and shorter length of stay in NCCU were associated with favourable outcome 5 years after NCCU admission. However, more studies are needed to address quality of life and long-term outcome of aSAH patients.

**Table 1 (abstract 000928)** Characteristics of the patients admitted to NCCU with aSAH, from 2018 to 2019

| | | Total |

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000929

**Introduction:** Recent studies in humans and rodents have demonstrated the beneficial effects of gabapentinoids administered early after spinal cord injury on the recovery of motor function. In humans, support for early gabapentinoid use is derived solely from studies in Europe, where patients are managed with gabapentinoids for neuropathic pain. Knowledge regarding standard of care in Canada is currently unknown.
**Objectives:** The goal of our study was to examine the administration of gabapentinoids in a Canadian acute spinal cord injury setting.
**Methods:** To this end, Vancouver General Hospital pharmacy data were linked with data from the Rick Hansen Spinal Cord Injury Registry between 2010 and 2019.
**Results**: In our sample of individuals with cervical spinal cord injury ($n = 257$), only 15% never received a prescription for gabapentinoids during their in-hospital stay at Vancouver General Hospital. 59% of individuals with cervical spinal cord injury were prescribed a gabapentinoid within the first 5 days of injury. The proportion of individuals prescribed gabapentinoids increased significantly from 75 to 90% after 2014. The proportion of early prescriptions nearly doubled over the same time period, from 40 to 75%.
**Conclusions:** These findings indicate a shift in the treatment of individuals with spinal cord injury at a single centre in Canada, towards early administration of gabapentinoids. Compared to Europe, our estimates of early gabapentinoid use in acute spinal cord injury care are substantially higher. The long-term impact of changes in standard of care in individuals with spinal cord injury should be evaluated in future studies.

### Association of clinical parameters with tolerance to supine position after prone cycle in ARDS patients under mechanical ventilation: preliminary results

M. C. Bachmann[1], R. Basoalto[2], Y. Jalil[1], V. Oviedo[1], D. Soto[1], G. Bugedo[1], A. Bruhn[1], J. Retamal[1]

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000930

**Introduction:** The prone position has been utilized since the 1970s to enhance oxygenation in mechanically ventilated patients with acute respiratory distress syndrome (ARDS). Physiologically, this maneuver optimizes gas exchange by recruiting the dorsal regions of the lungs, thereby improving the ventilation/perfusion (V/Q) ratio. Despite its benefits, prone positioning poses complications, necessitating clear understanding of its indications and duration. However, there remains controversy regarding the latter. Prolonged prone positioning may lead to severe muscle weakness, while shorter, repeated periods are associated with accidents and prolonged duration of invasive mechanical ventilation (IMV). Hence, precise determination of the optimal moment for supination is crucial.
**Objectives:** This study aims to identify the key factors related to tolerance of transitioning to the supine position, thereby enabling prediction of the safe cessation of prone positioning.
**Methods:** An observational clinical study was conducted in patients admitted to the ICU of the UC-CHRISTUS Clinical Hospital in Santiago, Chile, diagnosed with ARDS and connected to IMV in the prone position. The Research Ethics Committee of the School of Medicine of the Pontificia Universidad Católica de Chile approved this study. Informed consent was obtained from the patient's next of kin.
Laboratory exams, ventilatory parameters, and hemodynamics were recorded at baseline (prone position entry), one hour before supination (T0), and at 1, 8, 12, and 24 h post-supination (T1, T8, T12, and T24). Endothelial function was assessed at baseline using flow-mediated vasodilation, near-infrared spectroscopy (NIRS), and endothelial dysfunction markers in blood (angiopoietin-2, ECAM-1, VCAM-1, E-selectin, and P-selectin). Plasma inflammatory parameters, including IL-6, IL-8, and IL-10, were additionally assessed to ascertain the patient's inflammatory status and its potential impact. Arterial blood gas (ABG) analysis and distribution of ventilation and perfusion via electrical impedance tomography (EIT) were evaluated in both prone and supine positions. Lung aeration was assessed using lung ultrasound in both positions. Intolerance to the supine position was defined as the need for a second prone cycle within the first 24 h after the switch, and analysis was conducted in two groups: successful and failed. For the statistical analysis, GraphPad Prism 8.0 software was employed.
**Results:** The analysis included 20 patients, of whom 13 tolerated the position change (successful group). No significant differences were observed between groups in terms of demographics and severity of diagnosis (APACHE, SOFA). The average duration of the prone cycle was 5 days in both groups. The successful group exhibited higher ventilation support (Pmean) and significantly lower driving pressure values during the prone position (baseline) compared to the failed group. Notably, 85% of patients in the failed group had a driving pressure exceeding 15 cmH2O at the time of supination, whereas in the successful group, it was only 7%. EIT revealed a more dorsal distribution of ventilation during the prone position in the successful group, with no significant change observed after the position change, unlike the failed group. While no differences in baseline PaO2/FiO2 were found between groups, the failed group showed significantly lower values of PaO2/FiO2 at T0 and throughout the study period. Furthermore, no association was found between tolerance to position changes and pulmonary perfusion or endothelial dysfunction in this study group. Inflammatory parameters were also found to have no association with tolerance to changes in position.
**Conclusions:** In this patient cohort, oxygenation and lung mechanics emerged as the primary factors influencing tolerance to position changes, while perfusion did not significantly contribute to tolerance assessment. Larger studies are warranted to establish cut-off points for PaO2/FiO2 and driving pressure to predict patient tolerance to transitioning to the supine position. The final analysis of this study includes more advanced statistical analysis, which is still pending, for the determination of association.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000931

**Introduction:** Admissions due to cardiorespiratory arrest in Intensive Care Units (UCI) still have a high prevalence. A systematic evaluation of who can benefit from intensive care is necessary.
**Methods:** A retrospective observational descriptive study using data from UCI admissions between January 1st and December 31st, 2023, was conducted. Pearson's correlations, nonparametric tests, univariate and bivariate logistic regression were used.
**Results:** Of a total of 356 admissions from all causes, 51 were included (14,3%).
The mean age was 71.83 ± 11 and mostly male (70,6%); 62.74% had 2 or more personal history of high-risk disease.
76.5% of CRA occurred in the hospital and mostly in emergency department. Hypoxemia was the main cause (23,5%). The most frequent rhythm of CRA was asystole (53%) with a median duration of 11 ± 14 min. It showed a negative correlation with Glasgow after CRA ($p = 0.041$), with encephalopathy lesion on CT scan ($p = 0.009$) and when > 12 min was associated with a 6 times higher probability of death ($p = 0,013$).
The median of post-event Glasgow score was 3; patients With Glasgow < 6 were 3.85 times more likely to die ($p = 0.004$).
Reduced ventricular ejection fraction in post-arrest transthoracic ultrasound occurred in 64.35%, but it did not show a significant impact at outcomes. Post-arrest shock occurred in 62.7% of patients conditioning a 6,25 times greater probability of death ($p = 0.002$).
44.7% of patients had evidence of encephalopathy on CT scans and it was associated with a 6.33 × higher probability of death ($p = 0,012$).
47.1% of patients underwent EEG and 83% had dysfunction. However, this variable did not show a significant correlation with the final outcome. The median Glasgow after lifting sedation was 5 and was strongly correlated with the status and Glasgow score at discharge ($p \leq 0.001$).
The median length of stay in the unit was 5 days and at hospital discharge 21.56% of patients were alive.
An end-of-life decision was made in 35.3% and the most frequent was withdrawal of invasive life support (66.6%); it occurred with a median of 4 days. No patient was referred to palliative care.
The SAPSII index was a mean value of 68.96 ± 17.995 and APACHE II index of 30.41 ± 8.9. There was a significant negative relationship between severity indices and state at discharge (APACHE $p = 0.013$, SAPSII $p = 0.002$).
**Conclusions:** The mean age of patients admitted after CRA was higher than other studies. Although age and the presence of previous comorbidities are established factors of worse outcome this was not observed in the present study.
The main predictors of better outcome were: CRA duration < 12 min; Glasgow score after CRA/sedation lift, absence of post-CRA shock/encephalopathy and lower severity índices, corroborating the literature. The presence of reduced ejection fraction did not affect the outcome, contrary to expectations.
Mortality was high (78%) overlapping with the existing literature.
The end-of-life decision was infrequent and tended to be taken late.

**Introduction:** Major surgery and critical illness are associated with systemic inflammation that contributes to organ dysfunction and failure. Therapeutic strategies targeting selective molecular pathways have mostly failed to improve patient outcome. The dipeptidyl-peptidase 4 (DPP4) N-terminally cleaves more than eighty cytokines, chemokines and inflammatory mediators, thereby modulating their receptor preferences and activity (1). Clinically licensed DPP4 inhibitors (gliptins) are associated with vascular and organ protection, but their capability to modulate the acute systemic inflammatory response has not been dissected yet (2, 3).
**Objectives:** We here evaluated in mice and patients whether DPP4 inhibition during systemic inflammation can modulate inflammation associated with preservation of vascular function and organ integrity.
**Methods:** Wild type (WT) mice treated with either vehicle or 5 mg/kg of the DPP4 inhibitor sitagliptin and *Dpp4*-deficient mice were subjected to a paramedian laparotomy (major surgery model) or polymicrobial sepsis induction. The cellular and humoral immune response, vascular genomic profiles and function and histological parameters of organ integrity were assessed. In $n = 14$ patients undergoing cardiac surgery, the postoperative inflammatory response was compared in $n = 7$ patients with preoperative sitagliptin intake using a flow cytometry-based systems biology approach. Microvascular integrity was monitored using incident darkfield microscopy and clinical parameters were assessed.
**Results:** Sitagliptin application and *Dpp4*-deficiency were associated with reduced leukocytosis ($P < 0,01$ vs. vehicle-treatment in WT mice, $n > 5$ mice/group), mobilization of immature neutrophils

(P < 0,05) and reduced levels of various cytokines (i.e. TNFalpha, all $P < 0,05$) 8 h after laparotomy or induction of polymicrobial sepsis. Mice treated with sitagliptin showed a reduction in gene activation during systemic inflammation in the endothelium (< 2500 vs. > 4.500 differentially regulated genes) that correlated with maintained response of isolated arteries to the vasopressor phenylephrine ($P < 0,01$), reduced capillary leakage ($P < 0,001$ for albumin extravasation) and pulmonary edema formation ($P < 0,001$). In addition, DPP4 inhibition was associated with reduced tubular injury ($P < 0,001$) and hepatic tissue damage ($P < 0,001$) in septic m ice. In cardiac surgery patients, preoperative intake of sitagliptin induced multiple changes in both innate and adaptive immune responses 24 h after surgery that were associated with augmented functional characteristics of the microcirculation ($P = 0,019$) as well as reduced vasopressor ($P = 0,065$) and crystalloid requirements ($P = 0,009$).
**Conclusions:** Inhibition of DPP4 during surgery- or sepsis-associated systemic inflammation results in modulation of cellular and humoral immune response characteristics that correlate with augmented vascular function and preserved organ integrity.

**Introduction:** The enactment of the Organic Law Regulating Euthanasia (LORE) on June 21, 2021 has sparked increasing interest in its clinical application. However, research on this topic remains scarce. Furthermore, specific information regarding patients undergoing euthanasia as potential organ donors is even more limited.
**Objectives:** To analyze the characteristics of donors following Medical Assistance in Dying (MAiD), the donation process, and outcomes in the initial cases conducted at Hospital del Mar.
**Methods:** Retrospective, observational, and descriptive analysis of potential organ donors following MAiD identified at Hospital del Mar, Barcelona, from the enactment of the Organic Law Regulating Euthanasia (LORE) on June 21, 2021, until November 30, 2023. Data collected included donor age, sex, underlying condition leading to MAiD, responsible physician's specialty, need for intensive care unit (ICU) admission, type of MAiD (euthanasia vs. assisted suicide), location of MAiD administration and death, extraction method, number of organs retrieved and transplanted, total warm ischemia time (from medication administration to cold perfusion or start of normothermic regional perfusion), and functional warm ischemia time (from significant hypoperfusion to cold ischemia or start of normothermic regional perfusion). Variables are expressed as absolute numbers, percentages, and means (max–min).
**Results:** A total of 10 patients who obtained favorable resolution for MAiD were evaluated by the Transplant Coordination team. Among them, 6 had 4 absolute medical contraindications and 2 declined donation. Ultimately, 4 donors were identified, with 50% being women and a mean age of 68 years (range: 48–90). The underlying pathology was degenerative disease (ALS) in 75% of cases. In 3 cases, the responsible physician was a neurologist at Hospital del Mar, and in 1 case, it was their primary care physician. 75% required ICU admission as part of the controlled donation procedure. Euthanasia was chosen in all cases, with medication administration and death occurring in the operating room in 100% of cases. Rapid extraction was performed in 50% of donors, while the other 50% underwent normothermic regional perfusion using extracorporeal membrane oxygenation (ECMO) with sedation for orotracheal intubation and premortem cannulation. Total warm ischemia time was 21.75 min (range: 9–43), and functional warm ischemia time was 9.75 min (range: 5–21). A total of 15 organs were retrieved, with 12 transplanted (5 kidneys, 4 lungs, 2 livers, and 1 pancreas), yielding a transplant/donor organ ratio of 3.
**Conclusions:** Organ donation after euthanasia represents a viable source of transplantable organs. The typical profile involves patients with degenerative neurological conditions who die in the operating room. A significant proportion of these donors require ICU admission during the procedure.

**Topic:** Brain death, organ donation and transplantation

### Visual stress index estimation is a reliable parameter in monitoring mechanical ventilation safety

R. Jerez Sánchez[1], C. Sanmartino Gonzalez[1], M. Berenguer Rodriguez[1], C. Serra Sánchez[1], A. Márquez García[1], A. Tejero Pedregosa[1], L. L. Beltran Martínez[1], C. Tarancón Maján[1], D. Monge Donaire[1]

**Introduction:** It has been postulated that in patients undergoing controlled mechanical ventilation (CMV) with square flow waveforms, the straight shape of the pressure–time curve during inflation indicates that tidal ventilation (TV) occurs between the two inflection points of the pressure–volume curve, which identifies the pressures at which recruitment and overdistension begin. To analyze the shape of the pressure–time curve, the stress index (SI) has been defined, such that: when $SI = 1$, the line is straight and VT occurs in the safe zone; when $SI < 1$, the line is convex and VT occurs in the collapse zone; when $SI > 1$, the line is concave and VT occurs in the overdistension zone. Computing processing of the pressure–time curve data is required to measure SI, although it has been postulated that simple visual inspection could serve to estimate it.
**Objectives:** To analyze the accuracy of visual estimation of SI by a group of non-expert observers in mechanical ventilation (MV).
**Methods:** Measurement of SI in 19 patients undergoing CMV with square flow waveform using the FluxMed monitor. Patients were classified into three groups based on the measured SI: safe zone ($SI = 1$), overdistension ($SI \geq 1.1$), and collapse ($SI < 0.9$). Simultaneously with measurement, pressure–time curve of each patient was captured. Subsequently, curves were processed and sequentially presented to eight different non-expert observers in MV. After a brief introduction to the concept of SI, each observer completed a questionnaire in which they classified each trace, according to their visual perception into one of the following categories: safe zone, overdistension and collapse. The accuracy of the observers in correctly classifying the curves was analyzed.
**Results:** Nineteen mechanically ventilated patients were included in the study, with 31% (6) with an ARDS diagnose. Patients were ventilated with an average TV of 7.76 ml/kg ([6.5—11.8], CI 95%), and mean measured SI was 1.06 ([0.9—1.5] CI 95%). Visual estimation had a sensitivity of 72% for detecting overdistension ($SI \geq 1.1$) and a specificity of 89%. For collapse detecting ($SI \leq 0.9$), sensitivity was 87% and specificity 92%. There was an overall error percentage of 24%, with an underestimation percentage of 15%. Interobserver agreement was moderate (kappa index 0.442).
**Conclusions:** SI can be estimated visually by non-expert observers in MV and, therefore used to monitor bedside MV safety.

**Introduction:** The accuracy with which ICU specialists can perform an ultrasound study aimed at detecting vascular complications in the immediate postoperative period of liver transplantation was evaluated.
**Methods:** Cross-sectional observational study in the medical-surgical ICU of a tertiary hospital. All patients admitted after liver transplantation who were to undergo a standardized Doppler study performed by a specialist radiologist were included. The sample consisted of 29 ultrasound studies, conducted in 28 patients admitted between July and November 2023.
Intensivists (ICU group) who had undergone a previous training session in Doppler ultrasound aimed at ruling out vascular complications obtained measurements of resistance index (RI) and peak systolic velocity (PSV) in the hepatic artery and classified the flow pattern as "normal", "non-pathological hemodynamic variant (NPHV)", and "pathological". Additionally, flow and velocity in the portal vein (PV) were evaluated, and flow was categorized as "normal" and "pathological". The study by the ICU group was blinded to the standardized one performed within a period of 24 to 72 h. Concordance analysis was performed using Cohen's Kappa statistic for qualitative variables and the intraclass correlation coefficient (ICC) for quantitative variables.
**Results:** The most common indication for performing an ultrasound study was to evaluate the presence of vascular complications in the postoperative period (1–2 days) after liver transplantation.
The ICU group classified 17 (59%) patients with normal arterial flow, 11 (38%) with NPHV, and failed to visualize the artery in 1 (3%) case. The radiologist classified 18 (62%) patients with normal arterial flow and 11 (38%) with NPHV. Thus, pathological flow was ruled out in 97% of the cases evaluated in the ICU, and there was substantial agreement (Kappa 0.77) in distinguishing between normal flow and non-pathological variants.
Regarding flow in the PV, the ICU group classified 28 (97%) patients with normal arterial flow and 1 (3%) with pathological flow. There was total agreement in all 29 studies.
For RI, the ICC was 0.81 ($n = 27$). In the case of PSV, an ICC of 0.51 ($n = 24$) was obtained, while for velocity in the PV, an ICC of 0.88 ($n = 28$) was calculated between the ICU and radiology groups.
**Conclusions:** The performance of Doppler ultrasound by ICU specialists aimed at ruling out vascular complications in the immediate postoperative period of liver transplantation appears feasible after specific training.

**Introduction:** Onco-hematological patients are increasingly being admitted to intensive care units in the last 20 years, largely due to the improvement of treatments, which have not only extended survival but also enhanced their quality of life. It is necessary to understand the profile of onco-hematological patients admitted to the ICU.
**Objectives:** To understand the differential epidemiological characteristics according to underlying disease: medical, elective surgery and urgent surgery; and according to cause for admission: unrelated to cancer (UTC), post-surgical complications related to cancer (PRC), and medical complications related to cancer (MCRC) in oncological patients admitted to the ICU.
**Methods:** Retrospective study conducted in a second-level hospital ICU from January 2020 to December 2023. Patients with a history of both hematologic and solid organ neoplasms diagnosed up to 5 years prior to ICU admission were selected. The following variables were collected: age, sex, ICU length of stay, severity scales (SAPS 2, APACHE II), comorbidities, cancer type (solid, hematologic), anatomical tumor location, oncological and ICU support treatment, cause of admission, whether any form of limitation of life-sustaining treatment had been received, and outcome. Qualitative variables are expressed as percentages and quantitative variables as mean and standard deviation or as median and interquartile range (p25-p75). Bivariate analysis was performed using the Chi-square test for qualitative variables and the Kruskal–Wallis test for quantitative variables. A $p$-value < 0.05 was considered significant for all analyses.
**Results:** 163 of the 1543 patients (10.5%) admitted to the ICU during the study period had a history of neoplasm. There were no statistically significant differences related to the underlying disease or cause of admission regarding the neoplasm itself when analyzing age, severity at admission, ICU length of stay, or mortality. Many of the patients with a medical underlying disease presented immunosuppression (75.8%) compared to scheduled post-surgical patients (9.1%) and urgent post-surgical patients (15.2%). Sepsis was the most common reason for admission to the ICU in patients with a medical underlying disease (41.9%) and urgent post-surgical patients (41.9%), compared to 16.1% in scheduled post-surgical patients. Patients with solid colorectal neoplasms were mostly admitted after urgent surgery (38.6%). Patients admitted after urgent surgery more frequently received parenteral nutrition (40.6%) compared to scheduled post-surgical patients (31.3%) or those with a medical underlying disease (28.1%). When considering the cause of admission in relation to the neoplasm itself (UTC, PRC, and MCRC), neutropenia (87.5%) and malnutrition (70%) were more frequent in patients admitted for MCRC. In patients admitted for PRC, colorectal neoplasm was the most frequent (52.3%). In

other locations, admission was either unrelated to cancer or secondary to MCRC, with hematologic tumors predominating in the latter case (50%). Most of the patients who received ventilatory support beyond 24 h of admission were admitted for MCRC (60%). Among medical patients, a high percentage were admitted for non-cancer-related reasons (53.4%), while in scheduled surgical patients, admission was mostly related to cancer (84.6%). Among patients admitted for MCRC, a significant proportion underwent some form of limitation of therapeutic effort (48.5%) compared to the other groups (NRC: 42.4% and PRC: 9.1%; $p < 0.001$).

**Conclusions:**

- The main reason for admission to the ICU was related to cancer in patients who suffered from: neutropenia, malnutrition, scheduled post-surgical patients, colorectal location, hematologic tumors, chemotherapy, or immunotherapy treatment.
- Patients admitted for medical complications related to cancer are mostly intubated within 24 h of admission.
- Patients admitted for medical complications related to cancer are the group where some form of limitation was most frequently implemented.

### The relevance of shock index in pelvic trauma patients

R. Almeida[1], C. Costa[2], S. Carvalho[3], T. Costa[4], N. Gatta[5], J. M. Pereira[6], J. A. Paiva[6]
[1]Intensive Care Medicine, ULS Viseu-Dão Lafões, Viseu, Portugal; [2]Intensive Care Medicine, ULS Loures Odivelas, Loures, Portugal; [3]Intensive Care Medicine, ULS Trás-Os-Montes E Alto Douro, Vila Real, Portugal; [4]General Surgery, ULS Guarda, Guarda, Portugal; [5]Intensive Care Medicine, ULS São João, Porto, Portugal; [6]Intensive Care Medicine; Faculdade de Medicina da Universidade do Porto, ULS São João, Porto, Portugal
**Correspondence:** R. Almeida

**Introduction:** Trauma is one of the main causes of death and morbidity worldwide (1). Pelvic trauma (PT) is associated with high-energy injury mechanisms, which often leads to it being associated with other injuries (2). Mortality rates are high, especially in patients who are hemodynamically unstable (3).

**Objectives:** To analyze the association between the Shock Index (SI) and the severity and outcome of critically ill patients with PT.
**Methods:** Retrospective, single-center study of all patients over 18y with PT admitted to the emergency room (ER) of a Tertiary University Hospital between January 2020 and December 2023. The Young and Burges and the WSES classifications were used to classify PT and its instability. Coagulopathy was defined if ≥ 1 of the following conditions were met: PT > 15 s, aPTT > 40 s or fibrinogen < 150 mg/dL. The SI (heart rate divided by systolic blood pressure) ≥ 0,9 (4,5) was used as a predictor of severity. Major trauma was defined as Injury Severity Score (ISS) > 15 (6). Statistical analysis was done using SPSS version 29.0.2.0.
**Results:** A total of 111 patients were included, 83 were men (74,77%) with a mean age of 47y (± 18,82) and a median ISS of 25 (14–38). Median ICU and hospital length of stay were 5 (1,75–18,25) and 21,50 (9–44,5) days, respectively. 5 patients died in the ICU (4,5%) and 11 in the hospital (9,9%). SI was ≥ 0,9 (HSI) in 55 patients (49,55%) while 56 patients (50,5%) had SI < 0,9 (LSI). The most common mechanism of injury was falls (42,9%) in the LSI group and road accidents (40%) in the HSI group ($p = 0{,}0625$). Major trauma (ISS > 15) was more frequent in the HIS group (59% vs 41%; $p < 0{,}001$). The HSI group had higher median APACHE II (15,5 vs. 11,0; $p = 0{,}009$) and SAPS II (34,0 vs. 23,5; $p = 0{,}078$) scores. As for the WSES classification, a significantly higher proportion of patients in the HIS group were included in WSES grade IV (83,3% vs. 16,7%; $p < 0.001$). The majority of PT was classified as LC (79,5%), 14% as APC and 6,5% as VS according to The Young and Burges classification.
At ER admission, lactate > 2 mmol/l was significantly more frequent (59,3% vs 40,7%; $p = 0{,}003$) and median pH was significantly lower (7,31 vs. 7,36; $p = 0.019$) in HSI group. Patients in the HSI group presented a higher prevalence of coagulopathy (74,3% vs. 25,7%; $p < 0{,}001$) and tranexamic acid was more frequently administered in this population (63,6% vs. 36,4%; $p = 0{,}016$). No statistically significant differences between both groups were found with regard length of stay and mortality either in the ICU or in the hospital.
**Conclusions:** Although no statistically significant differences were found in the outcome of PT patients, SI ≥ 0,9 seems to correlate well with patient severity at ER admission. Thus, SI is an easy score to calculate that can be used as a triage tool for patients with PT, identifying those who need urgent treatment and stabilization and aiming to reduce associated morbidity and mortality.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000938

**Introduction:** Endothelial barrier breakdown is a key element in the pathophysiology of sepsis, leading to the formation of tissue edema and subsequent organ failure. Cleavage of the endothelial tyrosine kinase Tie2 from the cell surface, known as Tie2 shedding, has been described as a crucial step in the development of capillary leakage [1]. To date, there are no therapies targeting Tie2 shedding in septic patients with capillary leakage.

**Objectives:** This study aims to repurpose FDA-approved drug compounds to inhibit pathological Tie2 shedding in sepsis models with a potential beneficial impact on capillary leakage.
**Methods:** A high-throughput screening (HTS) was conducted to find potential inhibitors of Tie2 shedding utilizing SCREEN-WELL® FDA approved drug library with 800 unique compounds. Human umbilical vein endothelial cells (HUVEC) were treated with 10 µM of each compound for 24 h. Supernatants were then assessed for soluble Tie2 (sTie2) levels via enzyme-linked immunosorbent assay (ELISA) and a CCK-8 assay was utilized to evaluate cytotoxicity. Compounds that reduced sTie2 by over 20% while maintaining cell viability above 80% were identified as potential candidates. These candidates were subsequently verified through dose–response analysis, as well as by investigating their impact on the temporal progression of Tie2 shedding in HUVEC models with TNF-α-induced inflammation. One-way ANOVA was employed to analyze differences between treatment groups at different timepoints.
**Results:** The HST screening identified 7 compounds meeting the predefined criteria for potential candidates—namely ciclesonide, deferasirox, hydrocortisone, miconazole, montelukast, sertaconazole and 1,25-dihydroxyvitamine D3. Montelukast and ciclesonide showed the most pronounced effect, reducing sTie2 in supernatants to 58.3 ± 1.66 and 43.7 ± 0.08% of controls, respectively ($p < 0.001$). Treatment with 1, 10 and 100 µM of each compound demonstrated a dose-dependent decline of sTie2 (Fig. 1A). Investigation of the longitudinal trajectory of Tie2 revealed an increment of sTie2 over time in the control group (DMSO + PBS group), which could be enhanced by stimulating cells with TNF-α additionally (DMSO + TNF group). Treatment with ciclesonide and montelukast successfully antagonized TNF-α-induced sTie2 shedding (at 36 h $p < 0.001$, Fig. 1B).
**Conclusions:** FDA-approved compounds, including montelukast and ciclesonide, significantly affect Tie2 shedding in vitro and may offer protective off-target benefits for patients experiencing capillary leaks in sepsis.

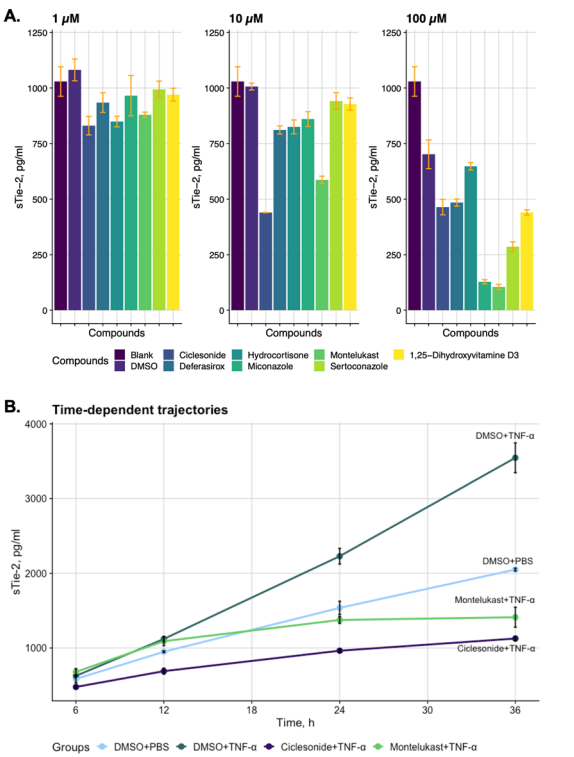

**Fig. 1 (abstract 000938)** A) Dose–response analysis: impact of various compounds on sTie2 levels in supernatants of HUVEC. B) Longitudinal analysis of sTie2 levels: sTie2 in HUVEC supernatants following TNF-α stimulation and treatment with montelukast and ciclesonide, with DMSO serving as control

### Neuroprotective effects of xenon application

A. Kuzovlev[1], O. Grebenchikov[1], A. Shabanov[1], R. Cherpakov[1]
[1] V.A. Negovsky research institute of general reanimatology, Federal research and clinical center of intensive care medicine and rehabilitology, Moscow, Russia
**Correspondence:** A. Kuzovlev

**Introduction:** The lack of effective strategies to prevent and minimize the consequences of acute damage to the central nervous system contributes to the search for new methods of neuroprotection. According to the obtained clinical and experimental data, the use of inhaled anesthetic xenon, whose neuroprotective potential has already been proven in a number of studies, is able to solve this problem.

**Objectives:** To identify the results obtained within the framework of the use of xenon in patients who have suffered an ischemic stroke.
**Methods:** The study included 24 patients who met the following inclusion criteria:

- Men and women between the ages of 18 and 75;
- Acute period of cerebral infarction;
- Severe neurological disorders (GCS < 12 points, NIHHS > 15 points, FOUR < 13 points);
- The need for a ventilator.
- Absence of a cerebral infarction in the previous 6 months;
- Absence of infectious diseases in the last month.

After randomization and inclusion of patients in the study, a standard protocol was followed based on current clinical recommendations for the treatment of ischemic stroke. Sedation was initiated within the first 12 hours from the moment of admission to the ICU or confirmation of the diagnosis of cerebral infarction. In the control group ($n = 12$), propofol sedation was performed at a dose of 2–4 mg/kg per hour using continuous intravenous perfusion. In the study group ($n = 12$), therapeutic anesthesia with Xenon was performed for 6 h at a concentration of 50 vol. % (0.5 MAC). The effectiveness of the therapy was assessed by evaluating such parameters as: indicators of GCS, NIHHS and FOUR on days 1, 3 and 8 from the start of sedation, as well as the level of neuronal damage protein S100ß.
**Results:** When assessing the level of consciousness on the Glasgow coma scale by 8 days against the background of xenon use, the results were significantly better than in the control group—7 [6–8] points in the control versus 13 [11–15] in the xenon group ($p = 0{,}026$). According to the FOUR scale, by day 8, a significant recovery in the level of consciousness was also noted against the background of xenon use—8 [7–8] points in the control group versus 14 [13–15] points in the study group ($p = 0{,}026$). The severity of neurological disorders on the NIHSS scale was also significantly lower against the background of xenon use—24 [12–27] points in the study group versus 32 [30–34] in the control group ($p = 0{,}008$). When assessing the level of S100 b protein on day 8, the concentration in the xenon group was significantly lower both in relation to the baseline level ($p = 0{,}04$) and compared with the protein level on day 8 in the propofol group ($p = 0{,}017$).
**Conclusions:** When comparing the effect of the sedation method on the level and speed of consciousness recovery, medical sedation with

xenon showed significantly better results compared with the use of propofol.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000940

**Introduction:** The role of the intensivist physician in the donation process is crucial throughout, from identifying potential donors, their admission to the ICU, providing care, to interacting with the family. We propose a review in the evolution of the donor profile at both national and regional levels in Spain and *Castilla y León* over the past 10 years.
**Objectives:** To describe the evolution of the organ donation process in Spain and compare it with data from *Castilla y León* (Spain). Furthermore, relate this evolution to intensivist role.
**Methods:** Retrospective descriptive analysis of the organ donation process in Spain and *Castilla y León* region between 2013 and 2022. We comparatively analyzed the donation rate, type of donation, cause of donation, donor characteristics, and evolution of family refusal.
**Results:** In the last ten years between 2013 and 2022, number of national donors has increased by 32.68%, and by 18% in *Castilla y León*, with an effective donor rate of 46.3 per million population (pmp) and 46 pmp, respectively. The highest rate was observed in 2019 (49 pmp), marked by a decrease in subsequent years due to the pandemic (37.4 pmp in 2020). Donations from controlled donation after circulatory death (DCD) accounted for 41.97% of total effective donations in the last year (rate 19.2 pmp), and 21.10% in *Castilla y León*. Between 2014 and 2017, DCD donations increased by 96.89%. In *Castilla y León*, there was an increase from 2 to 17 DCD donations from 2017 to 2018. The average age of the donor patient in Spain is 59.7 (SD 16.1) and 63.1 (SD 15.2) in *Castilla y León*. Most of them were male, and primary cause was acute cerebrovascular accident (ACVA), both nationally and regionally. Family refusal rate for donation stands at 16% nationally, a higher percentage than in 2019, which was 14%, the year with the highest number of donors. *Castilla y León* would be below the national average with a 13% family refusal rate.
**Conclusions:** The activity of the donation process in *Castilla and León* compared to Spain shows very similar data. In the early nineties, the National Transplant Organization (ONT) was established. Since then, there has been an annual increase in donation rates until 2020, interrupted by the pandemic, and to this day, the previous rates of effective donors have not been recovered. Currently, there is a noticeable growth in donation rates in controlled donation after circulatory death (DCD) in recent years, but also an increase in family refusal, likely influenced by current society. Therefore, the active participation of the intensivist physician in the process (donor detection, legal aspects, family interviews, organizational aspects, management, communication with the media), and coordination of organ donation is essential.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000941

**Introduction:** Osmolar therapy is a medical treatment strategy frequently used in patients with intracranial hypertension with the aim of decreasing cerebral edema. Within neurocritical care units, the use of hyperosmolar intravenous solutions is not exempt from side effects, and one of the most important is the possibility of developing acute kidney injury. The IRR is an index that continues to be researched, and in recent years it has found a field of study in cardiorenal syndrome and sepsis, two conditions that in the acute context have found the possibility of continuous serial follow-up. The prognostic value of this index as an early predictor of acute kidney injury remains to be clarified, there are pathologies that associate an effect of microvascular damage that is combined with greater systemic vascular rigidity. The aim of this study was to evaluate this index in patients receiving hyperosmolar therapy who developed acute renal injury by establishing a cut-off point.
**Objectives:** To evaluate the renal resistance index as a tool to predict the risk of acute kidney injury in neurocritical patients requiring hyperosmolar therapy.
**Methods:** The sample was collected from all patients who required management with hyperosmolar therapy and who met the inclusion criteria and without exclusion criteria, determining baseline serum levels of creatinine, sodium, and chlorine, and then Doppler IRR measurements were performed prior to hyperosmolar therapy at 24, 48, and 72 h.
**Results:** An ROC curve showed an area under the curve (AUC) of 0.68 (95% CI 0.49–0.87), with a sensitivity of 77.7% and a specificity of 35.7%. When the classification correction was performed via DLR+, the point was 0.56, with a sensitivity of 83.3% and a specificity of 71.4%.
**Conclusions:** A high index of renal resistance was correlated with the risk of developing water-induced renal injury, however, the sample size was limited to a statistically significant value.

## B-Hydroxybutyrate exposure restores mitochondrial function in skeletal muscle satellite cells of critically ill patients

A. Krajcova[1], L. Genserova[2], F. Duska[1]

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000942

**Introduction:** Dysfunction of skeletal muscle satellite cells might impair muscle regeneration and prolong ICU-acquired weakness, a condition associated with disability and delayed death. In recent years, there have been many efforts to prevent muscle catabolism and muscle loss through various rehabilitation approaches as well as nutritional support. Traditional ways of metabolic support have focused mainly on supplementation of proteins and amino acids, but failed to improve patient-centered outcomes. In turn, it has been hypothesized that ketone bodies might be used as an alternative, readily available fuel in critically ill patients [1].
**Objectives:** Before testing ketone bodies in clinical, outcome-based trials, we aimed to study ex vivo the metabolic effects of ketone bodies (β-OH-butyrate; β-OHB) in satellite cells isolated from vastus lateralis muscle biopsies of patients with ICU-acquired weakness.
**Methods:** Satellite cells were extracted by Bergström needle technique from vastus lateralis muscle biopsies of patients with ICU-acquired weakness ($n=10$; age $53\pm17.5$) and control group of healthy volunteers or patients undergoing elective hip replacement surgery ($n=10$; age $51.3\pm17.2$). The cells were exposed to standard culture media supplemented with β-OH-butyrate (5 mM) to assess its influence on cell proliferation by ELISA, mitochondrial functions by extracellular flux analysis, electron transport chain complexes by high resolution respirometry, and reactive oxygen species production by confocal laser scanning microscopy.
**Results:** Critical illness led to a significant decline in maximal respiratory capacity, ATP production and glycolytic capacity and increased reactive oxygen species production in ICU patients' cells. Notably, the function of complex II was impaired due to critical illness but restored to normal levels upon exposure to β-OH-butyrate (Fig. 1, parts B and D). Additionally, β-OH-butyrate significantly reduced reactive oxygen species production in both control and ICU groups (Fig. 1, part G). In ICU patients, cells exposed to β-OHB tended to increase proliferation, although these changes did not reach statistical significance (Fig. 1, part H).
**Conclusions:** Critical illness induces measurable bioenergetic dysfunction of skeletal muscle satellite cells. β-OH-Butyrate displayed a potential in rectifying complex II dysfunction caused by critical illness and this warrants further exploration.

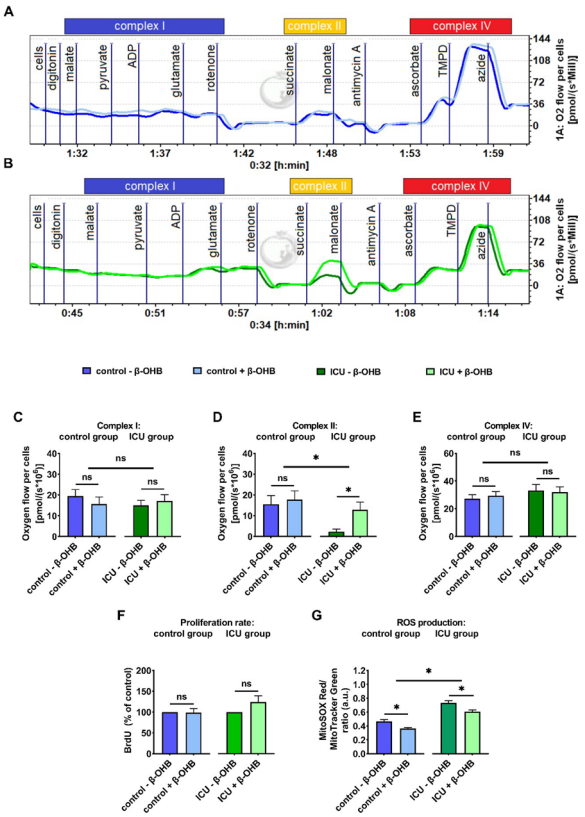

**Fig. 1 (abstract 000942)** Impact of β-OH-butyrate on skeletal muscle satellite cells. A) and B) Representative images of real-time oxygen flow measurement on high-resolution respirometry reflecting respiration linked to individual complexes of electron transport chain (complexes I, II and IV) normalized to 106 cells in control group and ICU group; C) respiration linked to complex I calculated as the oxygen flow after addition of 4 mM ADP and substrates for complex I (2.5 mM malate, 10 mM pyruvate and 15 mM of glutamate) minus the oxygen flow after addition of complex I inhibitor (rotenone). Data are presented as mean ± SEM and normalized to 106 cells; D) respiration linked to complex II calculated as the oxygen flow after addition of substrate for complex II (succinate) minus the oxygen flow after addition of complex II inhibitor (malonate). Data are presented as mean ± SEM and normalized to 106 cells; E) respiration linked to complex IV determined as the oxygen flow after addition of complex III inhibitor (antimycin A) and substrates for complex IV (ascorbate + TMPD) minus the oxygen flow after addition of inhibitor for complex IV (azide). Data are presented as mean ± SEM and normalized to 106 cells; F) proliferation rate demonstrating actively proliferating cells after staining with BrdU (= thymidine analogue incorporating into newly synthesized DNA of actively proliferating cells). Data are presented as mean ± SEM and normalized to control group (= medium with no β-OHB). G) ROS production determined as the fluorescence intensity of MitoSOXTM Red divided by fluorescence intensity of MitoTrackerTM Green (MitoSOXTM Red is a superoxide indicator specifically targeted to mitochondria, whilst MitoTrackerTM Green labels all mitochondria). Data are presented as mean ± SEM from values measured in 10 independent experiments ($n \geq 60$ cells per each condition). Note: *$p<0.05$, β-OHB = β-hydroxybutyrate, ADP = adenosine diphosphate, ICU = intensive care unit, ROS = reactive oxygen species, TMPD = N,N,N′,N′-tetramethyl-p-phenylenediamine dihydrochloride

### Spontaneous intra-cerebral hemorrhage in critically ill patients

S. Arenal López[1], S. Casanova Prieto[1], P. García Olivares[1], JM. Gomez[1], J. Lázaro Gonzalez[1], A. Blanco[1], M. Artabe[1], R. Ruiz Cacho[1]
[1]Intensive care unit, H.G.U Gregorio Marañón, Madrid, Spain
**Correspondence:** S. Arenal López
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000943

**Introduction:** Spontaneous intra-cerebral hemorrhage (ICH) comprises 10–15% of all strokes, is associated with high morbidity and mortality and requiring frequently the admission to intensive care units (ICU).
**Objectives:** To describe the characteristics of patients admitted to an intensive care unit in a third level hospital with diagnosis of spontaneous intra-cerebral hemorrhage.
**Methods:** Observational, retrospective study performed on patients with spontaneous ICH admitted to ICU of a third level hospital between 2022 and 2023 years. Epidemiological data, ICH risk factors, comorbidities, severity scores (APACHE II and ICH score), organic support, hemorrhage characteristics (including the presence of intraventricular involvement (IVH) and midline displacement), patient clinical characteristics and outcome defined by the modified Rankin score (mRS), were collected during ICU stay.
Descriptive data were reported as means with standard deviation (SD) for normally distributed continuous variables, medians with interquartile range (IQR) for non-normally distributed variables, and as percentages for categorical data.
**Results:** Eighty-nine patients were included. 63% were male, mean age was 60 ± 15 yrs and Charlson Comorbidity Index 0 (IQR 0–2). ICH risk factors were: hypertension 55%, dyslipidemia 36%, obesity 20%, diabetes 17%, smoker 26% and previous stroke 10%. Severity scores: APACHE II 21 ± 8, ICH score 3 (IQR 2–4), initial GCS 10 (5–14) and the neutrophil-to-lymphocyte ratio 5 (IQR 3–11). The arterial hypertensive was the most common cause of hemorrhage (65.2%), followed by arteriovenous malformation (15.7%), amyloid angiopathy (6.7%) and thrombocytopenia and/or coagulopathy (6.7%). The supratentorial location was the most frequently observed (75%), with brainstem involvement in 9% of patients. Over half of the patients (57%) exhibited midline shift on admission imaging, with a median of 3 mm (IQR 0–11). Intraventricular bleeding was associated with 66.3% of hemorrhages. Surgical intervention was performed in 24.7% of patients (hematoma evacuation and/or decompressive craniectomy). Ventricular drainage was placed in 28% of patients. During ICU stay, 85.4% required mechanical ventilation, and 36% underwent tracheostomy. Any ICU complications were observed in 80% of patients, highlighting: aspiration pneumonia (45%) and intracranial hypertension (25.8%). Other complications included rebleeding (10%), ventricular dysfunction (2.2%), and ARDS (2.2%). Nearly half of the patients (42.7%) experienced some infectious complication, highlighting: ventilator-associated pneumonia (23.6%), bloodstream (5.6%), tracheostomy-related bronchitis (17%), and other infections (23.6%). The ICU stay was 9 days (2–30) with a 51.7% of mortality and the hospital stay was 16 days (2–51) with a mortality of 55.1%
The functional status at discharge, assessed by the Rankin scale, indicated: asymptomatic (4.5%), non-disability (1.1%), mild disability (2.2%), moderate disability (12.4%), moderately severe disability (20.2%), severe disability (4.5%), and deceased (55.1%). Hence, 75.8% of patients exhibited an unfavorable outcome, defined as moderately severe disability, severe disability or death.
**Conclusions:** In our experience, the spontaneous intra-cerebral hemorrhage was mainly supratentorial location, with a significant volume of hematoma, frequently causing midline displacement and with reduced possibilities of surgical treatment. For these reasons, it is a devastating entity that is associated with severe disability and mortality.

**Topic:** Neurointensive care

### Skeletal muscle regeneration in survivors of critical illness

A. Krajcova[1], L. Genserova[1], M. Fric[1], J. Gojda[2], F. Duska[1]
[1]Department of Anaesthesia and Intensive Care Medicine, 3rd Faculty of Medicine UK, Prague, Czech Republic; [2]Department of Internal Medicine, 3rd Faculty of Medicine UK, Prague, Czech Republic
**Correspondence:** A. Krajcova
**Introduction:** Intensive care unit-acquired weakness (ICU-AW) is a common complication of critical illness associated with an increased morbidity and mortality [1]. *Skeletal muscle satellite cells* are considered to play a crucial role in muscle regeneration [2]. During injury, satellite cells are firstly activated from quiescent state, and subsequently they proliferate, differentiate and fuse into new myotubes (Fig. 1, A). In critically ill, dysfunction of these cells might lead to an impaired muscle regeneration and thus contribute to the development of muscle weakness.

**Objectives:** Our goal is to determine whether satellite cell number, their activation, differentiation or function is affected in critically ill with ICU-AW over time.
**Methods:** We enrolled 16 critically ill patients with MRC score < 48 points (= muscle weakness). We performed biopsy at "day 1" (< 72 h after admission to ICU) and after next 7 days. Muscle samples were frozen in isopentane for determination of satellite cell number (Pax 7 positive) in muscle fibers (type I and II). Satellite cells were isolated using magnetic beads technique to obtain the purified cell culture. Proliferation rate was observed at the different time points (after 24, 36, 48, 72 h) and determined using BrdU proliferation kit on fluorescence microscopy. The ability of cells to fuse into myotubes was determined after staining of cytoskeleton and nuclei and calculated as the % of nuclei located inside myotubes divided by the total number of nuclei. In both proliferating muscle cells and myotubes, Extracellular Flux Analyzer was used to measure oxygen consumption rate (OCR) at the baseline and after a sequential addition of ATP synthase inhibitor, uncoupler and complex III inhibitor which enabled to determine proton leak, ATP production, maximal respiratory capacity and non-mitochondrial respiration.
**Results:** All parameters were compared with sex- and age-matched metabolically healthy volunteers (n = 10). Number of satellite cells was significantly decreased in all types of muscle fibers. We also observed a tendency to decrease proliferation over time (Fig. 1, B). Fusion index was slightly decreased and highly variable between individual subjects (Fig. 1, D). The most significant result was decreased maximal respiratory capacity to 62% and 56% of control values in myotubes obtained from biopsies at day 1 and 7, respectively (Fig. 1, E).
**Conclusions:** Our pilot data show that the number of satellite cells is significantly decreased in muscle fibers obtained from critically ill with ICU-AW. Additionally, mitochondrial functions are affected in differentiated myotubes of critically ill with ICU-AW from biopsies obtained in the first week of ICU stay.

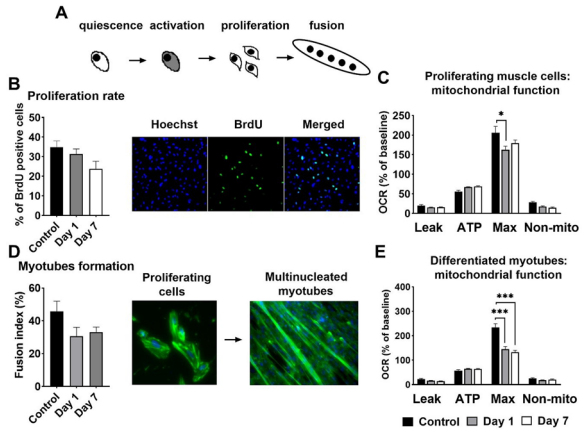

**Fig. 1 (abstract 000946)** **A)** Simplified scheme of satellite cell role in muscle regeneration. **B)** Proliferation rate calculated as the % of nuclei of proliferating cells accumulating BrdU (green)/ total number of cells (blue). *Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000947

**Introduction:** Intubation with an endotracheal tube (ETT) is a widely used technique in anesthesiology and intensive care units (1). After insertion, the ETT have to be secured to prevent its mobilization, unplanned extubation being specifically dreaded. To date, there are no formal recommendations about securing systems, and various practices are observed (2). A few studies have compared the resistance to extubation of these securing systems. Nevertheless, the forced extubation method was not rigorously standardized [manual traction (3) or counterweight release (4)]. In addition, forced extubation was defined as either an ETT mobilization with a magnitude chosen arbitrarily (4) or a modification of the securing system (5) (breakage, detachment). However, in real life practice, extubation does not systematically occur along with these events.
**Objectives:** The main objective of this prospective study with rigorous monitoring conditions was to compare the ability of widely used ETT securing systems to withstand a tensile stress simulating extubation on a mannequin. Four conditions of traction were evaluated: 2 speeds (5 and 50 cm/min) and 2 traction plans (sagittal and frontal).
**Methods:** This study was approved by the national Ethics Committee for Anesthesia and Critical Care Research on November 11, 2022 (IRB 00010254-2022-114). Along with the absence of securing system (control), 6 securing systems were assessed: 3 using cord (single, with knot, with adhesive band), 2 using adhesive elastic band (short 35 cm band and long 65 cm band) and, one standalone marketed device. A unique type of ETT was used (7.5 mm internal diameter). To be as realistic as possible, the mannequin's airway was pressurized using a mechanical ventilator. Extubation was defined as an abrupt loss of airway pressure (Fig. 1). ETT traction was performed till extubation by a tensile testing machine. The force required to achieve extubation was recorded. Five measurements per condition were collected. Results are presented as median and interquartile range [IQR]. Comparisons were performed with Wilcoxon test or Kruskal–Wallis test and Bonferroni post hoc analysis. A $p$-value < 0.05 was considered significant.
**Results:** In June 2023, 140 tests were completed.
Whatever the device, the force yielding extubation was lower when the traction was applied in the sagittal than in the frontal plan: 44 [26–57] and 108 [88–145] N ($p < 0.001$), respectively (pooled data). The traction speed had no significant influence: 65 [43–101] and 87 [35–117] N ($p = 0.4$) at 5 and 50 cm/min traction speed, respectively.
In the sagittal plan, unlike what was observed with other securing systems, the force yielding extubation was not different between both short and long adhesive elastic bands and the absence of securing systems. Forces yielding extubation with respect to the securing systems and the traction plan are detailed in Fig. 2.
**Conclusions:** Extubation is more easily observed when the ETT was pulled in the sagittal rather than the frontal plan and when it was secured with adhesive elastic bands. Other securing systems performed grossly similarly.

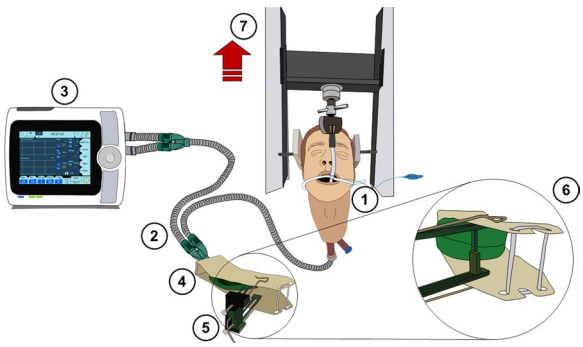

**Fig. 1 (abstract 000947)** The endotracheal tube, previously sealed, was inserted into the throat of the mannequin (1). It was then gripped to the tensile testing machine (2) and ETT cuff was inflated to 30 cm H2O (3). The ventilator was started to deliver a constant pressure of 20 cmH2O (4). The test lung (5) and the extensometer (6) were then under pressure (7). The traction could begin (8). As soon as the extubation occurred, the airway depressurized, immediately detected by the extensometer, and the test lung returned to its initial position (5). Thus, the precise moment marking extubation can be identified

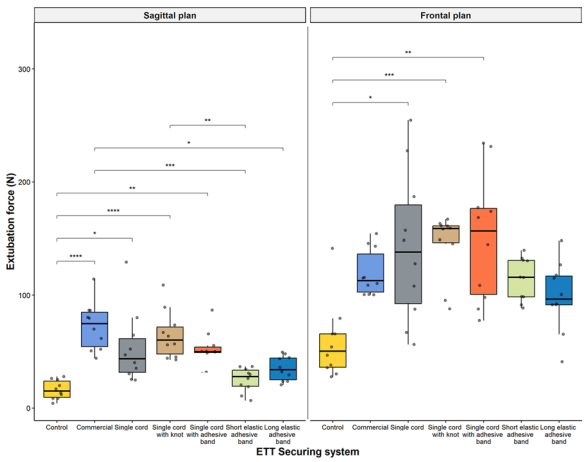

**Fig. 1 (abstract 000947)** Boxplots indicate the median value (thick black line) and the first and third quartile (thin black lines) of the force measurements at extubation with the respect of securing systems and traction plans. Comparisons were performed with Kruskal–Wallis test and Bonferroni post hoc analysis. ETT: endotracheal tube. *$p < 0.5$ **$p < 0.1$ ***$p < 0.01$ ****$p < 0.001$

### Central venous catheter and invasive mechanical ventilation as risk factor for catheter-related bloodstream infection and ventilator-associated pneumonia: a retrospective study

D. Faria Lopes[1], R. Assis[1], N. Catorze[1]
[1]Medicine Intensive Service, District Hospital of Abrantes, Abrantes, Portugal
**Correspondence:** D. Faria Lopes

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000948

**Introduction:** Catheter-related bloodstream infection (CRBSI) and ventilator-associated pneumonia (VAP) are linked to critical and possibly fatal outcome of intensive care unit (ICU) stay. Use of central venous catheter (CVC) and invasive mechanical ventilation bundles can considerably reduce CRBSI and VAP rates in hospitalized patients. However, despite widespread adoption of these bundles in hospitals worldwide, these nosocomial infections remain prevalent. In our case, we base our routine on the Portugal's National Health Service clinical guidelines and on the ERS/ESICM/ESCMID/ALAT guidelines.
**Objectives:** The aim of the present study was to determine whether longer duration of CVCs placement and mechanical invasive ventilation are related to CRBSI and VAP in hospitalized adults, despite the implementation of preventive bundles.
**Methods:** A retrospective study was performed among hospitalized patients who had a CVC and/or were invasively ventilated during a 6-month period (July 2022–December 2022) and developed CRBSI and VAP. Age, gender, SOFA, APACHE II, SAPS II, IMV days, CVC placement duration and length of stay were recorded. Two groups were made: group A, 2–10 days, and group B, > 10 days of IMV/CVC placement, that were compared regarding VAP and CRBSI development. We also evaluated whether the development of VAP and CRBSI events was associated with the length of stay in ICU. A $p$-value of $\leq 0.05$ was considered as statistically significant.
**Results:** We enrolled 204 patients with CVC placement, 115 (56.37%) males, mean age of 65,14 ± 17,73 years: 180 in group A, and 24 in group B. CRBSI was found in 6,67% of patients from group A, and in 29.17% of patients from group B ($p = 0{,}0004$). We also enrolled 61 patients on IMV, 36 (59,02%) males, mean age of 63.44 ± 14.64 years: 51 in group A and 10 in group B. VAP was found in 33.33% of patients from group A and in 70% of patients from group B ($p = 0.0299$). Patients who developed AVP and CRBSI events had an increased length of stay in ICU, $p = 0.00010$ and $p = 0.00012$, respectively.
**Conclusions:** Our findings suggest that duration of CVC placement and the number of days intubated remain important risk factors for CRBSIs and VAPs in ICU patients, even after the adoption of the aforementioned prevention bundles. Our results were below the expected, when compared with other European ICU numbers, making us believe that we need do audit bundles compliance. The development of CRBSIs and VAP contributed to worst outcomes like the increase in length of stay in ICU as we expected.

### Implementation of inhaled isoflurane for sedation in a district general hospital intensive care unit: what are the benefits?

S. Dempsey[1], S. Chokkalingam[1], T. Furniss[1]
[1]Critical Care, Warrington Hospital, Warrington, United Kingdom
**Correspondence:** S. Dempsey

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000950

**Introduction:** Sedation in intensive care is classically achieved with intravenous sedative agents, most commonly propofol with an opioid analgesic. However, in some patients, this combination is ineffective at producing adequate sedation to facilitate critical care interventions. Prior to 2023, our 18-bed unit in a district general hospital most commonly used intravenous midazolam as an alternative. Though effective, midazolam has significant downsides compared to propofol when used for sedation in ICU, including increased delirium [1], reduced gut motility [2,3] and prolonged effect after cessation of therapy [4]. As such, we sought to implement inhaled isoflurane, via a Sedaconda device, as an alternative sedation option for our ICU patients.
**Objectives:** We aimed to analyse the first six months of isoflurane use on our ICU and compare to our previous experience with IV midazolam prior to our implementation of inhaled sedation.
**Methods:** Data were collected via retrospective review of admission charts and medical notes of patients identified by a search of electronic isoflurane prescriptions. Where indication for isoflurane was not documented, this was provided by interpretation of the available clinical information at the time of data collection.
**Results:** 19 patients received isoflurane in our first 6 months of use. For 15 patients, the indication was difficulty with achieving adequate sedation with first-line sedatives, while 4 had alternative indications, such as short sedation duration ($n = 2$) and as a bronchodilator in obstructive airways disease ($n = 2$). The average length of isoflurane use was 5.4 days, with 6 patients remaining on isoflurane for 7 days or more. The incidence of side effects was low. Only 2/19 had documented delirium following sedation, and 1 patient developed paralytic ileus, who notably had also received IV midazolam during admission. 9 patients were changed to alternative sedative agents

before sedation was ultimately discontinued, including 3 who were switched to IV midazolam infusions.
**Conclusions:** We successfully implemented a new technology into regular use on our ICU, giving an alternative sedation option aside from intravenous agents. While initially introduced for "difficult to sedate" patients, this also allowed us to utilise isoflurane for its other characteristics, such as its bronchodilator effect [5] and shorter wake-up times [6]. Side effects were relatively rare with isoflurane, with delirium and paralytic ileus occurring infrequently compared to our previous experience with midazolam infusions. Isoflurane was often changed to an alternative sedative prior to sedation being discontinued, possibly reducing the benefits of its use. The reason for these changes was not clear. Whilst we cannot rule out undocumented inadequate or adverse responses to isoflurane, this could simply represent need for further staff training to improve familiarity with this new technology, or that the initial indication for isoflurane had resolved.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000951

**Introduction:** The impact of ICU-acquired weakness (ICU-AW) can be reduced by early physical rehabilitation programs that start from when the patient is still at the ICU. Therefore, detecting those patients with a higher risk or degree of muscle impairment remains a challenge. To date, optical technologies, such as near-infrared-spectroscopy (NIRS), have demonstrated their value in the evaluation of the health of the capillaries and microvasculature in muscles. We hypothesized that alterations in the microvasculature of the skeletal muscle would correlate with the degree of muscle weakness.
**Objectives:** To assess the relationship between ICU-acquired weakness (ICU-AW) and the microcirculatory status of the muscle.
**Methods:** Single-centre prospective observational study in a general ICU. Patients with > 48 h of mechanical ventilation (MV) were included, excluding cognitive and/or neurological disorders prior to or at admission. Muscle strength was assessed with dynamometry and the Medical Research Council sum score (MRC), and the microcirculatory status of the brachioradialis muscle measured non-invasively with photonic technology (Vascovid System) at awakening, ICU discharge, hospital discharge and at 6 months. Adding the 6-min walk test (6MWT) at 6 months. The Vascovid system quantifies tissue oxygen saturation (StO2) and microvascular flow (BFi). A transient ischemic test was used to obtain dynamic microvascular parameters, such as tissue metabolism and microvascular reactivity. ICU-AW was defined as MRC < 48, and altered 6MWT at < 400 m. Correlation analysis between strength and microcirculation was performed, as well as comparative and evolutionary analysis for the presence of ICU-AW and/or 6MWT alteration.
**Results:** We included a total of 57 ICU patients. Mean age was 63 ± 16 years old. The main cause of ICU admission was acute respiratory failure. At inclusion, 68% of the patients showed ICU-AW, which was associated with lower handgrip performance. The microcirculatory status was significantly different according to the presence of ICU-AW, in terms of oxygenation, microvascular reactivity, and baseline microvascular blood flow. Both MRC and the handgrip evaluation improved over time (Figs. 1 and 2). After 6 months, no differences in the MRC score and the handgrip evaluation were observed between those patients initially diagnosed with ICU-AW and those with preserved strength at inclusion, and no significant differences in microvascular parameters were observed over time.
At 6 months, 38% of patients had limited functional capacity, evaluated by the 6MWT. While MRC and handgrip values at inclusion were not different, microvascular oxygenation impairments in the first evaluation were associated to altered 6MWD (Fig. 3). The best predictive association was observed with StO2 values at inclusion. A ROC analysis exploring the predictive value of StO2 in the first examination for detecting a severely impaired 6-min walking test at 6 months, showed an AUC of 0.88 ($p = 0.001$).
**Conclusions:** We studied a critically ill population with high incidence of ICU-AW. Microcirculatory differences were detected according to the presence of ICU-AW. After a 6-month follow-up, strength parameters had recovered, and they did not differ between ICU-AW and no-ICU-AW at inclusion. However, severe alterations in functional exercise capacity were observed in almost 40% of the patients, which was not associated to a previous condition of ICU-AW. While strength parameters were not useful in predicting the observed functional capacity, microcirculatory parameters at inclusion, and mostly tissue oxygenation parameters, were associated to poor functional performance. The addition of microcirculatory evaluation early, in the recovery phase of the ICU stay, might help detecting those patients at risk of poor functional outcomes after the critical illness.

### Lactate as a predictor of citrate accumulation in critically ill patients undergoing continuous renal replacement therapy

M. M. Müller[1], P. D. Wendel Garcia[1], A. Weber[2], R. Schuepbach[1], S. David[1]

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000952

**Introduction:** Regional citrate anticoagulation (RCA) is the preferred option for anticoagulation in continuous renal replacement therapy (CRRT) due to its superior efficacy and reduced risk of bleeding [1]. Nevertheless, the use of RCA in patients with impaired organ perfusion is debated because of the potential for decreased citrate metabolism leading to citrate accumulation and subsequent toxicity. To date, only a limited number of studies have investigated the likelihood of citrate accumulation based on lactate levels as surrogate for a decreased metabolism capacity to choose the best anticoagulation strategy [2].

**Objectives:**

1 To investigate the association between plasma lactate levels prior to the initiation of CRRT and the risk of citrate accumulation.
2 To predict the likelihood of citrate accumulation based on lactate levels at baseline.

**Methods:** This single-center retrospective analysis enrolled ICU patients admitted between January 2018 and December 2021, who required CRRT with RCA. Baseline lactate levels just before CRRT initiation were selected as the predictor variable, while the occurrence of a calcium quotient (ratio of albumin-corrected total calcium to ionized calcium) $\geq 2.5$ served as the primary endpoint, suggesting citrate accumulation. Follow-up was two weeks or until the discontinuation of CRRT. Logistic regression models were used to investigate the association between lactate and citrate accumulation. Predicted probabilities to reach the primary endpoint were calculated for various lactate levels and graphically represented to identify potential threshold values for accurately forecasting citrate accumulation.

**Results:** Electronic documentation of CRRT was available for 878 patients. A calcium quotient of $\geq 2.5$ was observed at least once in 170 individuals (19.4%) during the two-week follow-up period and occurred on average 16 [IQR 8–96] hours after onset of CRRT. The median lactate levels at the start of the filter were overall 1.7 [IQR 1–2.6] mmol/L, 1.5 [IQR 1.0–2.8] mmol/L for patients without citrate accumulation and 3.25 [IQR 1.6–8.6] mmol/L for individuals with signs of citrate accumulation. Logistic regression models identified a significant association between lactate levels and the risk of citrate accumulation, indicating that the odds ratio of developing citrate accumulation increased by 1.19 [95% CI 1.15–1.24] with every 1 mmol/L increase in lactate levels ($p < 0.001$). Figure A presents the probabilities of citrate accumulation as a function of different lactate levels.

**Conclusions:** This investigation underscores lactate's potential as a predictive marker for citrate accumulation in critically ill patients undergoing CRRT with RCA. Additional studies from multiple sites are warranted to validate these results prospectively and to consolidate exact thresholds for precise risk assessment.

## minoglycosides in septic patients with impaired renal function

K. Parisi[1], V. Tsolaki[1], T. Amanatidis[1], I. E. Dimeas[2], M. E. Papadonta[1], K. Deskata[1], E. Asprodini[3], E. Zakynthinos[1]
[1]Intensive care, Larissa General University Hospital, Larissa, Greece; [2]Respiratory Department, Larissa General University Hospital, Larissa, Greece; [3]Laboratory of Pharmacology, Faculty of Medicine, University of Thessaly, Larissa, Greece
**Correspondence:** K. Parisi

**Introduction:** Sepsis is one of the main causes of mortality and morbidity in an ICU setting, while the responsible microorganisms most frequently isolated are multidrug-resistant Gram-negative bacteria. Aminoglycosides (AG) seem to be particularly effective in dealing with these microbes, however their potential toxicity, especially nephrotoxicity, often makes them an unsuitable treatment option.

**Objectives:** The purpose of this study was to achieve the most frequent administration interval of aminoglycosides during septic shock treatment with the complementary use of CVVHDF for effective clearance, in order to minimize toxicity after achieving a therapeutic serum concentration.
**Methods:** This is a randomized controlled study (randomization 2:1) which is conducted in the University Hospital of Larissa, Greece, and the data were collected between April 2023 and March 2024 (NCT06226441). Patients are included if they present with sepsis/septic shock, have impaired renal function (GFR $\leq$ 40 ml/min/1.73m$^2$) and are treated with an AG according to the treating physician. The patients are divided in two groups, according to the receipt of CVVHDF therapy (CVVHDF group-control group). CVVHDF is started despite the lack of absolute criteria for renal replacement therapy. The recorded data include: demographics, AG trough levels daily, the AG dose interval, the total AG doses received in each group. Comparisons between the groups were performed using Mann–Whitney *U* test or *t*-test, where applicable.
**Results:** Sixteen patients were included in the study, all intubated; 11 patients comprised the CVVHDF group and 5 the control group. The median age in CVVHDF group was 70 (51,77) vs 71 (71,78), $P=0.279$, the mean APACHE II score was 20 $\pm$ 2.1 vs 20 $\pm$ 2.9, $P=0.390$ and the mean sofa score was 8.6 $\pm$ 1.2 vs 10.4 $\pm$ 1.12, $P=0.197$. Day 2 and Day 3 AG trough levels were lower in the intervention group (D2, 4,5 $\pm$ 1,3 vs 7.1 $\pm$ 1.7 mg/L, $P=0{,}01$ and D3, 2 $\pm$ 0.88 vs 5 $\pm$ 0.53, $P<0{,}001$, respectively). Trough levels on days 4–9 did not differ between the study groups ( D4, 3.4 mg/L (1.6,12) vs 3.3 mg/L (2.8,5), $P=0.91$; D5, 2.2 mg/L (1.5,6) vs 2.5 mg/L (1.2,3.7) $P=0.841$; D6 3.7 mg/L $\pm$ 1.2 vs 6.1 mg/L $\pm$ 3.7, $P=0.158$; D7 3 mg/L $\pm$ 1.6 vs 5.5 mg/L $\pm$ 2.5, $P=0.09$; D8 3.5 mg/L $\pm$ 2.8 vs 4.5 mg/L $\pm$ 2; D9 5.1 mg/L $\pm$ 5.7 vs 4.2 mg/L $\pm$ 1.5, $P=0.722$). The mean dosing interval to the second and third dose was significant lower for the intervention group (50 $\pm$ 10 vs 96 $\pm$ 44 h, $P=0{,}006$ and 47 $\pm$ 14 vs 114 $\pm$ 30, $P<0{,}001$, respectively). The total dosing interval was significantly lower for the intervention group (48 $\pm$ 13 vs 100 $\pm$ 37 h, $P<0.001$). The total number of AG doses administered until day 7 was 3 (2,4) vs 2 (2,2), $P=0.002$. The number of doses received/total duration of treatment was 59% vs 30% ($P<0.001$), respectively.
**Conclusions:** Using CVVHDF concurrently with AG administration in patients with sepsis/septic shock and impaired renal function can provide an effective method for administering these drugs at shorter intervals.

## The role of echocardiographic measurement of ventriculoarterial coupling (RVPAC) in critically ill patients

U. Ljung-Faxen[1], O. Cavefors[2], J. Holmqvist[2], R. Björn[3], J. Oras[2]
[1]Perioperative Medicine and Intensive Care, Karolinska Universitetssjukhuset, Stockholm, Sweden; [2]Anesthesiology and intensive care medicine, Sahlgrenska University Hospital, Gothenburg, Sweden; [3]Department of cardiology, Sahlgrenska Universitetssjukhuset, Gothenburg, Sweden
**Correspondence:** J. Oras
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000955

**Introduction:** Right ventricular (RV) dysfunction is common and associated with worse outcome in critically ill patients. The right heart's ability to adapt to increased afterload with preserved ventriculoarterial coupling (RVPAC) is highly prognostic in non-ICU-patients but its role in the critically ill is still unclear. Due to the complexity of invasively measured RVPAC, the non-invasive surrogate tricuspid annular plane systolic excursion (TAPSE)/tricuspid regurgitation velocity (TRV) measured by echocardiography has been studied in various patient groups but the feasibility and prognostic value in ICU-patients is not fully understood.
**Objectives:** The aim was to assess RVPAC through TAPSE/TRV in a mixed ICU cohort in terms of feasibility, distribution, and prognostic significance.
**Methods:** This is a secondary analysis of a prospective echocardiographic study in a mixed population of critically ill patients primarily focusing on LV dysfunction[1]. Echocardiography was performed within 24 h from admission after initial resuscitation. Clinical data were recorded on admission and at time of echo. RV function was assessed through TAPSE, fractional area change (FRAC) and tissue Doppler in the RV free wall (RV S´). To estimate RVPAC TAPSE was divided by TRV. Since there are no accepted cut-offs of TAPSE/TRV patients were divided into the lowest and upper three quartiles.
**Results:** A total of 411 patients were included in the parent study of whom 266 (65%) had measurements of both TAPSE and TRV. The mean value of TAPSE was 2.1 $\pm$ 0.6 cm and for TRV 2.51 $\pm$ 0.46 m/s. The mean value of TAPSE/TRV was 0.88 $\pm$ 0.31 (median 0.84, interquartile range 0.67–1.10) ranging from 0.22 to 1.80. The cut-off for the lowest quartile was 0.67. Patients in the lowest quartile of RVPAC were older, had more often a history of hypertension, cardiac and pulmonary disease. Sepsis, a cardiovascular or respiratory reason for admission were more common. They had a higher heart rate, lower ejection fraction and displayed more impaired RV function with lower TAPSE, RV S´ and FRAC. Values of TRV were higher and pulmonary acceleration times lower.
There was a strong positive correlation between TAPSE and TAPSE/TRV ($R^2=0.719$) and a moderate inverse correlation between TRV and TAPSE/TRV ($R^2=-0.380$).
In a logistic regression analysis, echocardiographic parameters of RV function (TAPSE, FRAC, RV S´) and TAPSE/TRV were associated with an increased risk of death at 90 days. However, only TAPSE/TRV (OR 0.22 [0.06–0.90], $p=0.035$) and RV S´ (OR 0.89 [0.79–0.99], $p=0.037$) were associated with an increased risk of death after adjustment for SAPS 3, age and left ventricular ejection fraction.

**Conclusions:** In conclusion, RVPAC measured noninvasively as TAPSE/TRV is a promising and feasible echocardiographic parameter in critically ill patients. More impaired RVPAC is associated with LV dysfunction, cardiac, respiratory disease as well as sepsis. Despite the correlation between RVPAC and TAPSE, RVPAC may be a better prognostic marker than TAPSE and TRV alone. The value of RVPAC as a serial marker to evaluate treatment response remains to be elucidated.

### Very elderly trauma patients: the experience of a tertiary hospital ICU

M. P. Vidal[1], G. C. Almeida[1], I. Santos[1], A. Santos[1], P. Casanova[1], P. Martins[1]
[1]Intensive Care Unit, Unidade Local de Saúde de Coimbra—Hospitais da Universidade, Coimbra, Portugal

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000955

**Introduction:** Older adults constitute a more prominent population of patients admitted to the ICU as life expectancy rises. Age itself does not constitute a single criterion, but it is still unclear under what conditions older patients may benefit from ICU admission. The elderly suffer more severe consequences from traumatic injuries compared with the young, presenting unique challenges for physicians.
**Objectives:** Our goals were to analyze the outcomes at ICU discharge, 28-day and 90-day among very elderly trauma patients admitted to a tertiary hospital in a time span of 30 months.
**Methods:** This study was a was a retrospective review of trauma patients aged ≥ 80 years old admitted to the ICU between January 2021–June 2023. Statistical analysis was performed with logistic regression to analyze variables related to mortality. A $p$-value < 0.05 was considered statistically significant.
**Results:** In the 30 months analyzed, there were a total of 363 trauma patients admitted to the ICU. Of them, 39 were aged ≥ 80 years old (10.7%). The mean patient age was 84.6 ± 3.8 years. 17 patients (43.6%) suffered from polytrauma. Most frequent injury mechanism was fall from own height (15 patients, 38.5%), followed by road traffic accidents and fall from height 3 ≥ meters (8 patients each, 20.5%). Trauma brain injury was the most common injury, present in 23 patients (59%). The mean ISS was 37.28 ± 18.12, with a mean ICU stay of 15.5 ± 11.98 days and a mean time of mechanical invasive ventilation of 13.98 ± 11.80 days.
The probability of survival based on the TRISS methodology was 52.25 ± 31.51%. The ICU mortality rate was 25.64%, with an in-hospital mortality rate of 33.33% and a 3-month mortality rate of 61.76%.
A statistically significant relationship was found between the presence of polytrauma and mortality at 28 days ($p$ value < 0.05). No statistically significant relationship was found between the presence of isolated trauma (TBI, thoracic, abdominal, or pelvic) or hemorrhagic shock with ICU, 28-day and 90-day mortality.
Logistic regression analysis confirmed that previously anticoagulated patients had an increased ICU mortality risk (odds ratio, 6.55; confidence interval, 1.17–36.60; $p$-value < 0.05) and 28-day mortality risk (odds ratio, 4.44; confidence interval, 1.07–18.35; $p$-value < 0.05).
ICU mortality was related to limitation of life sustaining therapy in 4 patients (40%), and to brain death in 3 patients (30%).
**Conclusions:** The ICU mortality in the very elderly patients was lower than predicted based on the severity of injury. Polytrauma was associated with increased 28-day mortality, but not with ICU-mortality and 90-day mortality. Previous anticoagulation was associated with increased risk of ICU and 28-day mortality. ICU mortality is mostly associated with limitation of life sustaining therapy and brain death. More studies are needed to evaluate outcomes in the very elderly trauma patients, particularly at the early follow-up setting.

### Characteristics and outcomes among patients with stress ulcer after trauma: a nested case–control study in Japan

H. Iriyama[1], A. Komori[1], T. Kainoh[1], K. Nagata[1], T. Abe[1]
[1]Emergency and Critical Care Medicine, Tsukuba Memorial Hospital, 1187–299 Kaname, Tsukuba, Ibaraki, Japan, Tsukuba, Japan
**Correspondence:** H. Iriyama
**Introduction:** Stress ulceration is a major complication among patients admitted to the intensive care unit after trauma. However, there have been few prior studies investigating the characteristics and outcomes of patients with stress ulcers within the general trauma population.

**Objectives:** Our aim was to compare the characteristics and outcomes of patients with and without stress ulcers admitted to the intensive care unit after severe trauma.
**Methods:** This is a nested case–control study using the Japan Trauma Data Bank (JTDB) from 2004 to 2017. The JTDB is a nationwide trauma registry in Japan. We included patients who aged ≥ 18 years old; had blunt or penetrate trauma; underwent mechanical ventilation in the emergency department; admitted to the intensive care unit; and survived for more than 3 days after hospital admission. A nested case–control study (1:5) was conducted using propensity score matching. The variables included in the propensity score were age, gender, number of comorbidities, mechanism of injury, emergency medical service (helicopter or ambulance), vital signs at emergency department, and Injury Severity Score. Then, we performed descriptive analyses comparing patients with and without stress ulcers, using the Wilcoxon signed-rank and Chi-square tests for continuous and categorical variables, respectively.
**Results:** Among the entries in the JTDB database, we identified 186 patients with stress ulcers and 930 patients without, selected through propensity score matching. The median age was 59 (interquartile range (IQR): 41–72), and male was 794/1,116 (71.1%). Blunt trauma was 1,031 (92.4%) and penetrating trauma was 85 (7.6%), respectively. The median Injury Severity Score was 25 (IQR: 16–33).
Patients with stress ulcers had chronic heart failure and cirrhosis more than those without stress ulcers (3.2% vs. 1.0% [$p = 0.03$], 3.2% vs. 0.8% [$p = 0.01$], respectively). There was no consistent trauma pattern observed in the Abbreviated Injury Scale scores between the two groups. Notably, patients with stress ulcers underwent craniostomy as the initial surgical procedure more frequently than those without stress ulcers (9.1% vs. 4.5% [$p = 0.02$]). Several concomitant complications occurred more frequently in patients with stress ulcers than those without stress ulcers. Such complications included acute respiratory distress syndrome (9.7% vs. 2.9% [$p < 0.001$]), acute renal failure (5.4% vs. 1.7% [$p = 0.006$]), disseminated intravascular coagulation (22.6% vs. 5.3% [$p < 0.001$]), wound infection (18.8% vs. 4.1% [$p < 0.001$]), and sepsis (10.8% vs. 3.7% [$p < 0.001$]). However, in-hospital mortality did not differ significantly between the two groups (10.2% vs. 11.7% [$p = 0.66$]). Patients with stress ulcers had longer hospital stays compared to those without (66 [IQR: 32–120] days vs. 33 [IQR: 16–58] days [$p < 0.001$]).
**Conclusions:** While no consistent trauma pattern was observed among patients with stress ulcers after trauma; they did undergo craniostomy as the emergency surgical procedure more frequently than those without stress ulcers. Additionally, they had a higher incidence of several concomitant complications and longer hospital stays compared to those without stress ulcers.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000957

**Introduction:** In recent years, we have introduced technology in the ICU that transmits videos of ventilator screens to physicians' mobile phones. At the request of physicians who have used the system, we have added an application that performs automated interpretation of the recorded ventilator screen video and sends it to ICU physicians' mobile phones.
**Objectives:** To develop a tool which automatically interprets mechanical ventilation data from video recordings of ventilator screens.
**Methods:** Detection of ventilation parameters from the video and digitalization of pressure and flow graphs were programmed in MATLAB R2023b.
The output data from MATLAB is further analysed and presented in spreadsheet (Numbers 13.2., Apple) using its standard program functions. The graphs are digitalised and can be edited in spreadsheet using scroll cursors.
The spreadsheet is supplemented with an assessment of the presence of dyssynchronies and commentary manually.
The created worksheet, comprising two sheets (Fig. 1a, Fig. 1b), is shared with the doctors on their iPhones via iCloud drive.
**Results:** We have developed an app evaluating ventilator screens that is available on ICU physicians' mobile phones.
The resulting annotation includes:
- Automatic detection of ventilatory parameters from ventilator screen videos. Detected parameters are digitalised and exported in a spreadsheet format. Ventilation parameters are ordered, out-of-limit values are marked in red, Fig. 1a.
-Digitalised screen graphs are on a separate sheet with the capability to edit the data using the scroll cursor, Fig. 1b.
-Evaluation of the presence of dyssynchronies and commentary.
Conclusions: We have developed software for automatic clinical evaluation of the ventilation screen. The assessment is sent to the user's mobile phone. The expert system can potentially improve the level of mechanical ventilation in the ICU, saves physicians' time. In addition, it is an excellent educational tool.

### Enhancing protection for healthcare workers against respiratory infections: efficiency improvements in novel protective hoods through computational fluid dynamics analysis

J. Y. Hong[1], K. S. Sunb[2]

**Introduction:** The recent outbreaks of respiratory viruses such as SARS-CoV-2 highlight the need for improved protection for healthcare workers (HCWs), especially during aerosol-generating procedures (AGPs) like CPR, intubation, and suctioning. Current personal protective equipment (PPE) is not fully effective against aerosol transmission and can hinder medical procedures. This study introduces a protective hood optimized with Computational Fluid Dynamics (CFD) analysis to better protect HCWs by minimizing aerosol dispersion.
**Methods:** Our study utilized Computational Fluid Dynamics (CFD) analysis to design and optimize a novel protective hood, focusing on minimizing aerosol dispersion within medical environments. A critical step in our methodology was generating an internal concentration of PAO aerosol at 30 µg/L and assessing leakage using a photometer specific for PAO particles. Notably, the hood's open side was divided into nine segments to accurately identify the areas most susceptible to leakage. This comprehensive approach enabled us to determine the primary leakage points, which, intriguingly, were found to be near the suction area of the hood. To validate the CFD predictions, we conducted practical tests to compare the simulated leakage locations against actual leakage observations, ensuring that our design modifications were grounded in both theoretical and empirical evidence. This iterative process of analysis and testing was pivotal in refining the hood's design to effectively minimize leakage and enhance safety for healthcare workers.
**Results:** Leak tests showed that, even with the hood partially open, PAO particle leakage was less than 0.03%, with this minimal leakage contained within 10 s. Moreover, all generated aerosols within the hood were removed within 30 s, demonstrating a significant improvement over closed-system alternatives which took over 2 min for similar aerosol clearance, even at higher negative pressures exceeding − 50 Pa.
We identified differences in the primary leakage points based on the direction of aerosol generation (simulated coughing with PAO particles) and suction. Notably, the direction of simulated coughing and the suctioning action significantly influenced these leakage points. Leakage did not predominantly occur near the aerosol source or suction inlet; instead, it shifted due to complex airflow dynamics, including the effects of coughing, suction, and airflow along the walls. This led to unexpected leakage locations, underscoring the intricate interplay of airflow within the protective hood. The actual observed leakage patterns aligned with the predictions made by the CFD simulations, demonstrating the nuanced impact of cough and suction directions on aerosol containment.
This approach facilitated the accurate adjustment of the hood's airflow dynamics, enabling the establishment of an effective negative pressure environment that promotes swift aerosol clearance. The comparison between CFD simulations and actual performance confirmed the design's efficiency in reducing aerosol leakage.
Furthermore, the insights gained from the study underscore the importance of understanding the internal gas dynamics within the hood not only for enhancing device efficiency but also for minimizing the impact on patients. The principles derived from the hood's design and optimization process have potential applications beyond this specific device. This methodology could inform the development and refinement of various infection control measures within healthcare environments, emphasizing the critical role of precise airflow management in safeguarding both healthcare workers and patients.
**Conclusions:** This study highlights the effectiveness of using Computational Fluid Dynamics (CFD) analysis for optimizing protective hood designs to enhance healthcare safety by efficiently managing airflow and minimizing aerosol leakage. Insights into internal airflow dynamics emphasize the importance of precise design in reducing patient and healthcare worker exposure to airborne pathogens. The methodologies developed and validated here offer a foundational approach for improving infection control measures across various healthcare settings.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000960

**Introduction:** The triazole antifungal agent isavuconazole is a recommended treatment for invasive pulmonary aspergillosis (IPA) (1). While phase-III study results suggested that routine therapeutic drug monitoring of isavuconazole might not be required (2), more recent analyses including patients supported by extracorporeal membrane oxygenation (ECMO), observed a higher degree of variability and frequent underdosing (3). Further data are necessary to evaluate drug monitoring, time-dependent course of serum trough levels and potentially necessary dose adjustments in the specific critically ill patient population on ECMO.

**Objectives:** Retrospective analysis of isavuconazole plasma trough levels and dose adjustments during extracorporeal membrane oxygenation.
**Methods:** All adult critically ill patients treated at the University Hospital Zurich receiving isavuconazole and had a documented plasma level during ECMO support were included. Based on the literature, we defined targeted therapeutic thresholds at a plasma concentration > 1 mg/L in the first 7 days, followed by > 2.5 mg/L thereafter (4, 5).
**Results:** Out of 48 screened individuals, 16 patients were included in the analysis. Patients had a median Simplified Acute Physiology Score II of 47 [IQR 36, 58], were mostly female ($n = 9$, 56%) and their median age was 52 [IQR 39, 62] years. All patients were mechanically ventilated and 7 (44%) patients received kidney replacement therapy. Indication for isavuconazole was proven, probable and possible invasive pulmonary aspergillosis in 1 (6%), 6 (38%) and 7 (44%) patients, respectively. Two patients (12%) had another fungal infection. Isavuconazole was newly started in 14 (88%) patients during ECMO support with a loading dose of 6 × 200 mg over two days, followed by a maintenance dose of 200 mg daily. In two (12%) patients with preexisting isavuconazole, maintenance dose was administered without loading. Overall median isavuconazole trough plasma level was 1.9 [range 0.3–5.5] mg/L. Early isavuconazole levels (day 3 to 7) were available in 7 patients, median 1.2 [IQR 0.8, 1.5] mg/L. In these periods, two patients (29%) had plasma levels ≤ 1 mg/L. After > 7 days of therapy patient median trough level of isavuconazole was 1.9 [IQR 1.2, 2.7] mg/L. Levels ≤ 1 mg/L and ≤ 2.5 mg/L were registered in 6 (46%) and 12 (92%) patients after 7 days. Dose adjustment was performed in 6 (38%) patients.
**Conclusions:** Isavuconazole target plasma levels are often not achieved in critically ill patients with ECMO support. Dose adjustment towards higher doses was necessary in over one-third of patients, without any dose reduction. Thus, routine therapeutic drug monitoring and evaluation of higher doses in specific patient populations such as the collective on ECMO support seems warranted.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000962

**Introduction:** Patients classified as very elderly, 80 years or older, are a growing population in Brazil and worldwide. Understanding the peculiarities of this subgroup is essential to assess the benefit of admissions to intensive care units (ICU), aiming for proper resource allocation and the provision of the best hospital care (1–5).
**Objectives:** The objective of this study was to identify clinical variables that were related to hospital mortality of very elderly patients admitted to the ICU of a private tertiary hospital in Belo Horizonte, Brazil. And additionally, to develop a prognostic mortality model for this specific population according to different clinical profiles.
**Methods:** We conducted a single-center, observational, and retrospective study that included 1225 patients aged 80 years or older admitted to the ICU between January 1, 2019, to July 31, 2021, and registered in the Epimed database.
The primary outcome, hospital mortality, was calculated using point estimation and a 95% confidence interval (6).
Subsequently, univariate analyses were conducted to identify factors associated with hospital mortality. Bilateral hypothesis tests were performed at a significance level of 5% ($\alpha = 0.05$). Categorical variables were evaluated using Pearson's Chi-square test or exact tests (when necessary), while quantitative variables were assessed using the non-parametric Mann–Whitney test (7).
In the final stage, multivariate analysis was performed using logistic regression for hospital mortality. Variables included in the model were selected based on univariate analysis (p-value ≤ 0.25). Organizing a database of 1225 patients into two groups (75% for model construction and 25% for validation), a ROC curve with good predictive capacity was obtained (Fig. 1) (8).
**Results:** In univariate analysis, age was not a significant risk factor for hospital mortality (p = 0.61). Based on multivariate analysis, age, blood transfusion, Charlson Comorbidity Index, female sex, Simplified Acute Physiologic Score (SAPS 3), Sequential Organ Failure Assessment Score (SOFA), and tobacco consumption ($p = 0.006$) were identified as risk factors for hospital mortality in the population studied (Table 1).
From the logistic regression model, it was possible to simulate expected mortality according to 64 different patient profiles. The calculation was performed by varying the age from 80 to 110 years, with two levels for each explanatory variable (tobacco use, blood transfusion, gender, Charlson Comorbidity Index, SOFA Score, and SAPS 3). For quantitative variables, the low level was defined by the median and the high level by the 90th percentile. For each of the 64 patient types, graphs with mortality simulations were generated. By evaluating the extremes of risk, we analysed patients with high and low mortality risk, comparing other variables to age (Fig. 2).
**Conclusions:** Chronological age should not be used as an isolated parameter for medical decision-making, as it becomes a risk factor for mortality when associated with comorbidities, severity of acute illness, increased frailty, and decreased functionality. Thus, the importance of studies to validate prognostic scores in elderly patients admitted to ICU is highlighted.

**Table 1 (abstract 000962)** Multivariate analysis to identify factors associated with hospital motility in patients aged 80 years or older admitted to the ICU

| Variable | Regression Coefficient | Standard Error | Odds Ratio | P-value |
|---|---|---|---|---|
| Age | 0,053 | 0,021 | 1,05 | 0,013 |
| Blood transfusion | 0,740 | 0,252 | 2,10 | 0,003 |
| Charlson Comorbidity Index | 0,121 | 0,042 | 1,13 | 0,004 |
| Female | -0,484 | 0,202 | 0,62 | 0,017 |
| SAPS 3 | 0,029 | 0,005 | 1,03 | 0,000 |
| SOFA Score | 0,213 | 0,035 | 1,24 | 0,000 |
| Tobacco consumption | 0,924 | 0,335 | 2,52 | 0,006 |
| Constant | -8,079 | | | |

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000963

**Introduction:** Contrast-induced acute kidney injury (CI-AKI) is a complication associated with the intravascular administration of iodinated contrast, which represents a significant risk for patients with chronic kidney disease who require examinations or procedures that require its use. The ideal strategy to prevent IC-AKI remains debated, despite the main guidelines advocating intravascular hydration.

**Objectives:** Our objective was to perform an updated systematic review and meta-analysis comparing two important strategies in this scenario, the use of N-acetylcysteine (NAC) plus sodium bicarbonate (BIC) versus the use of BIC alone in patients already with chronic kidney disease, who will undergo angiography and percutaneous coronary intervention, with the goal of not occurrence of IC-IRA.

**Methods:** Articles were searched in PubMed, Embase and Cochrane until March 2024, for studies comparing the use of the two strategies, BIC only or BIC plus NAC with dosages according to the protocol of each study analyzed. The outcome of interest was an increase in serum creatinine (SCr) of 0.5 mg/dL or 25% compared to the patients' initial SCr level 48 h after contrast infusion. Statistical analysis was performed using R-4.3.3. Heterogeneity was assessed with $I^2$ statistics.

**Results:** 665 patients were included from 5 randomized clinical studies, with follow-up ranging from 2 to 30 days. Among patients, 338 underwent BIC plus NAC (50.8%) and 327 underwent BIC (49.2%). In the pooled analysis, the occurrences of AKI-IC were lower in patients undergoing BIC plus NAC (9.4%) compared to BIC alone (12.5%) (OR 0.73 95% CI [0.41;1.32], $p = 0.298$; $I^2 = 8\%$ $P = 0.36$; Fig. 1).

**Conclusions:** Our findings suggest a benefit in combining NAC with BIC, as evidenced by a lower occurrence of AKI-CI compared to BIC alone. However, the difference was not statistically significant. Our findings suggest that it is recommended to consider the inclusion of NAC with BIC in the preparation of high-risk patients, while more evidence and other comparisons involving other drugs.

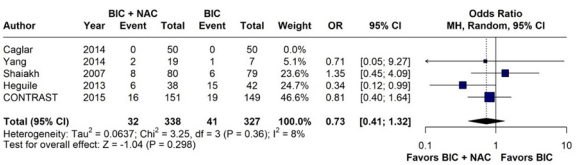

**Fig. 1 (abstract 00963)** Forest plot showing that recurrence of CI-AKI was less common in patients who received BIC plus NAC compared to BIC alone

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000964

**Introduction:** In Canada, hospitals have traditionally been designated as "community" or "academic". Community hospitals provide the majority of patient care while academic hospitals do the majority of clinical teaching and research [1]. A scoping review of the research publications of Ontario's large community hospitals (LCHs) from 2013 to 2015 identified the total research output for 44 hospitals was 798 publications, representing an annual output of 266 publications [2]. This disconnect between where the majority of patients receive their care and where health research is conducted leads to poor recruitment into clinical studies and decreased generalizability of research results [3].
**Objectives:** The purpose of this scoping review was to provide an updated picture of the research activities undertaken by Ontario's LCHs, describing the extent of research, type of publications and frequency of collaboration within and between Ontario's LCHs.
**Methods:** In adherence with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews guidelines, 3 medical databases (PubMed, Embase, and the Cumulative Index to Nursing and Allied Health Literature) were systematically searched for publications from January 2016 to December 2022 that included at least one author affiliated with an Ontario LCH. All publication types were included but the topic had to be hospital or medicine related. Screening and extraction occurred concurrently by 4 members of the research team. The first 20 articles were screened and extracted by all screeners to ensure consistency. Results were described using descriptive statistics.
**Results:** 3,719 publications were identified as including at least one author from one of 47 Ontario LCHs, representing an annualized output of 531 publications. The majority of publications were peer-reviewed full-text articles (96%). While the most common study design were observational studies (46%), randomized controlled trials were among the less frequent designs (9%). The most common disciplines of study were outpatient specialty care (31%), health systems research (22%), inpatient hospital care (12%) and surgery (11%). Across all articles, 722 (19%) displayed collaboration within the same LCH, 249 (7%) displayed collaboration between two or more Ontario LCHs, and 72 (2%) displayed collaboration both within and between Ontario LCHs. The remaining 2,676 (72%) publications involved only a single LCH-affiliated author, with all other authors being affiliated with academic institutions.
**Conclusions:** Health research by LCH-affiliated clinicians and researchers increased significantly in 2016–22 relative to 2013–5. Participation in randomized controlled trials, however, remains low, suggesting that further efforts are required to build clinical research infrastructure in LCHs.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000965

**Introduction:** Two randomized trials tested the hypothesis that reconnecting to mechanical ventilation (MV) for 1 h after a successful spontaneous breathing trial (SBT) would decrease extubation failure (EF). They demonstrated that the intervention reduced the reintubation rate within 48 h in patients with more than 12 h of MV (1) and might have been associated with a lower reintubation rate among patients with more than 72 h of MV before extubation (2).
**Objectives:** The primary objective is to evaluate the feasibility of performing a larger clinical trial to analyze whether reconnection to

MV for 1 h after a successful SBT reduces the risk of reintubation or death within 7 days in patients with more than 72 h of MV. Feasibility is defined as the capability to complete the study according to the planned schedule and with adherence above 90% to the procedures of the experimental group (reconnection to MV for 1 h [± 10 min] after SBT followed by extubation) and control group (extubation immediately after SBT).

**Methods:** This was a randomized feasibility (pilot) non-blinded multicenter trial conducted at four Brazilian sites. The study compared two weaning strategies from MV in critically ill patients admitted to intensive care units with more than 72 h of MV and who had a successful SBT on pressure support or T-tube. Eligible participants were randomized into two groups immediately after a successful SBT: (1) reconnection to MV using the previous ventilatory parameters for 1 h followed by extubation; (2) extubation immediately after SBT. The study protocol included: a daily assessment checklist for evaluating eligibility for weaning and SBT (1, 2); performing the SBT on pressure support or T-tube (3); assessment and management of laryngeal edema risk and (4, 5); use of non-invasive ventilation (NIV) and/or or high-flow nasal cannula (HFNC) after extubation in patients at high risk of EF (6, 7). As this was a study to assess feasibility (pilot), a convenience sample size of 60 patients was defined. Statistical analyses were realized using the intention-to-treat principle. The effect of treatment on the EF outcome was estimated using ratio of proportions and difference of proportions, and respective 95% confidence intervals. Kaplan–Meier curves were used to analyze the 7 days' time to reintubation outcomes that were compared using the log-rank test. The study was approved by the ethics and research committee of the participating centers (CAAE 70984323.1.1001.5362) and registered in clinical trials (Clinical Trials identifier: NCT 05999526).

**Results:** From November 2023 to March 2024, 66 patients fulfilled eligibility criteria and were enrolled in the study (Fig. 1), well within the planned schedule. Clinical characteristics were similar between groups. One patient was erroneously randomized, because he was not eligible, and thus was excluded from analysis. This patient was not extubated and was transferred to another hospital. The study intervention was performed as assigned in 95% of patients (control 33 [100%] vs intervention 30 [93.7%]). In the intervention group, the reconnection for one hour was not performed according to protocol in two patients: one patient required surgical intervention immediately before extubation (surgical curative), and this patient was reconnected to the MV for 130 min followed by extubation; and one patient was reconnected to MV but developed tachypnea and sweating and was not extubated (this case was classified as EF and included in intention-to-treat analysis). The other items of the protocol (checklist for assessing eligibility for weaning and SBT, SBT according to the protocol, assessment and management of laryngeal edema risk) had 100% adherence. NIV and/or HFNC after extubation in high-risk patients were used in 42.4% of patients in control group and 43.7% in intervention group. EF within 7 days occurred in 8 (25%) patients in the intervention group as compared to 14 (42.4%) patients in the control group (risk difference 17; 95% CI − 5.8 to 37.5). The Kaplan–Meier (Fig. 2) shows the behavior of the groups studied regarding EF in 7 days (hazard ratio, 0.53; 95% CI 0.22–1.23; $P = 0.14$).

**Conclusions:** This pilot study demonstrated the feasibility of performing a larger clinical trial to analyze whether reconnection to MV for 1 h after a successful SBT reduces the risk of reintubation or death within 7 days in patients with more than 72 h of MV.

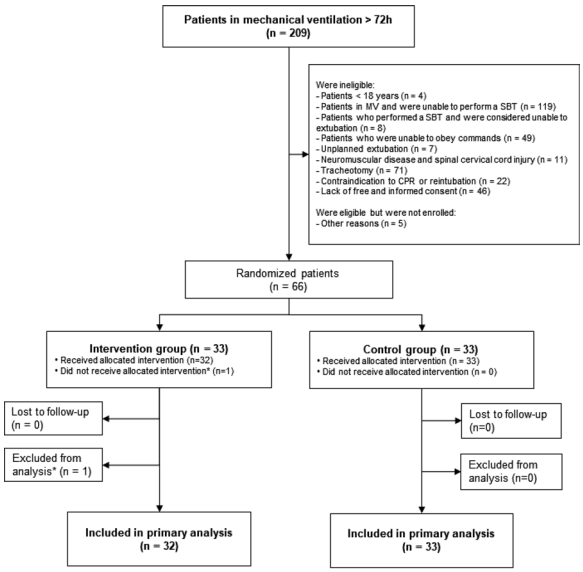

**Fig. 1 (abstract 000965)** Enrollment, randomization, intervention, and follow-up. ***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000967

**Introduction:** Red blood cell (RBC) transfusion is common in critically ill patients with sepsis. Our objective was to investigate RBC transfusion practices and to assess the impact of RBC transfusion on mortality in patients with sepsis admitted to the intensive care unit (ICU).
**Methods:** This study is a secondary analysis of the Korean Sepsis Alliance registry, a multicenter prospective observational cohort of patients with sepsis in South Korea. The included patients were aged ≥ 19 years and hospitalized in the intensive care unit for more than 48 h. Patients were excluded if there were medical reasons to transfuse (Fig. 1).
The primary outcomes were the occurrence of RBC transfusion within the first three days of ICU admission. Secondary outcomes were in-hospital mortality and possible physiological triggers for RBC transfusion. Data were collected from September 2019 to December 2022.
To investigate the association between RBC transfusion and in-hospital mortality, we conducted a 1:1 propensity score matching between transfused and non-transfused patients.
**Results:** A total of 3582 patients were included in final analysis (Fig. 1). The mean (SD) age was 71.6 (13.4) years, 58.4% were male (2,099/3,582). Transfused patients exhibited a higher incidence of abdominal infections and bacteremia (Table 1). A total of 1572 patients (43.8%) received 1 or more RBC transfusions during their ICU day 1–3 and 2563 RBC transfusion cases were identified. Of these, 88% (2,261/2,563) were carried out at hemoglobin levels of 7 or higher. The most common physiologic trigger for transfusion was a lactate level greater than 2 mmol/L (63.8%), followed by the use of two or more vasopressors (34.6%).
In a multivariable Cox regression model conducted in a propensity-score matched cohort, RBC transfusion was not associated with risk of in-hospital mortality (adjusted hazard ratio 1.02, 95% CI 0.91–1.13). However, a significant interaction was observed between RBC transfusion and in-hospital mortality in the subgroup delineated by a pH level of 7.2 (Fig. 2). The cubic spline curve analysis revealed that among individuals who did not receive RBC transfusion, a lower pH was associated with a higher mortality rate. However, in those who received RBC transfusion, the mortality rate did not continue to increase below a pH of 7.2 (Fig. 3).
**Conclusions:** In this study, 43.8% of sepsis patients admitted to the ICU received RBC transfusions within the first 3 days, and 88% of transfusions were carried out at hemoglobin levels of 7 or higher. Subgroup analysis revealed that RBC transfusion at a pH of 7.2 or less could potentially contribute to improved in-hospital mortality.

### First-attempt success of endotracheal intubation using hyper-angulated videolaryngoscopy versus conventional direct laryngoscopy: a randomized multiple cross-over cluster trial

M. Schmidt[1], S. Ott[1], L. M. Müller-Wirtz[1], A. Turan[1], K. Ruetzler[1]
[1]Department of OUTCOMES RESEARCH, Cleveland Clinic, Cleveland, United States of America
**Correspondence:** M. Schmidt
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000968

**Introduction:** Endotracheal tubes are usually inserted with direct laryngoscopy, but patients sometimes require multiple attempts which can provoke morbidity.1
Videolaryngoscopy improves airway visualization, but endotracheal tubes are nonetheless sometimes difficult to pass through the vocal cords. 2 Whether improved glottis visualization facilitates intubation and reduces intubation attempts remains unclear.
**Objectives:** We therefore tested the primary hypothesis that fewer intubation attempts are required when initial laryngoscopy is performed with videolaryngoscopy than with direct laryngoscopy in surgical patients.
**Methods:** We conducted a cluster-randomized multiple crossover trial in patients having cardiothoracic or vascular surgery at the Cleveland Clinic Main Campus, Cleveland, OH. Patients were randomized to either hyperangulated videolaryngoscopy or direct laryngoscopy for the initial intubation attempt. The primary outcome was number of intubation attempts. Secondary outcomes were intubation failure and a composite of airway and dental injuries. The trial was registered with clinicaltrials.gov (identifier NCT04701762), current trial status closed for enrollment.
**Results:** We enrolled 8,429 surgeries from March 2021 to December 2022. 4,413 (52%) surgeries were randomized to videolaryngoscopy, and 4,016 (48%) to direct laryngoscopy. About 70% of initial intubations were performed by nurse anesthetists or residents, supervised by attending anesthesiologists. Videolaryngoscopy reduced the need for multiple intubations by about a factor-of-four from 7.6 to 1.7% and reduced the number of intubation attempts compared to direct laryngoscopy [(OR 0.19 (95% CI 0.13, 0.28; $P<0.001$)] (Fig. 1). Intubation failed in 0.27% with videolaryngoscopy vs. 4% with direct laryngoscopy [RR 0.05 (95% CI 0.02, 0.12; $P<0.001$)] (Table 1). Airway and dental injuries did not differ between videolaryngoscopy (41 injuries, 0.93%) vs. direct laryngoscopy (42 injuries, 1.1%), RR 0.85 (95% CI 0.53, 1.39; $P=0.376$)].

**Table 1 (abstract 000968)** Treatment effect on the primary and secondary outcomes

| Outcome | Video (*N* = 4413) | Direct (*N* = 4016) | Treatment effect estimate (95% CI)[b] | *P* value |
|---|---|---|---|---|
| Secondary outcomes | | | Relative risk | |
| Intubation failure | 12 (0.27) | 161 (4.0) | 0.05 (0.02, 0.12)[a] | < 0.001 |
| Composite injury | 41 (0.93) | 42 (1.1) | 0.85 (0.53, 1.39)[a] | 0.376 |

[a] Relative risk (95% CI) and *P* value was estimated from generalized linear mixed effects log-binomial model (log link) adjusting for period, operating room and within-subject correlation, weighted by the stabilized weights

[b] Confidence intervals are interim-analysis adjusted, so actually 99.32%, but we refer to them as 95% for simplicity and to emphasize that alpha was controlled at 5% throughout the study

**Conclusions:** Videolaryngoscopy is a preferable initial approach for intubating surgical patients.

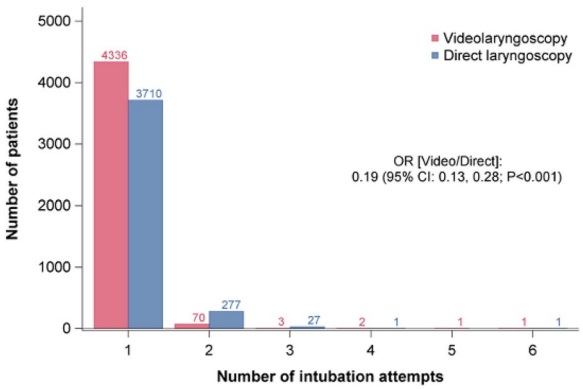

**Fig. 1 (abstract 000968)** Primary outcome by randomized group

### Epidemiology and outcomes of ventilator-associated events in mechanically ventilated patients: an observational study from tertiary medical center in Russia

S. Vladimirov[1], N. Matiushkov[2], I. Klimenko[3], D. N. Protsenko[2]
[1]MSc Student in Public Health Sciences, ITMO University,Saint Petersburg, MD at Kommunarka Medical Center, Moscow, Russia; [2]Department of Anesthesiology and Intensive Care, Pirogov Russian National Research Medical University, Moscow, Russia; [3]Medical Intensive Care Unit, Kommunarka Medical Center, Moscow, Russia
**Correspondence:** S. Vladimirov
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000969

**Introduction:** Mechanical ventilation (MV) is associated with multiple complications in intensive care units (ICU). In 2013, the American Centers for Disease Control and Prevention (CDC) replaced the ventilator-associated pneumonia (VAP) surveillance definition with definitions for ventilator-associated events (VAE). The VAE framework exploits a set of objective criteria of nosocomial respiratory deterioration, such as increase in FiO2 or PEEP for 2 or more consecutive days after at least 48 h of stable respiratory function. Several studies have shown a strong association of VAE with poor outcomes. However, the adoption of VAE surveillance outside the USA is still limited, possibly due to scarce research data in other regions. We decided to conduct an observational study to describe the epidemiology and outcomes of VAEs in a tertiary medical center in Moscow.
**Methods:** In our study, we used a local registry of mechanically ventilated patients in Kommunarka Medical Center. Medical and surgical patients that received MV between June 1, 2022, and December 1, 2023 for more than four consecutive days, were included in the analysis. The determination of VAE cases was performed using data from electronic health records in accordance with CDC criteria. We estimated VAE incidence in the analyzed cohort, and calculated mortality and number of ventilator-free days by day 28 in patients with and without VAE.
**Results:** 312 episodes of MV were analyzed, accounting for 4052 ventilator-days. We identified 31 VAE cases by day 28, so the incidence rate was 7,65 events per 1000 ventilator-days. Patients who developed VAE had higher 28-day mortality (HR, 2.52; 95% CI 1.46 to 4.36). The number of ventilator-free days was similar in VAE and non-VAE cases (mean [SD], 10[10] vs. 8[9], $p = 0.245$).
**Conclusions:** According to our research, the incidence of VAE was 7.65% by 28th day of MV. Presence of this condition was associated with increased risk of 28-day mortality. These findings suggest the importance of VAE surveillance in our region. We plan to enroll more patients in the study cohort to evaluate risk factors and long-term outcomes of VAE.

### Deciphering the ZBED6-regulated pathway: a translational approach to combat sepsis-induced muscle atrophy

H. Liu[1], P. Li[2], M. Meng[3], Y. Deng[3], R. Li[3], L. Yao[2], Y. Chen[1], E. Chen[1]

**Introduction:** Sepsis-induced muscle atrophy afflicts 40–70% of patients, significantly compromising their recovery and long-term health. Preliminary multi-omics analyses across human and porcine subjects have implicated the transcription factor ZBED6 in the development of muscle atrophy during sepsis. Utilizing a novel porcine model, we observed that ZBED6 deficiency mitigates muscle atrophy, suggesting its pivotal role, although the underlying mechanisms remain to be elucidated.
**Objectives:** This study aims to delineate the mechanisms by which ZBED6 influences sepsis-induced muscle atrophy and to validate these mechanisms in clinical settings. Understanding these pathways will facilitate the development of targeted therapeutic and diagnostic strategies focusing on ZBED6.
**Methods:** We employed multi-omics techniques to identify TGF-β3 as a critical mediator influenced by ZBED6. The regulatory effects of ZBED6 on TGF-β3 transcription were investigated using molecular biology approaches, including dual-luciferase reporter assays and chromatin immunoprecipitation followed by PCR (ChIP-PCR). In vitro experiments using ZBED6-knockout porcine models treated with TGF-β pathway agonists and inhibitors helped unravel both inhibitory and stimulatory effects within this pathway, providing insights into the molecular mechanisms at play. Additionally, we analyzed patient samples to assess the clinical relevance of these findings.
**Results:** Our results demonstrate that ZBED6 directly regulates TGF-β3 expression, a key mediator in sepsis-induced muscle atrophy. In the absence of ZBED6, septic pigs showed significantly reduced TGF-β3 levels, leading to diminished activation of the TGF-β signaling pathway and reduced muscle atrophy. Conversely, myotubes overexpressing ZBED6 exposed to septic conditions displayed increased TGF-β3 levels and enhanced muscle atrophy. Clinical data supported these findings, showing elevated ZBED6 and TGF-β activity in septic patients.
**Conclusions:** The ZBED6-TGF-β3 axis emerges as a novel and actionable therapeutic target for combating sepsis-induced muscle atrophy. Targeting this pathway could potentially reverse or halt the progression of muscle wasting, substantially improving patient outcomes in critical care settings. This study not only advances our understanding of sepsis pathophysiology, but also opens new avenues for targeted

therapeutic interventions, potentially transforming the landscape of critical care medicine.

### Time-specific mean arterial pressure thresholds to prevent unfavorable neurologic outcome in post-cardiac arrest patients

S. J. Lee[1], S. Kim[1], S. W. Lee[1], J. Song[1], K. S. Han[1]
[1]Emergency department, Korea University College of Medicine, Seoul, Republic of Korea.

**Introduction:** Mean arterial pressure (MAP) target provided in current guideline may not suffice due to impaired cerebrovascular autoregulation post-cardiac arrest. This study aims to determine optimal MAP thresholds over time to improve neurological outcomes using a machine learning approach.
**Methods:** In this retrospective study at Korea University Anam Hospital (2017–2020), adult post-cardiac arrest patients were analyzed to explore the relationship between MAP and neurological outcomes. Employing machine learning, particularly a random forest model, the study assessed hourly MAP measurements over the first 24 h post-arrest. Key variables, including demographics, cardiac arrest specifics, and treatment factors, were evaluated for their impact on outcomes. The analysis focused on understanding variable importance through random forest and the direction of variable associations via Shapley additive explanation (SHAP) values. This comprehensive approach aimed to identify optimal MAP thresholds in different post-arrest phases to refine neuroprotective strategies.
**Results:** Out of 1,014 cardiac arrest patients, 291 were eligible for the study, which reported a 40.5% in-hospital mortality rate and identified significant outcome predictors like age, witnessed arrest, and CPR duration. The random forest model excelled in predicting post-cardiac arrest outcomes, achieving an accuracy of 0.881 and an area under the curve of 0.850. This model was further analyzed due to its superior performance. The MAP recorded 6 h after Return of Spontaneous Circulation (ROSC), termed MAP006, was identified as highly significant, with early MAPs in 6 h ranking among the top 10 indicators. According to the SHAP summary, lower MAP values were positively linked to adverse outcomes, while higher values indicated better prognoses, especially within the first 6 h. The analysis of the area below the threshold (ABT) for incremental MAP ranges from 50 to 100 mmHg in each time segment showed that values below 75 mmHg in the first 6 h were strongly associated with negative outcomes. In later segments, this correlation was less apparent, prompting further subgroup analyses. Within the subgroup of cardiac causes, a consistent negative correlation between ABT and poor outcomes was observed, with the optimal MAP threshold for preventing adverse outcomes gradually increasing from 75 to 95 mmHg over time.

**Conclusions:**
In our study, machine learning analysis confirmed the highest correlation between the first 6 h post-resuscitation and unfavorable outcomes. Notably, exposure to a MAP below 75 mmHg during this period was most strongly associated with unfavorable neurologic outcomes. For patients with cardiac causes, subsequent periods also demonstrated a link between MAP levels and unfavorable outcomes, with the MAP threshold gradually increasing over time.

## 000973 Id entification of immune-related subtypes of sepsis and mechanistic signatures

T. Li[1]
[1]Department of Critical Care Medicine, West China Hospital, Sichuan University, Chengdu, China
**Correspondence:** T. Li
*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000973

**Introduction:** Sepsis, a life-threatening condition characterized by dysregulated host responses to infection, exhibits heterogeneity in immune response (1–3). Conventional therapies have not adequately addressed immune dysregulation in septic patients, emphasizing the urgent need for immune typing to enable precise management (4–6).
**Methods:** Through the 28 immune cell features annotated by single-sample Gene Set Enrichment Analysis and the consensus clustering, we analyzed the Gene Expression Omnibus (GEO) datasets (GSE65682) and clustered sepsis patients into two immune subtypes. Subsequently, various immune infiltration analysis methods, including ESTIMATE, CIBERSORT, quanTIseq, TIMER, MCP-counter, xCell, and Estimating the Proportion of Immune and Cancer cells (EPIC), were employed to evaluate immune infiltration in the two immune subtypes. We further analyzed the changes associated with inflammatory factors in both groups. Gene Set Variation Analysis (GSVA) approach was used to annotate 10 signaling pathways commonly altered in sepsis and to observe changes in these pathways in the two immune subtypes. We further incorporated the differential genes into GO and KEGG enrichment analysis to analyze the pathway alterations. We further analyzed the alterations and differences in glucose metabolism, lipid metabolism and protein metabolism in the two immune subtypes.
**Results:** We clustered sepsis patients into immune-normal (subtype 1) and immune-suppressed subtypes (subtype 2). Figure 1A–D shows that binary classification of sepsis subtypes based on immune infiltration was the best. Most of the immune cell infiltration of subtype 1 was higher than that of subtype 2, while macrophages and regulatory T cells were lower than that of subtype 2 (Fig. 1E, F). In addition, the subtype 1 ESTIMATE score and immunity score were higher than that of subtype 2 (Fig. 1G). To ensure that the two consensus clusters were not biased by the analytical algorithm, six other algorithms, including TIMER, quanTIseq, MCP-counter, xCell, EPIC, and CIBERSORT, were used to verify the stability and robustness of the ssGSEA results. (Fig. 2). Further analysis revealed significant differences in signaling pathway alterations and metabolic reprogramming between the two immune subtypes. The volcano plot demonstrates the most significantly altered genes between subtype1 and 2 groups. (Fig. 3A). The results showed that TGF-β pathway and Notch pathway were upregulated in the subtype 1, while the Hippo, Cell cycle, and PI3K pathways were upregulated in the subtype 2 (Fig. 3B). Gene Ontology (GO) analysis indicated that the variation of different subtypes lies in "regulation of inflammatory response", "leukocyte chemotaxis", "T cell differentiation", and "positive regulation of T cell activation" (Fig. 3C). Kyoto Encyclopedia of Genes and Genomes (KEGG) analysis suggested that some classical pathways, such as the "PI3K-Akt signaling pathway", "Cell adhesion", "MAPK signaling pathway", were altered between different subtypes (Fig. 3D). GSEA analyses further validated these alterations in immune and metabolism related signal, including "positive regulation of immune system process", "Dendritic cell apoptotic process", "Natural killer cell mediated cytotoxicity", "glucose catabolic process", " Glycolysis/Gluconeogenesis" (Fig. 3E, F).
**Conclusions:** We elucidated immune heterogeneity in septic patients, successfully stratifying them into immune-normal and immune-suppressed subtypes. Significant differences in immune infiltration and alterations in signaling pathways among different immune subtypes provide a theoretical basis for precision medicine in sepsis treatment. Moreover, our findings offer new insights into understanding immune regulatory mechanisms in sepsis and developing personalized therapeutic strategies.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000974

**Introduction:** Awake prone positioning (APP) has been widely adopted since the onset of the COVID-19 pandemic and has shown promise in reducing the need for intubation, as evidenced by our previous meta-analysis encompassing 10 randomized controlled trials (RCTs). As of now, 18 RCTs have been published. Given the evolving

nature of evidence surrounding APP, particularly its impact on mortality, it is imperative to reassess its effects.
**Objectives:** We aimed to evaluate the effects of APP on clinical outcomes in patients with COVID-19-related acute hypoxemic respiratory failure (AHRF).
**Methods:** We conducted an individual participant data meta-analysis. Two independent research teams searched PubMed, EMBASE, the Cochrane Library, and ClinicalTrials.gov for RCTs on APP in patients with COVID-19-related AHRF published in English from January 1, 2020, to July 1, 2022. We reached out to all principal investigators of both published and unpublished RCTs for their individual participant data. The primary outcome was survival without intubation, which was also defined as APP treatment success. Secondary outcomes included intubation, mortality, and death with intubation. We also explored predictors of APP success. Individual participant data provided by each trial were synthesized into a pooled dataset and analyzed using a 1-step mixed-effects model. Multivariate analyses were performed to identify the predictors associated to treatment success. The study was reported following the PRISMA-IPD guideline. The study protocol was prospectively registered with PROSPERO (CRD42022343625). Data from quasi-RCTs were included for sensitivity analysis.
**Results:** We included 11 RCTs (including 2 unpublished) with 2,453 patients and one quasi-RCT with 501 patients from 11 countries. Compared to the control group, APP significantly increased the likelihood of survival without intubation for COVID-19-related AHRF (odds ratio [OR] 4.166 [95% CI 1.797 to 9.658]), reduced the risk of intubation (0.269 [0.122 to 0.592]), mortality (0.274 [0.105 to 0.717]), and death with intubation (0.333 [0.134 to 0.827]). Similar results were observed in sensitivity analysis with the quasi-RCT. Predictors of APP success included age younger than 60 years, shorter time from hospitalization to enrollment ($\leq$ 1 day), treatment in the ICU, higher SpO2/FIO2 ratio before APP ($\geq$ 159), lower respiratory rate before APP ($\leq$ 24 breaths/min), and longer duration of APP within the first three days ($\geq$ 13 h).
**Conclusions:** Among patients with COVID-19-related AHRF, APP was associated with improved survival without intubation and reduced risks of intubation and mortality. Younger age, shorter time from hospitalization to enrollment, treatment in the ICU, higher SpO2/FIO2 ratio, lower respiratory rate before APP, and longer duration of APP within the first three days were associated with APP treatment success.

### Achievement of a negative fluid balance during the first 48 h is related to mortality in ARDS patients

J. Suwanbunyarit[1], W. Mongkolpun[2]
[1]Critical Care Department, Chaophraya Yommaraj Hospital, Suphanburi, Thailand; [2]Department of intensive care, Siriraj Piyamaharajkarun Hospital Mahidol University, Bangkok, Thailand
**Correspondence:** W. Mongkolpun
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000975

**Introduction:** Achievement of a negative fluid balance (NFB) increases arterial oxygenation which affects mortality and organ function.
**Objectives:** We aimed to evaluate whether a NFB in first 48 h affects mortality or an improvement in organ functions in ARDS patients.
**Methods:** ARDS patients (Berlin criteria) were included. SOFA scores, hemodynamic variables, P/F ratio, vasopressor dose, daily fluid balance for 72 h after ICU admission were recorded. NFB (furosemide, ultrafiltration) was initiated during first 48 h after ICU admission. Patients were separated by patients who did or did not achieve a NFB $\geq$ 1 L within 48 h without hypotension (success vs unsuccess). Patients were divided by ICU mortality and a reduction of SOFA scores $\geq$ 2 in 72 h ($\Delta$SOFA72).
**Results:** 52 ARDS patients were included. 34/52 (65%) patients were on HFNC. SOFA scores and PF ratios were 4 (3–4),119 (79–191). Lactate was 1.0 (0.5–1.5) mmol/L. 3 patients receiving vasopressor. All patients received intravenous furosemide 40 (20–80) mg/24 h. 32/52 (62%) patients were in success group and 23 (70%) of these patients had $\Delta$SOFA $\geq$ 2. 32 of 52 (61%) were survivors. There were no differences in SOFA scores, P/F ratios, hemodynamic variables, between patients in success and unsuccess, $\Delta$SOFA72 $\geq$ 2 vs $\Delta$SOFA72 < 2, survivors and non-survivors.
Patients with $\Delta$SOFA72 $\geq$ 2 (Fig. 1) and survivors (Fig. 2) had lower accumulative fluid balance at 48 h than another group. Mechanical ventilator (MV) and HFNC supporting days were lower in patients in success group than in unsuccess group (7 (5–11) vs 10 (7–12) days, $p < 0.05$, respectively).
**Conclusions:** To achieve a NFB $\geq$ 1 L in the first 48 h would be associated with reduced mortality and organ dysfunction.

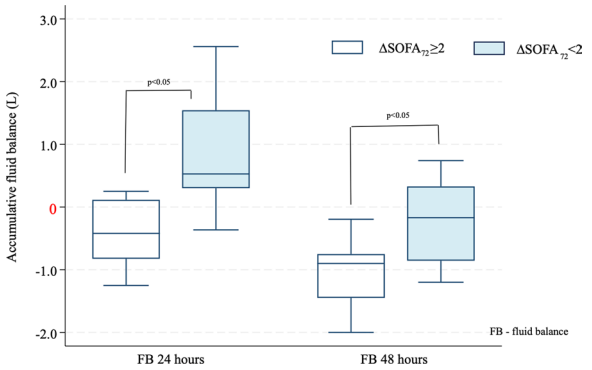

**Fig. 1 (abstract 000975)** Accumulative fluid balance at 24 and 48 h in patients with ?SOFA ≥ 2 vs < 2

### Substitution of PCR with IL-6 in NUTRIC-SCORE: early-stage analysis

M. Araujo Palacios[1], O. I. Aguilera Olvera[1], J. A. Villalobos Silva[1], G. Aguirre-Gomez[1], M. I. Muñoz Treviño[1], I. S. Salazar Puente[1]
[1]Critical care, High Specialty Regional Hospital of Ciudad Victoria, Ciudad Victoria, Mexico
**Correspondence:** M. Araujo Palacios
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000976

**Introduction:** The NUTRIC-SCORE scale, the first standardized nutritional risk (NR) scale for critically ill patients (2), incorporates variables commonly found in ICUs, including age, APACHE II, SOFA, comorbidities, days from hospital admission to ICU admission, and interleukin-6 (IL-6) (3). However, due to cost and limited availability, the original scale was modified to exclude IL-6 (2).
A high NR is indicated by a NUTRIC score > 6 points, although it was later adjusted to > 5 points (1). Given its accessibility, research has explored using C-reactive protein (CRP) instead of IL-6 as an inflammatory biomarker (1).
The optimal CRP cutoff values for predicting ICU mortality, ranging from 100mg/l to 152mg/l (4). Consequently, the minimum value is proposed as a substitute for IL-6. Despite this change, high nutritional risk is still defined as > 6 points.

**Objectives:** Estimate high NR and mortality given among the variants of the NUTRIC score.
**Methods:** A prospective cohort study was conducted on adult patients admitted to the ICU of a tertiary hospital in Mexico. Patients with mechanical ventilation and severe pneumonia were included. Data were summarized with means and standard deviations, while categorical data were presented as frequencies and percentages. Mortality scales including APACHE II, SOFA, NUTRIC, and modified NUTRIC were computed. IL-6 in the original scale was replaced by CRP with a cutoff of 100 mg/dl. ROC curve analysis was performed to calculate AUC along with sensitivity, specificity, and predictive values (5). Additionally, a Kappa test was conducted to assess agreement.
**Results:** 21 patients were included, hospitalized during 2023 with a diagnosis of severe pneumonia, 81% male, aged 46 years (±20), comorbidities hypertension 61%, type 2 diabetes mellitus 43%. Prognostic scales were calculated among the survivor and non-survivor groups, with BMI of 23 (±1)/29 (±3.6), APACHE II 6 (±2)/13 (±7), SOFA 4 (±0.5)/8 (±3), NUTRIC 2 (±0.5)/4 (±1.3), NUTRICm 3 (±0.5)/3 (±1.3), NUTRICpcr 2.3 (±0.5)/4 (±1.5), CRP 50 (±22)/146 (±120), IL-6 66.8 (±50)/60 (±101), and ICU stay of 5 (±1.5)/5.5 (1.3), respectively (Table 1). There was a mortality rate of 71%. The ROC AUC obtained the best accuracy with the SOFA score to predict mortality (Fig. 1), the NUTRIC and NUTRICm scales were 0.73, and NUTRICpcr was 0.77 (Fig. 2). The Kappa test for agreement value was 0.12 between the NUTRIC and NUTRICpcr scales.

**Table 1 (abstract 000976)** Diagnostic accuracy for severity scores and mortality

| | AUC | Sensitivity (%) | Specificity (%) | PPV (%) | NPV (%) |
|---|---|---|---|---|---|
| APACHE II | 0.93 | 86 | 75 | 87 | 100 |
| SOFA | 1 | 100 | 100 | 100 | 100 |
| NUTRIC | 0.73 | 60 | 68 | 25 | 100 |
| NUTRICm | 0.73 | 60 | 56 | 71 | 71 |
| NUTRICpcr | 0.77 | 70 | 50 | 73 | 67 |

**Conclusions:** The NUTRICpcr scale shows moderate accuracy in predicting patients with high nutritional risk; however, due to the small sample size, promising results are obtained, which could lead to a more accessible alternative.

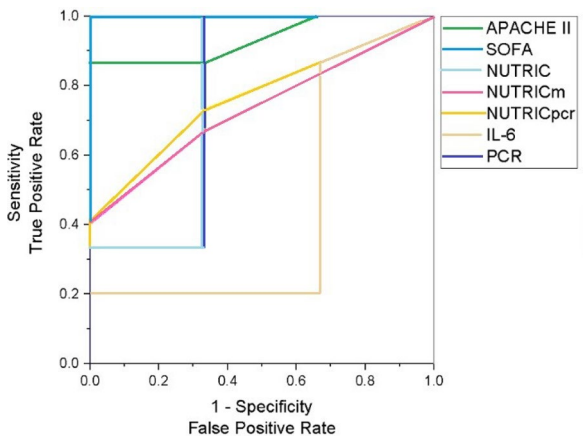

**Fig. 1 (abstract 000976)** AUC ROC with mortality and nutritional risk assessment scores and biomarkers

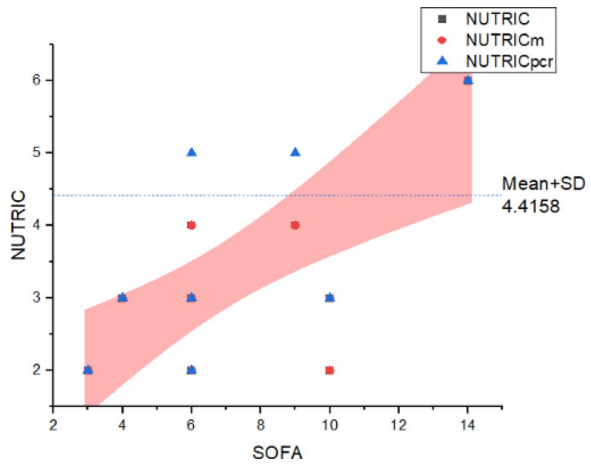

**Fig. 2 (abstract 000976)** Correlation between nutritional risk assessment and SOFA as prognostic scales for mortality ($r = 0.73$, 0.73, 0.70 for NUTRIC, NUTRICm and NUTRICpcr, respectively, $p = 0.000$)

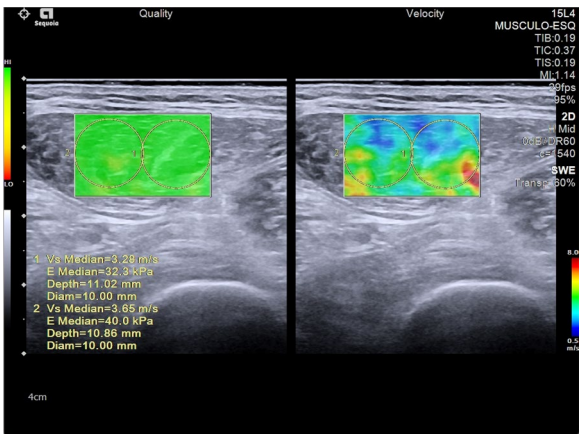
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000977

**Introduction:** Skeletal muscle wasting is characterized by an early and rapid loss of muscle mass, strength and quality affecting more than a half of critically ill patients and is associated with negative clinical outcomes. Shear wave elastography (SWE) is a non-invasive, objective and practical ultrasonographic (US) method that provides a quantitative measurement of muscle shiftiness, reflecting changes in muscle composition, such as increased fibrosis and adipose tissue deposition and demonstrated a higher reliability with eco-intensity on gray scale US and computed tomography in detecting muscle changes. This study aimed to characterize the SWE muscle changes in critically ill patients and the association with the clinical outcomes and mortality.
**Methods:** Prospective cohort study involving ultrasound measurements of quadriceps at baseline (MMA1) and day 7 to 10 (MMA2). Rectus femoris (RF) shear wave elastography (SWE) was measured by a trained registered dietitian using a linear array transducer 15-L (ACUSON Sequoia Ultrasound System, Siemens Healthineers) and applying minimal pressure accordingly with the US method and image acquisition protocol developed for the study. The size and number of the regions of interest (ROIs) differ because of the RF size variability among patients. The ROIs were placed to include the greater RF area, at the same level of the SWE image. The mean stiffness in kilopascal (kPa) and the mean velocity (m/s) was calculated. The severity of illness was assessed thought the Sequential Organ Failure Assessment (SOFA) and Acute Physiology and Chronic Health Evaluation II (APACHE II) scores, the duration and type of organ support, such as renal and ventilatory support, the ICU days and 90-day mortality were also collected. The data were statistically analyzed through Stata BE v18 v26 (Stata Corp, College Station, Texas 77845 USA).
**Results:** 20 patients (age 56 ± 16 years, 80% male) admitted in Medical Emergency and ECMO ICUs of S. José Hospital, CHULC EPE in Lisbon, Portugal. There was reduction in SWE from MMA1 (3,0 m/s ± 1,36; 33,7 kPa ± 31,3) to MMA2 (2,88 m/s ± 1,04; 28,6 kPa ± 21,1). A significant relationship between SOFA and APACHEII scores and SWE (m/s) ($p = 0,06$; $p = 0,03$) and SWE (kPa) ($p = 0,05$; $p = 0,02$) was observed. A larger sample is necessary to clarify the association between continuous renal replacement technique (CRRT) and mechanical invasive ventilation (MIV) duration and SWE (m/s) ($p = 0,08$; $p = 0,09$) and SWE (kPa) ($p = 0,07$; $p = 0,04$). A significant relationship between 90-day mortality and SWE (m/s) ($p = 0,02$) and SWE (kPa) ($p = 0,01$) was observed.
**Conclusions:** In critically ill patients with skeletal muscle wasting, RF shiftiness showed to reduce in the first week of ICU stay and was associated with worse clinical outcomes.



**Figures 1 (abstract 000977)** SWE on RF muscle. SWE quality panel (left) and color map SWE image (right) were simultaneously displayed on USG monitor and three consecutive images were acquired. Two circular region of interests (ROIs) were placed. Then the mean of ROIs in each of three SWE image were considered to represent the stiffness and shear wave velocity (SWV) of evaluated muscle

**Topic:** Metabolism, endocrinology, liver failure and nutrition

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000978

**Introduction:** Cardiogenic shock (CS) leads to prolonged intensive care unit stays heightened long-term morbidity, economic costs, and impacts survivor`s health related quality of life.
CS carries high in-hospital mortality rates, with incidences around 6–13% in acute coronary syndrome (ACS) and about 4% in heart failure (HF), though other etiologies can contribute. In Mexico, most records focus on ischemic heart disease.
The Cardiogenic Shock Working Group (CSWG) recently proposed a subclassification of CS into 3 phenotypes, synergistically associated with the Society for Coronary Angiography and Interventions (SCAI) classification for greater prognostic relevance.
Currently, there are few compilations with classifications, although none performed or validated in our population, thus the variability in treatment response is a problem we frequently face due to the absence of consensus on the treatment of choice based on severity scales or etiological classification. This would enable us to prioritize resources and scale treatment in a targeted manner.
**Objectives:** Our research aims to explore the frequency of each CS phenotype and its association with mortality in an intensive care setting in Mexico.
**Methods:** A historical cohort study included patients admitted to the intensive care unit with CS diagnosis according to CSWG and SCAI criteria, encompassing stages C, D, and E Phenotype classification with mortality probabilities estimated.
**Results:** From January 2021 to December 2023, 65 patients admitted to the intensive care unit with a diagnosis of CS were studied. Of these, 55% ($n=36$) were male and 45% ($n=29$) female, with an average age of $65.7 \pm 15.2$ years and an average length of stay of $6 \pm 32.4$ days. The distribution by phenotypes (Fig. 1) was 49% for phenotype I, 40% for phenotype II, and 11% for phenotype III. Twenty-two patients died, 46% from phenotype I, 27% from phenotype II, and 27% from phenotype III. SCAI staging showed 2% at stage C, 72% at stage D, and 26% at stage E, with 37% of stage D patients belonging to phenotype I. The main etiology was decompensated HF (Fig. 2), and pharmacological treatment predominated, with only 7.6% receiving mechanical support.

**Relation between proportion of phenotypes and SCAI stages**

| Phenotype/SCAI stage | C | D | E | Total |
|---|---|---|---|---|
| I | 2% (1) | 37%( 24) | 10% (7) | 49% (32) |
| II | 0 | 32% (21) | 8% (5) | 40% (26) |
| III | 0 | 3% (2) | 8% (5) | 11% (7) |
| Total | 2% (1) | 72% (47) | 26% (17) | |

**Conclusions:** The variability in treatment response underscores the need for consensus on treatment choices based on severity scales and etiological classification. The main mortality in CS phenotype observed in our population differed from previous studies, potentially due to our population's prevalent etiology of decompensated chronic HF and the proportion of patients with obesity. This study is the first to examine phenotypes and their prognostic correlation in Mexican population, highlighting the necessity for prospective studies with larger cohorts in our country.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000980

**Introduction:** The COVID-19 pandemic has severely burdened healthcare system capacities in many parts of the world. Intensive care unit (ICU) resources, including mechanical ventilation, are crucial for long-term crisis management, especially emerging new respiratory virus infections. However, few studies have examined nationwide medical resource utilization and COVID-19 mortality with international comparisons.
**Objectives:** This study aimed to evaluate the mortality of COVID-19 confirmed patients in South Korea using nationwide cohort data and describe characteristics independently associated with mortality. We also analyzed the characteristics and distribution of COVID-19 patients in Korea and healthcare utilization across the country. We aim to check the current level and help establish policies to distribute medical resources and systems effectively when similar infectious diseases become prevalent in the future.
**Methods:** This study used a cohort of 577,626 COVID-19 confirmed cases from October 8, 2020, to December 31, 2021, which combined the data from Korea Disease Control and Prevention and the National Health Insurance Service Claim Data. We analyzed 28-day mortality and in-hospital mortality according to the type of hospital and application of treatments. The treatments included a mechanical ventilator, extracorporeal membrane oxygenation (ECMO), vasopressor, high-flow nasal cannula, continuous renal replacement therapy (CRRT), and oxygen supply. Multivariate analysis using Cox's proportional hazards model was performed to compare the mortality of patients with COVID-19 infection.
**Results:** Among 577,626 confirmed cases, 7203 patients were dead during the follow-up period. 28-day mortality is 0.4%, and in-hospital mortality is 0.9%. Mortality is higher in older age and lower-income groups and increased with the Charlson Comorbidity Index. Tertiary general hospitals had higher mortality than general hospitals. During the pandemic period, 5956 patients applied for mechanical ventilators in South Korea. 3236 patients were admitted to the Tertiary General Hospital, and others were treated in the General Hospital. 726 patients used ECMO, and 214 patients were on CRRT machines. 60,182 patients were on oxygen therapy and 10,141 applied High Flow Nasal Cannula device. 16,674 patients experienced vasopressor therapy. Among 5956 mechanically ventilated patients, 28-day mortality is 7.1%, and in-hospital mortality is 15.5%. Mortality is also higher in older age and lower-income groups and increases with the Charlson Comorbidity Index. However, after multivariate analysis, the mortality of mechanically ventilated patients is higher in general hospitals compared with tertiary hospitals.
**Conclusions:** The study aimed to assess COVID-19 mortality and evaluate the nationwide medical resource utilization in South Korea. Among 577,626 confirmed cases, overall mortality is 1.2%. 28-day mortality and in-hospital mortality are 0.4% and 0.9%, respectively. Mortality increased with age and comorbidities, aligning with existing research. Among 5956 mechanically ventilated patients, 28-day mortality is 7.1%, and in-hospital mortality is 15.5%. However, mortality in the mechanical ventilation group was lower than in previous studies in other countries and higher in the patients admitted to general hospitals.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000981

**Introduction:** There has been limited data regarding the association of nosocomial infections (NI) with clinical outcomes and its predictors in patients with cardiogenic shock.
**Objectives:** This study aimed to investigate the clinical pictures and the association of NIs with clinical outcomes in patients with cardiogenic shock.
**Methods:** We analyzed 879 adult patients with cardiogenic shock who were admitted to the cardiac intensive care unit (ICU) in the single tertiary center between 2012 and 2020. All of the positive microbiological cultures that were obtained within the index cardiac ICU stay period were evaluated. Based on the international guidelines, 4 NIs were diagnosed; pneumonia, catheter-related bloodstream infections (CRBSI), primary bacteremia, and catheter-associated urinary tract infection (CAUTI). The primary outcome was ICU mortality and we also assessed ICU stay and in-hospital mortality.
**Results:** Among 879 patients, 242 (27.5%) patients developed a NI. The most common type of NI was pneumonia, followed by CRBSI, primary bacteremia, and CAUTI. Patients with NI had more experience of cardiac arrest before ICU admission (38.0% vs 23.2%, $p<0.001$), higher vasoactive-inotropic score (35.0 [18.0–135.0] vs 19.0 [8.0–40.0], $p<0.001$), and higher rates of undergoing extracorporeal membrane oxygenation (ECMO) (30.6% vs 13.5%, $p<0.001$). Both ICU mortality (33.4% vs 15.7%, $p<0.001$) and length of ICU stay (11.9 days [5.3–20.0] vs 3.2 days [2.0–6.0], $p<0.001$) were higher in patients with NIs than those without NIs. In-hospital mortality was also higher in patients with NIs (38.4% vs 19.5%, $p<0.001$). On multivariable analysis, ECMO (adjusted OR 2.35, 95% CI 1.44–3.84, $p=0.001$), cardiac arrest before ICU (adjusted OR 1.56, 95% CI 1.02–2.38, $p=0.040$), and diabetes mellitus (adjusted OR 2.14, 95% CI 1.55–2.95), $p<0.001$) were independent predictors of NI.
**Conclusions:** NI was associated with an increase in ICU and in-hospital mortality and length of ICU stay in patients with cardiogenic shock. ECMO, cardiac arrest before ICU, diabetes mellitus were important predictors of NI development.

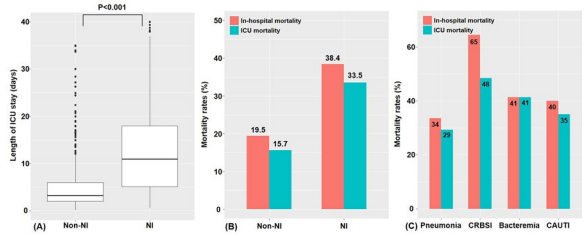

**Fig. 1 (abstract 000981)** A Box plot comparing the length of ICU stay in non-NI vs NI patients (3.20 [2.0–6.0] vs 11.9 [5.3–20.0], $p < 0.001$). B NI patients had higher in-hospital (38.4% vs 19.5%, $p < 0.001$) and ICU mortality (33.5% vs 15.7%, $p < 0.001$) than non-NI patients. C In-hospital mortality and ICU mortality according to NI types. Abbreviations: ICU, intensive care unit; NI, nosocomial infection; CRBSI, catheter-related bloodstream infection; CAUTI, catheter-associated urinary tract infection

**Introduction:** High-flow nasal cannula (HFNC) and continuous positive airway pressure (CPAP) are cautiously utilized in patients with acute respiratory distress syndrome (ARDS) because of potential risk of treatment failure. The new global definition of non-intubated ARDS allowed to be diagnosed even in patients receiving HFNC. However, the adequacy of oxygenation severity classification by partial arterial pressure of oxygen to fraction of inspired oxygen (P/F ratio) has not been well validated. We performed a post hoc analysis of the JaNP-Hi trial, a multicenter randomized controlled trial conducted in Japan, to investigate oxygenation in patients with HFNC and CPAP.
**Methods:** The JaNP-Hi trial included patients with P/F ration < 300 on CPAP at 5 cmH2O, assigning them to either HFNC or CPAP. The initial gas flow of HFNC and CPAP levels were set at 50 L/min and 10 cmH2O, respectively, and maintained for a minimum of 30 min. Patients were stratified into mild (P/F 200–299), moderate (P/F 100–199), and severe hypoxemia (P/F < 100) based on their oxygenation at CPAP at 5 cmH2O. The primary outcomes were treatment failure, defined as the need for intubation or death within 28 days across their oxygenation categories. Secondary outcomes included changes in oxygenation category and the agreement between P/F ratios measured at CPAP of 5 cmH2O and after 30 min of treatment allocation, using the Bland–Altman method.
**Results:** Among 85 analyzed patients, 47 (55%) received HFNC and 38 (45%) received CPAP. The median age was 75 years, with 61 (72%) male. The median P/F ratio was 173, with 31, 48, and 6 patients classified into mild, moderate, and severe hypoxemia, respectively. Treatment failure was observed in 16 (19%) patients, with intubation in 14 (21%) patients, and 28-day death in 8 (9%) patients. Treatment failure occurred more frequently in patients with moderate and severe hypoxemia compared with mild hypoxemia (1 (3%) mild vs. 12 (25%) moderate vs. 3 (50%) severe; $P = 0.045$). The HFNC group experienced 21 (45%) patients worsening oxygenation category after 30 min of allocation, contrasted with 1 (3%) patient in the CPAP group ($p < 0.001$). Fourteen of 19 (74%) mild patients managed with HFNC were classified into moderate, and 7 of 26 (27%) moderate patients were classified into severe. Bland–Altman analysis showed a mean bias of -45.4 (95% limits of agreement was -129.4 to 38.7) mmHg between P/F ratio at CPAP of 5 cmH2O and HFNC. Although 1 of 12 (8%) mild patients managed with CPAP was classified as moderate, oxygenation category worsened in no other patients. Bland–Altman analysis showed a mean bias of 21.2 (95% limits of agreement was − 67.9 to 110.3) mmHg between P/F measured at CPAP of 5 and 10 cmH2O.
**Conclusions:** Treatment failures were more frequently observed in patients with more severe hypoxemia under noninvasive respiratory support. These findings emphasize the importance of cautious oxygenation assessment, given the significant variability introduced by different respiratory support devices.

**Topic:** Acute respiratory failure and mechanical ventilation

**Introduction:** It is unknown whether associations of certain aspects of invasive ventilation with outcomes found in ARDS caused by other pulmonary infections (CLASSIC-ARDS) also exist in COVID-ARDS. The number of studies that directly compared ventilation management of COVID-ARDS with CLASSIC-ARDS is limited (1,2). This study aimed to identify associations with outcomes to investigate potential differences in practice of ventilation.
**Objectives:** To identify independent associations with mortality and ventilator-free days at day 60 (VFD–60) between COVID-ARDS and CLASSIC-ARDS patients and to investigate differences in ventilation management.
**Methods:** Individual patient data analysis of COVID-ARDS and CLASSIC-ARDS patients in six observational studies of invasive ventilation, four studies were conducted during the COVID-19 pandemic (PRoVENT-COVID, EPICCoV, CIBERESUCICOVID and SATI-COVID–19)

and two studies from before the COVID-19 pandemic (ERICC and LUNG SAFE) were included. Descriptive statistics were used to compare epidemiology and ventilation characteristics. Also, we performed a multivariable mixed–effects model to identify whether VT, PEEP and ΔP independent associations with 60-day mortality and the number of VFD-60.

**Results:** This analysis included 6702 COVID-ARDS patients and 1415 CLASSIC-ARDS patients. COVID-ARDS patients received lower median VT (6.6 [6.0 to 7.4] vs 7.3 [6.4 to 8.5] ml/kg PBW; $p < 0.001$) and higher median PEEP (12.0 [10.0 to 14.0] vs 8.0 [6.0 to 10.0] cm H2O; $p < 0.001$), a lower median ΔP (13.0 [10.0 to 15.0] vs 16.0 [IQR 12.0 to 20.0] cm H2O; $p < 0.001$) and higher median Crs (33.5 [26.6 to 42.1] vs 28.1 [21.6 to 38.4] mL/cm H2O; $p < 0.001$). After multivariable adjustment, higher ΔP had an independent association with higher 60-day mortality and less VFD-60 in both groups. Higher PEEP had an association with less VFD-60, but only in COVID-ARDS patients (Fig. 1).

**Conclusions:**

1 In COVID-ARDS a higher PEEP was independently associated with less VFD-60. This was not observed in CLASSIC-ARDS.
2 Our results show that key ventilator parameters significantly differ between COVID-ARDS and CLASSIC-ARDS. Patients with COVID-ARDS received a higher PEEP and lower tidal volumes.

| Parameter | Estimate (95%–CI) | p |
|---|---|---|
| VFD–60 | | |
| $V_T$, mL/kg PBW | | |
| COVID–ARDS | 0.1124 (-0.3773 – 0.6034) | 0.63 |

The estimate is the average effect of the predictor variable on the response variable, while controlling for the other variables in the model. A positive estimate suggests a proportional effect, whereas a negative estimate suggests an inversely proportional effect. Abbreviations: ARDS = acute respiratory distress syndrome; VFD = ventilator-free days and alive; IQR = interquartile range; N = number; CI = confidence interval; VT = tidal volume; PBW = predicted bodyweight; PEEP = positive end–expiratory pressure; ΔP = driving pressure

### An observational study of the use of external jugular cannulation for peripheral venous access

B. Shah[1]
[1]Critical care, ASHOKA HOSPITAL, Nashik, India
**Correspondence:** B. Shah
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000984

**Introduction:** External jugular vein (EJV) is not commonly used for peripheral short-term cannulation in spite of its prominent location and access. We prospectively studied the usage of EJV for IV cannulation and its complications.
**Objectives:** The objective of the study is to assess the safety profile for external jugular vein cannulation for hyperosmotic and vesicants infusions, at the same time preventing CVC access only for such infusions.
**Methods:** From July 2023to September 2023, all adult patients (age > 18 yrs) in a Tertiary care medical and cardiac ICU in which EJV was cannulated for short-term vascular access were included in the study and were followed up till removal or patient discharge. The indications, the number of days and the reason of removal were noted. The conversion from EJV to central venous cannulation was also followed. The common problems encountered during cannulations were also recorded.
**Results:** The most common indications to put peripheral EJV was difficult IV access and the use of cordarone and other hyperosmolar medications.
The complications noted are as under:

| Complications | No. of patients | Percentage |
|---|---|---|
| Thrombophlebitis | 4 | 8 |
| Purulent at insertion site | 0 | 0 |
| Induration | 3 | 6 |
| Blockage | 7 | 14 |
| Pain | 1 | 2 |

**Conclusions:** EJV cannulation for short-term peripheral IV access seems to be a safe route to give vesicant and hyperosmolar medications with minimal side effects.

**Introduction:** The Targeted Therapeutic Mild Hypercapnia after Resuscitated Cardiac Arrest (TAME) Randomized clinical trial showed no difference in mortality or favourable neurological outcome at 6-months after out-of-hospital cardiac arrest (OHCA) 0.1 However, the longer-term outcomes of TAME trial participants are unknown.
**Objectives:** To determine the mortality, neurological, functional and cognitive outcomes in TAME trial patients from New Zealand at 2 years post randomization.
**Methods:** Pre-planned, follow-up study of New Zealand TAME trial participants. TAME compared targeted therapeutic mild hypercapnia (TTMH) to targeted normocapnia (TN) for 24 h after OHCA. We evaluated mortality, neurological (favourable GOSE, score 5–8), functional

(poor modified Rankin Scale (mRS), score 4– 6), health related quality-of-life (HRQOL) (EQ-5D-5L) and cognitive (Montreal Cognitive Assessment-Blind assessment) outcomes.
**Results:** Of the 1700 TAME patients, 200 patients (8.5%) were enrolled in New Zealand of which 194 (97%) had 2-year data. We found no difference in mortality, neurological, functional, health related QOL, or cognitive outcomes in New Zealand TAME patients allocated to TTMH compared to TN (Table 1).

**Table 1 (abstract 000985)** 2-year outcomes of New Zealand TAME trial patients

| | TTMH ($n=102$) | TN ($n=98$) | Relative risk/ median difference (95%CI), $p$ value |
|---|---|---|---|
| Mortality, no. (%) | 38/98 (38.8%) | 37/96 (38.5%) | RR, 1.01 [0.69 to 1.48], $p=0.975$ |
| Favourable GOSE, no. (%) *(GOS-E 5 to 8)* | 46/87 (52.9%) | 48/88 (54.5%) | RR, 0.97 [0.67 to 1.40], $p=0.869$ |
| Poor mRS *(mRS 4–6)* | 40/87 (46%) | 38/88 (43.2%) | RR, 1.06 [0.74 to 1.53], $p=0.734$ |
| EQ5D-5L, in survivors | 0.9 [0.9, 1.0] | 1.0 [0.9, 1.0] | MD, − 0.05 (− 0.14 to 0.04), $p=0.258$ |
| Cognitive dysfunction#, in survivors, no. (%) | 13/47 (27.7%) | 7/50 (14%) | RR, 1.98 (0.93 to 4.19), $p=0.076$ |

GOSE, Glasgow outcome scale extended; MD, mean difference; mRS, modified Rankin scale score. #Cognitive dysfunction assessed using the MOCA-Blind

**Conclusions:** Our study now provides longer-term data on mortality and health outcomes of OHCA patients in New Zealand.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000986

**Introduction:** Nucleated red blood cells (NRBCs) in the peripheral blood of critically ill patients are associated with impaired outcome. The predictive value of NRBCs among the subgroup of critically ill patients with sepsis remains unanswered. The aim of the present analysis was to evaluate the predictive validity of NRBCs in septic patients.
**Methods:** This retrospective, observational study was conducted at the University Hospital Dresden, Germany. Data of critically ill septic patients were collected as part of the prospective Comprehensive Sepsis Center Study Dresden-Kreischa registry from 02/2020 to 11/2023. Daily NRBC values were recorded and their predictive validity on mortality was analyzed. A cut-off level based on the patient's maximum NRBC value during intensive care unit (ICU) stay was calculated using receiver operating curves (ROC)-analysis and Youden's method. Survival was depicted using Kaplan–Meier curves which were tested for significant differences with the log rank test.
**Results:** In total, 465 critically ill septic patients were analyzed. NRBCs were found in 93.1% of all patients. Patients who deceased had significantly higher NRBC values during their ICU stay compared to patients who survived (290/µl (60/2010) vs. 30/µl (10/170); $p<0.001$).
A cut-off of NRBCs of 100/µl was effectively dividing the study population into two groups with the most difference for ICU mortality (ROC area under the curve 0.75; 95% confidence interval (CI) 0.69–0.80; $p<0.0001$) (Fig. 1). Increased NRBC values of were found in 43.4% of all patients during the ICU stay and resulted in a fivefold risk of death (odds ratio 5.03; 95% CI 3.19–7.90; $p<0.0001$). Higher death rate of patients overshooting the determined cut-off during ICU-stay was confirmed using Cox proportional-hazards model (hazard ratio (HR) 2.39; 95% CI 1.62–3.59; $p<0.0001$).
NRBCs 100/µl were associated with a longer duration of ICU stay (31 (17; 51) vs. 21 (12; 34) days; $p<0.001$) and longer invasive ventilation (458 (224; 774) vs. 120 (30; 308) hours; $p<0.001$). Extracorporeal membrane oxygenation was significantly more often used in patients with increased NRBCs (30 (14.9%) vs. 3 (1.1%); $p<0.0001$). Patients with NRBC values below the threshold of 100/µl had a significant survival advantage (HR 0.43; 95% CI 0.30–0.62; log rank $p<0.0001$) (Fig. 2).
**Conclusions:** NRBCs predict mortality in critically ill septic patients with good prognostic power. Further studies are required to confirm the cut-off level of NRBCs and evaluate the clinical impact for prognostic enrichment.

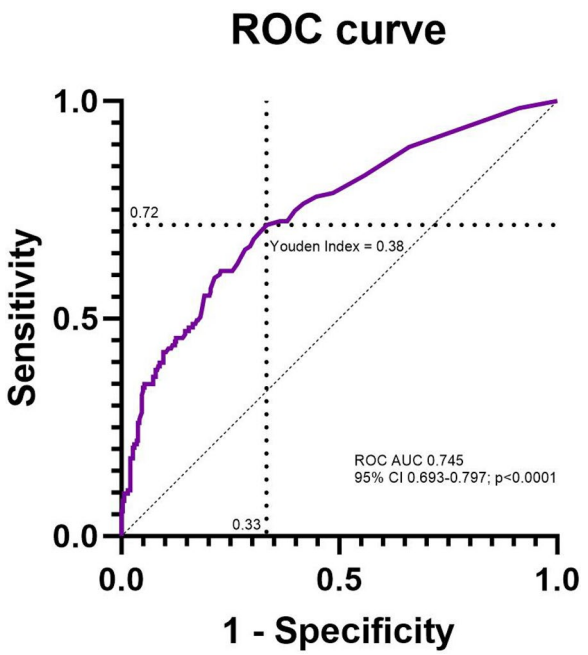

**Fig. 1 (abstract 000986)** Receiver operating curves (ROC) analysis for maximum nucleated red blood cells (NRBCs) values with the endpoint intensive care unit (ICU) mortality and analyzed Youden Index (0.38 at NRBCs 100/µl)

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000987

**Introduction:** Acute kidney injury is a frequent complication in the intensive care unit (ICU) leading to prolonged stay and increased mortality; severity staging requires markers such as creatinine which is late and with multiple factors that bias its measurement and interpretation. Renal ultrasound has increased its use, mainly the resistive index, in addition, the evaluation of renal perfusion in post-surgical patients has been described, however, its relationship with severity in acute kidney injury has not been demonstrated.
**Objectives:** To establish the correlation of the resistive index and renal perfusion pressure with the severity of acute kidney injury in the intensive care unit.
**Methods:** Cross-sectional study in the intensive care unit; patients with acute kidney injury were included and severity was staged according to KDIGO criteria, and renal vascular ultrasonographic measurements were obtained. Statistical analysis was with Kendal's Tau-b test and linear regression analysis.
**Results:** Final population of 81 patients, the variable that correlated with severity was renal perfusion pressure ($r=0.62$, $p\leq0.001$) and diastolic velocity ($r=0.30$, $p=0.007$), however, the resistive index had no correlation ($r=0.135$, $p=0.314$). Similarly, renal perfusion pressure correlated with changes in creatinine ($r=-0.554$), BUN ($r=-0.480$) and bicarbonate ($r=0.331$).

**Table 2 (abstract 000987)** Correlation of renal flow measured with ultrasonography with the level of severity of acute kidney injury by KDIGO scale

| | Correlation | *p* |
|---|---|---|
| Right kidney | | |
| Resistance index | 0.14 | 0.214 |
| Systolic velocity, cm/s | 0.167 | 0.135 |
| Diastolic velocity, cm/s | **−0.321** | **0.012** |
| Average speed, cm/s | **0.219** | **0.049** |
| Renal perfusion pressure, mmHg | **−0.695** | **<0.001** |
| Left kidney | | |
| Resistance index | 0.108 | 0.722 |
| Systolic velocity, cm/s | 0.183 | 0.102 |
| Diastolic velocity, cm/s | **−0.29** | **0.026** |
| Average speed, cm/s | 0.123 | 0.239 |
| Renal perfusion pressure, mmHg | **0.63** | **<0.001** |
| Average | | |
| Resistance index | 0.134 | 0.315 |
| Systolic velocity, cm/s | 0.169 | 0.132 |
| Diastolic velocity, cm/s | **−0.301** | **0.006** |
| Average speed, cm/s | 0.198 | 0.077 |
| Renal perfusion pressure, mmHg | **−0.775** | <0.001 |

It is described by Kendal's Tau-b correlation, with statistical significance with $p\leq0.05$.
Finally, it was found that renal perfusion pressure was correlated with changes in creatinine ($r=-0.554$, $p=0.001$, **Fig. 2)**, changes in BUN ($r=-0.480$, $p=0.001$) and with bicarbonate (0.331, $p=0.003$).
**Conclusions:** No statistically significant results were found in relation to the resistive index, however, we found that the decrease in renal perfusion pressure correlates with greater severity of acute kidney injury in the intensive care unit.

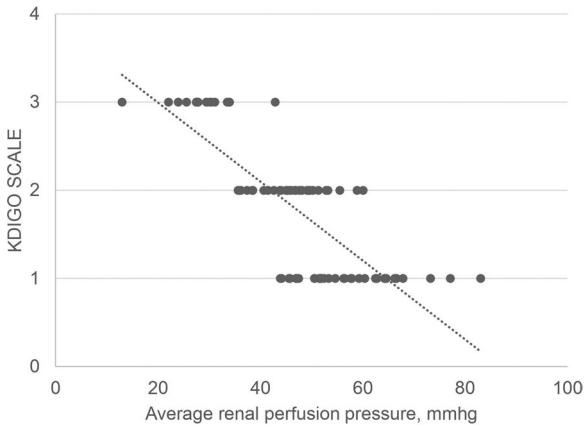

**Fig. 1 (abstract 000987)** Scatter diagram observing a negative correlation between the average renal perfusion pressure with the KDIGO scale ($r=-0.775$ 95% CI 0.644–0.883, $p\leq0.001$) as well as a relationship of $r^2=0.620$ $p\leq0.001$

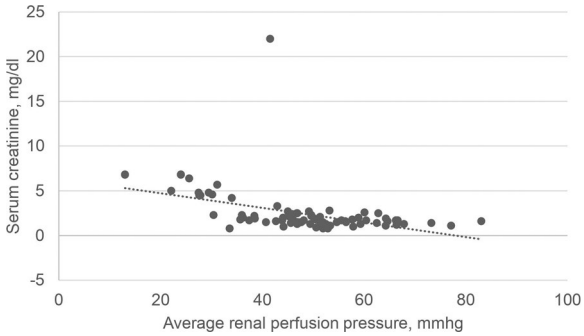

**Fig. 2 (abstract 000987)** Scatter diagram observing a negative correlation between average renal perfusion pressure with serum creatinine ($r = -0.408$ 95% CI 0.291–0.575, $p \leq 0.001$)

## The high tidal volume variability is associated with worse outcomes in the acute respiratory distress syndrome: a retrospective cohort study

J. H. Ahn[1], S. B. Hong[1], C. M. Lim[1], J. W. Huh[1]

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000988

**Introduction:** The impact of spontaneous breathing during mechanical ventilation on the outcome of acute respiratory distress syndrome (ARDS) has not been established. Spontaneous breathing of appropriate intensity and timing may improve atelectasis in the dependent lung regions, preserve diaphragm function, and thereby shorten the duration of mechanical ventilation. However, excessive spontaneous breathing, especially when lungs are vulnerable to injury, can induce patient self-inflicted lung injury or diaphragm injury, or exacerbate pre-existing lung injury.

**Objectives:** We hypothesized that higher tidal volume variability, reflecting excessive spontaneous breathing, would be associated with lung injury and worse outcomes in patients with ARDS. The aim of this study was to evaluate the effect of tidal volume variability on ventilator-free days in mechanically ventilated patients with ARDS using high-resolution tidal volume data collected through the patient monitor.
**Methods:** In this single-center, retrospective cohort study, adult ARDS patients who received mechanical ventilation in our medical intensive care unit between April 2018 and July 2019 were included. The study patients' expiratory tidal volume data during the first 7 days of mechanical ventilation were collected every 2 s from the patient monitors. The included patients were equally divided into three groups according to the coefficient of variation (CV) of all collected tidal volume values normalized by predicted body weight—low, intermediate, and high CV groups. The primary outcome was ventilator-free days within the first 28 days of mechanical ventilation.
**Results:** A total of 108 ARDS patients were categorized into the low, intermediate, and high CV groups (36 patients each). Baseline characteristics of the three groups were comparable except for a lower PaO2/FiO2 ratio in the low CV group (130 ± 50 mm Hg vs. 160 ± 57 mm Hg vs. 158 ± 50 mm Hg; P = 0.03). An average of 222,776 tidal volume data per patient were collected during the first 7 days of mechanical ventilation. The CV of the tidal volumes were 0.17 ± 0.03, 0.26 ± 0.02, and 0.38 ± 0.08 in each CV group, respectively. The number of ventilator-free days was significantly lower in the high CV group than in the intermediate CV group (0 [IQR, 0–2.5] days vs. 16 [IQR, 0–21.5] days; $P = 0.001$, statistically significant after Bonferroni correction). After adjustment for age, sex, body mass index, APACHE II score, and baseline PaO2/FiO2 ratio in the zero-inflated negative binomial model, high CV was significantly associated with more zero ventilator-free days compared with intermediate CV (odds ratio, 4.6; 95% CI [1.6–13.2]; $P = 0.005$).
**Conclusions:** Based on the high-resolution tidal volume data acquired from the patient monitor, high tidal volume variability during the first 7 days of mechanical ventilation in ARDS patients was associated with fewer ventilator-free days.

### Evaluating the implementation of a nurse-led family support intervention from the perspective of ICU health care professionals (FICUS study): results of an embedded qualitative study

S. Oesch[1], L. Verweij[1], R. Naef[1]
[1]Institute for Implementation Science in Health Care, University of Zurich, Zürich, Switzerland
**Correspondence:** S. Oesch
*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000989

**Introduction:** The FICUS hybrid study, initiated in 2021, aims to evaluate the effectiveness of a nurse-led interprofessional family support intervention (FSI) in intensive care units (ICUs), and tests whether active family support by a specialized family nurse in collaboration with the ICU team improves care quality and reduces negative effects on family members' mental health (Naef et al., 2022). In addition, integration of the FSI into real-world ICU contexts is also investigated (Oesch et al., 2023).
**Objectives:** To explore ICU team members' experiences with the FSI implementation.
**Methods:** Multicentre, qualitative evaluation using semi-structured focus group interviews ($n = 8$), conducted towards the end of the active implementation phase (September 2023 to January 2024). Overall, 65 ICU team members of the eight ICUs allocated to the intervention arm participated in the interviews with an average of eight participants per interview (range 6–11). Participants included ICU nurses, physicians, family nurses and leadership persons. Face-to-face interviews were conducted in hospital meeting rooms, with a median duration of 70 min (range 50–120 min). Interviews were audio-recorded, transcribed, and analysed using content analysis methods (Erlingsson & Brysiewicz, 2017; Graneheim et al., 2017).
**Results:** Findings indicated that FSI implementation in ICU teams was influenced by preexisting ICU implementation climate (team/organizational readiness, collaborative culture), capacity (staff and time resources), intervention adaptability, and the challenge of clinical study processes and requirements. Implementation was facilitated by clarifying responsibilities of the family nurse role, establishing FSI delivery structures and workflow, and by proactively engaging members of the team by implementation leaders (family nurse, ICU leadership persons). Participants perceived the FSI to provide valuable support for families to deal with uncertainty, emotional burden and information needs during ICU stay, and experienced a high need for post-ICU support. Overall, the FSI of the new family nurse role and family care pathway was experienced as a benefit to the ICU team, supporting their capacity to care for patients without neglecting families, and improving their interprofessional collaboration with families.
**Conclusions:** Team readiness and capacity, interprofessional leadership and implementation support, intervention adaptability, workflow redesign, and perceptions of benefit appeared to be essential to support successful FSI integration and delivery in intervention ICUs. Subsequent studies should explore implementation beyond a clinical trial context.

### Prevalence of upper limbs peripheral nerve injuries in patients undergoing prone positioning: a systematic review with proportional meta-analysis

F. Binda[1], S. Gambazza[2], F. Marelli[1], R. Veronica[1], M. Lusignani[3], G. Grasselli[4]
[1]Department of Anesthesia, Intensive Care and Emergency, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy; [2]Department of Healthcare Professions, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy; [3]Department of Biomedical Sciences for Health, University of Milan, Milano, Italy; [4]Department of Pathophysiology and Transplantation, University of Milan, Milano, Italy
**Correspondence:** F. Binda
*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**000995

**Introduction:** Prone positioning, a technique used since the 1970s to enhance oxygenation in adults with ARDS, gained widespread use during the COVID-19 pandemic. However, complications such as pressure ulcers, unplanned extubation, and nerve injuries like brachial plexopathy are well-documented. While the exact epidemiology of upper limb peripheral nerve injuries (PNI) related to prone positioning remains unclear, several cases have been documented during the

pandemic. Therefore, a meta-analysis of available studies on upper limb PNIs is proposed to address this gap in understanding.
**Methods:** This systematic review with proportional meta-analysis was conducted following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) and Meta-analysis of Observational Studies in Epidemiology (MOOSE) reporting guidelines. Four electronic databases including PubMed, the Cumulative Index to Nursing and Allied Health Literature, The Cochrane Library, and EMBASE were searched from inception to January 2024.
**Results:** A total of 8 studies (511 patients) were pooled in the quantitative analysis. All studies had a low or moderate risk of bias in methodological quality. The overall proportion of patients with upper limbs PNI was 13% (95%CI 5% to 29%). Figure 1 presents the pooled prevalence estimates of the included studies using a forest plot. The overall effect size is not statistically different from zero ($P = 0.0287$). Furthermore, there is large evidence of between-study heterogeneity ($P < 0.001$): the 84.55% of the variability in the effect-size estimates is due to the differences between studies. The estimated between-study variance τ2 is 1.62: we then expect that in some 90% of all populations, the true prevalence will fall in the approximate range of 1% and 71%. All studies included in the meta-analysis reported enrollment during the first wave of the COVID-19 pandemic. A total of 3 studies detected upper limbs PNI during the follow-up period, while only 1 study conducted specific diagnostic investigations before ICU discharge. Only 2 studies reported that a dedicated multidisciplinary team (consisting of intensivists, nurses, and respiratory therapists) performed the prone positioning maneuver.
**Conclusions:** Prone positioning remains a life-saving maneuver, and the potential risks related to it should not be underestimated. The low prevalence of upper limbs PNI among patients undergoing prone positioning stress the challenges of diagnosing such nerve injuries in complex clinical settings and raises concerns about potential selective reporting of cases during the COVID-19 pandemic.

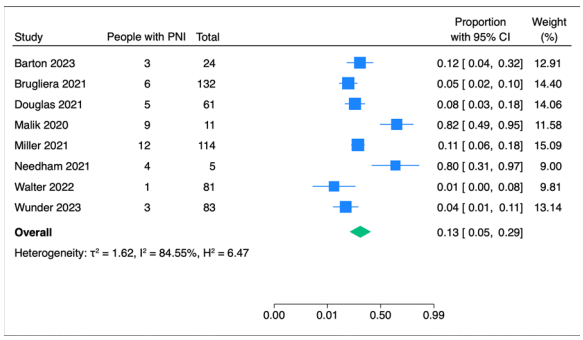

**Fig. 1 (abstract 000995)** The forest plot of the overall pooled prevalence of upper limbs PNI. A blue square is plotted for each study, with the size of the square being proportional to the study weight. The estimate of the overall effect size is depicted by a green diamond: its width represents the corresponding CI

### Does extending the duration of oseltamivir beyond 5 days improve outcomes in critically ill patients with severe influenza infection?

T. Kiser[1], E. Gutierrez[2], E. Burnham[3], P. M. Ho[3], M. Moss[3], R. Vandivier[3]
[1]Clinical Pharmacy, University of Colorado, Aurora, United States of America; [2]Clinical Pharmacy, University of Colorado Hospital, Aurora, United States of America; [3]Medicine, University of Colorado Anschutz Medical Campus, Aurora, United States of America

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000996

**Introduction:** Current WHO and CDC recommendations state that extending oseltamivir treatment duration is appropriate when the clinical course of influenza infection remains severe or progressive, despite 5 or more days of antiviral treatment; however, the evidence supporting this recommendation is limited.
**Objectives:** We aimed to describe the use of extended duration oseltamivir and evaluate differences in clinical outcomes based upon oseltamivir treatment duration in ICU patients with severe influenza.
**Methods:** This clinical effectiveness study utilized the Premier database and included ICU patients > 18 years old admitted to a US hospital between January 1, 2016 and December 31, 2021 who were treated with at least 2 days of oseltamivir therapy for a diagnosis of influenza. Patients were placed into standard duration (≤ 5 days) or extended duration (> 5 days) groups. The primary outcome was hospital mortality. Secondary outcomes included ICU and ventilation-free days, cost, and drug-related adverse events. A propensity-matched analysis, including matching for hospital length of stay, was used for evaluation of outcomes between groups.
**Results:** A total of 98,992 patients from 920 hospitals were evaluated: 23,699 (24%) in the extended duration and 75,293 (76%) in the standard duration oseltamivir group. At baseline, patients receiving extended duration therapy were more commonly receiving vasopressors (15.8% vs. 9.6%, $p < 0.01$), invasive mechanical ventilation (26.5% vs. 14.6%, $p < 0.01$), or non-invasive ventilation (31.3% vs. 21.4%, $p < 0.01$) compared to standard duration patients. After propensity matching ($n = 15,352$ per group), extended duration oseltamivir treatment was associated with reduced mortality (7.4% vs 8.9%, $p < 0.01$). This difference remained significant after adjusting for unbalanced covariates (OR 1.18; 95% CI 1.08–1.28; p < 0.01). Twenty-eight day ICU-free days (24 vs. 25 days, $p = 0.02$) and assisted ventilation-free days (25 vs. 25 days, $p =$ NS) were similar between treatment groups. No differences in potential oseltamivir related adverse effects ($p > 0.05$ for all) were observed between groups. Extended duration was associated with increased median hospital cost ($81,705 vs. $74,400, $p < 0.01$).
**Conclusions:** Extended duration oseltamivir was used in ~ 25% of ICU patients admitted with severe influenza. Utilization of extended duration oseltamivir therapy was associated with a trend towards improved mortality, suggesting that extending antiviral treatment beyond 5 days may be appropriate in certain critically ill patients with severe influenza.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000998

**Introduction:** Recent studies demonstrate cytomegalovirus (CMV) reactivation in apparently non-immunosuppressed critically ill patients with incidence ranging from 25% to as high as 60% across various cohorts [1, 2]. However there is a lack of knowledge on incidence of CMV reactivation in patients with acute necrotising pancreatitis (ANP), a condition notorious for intra-abdominal infections (both bacterial and fungal) during their clinical course.
**Objectives:** To study the incidence of intra-abdominal CMV reactivation in critically ill acute necrotizing pancreatitis (ANP) patients.
**Methods:** After institutional ethics committee approval and trial registration (NCT05898048), this prospective study screened all adult ICU patients having the diagnosis of ANP with at least 2 week duration of illness with a peripancreatic drain in situ according to clinical indication. Exclusions were age < 18 years, expected survival < 72 h, pancreatitis duration > 10 weeks, recent antiviral use, known immune deficiencies, haematological malignancies, immunosuppressive medication, chemotherapy/radiotherapy, and pregnancy. Eligible patients, in whom anti-CMV IgG antibodies were present, samples from peripancreatic collections (drain in closest proximity of pancreas) were collected weekly until the 10th week of illness or ICU discharge (whichever comes first) to assess the CMV reactivation and its viral load kinetics. CMV reactivation was defined as viral load > 1000/cc, using CMV quantitative real time PCR.
**Results:** During the study period (Jun 2023-Feb 2024), 20 out of 39 ANP patients met eligibility criteria. At ICU admission, these 20 patients had median age 35 years (IQR 24–40); 90% males, Charlson's co-morbidity index 0 (IQR 0–1). On the day of study inclusion median SOFA score was 6 (IQR 5–9), median day of illness 29 (IQR 17–38) with CT scan severity index (CTSI) 10 (IQR 9–10). CMV reactivation was observed in 9 out of 20 patients (45%). Among the patients who had CMV reactivation, 55.5% ($n = 5$) had concurrent bacterial and 11.1% ($n = 1$) had fungal infection in peripancreatic intra-abdominal collections (Fig. 1). The median day of CMV reactivation was 50 (IQR 44–56), with median copies of 25750/cc (3150–18975) (Fig. 2). The clinical characteristics of patients having CMV reactivation vis-a-vis non-reactivation were: age 39 vs 33 ($p = 0.17$), Charlson's co-morbidity index 0 vs 0 ($p = 0.23$), SOFA 6 vs 6 ($p = 0.76$), CTSI score 10 vs 10 ($p = 0.33$), day of pancreatitis at inclusion 28 vs 29 ($p = 0.65$), duration of ICU stay 60 vs 20 ($p = 0.01$). The mortality at ICU discharge in CMV reactivation group was 55.6% compared to 45.5% in the non-reactivation group ($p = 0.97$).
**Conclusions:** In patients with ANP, intra-abdominal CMV reactivation occurs in almost half of the patients during their 6th to 8th week of illness, with higher crude mortality in comparison to patients who did not have CMV reactivation. These patients have longer duration of ICU stay in comparison to patients without CMV reactivation.

### Extracellular vesicles derived from human umbilical cord mesenchymal stem cells attenuate septic acute kidney injury by delivering miR-125a-5p and miR-125b-5p to inhibit inflammation

C. Feng[1], T. Tao-Tao[2], Z. Q. Chen[2], L. Bi-Cheng[2], W. Zhong[1]
[1]Medicine, Tsinghua University, Beijing, China; [2]Medicine, Southeast University, Nanjing, China

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**000999

**Introduction:** Sepsis is a fatal disease with high morbidity and mortality, and acute kidney injury is a common complication. Recent studies have shown that excessive inflammatory response is a key mechanism for sepsis-induced acute kidney injury (SAKI). Extracellular vesicles derived from human umbilical cord mesenchymal stem cells (hucMSC-sEV) have the capacity for intercellular signaling communication, making them a novel therapeutic strategy for various diseases. Our previous study found that hucMSC-sEV has a protective effect on ischemia reperfusion-induced AKI. However, the use of hucMSC-sEV in SAKI has been rarely reported.
**Objectives:** To investigate the protective effect of hucMSC-sEV against SAKI and its potential mechanism.
**Methods:** hucMSC were extracted for culture and identification, and hucMSC-sEV were collected and characterized. SAKI model was

established by cecal ligation and puncture in vivo and HK-2 cells induced by LPS in vitro, and hucMSC-sEV was given. The weight change and survival rate of mice were counted daily. IVIS imaging systems assess the relationship between organ damage and sEV distribution. Serum levels of Scr, BUN, Cys-C and NGAL were measured to reflect renal function. The mRNA levels of Kim-1 and inflammatory markers (IL-1β, IL-6, TNF-a, MCP-1 and F4/80) were measured by qRT-PCR. HE and immunohistochemical/fluorescent staining were performed to assess tissue damage. RNA sequencing was used to explore the key effector molecules of SAKI. Analysis of protective molecules in sEV cargoes by exosome miRNA sequencing.

**Results:** We successfully isolated and characterized hucMSC-sEVs. hucMSC-sEV converge heavily on CLP-induced injury to the kidney, attenuate AKI by delivering miR-125a-5p and miR-125b-5p, miRNAs that are highly enriched in hucMSC-sEVs, and reduce mortality. miR-125a-5p and miR-125b-5p co-target to inhibit TNFR2 expression, which in turn inhibited the activation of NF-κB signaling pathway, reduced the level of inflammatory factors, and ameliorated kidney injury. Furthermore, hucMSC-sEV also significantly attenuated LPS-induced HK-2 cells injury in vitro. However, when miR-125a-5p and miR-125b-5p were knocked down in hucMSC, the protective effect of mucMSC-sEV against SAKI was reduced.

**Conclusions:** In SAKI, hucMSC-sEV may inhibit the inflammatory response and ameliorate renal injury by delivering miR-125a-5p and miR-125b-5p to co-regulate the TNFR2/NF-κB signaling pathway, thereby improving survival.

**Introduction:** Severely intoxicated patients are a common admission to UCI in case they do not respond to initial treatment in the emergency room. This can be accidental or intentional exposure to drugs of abuse, known or not, resulting in additional difficulties involved in their management until the identification of the causative toxin.
**Objectives:** Our main goal is to describe the epidemiology, and to establish whether there is a correlation between the patients' previous dependency status, and the development of intra-ICU complications, length of stay, days of mechanical ventilation and mortality.
**Methods:** This is a retrospective, observational study conducted in the ICU, during 2 years by systematic review of the medical records. Demographic data were collected, APACHE II score, toxicity causing SAI, intubation, days of mechanical ventilation, morbidity, need for dialysis, days of ICU stay. Mortality was not included due to the low mortality rate. Statistical analysis was performed using SPSS, using the $\chi 2$ test for normally distributed variables and the Mann–Whitney U test for non-normal variables, considering $p < 0.05$ the level of statistical significance.
**Results:** 31 subjects were included. Among the males, 88.2% had a history of previous dependence, of which 17.6% were homeless and 11.8% were institutionalized. The mean age was 45. The mean length of stay was 6 days. The APACHE score with previous dependence was 23.27 while in non-dependent patients it was 17.57. The most frequent intoxication was due to drugs of abuse 48.4%, followed by pharmaceuticals 45.2% and of these, up to 80.6% were caused by a combination of toxics. Complications included seizures, rhabdomyolysis, acidosis, subarachnoid hemorrhage, long QT, cardiac arrest and death, which globally accounted for 41.9% of all complications, followed by infection in up to 25.8%; delirium and withdrawal syndrome occurred in 6% of patients with previous dependence. Orotracheal intubation was required in 90.3% of patients, with no significant differences between the group with prior dependency and the group without it. The need for re-intubation after initial extubation was similar in the two groups but for different causes, with agitation predominating in patients with previous dependence. The need for dialysis was 12.9% overall and 28.6% among patients without previous dependence, mostly related to drug intoxication, which was statistically significant.
**Conclusions:** Most were male, with SAI due to combinations mostly including benzodiazepines. Intoxication by drugs of abuse predominates in patients with previous drug dependence as opposed to drug intoxication, which predominates in patients without dependence, although this was not statistically significant. Most patients (90.3%) required orotracheal intubation, with no significant differences between patients with and without previous dependence, with similar mean length of stay. In our sample there are no difference in terms of intra-ICU evolution between patients with and without prior dependency, which is counterintuitive, but could be explained by the good evolution of these patients in general. The need for dialysis was 12.9% overall and 28.6% among patients without previous dependence, mostly related to drug intoxication, which was statistically significant ($p = 0.032$). This is due to the fact that dialysis is part of the treatment of many drug intoxications and its use responds more to elimination treatment than to the development of acute renal failure.

**Introduction:** Finding an individualised mechanical ventilation (MV) strategy to ensure gas exchange while avoiding ventilator-induced organ damage is challenging in acute respiratory distress syndrome (ARDS).

**Objectives:** We aimed to develop a reinforcement learning-based decision support system (IntelliLung DSS) to dynamically suggest optimised ventilator settings using historic patient data and evaluate its performance in a porcine ARDS model.

**Methods:** Following approval of the institutional review board at the Medical Faculty Dresden (BO-EK-423082021), data from invasively ventilated adult patients with ARDS or pneumonia admitted to the intensive care units (ICU) of the University Hospital Dresden were used to develop the IntelliLung DSS. We randomly selected 80% of the data for training and 20% for the clinical evaluation. We used a discrete batch-constrained deep Q-learning (BCQ) approach to suggest optimised settings for positive end-expiratory pressure (PEEP), inspiratory oxygen fraction (FIO2) and respiratory rate (RR). The patient state was described using 12 variables of MV, gas exchange, haemodynamics and lab results as multidimensional time series in 10-min time steps. The rewards function of the algorithm was defined as ICU mortality and short-term pulmonary and physiological rewards within safe ranges. For prospective performance evaluation four pigs were anaesthetised after approval (AZ: 25-5131/522/24) and sequential lung injury was induced using surfactant depletion (LAVAGE), injurious MV (VILI) and continuous intravenous lipopolysaccharide infusion (LPS). A fixed tidal volume of 6 ml/kg was used throughout the experiment. PEEP, FIO2 and RR were set in each lung injury block in randomised order according to either the IntelliLung DSS or ARDS network protocol (ARDSnet, low PEEP table for PaO2/FIO2 > 175 mmHg and high PEEP table for PaO2/FIO2 < 175 mmHg at the respective baseline)[1] for 180 min each (cross-over design). Respiratory and haemodynamic variables were recorded every 15 min. Statistical analysis was performed with SPSS using a general linear model for repeated measurements (mean ± standard deviation).

**Results:** Data from 942 patients (653 male, 289 female; 64 ± 16 years, ICU mortality 25%, year of admission: 2010–2020) were used for algorithm development and clinical evaluation. In the clinical evaluation, the IntelliLung DSS more frequently suggested lower FIO2 (≤ 40%) and PEEP (≤ 10 cmH2O) and more frequently RR ≤ 18 /min compared to the clinician. In the animal study, RR was not significantly different between IntelliLung DSS (30 ± 2 $min^{-1}$) and ARDSnet (31 ± 4 $min^{-1}$, $P = 0.757$) (Fig. 1). In the LAVAGE block, FIO2 according to IntelliLung DSS was higher than during ARDSnet (43 ± 22 vs 37 ± 21%, $P = 0.038$), whereas in VILI and LPS blocks there was no significant difference between IntelliLung DSS and ARDSnet strategy (Fig. 1). In the VILI block, PEEP according to IntelliLung DSS was higher compared to ARDSnet (7.4 ± 1.3 vs 5.2 ± 0.7 cmH2O, $P < 0.001$), whereas in LAVAGE and LPS block there was no significant difference between IntelliLung DSS and ARDSnet (Fig. 1). In the LAVAGE block, the ratio of peripheral oxygen saturation (SpO2) to FIO2 was significantly lower during IntelliLung DSS than during the ARDSnet strategy, but not in the VILI and LPS block (Fig. 2). There was no significant difference in mechanical power (Fig. 2), mean arterial pressure (Fig. 2), cardiac output and arterial pH between IntelliLung DSS and ARDSnet strategy regardless of the lung injury block.

**Conclusions:** The IntelliLung DSS was applicable both clinically and experimentally. In the retrospective clinical evaluation, IntelliLung DSS proposed a ventilation strategy with lower FIO2 and PEEP values compared to the clinician. In the animal study, IntelliLung DSS allowed the individualisation of MV similar to the ARDSnet settings, avoiding extreme PEEP values.

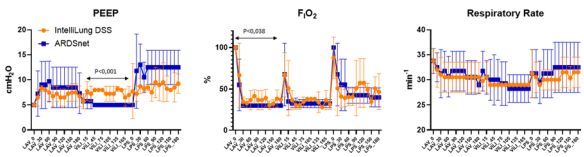

**Fig. 1 (abstract 0001001)** Mean and standard deviation. IntelliLung DSS, mechanical ventilation according to the IntelliLung decision support system; ARDSnet, mechanical ventilation according to the ARDS network protocol; PEEP, positive end-expiratory pressure; FIO2, inspiratory oxygen fraction; LAV, lung injury induced by surfactant depletion; VILI, lung injury induced by injurious mechanical ventilation; LPS, lung injury induced by intravenous lipopolysaccharide infusion; ns, not significant

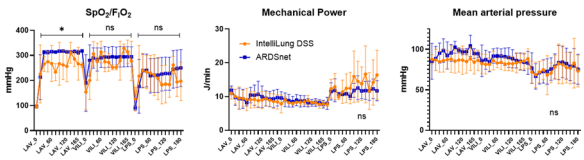

**Fig. 2 (abstract 0001001)** Mean and standard deviation. ***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001002

**Introduction:** Multiple trauma patients present a particular nutritional risk, since they exhibit high nitrogen demands and associated nutritional therapy challenges, caused by repeated surgical intervention or multiple imagistic procedures. Current published data regarding metabolic profile in the early acute phase are rather contradictory. However, there is currently a lack of clear data regarding metabolic profile description, especially in the early acute phase.
**Objectives:** This prospective observational randomized study aims to personalize energy and protein intake for severe multiple trauma patients by utilizing continuous monitoring of their metabolic profile.
**Methods:** This single-center pragmatic study was conducted at the Trauma Center of the Clinical Emergency Hospital of Bucharest. It included all patients with multiple trauma (Injury Severity Score (ISS) > 18) who were mechanically ventilated upon admission to the ICU or within the first 24 h of admission, and remained ventilated for at least 48 h. Patients excluded from the study were those under 18 years old, not intubated or not receiving mechanical ventilation, only on non-invasive ventilation, with contraindications to enteral feeding 48 h after admission, those who had undergone recent gastrointestinal surgical intervention, on chronic corticosteroid therapy and pregnant women. Indirect calorimetry was initiated within the initial 6 h of ICU admission to continuously evaluate the metabolic profile and energy needs using E-sCOVX® module paired with Carescape Monitor B450® (GE Healthcare, Helsinki, Finland). Nutritional support was started 48 h after admission or shock control, using a ramped fashioned approach. Statistical analysis of the database was performed using GraphPad Prism 10. Normality of data distribution was tested with the D'Agostino–Pearson test. Both descriptive data analysis and Pearson correlation coefficient were examined.
**Results:** Out of 38 patients with multiple trauma admitted to our unit, 29 were included in the final group study after applying the exclusion criteria. The median age in the study group was 43 (22–82) and 20 patients were male. BMI calculation, revealed a median value of 26,3 kg/m$^2$. Mean blood sugar level was 162.33 mg/dL (SD = 48.4). Trauma severity assessment revealed a median ISS score of 40 (18–66). Indirect calorimetry measurements in the first 6 h after admission revealed a mean VO2 (oxygen consumption) of 320.8 ml/min (SD = 77.59) and for rest energy expenditure (REE), the mean value was 2094 kcal/day (SD = 472.4). The high standard deviation value indicates increased variation in energy expenditure among patients. Furthermore, the range of REE values, from 1322 to 3167, highlights a broad spectrum of energy expenditure levels among multiple trauma patients, potentially influencing muscle loss, nutritional strategies, and rehabilitation outcomes. No significant correlation was observed between traumatic injuries (brain injuries, thoracic trauma or abdominal trauma) and metabolic profile. There was also no direct correlation observed between the SOFA and APACHE II scores and the metabolic profile data.
**Conclusions:** This study suggests the importance of real-time monitoring of the metabolic profile in multiple trauma patients to gain a deeper understanding of the acute injury's impact. The significant variation in REE within our cohort study and the absence of any correlation between traumatic assessment and severity scores, suggests that metabolic status should be assessed individually. We consider that the original metabolic response described (early/late flow phase) may not accurately identify nutritional needs and the true catabolic impact of trauma.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001003

**Introduction:** Active mobilization of critically ill patients reduces the development of intensive care unit-acquired weakness and improves patient outcome. (1, 2) However, active mobilization outside of clinical trials often remains inadequate. (3) Robotic assisted active mobilization might facilitate frequent and safe mobilization and can serve as a tool for precise control of mobilization intensity. VEMOTION (Reactive Robotics, Munich, Germany) enables robotically assisted in-bed patient mobilization, combining verticalization and gait-like leg movement.
**Objectives:** We therefore studied whether robotic assisted mobilization increases the total duration of mobilization when compared to a conventional mobilization strategy.
**Methods:** In this single center, prospective randomized clinical trial, we studied patients admitted to a Weaning Intensive Care Unit (ICU). Patients were randomized to receive either robotic assisted mobilization plus standard treatment, or standard mobilization alone. Predefined primary endpoints were the average minutes of mobilization per day and the total duration within 14 days. Secondary endpoints included the highest level of active mobilization as well as safety and feasibility of the intervention.
**Results:** Overall, 40 patients (13 women, mean age 64 ± 14 years) were analyzed. Daily duration of robotically assisted mobilization was significantly longer than standard active mobilization (65.3 ± 84.7 min vs 52.2 ± 73.3 min; $p = 0.009$) but not total duration in 14 days (intervention: 914.3 ± 629.8 min; control: 730.3 ± 433.8 min, $p = 0.534$). The overall level and frequency of mobilization were higher in the intervention group (Fig. 1).
**Conclusions:** A robotic assisted patient mobilization did not result in a significant increase of the total duration of mobilization in the 14 days after admission.

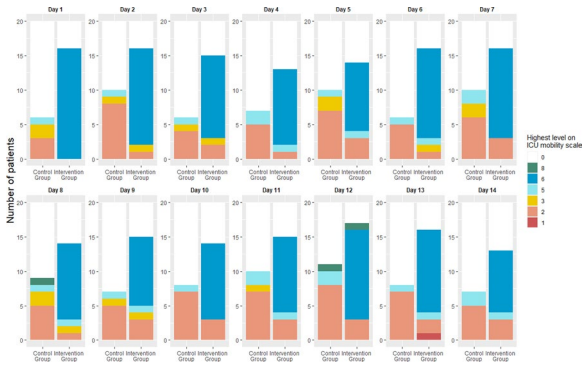

**Fig. 1 (abstract 0001003)** Highest level of mobilization according to the ICU Mobility Scale
ICU Mobility Scale: 0 (lying in bed), 1 (sitting and exercising in bed), 2 (passive movement from bed to chair, no standing), 3 (sitting on edge of bed), 4 (standing), 5 (transferring from bed to chair), 6 (marching in place at bedside), 7 (walking with assistance of two or more people), 8 (walking with assistance of one person), 9 (walking independently with gait aid), and 10 (walking independently without gait aid). Robotic mobilization was classified in category 6.

**Introduction:** Limited data are available on hyperoxia during early VA-ECMO support management.
**Objectives:** To evaluate the association between hyperoxia and 28-day mortality in adult patients with CS receiving VA-ECMO.
**Methods:** Adult patients diagnosed with CS receiving VA-ECMO support in the Chinese Society of ExtraCorporeal Life Support Registry database were included. Hyperoxia was defined as a PaO2 greater than 150 mmHg (mild:150 < PaO2 < 200, moderate: 200 ≤ PaO2 < 300 and severe: PaO2 ≥ 300). The primary outcome was 28-day mortality and the second outcome was renal replacement therapy (RRT), in-hospital mortality and successful weaning of VA-ECMO. Logistic regression model was used to examine the association between hyperoxia and outcomes by adjusting confounders.
**Results:** A total of 2351 patients were included in the final analysis. 28-day all-cause mortality was 39.0% and 48.5% patients received RRT while on ECMO course. 37.7% of patients with CS receiving VA-ECMO support were classified as hyperoxia, among which 319 patients were mild hyperoxia, 311 patients were moderate hyperoxia and 256 patients were severe hyperoxia. Hyperoxia (adjusted OR 1.523, 95%CI 1.157–2.006, $P=0.003$) was independently associated with higher 28-day mortality after adjusting confound factors. When the patients were divided into four groups according to different level of hyperoxia, moderate (adjusted OR 1.740, 95%CI 1.146–2.643, $P=0.009$) and severe (adjusted OR 2.049, 95%CI 1.324–3.173, $P=0.001$) hyperoxia was significantly related with 28-day mortality. Compared with normoxia, mild hyperoxia (adjusted OR 1.514, 95%CI 1.008–2.273, $P=0.046$), moderate hyperoxia (adjusted OR 1.788, 95%CI 1.218–2.858, $P=0.020$) and severe hyperoxia (adjusted OR 1.969, 95%CI 1.248–3.108, $P=0.004$) were independent risk factors of RRT.
**Conclusions:** Exposure to hyperoxia during early VA-ECMO support management was significantly associated with increased 28-day mortality and the requirement of RRT.

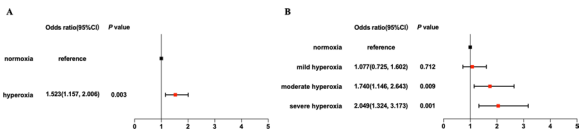

**Fig. 1 (abstract 001004)** Forest plot of risk-adjusted odds ratios of hyperoxia and 28-day mortality in patients with CS receiving VA-ECMO support. (A) Patients were divided into normoxia and hyperoxia groups. (B) Patients were divided into normoxia, mild hyperoxia, moderate hyperoxia, and severe hyperoxia groups. ***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001005

**Introduction:** Septic shock is associated with poor prognoses in intensive care units (ICUs)1). Although the effects of PMX-HP for septic shock patients is still controversial 2), PMX-HP therapy had been performed for longer than 2 h in Japan 3).
**Objectives:** The best available treatment for septic shock (BEAT-SHOCK) registry examined whether there was an association with PMX-HP and patients' prognosis for several subgroups using data from a registry study about severe septic shock which requires high-dose norepinephrine (≥ 0.2 μg/kg/min) in Japan.
**Methods:** The primary outcome was defined as the 28-day mortality rate, and the secondary outcomes were the 90-day mortality rate, the 28-day ICU-free days, 28-day vasopressor-free days and changes in blood pressure and vasoactive-inotropic score (VIS) within 48 h after ICU admission. In addition, subgroup analyses were performed on age, APACHEII and SOFA at ICU admission, lactate level, type of infection and VIS.

**Results:** In the registry, 309 patients' data were analyzed and the average age and APACHEII were 70.8 years old and 26.9. 82 patients were received PMX-HP therapy and the average length of PMX-HP therapy was 1016 min. The 28-day mortality rate was similar between groups (PMX group: 17.1%, non-PMX group: 18.9%, $P=0.71$). The 90-day mortality did not differ between groups (PMX group: 23.5%, non-PMX group: 27.1%, Log-rank $P=0.62$). The median 28-day ICU-free days in PMX group was significant shorter than non-PMX group (PMX group: 16, non-PMX: 18, $P=0.03$). In PMX group, blood pressure was significantly higher within 48 h after ICU admission, though no significant difference was observed in VIS reduction. In subgroup of lower VIS than 30, the 90-day mortality rate was significant lower in the PMX group (adjusted HR (95%CI): 0.21 (0.05–0.86)).
**Conclusions:** Prolonged PMX-HP was not associated with better prognosis, though PMX-HP provided higher blood pressure in acute phase. Further prospective trials of prolonged PMX-HP are needed to save severe septic shock patients.

### Study of incidence, risk factors and outcome of new onset cardiac arrhythmias in medical intensive care unit of a tertiary care hospital

D. A. Kaur[1], D. Bhasin[1], H. Singh[1], S. Sampley[1]
[1]PULMONOLOGY & CRITICAL CARE, Max Super Specialty Hospital, Mohali, Sahibzada Ajit Singh Nagar, India
**Correspondence:** D. A. Kaur
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001006

**Introduction:** Arrhythmias are a frequent occurrence in intensive care unit (ICU) patients. The incidence of arrhythmias in ICU has been documented up to 40%, especially in presence of sepsis and respiratory failure. Accurate identification of different arrhythmias is important for timely and appropriate treatment. Correct therapeutic option will be life saving and can also improve the quality of life of the patient.
**Objectives:** To study the incidence of various New Onset Cardiac Arrhythmias (NOCA) in medical intensive care unit. To study the risk factors associated with NOCA and the clinical outcome of NOCA in terms of ICU length of stay and in-hospital mortality.
**Methods:** A prospective observational study was conducted in adult Medical ICU of a 38 bedded multidisciplinary critical care unit of a tertiary care hospital. The study was conducted from August 2021 to July 2022. Patients diagnosed with NOCA were included in the study. Patients were diagnosed using American Heart Association guidelines 2015 and 2017. They were followed until ICU discharge or in hospital death. Incidence of NOCA, risk factors, frequency of different types of NOCA and outcome was assessed.
**Results:** A total of 1909 patients admitted to medical ICU from August 2021 to July 2022 were screened for NOCA and 49 patients were diagnosed with NOCA. The incidence of NOCA came out to be 2.56% with atrial fibrillation being the most common (34/49, 69.3%) NOCA followed by paroxysmal supraventricular tachycardia (5/49, 10.2%).

Age ≥ 60 years (32/49, 65.3%), male gender (36/49, 73.5%), sepsis as the cause of ICU admission (35/49, 71.4%), hypokalemia (23/49, 46.9%), acidosis (20/49, 40.8%) were the most common risk factors associated with NOCA. Hypertension was the most common comorbidity observed (25/49, 51%). 61% (30/49) of patients with NOCA got discharged while 31% (15/49) died and 8% (4/49) left against medical advice. Atrial fibrillation (10/15, 66.6%) was the most common NOCA associated with mortality.

**Conclusions:** Arrhythmias continue to be a serious complication in ICU patients. Identification and timely management of correctable risk factors can help decrease the incidence of arrhythmias and prevent morbidity and mortality.

**Introduction:** Sepsis is defined as an infection that results in one or more organ failures due to a dysregulated immune response (1). The incidence of sepsis has been steadily increasing in recent years, with rates ranging from 250 to 500 cases per 100,000 inhabitants per year. The overall mortality rate for sepsis is as high as 38% (2). In Catalonia, the average annual incidence stands at 264.1 cases of sepsis per 100,000 inhabitants per year (3, 4).

Sepsis morbidity and mortality are linked to both non-modifiable patient-dependent factors such as sex, age, and comorbidities, non-modifiable episode-dependent factors, such as the site of infection, source of acquisition, responsible microorganism, and immune response; and modifiable healthcare-related factors such as early detection and appropriate sepsis bundle performance. Comparative monitoring of outcomes for patients treated for septic shock could help to identify centers who needs improvement measures for sepsis code implementation.

Sepsis is defined as an infection that results in one or more organ failures due to a dysregulated immune response (1). The incidence of sepsis has been steadily increasing in recent years, with rates ranging from 250 to 500 cases per 100,000 inhabitants per year. The overall mortality rate for sepsis is as high as 38% (2). In Catalonia, the average annual incidence stands at 264.1 cases of sepsis per 100,000 inhabitants per year (3, 4).

Sepsis morbidity and mortality are linked to both non-modifiable patient-dependent factors such as sex, age, and comorbidities, non-modifiable episode-dependent factors, such as the site of infection, source of acquisition, responsible microorganism, and immune response; and modifiable healthcare-related factors such as early detection and appropriate sepsis bundle performance. Comparative monitoring of outcomes for patients treated for septic shock could help to identify centers who needs improvement measures for sepsis code implementation.

**Objectives:** To compare hospital length of stay and adjusted mortality rates among patients with septic shock in the Catalan Health Service (CatSalut) centers.

**Methods:** We defined cases as adult hospital discharges from 2018 to 2022 period with a diagnosis of septic shock (R6521: Severe sepsis with septic shock or T8112XA: Post-procedure septic shock). We collected data from the CMBD registry of CatSalut. We used demographic data, pre-existing comorbidity, episode-related (infection foci, organ failures and organ support treatments), and outcome data (inhospital or mortality and hospital length of stay) to create a risk-adjusted mortality and efficiency predictive model. We applied the predictive model to the cases of 2022. Finally, we ranked hospitals based on adjusted mortality and hospital stay.

**Results:** During the study period, we identified 25,298 cases of septic shock. 60.1% of the cases were male (with a median age of 68.6 years) and 39.9% were female (with a median age of 70.1 years). According to the Adjusted Morbidity Groups of CatSalut, 83% of patients had comorbidities with moderate or high associated risk. The most frequent site of sepsis were urinary, respiratory, and abdominal. Renal and respiratory system were the most common associated organ failure (50.6% and 25.5%, respectively). Overall hospital mortality was 37.9% (34.9% if shock was present upon admission and 49.1% if it was developed during hospitalization). When we applied the predictive model for the cases in 2022 period, we observed that 3 hospitals had lower mortality rates while 5 hospitals had higher mortality rates than expected, with statistically significant values (ROC curve of 0.74; confidence interval from 0.728 to 0.754). Regarding hospital stays, we did not find a statistically significant difference.

**Conclusions:** Constructing a predictive mortality model for septic shock helps to create a comparative analysis of mortality and efficiency. This can be useful for developing quality and safety programs related to sepsis management.

### Current status of end-of life care in intensive care unit: a pilot study

W. J. Seo[1]
[1]Pulmonology and Critical care medicine, Inje University Ilsan Paik Hospital, Goyang-si, Republic of Korea
**Correspondence:** W. J. Seo
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001008

**Introduction:** As South Korea transitions into a super-aged society, interest in life-sustaining treatments and end-of-life care has increased. Despite this, many patients admitted to intensive care units (ICUs) lack prior discussions about end-of-life care, leading to insufficient advance care planning due to the rapid progression of acute illnesses.
**Objectives:** This study aims to examine the current status of end-of-life care in ICU and understand guardians' perspectives and factors influencing life-sustaining treatments through a survey.
**Methods:** This study was conducted as a single-center, prospective pilot study. It included patients admitted to the medical intensive care unit (ICU) receiving treatments like vasopressors, mechanical ventilation, and hemodialysis. Surveys were conducted among the main guardians and medical staff during end-of-life care discussions and POLST (Physician Orders for Life-Sustaining Treatment) documentation. Electronic medical records (EMR) were also reviewed to collect patients' demographic information, hospitalization length, and intensive care details.
**Results:** From November 2023 to January 2024, 14 patients were included. Of those, eight patients (57.1%) were male, with a median age of 78. The median length of hospital stay was 25 days, with a median ICU stay of 13 days. POLST discussions with medical staff typically occurred around six days after ICU admission. Five patients (35.7%) died during ICU stay. Eight patients (57.1%) received mechanical ventilation; two patients received cardiopulmonary resuscitation (CPR) and cardioversion. Six patients (42.9%) were admitted to the ICU using a high-flow nasal cannula. Among the 14 patient's guardians, nine were patients' children, three were spouses, and in two cases, both spouses and children participated in the POLST discussion. Seven (50%) answered that they lived with the patients. The median value of the clinical frailty scale for the patients was 5, mainly indicating mild frailty. Four patients had previously completed advance care planning; nine had not, and one guardian was unsure. Regarding life-sustaining treatments, five patients (35.7%) had expressed a desire not to pursue them, another five (35.7%) had indirectly expressed their opinions, three (21.4%) had never considered it, and one desired life-sustaining treatments.
Among the participating guardians, ten (72.4%) answered well-informed and understood the prognosis of the patient's illness. Regarding the improvement of patients' condition, five (35.7%) guardians estimated it to be less than 25–50% of prior condition, while six (42.9%) believed it to be 0–25% for recovery. Six guardians (42.9%) wanted to discontinue intensive care immediately, citing disagreement with the patient's previous wishes or low chances for improvement. Despite eight guardians (57.1%) answered to continue treatment, half were unsure about additional treatment duration.

**Conclusions: Many elderly patients, often with chronic illnesses, experience rapid health deterioration due to acute illnesses. While patients with cancer or specific terminal diseases may have considered advance care planning before, many elderly do not document or express preferences regarding life-sustaining treatments. Sometimes, the patient's autonomy is not fully considered, and intensive care begins. In this study, over half of the patients (71.4%) expressed direct or indirect preferences regarding life-sustaining treatment. Guardians tend to respect the patient's pre-existing opinions or consider the likelihood of recovery and may discontinue intensive care.**
However, due to this study's small sample size, further statistical analysis or identifying trends is challenging. Further research into end-of-life care discussions in the ICU can not only address social costs, but also contribute to a dignified death.

### Extracorporeal removal of CO2 in acute respiratory distress syndrome due to SARS-COV-2 pneumonia

R. Marín Ráez[1], D. Muñoz-Mingarro Molina[1], AA. De Abreu Ramírez[1], OA. González Fernández[1], C. Martinez Martinez[1], MM. Panduro Meza[1], C. Soriano Cuesta[1], R. De Pablo[1]

**Introduction:** During the COVID-19 pandemic, many patients experience severe illness and high mortality due to respiratory failure and multiple organ dysfunction1. Measures like Extracorporeal Carbon Dioxide Removal Therapy (ECCO2R) have been utilized to enhance lung ventilation in acute respiratory distress syndrome (ARDS) patients. ECCO2R aids in maintaining protective mechanical ventilation (MV) and correcting respiratory acidosis, offering a less invasive alternative to extracorporeal membrane oxygenation (ECMO)2.
**Objectives:** Evaluate the efficacy, evolution, and complications related to ECCO2R in severe ARDS due to SARS-CoV-2 pneumonia.
**Methods:** This observational retrospective study analyzes ARDS patients admitted to a tertiary hospital's polyvalent ICU from 03/2020 to 01/2023, requiring ECCO2R therapy due to SARS-CoV-2.
Collected data include demographic variables and adjunctive treatments. Patients eligible for ECCO2R therapy exhibited respiratory acidosis (pH < 7.25, PaCO2 > 60) and/or driving pressure (DP) > 15 despite optimized MV and adjunctive therapies. Those meeting ECMO support criteria were excluded.
ECCO2R efficacy was assessed based on achieving pH > 7.25, PaCO2 < 60, and DP < 15. pH, PaCO2 and DP were measured at 0,2,24,48 and 72 h post-ECCO2R initiation to evaluate efficacy. Complications, including thrombotic, hemorrhagic, and infectious events, were recorded. Hospital mortality and its relationship with goal attainment was analyzed.
Results are presented as percentages and means ± standard deviation (SD). The Mann–Whitney test was employed for independent samples and quantitative variables.
**Results:** Twenty-four patients were analyzed. 83% were males with a mean age of 62 ± 9 years.
ECCO2R was indicated: 20% of cases for respiratory acidosis, 25% for DP > 15cmH2O, 55% for meeting both criteria.
The combined efficacy objective was achieved in 71% of patients at 48h and in 50% at 72h. Acidosis control was achieved within the first 24 h in 96% of cases. A DP < 15 was achieved in 66% at 24h and in 71% at 48h.
50% of ECCO2R patients had complications: 50% had circuit-related thrombotic events, 29% had non-severe hemorrhages, and 20% developed pneumonia. No catheter infections were observed.

Hospital mortality was 54.2%. Mortality rates were 71% for those not achieving combined efficacy within 24 h and 100% if not achieved within 48 h.
**Conclusions:** ECCO2R therapy effectively controlled acidosis and DP in ARDS patients with SARS-CoV-2 infection. Early acidosis control was observed, but significant outcomes relied on DP improvement within 48 h. Complications were frequent but generally not severe. In our study, failure to meet the 48-h objective was linked to 100% mortality.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001011

**Introduction:** Patients with ANCA vasculitis are frequently admitted to the intensive care units (ICUs). The impact of these admissions to the ICU on the course of their disease and their future outcomes is not yet fully known.
**Objectives:** We aimed to assess the characteristics at ICU admission and the consequences of an ICU stay in terms of morbidity and mortality in patients with ANCA vasculitis.
**Methods:** Retrospective observational study based on data collected from medical charts in two French Academic hospitals. The data from all adult patients with a diagnosis of ANCA vasculitis (defined according to the international criteria) admitted to medical wards or to the ICU, were extracted. We assessed the impact of ICU admission on 12-months mortality (primary outcome) and on renal function 12 months after admission.
**Results:** We included 143 patients who were hospitalized in participating centers between 2007 and 2022: 48 admitted to the ICU and 95 in hospitalized in conventional wards. Most patients were men (56, 6%), and their mean age was 64 (16) years. The vasculitis was most frequently microscopic polyangiitis (71, 49.7%). The reason for hospitalization was vasculitis flare in 90.2% and among those, 20.9% had pulmonary-renal syndrome.
Patient characteristics are described in Table 1. In the subgroup of 107 patients with a newly diagnosed vasculitis (30 (28%) in the ICU group and 77 (72%) in the conventional ward group), the mean BVAS score at admission was higher in the ICU group (21.6 ± 8.2 vs. 14.7 ± 6.0, $p < 0.001$) and decreased at 12 months from admission values by, respectively, a median [IQR] of − 15 [− 19;− 12] in the ICU group and − 12 [− 17;− 7] in the non-ICU group ($p = 0.039$).
Twelve months mortality was 9.2% ($N = 13$). ICU-patients had higher 12-month mortality (20.9% vs. 4.2%, $p = 0.004$), as well as higher rates of persisting kidney dysfunction (74.3% vs. 36.2%, $p < 0.001$) and infectious complications (27% vs. 15%, $p = 0.004$). Non-survivors were older (77 ± 11 vs. 62 ± 15 years, $p < 0.001$), with a higher rate of microscopic polyangiitis than survivors (92.3% vs. 46.4%, $p = 0.004$). The vasculitis was already known before admission in half of them (54% vs. 21% in patients alive at 12 months, $p = 0.014$) and there was no difference in the BVAS score at baseline (15.7 ± 7.17 in survivors vs. 17.6 ± 7.31 in non-survivors $p = 0.387$). There was no difference in the cause of first hospital admission, but non-survivors had higher SOFA (4.2 ± 2.4 vs. 2.1 ± 2.6, $p = 0.009$), IGS2 (44 ± 14 vs. 23 ± 14, $p < 0.001$) and APACHE2 (19 ± 6 vs.10 ± 6, $p < 0.001$) scores, and a more severe kidney dysfunction at admission with higher levels of serum creatinine and urea (401 ± 263 vs. 209 ± 210, $p = 0.023$ and 27 ± 11 vs. 13 ± 11, $p = 0.001$, respectively).
**Conclusions:** In patients with ANCA vasculitis, an ICU stay was associated with higher 12-month mortality and kidney dysfunction. Higher mortality was expected in these more severe patients. The next step of this study will be to assess the long-term impact of ICU admission on kidney function and disease activity adjusting on confounders.

**Table 1 (abstract 0001011)** Patient characteristics at admission

| | ICU group N = 48 | Conventional care group N = 95 | p-value |
|---|---|---|---|
| Admission SOFA score (med [IQR]) | 4.00 [3.00;5.00] | 1.00 [0.00;2.00] | <0.001 |
| Admission IGS2 score (mean, SD) | 40.3 ± 15.2 | 18.6 ± 10.1 | <0.001 |
| Admission APACHE2 score (mean, SD) | 17.4 ± 5.98 | 8.21 ± 5.47 | <0.001 |
| Charlson score (med [IQR]) | 4.00 [2.00;6.00] | 3.00 [1.00;4.00] | 0.010 |
| Medical history of diabetes n (%) | 16 (34.0%) | 10 (10.5%) | 0.001 |
| Medical history of vasculitis n (%) | 18 (37.5%) | 18 (18.9%) | 0.027 |
| Rapidly progressive glomerulonephritis at admission n (%) | 31 (64.6%) | 38 (40.0%) | 0.009 |
| Alveolar hemorrhage at admission n (%) | 17 (35.4%) | 8 (8.42%) | <0.001 |
| ENT symptoms at admission n (%) | 13 (27.1%) | 45 (47.4%) | 0.031 |
| Flare of vasculitis responsible for admission n (%) | 38 (79.2%) | 91 (95.8%) | 0.005 |
| Pulmonary-renal syndrome responsible for admission n (%) | 17 (35.4%) | 10 (10.5%) | 0.001 |

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001012

**Introduction:** Twenty-five percent of all intensive care patients receive one or more red blood cell (RBC) transfusion during their intensive care unit (ICU) stay (1). An increasing number of studies suggest that a restrictive transfusion policy is non-inferior or even superior to a liberal policy (2). Few studies have focused specifically on the elderly ICU population. In old age, reduced physiological reserves and frailty may hypothetically change the risk–benefit profile of transfusion. Risk factors for transfusion-related complications are more common in the elderly, potentially outweighing benefits. Uncertainty about the appropriate transfusion threshold in old age could result in different transfusion decisions for these patients. It is unknown whether elderly ICU patients are treated similarly to younger patients with respect to transfusion.

**Objectives:** To assess transfusion practices for elderly ICU patients and compare these practices to younger patients.
**Methods:** This is a substudy of the International Point Prevalence Study of Intensive Care Unit Transfusion Practices (InPUT), an international, multicenter, prospective, observational cohort study evaluating worldwide transfusion practices in the ICU (1). All patients aged 18 years or older admitted to the ICU during predefined weeks were included. Outcomes included the occurrence rate of RBC transfusion, the used transfusion thresholds and the main indications for RBC transfusions. For this sub-study, these outcomes were compared between patients of different age categories: < 65 years, 65–75 years, 75–85 years and > 85 years.
**Results:** In total 3643 patients from 233 centers across 30 countries were included. Among them, 53% ($N = 1942$) were younger than 65 years, 26% ($N = 935$) were 65–75 years, 17% ($N = 615$) were 75–85 years and 4% ($N = 151$) were older than 85 years. The occurrence rate of RBC transfusions did not differ between the age categories and ranged from 23 to 26% ($P = 0.99$). The hemoglobin threshold was higher in patients of 85 years and older (median 10.0 g/dL, IQR 8.0–10.0 g/dL) compared to those younger than 85 years (median 8.0 g/dL IQR 7.0–9.0 g/dL; $P < 0.001$). The stated reasons for RBC transfusion differed between age categories (Fig. 1). In patients 85 years or older, "*age of patient*" was more often stated as reason for transfusion (14.3%; $P < 0.001$) compared to 75–85 years (5.2%), 65–75 years (2.0%) and < 65 years (0.4%). *"To improve general state"* was also more often stated as reason for transfusion (17.6%, $P < 0.001$) in patients 85 years or older compared to 75–85 years (6.8%), 67–76 years (3.2%) and < 65 years (4.1%). *"Coronary ischemia"* was more often a reason for RBC transfusion in the patient group of 65–75 years (4.4%; $P < 0.001$) compared to > 85 years (2.2%), 75–85 years (3.3%) and < 65 years (1.0%).
**Conclusions:** Different transfusion strategies are applied in elderly patients compared to younger patients. It is unknown if this is a favorable practice.

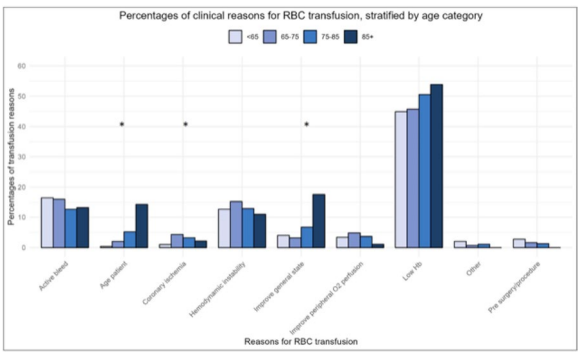

**Fig. 1 (abstract 0001012)** Overview of the percentage of clinical reasons stated for RBC transfusion, stratified by age category. Asterisks (*) indicate significant differences between age categories

## Quality of death in surgical ICUs: a preliminary investigation of medical staff perspectives

C. Kang[1], H. Lee[2], S. Y. Oh[3], L. Lim[2], M. Kim[1], H. G. Ryu[4]

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001014

**Introduction:** In the context of varying intensive care unit (ICU) characteristics, scarce investigations have delved into how medical personnel perceive death in Republic of Korea. This study aims to fill this gap by examining the perception of death among medical staff primarily in surgical ICUs, crucial for enhancing end-of-life care quality.
**Methods:** A preliminary prospective study was conducted from June 2023 to February 2024. The attending doctors and nurses responsible for the deceased patients were asked to participate in Quality of Dying and Death (QODD) questionnaire within 48 h after patient death. Higher score of QODD (20 questions, total score range 0 to 100) indicated a better quality of death.
**Results:** Findings from 61 completed questionnaires, representing 35 ICU staff members (18 doctors and 17 nurses) who cared for 23 deceased patients were analyzed. Doctors, compared to nurses, provided better QODD scores (21.6 ± 7.8 vs. 15.4 ± 9.0; $P = 0.008$, Fig. 1) despite less experience with patient death ($r = -0.43$, $P = 0.001$). Discussions about patient wishes and applying appropriate sedation correlated positively with better death quality, respectively ($r = 0.72$, $P = 0.01$; $r = 0.68$, $P = 0.01$). Additional findings revealed that despite advanced care planning and end-of-life decision documentation (82.6%), 21.7% received cardiopulmonary resuscitation within 24 h before death (Table 1).

**Table 1 (abstract 0001014)** Baseline characteristics of deceased patients ($N = 23$)

| Variables | |
|---|---|
| Age (year) | 64.9 ± 13.8 |

| GCS within 24h before death | 6.5 ± 3.8 |
| Cardiopulmonary resuscitation within 24 h before death | 5 (21.7) |
| DNR documentation | 2 (8.7) |
| End-of-Life decision documentation | 19 (82.6) |

Continuous data are expressed in mean ± SD or as n (%). APACHE II, acute physiology and chronic health evaluation II; SOFA, Sequential Organ Failure Score; ICU, intensive care unit; GCS, Glasgow Coma Scale; DNR, do not resuscitate.

**Conclusions:** Previous studies were predominantly conducted in medical ICUs, and in comparison, the quality of death scores in surgical ICUs were relatively lower. This preliminary report underscores the need for enhanced education, advanced care planning, and further research to improve end-of-life quality for both patients and medical staff.

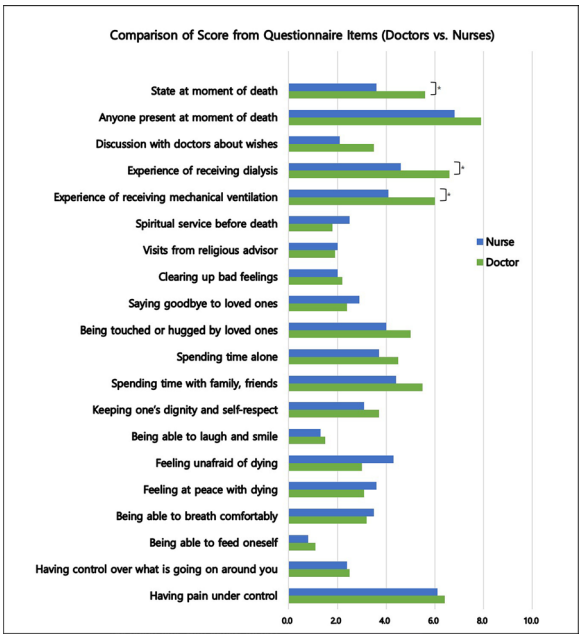

**Fig. 1 (abstract 0001014)** Individual score for each questionnaire items. *$P < 0.05$

### Kinetics of renin–angiotensin system circulating peptides following angiotensin-(1–7) administration in COVID-19 ICU patients

A. Calabrese[1], A. L. Valle Martins[2], F. A. Da Silva[2], T. Verano-Braga[2], F. S. Taccone[1], F. Annoni[1], R. A. S. Santos[2]

**Introduction:** The renin–angiotensin system (RAS) plays an important role in the pathogenesis of COVID-19 (1). In this context, modulation of the RAS using different drugs has yielded encouraging results (2). A recent randomized trial using continuous infusion of exogenous Angiotensin-(1–7) has just been completed.
**Objectives:** Analysis of the RAS circulating components (Angiotensin I, II, (1–7) and (1–5)) kinetics following Angiotensin-(1–7) administration in patients with COVID-19.
**Methods:** Secondary per-protocol analysis of a multicenter investigator-initiated, seamless phase 1–2 randomized clinical trial conceived to test the safety and efficacy of continuous short-term intravenous administration of Angiotensin-(1–7) in COVID-19 patients admitted to two intensive care units (ICU). Between August 2020 and July 2021, when the study was prematurely stopped due to low recruitment rate, 105 patients were included in both phases (28 in phase 1, open label and 77 in phase 2, double blind) and randomized to receive either intravenous Angiotensin-(1–7) for a maximum of 7 days or until ICU discharge or placebo. Blood from included patients was sampled at Baseline, 3, 24, 72 h and after 7 days. A chaotropic agent to arrest plasmatic proteases was added to the vials and circulating RAS peptides were measured using mass spectrometry-tandem liquid chromatography, and compared using a general linear mixed model fitted for restricted maximum likelihood (REML).
**Results:** Ang-(1–7), Ang-(1–5), Ang II and Ang I were measured in 49 patients in phase II (30 in the control group and 19 in the Ang-(1–7) group). Concerning canonical RAS, despite an increase in Ang-II levels in the treated group between baseline and T3, no overall differences were found between the groups ($p = 0.37$ for interaction, $p = 0.06$ for group at T3), similarly to what was observed in Ang-I levels ($p = 0.93$ for interaction). For the non-canonical RAS, there was no difference during the observations (for the interaction in the Ang-(1–5), $p = 0.33$ and in the Ang-1(1–7), $p = 0.62$). Overall, no significant difference in circulating Ang I, Ang II, Ang-(1–5) and Ang-(1–7) were observed between groups during Phase 2, as shown in Fig. 1.
**Conclusions:** In this study, intravenous Angiotensin-(1–7) administration did not significantly impact on RAS peptides kinetics of COVID-19 patients. The relatively small size of Angiotensin-(1–7) group and the possible increase in pulmonary tissue metabolism could explain these findings.

**Introduction:** The dissemination of Gram-negative bacteria resistant to carbapenems is a public health issue that has experienced an exponential growth after the COVID pandemic.
**Objectives:** The purpose of our study is to describe the distribution of these pathogens in our health care settings between 2021 and 23 in order to define the local epidemiology, and better control and antidissemination strategies.
**Methods:** A retrospective and descriptive study about infections and colonizations due to carbapenemase producing enterobacteria (CPE). Isolates from both hospital and primary health care settings were included. The characterization of strains and their drug sensitivity was

determined by MALDI Biotyper and Microscan Walkaway 96 according to EUCAST. For the discrimination of carbapenemases, the immunoassay NG-Test/CARBA-5 was used.

**Results:** During this period a total of 171 strains of CPE were isolated, of which 105 in men and 66 in women. Culture samples were mainly collected in the hospital setting (150 in hospital vs 21 in primary care). The mean age of patients was 73,64 years (CI 95% 61.17–86.12). Hospital admission was required for 135 patients (40 of them needing ICU). The mean APACHE II score at the time of admission was 18.47 (CI 95% 8.99–27.96). We found a mean length of stay of 50.98 days (CI 95% 18.89–83.08); Fig. 1. The 70.1% had been hospitalized in the previous five months, 50% in the case of ICU patients. As well as an accelerating growth in the isolation of CPE throughout the three years that we collected data, there were only three cases of culture positivity for CPE in 2021 in contrast to 41 cases in 2022 and 127 in 2023; Fig. 2.

The CPE most frequently observed was *K. pneumoniae* with a total of 136 positive cultures (79.5%), followed by *Citrobacter freundii*, seen in 12 (7%). The main sites of bacterial growth for CPE (Fig. 3) were urine cultures, 67 (39.1%), colonization screenings for multiresistant bacteria 55 (32.2%), aerobic cultures from tissue exudates and abscesses 36 (21%) and blood cultures 13 (7.6%).

Twelve of the strains of CPE detected had two different carbapenemases: 6 VIM + KPC, 4 OXA48 + NDM, 1 OXA48 + KPC and 1 OXA48 + VIM.

Antibiotics most frequently used were: fosfomycin 28.4%, trimethoprim/sulfamethoxazole 14.5%, meropenem/vaborbactam 12.7%.

**Conclusions:** In the post-pandemic period CPE have spread globally. In our setting, the most frequently found enterobacteria is *K. pneumoniae* and the predominant carbapenemase is KPC.

The analysis and active search for patients colonized or infected by CPE and patient follow-up until microbiological eradication is of crucial importance in order to provide a comprehensive clinical management. This includes targeted antibiotic treatment and other relevant measures like strict compliance of healthcare staff and visitors to infectious disease preventive rules, rational use of broad-spectrum antibiotics during shorter periods and the avoidance of unnecessary invasive procedures.

**Introduction:** Death determination is central to organ donation practices and is defined by the absence of brain function and circulation. Organ donation following circulatory arrest after withdrawal of life-sustaining measures has increased donation opportunities worldwide, but key research questions remain pertaining to the precise timing of death determination with a brain-based definition and whether neuromonitoring can aid in the timing of death determination.
**Objectives:** Following WLSM in critically ill humans, we aimed to (1) demonstrate feasibility of multimodal data collection of simultaneous cerebrovascular and cardiovascular physiologic data elements, and (2) describe the specific timing of cessation of cerebral circulation in the context of systemic circulatory arrest.
**Methods:** We conducted a single-center prospective interventional cohort study on critically ill patients to characterize circulatory arrest physiology during WLSM. Cerebrovascular monitoring consisted of middle and posterior cerebral artery blood velocities (MCAv, PCAv), jugular venous bulb oximetry (SjvO2), and regional cerebral oxygen saturation (rSO2). Cardiovascular monitoring consisted of mean arterial pressure (MAP) monitoring, telemetry, pulmonary artery catheter oximetry, and pulse oximetry. Serum and plasma bio-specimens were collected from the radial artery and jugular venous bulb before WLSM and after the systolic blood pressure reached below 60 mmHg. Brain, heart and spinal cord autopsies were conducted following death determination. Timing data for WLSM are reported as median [range].
**Results:** From May 2023 to February 2024, 25 patients were enrolled and completed data collection. Continuous MAP, MCAv, telemetry, and pulse oximetry from WLSM until death declaration or discharge from intensive care was collected in all patients. PCAv, SjvO2, and rSO2 were collected in 92%, 92% and 72% of patients, respectively. Pulmonary artery catheter oximetry was conducted in in 40% of patients. Serum and plasma bio-specimens were collected in 92% of cases. Brain, heart, and spinal cord autopsies were performed in 92%, 64%, and 24% of cases, respectively. The time from WLSM to < 5 mmHg pulse pressure was 45 [4, 405] min. The time difference between cessation of MCAv/PCAv and < 5 mmHg pulse pressure was + 65 [-3, + 2128] s and + 133 [+ 5, + 3545] s, respectively, with 8 patients having a difference > 4 min.
**Conclusions:** Following WLSM, simultaneous monitoring of cerebrovascular and cardiovascular data elements was feasible. There was considerable heterogeneity of time to death determination. Cessation of cerebral circulation preceded radial pulse pressure being < 5 mmHg. This highlights a temporal discordance between the cerebral and systemic circulation with implications for the timing of death determination and its impact on warm ischemic times in organ donation.

### Effects of hypertonic sodium lactate infusion on brain functions in a refractory cardiac arrest model using extracorporeal cardiopulmonary resuscitation

A. Moreau[1], F. Su[1], F. Annoni[1], FS. Taccone[1]
[1]Intensive care, Hospital Erasme—Cliniques Universitaires De Bruxelles, Brussels, Belgium
**Correspondence:** A. Moreau
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001019

**Introduction:** Extracorporeal cardiopulmonary resuscitation (ECPR) is increasingly used as a treatment for cardiac arrest (1). While hypertonic sodium lactate (HSL) has shown benefits in cardiac arrest models (2, 3), its effectiveness during ECPR has not been reported yet.
**Objectives:** To evaluate the effects of HSL infusion on brain functions in an experimental model of ECPR.
**Methods:** Twelve mixed-sex pigs underwent 5 min of untreated ventricular fibrillation (no-flow), followed by 25 min of conventional CPR (low-flow) and defibrillations. Veno-arterial extracorporeal membrane oxygenation was initiated at 30 min of resuscitation, where animals were randomly assigned to receive either balanced crystalloid (control group, $n = 6$) or hypertonic sodium lactate (HSL) infusion (HSL group, $n = 6$). Brain oxygen pressure (PbtO2) and intracranial pressure (ICP) were recorded during the whole experiment. Cerebral microdialysis (CMD) sampling was performed at baseline and every hour till the end of the experiment. Fluid resuscitation and norepinephrine were administered to maintain adequate hemodynamics. Twelve hours after return of spontaneous circulation, the animals were killed by an intracardiac potassium injection.
**Results:** In the HSL group, there was a trend toward lower norepinephrine requirement over time ($p = 0.1$). Blood lactate was not significantly different between the two groups ($p = 0.12$). PH, sodium and bicarbonate concentrations were significantly higher in HSL group ($p = 0.001$, $p < 0.0001$, $p < 0.0001$, respectively). While brain oxygenation values were similar between groups, ICP was significantly lower in HSL group compared to controls ($p = 0.01$) throughout the experiment. No significant differences in cerebral interstitial metabolites measured by cerebral microdialysis were observed between groups. Furthermore, transaminases and troponin I levels were comparable in both groups.
**Conclusions:** In this experimental model of ECPR, the infusion of HSL was associated with a significant reduction in ICP. No other significant effects on brain oxygenation and metabolism were observed.

**Taurine attenuates sepsis-induced skeletal muscle atrophy by modulating mitochondrial synthesis**

F. Ping[1]
[1]Deparment of critical care medicine, West China Hospital of Sichuan University, Chengdu, China
**Correspondence:** F. Ping
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001020

**Introduction:** Up to 90% of severe sepsis patients have muscle atrophy that hinders weaning from ventilatory support, prolongs hospitalization and is associated with an increased risk of death. Various factors such as inflammation, oxidative stress, and mitochondrial dysfunction have been identified to be associated with sepsis-induced skeletal muscle atrophy. Previous studies showing taurine as an antioxidant with a role in protecting against oxidative stress in the mitochondria. Taurine depleted mouse are reported to develop muscular dystrophy. Besides, taurine supplementation can improve exercise endurance in rats and healthy humans.
**Objectives:** This study was conducted to explore whether taurine attenuates sepsis-induced skeletal muscle atrophy in mice and its underlying mechanisms.
**Methods:** A mouse sepsis model was constructed by cecal ligation and puncture. Taurine was administered intravenously for three consecutive days prior to surgery, and mice were executed on the first and 14th postoperative days. Blood was collected for analysis of serum biochemistry and inflammatory factors. Quadriceps femoris was used for mitochondrial synthesis signaling pathway examination and electron microscopy analysis. Tibialis anterior and gastrocnemius muscles were separated from each group of mice and used for HE staining.
**Results:** Compared with the CLP group, the taurine-treated group attenuated the liver and kidney injury, reduced the serum levels of IL-1β, TNF-a, and IL-6, and significantly increased the mRNA level of PGC1a in quadriceps femoris on the first day after CLP. Meanwhile, scanning electron microscopy of quadriceps muscle revealed a significant reduction in the number of mitochondria, a decrease in intramitochondrial cristae, and rupture of mitochondrial membrane after CLP while the number of mitochondria in the taurine-treated group was relatively increased. On postoperative day 14, the cross-sectional area of tibialis anterior and gastrocnemius muscles of mice in the taurine-treated group was increased compared to the CLP group.
**Conclusions:** Taurine can ameliorate sepsis-induced skeletal muscle atrophy, and the underlying mechanism may be related to the promotion of mitochondrial biogenesis.

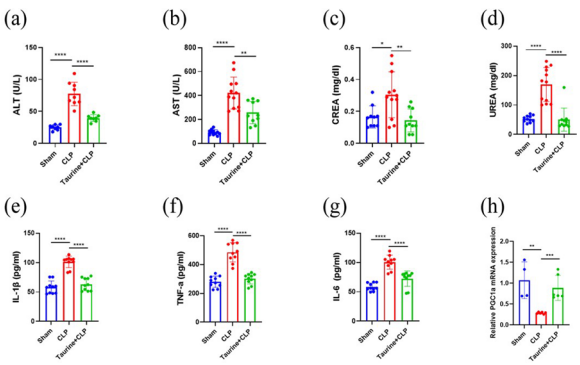

**Fig. 1 (abstract 0001020)** On the first postoperative day, taurine attenuates hepatic and renal injury, reduces serum inflammatory factor levels, and increases PGC1a mRNA expression in quadriceps femoris muscle in septic mice. ### Epidemiology of endotracheal tube blockage in intensive care unit: a prospective observational study

V. Bhardwaj[1], A. Samprathi[2], M. V. Mk[3], K. Saha[2], A. Alva[2]
[1]Critical care, Narayana Institute of Cardiac Sciences, Bommasandra, Bengaluru, India; [2]Critical Care, Narayana Institute of Cardiac Sciences, Bommasandra, Bengaluru, India; [3]Critical Care Medicine, Narayana Hrudayalaya, Bengaluru, India
**Correspondence:** V. Bhardwaj

**Introduction:** Endotracheal tube blockages (ETB) are not uncommon in ICU (1). ETB can be due to many reasons and clinical presentation is non-specific. Ventilator pressure alarms are inaccurate and hypoxia is a late sign of ETB. This can lead to life threatening complications if not intervened early. Prospective studies describing epidemiology of ETB in ICU are lacking.

**Objectives:** To determine the incidence and factors contributing to ETB.
**Methods:** 369 consecutive endotracheal tubes of ICU patients aged > 18 years were assessed post-extubation. The tube was initially assessed virtually through naked eye and later cut at the level of maximum blockage. An image of the tube was captured through a dedicated 12-megapixel mobile camera. The percentage of ETB was analyzed using SketchAndCalc application with a digital image processing algorithm (2) (Fig. 1). This trial is registered with the Clinical Trial Registry-India (CTRI/2023/10/058184 on 3/10/2023).
**Results:** Out of 369 tubes assessed, Cardiothoracic ICU (CICU) patients were almost twice that of the Medical ICU (MICU) patients (240 vs 129). 102 tubes (27.64%) had 0% obstruction. Overall incidence of overt ETB (defined as ETB of 10% or more) was 212.74 and was more in CICU patients (218.68 vs 204.78 per 1000 ventilator days). Overt ETB was seen more in males (81.66% in CICU and 65.89% in MICU) and open suction practice (218.68 vs 204.78 per 1000 ventilator days). Most common site of block observed in overt ETB was distal to the cuff (147 vs 40) and mixed secretion (blood with mucous) was more common (99 vs 88) (Fig. 2 and 3). Monitoring mechanism trigger (defined as ventilator peak airway pressure > 30 cmh20) was not breached in majority of the patients with overt ETB (4/10 in 90–100% ETB, 2/2 in 80–90% ETB, 2/2 in 60–70% ETB, 6/8 in 50–60% ETB, 12/15 in 40–50% ETB) (Fig. 4). Incidence of severe ETB (defined as ETB of 50% or more) was seen more in MICU patients (39.89 vs 13.91 per 1000 ventilator days) and with closed suction practice (39.89 vs 13.91 per 1000 ventilator days). Severe ETB was seen more in presence of coagulopathy (50.92 vs 16.59 per 1000 ventilator days). Coagulopathy (defined as platelet count < 75,000/mm3 and/or INR > 1.5 and/or APTT > 45 s) was present in 6/10 in 90–100% ETB, 2/2 in 80–90% ETB, 1/2 in 60–70% ETB, 2/8 in 50–60% ETB, 4/15 in 40–50% ETB. Emergency tube removal was seen in 22/369 patients (10/10 in 90–100% ETB, 0/2 in 80–90% ETB, 0/2 in 60–70% ETB, 1/7 in 50–60% ETB and 3/12 in 40–50% ETB). Mixed secretion (15/22) at the distal end (11/22) was more common. Emergency tube removal was mostly on the 4th ventilator day (VD) followed by 2nd VD and 1st VD (7 vs 5 vs 4).
**Conclusions:** Overt ETB was observed more in CICU patients and open suction practice. Severe ETB was observed more in MICU patients and closed suction practice. ETB are highly unpredictable and ventilator peak airway pressure alarms do not correlate with the degree of ETB. Duration of ventilation has poor correlation with the degree of ETB.

### De novo atrial fibrillation is not influenced by noradrenaline peak dose in patients with septic shock

L. Calabro[1], M. Pasetto[1], S. Zorzi[1], M. Polato[1], E. Vitali[1], F. Annoni[1], V. Labbe[1], K. Donadello[2], FS. Taccone[1]

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001022

**Introduction:** De novo atrial fibrillation (DNAF) is defined as occurrence of a new episode of atrial fibrillation in patients without previous history, which is a common complication in critically ill septic patients, 1 and is associated to higher risk of adverse outcomes 2. The need for vasopressor appears to be an independent predictor of DNAF3. To our knowledge, no study has explored the correlation between noradrenaline (NA) peak dose and DNAF in septic shock patients.
**Objectives:** To assess the relationship between NA maximum dose and DNAF in patients with septic shock.
**Methods:** This is a single-center retrospective study enrolling adult patients admitted in the Intensive Care Unit (ICU) of Erasme University Hospital between 1/01/2016 and 30/09/2023, requiring NA tartrate infusion for septic shock of any origin. Anonymized data were retrieved from electronic records. Univariate and multivariate analyses to identify potential predictor of DNAF occurrence were performed. The occurrence of DNAF and its association with ICU mortality and of ICU length of stay (LOS) were also assessed. For all tests, the null hypothesis is rejected for $p$ values < 0.05.
**Results:** A total of 506 patients were enrolled, with a median Sepsis Organ Failure Assessment score (SOFA) on admission of 10 (8–13) and lactate level on admission of 3.6 (2.1–6.4) mmol/L; 59.5% ($n = 301$) patients were on mechanical ventilation. Infections source was abdominal in 46.2% ($n = 234$) and respiratory in 25.7% ($n = 130$) of patients. The median NA peak dose was 0.57 (0.23–1.29) mcg/Kg*min, with a median time to peak of 10 (3–25) hours since introduction of NA. Overall, 97 (19.2%) patients presented at least one episode of DNAF. No correlation was found between NA dose and the occurrence of DNAF occurrence ($p = 0.48$). DNAF occurrence was significantly associated with age ($p = 0.05$), SOFA score on admission ($p = 0.04$), history of heart failure with reduced ejection fraction ($p = 0.04$), weight at admission ($p = 0.02$) and time to NA weaning from peak dose ($p = 0.01$). DNAF occurrence was significantly associated with longer ICU stay ($p < 0.01$), but not with higher probability of ICU mortality ($p = 0.53$).
**Conclusions:** In this study, the occurrence of DNAF was not associated with the peak NA dose in patients with septic shock. The impact of DNAF on patients' significant outcomes remains limited.

### VEntilator Settings in Pediatric patients––a European Registry (VESPER)

R. van Vliet[1], D. Van Meenen[1], R. Blokpoel[2], F. Paulus[1], M. J. Schultz[1], M. Kneijber[2]

**Introduction:** Critically ill pediatric patients frequently require ventilatory support (1), a potential life-saving therapy, however not without its associated risks. Studies on practice of ventilatory support in critically ill pediatric patients remain scarce, and those studies performed thus far show variation in practice (2–4). It should be noted that most studies date back from over ten years ago. Ventilation practice may have changed since then as new strategies and interventions have been introduced (5), and variance in practice could be substantial.
**Objectives:** The objectives of this study are to describe the practice of ventilatory support in critically ill pediatric patients across European centers, and to explore variance in key ventilator settings.
**Methods:** VESPER is a prospective, international, multicenter, observational study. Patients were included in hospitals throughout Europe, for a predefined 2-week period. Patients were eligible if: (1) aged ≤ 12 years; (2) admitted to the pediatric ICU of a participating hospital; (3) for ventilatory support expected to last more than 12 h. Patients admitted to a neonatal or adult ICU or patients that received ventilatory support because of a perinatal-related condition were excluded. Local investigators captured data on demographics and baseline characteristics at admission. Ventilator settings were collected on daily basis for a maximum of 7 days.
**Results:** A total of 131 patients were eligible for analysis of which the majority of patients were male (53%). The median age was 10 months [IQR: 2.0, 41.0]. The most common reason for admission was respiratory disease (43%). The most commonly used ventilation mode was pressure control ventilation (51%). Ventilator settings varied among patients and across different age groups (see figure).
**Conclusions:** VESPER gives insight into ventilation practice in critically ill pediatric patients receiving ventilatory support for at least 12 h. In this cohort, ventilator settings varied between patients and across different age groups. However, more patients are needed to investigate associations between ventilation practice and clinical outcome. A larger upcoming study will consider this, investigating ventilation practice in critically ill children worldwide, and exploring associations between practice and outcome.

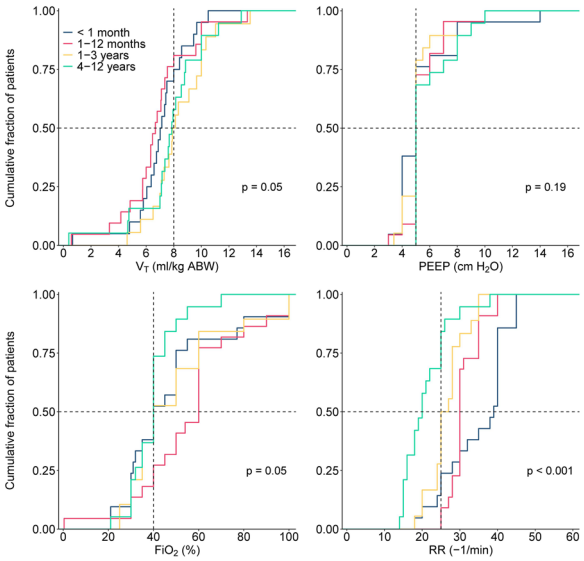

**Fig. 1 (abstract 0001017)** Cumulative frequency distribution of VT; PEEP; FiO2; and RR at day 0 for different age groups: < 1 month ($n = 21$), 1 to 12 months ($n = 22$), 1 to 3 years ($n = 20$), and 4 to 12 years ($n = 19$). Horizontal dotted lines represent the median for each variable, and vertical dotted lines represent the ideal cutoff for each parameter. Abbreviations: fraction of inspired oxygen (FiO2); positive end–expiratory pressure (PEEP); respiratory rate (RR); and tidal volume (VT)

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001026

**Introduction:** Central to circulatory arrest is the cessation of the brain's circulation and subsequent function thereafter leading to death. However, how the brain responds to stressors of progressive

hypotension and hypoxemia during circulatory arrest has not been described in humans despite it underpinning key concepts in the functioning of the human body and having relevance to resuscitation sciences and death determination.
**Objectives:** Following withdrawal of life-sustaining measures (WLSM) in critically ill humans, we aimed to determine the relationships between cerebrovascular physiology indices in response to progressive hypotension during circulatory arrest.
**Methods:** We conducted a single-center prospective interventional cohort study investigating the cerebrovascular physiology of circulatory arrest following WLSM in 25 humans. Prior to WLSM, multimodal neuromonitoring was implemented consisting of middle and posterior cerebral artery blood velocities (MCAv, PCAv) using transcranial Doppler, jugular venous bulb oximetry (SjvO2) and bilateral near-infrared spectroscopy for continuous frontal lobe regional oxygen saturation (rSO2). Mean arterial pressure (MAP) was monitored via an in situ radial arterial catheter. Relationships between cerebrovascular physiologic variables and MAP were assessed visually and relationships were model fit when appropriate.
**Results:** MCAv was linearly related to MAP with marked inter-individual variability of response ($n=21, =0.07, =0.91$, $P=0.02$). Similarly, PCAv and MAP responses were linearly related ($n=21, =0.07, =0.90$, $P=0.005$). There was a steeper slope response to a given change in MAP for MCAv compared to PCAv (0.42 cm/s/mmHg vs 0.30 cm/s/mmHg; $P<0.001$). SjvO2 had a variable downward curvilinear relationship with MAP ($n=19$). There was no discernible relationship between rSO2 and MAP ($n=15$).
**Conclusions:** Cerebral artery blood velocities and MAP slope responses were linear but heterogeneous between-individuals and between intracranial vessels, suggesting possible regional differences between the anterior and posterior cerebral circulation. The curvilinear relationship between SjvO2 and MAP was not replicated by rSO2.

**Topic:** Brain death, organ donation and transplantation

*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**001027

**Introduction:** Nurse turnover magnifies the problem of nurse shortage, now considered a global health emergency. High rates of intention to quit are reported among nurses, especially those working in Intensive Care Units (ICU).
One of the factors involved is job satisfaction, together with others such as moral distress, burnout syndrome, age, etc.
**Objectives:** The main objective of this study was to analyse the factors associated with the intention to leave among ICU nurses.
**Methods:** Cross-sectional descriptive study in which nurses from 3 ICUs in Gran Canaria participated. An electronic questionnaire was distributed, which included questions on socio-demographic and work variables, the validated Font Roja job satisfaction questionnaire and a final question on the participant's own intention to quit.
**Results:** ($n=152$). The ICU nurses' turnover intention found was 55,92% ($n=85$). Although the turnover intention in the paediatric ICU was higher, this was not statistically significant (60.8% vs. 55%, $p=0.604$). Overall job satisfaction was good (3.37/5) and was lower within those with intention to leave (3,97 vs 2,91, $p=0,000$).
**Conclusions:** There is a high turnover intention among ICU nurses, although no significant differences were found among the different ICUs. An inverse relationship was found between the intention to leave and job satisfaction.

*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**001029

**Introduction:** Addressing acute and critical illness in low-middle income countries (LMICs) is challenging due to limited healthcare resources, including shortages of oxygen systems, ventilators, and skilled professionals. Respiratory failure, a common Intensive Care Unit (ICU) admission cause, is particularly problematic in remote areas. To optimize patient outcomes, healthcare providers must adapt treatment strategies to work within these resource constraints.
**Objectives:**
1 To describe the clinical course, outcomes, and risk factors associated with mortality among patients with respiratory failure.
2 To assess the relationship between ventilatory support, oxygenation, and survival in patients using a tele-consultation service in remote resource-limited ICUs.

**Methods:** The Tele-ICU service at the Aga Khan University Hospital (AKUH) provided consultations to physicians treating patients in ICUs and High Dependency Units (HDUs) nationwide. A retrospective cohort study involving patients obtaining tele-consultations in remote ICUs between July 2020 and August 2021 was conducted. Our cohort consisted of severe and critically ill patients diagnosed with severe or critical SARS-Cov2 by RT-PCR. Analyses included descriptive statistics, univariate and multivariate regression models to assess factors influencing patient outcomes. Additionally, logistic regression models examined the impact of ventilatory support on survival, with patient outcome as the dependent variable and pO2 levels as the independent variable, while controlling for the effect of respiratory support levels. Finally, we generated a ROC curve using the lowest measured pO2 of each patient to identify the optimal inflection point for survival prediction.
**Results:** 197 patients were part of our cohort out of which 68 (34.5%) did not survive. Non-survivors had a slightly higher median age compared to survivors (67.5 vs 65 years). Symptoms at presentation included shortness of breath (77.7%), fever (73.6%), and dry cough (56.3%), with hypertension (47.1%) as the most common comorbidity. Diabetes mellitus (OR = 1.99, $p = 0.044$) and antiviral use (OR = 5.36, $p = 0.014$) were significantly associated with increased mortality on univariate and multivariate regression, respectively. Patients requiring Invasive Mechanical Ventilation (IMV) exhibited significantly higher mortality compared to nasal cannula and nasal prongs (OR = 26.89, 95%CI 1.50–483.24, $p = 0.026$). In contrast, there was no increase in mortality with the use of non-rebreather mask (NRM) (OR = 0.29, 95% CI 0.01–16.95, $p = 0.554$), high-flow nasal cannula (HFNC) (OR = 13.23, 95% CI 0.01–20,650.46, $p = 0.491$), CPAP (OR = 1.02, 95% CI 0.01–184.88, $p = 0.995$), and BiPAP (OR = 4.97, 95% CI 0.44–56.72, $p = 0.197$). The ROC curve identified a predictive pO2 cutoff of 49.6, with patients having almost 4.50 times higher odds (OR = 4.49) of survival at or above this level.
**Conclusions:** The study highlights the importance of respiratory support in navigating respiratory failure within resource-limited remote settings. Surprisingly, our findings challenge conventional assumptions, indicating that individuals may possess a greater resilience to hypoxia than previously thought. Moreover, the preferential use of non-invasive ventilation over invasive mechanical ventilation in such constrained environments may offer a potentially more effective treatment approach. These insights emphasize the imperative for tailoring appropriate therapeutic strategies and healthcare delivery to address the unique challenges seen in LMICs.

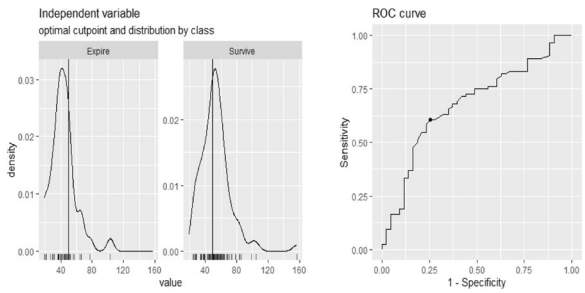

**Fig. 1 (abstract 0001029)** Using the ROC curve, the optimal cut-off oxygen level to predict survival was determined to be a pO2 of 49.6. The corresponding AUC value was 0.67, with sensitivity at 0.61, specificity at 0.74, PPV at 0.82, NPV at 0.49, and accuracy at 0.65. The odds ratio and risk ratio for the identified cut-off oxygen level of 49.6 were calculated as 4.49 and 2.37, respectively

### The influence of transfusion on the neurovascular unit in pediatric patients during correction of congenital heart defects

A. Ivkin[1]
[1]Laboratory of organ protection, Research Institute Of Complex Problems Of Cardiovascular Disease, Kemerovo, Russia
**Correspondence:** A. Ivkin
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001031

**Introduction:** A wide range of factors destructive to the brain in pediatric patients undergoing correction of congenital heart defects (CHD) increases the relevance of developing new methods of cerebroprotection. One such method could be limiting the use of transfusion, considering that components of donor blood can initiate a systemic inflammatory response and neuroinflammation leading to subsequent cerebral damage. To investigate the impact of transfusion on the development of cerebral injury during surgical correction of congenital heart defects in children under conditions of cardiopulmonary bypass (CPB) using a cellular model of the neurovascular unit (NVU).
**Methods:** For the experimental part of the study, a cellular model of the NVU was formed and incubated with serum from patients undergoing correction of septal CHD under CPB conditions (containing high interleukin concentrations) in different oxygen conditions with the fixation of transendothelial resistance as an indicator of NVU functional activity. Serum samples were collected after completion of CPB.
**Results:** When culturing the cellular model of the NVU with patient serum and without it under different conditions, with oxygen concentrations ranging from 1 to 4%, it was found that the transendothelial resistance in the 4% oxygen group did not differ from the control group throughout the 24-h observation period. At the same time, when culturing the NVU with patient blood serum, transendothelial resistance was significantly reduced after only 4 h and recovered to only 90% of normal after 24 h.
**Conclusions:** Considering that incubation with the serum simulated the effect of systemic inflammation on the brain, it can be concluded that the influence of transfusion (as a factor initiating systemic inflammation) can lead to NVU destruction. At the same time, avoiding transfusion, which essentially leads to chemical hypoxia, has a significantly lesser impact on the brain.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001032

**Introduction:** Septic shock is still a frequent cause of morbidity and mortality worldwide1. According to international guidelines noradrenaline is the first-line vasopressor of choice. Incremental doses of noradrenaline are associated with a higher risk of mortality2.
**Objectives:** To assess the correlation between noradrenaline (NA) dose and mortality in patients with septic shock.
**Methods:** This was a single-center retrospective study, including patients treated for septic shock between 2016 and 2022 in the Intensive Care Unit (ICU) at the Erasme Hospital, Brussels, Belgium. Demographics, clinical, hemodynamic laboratory data and severity scores, Acute Physiologic Assessment and Chronic Health Evaluation Scoring System II (APACHE II) and sepsis-related organ failure assessment (SOFA) scores were collected. NA doses were collected on admission, at peak dose, as well as time to halving and time to NA wean. Logistic regression was used to estimate the risk of death in intensive care in terms of NA levels. Optimal binning was used to create NA levels based on major changes in ICU mortality percentages. Unadjusted and adjusted ORs and their 95% CIs were estimated.
**Results:** A total of 506 patients were enrolled, with a median sepsis-related organ failure assessment score (SOFA) on admission of 10 (8–13) and lactate level at admission 3.6 (2.1–6.4) mmol/l. 59.48% ($n = 301$) of patients were on mechanical ventilation. ICU mortality was 36.2% ($n = 183$) In-hospital mortality was 44.5% ($n = 225$), average ICU length of stay was 6 (3–11) days. In hospital mortality was associated with older age ($p = 0.046$), the presence of atrial fibrillation ($p = 0.01$), diabetes mellitus ($p = 0.04$) and liver cirrhosis ($p = 0.005$), as well as high APACHE II ($p < 0.001$) and SOFA scores ($p < 0.001$), both on admission. NA peak dose also was associated with mortality ($p < 0.001$). From 0.29 to 0.69 mcg/kg/min of peak NA tartrate dose, the probability of death linearly increased when compared to the lowest NA ranges (e.g. 0.05–0.29 mcg/kg/min—25% mortality). However, mortality rates remained stable among a wide range of NA doses (Fig. 1). After correcting for confounders, the odds ratio for mortality in this group was 2.8 (95% CI 2.5–3.2) compared to the lowest range. Only for NA peak dose $\geq 3$ µg/kg/min, mortality rose again to 90%.
**Conclusions:** In this study, noradrenaline peak dose showed a ladder association with mortality. Noradrenaline doses higher than 3 µg/kg/min correspond to mortality higher than 90%.

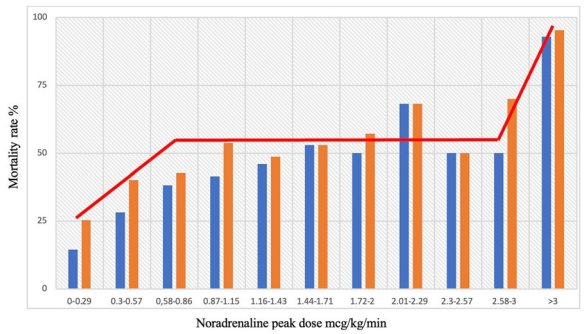

**Fig. 1 (abstract 0001032)** Noradrenaline peak dose and mortality. Blue bar: ICU mortality; orange bar: in-hospital mortality; red line: adjusted mortality risk

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001034

**Introduction:** Acute respiratory distress syndrome (ARDS) includes spectrum of conditions with different etiologies, pulmonary and extrapulmonary. Vasoactive intestinal peptide (VIP) is a hormone localized in the lungs. It has protective functions in lung. Aviptadil is a synthetic VIP and has been studied in various respiratory disease. Recently clinical trials have been conducted for the use of Aviptadil in ARDS associated with COVID-19 which showed reduction in mortality and hospital stay. We have used Aviptadil in patients with ARDS other than COVID-19.
**Objectives:** This study investigated the utility of intravenous Aviptadil in patients with acute respiratory distress syndrome (ARDS) not associated with COVID-19.
**Methods:** Patients aged more than 18 years, admitted to ICU with moderate to severe ARDS prespecified on the Berlin definition, P/F ratio of < 150 were included after taking consent from the guardian.

Pregnancy, chronic organ failure and end stage malignancies were the exclusion criteria. Aviptadil was administered intravenously over three days via an escalating dose regimen: 0.166 mcg/kg/h on day one, 0.332 mcg/kg/h on day two, and 0.489 mcg/kg/h on day three. The drug was given for 12 h each day using an infusion pump. All clinical parameters, adverse effects, arterial blood gases and imaging were noted.

**Results:** Of the 10 patients who received Aviptadil, 8 were males. Mean age was 36.6 years. Two patients had moderate while 8 had severe ARDS with mean P/F ratio was 94 ± 8. All patients had sepsis related ARDS. 5 patients had pulmonary cause for ARDS, all of them admitted with community acquired pneumonia with causative agent of influenza A virus in four patient while no pathogen was found in 1 patient, 3 patients had scrub typhus, one had sepsis with Fournier gangrene and one had sepsis with necrotizing fascitis of abdominal and chest wall.

Two patients had diabetes. One patient had history of ischaemic heart disease. Six patients were mechanically ventilated while one was managed with high flow nasal oxygen therapy.

Seven patients were started with Aviptadil within 24 h of admission while 3 were started after 72 h. Two patients received only two doses due to adverse event, one had hypotension while other had intracranial bleed. Rest eight patients received all three doses.

Five patients developed septic shock. Four had features of multiorgan dysfunction syndrome, three of which succumbed to death making mortality 30%. One patient who was on HFNO was weaned over next 3 days and discharged from ICU, while other three patients who were ventilated, were gradually weaned from ventilator with mean time of 4 ± 2 days and extubated. Radiological resolution was observed over 6 ± 2 days. Factors contributing to death were severity of ARDS, septic shock, and AKI.

**Conclusions:** This preliminary study suggests that Aviptadil may offer potential therapeutic benefits for non-COVID-19 ARDS, though larger trials are warranted to confirm efficacy, optimize dosing, and further investigate safety profiles and patient selection.

**Introduction:** Sepsis represents a high percentage of ICU admissions. One of the challenges that clinicians face is knowing how to differentiate septic processes from other non-infectious inflammatory processes.

**Objectives:** To identify potential protein biomarkers of differential expression between sepsis and non-infectious systemic inflammatory response syndrome (NISIRS).

**Methods:** Prospective observational study of a cohort of septic patients activated by the Sepsis Code and patients admitted with NISIRS, during the period 2016–2017. Samples were stored in the Sepsis Biobank. Demographic and analytical variables, organ dysfunction (SOFA), and hospital mortality were analyzed. Proteins were separated using multidimensional chromatography and identified by mass spectrometry. Recursive Feature Elimination (RFE) was used to select proteins that best classified patients with sepsis versus patients with NISIRS—Support Vector Classification (SVC) algorithm. Data are expressed as frequency (%) for categorical variables and mean (standard deviation) for quantitative variables. Tests used: McNemar (sensitivity, specificity, and accuracy) and trapezoidal rule (AUC). The study was approved by the Ethics Committee (PR(AG)11 2016, PR(AG)336 2016, PR(AG)210 2017), and patients or their relatives provided informed consent.

**Results:** A total of 277 patients (141 with sepsis and 136 with NISIRS) were included. Demographic and clinical data of patients are shown in Table 1. In the sepsis group, the most frequent infection foci were urinary 49 (34.8%), respiratory 47 (33.3%), and abdominal 44 (31.2%). All patients had positive cultures. The NISIRS group consisted of 107 (78.67%) patients in immediate postoperative cardiac surgery, 13 (9.55%) in immediate postoperative lung transplant, 5 (3.67%) patients in immediate postoperative liver transplant, 4 (2.94%) patients with hemorrhagic shock, and 3 (2.20%) patients with other pathologies (1.50%). After RFE, 31 proteins showed statistical differences between sepsis and NISIRS with an accuracy of 0.49 ± 0.035, precision of 0.967 ± 0.037, specificity of 0.910 ± 0.103, sensitivity of 0.964 ± 0.035, and AUC of 0.937 ± 0.053. The analyzed proteins (Table 2) include 12 involved in proteolysis regulation, 9 in innate immune response, 5 in complement activation, 5 in lipopolysaccharide response, 4 in coagulation, 2 in lipid metabolism, and eight proteins with other functions (Fig. 1). Of these proteins, PPBP, V1RL, C5, vWF, and SERPINA4 show a greater association with sepsis than NISIRS (Fig. 2).

**Conclusions:** Proteomic analysis allows for the identification of differential proteins between sepsis and NISIRS that may suggest new diagnostic and therapeutic targets.

**Table 1 (abstract 0001035)** Demographic characteristics of the study population

| Parameters | Total (n=277) | Sepsis (n=141) | NISIRS (n=136) | p |
|---|---|---|---|---|
| Men, n (%) | 162 (58.48) | 85 (60.28) | 77 (56.61) | 0.53 |
| Age, years (m±SD) | 63.3±15.61 | 63.9±15.67 | 62.1±15.58 | 0.54 |
| SOFA, median (25,75) | 5(3,7) | 7(5,8) | 3(2,6) | <0.05 |
| Norepin, n (%) | 121 (43.68) | 76 (53.90) | 45 (33.08) | <0.05 |
| ICU admission, n (%) | 206 (74.4) | 70 (49.64) | 136 (100) | <0.05 |
| Mech Vent, n (%) | 177 (63.9) | 41 (29.07) | 136 (100) | <0.05 |
| W cell x 106 (m±SD) | 14118.51±9149.92 | 13501.75±11021.54 | 14757.94±661.85 | 0.25 |
| Plat x109, median (25,75) | 130.85 (116.0,227.5) | 184.00 (114.0,278.5) | 157.00 (119.5, 195.2) | <0.05 |

**Introduction:** Brachial plexus block is an effective method for providing anaesthesia and analgesia to the upper limb. The plexus can be blocked at multiple sites depending upon the indication, procedure to be performed and patient characteristics. There are various approaches to brachial plexus at the infraclavicular level. These include para-coracoid approach, parasagittal approach and costoclavicular approach. The conventional para-coracoid approach aimed to deposit the drug dorsal to axillary artery in the lateral infraclavicular fossa. The brachial plexus in costoclavicular fossa is superficial, clustered together and has a consistent relationship to each other and axillary artery. So drug can be deposited using single injection with rapid onset. We hypothesise that brachial plexus block using ultrasound guided costoclavicular approach will have local anaesthetic sparing effect. So, we undertook this study to find the minimum effective volume of 0.5% ropivacaine for costoclavicular approach of brachial plexus block (CCB).
**Objectives:** Primary objective—to find the minimum effective volume of 0.5% ropivacaine in 90% patients (MEV 90) for ultrasound guided costoclavicular approach of brachial plexus block.
Secondary objectives: 1. To assess the onset of block using a composite score of 14/16 or above up to 30 min of the block. 2. To assess the success rate of the block. 3. To assess the block performance time. 4. To assess the adverse events associated with the block like vessel puncture, pleural puncture, paraesthesia or local anaesthetic toxicity.
**Methods:** This was a prospective observational study that included 52 ASA I/II patients in the age group of 18–65 years with BMI of 18–35 kg/$m^2$ posted for upper limb surgery. Ropivacaine 0.5% was administered using "Biased coin design up and down sequential method." Initial volume used was 20 ml of 0.5% ropivacaine for USG-guided CCB. In case of successful block, the next patient received 18 ml of drug. In case of failure, the same volume was used as 20 ml was decided to be the maximum volume. This continued till there was a successful block. After that, the volume was increased or decreased by 2 ml depending upon the response of the patient. This continued till 30 patients were recruited. Next 20 patients received the same volume of the drug.
**Results:** We observed that the mean age of patients was $28.5 \pm 11.42$ years. Out of 52 patients, 46 (88.5%) were males. Mean BMI was found to be $23.9 \pm 4.1$ kg/$m^2$. The imaging time (time between contact of probe and acquisition of satisfactory picture) was $2.65 + \pm 1.8$ min. Needling time (start of skin wheel to end of LA injection) was $5.50 \pm 2.6$ min. anaesthesia onset time was $29.2 \pm 7.9$ min. The minimum effective volume of 0.5% ropivacaine in 90% patients using isotonic regression plot was found to be 15.69 ml. We also observed that musculocutaneous nerve had the fastest onset of sensory block followed by median, ulnar and radial nerves. The motor block onset was also the fastest for musculocutaneous nerve T 10 min, followed by radial, median and ulnar at 20 min. The patients who did not have a composite score of 14/16 were considered a failure of block. The block was successful in 32 patients (61.5%) at 30 min and failure was noted in 20 patients (38.5%). Eleven patients required general anaesthesia at the end of 30 min while 9 had a delayed onset. None of the patients had any complications.
**Conclusions:** We concluded that the minimum effective volume of 0.5% ropivacaine in 90% patients (MEV 90) for ultrasound guided CCB was 15.69 ml using biased coin up and down method.

### Neuronal-specific enolase at 48 h as a prognostic marker in patients with recovered cardiac arrest

G. López Pérez[1], M. M. Petito Nuñez[1], V. J. Agudelo Giraldo[1], G. Reguan Font[1], S. M. Luna Solís[1], R. S. Avila Espinoza[1], G. Moreno-González[1]

**Introduction:** Neuronal-specific enolase (NSE) is the most studied biomarker for post-cardiac arrest coma prognostication. Currently, its practical clinical use involves measuring the serial kinetics of NSE during the first 72 h following the acute event. However, differences between this approach and the single or serial determination of NSE up to 48 h have not been studied.
**Objectives:** To determine if NSE at 48 h has similar sensitivity and specificity to that at 72 h for predicting outcomes in patients following recovered sudden cardiac arrest (SCA-R).
**Methods:** Retrospective observational study of patients admitted to intensive care units (ICUs) from November 2018 to November 2022

after experiencing out-of-hospital (OHCA) or in-hospital cardiac arrest (IHCA). Study variables: Age, sex, cardiopulmonary resuscitation (CPR) times, NSE values measured at 24, 48, and 72 h from the cardiac arrest, and hospital and ICU mortality. Qualitative variables were expressed as percentages, and quantitative variables as means with standard deviation or medians with ranges, depending on their distribution. Chi-square or Student's t-test were used for analysis, depending on the compared variables ($p < 0.001$). ROC curves were used to analyse the discriminative capacity of NSE measurements at 24, 48, and 72 h compared with patient mortality in the ICU.

**Results:** 206 patients were included, 75% male, with a mean age of 58 ± 14 years. 69.4% experienced OHCA and 27.2% experienced IHCA. Of the total, 71.4% progressed to mortality. Two groups were formed, ICU mortality versus ICU survival. Both CPR times and NSE measurements at 24, 48, and 72 h differed significantly between the two groups (Table 1). ROC curves were generated with NSE at 24, 48, and 72 h with an AUC of 0.809, 0.892, and 0.872, respectively (Fig. 1).

**Table 1 (abstract 0001038)** Distribution of patients according to their evolution in intensive care unit (ICU) towards survival or mortality following an SCA

| | | ICU survival | ICU mortality |
|---|---|---|---|
| Age | | 56 ± 15 | 59 ± 13 |
| Gender | Female | 16,4% | 26,5% |
| | Male | 83,6% | 73,5% |
| Place of SCA | OHCA | 61,8% | 74,1% |
| | IHCA | 38,2% | 23,8% |
| CPR Time (min) | Without CPR | 1,9 ± 2,9 | 3,1 ± 4,8 |
| | BLS | 4,9 ± 5,6 | 5,3 ± 5,6 |
| | ALS | 13,8 ± 11,7 | 19,2 ± 14,8 |
| | Total | 19,4 ± 12,5 | 24,7 ± 16 |
| NSE 24 h | | 29,5 (21,2–50) | 72 (39–117) |
| NSE 48 h | | 29 (17–40,5) | 131,0 (53,5–296,5) |
| NSE 72 h | | 27 (16,7–50,5) | 151 (59–324) |

Comparison based on qualitative variables, expressed as percentages, and quantitative variables, expressed as mean with standard deviation or median with range according to their distribution or non-parametric nature

ICU: Intensive Care Unit. SCA: sudden cardiac arrest. OHCA: out-of-hospital cardiac arrest. IHCA: in-hospital cardiac arrest. CPR: cardiopulmonary resuscitation. BLS: basic life support. ALS: advanced life support. NSE: neuronal-specific enolase

**Conclusions:** The determination of vital prognosis in patients who experience recovered sudden cardiac arrest is complex and requires the combination of several techniques. Single or serial determination of NSE up to 48 h may be sufficient to establish a poor long-term vital prognosis.

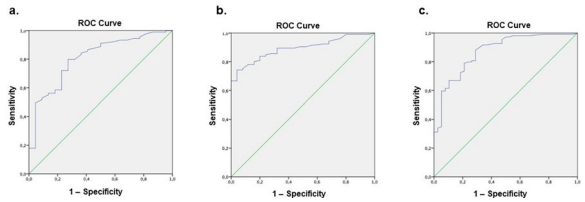

**Fig. 1 (abstract 0001038)** Neuronal-specific enolase at: (a) 24 h. AUC 0.809. Standard error 0.05. 95% CI (0.711–0.908). (b) 48 h. AUC 0.892. Standard error 0.028. 95% CI (0.838–0.947). (c) 72 h. AUC 0.872. Standard error 0.033. 95% CI (0.807–0.936)

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001040

**Introduction:** Several non-invasive neuromonitoring tools can provide a reasonable estimate of invasive intracranial pressure (ICP), especially when used in a multimodal combination (1). However, few data are available on the correlation among these different tools.

**Objectives:** To evaluate the concordance of four non-invasive neuromonitoring tools, commonly used to assess ICP.

**Methods:** This is a secondary analysis of previously published prospective data collected in adult intensive care unit (ICU) patients with traumatic brain injury (TBI), subarachnoid hemorrhage (SAH) or intracerebral hemorrhage (ICH), in whom invasive ICP monitoring had been initiated and different neuromonitoring tools simultaneously assessed (1). In particular, we compared the optic nerve sheath diameter (ONSD), the pulsatility index (PI) and estimated ICP (eICP) using transcranial Doppler, as well as the neurological pupil index (NPI) obtained via an automated pupillometry. ONSD values were considered abnormal if ≥ 6.0 mm; PI was considered abnormal if > 1.2, NPI was considered abnormal if < 3.0. Correlation and concordance between variables were assessed using the Pearson's r and Cohen's k coefficients, respectively.

**Results:** We studied 100 patients (TBI = 30; SAH = 47; ICH = 23) with a median age of 52 years. We observed a weak correlation between ONSD and PI ($r = 0.24$), ONSD and NPI ($r = -0.33$) and PI and NPI ($r = -0.28$); a moderate correlation between ONSD and eICP ($r = 0.54$) and PI and eICP ($r = 0.41$); a strong correlation between eICP and NPI ($r = -0.71$; $p < 0.05$ for all). We observed a poor concordance between ONSD and eICP ($k = 0.20$); a fair concordance between ONSD and PI ($k = 0.27$), eICP and NPI ($k = 0.30$) or between ONSD and NPI ($k = 0.29$); a moderate concordance between PI and NPI ($k = 0.46$); a good concordance between PI and eICP ($k = 0.69$).

**Conclusions:** We observed variable correlation and concordance among different non-invasive neuromonitoring tools, commonly used to estimate ICP. These tools are therefore not interchangeable.

**Correspondence:** A. Kirsch
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001041

**Introduction:** The presence of nucleated red blood cells (NRBC) in the peripheral blood of critically ill patients is associated with poor outcome. Evidence regarding the predictive value of NRBCs among patients with COVID-19-induced acute respiratory distress syndrome (ARDS) remains elusive. Therefore, the aim of the present study was to evaluate the predictive validity of NRBCs in these patients.
**Methods:** This retrospective study was conducted at the University Hospital Dresden, Germany. All adult patients with COVID-19-induced ARDS admitted to the intensive care unit (ICU) between 03/2020 and 03/2022 were analyzed. Daily NRBC values were assessed and their predictive validity on mortality was statistically evaluated.
A cut-off level based on the patient's maximum NRBC value during ICU stay was calculated using receiver operating curves (ROC)-analysis and further specified according to Youden's method. Independent predictors of mortality were identified with multiple logistic and COX regression analyses. Survival was depicted using Kaplan–Meier curves which were tested for differences using the log-rank test; $p < 0.05$ was considered statistically significant.
**Results:** In total, 413 critically ill patients with COVID-19-induced ARDS were analyzed. NRBCs were found in 97.6% of these patients. Patients who did not survive had significantly higher NRBC values during their ICU stay compared to patients who survived (1090/µl [310; 3883] vs. 140/µl [20; 500]; $p < 0.0001$). Patients with severe ARDS ($n = 374$) had significantly higher NRBC values during ICU stay compared to those with moderate ARDS ($n = 38$) (490/µl [120; 1890] vs. 30/µl [10; 476]; $p < 0.0001$).
A cut-off level of NRBC ≥ 500/µl was determined to best stratify risk (Fig. 1A) and was associated with a longer duration of ICU stay (12 [8; 18] vs. 18 [13; 27] days; $p < 0.0001$) and longer duration of mechanical ventilation (10 [6; 16] vs. 17 [12; 26] days; $p < 0.0001$). Extracorporeal membrane oxygenation (ECMO) was significantly more often implemented in patients above this threshold (52 [23.85%] vs. 126 [64.6%] patients; $p < 0.0001$). Logistic regression analysis with multivariate adjustment showed NRBCs ≥ 500/µl to be an independent risk factor of mortality (Odds ratio (OR) 4.72; 95% confidence interval (CI) 2.95–7.62; $p < 0.0001$). Patients with NRBC values below the threshold of 500/µl had a significant survival advantage than patients above the threshold (median survival 32 [95% CI 8.7–43.3] vs. 21 days [95% CI 18.2–23.8]; log-rank test, $p < 0.05$) (Fig. 1B).
Patients who once reached the NRBC threshold of ≥ 500/µl during their ICU stay had a significantly increased long-term mortality (median survival 489 days, log-rank test, $p < 0.01$, hazard ratio (HR) 3.2, 95% CI 1.2–8.5).
**Conclusions:** NRBCs predict mortality in critically ill patients with COVID-19 induced ARDS with high prognostic power. Further studies are required to confirm the clinical impact of NRBCs to eventually enhance decision-making and improve patient outcomes.

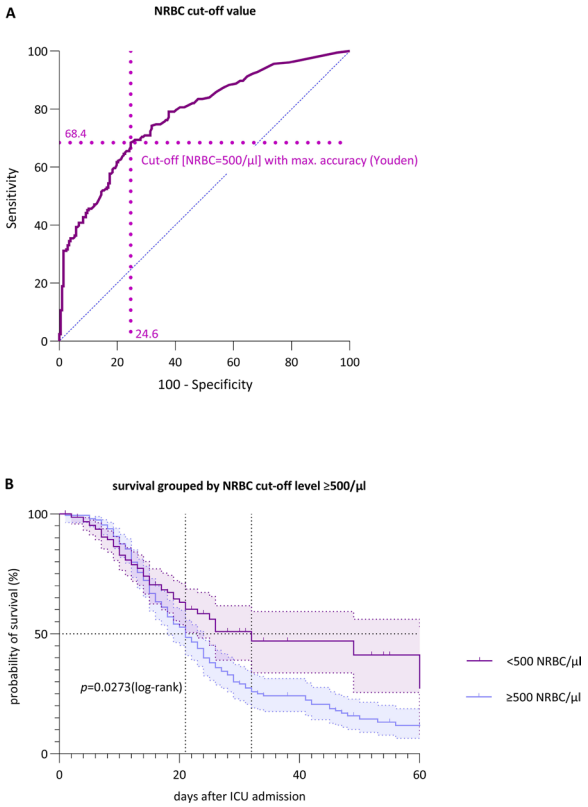

**Fig. 1 (abstract 0001041)** A receiver operator curve (ROC) for the determination of predictive validity of NRBC measurements. The highest sum of sensitivity and specificity was used for calculating a cut-off value. ROC area under the curve (AUC): 0.7793; 95% CI 0.7354–0.8233; $p < 0.0001$. B Probability of survival depicted as a Kaplan–Meier curve of patients with COVID-19 induced ARDS grouped by NRBC cut-off level of ≥ 500 NRBC/µl from ROC analysis.Log-rank test, *$p < 0.05$, $n = 413$, median survival < 500/µl: 32 days, ≥ 500/µl: 21 days

**Introduction:** Sepsis is defined as an infection that leads to one or more organ failures due to dysregulated immune response (1). In Catalonia, the average annual incidence of sepsis is 264.1 cases per 100,000 habitants per year that is increasing from 2005 to 2019 (3). Among sepsis cases admitted in Catalonia, 24% presented septic shock, with an associated mortality of 20% (2, 4).
In managing sepsis and its associated morbidity and mortality, there are both non-modifiable patient or episode-dependent factors, and modifiable healthcare-related factor (early detection, appropriate treatment for sepsis management). The effectiveness of initial sepsis management is time-dependent, requiring tools to facilitate screening and treatment of episodes. Monitoring and tracking the management process and patient outcomes for sepsis could help us to identify potential improvements in the sepsis care pathway.
**Objectives:** To describe the adherence to European guidelines (SSC) for sepsis and septic shock within the Catalan Healthcare System, based on key process indicators related to screening, goal directed therapies, and outcomes.
**Methods:** We performed an observational, retrospective, multicenter pilot study. It includes patients admitted to the Intensive Care Unit (ICU), with community-acquired sepsis in acute care hospitals in Catalonia over a 15-day period. We generated a data collection matrix with 11 key process indicators based on treatment-bundles for the 1 h, 3 h and 6 h. We collected data using the RedCap database.
**Results:** We obtained a sample of 41 patients from seven acute care hospitals, with a mean age of 61 years (65% male). In 24.39% of cases, sepsis detection occurred in a hospital without an ICU. The most common site of sepsis were respiratory (34.15%), biliary (21.95%), and urinary (17.07%). The mean APACHE II score was 18 (12–24) and the mean SOFA score was 8 (5–11). In 34% of cases, the time to activation criteria was less than 1 h. Blood cultures were performed before antibiotic therapy administration in 70.7% of patients with an antibiotic adequacy of 62.5%. In 42.8% of cases, the time for source control was less than 6 h. In 80% of cases, lactate monitoring was performed in the first hour and the sixth hour. Antibiotic treatment adjustment occurred in only 25.64% of cases. The sepsis in-hospital mortality rate stands at 19.51%. Finally, we compared the results from the 7 hospitals and we divided into quartiles based on adherence to the recommendations.
**Conclusions:** The RSiXS serves as a centralized registry for monitoring the care process of sepsis in the Catalan territory. It could be applicable to all types of hospitals. The bundles emphasize timely intervention and serve for improving patient outcomes during sepsis and septic shock. The registry allows the generation of individual and collective report for monitoring the care process of sepsis management and subsequent quality analysis of sepsis management in Catalonia.

### Changing trends in the bacteriological profiles and antibiotic susceptibility at a burn ICU in Greece

I. Mouskeftara[1], S. Gkiti[2], M. Papaioannou[1], V. Souloutsi[1], G. Vasileiadou[1], V. Voutsas[1], P. Kontou[1], A. Lavrentieva[1]
[1]A-ICU, Burn ICU, General Hospital of Thessaloniki "George Papanikolaou", Thessaloniki, Greece; [2]Microbiological Department, "George Papanikolaou" General Hospital of Thessaloniki, Thessaloniki, Greece
**Correspondence:** A. Lavrentieva
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001043

**Introduction:** Infectious complications is a major cause of morbidity and mortality in Burn units.
**Objectives:** This study aimed to determine the changing trends of causative bacteria and antibiotic susceptibility over the past decade.

**Methods:** This study retrospectively analyzed the positive blood cultures of patients admitted to the burn unit in years 2014 and 2023. Changing trends in the bacteriological profiles and antibiotic susceptibility were recorded and analyzed.
**Results:** A total of 150 of positive blood cultures were detected. Gram-negative bacteria were isolated in 69% of the cases in 2014 and in 74.3% in 2023; Pseudomonas aeruginosa was identified as the common isolate. Pseudomonas aeruginosa (22.6% in 2014 and 33% in 2023) and Acinetobacter Baumannii complex (16.7% in 2014 and 19.7% in 2023), followed by Klebsiella spp (14.3% in 2013, 6% in 2023) were the dominant Gram-negative bacteria during both during the years 2014 and 2023.
Gram-positive bacteria were isolated in 20.2% of the cases in 2014 and in 13% in 2023. Coagulase-negative Staphylococci (CoNS) were identified as the common isolate during both periods. Fungi were isolated in 10.8% (2014) and 12.6% (2023) cases. Among fungi, Candida albicans (5.8%) followed by Candida glabrata (1.25%) were the dominant fungi in 2014, but Candida albicans was replaced by Candida glabrata (4.5%) and was the prevalent fungus in 2023. Comparative analysis showed a significant reduction in Gram positive bacteria during the last decade (36% decrease).
Multidrug resistant microorganisms presented 97% of Pseudomonas aeruginosa and Acinetobacter Baumannii complex and 83% of Klebsiella spp in 2023. Concerning the change in antibiotic resistance generally the resistance increased during the decade.

**Table 1 (abstract 0001043)** Changes in antibiotic resistance

| | Ciprofloxacin | Colimycin | Tigecycline | Carbapeneme |
|---|---|---|---|---|
| Pseudomonas | 60% increase | 5% increase | | 25% increase |
| Acinetobacter | No change | 45% increase | 60% increase | No change |
| Klebsiella spp | No change | 10% increase | 15% decrease | 10% decrease |
| E. coli | No change | 6% increase | | 5% increase |

**Conclusions:** The etiological profile of burn sepsis has undergone a significant change in the last decade. Reduction in Gram-positive bacteria and increase in non-albicans Candida species was observed. Antibiotic resistance has increased, and continuous surveillance for antibiotic susceptibility is required to ensure efficient therapeutic outcomes.

**Topic:** Infections and prevention.

**Correspondence:** S. Tmani
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001044

**Introduction:** Severe acute respiratory infection (SARI) is the cause of an important mortality worldwide. In Tunisia, different sentinel SARI centers have participated in the national data collection to better identify microbiological, clinical and evolutionary features.
**Objectives:** To assess clinical, therapeutic and evolutionary characteristics of severe seasonal influenza in patients admitted in Zaghouan's intensive care unit (ICU).
**Methods:** We conducted a descriptive retrospective study including patients admitted for severe acute respiratory infection (SARI) in the ICU of Zaghouan's regional hospital in Tunisia between October 2022 and May 2023. All patients had their nasopharyngeal swab tested for viruses. Demographic, clinical, therapeutic and evolutionary data were collected.
**Results:** We included 74 patients who all underwent nasopharyngeal sampling for SARI. A male predominance was observed with a gender ratio of 1.8. Median age was 54 years [15–81]. All patients were transferred to the ICU from the emergency department except for 7(9%) who were transferred from other departments. Three patients (4%) have been to Saudi Arabia for religious rituals within two weeks prior to the respiratory infection. Only 3 patients (4%) were vaccinated against influenza.
Nasopharyngeal swab testing was positive in 44 patients (60%): H1N1/pdm 2009virus in 15 patients (20%), H3N2 influenza A virus in 3 patients (4%) and influenza B virus in 4 (5%), SARS-CoV-2 in 6 (8%), rhinovirus in 5 (6%), adenovirus in 2 (2%), human bocavirus in 2 (2%) among other viruses. Bacterial coinfections were noted in 4 cases: Enterobacter cloacae, Escherichia coli, Pseudomonas aeruginosa and *Mycobacterium tuberculosis.*
The mean time between symptom onset and hospitalization was $3 \pm 3$ days. At least one comorbidity was noted in 70 patients (95%): heart disease in 40 patients (54%) and diabetes in 16 (22%). Sixteen female patients (22%) were pregnant. Fever was found in 36 cases (48%) with a median temperature of 38 °C [36–40]. A cough was reported in 41 patients (55%). All patients had signs of respiratory distress upon admission, circulatory failure was noted in 21 cases (28%), neurological distress in 15 (20%) and acute kidney injury in 17(23%). Signs of radiological severity were observed in 31 patients (42%). Mechanical ventilation was needed in 35 patients (47%). Systemic steroids were administered in 13 patients (17%), antivirals in 10 (13%) and antibiotics in 35 (47%). The mortality rate was 28%.
**Conclusions:** Severe acute respiratory infections represent a significant challenge to healthcare systems. Therefore, it is crucial to prioritize vaccination campaigns to reduce health costs and mortality.

**Topic:** Infections and prevention

### Morbidity and mortality in adult patients infected by SARS CoV-2 admitted to the intensive care unit at the University Hospital of Maracaibo during March 2020–March 2022 period

A. Mujica[1], M. Gonzalez[1]
[1]ICU, Hospital Universitario, Maracaibo, Venezuela
**Correspondence:** A. Mujica
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001045

**Introduction:** The first two cases of COVID-19 in Caracas, Venezuela, were reported two days after the World Health Organization declared a pandemic on 2020. Soon after, Venezuela declared a state of emergency in the health system. Due to the complex transmission of some *SARS CoV-2* variants, the wide range of symptoms, aggressive progression from severe to critical illness and lack of access to diagnostic tests, the total of deaths by COVID19 are still unknown in

Venezuela. University Hospital of Maracaibo was selected as a sentinel and the ICU was one of the most important of the west of the country.

**Objectives:** To determine the morbidity and mortality in adult patients infected by *SARS CoV-2* admitted to the Intensive Care Unit of the University Hospital of Maracaibo between March 2020 and March 2022.

**Methods:** The research was cross-sectional, descriptive, cohort type. This study included 299 patients aged 18 years or older infected by *SARS CoV-2* (RT-PCR confirmed) who were admitted to the ICU. The evaluation and registration of the patients was carried out by intensivists and residents of the Critical Care Medicine postgraduate program at the University of Zulia. SPSS software for Windows, version 24.0, was used for statistical analysis. Spearman's correlation coefficient was used for non-parametric variables and Pearson's correlation coefficient for parametric variables.

**Results:** The mortality rate was 74.6% ($n = 223$) seen in Table 1. The highest mortality rate was concentrated in two peaks during the periods May–July 2020 and May–July 2021 (Fig. 1). COVID19 vaccine coverage started in February 2021 only for health care providers and COVID19 vaccine was available for all Venezuelans in August 2021. During the first year of the pandemic, a higher risk of mortality was observed in men (OR: 2.14; 95% CI: 1.16–4.13) and in patients ≥ 51 years (OR: 2.26; 1.13–4.54). Hypertension (HBP) was the most frequent comorbidity (35.8%), as a single previous diagnosis (14.4%) or in combination with obesity (OB: 15.7%) and type 2 diabetes mellitus (T2DM: 9%). Individuals with HBP + OB had a higher risk of requiring IMV (OR: 2.19 [95% CI 1.10–4.6]), VAP (OR: 4.26 [95% CI 1.47–10.32]) and death (OR: 2.78 [95% CI 1.24–6.80]) and patients with HBP + T2DM had a higher risk of myocardial dysfunction (OR: 2.96 [95% CI 1.27–6.9]) (Table 2).

A high number of patients required invasive mechanical ventilation (IMV) (199/200, 66.6%). Mortality in these patients was 93.5% (Table 3). The degree of severity of Acute Respiratory Distress Syndrome (ARDS) was linearly associated with the PEEP value ($p = 0.001$) and mortality ($p = 0.001$). The mortality rate was 10%, 22.4%, and 58.2% for mild, moderate, and severe degrees of ARDS. Significant differences were found between survivors/non-survivors groups in gradient (324/423), PaFiO2 (170.5/86 mmHg) and shunt (14/21) values. Septic shock (39,56%) and acute kidney injury (25,4%) were associated with a higher mortality risk of 18.49 (CI 95% 6.53–52.34) and 18.37 (95% CI 4.38–76.93), respectively. A protective effect of remdesivir on mortality was observed in the non-IMV group (OR: 0.248; 95% CI 0.105–0.583) (Table 4).

**Conclusions:** Male gender and age ≥ 51 years were significantly associated with mortality in patients infected with SARS CoV-2 during the first year of the pandemic. Hypertension alone or combined with OB and DM2 was associated with worse clinical outcome and mortality due to *SARS CoV-2* infection. The requirement for IMV behaved as a predictor of mortality, associated with an increased risk of septic shock, acute kidney injury, VAP and pneumothorax and mortality. A protective effect of remdesivir on mortality was found in non-IMV patients.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001046

**Introduction:** Appropriate dosing of anticoagulants is crucial in preventing adverse events in critically ill patients (1). However, discrepancies often arise between anti-Xa activity and activated partial thromboplastin time (aPTT) measurements in patients receiving unfractionated heparin (UFH), and the underlying biological mechanisms behind are not fully elucidated (2).
**Objectives:** To evaluate whether the disagreement between anti-Xa activity and aPTT values in critically ill patients could be explained by disease severity.
**Methods:** Retrospective analysis of patients admitted to our Intensive Care Department, treated with continuous UFH for any reason, in whom concomitant measurements of Anti-Xa activity and aPTT were performed. Several biological and clinical parameters were collected at the moment when each anticoagulation test was performed. We classed each sample by using two different nomograms as in infra-therapeutic, therapeutic (aPTT ratio between 1.6 and 2.5 or anti-Xa value between 0.3 and 0.7 U/mL) or supra-therapeutic ranges. Thereafter, in group 1 we included samples with aPTT lower than anti-Xa values, in group 2 samples with concordant aPTT and anti-Xa values, and in group 3 samples with aPTT higher than anti-Xa values.
**Results:** We retrieved 132 patients with 823 blood coagulation samples between Aug-2022 and Feb-2023. Median age was 61 (52–70)

years, body weight was 80 (67–94) kg and 36% had sepsis. The main reasons for UFH administration were atrial fibrillation (35%), pulmonary embolism (24%), extracorporeal membrane oxygenation support (14%), mechanical cardiac valve (13%), and thromboprophylaxis (14%). The agreement between aPTT and anti-Xa values was poor with an intra-class correlation coefficient of 0.30 (0.24–0.36); and 235 (29%) samples were in group 1, 437 (53%) in group 2 and 151 (18%) in group 3 (Fig. 1). Higher degrees of disease severity and organ dysfunction were found in group 3 (Table 1).

**Table 1 (abstract 0001046)** Comparison of different parameters in the 3 different groups

| Variable | Group 1 | Group 2 | Group 3 | *P* |
|---|---|---|---|---|
| Leucocytes (cells × 103/µL) | 13.1 (9.2–17.6) | 12.7 (9.3–16.9) | 12.0 (8.1–17.5) | 0.15 |
| Platelets (cells × 103/µL) | 277 (167–401) | 222 (126–316) | 86 (50–144) | < 0.01 |
| Creatinine (mg/dL) | 0.7 (0.5–1.5) | 1.2 (0.7–2.1) | 1.4 (1.1–2.1) | < 0.01 |
| Norepinephrine (mcg/kg/min) | 0.02 (0.00–0.13) | 0.00 (0.00–0.11) | 0.10 (0.00–0.41) | < 0.01 |
| PaO2/FiO2 ratio | 243 (178–324) | 243 (183–324) | 250 (184–371) | 0.49 |
| Total bilirubin (mg/dL) | 0.4 (0.3–0.7) | 0.5 (0.3–0.9) | 1.7 (0.6–6.2) | < 0.01 |
| pH | 7.44 (7.40–7.48) | 7.44 (7.40–7.48) | 7.41 (7.38–7.45) | < 0.01 |
| Bicarbonate (mmol/L) | 28 (25–33) | 26 (24–30) | 24 (21–27) | < 0.01 |
| Lactate (mmol/L) | 1.0 (0.7–1.3) | 0.9 (0.7–1.3) | 2.1 (1.4–4.2) | < 0.01 |
| Total SOFA score | 6 (3–8) | 6 (4–9) | 12 (7–16) | < 0.01 |
| ICU mortality (%) | 18% | 16% | 63% | < 0.01 |

**Conclusions:** In this cohort of patients under UFH, higher organ dysfunction and disease severity were observed in samples with aPTT values higher than anti-Xa activity. It should be preferable to use aPTT values in more severe patients to decrease their risk of bleeding.

| | | *aPTT monitoring protocol* | | |
|---|---|---|---|---|
| | | *Infra therapeutic range* | *Normal therapeutic range* | *Supra therapeutic range* |
| *Anti-Xa activity monitoring protocol* | *Supra therapeutic range* | **12 (1.5)** | **29 (3.5)** | **41 (5.0)** |
| | *Normal therapeutic range* | **194 (23.6)** | **165 (20.0)** | **44 (5.3)** |
| | *Infra therapeutic range* | **231 (28.1)** | **63 (7.7)** | **44 (5.3)** |

**Fig. 1 (abstract 0001046)** Disagreement between aPTT and antiXa values in patients samples under UFH. White zone: concordant values. Light gray zone: aPTT lower than antiXa values. Dark gray zone: aPTT higher than antiXa values

### Development and validation of AI-model to predict refractory septic shock

V. Gandhi[1], P. Khanna[2]
[1]Anesthesiology Pain Medicine and Critical Care, AIIMS Hospital, New Delhi, India; [2]Anaesthesia,pain medicine & critical care, All India Institute Of Medical Sciences, New Delhi, New Delhi, India

*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**001047

**Introduction:** Prediction of refractory septic shock in patients with sepsis helps the clinician gain additional lead time, facilitate early referral to the tertiary care center, enable early ICU admission, and facilitate shared decision-making with the family members. These subgroups of patients are often poorly represented in large RCTs investigating the efficacy of interventions in septic shock (1). As per our best knowledge, the literature currently lacks an "AI model" for predicting refractory septic shock in patients with sepsis.
**Objectives:** To extract the variables that will contribute significantly to predicting refractory septic shock, select variables for developing the AI model, develop an AI model from the selected variables, and prospectively validate the developed AI model.
**Methods:** This is an ambispective study conducted in the intensive care units of the All India Institute of Medical Sciences, New Delhi, India. Institutional ethical committee approval was obtained, and CTRI registration was completed. It is a two-stage study. The first phase involves the development of an AI model, utilizing retrospective clinical, laboratory, and radiological data of patients admitted to the medical and surgical ICU with sepsis. The second phase will be the prospective validation of the developed AI model.
**Results:** The first phase of the study was completed. We analyzed 72 variables for 800 patients and found 16 features above the top 30% threshold. The test accuracy was $0.760 \pm 0.095$ (F1 score: $0.744 \pm 0.061$), and the validation accuracy of the same was $0.792 \pm 0.045$ (F1 score: $0.782 \pm 0.063$). Adding Ph and Procalcitonin to the previous 16 features, the test accuracy was $0.760 \pm 0.033$, the F-score was $0.759 \pm 0.033$, and the validation accuracy was $0.809 \pm 0.044$, the F1Score was $0.807 \pm 0.045$. Prospective validation of the model is ongoing.
**Conclusions:** The currently developed artificial intelligence model has achieved acceptable accuracy in predicting refractory septic shock. If prospective validation shows acceptable predictive accuracy, the Prediction AI model can be useful for identifying patients at high risk of refractory septic shock. Customizable risk thresholds can be set for individual clinical installations depending on available resources and local practice requirements.

### Physicians' attitudes towards decisions to withhold or withdraw life-sustaining treatment in children in intensive care in Sweden

M. Ahlerup[1], J. A. Malmgren[2], G. C. Albert[1], L. Block[2]
[1]Department of Pediatric Anaesthesia/Surgical Operations/Intensive Care, Östra Sjukhuset—Sahlgrenska University Hospital, Gothenburg, Sweden; [2]Dpt of anaestsia and intensive care, inst of clinical sciences, Sahlgrenska University Hospital, Gothenburg university, Sahlgrenska Academy, Gothenburg, Sweden
**Correspondence:** M. Ahlerup
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001048

**Introduction:** Sometimes, intensive care is not in the patient's best interest, but other values should be prioritised. This can be due to futility of care, poor neurological outcome or short life expectancy, even with critical care. The decision to withhold or withdraw life-sustaining treatment is complex, with several parameters to consider. The prognosis of the child might be uncertain, but the parents' wishes and legal issues should also be considered. We know there is variability in how these decisions are made between European regions. This issue of end-of-life decision-making in pediatric critical care has yet to be studied in Sweden.
**Objectives:** This study aims to investigate the attitudes and experiences of end-of-life decisions for pediatric patients among Swedish intensive-care specialists.
**Methods:** This is an observational national survey study. A selection of hospitals that treat children under 15 years of age for more than 48 h at least ten times a year are contacted. A web-based questionnaire is distributed to physicians employed in the intensive care department of such a hospital. The questionnaire consists of 50 questions concerning the respondent's own experience of end-of-life care in children, their view on the ethics of withhold and withdraw decisions, facilitating factors in the work climate and their views on shared decision-making and conscientious objection. Answering the survey is voluntary, and no reimbursement is offered. All study data are collected and treated anonymously.
**Results:** The answers from the questionnaire are analysed with descriptive statistics.
**Conclusions:** Increased knowledge of physicians' attitudes and experiences of withhold and withdraw decisions in Swedish pediatric critical care is vital to understanding how these decisions are made. An understanding of how these decisions are made is necessary to supply supporting systems and education to ensure that these decisions are always made in an as objective and fair manner as possible. This will affect the patient's quality of life and access to palliative care, give them a chance to make choices for the final time.

**Correspondence:** G. Parzibut
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001049

**Introduction:** The number of patients admitted to the ICU for C-ARDS has decreased significantly since the start of the pandemic in March 2020. The role of the evolution of variants or collective immunity is not established. C-ARDS is defined with CT chest imaging (CT), positive PCR test nasopharyngeal in accordance with the Berlin criteria. An artificial intelligence tool (IA) evaluating the quantitative lesion extension by an approach combining tools of radiomics and automated quantification was developed as part of the project European Dragon to quantify, based on CT imaging, the volumetric extension lesions recognized as typical of COVID-19 infection during the pandemic (1). We sought to quantify the objective reduction in C-ARDS episodes during time and to measure the links with the evolution of variants.
**Methods:** Single-center retrospective study in the ICU of a Belgian tertiary hospital between 02/01/2020 and 01/31/2023. Extraction of clinical-radiological data from patients with acute respiratory failure (ARF) and positive PCR COVID. Automated analysis of imaging determining a severity score anatomical and percentages of infected surface per lung lobe. Determination of patient groups by principal component analysis based on image analysis.
Use of national epidemiological data. Nonparametric tests and regression logistics (SAS and R).
**Results:** In the initial cohort of 1017 patients admitted to the ICU with a positive COVID PCR, 631 patients had a CT scan analyzed by the quantification tool. First, admissions were separated according to 6 successive predominant variants (ancestral, alpha, delta, omicron BA.1, BA.2 then BA.5) or 5 vaccination campaigns. The probability of a patient having ARDS was significantly lower from delta variant ($p = 0.0028$). Moreover, logically, the vaccination campaigns demonstrate a drop in the number of admissions for C-ARDS.
Secondly, based on imaging, the severity is also significantly decreased from BA.2 and BA.5 variants (Figure, $p < 0.0001$). Finally, a principal component analysis allows to distinguish 4 groups based on severity and anatomical distribution. The most severe groups and upper lobe damage decreases over time as well.
**Conclusions:** Automated IA tool analysis of CT scans of patients suffering from COVID makes it possible to confirm the extension of the lesion as well as its distribution by lobe allowing an approach automated quantitative. It also makes it possible to document the reduction in serious cases over time. The predominance of delta and then omicron variants in our region was associated with this reduction.

### Lactate ameliorates sepsis-induced lung injury via mTOR–ATF4 signaling pathway

R. Li[1], J. Li[2], M. Meng[3]
[1]Critical Care Medicine, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China; [2]Department of Critical Care Medicine, Binzhou Medical University, Yantai, China; [3]Department of Critical Care Medicine, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China.
**Correspondence:** J. Li.
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001050

**Introduction:** Sepsis induces lung injury by overwhelmed activation of alveolar macrophages (AM) which is dependent on glycolysis and increased level of lactate. Metabolism is the new therapeutic target for the prevention and treatment of sepsis. We previously found that inhibition of mTOR signaling downregulated the expression of macrophage-derived cytokine IL-6 and IL-1β, improving the survival of septic mice.
**Objectives:** To determine the role of lactate against sepsis-induced lung injury and the regulatory mechanisms.
**Methods:** Adult male C57BL/6N mice(6–8 weeks old) were pre-treated by intra-tracheal application of lactate(300 μg/kg).Sepsis was induced by cecal ligation and puncture (CLP), and the broncho-alveolar lavage fluid (BALF), plasma, and lung tissues was harvested 16 h after the onset of sepsis. BALF protein concentrations were measured using BCA; the pathological changes of the lung tissue were demonstrated by HE staining;Il-6 levels in both BALF and plasma were determined by Elisa; lung neutrophil deposition was evaluated with Western blotting. In vitro, alveolar macrophage cell line (MH-S) was pre-treated with lactate (10 mM) and follow stimulated with lipopolysaccharide (LPS,1 μg/mL). The level of related inflammatory mediators and M2 macrophage marker Arg1 were assessed by ELISA, RT-qPCR, and Western blot, respectively. We probed the expression of mTOR and downstream effectors, ATF4, PFKFB3 by Western blotting. To determine the role of lactate against sepsis-induced lung injury and the regulatory mechanisms, LPS-induced MH-S cells were pre-treated with rapamycin (100 nM, an inhibitor of mTOR), and MHY1485 (10 μM, an activator of mTOR). Additionally, LPS-induced MH-S cells were pre-treated with ATF4 (siRNA knock-down) and I-152 (2 mM, an ATF4 activator). LPS-induced MH-S cells were pre-treated 3-PO (50 μM, an inhibitor of PFKFB3), and the level of Arg1, ATF4, and PFKFB3 were assessed by ELISA, RT-qPCR, and Western blot, respectively.
**Results:** Lactate pre-treatment significantly reduced IL-6 levels in BALF and plasma, decreased total protein in BALF supernatant, improved lung tissue pathology, and diminished neutrophil infiltration in septic mice. In vitro, lactate suppressed LPS-induced mRNA expression of IL-6, TNFα, and other pro-inflammatory factors in MH-S cells, reduced IL-6 in supernatants, and increased IL-10 and Arg1 expression. LPS stimulation markedly raised levels of p-mTOR, p-p70S6K, ATF4, PFKFB3, and IL-6, but these were effectively attenuated by lactate pre-treatment, with concurrent Arg1 upregulation. Rapamycin pre-treatment similarly reduced p-p70S6K, ATF4, PFKFB3, and IL-6 levels, while increasing Arg1 post-LPS challenge. The lactate's inhibitory effect on LPS-induced p-mTOR, p-p70S6K, ATF4, PFKFB3, and IL-6 was reversed by MHY1485. ATF4 knockdown notably decreased PFKFB3 and TNF-α in supernatants and increased Arg1 protein expression. I-152 counteracted LPS-induced increases in IL-6 mRNA, PFKFB3, and Arg1 proteins. Finally, 3-PO pre-treatment post-LPS exposure reduced expressions of pro-inflammatory factors such as IL-1β, TNFα, MCP-1, and IL-6.
**Conclusions:** Lactate downregulates PFKFB3-mediated glycolysis through modulation of the mTOR-ATF4 signaling pathway, resulting in an attenuated inflammatory response and mitigation of sepsis-induced lung injury. This study highlights a potential therapeutic role for lactate in sepsis management.

### Team-based nursing in neuro intensive care unit

K. Kaur[1], S. Nor Osman[2], S. Lulkan[1], J. K. Yoke Shen[1], E. Koh Chee Seng[2]
[1]nursing, Tan Tock Seng Hospital, Singapore, Singapore; [2]Nursing, Jalan Tan Tock Seng, Tan Tock Seng Hospital, Singapore, Singapore, Singapore

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001051

**Introduction:** Traditionally, Neuroscience Intensive Care Unit (NICU) with 18-bed capacity has 1 Registered Nurse (RN) assigned as Nurse in-charge (NIC) to provide patient care and administrative work, e.g., assigning staff and coordinating patient movement. This reduces the efficiency of RNs as they have to multi-task.
**Objectives:** Team-based Nursing (TBN) was introduced in May 2021 to allow nurses to utilize their strengths and license to their full potential. This study investigated its effectiveness with the aim of improving staff satisfaction and reducing workload of nurses without compromising patient safety.
**Methods:** Two clinical indicators—reported incidents of medication errors and compliance of 4-point catheter bundle care were compared before and after implementation of TBN. An anonymised staff satisfaction survey was conducted two years post implementation to measure staff satisfaction.
**Results:** The average (SD) medication errors reported for 1000 patient-days reduced slightly, 18.1 (10.8) pre vs 12.0 (6.8) post-TBN, $p$ value = 0.057. *Chart 1* showed the monthly reported medication errors

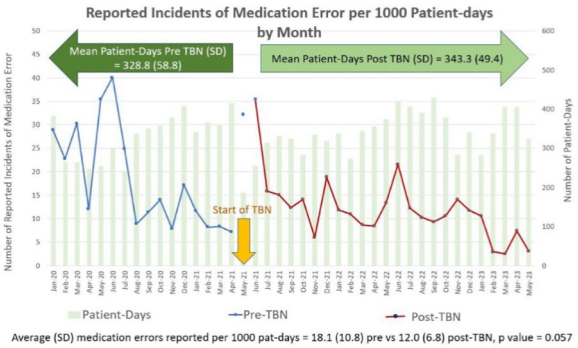
and patient-days. The average compliance of 4-point catheter bundle care is 96% pre vs 97.4% post.

Out of 75 RNs who were invited to participate in the survey, 60 RNs (80%) responded. 86.4% of nurses felt that the nursing care have improved since the start of TBN and the same percentage of nurses felt that Team leaders are of great help especially when taking over during breaks and administering new, STAT orders when principal nurses are not able to do so.

**Conclusions:** Prior to the commencement of TBN in NICU, there was 1 NIC, 9 principal nurses (PN) and 3 enrolled nurses (EN) per shift. The tasks performed by NIC and team leaders were as shown in *Table 1*.

In TBN setup, the workforce is re-engineered. 1 EN is assigned per shift to monitor the telemetry and 3 Team Leaders (all RNs) who each lead 3 RNs share the workloads of previous NIC and are more available for patient care (Table 1 and Fig. 1). Smaller teams result in higher accountability towards patients. 75% of staff are on the ground during break times; patient's safety is not compromised. At the height of pandemic, while non-ICU trained nurses were deployed to work alongside the stretched ICU nursing staff, TBN has enabled the ICU-trained Team Leaders to work closely with augmented non-ICU trained staff without compromising patient and staff safety. More RNs were trained to perform the role of a team leader. This allowed the RNs to develop and sharpen their leadership potential. Team Leaders can now help to mentor the new RNs while performing their duties.

TBN not only allows efficient utilization of manpower, but also fosters teamwork and camaraderie among nurses. This makes the most hectic shifts more manageable, hence improved staff satisfaction without compromising patient safety as indicated by stable reported incidents on medication errors and 4-point catheter bundle care compliance.



Reported incidents of medication error per 1000 patient-days by month

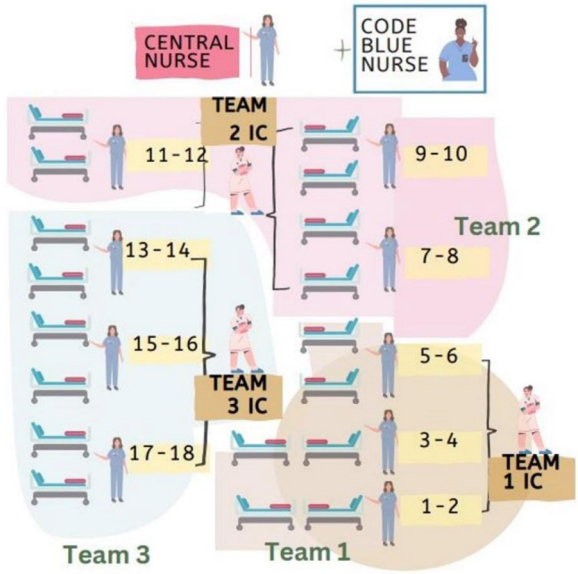


**Fig. 1 (abstract 1051)** Illustration of TBN

**BEFORE**
**Tasks of NIC**

- Sets staff assignment for next shift
- Set meal breaks for next shift
- Check staffing for next day during PM shift
- Prepare next day on-call list
- Update patient handover sheet and census board
- Handover important patient information during roll call
- Follow Doctors' rounds
- Manage ward situation:
  - Liaise with ICU gatekeeper on the availability of beds and admissions
- Take over Principal Nurse during breaks, scans, transfer, dialysis etc.
- Holds the Red & Blue Key (CD, CCOD cupboard, Med-trolley)
- Holds Yellow Key (Aspen, Property cupboard)
- Holds the ward handphone
- CD count (Including Pharmaceutical Fridge items)
- EN performs Glucometer QC check at 2am and covers telemetry monitoring duty during breaks.

**AFTER**
**Tasks of Team Leaders**

| Team Leader 1 | Team Leader 2 | Team Leader 3 |
|---|---|---|
| • Set staff assignment for next shift | • To hold Red & Blue key (CD, CCOD cupboard, Med-trolley) | • Holds Yellow key (Aspen, Property cupboard) |
| • Set meal breaks for next shift | • CD count (Including Pharmaceutical Fridge items) | • Holds the ward handphone |
| • Check staffing for next day during PM shift | • Glucometer QC at 2am | • Central roll call |
| • Prepare next day on-call list | | • Takeover Central for breaks |

- Follow Doctors' round
- Manage ward situation:
  - Liaise with ICU gatekeeper on availability of beds and admissions
- Determine the sequence of new admission for the shift and communicate with own team members of 3

**Table 1 (abstract 1051)** Tasks of NIC and team leaders before and after TBN

**Introduction:** Patients undergoing liver transplantation (LT) are particularly susceptible to postoperative nosocomial infections due to the prolonged hospitalization and the need for immunosuppressive therapy to prevent organ rejection. (1) Moreover, cirrhotic liver disease (LD) causes a deregulation of the immune system known as cirrhosis-associated immune dysfunction (CAID). CAID is primarily attributed to a defect in enteric compartmentalization, leading the immune system to develop a phenotype of chronic pro-inflammatory response and subsequent immune paralysis that increase the risk of infections. (2) This phenomenon is particularly prominent in acute on chronic liver failure (ACLF). Abnormalities in immunoglobulin (IG) levels are frequently observed in patients with LD and may be correlated with the degree of polyclonal B lymphocyte activation. (3) It is still unclear whether there is a correlation between IG levels and susceptibility to infection development.
**Objectives:** To study the association between pre-LT level of IG subclasses (IgG, IgM, and IgA) and the onset of infections in post-LT period in patients with or without ACLF.
**Methods:** We performed an observational retrospective monocentric study. We included patients admitted to intensive care unit (ICU) after LT. We collected IG levels at day of LT, together with perioperative clinical and microbiological data. The primary endpoint was the association between pre-LT IG levels and the incidence of post-LT infections in patients with or without ACLF. Continuous variables were compared using the Wilcoxon signed rank test or the Kruskal–Wallis test while categorical variables were compared using the Chi-square test.
**Results:** A total of 103 patients undergoing LT were included in the study, of whom 20 patients were diagnosed with ACLF. Thirty patients (29%) developed post-LT infection of whom 21 (70%) were caused by multi-drug resistant bacteria. 30% of the infections were associated with bacteriemia. As expected, patients with ACLF present a significantly higher risk of developing post-LT infections (odds ratio 4.8 CI 1.7–13.5). The values of all IG subclasses directly correlate with the severity of LD (measured with MELD-Na score) (Fig. 1) but we did not find any correlation between any IG level subgroups and the development of postoperative infections (p.0,53, 0,23 and 0,13 for IgA, IgG and IgM, respectively) (Fig. 2). Nor they correlate with ICU stay (p.0,82, 0,38 and 0,13 for IgA, IgG and IgM, respectively) and mortality (p.0,95, 0,27 and 0,78 for IgA, IgG and IgM, respectively).
**Conclusions:** Pre-LT values of all IG subclasses are directly correlated with the severity of LD. No correlation was observed between IG levels and the development of post-LT infections in both ACLF and no-ACLF patients. Further studies will be required to assess the kinetic of IG post-LT and the development of infections.

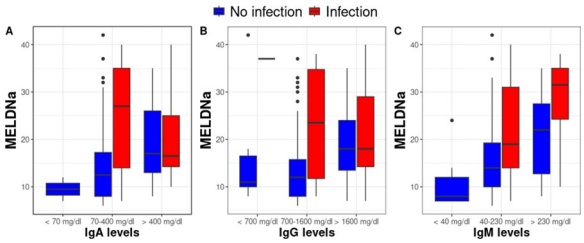

**Fig. 1 (abstract 0001053)** Correlation between MELDNa score and pre-LT level of IG subclasses with infections

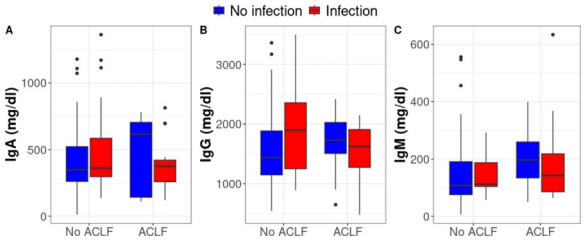

**Fig. 2 (abstract 0001053)** Correlation between pre-LT level of IG subclasses in ACLF and No-ACLF subpopulations with infections

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001054

**Introduction:** Pulmonary embolism (PE) is a prevalent condition which clinical spectrum encompasses various presentations with divergent outcomes, with approximately half of cases diagnosed in emergency settings. Timely diagnosis and treatment have demonstrated significant enhancements in patient outcomes and survival rates.
**Objectives:** The main objective of the study is to analyze the radiological or echocardiographic variables most related to the need for fibrinolysis or mechanical thrombectomy in patients admitted for acute PE in the ICU of a tertiary hospital. As secondary objectives, we aim to describe the demographic, clinical, hemodynamic, and evolutionary characteristics of these patients.

**Methods:** This is a retrospective observational study including all patients diagnosed with PE upon admission to the ICU via CT angiography over a period of 18 months (July 2022 to November 2023). Demographic, hemodynamic, radiological (location of filling defects, dilatation of *Truncus Pulmonalis*, right cavities, or radiological conclusion of hemodynamic compromise), and echocardiographic (tricuspid annular plane systolic excursion (TAPSE), tricuspid annular systolic velocity (RV S')) data were collected for each patient. The relationship of each variable with the need for reperfusion (fibrinolysis or thrombectomy) is expressed in terms of positive or negative predictive value (PPV, NPV). Statistical analysis was performed using R 4.1 for Windows.
**Results:** During the study period, 93 patients were included. The median age was 63 years (IQR 53.73). 57% of the patients were males. Severity stratification according to ESC guidelines was high risk in 26% of patients, high intermediate in 52%, and low intermediate in 21%. 12% of patients had secondary cardiopulmonary arrest, and in-hospital ICU mortality was 11%. PPV and NPV for the studied variables are presented in Table 1.

**Table 1 (abstract 0001054)** PPV and NPV for the studied variables

| Study | Variable | PPV (%) | NPV (%) |
|---|---|---|---|
| TC | *Truncus Pulmonalis* dilatation | 42 | 70 |
| | Radiological conclusion: evidence of hemodynamic impact | 42 | 88 |
| Echocardiogram | TAPSE | 53 | 88 |
| | RV S' | 58 | 87 |

**Conclusions:** The PPV of any of the variables in isolation is generally low. The studied echocardiographic and radiological variables independently present a high NPV for the need for reperfusion.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001055

**Introduction:** The Macklin effect is a radiological tomography sign in which a rupture of the alveolar wall is observed, causing air dissection along the pulmonary bronchovascular structure and interstitial emphysema. This sign has been described as a predictor of pneumothorax (PNX) and/or pneumomediastinum (PNM) [1, 2].
**Objectives:** To ascertain the correlation between the Macklin effect and barotrauma such as PNX and PMD in COVID-19 patients admitted to our Intensive Care Units (ICUs) during the Italian pandemic period.
**Methods:** Retrospective study on COVID-19 ARDS patients admitted to the ICUs of the University Hospital Integrated Trust of Verona during the first, second and third Italian pandemic waves. All screened patients belong to the REINSURE-ARDS Registry of the AOUI of Verona (1946CESC).
Patients with a computed-tomography (CT) executed during their hospitalization were included in the study; all available CTs were evaluated in the search for barotrauma and/or Macklin sign.
**Results:** Among 514 patients admitted to our ICUs during the first three pandemic waves, 367 patients (269 men, 98 women, median age 65 years [57–73]) underwent chest CT for COVID-19 ARDS, had radiological signs of interstitial pneumonia and were included in this study. Of these, 278 (75.7%) patients were intubated and managed with protective invasive mechanical ventilation.

**patients (13.6%) had clinical signs of barotrauma, which was radiologically confirmed; 29 (7.9%) patients had a positive Macklin sign on imaging investigations.**
Among patients positive for barotrauma, 26 (54%, true positive rate 54%) had a positive Macklin sign (Macklin/barotrauma ratio: first wave: 0/5; second wave: 16/24; third wave: 10/19). Considering patients with a positive Macklin sign, 7 presented the sign from a previous negative CT, while 11 had a subsequent negative control CT.

Furthermore, the positive Macklin sign was found in radiological exams executed in a preceding hospital stay in 3 patients, during the studied ICU recovery in 21 patients and in subsequent exams in 2 patients.
The patients who tested positive for the sign presented 10 PNM, 8 bilateral PNX and PNM, 7 right PNX and PNM and 1 left PNX and PNM.
Lastly, three patients with positive Macklin sign tested negative for PNX or PNM (false positive rate 10.3%).
All Macklin positive patients were managed with invasive mechanical ventilation.
**Conclusions:** Our data confirm the positive predictive value of the Macklin sign, nevertheless with lesser accuracy compared to the available literature.
Lodi V and Boffa E equally contributed to this work.

**Introduction:** Inhaled sedation with halogenated agents such as sevoflurane is widely used for inducing and maintaining anesthesia in surgery. More recently it has been incorporated to the intensive care unit (ICU) setting as first line therapy or for those patients in whom all other anesthetics fail to achieve a deep sedation.
**Objectives:** The aim to describe the safety and effectiveness of inhaled sedation with sevoflurane given through the Anaesthetic Conserving Device Sedaconda®ACD (Sedana Medical) to invasively ventilated patients in the ICU and to determine the reduction in propofol, benzodiazepines, opioids perfusions and other drugs once it was initiated.
**Methods:** A retrospective observational descriptive study during a five-month period including all the patients admitted to the ICU to whom inhaled sevoflurane was administered as rescue therapy for sedation. Data were collected from a total of 11 patients.
**Results:** The diagnoses of the patients at the time of admittance were: community acquired pneumonia (CAP) 6 cases (2 of them needed venovenous-ECMO), polytrauma patients 2 cases, septic shock of abdominal origin 2 patients and 1 case of refractory status epilepticus.
The mean age was 53.73 years (CI 95% 41.58–65.88), the average for SOFA and APACHE II scores at the time of ICU admittance were 9.73 (CI 95% 5.23–14.23) and 22.91 (CI 95% 12.77–33.04), respectively. Mean length of stay in ICU was 33.46 days and the average duration of invasive mechanical ventilation was 26.92 days. Figure 1.
Prior to the utilization of inhaled sevoflurane all 11 patients required two or more sedative drugs as well as analgesia with opioid perfusion and neuromuscular blocking agents (NMBA).
The sedative agents more frequently used in our group of patients were: propofol, administered in 100% of the patients, midazolam in 54.5% of them, ketamine 45.5% and dexmedetomidine 36.4%. NMBA (cisatracurium) was required in continuous perfusion in all cases. Figure 2.
Once sevoflurane was started, opioids could be down-titrated by more than 50% of the initial dose in 63.6% of the patients. Sevoflurane led as well to discontinuation of at least one sedative drug in 100% of our group of patients.
There were only two secondary effects reported. A polytrauma patient with no head injury developed diabetes insipidus; and another patient with severe CAP who required VV-ECMO had ventricular tachyarrythmias due to long QT interval. In both cases the effects disappeared and there were no relapses of the incidents described after termination of sevoflurane.
**Conclusions:** Inhaled sedation with halogenated agents is presented in clinical guidelines as first-line therapy for patients in the ICU, in the same level as propofol. In spite of the adverse events described in our patient sample, sevoflurane has been proven safe and effective in reducing and even withdrawing other anaesthetic drugs in those patients in whom aimed sedation scores are difficult to reach.

*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**001058

**Introduction:** Spontaneous subarachnoid hemorrhage (SAH) represents a subset of hemorrhagic strokes, comprising approximately 10% of all stroke cases globally. This condition poses significant challenges due to its high morbidity, mortality rates, and associated healthcare expenditures. Moreover, it is recognized as a time-sensitive pathology. In an effort to ensure equitable access to care for all affected patients within the Catalan community, a collaborative guardship program, known as Great Guardship (GG) was established in 2022 among select tertiary hospitals equipped with specialized neuro-radiology, interventional radiology, neurosurgical, and intensive care units. Our hospital joined this initiative in June 2022, contributing to a coordinated approach in managing this complex medical condition.
**Objectives:** To determine whether there are differences in the demographic, clinical characteristics, functional outcomes and mortality of patients with a diagnosis of spontaneous SAH admitted before and after our participation as healthcare provider tertiary center in the GG.
**Methods:** A retrospective cohort study was conducted, including all consecutive patients with a diagnosis of spontaneous SAH admitted between March 2018 and July 2023 to the intensive care unit of a tertiary hospital. We compared data from patients admitted before and after inclusion in the GG circuit (May 2022). The association between GG participation and mortality, as well as functional status at ICU discharge (measured by modified Rankin score, mRS), was analyzed via multivariate analysis, adjusting for potential confounding variables including SAPS II, APACHE II, CT Fisher grading scale, WFNS scale, and time to arteriography in hours.
**Results:** A total 116 patients with spontaneous SAH, in 90 (77.6%) a culprit aneurysm was confirmed, of these 47 (52%) were admitted in pre-GG period and 43 (48%) in GG. GG patients had a lower percentage of women (63% vs 83%) and lower severity according to WFNS scale (IV/V score: 55.8% vs 85.1%), SAPS II (41 vs 54) and APACHE II (15 vs 20). Additionally, more diagnostic arteriographies were performed in the GG group (41% vs. 32%), with a shorter time from admission to arteriography (6.4 vs. 13.9 h). Additionally, more diagnostic arteriographies were performed in the GG group (41% vs. 32%), with a shorter time from admission to arteriography (6.4 vs. 13.9 h). No significant differences in complications were observed. In multivariate analysis, neither the association between GG and mortality (odds ratio 1.67, 95% CI [0.36–7.19]) nor GG and mRS (odds ratio 0.43, 95% CI [− 0.41–1.30]) were significant. Further details and data are provided Table 1.
**Conclusions:** Inclusion in GG circuit resulted in a change in the clinical profile of the patient towards lower severity, an increase in the rate arteriography utilization and a reduction in time to arteriography. No differences were observed in terms of complications or association between admission during GG and mortality or functional status at discharge.

**Introduction:** Sepsis is a medical condition that affects 30 million people worldwide every year. It leads to 27 million hospitalizations and causes 6 million deaths annually. It's crucial to identify septic patients early in the emergency department (ED).
**Objectives:** Our study aimed to analyze the changes in cytokine levels in patients who presented with suspect infection and either developed or did not develop organ dysfunction, which was measured by the SOFA score, during the first 24 h.
**Methods:** We conducted a prospective observational cohort study on patients with suspected infection with a high risk of developing sepsis (measured by a NEWS scale of $\geq 3$). We drew blood and performed severity scores at baseline, 4 h, and 24 h. We defined sepsis according to the Sepsis 3 definition. We modeled cytokine time series using LOESS smoothing.
**Results:** We analyzed data from 43 patients, of whom 30 (69%) developed sepsis within the first 24 h. There were no significant differences in age or comorbidities between the two groups. None of the cytokine trajectories measured provided an early indication of patients who experienced sepsis, as shown in Fig. 1.
**Conclusions:** In this exploratory analysis, we found that the measures and trajectories of cytokines during the first 24 h did not allow for an early prediction of sepsis in high-risk patients.

### Intracranial haemorrhage, brain-stem death testing and organ donation: a simulation and traditional-based education series

R. Jayasundera[1], I. Dissanayake[1]
[1]Intensive Care, Whittington Hospital, London, United Kingdom
**Correspondence:** R. Jayasundera
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001062

**Introduction:** In the UK, diagnosis of death using neurological criteria (DNC) typically falls under the remit of intensive care doctors. (1) Once DNC has been confirmed, patients are referred to be considered for organ donation (OD). (2) A common cause of brain stem death is intracranial haemorrhage (ICH). (3) Two learning theories used in medical education include behaviourism and constructivism. (4) Traditional-based education typically adopts a behaviourist approach (5) and simulation-based education (SBE) uses both theories. (6) The Whittington is a 360-bed district general hospital (DGH) in North London, with a 12-bed Intensive Care Unit (ICU). On occasion, we admit patients with ICH, not suitable for neurosurgical interventions and hence not transferred to our local neurosurgical centre. These patients generally have poor outcomes, and a significant proportion are diagnosed DNC. Between March 2023 and March 2024 at the Whittington, there were 22 referrals for OD; 7 of whom met the criteria for diagnosing DNC, which all subsequently underwent. 1 proceeded to donate. Relative infrequency of admissions with ICH, DNC, and proceeding OD leads to unfamiliarity and lack of confidence amongst clinical staff in managing these patients. We used SBE and traditional teaching to educate ICU and non-ICU staff about DNC and the OD process. We also educated staff on neuro-ICU principles in a DGH, contextualising DNC and OD around a simulation of acute ICH and raised intracranial pressure (ICP).
**Objectives:** 1. Use SBE to expose participants to management of neuro-ICU patients in a DGH. 2. Use SBE to develop communication skills when discussing poor prognosis with next of kin. 3. Educate clinical staff regarding when and how to undertake brain stem death testing. 4. Raise awareness of OD, and OD statistics relevant to Whittington.
**Methods:** We used high-fidelity simulation, clinical skills workshops, and small-large group lectures. In the first simulation, participants managed a patient with acute ICH with raised ICP who did not respond to interventions. The second simulation was communications-based, discussing poor prognosis of this patient with the next of kin. This scenario included a professional actor as the next of kin. A non-validated questionnaire consisting of Likert-scale questions was completed by participants. Additionally, we conducted immediate post-simulation debriefs which utilised the PEARLS (promoting excellence and reflective learning in simulation) framework to facilitate both technical and non-technical debriefs. (7) The final interactive aspect was a skills workshop in which diagnosis of DNC was demonstrated and participants could perform the steps required to diagnose DNC. To complete the series, we presented lectures for ICU clinical staff and a Grand Round targeting the wider hospital clinical staff, outlining the process of diagnosing DNC and highlighted our hospital's statistics for OD.

**Results:** Two questions were of interest; "Simulation has improved knowledge of this topic", and "Human factors (HF) knowledge has improved following this simulation". Regarding the raised ICP scenario, 75% 'strongly agreed' there was improvement in their knowledge following the simulation. 50% 'strongly agreed' their HF understanding had improved. Regarding the difficult communications simulation, 50% 'strongly agreed' that HF knowledge had improved. Participants found the actor to be very helpful for developing communication skills and helping with immersion in the simulation. For the skills workshop, participants commented on the usefulness of going through the steps of diagnosing DNC. Feedback from the Grand Round was also favourable with participants commenting on increased awareness and knowledge of the OD process.
**Conclusions:** This series led to an overall increase in the perceived knowledge of managing patients with ICH, raised ICP, diagnosis of DNC, and the overall OD process. We plan to incorporate these simulations, alongside the skills workshop, into our regular simulation programme. Our aim is that these occur once per academic year. Additionally, we will initiate an annual update (June each year) of the hospital's OD statistics and present at the departmental educational meeting which will be open (in-person and remotely) to the entire hospital. One of the main constraints was lack of training time, particularly amongst ICU nursing staff. We aim to run the simulations on dedicated nurse training days to ensure nurse participation.

### Systemic immune-inflammation index (SII) as useful biomarker to predict the outcomes in patients underwent living donor liver transplantation

D. Hong[1], S. J. Kim[1], H. S. Chung[1]
[1]Department of anesthesiology and pain medicine, EunPyeong St.Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001063

**Introduction:** The inflammatory reaction, which plays a key role in graft survival, is associated with the post-transplant prognosis. We hypothesized that systemic immune-inflammation index (SII) could provide more valuable information in assessing the outcomes in patients with end-stage liver diseases (ESLD) after living donor liver transplantation (LDLT).
**Methods:** Three hundred and seventy-eight patients with end-stage liver diseases who underwent LDLT from March 2016 to October 2023 were analyzed in this retrospective study. Demographic, and biochemical data were obtained using electric medical records system. We analyzed the relation between the SII and the outcomes including pre- and post-operative model for end-stage live disease (MELD) score, short-term (one month) mortality, time for mechanical ventilation, and stay duration of intensive care unit and hospital day based on Pearson correlation coefficient using correlation analysis, and investigated the cut-off value of SII identifying short-term mortality using area under the receiver operating curve (AUROC). Multivariate logistic analysis was used to assess the risk factors of short-term mortality.
**Results:**: SII were significantly correlated with pre- and post-operative model for end-stage live disease (MELD) score, short-term mortality, time for mechanical ventilation, and stay duration of intensive care unit and hospital day ($P < 0.05$). Platelet-to-lymphocyte ratio (PLR) showed a statistically significant correlation with short-term mortality and time for mechanical ventilation. Neutrophil-to-lymphocyte ratio (NLR) were correlated with pre- and post-operative model for end-stage live disease (MELD) score, short-term mortality, and time for mechanical ventilation. The cut-off value of SII in predicting short-term mortality after LDLT was $275 \times 10^9$ cells/L (AUROC = 0.603; sensitivity, 53.3%; and specificity 69.5%).
**Conclusions:** The SII may serve as a convenient, low-cost and noninvasive prognostic biomarker for patients after LDLT for ESLD.

### Evaluating the carbon footprint arising from laboratory investigations in the intensive care unit (ICU)

S. Goh[1], Y. H. J. Tan[1], S. A. Lie[1]
[1]Department of Anaesthesiology and Perioperative Medicine, Singapore General Hospital, Singapore, Singapore
**Correspondence:** S. Goh
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001064

**Introduction:** Currently, healthcare contributes 4–5% to global carbon emissions [1, 2]. Of this, the intensive care unit (ICU) produces three times more carbon emissions than the general ward [3]. Total carbon emissions per patient day in ICU ranged from 88 to 178 kg CO2-e [3, 4], predominantly contributed by energy consumption and consumables [5]. However, no studies have studied the carbon footprint arising from laboratory investigations in the ICU.
**Objectives:** Our study aims to evaluate the carbon footprint arising from laboratory investigations in the ICU over a 4-month period.
**Methods:** A retrospective single-center cohort study was conducted in the Surgical ICU in Singapore General Hospital. The number of laboratory investigations ordered for all patients admitted from May to August 2023 was extracted from the electronic medical records system. Existing process-based Life Cycle Assessment (LCA) data were used to determine the carbon footprint of the investigations ordered [6, 7]. Some examples of investigation and their CO2-e (kg CO2-e/test) used are full blood count (0.0386), coagulation profile (0.0663), C-reactive protein (0.0005), arterial blood gas (0.049), urea and electrolyte test (UECr, 0.143).
**Results:** 131 patients were admitted to the ICU for a total of 604 patient days. An average of 13.2 investigations were ordered per patient day. The total carbon emissions over this period was 739 kg CO2-e, which equates to driving 3041 km, or an average of 1.22 kg CO2-e per patient day. The most common investigation ordered was UECr, while liver panel ± Gamma-glutamyl transpeptidase generated the highest total carbon emissions (0.3137) (Table 1). 20.7% of investigations lacked available LCA data. These include fibrinogen, procalcitonin, lactate, ketones, creatinine kinase, Troponin-T and NT-proBNP. It is uncertain how much these investigations contribute to the total emissions attributable to laboratory investigations in the ICU.
**Conclusions:** Our study quantified the carbon footprint contributed by laboratory investigations in ICU from available LCA data. Adopting a holistic approach to environmental sustainability, ICUs' laboratory investigations also contribute to generate greenhouse gases, albeit small, and can be targeted to reduce unnecessary carbon footprint. There will be aggregation of marginal gains if any such measures of reducing unnecessary investigations can be extended to the rest of healthcare. This can lead to benefits such as cost reduction [8], iatrogenic anemia and need for blood transfusions [9].

**Table 1 (abstract 0001064)** Number of laboratory tests ordered from May to August 2023 and carbon emissions attributed

**Correspondence:** C. Costa
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001065

**Introduction:** Pelvic trauma (PT) represents 3% of all trauma and is among the most serious and deadly trauma-related lesions. Its management involves a multidisciplinary approach and surgical treatment is frequently crucial to improve patient outcome.
**Objectives:** To compare two different definitive surgical timing strategies [early (< 48 h) (EDS) and late (> 48 h) (LDS)] in critically ill patients with PT and to evaluate its impact in the outcome.
**Methods:** Retrospective single-centre study of all patients over 18 years with PT admitted to a ICU of a Tertiary University Hospital between January 2020 and December 2023. SPSS was used for statistical analysis.
**Results:** Forty patients (36%) of the 112 critically ill PT patients were submitted to definitive surgical treatment, mainly male (80%) with median age of 47y. Median Injury Severity Score (ISS) was 25. Concomitant brain (BT) and thoracic trauma were present in, respectively, 37,5% and 35% of the patients. According to the Young Burges (YB) classification, 7,5% of PT resulted from antero-posterior compression (APC), 87,5% from lateral compression (LC) and 5% from vertical shear (VS). Most PT were grade I (70%) of WSES classification and only 7,5% were grade IV. Shock index (SI) was ≥ 0,9 in 45% of the patients. ICU and hospital length of stay (LOS) were 12 and 41,2 days, respectively. Only one patient (2,5%) died in the hospital.
Median time for definitive surgical treatment was 96h after ICU admission. EDS was done in 7 patients (17,5%) and LDS in the remaining 33 patients (82,5%).
LDS patients were significantly younger (41 vs. 69y; $p < 0{,}001$). Falls were the main mechanism of PT in both groups (57% in EDS vs. 55% in LSD) and it did not influence the time of surgery. EDS patients had a higher Glasgow Coma Scale (GCS) ($p = 0{,}011$). Serum lactate, arterial pH, haemoglobin and coagulation times on admission did not influence timing of surgical decision. However, EDS patients had significantly higher median serum fibrinogen levels (292 vs 215 mg/l; $p = 0{,}049$). Although not statistically significant, LSD was more frequent in patients with SI ≥ 0,9 (94,4% vs 5,6%; $p = 0{,}105$) or with lactate > 2mmol/l (90,9 vs 9,1%; $p = 0{,}205$).
No differences were found regarding general severity scores but an ISS ≥ 15 was significantly more frequent in LSD group (81,3% vs 28,6%; $p = 0{,}012$).
All APC types of fractures had EDS while LC and VS fractures had more frequently LDS ($p < 0{,}001$). No relationship was found between WSES classification and surgical timing strategy ($p > 0{,}721$).
Median ICU LOS was higher in the LSD group but without statistical significance (11 vs 2 days; $p = 0{,}063$).
**Conclusions:** Most patients were submitted to LDS. Age, GCS, ISS ≥ 15 and YB classification were associated with time to definitive surgery. Hemodynamic instability on admission seems to support LDS. EDS shows a tendency to shorter ICU LOS without impacting mortality.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001066

**Introduction:** Systemic Inflammation Response Syndrome (SIRS) is a critical condition characterized by an overwhelming inflammatory state leading to organ failure and increased mortality. The gut microbiome has emerged as a novel therapeutic target for SIRS due to its significant role in modulating the body's immune response.
**Objectives:** This study aimed to evaluate the therapeutic efficacy of the Xuanfei Baidu formula (XFBD) in the treatment of SIRS and to elucidate the role of gut microbiome modulation in its therapeutic action.
**Methods:** We applied a combination of 16S rRNA sequencing and fecal microbiota transplantation (FMT) to determine the impact of XFBD on the gut microbiome of SIRS-induced mice. Additionally, we

isolated 51 compounds from XFBD and tested their gut microbiome remodeling effects in vitro to mimic the healthy gut microbiota structure. We then formulated various gut microbiome remodeling compound (GMRC) cocktails from these compounds and assessed their efficacy in treating SIRS.
**Results:** XFBD treatment significantly lowered mortality and reduced inflammatory markers in SIRS mice. The beneficial effects of XFBD were partially attributed to alterations in the gut microbiome, as evidenced by FMT experiments. In vitro analysis of the 51 XFBD compounds revealed distinct capacities to reshape the microbial structure towards that of healthy controls. Among the GMRC cocktails created, GMRC cocktail C—composed of aucubin, gentiopicroside, syringic acid, gallic acid, p-hydroxybenzaldehyde, para-hydroxybenzoic acid, and isoimperatorin—was most effective in modulating the gut microbiota and improving SIRS outcomes. Further, in vitro experiments confirmed GMRC cocktail C's ability to rebalance the bacterial composition in samples from SIRS patients.
**Conclusions:** The findings highlight the Xuanfei Baidu formula's promising therapeutic potential in treating SIRS through gut microbiome modulation. The study also emphasizes the significance of innovative treatments targeting the microbiome, such as the development of GMRC cocktails, offering new avenues for managing SIRS and enhancing patient survival.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001069

**Introduction:** Isavuconazole (ISV) gained relevance in recent years in our unit as an alternative to voriconazole in pulmonary aspergillosis (PA) due to the absence of the need to monitor serum concentrations, action spectrum and safety profile.
**Objectives:** To describe ISV use in critically ill patients admitted in our intensive care unit (ICU) with suspected PA diagnosis, analyzing patient's characteristics, indication for ISV initiation, if it was empirical or guided, PA diagnosis, ISV tolerance and treatment length.
**Methods:** A descriptive retrospective observational study of ISV use in patients admitted in our ICU from September 2019 to July 2023. PA diagnosis was obtained from bronchoalveolar lavage (culture/PCR/galactomannan), bronchial aspirate culture or peripheral blood galactomannan.
**Results:** During the study period, 2098 patients were admitted in our ICU, whom 112 (5.33%) received treatment with ISV. The average age was 61.11 years (95% CI 59.01–63.21). 78 (69.74%) were men. The most relevant medical histories were: high blood pressure 50 patients (44.64%), dyslipidemia 32 (28.57), active smokers 22 (19.64%), obesity 28 (25%) and diabetes 31 (27.67%). The average APACHE II score was 18.50 (95% CI 17.20–19.80). Mainly reasons for ICU admission were in 69 (61.60%) patients COVID pneumonia, 9 (8.03%) community-acquired pneumonia and 9 (8.03%) abdominal sepsis. The average SOFA score at the beginning of ISV treatment was 7.71 (95% CI 7.16–8.25). 24 (21.42) patients were under continuous renal replacement therapy and 3 (2,67%) with ECMO therapy. ISV treatment was initiated due to ventilator-associated pneumonia in 81 (72.32%) patients and 17 (15.17%) cases due to febrile-syndrome without identified focus. 48 (42.85%) patients were diagnosed with PA. Treatment with ISV was empirical in 99 patients (88.39%). The overall average duration of treatment was 13.39 days (95% CI 11.71–15.07), with 18.08 days (95% CI 15.12–21.04) in patients with PA and 9.72 days (95% CI 8.30–11.14) in those who were not PA. The reason for treatment discontinuation was in 33(29.46%) cases due to determination of non-PA, 51 (45.53%) cases due to the end of treatment and 28 (25%) due to exitus. Treatment was tolerated without adverse effects that required discontinuation of ISV.
**Conclusions:** ISV use as antifungal treatment has been indicated in patients with suspected PA. The average SOFA score at the beginning of treatment was 7.71 (95% CI 7.16–8.25). In PA-diagnosed patients, treatment was 18.08 days. No ISV treatments ended because of adverse effects.

**Correspondence:** J. P. Nuñez Casco
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001070

**Introduction:** Pulmonary embolism (PE) is a common form of venous thrombosis that sometimes can be fatal. Risk factor such a recent major surgery and cancer, mainly lung, gastric and cerebral, carries a higher risk of developing PE. The most used scale for determining the severity of the PE is the PESI scale, been class IV and V with the higher risk of death. High-risk PE requires an urgent diagnosis and treatment strategy, with thrombolytic treatment indicated as the first option. Mechanical thrombectomy is indicated in high-risk PE on those cases where thrombolysis is contraindicated or has failed, having the potential advantage of immediate removal of the thrombus and restoration of pulmonary blood flow.
**Objectives:** To describe 6 cases of high-risk pulmonary thromboembolism admitted to the ICU of the Hospital of León who underwent urgent endovascular reperfusion treatment given the situation of hemodynamic instability and contraindication to fibrinolytic therapy.
**Methods:** Retrospective observational study that was carried out in the ICU during 2023 analyzing the data of patients who were diagnose of high-risk PE and hemodynamic instability and underwent mechanical thrombectomy.
**Results:** A higher incidence of high-risk PE is observed in men (67%) than in women (33%). It was observed that the most common risk factors among patients were arterial hypertension (67%), smoking (50%), morbid obesity (50%), and lung and brain cancer (33%). At the time of admission all patients had a high-risk PESI, class IV (50%) and class V (50%) with a higher mortality in PESI V (67%). All 6 cases were massive PE, define as obstruction of the pulmonary arterial tree that exceeds 50% of the cross-sectional area. All had in common right ventricular dysfunction at the time of diagnosis. All of the patients underwent mechanical thrombectomy, only 1 of them was due to failure of fibrinolysis resulting in a fatal outcome. In all of the other cases was because of contraindications for fibrinolysis.
Mortality was observed in 50% if the cases (3), in these 3 cases during the procedure it was not possible to observe pulmonary vein occlusion due to lack of progression of the contrast towards the trunk of the pulmonary artery, probably due to the material use during the procedure, secondary cardiopulmonary resuscitation maneuvers were performed that led to death. All three cases that survived, mechanical thrombectomy with extraction of the thrombus was performed with

no incidences. The median number of days admitted to the ICU was 12 of those patients who survived.
**Conclusions:** Although these results should be interpreted with caution due to a low number of patients treated, we observed that mechanical thrombectomy can result in better outcomes when the extraction of the thrombus is successful. Are we looking into the future of PE treatment?

**Fig. 1 (abstract 001070)** Mechanical thrombectomy in pulmonary embolism

**Introduction:** The COVID-19 pandemic placed an extraordinary burden on ICUs in Sweden due to its low number of ICU beds per capita. (1) Previous Swedish data suggest that individuals with an immigrant background, lower levels of education, and lower income were more likely to experience severe COVID-19 requiring mechanical ventilation, (2) which is in line with international data. (3) It is unclear if this translated to a higher risk of death post ICU-admission (2, 3).
**Objectives:** This study aimed to evaluate 90-day mortality following ICU admissions in COVID-19 patients with acute hypoxemic respiratory failure (AHRF) across various socioeconomic and country-of-origin groups in Sweden.
**Methods:** Registry-based cohort study of all adults (≥ 18 years) admitted to Swedish ICUs with PCR-confirmed SARS-CoV-2 infection (ICD-10 diagnosis code U07.1) and AHRF between 6 March 2020 and 31 December 2022. Intensive care data were combined with socioeconomic and comorbidity data from multiple national quality registries. Our primary outcome measure was 90-day mortality.
Country-of-origin and socioeconomic factors (income and education) were considered as main exposures in a multivariable logistic regression analysis, and adjusted covariates included in the model were age, sex, multiple comorbidities, SAPS III score and pandemic wave.
**Results:** 8061 patients were included. The majority of patients were born in a Nordic country (64.6%). The largest non-Nordic group was Asian (16.5%). When compared to the highest income quartile four as reference, only quartile two was significantly associated with 90-day mortality (OR 1.2, 95% CI 1.0–1.5, $p < 0.05$). There were no differences due to educational level. Compared to persons with Nordic country-of-origin, Asian (OR 1.3, 95% CI 1.1–1.6, $p < 0.01$), South American

(OR 1.5, 95% CI 1.0–2.3, $p < 0.05$) and African (OR 1.4, 95% CI 1.0–2.0, $p < 0.05$) individuals had increased risk of death.
**Conclusions:** Both country-of-origin and income level are independently associated with an increased risk of death at 90 days in ICU patients with AHRF due to COVID-19. However, no differences were seen due to level of education.

**Introduction:** Severe pneumonia remain a major cause of morbidity and mortality worldwide (1). Both diagnosis and treatment pose significant challenges (2). The FILMARRAY® Pneumonia Panel Plus (FAPP) provides fast real-time results, enabling targeted antimicrobial therapy and reducing the use of broad-spectrum antibiotics (3, 4).
**Objectives:** To evaluate the impact of FAPP implementation on antimicrobial decision-making in critically ill patients with suspected pneumonia.
**Methods:** A retrospective descriptive study was conducted in a 22-bed polyvalent ICU in Spain, with a 24/7 microbiology laboratory, between January 2023 and February 2024. All cases in which FAPP was requested were analyzed, including microbiological results and the therapeutic approach. Changes in antibiotic treatment were classified as positive (escalation/initiation) or negative (de-escalation/discontinuation). Culture results were considered positive for those microorganisms detectable by the multiplex PCR filmarray.
**Results:** 188 respiratory samples from critically ill patients were analyzed. 156 (83%) were obtained from patients with invasive mechanical ventilation. 91 (48.4%) were considered nosocomial infections. 124 (66%) FAPP samples were positive, with a positive culture concordance in 45 (36.2%). There was no case where FAPP was negative and culture positive. In 42%, a positive FAPP with a negative culture was obtained (Table 1).
After the FAPP results were known, therapeutic adjustments were made in 69 cases (36.7%): 68.1% (47 samples) were based on de-escalation or discontinuation of antibiotics, and 31.8% (22 samples) on escalation or initiation of antibiotics. All changes classified as positive had a positive FAPP result ($p < 0{,}002$) (Table 1). In 54.8% of the positive samples, it was detected only 1 pathogen, in 33% 2 pathogens, and in 23% ≥ 3.

The most commonly identified bacteria were *Haemophilus influenzae, Staphylococcus aureus,* and *Streptococcus pneumoniae*. In 5 cases, two resistance factors were detected: methicillin resistance in *S. aureus* (MRSA) and class B carbapenemase(VIM). However, a therapeutic change was done in 100% of the cases, 80% were escalated/initiated and 20% were de-escalated/discontinued antibiotics.

### Optimization of infusion therapy in the postoperative period in children with congenital heart defects

A. Sharipov[1], A. Alimov[2]
[1]Emergency and Critical care, Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan; [2]Intensive Care Unit, National Children Medical Center, Tashkent, Uzbekistan
**Correspondence:** A. Sharipov
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001074

**Introduction:** In recent years in Uzbekistan, congenital heart defects (CHD) have taken a leading position in prevalence compared to other developmental defects in. Key recommendations are to use isotonic balanced solutions to restrict IV-MFT infusion volumes [1]. But the optimal strategy for fluid replacement after major surgery remains unclear and there is considerable interest in the investigation of more restrictive fluid regimens [2]. Recent evidence suggests that acetate-buffered infusions result in better hemodynamic stabilization [3].
**Objectives:** The purpose of the study is to optimize infusion therapy in the postoperative period of cardiac surgery. We examined 40 cardiac intensive care patients under the age of 6 months in the intensive care unit of the Children's National Medical Center.
**Methods:** The study material was the assessment of clinical and central hemodynamic parameters using echocardiography (EchoCG), central venous pressure (CVP), invasive measurement of blood pressure (ABP), acid–base balance (ABG). All patients were divided into two groups depending on the volume of infusion therapy. The 1-st group included 20 children with IV-MFT according to Holiday and Segar (4 ml/kg/hour of general volume), the 2-nl group included 20 children with IV-MFT according to an optimized regimen (1 ml/kg/hour) were calculated separately from the volume of inotropic and vasoactive support. The solution of choice for fluid support was Ringer's solution in both groups. Inotropic support in both groups was provided with adrenaline 0.05 mcg/kg/min, milrinone 0.5 mcg/kg/min.
**Results:** As a result of the work, EchoCG comparison showed significant differences between the groups: EFLV in the 1-st group did not exceed 46%, when in the 2-nd group it reached figures above 52%. EDV, on the contrary, was higher in the 1-st group by 20% (9.78 ml and 8.15 ml, respectively). We also noted differences in the compared groups in the following parameters: CVP in the 1-st group 13–14, in the 2-nd group 11–11.5; sodium in the 1-st group 128, in the 2-nd group 141; calcium—no difference. In the 1-st group, we identified signs of metabolic acidosis (pH < 7.32), and in the 2-nd group the pH value remained within the range of 7.34–7.42. BE in the 1-st group was 3 times less than in the study group (− 4.5 and − 1.5, respectively); ABP—41.8 mmHg (1 group) and 47.3 mmHg (2 group), diuresis—0.8 ml/kg/hour (1 group) and 1.5 ml/kg/hour (2 group).
**Conclusions:** Our proposed optimization of infusion therapy in the postoperative period of cardiac surgery, based on separate calculation of the main infusion at the rate of 1 ml/kg/hour of the volume of inotropic and vasoactive support, showed a significant difference compared with the control group in favor of reducing the hemodynamic load. This made it possible to reduce the shortening of the period of mechanical ventilation and the stay of children in the ICU. Nevertheless, we consider continuing research in this field.

**Introduction:** When mechanical ventilation is not enough, extracorporeal membrane oxygenation could play a role as a form of rescue therapy and may provide beneficial results in the hands of skilled clinicians in centers with experience in using ECMO properly in selected patients.
**Objectives:** To describe the characteristics of patients admitted to a third-level hospital critical care unit over the past two decades who required the use of extracorporeal membrane oxygenation (ECMO) support.
**Methods:** Observational, retrospective study of ECMO patients over the past two decades in the ICU of H.G.U Gregorio Marañón. Epidemiological data, comorbidities, clinical characteristics prior to the initiation of the technique, organic supports used, complications, severity scales, and outcomes according to RESP score and functional class at one year according to the mMRC scale were collected. For descriptive analysis, quantitative variables were expressed as mean with standard deviation if their distribution was normal, or as median with interquartile range otherwise. Qualitative variables were expressed as percentages.
**Results:** 91 patients on ECMO during the reviewed period, with ECMO-VV used in 95% of cases. Indications for ECMO-VV were refractory hypoxemia (44%), severe hypoxemia/acidosis (6%), severe hypoxemia and severe respiratory acidosis (42%), and 8% as support prior to a procedure. ECMO-VA accounted for 5%, with cardiac dysfunction related to sepsis (20%), cardiogenic shock (40%), and pulmonary embolism (40%). Age: 49 ± 12 years, 68% male, BMI 28 ± 6, APACHE II score on admission 14 ± 8. Comorbidities: obesity 69%, hypertension 72%, lung disease 5%, diabetes 14%, cardiovascular disease 15%. immunosuppression 20%.
Pre-ECMO: APACHE II 17 ± 8, SOFA 8 ± 4, PO2/FiO2 73 ± 21, pCO2 70.6 ± 19.4 mmHg, days on mechanical ventilation (MV) 9 ± 11, MV > 7 days 50%. 65% received aggressive MV (plateau pressure > 30 cmH2O, driving pressure > 15 cmH2O) for 1.38 ± 1.8 days. Inhaled nitric oxide 61.5%, prone positioning sessions 3 (1–5), neuromuscular blockade 100%, vasopressor drugs 69%, and acute respiratory distress syndrome (ARDS) with extracorporeal membrane oxygenation (ECMO) 19%. Complications: ventilator-associated pneumonia (VAP) 14%, bloodstream infection (BSI) 9%, arrhythmia 10%, pneumothorax 8%. ECMO days: 16 ± 9, total MV days: 44 ± 20, tracheostomy 61%. ECMO mortality 50%, ICU mortality 61%, reasons: Acute Exacerbation of Chronic Obstructive Pulmonary Disease (AECOPD) 44%, Multiple Organ Dysfunction Syndrome (MODS) 31%, Cerebrovascular Accident (CVA) 12%. ICU stay 53 ± 27 days, hospital stay 73 ± 58 days. ICU and hospital survival rate: 48%. RESP Score: Group I 2%, Group II 22%, Group III 40%, Group IV 12%, Group V 1%, with associated survival rates: Group I 100%, Group II 74%, Group III 33%, Group IV 55%, Group V 100%. Functional class at one year (mMRC): Class II 30%, Class III 70%.

**Conclusions:** High hospital stay, complications, and mortality of critical patients who required ECMO. Marked deterioration of functional class in one-year survivors.

**Topic:** Acute respiratory failure and mechanical ventilation

### Efficacy of balloon-supported manual compression hemostasis for Impella sheaths

M. Higuchi[1], D. Ikechi[2], Y. Chiba[3]
[1]Devision of Cardiovascular Intensive Care, Mito Saiseikai General Hospital, Mito, Japan; [2]Devision of Cardiovascular Intensive Care, Mito Saiseikai General Hospital, Mito, Japan; [3]Devision of Cardiology, Mito Saiseikai General Hospital, Mito, Japan
**Correspondence:** M. Higuchi
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001076

**Introduction:** The efficacy of Impella in cardiogenic shock has been widely reported; however, Impella, which requires a large-bore sheath, may require prolonged pressure hemostasis or cause difficulty in hemostasis by manual compression after removal. Therefore, surgical hemostasis (SH) is used, which is highly invasive and carries the risk of infection. Thus, hemostatic device techniques (HDT) using suture-meditated closure systems and, more recently, hemostatic devices based on collagen plugs have been reported. However, HDT also pose a risk of infection and difficulty using alternative techniques in the event HDT hemostasis fails.
**Objectives:** The balloon-supported manual compression hemostasis method (BSMC) can shorten the time to hemostasis while avoiding the risk of infection by not leaving sutures or collagen plugs, and can also be used as an alternative technique when hemostasis is difficult to achieve.
We investigated the efficacy and safety of BSMC as a method of hemostasis for Impella compared to SH and HDT.
**Methods:** This study included 31 patients who underwent Impella removal from 55 consecutive patients treated with Impella at Mito Saiseikai General Hospital from June 2020 to May 2024. Three types of hemostasis methods were used: BSMC, SH, and HDT (all with a suture-meditated closure system). The success rate, time to hemostasis, and perioperative complications of each method were investigated.
**Results:** Sixteen patients underwent BSMC, eight underwent SH, and seven underwent HDT.
The success rate of BSMC was 93.8% (14/15) (excluding one case of thrombus occlusion), 100% (8/8) with SH, and 85.7% (6/7) with HDT ($p = 0.72$).
The time to hemostasis was $18.9 \pm 8.93$ min for BSMC, $35.3 \pm 10.7$ min for SH, and $10.0 \pm 5.13$ min for HDT. The time to hemostasis for BSMC was significantly shorter than that of SH ($p < 0.001$) and was not significantly different from that of HDT ($p = 0.16$). In one case using BSMC in which hemostasis was difficult, hemostasis was achieved using SH, and balloon compression was used to control bleeding.
There was one case of wound dehiscence with SH and one case of wound infection requiring antimicrobial therapy with HDT, but none with BSMC.
**Conclusions:** BSMC significantly shorter hemostasis time compared to SH and had no significant differences compared to HDT, and it had no complications associated with hemostasis. Thus, BSMC may be an effective hemostatic option after Impella removal.

**Introduction:** Mechanical ventilation (MV) is associated with severe adverse outcomes in critically ill patients and the impact of ventilator induced diaphragmatic dysfunction (VIDD) is still unclear.
**Objectives:** (i) To assess the association between quadriceps thickness and strength in patients in intensive-care unit (ICU); (ii) to assess time to reach the sitting position as a functional outcome.
**Methods:** Clinical Trial number NCT06289244. Critically ill adults requiring at least 48 h of invasive MV were consecutively enrolled. Quadriceps strength over the ICU stay period was assessed by rectus femoris cross-sectional area (CSA), Medical Research Council (MRC) sum-score, and dynamometer measurement. In addition, the association between muscle strength and muscle thickness variation in peripheral and respiratory muscles was investigated using multivariable mixed-effect model. Time to sitting position was used as dependent variable in multivariable Cox model to understand the relationship of peripheral and respiratory muscles' strength and thickness variation.
**Results:** So far, we included 36 over 50 patients (females 36.1%), as our target sample size (72%). Mean age was 56.3 (16.2) years, and they spent 12.7 (10.4) days on MV during 16.6 (12.4) days of ICU stay. Preliminary results showed several strong positive correlations: rectus femoris CSA and quadriceps thickness ($\rho = 0.55$, $p < 0.001$), respiratory muscle strength and MRC ($\rho = 0.73$, $p < 0.001$), respiratory muscle strength and quadriceps extensor right ($\rho = 0.67$, $p < 0.001$) and MRC and quadriceps extensor right ($\rho = 0.78$, $p < 0.001$) (Fig. 1). For those evaluated at ICU discharge ($n = 21$), 17 (81%) scored < 48 on the MRC scale. In patients with preserved diaphragm function, median time to sitting position was 7 (interquartile range (IQR): 6–18 days), compared to 17 (IQR = 16-) days in patients with impaired diaphragm function. Among these, the 35.4% (95%CI: 18.6; 67.3) did not reach sitting position after 14 days of ICU stay compared to patients without diaphragm waste (75% (95%CI: 50.3; 100.0).
**Conclusions:** The current results provide encouraging evidence supporting the use of ultrasound and dynamometer in combination with the MRC scale to assess peripheral muscle strength in ICU patients. The diaphragm function seems to have a key role guiding rehabilitation interventions promptly.

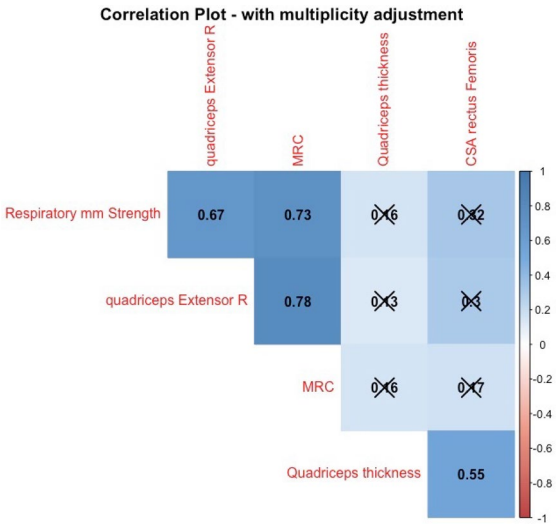

**Fig. 1 (abstract 001077)** Correlation Plot- with multiplicity adjustment. *Abbreviations: R = right; MRC = Medical Research Council; CSA = cross-sectional area; mm = muscles

**Introduction:** In patients scheduled for surgery, there are often cases where the surgery is delayed due to excessively high blood pressure upon entering the operating room. 'White coat hypertension is a unique entity, in which there is rise of blood pressure noted in patients who are normotensive in non-medical settings, but develop hypertension on entering in a medical facility. This phenomenon is also noticeable in the medical environment, especially when patients are nervous about entering the operating room.
**Methods:** We reviewed the electronic medical records of patients who had undergone Phacoemulsification and Posterior capsular lens insertion (PE & PCL) for cataract with monitored anesthesia care (MAC). Patients receiving psychiatric medication were excluded. Data were compared and analyzed by extracting the first vital signs in the ward on the day of surgery, three vital signs every 3 min immediately after entering the operating room, and three vital signs every 5 min after transfer to the recovery room.
**Results:** Vital signs (HR, SBP, and MBP) showed significant changes over time except for DBP, and blood pressure and heart rate fluctuations were greatest immediately after entering the operating room (Fig. 1). Additionally, these changes showed significant results regardless of hypertension as an underlying disease.

**Table 1 (abstract 001078)** Demographic data

| | | |
|---|---|---|
| Gender [*n* (%)] | | |
| Male | 62 | (51.2) |
| Female | 59 | (48.8) |
| Age (year) | 70.5 | ± 10.5 |
| Height (cm) | 160.8 | ± 9.1 |
| Weight (kg) | 63.9 | ± 11.9 |
| HTN [*n* (%)] | 53 | (43.8) |
| DM [*n* (%)] | 22 | (18.2) |
| CVA [*n* (%)] | 20 | (16.5) |

Data are presented as mean ± SD or mean

HTN: hypertension; DM: diabetes mellitus; CVA: cerebrovascular accident

**Conclusions:** When a perioperative patient shows unstable vital signs, emotional control or light sedation is a factor to consider in stabilizing the patient.

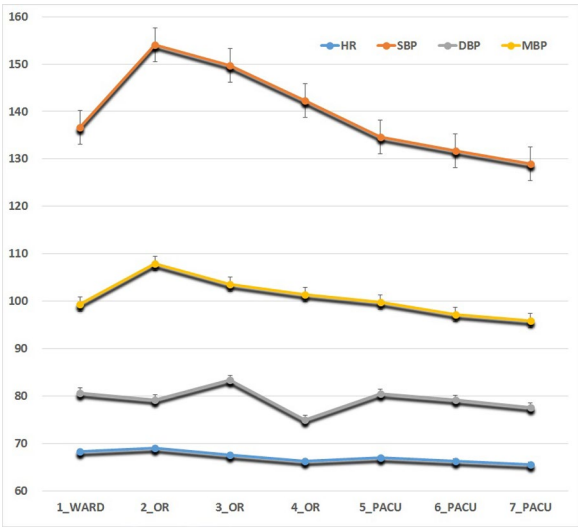

**Fig. 1 (abstract 001078)** These graphs show the mean and standard error of changes in vital signs over time. HR: heart rate; SBP: systolic blood pressure; DBP: diastolic blood pressure; MBP: mean blood pressure; OR: operating room; PACU: post anesthesia care unit

**Topic:** Perioperative care

*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**001079

**Introduction:** The oleander (*Nerium oleander*) is a widespread ornamental plant. Ingestion of this shrub is capable of causing the death of an adult, due to the presence of oleandrin in the leaf, flowers and stem, a substance similar to digoxin. Oleander poisoning is uncommon but serious.
**Objectives:** Describe cardiovascular complications following oleander poisoning in the intensive care unit.
**Methods:** It was a retrospective study including all patients hospitalised for intoxication by oleander in a medical intensive care unit over a period of 19 years (January 2005 to December 2023).
It was decided that the patient had been poisoned by oleander given the circumstances of the accident; consumption of part of the plant with signs of oleander poisoning.
**Results:** Seven patients were admitted to the intensive care unit with oleander poisoning during the course of the study.
The mean age was 43 ± 16 years, with a sex ratio of 0.14. Two patients were diabetic and one had coronary artery disease.
All patients used the plant as an infusion for therapeutic purposes; three patients used it for slimming purposes, one patient used it for abortifacient purposes, two patients used it to relieve joint pain and one patient used it on the advice of a charlatan to treat cancer.
The average consultation time after ingestion was 3.5 h.
Five patients had neurological signs on admission and all patients had digestive signs.
Six patients presented with cardiovascular signs. One patient presented with ST-elevation myocardial infarction and normal coronary angiography. One patient presented with non-ST-elevation myocardial infarction, two patients presented with a repolarisation disorder with a diffuse flat T wave, one patient presented with an extended inferior and anterior digital cup and one patient presented with sinus bradycardia that responded to atropine.
All our patients had a favourable outcome, with an average hospital stay of 3 days.
**Conclusions:** Plant poisoning with cardiovascular complications is rarely reported. Management of oleander poisoning requires rapid diagnosis and close cardiac monitoring.

**Topic:** Poisoning/Toxicology/Pharmacology

*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**001081

**Introduction:** Although temporary mechanical circulatory support devices are increasingly used in the management of cardiogenic shock (CS), several open questions regarding the kind of support and timing of institution/weaning remain open. Echocardiography is widely applied to drive the weaning process from veno-arterial extracorporeal membrane oxygenation (VA-ECMO), although there are no standardized protocols.
**Objectives:** We sought to evaluate the accuracy of echocardiographic indices in predicting successful weaning from VA-ECMO in CS patients. We tested total isovolumic time (tIVT), an index of ventricular performance(1,2) and longitudinal function (MAPSE) on top of the commonly used parameters (left ventricular ejection fraction, LVEF; E/e' at mitral valve; left ventricular velocity time integral, LV VTI; TAPSE; right ventricular S' at tissue Doppler imaging, RV S').
**Methods:** Multicentric prospective study on adults receiving VA-ECMO due to refractory CS and/or cardiac arrest (CA) from 2012 to 2020. Echocardiography was performed at VA-ECMO placement and during the weaning trials. Weaning trials were performed daily starting from 48 h after VA-ECMO institution. A stepwise decrease of VA-ECMO blood flow was applied, until reaching 1 or 1.5 L/min. Successful weaning was defined as removal of VA-ECMO with no requirement for further MCS in the following 30 days.
**Results:** 76 patients were enrolled (23.8% female, 54.2 ± 10.6 years old), 52.6% due to CA. Median duration of VA-ECMO was 58 h; 47 (61.8%) had intra-aortic balloon pump inserted upfront. In-hospital mortality was 62.4% overall, 40% for CS without CA. 6 of the 32 weaned patients died in hospital for multiorgan failure due to septic shock. The baseline echocardiographic parameters associated with successful weaning were (Fig. 1): stroke volume (SV) > 13.2 ml (HR 4.12 [1.71–9.95], *p* 0.002), tIVT > 23.6 min/sec (HR 0.14 [0.02–1.03], *p* 0.053), LV VTI > 6.6 cm (HR 4.99 [1.94–12.87], *p* < 0.001), MAPSE > 6.15 mm (HR 4.42 [1.90–10.24], *p* 0.001), TAPSE > 11 mm (HR 10.13 [1.37–7.02], *p* 0.023), RV S' > 7 cm (HR 5.40 [1.45–20.12], p 0.012). LVEF, E/e' and S' at mitral valve did not reach the statistical significance. Figure 2 shows Kaplan–Meier analysis on echocardiographic indices collected during the last weaning trial and their hazard ratios.
**Conclusions:** Echocardiography is pivotal in defining cardiac recovery and monitoring the weaning trial. Indices reflecting ventricular performance and delivered flow from LV were associated with weaning success both at VA-ECMO institution and throughout the weaning trials. Parameters reflecting ventricular activation and systo-diastolic interaction already demonstrated superiority in defining ventricular performance. Considering the known limitations of LVEF (HR, loading and LV dyssynchrony dependence), tIVT and MAPSE should be introduced in the standard evaluation in the acute setting.

**Introduction:** In the intensive care unit (ICU), delirium poses a substantial public health concern, particularly among patients requiring mechanical ventilation (MV) (1). Although delirium has been described in COVID-19 patients requiring MV (2), limited data exist regarding delirium incidence in patients receiving high-flow oxygen therapy (HFNO) or non-invasive mechanical ventilation (NIV).
**Objectives:** To assess the prevalence of delirium in ICU COVID-19 patients receiving HFNO or NIV.
**Methods:** We conducted a secondary analysis of a previously published multicenter cohort study (3), in which we exclusively considered COVID-19 patients receiving HFNO or NIV and who never required MV during their ICU stay. The primary outcome was the prevalence of delirium in the two groups. Secondary outcome was to investigate risk factors associated with development of delirium in this cohort.
**Results:** From a total of 2088 patients, 187 patients were eligible for the final analysis, 90 (48%) treated with HFNO and 97 (52%) treated with NIV. No significant differences in demographics, Charlson comorbidity index, Simplified Acute Physiology Score (SAPS) II, Glasgow Coma Scale (GCS) and the Richmond agitation-sedation scale (RASS) on the day of ICU admission were found between the two groups. Delirium prevalence was 9% ($n=8$) in the HFNO and 18% ($n=23$) in the NIV group (OR 2.34 (95% CI 0.96–5.68); $p=0.6$), with a predominance of hyperactive delirium in both populations (64% and 67%%, respectively). Figure 1 shows cumulative incidence of delirium over time in the two strategies. The time elapsed between the date of ICU admission and the onset of delirium was also comparable in the two groups ($p=0.67$). There were no significant differences between the two groups in the ICU length of stay and mortality at 28 days after admission. No multivariate analysis was performed due to the limited number of delirium events.
**Conclusions:** In this study, the prevalence of delirium was around 15% among COVID-19 patients admitted to intensive care units undergoing HFNO or NIV.

### Observations on post-resuscitation care: a retrospective analysis using the 2023 ERC-ESICM quality indicators framework

N. Daines[1], M. Burgess[2], J. Porter[2], R. Gray[2]

[1]Intensive Care, University Hospitals Sussex NHS Foundation Trust, Brighton, United Kingdom; [2]Intensive Care, Royal Sussex County Hospital, Brighton and Hove, United Kingdom

**Correspondence:** N. Daines

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001084

**Introduction:** Following return of spontaneous circulation (ROSC) after out of hospital cardiac arrest (OHCA), the primary goal of post-resuscitation care is to implement therapies that increase the likelihood of disability-free survival [1]. In 2023, the ERC, EUSEM, ESC and

ESICM jointly proposed a quality indicators (QIs) framework for evaluating post-resuscitation care [2]. Based on the 2020 International Consensus on Cardiopulmonary Resuscitation Science with Treatment Recommendations, the quality indicators framework is structured around 6 primary and 12 secondary QIs [2, 3].
**Objectives:** To evaluate patient outcomes data including 3-month survival after OHCA using the 2023 ESC-ESICM QIs framework and report our observations on the process.
**Methods:** Single-centre retrospective analysis of all patients admitted to our tertiary referral and major trauma centre ITU at the Royal Sussex County Hospital, over one calendar year (September 2022 to August 2023) with a diagnosis of OHCA. Clinical data were obtained from electronic patient records and outcome data from ITU follow-up clinics.
**Results:** There were 66 OHCA admissions during the study period. Overall mortality was 56%, higher than the all-cause unit risk-adjusted mortality of 20.2%. The initial rhythm was shockable in 47% of cases. Mortality was 38% in the shockable group vs 81% in the non-shockable group. There was minimal difference between the age of non-survivors and survivors (median 66 vs 62 years, IQR 74 to 49 vs 75 to 52, respectively). The causes of OHCA are shown in Fig. 1. We were unable to ascertain fulfilment of QI domain 2.1 and 2.2 as we do not routinely record timing data for bedside transthoracic echocardiography or time to wire which in turn meant the composite QI could not be calculated. Of surprise to us, in 27% of cases we did not achieve targeted temperature management (TTM) to less than 37.7 °C for 72 h post-arrest. There was 100% compliance with domain 1 (structural QIs) and 6.2 (discharge and follow-up).
**Conclusions:** OHCA makes up a disproportionate share of our unit mortality, particularly in the case of non-shockable rhythms. As a strength of the 2023 QIs framework, we have identified TTM as a specific area for intervention to improve quality of care. We have also identified follow-up of survivors (domain 6.2) as being an area in which we perform well.
As an inherent limitation of this study, we analysed patients that survived to ITU admission, which may under-estimate the mortality and quality of care that occurs between ROSC and ITU admission in early non-survivors.
As an observation of the 2023 ERC-ESICM QIs framework, it arguably leans toward cardiac causes of OHCA, though in our institution this made up just 23–26% of admissions. A future revision of the framework may consider special patient groups such as traumatic and neurosurgical causes of OHCA where investigations such as echocardiography may delay other time critical life-saving interventions.

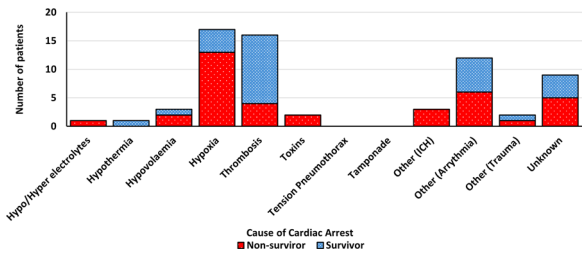

**Fig. 1 (abstract 001084)** Bar chart of OHCA by cause and 3-month survival

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001086

**Introduction:** Acute kidney injury (AKI) is a frequent complication in the intensive care unit (ICU). About 15% of critically ill patients with AKI require renal replacement therapy, commonly in the form of continuous renal replacement therapy (CRRT). The abundance of electronic health record (EHR) and CRRT device data allows for the development and validation of data-driven digital health solutions to enhance CRRT delivery. This project aimed to develop a data pipeline to feed scalable smart dashboards of patient- and CRRT-relevant data to monitor key performance CRRT indicators and patient outcomes.
**Methods:** We utilized EHR and CRRT device data from the University of Alabama at Birmingham from January 2022 to February 2024. We extracted CRRT device data ($n = 42$ devices) every month via a manual process by a nurse collecting the CRRT machine data cards. The data from CRRT cards were then uploaded to a secure storage location for data processing. We created an ETL (extract, process, and loading) data process in a virtual server environment using Python code to clean and normalize the data. We then connected the Python data pipeline to feed the visualization layer via the Tableau cloud server and to refresh automatically the dashboards. For the visualization layer, we designed specific interactive dashboards with Tableau that exhibit key performance CRRT indicators that are sustainably trackable on a weekly or monthly basis. A key part of the overall solution relies on accurate patient matching. Patient matching is a complex process, made easy by a proprietary algorithm created during this process. The dashboards have been customized to meet the needs of the end-users and provide dynamic tools to filter by many variables such as date, machine, alarm type, service unit, diagnosis, demographics, and many others.
**Results:** We developed smart dashboards in Tableau that incorporate data visualization of pre-selected CRRT and EHR parameters, as well as AI-powered data analytics techniques to support providers in viewing and exploring these data for multiple use cases including quality assurance, process or clinical outcome predictions and patient subphenotyping, thereby identifying previously unnoticed patterns in EHR and CRRT data to augment support clinical decision-making.
**Conclusions:** The development of digital health solutions that integrate multimodal data from EHR and CRRT devices is feasible. While this is a key milestone to enable AI-powered CRRT delivery, the impact

of these digital health solutions on processes and clinical outcomes needs to be tested with contemporary implementation science tools.

## Importance of clinical frailty scale as an outcome prediction tool combined with SOFA and APACHE II score for ICU patients > 65 years of age

P. Antoniou[1], K. Tsoumani[1], S. Mantzoukis[1], E. Kosma[1], D. Lepida[1], K. Bakas[1], O. Ygropoulou[1], D. Rizos[1], O. Mousafiri[1]

**Introduction:** There are several tools created for the prediction of outcomes in the Intensive Care Unit (ICU), such as Sequential Organ Failure Assessment (SOFA) score and APACHE II score that are validated to be used in the ICU and provide crucial information for every patient in order to improve his outcome. In Greece even more ICU patients are > 65 years old and most of them are frail. Clinical Frailty Scale (CFS) is the only frailty quantification tool that can be used in ICU, due to the patient's inability to provide information.
**Objectives:** The aim of this study is to explore the importance of another prediction tool such as the CFS score that includes frailty for ICU patients > 65 years old, due to the different characteristics, comorbidities, polypharmacy and sarcopenia of this group of patients. Another aim is to compare its value in comparison to APACHE II and SOFA score.
**Methods:** 90 ICU patients > 65y.o were included in this study. Their demographics, clinical findings, CFS, SOFA, APACHE II scores on admission, outcome, length of stay (LOS), ventilator- and vasopressor-free days were recorded and statistically analyzed.
**Results:** Out of the 90 ICU patients, 62% were male, the mean age was 74.3 (range 65 to 97), with a mean BMI of 28.8 ± 3.9 and had on average 1.7 ± 1.5 comorbidities (range 0–5). 64% of them were smokers and only 22% had alcohol consumption regularly. Their length of stay was 17 ± 8 days and had a survival rate of 57.1% for all frailty scores. The highest survival rate was for CFS from 1 to 4 (77.2% survival rate) vs 46.8% for CFS from 5 to 9, and the first group had more ventilator-free days (9.7 vs 5.4), more vasopressor-free days (11.7 vs 6.6) and less LOS (10.4 vs 17.3) in comparison to the second more frail group. High CFS of 8 or 9 have less LOS due to death during the first days of hospitalization (avg 10.6) and lower CFS of 1 and 2 had as well less LOS (avg 7.5). The most days spent in the ICU can be found at the CFS = 5 group (avg 27.5). CSF = 2 had the best survival rate of 100%, followed by CFS = 3 (85.7%). On the contrary, CFS = 9 had 100% mortality rate followed by CFS = 8 (80% mortality rate).
**Conclusions:** CFS is an important predictive tool to be used with APACHE II and SOFA score as even more frail patients are admitted to the ICU and their different characteristics, comorbidities and their lower capacity to manage in an ICU environment separate them from the general population. Identifying the frail patients in an ICU can be challenging, but is important to improve outcomes and decrease their LOS.

**Introduction:** Acute kidney injury (AKI) is a comprehensive clinical syndrome characterized by a sudden decline in kidney function, potentially leading to fluid imbalance, metabolic acidosis, and electrolyte disorders. It represents one of the most prevalent organ dysfunctions observed in critically ill patients and is typically linked with increased morbidity and mortality rates. The management of AKI primarily involves supportive care, with continuous renal replacement therapy (CRRT) utilized in patients experiencing severe kidney injury or its complications. CRRT is necessary in a minority of all critically ill patients and, despite intensive dialysis interventions, is associated with mortality rates ranging from 50 to 80%. While previous studies have identified numerous potential factors, there remains uncertainty regarding those specifically associated with higher mortality rates among patients requiring CRRT. This study was conducted to pinpoint factors that elevate the risk of mortality among patients in our unit requiring CRRT, with the aim of devising strategies to enhance their overall outcomes.
**Objectives:** This study aims to evaluate which factors confer a higher risk of dying on the patients who underwent renal replacement therapy in an ICU in southern Portugal between 2018 and 2022.
**Methods:** We performed a retrospective study and univariable statistical analyses on patients who underwent renal replacement therapy in the ICU between 1 January of 2018 and 31 December of 2022 in order to identify risk factors for mortality.
**Results:** Among the 101 patients enrolled, 65.4% were male, with a mean age of 65.45 (± 12.35) years, and a previous history of chronic kidney disease (CKD) was present in 26.73%. The majority of patients required ICU care due to medical reasons (83.2%) compared to 16.8% with surgical pathologies as the primary reason for admission. Among these, the most common nosologic groups in which the patients' diseases were classified were the digestive system (23.8%), respiratory system (21.8%) and infectious diseases (13.9%). The most common indications for starting CRRT were the patient's inability to manage volume, severe nitrogen retention and severe acidosis.
Despite efforts to maintain adequate hemodynamic stability, all patients except for 4 had at least one evaluation of mean arterial pressure (MAP) below 75 mmHg, and only 24 (23.8%) had no reported values of MAP < 60 mmHg. Additionally, 67.3% of patients experienced episodes of hyperglycemia (defined by serum glucose levels > 180 mg/dL) and 77.2% required invasive mechanical ventilation (IMV). The mortality rate among patients requiring CRRT was 43.6%.
Among the parameters evaluated, age was positively correlated with a higher risk of mortality ($p = 0.015$). Furthermore, a higher number of reported episodes of MAP < 75 mmHg ($p = 0.036$), a higher number of episodes of MAP < 60 mmHg ($p = 0.017$), and IMV ($p = 0.003$) were positively correlated with death. However, neither sex, a previous history of CKD, the type or diagnosis at admission, the indication to start CRRT, nor the number of episodes of hyperglycemia were correlated with a higher risk of mortality ($p > 0.05$).
**Conclusions:** Not surprisingly, among patients with AKI who require CRRT, older age is associated with a higher risk of mortality, likely due to increased comorbidities and reduced physiological reserve. Although CRRT is better tolerated in unstable patients compared to intermittent modalities, it can have hemodynamic consequences. In the context of critical illness, a higher frequency of hypotension episodes and subsequent hypoperfusion is expected, further increasing the risk of mortality. A similar trend is observed with invasive mechanical ventilation (IMV)—patients with more critical conditions are at a higher risk of adverse outcomes. IMV is linked to prolonged ICU stays, increased infectious complications, and higher mortality rates. When combined with CRRT, the prognosis worsens. Interestingly, hyperglycemia did not independently increase the risk of mortality among our patients. Our study results confirm some of our suspicions while highlighting the need for improved patient care. In certain cases, despite our best efforts, outcomes may remain unchanged due to extreme circumstances. However, in others, meticulous hemodynamic monitoring and resuscitation strategies may significantly impact survival rates.

### Performance, correlation and agreement of SaO2/FiO2 and imputed PaO2/FiO2 in patients under invasive mechanical ventilation and extracorporeal membrane oxygenation (ECMO) therapy in a high-altitude facility

**Introduction:** Linear imputation models have been used to validate SpO2/FiO2 instead of PaO2/FiO2 in various pathologies, particularly in the diagnosis and treatment of ARDS (1–3). Although Rice and Pandharipande found a correlation between the indices, a few years later a nonlinear imputation equation developed by Severinghaus based on the sigmoid behavior with respect to the hemoglobin saturation curve, blood pressure and oxygen saturation. This equation was validated by Brown in patients with ARDS and showed better performance and correlation than the equation first developed (4–7). Given the scarce information on normal oxygenation values in patients living at high altitude, the behavior of these imputation methods in patients

undergoing invasive mechanical ventilation and ECMO support with different pathologies is not known, as they are usually excluded from studies.

**Objectives:** The primary aim of this study was to ascertain the performance, correlation, and concordance between PaO2/FiO2 and SaO2/FiO2, alongside imputed PaO2/FiO2, in patients undergoing invasive mechanical ventilation and ECMO support at a high-complexity healthcare facility over the period spanning from 2020 to 2023.

**Methods:** We conducted a cross-sectional, single-center study with an analytical component, utilizing a database of adult patients admitted to the Extracorporeal Life Support Unit who required ECMO support for at least 24 h. For quantitative variables, we calculated measures of central tendency and dispersion, while for qualitative variables, we determined frequencies and percentages. Diagnostic accuracy measures including sensitivity, specificity, positive and negative predictive values were assessed for PEEP greater and less than 10 cmH2O, PaCO2 greater and less than 35 mmHg, and hemoglobin greater than 12 mg/dL, using severe hypoxemia as a reference for comparison. Additionally, an analysis of the area under the receiver operating characteristic curve (AUROC) with a 95% confidence interval was performed. Pearson's correlation coefficient (for normal distribution) or Spearman's correlation coefficient (for non-normal distribution) was employed to assess correlations between the SpO2/FiO2 determined with the oximeter and PaO2/FiO2 determined from arterial gases or various imputation formulas. Furthermore, the intraclass correlation coefficient was used to evaluate agreement. Statistical significance was set at a $p$-value < 0.05.

**Results:** 272 patients requiring ECMO therapy were included, with a mean age of 42.80 years (SD: 12.33). Among them, 65.44% were men ($n = 178$), with a mean body mass index (BMI) of 28.74 kg/m$^2$. Common comorbidities included obesity (34.93%, $n = 95$) and hypertension (20.22%, $n = 55$). The average ICU length of stay was 29.63 days (SD: 26.7), and 37.87% of patients ($n = 103$) died in the ICU. Sixty-two percent required ECMO veno-venous (VV ECMO) configuration, while 36% required ECMO veno-arterial ($n = 168$). The overall mortality rate was 37.87% ($n = 103$). The AUROC for SaFiO2 in non-severe hypoxemia in VV ECMO patients was 0.939 (CI 0.89–0.99) with an LR + of 6.53 and an LR- of 0.10 (Fig. 1) those with PEEP > 10 cmH2O, it was 0.938 (CI 0.88–0.99) with an LR + of 5.96 and an LR- of 0.09. For patients with hypercapnia, it was 0.931 (CI 0.87–0.99) with an LR + of 5.45 and an LR- of 0.07. Regarding anemia with hemoglobin < 10 g/dL and in the case of hyperbilirubinemia (total Bilirubin > 3 mg/dL), the AUROC of SaO2FiO2 was 0.993 (CI 0.98–1.00) and 0.667 (CI 0.01–1.00) respectively. (Table 2). The AUROC for SaFiO2 in severe hypoxemia in VV ECMO patients was 0.060 (CI 0.01 – 0.11) with an LR + of 0.24 and an LR- of 13.59. For those with PEEP > 10 cmH2O, it was 0.062 (CI 0.01–0.12) with an LR + of 0.26 and an LR- of 16.36. For patients with hypercapnia, it was 0.068 (CI 0.00–0.13) with an LR + of 0.27 and an LR- of 22.53. Regarding anemia with hemoglobin < 10 g/dL and in the case of hyperbilirubinemia (total Bilirubin > 3 mg/dL), the AUROC of SaO2FiO2 was 0.006 (CI 0.00–0.02) and 0.333 (CI 0.00–0.98), respectively.

**Conclusions:** Patients requiring VV ECMO support, the use of SaO2/FiO2 had a high correlation and agreement with PaO2/FiO2 > 150 and may be an alternative and reliable method to guide diagnosis and treatment. However, the opposite occurred when the PaO2/FiO2 was < 150, where good performance was not found.

### Correlation and validity of PaO2/FiO2 and Spo2/Fio2 and PaO2 imputation methods in patients with COVID-19 and invasive mechanical ventilation at 2600 m above sea level

**Introduction:** PaO2/FiO2 (P/F) is part of the definition and classification of respiratory distress syndrome (ARDS) (1) but requires arterial blood gases (ABG) (2), which is not always available in low-resource settings (3), so it has been proposed that a non-invasive surrogate for (P/F) is the ratio of percent hemoglobin saturation on pulse oximetry (SPO2) to inspired fraction of oxygen (FIO2): SPO2/FiO2 (S/F) (4). Mathematical models have also been proposed to estimate PaO2 without direct measurement of O2 in GSA, by imputation of PaO2 (5), but all these indexes have not been validated in ARDS patients by COVID 19 at 2600 m above sea level (6).
**Objectives:** To determine the correlation and concordance between P/F and S/F and non-invasive methods of imputation: linear, non-linear and logarithmic P/F. To determine the ability of S/F to discriminate severe hypoxemia in patients at 2600 m. above sea level (a.s.l.), under positive pressure ventilation and diagnosis of COVID 19.
**Methods:** Retrospective cross-sectional study of patients with COVID 19, at 2600 m a.s.l. Spearman correlation between P/F and S/F and noninvasive methods was calculated. A generalized linear model was used to calculate an S/F value for a $P/F = 150$, then the validity to detect severe hypoxemia ($P/F \leq 150$) was evaluated by calculating sensitivity (SE), specificity (ES), positive predictive value (PPV), negative predictive value (NPV) and area under the curve (AUROC), finally a Bland–Altman (BA) comparison was performed to assess concordance.
**Results:** Among 292 patients with COVID 19 at 2600 m asl, a positive correlation was found between P/F and S/F of 0.90 ($p < 0.001$), P/F and P/F by linear imputation of 0, 90 ($p < 0.001$), P/F and P/F by logarithmic imputation of 0.87 ($p < 0.001$) and P/F and P/F and P/F by nonlinear imputation of 0.94 ($p < 0.001$). The equivalence relationship between S/F and P/F was described by the equation $S/F = 43.97 + 1.07 \times P/F$ (AIC 11.12), with S/F being 195.04 when P/F was 150. $S/F > 200$ had an SE of 78.2%, ES of 95.9%, PPV 95.6 and NPV 76.1 and an AUROC of 0.96 to detect $P/F \geq 150$, the other performance data for detection of non-severe hypoxemia are shown in Table 1. On the other hand, P/F and S/F showed little agreement between extreme values, as shown in Fig. 1.
**Conclusions:** In patients with COVID-19, S/F is a noninvasive index that shows a significant and strong correlation with P/F and P/F imputation methods. A $P/F = 150$ equals $S/F = 195.04$, given the ability to discriminate non-severe hypoxemia may be useful in low-resource settings without GSA; however, when hypoxemia is severe, its usefulness is limited.

**Table 1 (abstract 001090)** Oxygenation indexes for the diagnosis of non-severe hypoxemia

| Oxygenation indexes | SE (CI 95%) | ES (CI 95%) | PPV (CI 95%) | NPV (IC 95%) | AUROC (IC 95%) |
|---|---|---|---|---|---|
| P/F ≥150 | 100 (100-100) | 61,9 (59,1-64,6) | 78,2 (75,9-80,5) | 100 (100-100) | 1 (1-1) |
| S/F ≥200 | 78,2 (75,9-80,5) | 95 (93,8-96,2) | 95,6 (94,4-96,7) | 76,1 (73,7-78,5) | 0,96 (0,95-0,97) |
| P/F linear imputation ≥150 | 87,5 (85,7-89,4) | 92,7 (91,3-94,2) | 94,3 (93-95,6) | 84,5 (82,5-86,5) | 0,96 (0,95-0,97) |
| P/F logarithmic imputation ≥150,21 | 54,7 (51,9-57,5) | 98,7 (98,1-99,4) | 98,3 (97,6-99) | 61,4 (58,7-64,2) | 0,95 (0,94-0,96) |
| P/F nonlinear imputation ≥150,67 | 84,4 (82,4-86,5) | 93 (91,6-94,5) | 94,3 (93-95,6) | 81,4 (79,2-83,6) | 0,96 (0,95-0,97) |

SE: sensitivity, ES: specificity, PPV positive predictive value, NPV negative predictive value, AUROC area under the curve

Bland-Altman

| | | 95% Confidence Interval | |
|---|---|---|---|
| | Estimate | Lower | Upper |
| Bias ( n = 292 ) | 39.1 | 34.2 | 43.9 |
| Lower limit of agreement | −43.7 | −52.1 | −35.4 |
| Upper limit of agreement | 121.9 | 113.6 | 130.2 |

### Causal mediation analysis shows no evidence of EBV reactivation being responsible for the association between an immunosuppressed sepsis endotype and adverse outcomes

**Introduction:** Protracted sepsis can result in the development of functional immunosuppression in previously immunocompetent individuals. Systemic immunosuppression results in failure to eradicate the primary infection and a susceptibility to acquiring lethal secondary opportunistic infections (1). Epstein–Barr virus (EBV) has been shown to be the most commonly reactivated virus amongst patients with septic shock (2, 3). EBV reactivation is associated with increased patient morbidity and mortality as well as with the previously described Sepsis Response Signature (SRS) 1 endotype, which is characterised by an immunosuppressed immune profile (4). The SRS endotypes have recently been translated to a quantitative scale (SRSq score) which is reflective of the extent of immune dysfunction for an individual patient (5). A higher SRSq score corresponds to the SRS1 endotype.
**Objectives:** In this study, we aimed to examine whether EBV reactivation causally mediates the association between a high SRSq (parameter to assess immune dysregulation) and outcome. Outcomes were defined as 28-day mortality, ICU length of stay (LOS), and Day 5 SOFA score.
**Methods:** Data from RNA-sequencing of peripheral blood leukocytes, and digital droplet PCR (ddPCR) of plasma to quantify EBV reactivation, were analysed for patients admitted to ICU and recruited to the UK Genomic Advances in Sepsis (GAinS) study (5,6). The quantitative readout obtained from ddPCR was used in the causal mediation models. SRSq score was available for each patient, previously calculated using the *SepstratifieR* package available in R (5). Causal mediation analysis was undertaken using the *mediation* package in R.
**Results:** 619 patients were previously assessed for EBV reactivation with ddPCR. 399 unique patients had RNA-seq data and of these 137 patients had EBV reactivation. EBV reactivation was significantly associated with SRSq (p-value 0.002) and 28d mortality (p-value 0.02). We did not find evidence that EBV reactivation causally mediates the association between high SRSq and any of the outcomes tested (Fig. 1).
**Conclusions:** EBV reactivation on the background of an immunosuppressed endotype does not mediate any of the adverse outcomes investigated, raising the hypothesis that EBV may be a bystander rather than the causal agent of patient morbidity and mortality. However, the absence of a significant causal mediation effect due to EBV may result from the effect of EBV reactivation being small and therefore this study being inadequately powered, or the effect of EBV reactivation being large but only in a subset of patients, thus the effect being diluted within this potentially heterogeneous cohort. Future work should focus on the mechanisms by which EBV reactivation

affects the host to determine whether it is a harmful or bystander pathogen.

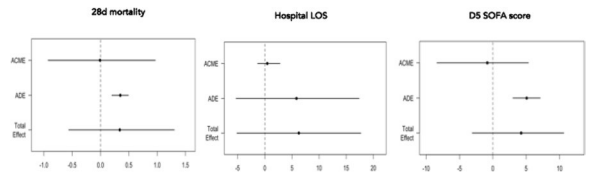

**Fig. 1 (abstract 001092)** EBV reactivation on the background of an immunosuppressed endotype does not mediate any of the adverse outcomes investigated here

**Introduction:** A new method to evaluate cardiac output (CO) with a pulmonary artery catheter (PAC) has been proposed. Using a traditional PAC, the software in the HemoSphere monitor (Edwards Lifescience, Irvine, USA) allows a quasi-continuous cardiac output (FastCCO) monitoring, based on the analysis of the pulmonary artery pulse waveform. A new method to evaluate cardiac output (CO) with a pulmonary artery catheter (PAC) has been proposed. Using a traditional PAC, the software in the HemoSphere monitor (Edwards Lifescience, Irvine, USA) allows a quasi-continuous cardiac output (FastCCO) monitoring, based on the analysis of the pulmonary artery pulse waveform.
**Objectives:** We investigated whether FastCCO reliably measures absolute values of CO and tracks its changes, compared to intermittent cardiac output (iCO) obtained with pulmonary thermodilution.
**Methods:** In sub-analysis of a prospective observational study (NCT05524558), patients with acute respiratory distress syndrome were monitored with a PAC. Measurements of iCO were done at high positive end-expiratory pressure (PEEP) (T1), after a passive leg raising (PLR) at high PEEP (T2), at low PEEP (T3) and after a PLR at low PEEP (T4). At each timepoint, values of FastCCO were collected immediately before thermodilution which measured iCO. Absolute values of CO were compared by a Bland and Altman analysis for multiple measurements per subject. Correlations between changes in CO were assessed by the Spearman coefficient and trend analysis were performed.
**Results:** Considering absolute values of CO ($n=113$) obtained in 14 patients, the bias (lower to upper limits of agreement) between iCO and FastCCO were 0.20 (−2.20 to 2.60) L/min and the percentage error was 37%. Considering all changes of CO between different timepoints (T1 vs. T2, T1 vs. T3 and T3 vs. T4; $n=86$), the coefficient of correlation between iCO and FastCCO was $r=0.35$ ($p=0.001$). Considering only changes of iCO > 12% ($n=14$), the coefficient of correlation between iCO and FastCCO was $r=0.54$ ($p=0.049$) and the concordance rate between the changes in FastCCO and in iCO was 86% ($p=0.0485$).
**Conclusions:** Compared to iCO, the FastCCO did not reliably estimate the absolute values of CO. However, it may track trends of CO changes induced by PLR or PEEP. More data are needed to determine whether FastCCO can be used to reliably track transient changes in CO to detect preload responsiveness and to individualize fluid therapy. The study is ongoing.

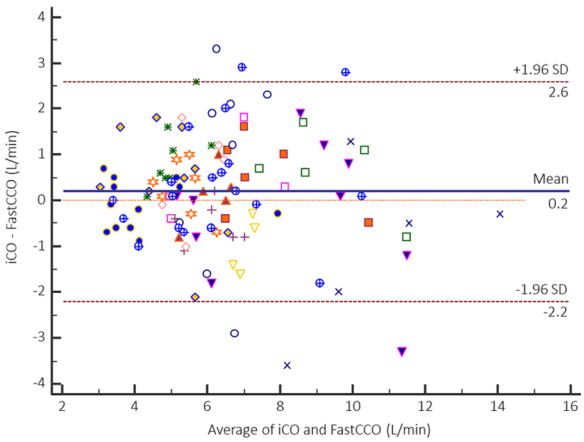

**Fig. (abstract 001147)** Bland–Altman plot for the absolute values of cardiac output obtained by pulmonary thermodilution (iCO) and by pulmonary artery pulse waveform analysis (FastCCO), considering all pairs of measurements ($n=113$)

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001094

**Introduction:** Low–middle-income countries are at high risk of the morbi-mortality caused by the worldwide problem of antibacterial resistance. The poor infrastructure of healthcare systems, the absence of infection prevention societies and antimicrobial stewardship programs, and the paucity of documented reports about antibiotic use

within hospitals and intensive care units (ICUs) contribute to the persistence and even worsening of the threat.
**Objectives:** To report the utilization trends of antibiotics in a Tunisian medical ICU.
**Methods:** A retrospective study conducted over the course of 1 year, from January 1st 2023 to December 31st 2023. All consecutive patients admitted to the medical ICU were included and had their medical charts and records reviewed. Extracted data included demographics, diagnoses on admission, indications, daily-defined doses (DDD), durations of antibiotics, prescribed and results from bacterial culture samples, antibiotic susceptibility testing, occurrence of healthcare-associated infections, length of stay and mortality.
**Results:** 368 patients were admitted to the ICU. Median age, 61 [41–71] years; Charlson Comorbidity Index, 3 [1–4]; and main diagnoses on admission were pneumonia, 164 (44.6%), and shock, 46 (12.5%). Invasive mechanical ventilation (IMV), 120 (32.6%) patients; IMV duration, 8.2 ± 8.9 days; length Of ICU stay, 8.74 ± 9.2 days (LOS deaths, 11.4 ± 14.3; LOS survivals, 8.1 ± 7.3; LOS IMV, 12.3 ± 11.2). Overall mortality, 20.1% and 28.7% for those having received antibiotics. 129 (35.1%) patients had received antibiotics within 3 days before ICU admission of which 42 (32.6%) were stopped on admission. Throughout their ICU stay, 195 (53%) patients had received antibiotics. Most commonly used antibiotics with their respective DDDs per 100 patient-days were third-generation cephalosporins (78 (40%), 17.1), amoxi-clav (70 (35.8), 12.2), fluoroquinolones (70 (35.8%), 11.7), imipenem/cilastatin (66 (33.8%), 20.4), vancomycin (36 (18.5%), 7.7) and colistin (36 (18.5%), 10.3). Total DDDs within the ICU over the one-year study period were at 93.6.
In patients having received antibiotics, 186 (95.4%) had at least one microbiological test prescribed. The positivity ratio of blood samples was 51/413 (12.3%); tracheal aspirates, 81/219 (37%) and urinary cultures, 28/169 (16.6%). Total isolated pathogens was 155, mainly: *Klebsiella pneumonia* (42 (27.1%), 21 (50%) carbapenem-resistant); *Pseudomonas aeruginosa* (33 (21.2%), 24 (72.7%) only colistin-susceptible); and *Acinetobacter baumannii* (28 (18.1%), 28 (100%) imipenem-resistant only colistin-susceptible). Healthcare-associated infections were documented in 55 (14.9%) patients; VAP, 38 (10.3%) and CLAPSI, 17 (4.6%). Mean antibiotic duration was 7.3 ± 6.7 days with a maximum of 62 days.
**Conclusions:** This study highlights the significant utilization of broad-spectrum antibiotics in a Tunisian ICU. This contrasted with limited microbiological results and high rates of MDR bacteria.

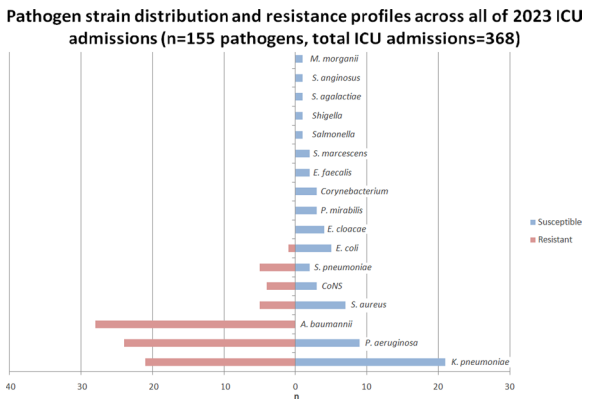

**Fig. (abstract 001147)** Pathogen strain distribution and resistance profiles amongst all 155 pathogens isolated over the 368 admission of the year 2023

### The impact of preoperative crystalloid administration on non-invasive cardiac output measurements in patients undergoing general anaesthesia for non-cardiac surgery—preliminary results of a secondary aim analysis

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001095

**Introduction:** Perioperative haemodynamic management is critical to patient care, especially during major non-cardiac surgery. Cardiac output (CO) is a haemodynamic parameter that reflects the volume of blood pumped by the heart per unit of time. Monitoring CO provides physicians with valuable information for fluid management and optimising oxygen supply to vital organs.
Non-invasive methods for measuring CO are viable alternatives to invasive monitoring methods such as pulse contour analysis. These techniques are associated with fewer complications, making them suitable for routine use in non-cardiac surgery. It might also be used to assess the effect of a preoperative fluid bolus on post-induction blood pressure.
**Objectives:** This preliminary secondary aim analysis of a randomised controlled interventional study entitled "Effect of Pre-operative Intravenous Crystalloids on Post-Induction Blood Pressure" (ClinicalTrials.govNCT05079269) aims to investigate the effects of preoperative administration of crystalloid fluid on CO during the first 20 min after induction of anaesthesia or until the surgical incision, whichever occurred first.
**Methods:** In the main study, patients were randomly assigned to receive a weight-adjusted balanced, isotonic crystalloid solution before induction of anaesthesia (intervention group) or to standard of care (SOC group). The study was performed at the Medical University Hospitals in Graz and Vienna, Austria. This analysis compares the non-invasive CO measurements between the two groups. CO was measured using the CNAP-Monitor (CNSystems, Graz, Austria). Data from the electronic medical records of patients enrolled in this prospective trial were collected. Patients were categorised based on preoperative crystalloid administration. Demographics, comorbidities, intraoperative fluid management, and haemodynamic variables of available data were analysed. Descriptive statistics summarised the data, comparing groups using the Mann–Whitney *U* and Student's *T* tests.
**Results:**

**Table 1 (abstract 001095)** Demographics and results

| | Fluid ($n = 36$) | SOC ($n = 36$) | *p* value |
|---|---|---|---|
| Age, mean (SD) | 70 (14.73) | 72 (7.53) | 0.352 |
| Male, n (%) | 26 (72.2) | 29 (80.5) | – |
| Height [cm], mean (SD) | 171.972 (8.31) | 173.306 (8.75) | 0.510 |
| Weight [kg], mean (SD) | 82.111 (13.89) | 83.889 (13.28) | 0.581 |
| Intervention fluid received preoperatively (ml), mean (SD) | 573.611 (216.95) | – | – |
| Total volume received intraop [ml], median [IQR] | 1416 [1151.25;2674.75] | 2246 [1318.50;3323.25] | 0.114 |

| | Fluid ($n=36$) | SOC ($n=36$) | *p* value |
|---|---|---|---|
| Total norepinephrine [mg], median [IQR] | 0.135 [0.12;0.48] | 0.343 [0.15;0.94] | 0.071 |
| Total phenylephrine [mg], median [IQR] | 0.200 [0.20;0.38] | 0.400 [0.20;0.85] | 0.452 |
| Total ephedrine [mg], median [IQR] | 25 [13.75;32.50] | 22.5 [10.00;35.00] | 0.926 |

For a total of 72, each group included 36 patients. The preliminary results show no statistically significant difference between mean CO between the groups (5.01;4.98, $p=0.83$). The majority of participants in both groups were male. On average, patients in the intervention group required less norepinephrine and phenylephrine (see Table).

**Conclusions:** Although our study did not provide statistically significant results, these preliminary data revealed a trend towards increased CO in patients who received the intervention. In addition, it showed that patients in the intervention group had a lower average requirement for intraoperative fluids and vasopressors compared to those who received standard care. In conclusion, our results suggest that the intervention has the potential to improve cardiac performance and reduce the need for vasopressors in patients undergoing non-cardiac surgery. However, the main study is not powered for this secondary analysis. Potential non-significant results should be evaluated with a larger sample size to validate these observations.

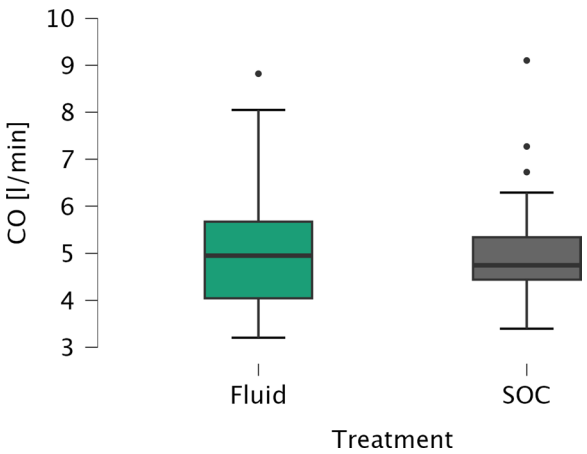

**Fig. (abstract 001095)** .
Mean cardiac output measurements within the first 20 min post-induction comparing the intervention group who received a weight-adjusted crystalloid bolus before induction of anaesthesia with standard of care.

*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**001097

**Introduction:** Whether different cooling methods and their precision on target temperature influence cardiac arrest outcomes are unclear. In this study, we primarily aimed to study the performance of targeted temperature management (TTM) at 33 °C in patients treated with intravascular- versus surface-cooling devices after out-of-hospital cardiac arrest (OHCA).

**Methods:** This is a post hoc analysis of the TTM2 trial (NCT02908308), in which TTM at 33 °C initiated after hospital arrival was compared with normothermia. Patients randomized to TTM at 33 °C who underwent cooling with a device were eligible in this study. The main outcome was high-quality cooling performance during TTM, defined as the proportion of patients reaching target temperature < 33.5 °C within 4 h from initiation of cooling, the time outside temperature ranges during maintenance, rewarming rate and post-TTM fever (i.e. one episode of core temperature > 38 °C). As exploratory outcomes, survival with good neurological status, defined as modified Rankin Scale (mRS) scores of 0–3, at 6 months was analyzed using propensity score matching.

**Results:** Among 930 patients randomized to TTM at 33 °C, 876 (mean age 64 years, 80% men) underwent hypothermia with a cooling device and were included in this study. Of those, 266 patients (30%) were treated by intravascular devices and 610 (70%) by surface-cooling devices. The proportion of patients reaching target temperature within 4 h was higher with intravascular cooling (66.5% vs. 49.6%; $p<0.001$) (Figure 1). In addition, temperature outside ranges during the cooling period and post-TTM fever were lower (9.7% vs. 43.4%; $p<0.001$ and 8.7% vs. 21.5%; $p<0.001$, respectively) in the intravascular devices group than the other (Figure 2). In the explorative propensity score matching analysis, 133 of 252 (52.8%) patients in the intravascular cooling group and 109 of 252 (43.3%) patients in the surface-cooling group were alive at 6 months with mRS scores of 0–3 (conditional OR 1.56, 95% CI 1.06–2.29; $p=0.02$).

**Conclusions:** Among patient randomized to TTM to 33 °C after OHCA in the TTM2 study, intravascular cooling, compared with surface cooling, was associated with more rapid cooling, less temperature variability and less post-TTM fever.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001100

**Introduction:** Every day, around 1000 individuals across Europe experience an out-of-hospital cardiac arrest (OHCA). Mortality rate exceeds 90% (1,2). Extracorporeal cardiopulmonary resuscitation (eCPR) is a time-sensitive salvage procedure for selected refractory cardiac arrest (rCA) (3). To improve both access to eCPR and survival with good neurological outcomes, description and characterization of causes for delay between OHCA and hospital arrival are crucial.
**Objectives:** To identify and characterize all chain-of-survival timepoints between the occurrence of OHCA and effective VA-ECMO implementation.
**Methods:** A prospective observational study was conducted on selected patients with OHCA and rCA in the urban area of Lisbon between September 2023 and March 2024 at an ECMO referral centre. Eligible patients were all those with age > 18-years and OHCA with a rCA. Patients were treated according to a prespecified institutional eCPR/uDCCD combined program (4). Figure 1 shows identified rate-limiting steps. Primary objective was to characterize specific time points between OHCA and ECMO retrieval, namely no-flow, low-flow, extraction time, transport to hospital time and cannulation time. Secondary objective was to correlate those variables with survival at 24 h, ICU and hospital discharge.
**Results:** During the study period, 29 patients were referred to our eCPR/uDCCD program. Mean age was 52 ± 11.3; eight patients were included in the eCPR branch (27.6%), 11 were included in the organ donation branch (37.9%). Six patients had return of spontaneous circulation (20.7%) and 4 were excluded. Considering the 8 eCPR patients, 4 survived at 24 h and 2 were discharged from hospital. All but 3 patients with rCA were promptly identified (89.7%). No-flow 1 had a median time of 8 min (IQR 0–11.5), and no-flow 2 was 8 min (IQR 0–14) (see Figure 1). Time to advanced life support was 11 min (IQR 10–16) and time to first contact with ICU was 17 min (IQR 11–23). Victim extraction time was 10 min (IQR 25–19) and total scene delay 31.5 min (IQR 4–19). Transit time to hospital was 17 min (IQR 10–25). Globally, mean total low-flow time was 80 min (IQR 62.5–104); in patients submitted to eCPR, low-flow time was 79.5 min (IQR 56–107.25). Time from CA to hospital was 60 min (IQR 50–71). Total time since CA to cannulation in eCPR was 83.5 min (IQR 56–107.25). A significant statistical correlation was seen between survival at 24 h and extraction time ($p = 0.045$), which did not hold when adjusted to only eCPR group.
**Conclusions:** Reducing total scene duration is crucial to optimize pre-hospital chain efficiency, improve eCPR accessibility and, thereby, enhance survival rates. This emphasizes the need for rapid decision-making, prioritizing an early ICU contact by the emergency medical teams and a prompt patient extraction by the pre-hospital teams.

**Introduction:** Sepsis is a common reason for hospitalization in emergency departments. The initial assessment of severity is essential. The aim of our study was to evaluate the prognostic value of the shock index combined with procalcitonin (PCT) for assessing the prognosis of patients hospitalized in the emergency department for sepsis.
**Methods:** This is a prospective observational study conducted over a 6-month period between June and December 2023. Adult patients hospitalized in the emergency department for sepsis were included. The diagnosis of sepsis was based on a suspected or presumed infection associated with a SOFA score $\geq 2$. PCT measurement was performed upon admission. The primary outcome was in-hospital mortality.
**Results:** We included 159 patients. The mean age was $66 \pm 31$ years. The main comorbidities were (%): diabetes (46), hypertension (23.8), and stroke (14%). The most frequent reasons for consultation were (%): asthenia (60) and fever (51). The rate of shock occurrence was 3.1%. In-hospital mortality in our series was 35%. The median shock index was $0.80 \pm 0.32$. A shock index value > 0.9 was not statistically associated with higher mortality ($p = 0.09$). ROC curve analysis of PCT for mortality showed an AUC of 0.720, with a threshold of 0.25 associated with higher mortality in univariate analysis ($p = 0.024$). The shock index combined with a PCT > 0.25 ng/L was statistically associated in univariate and multivariate analyses with higher mortality ($p = 0.001$, OR = 3.49; 95% CI [1.6; 7.5]).
**Conclusions:** The shock index combined with a PCT > 0.25 ng/L is an independent marker associated with in-hospital mortality in patients admitted to the emergency department for sepsis.

**Topic:** Sepsis

**Introduction:** Long COVID has emerged as a major healthcare problem. Although many pathophysiological pathways have been proposed, a comprehensive mechanism of disease remains to be elucidated. Supposed pathophysiology includes persistent low-grade inflammation and microthrombosis, leading to fibroblast activation and ongoing tissue remodeling. Molecular imaging with [$^{68}$Ga]FAPI (which binds to fibroblast activation protein (FAP)) PET allows for whole-body assessment of in vivo fibroblast activation.
**Objectives:** To explore lung FAP activity in former critical COVID-19 patients with persistent dyspnea complaints.
**Methods:** A prospective observational study (NCT05981885) was conducted in patients with self-reported complaints of dyspnea more than 3 months after hospital discharge for confirmed SARS-CoV-2 infection requiring mechanical ventilation or high-flow nasal oxygen therapy. Each subject underwent a [$^{68}$Ga]FAPI PET/CT, HRCT and lung function test. [$^{68}$Ga]FAPI uptake was quantified as the standardized uptake value corrected for lean body mass (SUL). To compare the diffuse (homogeneous, non-focal) lung uptake between the long COVID group and controls, all specific [$^{68}$Ga]FAPI uptake areas were extracted by segmenting the < 50% isocontour of the SUVmax of the lung. Blood pool activity of the vena cava inferior was used for background correction. Muscle uptake was measured in the paravertebral muscles. HRCT was analyzed visually for the presence of ground glass opacities. Fifteen age- and sex-matched subjects without pulmonary pathology, recruited from two centers using similar settings, scanned for oncological reasons, were used as controls.
An independent samples T-test was used for group comparison. The correlation between clinical markers and [$^{68}$Ga]FAPI was explored using Pearson's or Spearman's test.
**Results:** Eighteen long COVID patients were included: 10 males (56%), mean age 60.6 years ($\pm$SD 8.3), BMI of 35.8 kg/m$^2$ (mean $\pm$ SD 8.6), DLCO of 77.3% ($\pm$SD 21.5) and FVC of 85.6% ($\pm$SD 16.5) predicted. Scans were performed at a median of 30 months (IQR 7.5–34.3) after discharge.
Increased uptake of [$^{68}$Ga]FAPI was observed in the lungs of long COVID patients, SULmean $1.2 \pm$SD 0.4 compared to SULmean $0.7 \pm$SD 0.3 ($p = < 0.001$) in controls (Figure 1A). After background adjustment, this difference increased for the whole lung and diffuse uptake (Figure 1B and C). The predicted DCLO and FVC showed moderate correlation with the lung SUL ($r = -0.5$, $p = 0.04$ and $r = -0.5$, $p = 0.035$, respectively) whereas the presence of ground glass opacities ($p = 0.07$), time after discharge ($p = 0.11$) and BMI ($p = 0.60$) did not correlate. Mean paravertebral muscle [$^{68}$Ga]FAPI uptake did not differ between long COVID patients and controls ($p = 0.12$).
**Conclusions:** Patients with long-term complaints of dyspnea after hospitalization for severe acute COVID showed increased pulmonary FAP expression, suggesting persistent fibroblast activity.

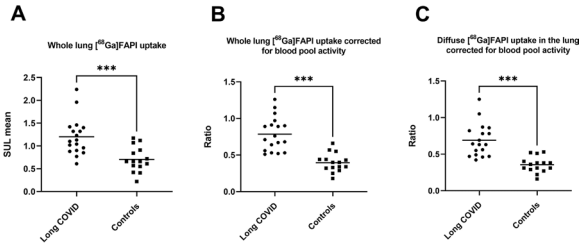

**Fig. 1 (abstract 001102)** A. Average [68Ga]FAPI uptake of the whole lung expressed as the mean standardized uptake value using lean body mass (SULmean). B. Average [68Ga]FAPI uptake of the whole lung corrected for blood pool activity of the vena cava inferior. C. **Introduction:***Acinetobacter baumannii* infections pose a significant clinical challenge in critically ill patients undergoing IMV, leading to considerable morbidity, mortality, and healthcare burden. Understanding the epidemiology and risk factors is essential for guiding infection prevention and improving patient outcomes.
**Objectives:** To determine the frequency, risk factors, and outcomes of *Acinetobacter baumannii*-associated VAP and CLABSI in mechanically ventilated patients.
**Methods:** This was a retrospective study of patients hospitalized from January 2023 to December 2023, in a medical intensive care unit who required IMV for more than 48 h. VAP and CLABSI were identified using a combination of clinical and laboratory criteria. Univariate analysis and multivariable logistic regression were used to analyze the associated factors with *Acinetobacter baumannii*-associated VAP and CLABSI.
**Results:** 340 patients were admitted to the ICU, and 114 (33.5%) required IMV and met the inclusion criteria. Patients' characteristics were: median age, 58 [41–69] years; median SAPSII on admission, 33 [22–44]; median SOFA score, 4 [2–8]; median IMV duration, 4 [2–9]; central-venous-catheter (CVC), 78 (68.4%); CVC duration, 5 [2–7]. Median length-of-stay was at 8 [4–16] days. The overall mortality rate was 48.2%.
Overall, 21 (18.4%) patients developed VAP with density incidence rate estimated at 14 VAP/1000 ventilator days, and 10 (8.8%) patients developed CLABSI with density incidence rate estimated at 9 VAP/1000 catheter days. 31 pathogens were isolated. The most frequently isolated pathogen was *Acinetobacter baumannii*, 13 (42%), followed by *Klebsiella pneumoniae*, 10 (32.2%) and *Pseudomonas aeruginosa*, 5 (16.1%).
Univariate analysis showed that acute respiratory failure on admission (84% vs 59%, $p=0.035$), tobacco use (84% vs 42%, $p=0.019$), septic shock (100% vs 68%, $p=0.030$), tracheostomy (46% vs 9.6%, $p=0.020$), IMV duration (12 [10–18] vs 4 [2–9], $p=0.000$) and length-of-stay (24 [18–28] vs 8 [4–16], $p=0.000$) were associated with *Acinetobacter baumannii* infection. Multivariate analysis found that length-of-stay (RR, 2; 95% CI [1.6–3]; $p=0.010$) and IMV duration (RR, 2.7; 95% CI [1.5–5.6]; $p=0.000$) were risk factors independently associated with *Acinetobacter baumannii* infection.
**Conclusions:***Acinetobacter baumannii*-associated VAP and CLABSI were frequent in the ICU and they had adverse outcomes, including prolonged mechanical ventilation and length of stay and higher septic shock incidence. These findings highlight the need for effective preventive strategies and targeted management approaches.

**Topic:** Infections and prevention

### Effect of pre-operative intravenous crystalloids on post-induction blood pressure—methods abstract

M. Eichinger[1], A. Pichler[1], M. Eichlseder[2], N. Schreiber[1], H. Essber[1], D. West[2], P. Zoidl[2]
[1]1Divison of Anaesthesiology and Intensive Care Medicine 1, Department of Anaesthesiology and Int, Medical University of Graz, Graz, Austria; [2]Divison of Anaesthesiology and Intensive Care Medicine 1, Department of Anaesthesiology and Int, Medical University of Graz, Graz, Austria
**Correspondence:** M. Eichinger
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001104

**Introduction:** Intraoperative hypotension is associated with postoperative outcomes and complications (1). Post-induction hypotension is very common due to anaesthetics and preoperative hypovolemia. Interestingly, the effect of preoperative fluid administration on post-induction hypotension remains unknown. Therefore, we conduct a randomized intervention cohort study evaluating the effect of a pre-operative fluid bolus administration on post-induction hypotension as compared to the clinical standard of care.
**Methods:** This multi-centre study will be performed at the Medical University of Graz and the Medical University of Vienna, Austria. The intervention group will receive a balanced crystalloid solution bolus of 500 (< 90 kg) to 1000 mL (> 90 kg BW) within 60 (± 15) min before induction of anaesthesia. The control group will be treated according to the current clinical standard of care. We planned to enroll 550 patients. Our primary aim is to compare the effect of intravenous pre-operative crystalloid administration before induction with the standard of care on post-induction hypotension. As secondary aims, we will evaluate the incidence and amount of vasopressor use during the post-induction period between both groups. We will also evaluate the effect on cardiac output between both the groups. The study is registered at ClinicalTrials.gov with the identifier NCT05079269.
**Results:** Post-induction hypotension mainly depends on age, pre-existing arterial hypertension, and diabetes mellitus (2). One simple but potential intervention to attenuate blood pressure drops might be the administration of a pre-operative fluid bolus. Since there is no consensus on the use of pre-operative fluid treatment to prevent post-induction hypotension, we conducted this adequately powered study to answer this question.
**Conclusions:** This appropriately powered study will answer the question of the utility of a pre-operative fluid bolus administration, which might improve perioperative outcomes through a simple intervention.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001105

**Introduction:** Acute respiratory failure is a common reason of admission in the intensive care unit (ICU) and is often presented in patients with medical history of cardiovascular disease. The presence of both entities can impair the outcome of critically ill patients as they increase their frailty.

**Objectives:** The aim of this study is to determine whether the presence of cardiovascular disease in patients with acute respiratory failure has an impact concerning the extubation and the role of tracheostomy in the dismission from the ICU.
**Methods:** A total of 30 patients who were admitted in the ICU following an acute respiratory failure were included in the study and retrospectively studied. All the patients included in the study presented acute respiratory failure as cause of admission. The presence of cardiovascular disease (included atrial fibrillation), the outcome of tracheostomy in terms of dismission from the ICU, the number of patients who underwent extubation and also the number of reintubated patients, the number of ventilation-free days and of vasopressor-free days, and the length of stay (LOS) were retrospectively recorded and statistically analyzed.
**Results:** The mean age of the patients in the study was 74.6 years (range 51 to 97), with a mean APACHE II score of 35.3 ± 8, a mean SOFA score of 13 ± 2 and mean LOS of 18.69 ± 7.5. Of the 28% of the patients who were extubated, half presented only acute respiratory failure and 1 had also a medical history of cardiovascular disease. None of the patients who were reintubated had cardiovascular disease. 56.2% of the patients underwent tracheostomy, and 66% had cardiovascular disease. In the tracheostomy group, the average survival was 77.7%, with a mean LOS of 25.7 ± 10. The patients with acute respiratory failure and cardiovascular disease who underwent tracheostomy had a survival rate of 91% and were dismissed from the ICU on average after 17.5 ± 4 days. From the patients with cardiovascular disease, 30% had a Po2/FiO2 < 100, 38% had a Po2/FiO2: 100–200 and 32% had a Po2/FiO2 > 200.
**Conclusions:** Acute respiratory failure when combined with cardiovascular disease has a negative impact in the prospective of extubation. This study resulted that tracheostomy leads to a positive outcome and a dismission from the ICU. The sample of patients was of limited number and more studies are needed to validate the results of this study.

**Correspondence:** M. Van Mol
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 001106

**Introduction:** The challenges experienced after discharge from an intensive care unit (ICU) require adequate support [1]. Digital services might offer opportunities for delivering remote personalized follow-up service after discharge from the intensive care unit (ICU) [2]. However, little is known about critical care survivors' needs and priorities in digital ICU follow-up support, particularly in an international context.
**Objectives:** To describe the needs and priorities in e-health follow-up service among critical care survivors in four European countries, in specific: Germany (DE), Croatia (HR), the Netherlands (NL), and the United Kingdom (UK).
**Methods:** A qualitative design with focus group interviews has been conducted with critical care survivors recruited from two hospitals (HR, NL) and two patient self-help groups (DE, UK). Inclusion criteria comprised ICU-stay exceeding 48 h, age 18 years or older, proficiency in the respective local language for effective communication and comprehension of study information, and general stability in physical, mental, and cognitive aspects. An a-priory developed interview guide has been composed, pre-tested, and used in local language. Thematic analysis was used to analyze the data.
**Results:** Four focus groups included 22 participants of which half being women ($n = 11$). Their ICU admission varied from 6 days to 9 weeks. We identified three main themes: quality of life post ICU; adequate information in the post ICU period, and the role of technology and suggested e-health functionalities. Each main theme is divided in several subthemes (Figure 1). Participants in all four countries reported significant decline in quality of life post-ICU, facing physical, psychological, social and informational difficulties. They identified informational needs including recognition of health-related symptoms, contact information of relevant healthcare professionals, and offering answers to frequently asked questions. The preferences for an e-health tool in ICU follow-up service included simple functionalities, such as large buttons and a voice-controlled password, and should offer space for communication and interaction. Sharing similar experiences via a chat option could turn into a major source of online community support.
**Conclusions:** The most suggested functionalities for e-health were in line with general needs in ICU follow-up service. Critical care survivors in four European countries (DE, HR, NL, and UK) identified a preference for a digital tool including a simple interface, multi-mode accessibility to facilitate their needs, informative material, and virtual space for communication with peers and healthcare professionals. Future research should investigate the differences among international healthcare systems and assess technological readiness and infrastructure in each country to support the implementation of an e-health follow-up service.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 001108

**Introduction:** In the management of acute intoxications, the use of antidotes is crucial. It acts through various mechanisms to counteract the harmful effects of toxins, highlighting the need for constant reevaluation of their use in clinical practice.
**Objectives:** To describe the epidemiological profile of antidotes used and their clinical impact in the management of acute intoxications.
**Methods:** This was a retrospective, observational study conducted over a 3-month period, from January to March 2023. Patients included were those admitted to the toxicological intensive care unit with a diagnosis of intoxication confirmed by positive toxicological screening. The primary outcome was the use of an antidote.
**Results:** We included 119 patients, with a mean age of $30 \pm 16$ years. The sex ratio was 0.52. The main comorbidities were hypertension (5.9%), diabetes (5.9%), and neurological disorders (11.8%). Fifty-seven patients had psychiatric history (47.9%). All patients were admitted for acute intoxication, with 97 (81.5%) related to drug intoxication. Benzodiazepines were the most commonly reported toxin in our patients, with 20 cases (16.8%). Antidotes were used in 34 cases, accounting for 28.6%. The most commonly used antidote was naloxone, used in 11 opioid intoxications. On admission, there was no statistically significant difference in Glasgow Coma Scale (GCS) scores, but in subsequent assessments, there was a significant difference (GCS of 14.5 vs. GCS of 8.5, $p = 0.048$). Multivariate analysis showed that the use of an antidote was associated with less need for mechanical ventilation ($p = 0.001$, OR 2.67, CI [1.34; 5.38]), fewer cases of inhalation pneumonia ($p = 0.007$, OR 1.685, CI [0.953; 2.981]), and shorter ICU stays (mean stay of 3.8 days vs. 5.1 days, $p = 0.03$). There were no statistically significant differences in laboratory parameters. In addition, patient outcomes were similar, with a good outcome in most of cases.
**Conclusions:** In conclusion, our study highlights the importance of antidotes in the management of acute intoxications, with a significant impact on clinical outcomes. A better understanding of the use of antidotes could improve the management and prognosis of intoxicated patients.

**Table 1 (abstract 001108)** Frequency of antidotes use

| ANTIDOTES | N | % |
|---|---|---|
| Naloxone | 11 | 32.4 |
| Atropine | 8 | 23.5 |
| Flumazenil | 6 | 17.6 |
| N acetylcysteine | 9 | 26.5 |
| **Total** | **34** | **100.0** |

**Topic:** Poisoning/Toxicology/Pharmacology

### Severe trauma in elderly patients: a real life picture!

H. Veiga[1], S. Teixeira[1], S. C. Alves[1], H. Macedo[1], J. Amado[1], N. Gatta[1], J. M. Pereira[1], J. A. Paiva[1]
[1]Intensive Care, São João University Hospital, Porto, Portugal
**Correspondence:** H. Veiga
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001009

**Introduction:** Trauma affects all ages. However, the elderly are a special population with multiple comorbidities and lower functional reserve that is growing in developed countries in which trauma incidence is increasing and consequently in the Intensive Care Unit (ICU).
**Objectives:** To characterize critically ill elderly trauma patients and evaluate the impact of the old age ($\geq 65$ y) in the outcome.
**Methods:** This a retrospective, single-center study of all trauma patients consecutively admitted to an ICU of a Tertiary University Hospital from 2019 to 2021. Population was divided in two groups: $< 65$ y and $\geq 65$ y patients (OP). OP were further divided in very old ($> 80$ y) (VOP) and 65–80 y patients. Besides demographic data, type of trauma, severity scores, type of organ support used, ICU length of stay (LOS) and ICU, hospital and 1-year mortalities were collected. SPSS was used for statistical analysis.
**Results:** Of the 458 patients included, 184 (40.2%) were $\geq 65$ y old (median 76 y) of which 69 (15%) were older than 80 y.
Although most of the trauma patients were male, female gender was more frequent in the OP group (41.85% vs 19.71%, $p < 0.001$). The prevalence of comorbidities was higher in the OP (95.1% vs 51.5%, $p < 0.001$) without differences between the VOP and the 65–80 y group (97.1% vs 93.9%, $p = 0.332$). Although median SAPS II score was significantly higher in OP (32.5 vs 22; $p < 0.001$) without differences between VOP and 65–80 y group (34 vs 31; $p = 0.38$), Injury Severity Score (ISS) was significantly lower in OP (10 vs 16; $p = 0.0013$). The prevalence of isolated traumatic brain injury (TBI) was higher in the OP group (36.1% vs 25.1%; $p = 0.008$) but polytrauma with (29.5% vs 42.4%, $p = 0.005$) or without TBI (14.8% vs 25.1%, $p = 0.008$) were significantly less frequent. There were no differences between VOP and 65–80 y group, except for monotrauma which was more prevalent in the VOP (27.9% vs 13.9%; $p = 0.02$). Except for need of invasive mechanical ventilation (IMV) (31.5% in OP vs 44.2% in $< 65$ y; $p = 0.007$), no differences were found between both groups regarding organ support and ICU LOS.
ICU mortality was higher in OP but the difference did not reach statistical significance (10.4% vs 5.5%, $p = 0.068$). Yet, hospital (16.8% vs 7.0%; $p < 0.001$) and 1-year mortality (32% vs 14%; $p < 0.001$) were significantly higher in the OP. Nonetheless, no difference in mortality at any time frame was observed between the VOP and 65–80 y. In logistic regression analysis, age $> 65$ y was an independent risk factor for hospital (OR 2.6; 95% CI 1.1–6.5; $p = 0.033$) and 1-year mortality (OR 2.5; 95% CI 1.02–6.26; $p = 0.046$).
**Conclusions:** Critically ill elderly trauma patients are usually men with comorbidities. On admission, they present higher SAPS II score but lower ISS scores and are less frequently submitted to IMV. Age $> 65$ y is an independent risk factor for hospital and 1-year mortality, but not for ICU mortality.

**Topic:** Trauma

## 001110

### Ventilator-associated pneumonia in patients admitted to the ICU for traumatic brain injury and subarachnoid hemorrhage: a study of risk factors and prognosis

K. Tsoumani[1], P. Antoniou[1], K. Bakas[1], E. Kosma[1], D. Lepida[1], S. Mantzoukis[1], O. Ygropoulou[1], D. Rizos[1], O. Mousafiri[1]
[1]Intensive Care Unit, General Hospital of Ioannina G. Hatzikosta, Ioannina, Greece
**Correspondence:** P. Antoniou
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001110

**Introduction:** Ventilator-associated pneumonia (VAP) is common in Intensive Care Unit (ICU) patients under mechanical ventilation over 48 h and can significantly increase ventilator days and ICU length of stay (LOS). Several risk factors have been studied, such as the male gender, several comorbidities, prior antibiotic therapy, corticosteroids and the type of sedation.
**Objectives:** The aim of this study is to examine the risk factors of developing VAP and how they affect outcome and LOS for ICU patients hospitalized for acute neurological reasons, such as traumatic brain injury (TBI) and hemorrhagic strokes.

**Methods:** A total of 20 ICU patients suffering from TBI or subarachnoid hemorrhage (SAH) with a GCS < 6 before intubation were retrospectively studied, and their demographics, comorbidities, clinical findings, whether they were tracheotomized or not, their medication, prognostic scores, total ICU days and outcome were recorded.
**Results:** The mean age of the patients was 74.1 y.o. (55–89) with 63.1% women. They had a mean of ventilator-free days (28 d) of 9.5 ± 8, with 8.5 mean SOFA score on admission and mean APACHE II score of 21. Mean LOS for all the patients was 16.7 ± 9.7 and a tracheotomy was performed on 57.9% of the patients. VAP was found in 36.3% of the patients during their ICU stay and were divided into two groups, those that had a tracheostomy and those that were intubated. In the tracheostomy group, 87% of the patients developed VAP, half of them before day 10 of hospitalization and had a mean LOS of 24.2 ± 8.7 days. In the non-tracheotomy group, 12.5% developed VAP, all after day 10 of hospitalization and had a mean LOS of 20 days. Smokers had a higher incidence of VAP (59% vs 22.7 non-smokers), while diabetes mellitus was found in 67% and thrombocytopenia in 55% of the patients who suffered from VAP. 63% of the patients in need of blood transfusion developed VAP.
**Conclusions:** VAP is more common in ICU patients with TBI and SAH who smoke, who have a tracheostomy and several comorbidities, mostly diabetes mellitus. It is positively correlated with thrombocytopenia and the number of transfusions during ICU stay as well as increases the days spent on mechanical ventilation and total ICU length of stay. The outcome of these patients does not seem to be affected by VAP, but from the main admission reason. More studies are needed for this subgroup of ICU patients, to identify the main risk factors and personalize their treatment within the ICU.

### Acute poisoning in elderly patients in the intensive care unit: epidemiology and prognosis

H. Ben Ghezala[1], B. H. Asma[1], M. Kharrat[1], A. Ben Jazia[1], N. Brahmi[1]
[1]Critical Care Unit Mahmoud Yaacoub Emergency Medical Center, University of Tunis El Manar, Rommana, Tunisia
**Correspondence:** H. Ben Ghezala
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001111

**Introduction:** By 2030, people aged 60 or over are expected to represent nearly 18% of the Tunisian population. Acute poisoning in elderly patients is an emerging problem all over the world. Few studies were conducted describing acute poisoning in elderly patients.
**Objectives:** The objective of our study was to describe the epidemiological, clinic-biological, therapeutic and evolutionary features of poisoning in elderly patients.
**Methods:** It was a retrospective, descriptive, observational study of patients aged more than 65 years who required hospitalization in the medical intensive care unit at the Mahmoud Yaacoub Center for Medical Assistance and Emergencies for acute poisoning over a 16-year period from January 2007 to December 2022. Statistical analyses were performed using SPSS 20.0 software.
**Results:** Three hundred patients were included. The mean age was 71 ± 7 years with a gender ratio of 0.91. The most frequent comorbidities were: hypertension (43.3%) and diabetes (26.7%). Poisoning severity was moderate in 113 patients (38%) and severe in 98 (25%). Poisoning was deliberate self-harm in 50% of cases ($n = 150$), mainly due to drugs (65.3%), followed by organophosphates. The most common drugs were psychotropics and anti-hypertensive medications. Carbon monoxide (CO) was the main cause of accidental poisoning (59.5%). Chemical submission was found in 8 patients. Seventy-three patients (24.3%) developed coma following acute poisoning, requiring invasive ventilation. The most frequent laboratory abnormalities were: high white blood cell count (40.7%), followed by anemia (28%) and hypokalemia (24%). The mean length of stay was 3 ± 2 days. Thirteen patients died with a mortality rate of 4.3%. In multivariate analysis, the independent risk factors of mortality were evolutionary complications as rhythm disorders ($p = 0.007$), septic shock ($p = 0.001$), cardiogenic shock ($p = 0.001$) and dyskalemia ($p = 0.005$).
**Conclusions:** Poisoning in the elderly is becoming increasingly frequent, mostly voluntary, with a significant mortality rate.

**Topic:** Poisoning/Toxicology/Pharmacology

## 001112

### Acute heart failure in a Tunisian medical ICU: prognosis and risk factors

I. Ben Saida[1], M. Ben Amira[2], C. Zegdane[2], K. Meddeb[1], A. Yacoub[2], E. Ennouri[1], I. Belhouchet[2], I. Bemri[2], M. Zghidi[1], M. Boussarsar[1]
[1]University of Sousse, Faculty of Medicine of Sousse, Research Laboratory Heart Failure, LR12SP09, Farhat Hached University Hospital, Medical Intensive Care Unit, 4000, Sousse, Tunisia, Sousse, Tunisia; [2]University of Sousse, Faculty of Medicine of Sousse, Farhat Hached University Hospital, Medical Intensive Care Unit, 4000, Sousse, Tunisia, Sousse, Tunisia
**Correspondence:** M. Boussarsar
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001112

**Introduction:** Acute heart failure (AHF) is a growing critical care concern with high morbidity and mortality. Despite advancements, survival rates remain low, posing a significant healthcare burden. Accurate risk stratification is crucial for optimizing patient outcomes and resource allocation.
**Objectives:** To describe the characteristics of ICU admitted patients with AHF, and identify independent predictors of poor prognosis.
**Methods:** It is a retrospective study of admitted AHF patients in the medical ICU of Farhat Hached University Hospital between January 2011 and December 2023. Variables found to be statistically significant in univariate analysis were included in a multivariate regression model to identify factors independently associated with poor prognosis.
**Results:** One hundred and seventy-three patients were included with a median age of 70 [57–76.5] years. 101 (58.4%) were men. Hypertension 95 (54.9%), diabetes mellitus 82 (47.4%), and chronic obstructive pulmonary disease 31 (17.9%) were the most outstanding associated pathologies. SAPSII was 38 [27–50]. One hundred and twelve (64.7%) patients received vasopressors on admission. Acute coronary syndrome 88 (50.9%) was the most common cause of AHF. Median duration of ICU stay was 4 [2–8] days. The mortality rate was 53.2%.
Univariate analysis identified several factors associated to fatal outcome: physiological reserve [McCabe score ≥ 2 ($p = 0.000$), Knaus C or D ($p = 0.00$), WHO Performance status ≥ 3 ($p = 0.003$), NYHA ≥ 2 ($p = 0.004$)], severity on admission [severe acute respiratory failure ($p = 0.000$), vasopressors use ($p = 0.000$), SAPSII ($p = 0.00$), and

Glasgow coma scale ≤ 12 ($p = 0.034$)] and referral from cardiology ward ($p = 0.000$). A multivariate regression model identified the following factors as independently associated with mortality: OMS ≥ 3 (OR, 4.644; 95% CI [1.755–12.289]; $p = 0.002$), vasopressors use on admission (OR, 7.84; 95% CI , [2.64–23.32]; $p < 0.001$), SAPS II (OR, 1,05; 95% CI, [1.01–1.09]; $p = 0.005$) and referral from cardiology ward (OR, 9.01; 95% CI [2.053–39.55]; $p = 0.004$).

**Conclusions:** This study highlights the high mortality rate of AHF patients in the ICU. Physiological reserve (WHO performance status), admission severity (SAPS II and vasopressors use), and referral from a cardiology ward emerged as independent predictors of mortality.

**Topic:** Cardiovascular issues in ICU

## 001114

### Prognostic value of admission serum biomarkers and inflammation biomarkers for patients with acute kidney injury after cardiac arrest

P. Antoniou[1], K. Tsoumani[1], S. Mantzoukis[1], K. Bakas[1], E. Kosma[1], D. Lepida[1], O. Ygropoulou[1], D. Rizos[1], O. Mousafiri[1]
[1]Intensive Care Unit, General Hospital of Ioannina G. Hatzikosta, Ioannina, Greece
**Correspondence:** P. Antoniou
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001114

**Introduction:** Acute kidney injury (AKI) in cardiac arrest patients has a high prevalence and is combined with an increased Intensive Care Unit (ICU) length of stay (LOS) and poorer outcomes. Many risk factors have been found, different strategies are being used and importance is given to temperature and systolic blood pressure to achieve higher survival. AKI can be part of systematic inflammation concurrent to cardiac arrest and many patients have high values of blood inflammation markers but not many studies exist examining the correlation between inflammation markers and survivability in these patients after cardiac arrest.
**Objectives:** The aim of this study is to determine which patients who develop AKI after cardiac arrest have better outcomes and which serum biomarkers and inflammation biomarkers may affect the need for mechanical ventilation and the LOS.
**Methods:** A total of 30 patients who were admitted to the ICU for more than 48 h following a cardiac arrest with successful resuscitation from 01/01/2023 to 01/01/2024 were retrospectively studied and included in this study. All patients in this study developed AKI during the first 2 days of admission and patients with chronic kidney disease were excluded. Their demographics, comorbidities, continuous renal treatment (CRRT) hours, creatinine levels, CRP, procalcitonin, troponin and CK levels, as well as ventilator-free days (28 d), vasopressor-free days (28 d), LOS and outcome were retrospectively recorded and statistically analyzed.
**Results:** The mean age of the patients in the study was 72 y (28–88), with a mean APACHE II score of 26.4 ± 7.3, a mean SOFA score of 11.4 ± 2.3 and mean LOS of 19.6 ± 5.8, with 51.6% survival amongst all the patients with cardiac arrest and AKI. 38% of the patients needed CRRT and the rest were treated conservatively. Patients that survived had lower mean PCT and CRP values in comparison to patients who did not survive—13.1 ± 0.3 vs 24.1 ± 0.4 and 9.6 ± 1.2 vs 13.7 ± 0.7, respectively. Troponin levels (ng/L) were mostly equal between the survivors and non-survivors (1839 ± 350 vs 1715 ± 229), as well as WBC (k/μl) (15.209 ± 1.521 vs 14.133 ± 1.436). Mortality of the patients treated with CRRT was 80% and 38% for the patients with conservative treatment. Mean LOS for the CRRT group was 29.6 vs 14.1 for the conservative group and both groups had a difference in ventilator-free days—2.4 vs 9.2 and vasopressor-free days—1.6 vs 8.2.
**Conclusions:** AKI in cardiac arrest patients has a high mortality rate, either when treated conservatively or with CRRT. Patients with conservative treatment tend to have better outcomes, shorter LOS and more ventilator and vasopressor-free days. Smoking, high admission CRP and PCT have a negative prognostic value. Levels of troponin and WBC do not seem to affect LOS and outcomes. More studies are needed to validate the prognostic values of several serum blood values and inflammation biomarkers for AKI after cardiac arrest.

**Correspondence:** M. Boussarsar
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001115

**Introduction:** The immediate post-intensive care unit (ICU) phase is recognized as a critical period, especially for individuals grappling with chronic respiratory failure (CRF). Beyond the ICU discharge, CRF patients face a spectrum of challenges, ranging from the threat of lung function decline to recurrent exacerbations, alongside the imperative need for sustained respiratory support. In this context, understanding the trajectory of post-ICU outcomes among CRF patients is indispensable.
**Objectives:** Investigate the respiratory support management of patients with CRF after ICU discharge. Analyze the outcomes, hospital readmissions, and deaths, across the two-year longitudinal follow-up.
**Methods:** This retrospective cohort study examines patients diagnosed with chronic respiratory failure (CRF) discharged from the ICU between January 2022 and March 2024. Prospective data were collected via an electronic register, encompassing patients' ICU characteristics and longitudinal follow-up details, including home ventilatory management and outcomes. For patients not referred to consultation or who were no-shows, electronic medical records (EMRs) and phone interviews were utilized to ascertain outcomes.
**Results:** Out of 250 ICU-discharged patients following acute exacerbation of CRF, 201 (80.4%) had chronic obstructive pulmonary disease (COPD), 32 (12.8%) had obesity hypoventilation syndrome, and 17 (6.8%) had neuromuscular disease. 191 (76.4%) patients received non-invasive ventilation (NIV), while 59 (23.6%) required invasive mechanical ventilation (MV) during the ICU stay. ICU deaths totaled 21 (8.4%). Subsequently, 96 (38.4%) patients were readmitted to the hospital during the 2-year follow-up. The overall mortality rates at 3 months and 1 year were 8 (3.2%) and 17 (6.8%), respectively.
Among the cohort, only 109 patients attended the post-ICU. Home ventilatory support was, NIV, 64 (58.7%), long-term oxygen therapy

(LTOT) 5 (4.6%), room air 28 (25.7%), and tracheostomy 12 (11%). Of 43 NIV-ventilated patients with available compliance reports at 3 months, the mean NIV duration was 11.5 ± 5.1 h/day. The 33 patients discharged without NIV had a mean PaCO2 of 40.4 ± 8.1 mmHg, with none subsequently prescribed NIV. The overall trends in ventilatory support exhibited a decline, with 19.2% transitioning away from NIV at 3 months.
Across the 24-month follow-up period, mean PaCO2 and PaO2 remained stable between 40.7–47.8 and 58.1–67.1 mmHg, respectively.
**Conclusions:** This study reveals poor outcomes in CRF patients post-severe acute exacerbation, likely attributable to underlying conditions, acute presentation severity, and therapeutic gaps despite adequate home ventilatory management. Tailored trajectories may optimize CRF patient care.

**Topic:** Acute respiratory failure and mechanical ventilation

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 001117

**Introduction:** Lung transplant recipients invariably share recognized risk factors for acquisition of multidrug-resistant (MDR) bacteria. MDR bacteria carriage increases the complexity of patient management in the Intensive Care Unit (ICU).
**Objectives:** We investigated the incidence and impact of MDR bacteria acquisition, on 28-day patient outcomes post-lung transplantation, in a single heart and lung transplantation centre.
**Methods:** Our lung transplant programme was launched at June 2019, and the first patient was transplanted at October 2020. All transplantation (LT) recipients admitted to ICU of our hospital were studied retrospectively, until January 2023. Data were collected regarding MDR bacteria commonly encountered in critical care, for which a national mandatory reporting requirement is in place. These include carbapenem-resistant organisms (CROs), specifically *Acinetobacter*, *Klebsiella* and *Pseudomonas*, as well as methicillin-resistant *Staphylococcus aureus* (MRSA). They were isolated from the respiratory tract, blood, urine, rectal swab or drainage, according to routine protocols.
**Results:** Twenty bilateral LT recipients were screened. Median age was 49 years (IQR 48–59 years) and 6 of them (30%) were women. MDR bacteria were identified in 8 out of 20 patients (40%) and 62.5% of them demonstrated bloodstream infections. Three of them were already MDR bacteria carriers on admission to the ICU. Median time from ICU admission to MDR bacteria acquisition was 3 days (IQR 3–6 days). *Pseudomonas* aeruginosa ($n = 3$) and *Klebsiella pneumoniae* ($n = 3$) were isolated mainly from the respiratory tract.
Median ICU stay for LT recipients with identified MDR bacteria was 32 days (IQR 32–118 days) versus 10 days (10–16 days) for those without MDR bacteria infection. Mortality at 28 days was 37.5% (3/8) versus 25% (5/20) overall 28-day mortality for LT recipients.
**Conclusions:** Our preliminary findings suggest high incidence of MDR bacteria after LT with frequent bloodstream infections in our centre. Patients presented with MDR bacteria had 3 times greater ICU stay and higher mortality. Continuous screening, early diagnosis and prompt response to treating these pathogens facilitates the way to a successful bilateral lung transplantation.

**Introduction:** Critically ill cancer patients pose unique challenges in the ICU due to underlying malignancies and treatment toxicities. However, data on the characteristics and outcomes of this specific population in developing countries, as Tunisia, remain limited.
**Objectives:** This study aimed to describe the clinical profile and identify independent predictors of in-ICU mortality among critically ill cancer patients.
**Methods:** It is a retrospective study conducted in the medical ICU of Farhat Hached University Hospital between January 2007 and December 2023. All cancer patients with complete records were included. Baseline demographics, clinical features, severity scores, tumor characteristics, and outcomes were collected. Univariate and multivariate analyses were carried out to identify factors independently associated to poor prognosis.
**Results:** During the study period, 5467 patients were admitted. One hundred (1.83%) patients had malignancy. Among these, 58 (58%) had hematological malignancies and 42 (42%) had solid tumors, of whom 28 (28%) had evidence of metastases. Clinical characteristics were: median age, 57.5 [46–66] years; male, 58 (58%); WHO performance status 0 to 1, 63 (63%); mean SAPSII, 52.45 ± 20.8; invasive mechanical ventilation (IMV), 64(64%); median duration of IMV, 2 [2–5.25] days; vasopressors use, 66 (66%). The main reasons for admission were: acute respiratory failure, 46 (46%); septic shock, 26 (26%); coma, 17 (17%) and miscellaneous 11 (11%). The median length of ICU stay was 5 [3–10] days and the mortality rate was 59%. On univariate analysis, the factors associated with mortality were IMV on admission (24.4% vs 91.5%; $p < 0.001$) and vasopressor use (31.7% vs 89.8%; $p < 0.001$). Multivariate regression model identified two factors as independently associated with mortality: IMV on admission (OR, 14.6; 95% CI [3.95–53.9]; $p = 0.000$) and vasopressors use (OR, 4.73; 95% CI [1.25–17.9]; $p = 0.022$).
**Conclusions:** This study highlights the high mortality rate of critically ill cancer patients. Requirement for IMV and vasopressor use on ICU admission were independently associated with mortality.

**Topic:** Haematologic-oncologic issues in the ICU

**Introduction:** Imaging of pulmonary ventilation, perfusion and ventilation-perfusion ratio may be used to tailor ventilator settings allowing patient centred therapy of lung injury. Yet, determination of ventilation/perfusion maps (V̇/Q maps) in the clinical scenario requires an extensive protocol of additional measurements.
**Objectives:** In this investigation, we propose a protocol composed of dual-energy computed tomography (DECT) and static computed tomography (CT) to derive V̇/Q maps. The derived surrogate for shunt blood flow is compared to intrapulmonary shunt as determined using standard formulae based on blood gas analysis.
**Methods:** Relative pulmonary perfusion Q was determined using DECT derived iodine algorithm (SOMATOM Definition Edge, Twin Beam, Siemens) after intravenous injection of iodine contrast agent (60 ml, 4 ml/s, Ultravist 370, Bayer) during either two-lung (TLV) or one-lung ventilation (OLV) with different concentrations of inhalative nitric oxide (0, 5, 10, 20 ppm) in three anaesthetized pigs (approval #25-5131/496/33). Ventilation maps V̇ were derived by diffeomorphic co-registration of static thorax CT scans taken at end-inspiratory and end-expiratory lung volume (Advanced Normalization Toolkits, Bspline spatial 5 stage regularization, ANTs neighborhood cross correlation) [Avants et al. Motta-Ribeiro et al.]. A cutoff Cshunt to identify shunt regions SVQ with V̇/Q ≤ Cshunt was determined from regression analysis (slope s, offset z, coefficient of determination $R^2$ and root-mean square error RMSE) of the sum of pulmonary blood volume within the respective shunt region and intrapulmonary shunt from blood gas analysis (SBGA). Among tested Cshunt 1/200, 1/100, 1/10, 1/6, 1/5 and 1/4, the ideal cutoff was considered the one with slope closest to unity, offset close to zero and lowest RMSE during TLV.
**Results:** Relative ventilation V̇, perfusion Q and V̇/Q maps during OLV are shown in Figure 1. In TLV, slope was closest to 1 with $s = 0.98$, offset $z = 0\%$ and RMSE lowest with 1.5%, for Cshunt = 1/6. Over all measurements, SVQ was moderately associated with SBGA ($s = 0.620$, $z = 23.1\%$, $R^2 = 0.409$, $P = 0.010$, Figure 2). In OLV, different iNO concentrations resulted in alterations of pulmonary shunt SVQ—unidirectional for both measures—however, more pronounced in SBGA ($s = 0.219$, $z = 40.3\%$ $R^2 = 0.493$, $P = 0.011$).
**Conclusions:** The proposed protocol allows the determination of ventilation-perfusion maps with only three ventilatory holds and a iodine angiography. Shunt blood flow had a moderate association with intrapulmonary shunt.

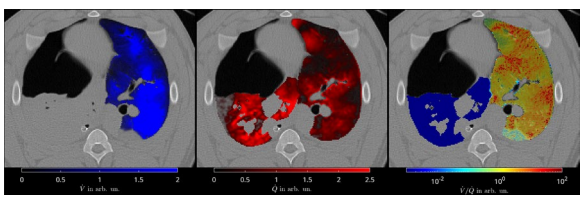

**Fig. (abstract 001119)** .
Representative transversal slides of tidal ventilation V?, pulmonary blood volume Q? and ventilation-perfusion V?/Q? (from left to right) in one-lung ventilation.

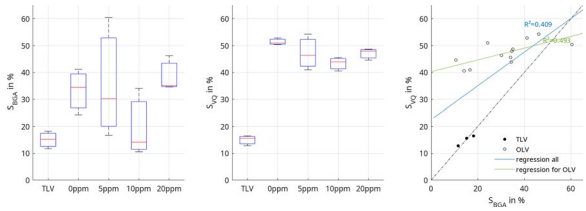

**Fig. (abstract 001119)** .
Pulmonary right-left shunt SBGA from blood gas analysis (left) and pulmonary right-left shunt SVQ as determined from the ventilation-perfusion maps (center) per intervention, and their association (right): with two lung ventilation (TLV), one-lung ventilation (OLV) and parts per million (ppm).

**Introduction:** In the era of precision medicine, a groundbreaking paradigm has surfaced within ICU care, centered on the concept of treatable traits. This innovative approach aims to customize interventions to match the unique needs of each patient, thereby maximizing management efficiency and outcomes.
**Objectives:** This study investigates the predictive capacity of different machine learning techniques in identifying ICU mortality at admission based on treatable traits, thereby advancing the paradigm of precision medicine in critical care.
**Methods:** A retrospective analysis of single-center dataset, comprising information related to 710 patients consecutive ICU admissions throughout a two-year period (2022–2024) mainly balanced between medical respiratory and cardio-circulatory diagnoses, focusing on treatable traits on ICU admission. Different machine learning algorithms including logistic regression, random forest, decision tree, ADA-boost, XGboost, K-nearest neighbors (KNN), and long short-term memory (LSTM) were trained and tested on the dataset. To optimize model performance, the best hyperparameters were searched for each machine learning technique employed in this study. Performance metrics including accuracy and area under the receiver operating characteristic curve (AUC-ROC) were assessed to compare the predictive capabilities of each model. The features included in the respective models were selected by experts guided by clinically relevant treatable traits.

**Results:** Among the identified treatable traits at ICU admission, ten traits were included in the models (sepsis, peripheral hypoperfusion, dysoxia, acidosis, arrhythmia, right heart failure, acute kidney injury, rapid shallow breathing, hypoxemia, and pancytopenia). Among the various machine learning techniques investigated, XGboost demonstrated the highest performance in predicting ICU mortality based on treatable traits (accuracy, 88.73% and AUC, 0.85). Logistic regression and ADA-Boost followed with accuracies of 83.1% and 83%, respectively, and AUC-ROC values of 0.89 both. KNN reached an accuracy of 82.39% with an AUC of 0.78. Decision tree showed a maximum accuracy of 86.97% with an AUC of 0.63. Random forest achieved an accuracy of 87.32% with an AUC of 0.80. Finally, the LSTM model attained an accuracy of 85.21% with an AUC of 0.87.
**Conclusions:** The present study identifies good discriminative properties of a model integrating clinically relevant treatable traits suggesting a certain interest to include the treatable traits approach in the management of critically ill patients.

**Introduction:** Ventriculo arterial coupling (VAC) reflects cardiovascular performance and efficiency. Is there interaction between ventricular pump ejection and the subsequent change in arterial pressure. The response to vasopressors in VAC is variable. It has been described that noradrenaline could increase end systolic elastance (Ees) and arterial elastance (Ea) but vasopressin only increases Ea; therefore, this could lead to VA decoupling.
**Objectives:** The aim of our work was to evaluate whether patients who received noradrenaline plus vasopressin had ventriculo arterial decoupling and higher Ea values than those who received only noradrenaline.
**Methods:** A prospective study was conducted in a 24-bed medical-surgical intensive care unit (UCI) in Argentina. We included patients with shock who received hemodynamic monitoring with transpulmonary thermodilution. We measured the hemodynamic variables of the first transpulmonary thermodilution measurement.
For the Ea calculation, we use the formula (TAM*0.9)/VS. For Ees, we applied the same principle of measurement in echocardiography, so we use the formula TAS/[(GEDVI/4)-VS]. Statistical analysis was performed by means of student ***t*** test for variables with normal distribution and Mann–Whitney test for variables with abnormal distribution.
**Results:** We included 25 patients with shock, and 18 of them had distributive shock. 11 were female. Mean age was 57 [40–65]. Apache II and SOFA scores were 20 [10–27] and 8 [4–9], respectively. There were statistical significant differences in VVS, noradrenaline dose and RVSI. Hemodynamic variables are shown in Table 1.
**Conclusions:** Vasopressin plus noradrenaline use had shown higher VAC values in comparison with noradrenaline alone, but this did not reach statistical significance. Contrary to what we assumed, the norepinephrine group presented higher Ea values and lower Ees.

**Table (abstract 001121)** Hemodynamics characteristics

| | All | Noradrenaline | Vasopressin y Noradrenalina | P |
|---|---|---|---|---|

### Pyroptosis-derived exosomes contribute to endothelial injury in sepsis by triggering leukocyte–endothelium adhesion

Z. Hu[1], Q. Sun[2], W. Huang[2], F. Peng[2], Y. Yang[2]
[1]School of Medicine, Southeast University, Nanjing, China; [2]ICU, Zhongda Hospital, Southeast University, Nanjing, China
**Correspondence:** Z. Hu
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001122

**Introduction:** Sepsis is a life-threatening organ dysfunction caused by dysregulated host responses to infection, with endothelial injury the pivotal feature [1]. Diverse range of factors are associated with endothelial dysfunction [2]. Recent studies demonstrated the importance of exosomes of different origin in transporting biologically active substances and cell–cell communication [3,4].
**Objectives:** The aim of our study was to investigate the effect and mechanism of pyroptosis-derived exosomes (Pyro-Exos) on sepsis-related endothelial injury.
**Methods:** Pyro-Exos were isolated from supernatants of pyroptotic cell culture medium and plasma using ultracentrifugation. They were injected to mice or co-cultured with endothelial cells. Strategies including HE staining, immunofluorescence, western blot, qPCR and ELISA were applied to investigate their effects on endothelial injury in vivo. Leukocyte adhesion assay and western blot were used to evaluate the adhesion function of endothelium in vitro.
**Results:** The amount of exosomes in septic mice was significantly higher than that in the sham group. However, inhibition of pyroptosis using disulfiram decreased the exosomes in septic mice (Fig. 1a). Exosomes extracted from sham (Sham-Exos), sepsis (CLP-Exos) and sepsis without pyroptosis (CLP-Exos-Pyro) were injected into healthy mice. Compared with CLP-Exos, CLP-Exos-Pyro contributed to lung injury and increase of inflammatory factors (Fig. 1b–d). Then, we extracted CtrlExos and Pyro-Exos from THP-1 monocytes and injected them into mice. The number of exosomes was significantly higher in pyroptotic cells than control (Fig. 1e). Pyro-Exos contribute to lung inflammation, increase of cytokines and increase of wet weight to body wet ratio in vivo (Fig. 1f–i). Through transcriptome sequencing of endothelial cells treated with Ctrl-Exos and Pyro-Exos, we found that

differently expressed genes were mainly enriched in pathways related to leukocyte-endothelium adhesion (Fig. 1j). In vivo, the expression of ICAM1 on endothelial cell was greatly increased in mice injected with PyroExos (Fig. 1k). In vitro, the number of leukocytes adhered to endothelium was significantly higher with the intervention of Pyro-Exos (Fig. 1l, m). The expression of ICAM1 and P-selectin increased as well (Fig. 1n).

**Conclusions:** Pyro-Exos contribute to endothelial injury in sepsis by the means of triggering leukocyte–endothelium adhesion.

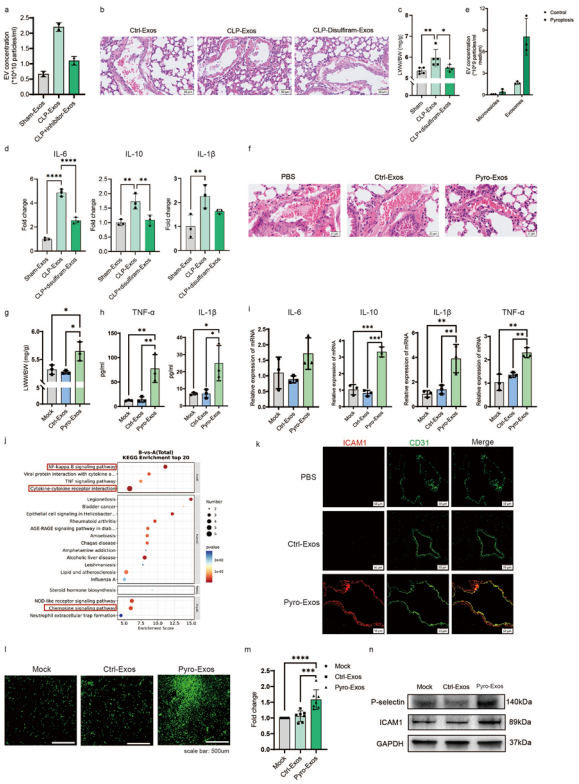

**Fig. 1 (abstract 001122)** Pyroptosis-derived exosomes contribute to endothelial injury in sepsis by triggering leukocyte–endothelium adhesion. a) The amount of exosomes in plasma of sham, CLP and CLP + disulfiram mice. b–d) The lung injury, lung wet weight-to-body mass ratio and inflammatory factors of mice injected with Sham-Exos, CLP-Exos and CLP-Exos$^{-Pyro}$. e) The amount of exosomes of control and pyroptotic THP-1 cells. f–i) The lung injury, lung wet weight-to-body mass ratio and inflammatory factors of mice injected with PBS, Ctrl-Exos and Pyro-Exos. j) The transcriptome sequencing of endothelial cells treated with Ctrl-Exos and Pyro-Exos. k) The immunofluorescence of ICAM1 and CD31 in lung tissue of mice injected with PBS, Ctrl-Exos and Pyro-Exos. l–m) In vitro assessment of leukocyte-endothelium adhesion. n) Western blot of P-selectin and ICAM1 of endothelial cells treated with PBS, Ctrl-Exos and Pyro-Exos

### Effect of an Shenfu injection on 28-day mortality in patients with sepsis: a single-center retrospective study

J. Li[1], D. Yunxin[2], M. Meng[3]
[1]Department of Critical Care Medicine, Binzhou Medical University, Yan Tai Shi, China; [2]Critical Care Medicine, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China; [3]Department of Critical Care Medicine, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China
**Correspondence:** J. Li
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001124

**Introduction:** Sepsis is the leading cause of mortality in intensive care unit (ICU). Shenfu injection (SFI) is commonly used to treat patients with sepsis, septic shock, heart failure, and other conditions in clinical practice.
**Objectives:** This purpose of the study was to determine the effect of SFI vs control on 28-day mortality among patients with sepsis.
**Methods:** The Shenfu injection in sepsis patients (SFI) study was conducted on the clinical data of 807 sepsis patients admitted to the ICU at Ruijin Hospital from January 2013 to January 2023. Patients were divided into a treatment group ($n = 176$) and a control group ($n = 631$) based on their use or non-use of Shenfu injection, respectively. Propensity score matching was performed for age, gender, infection site, and other relevant factors. We evaluated the 28-day mortality rate, mechanical ventilation–free days, and vasoactive drug-free days. The safety outcomes included any adverse events (AEs) and severe adverse events (SAEs) through 28 days of follow-up.
**Results:** There were 154 successfully matched groups in this study, the baseline demographics, severity of illness, SOFA score, APACHE II score and comorbidities were well balanced between the study groups. In this patients, the 28-day mortality rate was significantly different between the control group and the SFI group (35 of 154 patients [22.73%] vs 15 of 154 patients [9.74%], respectively; $P < 001$). The median length of stay in ICU of the SFI group which was 16.5 days (IQR 8–35.25 days) was higher than median length of stay in ICU of the control group which was 16 days (IQR 8–41.251 days), $P < 0.05$. Compared with the control group, vasoactive drug-free days in the SFI group was higher than that of the control group (SFI group, 19.35 ± 6.86 days, vs control group, 16.64 ± 8.91 days), $P < 0.01$. Moreover, the D-Dimer level in the SFI group was lower than that of the control group (SFI group, 3.13 ± 4.25 mg/L, vs control group, 4.19 ± 5.11 mg/L), $P < 0.05$. In subgroup analyses, the SFI group had a protective effect in sepsis patients with age < 60 years (OR, 0.049; 95% CI 0.003–0.935), male (OR, 0.314; 95% CI 0.141–0.700), no chronic heart failure (OR, 0.342; 95% CI 0.171–0.683), Charlson index < 3 points (OR, 0.381; 95% CI 0.184–0.787), and no progression to septic shock state (OR, 0.390; 95% CI 0.197–0.773).
**Conclusions:** In this single-center retrospective study among patients with sepsis, the administration of SFI reduced 28-day mortality compared with the control.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 001125

**Introduction:** Non-invasive oxygen therapy in COVID-19 patients reduces the risk of intubation compared to conventional oxygen therapy. However, it is unclear whether delayed intubation has adverse effects on the mortality and prognosis of severe COVID-19 patients undergoing treatment with high-flow nasal oxygen therapy (HFNO).
**Objectives:** We aim to analyze the risk factors for intubation and mortality among COVID-19 patients receiving HFNO.
**Methods:** In 2020, a retrospective multicenter study was conducted on 908 severe COVID-19 patients admitted to 26 intensive care units (ICUs) in Korea who received HFNO. We divided patients treated with HFNO into two groups: those who were intubated and those who were not, and we used multivariable regression analysis to identify risk factors for intubation.
**Results:** A total of 908 critically ill COVID-19 patients treated with HFNO were enrolled in this study. Out of these, 474 (52%) patients received HFNO treatment, while 434 (48%) underwent intubation. The median age was 67.5 years, with 546 males (60%) and 362 females (40%). Comparing with HFNO, the intubation groups had a lower median duration of HFNO (3.0 vs. 8.6 days; $p<0.001$), platelet count (190,000 vs. 201,000; $p=0.042$), and a higher sequential organ failure assessment score (4.0 vs. 3.3; $p<0.001$), as well as a higher clinical frailty scale before discharge (4.2 vs. 3.8; $p=0.01$). There were no significant differences in ICU or hospital mortality between the HFNO and intubation groups (81 [17.1%] vs. 100 [23%]; $p=0.043$ and 98 [20.7%] vs. 111 [25.6%]; $p=0.076$). Lower PaO2/FiO2 and ROX (ratio of oxygen saturation/fraction of inspired oxygen) index were associated with the intubation risk factor, with an odds ratio (exp [β]) of 0.992 (95% CI [0.989–0.995]) for PaO2/FiO2 and 0.887 (95% CI [0.831–0.948]) for the ROX index, both $p<0.001$.
**Conclusions:** In severe COVID-19 patients receiving HFNO, lower PaO2/FiO2 and ROX index values were associated with an increased risk of intubation. However, when comparing patients receiving HFNO patients, intubation did not influence hospital or ICU mortality.

**Introduction:** Delirium, anxiety and pain are states of stress resulting from the critical illness, the treatments, and techniques received during the critical situation. They are frequent in patients admitted to the Intensive Care Unit and can compromise their evolution and prognosis (1)(2)(3). The use of music therapy guided by a music therapist in patients with stress (anxiety, delirium and pain) can help to comfort and reduce stress (4)(5).
**Objectives:** To investigate the impact of a music therapy intervention guided by a music therapist, with the aim of improving comfort and reducing stress symptoms in critically ill patients.
To analyze the levels of stress (cortisol) and well-being (melatonin) metabolites in saliva.
**Methods:** This is a prospective and observational study carried out in an Intensive Care Unit for 6 months. Patients with symptoms of stress (anxiety, pain and/or delirium) and a level of consciousness that allowed correct communication (Glasgow > 10 or RASS > -2) were included. Patients with neurological or auditory pathology were excluded. Before and after the intervention, stress symptoms were identified and collected through validated scales. Saliva sample (Salivette®) was collected to determine cortisol and melatonin levels before and after intervention. Demographic, admission, physiological variables and adverse effects were collected. Statistical significance was considered, $p<0.05$.
**Results:** Fourteen interventions were analyzed. 57% were women, with an average age of 56.9 (± 16.1), APACHE II of 17 (5–30) and SOFA of 3 (0–12). The reason for admission was medical in 78.6%, the average number of days before the intervention was 13 (14.6) and 50% received invasive mechanical ventilation. All patients presented symptoms of stress: 5 (35%) of them were delirious, 8 (57%) had severe pain and 2 suffered anxiety.
After the intervention, the delirium was resolved in 100% (5) and comfort improved significantly ($p<0.01$) in most of patients (9 (64%)). In patients with moderate VAS (6 (42%)), the cortisol decreased in saliva after the intervention by 1.6 (1.1–30.2) vs 1.2 (0.6–7.4) ($p<0.04$) and the cortisol/melatonin ratio (5.8 (0.15–249.6) vs 3.7 (0.08–40.8) ($p<0.02$). In cases of intense VAS, cortisol levels also decreased, although not significantly (3.29 (1.1–10) vs 2.44 (1.03–13). No differences were found in the physiological variables before and after the intervention. No adverse effects were described with the intervention.
**Conclusions:** Music therapy guided by a music therapist is a viable and safe intervention in the critically ill patient. The benefits can be observed at a clinical level (improvement in comfort and delirium) and at a metabolic level (decrease in cortisol in saliva and in the cortisol/melatonin ratio). This pilot study will allow a broader study to be carried out.

**Introduction:** Disparities in pulse oximetry accuracy, disproportionately affecting patients of color, have been associated with serious clinical outcomes. Although many have called for pulse oximetry hardware replacement, the cost associated with this replacement is not known.
**Objectives:** To estimate the cost of replacing all pulse oximetry hardware throughout a hospital system.
**Methods: Methods**: This single-system survey was conducted at Duke University Health System in 2023, which is one academic quaternary medical center with three hospitals. The main outcomes and measures were the cost of fleet replacement as identified by current day prices for hardware.
**Results:** New and used prices for 3,542/4,136 (85.6%) across three hospitals for pulse oximetry devices were found. The average equipment cost to replace pulse oximetry hardware is $6,834.61 per bed. Replacement and integration costs are estimated at $14.2–17.4 million for the entire medical system. Extrapolating these costs to 5,564 hospitals in the United States results in an estimated cost of $8.72 billion.
**Conclusions:** "Simply replacing" pulse oximetry hardware to address disparities may be neither simple, cheap, or timely. Solutions for addressing pulse oximetry accuracy disparities leveraging current technology may be necessary.

**Table 1 (abstract 001127)** Average replacement cost for all beds in a hospital across the system

| | | Duke University Hospital | Duke Raleigh Hospital | Duke Regional Hospital | Duke University Health System |
|---|---|---|---|---|---|
| total number of devices | | 2758 | 708 | 670 | 4136 |
| devices with prices | | 2,351 (85.2%) | 600 (84.7%) | 591 (88.2%) | 3,542 (85.6%) |
| number of beds | | 1,048 | 186 | 373 | 1,607 |
| special care beds | | 332 | 28 | 22 | 382 |
| operating rooms | | 53 | 18 | 20 | 91 |
| number of models | Multi-Parameter Module/Monitor | 39 | 24 | 13 | 48 |
| | Pulse Ox Module/Monitor | 28 | 9 | 5 | 34 |
| | Vital Signs Monitor | 53 | 9 | 8 | 58 |
| replacement cost (thousands) | | $ 7,138.06 | $ 2,375.66 | $ 1,482.71 | $ 10,983.22 |
| average replacement cost per bed | | $ 6,811.12 | $ 12,772.34 | $ 3,975.10 | $ 6,834.61 |
| integration costs | 250 hours | $ 2,650.00 | $ 1,425.00 | $ 775.00 | $ 3,250.00 |
| | 500 hours | $ 6,400.00 | $ 2,150.00 | $ 950.00 | $ 6,400.00 |
| total replacement & integration | 250 hours | $ 9,788.06 | $ 3,800.66 | $ 2,257.71 | $ 14,233.22 |
| | 500 hours | $ 13,538.06 | $ 4,525.66 | $ 2,432.71 | $ 17,383.22 |

Based on the number of devices with prices, this table reflects the cost of replacing pulse oximeters by individual hospitals, along with across the three hospitals together. Prices for costs are in thousands (e.g., total replacement and integration at Duke University Hospital $9.8–13.5 million, Duke Raleigh Hospital $3.8–4.5 million, Duke Regional Hospital $14.2–17.3 million).

**Introduction:** In patients admitted to the intensive care unit (ICU), muscle mass and bone density are important determinants of short-term outcomes, including in-hospital mortality and discharge disposition[1–6]. It is uncertain if these same risk factors determine post-ICU disability and mortality. We hypothesized that muscle indexes and bone density, measured in the first 14 days of ICU admission, are determinants of 7-day post-ICU disability, captured as the functional independence measure (FIM), and of 1-year mortality. These insights may enhance prognostic information for patients and families during and after an episode of critical illness.
**Objectives:** The primary objective of this study was to assess the association between muscle indexes and bone density—measured on a single abdominal CT scan within the first 14 days of ICU admission—and 1-year mortality in chronically critically ill patients. The secondary objective was to examine how these same measurements relate to the 7-day post-ICU FIM.
**Methods:** This study used the Canadian RECOVER Program (Phase 1) cohort [7], comprised of patients requiring mechanical ventilation for $\geq$ 7 days. Patients who underwent abdominal CT scans within the first 14 days of ICU admission and as part of their clinical management were included. If patients had multiple CT scans, only the first ICU scan was retained for analysis. Skeletal Muscle Index (SMI), Psoas Muscle Index (PMI), and trabecular bone density were measured at the L3 vertebral level. Uni- and multivariable logistic regressions were performed to assess the association between each of SMI, PMI, bone density and 1-year mortality. Uni- and multivariable linear regressions were performed to assess the association between each of SMI, PMI, bone density and the 7-day post-ICU FIM.

**Results:** One hundred patients were included; the median age was 57 [IQR: 45–65] and 43% were female. Median values showed that 1-year non-survivors had lower muscle indexes and bone density than survivors: SMI was 27.9 $cm^2/m^2$ [IQR: 21.8–32.8] vs. 33.8 $cm^2/m^2$ [IQR: 27.8–46.6], $p = 0.03$; PMI was 3.3 $cm^2/m^2$ [IQR: 2.5–4.5] vs. 4 $cm^2/m^2$ [IQR: 3.2–5.6], $p = 0.02$; and bone density was 131 Hounsfield units (HU) [IQR: 100–196] vs. 175 HU [IQR: 131–220], $p < 0.01$. Multivariable logistic regression analysis showed significant associations with 1-year mortality for decreased values of SMI (Odds ratio (OR) per 10-unit decrease in SMI: 2.00, 95% CI 1.25–3.33, $p < 0.01$), PMI (OR per 1-unit decrease in PMI: 1.67, 95% CI 1.11–2.5, $p = 0.02$), and bone density (OR per 10-unit decrease in bone density: 1.11, 95% CI 1.09–1.27, $p = 0.03$) (Figure 1). However, no significant association was found between muscle indexes, bone density, and the 7-day post-ICU FIM.
**Conclusions:** Muscle indexes and bone density measured in the first 14 days of ICU admission are associated with up to 1-year mortality in chronically critically ill patients. These findings may facilitate better identification of patient trajectories and inform clinical decision-making.

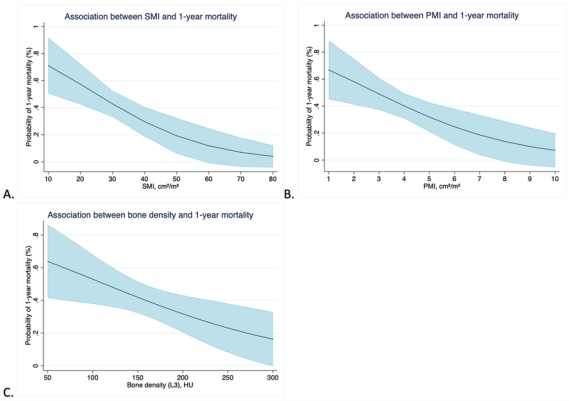

**Fig. (abstract 001128)** Association between SMI, PMI, bone density and 1-year mortality. Association between various musculoskeletal measurements and 1-year mortality, illustrating the fitted probabilities and 95% confidence intervals for 1-year mortality. Models have been adjusted for age, sex, Charlson Comorbidity Index, ICU length of stay (≤ 14 days or > 14 days), and, specifically for analyses involving SMI and PMI, the timing (days) of the CT scan relative to the ICU admission. **Introduction:** Fluid overload (FO) is considered, alongside age, one of the most significant prognostic factors in patients admitted to Intensive Care Units [1]. However, we lack sufficient evidence to define a duration or quantity of volume overload detrimental to patient prognosis.
**Objectives:** To determine the influence of persistent FO from 72 h after admission to the Intensive Care Unit (ICU) on the mortality of patients admitted for any reason to a polyvalent ICU. FO was defined as an accumulated fluid balance (AFB) exceeding 10% [2] of the patient's weight at the time of admission to the ICU.
**Methods:** This is a single-center retrospective cohort study of patients admitted for more than 14 days for any reason to a polyvalent ICU between January 2022 and December 2023. Clinical and demographic data were recorded, including intra-ICU mortality (ICU-M), days of mechanical ventilation (D-MV), and length of ICU stay (L-ICU). Logistic regression and ROC curve analyses were performed, comparing fluid overload at 72 h, 7 days, and 14 days post-admission with adjusted ICU-M for D-MV and L-ICU.
**Results:** A total of 146 patients were included, of whom 77.4% were male. Admission reasons were respiratory in 34.2%, neurological in 28.7%, infectious in 23%, cardiac in 7%, polytrauma in 15%, and digestive in 4.1% cases. The accumulated fluid balance (AFB) at 72 h was 3422 ml (−7300–15,000 ml), at 7 days was 5680 ml (−12,200–27,700 ml), and at 14 days was 7330 ml (−20,000–45,000 ml). ICU-M mortality was 28.3%. L-ICU averaged 22.9 days (2 to 53 days). The mean D-MV was 22.4 days (ranging from 1 to 56 days).
Table 1 displays the logistic regression results illustrating the correlation between FO and ICU-M, D-ICU, and D-MV.
In Figure 1, ROC curves at 72 h (a), 7 days (b), and 14 days (c) are presented. The curves displayed an AUC of 0.75, 0.72, and 0.72 at 72 h, 7 days, and 14 days, respectively.

**Table 1**

| | ICU-M OR (95% CI) *p* | L-ICU OR (95% CI) *p* | D-MV OR (95% CI); *p* |
|---|---|---|---|
| FO 72 h | 5.1 (2.1–12.2) p 0.000 | 1.26 (0.49–3.2) p 0.62 | 1.7 (0.6–4.3) p 0.3 |
| FO 7 d | 3.5 (1.6–7.2) p 0.04 | 2.2 (1.0–4.8) p 0.04 | 1.2 (0.6–2.6) p 0.58 |
| FO 14 d | 3.2 (1.4–7.1) p 0.004 | 2.6 (1.3–5.5) P 9 0.01 | 1.6 (0.8–3.2) p 0.22 |

**Conclusions:** Persistent fluid overload at 72 h, 7 days, and 14 days post-admission, defined as an accumulated fluid balance > 10% of the patient's weight at admission, correlates independently with adjusted intra-ICU mortality when adjusted for ICU length of stay and duration of mechanical ventilation. The area under the curve ROC curve analyses is good at 72 h and acceptable at 7 and 14 days post-admission.

## Severe metabolic acidosis in ICU patients correlates with a greater decrease in platelet count in the following days

I. Grad[1], P. Gradišek[1], M. Sostaric[1], J. Kšela[2], P. Fister[3], P. Vovk Racman[1]

*Intensive Care Medicine Experimental* 2024, **12(suppl 1):**001130

**Introduction:** Many studies have shown that the decline in platelet count in patients after ICU admission is a useful marker of the severity of critical illness. Patients with a greater decline in platelet count tend to have worse prognosis. To date, the reason for the drop in platelet count in patients after admission to the ICU has not been sufficiently clarified. In severe decompression sickness, it is assumed that blood/gas bubble interactions and bubble-induced endothelial damage cause the activation of platelets and their consumption. Therefore, the relative decrease in platelet count is a recognised marker of the severity of decompression sickness. We hypothesize that the physicochemical process of gas bubble formation may be the reason for a similar mechanism of platelet activation, consumption and resulting count decline in critically ill patients.
**Objectives:** Rapid acidification of a solution, containing bicarbonate ions (HCO3-) could cause carbon dioxide (CO2) supersaturation and the formation of gas bubbles. The gas bubbles initially form due to CO2 supersaturation, but then other dissolved gases also diffuse into the bubbles in amounts, proportional to the partial pressure of each dissolved gas. A simple demonstration of this process is the addition of common salt (NaCl) to a glass of carbonated beverage (Figure 1). Blood is an HCO3- containing solution and critically ill patients often develop a sudden onset of profound metabolic acidosis. We assume that a similar gas bubble forming process could be a reason for observed platelet count decline in critically ill patients after admission to the ICU. To evaluate this prediction, we investigated the correlation of metabolic acidosis severity and later platelet count trend in ICU patients.
**Methods:** We analysed the correlation between the severity of metabolic acidosis on admission and the subsequent evolution of platelet count in all ICU patients, admitted to our ICU in a 1-year period (1.1. to 31.12.2020). We observed the correlation between the lowest base excess (BE) of each patient in the 24 h before to 24 h after ICU admission and the relative change in platelet count in the following 2 days after ICU admission.
**Results:** Our study showed a weak to moderate correlation between the severity of metabolic acidosis (represented by a more negative BE) on ICU admission and the relative decrease in platelet count in the first 2 days after admission (represented by deltaT: a more negative deltaT represents a greater decrease in platelet count). The Pearson correlation coefficient is 0.34 with a 95% confidence interval 0.23–0.42, $p < 0.001$ (Graph 1).
**Conclusions:** Patients with a more negative BE on admission to the ICU tend to have a greater relative decrease in platelet count in the following days.

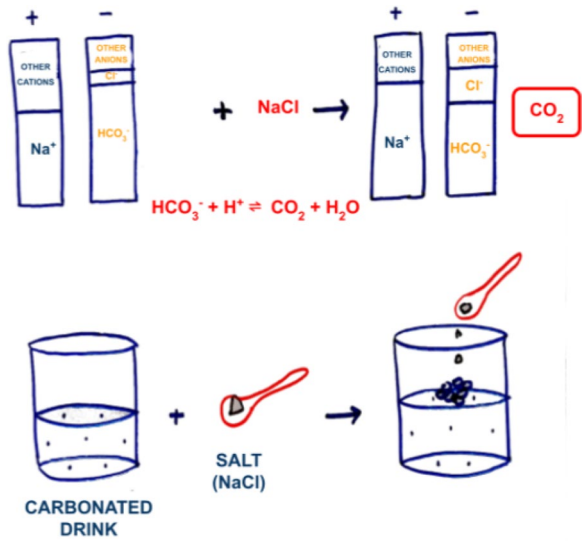

**Fig. 1 (abstract 001130)** After adding salt to a HCO3- containing solution, additional gas bubbles emerge

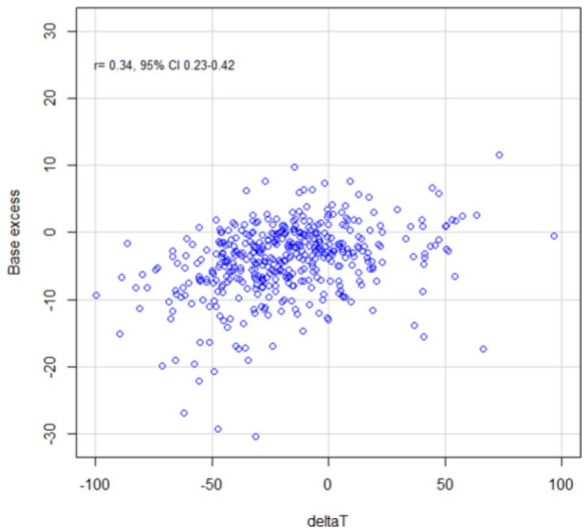

**Graph 1 (abstract 001130)** Correlation between the severity of metabolic acidosis (more negative BE) and the relative decrease in platelet count 2 days after ICU admission (deltaT). Legend: deltaT = (T2-T0)/T0 × 100; T0: platelet count on admission; T2: lowest platelet count on day 2 after admission to the ICU

**Introduction:** Critical illness remains a global issue, significantly contributing to in-hospital mortality. In Tunisia, a low-middle income country, critical care beds are significantly limited reaching a maximum of 8 intensive care unit (ICU) beds per 100 000 people owing to surge beds during the COVID-19 pandemic. This results in a number of critically ill patients being refused ICU-admission, potentially resulting in evitable deaths. ICU-refusal practices are rarely documented and non-escalation practices even less.
**Objectives:** To report the rates, reasons and outcomes of patients who were refused ICU admission.
**Methods:** A preliminary analysis of an ongoing prospective study in the medical ICU of Farhat Hached University Hospital, Sousse, Tunisia. These results are over the course of 8 months from August 1st 2023 to March 31st 2024. We included all consecutive patients for which the on-call intensivists were solicited for ICU-admission. Data were collected in a specific online case report form. Collected data included date and time of ICU solicitation, referral sources, patients' demographics, comorbidities, acute presentation diagnosis and severity, reason for refusal and patient outcome evaluated at day 5 of refusal.
**Results:** The ICU team was solicited for a total of 731 patients, and 511 (69.9%) were refused ICU admission. Patients refused for ICU admission had a mean (± SD) age of 61 ± 17.7 years; mostly male, 298 (58.3%); at least two comorbidities, 475 (93%); World Health Organization performance status score, 2.3 ± 1.2. Calls were mainly from the emergency department, 307 (60.1%) and medical wards, 145 (28.4%). Main reasons for solicitation were respiratory distress, 314 (61.4%); neurological distress, 72 (14.1%) and shock, 69 (13.5%). Reasons of refusal were no beds available, 281 (55.5%); too-well-to-benefit, 91 (17.8%); too-sick-to-benefit, 67 (13.1%); poor prognosis of the underlying condition, 39 (7.6%) and unavailable treatment options, 18 (3.5%). Non-escalation was decided for only 49 (9.6%) patients. Upon reevaluation at day 5 of refusal, overall mortality was at 26%. As for those who were refused for lack of ICU beds, 49 (17.4%) had died; 15 (5.3%), later admitted to our ICU; 52 (18.5%) transferred to another ICU and 147 (51.8%) still at the same department. As for those who were judged as too-sick-to-benefit, 30 (44.8%) patients had died by day 5 and 8 (8.8%) patients judged too-well-to-benefit had died.
**Conclusions:** The current study reveals concerning trends in critical care accessibility and outcomes. High refusal rates, predominantly due to ICU bed shortages, underscore systemic challenges in

healthcare delivery. Moreover, the observed elevated mortality post-refusal emphasizes the urgent need for interventions to enhance ICU capacity.

**Introduction:** Sepsis often leads to complications in the coagulation system. The mortality rate for patients with sepsis-induced coagulopathy is twice that for patients with sepsis without coagulopathy [1]. Thrombocytopenia can occur during sepsis despite increased platelet consumption via various pathways or owing to decreased platelet production [2]. A higher rate of platelet count reduction, independent of the absolute platelet count, is associated with increased mortality and coagulopathy-induced complications [3].
**Objectives:** To identify the intricate mechanisms underlying thrombocytopenia in patients with sepsis-induced coagulopathy by identifying the genes involved in cellular signaling and microRNA (miRNA) regulation.
**Methods:** This single-center, prospective, observational study included 40 and 73 adult patients with sepsis in the exploratory and validation phases, respectively. Utilizing next-generation sequencing data analysis and software-driven assessment of intracellular signaling pathway activity, we identified mRNA candidates who exhibited different expression levels between patients with sepsis with reduced platelet counts and those without reduced platelet counts in the exploratory phase. The expressions of these candidate mRNA and miRNA that interact with them during the validation phase were quantitatively evaluated using real-time polymerase chain reaction. The protein levels were analyzed using enzyme-linked immunosorbent assay.
**Results:** An increase in the mRNA levels in the key genes, particularly those associated with the inflammasome pathway and cell adhesion pathway, was accompanied by a decrease in miRNA expression, suggesting a potential regulatory role of miRNAs in the reduction of platelet count. The findings of the protein-level analysis corroborate the upregulation of the main genes associated with a decrease in the platelet count [Figs. 1, 2, 3].
**Conclusions:** The activation of intraplatelet pyroptosis-related inflammasome and cell adhesion molecules increases platelet consumption despite the increase in the production of platelets in patients with sepsis who have decreased platelet counts. Furthermore, altered miRNAs may serve as indicators for predicting a decrease in platelet counts.

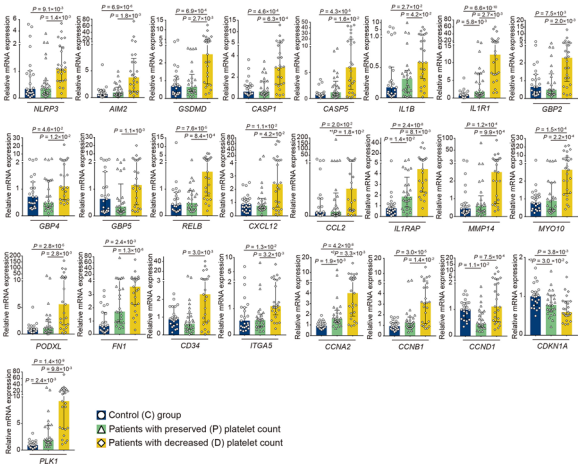

**Fig. 1 (abstract 001132)** Validated quantitative polymerase chain reaction of candidate mRNAs in the exploratory phase
The representative mRNAs related to inflammasome are shown. Values are normalized to the level of Actb and expressed as fold change with respect to the levels in the control (C) group.

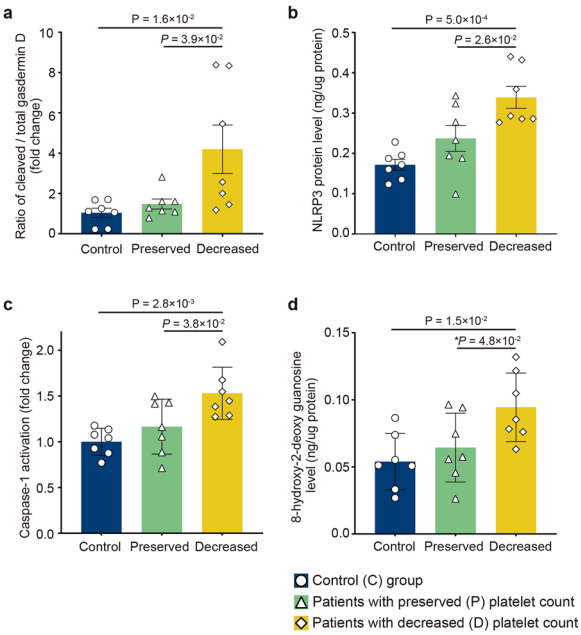

**Fig. 2 (abstract 001132)** Expression of protein levels of specific key genes. **a–c.** An increase in the protein levels of specific key genes that were upregulated in the inflammasome-pyroptosis pathway is confirmed. Values are expressed as fold change with respect to the levels in the control (C) group (**a** and **c**). **d.** Enzyme-linked immunosorbent assay was used to examine the levels of 8-hydroxy-2′-deoxyguanosine, a marker of the primary type of DNA damage caused by reactive oxygen species, in the three groups. *The *P*-value was the result for the preserved (P) vs. decreased (D) group according to the *t*-test. The value for one-way analysis of variance with Tukey's post hoc test was $7.7 \times 10{-}2$

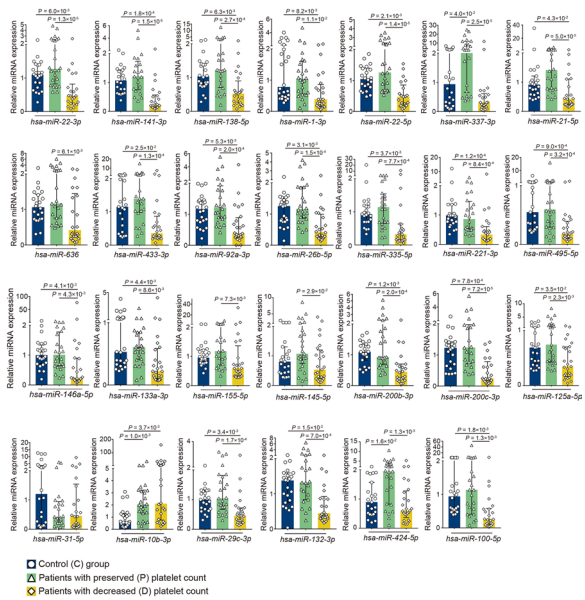

**Fig. 3 (abstract 001132)** Validated quantitative polymerase chain reaction of candidate miRNAs
The results of qualitative polymerase chain reaction (PCR) of microRNAs that were experimentally validated in miRTarBase as having a target for the nominated mRNAs. The values are normalized to spike in control (cel–miR–39) and expressed as fold change with respect to the levels in the control (C) group.

**Introduction:** Toxic epidermal necrolysis (TEN) is a rare, potentially life-threatening mucocutaneous disease characterized by widespread epidermal necrosis and mucosal involvement. The incidence of toxic epidermal necrolysis estimated at 0.4 to 1.2 cases per million person-years.
**Objectives:** This study aimed to determine the clinical characteristics and outcomes of patients admitted to the intensive care unit (ICU) with a diagnosis of TEN.
**Methods:** A retrospective study was performed in the critical care of Farhat Hached University Hospital of Sousse between January 1995 and December 2023. Data were collected by reviewing the medical patients' charts. Clinical characteristics, causative drugs, treatment, and outcomes were retrospectively recorded. A multivariate regression analysis was used to identify risk factors for ICU mortality in those patients.
**Results:** Forty patients were recorded. Patients' characteristics were as follows: mean age, 45.8 ± 21.4 years; male, 11 (27.5%); median Charlson Comorbidity Index, 3.5 [0–4]; referred from dermatology department, 20 (50%) and mean SAPSII, 23.8 ± 11.44. The average affected skin area was 50 ± 20.44% of the total body surface area. Mucosal involvement was present in 33 (82.5%) patients, with oropharyngeal involvement in 29 (72.5%), ocular involvement in 21 (52.5%), and genital involvement in 25 (62.5%). Nikolsky sign was positive in 34 (85%) patients. The most common drugs that triggered TEN were antibiotics in 11 (27.5%) cases, allopurinol in 9 (22.5%) cases, anticonvulsants in 9 (22.5%) cases, non-steroidal anti-inflammatory drugs in 9 (22.5%) cases, antipsychotic drugs in 1 (2.5%) case and paracetamol in 1 (2.5%) case. Eighteen (45%) patients required invasive mechanical ventilation (IMV), 10 (25%) vasoactive drugs, and 2 (5%) renal replacement therapy. The mortality rate was 16 (40%), which aligned with the predicted mortality based on the SCORTEN score (a severity-of-illness scoring system for TEN prognosis).
Univariate analysis revealed the following factors to be associated with fatal outcome: skin superinfection (50% vs 4.2%, $p = 0.001$), IMV (12.5% vs 93.8%, $p = 0.001$) and acute renal failure (37.5% vs 75%, $p = 0.02$).
Skin superinfection was the only independent factor of ICU mortality (OR, 23; 95% CI [2.47–213.7]; $p = 0.006$).
**Conclusions:** The present study demonstrated a severe prognosis in TEN patients. Common medications implicated in TEN were antibiotics, allopurinol, anticonvulsants, and non-steroidal anti-inflammatory drugs. Skin superinfection was identified as the sole independent factor associated with mortality.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001135

**Introduction:** The expression of indoleamine 2,3-dioxygenase 1 (IDO1) is upregulated in sepsis and its activity correlates with the degree of hypotension and mortality (1,2). IDO1 catalyzes the conversion of tryptophan to kynurenine, a proposed systemically active vasodilator.
**Objectives:** This study aimed to evaluate the effects of IDO1 inhibitors on endotoxemia.
**Methods:** In vitro, the IDO1 inhibitors Epacadostat (Epa), Linrodostat (Lin) or PF-06840003 were added to primary human pulmonary arterial endothelial cells challenged with interferon-γ. After 48 h, kynurenine in the supernatant was measured photometrically using Ehrlich's reagent.

In vivo, mice were injected intraperitoneally (i.p.) with lipopolysaccharide (LPS). Mice received either Epa, Lin, PF or the vehicle i.p. simultaneously. After 18 h, invasive hemodynamic monitoring and mechanical ventilation were established. Following exsanguination, serum and lungs were frozen in liquid nitrogen. Serum levels of tryptophan and kynurenine were measured using high-performance liquid chromatography coupled with mass spectrometry. Expression of IDO1 in lung homogenates was assessed by Western blot. Serum levels of inflammation-associated cytokines were measured using a fluorescence-encoded multiplex bead assay (LEGENDPLex; Biolegend).

**Results:** All three IDO1 inhibitors suppressed kynurenine production in the inflammatory arterial endothelial cell model in a monotonically increasing dose–response relationship (Fig. 1 A, B, C).

In mice, LPS led to a reduced mean arterial blood pressure (66 ± 15 mmHg vs 87 ± 11 mmHg; $p = 0.03$; Fig. 2A) and an elevated heart frequency (551 ± 55/min vs. 367 ± 81/min; $p < 0.01$; Fig. 2B). Administration of Lin attenuated the decrease in mean arterial blood pressure (Lin: 96 ± 11 mmHg; $p = 0.01$; Fig. 2E), whereas administration of Epa exhibited a similar trend but did not reach statistical significance (85 ± 8 mmHg; $p = 0.09$; Fig. 2E). None of the inhibitors showed any effect on the elevated heart rate (Epa: 533 ± 44/min, Lin: 550 ± 34/min, PF: 494 ± 43/min; Fig. 2F).

The serum of endotoxemic mice showed a tenfold increase in the kynurenine/tryptophan ratio ($p < 0.0001$; Fig. 2C) which was attenuated by all three inhibitors (increase under Epa treatment 3.4-fold, Lin: 4.7-fold, PF: 4.3-fold; $p < 0.0001$; Fig. 2G). The analysis of lung tissue confirmed the up-regulation of IDO1 expression after LPS administration (Fig. 2D).

Endotoxemic animals exhibited a notable increase in inflammatory cytokines IL-23, IL-1α, IFN-γ, TNF-α, MCP-1, IL-12p70, IL-1β, IL-10, IL-6, IL-27 and GM-CSF. Application of Epa or PF seemed to modulate this inflammatory cytokine pattern in a complex way.

**Conclusions:** This study confirms the suppression of kynurenine production by Epa, Lin and PF in both a cell and animal model of inflammation and endotoxemia. In addition, administration of Epa or Lin resulted in the attenuation of LPS-induced hypotension, suggesting a potential therapeutic strategy for managing sepsis-associated hypotension.

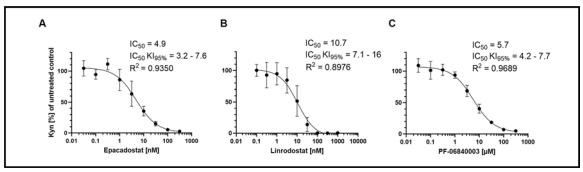

**Fig. I (abstract 001135)** **A–C** Dose–response curves of Epacadostat, Linrodostat and PF-06840003 after challenge of hPAEC with 50 ng/ml IFN-γ; Epa and PF $n = 4$, Lin $n = 6$.

### Treatable traits (TTs) as a novel comprehensive approach to clinical decision-making, management and prognostication in medical intensive care: a retrospective analysis

E. Ennouri[1], S. Ben Othmen[2], K. Meddeb[1], R. Toumi[1], O. Hasnaoui[2], W. Ben Maria[2], T. Nefzaoui[1], M. Zghidi[1], I. Ben Saida[1], M. Boussarsar[1]
[1]University of Sousse, Faculty of Medicine of Sousse, Research Laboratory Heart Failure, LR12SP09, Farhat Hached University Hospital, Medical Intensive Care Unit, 4000, Sousse, Tunisia, Sousse, Tunisia; [2]University of Sousse, Faculty of Medicine of Sousse, Farhat Hached University Hospital, Medical Intensive Care Unit, 4000, Sousse, Tunisia, Sousse, Tunisia
**Correspondence:** M. Boussarsar
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 001136

**Introduction:** At the era of precision medicine, TTs have emerged as an interesting approach that could enhance clinical decision-making procedures and define early therapeutic targets, ultimately improving prognosis by promoting personalized care.

**Objectives:** To describe the typology, prevalence, and distribution of treatable traits among medical critical care patients and to analyze associations with diagnoses and outcomes.

**Methods:** This is a retrospective analysis of prospectively collected data in a medical intensive care unit throughout a 2-year period (2022–2024). All data were collected on a predefined specific data collection form, including patients' characteristics and outcomes. Predefined TTs and their respective biomarkers were identified within the patients' EMRs. Univariate analysis was used to characterize patients and describe the typology, prevalence, and distribution of TTs. Flows and correlations between TTs and diagnoses were performed and depicted in a chord diagram. A binary logistic regression was used to identify TTs independently associated with ICU mortality. TTs with the highest OR were referred to as TTs with leverage effect, and the remaining as TTs of interest.

**Results:** 710 patients were included (respiratory, 456 (64.2%); cardiocirculatory, 88 (12.4%); others, 154 (21.7%)). 239 (33.7%) patients underwent IMV. The mean LOS was 8.54 ± 8.59. 142 (20%) patients were died. 54 TTs were identified in four domains: underlying condition, clinical characteristics, physiological condition, and biological abnormalities. Obstructive ventilatory disorder, rapid-shallow breathing, hyperinflation, and peripheral hypoperfusion were common in this medical intensive care setting. Different TTs correlate with the different diagnostic spectra (Fig. 1). Multivariate analysis identified ten TTs to be independently associated with mortality. Among the strongest, referred to as TTs with leverage effect, were sepsis, peripheral hypoperfusion, arrhythmia, dysoxia, AKI, and seizures (OR [95% CI], p: 3.4 [1.9, 6.1], < 0.0001; 2.7 [1.5, 4.9], 0.001; 4.1 [2.1, 7.9], < 0.0001; 2.8 [1.6, 5], < 0.0001; 3.8 [2.2, 6.6], < 0.0001; 2.9 [1.1, 7.7], 0.036). The remaining TTs were referred to as TTs of interest, respectively, hypoxemia and right heart failure (OR [CI 95%], p: 1.9 [1.1, 3.3], 0.022; 1.9 [1.1, 3.7], 0.036).

**Conclusions:** In this medical ICU setting, the concept of treatable traits encompasses a wide myriad of factors. While some treatable traits are common, others are shared across various diagnoses. When evaluating outcomes, certain traits may be considered of interest, while others may exhibit a leveraging effect.

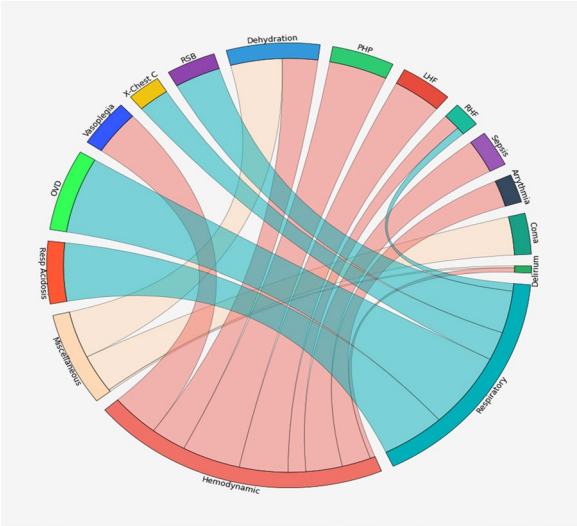

**Fig. 1 (abstract 001136)** Chord diagram plotting correlations between treatable traits and diagnoses

### Lung protective ventilation adherence in two UK intensive care units

B. Millette[1], R. Taylor[1], J. Robbins[1]
[1]Intensive Care, Stoke Mandeville Hospital, Aylesbury, United Kingdom
**Correspondence:** B. Millette
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001137

**Introduction:** Lung protective ventilation is a crucial aspect of the management for patients who require mechanical ventilation in intensive care. It is particularly important in acute respiratory distress syndrome (ARDS). Several national (1, 2) and international guidelines (3) stress the importance of adhering to safe pressures (plateau pressure [Pplat] < 30 cmH2O) and tidal volumes (6-8 mL/kg predicted body weight [PBW]) to improve outcomes in mechanically ventilated patients.
**Objectives:** We undertook an audit of lung protective ventilation in two separate intensive care units within our hospital trust in order to determine our adherence to the standards set out in the UK Faculty of Intensive Care Medicine's Guidelines for the Provision of Intensive Care Services1 (GPICS).
**Methods:** We conducted a retrospective audit of all mechanically ventilated patients admitted to both intensive care units over a 3-month period (Nov 2022–January 2023). We excluded chronically ventilated spinal injuries patients, patients extubated immediately postoperatively and patients without a recorded weight. Data collected included demographics, diagnosis, ICU mortality, presence of ARDS, hours of mechanical ventilation subdivided by respiratory mode (Hamilton ventilator modes used: DuoPAP, Adaptive support ventilation [ASV], airway pressure release ventilation [APRV] and spontaneous), hours of mandatory (i.e. no spontaneous effort) ventilation, hours of Pplat ≥ 30 cmH2O, hours of tidal volume (VT) > 6 mL/kg PBW (for those with ARDS) and hours of VT > 8 mL/kg PBW (for those without ARDS). Statistical analysis was conducted using Fisher's exact test.
**Results:** During the time period in question, 70 patients requiring mechanical ventilation were admitted to our ICUs. 9 patients were excluded (chronically ventilated spinal patients—2, patients extubated immediately post op—5, patients without a recorded weight—2) leaving 61 patients for analysis. The mean age of this population was 62. 41 were medical patients and 20 were surgical patients. 7 patients fulfilled the Berlin 2012 criteria for ARDS of whom 5 received a diagnosis of ARDS during their ICU stay. Patients were ventilated for a median of 60 h and 14 patients (23%) were mechanically ventilated for more than 1 week. Overall mortality was 39%.
ARDS patients had a Pplat ≥ 30 cmH2O for 19.5% of total ventilated hours. This was significantly higher in spontaneous ventilation mode on the ventilator compared to ASV, APRV and DuoPAP. (31.5% vs 11.8% 12.2% and 12.2% respectively, Fisher's exact test $p < 0.001$).
ARDS patients had VT > 6 mL/kg PBW for 96.7% of mandatory ventilated hours and this was not significantly different between ventilator modes.
Patients without ARDS had a Pplat ≥ 30 cmH2O for 2.9% of total ventilated hours. This was significantly lower in spontaneous ventilation mode compared to DuoPAP and ASV. (0.9% vs 4.7% and 3.8%, Fisher's exact test $p < 0.0001$).
Patients without ARDS had VT > 8 mL/kg PBW for 26.8% of mandatory ventilated hours. This was significantly higher in DuoPAP compared to ASV (29.9% vs 16.8% Fisher's exact test $p < 0.0001$).
**Conclusions:** This audit highlighted a worrying lack of adherence to lung protective ventilation in our patient population. This was particularly pronounced in patients with ARDS for whom the vast majority of mandatory breaths delivered were in excess of 6 mL/kg PBW and unsafe pressures were delivered in one in 5 breaths. In non-ARDS patients, the closed-loop ventilation mode ASV was found to be significantly more likely than DuoPAP to deliver safe VT < 8 mL/kg PBW. On the basis of these results, we have implemented a package of remedial interventions including: first-line use of a volume-controlled ventilation mode in ARDS patients, first-line use of ASV in non-ARDS patients and wide ranging multidisciplinary education. We plan to reaudit in the near future to ensure that these measures have been successful in improving the delivery of lung protective ventilation in our intensive care units.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001139

**Introduction:** Optimizing ventilation strategies is crucial in critically ill COPD patients on NIV. Pulmonary hyperinflation may worsen the already compromised gas exchange by promoting alveolar dead space through alveolar capillary compression. Ventilatory ratio (VR), offering insights into gas exchange dynamics, is correlated to increased dead space ventilation. Despite the rationale supporting the use of VR as a prognostic marker in acute exacerbation of COPD (AECOPD), its clinical utility in guiding NIV management remains incompletely elucidated.
**Objectives:** To investigating the utility of ventilatory ratio trends in predicting NIV outcomes in COPD patients admitted to the ICU.
**Methods:** This is a preliminary analysis of an ongoing prospective observational trial in the medical ICU of Farhat Hached teaching hospital, Sousse, Tunisia, including all consecutive patients with AECOPD requiring NIV. The trial started on March, 1st, 2022 and the current analysis is performed after 22 months, on December 31st, 2023. Demographic and baseline clinical characteristics were collected. Clinical parameters, NIV-related variables and arterial blood gases were recorded at the start of NIV and hourly until H4. NIV failure was defined as the need for invasive mechanical ventilation. Receiver operating characteristic (ROC) curve analysis was employed to evaluate discriminative properties. Chi-square was used to compare categorical variables and Mann–Whitney *U* test to compare continuous variables. Areas under the ROC curves were compared to examine discriminative properties and identify cutoffs for mortality prediction.
**Results:** 200 were included in this preliminary analysis. Mean ± SD age, 67.6 ± 10.1 years; Charlson Comorbidity Index, 4.1 ± 1.4; mainly GOLD E, 163 (81.5%); baseline dyspnea mMRC 3–4, 124 (62%); under home NIV, 57 (28.5%) and long-term oxygen, 42 (21%). On ICU-admission: SAPS II, 28.9 ± 5.6; high work of breathing, 135(67.5%); hypercapnic encephalopathy, 181 (90.5%); pH, 7.30 ± 0.1 and PaCO2, 66.6 ± 13.3 mmHg. NIV failure, 58 (29%); death, 17 (8.5%). On univariate analysis, VR was significantly associated to NIV failure (median [IQR]) (overall, NIV success group, NIV failure group, p) at H1 of NIV (3.3 [2.7–4.1], 3.3 [2.6–4.1], 3.6 [3.1–4.2], $p = 0.035$); H2, (3.5 [2.8–4.3], 3.3 [2.7–3.9], 4.1 [3.5–5.3], $p < 0.000$); H3, (3.1 [2.6–4.4], 2.9 [2.5–3.9], 4.1 [3.3–5.9], $p < 0.000$) and H4, (3.1 [2.4–4.2], 2.8 [2.3–3.4], 4.6 [4–7.3], $p < 0.000$). ROC curves for VR at H2 and H4 are displayed in Figure 1. Cutoff values for VR at H2 and H4 were, respectively, 3.86 and 3.61. At H2 VR < 3.86 significantly associated to NIV success [86 (81.1%) vs 20 (18.9%), $p = 0.001$] as well as at H4, VR < 3.61 [116 (92.8%) vs 9 (7.2), $p < 0.000$].
**Conclusions:** In this preliminary analysis, we found that elevated VR values were significantly associated with NIV failure in critically ill COPD patients, with identified cutoff values providing potential prognostic markers at different time points during NIV initiation.

## Disparities in arterial blood gas laboratory test ordering by race, ethnicity, and sex persist beyond illness severity

J. Matos[1], S. Hao[1], M. Alwakeel[2], D. Naamani[3], L. A. Celi[4], C. Hong[5], A. K. I. Wong[1]

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001141

**Introduction:** The accuracy of pulse oximetry readings varies across races, which underscores the importance of routine arterial blood gas (ABG) testing, the gold standard for assessing arterial oxygen saturation. This study investigates the occurrence, timing, and frequency of ABG tests among critically ill patients.
**Methods:** The study analyzed data from three intensive care unit (ICU) electronic health records databases: MIMIC-III, MIMIC-IV, and eICU-CRD, encompassing records from 2001 to 2019 from 209 U.S. hospitals or ICUs. The analysis included the' first ICU admission of adult patients lasting longer than 12 h. Patients with missing demographic information or sequential organ failure assessment (SOFA) score were excluded.
The study evaluated three primary outcomes related to ABG tests during ICU admissions: the incidence of ABG test; the time to first ABG test; and the frequency of subsequent ABG tests. We adjusted for potential confounders, including illness severity (SOFA), hospital practice (categorized by US region, number of beds, and teaching status), and demographics (age, sex, race and ethnicity). To assess the likelihood of undergoing an ABG test, multivariate logistic regression models were used to compare patients with and without ABG tests across the above-mentioned covariates. The analysis of time until the first AGB test employed fine-gray competing risk models, calculating hazard ratios while considering ICU discharge and mortality as competing risk, with right-censored observations. Finally, multivariate linear regressions were used to compare the frequency in ABG testing among ICU admissions with at least one ABG test.
**Results:** 184,961 ICU stays were considered (MIMIC-III: 14,427; MIMIC-IV: 53,150; eICU-CRD: 117,384). 3,798 (2.1%) patients were Asian, 22,324 (12.1%) Black, 7,439 (4.0%) Hispanic/Latino, and 151,400 (81.9%) White. The median age was 66.0 years [IQR: 54.0, 77.0]; the median SOFA at admission was 4.0 [IQR: 2.0, 6.0]. Among these patients, 51,971 (28.1%) had an ABG collected, with the first ABG test occurring at a median of 4.9 [IQR: 1.3,15.4] hours after admission, and a median average rate of 0.9 [IQR: 0.4,1.6] ABGs per day. ICU mortality was observed in 6,310 (3.4%) patients.
Disparities were noted in the likelihood of undergoing ABG testing among racial groups and sex ($p < 0.0001$). Compared to White and male patients, Asian, Black and female patients were significantly less likely to undergo ABG testing [OR (95% CI): Asian, 0.848 (0.783–0.920); Black, 0.770 (0.743–0.799); Female, 0.914 (0.894–0.935)]. In addition, these groups experienced delays in the first ABG test [HR (95% CI): Asian, 0.860 (0.804–0.919); Black, 0.786 (0.762–0.811); female, 0.927 (0.910–0.944)]. Among patients with at least one ABG, Black and female patients had lower ABG ordering rates [coefficients (95% CI): Black, −0.093 (−0.130, −0.056); female, −0.074 (−0.097, −0.051)].
**Conclusions:** Black and female patients were less likely to have an ABG ordered, had a greater delay to the first ABG, and a lower rate of ABGs, compared to White and male patients.
Clinical implications:
Considering recent literature on similar disparities regarding oxygen therapy and associated outcomes, our findings add a new layer of complexity to inequities in oxygen management.

### An analysis of potassium supplementation practices in a large cardiac surgical intensive care service in London, UK

K. Knaak[1], M. Mutalemwa[1], E. Schellhase[1], M. Miller[1], R. Sloss
[1]College of Pharmacy, Purdue University, West Lafayette, United States of America
**Correspondence:** R. Sloss
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001142

**Introduction:** Serum potassium monitoring and supplementation in intensive care (ICU) settings is well established to improve outcomes (1). In our service, a target a range of 4.5–5.0 mmol/L is recommended to reduce the incidence of post-operative atrial fibrillation (2).
While potassium supplementation has proven benefit, use of concentrated potassium products via the intravenous (IV) route is associated with patient safety risks, and has significant cost and environmental consequences (3).
This service evaluation reviewed potassium supplementation practices during the first 72 h of ICU admission following cardiac surgery.
**Objectives:**
1. Evaluate the frequency of potassium supplementation and the potassium level incrementation achieved.
2. Determine the choice of route for potassium supplementation in the first 24 h, compared to 24–72 h following ICU admission.
3. Determine the cost impact of potassium supplementation and potential cost-saving opportunities.

**Methods:** This study was a retrospective evaluation investigating data from surgical ICU admissions during a 2-month period.
Data were extracted from electronic records, de-identified, password protected, and stored in Microsoft Excel. Data included: potassium formulation(s) (route and dose) during first 72 of admission, and potassium levels (before and throughout the following 12 h). Data were analysed using Microsoft Excel.
**Results:** During the study period, 45 patients (86.5%) received potassium supplementation, with each patient receiving an average of 5.4 doses and most doses administered via IV infusion* (Figure 1).
Patients receiving IV potassium had an average pre-supplementation potassium of 3.99 mmol/L and increased to 4.29 mmol/L at 6–12 h (average increase: 0.296 mmol/L). Patients receiving enteral potassium** had an average pre-supplementation potassium of 3.92 mmol/L and increased to 4.27 mmol/L at 6–12 h (average increase: 0.352 mmol/L).
Expenditure on IV potassium products was £1,686.42 (243 doses), while in this same period, £2.09 was spent on enteral products (15 doses).
*IV potassium infusion administered as 20 mmol in 100 mL sodium chloride 0.9%.
**Enteral potassium doses ranged from 12 mmol to 36 mmol per dose.
**Conclusions:** Potassium supplementation occurred routinely with a comparable increase in potassium level observed with both IV and enteral formulations. Analysis of a greater sample size may produce more reliable efficacy comparisons.
While most patients would have had an enteral route available within 24 h of admission, most patients remained on IV potassium formulations throughout the 72-h period.
In this cohort, switching half of IV potassium doses given in the 24–72 h period to enteral would have reduced total expenditure by 25% (£415.84).
Although not defined in this study, the environmental impact of IV infusions is also considerable, given the number of doses used.
Greater use of enteral supplementation could significantly reduce cost, plastic waste and patient safety risk while having a comparable clinical effect.

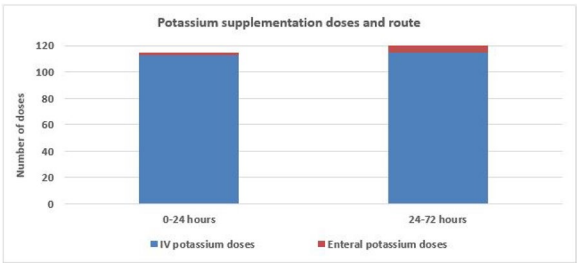

**Fig. 1 (abstract 001142)** Number and administration route of potassium supplementation doses given from 0 to 72 h of admission to cardiac surgical ICU

### SepsisSCA: a comprehensive database integrating single-cell transcriptome atlas of sepsis

W. Huang[1]
[1]ICU, Zhongda Hospital, Nanjing, China
**Correspondence:** W. Huang
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001143

**Introduction:** Sepsis is a leading cause of mortality in the intensive care unit. To date, treatment of sepsis is limited by heterogeneity of immune response and incomplete description of cellular atlas1. Prior bulk-sequencing have identified the host-gene expression profiling of sepsis, but have not resolved signatures in transcriptional states of specific cell types2. Recent advances in single-cell RNA sequencing (scRNA-seq) technology provides an unprecedented opportunity to comprehensively characterize the heterogeneity of immune system in sepsis but poses computational challenges on integrating and utilizing the massive published datasets to inform treatment. Thus, there is an urgent need to build a dedicated resource to decode the various function of immune cells and parenchymal cells in sepsis.
**Objectives:** We developed SepsisSCA (Sepsis Single Cell Atlas), the dedicated database that aims to comprehensively explore the cellular signatures of sepsis at single-cell level.
**Methods:** We systematically collected sepsis-related scRNA-seq datasets in human and mouse from Sequence Read Archive (SRA), Gene Expression Omnibus (GEO). For each dataset, we carefully read the original paper, if available, and extracted the metadata, including the tissue types and potential pathogens, sites of infection. For each dataset, we performed several basic analysis of high-quality cancer single-cell expression, including PCA and t-SNE analysis.
**Results:** We developed SepsisSCA, a large-scale curated database that aims to comprehensively explore distinct functional cellular states of sepsis at single-cell level. SepsisSCA integrates single-cell transcriptomic profiles of nearly 500 thousand cells from 12 high-quality sepsis datasets across 6 tissue types. All the data were uniformly processed with a standardized workflow, including quality control, batch effect

removal, clustering, cell-type annotation, differential expression analysis and functional enrichment analysis. SepsisSCA provides interactive gene expression visualization across multiple datasets at the single-cell level or cluster level, allowing systematic comparison between different cell-types, patients, tissue origins.
**Conclusions:** In summary, SepsisSCA provides a user-friendly interface for systematically visualizing, searching and downloading gene expression atlas in the sepsis from multiple tissues, enabling fast, flexible and comprehensive exploration of sepsis.

### Stratifying risk in ACLF-3 patients for liver transplantation: the impact of cardiac and respiratory failures on 1-year post-transplant outcomes

H. Wozniak[1], X. Zhao[2], S. Chen[2], M. Bhat[2]
[1]Département de Médecine Aigue, Hôpitaux Universitaires de Genève (HUG), Genève, Switzerland; [2]Multi-Organ Transplant Program, Toronto General Hospital, University Health Network, Toronto, Canada

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001144

**Introduction:** Patients with acute-on-chronic liver failure grade 3 (ACLF-3) are a severely ill patient group [1–3], with 1-year post-liver transplantation (LT) survival rates varying between 50 and 80% [1, 5, 6]. This suggests that some ACLF-3 patients may be unsuitable candidates for LT, a challenge highlighted in the latest European Association for the Study of the Liver (EASL) guidelines [5].
**Objectives:** We aimed to investigate whether certain organ failure (OF) combinations in ACLF-3 patients are associated with higher 1-year post-LT mortality, to improve risk assessment and LT candidacy decisions. We hypothesized that combinations involving circulatory and/or respiratory failures would present worse outcomes. Beyond survival, we also sought to evaluate 1-year post-LT functional status according to OF types.
**Methods:** We used the Scientific Registry of Transplant Recipients (SRTR) database, selecting patients who met the ACLF-3 criteria as per the CLIF-EASL definitions at the time of LT. We categorized patients based on their OF type at the time of LT into three groups: 1) cardiac failure with other OF; 2) both cardiac and respiratory failures with other OF; 3) all other possible combinations. We conducted Kaplan–Meier survival analysis and multivariable Cox regression models adjusting for sex, age, and the number of OF. For functional status 1-year post-LT, we used the Karnofsky Performance Status and performed multivariable logistic regression models, adjusting for sex, age, and pre-LT functional status.
**Results:** We included 5,054 ACLF-3 patients, among which 33.7% were women. Within this cohort, 14% (728/5,054) died within 1-year post-LT. The distribution of patients across the study groups was: 429 patients had cardiac failure with other OF; 1,268 had both cardiac and respiratory failures with other OF; and 3,357 had all other possible combinations of OF. No patients had respiratory failure without accompanying circulatory failure. Our Kaplan–Meier analysis (Figure 1) and Cox models showed that patients with both cardiac and respiratory failures with other OF experienced higher post-LT mortality compared to the other groups. The 1-year hazard ratio (HR) for death for patients with both cardiac and respiratory failures with other OF was 1.51 (95% CI 1.07–2.13, $p=0.02$), compared with those with cardiac failure plus other OF; and 1.27 (95% CI 1.03–1.57, $p=0.02$), compared with those with all other possible combinations of OF. Within the group of cardiac, respiratory, and other OF, there was no significant difference in HR between any combination. Having both cardiac and respiratory failures with other OF was associated with worse functional status compared with those with cardiac failure plus other OF (OR 1.35, 95% CI 1.16–1.52, $p<0.01$).
**Conclusions:** Our findings highlight the importance of OF combinations in assessing LT candidate risk in ACLF-3 patients. Specifically, having both respiratory and circulatory failure at LT time is a poor prognostic sign, regardless of the total number of OF.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001145

**Introduction:** Neurological complications represent significant challenges in adult patients undergoing treatment with extracorporeal membrane oxygenation (ECMO) support [1]. According to the Extracorporeal Life Support Organization (ELSO), neurological complications in patients on ECMO support are defined as brain death, seizures, ischemic cerebral vascular events, intracerebral hemorrhage, or diffuse cerebral ischemia [2]. In this retrospective study, we aim to shed some light on the outcome and association between the primary diagnosis of patients in ECMO and neurological complications.
**Objectives:** To characterize the neurological complications and primary diagnosis of adult patients treated with ECMO in a midsize ECMO center.
**Methods:** We conducted a retrospective cohort study based on the review of the clinical records of all patients treated with ECMO in a referral ECMO centre in the Lisbon area. The timeframe for this study is January 2016 until December 2022.
**Results:** We identified 17 in 226 (7.5%) patients with neurological complications, 12 were male (70%). The mean time on ECMO support in days was 22 days with the maximum of 86 days. All patients identified with neurological complications were treated with veno-venous (VV) ECMO. The main diagnosis was pneumonia ($n=16$) and pulmonary embolism ($n=1$). The main neurological complications were intracranial haemorrhage ($n=10$) ischemic stroke ($n=3$) and seizures ($n=4$). A total of 9 patients died (52%). To assess the association between primary diagnostic and neurological complications in patients treated with ECMO, we have apply the Fisher's Exact Test and $p \approx 0.4118$.
**Conclusions:** In this cohort of adult ECMO patients, neurologic complications were associated with high morbidity and mortality, and in ao population, only related with VV ECMO.
We conclude that there is not enough evidence to conclude the existence of a significant association between the primary diagnosis (pneumonia vs pulmonary embolism) and the development of neurological complications during ECMO support.
Our findings emphasize the relevance of vigilant monitoring and proactive management strategies in order to mitigate these complications. Further research is of paramount to address this aspect and improve patient management.

**Correspondence:** B. François
***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001146

**Introduction:** Sepsis management requires accurate and timely diagnosis which remains clinically challenging. In this context, biomarkers might facilitate the identification of patients suffering from sepsis. Pancreatic stone protein (PSP), a remote damage sensing protein, demonstrated promising sensitivity (Se) and specificity (Sp) for sepsis diagnosis. In the study AB-PSP-001 [1], PSP showed a strong association with the clinical diagnosis of sepsis, with a continuous increase in PSP level up to 3 days before diagnosis compared to C-reactive protein (CRP) and PCT.
**Objectives:** This post-hoc analysis aims to assess the Se and Sp of PSP as a predictive tool for sepsis diagnosis before the onset of clinical symptoms with a risk stratification grid at different cutoff levels of PSP and its combination with CRP on the day of sepsis onset. An independent endpoint adjudication committee of 3 ICU experts blinded to PSP, CRP and PCT results evaluated all patients for sepsis onset.

**Methods:** This study involved 14 ICUs in France, Switzerland, Italy, and United Kingdom. Adult ICU patients at risk of nosocomial sepsis and expected to stay at least 7 days and/or to be mechanically ventilated for at least 5 consecutive days were included. A total of 243 participants (190 non-septic and 53 septic patients) were recruited. PSP was measured daily.
We evaluated the Se and Sp of PSP measurements and devised a risk stratification grid (Table 1) for sepsis diagnosis by employing various PSP cutoff levels that could be useful in clinical practice. PSP combined with CRP on the day of sepsis (Day 0) was also evaluated.
**Results:** PSP level ≥ 300 ng/ml significantly enhances the likelihood of sepsis diagnosis with a Sp as high as 83%. In addition, if the level of PSP is ≤ 100 ng/ml prior to the onset of sepsis, it is likely to rule out sepsis. These findings indicate that PSP has potential utility as a predictive biomarker for sepsis.

**Table 1 (abstract 001146)** Conversion table of PSP concentrations into classes expressing sepsis risk. Se and Sp from 3 days before the endpoint adjudication committee diagnosis of sepsis

| PSP concentration [ng/ml] | Risk level | | Day-3 | Day-2 | Day-1 | Day 0 |
|---|---|---|---|---|---|---|
| ≥ 100 | Moderate risk of sepsis | Se | 58% | 67% | 76% | 81% |
| | | Sp | 43% | | | |
| ≥ 200 | High risk of sepsis | Se | 42% | 31% | 57% | 55% |
| | | Sp | 74% | | | |
| ≥ 300 | Very high risk of sepsis | Se | 33% | 27% | 39% | 42% |
| | | Sp | 83% | | | |

PSP combined with CRP on the day of sepsis diagnosis also shows promising result with an improved ROC curve (Figure 1). This combination could be a useful biomarker association.
**Conclusions:** The results of this post-hoc analysis of the AB-PSP-001 study highlight the potential of PSP as a practical tool for early diagnosing sepsis. PSP + CRP could enhance the current diagnostic procedures for sepsis by providing a more accurate diagnosis. Further analyses are needed.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001147

**Introduction:** Lung ultrasound (LUS) and the venous excess ultrasound score (VExUS) are promising tools for evaluating fluid overload (1, 2). LUS assesses pulmonary oedema, whereas VExUS assesses venous congestion. These are similar yet different entities with a possible common pathophysiological pathway. It is unknown, how many critically ill patients with pulmonary oedema also have venous congestion.
**Objectives:** The aim of this study is to investigate the incidence of positive and negative LUS and VExUS findings in the intensive care unit (ICU) and to describe the incidence of 30-day mortality, need for mechanical ventilation and renal replacement therapy for different scores.
**Methods:** This is a preliminary analysis of an ongoing prospective cohort study performed in a tertiary ICU in Amsterdam, the Netherlands. All patients who were expected to be admitted for more than 24 h were eligible for this study. Patients were excluded in case of: a BMI > 40 or where the ultrasound was not obtainable and with a previous history of interstitial lung disease, venous porta obstruction or similar diseases. Ultrasound examinations were performed by a trained operator within the first 48 h of admission. A LUS score of ≥ 13 and a VExUS score of ≥ 2 were considered positive (3, 4). Thus, identifying 4 phenotypes: 1. positive LUS and VExUS, 2. positive LUS (and negative VExUS), 3. Positive VExUS (and negative LUS); and 4. Negative ultrasound findings (negative LUS and VExUS). Descriptive statics were used to describe the incidence of positive and LUS and VExUS findings, mortality and use of renal replacement therapy (RRT).
**Results:** A total of 116 patients were included in this analysis. Median age of the overall cohort was 68 [56–74], median sofa score was 7 [5–10] and 65% were male. Characteristics per phenotype are shown in Table 1. The ultrasound negative phenotype was most frequently encountered in 79 (68%) patients, followed by the positive LUS phenotype 25(22%), followed by the positive VExUS and LUS and positive VExUS phenotype with 6 (5%) patients, as shown in Figure 1. The highest mortality (50%) was encountered in VExUS positive patients, followed by the LUS and VExUS positive phenotype 33%. RRT was used least often in the positive LUS phenotype (12%) and comparably often in the other phenotypes (~ 17%). Results are limited by the small sample size of some of the groups.
**Conclusions:** Incidence of positive LUS and VExUS within 48 h of admission is relatively rare in a general ICU population. However, patients with a positive VExUS and a positive or negative LUS might be at a higher risk of worse outcomes.

**Introduction:** The study, prevalence and concern about knowledge of neurological assessment has allowed us to improve the identify the neurological status of our patients after a fatal event, highlighting cardiorespiratory arrest. This advance will allow us to improve the care necessary for a better recovery, even to reduce the rate of the greatest negative event such as the death of this type of patient and to be able to balance the pessimistic prognosis. The main cause of death in these patients is due to the decision to limit or adapt life-sustaining treatment (ALST). Current guidelines recommend a strategy of combining several predictors of poor prognosis included in the examination and complementary tests (EEG, neuroimaging and biomarkers).
**Objectives:** Analyze neuro-prognosis taking the Glasgow Outcome Score as a reference (3–5: good, 1–2: bad).
Analyze the role of enolase as a predictor of neurological prognosis.
**Methods:** Observational, retrospective, single-center study. Patients admitted: recovered CRP since January of 2019, > 18 years are included. We excluded patients with head trauma.
**Results:** N: 127 patients (31.5% women and 68.5% men), mean age 61.18 years (minimum age 21 and maximum age 87). 50.4% occurred in the hospital and 48.8% out-of-hospital settings. Cause: 29.1% due to ACS, 27.6% due to respiratory causes, 5.5% poisoning, 29.1% arrhythmia, 6.3% hemorrhage and 2.4% surgical complication. 32.3% had a good neurological prognosis, with recovery, with the remaining 67.7% having a poor prognosis (of these, 81.4% had ALST performed in the ICU, 7% in the ward, and 11.6% had sequelae). In 36%, the decision for ALST was for neurological involvement, in 50% due to FMO and in 2.3% due to different causes. To make this decision, different predictors of poor prognosis were combined, without being able to establish a clear pattern; 100% of patients with ALST due to neurological involvement had a score > 3 on the GOS. Average limitation time was 3.71 days. Determination of enolase did not follow an established protocol; for this reason, we analyzed the maximum determination recorded in all patients during their evolution, with a general mean of 59.91, this mean being 73.81 in patients with a poor prognosis and 36.80 in patients with a good evolution. Enolase has been recorded in 33 patients who had a good prognosis and 23 patients in whom ALST was decided due to neurological involvement, with the maximum enolase peak being 30.80 in the first group and 82.15 in the second one. We performed ROC Curve with area under the curve of 0.848 so we can conclude that high enolase values can be used to evaluate neurological involvement.
**Conclusions:** Enolase can be a good predictor of poor neurological outcome, so together with the clinical examination (GOS) and other complementary tests such as EEG, N20 and neuroimaging, it can facilitate the decision-making of ALST in patients with poor outcome.

**Introduction:** In mechanically ventilated (MV) patients, diaphragm dysfunction is associated with a higher risk of weaning failure. Ultrasound studies have shown that decreased diaphragm excursion (DE) at the initiation of the spontaneous breathing trial (SBT) could identify patients at risk of weaning or extubation failure. DXT (Respinor, Norway) is a novel ultrasound-based medical device that provides continuous diaphragm monitoring of DE.
**Objectives:** The aim of the study was to validate whether DE measured with DXT could identify patients at increased risk of weaning failure and extubation failure.
**Methods:** Two multinational, multicenter, prospective, blinded studies (DE-RISK WF and DE-RISK WF II) were performed in 8 European hospitals. Data were pooled for this analysis. Patients on MV who met SBT criteria were enrolled. Continuous DE measurements were conducted during the patients' first SBT. Median DE during the second minute of the SBT was used in the analysis. The primary outcome was weaning failure, defined as SBT failure or reintubation within 48 h following extubation. The secondary outcome was extubation failure rate defined as reintubation within 48 h of extubation. Diaphragm dysfunction was defined as DE < 1.1 cm (DE RISK WF I) or < 1.0 cm (DE-RISK WF II) for the primary outcome and as DE < 1.1 cm for the secondary outcome. The hypothesis was that patients with DE under the threshold will have significantly higher rate of weaning and extubation failure.
**Results:** 304 patients were included in the analysis. 73 patients failed the SBT. Of the 231 patients who succeeded the SBT, 182 were extubated on the same day. Among them, 17 were reintubated within 48 h. Weaning failure rate was 43%. DE was 1.6 cm in weaning success patients and 1.5 cm in those who failed weaning ($p = 0.235$). Diaphragm dysfunction (DE < 1.1 or 1.0 cm) was observed in 44% of weaning success patients and 45% of weaning failure patients ($p = 0.906$), resulting in a relative risk of 1.0 (95% CI 0.8–1.3, $p = 0.906$) for weaning failure. Extubation failure rate was 9%. DE was 1.4 cm in extubation success patients and 0.8 cm in those who failed extubation ($p < 0.001$). Diaphragm dysfunction (DE < 1.1) was observed in 44% of extubation success patients and 88% of extubation failure patients ($p = 0.0004$), resulting in a relative risk of 8.2 (95% CI 1.9–35.1, $p = 0.004$) for extubation failure. No adverse device effects were observed.
**Conclusions:** Continuous monitoring of DE with DXT during the SBT can identify patients at increased risk of extubation failure.

**Introduction:** In Europe, intensive care unit (ICU) patients older than 80 years have a 30-day mortality rate of 30%, and many survivors are readmitted to hospital or institutionalized [1–3]. It is important to assess therapeutic benefit for elderly patients against their frailty [4–7]. Clinical Frailty Scale (CFS) is a clinically focused frailty screening tool that effectively predicts short-term mortality in elderly ICU patients [6]. However, its use to predict long-term outcomes in this population is less established.
**Objectives:** This study aims to determine if pre-admission assessment of CFS and the health-related quality of life (HRQOL) instrument EQ-5D-5L in elderly patients is associated with 12 months outcome for frailty, HRQOL and mortality.
**Methods:** This is an ongoing observational study that include patients from five Norwegian ICUs, four at university hospitals and one at a local hospital. It plans to enroll 350 patients aged 65 years or older requiring ≥ 24 h of invasive mechanical ventilation.
Patients are assessed for pre-admission frailty (CFS) and HRQOL (EQ-5D-5L) at baseline, as well as 3 and 12 months post-inclusion, with next of kin interviewed if necessary. Follow-ups are conducted via questionnaires and telephone interviews. Post-ICU mortality data are obtained from the National Population Register and medical journals. Secondary measures include patient characteristics, disease severity, ICU treatment and discharge destination.
**Results:** Preliminary results from 278 included patients with a mean age of 74 years (range 65–88), 33% of whom are women, are presented. 96 patients (25%) were excluded, mainly due to missed for inclusion, non-consent and foreign tourists. Cardiac disease was the predominant comorbidity. Only 9 patients (3%) had treatment limitations prior to ICU admission.
At baseline, 147 patients (55%) were living without frailty (CFS 1–3), 114 (42%) with mild to moderate frailty (CFS 4–6) and 7 (3%) with severe frailty or terminal illness (CFS 7–9). The median CFS-score was 3, increasing at 3 and 12 months post-inclusion (Fig. 1). Baseline HRQOL, measured by EQ-5D-5L VAS (visual analogue scale) was 66 (SD = 23). The EQ-5D-5L score for physical function variables was consistent with the frailty score (Fig. 2).
After hospital discharge, 93 patients (33%) had a rehabilitation stay and 20 (7%) were readmitted to the ICU. 123 patients (44%) have died during the study period, and in-hospital mortality is 35%. The preliminary odds of mortality seem to be affected by baseline CFS and age.
**Conclusions:** Preliminary data underscore the utility of CFS and EQ-5D-5L to describe the long-term trajectory of elderly ICU patients.

Frailty prior to severe critical illness seem to influence long-term prognosis. Given the high mortality rate in this cohort, frailty screening upon ICU admission could support patient selection, treatment strategies and long-term follow-up.

The study is registered in ClinicalTrials.gov; NCT06012942.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001151

**Introduction:** Valproic acid (VPA) is recognized for its rapid and extensive oral absorption, boasting nearly 100% bioavailability, with approximately 90% of VPA binding to serum plasma proteins, primarily albumin. However, this binding percentage may alert in the presence of hypoalbuminemia or due to competition with other medications, potentially resulting in toxicity and side effects. Therapeutic drug monitoring (TDM) is crucial to ensure efficacy and safety, although the effect of adjusted valproic acid levels has been extensively studied, there is a lack of data regarding patient outcomes in individuals with hypoalbuminemia receiving VPA.
**Objectives:** This study aims to evaluate the impact of adjusted valproic acid levels in predicting effectiveness and potential adverse effects compared to total valproic acid levels in patients with hypoalbuminemia.
**Methods:** This single-center retrospective cohort study investigated adult patients with hypoalbuminemia (albumin level < 35 gm/L) who experienced seizures or epilepsy and received valproic acid treatment between January 1, 2016, and December 31, 2022. Eligible patients maintained therapeutic levels of total valproic acid, with albumin levels measured within 48 h of valproic acid administration. Adjusted

valproic acid levels were calculated based on albumin levels using a Hermida and Tutor derived equation. Patients were followed from the initial therapeutic level of valproic acid until either death or hospital discharge. The primary aim of the study was to assess the impact of adjusted valproic acid levels on predicting effectiveness and potential adverse effects compared to total valproic acid levels. Statistical analyses were performed using receiver operating characteristics (ROC) curves, and differences in the area under the curves (AUCs) by the DeLong method. Safety outcomes such as hepatotoxicity, hyperammonemia, hyponatremia, and thrombocytopenia were considered as primary endpoints, while secondary endpoints included predicting seizure occurrence, status epilepticus, and the requirement for supplementary antiepileptic medications during hospitalization. Approval for the study was granted by the King Abdullah International Medical Research Center (KAIMRC) in January 2023 (reference number: NRC23R/019/01).

**Results:** Out of 1622 screened patients, 71 with hypoalbuminemia received VPA. The ROC analysis results showed that the threshold of aVPAc (154.19 mg/dL) had higher sensitivity (86% vs. 71%) and lower specificity (47% vs. 72%) compared to the tVPA at a threshold of (67.53 mg/dL) in predicting hepatotoxicity with (ROC-AUC 0.64 [CI: 0.41–0.86; $p = 0.51$]; however, the outcome was not statistically significant. In addition, five patients representing (23%) had significant hyper-ammonia during their admission with aVPAc at a threshold level of 188.00 mg/dL, and they exhibited higher sensitivity (100% vs. 40%) and lower specificity (82% vs. 88%) in predicting hyperammonemia compared to the tVPA with a threshold of (74.32 mg/dL) (ROC-AUC 0.95 [CI: 0.87–1.0; $p = 0.02$]. Moreover, 55% of the patients receiving valproic acid required additional anti-seizure, and at aVPAc threshold (131.54 mg/dL) compared to the tVPAc at level (60.32 mg/dL), aVPAc show lower sensitivity (44% vs. 64%) and higher specificity (84% vs. 72%) with (ROC-AUC 0.69 [CI: 0.57–0.82; $p = 0.04$]. In regards to the other outcomes, no statistically significant differences were observed for hepatotoxicity, hyponatremia, or seizure occurrence.

**Conclusions:** Adjusted valproic acid concentrations (aVPAc) have demonstrated increased sensitivity and specificity in predicting hepatotoxicity and hyperammonemia compared to total valproic acid concentrations (tVPAc). This highlights the potential of aVPAc for enhancing safety monitoring in hypoalbuminemic patients.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001155

**Introduction:** Fibrinolysis alterations are very common in septic patients and are associated with worse outcome; however, there is currently no gold standard for the diagnosis of fibrinolysis impairment. The viscoelastic device ClotPro® provides the opportunity to detect fibrinolysis alterations, thanks to the tissue plasminogen activator (TPA) test.

**Objectives:** The POCEFIS study investigates the prevalence of fibrinolysis impairment in septic patients, defined as a prolonged ClotPro® TPA lysis time. The reference range for TPA lysis time is established within a cohort of healthy volunteers. Secondary objectives include examining the relationship between fibrinolysis abnormalities assessed by ClotPro® and standard coagulation tests (PT, aPTT, platelets, fibrinogen, D-dimer), as well as other specific markers (PAI-1, PAI-1 activity, TAFI, protein-C, protein-S, Factor XIII), degree of inflammation (PCR, PCT, IL-1β, IL-6, IL-8, TNF-α, ADM), diagnostic DIC scores, prevalence of multiorgan failure, length of stay in the intensive care unit (ICU), and ICU mortality. Moreover, the study aims to assess the evolution of fibrinolysis abnormalities over time in relation to the course of sepsis.

**Methods:** This is a nonpharmacological, single-center, prospective, cohort study. It includes patients over 18 years old admitted to the General ICU of IRCCS Ca' Granda Ospedale Maggiore Policlinico in Milan, Italy, with sepsis or septic shock, requiring vasopressors to maintain a MAP $\geq$ 65 mmHg despite adequate fluid resuscitation. Patients must be enrolled within 12 h of sepsis/septic shock diagnosis. Exclusion criteria encompass known coagulation disorders, ECMO, and the use of oral anticoagulants. A ClotPro® TPA test is performed at admission and on days 1, 2, 3, and 7. Specific markers of coagulation and inflammation are tested at enrollment and on day 7. Routine laboratory tests are performed daily. The study ends at 28 days or upon ICU discharge.

**Results:** From January 20th to March 30th 2024, 13 patients were enrolled. 54% were female, with a mean age of 68.8 years. Gastrointestinal tract was the most common site of infection (46%), followed by the urinary tract (31%) and lower respiratory tract (15%). Patients' severity was calculated by SOFA score obtaining a median of 9.

ClotPro® TPA decreased during the first 24–48 h, indicating impaired fibrinolysis. Progressive TPA maximum lysis normalization was observed in subjects with favorable outcome, differently from those who died in the ICU ($n = 3$, 23%) (see Graphic 1).

**Conclusions:** The ClotPro® TPA test may be a feasible system that may enable the assessment of fibrinolysis impairment in septic patients. The findings of this study hold promise for advancing early diagnosis, prognostics stratification, and the development of targeted therapeutic options in the field of coagulation for septic patients.

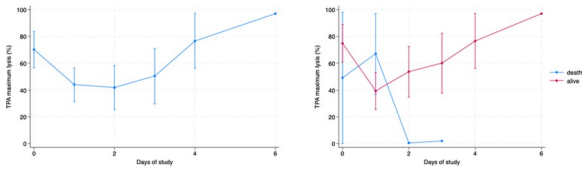

**Fig. (abstract 001155)** TPA maximum lysis over time

### Utility of the cerebrospinal fluid lactate as a biomarker for neurological disease and central nervous system bacterial infections

M. Lladó Vilar[1], S. Foradada Ubach[1], J. M. Morales Pedrosa[2], B. Vélez Jaigua[1], A. Taché Sala[1]

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):** 001156

**Introduction:** Cerebrospinal fluid (CSF) lactate can be elevated in several neurological disorders. Lactate is an excellent biomarker for diagnosing any neurological disease (ND) and specifically in central nervous system bacterial infections (CNSBI), because its concentration in CSF depends upon cerebral anaerobic glycolysis and is independent to plasma concentration (normal CSF lactate values: 1.2–2.7 mmol/L).
**Objectives:** To evaluate the utility of CSF lactate as a biomarker of any ND or CNSBI.
- To determine a cutoff point for CSF lactate for ND and CNSBI.
**Methods:** Observational and prospective study of patients admitted to 2 Intensive Care Units (ICU) from July 2017 to March 2024, aged 18 years or older who underwent CSF sampling. Demographic variables, ICU mortality and CSF parameters were analysed. Patients were categorized into various subgroups based on their final diagnosis. ND was defined as pathological findings in clinical examinations or complementary tests.
**Results:** We examined 195 CSF samples from 169 patients, with a male majority (67.2%) and a mean age of 55.79 ± 16.7 years. The mortality rate was 27.13%. CSF lactate, glucose, leukocytes and proteins were recorded.
Patients were divided into 2 groups: ND ($n = 138$) and non-ND ($n = 57$). Significant differences were found in lactate and protein levels between the 2 groups (Table 1a). The cutoff point for CSF lactate in ND was 2.94 mmol/L (AUC: 0.845) (Table 2, image 1) with sensitivity of 66.67%, specificity of 98.24%, PPV of 98.92% and NPV of 54.90%.
In the ND group, 42 patients were categorized as CNSBI and 96 as non-bacterial ND. Significant differences were observed in lactate, glucose and protein levels between the 2 groups (Table 1b). The cutoff point for CSF lactate in CNSBI was 5.16 mmol/L (AUC: 0.943) (Table 3, image 2) with sensitivity of 88.10%, specificity of 84.38%, PPV of 71.15% and NPV of 94.19%.

**Table 1**

| | (a) $N = 195$ | | | (b) $N = 138$ | | |
|---|---|---|---|---|---|---|
| | ND ($n = 138$) | Non-ND ($n = 57$) | $p$ | CNSBI ($N = 42$) | Non-CNSBI ($N = 96$) | $p$ |
| Lactate (mmol/L) | **5.5 ± 4.21** | **1.98 ± 0.43** | **< 0.001** | **10.28 ± 4.23** | **3.42 ± 1.83** | **< 0.001** |
| Glucose (mg/dL) | 76.54 ± 70.70 | 90.86 ± 17.86 | > 0.001 | **30.87 ± 37.18** | **96.53 ± 72.71** | **< 0.001** |
| Leukocytes (/mcL) | 1156.98 ± 5330.23 | 18.14 ± 45.87 | > 0.001 | 3300.59 ± 9258.28 | 219.11 ± 1028.95 | > 0.001 |
| Proteins (mg/dL) | **211.32 ± 279** | **73.33 ± 110.47** | **< 0.001** | **466.6 ± 360,50** | **99.63 ± 123.37** | **< 0.001** |

**Table 2**

| $N = 195$ | ND ($n = 138$) | Non-ND ($n = 57$) | |
|---|---|---|---|
| < 2.94 mmol/L | 33.33% (46) | 98.25% (56) | **< 0.001** |
| ≥ 2.94 mmol/L | 66.67% (92) | 1.75% (1) | **< 0.001** |
| Total | 100% (138) | 100% (57) | |

**Table 3**

| $N = 138$ | CNSBI ($N = 42$) | Non-CNSBI ($N = 96$) | $p$ |
|---|---|---|---|
| < 5.16 mmol/L | 11.91% (5) | 84.37% (81) | **< 0.001** |
| ≥ 5.16 mmol/L | 88.09% (37) | 15.63% (15) | **< 0.001** |
| Total | 100% (42) | 100% (96) | |

**Conclusions:** CSF lactate might aid in diagnosing ND, particularly CNSBI. A CSF lactate cutoff above 2.94 mmol/L showed good accuracy, sensitivity, and specificity for any ND diagnosis. Moreover, a cutoff above 5.16 mmol/L aids in distinguishing CNSBI from other NDs, exhibiting favorable sensitivity and specificity.
Further samples are needed to determine if CSF lactate outperforms other biomarkers in CNSBI diagnosis.

**Introduction:** The Rapid Response Team (RRT) and Critical Care Outreach Team (CCOT) are designed to prevent deterioration of patients' condition, resulting in reduction of in-hospital mortality rates. Recent evidence suggests that the activation of the RRS could also play a crucial role in palliative care by promoting end-of-life discussions. However, there is few research reporting on the changes in code status following the involvement of the RRT and CCOT.
**Objectives:** To investigate the characteristics of patients who underwent a change in code status following the intervention of either the rapid response team or the critical care outreach team at our institution.
**Methods:** This is a descriptive study. Chart review was conducted for patients hospitalized in Tokyo Bay Urayasu Ichikawa Medical Center from April 2018 to March 2023. Patients whose code status changed within 72 h of the activation of either the RRT or the CCOT were included. Variables measured included age, gender, primary department (medical or surgical), changes in code status (full code, do not attempt resuscitation (DNAR), limited treatment, or comfort measures only (CMO)), presence of family conferences, the affiliation of the physician providing the family conference (primary physician or RRT), location of the family conference (general ward or ICU), unexpected ICU admissions, unexpected in-hospital cardiac arrests, implementation of palliative care, and discharge route (discharge to home, death, transfer, or discharge to a facility).
**Results:** The RRT was activated for a total of 1579 cases with 33 (2.1%) cases experiencing a change in code status, while CCOT was involved in 6196 cases, with 27 (0.43%) cases experiencing a change in code status. The median age was 82 years (IQR 76–90) for the RRS group and 81 years (IQR 76–86) for the CCOT group. The patients under the service of internal medicine accounted for 24 (72.7%) in the RRT group and 24 (88.9%) in the CCOT group. Family meetings were held by the primary physician after the activation of RRS in 28 (84.8%) cases and CCOT in 26 (96.3%) cases. Code status changed from full code to DNAR or CMO in 22 (66.7%) cases in the RRS group and 24 (88.9%) cases in the CCOT group. Changes from limited treatment to full code were noted in 4 (12.1%) cases in the RRS group and 1 (3.7%) case in the CCOT group. Changes from limited treatment to CMO were seen in 4 (12.1%) cases in the RRS group and 2 (7.4%) cases in the CCOT group. Unexpected ICU admissions were reported in 9 (27.3%) cases in the RRS group and 1 (3.7%) cases in the CCOT group. There were no unexpected in-hospital cardiac arrests in either group. Palliative care was implemented in 19 (72.7%) cases in the RRS group and 12 (44.4%) cases in the CCOT group. Deaths during hospitalization occurred in 18 (54.5%) cases in the RRS group and 11 (40.7%) cases in the CCOT group.
**Conclusions:** Although changes in code status following the involvement of the RRS and CCOT were infrequent, the findings suggest that the RRS and CCOT may have facilitated appropriate changes in code status, potentially leading to the provision of appropriate palliative care or treatment for the patients. Further research is needed to explore role of RRT and CCOT more comprehensively.

***Intensive Care Medicine Experimental*** 2024, **12(suppl 1):**001158

**Introduction:** Acute liver failure (ALF) presents a grave risk to patient survival. High-volume plasma exchange (TPE-HV) has emerged as a potential therapeutic intervention for either bridging patients to transplantation or aiding in recovery. Despite demonstrated benefits in randomized controlled trials [1], the adoption of TPE-HV remains challenging in Latin America, where acute kidney injury frequently complicates ALF, with conventional extracorporeal support primarily focusing on renal replacement therapy, showing limited efficacy [2].
**Objectives:** Evaluate whether TPE-HV improves 30-day survival in non-transplanted ALF patients.
**Methods:** A retrospective study was conducted involving 20 ALF patients: 12 receiving standard medical treatment (SMT) and 8 receiving SMT in combination with TPE-HV. TPE-HV was administered at a volume of 8–12 or 15% of body weight, using fresh frozen plasma as replacement fluid [3]. Baseline clinical data were compared using the Mann–Whitney test, mortality was assessed using the Chi-square test, and survival analysis of mechanical ventilation days between groups was conducted using the Kaplan–Meier test. In addition, a binary logistic model was utilized to evaluate mortality probability in SMT and TPE-HV groups and its interaction with hepatic encephalopathy (HE).
**Results:** Baseline clinical characteristics were comparable between the two groups, except for higher hepatic encephalopathy (HE) in the TPE-HV group ($p=0.027$) and lower sodium levels in the same group ($p=0.032$, Table 1). The 60% of the etiology of ALF was hepatitis, followed by DILI (20%), mycetism (15%) and ALL (2%). Overall survival was significantly higher in the TPE-HV group (87.5%) compared to the SMT group (50%, $p=0.0001$). Though the median duration of mechanical ventilation was shorter in the TPE-HV group (2 days) compared to the SMT group (3 days), statistical analysis did not reveal significant differences ($p=0.63$, Fig. 1). The probability of mortality decreased from 60% in SMT group to less than 10% in the TPE-HV group. No interaction effect with HE was found (Fig. 2).

**Table 1 (abstract 001158)** Baseline clinical characteristics of the two groups; SMT and TPE-HV

| | SMT ($n=12$) | TPE-HV ($n=8$) | *p* value |
|---|---|---|---|

**Introduction:** There is good physiological basis to understate that excess fluid administration increases both right and left atrial pressures, resulting in venous congestion, tissue edema leading to increased rates of acute kidney injury(1). At bedside, in patients with poorly accessible thoracic and abdominal wall examination after sternotomy, thoracotomy, or laparotomy; transthoracic echocardiographic (TTE) and venous excess ultrasound (VEXUS) examinations might be challenging because of suboptimal echogenicity, due to unfavourable anatomy and sometimes, positive pressure ventilation (2). A recent observational study identified that nearly 25% of their patients in their cohort had inadequate renal Doppler scans (3). In these instances, the femoral vein, which is an easily accessible site for venous catheters, is easily available for ultrasound evaluation. A good correlation has also been demonstrated between Femoral Vein Doppler and VEXUS to identify venous congestion in patients after a major cardiac surgery (4). Visual assessment of the femoral vein flow could be used to binarily note if the patient has a congestive state or not. We hypothesized that the presence of a pulsatile femoral vein flow could predict the onset of AKI in the subsequent 7 days in patients with complicated intra-abdominal infections and abdominal sepsis.
**Objectives:** To determine the association between femoral vein pulsatility measured (measured by Doppler ultrasonography) within 24 h of ICU admission and development of acute kidney injury within 7 days, in patients with complicated intra-abdominal infections and abdominal sepsis i.e. complicated intra-abdominal infections leading to sepsis, as defined by Sepsis-3.
**Methods:** 30 adult patients, aged 18–65 years diagnosed with complicated intra-abdominal infections and abdominal sepsis (complicated intra-abdominal infections leading to sepsis and septic shock) were included after institutional ethics committee approval. Patients with inadequate window for USG, patients in respiratory distress (respiratory rate > 35/min, accessory muscles of respiration in use), patients with liver cirrhosis, portal thrombosis, deep vein thrombosis of lower limb, pregnancy, chronic venous limb disease, chronic kidney disease, patients with AKI on admission, patients with unilateral nephrectomy and renal malignancies were excluded. USG examination for femoral vein pulsatility was done by a trained intensivist with more than 5 years' experience in bedside ultrasound. Normal femoral vein Doppler (FVD) was defined as antegrade mildly pulsatile uninterrupted pattern with respiratory variation and retrograde flow of less than 1/3rd of antegrade flow. FVD was considered suggestive of venous congestion if either of the criteria was fulfilled: i) pulsatile in nature; ii) retrograde flow velocity of more than 10 cm/s; iii) retrograde flow velocity being more than 1/3rd of antegrade flow velocity (flow reversal).
**Results:** FVD was described as normal, pulsatile, or pulsatile with flow reversal. Pulsatile and pulsatile with flow reversal FVD patterns were considered suggestive of venous congestion. Out of 30 patients included in the interim analysis, 18 patients (60%) developed AKI as defined by KDIGO criteria. AKI stage 1 in 8 patients, AKI stage 2 in 8 patients, AKI stage 3 in 2 patients. FVD patterns consistent with congestion were seen in 12 patients (66.6%) out of 18 patients who developed AKI. Pulsatile FVD was seen in 7 patients, retrograde flow velocity of more than 10 cm/s in 3 patients, retrograde flow velocity being more than 1/3rd of antegrade flow velocity (flow reversal) in 2 patients. The presence of a pulsatile femoral vein flow could predict the onset of AKI in the subsequent 7 days in patients with complicated intra-abdominal infections and abdominal sepsis with a sensitivity of 66%, specificity of 83%, positive predictive value of 85%, and a negative predictive value of 62.5%
**Conclusions:** The presence of a pulsatile femoral vein flow could predict the onset of AKI in the subsequent 7 days in patients with complicated intra-abdominal infections and abdominal sepsis with a PPV of 85% and NPV of 62.5%.

**Introduction:** Sepsis is life-threatening organ dysfunction due to a dysregulated host response to infection and is an important global health problem [1]. For instance, sepsis continues to be the leading cause of in-hospital deaths in China, where the overall mortality is still as high as 35–45% [2]. An in-depth exploration of novel therapeutic targets for sepsis is urgently needed. Heparin-binding protein (HBP) is precomposed and mainly exists in the azurophilic granules and secretory vesicles of neutrophils [3]. Previous research demonstrated that the strongest indicator of the development of sepsis is an elevated plasma HBP level in cases of sepsis with organ failure [4], [5]. Given that HBP can assess vascular leakage and infection in patients, it might become potential marker to monitor patients with sepsis and septic shock.
**Objectives:** To investigate the relationship between the dynamics of HBP and prognosis of patients with sepsis.
**Methods:** This single-center, prospective and observational clinical study included 110 patients who met the Sepsis-3.0 diagnostic criteria in the ICU of Zhongda Hospital affiliated to Southeast University. All patients were followed up to 28 days. Plasma levels of HBP on admission day1, 3 and 7 were recorded, as well as procalcitonin (PCT), high-sensitive C-reactive protein (hs-CRP) and clinical characteristics.
